Renal cell carcinoma (RCC), including its main subtypes, exhibits substantial biological variability. While many tumors follow an indolent course, others demonstrate aggressive behavior with metastatic potential and resistance to therapy. Classical imaging predictors—such as tumor size, necrosis, vascular invasion, and irregular margins—remain essential in clinical assessment, although showing limited specificity in determining tumor behavior. Radiomics provides a noninvasive, quantitative approach to assess tumor heterogeneity. Parameters like entropy, skewness, kurtosis, and contrast enhancement ratios have shown significant correlations with tumor grade and aggressiveness. RAD-scores derived from these features outperform traditional TNM staging in prognostic accuracy.Radiomics-based nomograms facilitate the development of personalized treatment strategies and follow-up protocols. We propose a diagnostic workflow that integrates classical imaging features with radiomic data to improve risk stratification and support individualized management in RCC.

GUEE-15 MALE INFERTILITY: A RADIOLOGIC FRAMEWORK FOR DIAGNOSIS

Billy S. Chien, MD (*Presenter*)
James Hwang, MD (*Abstract Co-Author*)
Mark D. Sugi, MD (*Abstract Co-Author*)
Grace G. Zhu, MD (*Abstract Co-Author*)
Ichiro Ikuta, MD, MMedSc (*Abstract Co-Author*)
Ajay Malhotra, MD, MMM (*Abstract Co-Author*)
Sadhna Verma, MD, MBA (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

• Define infertility and highlight the prevalence and significance of male infertility.• Present a structured framework for categorizing causes of male infertility.• Discuss the anatomical structures and physiological pathways that are associated with each category of male infertility.• Summarize the essential components of clinical evaluation required for comprehensive evaluation of male infertility including history, physical examination, and biochemical workup.• Ensure inclusive infertility evaluation by recognizing the unique gender identities and varying reproductive organs of each patient.• Review the critical role of various imaging modalities for diagnosing common etiologies of male infertility.

TABLE OF CONTENTS/OUTLINE

• Overview of infertility with emphasis on the epidemiology and clinical relevance of male infertility.• Review of the anatomical structures and organ systems involved in male reproductive function.• Provide an algorithmic approach for evaluating infertility including history, physical exam, biochemical workup, and imaging.• Organize causes of male infertility into pre-testicular, testicular, and post-testicular categories.• Pre-testicular causes of male infertility: pituitary tumors, Klinefelter syndrome, Kallmann syndrome• Testicular causes of male infertility: varicocele, testicular torsion, epididymo-orchitis, testicular microlithiasis, cryptorchidism, testicular malignancy.• Post-testicular causes of male infertility: epididymal pathology, vas deferens pathology, seminal vesicle pathology, ejaculatory duct pathology, urethral obstruction, Müllerian duct cyst, utricle cyst.

GUEE-16 BEYOND PROSTATE ADENOCARCINOMA: IMAGING OF DE NOVO AND TREATMENT-EMERGENT NEUROENDOCRINE PROSTATE CARCINOMA

Mahsa Taherzadeh, MD (*Presenter*)
Haaris Khan (*Abstract Co-Author*)
Urooba Nadeem (*Abstract Co-Author*)
Naveen Rajamohan, MD,MBBS (*Abstract Co-Author*)
Kareem K. Elfatairy, MBBCh, PhD (*Abstract Co-Author*)
Jovan Begovic, MD (*Abstract Co-Author*)
Kevin Courtney (*Abstract Co-Author*)
Orhan K. Oz, MD,PhD (*Abstract Co-Author*)
Daniel Lee (*Abstract Co-Author*)
Asim Afaq, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Neuroendocrine prostate cancer is a lethal type of prostate cancer, which is clinically challenging given the often-advanced presentation, rapidly progressing course, lack of responsiveness to therapies, and overall poor prognosis. 2. Although de novo neuroendocrine prostate cancer is rare (<2%), treatment-emergent neuroendocrine prostate cancer (t-NEPC) has been reported in up to 15-30% of metastatic castration-resistant prostate cancer, thought to arise from lineage plasticity induced by

prolonged androgen receptor-targeted therapy. 3. Cross-sectional imaging considerations include a lack of typical concordance with serum biomarkers (prostate-specific antigen) and advanced disease at presentation. 4. Molecular imaging considerations include the potential lack of uptake on PSMA PET, both within the prostate gland and in metastases, and the potential utility of FDG and DOTATATE PET, depending on tumor differentiation. 5. t-NEPC should be considered in patients undergoing assessments for PSMA radioligand therapies, as this would limit the potential benefit from these treatment options.

TABLE OF CONTENTS/OUTLINE

1. Diagnostic considerations of neuroendocrine prostate cancer 2. Different types of neuroendocrine tumors within the prostate i) De novo neuroendocrine tumors ii) Treatment-emergent neuroendocrine prostate carcinoma (t-NEPC) 3. Mechanisms contributing to t-NEPC development 4. Imaging features of de novo and t-NEPC in CT, MRI, PET/CT with FDG, DOTATATE, and PSMA radiotracers with histopathological correlation

GUEE-17 UNMASKING TESTICULAR MASSES: RADIOLOGIC FEATURES TO DISTINGUISH MALIGNANCY, BENIGNITY AND MIMICS

Sofia Pividori, MD (*Presenter*)
Felicitas Aguirre (*Abstract Co-Author*)
Paula Hernandez Garrigo (*Abstract Co-Author*)
Maria Agustina Ruiz Dalvit (*Abstract Co-Author*)
Julio R. Coronil, MD (*Abstract Co-Author*)
Teresa A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Testicular masses represent a diagnostic challenge, requiring precise imaging to guide management. This exhibit reviews key imaging features on Ultrasound (US) and Magnetic Resonance Imaging (MRI) to differentiate intratesticular from extratesticular lesions, distinguish malignant from benign masses, and identify pseudotumors or mimics. Malignancies are primarily germ cell tumors— seminomatous and non-seminomatous types—as well as other malignancies such as lymphoma, Sertoli cell tumors, Leydig cell tumors, granulosa cell tumors, fibromas, and metastases. MRI provides superior soft tissue contrast and functional information compared to ultrasound, offering added value in complex or indeterminate cases. MRI can help differentiate seminomatous from non-seminomatous tumors by evaluating features such as lesion shape, the presence of a capsule or septa, hemorrhage, necrotic or cystic changes, and enhancement patterns. Additionally, it contributes to surgical planning by delineating tumor extension. Recognizing imaging patterns specific to tumor subtypes and mimics is critical for accurate diagnosis and effective management.

TABLE OF CONTENTS/OUTLINE

Introduction to Testicular Masses. General overview and radiologic features. Ultrasound imaging and MRI Protocols for Testicular Masses. Comparative analysis of Seminomatous and Non-Seminomatous Tumors. Pitfalls and Mimics: Sample cases of Leydig Cell Hyperplasia, Infarctions, Extratesticular lesions with radio-pathological correlation. A practical approach to Testicular Masses.

GUEE-18 RENAL CANCER STAGING FOR NEPHRON-SPARING SURGERY

Vitor C. Maiolo, MD (*Presenter*)
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)
Thais Mussi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Review the staging of kidney cancer. Assess imaging findings that lead to accurate staging. Describe key imaging features for local staging and new tools available for surgical planning. Reaffirm the importance of precision medicine in reducing unnecessary radical approaches.

TABLE OF CONTENTS/OUTLINE

MATERIAL AND METHODS Describe the anatomic features of kidney tumors on imaging modalities used in their evaluation and correlate them with staging. STEP BY STEP EVALUATION Systematic approach to staging kidney lesions. Evaluation of imaging features and new imaging tools to correlate with surgical decision-making. 1) LESIONS LIMITED TO RENAL PARENCHYMA Typical cases of kidney cancer (T1/T2 stages) and their radiologic appearances. Staging classification based on tumor size. 2) LESIONS NON LIMITED TO RENAL PARENCHYMA Typical cases of kidney cancer (T3/T4 stages) and their radiologic appearances. Discuss the implications of contiguous and distant tumor spread. CONCLUSION Provide example cases of MRI and CT acquisitions used for accurate staging of renal cancer. Optimize surgical nephrectomy indications based on imaging findings. CLINICAL RELEVANCE STATEMENT Valuable imaging information to optimize surgical approach Elucidate the surgical implications of precise radiologic characterization of kidney tumors.

GUEE-19 DECODING UROTHELIAL CARCINOMA: WHAT EVERY RESIDENT SHOULD KNOW

Gabriel Figueiredo, MD (*Presenter*)
Rafael Camilo, MD (*Abstract Co-Author*)
Vitor C. Romano, MD (*Abstract Co-Author*)
Thais Mussi, MD, PhD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Understand the epidemiology and classification of urothelial carcinoma by anatomical site. Identify the most appropriate imaging modality according to the topography of the lesion. Review key imaging features of urothelial carcinoma in the bladder, ureters, and renal pelvis. Highlight the role of CTU and MRI, including VI-RADS, in diagnosis, staging, and treatment planning. Present didactic cases to illustrate radiological patterns and optimize resident learning.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION Overview of urothelial carcinoma prevalence and classification by anatomical site; Emphasis on increasing the incidence and importance of imaging in management; UPPER URINARY TRACT Overview: Represents 5-10% of urothelial carcinomas, mainly affecting the renal pelvis and ureter. Imaging Protocol: CT urography is the gold standard; MRI is used in selected cases. Radiologic Features: Wall thickening, irregular filling defects, and obstructive signs are key findings. LOWER URINARY TRACT Overview: Accounts for 90-95% of cases, mostly involving the bladder. Imaging Protocol: Multiparametric MRI is preferred, especially for preoperative assessment. Radiologic Features: VI-RADS helps differentiate superficial from invasive tumors; structured reporting improves clarity and communication. CONCLUSION Imaging is central to diagnosis, staging, and treatment planning; Topography-specific approach improves diagnostic accuracy; Radiologists must be familiar with urothelial carcinoma patterns and protocols to contribute effectively to patient care;

GUEE-20 WHAT'S NEW IN PRECISE V2? FROM MYSTERY TO MASTERY IN ACTIVE SURVEILLANCE

Levi B. Oliveira, MD (*Presenter*)
Hilton M. Leao Filho, MD, PhD (*Abstract Co-Author*)
Fernando Yamauchi (*Abstract Co-Author*)
Martin Horwarth, MD (*Abstract Co-Author*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)

TEACHING POINTS

MRI plays a pivotal role in active surveillance and watchful waiting strategies for managing prostate cancer. It supports better patient selection for biopsy, contributes to prognostic assessment and is essential for lesion monitoring over time. PRECISE provides a standardized framework for assessing longitudinal changes in prostate MRI

during active surveillance. Understanding the PRECISE scoring system helps radiologists communicate disease stability or progression effectively, guiding clinical decision-making. PRECISE version 2 introduces refinements that enhance reproducibility and reduce ambiguity in lesion monitoring over time.

TABLE OF CONTENTS/OUTLINE

- Introduction - Definition of active surveillance. - What is PRECISE and how can we use it. - Key elements of PRECISE version 1. - Updates in PRECISE version 2: highlight the main radiological features of PRECISE v2 and provide practical guidance for its application in daily clinical practice. - Pitfalls - Take-home notes - References

GUEE-21 CAUGHT BETWEEN A LESION AND A HARD PLACE: DECODING RENAL MASSES - A STRUCTURED IMAGING GUIDE FOR RESIDENTS

Nicole Dittrich, MD, PhD (*Presenter*)
Abrahao Elias Neto, MD (*Abstract Co-Author*)
Larissa R. Favaro (*Abstract Co-Author*)
Daniel Bekhor, MD (*Abstract Co-Author*)
Eduardo O. Pacheco, MSc, MD (*Abstract Co-Author*)
Ulysses S. Torres, MD, PhD (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit provides trainees with a structured approach to evaluating renal masses, using flowcharts and illustrative practical cases. It covers the imaging features and diagnostic challenges of common and uncommon benign and malignant renal tumors, as well as diagnostic pitfalls. The exhibit presents the Bosniak classification and the Clear Cell Likelihood Score, both explored through practical cases, along with updates from the 2022 WHO classification of renal neoplasms, emphasizing recent imaging-related changes.

TABLE OF CONTENTS/OUTLINE

Structured approach to renal masses evaluation, presented through a comprehensive flowchart and illustrated with didactic cases. Benign renal tumors such as lipid-rich and lipid-poor angiomyolipomas, oncocytomas, localized cystic renal disease, and hemorrhagic or proteinaceous cysts will be demonstrated, emphasizing their imaging features. Malignant renal tumors , including metastases, clear cell, papillary and chromophobe RCC, mucinous tubular and spindle cell carcinoma, will be illustrated with key imaging characteristics. Uncommon renal masses such as lymphoma, Langerhans cell histiocytosis, mixed epithelial and stromal tumor will be discussed. Common diagnostic pitfalls will be addressed through cases of anatomical variants and benign mimickers , including acute focal nephritis (nephronia), hypertrophied column of Bertin, duplicated collecting system, calyceal diverticulum, subcapsular hematoma, kidney scarring, infarction, renal artery aneurysm, renal abscess, and nephrocutaneous fistula. Bosniak classification, ccLS and the new 2022 WHO classification of renal neoplasms will be presented, with practical imaging cases.

GUEE-22 THE RADIOLOGIST'S DECLASSIFIED RENAL TRANSPLANT EVALUATION SURVIVAL GUIDE

Raissa Cabral Pili, MD (*Presenter*)
Fabio Franco De Oliveira Junior (*Abstract Co-Author*)
Gustavo Yamada, MD (*Abstract Co-Author*)
Milena Yonamine (*Abstract Co-Author*)
Tiago Petrucci (*Abstract Co-Author*)
Adriano Fregonesi (*Abstract Co-Author*)
Daniel Lahan-Martins, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purposes of this education exhibit are: - Review the normal renal transplant anatomy and correlate it with clinical images of the surgery technique. - Present a step-by-step guide on how to evaluate the different renal transplant complications in ultrasound (US) and computed tomography (CT). - Review the most common timing of renal transplant complications.

TABLE OF CONTENTS/OUTLINE

- Renal transplant surgical technique and allograft anatomy illustrated and compared to surgical pictures. - A step-by-step guide on how to evaluate renal transplant complications, illustrated by selected cases from the database of a Tertiary University Hospital, that contains: B-mode Ultrasound: main findings of the renal parenchyma, renal sinus and the topography[1] and features[2] of different fluid collections. Doppler Ultrasound: evaluation of renal transplant artery and vein and intrarenal arteries and diagnosis of renal artery stenosis, renal artery or vein thrombosis and pseudoaneurysm. CT: main findings of the renal parenchyma, renal sinus, the arterial/venous flow and the topography[1] and features[2] of different fluid collections. - Most common timing of different renal transplant complications. [1] subcapsular, perinephric and intraparenchymal. [2] lymphocele, urinoma, hematoma and abscess.

GUEE-23 A MULTIMODAL APPROACH TO THE ASSESSMENT OF HEMOSPERMIA-RADIOLOGICAL INSIGHTS INTO AN OVERLOOKED CONDITION

Fabiana Campos, MD (*Presenter*)
Alexandre Pasquali (*Abstract Co-Author*)
Daniel L. Cardoso, MD (*Abstract Co-Author*)
Rafael R. Santos Ferreira, MD (*Abstract Co-Author*)
Pyetra Oliveira, MD (*Abstract Co-Author*)
Mariana Costa, MD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Regis Otaviano Bezerra, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Hemospermia is typically idiopathic, benign, and self-limiting. In persistent cases, it remains underestimated, with imaging findings underreported. A multimodal imaging approach is essential. Radiologists play a key role in early diagnosis and guiding appropriate treatment.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION: • Definition and epidemiology of hemospermia. • Scarcity of literature on imaging findings. • Importance of imaging in differential diagnosis. CLINICAL PRESENTATION • Patient profiles: age range, duration of symptoms, associated complaints. • Most cases are self-limited, with the persistent form often neglected due to lack of studies in the area. MULTIMODAL IMAGING APPROACH • Magnetic Resonance Imaging, Transrectal Ultrasound, and Retrograde Urethrocystography: advantages and limitations.• Examples of findings: protein/hematic content in seminal vesicles, wall thickening, cysts (prostatic utricle, bladder neck), early venous enhancement post-trauma, ejaculatory duct obstruction. THE CREATION OF AN ACRONYM (MOIST) • (M) Malignancy : Elevated PSA and image-guided biopsy. • (O) Obstructions : Cysts and obstructive changes identified on imaging. • (I) Infection/Inflammation : Hematic content and vesicular retraction. • (S) Systemic : Metabolic disorders, with a focus on severe hypertension and advanced liver disease. • (T) Trauma : Arteriovenous fistula formation evidenced by early enhancement. TAKE HOME • Persistent hemospermia requires structured investigation with the help of a new acronym (MOIST). • Multimodal imaging is essential for identifying clinically relevant causes.• New radiological studies are needed to expand the knowledge about this neglected condition.

GUEE-24 DECODING SOLID RENAL LESIONS: A MULTIMODAL IMAGING PRIMER FOR RESIDENTS

Arianne Idaly Ramos Galvan, MD (*Presenter*)

TEACHING POINTS

Review the differential diagnosis of solid renal lesions and their key imaging characteristics.Understand the strengths and limitations of ultrasound, CT and MRI in lesion characterization.Review optimal CT and MRI imaging protocols for renal lesions characterization. Apply practical imaging algorithms to distinguish benign from malignant lesions. Recognize imaging pitfalls and avoid common misdiagnoses.

TABLE OF CONTENTS/OUTLINE

Introduction: importance of multimodal assesment in solid renal lesions.Imaging techniques overview: role of ultrasound, CT and MRILesion specific imaging features: Benign vs malignant clues Diagnostic algorithms: A practical step by step guide Pitfalls and how to avoid them: lessons leartned Summary: key takeaways for resident practice

GUEE-25 BEYOND THE FAT: CHALLENGES IN DIAGNOSING RENAL ANGIOMYOLIPOMAS

Carolina Carotenuto Ramos, MD (*Presenter*)
Marina Joseane Pachecco, MD (*Abstract Co-Author*)
Francisco Victor Henrique, MD (*Abstract Co-Author*)
Matheus Brunetto, MD (*Abstract Co-Author*)
Gabriel Alves, MD (*Abstract Co-Author*)
Martin Horwarth, MD (*Abstract Co-Author*)
Matheus M. Gomes SR, MD (*Abstract Co-Author*)
Fernando I. Yamauchi, MD (*Abstract Co-Author*)
Daniel Lahan-Martins, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Angiomyolipoma (AML) is the most common benign solid tumor of the kidney. It is typically asymptomatic and often identified incidentally on imaging studies performed for unrelated indications. In most cases, AML demonstrates characteristic radiologic features that enable a confident and noninvasive diagnosis. However, diagnostic interpretation can be challenged by atypical imaging features, such as fat-poor angiomyolipomas, intralesional hemorrhage, aneurysmal formations, or extension into the renal vein. Furthermore, certain neoplasms may closely resemble AMLs on imaging—most notably, clear cell renal cell carcinomas containing macroscopic fat, as well as primary retroperitoneal liposarcomas, with or without direct renal involvement. This educational exhibit seeks to illustrate and review both the typical and atypical imaging features of renal angiomyolipomas across ultrasound, computed tomography, and magnetic resonance imaging, while also emphasizing potential diagnostic pitfalls that may challenge accurate interpretation.

TABLE OF CONTENTS/OUTLINE

1. Overview of the typical and atypical features of renal AMLs. 2. Renal Angiomyolipoma Subtypes: Classic, Epithelioid, and Hypocellular Variants. 3. Pitfalls: when AML lacks visible fat — how to avoid misdiagnosis. 4. Imaging features that aid in differentiating fat-poor AMLs from other tumors. 5. Case-Based Review: Diagnostic Pearls and Common Misinterpretations.

GUEE-26 FOCAL ABLATIVE THERAPY OF PROSTATE: ROLE OF PROSTATE MR AND PSMA PET

Swathi Kisara, MD (*Presenter*)
Sadina Shrestha, MD, MBBS (*Abstract Co-Author*)
Mandeep S. Virk, MBBS, MD (*Abstract Co-Author*)
Varaha Tammisetti, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the rationale of focal ablative therapy of prostate, available types of focal therapy, inclusion and exclusion criteria.Illustrate current role of prostate MR and PSMA PET in tumor mapping, tumor volume estimation, multifocality and tumor mapping.Illustrate expected post ablation appearances after focal therapy, in-field treatment failure/recurrence and out of field failure on prostate MR and PSMA PET.Understand the two scoring systems TARGET and PI-FAB in detection of failure, surveillance on prostate MR and their limitations.Understand evolving role of PSMA PET.

TABLE OF CONTENTS/OUTLINE

Rationale and types of Focal ablative therapy of prostate cancerRole of Prostate MR and PSMA PET in tumor mapping, multifocality, tumor volume estimation and treatment planningExpected immediate and late MR imaging appearances post ablation.Patterns of recurrence/failure in-fieldPatterns of out of field failure/new tumors Role of Prostate MR in detection of failure and surveillance after focal therapy: Comparison of the two scoring systems Transatlantic recommendations for prostate gland evlaution using MRI after focal therapy (TARGET) and Prostate Imaging after Focal therapy (PI-FAB) and their limitations Evolving role of PSMA PET in detection of intraprostatic failure, surveillance Future considerations and Conclusions

GUEE-27 ACCELERATED MRI TECHNIQUES FOR PI-RADS COMPLIANT PROSTATE IMAGING: PRINCIPLES, IMPLEMENTATION, AND CLINICAL IMPACT

Abdelrahman Elshikh, MBBCh (*Presenter*)
Eugene Milshteyn, PhD (*Abstract Co-Author*)
Nabih Nakrour, MD (*Abstract Co-Author*)
Rory L. Cochran, MD,PhD (*Abstract Co-Author*)
Maximilian Pohl, MD (*Abstract Co-Author*)
Arnaud Guidon, PhD (*Abstract Co-Author*)
Ajeetkumar Gaddipati (*Abstract Co-Author*)
Anand Kumar Venkatachari (*Abstract Co-Author*)
Xinzeng Wang (*Abstract Co-Author*)
Patricia Lan (*Abstract Co-Author*)
Mukesh G. Harisinghani, MD (*Abstract Co-Author*)

TEACHING POINTS

Gain insight into the current PI-RADS v2.1 standards and the extended scan times associated with conventional prostate MRI protocols. Explore advanced acceleration methods for T2-weighted and diffusion-weighted imaging that preserve diagnostic integrity. Understand how accelerated prostate MRI protocols enhance workflow efficiency and diagnostic confidence in clinical practice. Learn about practical implementation strategies and potential future advancements in accelerated prostate imaging.

TABLE OF CONTENTS/OUTLINE

Prostate MRI Standards and Acceleration Basics - Overview of PI-RADS v2.1 requirements and typical scan durations - Challenges associated with standard acquisition methods - Core principles behind MRI acceleration techniques Accelerated T2-Weighted Imaging Approaches - 2D techniques: reduced field of view, optimized echo spacing, hyper-echoes - 3D acquisitions enhanced with deep learning reconstruction (e.g., CUBE) - Influence on transition zone evaluation and PI-RADS classification - Comparative analysis—quantitative and qualitative—with conventional imaging Advanced Diffusion-Weighted Imaging Techniques - Fundamentals of diffusion contrast and associated phase correction challenges - Application of deep learning-based phase correction (DLPC) - Methods for improving signal-to-noise ratio and minimizing noise floor - Impact on peripheral zone analysis and PI-RADS scoring accuracy Clinical Integration and Validation - Case studies highlighting diagnostic equivalence - Strategies for incorporating accelerated protocols into routine workflow - Evaluation of effects on patient throughput and imaging quality Challenges and Future Perspectives Conclusion

GUEE-28 KEEP YOUR EYE ON THE BALL: A PRACTICAL APPROACH TO TESTICULAR ULTRASOUND

Bruno Ramos, MD (*Presenter*)
Daniel L. Cardoso, MD (*Abstract Co-Author*)
Mariana Costa, MD (*Abstract Co-Author*)
Pyetra Oliveira, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Regiany Alessandra Garcia Jureidini, MD, MBA (*Abstract Co-Author*)
Marcello S. Rovella, MD (*Abstract Co-Author*)
Luciana Cerri, MD, PhD (*Abstract Co-Author*)
Alexandre Pasquali (*Abstract Co-Author*)

TEACHING POINTS

To present a practical, case-based approach to testicular ultrasound (US), highlighting key diagnostic pearls and pitfalls. To review essential scanning techniques and normal anatomy as the foundation for accurate interpretation. To differentiate the main causes of acute scrotal pain, focusing on imaging patterns that distinguish torsion, infection, and trauma. To identify sonographic features of common testicular lesions, both benign and malignant, and recognize when further imaging (e.g., MRI) is indicated. To improve diagnostic confidence and clinical decision-making through an algorithmic framework for scrotal ultrasound evaluation

TABLE OF CONTENTS/OUTLINE

Initial Steps in Testicular US: Technique and Anatomy Acute Scrotum: Differentiating Torsion from Infection Intratesticular and Extratesticular Lesions: Benign vs Malignant Scrotal Trauma: Key Findings and Surgical Triggers Post-Operative Changes: What to Expect Cryptorchidism: Imaging Evaluation and Long-Term Follow-Up When Is MRI Indicated? Summary: An algorithmic framework for testicular US

GUEE-29 HEREDITARY RENAL CANCER SYNDROMES: UPDATED SCREENING GUIDELINES AND EVOLVING IMAGING ROLES

Satheesh Krishna, MD (*Presenter*)
Eva Carolina P. Serrao, FRCR, PhD (*Abstract Co-Author*)
Kay Wu, MD, MS (*Abstract Co-Author*)
Maria T. Wetscherek, MD (*Abstract Co-Author*)
Nicola Schieda, MD (*Abstract Co-Author*)
Myles T. Taffel, MD (*Abstract Co-Author*)
Sreeharsha Tirumani, MD (*Abstract Co-Author*)
Sungmin Woo, MD, PhD (*Abstract Co-Author*)
Atul B. Shinagare, MD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)
Ankush Jajodia, MD, MBBS (*Abstract Co-Author*)
Rajesh Bhayana, MD, FRCPC (*Abstract Co-Author*)
Susan Prendeville (*Abstract Co-Author*)

TEACHING POINTS

Recognize key hereditary renal cancer syndromes and their implications for patient screening and management. Understand recent updates in screening recommendations, including age to initiate, frequency, and modality selection. Identify optimal imaging modalities, including the expanding role of MRI, in surveillance of these syndromes. Appreciate the importance of risk stratification, family history, and genetic profiling in tailoring screening strategies. Review imaging features of hereditary renal tumors and tips for early, accurate detection.

TABLE OF CONTENTS/OUTLINE

What are hereditary renal cancer syndromes? Why are they critical to identify early? How have recent guidelines evolved regarding screening for VHL, HPRC, BHD, and other key syndromes? When should screening start, and how often should it be performed? How does this differ by syndrome and mutation type? What is the role of MRI versus ultrasound or CT in surveillance—what are the advantages, limitations, and recommended protocols? How can imaging be tailored to each syndrome—should there be a one-size-fits-all approach or individualized screening? What do we know about imaging phenotypes of tumors in hereditary syndromes—and how can these help distinguish indolent from aggressive lesions? What is the impact of genotype-phenotype correlations on imaging and surveillance planning? How do we balance over-surveillance and incidental findings with the need for early cancer detection? Can we use AI or structured reporting to improve detection, reduce variability, and streamline workflow in hereditary renal cancer screening? What is the radiologist's role in multidisciplinary hereditary cancer clinics and genetic counseling workflows?

GUEE-30 NOT ALWAYS A PERFECT MATCH!! THE DISCREPANCIES BETWEEN PROSTATE MRI AND PSMA PET-CT FINDINGS

Ana Lemos (*Presenter*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
Ana Luiza Calado Novaes, MD (*Abstract Co-Author*)
Gabriel L. Gouvea, MD (*Abstract Co-Author*)
Arthur Ogata, MD (*Abstract Co-Author*)
Thalyne Lima (*Abstract Co-Author*)
Fernando Taliberti Pereira de Souza SR, MD (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Discrepancies between prostate multiparametric magnetic resonance imaging (mpMRI) and prostate-specific membrane antigen (PSMA) PET- computed tomography (CT) findings are common, occurring in up to 50% of cases in some series. These inconsistencies may be related to: a) image acquisition techniques; b) tumor-related factors such as heterogeneity, PSMA expression, and lesion size; c) variability in readers' interpretation. Some of these discrepancies have significant clinical implications and should be promptly recognized.

TABLE OF CONTENTS/OUTLINE

Introduction: essential concepts of prostate cancer classification are introduced, along with a discussion of the roles of mpMRI and PSMA PET-CT in diagnosis and staging. Objective: to examine the sources of discrepancies between the two imaging modalities, with a focus on those with clinical relevance. Institutional cases are presented to illustrate discordant findings and their respective clinical significance. Imaging Findings: the diagnostic criteria for clinically significant prostate cancer using MRI and PSMA PET-CT are presented, highlighting the limitations of each method. A correlation between the Prostate Imaging-Reporting and Data System (PI-RADS) and PRIMARY scores is included to assist radiologists in interpreting and reconciling findings from both modalities. Discussion: mpMRI and PSMA PET-CT are often complementary imaging techniques. When used together, they can provide added diagnostic value in the assessment of patients with prostate cancer.

GUEE-31 A COMPREHENSIVE APPROACH TO RENAL MASSES: ENHANCING DIAGNOSTIC AND PROGNOSTIC ASSESSMENT

Marilia Da Cruz Fagundes, MD (*Presenter*)
Guilherme Naves, MD (*Abstract Co-Author*)
Mauricio Zapparoli, MD, MSc (*Abstract Co-Author*)
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*)
Alice Schuch, MD (*Abstract Co-Author*)
Marcelo D. Gusmao, MD (*Abstract Co-Author*)

Giovanna S. Torre (*Abstract Co-Author*)
Thais Mussi, MD, PhD (*Abstract Co-Author*)
Satheesh Krishna, MD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Review the imaging characteristics of renal masses, including nonneoplastic lesions and benign and malignant neoplasms - Discuss multimodality imaging characteristics (US, CT, MRI) that facilitate individualized prognostic assessment of renal lesions - Introduce radiological features indicative of indolent and malignant behavior - Illustrate the clinical application of structured classification systems in personalized decision-making, such as Bosniak classification (for cystic masses) and Clear Cell Likelihood Score (ccLS for solid masses) - Emphasize that the ccLS predicts the likelihood that a solid renal mass is a clear cell RCC (ccRCC), and ccRCC is the most common cause of metastatic RCC - Present the work-in-progress Kidney Imaging Reporting and Data System (KI-RADS), which combines cystic and solid masses into a single rubric, aiming to predict the aggressiveness of suspected kidney cancer

TABLE OF CONTENTS/OUTLINE

1. Introduction: a. Renal Anatomy b. Epidemiology and Clinical Relevance of Renal Masses 2. Imaging Evaluation: a. Benign and indolent masses: i. Classic Fat-rich Angiomyolipoma ii. Fat-poor Angiomyolipoma iii. Oncocytoma iv. Mixed Epithelial and Stromal Tumor v. Multilocular Cystic Renal Neoplasm of Low Malignant Potential b. Malignant masses: i. Clear cell RCC ii. Papillary RCC iii. Chromophobe RCC iv. Urothelial Cell Carcinoma v. Renal Lymphoma vi. Renal Metastasis vii. Other less common neoplasms c. Suggestive features of aggressive behavior: i. Size ii. Growth rate iii. Infiltrative margins iv. Necrosis pattern v. Enhancing tissue volume 3. Classification Systems: a. Bosniak Classification b. ccLS c. KI-RADS 4. Future Directions

GUEE-32 UNIFYING ADRENAL IMAGING: INSIDE THE SAR LEXICON FOR CT AND MRI INTERPRETATION

Colin McQuade, MBBCh, FFR(RCSI) (*Presenter*)
Eva Carolina P. Serrao, FRCR, PhD (*Abstract Co-Author*)
Vanessa Murad, MD (*Abstract Co-Author*)
Satheesh Krishna, MD (*Abstract Co-Author*)
Jorge A. Abreu Gomez, MD (*Abstract Co-Author*)

TEACHING POINTS

• A standardized adrenal imaging lexicon enables clear communication between radiologists and other healthcare providers, facilitates consistent clinical adoption, enhances diagnostic accuracy, and promotes inter-reader agreement. • Understanding the context of use (COU) is essential: some terms are broadly applicable across all adrenal imaging, while others are specific to certain clinical or research scenarios. • The lexicon serves as a comprehensive reference for both novice and experienced radiologists aiming to improve imaging interpretation, standardize practice, and support reproducible research.

TABLE OF CONTENTS/OUTLINE

Background (a) Challenges in adrenal lesion characterization (b) variability in terminology and reporting practices Lexicon Development (a) Consensus process by the SAR Adrenal Neoplasm Disease-Focused Panel (b) methodology and goals Lexicon Structure (a) General terms: Broad descriptors relevant to any adrenal imaging (b) Technical terms: Imaging acquisition and protocol-related terminology (c) Imaging feature terms: Morphology, composition, enhancement patterns, and other visual attributes Future Directions (a) Integration into structured reporting (b) Role in radiology education, decision support tools, and artificial intelligence applications Conclusions (a) Promoting the lexicon as an atlas for radiologists at all levels (b) Advancing standardization, communication, and research reproducibility in adrenal imaging

GUEE-33 UROTHELIAL CARCINOMAS OF THE UPPER URINARY TRACT: NEW TREATMENT PARADIGMS AND NEW IMAGE REQUIREMENTS

Maria Eduarda De Oliveira Fernandes (*Presenter*)
Rafaella Baratta Colla (*Abstract Co-Author*)
Leandro Dias Almeida, MD (*Abstract Co-Author*)
Andre De Freitas Secaf, MD (*Abstract Co-Author*)
Thalyne Lima (*Abstract Co-Author*)
Alexandre S. Morgado (*Abstract Co-Author*)
Gabriel L. Gouvea, MD (*Abstract Co-Author*)
Fernando T. Souza (*Abstract Co-Author*)
Arthur Ogata, MD (*Abstract Co-Author*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-Urothelial carcinoma of upper urinary tract (UTUC) accounts for 5-10% of all urothelial cancers, usually associated to poor prognosis; -Radical nephroureterectomy (RNU) is still the standard treatment, with excellent oncological results at expenses of renal function; -Imaging plays a major role in the diagnosis of UTUC with Computed Tomography Urography (CTU); -Molecular diagnosis, imaging and minimally invasive treatment have allowed better risk stratification and kidney-sparing therapeutics for low-risk lesions; -MRI (magnetic resonance imaging) has been proposed for definition of the T-staging and CT/MRI to follow patients submitted to kidney-sparing therapies.

TABLE OF CONTENTS/OUTLINE

- Introduction: UTUCs are rare but aggressive lesions. Although RNU remains the standard treatment, management strategies have evolved with the incorporation of molecular diagnostics, imaging, and conservative therapies. - Objective: To discuss the foundations of standard and emerging therapies for UTUC lesions, and to examine the evolving role of imaging in managing these patients. - Imaging findings: CTU is the method of choice for diagnosing UTUC due to its superior accuracy, while also enabling evaluation of alternative causes of hematuria. Despite its excellent performance and widespread acceptance as the standard of care, there is considerable variability in how CTU examinations are performed in clinical practice. MRI has been proposed as a tool to estimate the depth of UTUC invasion. Cross-sectional imaging of the upper urinary tract is recommended by major urological societies, although there is variation in the recommended frequency and duration of follow-up after endoscopic treatment.

GUEE-34 STANDARDIZED LANGUAGE, SMARTER SURVEILLANCE: MRI LEXICON FOR PROSTATE CANCER FOLLOW-UP

Jorge A. Abreu Gomez, MD (*Presenter*)
Diana C. Baptista, MD (*Abstract Co-Author*)
Andres Kohan, MD, MMedSc (*Abstract Co-Author*)
Vanessa Murad, MD (*Abstract Co-Author*)
Ridda M. Younes I, MD (*Abstract Co-Author*)

TEACHING POINTS

• Active surveillance (AS) is a guideline-recommended management strategy for low-risk and select intermediate-risk prostate cancer, enabling deferral of curative treatment until there is evidence of progression • MRI plays a central role in AS, offering non-invasive, reproducible evaluation of tumor stability and progression • The PRECISE (Prostate Cancer Radiological Estimation of Change in Sequential Evaluation) v2 scoring system offers a standardized lexicon for interpreting serial prostate MRIs in the AS setting, enhancing diagnostic confidence and communication with urologists • Terms within the lexicon are defined by their Context of Use (COU)—some are broadly applicable across all prostate MRI interpretations, while others are specific to AS in clinical or research environments • Familiarity with PRECISE v2 facilitates structured reporting, improves inter-reader agreement, guides clinical decision-making, and supports multicenter data reproducibility

TABLE OF CONTENTS/OUTLINE

Background: Rationale for AS and the evolving role of MRI Importance of MRI: Benefits over traditional follow-up, with emphasis on consistency and reproducibility Standardization in Practice: Why structured lexicons matter in prostate MRI reporting PRECISE v2 Overview: Description, scoring system, and COU framework for terms Imaging Examples: MRI cases illustrating PRECISE scores 1-5 Future Directions: Impact on education, research, and integration into clinical workflows

GUEE-35 BEYOND VI-RADS: REVIEWING DIFFERENTIAL DIAGNOSIS IN BLADDER PATHOLOGIC CONDITIONS

Othon Shiroma, MD (*Presenter*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)
Martin Horwarth, MD (*Abstract Co-Author*)
Fernanda G. Velloni, MD (*Abstract Co-Author*)

TEACHING POINTS

Non-neoplasic bladder abnormalities can mimic malignancy on imaging and should be recognized to avoid misdiagnosis and unnecessary interventions. A systematic assessment to identify and review of bladder wall thickness, contour effect, intraluminal content across US, CT and MRI helps narrowing the differential diagnosis Radiologists play a key role at identifying subtle imaging clues of functional, inflammatory and reactive bladder conditions that are often overlooked in routine evaluations.

TABLE OF CONTENTS/OUTLINE

- INTRODUCTION - BLADDER ANATOMY REVIEW - FUNCTIONAL AND MECHANICAL CHANGES - BLADDER WALL ABNORMALITIES - CONTOUR DISTORTIONS AND OUTPOUCHINGS - FILLING DEFECTS AND LUMEN LESIONS - INTRAMURAL MASS AND UNUSUAL ENTITIES - TAKE-HOME MESSAGES - REFERENCES

GUEE-36 RADIOLOGICAL INSIGHTS INTO MEDICATION-INDUCED CHANGES IN FEMALE PELVIC ORGANS AND PATHOLOGIES

Lavinia Dias, MD (*Presenter*)
Caroline De Nicola (*Abstract Co-Author*)
Sophia Chamie (*Abstract Co-Author*)
Christina Tserou (*Abstract Co-Author*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Izabela P. Franco, MD (*Abstract Co-Author*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Luciana G. Matteoni-Athayde, MD (*Abstract Co-Author*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Understand the impact of common medications used in female treatments on imaging patterns observed in pelvic organs. Recognize key radiological findings induced by hormonal therapies, contraceptives, and oncological treatments. Correlate findings from ultrasound, CT, MRI, and other imaging modalities in the assessment of female pelvic pathologies influenced by medications.

TABLE OF CONTENTS/OUTLINE

Hormonal Effects and Endocrine Modulation Therapies GnRH Analogues in Precocious Puberty: Imaging findings such as vascular reversal and uterine volume reduction. Ovarian Stimulation in IVF : Post-stimulation findings (multicystic ovaries) and complications like OHSS. Hormonal Therapies in Menopause: Imaging features of myoma growth and worsening of adenomyosis. Impact on myometrial hypertrophy and ovarian effects. Contraceptive and Common Gynecological Therapies Combined Oral Contraceptives: Endometrial atrophy and ovarian volume reduction. Levonorgestrel IUD: Endometrial atrophy and functional cyst formation. Dienogest and Norethindrone: Regression of endometriosis implants and volume reduction in deep infiltrative lesions. Aromatase Inhibitors (e.g., Letrozole): Effects on endometriosis and myoma reduction. GnRH Agonists and Antagonists: Imaging features associated with suppression of ovarian function and endometriosis. Effects of Antineoplastic Medications Chemotherapy: Radiological features of ovarian atrophy, absence of follicles, and signs of iatrogenic menopause. Tamoxifen: Endometrial hyperplasia and altered endometrioma patterns, including paradoxical growth of endometriotic lesions. Alternative Therapies

GUEE-37 TRANSURETHRAL ULTRASOUND ABLATION (TULSA) FOR PROSTATE CANCER: COMPREHENSIVE OVERVIEW AND EXPERIENCE FROM A HIGH-VOLUME CENTER

Naveen Rajamohan, MD,MBBS (*Presenter*)
Kareem K. Elfatairy, MBBCh, PhD (*Abstract Co-Author*)
Jesus Pineda Ramirez, MD (*Abstract Co-Author*)
Asim Afaq, MD (*Abstract Co-Author*)
Gaurav Khatri, MD (*Abstract Co-Author*)
Daniel N. Costa, MD (*Abstract Co-Author*)
Jovan Begovic, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the mechanism, types of TULSA ablation, workflow, and advanced post treatment imaging for this novel minimally invasive prostate cancer therapy. 2. Illustrate our institutional experience with one-year post-TULSA multiparametric MRI and PSMA PET/MRI surveillance, with correlation to pathologic outcomes. 3. Highlight imaging pearls and pitfalls in detection of recurrence following TULSA with pathological correlation using in-bore MRI-guided prostate biopsy.

TABLE OF CONTENTS/OUTLINE

Content Outline 1. Overview of Transurethral Ultrasound Ablation (TULSA) a. Principles and mechanisms b. Personnel requirement c. TULSA-Pro system 2. Pre-Procedural Considerations a. Work-up and patient selection b. Contraindications (absolute and relative) c. Implementation of eConsult workflow 3. TULSA Procedure a. Step-by-step technique b. Intra-procedural monitoring c. MR thermometry 4. Post-Ablation Surveillance at One-Year a. One-year surveillance protocols b. Expected post-treatment changes c. In-field versus out-of-field recurrence 5. Imaging Pearls and Pitfalls a. Case examples with one-year follow up and pathologic correlation. b. Common interpretive challenges and tips to avoid misdiagnosis

GUEE-38 FUNCTIONAL ADRENAL PATHOLOGIES: IMAGING APPROACH TO ENDOCRINE CLINICAL AND BIOCHEMICAL PHENOTYPES

Mahmoud S. Diab, MSc,MBBCh (*Presenter*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)
Michael T. Corwin, MD (*Abstract Co-Author*)
Mindy X. Wang, MD (*Abstract Co-Author*)
Myles T. Taffel, MD (*Abstract Co-Author*)
Elaine M. Caoili, MD, MS (*Abstract Co-Author*)
Khaled M. Elsayes, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Discuss the imaging phenotypes of adrenal lesions associated with hormonal hypersecretion or adrenal insufficiency. Correlate clinical and biochemical phenotypes with imaging features to reach a confident diagnosis. Illustrate various pitfalls and mimics that may lead to misclassification of functioning adrenal masses.

TABLE OF CONTENTS/OUTLINE

1. Introduction Overview of adrenal zonal anatomy and associated hormones Functional lesions and why imaging matters 2. Clinical and Biochemical Profiles Endocrine syndromes: Cushing, Conn, pheochromocytoma, androgen excess Role of hormonal testing and lab thresholds 3. Imaging Patterns of Functioning Masses Adenomas, pheochromocytoma, ACC, hyperplasia subtypes Imaging clues on CT, MRI (chemical shift, enhancement, fat content) Imaging correlates of hormonal subtypes (ACTH-dependent/independent) 4. Special Scenarios and Pitfalls Congenital adrenal hyperplasia, myelolipoma with functional transformation Cystic pheochromocytoma, hemorrhage with increased plasma metanephrine mimicking pheochromocytoma Misinterpreted imaging findings due to artifact, overlap, or atypical appearance 5. Take-Home Message Multimodal approach integrating imaging, laboratory, and clinical features

GUEE-39 MRI-GUIDED TRANSURETHRAL ULTRASOUND ABLATION FOR PROSTATE CANCER: A COMPREHENSIVE MANUAL TO MPMRI-BASED EVALUATION AND PITFALL AVOIDANCE

Enis Yilmaz, MD (*Presenter*)
Omer Esengur, MD (*Abstract Co-Author*)
Bradford J. Wood, MD (*Abstract Co-Author*)
Sandeep Gurram (*Abstract Co-Author*)
Peter Pinto (*Abstract Co-Author*)
Baris Turkbey, MD (*Abstract Co-Author*)

TEACHING POINTS

• Transurethral ultrasound ablation (TULSA) is a minimally invasive, MRI-guided focal therapy for localized prostate cancer and benign prostatic hyperplasia.• TULSA provides targeted ablation with real-time thermal monitoring, offering reduced side effects compared to whole-gland treatments.• Post-treatment MRI interpretation requires distinguishing expected ablation changes from true cancer recurrence, which may be subtle to untrained readers.

TABLE OF CONTENTS/OUTLINE

1. Patient Selection: Review of eligibility criteria, including clinical, PSA, and imaging parameters.2. Procedure Overview: Annotated procedural diagram illustrating transurethral probe placement and sonication zones.3. Imaging Correlates:a. Pretreatment multiparametric MRIb. Immediate post-ablation MRI appearance. c. Follow-up MRI highlighting post-treatment changes versus recurrent disease4. Pitfalls and Pearls: Challenges in image interpretation and tips for radiologists unfamiliar with focal therapy follow-up.5. Clinical Relevance: Role of TULSA in modern prostate cancer management and its potential to reduce the burden of overtreatment.

GUEE-40 HEREDITARY GENITOURINARY CANCER SYNDROMES: ROLE OF IMAGING IN SCREENING AND SURVEILLANCE

Andrea Carolina Morales-Lara, MD (*Presenter*)
Surbhi Raichandani, MD (*Abstract Co-Author*)
Aarti Sekhar, MD (*Abstract Co-Author*)
Ayushi Gupta, MD (*Abstract Co-Author*)

TEACHING POINTS

Hereditary genitourinary (GU) cancer syndromes include von Hippel-Lindau (VHL), tuberous sclerosis (TS), Li-Fraumeni, hereditary leiomyomatosis and renal cell cancer (HLRCC), multiple endocrine neoplasia type 2 (MEN 2a and 2b), hereditary paraganglioma-pheochromocytoma, and others. Knowledge of these syndromes is essential for radiologists who may have the first opportunity to unify the diagnosis. These syndromes pose unique challenges and special opportunities in early cancer detection with imaging playing a central role in screening, surveillance, and guiding interventions to improve patient care.

TABLE OF CONTENTS/OUTLINE

1. Review key GU cancer syndromes including genetic foundations. 2. Recognize imaging features and diagnostic clues highlighting characteristic patterns through case-based examples. 3. Discuss screening and surveillance guidelines with recommendations from societies such as ACR and NCCN. 4. Understand the role of imaging and its impact in clinical decision-making for longitudinal care.

GUEE-41 RADIOLOGICAL ASSESSMENT OF THE PENIS; A DETAILED MULTIMODALITY REVIEW

Margaret Adejolu, FRCR,MRCP (*Presenter*)

TEACHING POINTS

1. To demonstrate the normal penile anatomy with an emphasis on ultrasound (US) and magnetic resonance imaging (MRI). 2. To provide guidance to radiologists to optimize imaging modality selection in the diagnostic workup of penile diseases. 3. To demonstrate common penile pathology and highlight key information required by urologists to help inform surgical planning and conservative treatment strategies.

TABLE OF CONTENTS/OUTLINE

Introduction 1. Anatomy of the penis and scrotum on US and MR imaging 2. Common indications for penile-specific imaging and optimal imaging modalities 3. MR protocol for penile Imaging 4. Imaging of penile Pathology • Neoplastic: Primary malignancy, metastasis • Inflammatory: Peyronie's disease, abscesses, pyoderma gangrenosum • Traumatic: Fractured penis • Post surgical: Complications of penile prosthesis • Vascular: Penile varices, thrombophlebitis 5. Pitfalls in imaging of the penis

GUEE-42 NOT SO RETRO: A MODERN LOOK AT RETROPERITONEAL PATHOLOGY

Wilfred R. Furtado, MD (*Presenter*)
Amanda C. Gibson, DO (*Abstract Co-Author*)
Leslie Nelson, DO (*Abstract Co-Author*)
Aman Khurana, MD (*Abstract Co-Author*)
James T. Lee, MD (*Abstract Co-Author*)
Joseph W. Owen, MD (*Abstract Co-Author*)
Andres R. Ayoob, MD (*Abstract Co-Author*)

TEACHING POINTS

The retroperitoneum is a component of the abdominal cavity located between the posterior parietal peritoneum and the transversalis fascia of the posterior abdominal wall, extending from the diaphragm cranially to the pelvic inlet caudally. Discrete fascial planes divide the retroperitoneum into three compartments (perirenal, anterior pararenal, and posterior pararenal) and allow these compartments to communicate with the pelvic extraperitoneal spaces. The retroperitoneum and extraperitoneal pelvis are affected by a variety of conditions including inflammatory, infectious, neoplastic, and traumatic processes. Diagnosis and identification of complications and disease spread in the retroperitoneum, as elsewhere throughout the body, depends predominantly on answering two questions - where is the abnormality located and what is the abnormality made of? Localization hinges on knowledge of anatomy, while composition determination depends on a knowledge of basic physics. Applying this approach enables radiologists to optimize search patterns, appropriately localize abnormalities, and narrow differential diagnoses. This review will use a case-based method to model this approach to image interpretation.

TABLE OF CONTENTS/OUTLINE

Define the facial planes and spaces of the retroperitoneum and extraperitoneal spaces of the pelvis, utilizing pathologic conditions to highlight anatomy. Describe techniques to localize abnormalities to the retroperitoneum and define their origin within an organ, compartment, or interfascial plane Discuss clinical cases modeling a systematic approach to define the location of the abnormality and characterize its composition (fluid, solid, fat, calcium, gas, etc.)

GUEE-43 NOT JUST TWO ROADS DOWN: RADIO-PATHOLOGIC PICTORIAL REVIEW OF THE URETER

Javier Azpeitia Arman, MD (*Presenter*)
Rosa M. Lorente-Ramos, MD, PhD (*Abstract Co-Author*)
Miguel Leon Garcia, MD (*Abstract Co-Author*)
Lorena Melian Iribar, MD (*Abstract Co-Author*)
Javier Azpeitia-Hernandez, MD (*Abstract Co-Author*)
Itxaso Galan-Gonzalez (*Abstract Co-Author*)

TEACHING POINTS

To review the embryology and anatomy of the ureter. To illustrate imaging findings of the ureter, including normal variants, inflammatory/infectious diseases, and tumors. To analyze the correlation between intravenous urography, US, CT, and MRI features with pathology in ureteral lesions. To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Although ureterolithiasis is the most frequent and urothelial carcinoma the most important differential diagnosis for ureteral lesions, different entities may involve the ureter. We review imaging findings, with clues to interpretation, and provide pathologic correlation. We will highlight how pathologic correlation informs imaging interpretation. We present: -Embryology. -Anatomy -Utility of imaging methods: multi-detector computed tomography (MDCT) urography, intravenous urography, MRI, and US. -Pathologic entities: congenital (incomplete and complete duplication, megaureter, ectopic ureteral insertion ureterocele, retrocaval ureter), inflammatory diseases (ureteritis cystica, tuberculosis); ureteral thickenings after obstruction, surgery or radiotherapy; obstruction (ureterolithiasis, blood clots, ureteropelvic junction obstruction and strictures, endometriosis, malacoplakia, retroperitoneal fibrosis); tumors: benign (papilloma, fibroepithelial polyps, villous adenoma) and malignant (ureteral transitional cell carcinoma, mesenchymal tumors, prostatic and gastric metastases, ureteral lymphoma); miscellanea (trauma, diverticula, ureteral pseudodiverticulosis, hernia, extrinsic compression/displacement, postsurgical images in different techniques).

GUEE-44 FAT AND THE ADRENALS: FRIEND TO RADIOLOGISTS (WITH SOME CAVEATS)

Yihan Cao, MD (*Presenter*)
Ryan Chung, MD (*Abstract Co-Author*)
Peter Sadow (*Abstract Co-Author*)
Michael A. Blake, MBBCh, MRCPI (*Abstract Co-Author*)

TEACHING POINTS

· Variations in retroperitoneal fat affect adrenal visibility · Microscopic fat-containing adrenal lesion = adenoma Exception - metastases from extra-adrenal tumors with microscopic fat · Macroscopic fat-containing adrenal lesion = myelolipoma Exception - myelolipomatous degeneration or macroscopic fat-containing metastases · Differentials for peri-adrenal fat-containing lesions include both benign (neoplastic and non-neoplastic) and malignant lesions

TABLE OF CONTENTS/OUTLINE

1. Impact of retroperitoneal fat on the visualization of the adrenal glands Abundant fat improves visualization, while paucity can obscure adrenal pathology. Sex-based fat distribution and the TOFI (thin-outside-fat-inside) phenotype also impact visibility. 2. Microscopic fat-containing adrenal lesions Microscopic fat is typical of adenomas, which show signal drop on OOP images. Key caveats: (1) IP signal drop often suggests calcification or iron deposition; (2) metastases from HCC or clear cell RCC may also contain microscopic fat; (3) metastasis to an adenoma (collision tumor) may show two distinct parts or peripheral signal loss on CSI. 2.2 Macroscopic fat-containing adrenal lesions Macroscopic fat is typical of myelolipoma, which may enlarge with hematopoietic stress and mimic liposarcoma. Large myelolipomas can occur in congenital adrenal hyperplasia. Myelolipomatous degeneration may be seen in adenomas and adrenocortical carcinoma. Adrenal liposarcoma metastases are rare but possible. 3. Fat-containing peri-adrenal lesions These include benign entities (renal angiomyolipoma, fat necrosis, hemostatic agents, brown fat on FDG-PET) and malignant lesions such as retroperitoneal liposarcoma.

GUEE-45 CYST-EMS CHECK: A MULTIMODALITY EXPLORATION OF RETROPERITONEAL CYSTIC MASSES

Michelle Li, BS (*Presenter*)
Mahan Mathur, MD (*Abstract Co-Author*)

TEACHING POINTS

Cystic retroperitoneal masses are rare and often present with non-specific clinical and imaging findings; therefore, they can be challenging to diagnose prospectively. However, accurate assessment is crucial to prompt appropriate treatment considerations, such as watchful waiting, biopsy, or surgical resection. Diagnosis can be aided by some important imaging findings, such as tumor size, location, and tissue composition. This presentation will explore and differentiate cystic retroperitoneal masses (including solid masses with cystic change/necrosis) by highlighting their epidemiology, appearance on multi-modal imaging, histopathology, and treatment. After the module, the learner should be able to do the following: 1) Compare and contrast the imaging appearance of various cystic retroperitoneal neoplasms. 2) Elucidate appropriate management methods for these lesions.

TABLE OF CONTENTS/OUTLINE

1) Introduction 2) Lymphatic malformation 3) Lymphangiomatosis 4) Lymphangioleiomyoma 5) Cystic teratoma 6) Cystic mesothelioma 7) Epidermoid cyst 8) Tailgut cyst 9) Bronchogenic cyst 10) Cystic change in solid neoplasm (Leiomyosarcoma, Paraganglioma, Nerve sheath tumors) 11) Pseudomyxoma retroperitonei 12) Conclusion

GUEE-46 PROSTATE ARTERY EMBOLIZATION AND IMAGING-BASED BIOMARKERS: CURRENT TOOLS IN MONITORING TREATMENT RESPONSE AND EMERGING STRATEGIES

Gavin Wu, BA (*Presenter*)
Umairullah Lodhi, MD (*Abstract Co-Author*)
Jason C. Hoffmann, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the role of imaging in pre-procedural evaluation and post-treatment response after prostate artery embolization (PAE), with emphasis on objective markers beyond symptom scores. 2. Review common imaging modalities, including MRI and CT, and their associated biomarkers such as prostate volume reduction, perfusion changes, and tissue viability. 3. Recognize emerging tools like radiomics and theranostic imaging that may improve standardization and predictive modeling.

TABLE OF CONTENTS/OUTLINE

Background: PAE is a minimally invasive treatment for BPH-associated lower urinary tract symptoms, especially in patients with significantly enlarged prostates (>80g). Imaging biomarkers provide objective assessment of treatment response and may complement clinical and biochemical endpoints. Imaging Modalities and Biomarkers: MRI and CT are used to assess prostate volume, perfusion, and infarction. Key biomarkers include non-perfused volume, ADC values, and DCE-MRI curves. Ultrasound may assess gland size and post-void residuals. Emerging Tools and Future Directions: Quantitative imaging may correlate with clinical outcomes, and emerging techniques such as radiomics and AI-based analysis are being explored for their potential in enhancing standardization and predictive modeling. Conclusion: Validated imaging biomarkers may enhance post-PAE monitoring and overall patient management by identifying individuals at higher risk of reintervention. This could enable tailored follow-up and patient education. Standardized protocols and further research are needed to support broader clinical use.

GUEE-47 DUAL-ENERGY CT APPLICATIONS FOR RENAL TUMOR ASSESSMENT: WHAT THE RADIOLOGIST AND UROLOGIST NEED TO KNOW

Shingo

Harashima (*Presenter*)
Haruhiko Machida, MD (*Abstract Co-Author*)
Rika Fukui (*Abstract Co-Author*)
Toshiya Kariyasu (*Abstract Co-Author*)
Makiko Nishikawa, MD (*Abstract Co-Author*)
Hidenori Yamaguchi (*Abstract Co-Author*)
Etsuko Tate, MD (*Abstract Co-Author*)
Wakana Samejima (*Abstract Co-Author*)
Yuta Hirose, MSc (*Abstract Co-Author*)
Isao Tanaka (*Abstract Co-Author*)
Yun SHEN (*Abstract Co-Author*)

TEACHING POINTS

1. To introduce current limitations in renal tumor assessment by single-energy CT (SECT). 2. To describe basic principles & various imaging/analyzing techniques of dual-energy CT (DECT) relevant to renal tumors. 3. To illustrate clinical utilities of DECT over SECT in renal tumor assessment by presenting various clinical images.

TABLE OF CONTENTS/OUTLINE

1. Current limitations in renal tumor assessment by SECT : a) Limited detection of poorly enhancing lesions, b) Beam-hardening (BH) artifact (pseudoenhancement), c) Limited differentiation of cystic vs. solid lesions, d) Greater radiation/contrast media (CM) dose, e) Limited renal tumor characterization; 2. Basic principles & imaging/analyzing techniques of DECT : a) Virtual monochromatic (VMI) & material decomposition imaging (MDI), b) keV-HU curve & effective atomic number (Z) analysis, c) Improved DECT image quality by metallic artifact reduction software (MARS)/iterative (IR) & deep-learning reconstruction (DLR); 3. Clinical utilities of DECT over SECT in renal tumor assessment : a) Improved detection of poorly enhancing lesions/CM dose reduction: low-keV VMI/iodine-enhanced MDI/IR/DLR, b) Reduced BH/metallic artifact: high-keV VMI/MARS, c) Differentiation between cystic and solid lesions: iodine-enhanced MDI, d) Assessment of tumor grade/viability/response to chemotherapy: iodine-enhanced MDI/iodine density quantification, e) Reduced radiation dose: virtual non-contrast imaging (iodine-suppressed MDI), f) Assessment of lipid-rich tumors (e.g., angiomyolipoma): fat-enhanced MDI/keV-HU curve/effective Z, g) Bone metastasis detection: hydroxyapatite/calcium-suppressed MDI.

GUEE-48 ROCK HARD RADIOLOGY: A PRACTICAL GUIDE FOR RESIDENTS ON UROLITHIASIS IMAGING

Bruna Reis, MD (*Presenter*)
Thamiris Garcia, MD (*Abstract Co-Author*)
Priscila Crabi (*Abstract Co-Author*)
Heraldo Pereira (*Abstract Co-Author*)

TEACHING POINTS

Non-contrast-enhanced CT is the gold standard for diagnosis, offering high sensitivity and specificity. Structured CT reporting in urolithiasis is essential for guiding clinical decisions and standardizing communication between radiologists and referring physicians. This educational exhibit is specifically designed for radiology residents, underscoring the importance of accurate detection, localization, and characterization of urinary calculi. Comprehensive CT reports should include the number, size, location, attenuation, and skin-to-stone distance of calculi, as well as associated findings, potential complications and procedurally relevant anatomy. Mastery of appropriate measurement techniques and detailed knowledge of urinary tract anatomy are essential for diagnostic accuracy and effective treatment planning. Differentiation of urinary stones from mimickers and the correct assessment of hydronephrosis and complications are fundamental competencies for radiologists in training.

TABLE OF CONTENTS/OUTLINE

Introduction Clinical relevance of urolithiasis Role of imaging in diagnosis and management Essential Elements of the CT Report Urinary Tract Anatomy and Variations Key anatomical landmarks Congenital and acquired variants affecting management Case-Based Review Educational cases with imaging examples Diagnostic Challenges and Pitfalls Related Complications Treatment Considerations Imaging findings influencing conservative vs. surgical treatment strategies Recognition of post-treatment complications Follow-Up Imaging Conclusion Summary of key educational points Empowering residents to improve diagnostic confidence and reporting quality

GUEE-49 REAL-TIME IN VIVO VISUALIZATION OF RETROPERITONEAL INTERFASCIAL PLANES: INSIGHTS FROM CT-GUIDED HYDRODISSECTION DURING RENAL CRYOTHERAPY

Kaori Yamada, MD, PhD (*Presenter*)
Yosuke Maehara (*Abstract Co-Author*)
Hiroshi Miura (*Abstract Co-Author*)
Tatsuya Hirota (*Abstract Co-Author*)
FUMIYA HONGO (*Abstract Co-Author*)
Osamu Ukimura (*Abstract Co-Author*)
Kei Yamada, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The traditional tricompartmental model has long served as the foundation for retroperitoneal anatomy. The concept of interfascial planes —such as the retromesenteric (RMP) , retrorenal (RRP) , and lateroconal (LCP) planes—has been recognized since the late 20th century , primarily based on cadaveric studies. However, CT-guided hydrodissection now enables real-time in vivo visualization of these planes. This exhibit aims to: (1) Review retroperitoneal interfascial anatomy based on hydrodissection imaging; (2) Describe the RMP, RRP, LCP, combined plane, and subfascial plane, including their continuities and anatomical variants; (3) Highlight key anatomical patterns that may refine traditional understanding.

TABLE OF CONTENTS/OUTLINE

(1) Overview - Introduction to the tricompartmental theory and the concept of interfascial planes. (2) Interfascial Planes - Definitions and relationships of the RMP, RRP, and LCP. (3) Lateral Continuity - Fascial trifurcation and interconnection of the three planes. (4) Superior Extension - Fusion patterns near the diaphragm. (5) Inferior Continuity - Merging of RMP and RRP into the pelvic retroperitoneum via the iliac fossa. (6) Medial Spread - Patterns of midline crossover and possible barriers related to the primitive descending mesocolon. (7) Retrorenal Variants - Two medial morphologies: termination at the psoas major vs. continuity with the anterior renal fascia. (8) Subfascial Plane - Latent cavity along the transversalis fascia, with posterior and anterior connections. (9) Conclusion - Summary of anatomical insights gained from hydrodissection imaging.

GUEE-50 INTERPRETING PROSTATE MRI AFTER FOCAL THERAPY WITH TARGET PRECISION

Andrea L. da Silva, MBBCh (*Presenter*)
Andrea G. Rockall, FRCR, MRCP (*Abstract Co-Author*)
Henry H. Tam, FRCR (*Abstract Co-Author*)
Amish Lakhani, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Review the eligibility criteria for prostate cancer focal therapy. Outline focal therapy options (including high-intensity focussed ultrasound, cryotherapy) and appropriate lesion selection. Emphasise MRI protocol post-treatment, including the importance of DCE imaging. Demonstrate typical early and late post-treatment imaging appearances with case examples. Introduce the TARGET recommendations for scoring in post-focal therapy reporting. Compare TARGET with other scoring systems in post-treatment prostate evaluation.

TABLE OF CONTENTS/OUTLINE

Minimally invasive focal therapies are shifting prostate cancer management, offering outcomes comparable to radical treatments with reduced morbidity. Imaging remains crucial for detecting recurrence. Post-treatment changes can make detection of viable disease challenging on MRI. Whilst bi-parametric MRI may be sufficient in the detection of clinically significant prostate cancer, dynamic contrast-enhanced imaging is essential post-focal therapy for optimal detection of recurrent disease. This exhibit outlines MRI protocol and common imaging appearances after treatment, with case examples highlighting diagnostic pitfalls. The TARGET recommendations provide a practical, structured reporting system for assessing the focal therapy-treated prostate, enabling standardised risk stratification and guiding follow-up decisions. We compare TARGET with other scoring systems, demonstrating its ease of use and clinical utility. Radiologists will gain tools to enhance diagnostic confidence and reporting consistency after focal therapy.

GUEE-51 ROLE OF NON-CONTRAST MR UROGRAPHY IN UPPER TRACT UROTHELIAL CARCINOMA: BEYOND AN ALTERNATIVE TO CT

Wei Wang (*Presenter*)
Jian-Xing Qiu, MD (*Abstract Co-Author*)
Jingyun Wu (*Abstract Co-Author*)

TEACHING POINTS

(1) Understand the limitations of CT urography and the emerging role of non-contrast MR urography (MRU) in upper tract urothelial carcinoma (UTUC) evaluation. (2) Recognize the key MRI features of UTUC (papillary, flat, invasive) and the added value of DWI in tumor detection and characterization. (3) Discuss the role of MRU in T-staging, differential diagnosis, and post-treatment follow-up with case examples.

TABLE OF CONTENTS/OUTLINE

1. Introduction to UTUC (1) Epidemiology & Clinical Presentation (2) Diagnostic Challenges 2. Imaging Modalities for UTUC: Strengths & Limitations (1)CT Urography (First-line choice) (2)MR Urography (Non-Contrast) Pros: No radiation, no iodinated contrast, superior soft-tissue contrast, functional imaging (DWI), safe for (follow-up) examination in patients with renal insufficiency; Cons: Longer scan time, lower spatial resolution vs. CT, cost 3. Suggested MRU Protocol & Essential Sequences T2WI (ax, cor)/DWI/Static-Fluid MRU 4. MRI findings of UTUC Papillary/Flat/Invasive Tumor 5. MRI in Local T-Staging Renal Pelvic/Ureteral UC staging 6. Differential Diagnosis 7. Post-Treatment Follow-Up 8. Summary

GUEE-52 ENDOMETRIOSIS WITHOUT BORDERS: COMMON AND UNCOMMON SITES AND PRESENTATIONS

Sreeja Sanampudi, MD (*Presenter*)
Azarin Shoghi, MD,MS (*Abstract Co-Author*)
Crystal H. Bruce (*Abstract Co-Author*)
David T. Fetzer, MD (*Abstract Co-Author*)
Gaurav Khatri, MD (*Abstract Co-Author*)
Ravi K. Kaza, MD (*Abstract Co-Author*)

TEACHING POINTS

Endometriosis can occur in uncommon locations such as bowel wall, bladder, mesentery, umbilicus, and thorax Unusual clinical presentations include peritonitis, cyclic pleural effusions, pneumothorax, and tuboovarian abscesses US is important in screening for endometriosis, particularly in common locations MRI is used for complex and extra-pelvic endometriosis Identifying atypical imaging appearances of endometriosis aids in accurate diagnosis and prevents mismanagement

TABLE OF CONTENTS/OUTLINE

1. Introduction Epidemiology and typical locations Pathophysiology for atypical locations 2. Imaging Modalities Role of US, CT, and MRI Findings specific to hemorrhagic/endometrial tissue 3. Uncommon Anatomical Locations Bowel wall involvement Rectosigmoid junction, "mushroom cap" sign Mesentery MRI appearance of cystic lesions Bladder and ureters Focal bladder wall thickening, hydronephrosis Umbilical endometriosis (Villar's Nodule) Cutaneous/subcutaneous lesion Abdominal wall C-section scar Thorax and pleura Cyclic hemothorax and catamenial pneumothorax 4. Uncommon clinical presentations Peritonitis Diffuse peritoneal enhancement, ascites Tuboovarian abscess Complex cystic adnexal masses with gas-fluid levels Pneumothorax 5. Differential Diagnosis and Diagnostic Pearls Endometriosis vs. malignancy, abscess, IBD Importance of menstrual history and correlation with cyclic symptoms 6. Clinical Impact and Management Role of radiology in surgical planning Multidisciplinary collaboration 7. Summary and Take-Home Messages High suspicion in patients with chronic pelvic pain and non-specific symptoms Recognizing imaging signs can guide minimally invasive diagnosis and treatment

GUEE-53 VIRTUAL HYSTEROSALPINGOGRAPHY (CT-VHSG): A NOVEL APPROACH FOR EVALUATING UTERINE ANOMALIES

Juan Cruz Gallo, MD, MD (*Presenter*)
Patricia M. Carrascosa, MD, PhD (*Abstract Co-Author*)
Jimena B. Carpio, MD (*Abstract Co-Author*)
Carlos Capunay, MD (*Abstract Co-Author*)
Mariano Baronio, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the embryological basis and classification of congenital uterine anomalies, including their impact on fertility, pregnancy loss, and obstetric complications. Compare CT-VHSG with conventional imaging techniques highlighting diagnostic advantages and limitations. Learn the technical approach for performing CT-VHSG, including patient preparation, acquisition protocols, and 3D reconstruction techniques. Recognize the imaging features of common Müllerian anomalies through case-based examples using CT-VHSG. Explore the clinical role of CT-VHSG in reproductive counseling and patient management, including its potential integration with AI-assisted interpretation and future advancements in minimally invasive imaging.

TABLE OF CONTENTS/OUTLINE

Overview of Congenital Uterine Anomalies Etiology and classification of Müllerian anomalies Prevalence and reproductive implications Imaging Techniques for Uterine Anomaly Detection Comparative review of HSG, ultrasound, MRI, and CT-VHSG Advantages and limitations of each modality CT-VHSG: Technical Approach and Diagnostic Value Procedure protocol, patient preparation, and acquisition techniques 3D imaging reconstruction for enhanced uterine morphology assessment Radiation dose considerations and safety profile Case-Based Review of Common Uterine Anomalies Unicornuate uterus, bicornuate uterus, didelphys uterus, and arcuate uterus Imaging findings and key differentiating features using CT-VHSG vs. other modalities. Clinical Implications and Future Perspectives Role of CT-VHSG in patient management and reproductive counseling Potential integration of AI-assisted interpretation for enhanced accuracy

GUEE-54 PROSTATE IMAGING: WIDENING THE SPECTRUM OF DISORDERS WITH MIMICKERS OF ADENOCARCINOMA AND BEYOND

Umran Esen, MD (*Presenter*)
Emre Unal, MD (*Abstract Co-Author*)
Aycan Uysal, MD (*Abstract Co-Author*)
Turkmen Ciftci (*Abstract Co-Author*)
Devrim Akinci (*Abstract Co-Author*)

TEACHING POINTS

1. A wide range of disorders may mimic prostate adenocarcinoma, and differentiating benign from malignant lesions can be challenging. 2. Inflammation of the prostate is a major limitation against definitive imaging-based diagnosis. 3. Both primary and metastatic malignant neoplasms of the prostate may mimic each other on cross-sectional imaging. 4. Awareness of these mimickers is essential, as clinical history and laboratory tests may fail to provide sufficient diagnostic information.

TABLE OF CONTENTS/OUTLINE

1. Introduction (Brief overview of prostate adenocarcinoma and typical imaging characteristics-including peripheral and central zone examples) 2. Differential Diagnosis: A Case-Based Approach (a. Inflammation of the prostate: the great mimicker of malignancy; b. Cystic lesions: not solid, not malignant; c. Benign but deceptive: non-neoplastic conditions; d. Malignancy, yet not primary; e. Primary malignancy, yet not adenocarcinoma; f. Miscellaneous) 3. Summary and Conclusion

GUEE-55 TULSA FOR PROSTATE CANCER: MRI-BASED PRE-TREATMENT PLANNING AND POST-TREATMENT ASSESSMENT — AN EMERGING ALTERNATIVE IN THE FOCAL THERAPY SPECTRUM

Satoru Takahashi, MD, PhD (*Presenter*)
Masayoshi Miura (*Abstract Co-Author*)
Hiroshi Higashiyama (*Abstract Co-Author*)
Yasuhito Yamaoka (*Abstract Co-Author*)

TEACHING POINTS

Transurethral ultrasound ablation (TULSA) is a novel MRI-guided treatment for localized prostate cancer (PCa), uniquely performed via a transurethral approach with real-time MRI thermometry, enabling both focal and whole-gland ablation with high precision. The objectives of this exhibit are: To understand the procedural workflow and technical principles of TULSA To recognize the role of multiparametric MRI (mpMRI) in patient selection and treatment planning To illustrate characteristic MRI findings immediately after TULSA and during follow-up To distinguish expected post-TULSA changes from imaging features indicative of treatment failure or recurrence

TABLE OF CONTENTS/OUTLINE

Focal therapies in PCa Overview of cryotherapy, RFA, HIFU, and TULSA Comparative characteristics of each treatment modality Technical aspects of TULSA Equipment overview Transurethral ultrasound transducer Cooling mechanisms for urethra and rectum Real-time MRI thermometry and procedural control Pre-treatment evaluation with mpMRI Lesion localization and patient selection Assessment of neurovascular bundles and sphincters Evaluation of calcifications and venous plexus Post-treatment MRI findings Immediate changes and serial evolution Prostate volume reduction and shape distortion Urethral preservation assessment Treatment-related complications Urethral obstruction and necrosis Soft tissue thermal injury Cystostomy requirements Detection of residual or recurrent disease Local recurrence, seminal vesicle involvement Nodal or bone metastasis Interpretive pitfalls and differential considerations Coagulative necrosis vs. abscess or inflammation

GUEE-56 RECURRENCE IMAGING AFTER DEFINITIVE THERAPY OF THE PROSTATE CANCER

Satoru Takahashi, MD, PhD (*Presenter*)
Yoshiko Ueno, MD, PhD (*Abstract Co-Author*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Munenobu Nogami, MD, PhD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Structured reporting and data systems (RADSs) help radiologists standardize interpretation and communication of prostate cancer (PCa) imaging findings. PI-RADS is widely used for identifying biopsy candidates and tumor localization, but imaging plays a broader role throughout PCa management, including nodal and distant staging, recurrence assessment, and evaluation of metastatic disease. Node-RADS, PSMA-RADS, PI-RR, and MET-RADS-P are emerging tools designed to guide these advanced diagnostic and therapeutic steps. Radiologists should understand the principles, clinical indications, and evaluation methods of each RADS. This exhibit offers an overview of how these RADSs are applied in real-world scenarios, supported by case-based illustrations and evidence-based review.

TABLE OF CONTENTS/OUTLINE

Clinical Workflow of Prostate Cancer and Corresponding RADSs Biopsy indication and localization: PI-RADS T-staging: PI-RADS N-staging: Node-RADS, PSMA-RADS M-staging and CRPC assessment: MET-RADS-P, PSMA-RADS Recurrence evaluation: PI-RR Imaging Modalities Used in Each Step Multiparametric MRI (mpMRI), contrast-enhanced CT, whole-body MRI, and PSMA-PET Evaluation Guide for Each RADS Technical requirements, categorization methods, and structured interpretation Clinical case presentations to demonstrate practical application Current Evidence and Limitations Diagnostic accuracy, interobserver agreement, and findings from recent literature and meta-analyses

GUEE-57 MULTIPARAMETRIC MRI AND PI-RR SYSTEM FOR LOCAL RECURRENCE OF PROSTATE CANCER: TECHNIQUE, INTERPRETATION, AND CLINICAL IMPACT

Satoru Takahashi, MD, PhD (*Presenter*)
Yoshiko Ueno, MD, PhD (*Abstract Co-Author*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Munenobu Nogami, MD, PhD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Biochemical recurrence (BCR) is a frequent challenge after radical prostatectomy (RP) or radiation therapy (RT) for prostate cancer (PCa), requiring accurate localization of recurrence to guide salvage or systemic treatment. The Prostate Imaging for Recurrence Reporting (PI-RR) system standardizes multiparametric MRI acquisition and interpretation for detecting local recurrence after RP or RT. Familiarity with post-treatment pelvic anatomy and structured MRI assessment improves diagnostic accuracy and clinical decision-making. This exhibit illustrates the utility, workflow, and limitations of the PI-RR scoring system in real-world practice.

TABLE OF CONTENTS/OUTLINE

Treatment Strategies for PCa - Overview of RP, RT, and salvage treatment approaches based on current guidelinesPost-Treatment Imaging Anatomy - Key anatomic changes following RP- Imaging findings after RTMRI Acquisition Protocol - Sequences: multiplanar T2-weighted, large-FOV T1-weighted/DWI, and DCE- Tips for optimizing local recurrence detectionPI-RR Scoring System - Criteria and application after RP and RT- Visual examples of PI-RR categoriesClinical Applications - Use of PI-RR in routine clinical scenarios- Role in guiding further imaging or treatment decisions- Case-based demonstrationCurrent Evidence and Limitations - Diagnostic accuracy and inter-reader agreement- Literature overview and future perspectives

GUEE-58 IMAGING OF THE PERIRENAL SPACE

Maria Zulfiqar, MD, MBBS (*Presenter*)
Michael Weston, MD (*Abstract Co-Author*)
Anup S. Shetty, MD (*Abstract Co-Author*)
Mark J. Hoegger, MD, PhD (*Abstract Co-Author*)
Kumaresan Sandrasegaran, MD (*Abstract Co-Author*)
Nelly Tan, MD (*Abstract Co-Author*)
Daniel R. Ludwig, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Akira Kawashima, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Illustrate the anatomy of the perirenal space with emphasis on radiological correlation. 2. Case based discussion of the spectrum of pathology in the perirenal space.

TABLE OF CONTENTS/OUTLINE

• Trauma: Pneumo-retroperitoneum; Grade 4 renal injury leading to urine leak; Perinephric hematoma commonly involves retroperitoneal zones 1 and 2. • Infection or inflammation: Perirenal abscesses; Fat stranding from pyelonephritis and urinary outflow obstruction; Forniceal rupture/urine leak Spread of inflammation from pancreatitis, ruptured duodenal ulcer, lumbar discitis osteomyelitis • Vasculature: Venous collaterals from renal vein/IVC obstruction; Arteriovenous fistula • Lymphatic: Renal/perirenal lymphangiectasia; Lymphatic leak • Masses: --Nonneoplastic masses: Retroperitoneal fibrosis/IgG4; Amyloidosis, renal replacement lipomatosis; Perinephric myxoid pseudotumor of fat; Gossypiboma --Neoplastic masses: Benign: Extramedullary hematopoiesis, Rosai-Dorfman disease; renal AML, retroperitoneal lipomatosis, Neurogenic tumors: Neurofibroma/ganglioneuroma. Malignant: Lymphoma; Erdheim-Chester disease; liposarcoma; Myxoid sarcomatous tumors; Leiomyosarcoma; Metastasis.

GUEE-59 WHO 2022 CLASSIFICATION OF RENAL CELL TUMORS: WHAT THE RADIOLOGIST NEEDS TO KNOW

Kumaresan Sandrasegaran, MD (*Presenter*)
ABHIJIT DAS (*Abstract Co-Author*)
Komal A. Chughtai, MD (*Abstract Co-Author*)
Amar Shah, MD (*Abstract Co-Author*)
Nelly Tan, MD (*Abstract Co-Author*)
Maria Zulfiqar, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Obtain a broad overview of World Health Organization (WHO) 2022 Classification of renal tumors 2. Review the newer tumors included in this classification 3. Learn some of the unique imaging and clinical features of newer renal tumors

TABLE OF CONTENTS/OUTLINE

1. 2022 classification (version 5) of renal tumors 2. Uncommon Renal Tumors 3. Molecularly-defined renal cancers 4. Clinical and imaging features that point to diagnosis of: a. Clear Cell Papillary Renal Cell Tumor b. Tubulocystic Carcinoma c. Eosinophilic Solid and Cystic Renal Cell Carcinoma (RCC) d. TFE3-Rearranged RCC e. Fumarate Hydratase-Deficient RCC f. ALK-Rearranged RCC

GUEE-60 MR-GUIDED FOCAL HDR BRACHYTHERAPY FOR PROSTATE CANCER: RADIOLOGIST'S EXPANDING ROLE IN MONOTHERAPY, BOOST, AND SALVAGE SETTINGS

Jorge A. Abreu Gomez, MD (*Presenter*)
Stephanie Trujillo C, MD (*Abstract Co-Author*)
Vanessa Murad, MD (*Abstract Co-Author*)
Adriano Basso Dias, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

MR-guided focal HDR brachytherapy is a promising minimally invasive treatment for prostate cancer, enabling precise dose delivery with minimized toxicity. This technique can be applied as monotherapy, a boost following EBRT, or as salvage therapy in recurrent disease. MRI plays a critical role throughout the treatment process —from lesion targeting and catheter placement to post-treatment surveillance and assessment of recurrence. Familiarity with expected post-treatment MRI findings and imaging features of recurrence is essential for radiologists involved in prostate cancer management.

TABLE OF CONTENTS/OUTLINE

Clinical background and evolving role of HDR brachytherapy in prostate cancer treatment Overview of HDR brachytherapy indications: monotherapy, boost after EBRT, and salvage use Advantages of MR-guided HDR: real-time targeting, superior tissue contrast, and dosimetric precision MRI-based patient selection and focal lesion targeting. MRI-guided HDR workflow: imaging protocols, catheter placement, treatment planning Post-treatment MRI findings: expected findings vs. residual / recurrent disease Radiologist's role across monotherapy, boost, and salvage settings

GUEE-61 EXTRA-OVARIAN MUCINOUS CYSTIC NEOPLASMS: THE OVARIAN MIGRATION VESTIGE THEORY

Heather M. Martin, MD, MPH (*Presenter*)
Korosh Khalili, MD (*Abstract Co-Author*)

TEACHING POINTS

Extraovarian mucinous cystic tumors with ovarian-type stroma (OTS) share clinical, radiologic, and pathologic features despite arising in anatomically distinct locations. These tumors occur almost exclusively in women and commonly present as multilocular cystic masses in very specific locations , often with identical histologic profiles but thought of and classified as unrelated tumors. The ovarian migration vestige theory postulates that these tumors originate from ectopic gonadal or Müllerian progenitor cells displaced during embryonic ovarian descent , accounting for their similar appearance and peculiarly specific locations, even within the same organ. This developmental model reframes seemingly unrelated tumors as part of a unified disease process, challenging traditional organ-based classification schemes. Understanding the shared embryologic origin of OTS-associated tumors may improve diagnostic accuracy and clarify clinical management.

TABLE OF CONTENTS/OUTLINE

Overview of Ovarian Development and Descent Review of the ovarian migration vestige theory (Visual Embryology Diagram) Discuss the peculiar location for each tumor in respect to the ovarian descent pathway. Pictorial review of tumors with diagnostic tips to allow specific diagnosis: Mucinous cystic neoplasm of the liver Pancreatic mucinous cystic neoplasm Retroperitoneal mucinous cystadenoma and variants Renal mixed epithelial and stromal tumor/Multilocular cystic nephroma Ovarian mucinous neoplasm

GUEE-62 BEYOND THE SURFACE: EXPLORING RADIOLOGY'S FRONTIER WITH TRANSPERINEAL ULTRASOUND

Reham M. Ellessy, MBBCh (*Presenter*)
Grace G. Zhu, MD (*Abstract Co-Author*)
Cary L. Siegel, MD (*Abstract Co-Author*)
Douglas M. Rogers, MD (*Abstract Co-Author*)
Moataz Ahmed Sayed Mohammed Soliman, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

Objectives of this exhibit include: Provide an overview of the anatomy of the pelvic floor and the role of transperineal ultrasound in visualizing pelvic structures. Showcase transperineal ultrasound its imaging appearance across multiple different pathologies Highlight the advantages and limitations of transperineal ultrasound compared to other imaging modalities

TABLE OF CONTENTS/OUTLINE

1) Introduction a) Review anatomy of the pelvic floor and perineal region b) Briefly review the role of different imaging modalities (fluoroscopy, MRI, Ultrasound) in visualization and dynamic assessment of the perineum c) Review the technique involved in transperineal ultrasound, with focus on the protocol, transducer selection, and patient preparation 2) Review of pathology and imaging examples of transperineal ultrasound a) Pelvic fistulas b) Pelvic floor dynamics c) Perineal masses d) Vaginal abnormalities i) Vaginal and peri-vaginal cysts ii) Vaginal tumors (1) Benign (2) Malignant iii) Congenital anomalies iv) Vaginal foreign bodies e) Mullerian duct anomalies 3) Advantages and Disadvantages of transperineal ultrasound to other modalities

GUEE-63 MICROVASCULAR FLOW IMAGING FOR TESTICULAR DISEASE: CASE-BASED LEARNING IN ULTRASOUND DIAGNOSIS

Arisa Kameda (*Presenter*)
Kiyoyuki Minamiguchi (*Abstract Co-Author*)
Katsutoshi Horiuchi, MD (*Abstract Co-Author*)
Mako Iwata (*Abstract Co-Author*)
Ayano Takeda, MD (*Abstract Co-Author*)
Toshihiro Tanaka, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to highlight the advantage of Microvascular Flow Imaging (MVFI) over conventional Doppler techniques in evaluating testicular vascularity, to illustrate characteristic MVFI findings through representative cases of acute scrotal diseases and testicular tumors, and to demonstrate how MVFI can be effectively incorporated into an ultrasound-based diagnostic approach for testicular disease

TABLE OF CONTENTS/OUTLINE

Ultrasonography is commonly used as the first-line modality for evaluating testicular lesions and is convenient for assessing blood flow. However, even in normal testis, assessing blood flow can be difficult due to clutter and motion artifacts, making it challenging to detect flow in the target region. MVFI is an advanced Doppler technique that visualizes fine, low-velocity blood flow difficult to see with conventional Doppler. MVFI improves the detectability of subtle vascular signals and allows detailed assessment of microvascular architecture. This exhibit presents the clinical utility of MVFI in assessing various testicular diseases, focusing on its diagnostic advantages and integration into an ultrasound-based approach. I. Introduction• Characteristics of MVFI: basic principles and clinical application• Comparison with Other Blood Flow Imaging (e.g. Color Doppler Imaging, Power Doppler Imaging, Advanced Dynamic Flow) II. Case series• Acute scrotal diseases (Testicular torsion/ Appendiceal torsion/ Segmental testicular infarction/ Testicular injury)• Tumorous diseases (Germ cell tumor/ Malignant lymphoma/ Epidermoid cyst/ Angioma/ Adrenal rest tumor)

GUEE-64 IGG4-RELATED DISEASE IN THE URINARY TRACT; IMAGING FINDINGS AND MIMICKERS

Fumiko Yagi, MD (*Presenter*)
Hirotaka Akita (*Abstract Co-Author*)
Yoshitake Yamada, MD, PhD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

(1) Understanding the pathophysiology of IgG4-related diseases (IgG4-RD) in the urinary tract (2) Understanding useful radiological findings, differential diagnoses, and mimickers of IgG4-RD in the urinary tract

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Pathophysiology of IgG4-RD III. Clinical manifestations IV. Diagnosis and classification criteria V. Treatment VI. IgG4 related diseases in the urinary tract, differential diagnoses, and mimickers A. Overview of IgG4-RD in the urinary tract B. Importance of IgG4-RD in the urinary tract C. Kidney lesions, differential diagnoses, and mimickers (Erdheim-Chester disease, Rosai-Dorfman disease, malignant lymphoma, tuberculoma, sarcoidosis, and renal granulomatous disease) D. Renal Pelvic lesions, differential diagnoses, and mimickers (carcinoma and pyelitis) E. Adrenal lesions, differential diagnoses, and mimickers (carcinoma and malignant lymphoma) F. Ureteral lesions, differential diagnoses, and mimickers (carcinoma, amyloidosis, and endometriosis) G. Bladder lesions, differential diagnoses, and mimickers (carcinoma, malignant lymphoma, leiomyoma, amyloidosis, and endometriosis) H. Urethral lesions, differential diagnoses, and mimickers (malignant lymphoma, leiomyoma, amyloidosis, and urethral diverticulum carcinoma) I. Prostatic lesions, differential diagnoses, and mimickers (carcinoma, malignant lymphoma, and granulomatous prostatitis) J. Testes lesions, differential diagnoses, and mimickers (testicular tumors and hydrocele due to retroperitoneal fibrosis secondary to IgG4-RD) K. Retroperitoneal lesions, differential diagnoses, and mimickers (metastatic gastric cancer and Erdheim-Chester disease)

GUEE-65 BEYOND THE GLOW: DECODING PSMA-PET IN PROSTATE CANCER IMAGING

Paula Ribeiro de Britto Borges, MD (*Presenter*)
Luciana Costa, PhD (*Abstract Co-Author*)
Thais Lemos (*Abstract Co-Author*)
Ivana M. Abuhid, MD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize physiologic patterns of PSMA uptake to avoid false-positive interpretations. • Identify benign conditions with PSMA expression, including fractures, degenerative bone changes, meningiomas, and hemangiomas. • Illustrate non-prostatic malignancies with PSMA uptake and their diagnostic implications. • Emphasize the importance of anatomic correlation and clinical context in differentiating true-positive findings. • Improve diagnostic confidence in PSMA PET/CT through real-world case-based learning.

TABLE OF CONTENTS/OUTLINE

PSMA PET/CT has revolutionized the management of prostate cancer, particularly in staging, therapeutic planning, and detection of biochemical recurrence. However, PSMA expression, is not exclusive to prostate malignancies, posing interpretative challenges in clinical practice. This educational exhibit highlights common pitfalls based on recent literature (Radiology, 2023-2025), exemplified through cases from a high-volume oncologic imaging center. Case examples include uptake in fractures, degenerative bone changes, vertebral hemangiomas, acute and chronic inflammatory processes, chronic thyroiditis, thyroid cancer, lung cancer, among others. Interpretation strategies will focus on uptake intensity, anatomic distribution, CT morphological features, clinical and laboratory correlation, and integration with other imaging modalities. Understanding these pitfalls is essential for radiologists and nuclear medicine physicians to ensure accurate interpretation, reduce diagnostic erros, and improve patient oucomes.

GUEE-66 GETTING TO KNOW THE GUBERNACULUM

Douglas M. Rogers, MD (*Presenter*)
Reham M. Ellessy, MBBCh (*Abstract Co-Author*)
Grace G. Zhu, MD (*Abstract Co-Author*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Paula J. Woodward, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Explain the normal embryological function of the gubernaculum in males and females, followed by description of the myriad developmental abnormalities 2) Provide a multi-modality, case-based review of the wide array of abnormalities involving development along the gubernaculum, focused on clinically relevant and symptomatic findings

TABLE OF CONTENTS/OUTLINE

1) Introduction/Background a) Normal Gubernaculum Embryological Development a. Males b. Females b) Anatomy 2) Male Gubernaculum Abnormalities a) Abnormal Testicular Descent a. Cryptorchidism i. Germ Cell Tumors ii. Intra-pelvic Torsion b. Cross-fused Testicular Ectopia c. Retractile Testis b) Testicular Agenesis/Hypoplasia c) Congenital Inguinal Hernia/Communicating Hydrocele d) Testicular Torsion a. Extravaginal b. Intravaginal e) Complete Androgen Insensitivity Syndrome f) Spleno-gonadal Fusion 3) Female Gubernaculum Abnormalities a) Round Ligament (caudal portion) a. Canal of Nuck Pathology i. Congenital Inguinal Hernia ii. Hydrocele 1. Communicating 2. Encysted b. Round Ligament Varices c. Endometriosis d. Round Ligament Masses b) Ovarian Ligament (cranial portion) a. Undescended/Ectopic Ovary b. Ovarian Torsion c) Mullerian Abnormalities a. Accessory Cavitated Uterine Mass b. Mayer-Rokitansky-Kuster-Hauser Syndrome (MRKH)

Head & Neck Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

HNEE-1 DON'T BE SWALLOWED! ANATOMY AND DISEASES OF THE ORAL CAVITY

Tamara Hernandes Ricci, MD (*Presenter*)
Carlos Alberto F. Coelho Neto, MD (*Abstract Co-Author*)
Luis G. Duarte, MD (*Abstract Co-Author*)
Anna P. Riello, MD, MSc (*Abstract Co-Author*)
Rodrigo J. Araya Rojas, MD (*Abstract Co-Author*)
Soraia A. Souza, MD, MS (*Abstract Co-Author*)
Marcio Ricardo T. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

• Detailed analysis of normal anatomy and regions of interest within the oral cavity, including the mucosal lip, buccal mucosa, hard palate, oral tongue, floor of the mouth, retromolar trigone, upper and lower alveolar ridges (maxilla and jaw).• Discussion of key dynamic imaging techniques to better characterize oral lesions and their avidity, such as puffed-cheek, open mouth and tongue protrusion• Evaluate computed tomography (CT) and magnetic resonance imaging (MRI) as tools to identify and make differential diagnoses of the main diseases of the oral cavity, with the aim of guiding treatment and prognosis

TABLE OF CONTENTS/OUTLINE

• Introduction highlighting the normal anatomy • Comparison between TC and MRI finds.• Overview the main imaging characteristics of the main oral cavity diseases divided by subsites Main Pathologies discussed: squamous cell carcinoma, lesions of the minor salivary glands (including pleomorphic adenoma, adenoid cystic carcinoma and mucous retention cysts), ranula, cysts of various etiologies (dermoid cyst, enteric duplication cyst, complications related to dental infecction, tongue atrophy due to cranial nerve paralysis, vascular anomalies, mandibular and palatal torus, submandibular sialolithiasis, boutonnière disease. • Conclusion.

HNEE-2 SO DO YOU REALLY KNOW YOUR CRANIAL NERVES??? - A RADIOLOGIST'S REFRESHER

Janani Baradwaj, MD, FRCR (*Presenter*)
Anu Kamalasanan, FRCR, MBBS (*Abstract Co-Author*)
Thiru A. Sudarshan, DMRD, FRCR (*Abstract Co-Author*)
Janani Asogan Vaishnavi, MD, FRCR (*Abstract Co-Author*)
Richard D. White, MBChB, FRCR (*Abstract Co-Author*)
Brahadesh Sivakumar (*Abstract Co-Author*)

TEACHING POINTS

Understanding the segmental anatomy of cranial nerves is essential for accurate localization and interpretation on MRI. Tailoring MRI protocols based on clinical suspicion ensures comprehensive evaluation and avoids missed pathology. Precise anatomical coverage—from brainstem to skull base and beyond—is key to evaluating the full course of each nerve. Radiologic signs of perineural tumor spread must be actively sought, as they significantly impact staging and treatment. Careful assessment of skull base foramina is necessary to detect subtle abnormalities indicating nerve involvement. Recognition of muscle denervation changes can serve as an important indirect clue to cranial nerve dysfunction. Common cranial nerve pathologies follow recognizable imaging patterns that aid in differential diagnosis. Radiologists play a crucial role in surgical planning by accurately mapping nerve involvement and guiding management decisions.

TABLE OF CONTENTS/OUTLINE

To review the normal MRI anatomy and expected imaging appearance of all 12 cranial nerves using high-resolution sequences. To outline the optimal MRI techniques, sequences, and anatomical coverage required for comprehensive cranial nerve evaluation. To illustrate common and clinically significant pathologies affecting cranial nerves with radiological-clinical correlation

HNEE-3 THYROID ECHOES: FROM SOUND WAVES TO SMART TECH

Marina Joseane Pachecco, MD (*Presenter*)
Carolina Carotenuto Ramos, MD (*Abstract Co-Author*)
Isabelle Lopes Passos De Fabbri, MD (*Abstract Co-Author*)
Geovana Ribeiro, MD (*Abstract Co-Author*)
Michelle Thais Wirtti Jorge (*Abstract Co-Author*)
Gabriel Alves, MD (*Abstract Co-Author*)
Peter C. Francolin (*Abstract Co-Author*)
Fernando L. Pereira, MD (*Abstract Co-Author*)
Eduardo D. Chiovatto, MD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Ultrasonography is the gold standard for thyroid evaluation due to its wide availability, high sensitivity and real-time imaging capability. This review addresses the main technical aspects, normal thyroid anatomy and common anatomical variants, while also exploring the evaluation of focal and diffuse thyroid diseases. It also discusses advanced techniques such as microbubble contrast-enhanced ultrasonography (CEUS), Doppler and elastography for lesion characterization. Finally, the use of artificial intelligence as a tool to enhance diagnostic accuracy and improve workflow is highlighted.

TABLE OF CONTENTS/OUTLINE

Ultrasonography Technique: The Foundation of Diagnostic Accuracy Transducer selection, patient positioning and main settings; tips for longitudinal/transverse sections and identification of artifacts and pitfalls. Ultrasonographic Findings of Normal Thyroid Anatomy, measurements, echogenicity and common anatomical variants. Diffuse

Thyroid Disease: Recognition and Differentiation Sonographic patterns of Hashimoto's thyroiditis, Graves' thyroiditis, subacute thyroiditis, post-radiotherapy thyroiditis, and Riedel's thyroiditis. Thyroid Nodules: Comprehensive Evaluation Assessment of the thyroid nodule, TI-RADS classification, identification suspicious features, indications for follow-up and biopsy, the use of Doppler, CEUS (microbubble contrast-enhanced ultrasound), and elastography. The Use of Artificial Intelligence as a Valuable Ally Applications of AI in automating TI-RADS classification, improving clinical workflow, and exploring future perspectives.

HNEE-4 BEYOND PLEOMORPHIC: UNCOMMON PAROTID TUMOURS- RADIOLOGY-PATHOLOGY CORRELATION

Janani Baradwaj, MD, FRCR (*Presenter*)
Janani Asogan Vaishnavi, MD, FRCR (*Abstract Co-Author*)
Anu Kamalasanan, FRCR, MBBS (*Abstract Co-Author*)
Thiru A. Sudarshan, DMRD, FRCR (*Abstract Co-Author*)
Richard D. White, MBChB, FRCR (*Abstract Co-Author*)
Gayathri Srinivasaraghavan (*Abstract Co-Author*)

TEACHING POINTS

Parotid swellings may arise from neoplastic, inflammatory, or obstructive causes - accurate imaging helps narrow the differential.Not all solid parotid tumours are pleomorphic adenomas/Warthin’s. Histologic subtypes often correlate with signal characteristics (e.g, oncocytic components = T1 hyperintensity) Radiologic-pathologic correlation improves confidence and guides management.- MRI is the modality of choice for deep lobe lesions and assessing malignant potential. CE-T1WI - tumor extent, perineural spread, nodal involvement. DWI and contrast-enhanced sequences help differentiate low vs. high-grade lesions.- Ultrasound remains first-line for superficial lesions and guiding FNAC. Evaluate vascularity, margins, and cystic/solid nature. Useful in bilateral or multifocal lesions (e.g., Warthin’s tumor).- CT neck with contrast is beneficial for calcifications, osseous involvement, pre-operative planning and staging. Location matters - deep lobe tumors, facial nerve proximity, or skull base extension for surgical planning.

TABLE OF CONTENTS/OUTLINE

Describe relevant imaging findings of Parotid tumours to reliably differentiate benign versus malignant lesions. To assess the clinical impact of precise lesion localisation on surgical planning, particularly in preserving facial nerve function. To correlate imaging findings with pathology for diagnostic confirmation and accuracy. To highlight scenarios where imaging can guide conservative management, avoiding unnecessary surgical intervention. To address current limitations and challenges in imaging evaluation of parotid masses, including diagnostic pitfalls and mimics.

HNEE-5 THE AIR UP THERE: A JOURNEY THROUGH AIR IN UNEXPECTED PLACES OF THE HEAD AND NECK

Antonio De La Cruz, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Juan Gonzalez, MD (*Abstract Co-Author*)
Maximiliano Carrera (*Abstract Co-Author*)
Neian Contreras Alvarado (*Abstract Co-Author*)
Jose A. Lara, MD (*Abstract Co-Author*)

TEACHING POINTS

Provide an anatomical review of head and neck anatomical landmarks.Use a hot air balloon journey analogy to identify abnormal air locations and patterns.Correlate clinical scenarios with specific air-related findings.Reinforce air related pathologies of head and neck using real cases and illustrations to enhance retention and diagnostic precision.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Air-Related Head and Neck Anatomy IV. Pathologies a. Traumatic: Pneumocephalus, Orbital Emphysema, Subcutaneous Emphysema b. Infectious/Iatrogenic: Cavernous Sinus Air, Pneumorrhachis, pneumoventricle, pneumocephalus c. Pressure-related: Pneumoparotid d. Spontaneous/Unusual: Pneumosinus Dilatans, Orbital Air Tamponade VI. Pathophysiology and Clinical Context VII. Memorable analogies VIII. Conclusion Abstract:Air is vital for life, but when found outside normal compartments in the head and neck, it may indicate pathology. This exhibit uses a hot air balloon journey to explore ectopic air in regions like the ventricles, cranial vault, parotid spaces, and neck. Pathologies are categorized as traumatic, infectious/iatrogenic, pressure-related, spontaneous, or interventional. CT and MRI cases highlight imaging patterns, complications, and relevance, enhancing diagnostic accuracy through a visual, memorable approach.

HNEE-6 LIGHTS, CAMERA, INFECTION! STARRING THE MAJOR INFECTIOUS EMERGENCIES OF THE HEAD AND NECK

Marcela Mazzetto Cavalcante, MD (*Presenter*)
Cristian Lima Duarte, MD (*Abstract Co-Author*)
Anna C. Silva (*Abstract Co-Author*)
Yolanda Maroto Teixeira, MD (*Abstract Co-Author*)
Lilian Oliveira, MD (*Abstract Co-Author*)
Vitor Dias, MD (*Abstract Co-Author*)
Patricia Oliveira-Szejnfeld, MD (*Abstract Co-Author*)
Roberto Bastos, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Identify the main infectious emergencies of the head and neck and acknowledge their frequent occurrence in clinical practice due to multiple etiologies. 2) Describe fascial planes and spaces of the neck and other relevant head and neck anatomic landmarks. 3) Recognize the critical role of CT and MRI in the diagnostic process, particularly in detecting characteristic imaging patterns. 4) Understand that prompt identification facilitates tailored monitoring and intervention strategies. 5) Endeavor to make the study of these pathologies accessible and less intimidating for radiologists.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Imaging modalities 3. Head and neck anatomy 4. Disease processes categorized by anatomic region: 4.1 Orbits 4.2 Mastoids 4.3 Face 4.4 Neck Summary 5. Take Home Messages

HNEE-7 THE PAROTID SPECTRUM: A COMPREHENSIVE TUMOR ODYSSEY

Dario Nascimento Ferreira Alves, MD (*Presenter*)
Isabela D. Alves, MD (*Abstract Co-Author*)
Maria Vitoria Ludwig, MD (*Abstract Co-Author*)
Luiz R. Uchoa, MD (*Abstract Co-Author*)
Vinicius T. Goncalves, MD (*Abstract Co-Author*)
Jorge T. Takahashi, MD (*Abstract Co-Author*)
Ula Passos, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Parotid Anatomy 2. Benign Parotid 3. TumorsMalignant 4. Parotid Tumors 5. Metastases and Unusual Tumors 6. Tumor Mimics 7. Permeability Curves 8. Postoperative Findings 9. Diagnostic Approach of Parotid Tumors

TABLE OF CONTENTS/OUTLINE

1. Introduction 1.1 Overview of Parotid Gland Tumors 1.2 Clinical and Radiological Relevance 1.3 Objectives of the Review 2. Anatomy of the Parotid Gland 3. Parotid Gland Tumors 3.1 Benign Tumors 3.1.1 Pleomorphic Adenoma: Epidemiology, Imaging Features, and Management 3.1.2 Warthin's Tumor: Characteristics and Association with Smoking 3.1.3 Other Benign Lesions (e.g., Hemangiomas, Lipomas) 3.2 Malignant Tumors 3.2.1 Mucoepidermoid Carcinoma: Prevalence and Imaging Findings 3.2.2 Adenoid Cystic Carcinoma and Other Primary Malignancies 3.2.3 Clinical Indicators of Malignancy (Pain, Facial Nerve Palsy) 3.3 Metastatic Tumors 3.3.1 Common Sources (Squamous Cell Carcinoma, Melanoma) 3.3.2 Imaging Differentiation from Primary Tumors 3.4 Unusual Tumors 3.4.1 Lymphomas and Rare Histologies 3.4.2 Carcinoma Ex-Pleomorphic Adenoma 3.4.3 Diagnostic Challenges 4. Permeability Curve Patterns 5. Postoperative Findings 5.1 Expected Imaging Findings After Parotidectomy 5.2 Complications 5.3 Surveillance for Tumor Recurrence 5.4 Role of Imaging in Detecting Recurrence vs. Benign Changes 6. Management and Prognosis 6.1 Surgical Approaches 7. Conclusion 7.1 Summary of Key Points 7.2 Future Directions in Parotid Tumor Imaging and Management 8. References

HNEE-8 SEGMENT-SPECIFIC OPTIMIZED MRI PROTOCOLS FOR CRANIAL NERVES IN NEUROOPHTHALMOLOGY WITH ILLUSTRATIVE CASES

Yebin Kim, MD (*Presenter*)
GO WOON PARK (*Abstract Co-Author*)
Eunhee Kim, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit presents segment-specific MRI protocols optimized for visualizing cranial nerves (CN) 2, 3, 4, and 6 in neuroophthalmology. For high-resolution imaging, 3D sequences are preferred over 2D, and coronal planes are generally superior to axial/sagittal planes in orbit and cavernous sinus. Each anatomical segment requires specific MRI sequences: Brainstem Sub-3mm thin-section RESOLVE DWI reduces susceptibility artifacts while visualizing acute pathologies Cisternal segment 3D proton density imaging enhances nerve-vessel differentiation; small FOV 3D Trufi best visualizes the diminutive CN4 Cavernous segment 3D CE coronal T1 VIBE provides superior visualization of CNs traversing the cavernous sinus compared to 3D CE T1 MPRAGE Orbital Apex 3D CE T1 SPACE with Dixon method provides superior black blood imaging for detecting pathologic lesions Intraorbital segment 3D DESS images visualize peripheral branches of CN3, CN4, and CN6 to extraocular muscles Optic Nerve 2mm thin-section coronal T2WI with fat suppression enables detection of optic nerve atrophy, nerve sheath dilatation, and clear differentiation from surrounding structures The exhibit includes representative clinical cases demonstrating the diagnostic value of each protocol.

TABLE OF CONTENTS/OUTLINE

Segmental approach for CN 2, 3, 4, and 6 Brainstem Segment: Thin-section RESOLVE DWI Cisternal Segment: 3D PDWI vs 3D T2 SPACE; Small FOV 3D Trufi for CN4 Cavernous Segment: 3D CE T1 VIBE vs 3D CE T1 MPRAGE Orbital Apex: 3D CE T1 SPACE with Dixon method benefits Intraorbital Segment: 3D DESS for peripheral CN branches Optic Nerve: Thin-section coronal T2WI vs T2 FLAIR Protocol selection algorithm and future directions

HNEE-9 DECODING THE PAROTID PUZZLE: IMAGING INSIGHTS INTO SALIVARY GLAND DISEASE

Claudia Viescas Huerta, MD (*Presenter*)
Isabel Fonseca Buelga, MD (*Abstract Co-Author*)
Diego Alejandro Garcia Paredes, MD (*Abstract Co-Author*)
Sergio Sintes (*Abstract Co-Author*)
Elisa Antolinos Macho, MD (*Abstract Co-Author*)
Juan V. Quintana Perez, MD (*Abstract Co-Author*)
Beatriz Alba Perez, MD (*Abstract Co-Author*)
Abel Gonzalez Huete, MD (*Abstract Co-Author*)

TEACHING POINTS

1.To review the anatomy of the parotid space, its boundaries and content. 2.To review the anatomy of the facial nerve. 3.To explain the benign non tumoral pathology of the parotid gland with illustrative cases. 4.To discuss the optimal approach to manage a lesion in the parotid space. 5.To review the main benign and malignant tumors of the parotid gland with their imaging findings.

TABLE OF CONTENTS/OUTLINE

1.Anatomy: parotid space and facial nerve. 2.Benign non tumoral parotid gland pathology: congenital anomalies, inflammatory and autoimmune diseases. 3.First approach to tumoral pathology: localization of the lesion, number, extension and imaging characteristics. 4.Benign tumors: pleomorphic adenoma, Warthin tumor, oncocytoma and hemangiomas. 5.Malignant tumors: lymphoma, epithelial tumors and metastasis. 6.Perineural spread. 7.Summary.

HNEE-10 SALIVARY SECRETS UNVEILED: A RADIOLOGIST'S GUIDE TO COMMON DISORDERS OF THE MAJOR SALIVARY GLANDS

Hatice Aydin, MD (*Presenter*)
Gozde Ozer IV, MD (*Abstract Co-Author*)
Ekim Gumeler, MD (*Abstract Co-Author*)
Elif Bulut (*Abstract Co-Author*)

TEACHING POINTS

The major salivary glands—parotid, submandibular, and sublingual—are subject to a diverse range of disorders that can pose diagnostic challenges due to overlapping clinical and imaging features. This presentation aims; 1. To provide a detailed review of the radiological anatomy and pathology of the major salivary glands, emphasize radiological features through illustrative cases. 2. To highlight key imaging characteristics of common salivary gland pathologies and present an evidence-based imaging approach to their diagnosis. The role of various imaging modalities—including ultrasound, computed tomography, and magnetic resonance imaging—is discussed in detail.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of basic anatomy and common anatomical variants (e.g., accessory parotid gland, facial process, congenital agenesis) Imaging modalities and differential diagnosis Role of US, CT, and MRI Suggested imaging workflow and differential diagnosis algorithm Benign neoplastic lesions Epithelial: Pleomorphic adenoma, Warthin tumor, oncocytoma Non-epithelial: Lipoma, infantile hemangioma, vascular malformations Malignant neoplastic lesions Mucoepidermoid carcinoma Adenoid cystic carcinoma Acinic cell carcinoma Lymphoma Metastatic disease to the salivary glands Lesions mimicking neoplasia Intraparotid lymph nodes Branchial cleft cysts Ranula Inflammatory disorders Infectious sialadenitis Obstructive sialadenitis/sialolithiasis Juvenile idiopathic recurrent parotitis Systemic diseases affecting the salivary glands Sjögren's disease IgG4-related disease Benign lymphoepithelial lesions (HIV-associated)

HNEE-11 LUMPS AND BUMPS IN THE CERVICOTHORACIC TRANSITION: A RADIOLOGICAL APPROACH TO CYSTIC LESIONS

Lavinia Dias, MD (*Presenter*)
Roberta Linhares, MD (*Abstract Co-Author*)
Felipe Siqueira (*Abstract Co-Author*)
Thiago A. Miranda, MD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)
Daniel V. Sumi, MD (*Abstract Co-Author*)
Carolina R. Soares, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)

TEACHING POINTS

-Understand the embryological and anatomical origins of cystic lesions in the cervicothoracic region and their clinical implications. -Recognize key imaging features of common cystic lesions including thyroglossal duct cysts, branchial cleft cysts, and lymphatic malformations. -Discuss critical diagnostic challenges, pitfalls, and differential diagnoses of cystic versus cystic-appearing masses. -Correlate findings across ultrasound, CT, and MRI to improve lesion characterization.

TABLE OF CONTENTS/OUTLINE

Introduction -Overview of the diagnostic complexity of cystic lesions at the cervicothoracic junction. -Importance of precise lesion characterization to guide management. Classification and Diagnostic Approach -Thyroglossal Duct Cyst: Midline/paramedian lesions from persistent thyroglossal duct. -Branchial Cleft Cyst: Lateral neck lesions due to embryological remnants. -Thymic and Parathyroid Cysts: Developmental anomalies presenting in lower neck. -Thyroid Cysts: Benign or degenerative changes in neoplasms. -Neurogenic Cysts: Associated with nerve sheath tumors or sympathetic ganglia. -Lymphatic Malformations (Cystic Hygroma): Frequently extending into the thoracic cavity. -Lymphoceles/Fistulas. -Abscesses and Suppurative Lymphadenitis: Infectious processes mimicking cystic masses. -Metastatic Disease: Particularly from papillary thyroid carcinoma or HPV-related oropharyngeal SCC. Imaging Modalities and Diagnostic Tools -Advantages and limitations of US, CT, and MRI in the evaluation of cervicothoracic cystic lesions. -Role of cross-sectional imaging in identifying anatomical relationships and internal lesion characteristics.

HNEE-12 ANATOMY OF SILENCE: A RADIOLOGIST'S PRIMER ON INNER EAR MALFORMATIONS

Hugo Tames, MD (*Presenter*)
Carlos Toyama (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the Anatomy and Embryology of the Inner Ear Understand the key stages of inner ear development and recognize normal anatomy as a foundation for identifying congenital malformations. Provide a Practical Classification Guide for Inner Ear Malformations Learn a structured, imaging-based approach to classify inner ear anomalies using CT and MRI, including cochlear aplasia, common cavity, and incomplete partition types. Discuss the Imaging Implications for Clinical Management and Treatment Planning Recognize how accurate identification of malformations impacts surgical candidacy, particularly for cochlear implantation, and guides prognostic expectations.

TABLE OF CONTENTS/OUTLINE

- Introduction- Brief review of inner ear embryology and anatomy- Classification of inner ear malformations: Complete Labyrinthine Aplasia. Rudimentary Otocyst. Cochlear aplasia. Common Cavity.Cochlear Hypoplasia. Incomplete partition type 1. Incomplete partition type 2. Incomplete partition type 3. Enlarged Vestibular Aqueduct. Cochlear Aperture Anomalies. - Implications of imaging findings for treatment and prognostic expectations. - A step-by-step guide to the accurate classification of inner ear malformations. - Take home messages

HNEE-13 SKULL BASE OSTEOMYELITIS: WHEN THE RAMPART PUTS THE BRAIN AT RISK

Elena Luque, MD (*Presenter*)
Ester Carballo, MD (*Abstract Co-Author*)
Tomas Ganado (*Abstract Co-Author*)
Pablo Garcia Perez (*Abstract Co-Author*)
Salome Merino, MD (*Abstract Co-Author*)

TEACHING POINTS

To review skull base osteomyelitis (SBO): epidemiology, potential origins and mechanisms of spread. To delve into SBO imaging findings, complications and main differential diagnosis.

TABLE OF CONTENTS/OUTLINE

General review. SBO is an infrequent but potentially lethal complication of malignant external otitis, which leads to bone and soft tissue destruction. Atypical presentations from non-otogenic origins can also appear. The most common pathogen is P. aeruginosa, followed by S. aureus. Other rare pathogens, such as Nocardia , A. chlamydospora or T. canis might be found. In immunosuppressed patients, fungal organisms must be considered. Symptoms are nonspecific and include otalgia, otorrhea, headache, cranial nerves palsy, etc. Imaging findings CT is usually the initial imaging modality, essential for assessing bone lesions (erosion, demineralization). Evaluation of petrous portion of temporal bone is mandatory. In typical SBO, the external auditory canal and temporal bone are usually the epicenter of the disease, while atypical SBO more commonly involves the central skull base, particularly the sphenoid bone. MRI highlights soft tissue and bone marrow infiltration. Key findings include effacement of fat planes and soft tissue mass with T1-hypo/isointensity, T2-hyperintensity and contrast enhancement. When bone marrow is involved, typical findings include T1-hypointensity and STIR hyperintensity. Findings may mimic malignancy, including nasopharyngeal carcinoma, endolymphatic sac tumor, metastasis, etc. Complications: Progression of SBO can result in both extracranial and intracranial complications, including cranial nerves palsy, sinus vein thrombosis, abscesses, etc.

HNEE-14 BEYOND NODULES: WHAT THE RADIOLOGIST NEEDS TO KNOW ABOUT THE THYROID GLAND

Maria Zulfiqar, MD, MBBS (*Presenter*)
Anup S. Shetty, MD (*Abstract Co-Author*)
Katharina Feister, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Nirvikar Dahiya, MD (*Abstract Co-Author*)
William D. Middleton, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Illustrate various pathologic conditions involving the thyroid gland other than typical thyroid nodules with emphasis on diffuse thyroid disease. 2. Delineate multimodality imaging with focus on ultrasound.

TABLE OF CONTENTS/OUTLINE

• Congenital: Thyroid agenesis/hemiagenesis; Sublingual thyroid; Intrathyroidal ectopic thymus. • Trauma: Thyroid rupture; Intrathyroidal hematoma; pseudoaneurysm • Thyroiditis: -Acute suppurative thyroiditis -Subacute granulomatous thyroiditis (de Quervain) -palpation thyroiditis/multifocal granulomatous folliculitis -Autoimmune thyroiditis: *Chronic lymphocytic thyroiditis (Hashimoto) *Diffuse toxic goiter/Grave's disease *Fibrosing variant Hashimoto *Painless/silent thyroiditis *Post-partum thyroiditis -Riedel thyroiditis/IgG4 • Drug induced thyroiditis: Amiodarone; Immunotherapy; Lithium • Other diffuse disease: Amyloidosis; lipomatosis • Atypical and rare thyroid nodules and masses: *Cystic: Epidermal inclusion cyst; branchial cleft cyst*B enign neoplasms: Adenolipoma; intrathyroid parathyroid adenoma *Malignant neoplasms: Lymphoma; metastasis; anaplastic thyroid cancer; Langerhans cell histiocytosis.

HNEE-15 HIGH-RESOLUTION TRANSORAL ULTRASONOGRAPHY: TECHNIQUE, NORMAL ANATOMY, AND PATHOLOGY

Sophie K. Wilkinson, MBChB, FRCR (*Presenter*)
Martin Garset-Zamani (*Abstract Co-Author*)
Timothy J. Beale, MBBS (*Abstract Co-Author*)
Gitta Madani, MBBS (*Abstract Co-Author*)
Tobias Todsen (*Abstract Co-Author*)

TEACHING POINTS

1 Transoral ultrasound (US) provides high-resolution imaging of the oropharynx using small high-frequency probes in direct contact with the mucosa. In contrast to transcervical US, this technique can improve detection of smaller head and neck cancers that are otherwise clinically occult. 2 Palatine tonsils are striated with deep crypts. Key anatomical landmarks in the tonsillar fossa include the superior constrictor muscle, medial pterygoid muscle, and internal carotid artery. Other parapharyngeal structures that can be identified include retropharyngeal lymph nodes, internal and external carotids, internal jugular vein, stylopharyngeal-, styloglossal-, and stylohyoid muscles, digastric muscle, and deep lobe of the parotid gland. 3 The lingual tonsil is striated with more ovoid, shallower crypts. Key landmarks include the lateral hyoglossus muscle, the hyoid bone and lingual artery. 4 Carcinomas or lymphomas appear solid with hypervascular and chaotic doppler patterns. Benign lesions such as cysts or abscesses can be differentiated due to their avascular centers. Distinction between pathology superficial to- or profound to the constrictor muscle is critical for accurate diagnosis and treatment.

TABLE OF CONTENTS/OUTLINE

1. Introduction and clinical relevance of transoral US 2. Transoral US landmarks (tonsil) 3. Transoral US landmarks (base of tongue) 4. Imaging of oropharyngeal pathologies (carcinoma, lymphoma, abscesses) 5. Transoral US-guided biopsy techniques

HNEE-16 JAWS 2025 - IMAGING AND PATHOLOGY OF MANDIBULAR MASS LESIONS

Tanvi Agarwal, MBBS (*Presenter*)
Prateek Hongal (*Abstract Co-Author*)
Richard D. White, MBChB, FRCR (*Abstract Co-Author*)
Anu Kamalasanan, FRCR, MBBS (*Abstract Co-Author*)
Thiru A. Sudarshan, DMRD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

• Odontogenic lesions are related to the teeth or above the inferior alveolar canal. • Non odontogenic lesions are not related to teeth and are usually below the inferior alveolar canal. • Differentiation of the mandibular lesion into radio-opaque and radiolucent lesions help in narrowing the differential diagnosis. • Lesions are characterized based on density, loculations, margin, content, relation, effect on teeth, adjacent bone and soft tissue component. • Resorption and destruction of tooth and soft tissue components are often seen in neoplastic lesions rather than benign lesions. • Essential reporting elements, including lesion size, margins, cortical status, relation to the inferior alveolar nerve, tooth involvement, and signs of aggressiveness.

TABLE OF CONTENTS/OUTLINE

1. Embryological development and odontogenesis2. Anatomy of the mandible and tooth3. Imaging modalities 4. WHO Classification5. Multi-modality imaging and differentiating features of mandibular lesions (with pathological correlation where available), including: I. Benign:a) Hemangioma of the mandibleb) Dentigerous cystc) Odontogenic keratocystd) Radicular cyst e) Bilateral OKC - Gorlin-Goltz syndrome f) Complex odontoma.g) Ameloblastoma h) Cementing fibromas i) Calcifying odontogenic tumor (Pindborg tumor) j) Fibro-cemento-osseous lesionsk) Cemento-osseous fibrous dysplasial) Non-ossifying fibroma m) Periostitis n) Osteomyelitis o) Sclerosing osteomyelitis p) Osteoradionecrosis q) Medication-related osteonecrosis of the jaw r) Idiopathic osteosclerosis of the mandible II. Malignant:a) Myeloma b) Squamous cell carcinoma of the mandible c) Lymphoma d) Undifferentiated carcinoma e) Chondrosarcoma

HNEE-17 LOST IN THE LABYRINTH? UNRAVELING INNER EAR DISEASES

Pedro Oertel D'Amico, MD (*Presenter*)
Hugo Tames, MD (*Abstract Co-Author*)
Murilo Vega, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)

TEACHING POINTS

- Learning normal inner ear anatomy and it’s imaging appearance - Understanding clinical, epidemiological and physiopathological characteristics of inner ear diseases, as well as knowing it’s appearance on imaging studies and common differentials

TABLE OF CONTENTS/OUTLINE

INTRODUCTION - Overview of temporal bone anatomy, focused on sectional imaging of the inner ear, osseous and membranous labyrinths, and it’s subdivisions - Common differential diagnoses of the osseous or membranous labyrinths OTIC CAPSULE ABNORMALITIES - Discussion and illustrative cases of otic capsule abnormality differentials, with special consideration to otosclerosis, osteogenesis imperfecta, otosyphilis and Paget’s disease - Imaging differential of the different conditions with illustrative cases THIRD WINDOW SYNDROMES - Concepts and clinical presentation - Discussion of underlying conditions (e.g. semicircular canal dehiscence, enlarged vestibular aqueduct) and imaging characteristics through illustrative cases LABYRINTHITIS AND POST-INFLAMMATORY CHANGES - Overview of inflammatory responses in the inner ear - Showcase imaging of acute labyrinthitis and the evolution to labyrinthitis ossificans INTRALABYRINTHINE FLUID CHANGES - Discussion of fluid changes within the labyrinth, focusing on endolymphatic hydrops and related pathology, also touching upon intralabyrinthine hemorrhage - Detail relevant technical considerations to imaging endolymphatic hydrops INTRALABYRINTHINE SCHWANNOMAS AND OTHER LESIONS - Different imaging appearance of intralabyrinthine schwannomas illustrated through cases - Approach to identifying and characterizing other mass-like lesions in and around the labyrinth

HNEE-18 IMAGING OF CRANIAL NERVES: ANATOMY, FUNCTION AND PATHOLOGY

Asier Uriarte Morillas, MD (*Presenter*)
Ibone Saralegui Prieto (*Abstract Co-Author*)
Inigo Vicente Olabarria, MD (*Abstract Co-Author*)
Irune Perez Arroyuelos (*Abstract Co-Author*)
Paula Garcia Barquin, MD (*Abstract Co-Author*)

TEACHING POINTS

There are 12 paired cranial nerves that control motor and sensitive functions of the head and neck. Cranial nerve dysfunctions are a common reason for patient consultation and their detection represents a challenge both for clinicians and radiologists. Cranial nerve disorders have a wide range of etiologies, ranging from traumatic, infectious, inflammatory, vascular, neurodegenerative to neoplastic causes. Clinical examination is often not enough to pinpoint the underlying cause, so imaging techniques (mainly magnetic resonance imaging and computed tomography) are often indicated when cranial nerve pathology is suspected. The anatomy and function of cranial nerves is complex and its knowledge is of utmost importance for the radiologist in order to detect pathology. The purpose of this exhibit is to review cranial nerve anatomy and function, display the range of imaging modalities and their use in depicting cranial nerve pathology and make a case-based review of common and uncommon cranial nerve disorders.

TABLE OF CONTENTS/OUTLINE

1- Introduction 2- Imaging modalities: MRI (sequences for intracranial, cisternal segments and extracranial segments) and CT 3- Cranial nerve anatomy and function: Several original illustrations depicting cranial nerve anatomy and function 4- Case based review of a wide variety of pathology affecting cranial nerves 5- Take home points

HNEE-19 ADVANCED NECK ULTRASOUND IN POST-THYROIDECTOMY SURVEILLANCE: PEARLS AND PITFALLS WITH USE OF HIGH-FREQUENCY TRANSDUCERS

Emanuela Mendes Junqueira Barros, MD (*Presenter*)
Alex Dias, MD (*Abstract Co-Author*)

Thiago Jose Pinheiro Lopes, MD (*Abstract Co-Author*)
Pyetra Oliveira, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Luciana Cerri, MD, PhD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Davi D. Romao, MD (*Abstract Co-Author*)
Regiany Alessandra Garcia Jureidini, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

Imaging is an integral part of postoperative surveillance of patients with thyroid cancer, which primarily relies on serial serum thyroglobulin measurements combined with US. Recent technological progress has elevated high-frequency ultrasonography (HFUS) into a highly valuable diagnostic tool for enhancing the diagnostic precision of the US in anatomically complex regions, such as the neck. In post-thyroidectomy follow-up, HFUS enables precise visualization of the thyroid bed, lymph node compartments, and adjacent soft tissues, making it essential for detecting locoregional recurrence, residual disease, or metastatic lymph nodes.

TABLE OF CONTENTS/OUTLINE

1. Introduction: an overview of diagnosis, staging and treatment of thyroid cancer 2. Clinical surveillance after thyroid cancer: a) How to interpret the main biochemical markers levels for monitoring recurrence/disease b) Imaging surveillance: the role of US, RAI imaging, CT, MRI and PET/CT after thyroidectomy 3. Imaging surveillance: a case-based review with radiological-pathological correlations 4. Imaging pearls and pitfalls: a) Normal and abnormal HFUS findings: how to avoid diagnostic errors and misinterpretation b) Early and late complications after thyroidectomy. c) A road map to common sites of disease recurrence and metastasis 5. Challenging and emerging applications a) Elastography and contrast-enhanced US b) Ultra-high frequency US c) Radiomics and artificial intelligence 6. Summary and take-home messages Slide 1: expected findings Slide 2: parathyroid Slide 3: neuromas Slide 4: nodal metastasis Slide 5: recurrence

HNEE-20 ISOLATED LYTIC SKULL LESION: WHEN SHOULD LANGERHANS CELL HISTIOCYTOSIS BE CONSIDERED?

Thiago Munoz Ruiz, MD (*Presenter*)
Lara Quiche, MD (*Abstract Co-Author*)
Marcos V. Camargo, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Thiago A. Miranda, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the principles and physiopathology of the Langerhans Cell Histiocytosis (LCH), particularly the isolated lytic skull lesion presentation. To recognize the imaging features of the isolated bony LCH in the skull, and to review the differential diagnosis, highlighting the key diagnostic features. To demonstrate a practical approach in the evaluation of an isolated lytic lesion in the skull. To highlight the role of the radiologist in differentiating an isolated lytic skull lesion, and when to consider LCH.

TABLE OF CONTENTS/OUTLINE

Introduction, Physiopathology and Clinical Presentation Key imaging features, with teaching cases Differential Diagnoses Practical Approach Take Home Messages References

HNEE-21 FROM RESONANCE TO RELEVANCE: ADVANCED MRI IN HEAD AND NECK NODULES

Carlos Jorge da Silva, PhD, MD (*Presenter*)
Murilo Vega, MD (*Abstract Co-Author*)
Isadora Campos De Matos (*Abstract Co-Author*)
Elder Henrique, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the use of DWI and semiquantitative analysis of T1 permeability curves as ancillary techniques for evaluating head and neck nodules. Demonstrate the application of these ancillary techniques in multiparametric assessment for tumor cellularity/aggressiveness, microvascular architecture, and treatment response.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of head and neck tumor epidemiology in the United States, highlighting key prognostic factors such as delayed diagnosis and recurrence detection challenges. Emphasis on imaging biomarkers' role in enabling early and accurate diagnosis using new MR ancillary techniques. Techniques and Applications Diffusion-weighted imaging (DWI) Semiquantitative analysis of T1 permeability curves Detailed Content We present conventional MR sequences alongside ancillary DWI and T1 permeability to enhance predictive accuracy in tumor histology, cellularity/aggressiveness, microvascular architecture, and treatment response, illustrated by: Pleomorphic adenoma Warthin tumor Parotid gland acinic cell carcinoma Parotid gland solitary fibrous tumor Orbital MALT lymphoma (pre- and post-treatment) Squamous cell carcinoma of the nasopharynx (pre- and post-treatment) Take-home Messages DWI and semiquantitative analysis of T1 permeability are crucial non-invasive tools for tumor characterization. They provide insights into cellular density and microvascular architecture, enhancing diagnostic accuracy for early assessment of tumor aggressiveness, treatment response, and prognostic stratification. Their integration into routine imaging protocols represents a precision imaging improvement and supports personalized oncologic care.

HNEE-22 THE ROLE OF NUCLEAR MEDICINE IN HEAD AND NECK RADIOLOGY: DIAGNOSTIC AND FUNCTIONAL PERSPECTIVES

Maria Vitoria Ludwig, MD (*Presenter*)
Dario Nascimento Ferreira Alves, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)
Isabela D. Alves, MD (*Abstract Co-Author*)
Luiz R. Uchoa, MD (*Abstract Co-Author*)
Ula Passos, MD (*Abstract Co-Author*)
Vinicius T. Goncalves, MD (*Abstract Co-Author*)
Matheus Waitman, MD (*Abstract Co-Author*)
Carolina Mautoni, MD (*Abstract Co-Author*)
Jorge T. Takahashi, MD (*Abstract Co-Author*)

TEACHING POINTS

Nuclear medicine plays a pivotal role in head and neck radiology, providing both diagnostic and functional insights. Radiotracer-based imaging enhances tumor detection, staging, and therapy planning. Theranostic approaches enable targeted treatment of conditions such as neuroendocrine tumors and paragangliomas. Recognizing non-oncologic uses and common pitfalls improves diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

Oncologic Applications I - HNSCC : Role of 18 F-FDG PET-CT in staging, recurrence assessment, and surgical decision-making; Oncologic Applications II - Neuroendocrine Tumors : 68Ga-DOTATOC and 18F-FDG PET-CT aid in evaluating MTC and paragangliomas. In MTC, calcitonin favors DOTATOC, while CEA favors FDG. Paragangliomas show high uptake on DOTATOC/DOTATATE, supporting diagnosis and 177Lu-DOTATATE therapy; Oncologic Applications III - Theranostics : Radioiodine therapy targets thyroid remnants and metastases. 68Ga-DOTATATE PET detects meningioma recurrence and subcentimeter lesions, aiding radiotherapy and surgery. 177Lu-DOTATATE PRRT benefits refractory meningiomas with somatostatin receptor expression; Oncologic Applications IV - Future Directions : Emerging roles of PSMA PET-CT in the evaluation of adenoid cystic carcinoma; Non-Oncologic Applications : Functional imaging in chronic infections and inflammatory diseases; Pitfalls : Physiological uptake patterns and artifacts that may mimic disease, emphasizing the importance of anatomical correlation.

HNEE-23 DIAGNOSTIC ERRORS IN HEAD AND NECK IMAGING: LEARNING FROM ERRORS AND BIASES

Naoko Saito, MD, PhD (*Presenter*)
Naoki Takemasa (*Abstract Co-Author*)
Osamu Sakai, MD, PhD (*Abstract Co-Author*)
Tsuyoshi Tajima, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Diagnostic errors can be classified into three types: missed diagnosis (failure to detect an existing abnormality), misdiagnosis (incorrect interpretation of an identified finding), and delayed diagnosis (correct diagnosis made too late). The head and neck region is particularly susceptible to diagnostic errors due to its complex anatomy and various pathologies. Accurate diagnosis in this area is crucial, as errors can lead to significant clinical consequences, including delayed treatment or inappropriate management. This exhibit presents a variety of diagnostic error cases in head and neck imaging, categorizes each case by error type, and discusses diagnostic pitfalls as well as strategies for error reduction. The teaching points are: To understand the classification and causes of diagnostic errors To recognize common error patterns and the role of human factors in improving diagnostic accuracy To review illustrative cases of diagnostic errors in head and neck imaging with emphasis on error types, pitfalls, and preventive strategies

TABLE OF CONTENTS/OUTLINE

Classification of diagnostic errors in radiology Perceptual errors in head and neck imaging Cognitive biases in head and neck imaging Technical errors in head and neck imaging Case-based review: examples of missed diagnosis, misdiagnosis, and delayed diagnosis with analysis of error types and teaching points Strategies to reduce errors Current role and limitations of AI in reducing human error in head and neck imaging

HNEE-24 MUCORMYCOSIS: WHEN THE AIR TURNS DEADLY

Carolina Souza, MD (*Presenter*)
Maria Beatriz Pereira Ferreira (*Abstract Co-Author*)
Thais Silva (*Abstract Co-Author*)
Fernanda Nery, MD (*Abstract Co-Author*)
Henzo Ota, MD (*Abstract Co-Author*)
Mariana Rossi Corregliano, MD (*Abstract Co-Author*)
Renato Sartori (*Abstract Co-Author*)

TEACHING POINTS

• Mucormycosis is a highly invasive and rapidly progressive fungal infection, most common in immunocompromised patients, especially those with uncontrolled diabetes. • The rhino-orbito-cerebral form can quickly spread to the orbit and central nervous system via angioinvasion, frequently leading to severe complications such as orbital apex syndrome or cavernous sinus thrombosis, with potential involvement of multiple cranial nerves. • Imaging plays a central role in early diagnosis. Key imaging findings include the “black turbinate sign” on MRI and sinus hyperdensities on CT. • Early recognition and multidisciplinary management are crucial to reduce the high morbidity and mortality associated with this condition.

TABLE OF CONTENTS/OUTLINE

1. Introduction Epidemiology, Risk Factors, Clinical Presentation, Pathophysiology, Histopathology 2. Clinical case Clinical case of a patient with mucormycosis, presenting with exuberant clinical manifestations and involvement of multiple cranial nerves. Anatomy review. Nasopharyngoscopy. 3. Imaging Findings Main CT findings, pattern of involvement in the MRI, early signs, orbital involvementIntracranial extension. 4. Evolution Series of CT images showing the progression of the disease. 5. Complications Orbital apex syndrome; Cavernous sinus thrombosis; Central nervous system invasion; Bone erosion.

HNEE-25 "KEEP AN EYE IN YOUR WATER CYCLE”, ASSESSMENT OF DISEASES OF THE LACRIMAL SYSTEM

Max Yunior Orsi Salazar, MD (*Presenter*)
Alan Iuno R. Araujo (*Abstract Co-Author*)
Ademar Jose d. Paes Junior (*Abstract Co-Author*)
Soraia A. Souza, MD, MS (*Abstract Co-Author*)
Marcio Ricardo T. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Anatomy: Lacrimal gland. Nasolacrimal drainage system and relationships to orbital and sinonasal structures.2. Imaging Modalities: CT (bone evaluation), MRI (soft-tissue contrast), and dacryocystography (contrast-enhanced dynamic assessment).3. Pathological Spectrum: inflammatory (dacryocystitis), chronic (dacryolithiasis), post-traumatic (ductal stenosis), and neoplastic (adenoid cystic carcinoma, lymphoma).4. Key Findings: CT evaluation of calcifications/bone erosions and osseous lacrimal pathway stenosis; MRI evaluation of lesion signal characteristics; dacryocystography for obstructive sites.

TABLE OF CONTENTS/OUTLINE

1. Anatomy of the Lacrimal Drainage System• Anatomical landmarks.2. Imaging Techniques• X-ray/CT/MRI protocols, dacryocystography (contrast administration, dynamic imaging).3. Inflammatory Pathologies• Acute dacryocystitis (soft tissue swelling, dacryocystitis, abscess formation).4. Chronic Benign Pathologies• Dacryolithiasis (contrast pooling), nasolacrimal duct obstruction (focal stenosis), dacryocystocele.5. Post-Traumatic Lesions• Canalicular laceration, bony nasolacrimal duct fractures.6. Neoplasms• Benign (pleomorphic adenoma) vs. malignant (adenoid cystic carcinoma, lymphoma).

HNEE-26 A SUPER-HEAR-O IMAGING GUIDE TO POSTOPERATIVE COMPLICATIONS IN COCHLEAR IMPLANTS

Kristina Ramirez Garcia, MD (*Presenter*)
Eben Cerrillos (*Abstract Co-Author*)
Almudena Perez-Lara, MD, PhD (*Abstract Co-Author*)
Shivaprakash B. Hiremath, MBBS, FRCR (*Abstract Co-Author*)
Griselda T. Romero Sanchez, MD (*Abstract Co-Author*)

TEACHING POINTS

1 Describe aspects of cochlear implants and post-surgical imaging recommendations 2 Discuss various complications associated with the surgical placement of cochlear implant electrode arrays 3 Illustrate Imaging findings of cochlear implants with complications and implications for further management

TABLE OF CONTENTS/OUTLINE

1 Inner Ear Anatomy Overview 2 Cochlear Implantation Surgery Structure Implant Types 3 Imaging of Cochlear Implants Imaging Techniques Imaging Software Assessment Tools Adequate Positioning of Cochlear Implants 4 Cochlear Implants Complications 4a Device Failure 4b Intraoperative Complications 4c Postoperative

Complications Incomplete electrode insertion Kinking Tip fold over Scalar traslocation Electrode migration CSF leaks Flap infection, subcutaneous hematoma or seroma Other infectious, meningitis, mastoiditis, abscess

HNEE-27 ALL ABOUT THE LARYNX: COMMON AND EVEN RARE CASES!

Marcio Ricardo T. Garcia, MD (*Presenter*)
Roberta C. Andrade, MD (*Abstract Co-Author*)
Raphael M. Reali, MD (*Abstract Co-Author*)
Rodrigo J. Araya Rojas, MD (*Abstract Co-Author*)
Suresh K. Mukherji, MD, MBA (*Abstract Co-Author*)
Soraia A. Souza, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Detail laryngeal anatomy; explain the correct assessment of laryngeal imaging; review the main causes of laryngeal disorders; detail tumor-related causes; detail inflammatory causes; detail other less common causes: vocal fold paralysis, autoimmune diseases, foreign bodies, and surgical complications

TABLE OF CONTENTS/OUTLINE

Introduction Larynx Anatomy; laryngeal Imaging Assessment. Tumors Benign Lesions: papillomatosis, neurofibromas, enchondromas; Malignant Lesions: squamous cell carcinoma, chondrosarcoma, synovial sarcoma. Inflammatory Conditions: Reflux laryngitis, epiglottitis, laryngotracheobronchitis, Reinke's edema, chondroradionecrosis, paracoccidioidomycosis, histoplasmosis, tuberculosis; leishmaniasis. Vascular Abnormalities Vascular malformations (non-neoplastic); vascular tumors (neoplastic), pyogenic granuloma, hemangioma. Other Conditions Vocal cord paralysis, autoimmune diseases, foreign body aspiration, vallecular cyst, laryngoceles, vocal cord polyps, nodules, and granulomas, laryngomalacia, trauma / fracture, amyloidosis, surgical complications, thyroplasty for gender reassignment.

HNEE-28 PETROUS APEX: PEARLS AND PITFALLS

Barbara Sonvenso Ambrosio, MD (*Presenter*)
Natalia Yoshida, MD (*Abstract Co-Author*)
Marcos Marins, MD (*Abstract Co-Author*)
Emily Gazzoli (*Abstract Co-Author*)
Ian Caldas (*Abstract Co-Author*)
Barbara P. Pfluck, MD (*Abstract Co-Author*)

TEACHING POINTS

- Recognize the anatomy.- Provide a practical guide for radiological assessment through imaging patterns.Review main anatomical pathologies of the petrous apex.

TABLE OF CONTENTS/OUTLINE

The radiologist plays a crucial role in the proper evaluation of the petrous apex, contributing to appropriate patient management. First, we will review anatomy and anatomical variations for correct interpretation and to identify 'pitfalls' that mimic pathologies. We will describe imaging aspects on both MRI and CT of the main lesions, analyzing growth patterns, infiltrative effects, margins, and contrast enhancement, in addition to a detailed analysis of other specific findings, such as the lesion's signal on MRI sequences which help determine its tissue composition. CT will assess bone involvement and intralesional calcifications. We will bring images and short texts where we will present anatomical variations such as: asymmetric pneumatization, effusion (trapped fluid), vascular and neural channels, and arachnoid granulation. Examples of some pathologies that will be discussed are cholesterol granuloma, petrous apicitis, cholesteatoma, cephalocele, chordoma, and metastasis. Finally, we will assemble a flowchart for a facilitated and comprehensible approach to the findings and pathologies presented.

HNEE-29 HARD TO EXPLAIN SOFT FINDINGS: A RADIOLOGICAL REVIEW OF PALATAL LESIONS

Lucas P. Caldas, MD (*Presenter*)
Augusto S. Serpa, MD (*Abstract Co-Author*)
Murilo Vega, MD (*Abstract Co-Author*)
Mariana Rossi Corregliano, MD (*Abstract Co-Author*)
Rodrigo W. Murakoshi, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)

TEACHING POINTS

This study aims to review the key anatomic aspects and structures of the palate and its components, making a correlation with the types of lesions that might affect this structure, focusing on the main imaging characteristics, especially on CT and MRI, correlating it with anatomical and pathological implications. The purpose of this exhibition is to: Review the anatomical structure of the hard and soft palate, and how to differentiate the various types of lesions (benign, malignant, inflammatory/infectious and miscellaneous) that can affect this region; Discuss imaging clues that may suggest aggressive nature of the lesion, which might need further investigation or biopsy, or benign imaging findings that might not need intervention; Highlight potential complications or patterns of extension to adjacent structures, including the nasal cavity, maxillary sinus, and oropharynx;

TABLE OF CONTENTS/OUTLINE

Overview of the hard and soft palate anatomy, with schematic illustrations and emphasis on clinical relevance for lesion assessment; Classification and imaging features of the most common lesions affecting the palate: benign, malignant, inflammatory/infectious and miscellaneous; Case-based review with examples of CT and MRI subtle findings, correlating them with histopathological findings.

HNEE-30 IMAGING THE GREAT PRETENDERS: PSEUDOTUMORAL LESIONS OF THE ORAL CAVITY AND OROPHARYNX

Isabela D. Alves, MD (*Presenter*)
Luiz R. Uchoa, MD (*Abstract Co-Author*)
Vinicius T. Goncalves, MD (*Abstract Co-Author*)
Jorge T. Takahashi, MD (*Abstract Co-Author*)
Ula Passos, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the imaging anatomy of the tongue and oral cavity; Recognize common pseudotumoral lesions that may mimic malignancy; Differentiate granulomatous, infectious/inflammatory, and cystic entities; Identify key imaging features that help in avoiding misdiagnosis; Emphasize the importance of considering congenital lesions in pediatric patients; Support a structured approach to lesion characterization and differential diagnosis

TABLE OF CONTENTS/OUTLINE

Clinical Challenge: Distinguishing Tumors from Mimics | Relevance of Imaging in Initial Assessment | Imaging Anatomy of the Tongue and Oral Cavity | Pseudotumoral Lesions by Etiology - Granulomatous Lesions (Paracoccidioidomycosis, Tuberculosis and Sarcoidosis) - Infectious and Inflammatory Lesions (Actinomycosis, Odontogenic Abscesses, Mucositis and Necrotizing Infections, Syphilitic Involvement of the Oropharynx, Myiasis of the Oropharynx)- Cystic and Congenital Lesions (Enteric Duplication Cysts, Dermoid and Epidermoid Cysts, Ranulas and Mucoceles, Hamartomas) | Imaging Patterns and Diagnostic Tips | Case-Based Approach

HNEE-31 ONODI'S CELL: THE IMPORTANCE OF THIS ANATOMIC VARIATION FOR PLANNING SURGERY AND TO AVOID COMPLICATIONS RELATED TO OPTIC NERVES AND INTERNAL CAROTID ARTERIES

Rainer G. Haetinger, MD, PhD (*Presenter*)
Silvia M. Mello (*Abstract Co-Author*)
Paula Cristina Amaral, MD (*Abstract Co-Author*)
Nizam Almeida, MD (*Abstract Co-Author*)

TEACHING POINTS

Detailed imaging assessment in Onodi's cell is essential for a correct surgical approach and reduction of the risk of complications. The radiologist must always be careful to describe this anatomical variation in order to guide surgeons and predict possible complications associated with diseases that may affect Onodi's cells. There are many shapes and sizes of this variation and Radiologists have to be familiar with them and describe all the relations in reports. There is risk of optic nerve damage, Internal carotid artery injury with severe bleeding, CSF fistula due to a breach in the base of the skull.

TABLE OF CONTENTS/OUTLINE

In 1907 Prof. A. Ónodi, from Budapest, Hungary, published a study about the optic nerve and its relation to the paranasal sinuses. In honor of him, the sphenoethmoidal cell is called Onodi's cell, which corresponds to an ethmoidal cell in contact to the optic canal/nerve. Usually the optic canal is related to the sphenoid sinus. In the author's collection many variants and shapes were found, which will be demonstrated in this presentation. In addition to the optic canal, the Onodi's cell may also establish relationship to the internal carotid artery and the cavernous sinus. For this reason, the knowledge about is very important to radiologists and surgeons. In the Opinion of the authors, due to its importance, should be described in any report of the paranasal sinuses and/or skull base. In the sense of highlight the importance of this anatomical variation, many examples of concomitant diseases and some complications are shown in this poster.

HNEE-32 UNDERSTANDING NECK DISSECTION: BRIDGING RADIOLOGY AND SURGERY

Leticia Costa (*Presenter*)
Diogo C. Medeiros, MD (*Abstract Co-Author*)
Murilo B. Cintra (*Abstract Co-Author*)
Bruno B. Nobrega SR, MD (*Abstract Co-Author*)
Soraia A. Souza, MD, MS (*Abstract Co-Author*)
Suresh K. Mukherji, MD, MBA (*Abstract Co-Author*)
Marcos D. Pinheiro II, MD (*Abstract Co-Author*)
Marcio Ricardo T. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

br /> • Review the anatomy of cervical lymph node levels critical for surgical planning and radiological interpretation.• Illustrate the types of neck dissections (radical, modified radical, and selective) with their anatomical and clinical implications.• Correlate postoperative imaging findings with the type of neck dissection performed, emphasizing key signs of preserved or sacrificed structures.

TABLE OF CONTENTS/OUTLINE

1. Anatomy of Cervical Lymph Node Levels o Detailed anatomical landmarks and drainage pathways. 2. Types of Neck Dissection and Surgical Indications o Radical Neck Dissection (RND) o Modified Radical Neck Dissection (MRND Types I-III) o Selective Neck Dissection (SND, including SOHD, LND, CND) 3. Postoperative Imaging Correlation o CT findings illustrating fat pad loss, gland preservation, and muscular atrophy. 4. Clinical and Surgical Relevance o How imaging findings guide clinical decision-making, recurrence surveillance, and complication recognition. 5. Summary and Teaching Images o Key illustrated examples with annotated CT images correlating surgical techniques and postoperative anatomy

HNEE-33 NI-RADS: A PRACTICAL GUIDE FOR IMPLEMENTATION IN RADIOLOGY SERVICES

Vanessa C. Maldonado, MD (*Presenter*)
Thiago A. Miranda, MD (*Abstract Co-Author*)
Daniel V. Sumi, MD (*Abstract Co-Author*)
Suheyla P. Ribeiro, MD (*Abstract Co-Author*)
Hugo Tames, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Carolina R. Soares, MD (*Abstract Co-Author*)

TEACHING POINTS

The ACR NI-RADS system represents an advancement in standardizing radiological reports for patient surveillance in head and neck cancer, and consists of categories that stratify tumor recurrence risk. Our objective is to provide a step-by-step approach for implementing its use, facilitating its adoption in clinical practice. Successful implementation requires: multidisciplinary team formation, protocol standardization, report template development, and training. Training models such as Entrustable Professional Activities (EPAs) can be very useful. Challenges include interobserver variability in borderline categories and adaptation to different institutional resources. Decision flowcharts have proven effective in overcoming these challenges and promoting greater concordance among observers.

TABLE OF CONTENTS/OUTLINE

ACR NI-RADS introduction and overview Implementing a new report model: a challenge on its own! - How was it done for other RADS? - NI-RADS: From literature to daily practice How to implement NI-RADS: step-by-step - Planning - Preparation - Training - Implementation - Monitoring and continuous improvement Team training: using EPAs for NI-RADS supervised implementation at institutional level Continuous improvement: - Peer learning meetings - Multidisciplinary team involvement: feedback from Tumor Board meetings - PDSA strategy: Plan-Do-Study-Act

HNEE-34 DON'T WASTE YOUR TIME - I AM NOT A LESION: PSEUDOLESIONS AND PITFALLS IN HEAD AND NECK IMAGE

Luis G. Duarte, MD (*Presenter*)
Diogo C. Medeiros, MD (*Abstract Co-Author*)
Anna P. Riello, MD, MSc (*Abstract Co-Author*)
Soraia A. Souza, MD, MS (*Abstract Co-Author*)
Marcio Ricardo T. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Emphasize the importance of recognizing pseudolesions and imaging pitfalls in the head and neck (H&N) region that can mislead radiologists, resulting in misdiagnosis and unnecessary interventions. Present a variety of pseudolesions and pitfalls, aiming to help radiologists avoid errors and optimize time. Familiarize radiologists with unusual findings and specific anatomical variants of the H&N by turning them into a practical visual reference.

TABLE OF CONTENTS/OUTLINE

Introduction Case-based review by region or structure in the follow order: A. Orbit: Pseudoproptostis on myopia, Microphthalmia, Lacrimal, gland and fat orbital prolapses, Orbital varix B. Muscles: Masseter hypertrophic, Hypertrophic of the anterior belly of digastric, Same distal insertion of anterior belly of digastric C. Vessels: Dominant internal jugular vein due to vascular malformation drainage, Retropharyngeal carotid arteries, Thoracic duct (neck pathway) D. Glands: Lingual thyroid, Accessory parotid gland, Submandibular gland agenesis, Liposubstitution of salivary glands, Cervical extension of thymus, Spontaneous air dilation of the parotid duct E. Larynx and Esophagus: Proximal esophageal varices, Cricoid ridge ossification F. Mastoid: Cochlear cleft, Dehiscent high jugular bulb to tympanic cavity G. Bones: Mandibular and palatine torus, Mandibular and maxillary exostoses, Meningoceles and cephaloceles, Mandibular condyle hyperplasia H. Developed variations: Foramen of Huschke, Arrested pneumatization I. Anatomic findings: Cerebellar floccules in the cerebellopontine cistern, Septal appendix J. Foreign bodies: Gum, candies, saliva, and cosmetic filler materials Conclusion and take-home messages

HNEE-35 BEYOND B MODE PRACTICAL APPLICATION OF CEUS IN THYROID NODULE EVALUATION AND HISTOPATHOLOGIC CORRELATION FOR RADIOLOGY RESIDENTS

Sofia Renee Acuna Barrera, MD, MD (*Presenter*)
Veronica Espinosa Cruz, MD (*Abstract Co-Author*)
Alejandro Garcia Pena, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the complementary use of CEUS for the evaluation of thyroid nodules Recognize the patterns of benignity and malignancy according to the vascularization of thyroid nodules characterized by CEUS Identify which are the hemodynamic characteristics and recognize the imaging findings to differentiate a benign nodule from a malignant one Know and provide basic concepts of the quantitative parameters of post-processing of thyroid nodules enhanced by CEUS through the Time intensity Curves and their interpretation

TABLE OF CONTENTS/OUTLINE

Introduction Incidence of thyroid nodules and why complement a thyroid nodule with CEUS. How is CEUS applied to the patient. What to evaluate in a thyroid nodule through CEUSNodule Vascularization Brief vascular anatomy of the thyroid in benign or malignant nodule. Homogeneous: description, imaging findings compared with grayscale and histopathologic correlation based on clinical cases. Heterogeneous: description, imaging findings compared with grayscale and histopathologic correlation based on clinical casesHemodynamic Characteristics Assessment of blood flow and contrast distribution. Centrifugal: description, imaging findings compared with grayscale and histopathologic correlation based on clinical cases Centripetal: description, imaging findings compared with grayscale and histopathologic correlation based on clinical cases Scattered: description, imaging findings compared with grayscale and histopathologic correlation based on clinical casesEnhancement Time Quantitative Evaluation and what its parameters are Time intensity Curves and contrast behavior

HNEE-36 DIAGNOSIS OF EXTRAOCULAR MUSCLE (EOM) PATHOLOGIES: AN IMAGING GUIDE - CAUSES, KEY IMAGING FINDINGS, AND PITFALLS

Mario Mahecha, MD (*Presenter*)
Munevver Duran (*Abstract Co-Author*)
Andres F. Mejia Leon, MD (*Abstract Co-Author*)
Santiago Aristizabal (*Abstract Co-Author*)
Juan Ricardo, MD (*Abstract Co-Author*)
David E. Timaran Montenegro, MD (*Abstract Co-Author*)
Laura Acosta, MD (*Abstract Co-Author*)
Eliana E. Bonfante, MD (*Abstract Co-Author*)

TEACHING POINTS

CT and MRI are essential for evaluating extraocular muscle (EOM) pathologies. Thyroid eye disease (TED) is a leading cause of EOM that presents with enlargement while sparing the tendinous insertions. Infectious, neoplastic, traumatic, vascular, metabolic, and inflammatory conditions present with distinct imaging characteristics.

TABLE OF CONTENTS/OUTLINE

Objectives • Classify EOM pathologies, including infectious, neoplastic, traumatic, vascular, and metabolic causes. • Develop a visual guide to help radiologists distinguish between different EOM pathologies. • Introduce an interactive tool to help identify common imaging pitfalls. Introduction • Differentiating EOM pathologies is critical, as treatments vary. • Imaging helps assess muscle involvement, adjacent structures, and diagnostic features. EOM Pathologies • Infectious Bacterial/fungal orbital cellulitis. • Neoplastic Orbital lymphoma, rhabdomyosarcoma, metastases. • Traumatic/Vascular EOM thickening, hemorrhage, or edema (e.g., carotid-cavernous fistula, dural AV fistula, ophthalmic vein thrombosis, orbital cavernous malformation). • Metabolic/Neuromuscular Thyroid-associated orbitopathy, myasthenia gravis, mitochondrial disease, muscular dystrophies • Inflammatory IgG4-related disease, sarcoidosis. Pitfalls • Measuring size without assessing pattern/symmetry. • Misreading normal variants. • Artifacts mimicking disease. • Lack of clinical correlation. • Missing neoplastic infiltration. Conclusions • While TED is most common, other EOMEs must be considered. • Systematic evaluation of muscle pattern, symmetry, and clinical data improves diagnosis.

HNEE-37 APPROACH TO LYTIC LESIONS OF THE SKULL BASE: PATTERNS, DIFFERENTIALS AND PITFALLS

Nithin Krishnan, MBBS, MD (*Presenter*)
Swetha M. Nair, MBBS, MD (*Abstract Co-Author*)
Amit Janu, MBBS, MD (*Abstract Co-Author*)
Nilesh Sable (*Abstract Co-Author*)
Munita Bal, MBBS (*Abstract Co-Author*)
Nitin S. Shetty, MBBS, MD (*Abstract Co-Author*)
SUYASH KULKARNI (*Abstract Co-Author*)
Deepa Nair (*Abstract Co-Author*)

TEACHING POINTS

1. Explore the differential diagnosis of lytic lesions involving the skull base. 2. Understand key anatomical compartments of the skull base and how lesion location influences differential 3. Interpret imaging characteristics on CT and MRI that help narrow differential diagnosis- such as lesion margins, enhancement, matrix, and bone remodeling or destruction. 4. Recognize characteristic imaging findings of specific entities such as chordoma, chondrosarcoma, lymphoma, multiple myeloma, Ewing's sarcoma, Rhabdomyosarcoma, epithelial malignancies with secondary bone involvement and certain benign conditions like fibrous dysplasia and giant cell tumor.

TABLE OF CONTENTS/OUTLINE

1. Atlas of common differential diagnosis of lytic lesions of the skull base. 2. Overview and anatomy: Brief anatomy of the skull base relevant to various lytic lesions. 3. Imaging patterns and key differentials of various skull base lytic lesions on multimodality imaging. 4. Case-based diagnostic algorithm: Case vignette with key imaging findings, pearls and pitfalls 5. Summary, takeaway points and suggested workup.

HNEE-38 CHASING CANCER COMEBACKS: NI-RADS INSIGHTS INTO ORAL CAVITY SQUAMOUS CELL CARCINOMA ON PET-CT AND MRI

Jitin Goyal, MBBS (*Presenter*)

TEACHING POINTS

Surgery, with or without chemoradiation, is the primary treatment for head and neck cancers (HNC). However, distinguishing recurrence from post-treatment changes is challenging due to surgical alterations and radiation-induced fibrosis. Imaging plays a key role in detecting recurrence early, enabling salvage treatments. In oral cavity

cancers, reconstructive surgery and post-treatment trismus complicate clinical examination. Post-contrast imaging can show enhancement from both recurrent disease and post-treatment scarring. Additionally, artifacts on diffusion-weighted imaging (DWI) complicate interpretation. The Neck Imaging Reporting and Data System (NI-RADS) was developed to standardize post-treatment surveillance, initially for contrast-enhanced CT and PET, but newer studies highlight the role of MRI, especially DWI and T2-weighted imaging, in improving diagnostic accuracy. NI-RADS categorizes post-treatment findings into four levels: NI-RADS 1 (no recurrence), NI-RADS 2 (low suspicion), NI-RADS 3 (high suspicion), and NI-RADS 4 (definite recurrence). This framework aids in clinical management, though interobserver variability requires further study to solidify its clinical utility.

TABLE OF CONTENTS/OUTLINE

Clinical cases with pictorial depiction of recurrence on MR with conventional T2WI, diffusion and 18 FDG PET-CT in post surgical cases of head and neck cancers.

HNEE-39 HEAD AND NECK MANIFESTATIONS OF AMYLOIDOSIS

Wankler Dias Canhadas Junior (*Presenter*)
Raifran Neto, MD (*Abstract Co-Author*)
Sara Rosalino, MD (*Abstract Co-Author*)
Alvaro Peixoto De Morais (*Abstract Co-Author*)
Felipe Correa Brito, MD (*Abstract Co-Author*)
Gabriela Fernanda Riboli Favaro (*Abstract Co-Author*)
Henrique B. Zuppani, MD (*Abstract Co-Author*)
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*)
Marnya Wellysa Leite Tavares, MD (*Abstract Co-Author*)
Silvia M. Mello (*Abstract Co-Author*)
Fernanda B. Assuncao, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the main concepts of amyloidosis. Highlight head and neck involvement and its radiological findings. Improve the diagnostic approach by correlating multimodality imaging and clinical findings

TABLE OF CONTENTS/OUTLINE

Amyloidosis is a group of rare disorders (with an incidence of 5-10 cases per million people per year) characterized by the extracellular deposition of insoluble, misfolded proteins, often forming ß-sheet rich fibrils, in various organs, leading to cellular and organ dysfunction. This disease can be categorized into localized and systemic forms of amyloidosis, and subdivided by protein subtype.Although involvement of this topography represents a small fraction of amyloidosis cases in general, it is estimated that up to 20% of patients with the disease present manifestations in this region, frequently associated with the AL (immunoglobulin light chain) subtype.The larynx is the most affected site, followed by the tongue, nasopharynx, palatine tonsils, orbits, salivary glands and, more rarely, the paranasal sinuses. Some types of amyloidosis, such as AL (light chain), can mimic neoplastic lesions both clinically and radiologically. Although it is a rare entity, head and neck amyloidosis presents well-defined clinical and radiological characteristics. Therefore, imaging plays an essential role in assessing the extent and morphological pattern of the disease, aiding in surgical planning and monitoring recurrences, in addition to differentiating it from neoplasms, inflammatory processes, as well as infectious diseases such as tracheobronchial tuberculosis.

HNEE-40 BRACHIAL PLEXUS BEYOND TRAUMA: A CLINICAL AND RADIOLOGICAL PRACTICAL GUIDE

Vinicius Martins, MD (*Presenter*)
Yasmin Fernandes De Aquino, MD (*Abstract Co-Author*)
Odilo M. Queiroz, MD (*Abstract Co-Author*)
Marina Nori Hilario, MD (*Abstract Co-Author*)
Marnya Wellysa Leite Tavares, MD (*Abstract Co-Author*)
Carolinny Cruvinel Maia, MD (*Abstract Co-Author*)
Alex Fernandes (*Abstract Co-Author*)
Rainer G. Haetinger, MD, PhD (*Abstract Co-Author*)
Fernanda B. Assuncao, MD (*Abstract Co-Author*)
Alex Baeta (*Abstract Co-Author*)
Silvia M. Mello (*Abstract Co-Author*)

TEACHING POINTS

To present a practical review of the main etiologies, clinical features, and diagnostic strategies of non-traumatic lesions of the brachial plexus, providing tools to facilitate radiological assessment and therapeutic management, emphasizing the importance of a multidisciplinary approach.

TABLE OF CONTENTS/OUTLINE

Non-traumatic lesions of the brachial plexus are frequently underdiagnosed due to their variable and complex clinical presentation. They may result from inflammatory, infectious, immune-mediated, metabolic, hereditary, neoplastic conditions, or radiotherapy-related causes. Their identification depends on the analysis of clinical history, physical examination, and complementary exams, including magnetic resonance imaging (MRI), and represents a challenge for radiologists, as imaging findings may appear similar, especially in non-neoplastic etiologies. Selected cases included primary and secondary neoplastic lesions of the brachial plexus, such as schwannomas, neurofibromas, plexiform neurofibroma, lymphoma, metastases; extrinsic compressions by tumors and secondary infiltration from thoracic neoplasms (Pancoast); inflammatory/infectious causes: Sarcoidosis, Parsonage Turner, COVID, Dengue; immune-mediated conditions such as Chronic Inflammatory Demyelinating Polyneuropathy (CIDP), Lewis Sumner, and Guillain-Barré; radiotherapy-induced plexopathies; other causes like porphyria and paraneoplastic syndrome. In neoplastic pathologies, tumoral infiltration of brachial plexus structures was also observed. A practical approach to non-traumatic lesions of the brachial plexus requires knowledge of their various etiologies and diagnostic nuances.

HNEE-41 DON'T LOSE FACE: IMAGING THE INTRICACIES OF FACIAL NERVE DISORDERS

Geovana L. Franco, MD (*Presenter*)
Augusto S. Serpa, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)
Carlos Toyama (*Abstract Co-Author*)
Hugo Tames, MD (*Abstract Co-Author*)

TEACHING POINTS

Imaging is crucial for evaluating atypical, progressive, or refractory peripheral facial paralysis. Detailed anatomical knowledge of the facial nerve and careful application of imaging techniques are essential for accurate diagnosis and appropriate management. This exhibit presents a practical imaging approach to peripheral facial paralysis, emphasizing common and uncommon causes, and outlining key CT and MRI findings to guide clinical decision-making. Recognize imaging features of common and uncommon facial nerve pathologies, including idiopathic, infectious, neoplastic, traumatic, and congenital/syndromic etiologies. Bell’s palsy: thickening and non-nodular enhancement. Herpes zoster oticus/ Ramsay-Hunt syndrome: edema and enhancement of the intracanalicular portion of VII and VIII, cochlea and vestibule, and vesicular lesions on the pavilion and external auditory canal. Otologic infections/inflammations: chronic otomastoiditis cholesteatomatous. Syndromic: Moebius, Van Buchem Disease. Traumatic lesions: temporal bone fractures, spurs, asymmetrical geniculate ganglion. Tumors (schwannoma, venous malformation, metastases): infiltrative vs expansive, and focal nodular enhancement.

TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Imaging findings by etiology and tips for differential diagnosis.3. Pearls and Pitfalls: Post-contrast enhancement patterns; Importance of contralateral comparison; Search distant lesions (parotid, pons, skin); 4. Take-home message.

HNEE-42 TEMPORAL BONE SURGERIES AND THEIR COMPLICATIONS: WHAT THE RADIOLOGIST DOESN'T WANT TO FIND

Barbara P. Pfluck, MD (*Presenter*)
Natalia Yoshida, MD (*Abstract Co-Author*)
GRAZIELE AMBROSIO (*Abstract Co-Author*)
Barbara Sonvenso Ambrosio, MD (*Abstract Co-Author*)
Marcos Marins, MD (*Abstract Co-Author*)

TEACHING POINTS

Postoperative imaging of temporal bone is challenging and requires knowledge of anatomy and surgical techniques to correctly evaluate therapeutic success and for early detection of postoperative complications and recurrences. Accurate imaging characterization of postsurgical complications (e.g., infections, collections, cerebrospinal fluid (CSF) fistulas, neurovascular structure injuries, problems with prostheses or implants) is vital to guide appropriate clinical management and/or reinterventions. This guide reviews the main otologic surgeries (mastoidectomies, tympanoplasties with prostheses, ossicular reconstruction, cochlear implants and approaches to the cerebellopontine angle) and their possible complications imaging aspects in order to properly identify which one needs conservative treatment or new surgical intervention. Correlation with relevant computed tomography (CT) and intraoperative images was also made.

TABLE OF CONTENTS/OUTLINE

Illustration and didactic review of relevant aspects of the anatomy of the temporal bone for an adequate assessment of the imaging features of the main surgical procedures. The role of imaging in predicting major and minor complications on postoperative temporal bone imaging. Key aspects to help the accurate interpretation of usual postoperative patterns and it's prompt differentiation from unexpected outcomes and complications.

HNEE-43 DEEP DIVE INTO THE JAW: CT AND MRI FEATURES OF ODONTOGENIC KERATOCYSTS AND THEIR MIMICKERS

Leonardo Bandeira de Andrade, MD (*Presenter*)
Mario Padula, MD (*Abstract Co-Author*)
Rodrigo W. Murakoshi, MD (*Abstract Co-Author*)
Bruno C. Olivetti, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Isabela D. Alves, MD (*Abstract Co-Author*)
Ula Passos, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the typical imaging features of odontogenic keratocysts (OKC). Differentiate odontogenic keratocysts (OKCs) from other odontogenic cystic lesions, as well as from non-odontogenic entities based on imaging characteristics. Understand the clinical, epidemiological, and pathophysiological aspects of odontogenic keratocysts (OKCs), including their imaging features, typical treatment approaches, and post-treatment imaging findings.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION: Brief overview of OKC definition, epidemiology, histology and symptoms IMAGING: Multiple illustrative cases demonstrating the imaging features of OKCs on panoramic radiography, computed tomography (CT), and magnetic resonance imaging (MRI), including neurography sequence, with a particular emphasis on MRI. GORLIN GOLTZ SYNDROME: Definition and most commonly clinical presentation and imaging findings. DIFFERENTIAL DIAGNOSIS: Imaging findings and illustrative cases of ameloblastomas, dentigerous cysts, radicular cysts, odontogenic abscesses, mucoceles, and lymphomas, with emphasis on the imaging characteristics that help distinguish them from odontogenic keratocysts (OKCs). TREATMENT: Most commonly treatment modalities, including enucleation and marsupialisation. FOLLOW UP: Normal postoperative imaging appearances, features suggestive of recurrence or residual lesion, and imaging findings that may indicate malignant transformation.

HNEE-44 EYE SEE WHAT YOU DID THERE - THE ROLE OF IMAGING IN STRABISMUS

Felipe Correa Brito, MD (*Presenter*)
Otavio Yamamoto, MD (*Abstract Co-Author*)
Jacqueline Juhasz (*Abstract Co-Author*)
Paola Yoshimatsu Izelli, MD (*Abstract Co-Author*)
Gabriela Fernanda Riboli Favaro (*Abstract Co-Author*)
Wankler Dias Canhadas Junior (*Abstract Co-Author*)
Raifran Neto, MD (*Abstract Co-Author*)
Sara Rosalino, MD (*Abstract Co-Author*)
Henrique B. Zuppani, MD (*Abstract Co-Author*)
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*)
Fernanda B. Assuncao, MD (*Abstract Co-Author*)

TEACHING POINTS

Examine the normal anatomy and physiology related to ocular motility; Explore the primary causes and secondary causes, as also, the risk factors associated with strabismus; Analyze the key radiographic findings of strabismus identified through computed tomography and magnetic resonance imaging; Discuss the role of the radiologist in the diagnosis and therapeutic monitoring of patients with strabismus.

TABLE OF CONTENTS/OUTLINE

Essential orbital anatomy and physiology; Definition of strabismus and its epidemiology; Systematic structural assessment that the radiologist must perform; Analysis of the different causes of strabismus associated with the main imaging findings; Congenital: Orbital syndromes, malformations, neural hypoplasia. Acquired: Trauma, inflammatory diseases, neuropathies, orbital tumors, myopathies. Neurological: Ischemic, compressive or inflammatory lesions of the cranial nerves (III, IV, VI). Muscles: Heaving eyes syndrome (esotropia in high myopia), Sagging eye syndrome, Grave´s diseases, Idiopathic inflammatory Others: Post-traumatic muscle entrapment or restriction by orbital masses, lymphomas, metastases The role of the radiologist in diagnosis and therapeutic monitoring of patients with strabismus. Summary Strabismus can have multiple causes, and imaging is essential to guide diagnosis and management; Knowledge of the anatomy and patterns of muscle and neural involvement allows for better interpretation of radiological findings; Radiologists play an essential role in the pre- and post-surgical evaluation of strabismus;

HNEE-45 IMAGING EVALUATION OF HYPOGLOSSAL PALSIES: AN ANATOMICAL AND ETIOLOGICAL APPROACH

Paula Cristina Amaral, MD (*Presenter*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)
Bruno S. Inada, MD (*Abstract Co-Author*)
Marina Nori Hilario, MD (*Abstract Co-Author*)
Marcos Sakano (*Abstract Co-Author*)
Camila Almeida, MD (*Abstract Co-Author*)
Guilherme L. Gaiotto, MD (*Abstract Co-Author*)
Vinicius Martins, MD (*Abstract Co-Author*)

TEACHING POINTS

Hypoglossal nerve palsy (cranial XII) can significantly impair tongue movement, resulting in deviations, fasciculations, or muscle atrophy. Imaging assessment of anatomical structures along the nerve pathway is crucial to identify pathological changes and determine underlying causes, guiding diagnosis and clinical management.

TABLE OF CONTENTS/OUTLINE

The hypoglossal nerve originates in the hypoglossal nucleus, located in the dorsal portion of the medulla oblongata. Its fibers emerge from the skull through the hypoglossal canal. After leaving the canal, the nerve descends laterally, positioning itself between the internal carotid arteries and the internal jugular vein, in the parapharyngeal space. It then crosses the lingual arteries and is distributed to innervate all the muscles of the tongue, except the palatoglossus muscle, which is innervated by the vagus nerve via the pharyngeal plexus.Detailed knowledge of this trajectory is essential for correlating clinical and radiological findings, allowing the identification of lesions.Magnetic resonance imaging is the modality of choice for evaluating the hypoglossal nerve trajectory. MR angiography can be used to evaluate arterial dissections or vascular compressions. Computed tomography of the skull is complementary, especially to identify fractures, bone erosions or calcifications.The main causes of hypoglossal nerve palsy can be categorized according to the affected segment and the nature of the injury. Inspection between clinical and imaging results is essential to determine the level of the injury and guide therapeutic conduct, which can range from observation to surgical interventions.

HNEE-46 OPTIC NEUROPATHIES ON MRI AND CT: A PRACTICAL GUIDE FOR EVERY RADIOLOGIST

Igor Amorim, MSc (*Presenter*)
Marcella Brandao, MD, MEd (*Abstract Co-Author*)
Bruno V. Fahel, MD (*Abstract Co-Author*)
Paulo H. Fujita (*Abstract Co-Author*)
Mariluze Sardinha (*Abstract Co-Author*)
Paulo Mariz Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

- Present a practical, image-based approach to optic neuropathies, highlighting essential radiologic patterns. - Reinforce the anatomical segmentation of the optic nerve and its relevance for diagnostic reasoning. - Illustrate key CT and MRI findings across major etiologic categories of optic nerve involvement. - Enable radiologists to build efficient, confident differential diagnoses in common and atypical presentations.

TABLE OF CONTENTS/OUTLINE

- Anatomical overview Segmental division of the optic nerve (intraocular, intraorbital, intracanalicular, intracranial) as the basis for interpretation. - Inflammatory, autoimmune and demyelinating lesions Includes optic neuritis and neuromyelitis optica, differentiated by topography, enhancement pattern, and clinical context. - Gliomatous infiltration Classic findings in NF1-associated optic pathway gliomas and perineural gliomatosis. - Congenital anomalies Recognition of optic nerve coloboma and its distinct “egg-shaped” excavation pattern. - Meningeal lesions Typical concentric perineural enhancement in meningioma, including the “tram-track sign” as a diagnostic clue. - Extrinsic compressive and infiltrative processes: Orbital disorders such as thyroid-associated orbitopathy, melanoma, and perineural tumor spread with secondary optic nerve involvement.

HNEE-48 BEYOND THE MUCOSA: IMAGING SPECTRUM OF PARANASAL SINUS COMPLICATIONS AND AGGRESSIVE INFECTIONS

Oreanna Quintero, MD (*Presenter*)
Andres F. Caliz Cabrales, MD (*Abstract Co-Author*)
Sara Gomez Milanes, MD (*Abstract Co-Author*)
Julian M. Gandur, MD (*Abstract Co-Author*)
Jesus Eduardo Barreto Fernandez (*Abstract Co-Author*)
Luz A. Unigarro, MD (*Abstract Co-Author*)
Alejandro Blanco Rojas, MD (*Abstract Co-Author*)
Carolina Tramontini (*Abstract Co-Author*)

TEACHING POINTS

Sinusitis: Beyond mucosa, consider orbital, osseous, intracranial, aggressive infections (high morbidity/mortality).Imaging (CT/MRI) key for early dx, extent, therapy guidance.Uncomplicated: Mucosal thickening, air-fluid, opacification, OMC obstruction. Chronic: Persistent thickening, polyps, bone remodeling.Orbital: Pre/postseptal cellulitis, subperiosteal/orbital abscess (proptosis, chemosis, fat stranding, rim-enhancing collections - MRI best).Osseous: Osteomyelitis (Pott's Puffy Tumor), mucocele (bone erosion/expansion).Aggressive Fungal (IFS): Rapid, T2 hypointense, bone erosion, vascular/orbital/intracranial invasion.Intracranial Spread: Epidural/subdural abscess, empyema, meningitis, cerebritis, brain abscess, sinus thrombosis (rim-enhancing, DWI restriction, venous defects - MRI+DWI).Red Flags: Bone erosion, T2 hypointense, intracranial/dural enhancement, proptosis, venous thrombosis, pneumocephalus.Early recognition of red flags crucial for timely management.

TABLE OF CONTENTS/OUTLINE

I. Intro: Beyond Simple Sinusitis II. Uncomplicated Sinusitis A. Acute Patterns B. Chronic Patterns III. Local Spread: Orbital A. Pre/Postseptal Cellulitis B. Subperiosteal Abscess C. Orbital Abscess IV. Local Spread: Osseous A. Osteomyelitis (Pott's) B. Mucocele/Pyocele V. Critical Crossings: Intracranial & Aggressive A. Acute Invasive Fungal Sinusitis B. Intracranial Spread VI. Conclusion: Beyond Sinus Cavity A. Summary B. Imaging Red Flags C. Take-Home Message

HNEE-49 IMAGING EVALUATION FOR POST-OPERATIVE COCHLEAR IMPLANTS

Krishnakumari A. Modi, MBBS (*Presenter*)
Otavio Augusto Ferreira Dalla Pria, MD (*Abstract Co-Author*)
Gul Moonis, MD (*Abstract Co-Author*)
Amy F. Juliano, MD (*Abstract Co-Author*)
Nitesh Shekhrajka, MD,MBBS (*Abstract Co-Author*)

TEACHING POINTS

Cochlear implants (CI) surgery an effective treatment in children and adults with severe to profound hearing loss. Imaging plays a crucial role in preoperative and postoperative evaluation of CI. Imaging is used to confirm the desired positioning and insertion depth of the electrode array, which affects sound coding strategies and hearing outcomes as well as detects immediate and late post operative complications.

TABLE OF CONTENTS/OUTLINE

• Overview of CI components. • Review various types of electrodes. • Describe normal postoperative imaging findings. • Identify unfavorable positioning of the electrodes and immediate and late complications. • CI and MRI safety

HNEE-50 IMAGING EVALUATION OF CONGENITAL NON-SYNDROMIC INNER EAR MALFORMATIONS

Krishnakumari A. Modi, MBBS (*Presenter*)
Otavio Augusto Ferreira Dalla Pria, MD (*Abstract Co-Author*)
Gul Moonis, MD (*Abstract Co-Author*)
Amy F. Juliano, MD (*Abstract Co-Author*)
Nitesh Shekhrajka, MD,MBBS (*Abstract Co-Author*)

TEACHING POINTS

Hearing loss in children can significantly impact speech and language development, influencing their academic performance and socio-economic well-being. Imaging studies reveal inner ear malformations in up to one-third of children with sensorineural hearing loss, which may either be isolated or syndromic. A thorough understanding of inner ear embryology, anatomy, and characteristic imaging features is essential for early diagnosis, appropriate intervention, and prevention of complications. In this exhibit, we aim to provide a concise overview of embryologic development of the inner ear, relevant anatomical structures, imaging modalities, and the latest classification of isolated (non-syndromic) inner ear malformations, illustrated with representative graphics and imaging cases.

TABLE OF CONTENTS/OUTLINE

• Review inner ear embryology with simple graphic representations. • Imaging anatomy of key inner ear structures on CT and MRI. • Review the latest classification of non-syndromic inner ear malformations. • Case based review of inner ear malformations with imaging examples and graphic representations.

HNEE-51 DON'T LOSE YOUR HEAD: A RADIOLOGISTS' GUIDE TO POSTSURGICAL IMAGING OF ADVANCED HEAD AND NECK TUMORS

Augusto S. Serpa, MD (*Presenter*)
Erika Eberle (*Abstract Co-Author*)
Geovana L. Franco, MD (*Abstract Co-Author*)
Felipe Welter Langer, MD (*Abstract Co-Author*)
Lucas P. Caldas, MD (*Abstract Co-Author*)
Carlos Jorge da Silva, PhD, MD (*Abstract Co-Author*)
Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*)
Eloisa M. Gebrim, MD (*Abstract Co-Author*)
Samya S. Alves, MD (*Abstract Co-Author*)
Heitor C. Alves, MD (*Abstract Co-Author*)
Bruna G. Dutra (*Abstract Co-Author*)
Rebeca O. Francelino, MD (*Abstract Co-Author*)
Raquel A. Moreno, MD (*Abstract Co-Author*)

TEACHING POINTS

- Management of advanced head and neck malignancies requires a multidisciplinary approach, tailored to tumor location, stage, histopathology, and patient-specific factors. - Surgical resection, often combined with radiation therapy, plays a central role but frequently results in complex posttreatment changes and altered anatomy that complicate imaging interpretation. - This educational session provides a comprehensive review of posttreatment imaging in head and neck cancer patients, emphasizing recognition of expected postoperative findings, major complications, and imaging clues for tumor recurrence.

TABLE OF CONTENTS/OUTLINE

1) Common Surgical and Reconstructive Techniques - Impact on local anatomy and key imaging considerations. 2) Expected Posttreatment Imaging Findings- Normal early and delayed postoperative appearances. 3) Identifying tumor recurrence - Imaging strategies to differentiate recurrent disease from benign postoperative alterations. 4) Major Postoperative Complications - Recognition of common complications including: osteoradionecrosis and osteomyelitis, abscess formation and fluid collections, flap failure (e.g., pedicle thrombosis) and chylous fistula. 5) Conclusion and Future Directions - evolving imaging techniques and emerging robotic techniques.

HNEE-53 UPDATES ON THE 9TH AJCC/UICC NASOPHARYNGEAL CANCER TNM STAGING AND THE ROLE OF MULTIMODALITY IMAGING

Anna Theresa Dantes (*Presenter*)
Takashi Hiyama, MD, PhD (*Abstract Co-Author*)
Hirofumi Kuno, MD, PhD (*Abstract Co-Author*)
Tatsushi Kobayashi, MD (*Abstract Co-Author*)
Ron C. Pilotin, MD (*Abstract Co-Author*)

TEACHING POINTS

The American Joint Committee on Cancer (AJCC) and the Union for International Cancer Control (UICC) published the 9 th version of Nasopharyngeal Cancer TNM Staging Classification in January 2025. This new edition establishes a paradigm shift from primarily clinical-based criteria to incorporation of radiologic parameters, highlighting the role of imaging in nasopharyngeal cancer (NPC) staging. In the T category, emphasis is now given to unequivocal radiologic evidence of cranial nerve involvement as a T4 criterion. The N category now includes imaging-detected advanced extra-nodal extension as a parameter for upstaging to N3. Furthermore, the M category is now subdivided into M1a and M1b according to the number of metastatic lesions and organs involved. The objectives of this presentation are: 1) to review the updates in the 9 th version of the AJCC and UICC TNM staging for NPC, comparing it with the 8 th edition; 2) to discuss the role of multimodality imaging in the proper staging of NPC patients; and, 3) to explore possible challenges in applying these new criteria in practice.

TABLE OF CONTENTS/OUTLINE

1. 9 th version of NPC TNM staging classification vis-a-vis the 8 th edition 2. Case discussion a. T Category b. N Category c. M Category 3. Potential challenges in applying the new criteria in radiology practice 4. Summary and conclusion

HNEE-54 PHOTON-COUNTING CT-DACRYOCYSTOGRAPHY: A SINGLE-CENTER CASE SERIES AND LITERATURE REVIEW

Renske Gahrmann, MD, PhD (*Presenter*)
Aaike S. van Den Berg, MD (*Abstract Co-Author*)
Marcel L. Dijkshoorn (*Abstract Co-Author*)
Sophie E. Veldhuijzen van Zanten, MD (*Abstract Co-Author*)
Anke W. van der Eerden, MD (*Abstract Co-Author*)

TEACHING POINTS

Photon-Counting CT dacryocystography (PCCT-DCG) provides superior anatomical detail with excellent spatial resolution and soft-tissue contrast, outperforming CBCT and MDCT for nasolacrimal drainage system (NLDS) evaluation. A dynamic scanning protocol incorporating timed acquisitions and patient maneuvers enhances diagnostic yield. Clinical utility spans trauma, infection, dacryocystocele, and post-dacryocystorhinostomy (DCR) evaluation. Early adoption of PCCT-DCG in the diagnostic pathways may reduce reliance on more invasive tests and improve diagnostic efficiency.

TABLE OF CONTENTS/OUTLINE

Introduction covering epiphora basics, NLDS obstruction etiologies, and current imaging modalities. Technical advantages of PCCT-DCG, including superior bone and soft-tissue imaging, artifact reduction, reconstruction techniques, and optimized radiation dose efficiency compared to CBCT, MDCT, fluoroscopy, and dacryoscintigraphy. Protocol details: non-contrast CT, eyedrop contrast administration, and dynamic scanning. Case series summary highlighting patient characteristics and representative findings. Discussion of diagnostic value and clinical implications in diagnostically challenging cases, where conventional outpatient examinations such as irrigation tests, fail to provide definitive answers.

HNEE-55 NAVIGATING THE NECK: A GUIDE TO CAROTID BODY PARAGANGLIOMAS FOR RESIDENTS

Willington Zapata Salazar, MD (*Presenter*)

TEACHING POINTS

Recognize the anatomy, origin, and characteristic imaging features of carotid paragangliomas, including their vascular behavior, key diagnostic signs, and relevance for surgical risk stratification. Describe a structured, multimodality imaging approach, Doppler ultrasound, CT, MRI, and PET when indicated and apply the Shamblin classification to support accurate diagnosis and presurgical planning.

TABLE OF CONTENTS/OUTLINE

Carotid paragangliomas and their clinical importance. Location and nearby anatomical structures. Imaging approach using Doppler, CT, MRI, and PET CT protocol and key features for surgical planning. Shamblin classification for tumor description. Structured interpretation approach for radiology residents.

HNEE-56 CRACKING THE CASE: TEMPORAL BONE TRAUMA REVIEW FOR THE ON-CALL RADIOLOGIST

Brian Nguyen, MD (*Presenter*)
Hunter R. Carlock, MD (*Abstract Co-Author*)
Quinn Magiera, MD (*Abstract Co-Author*)
Mitchel Pham, MD (*Abstract Co-Author*)
Anthony Portanova, MD (*Abstract Co-Author*)

TEACHING POINTS

This project aims to deliver a focused yet comprehensive review of temporal bone trauma imaging, emphasizing key reporting considerations in the on-call setting. Topics of discussion will include mechanisms of injury, fracture patterns, and a comparison of classic versus modern classification systems. A case-based review will highlight the imaging appearance of important complications such as ossicular disruption, CSF leak, and facial nerve paralysis. A brief overview of normal temporal bone anatomy will be provided, limited to what is essential for identifying fracture morphology, complications, and commonly misinterpreted “pseudofractures” caused by normal fissures, sutures, and canaliculi. The presentation will also include a practical reporting checklist to support a structured search pattern at the workstation.

TABLE OF CONTENTS/OUTLINE

Introduction to Temporal Bone Trauma - Epidemiology and clinical relevance Review of Normal Anatomy - Key anatomical landmarks on CT with illustrations - Normal "pseudofractures" (sutures, fissures, canaliculi etc.) Fracture Classifications - Traditional classification: longitudinal vs. transverse vs. mixed - Modern classification: otic capsule-sparing vs. otic capsule-violating Case-Based Review - e.g. ossicular chain injury, CSF leak, facial nerve injury, vascular injury On-call Reporting Checklist - Practical tool for workstation use, search pattern augmentation Summary and Take-Home Points - High-yield recap

HNEE-57 A REAL PAIN IN THE NECK: CASE-BASED REVIEW OF HEAD AND NECK CANCER NODAL STAGING WITH IMAGING-BASED EVALUATION OF EXTRANODAL EXTENSION

Alexander D. Wong, MD, MPH (*Presenter*)
Jumanah M. Ardawi, MBBS (*Abstract Co-Author*)
Carlos I. Torres, MD (*Abstract Co-Author*)
Eugene Yu, MD (*Abstract Co-Author*)
Colin S. Poon, MD, PhD (*Abstract Co-Author*)
Jeffrey Chankowsky, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Targeted review of anatomy pertinent to nodal staging in head and neck cancer. Overview of existing classification systems for grading likelihood of imaging detected extranodal extension (iENE). Present a case-based review and practical approach to nodal staging and detection/grading of iENE

TABLE OF CONTENTS/OUTLINE

Extranodal extension of tumor is an important predictor of negative prognosis in head and neck cancer. Although assessment of pathology-detected ENE (pENE) is well established, detection and grading of iENE is unclear with lack of consensus. As such, it has not been integrated into any staging systems nor is it used to inform clinical management to date. Recent efforts have been made to establish a clear grading system and use of a standardized lexicon for report generation during radiological assessment of iENE, which will improve future research in validating imaging-based assessment and permit imaging to play a greater role in guiding treatment decisions, monitoring disease course and response to treatment. The objective of this exhibit is to provide a practical approach to nodal staging in head and neck cancer and detection and grading of iENE through cased-based review. The exhibit will start with a targeted review of relevant anatomical landmarks that are important to identify during head and neck cancer nodal staging. Subsequently, we will provide an overview of nodal staging systems and present an image-based grading system of iENE derived from a multi-national consensus group, with an emphasis on discussion surrounding accuracy/performance in available validation studies. Finally, we will present a practical approach to nodal staging and grading the degree of iENE through case-based review.

HNEE-58 FROM SIGNAL TO SIGHT: USING MRI TO UNCOVER THE OPTIC NERVE

Pavan Kottamasu, MD, MBA (*Presenter*)
Hunter R. Carlock, MD (*Abstract Co-Author*)
Jeevak Almast, MD (*Abstract Co-Author*)
Steven P. Meyers, MD, PhD (*Abstract Co-Author*)
Shehanaz K. Ellika, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

(1) Review the anatomy of the optic nerve (ON) and discuss MR imaging sequences that adequately assess the ON (2) Discuss the clinical role of MR imaging in diagnosis and management of ON pathology (3) Present common ON pathologies and describe their associated MR imaging findings (4) Identify common imaging pitfalls that occur when evaluating the ON

TABLE OF CONTENTS/OUTLINE

(I.) Defining the segments of the optic nerve (ON) on imaging (II.) MR imaging sequences to include when evaluating the ON (III.) Common ON/nerve sheath pathologies (IIIa.) Congenital/hereditary ON pathologies (IIIb.) Demyelinating disorders (IIIc.) Inflammation of the ON (IIId.) ON neoplasms (IIIe.) Ischemic optic neuropathy (IIIf.) Other ON pathologies (IV.) Common imaging pitfalls when evaluating the ON

HNEE-59 ILLUSTRATING PARATHYROID GLAND PATHOLOGY IN PRIMARY, SECONDARY, AND TERTIARY HYPERPARATHYROIDISM: A PICTORIAL REVIEW

Sofia Ventura-Diaz, MD (*Presenter*)
Andrea Chen (*Abstract Co-Author*)
Ipshita Kak (*Abstract Co-Author*)
James Young (*Abstract Co-Author*)
Ryan P. Rebello, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the physiology and normal anatomy of the parathyroid glands, and the imaging appearance of the different causes of primary (PHPT), secondary (SHPT) and tertiary hyperparathyroidism (THPT).

TABLE OF CONTENTS/OUTLINE

Hyperparathyroidism is a cause of substantial morbidity and health care costs. Whilst the diagnosis of hyperparathyroidism is made biochemically, it is important to recognize the most common imaging findings of the PHPT, SHPT and THPT for adequate preoperative localization, as it can potentially be cured surgically. Hyperparathyroidism can result from an intrinsic abnormality (PHPT or THPT) or from extrinsic stimulation secondary to imbalance in the calcium homoeostasis that stimulates production of PTH (SHPT). PHPT represents the most common cause of hypercalcemia and the third most common endocrine disorder. The most common cause of PHPT results from a single parathyroid adenoma (85-90%), hyperplasia (6%), double parathyroid adenoma (4%), and parathyroid carcinoma (<1%). Parathyroid cysts are extremely rare (<0.5%) and the majority (80%) are non-functioning. SHPT arises when increased secretion of PTH is a response to lowered ionized calcium as a result of kidney, liver, or bowel disease. It can be either caused by Vitamin D deficiency, a relatively common cause in the elderly, or as the result of chronic kidney disease (CKD). It is characterized by 4 gland hyperplasia. THPT is a state of autonomous secretion of PTH as a result of longstanding CKD and SHPT. Like SHPT, it is most commonly associated with 4 gland hyperplasia. The most commonly performed imaging modalities for preoperative localization are US, nuclear medicine imaging, and multiphasic CT.

HNEE-60 CT AND MRI IMAGING CHARACTERISTICS OF EYELID LESIONS

Masaya Kawaguchi (*Presenter*)
Hiroki Kato (*Abstract Co-Author*)
Shingo Omata, MD (*Abstract Co-Author*)
Masayuki Matsuo, MD (*Abstract Co-Author*)

TEACHING POINTS

The eyelid covers the eyeball and is divided into an upper and lower eyelid that opens and closes to protect the eyeball. The eyelid is composed of skin, appendages, muscle, fat, and fibrous connective tissue, and a variety of lesions can occur. The majority of eyelid tumors (85%) are benign tumor and malignant tumors are leratively rare. However, CT and MRI scans are rarely performed for benign tumors because of the small size of these lesions. Eyelid imaging is used mainly to investigate malignancy, inflammation, and systemic autoimmune disease. Benign tumors of the eyelid include epidermoid cysts, dermoid cysts, pilomatricomas, chalazion, hordeolum, and hemangiomas. Malignant tumors include basal cell carcinoma, squamous cell carcinoma, malignant melanoma, Merkel cell carcinoma, signet-ring cell/histiocytoid carcinoma, and sebaceous carcinoma. Non-neoplastic lesions include cellulitis, IgG4-related disease, and Erdheim-Chester's disease. There have been no reviews on the imaging findings of eyelid lesions. This article aimed to describe imaging findings of eyelid lesions.

TABLE OF CONTENTS/OUTLINE

Introduction. Anatomy. Skin and subcutaneous tissue, Orbicularis oculi, Tarsal plates, Levator apparatus, Conjunctiva. Benign tumor. Epidermoid cysts, Dermoid cysts, Pilomatricomas, Chalazion, Hordeolum, and Hemangiomas. Malignant tumor. Basal cell carcinoma, Squamous cell carcinoma, Malignant melanoma, Signet-ring cell/histiocytoid carcinoma, Sebaceous carcinoma, and Metastasis. Non-neoplastic lesion. Cellulitis, IgG4-related disease, and Erdheim-Chester's disease. Summary.

HNEE-61 DON'T GET LOST, USE THE LANDMARKS: A COMPREHENSIVE GUIDE TO NECK ULTRASOUND AND LYMPH NODES

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Ana Ayala (*Abstract Co-Author*)
Zofia Marrero (*Abstract Co-Author*)
Andrea M. Ruiz Mojica, MD (*Abstract Co-Author*)
Wilma Rodriguez-Mojica, MD (*Abstract Co-Author*)

TEACHING POINTS

Provide an anatomical review of cervical lymph node levels.Explain key landmarks and anatomical relationships necessary for adequate identification.Use a hiking analogy to simplify learning, comparing cervical lymph node levels to different points on a hiking trail for visualization and easier recall.Review appropriate transducer positioning.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Anatomy Review IV. Cervical Lymph Nodes Levels: Sonographic Features, hiking analogy and imaging techniques VII. Base Camp VI. Forested Trail III. Waterfall IV. Rest Stop Vb. Boulder Field Va. Climbing Zone IIb. Ridge Trail IIa. Summit Plateau Ib. Nearing the Mountain Range Ia. The Peak VII. Conclusion Cervical lymph node levels are essential for evaluating nodal involvement in malignancies, infections, and other pathological conditions. Nevertheless, accurate identification can be challenging. This exhibit reviews cervical lymph node anatomy, highlighting key landmarks and relationships for precise localization. Using a creative "hiking analogy," it guides radiologists from the "base camp" to the "peak" for easier recall. Real images of lymph node levels and transducer positioning are included to connect anatomical knowledge with ultrasound technique.

HNEE-62 ULTRASOUND IN ACTIVE SURVEILLANCE OF PAPILLARY THYROID MICROCARCINOMA: A PRACTICAL GUIDE FOR RADIOLOGISTS

Ji Ye Lee, MD, PhD (*Presenter*)

TEACHING POINTS

Active surveillance (AS) is an emerging and increasingly accepted management strategy for patients with low-risk papillary thyroid microcarcinoma (PTMC), aiming to reduce overtreatment while maintaining excellent prognosis.As AS gains clinical attention across disciplines, radiologists should be familiar with the criteria, imaging protocols, and follow-up strategies essential for proper patient selection and monitoring.Standardized, high-quality ultrasound (US) plays a pivotal role in detecting imaging features that support or contraindicate AS, including subtle signs of gross extrathyroidal extension (ETE), lymph node metastasis (LNM), and tumor progression.

TABLE OF CONTENTS/OUTLINE

1. Indications for Active Surveillance (AS) and Immediate Surgery 1) Criteria for selecting AS vs. immediate surgery based on tumor size, cytology, and imaging features2) Role of patient preference and imaging findings without biopsy 2. Imaging Tools for pre-AS Evaluation 1) Recommendations for baseline US in ETE and LNM assessment 2) Are neck CT and chest CT necessary before AS? 3. How to assess ETE and LNM on US 1) Imaging signs suggesting high risk of gross ETE (e.g., strap muscle, trachea, recurrent laryngeal nerve invasion)2) FNA and thyroglobulin washout for suspicious LNM3) Imaging assessment of appropriateness for AS 4. Standardized US Technique During AS 1) Consistent measurement methods using identical imaging planes2) Importance of image reproducibility in longitudinal follow-up 5. Evaluation of Tumor Progression 1) Criteria for defining tumor size enlargement2) New imaging features suggesting ETE or LNM 6. Recommended Imaging Interval during AS 7. Indications for Surgical Conversion

HNEE-63 MENIERE'S DISEASE: GUIDE TO INTERPRETATION AND REPORTING

Rishi D. Patel, MD (*Presenter*)
Miriam Redleaf, MD (*Abstract Co-Author*)
Burce Ozgen Mocan, MD (*Abstract Co-Author*)

TEACHING POINTS

Menière’s disease (MD) is an inner ear disorder traditionally diagnosed clinically, but advances in MRI have made MRI an increasingly valuable tool in evaluating patients with suspected MD. MR imaging can assess endolymphatic hydrops (EH), characterized by distention of the endolymphatic spaces within the cochlea and vestibule. This exhibit will review the anatomy of the inner ear as it is presented on 3D FLAIR post-gadolinium images. We will present imaging findings of MD using illustrative case examples while proposing a multisequence, multiplanar search pattern to systematically approach the inner ear to optimize diagnostic accuracy. The grading systems

that have been developed will also be reviewed and illustrated. Finally, a basic schematic will be provided to report imaging findings to communicate the degree and extent of disease.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Menière Disease and the role of the radiologist. 2. Imaging findings of normal inner ear structures, endolymph, and perilymph on delayed post-contrast FLAIR & REAL IR sequences. 3. Identifying abnormalities and using endolymphatic hydrops grading system. 4. Diagnostic search pattern. 5. Important considerations in reporting.

HNEE-64 SCALP SECRETS - UNCOVERING SUPERFICIAL LESIONS WITH IMAGING

Carolina A. Almeida, MD (*Presenter*)
Maria Carolina Zafra Paez (*Abstract Co-Author*)
Bruna Duque-Estrada (*Abstract Co-Author*)
Flavia M. Costa, MD, PhD (*Abstract Co-Author*)
Clarissa C. Moraes Do Carmo, MD (*Abstract Co-Author*)

TEACHING POINTS

1. High-frequency ultrasound is a powerful, accessible tool for evaluating superficial scalp lesions, providing key information on lesion location, echotexture, and vascularity.2. Recognizing sonographic patterns helps differentiate common benign entities (e.g., trichilemmal cyst, lipoma, pilomatricoma) from potentially malignant lesions (e.g., squamous cell carcinoma).3. Knowledge of the layered anatomy of the scalp is essential for accurate interpretation and for guiding further workup or intervention, especially in ambiguous or atypical presentations.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of scalp lesion evaluation with emphasis on dermatologic ultrasonography, CT and MRI. Anatomy Review Imaging appearance of the scalp layers and relevance for lesion localization. Case-Based Imaging Gallery Pilar (trichilemmal) cyst Pilomatricoma Lipoma Osteoma Nevus sebaceous of Jadassohn Squamous cell carcinoma Subgaleal hematoma Pattern-Based Diagnostic Approach Algorithm for narrowing the differential diagnosis based on lesion location, echogenicity, presence of calcifications, and Doppler flow. Take-Home Messages Practical pearls to enhance diagnostic confidence and guide management decisions.

HNEE-65 SPOTLIGHT ON SARCOMAS: UNRAVELING HEAD AND NECK TUMORS

Tamara Hernandes Ricci, MD (*Presenter*)
Carlos Alberto F. Coelho Neto, MD (*Abstract Co-Author*)
Murilo B. Cintra (*Abstract Co-Author*)
Gustavo S. Boasquevisque, MBBS (*Abstract Co-Author*)
Soraia A. Souza, MD, MS (*Abstract Co-Author*)
Marcos D. Pinheiro II, MD (*Abstract Co-Author*)
Marcio Ricardo T. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review the main types of sarcomas that can occur in this region.• Characterize the key imaging features of each type to aid in differentiation.• Guide radiologists in recognizing the primary types of sarcomas, as well as providing important details about tumor extent and histological grade for a comprehensive assessment.

TABLE OF CONTENTS/OUTLINE

• Introduction highlighting the general aspects of sarcoma, WHO classification and types of sarcomas. • Overview the main images characteristics of sarcomas, providing clues about tumor grade, composition, extent, and involvement of adjacent structures. • Describe and show images of the principal types of sarcomas: osteosarcomas (including osteoblastic subtype), liposaromas, fibrosarcomas, liposarcoma, chondrosarcoma, undifferentiated pleomorphic sarcoma/malignant fibrous histiocytoma, rhabdomyosarcoma (including embrionary subtype), leiomyosarcoma, angiosarcoma, carcinosarcoma, alveolar soft part sarcoma, synovial sarcoma and ewing sarcoma. • Conclusion.

HNEE-66 IMAGING FINDINGS IN OVAL AND ROUND OTIC WINDOWS, WITH AN INSIGHT ON THIRD WINDOW ANOMALIES

Diego Alejandro Garcia Paredes, MD (*Presenter*)
Juan Gredilla (*Abstract Co-Author*)
Juan V. Quintana Perez, MD (*Abstract Co-Author*)
Beatriz Alba Perez, MD (*Abstract Co-Author*)
Montserrat Medina Diaz, PhD (*Abstract Co-Author*)
Juan S. Martinez San Millan, MD, PhD (*Abstract Co-Author*)
Isabel Fonseca Buelga, MD (*Abstract Co-Author*)
Claudia Viescas Huerta, MD (*Abstract Co-Author*)
Sergio Sintes (*Abstract Co-Author*)

TEACHING POINTS

1. Review of the normal oval and round windows and their roles in sound transmission. 2. Review of the first line imaging modality used for the evaluation of normal and abnormal windows and the different reconstructions used to better visualize these alterations. 3. Discuss the imaging findings of some of the different pathologies affecting the different windows with a special mention about those 'mimickers' that can affect all the different windows. 4. Brief description of what is considered a third window abnormality and classic symptoms manifested by these. 5. Explain pathological air and bone conduction.

TABLE OF CONTENTS/OUTLINE

1. Teaching points. 2. Introduction. - Anatomy of the normal middle and inner ear. - Normal sound transmission. 3. Imaging modality and reconstructions used. 4. Pathologies and imaging findings. - Oval and round windows: Otoesclerosis/otospongiosis, Atresia, Hypoplasia, Obliteration. - Third window: Clinical manifestations and physiological explanation, Natural (Tullio´s phenomenon), Adquired (Otic capsule destruction). - Mimickers. 5. Conclusions 6. Bibliography

HNEE-67 HORNER SYNDROME - NO SWEAT APPROACH TO LESION LOCALIZATION

Alok A. Bhatt, MD (*Presenter*)

TEACHING POINTS

1. Oculosympathetic pathway starts in the hypothalamus and ends in the eye, providing sympathetic innervation to sweat glands of the face and body, dilator muscles of eyes, and retractor muscles of eyelids. 2. Any pathology along the course of the oculosympathetic pathway can cause Horner Syndrome (anhidrosis, myosis, and ptosis). 3. Additional symptoms may occur depending on the location of lesion. 4. Acute unilateral face/neck/head pain with Horner Syndrome needs evaluation with CTA head and neck to evaluate for dissection.

TABLE OF CONTENTS/OUTLINE

Objectives 1. Review the clinical symptoms of Horner syndrome as it relates to the anatomy of the oculosympathetic pathway. 2. Review the various pathologies that can cause Horner Syndrome. 3. Discuss appropriate imaging modalities and protocol depending on the clinical symptoms of Horner Syndrome. Summary: Horner Syndrome is an oculosympathetic paresis, consisting of anhidrosis, miosis, and ptosis. The oculosympathetic pathway begins in the hypothalamus and ends in the eye. It provides sympathetic innervation to sweat glands of the face and body, dilator muscles of eyes, and retractor muscles of eyelids. There are 3 sets of neurons (first order, second

order, and third order) and 2 relay centers (ciliospinal center of Budge-Waller and superior cervical ganglion). Any pathology along the course of the oculosympathetic pathway can cause symptoms of Horner Syndrome. Additional symptoms may occur depending on the location of lesion. This exhibit reviews the various lesions that can occur along the oculosympathetic pathway with illustrations and image rich examples.

HNEE-68 DIAGNOSTIC QUALITY OF 3D T1 FSE MR IMAGING COMPARED TO CONVENTIONAL 2D T1 FSE IN ASSESSMENT OF HEAD AND NECK SQUAMOUS CELL CARCINOMA

Momin Muzaffar, MD (*Presenter*)
Erica Hallman, MD (*Abstract Co-Author*)
Jonathan Wang, MD (*Abstract Co-Author*)
Olga Pasternak Wise, MD, MS (*Abstract Co-Author*)
Heather Whitney, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Historical difficulties of employing 3D isotropic imaging in the neck can be overcome with recent advances in MR technology coupled with deep learning (DL) algorithms. 2. The most common artifacts encountered with 3D FSE T1w imaging include motion and compressed sensing (CS) artifacts. 3. 3D FSE T1w imaging affords improved contrast to noise ratio and comparable in-plane resolution with the added advantage of isotropic acquisition allowing multiplanar reformats although fat suppression in the infrahyoid neck on post contrast images is inferior to 2D Dixon techniques. 4. 3D FSE T1w imaging is advantageous in evaluating head and neck squamous cell carcinoma and nodal disease.

TABLE OF CONTENTS/OUTLINE

1. Overview of 3D FSE acquisition versus 2D FSE acquisition a. Harnessing CS and DL algorithms for accelerating image acquisition b. Advantages of 3D FSE sequences compared to 3D GRE sequences in the neck c. Common artifacts: Motion, CS artifacts, non-laminar vascular flow artifact, susceptibility artifact, aliasing, heterogenous fat suppression 2. Normal anatomy with 3D FSE T1w imaging vs 2D T1w imaging a. Suprahyoid deep spaces including parapharyngeal space, pterygopalatine fossa, masticator space, carotid space, and retropharyngeal space b. Skull base foramina and cranial nerves c. Nasopharynx, oropharynx, hypopharynx d. Larynx and hypopharynx e. Neck vessels on black blood sequences 3. Head and neck squamous cell carcinoma (SCCa) with 3D FSE T1w imaging vs 2D T1w imaging including cavity and oropharyngeal SCCa; laryngeal SCCa including detection of cartilaginous invasion and extralarygneal tumor; perineural tumor spread; and nodal disease with extranodal extension.

HNEE-69 COCHLEAR IMPLANTS: POSTOPERATIVE EVALUATION AND CASE-BASED REVIEW OF MALPOSITIONS

Nicholas W. Kemper, MD (*Presenter*)
Yi Zhang, DO (*Abstract Co-Author*)
Kevin Jacob (*Abstract Co-Author*)
Jerry Lin (*Abstract Co-Author*)
Peter Roland (*Abstract Co-Author*)
Suresh K. Mukherji, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

1. This multi-institutional exhibit will provide a detailed case-based review of Intra-cochlear and Extra-cochlear malpositions for decreased cochlear implant performance, including companion cases and clinical presentations. 2. Introduce imaging for anatomy-based fitting of cochlear implants. 3. Recognize normal insertion of cochlear implants and important intra-operative considerations. 4. After viewing this exhibit, radiologists will have practical tools for developing a differential of anatomical post-implant complications

TABLE OF CONTENTS/OUTLINE

1. Main components of cochlear implant, 2. Types of cochlear implant insertions, 3. Considerations for anatomic-based fitting:, 3a. Tonotopic organization, 3b. Electrode length to cochlear duct length, 3c. Angular insertion depth, 3d. Perimodiolar vs. Lateral wall electrodes, 4. Indications for post-operative imaging, 5. Normal post-op imaging of cochlear implant insertion, 6. Intra-cochlear complications (case-based):, 6a. Underinsertion, 6b. Overinsertion, 6c. Tip foldover, 6d. CI scalar translocation into the scala vestibuli, 6e. Electrode basal buckling, 7. Extra-cochlear complications and malpositionings (case-based):, 7a. Middle ear, 7b. Vestibular placement, 7c. Cochlear aqueduct, 7d. Carotid canal, 7e. IAC and posterior fossa, 7f. Facial nerve contacts

HNEE-70 TI-RADS GUIDELINES; HOW USEFUL ARE THEY IN REAL-WORLD PRACTICE?

Betul Uzunoglu, MD (*Presenter*)
Tolga Orhan, MD (*Abstract Co-Author*)
Aysegul Gormez, MD (*Abstract Co-Author*)
O. Melih Topcuoglu, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the imaging criteria of the currently available TI-RADS guidelines using case examples.2. To discuss the advantages and disadvantages of each TI-RADS guideline in the detection of malignant thyroid nodules with regard to unnecessary biopsies. 3. To describe the algorithmic approach of each guideline to avoid unnecessary biopsies using representative cases. 4. To describe the algorithmic approach of each guideline to avoid missing malignant thyroid nodules in representative cases.

TABLE OF CONTENTS/OUTLINE

1. Overview of all currently available TI-RADS guidelines. 2. Details of sonographic evaluation in determining TI-RADS scores. 3. Highlighting the reasons for increased malignancy miss rates in each guideline 4. Highlighting the reasons for increased unnecessary biopsy rates 5. Algorithmic approach to the following questions: a. Which is better: not to miss any malignancy of any size, or not to cause additional health burden with unnecessary biopsies? b. Is it possible to use a combination of criteria from different guidelines in routine practice? c. Is it practical to define a term "suspicion of clinically insignificant thyroid malignancy" in thyroid imaging? 6. Conclusion

HNEE-71 UNMASKING PAROTID PATHOLOGIES: IMAGING INSIGHTS AND DIAGNOSTIC STRATEGIES

Ahmed E. Abdelmonem, MBBCh (*Presenter*)
Suryansh Bajaj, MD (*Abstract Co-Author*)

TEACHING POINTS

Pediatric parotid lesions represent a diverse group of pathologies with overlapping imaging features, often misattributed to adult populations. Systematic categorization by pathologic type—infectious/inflammatory, congenital/developmental, autoimmune, adenopathy, and neoplastic—improves diagnostic accuracy. Certain lesions demonstrate characteristic imaging findings: phleboliths in hemangiomas, fluid-fluid levels in venolymphatic malformations, and multifocal punctate sialectasis in juvenile recurrent parotitis. MR sialography and high-resolution ultrasound play a critical role in evaluating pediatric parotid pathology. Awareness of age-specific entities and their imaging appearance ensures timely diagnosis and appropriate clinical management.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of pediatric parotid anatomy and diagnostic challenges Epidemiologic considerations in pediatric vs. adult populations Imaging Techniques Role of ultrasound, MR sialography, and conventional sialography Pathologic Classification Inflammatory/Infectious Lesions Congenital/Developmental Lesions Autoimmune Disease (e.g., Sjögren’s syndrome) Lymphadenopathy and Reactive Nodes Mesenchymal Neoplasms (e.g., neurofibroma, rhabdomyosarcoma) Benign and Malignant

Parenchymal Neoplasms Imaging Pearls and Pitfalls Key distinguishing features of select lesions Mimics and overlapping appearances Summary Diagnostic approach and key take-home points

HNEE-72 UNLOCKING THE VOICE: A DYNAMIC CT PERSPECTIVE

Pradipta Debnath, MD (*Presenter*)
Aaron Friedman (*Abstract Co-Author*)
Anisha Noble (*Abstract Co-Author*)
Robert J. Fleck JR, MD (*Abstract Co-Author*)

TEACHING POINTS

Discuss need, benefits and limitations of dynamic voice CT (DVCT) in pre-surgical evaluation of voice pathologies Outline the implementation of DVCT technique and post-processing Review of common findings on DVCT

TABLE OF CONTENTS/OUTLINE

Background: Discuss the background of dysphonia and voice pathology Demonstrate the limitations of clinical evaluation with nasopharyngolaryngoscopy and how DVCT helps voice surgeons develop a plan for treatment Review of current literature on the use of DVCT to guide surgical treatment Using a case-based approach highlight benefits and limitations of DVCT in our patients and how to evaluate and interpret these images to provide the information the surgeon needs to plan treatment Summary: Take home points

HNEE-73 RADIOLOGIC FEATURES OF EAR DISEASES ON TEMPORAL BONE CT WITH CLINICAL CORRELATION

Yuka Takahashi (*Presenter*)
Fumiyo Higaki (*Abstract Co-Author*)
Akiko Sugaya (*Abstract Co-Author*)
Takahiro Kitayama, MD, PhD (*Abstract Co-Author*)
Yusuke Morimitsu (*Abstract Co-Author*)
Tomohiro Inoue (*Abstract Co-Author*)
Noriaki Akagi, RT (*Abstract Co-Author*)
Yudai Asano (*Abstract Co-Author*)
Katsuhide Kojima (*Abstract Co-Author*)
Yusuke Matsui, MD, PhD (*Abstract Co-Author*)
Takao Hiraki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The temporal bone contains complex anatomical structures that play critical roles in hearing and balance. Accurate interpretation of temporal bone CT is essential for diagnosing a wide range of otologic conditions. This educational exhibit aims to provide a comprehensive review of the anatomy of the temporal bone, followed by a systematic overview of common and important diseases including external auditory canal carcinoma, cholesteatomatous otitis media, otitis media with effusion, ossicular chain discontinuity, otosclerosis, middle and inner ear malformations, and schwannoma, among others. Through representative CT images, we illustrate the characteristic radiologic features of each condition and highlight key points for differentiation. In addition, clinical correlations are presented to emphasize the relevance of imaging findings to patient symptoms and management. This exhibit is intended to contribute to improved diagnostic accuracy in the evaluation of ear disorders.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Anatomy of the temporal bone 3. Classification of ear diseases 4. Detailed discussion of each disease - including a review of the imaging characteristics of each disease and its differential diagnoses. For cases that underwent surgery, imaging findings are compared with intraoperative observations. 5. Summary

HNEE-74 IMAGING OF TRIGEMINAL NEURALGIA AT 7T

Gabriel M. Swenson, MD (*Presenter*)
Nicholas A. Koontz, MD (*Abstract Co-Author*)
Alicia Chen, MD (*Abstract Co-Author*)
Ichiro Ikuta, MD, MMedSc (*Abstract Co-Author*)
Yuxiang Zhou, PHD (*Abstract Co-Author*)
Justin Cramer, MD (*Abstract Co-Author*)

TEACHING POINTS

7T MRI provides superior trigeminal nerve imaging to standard 1.5T or 3T due to higher spatial resolution and decreased noise. 7T trigeminal imaging is intracranial-only due to coil limitations, which regardless covers the most common imaging indications.

TABLE OF CONTENTS/OUTLINE

Trigeminal neuralgia most commonly results from neurovascular compression at the nerve root entry zone (REZ). 7 Tesla (7T) MRI shows promise for improved imaging of this entity due to decreased image noise, higher spatial resolution, and higher tissue contrast resolution. We describe our development of a 7T trigeminal protocol, with side-by-side examples with 3T to highlight the benefit. Traditional trigeminal nerve protocols image the nerve from its nuclei through the face. Only head and knee coils are FDA approved for 7T, and the face cannot be completely imaged due to image artifact. Increased susceptibility at 7T also impairs imaging within the skull base. We designed a 7T imaging protocol focusing on the REZ and cisternal segments. The protocol was developed on the 7T MRI from Siemens (Terra.X), utilizing a new parallel transmit head coil to reduce susceptibility, a conventional limitation of 7T imaging. Most essential is the small field of view T2 SPACE 3D, performed at half the slice thickness and the same in-plane resolution as 3T. By keeping the same resolution, image noise is greatly decreased. Whole brain sagittal 3D FLAIR and 2D DWI complete evaluation of the posterior fossa. We are currently trialing two different post-contrast T1 sequences: whole brain MPRAGE and SPACE.

HNEE-75 US-11: AN 11 POINT TECHNIQUE FOR ULTRASOUND OF THE PEDIATRIC NECK

Anu Kamalasanan, FRCR, MBBS (*Presenter*)
Manoj Mohan, FRCR, MBBS (*Abstract Co-Author*)
Ananth K. Shenoy, MRCP, FRCR (*Abstract Co-Author*)
Richard D. White, MBChB, FRCR (*Abstract Co-Author*)
Thiru A. Sudarshan, DMRD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1) Systematic imaging of the neck is ideal for exact localization of pathology and clinical communication.2) A detailed knowledge of sonographic landmarks is vital to avoid missing pathologies, as children may be uncooperative or unable to achieve the usual scanning position. Sternocleidomastoid muscle separates anterior and posterior triangles of the neck. Anterior bellies of digastric and omohyoid muscles, mylohyoid muscle, carotid bifurcation, hyoid and angle of the mandible are crucial landmarks. 3) Tonsils and peritonsillar abscess can be visualized in the submandibular plane. 4) Thyroglossal duct cyst indents the midline preepiglottic fat space extending cranially posterior to the hyoid. 5) Developmental branchial cleft abnormalities are along a line from pre auricular region to sternal notch. 6) Vocal cords can be assessed dynamically with ultrasound. 7) Suppurative nodal disease is common in children. Distinction between nodal tuberculosis, acute infection and malignancy is from clinical history, examination, lab findings and tissue microbiology/pathology. 8)Clinical syndromes can present with complex neck findings.

TABLE OF CONTENTS/OUTLINE

Imaging of the neck is complex due to the volume and variety of tissue contained in a small space. With this poster we aim to simplify neck imaging by introducing systematic neck ultrasound technique in 11 stations. We aim to demonstrate correlative surface anatomy and sonographic landmarks defining the 11 stations. Pictorial review of normal sonographic appearance with correlative clinical and cross sectional anatomy. Common pathology of the paediatric neck on Ultrasound with cross section correlation, where available, will be provided.

HNEE-76 'A TIGHT SQUEEZE': A PICTORIAL REVIEW OF THORACIC OUTLET SYNDROME

Pranit Sukumar (*Presenter*)
Janani Asogan Vaishnavi, MD, FRCR (*Abstract Co-Author*)
Janani Baradwaj, MD, FRCR (*Abstract Co-Author*)
Anu Kamalasanan, FRCR, MBBS (*Abstract Co-Author*)
Richard D. White, MBChB, FRCR (*Abstract Co-Author*)
Thiru A. Sudarshan, DMRD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Thoracic outlet syndrome refers to a group of clinical syndromes caused by congenital or acquired compression of the subclavian vessels and/or brachial plexus as they exit the superior thoracic aperture. The thoracic outlet can be divided into three compartments as the interscalene triangle, the costoclavicular space and the retropectoralis minor space. History taking and physical examination provide information regarding the structures affected. Imaging work up consists of radiograph of the cervical spine, dynamic doppler ultrasonography, dynamic CT angiography and MRI with postural manoeuvres (with arms in neutral position and in hyperabduction). Dynamic imaging is useful in assessing vascular compression. MRI allows visualisation of the brachial plexus and nervous compromise. Criteria used for neurological compression include, effacement of surrounding fat and/or contact with bony or fibrous structures. A range of imaging modalities can be utilised in the evaluation of thoracic outlet syndrome, however none of the investigations have 100% sensitivity and specificity.

TABLE OF CONTENTS/OUTLINE

1. Define thoracic outlet syndrome including various clinical presentations. 2. Radiological anatomy of the thoracic outlet, as defined by three compartments/tunnels. 3. Explain various causes of thoracic outlet syndrome. 4. Role of imaging in the evaluation of thoracic outlet syndrome including dynamic imaging with postural manoeuvres. 5. Provide a pictorial review of thoracic outlet syndrome of various aetiologies encountered in our centre.

Abstract Archives of the RSNA, 2025

INEE

Imaging Informatics Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

INEE-1 CARDIA: CLOUD-BASED AI-ENHANCED PLATFORM FOR COLLABORATIVE RADIOLOGY EDUCATION AND CASE ARCHIVING

A Ankush, MBBS, MD (*Presenter*)
Janardhana Ponnatapura, MD (*Abstract Co-Author*)

TEACHING POINTS

- Demonstrate the implementation of CARDIA (Cardiothoracic AI-enhanced Radiology Data & Imaging Archive): A secure, cloud-based platform for collaborative radiology education, leveraging Google Workspace (Sheets, Drive, Apps Script) for data storage, management, and visualization. - Highlight scholarly database grounded AI integration to enrich submitted case data with scholarly insights. - Promote a reproducible model for academic institutions to build their own teaching repositories.

TABLE OF CONTENTS/OUTLINE

I. Educational Gap in Radiology Training Lack of centralized, AI-enhanced teaching archives setup. II. System Overview CARDIA architecture and GCloud integration. Complete CRUD (Create, Read, Update, Delete) application for case archive management. Cloud-native, low-barrier tech stack. III. Case Submission Workflow User sign-in restricted to pre-authorized users via secure Google OAuth. Atomic updates via the GSheets API ensure real-time collaboration with conflict-free edits. Automatic unique GDrive folder for case-images. IV. AI-Powered Insights Integrated scholarly grounded search LLMs to enhance the depth and accuracy of educational content. V. Case Retrieval and Visualization Image previews within a filterable list, searchable by tags using logical operators (e.g., 'CT' AND 'MRI'). VI. Impact & Scalability Applications in residency/fellowship programs. Structured data collection for research. Facilitates multi-institutional collaboration for educational databases.

INEE-2 AUTONOMOUS AI AGENTS: RADIOLOGY'S NEXT FRONTIER

Parsa Rouzrokh (*Presenter*)
Pouria Rouzrokh, MD, MPH (*Abstract Co-Author*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Artificial intelligence is advancing from narrow, single-task models toward more autonomous AI agents that can reason, use tools, and adapt independently. In diagnostic radiology, such agents promise to manage complex, multi-faceted cases that overwhelm traditional AI models. This presentation introduces autonomous AI agents as a natural next step in AI's evolution and shows how multiple agents working together—a multi-agent system—can collaboratively address intricate workflow challenges. We will examine why these agents are needed, how they can be built, and what benefits they offer in real-world radiology scenarios. Aimed at expanding general radiologists' knowledge of agentic systems, the session equips attendees with core concepts and practical examples of these AI assistants, laying the groundwork for assessing their potential roles in routine practice.

TABLE OF CONTENTS/OUTLINE

1- Problem Statement: Why Agents?: Sets the stage by outlining rising imaging complexity and the need for smarter AI assistance; 2- Autonomous AI Agents Defines an agent, and highlights key components; 3- Building an Agent Outlines the basic steps to combine the raw components into a functioning assistant, illustrated with no-code examples. 4- Agent vs Model A brief comparison of these approaches focused on common radiology tasks. 5- Multi-Agent Systems: Describes coordinated teams of agents sharing roles and context on the same case. 6- Agentic AI in Radiology Workflows Explores the potential applications of single- and multi-agent systems throughout the radiology workflows. 7- Limitations & Safety Examines the principal constraints, risks, and oversight requirements when deploying agentic AI in radiology.

INEE-3 AI AGENTS IN RADIOLOGY: THE NEXT EVOLUTION IN INTELLIGENT WORKFLOWS

Bardia Khosravi, MD, MPH (*Presenter*)
Pouria Rouzrokh, MD, MPH (*Abstract Co-Author*)
Shahriar Faghani, MD (*Abstract Co-Author*)
Mana Moassefi, MD, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Differentiate between basic LLMs (chatbots), augmented LLMs, and full AI agents to understand their distinct capabilities and applications 2. Identify how AI agents can address specific radiology workflow pain points through automation, flexible processing, and integration with existing systems 3. Evaluate the challenges and limitations of AI agent implementation in clinical radiology practice, including security considerations and appropriate levels of autonomy

TABLE OF CONTENTS/OUTLINE

1. Understanding the AI Agent Spectrum in Radiology a) From chatbots to autonomous agents: key differences and capabilities b) How agents differ from traditional radiology AI algorithms c) The evolution of intelligence: basic LLMs ? augmented LLMs ? agents ? multi-agent systems 2. AI Agent Architecture and Implementation a) Core components of AI agents: planning, execution, feedback loops, and memory b) Tool use in radiology context: connecting to PACS, RIS, EHR and clinical databases c) Multi-agent workflows: hierarchical, collaborative, and sequential arrangements 3. Clinical Applications of AI Agents in Radiology a) Workflow optimization: triage, prioritization, and resource allocation b) Image analysis: coordinating specialized AI models and standardizing outputs c) Report generation: contextualizing findings with clinical data d) Quality improvement: monitoring protocol adherence and outcomes 4. Challenges and Considerationsa) Security, privacy, and HIPAA compliance in agent implementations b) Determining appropriate levels of agent autonomy in clinical settings c) Regulatory considerations and documentation requirements 5. Future Directions and Conclusion

INEE-4 DIGITAL TWINS IN NEURO-ONCOLOGY: CURRENT LANDSCAPE AND FUTURE DIRECTIONS

Angelica Kurtz, BA (*Presenter*)
Moinak Bhattacharya (*Abstract Co-Author*)
Gagandeep Singh, MD, MBA (*Abstract Co-Author*)
Annie Singh (*Abstract Co-Author*)
Prateek Prasanna, PhD (*Abstract Co-Author*)
Angela Lignelli-Dipple, MD (*Abstract Co-Author*)

TEACHING POINTS

Define digital twins and their applications in medicine Describe the data required to create an effective digital twin model Discuss previous work in digital twins in neurology and neuroradiology Identify the gaps in digital twin research in neuro-oncology Explain future radiologic uses in neuro-oncology

TABLE OF CONTENTS/OUTLINE

1. Defining digital twins Digital twins are virtual replicas of physical systems that can be updated with real-time characteristics of the physical system. The virtual digital twin can then be used to predict responses of the physical system to certain events or stimuli. Digital twins were originally used as replicas of industrial and mechanical systems for improving performance, predicting maintenance requirements, etc. 2. Digital twins in medicine Similar to their applications in industry, digital twins in medicine are virtual models calibrated to an individual patient and updated with new patient data over time, with the goal of predicting a patient's individual treatment response before treatment is even administered 3. Required data Mechanistic modeling versus machine learning/AI In oncology, required data includes characteristics of the tumor itself and its surrounding environment 4. Existing research 5. Digital twins in neuro-oncology There is a distinct paucity of research in neuro-oncology Our lab created a model that was able to successfully predict lung cancer treatment response. While this model itself is not a digital twin, we hope to use it as the basis for a digital twin model for brain tumor treatment response The future of digital twins in neuro-oncology includes predicting patient response to chemotherapy regimens, radiation, and surgical resection

INEE-5 TALK TECH TO ME: AI IN RADIOLOGY FOR THE UNINITIATED

Trupti Devaraja, MBBS, MD (*Presenter*)
Harshithaa Varatharajan (*Abstract Co-Author*)
Sujith R. Swamy, MBBS (*Abstract Co-Author*)
Shreelatha Aladangady (*Abstract Co-Author*)
Malathi S. Bhat, MBBS (*Abstract Co-Author*)

TEACHING POINTS

With the rapid integration of artificial intelligence (AI) into radiology, a significant gap has emerged between the technological sophistication of AI tools and the practical understanding required for their effective use in clinical practice. This educational exhibit aims to bridge that gap by demystifying key principles of AI, machine learning (ML), and deep learning (DL), highlighting their real-world applications in radiology, and fostering a deeper understanding of their strengths, limitations, and collaborative potential.

TABLE OF CONTENTS/OUTLINE

The Case for AI in Radiology: Establishing the clinical and operational need for artificial intelligence today. Foundations of Artificial Intelligence: Clarifying core concepts and terminology in a radiologist-friendly manner. Current Applications of AI in Radiology: Highlighting real-world use across diagnosis, segmentation, radiomics, and workflow enhancement. Limitations and Ethical Considerations: Addressing the challenges, risks, and responsibilities of AI integration in clinical practice. Radiologist-AI Collaboration: Emphasizing complementary strengths and the importance of human oversight. Future Directions in AI for Radiology: Exploring emerging innovations, ongoing research, and the evolving role of AI in imaging.

INEE-6 ZERO-SHOT ENTITY RECOGNITION EXPLAINED: A GUIDE TO BERT-BASED NLP FOR RADIOLOGY REPORTS

Mladen Zecevic (*Presenter*)
Shannon Morrissey (*Abstract Co-Author*)
Andrew March (*Abstract Co-Author*)
Janet M. Busey, MS (*Abstract Co-Author*)

TEACHING POINTS

Named Entity Recognition (NER) is a technique that automatically finds and categorizes key terms (like anatomy, diagnoses, or treatments) in a text. Tokenization breaks text into smaller units (tokens), typically dictionary-based words or subwords. Computers understand numbers, not words, so word embeddings convert each token into a list of numbers that captures its meaning or context. BERT functions like a "reader" that comprehends context holistically, while GPT operates as a "writer" that builds content sequentially based on previous tokens. Model pretraining builds a strong language foundation, fine-tuning sharpens the model for the specific task of radiology NER, and zero-shot learning allows it to recognize new entity types without additional training. GLiNER is a model that can identify new types of entities in radiology reports without prior training, turning free text into structured, labeled data.

TABLE OF CONTENTS/OUTLINE

Introduction Tokenizer: Breaking Text into Smaller Pieces Word Embeddings: Turning Tokens into Numbers Transformers: The Engines Behind Modern NLP Transformers: BERT vs. GPT BERT: Training vs. Fine-Tuning vs. Zero-Shot GLiNER: BERT Goes Zero-Shot for NER

INEE-7 BEYOND THE NOISE: AICE'S ROLE IN RESCUING LOW-DOSE CT - A PIXEL-BY-PIXEL JOURNEY: CASE SHOWDOWN: CONVENTIONAL VS. AICE-RECONSTRUCTED IMAGES IN CHALLENGING SCENARIOS

CE WANG (*Presenter*)
Tongyin Zhang (*Abstract Co-Author*)

TEACHING POINTS

AiCE Fundamentals : Uses deep CNNs trained on high/low-dose CT pairs to suppress noise while preserving anatomy. IR Limitations : Over-smoothing, residual noise, loss of low-contrast details. AiCE Superiority : Addresses photon starvation, metal artifacts, detects subtle lesions (subcentimeter nodules, tumor invasion, IBD activity). Validation : Confirmed via NPS, MTF (>0.8 at 0.5 cycles/mm), SSIM (>0.92). Dose Optimization : =50% dose reduction in neurology, abdomen, thorax.

TABLE OF CONTENTS/OUTLINE

1.Low-Dose CT Challenges & AiCE Innovations 2. AiCE vs. IR: Clinical Performance Obesity : 60% noise reduction improves hepatic metastasis margins. Metal Artifacts : Streak suppression clarifies pancreatic tumor vascular invasion. Low-Contrast Lesions : 45% noise reduction in brain CT enhances stroke diagnosis; 50% CNR boost in CTE clarifies IBD inflammation. Thoracic Imaging : 35% higher MTF sharpens ground-glass nodules and fibrosis. 3. Validation & Clinical Implementation Metrics : 50-70% noise reduction (NPS), MTF >0.8 (pancreatic imaging), SSIM >0.92. Radiologist Preference : 90% endorse AiCE for IBD activity and lung nodules. Protocols : 40-50% dose reduction in stroke, pancreatic cancer, and CTE imaging. Future : Liver metastasis tracking, trauma protocols, pediatric applications (Crohn's, cystic fibrosis). 4. Future Directions Oncology : Track liver metastasis response. Trauma : Low-dose polytrauma protocols. IBD : Optimize mucosal healing assessment. Pediatrics : Dose-sensitive protocols for frequent imaging. 5. Conclusion AiCE redefines LDCT by balancing dose reduction and diagnostic precision. Adopt AI-driven reconstruction for safer, high-quality imaging in complex cases.

INEE-8 CREATING CUSTOM APPLICATIONS BASED ON 3D SLICER

Beatriz Paniagua, PhD (*Presenter*)
Jean-Christophe Fillion-Robin, MSc (*Abstract Co-Author*)
Samantha Horvath (*Abstract Co-Author*)

TEACHING POINTS

3D Slicer is a widely used open-source software platform for visualization and analysis of medical images. Known for its flexibility, Slicer supports over 200 community-developed extensions enabling advanced workflows for biomedical research, including DICOM handling, AI-based analysis, and segmentation. However, its broad capabilities can pose a steep learning curve for new users or teams with focused goals. To address this, Kitware developed the SlicerCustomAppTemplate—a lightweight framework that wraps the core of 3D Slicer. This template allows developers to build custom applications with streamlined interfaces and targeted features, incorporating specific branding, specialized modules, and tailored workflows suited for particular research or clinical domains. This educational exhibit introduces Slicer's modular architecture, demonstrates how the SlicerCustomAppTemplate supports efficient custom app development, and includes a hands-on session where attendees will build their own simplified Slicer-based tool. This approach empowers research groups, startups, and organizations to create and share customized Slicer versions, optimized for specific use cases without the burden of unrelated features. By the end of the session, participants will: Understand Slicer's modular design Learn how to start with the SlicerCustomAppTemplate Use custom apps to streamline research workflows Help translate research into minimum viable products

TABLE OF CONTENTS/OUTLINE

Introduction to 3D Slicer Modular Architecture Deep Dive SlicerCustomAppTemplate Overview Custom Application Development Workflow SlicerCustomAppTemplate case study: SlicerSALT Hands-On Exercise

INEE-9 LET THE ALGORITHM DRAW: UNDERSTANDING GANS, DIFFUSION, AND GPT IN RADIOLOGY

Yaara Artsi (*Presenter*)
Eyal Klang, MD (*Abstract Co-Author*)
Eli Konen, MD, MD (*Abstract Co-Author*)
Vera Sorin, MD (*Abstract Co-Author*)

TEACHING POINTS

Teaching Points: • Understand how generative models—GANs, Stable Diffusion, and GPT-powered systems—operate in radiologic imaging. • Identify practical uses: rare-pathology simulation, data augmentation, segmentation aid, and privacy-preserving synthetic look-alikes. • Recognize fidelity metrics, regulatory limits, and ethical pitfalls of synthetic images.

TABLE OF CONTENTS/OUTLINE

Outline: I. Introduction: Why Let the Algorithm Draw? • Visual challenge: Real vs. AI-generated image • Timeline of generative AI in radiology (GAN ? Stable Diffusion ? GPT) II. GANs - Adversarial learning and image realism III. Stable Diffusion - Denoising in compressed feature space IV. GPT-Based Systems - Prompt-to-image generation with clinical language V. Applications in Radiology Practice • Rare pathology simulation and case diversification • Few-shot segmentation and data augmentation • Anonymized synthetic look-alikes for privacy VI. Considerations for Use • Fidelity metrics (FID, SSIM, Turing tests) • Regulatory landscape and FDA guidance • Limitations, risks, and bias mitigation VII. Future Directions and Clinical Integration • Prompt-to-PACS workflows • Open-source tools and education • Responsible adoption and ethical AI use in imaging

INEE-10 EVALUATING THE RETURN ON INVESTMENT FOR AI ALGORITHMS IN THE RADIOLOGY PRACTICE: THE IMPORTANCE OF ESTABLISHING KEY PERFORMANCE INDICATORS

Michele A. Powell, RT, ARRT (*Presenter*)
Holly Meyer, RT, MS (*Abstract Co-Author*)
Cole Cook (*Abstract Co-Author*)
Emily Sheedy, BS, MBA (*Abstract Co-Author*)
Amanda Mensing (*Abstract Co-Author*)
Matthew Edwards (*Abstract Co-Author*)
Gian Marco Conte, MD, PhD (*Abstract Co-Author*)
Daniel J. Blezek, PhD (*Abstract Co-Author*)
Andrew Missert, PhD (*Abstract Co-Author*)
Jeremy D. Collins, MD (*Abstract Co-Author*)
Panagiotis Korfiatis, PhD (*Abstract Co-Author*)
Timothy L. Kline, PhD (*Abstract Co-Author*)
Eric E. Williamson, MD (*Abstract Co-Author*)

TEACHING POINTS

-Process and methods for assessing the Return on Investment (ROI) for AI Algorithms -Key metrics to establish value of product -Advantages and lessons learned associated with gathering Objective and Key Results (OKRs) and Key Performance Indicators (KPIs)

TABLE OF CONTENTS/OUTLINE

Purpose: 1. Describe a framework that assists in determining the overall value of internally developed Artificial Intelligence (AI) algorithms integrated into a radiology practice. 2. Propose how this framework can provide insights into the value proposition for developing algorithms internally vs. purchasing commercial products. Process -Algorithm ROI Evaluation Process -Algorithm Readiness Evaluation -Post-Production Monitoring -Annual Reviews -Gathering OKRs ROI -Clinical Improvements -Patient Care Outcomes -Finance -Academic and Data Contributions KPI Metrics -Operational Efficiency -Algorithm Performance -Revenue and Growth Lessons Learned -Algorithm ROI Evaluation Process Planning -Stakeholder Engagement -Change Management -Ongoing Evaluation Conclusion Evaluating the ROI of AI algorithms in radiology involves implementing structured processes and methods. Key metrics gathered at multiple points throughout the process allow for insights and advantages of these products. This comprehensive approach will enable radiology practices to make more informed decisions, optimize clinical workflows, and better serve the needs of the patient.

INEE-12 REINVENTING LAXATIVE-FREE CT COLONOGRAPHY: GENERATIVE AI MEETS PHOTON-COUNTING CT

Hiroyuki Yoshida, PhD (*Presenter*)
Janne J. Nappi, PhD (*Abstract Co-Author*)
Rie Tachibana, PhD (*Abstract Co-Author*)
Toru Hironaka (*Abstract Co-Author*)
Dufan Wu, PhD (*Abstract Co-Author*)
Rajiv Gupta, PhD, MD (*Abstract Co-Author*)
Katsuyuki Taguchi, PhD (*Abstract Co-Author*)
Masaki Okamoto, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

(1) Explain the emerging role of laxative-free CT colonography in colorectal cancer (CRC) screening. (2) Explain the role of photon-counting CT in addressing the challenges of laxative-free CT colonography. (3) Explain the role of generative artificial intelligence (Gen AI) in unlocking the potential of laxative-free photon-counting CT colonography as a CRC screening test.

TABLE OF CONTENTS/OUTLINE

1. Introduction: the importance of CRC screening; the emerging role of laxative-free CT colonography. 2. Photon-counting CT: how it addresses the remaining challenges of the laxative-free CT colonography technique. 3. Gen AI: enables an effective computer-assisted laxative-free photon-counting CT colonography examination: virtual bowel cleansing; automated detection of polyps; risk assessment; putting it all together. 4. What we know and don't know: outcomes from clinical laxative-free CT colonography trials; photon-counting CT colonography: preliminary results.

INEE-13 GENERATIVE ADVERSARIAL NETWORKS IN RADIOLOGY: FROM NEURAL DUELS TO CLINICAL TOOLS

Pranav Ajmera, MD (*Presenter*)
Parv Mehta (*Abstract Co-Author*)
Ashish R. Khandelwal, MD (*Abstract Co-Author*)

TEACHING POINTS

• Radiologists must grasp the fundamentals of Generative Adversarial Networks (GANs) to critically engage with emerging AI tools in imaging. • GANs are enabling a new era of radiologic innovation—from generating synthetic data to reconstructing low-dose images with near-diagnostic fidelity. • Beyond technical novelty, GANs are solving real-world clinical problems, such as limited data availability and modality-specific imaging gaps. • Understanding GAN pitfalls (e.g., hallucinations, mode collapse) and metrics (FID, SSIM, Dice) ensures meaningful interpretation of AI results. • Ethical literacy is essential as GANs evolve—radiologists must advocate for transparency, fairness, and validation in generative AI deployment. • Educating trainees in GAN concepts equips them to practice in an AI-integrated clinical future.

TABLE OF CONTENTS/OUTLINE

1. GAN Fundamentals for Radiologists Generator-discriminator dynamics GANs vs. traditional AI models 2. Architectural Landscape DC-GAN, CycleGAN, SR-GAN, Conditional GAN, WGAN Task-specific models and their imaging relevance 3. Performance Evaluation Demystified Key metrics: FID, IS, SSIM, PSNR, Dice Score Limitations of current benchmarks 4. Clinical Integration Across Subspecialties Synthetic data generation and augmentation Image reconstruction and low-dose enhancement Modality conversion (e.g., MR-to-CT, PET-to-MR) Tumor segmentation and abnormality detection Disease progression simulation 5. Ethical & Practical Considerations Hallucinations, data consent, algorithmic bias Importance of transparent and validated deployment 6. Conclusion: The Future Radiologist's Toolkit Why familiarity with GANs is now essential

INEE-14 REVIVING GI-FLUOROSCOPY: AI-DRIVEN ARCHIVE

Mei Carter (*Presenter*)
Ethan Vyhmeister (*Abstract Co-Author*)
Amanda Aguilera, MD (*Abstract Co-Author*)

TEACHING POINTS

GI fluoroscopy, once a cornerstone of radiology training, has declined with the rise of cross-sectional imaging and retirement of experienced radiologists, yet remains essential for evaluating diverse GI pathology. To address the educational gap, we developed an AI-powered, web-based teaching tool that curates and annotates over 1,000 legacy GI fluoroscopy cases, many paired with CT, and supplements them with Radiopaedia images. The platform bridges residents' CT knowledge to fluoroscopic findings via a searchable case archive, Socratic-style AI feedback, and GPT-4 tutoring. It uses microlearning, active recall, and real-time case interaction. Users search by symptom or diagnosis, compare modalities, and engage with structured prompts. A tiered curriculum enables skill progression, while a faculty validation dashboard ensures quality, accuracy, and iterative AI refinement. This is a modern, scalable solution that revitalizes GI fluoro education.

TABLE OF CONTENTS/OUTLINE

Introduction: GI fluoro is essential but underrepresented. Educational Tool: AI-powered platform with 1,000+ legacy cases and Radiopaedia. Learning Bridge: CT-fluoro pairing supports interpretation. Design: Microlearning, recall, AI Socratic feedback. Curriculum: Tiered by difficulty; faculty oversight. Impact: Builds diagnostic confidence and bridges training gaps.

INEE-15 REALITY CHECK: FDA-APPROVED AI PRODUCTS IN MSK IMAGING AND WHAT THEY REALLY DELIVER

Pranav Ajmera, MD (*Presenter*)
Girish Gandikota, MD (*Abstract Co-Author*)
Rajesh Botchu, MBBS (*Abstract Co-Author*)

TEACHING POINTS

• FDA-approved AI tools are emerging across musculoskeletal (MSK) imaging, supporting tasks like fracture detection, bone age estimation, and joint disease classification. • Radiologists must understand the scope and regulatory status of these tools to evaluate their relevance and limitations. • These solutions enhance diagnostic consistency, speed, and workflow efficiency—particularly in trauma and pediatric settings. • Awareness of FDA pathways, intended use claims, and validation gaps is essential for responsible adoption. • Ethical use requires oversight of algorithm bias, generalizability, and data transparency.

TABLE OF CONTENTS/OUTLINE

Introduction Rationale for evaluating FDA-approved AI in MSK imaging Impact on clinical workflow, diagnosis, and standardization Understanding FDA Clearance 510(k) vs. De Novo vs. PMA pathways AI-specific regulatory developments Categorization of FDA-Cleared AI Tools in MSK Radiology Fracture detection (e.g., wrist, hip, spine, ribs) Bone age estimation (pediatric growth assessment) Joint assessment (e.g., knee OA grading) Post-op assessment (implant positioning, fusion analysis) Technical Overview of Common Algorithms Deep learning models (CNNs, object detection frameworks) Device integration (PACS plug-ins, cloud-based systems) Clinical Use Cases and Limitations Case examples of impact in trauma and emergency imaging Barriers: validation gaps, interpretability, legal liability Ethical and Operational Considerations Algorithm bias, data privacy, the role of radiologists in oversight Conclusion and Future Directions Responsible adoption, regulatory vigilance, collaborative validation

INEE-16 MODELING UNCERTAINTY IN AI-DRIVEN RADIOLOGY REPORT ANALYSIS VIA A DUAL SCORING FRAMEWORK

William W. Boonn, MD (*Presenter*)
Akash R. Pattnaik (*Abstract Co-Author*)
Kalina Slavkova (*Abstract Co-Author*)
Jean-Benoit Delbrouck (*Abstract Co-Author*)
John M. Paulett, MS (*Abstract Co-Author*)
Woojin Kim, MD (*Abstract Co-Author*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)
Khan M. Siddiqui, MD (*Abstract Co-Author*)
Adam E. Flanders, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the difference between source-level (radiologist) and model-level (LLM) uncertainty in radiology report interpretation. Learn how the Radiologist Confidence Score (RCS) and Language Model Confidence Score (LMCS) separately quantify and categorize these uncertainties. Explore how categorizing uncertainty by source improves explainability, triage, calibration, and QA workflows. Review practical applications of dual confidence scoring for more interpretable AI systems in radiology. Discover how fine-grained subcategories like contradiction or diagnostic specificity support richer insight and downstream decision-making.

TABLE OF CONTENTS/OUTLINE

Introduction Role of uncertainty in radiology language and AI interpretation RCS and LMCS Overview Independent scoring of report clarity and model certainty Uncertainty Categories Taxonomy of RCS (image quality, diagnostic specificity) and LMCS (contradiction, ambiguity, etc.) Applications QA, explainability, model calibration, and radiologist feedback Integration with Existing Frameworks Alignment with existing report analysis frameworks, potential for structured error analysis Conclusion The RCS /LMCS framework offers a practical and conceptually grounded approach to uncertainty modeling in radiology AI. By distinguishing between radiologist- and model-driven uncertainty, it enables systems that not only extract findings but also communicate when and why they may be uncertain. This supports more explainable, auditable, and trustworthy report analysis in AI workflows.

INEE-17 CTRL + ALT + SECURE: CYBERSECURITY IN RADIOLOGY

Vidya Sankar Viswanathan, MBBS (*Presenter*)
Joshua Volin, MD (*Abstract Co-Author*)
Peter A. Harri, MD (*Abstract Co-Author*)
Nabile M. Safdar, MD, MPH (*Abstract Co-Author*)
Elias Kikano, MD (*Abstract Co-Author*)

TEACHING POINTS

Cyberattacks in radiology can delay diagnoses, disrupt procedures, and impact clinical care, making cybersecurity essential to patient safety. Radiologists play a hands-on role in securing their clinical ecosystem, from reporting threats to shaping AI tool usage, not just IT. Actions like avoiding credential sharing, recognizing phishing attempts, and securing workstations prevent major breaches. A culture of shared responsibility, strong leadership, and routine cybersecurity education empowers all levels to respond effectively The rise of AI in radiology introduces unique cybersecurity risks- vetting tools, safeguarding data, and ensuring ethical use now require active oversight.

TABLE OF CONTENTS/OUTLINE

Growing Cyberattack Landscape in Radiology Overview of rising healthcare cyberattacks Anatomy of a real-world ransomware attack Why Radiology is Especially Vulnerable High-value PHI, fully digital workflows (PACS, RIS, EHR, Cloud) 24/7 operational requirements with little downtime Patient Care at Risk Delayed diagnoses, canceled procedures, disrupted care Financial consequences for systems, practices, and patients Governance in Action Key national, state, and institutional policies Governance structure in academic vs private practice Practices to Prevent Breaches Multi-factor authentication, encrypted storage, secure image sharing Credential sharing, phishing scams, and workstation security Handling anonymized data and HIPAA gray zones in research Cyberproofing the AI Workflow Security risks of AI integration AI tool deployment governance Radiologists' role in secure, ethical AI adoption

INEE-18 RETHINKING DIFFUSION FOR MEDICAL IMAGING

Yuki Ikuno (*Presenter*)
Atsushi Teramoto, PhD (*Abstract Co-Author*)
Hiroshi Fujita, PhD (*Abstract Co-Author*)

TEACHING POINTS

Recent diffusion models have advanced medical imaging, aiding diagnosis and privacy. Yet, their complexity and large parameter counts present major challenges for efficient use and accessibility: Enormous computational resource requirements Training on large-scale medical images (e.g., MRI, CT) requires substantial computing power, time, and energy. Constraints on individual research activities High hardware requirements restrict clinicians and domain experts from conducting independent, field-driven research. Model expansion and increased training difficulty High-resolution or conditional generation tasks demand larger models, leading to unstable and repeated training cycles. Data scarcity and task dependence Tasks like rare disease analysis or report-based synthesis need well-annotated paired data, which is hard to collect. We believe these issues pose significant barriers for researchers in medical imaging. To address them, we introduce two diffusion-based approaches. Latent Diffusion Model (LDM) A resource-efficient approach that performs the diffusion process in a learned latent space rather than in pixel space, reducing computational costs and enabling individual research. Retrieval-Augmented Diffusion Model (RDM): A semi-parametric design that retrieves semantically similar examples from external databases to enhance generalization, adaptability, and control without additional training.

TABLE OF CONTENTS/OUTLINE

1. Current Challenges in Diffusion-Based Generative Models. 2. Cost-Efficient Training with the Latent Diffusion Model (LDM). 3. Zero-Shot Generative Modeling via the Retrieval-Augmented Diffusion Model (RDM)

INEE-19 TRANSFORMING PATIENT CARE: RADIOLOGIST-DRIVEN CONSULTATIONS WITH OPPORTUNISTIC CT SCREENING

Karthika Devi D S, MBBS (*Presenter*)
Adnan Ahmad (*Abstract Co-Author*)
Samriddhi Sivakumar (*Abstract Co-Author*)
Domenico Mastrodicasa, MD (*Abstract Co-Author*)
Sarabjeet Singh, MD, MBA (*Abstract Co-Author*)
Dania Daye, MD,PhD (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)
Dushyant Sahani, MD (*Abstract Co-Author*)

TEACHING POINTS

? In modern health care, opportunistic CT screening offers a unique approach for radiologists to enhance patient care by extracting and analyzing CT data. ? This educational exhibit explores the potential of collaborative consultations driven by radiologists, using CT scans to predict health risks, including chronic conditions. ? This exhibit aims to provide a perspective on adopting innovative strategies that can improve patient care and drive the future of healthcare.

TABLE OF CONTENTS/OUTLINE

1. Value of CT data extraction - targeted investigation and management: ? The value of opportunistic screening - Routine imaging is used to identify incidental findings that may have significant health implications. ? Describe body composition analysis tools currently available. 2. AI-enabled patient data extraction: ? Post-scanning AI: Data extraction & quantification (body composition analysis, organ volumetry, other biomarkers) to assess disease severity and overall risk assessment. ? Integrated diagnostic capabilities (Imaging + EHR+ lab + genomics) - Novel combined diagnostic tools with superior analytics for disease and outcome prediction. 3. Radiologist-driven patient consultation: ? AI-enabled predictive capability of these integrated data enables radiologists for collaborative patient consultation - drives shared decision-making, increases radiologist's visibility & impact of radiology in patient management. ? These consultations can guide lifestyle modifications, facilitate early detection of diseases, and prompt timely interventions, ultimately improving health outcomes and reducing health care costs.

INEE-20 DIFFUSION WITHOUT INFUSION: A REVIEW OF DIFFUSION MODELS FOR SYNTHETIC CONTRAST-ENHANCED IMAGING

Neel Mistry, MD (*Presenter*)
Pouya Shiri (*Abstract Co-Author*)
Xin Yi, PhD (*Abstract Co-Author*)
Scott J. Adams, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Describe generative artificial intelligence (AI) methods for synthetic contrast-enhanced imaging to reduce reliance on iodinated and gadolinium-based contrast agents for CT and MRI 2. Describe the principles of diffusion models and their relevance to medical image synthesis 3. Compare diffusion models with other architectures for

synthetic contrast-enhanced image generation 4. Identify challenges and limitations related to synthetic contrast-enhanced imaging 5.Discuss future directions to enable deployment of synthetic contrast-enhanced imaging in clinical practice.

TABLE OF CONTENTS/OUTLINE

Clinical Motivation Risks and drawbacks of iodinated and gadolinium-based contrast agents and unmet clinical needs Overview Generative artificial intelligence (AI) methods for synthetic contrast-enhanced imaging, with a focus on diffusion models Diffusion Models: Key models including DDPM, DDIM, Latent Diffusion, Consistency, and Bridge Diffusion Example Diffusion Model : SC-BBDM as a structure preserving model Comparison of Methods: compare diffusion models to other generative AI methods for synthetic contrast-enhanced image generation Evaluation Methods Quantitative metrics (e.g., PSNR, FID, SSIM), segmentation overlap, and clinical review Limitations anatomical inconsistency, memory constraints, and diagnostic uncertainty Future Directions few-shot learning, biomarker generation, and clinical task alignment Conclusion Summary of current progress and paths to clinical deployment.

INEE-21 REGULATION AND ETHICS IN ENSEMBLE AI: BALANCING INNOVATION AND RESPONSIBILITY

Sarang Ingole, MBBS (*Presenter*)
Easwar Lakshmi Narayanan, MD (*Abstract Co-Author*)
Amit Kumar (*Abstract Co-Author*)
Vidur Mahajan, MBA, MBBS (*Abstract Co-Author*)
Devanshi Thakkar (*Abstract Co-Author*)

TEACHING POINTS

• Ensemble AI integrates multiple model outputs to improve diagnostic accuracy but raises unique regulatory and ethical challenges. • Regulatory frameworks (FDA SaMD, PCCPs, EU AI Act) are evolving to address lifecycle oversight, adaptivity, and ensemble risks. • Ethical concerns include bias amplification, compounded opacity, and unclear accountability for errors. • Best practices include ensemble-specific validation, explainability tools (SHAP, LIME), human-in-the-loop oversight, and real-world monitoring. • Radiologists need skills to assess ensemble AI limitations and ensure responsible, fair deployment.

TABLE OF CONTENTS/OUTLINE

Introduction to Ensemble AI Definition, rationale, and types Clinical value in enhancing robustness Global Regulatory Landscape FDA: SaMD guidance, GMLP, PCCPs EU: AI Act classification, MDR integration Ethical Considerations Unique to Ensembles Algorithmic bias propagation across component models Compounded opacity and explainability challenges Responsibility in distributed model decisions Data governance and consent across diverse training sets Best Practices for Deployment Ensemble-specific validation, model interaction tracking Transparency via SHAP, LIME applied to ensemble outputs Defined clinician oversight roles and update governance Case Study Chest radiograph ensemble AI deployment Real-world performance, limitations, and future outlook Conclusion and Future Directions Need for interdisciplinary oversight and evolving standards Radiologist's expanding role in ethical AI adoption and governance

INEE-22 ONTOLOGIES FOR IMPROVING AI MODEL AND DATASET DISCOVERABILITY

Abhinav Suri, BA, MPH (*Presenter*)
Charles E. Kahn JR, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to give viewers an introduction to the world of ontologies and how they can be used to encode information. We will discuss ontologies further in the context of artificial intelligence (AI). Specifically, we aim to show how AI models, datasets, and projects can be described using ontologies and how doing so promotes Findable, Accessible, Interoperable, and Reusable (FAIR) principles (which viewers will also be introduced to). We will also cover the basics of current attempts in AI research to satisfy FAIR principles by discussing "model cards", but also highlight how they come up short when describing medical projects. Lastly, we will touch on existing initiatives in the medical AI research field to encode metadata about projects. Specifically, we will focus on three attempts to do so: the Radiology Ontology for AI Datasets, Models, and Projects (ROADMAP), the Coalition for Health AI (CHAI) Model Card, and the FDA Model Card. We will highlight the use cases, benefits, and shortcomings of each.

TABLE OF CONTENTS/OUTLINE

1. Introduction to basics of AI and terminologies (specifically what are models, datasets, and projects); 2. Introduction to the definition of an ontology; 3. Creation of a toy ontology to introduce the idea of relationships within intologies; 4. Brief overview of extant ontologies in medicine such as RadLex; 5. Introduction to FAIR principles; 6. Introduction to model cards and shortcomings in medical AI work; 7. Overview of ROADMAP ontology, CHAI model card, and FDA model cards; 8. Comparisons of use cases for all medical AI model cards

INEE-23 ARTIFICIAL INTELLIGENCE LITERACY: WHAT DOES THE RADIOLOGIST SHOULD KNOW?

Maxime Bouthillier, MD (*Presenter*)
An Ni Wu, MD (*Abstract Co-Author*)
Jan Valosek (*Abstract Co-Author*)
Julien Cohen-Adad (*Abstract Co-Author*)
Laurent Letourneau-Guillon, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

Artificial intelligence (AI) is increasingly integrated into routine radiology practice and will likely expand further. However, for radiologists without a technical background, the terminology used by AI developers and manufacturers can be challenging to interpret. A clear understanding of common AI-related semantics helps radiologists grasp the scope of AI tools or research and think critically about their quality and relevance. As the field rapidly evolves, fundamentals from model development to clinical deployment remain key to evaluating tool quality. While in-depth knowledge of model architecture may not be essential, familiarity with standard data science performance metrics, sometimes named differently than in medical sciences, is crucial. AI models, whether from deep or machine learning, are often challenging to interpret: visual tools have thus been developed to reveal which features influence model predictions. The same applies to assessing internal and external validity. While some AI advances are now routinely used, imaging analysis remains the central challenge where federated learning may offer a promising solution to privacy and data-sharing limitations. This exhibit summarizes key concepts every radiologist should know to support the safe, responsible and effective integration of AI in clinical workflows.

TABLE OF CONTENTS/OUTLINE

Effective Integration of Artificial Intelligence: Must-Know Concepts for Radiologists. From Development to Deployment: AI Task-Specific Considerations. Relevant Performance Metrics for AI-based Model Evaluation. Common Visualization Tools for AI-based Model Results. AI in Radiology: 2025 Challenges & Opportunities — Where Are We Headed?

INEE-24 EVALUATION METHODS AND METRICS FOR AUTOMATED RADIOLOGY REPORT GENERATION

Samantha Leech, MD (*Presenter*)
Neel Mistry, MD (*Abstract Co-Author*)
Ashani Shah (*Abstract Co-Author*)
Scott J. Adams, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Describe the key dimensions and challenges of evaluating radiology reports generated by large language models and other generative AI systems. • Compare traditional NLP metrics and specialized radiology evaluation tools for assessing lexical similarity, factual accuracy, and clinical utility. • Describe radiologist-in-the-loop

evaluation strategies and real-world monitoring tools for validating generative AI outputs. • Describe current benchmarks, datasets, and emerging frameworks that support robust assessment of AI-generated radiology reports.

TABLE OF CONTENTS/OUTLINE

1. Introduction • Current status of AI for automated radiology report generation • Key dimensions for evaluating AI-generated radiology reports 2. Categories of Evaluation Metrics • Lexical and semantic similarity metrics • Label- and concept-based metrics • Error-specific analysis • LLM-based evaluation and clinical judgment scoring 3. Radiologist-in-the-Loop Evaluation Strategies• Human ratings and error annotation • Discrepancy scoring and adjudication• Edit-based metrics in real-world deployment 4. Datasets and Benchmarking Resources • Public and institutional datasets • Evaluation benchmarks and leaderboards 5. Deployment Metrics and Continuous Monitoring 6. Limitations, Risks, and Best Practices

INEE-25 BUILDING DIGITAL TWINS FOR MEDICAL APPLICATIONS: A REVIEW OF MODELING APPROACHES AND TECHNIQUES

Zhihua Qi, PhD (*Presenter*)

TEACHING POINTS

To understand the principles behind the three commonly used modeling approaches in building digital twins To recognize the strengths and the drawback of the modeling approaches To review tools and resources available for modelling digital twins in various clinical applications

TABLE OF CONTENTS/OUTLINE

1. The history and the current state of digital twins 2. The roles of digital twin in medicine 3. General framework for the development and the application of digital twins in medical applications 4. Main types of modelling approaches a. Monte Carlo method i. Basic concepts and methods ii. Tools and resources iii. Example solutions and applications b. Partial differential equations i. Basic concepts and methods ii. Tools and resources iii. Example solutions and applications c. Deep neural network i. Basic concepts and methods ii. Tools and resources iii. Example solutions and applications 5. Other emerging approaches and techniques 6. Outlook of digital twins in the era of big data and medical AI 7. Summary

INEE-26 SIMPLE TIPS FOR WORK FLOW EFFICIENCY IN AN EVER ADVANCING MODERN WORLD

Ryan Walsh, MBBCh, BSc (*Presenter*)

TEACHING POINTS

In today's fast-paced healthcare environment, radiology professionals must optimise digital workflows to meet rising demands for speed and accuracy. This educational exhibit focuses on practical, actionable tips for improving workflow efficiency using PACS systems, the example being Sectra PACS. Learn to harness keyboard and mouse shortcuts for rapid image measurement and navigation, implement smart display protocols for consistent and automated image layouts, and utilise dictaphone and headset shortcuts to streamline reporting. Special attention is given to advanced tools such as general image fusion, particularly for multiple sclerosis 3D FLAIR follow-up scans, enabling seamless comparison of current and prior studies. Real-world examples demonstrate how these strategies can be easily adopted to reduce repetitive tasks, enhance productivity, and improve diagnostic quality. By mastering these simple yet powerful techniques, radiology teams can fully leverage PACS systems to thrive in an ever-advancing modern world.

TABLE OF CONTENTS/OUTLINE

Introduction: The Need for Workflow Efficiency; Keyboard Shortcuts; Smart Display Protocols and Automated Layouts; Mouse Shortcuts and Customisation; Dictaphone and Headset Integration; Advanced Fusion Tools for MS 3D FLAIR; Real-World Applications and Case Studies; Conclusion: Maximising Sectra PACS in Modern Radiology

INEE-27 BUILT BY RADIOLOGISTS, FOR RADIOLOGY: DEVELOPING AN IN-HOUSE GENERATIVE AI SOLUTION -TOOLS, APPLICATIONS, AND CHALLENGES

Naga Sai Rasagna Mareddy, MBBS (*Presenter*)
Kimia Kamrani (*Abstract Co-Author*)
Ahmed Benghatnsh, MD (*Abstract Co-Author*)
Ramandeep Singh, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1.Recognize how generative AI can assist in reducing fatigue and improving efficiency by automating time-consuming elements of the radiology workflow, such as prior report summarization and impression drafting.2.Understand the limitations of commercial AI platforms, particularly in multimodal performance, cost, and alignment with radiology-specific tasks. 3.Explore the potential of open-source foundation models and custom in-house tools tailored to radiology, allowing for flexibility in integration and fine-tuning for local practice needs. 4.Review real-world applications of generative AI across imaging and reporting, with emphasis on clinical relevance, reliability, and workflow compatibility. 5.Identify key implementation challenges, including data privacy, regulatory uncertainty, inconsistent model output quality, and limited explainability in high-stakes imaging tasks. 6.Emphasize the role of radiologists in guiding the development, validation, and safe use of generative AI tools to ensure clinical accuracy and patient safety.

TABLE OF CONTENTS/OUTLINE

1.Rationale: Why radiology needs custom in-house gen AI tools. 2. AI Landscape: Infrastructure, model types, and platform trends.3. Tool Comparison: Commercial vs. open-source generative AI systems. 4.Imaging Use Cases: Vision-language models in image interpretation. 5.Text Use Cases: Report summarization and language model applications. 6.Challenges: Hallucination, PHI handling, integration, and regulation.7.Next Steps: Building radiologist-aligned, institutionally controlled gen AI tools.

INEE-29 THE AI REPORT CARD: A RADIOLOGIST'S CHECKLIST FOR SAFE, FAIR, AND EFFECTIVE AI

Harshithaa Varatharajan (*Presenter*)
Trupti Devaraja, MBBS, MD (*Abstract Co-Author*)
Shreelatha Aladangady (*Abstract Co-Author*)
Sujith R. Swamy, MBBS (*Abstract Co-Author*)
Malathi S. Bhat, MBBS (*Abstract Co-Author*)

TEACHING POINTS

This exhibit provides radiologists with a practical framework to evaluate AI tools before clinical adoption. It simplifies key metrics (e.g., sensitivity, specificity, AUC-ROC), highlights the importance of diverse training data, and addresses issues like explainability, subgroup performance, and automation bias. By breaking down regulatory nuances, workflow fit, and long-term monitoring, it empowers clinicians to assess AI for safety, fairness, and real-world usability.

TABLE OF CONTENTS/OUTLINE

Metrics That Matter - Decode sensitivity, specificity, AUROC, PPV, NPV, and F1 score. Understand relevance for different tasks and common pitfalls like missing confidence intervals. Generalizability - Assess whether the model works on your population. Identify gaps by age, sex, scanner, comorbidities. Black Box Breakdown - Who labeled the data? What was excluded? Understand how data quality shapes outcomes. Bias Detection - Spot selection, measurement, and systemic bias. Subgroup analysis reveals hidden clinical risks. Regulatory ? Ready - FDA/CE clearance doesn't guarantee performance. Know what's covered and what's not. Workflow Fit - Evaluate PACS/RIS integration, UX, and reporting efficiency. Model Drift - Monitor how model performance changes post-deployment. Ask about versioning and retraining. AI Evaluation Toolkit - 1-pager with key vendor questions, metrics cheat sheet, and integration checklist. QR Corner - Link to downloadable tools, mock vendor form, and trust survey.

INEE-30 FROM ANNOTATION TO APPLICATION: DEVELOPING AI SEGMENTATION MODELS FOR RECTOSIGMOID ENDOMETRIOSIS IN PELVIC MRI

Heber Colares Costa, MD (*Presenter*)
Joao J. Stern, MD (*Abstract Co-Author*)
Ingrid Ferreira (*Abstract Co-Author*)
Paula d. Miguelotte Juliao, MD (*Abstract Co-Author*)
Luciana C. Belem, MD, MSc (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Leonardo K. Bittencourt, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Deep endometriosis is a severe, often underdiagnosed condition that commonly affects the rectosigmoid region. Magnetic Resonance Imaging (MRI) offers high diagnostic value for deep endometriosis but requires expert interpretation. AI segmentation models, especially those based on deep learning, can aid radiologists by improving lesion detection, standardizing reporting, and reducing interpretation time. Building clinically useful models requires high-quality annotated datasets, appropriate model architecture, and robust validation. Radiologists are essential stakeholders in the development, evaluation, and integration of AI tools into clinical workflows. Understanding the technical and operational challenges of AI implementation is crucial for safe and effective adoption.

TABLE OF CONTENTS/OUTLINE

Introduction and Clinical Relevance Clinical implications of accurate detection and staging MRI Features of Rectosigmoid Endometriosis Imaging protocol and key sequences Typical signal characteristics and differential diagnoses Common pitfalls and variability in interpretation AI in Pelvic MRI: Why and How Overview of AI techniques for medical image segmentation Role of AI in supporting radiology and multidisciplinary care Step-by-Step: Developing a Segmentation Model Data and annotation strategies Evaluation metrics Potential Benefits Improved detection and quantification of lesions Reduction in interobserver variability Assistance in surgical planning and interdisciplinary communication Challenges in Development and Clinical Integration Future Perspectives Summary and Final Considerations

INEE-31 FROM NOVICE TO EXPERT: PARALLELING AN AI TOOL WITH A RADIOLOGY RESIDENT

Syed Muhammad Awais Bukhari, MD (*Presenter*)
Sreyes Venkatesh (*Abstract Co-Author*)
Wilson Liou (*Abstract Co-Author*)
Annie Singh (*Abstract Co-Author*)
Komal M. Awan, MD (*Abstract Co-Author*)
Charit R. Tippareddy, MD (*Abstract Co-Author*)
Amit Gupta, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the developmental journey of an AI tool and how it parallels the training path of a radiology resident. 2. Define artificial intelligence, machine learning, and deep learning within the context of medical imaging. 3. Explore various machine learning paradigms including supervised, semi-supervised, and reinforcement learning. 4. Appreciate the clinical applications and regulatory milestones of DL tools alongside real-world radiology training benchmarks. 5. Envision the future of radiology with emerging concepts such as multimodal AI and the virtual resident.

TABLE OF CONTENTS/OUTLINE

Introduction: A Parallel Journey Overview of the exhibit concept: AI development vs. resident training. Rationale for using this analogy Training Phase AI Tool: Labeled dataset supervised by expert radiologists; supervised learning via CNNs. Radiology Resident: Guided education under faculty; exposure to curated cases and didactics. Testing Phase AI Tool: Internal testing on unseen data Radiology Resident: In-training evaluations and supervised reads on new cases. Validation and Authorization Phase AI Tool: External validation using institutional datasets; FDA approval. Radiology Resident: ABR Core and Certifying Exams; full licensure. Deployment Phase AI Tool: Integration into clinical practice with institutional oversight. Radiology Resident: Transition to clinical independence Monitoring Phase AI Tool: Continuous performance assessment (e.g., accuracy, sensitivity). Radiology Resident: QA processes, CME, and ongoing professional development. Deep Learning Models in Radiology AI Learning Methods Future Directions Multimodal AI integration Concept of the "Virtual Resident"

INEE-32 SPATIAL COMPUTING AND EXTENDED REALITY GUIDANCE IN HEPATOBILIARY-PANCREATIC INTERVENTIONAL RADIOLOGY AND SURGERY: MACHINE LEARNING-DRIVEN ORGAN TRACKING FOR PROCEDURAL EDUCATION

Maki Sugimoto, MD, PhD (*Presenter*)

TEACHING POINTS

The integration of spatial computing and extended reality (XR) technologies, machine learning-based organ modeling, and real-time object tracking-provides innovative educational benefits specifically for hepatobiliary-pancreatic (HBP) interventional radiology (IVR) and surgery.In percutaneous HBP IVR such as TACE, RFA, liver biopsy, PTCD, and EUS-BD, XR enables immersive 3D visualization and dynamic overlays of patient-specific anatomy and procedural plans, enhancing spatial understanding and procedural safety. For laparoscopic and robotic HBP surgery, XR guidance supports intraoperative navigation through real-time anatomical overlays and instrument tracking, improving accuracy and decision-making in complex procedures. Machine learning-driven tracking enables precise localization of organs and tools, reducing errors and facilitating hands-on, simulation-based training without patient risk. XR platforms promote efficient, sustainable educational workflows by minimizing reliance on physical models and external monitors.

TABLE OF CONTENTS/OUTLINE

Introduction to Spatial Computing and XR in HBP IR and Surgery - Overview of XR and spatial computing; educational impact for HBP IR and surgery Machine Learning-Based Organ Modeling and Tracking - Data acquisition, 3D modeling, and real-time tracking in HBP procedures XR Guidance in Percutaneous HBP Interventions - Application in TACE, RFA, liver biopsy, PTCD, and EUS-BDXR in Laparoscopic and Robotic HBP Surgery - Real-time anatomical overlays and intraoperative navigation Educational Benefits and Workflow Optimization - Simulation-based training, knowledge retention, and sustainability

INEE-33 NATIONAL CANCER INSTITUTE IMAGING DATA COMMONS: DATA + TOOLS + COMPUTE TO POWER YOIR AI EXPLORATIONS

Andriy Fedorov, PhD (*Presenter*)
David Gibbs (*Abstract Co-Author*)
David Pot, PhD (*Abstract Co-Author*)
David A. Clunie, FRANZCR,MBBS (*Abstract Co-Author*)
Steve D. Pieper, PhD (*Abstract Co-Author*)
Christopher Bridge, DPhil (*Abstract Co-Author*)
Andre Homeyer (*Abstract Co-Author*)
Ulrike Wagner (*Abstract Co-Author*)
Granger Sutton (*Abstract Co-Author*)
Ron Kikinis, MD (*Abstract Co-Author*)

TEACHING POINTS

NCI Imaging Data Commons (IDC) is a cloud-based repository of publicly available cancer imaging data co-located with analysis and exploration tools. IDC, part of the NCI Cancer Research Data Commons (CRDC), provides access to a large, comprehensive, and expanding collection of cancer research imaging data. IDC uses a

combination of commercially available (Google Cloud Platform (GCP), Amazon Web Services (AWS)) and open source components. The IDC portal (https://imaging.datacommons.cancer.gov) and SQL interface enable exploration and visualization of data and cohort building. As of Spring 2025, IDC hosts over 85 TB of freely available radiology and digital pathology image data harmonized using the DICOM standard, and available in both GCP and AWS. IDC enables both efficient cloud-based data processing and simple data download for on-premise analysis. We will present the scope and status of IDC (new datasets, new portal and visualization features), accompanying tools (python data access interface, query, dashboards, integration with AI models from MHub.AI and 3D Slicer), demonstrations of utility of cloud-based computation (cloud-based notebooks, scalable workflows, JetStream2 demonstration), use cases (including scientific studies utilizing IDC) and plans for future development, along with live interactive demonstrations.

TABLE OF CONTENTS/OUTLINE

Overview of CRDC and IDC; Data curation; Portal; Viewer; Organization of data; Integration of tools; Documentation and user support resources; Hands-on demonstrations of python interface, notebooks, 3D Slicer and MHub.AI integration; Large scale computing using CRDC Cloud Resources; Status update and plans for future development.

INEE-34 INTELLIGENT CT PROTOCOL ADVISOR: HOW CAN WE ENSURE SAFETY, EFFICIENCY, AND EQUITY IN CT IMAGING?

Caroline Novis, MD (*Presenter*)
Pedro Gaspar Dos Santos, MD (*Abstract Co-Author*)
Joao Henrique Barros Penteado Furlan, MD (*Abstract Co-Author*)
Joao Cortez, MD (*Abstract Co-Author*)
Mateus Esmeraldo, MD (*Abstract Co-Author*)
Izaely R. Prates, MD (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)
Shri Krishna Jayanthi, MD (*Abstract Co-Author*)

TEACHING POINTS

To introduce an intelligent, automated CT protocol advisor that standardizes protocol selection based on clinical history. To demonstrate how the tool enhances workflow efficiency, promotes equitable imaging access, and reduces radiation exposure and protocol variability. To present the clinical logic and development process, emphasizing its application in diverse practice settings with limited resources or specialized staff.

TABLE OF CONTENTS/OUTLINE

Introduction : Background on challenges in protocol standardization and its impact on safety, efficiency, and equity. Development : Literature review and guideline-based protocol mapping; creation of a keyword recognition system using Python. Clinical History Input : Integration of information from referrals and pre-scan interviews to drive protocol recommendations. Workflow Integration : Use cases across a wide range of clinical indications illustrating improved decision-making and workflow without RIS/PACS dependence. Results : Retrospective validation of the tool in multiple anatomic regions and clinical contexts, assessing accuracy, consistency, and adherence to guidelines. Discussion : Benefits in under-resourced settings, pediatric imaging, and standardization of complex protocol requirements, including dynamic maneuvers. Conclusion : Intelligent tools can empower consistent, safe, and efficient imaging pathways independent of infrastructure.

INEE-35 AI FOR RADIOLOGY EDUCATION: VALIDATED QUESTION GENERATION, ADAPTIVE LEARNING, AND GAMIFIED ENGAGEMENT

Hyunji Kim (*Presenter*)
Young-Tak Kim, PhD (*Abstract Co-Author*)
Kevin Fialkowski, MD (*Abstract Co-Author*)
Michael H. Lev, MD (*Abstract Co-Author*)
Jeanne B. Ackman, MD (*Abstract Co-Author*)
Manisha Bahl, MD, MPH (*Abstract Co-Author*)
Marc D. Succi, MD (*Abstract Co-Author*)
Rory L. Cochran, MD,PhD (*Abstract Co-Author*)
Shaunagh McDermott, MBBCh (*Abstract Co-Author*)
Michael S. Gee, MD, PhD (*Abstract Co-Author*)
Synho Do, PhD, MS (*Abstract Co-Author*)

TEACHING POINTS

•Introduce a proof-of-conect AI-augmented platform designed to deliver personalized learning through automatically generated diagnostic questions. •Describe the hybrid quality assurance framework that combines user feedback and statistical analysis of response patterns to identify flawed items for expert review, ensuring scalable content validation. •Explain how the platform delivers personalized learning experiences by adapting question difficulty in real time based on learner performance. •Highlight how the system supports continuous learner engagement through progression feedback and gamified elements.

TABLE OF CONTENTS/OUTLINE

1.AI for Educational Content Generation: Define the role of AI in radiology education as a tool for generating validated, personalized learning content rather than supporting clinical decision-making. Introduce an AI-augmented platform that delivers clinically relevant and quality-assured diagnostic questions aligned with educational goals. 2.Quality Assurance Mechanism: Describe the hybrid quality assurance system that combines structured user feedback with statistical response analysis. Explain how flagged questions are escalated for expert review to validate and refine clinical quality. 3.Personalized Learning via Adaptive Difficulty Adjustment: Explain the real-time adaptive difficulty mechanism that dynamically adjusts question levels based on user performance. Illustrate how this supports personalized learning trajectories and cognitive engagement. 4.Learner Engagement and motivation: Demonstrate how gamification elements are integrated to enhance learner motivation, engagement, and structured progression.

INEE-36 SEGMENTATION OF MEDICAL IMAGES USING DEEP LEARNING AND FOUNDATION MODELS

Chiharu Kai, PhD (*Presenter*)
Sachi Ishizuka (*Abstract Co-Author*)
Hideaki Tamori (*Abstract Co-Author*)
MASATO NAKAYA (*Abstract Co-Author*)
Hikaru Sasaki (*Abstract Co-Author*)
Tsunehiro Otsuka (*Abstract Co-Author*)
Satoshi Kasai, PhD (*Abstract Co-Author*)

TEACHING POINTS

We will present our research on applying Deep Learning and Generative AI (Foundation Models) to multiple medical images to characterize various segmentation models. The purpose of this exhibit is to: - Recognize various types of segmentation models - Understand the benefit of medical image segmentation by use of Deep Learning and Foundation models - Learn about characteristics of Foundation Models (Segment Anything Model: SAM and MedSAM) and accuracy improvement methods (Low-Rank Adaptation: LoRA) - Review the characteristics and clinical usefulness of applying various segmentation models to a variety of medical images.

TABLE OF CONTENTS/OUTLINE

1) Introduction and comparison of current segmentation model types 2) Transition of segmentation model 3) Deep Learning (U-Net) 4) Foundation Model (SAM) 5) Foundation Model (MedSAM) 6) Introduction of accuracy improvement methods (LoRA) besides fine-tuning 7) Our research: applying various segmentation models to Mammogram (Breast: Breast tissue) and MRI (Brain: Glioma), comparing the results, and identifying the characteristics of each model - Materials and Methods - The results of the Dice score and output images - Discussion of each model (Review the characteristics and clinical usefulness) 8) Clinical usefulness of medical image segmentation by use of Deep Learning and Foundation models 9) Summary

INEE-37 ARTIFICIAL INTELLIGENCE (AI)-ASSISTED CHEST X-RAY DIAGNOSTIC SYSTEM FOR THE ENTIRE TUBERCULOSIS (TB) CARE IN THAILAND

Hiroshi Yoshioka, MD, PhD (*Presenter*)
Antoine Choppin, MS (*Abstract Co-Author*)
Lalita Kaewwilai (*Abstract Co-Author*)
Orawan Kaewboonchoo (*Abstract Co-Author*)

TEACHING POINTS

1) To learn current status of tuberculosis (TB) in Southeast Asia including Thailand, 2) To review artificial intelligence (AI)-assisted chest x-ray (CXR) system for detection and differential diagnosis of TB, 3) To discuss AI-assisted CXR system for comparison/follow-up function of TB during treatment, 4) To discuss AI-assisted mobile CXR bus TB screening, 5) To discuss future AI-assisted CXR system in Thailand

TABLE OF CONTENTS/OUTLINE

1) Status of TB in Southeast Asia including Thailand, 2) WHO guideline for TB, 3) Problems of TB care in Thailand, 4) AI software for TB, 5) AI-assisted CXR for detection and differential diagnosis of TB, 6) AI-assisted CXR for comparison/follow-up function of TB, 7) Status and problems of mobile CXR bus TB screening in the communities in Bangkok, 8) Application for AI-assisted mobile CXR bus TB screening, 9) Limitations of AI-assisted CXR diagnosis system for TB, and 10) Future AI-assisted TB CXR diagnosis system including predictive AI

INEE-38 DEVELOPING AI FOR PEDIATRIC RADIOLOGY: AUTOMATED LEG LENGTH MEASUREMENT USE CASE

Andrew Johnston, MD, MBA (*Presenter*)
Lina Cheuy (*Abstract Co-Author*)
Arogya Koirala, BS, MS (*Abstract Co-Author*)
Hye Sun Na (*Abstract Co-Author*)
Akshay Chaudhari, PhD (*Abstract Co-Author*)
David B. Larson, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

[1] Development of pediatric algorithms has lagged progress seen in adult AI. In many use cases of image-based AI, tools used for adults cannot be applied to children because pediatric anatomy is different than adult anatomy. [2] Expertise in the task to be automated enables curation of high-quality datasets. [3] Anatomic landmark localization is a robust approach for image-based algorithm development. [4] Successful AI deployment requires building consensus and deep involvement from experts in radiology, process improvement, and AI.

TABLE OF CONTENTS/OUTLINE

[1] Needs Assessment - Clinical need, amenability to automation, leg length example. [2] Model Training - Understanding the task to be automated, pediatric anatomy and landmark selection, creating labeling instructions. [3] Development strategy - Clinical experts, AI experts, and process experts. [4] Development process - Data labeling, training the algorithm, developing UI for product use, developing monitoring platform. [5] Implementation considerations - Development, building in reliability, post-deployment monitoring

INEE-39 POST-DEPLOYMENT MONITORING OF RADIOLOGY AI: A PRACTICAL GUIDE

Cole Cook (*Presenter*)
Vera Sorin, MD (*Abstract Co-Author*)
Panagiotis Korfiatis, PhD (*Abstract Co-Author*)
Gian Marco Conte, MD, PhD (*Abstract Co-Author*)
Andrew Missert, PhD (*Abstract Co-Author*)
Daniel J. Blezek, PhD (*Abstract Co-Author*)
Christoph Wald, MD, MBA (*Abstract Co-Author*)
Tim Leiner, MD, PhD (*Abstract Co-Author*)
Timothy L. Kline, PhD (*Abstract Co-Author*)
Jeremy D. Collins, MD (*Abstract Co-Author*)

TEACHING POINTS

- AI performance may drift after deployment. Drift may be abrupt or gradual as imaging protocols, hardware, or demographics change.- Systematic surveillance of input features, operational parameters, and task-specific metrics enables early detection of performance degradation.- Statistical process-control dashboards enable the identification of significant deviations from historical baselines.- A human-in-the-loop workflow of AI-radiologist disagreements can drive continuous quality improvement.

TABLE OF CONTENTS/OUTLINE

1. Introduction (a) Rapid AI adoption, regulations, and the necessity of post-deployment validation and monitoring. 2. Data vs concept shift; abrupt vs gradual drift with examples. 3. What to monitor (a) Input data (b) Operational parameters (c) Task-specific performance metrics (d) User engagement (e) Workflow and patient impact 4. Monitoring pipeline - statistical process-control dashboards; periodic checkpoints vs sliding-window updates, including examples. 5. Ground truth- generation at scale - LLM assisted labeling of -free text- reports; expert image correction capture as part of the workflow, including examples. 6. Human-in-the-loop feedback and alerting for AI-human disagreements, with examples. 7. Practical implementationa. Step-by-step examples from practiceb. Challenges and lessons learned. 8. Current and future efforts/directions - Reference labs for AI evaluation, ACR & other society initiatives, and regulatory perspectives.

INEE-40 MHUB.AI - SIMPLE AND REPRODUCIBLE AI FOR MEDICAL IMAGING

Leonard Nuernberg, MSc, BSc (*Presenter*)
Dennis Bontempi, MSc (*Abstract Co-Author*)
Suraj Pai, BEng (*Abstract Co-Author*)
Andriy Fedorov, PhD (*Abstract Co-Author*)
Curtis Lisle (*Abstract Co-Author*)
Hugo Aerts, PhD (*Abstract Co-Author*)

TEACHING POINTS

Machine learning shows promise in medical imaging but struggles with clinical adoption due to a lack of accessible and well documented models. Existing models often require significant effort to implement, creating an "implementation gap" between research and practice. Variations in datasets, technologies, and input formats hinder direct model comparisons. We developed MHub, a one-command framework for running ML models in medical imaging. MHub models are containerized with Docker, including inference code, dependencies, and model weights. It supports zero-configuration execution on DICOM data through native integration for medical imaging formats. Each model adheres to a structured template with Dockerfiles, MHub modules, workflows, and metadata. The platform includes our model collection, the MHub framework, online documentation, and a self-service contribution system. MHub offers tools for data organization and conversion, making it framework-agnostic and compatible with DICOM workflows. MHub has deployed over 30 models across modalities like CT, MR, PT, and SM, operating directly on DICOM data and producing harmonized outputs for easy comparison. Sample input and output data accompany each model. MHub provides a simple, reproducible, DICOM-compatible solution. The user-friendly design and standardization promote wider adoption of ML models in medical imaging.

TABLE OF CONTENTS/OUTLINE

Overview of the MHub.ai platform and model repository. Deployment template und Framework; Documentation and tutorials; Hands-on demo of model execution, notebooks; 3D Slicer and IDC integration; Use case scenarios; Contributor guidance: How to make your model simple and reproducible through MHub.ai.

INEE-41 PROGRESSIVE DISEASE RESPONSE: CHALLENGES AND INSIGHTS ACROSS IMAGING TREATMENT RESPONSE CRITERIA GUIDELINES

Tagwa Idris, MBBS (*Presenter*)
Mark A. Anderson, MD (*Abstract Co-Author*)
Gordon J. Harris, PhD (*Abstract Co-Author*)
Annick D. Van den Abbeele, MD (*Abstract Co-Author*)

TEACHING POINTS

• Provide a comprehensive review of the progressive disease (PD) designation across imaging-based treatment response criteria • Highlight key challenges in assessing progressive disease using response assessment criteria guidelines • Elaborate on the complexities involved in evaluating progressive disease in non-measurable lesions • Navigate unique challenges in the context of immunotherapy and immune-related response patterns • Illustrate case-based examples that demonstrate the variability in PD designations and the integration of both imaging and clinical findings, with an emphasis on adjudication gaps and decision-making ambiguity

TABLE OF CONTENTS/OUTLINE

• Overview of progressive disease guidelines in response assessment criteria, including solid tumors, hematological malignancies, prostate cancer, and beyond • Similarities and key differences of progressive disease definitions across response criteria • Challenges in subjective assessment of progressive disease in non-measurable disease • Encounters of progressive disease assessment following immunotherapeutic agents including pseudoprogression, delayed responses, and hyperprogression • Case-based scenarios highlighting the nuances and limitations of progressive disease assessment • Summary and future directions • References

INEE-42 NO VALID MULTICENTER STUDY WITHOUT ACCOUNTING FOR CENTER EFFECTS

Leeha Ryu, MS (*Presenter*)
Kyunghwa Han, PhD (*Abstract Co-Author*)
Jin Hur, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize the importance of accounting for center effects in multicenter studies to ensure valid and unbiased results. 2. Review commonly used statistical methods applicable to multicenter data across various outcome types. 3. Understand the practical implications of using different methods through real-world application and literature examples.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Multicenter Data: - Characteristics of multicenter studies - Factors contributing to between-center heterogeneity 2. Overview of Statistical Methods: - Introduction to different analytical approaches applicable to multicenter data - Brief overview of methods used depending on outcome type 3. Literature Overview: - Usage patterns of statistical methods applied in published multicenter studies - Representative examples of appropriate model use 4. Applied Analysis Using Real Data: - Comparison of results across different statistical methods 5. Conclusion and Practical Takeaways

INEE-43 AI-ASSISTED ANEURYSM DETECTION AND ANALYSIS: RECENT ADVANCES

Donghyun Won, MD (*Presenter*)
Yeongheon Mok (*Abstract Co-Author*)
Dohoon Kim (*Abstract Co-Author*)
YEONGJUN KIM (*Abstract Co-Author*)
Juheon Hwang (*Abstract Co-Author*)
Jaesik Min (*Abstract Co-Author*)
Deok H. Lee, MD (*Abstract Co-Author*)
Yunsun Song, MD, PhD (*Abstract Co-Author*)
Yoojin Nam, MD (*Abstract Co-Author*)
Seon Moon Hwang (*Abstract Co-Author*)
Joon Ho Choi (*Abstract Co-Author*)
Boseong Kwon (*Abstract Co-Author*)

TEACHING POINTS

Artificial intelligence for intracranial aneurysm detection has rapidly evolved from 2D to 3D approaches, addressing the growing neuroimaging workload that contributes to clinically significant missed detection rates. However, there still exists a notable performance gap between regulatory approval studies and real-world implementation, for example, far reduced sensitivity often observed in clinical settings. This discrepancy occurs when the pixel/voxel-based AI models that are trained on specific imaging protocols perform inconsistently across different clinical environments. Our geometry-based approaches offer robustness to this problem by capturing the spatial relationships of vessels through point cloud representations, differentiating spherical aneurysm expansions from cylindrical normal vessels using normal vector analysis. This transformation-based approach maintains its performance across different hospitals, modalities, and protocols. It enables comprehensive analysis beyond simple detection toward registration, longitudinal comparison, quantitative measurement, and ultimately rupture risk prediction.

TABLE OF CONTENTS/OUTLINE

1. Clinical Implementation Challenges - Limitations of pixel/voxel-based AI models in clinical settings 2. Introduction of EVG-NET: Entire Vasculature with 3D Geometry-guided NETwork 3. Experimental Validation 4. Future Directions and Summary

INEE-44 UNDERSTANDING AI HALLUCINATIONS IN GENERATIVE MEDICAL IMAGING: MECHANISMS, MANIFESTATIONS, AND MITIGATION STRATEGIES

Annie Singh (*Presenter*)
Fatima Qureshy, MBBS (*Abstract Co-Author*)
Moinak Bhattacharya (*Abstract Co-Author*)
Angela Lignelli-Dipple, MD (*Abstract Co-Author*)
Prateek Prasanna, PhD (*Abstract Co-Author*)
Gagandeep Singh, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

-Understand the role of generative AI in image generation and interpretation. -Distinguish hallucinations from distorted information, disinformation, and misinformation. -Identify key causes and types of hallucinations. -Review image examples demonstrating hallucination. -Discuss strategies to mitigate hallucinations through data-level, model-level, and system-level safeguards.

TABLE OF CONTENTS/OUTLINE

1. Introduction Background of Generative AI and LLMs in radiology and trends in AI driven image generation. Understanding the risks that AI hallucinations pose to patient safety, diagnostic accuracy, and clinical trust. 2. Anatomy of AI Hallucination: Defining hallucinations and distinguishing them from other forms of information distortion. This section explores key mechanisms behind hallucinations, including data bias and noise, overfitting, model limitations (e.g., source-reference divergence), and lack of contextual understanding. Hallucinations are classified into three types: (i) Anatomical, (ii) Pathological, and (iii) Modality-inconsistent 3. Illustrative case studies Demonstrative examples of AI generated hallucinations with input prompt, output generated, and observed discrepancies. 4. Workflow Strategies; Safeguard against AI Hallucinations: Discusses mitigation strategies across three levels, (i) Data level methods (data curation and annotation), (ii) Model level methods (prompt tuning, hallucination maps, image masking), and (iii) System level methods (human-AI feedback loop and model cross validation) 5. Conclusion: Summarizing key concepts and emphasizing on awareness, interpretive caution, and the need for radiologist involvement in AI validation.

INEE-45 UNLOCKING HIDDEN CT BIOMARKERS: AI-PREDICTED BIOLOGICAL LUNG AGE AND MULTI-DISEASE CORRELATIONS

Jaewon Jung (*Presenter*)
Sriya Kappagantu (*Abstract Co-Author*)
Audrey Burnett (*Abstract Co-Author*)
Xiaowen Yin (*Abstract Co-Author*)
Tician Schnitzler, MD, MSc (*Abstract Co-Author*)
Yasuhito Mitsuyama (*Abstract Co-Author*)
Daiju Ueda, MD, PhD (*Abstract Co-Author*)
Jae Ho Sohn, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Chest CT scans contain hidden biomarkers of biological lung aging beyond their diagnostic role. CT-based AI prediction of lung age offers a quantitative biomarker of biological lung aging, with significant correlations to multiple chronic diseases. The Lung Aging Index , defined as the discrepancy between AI-predicted lung age and chronological age, correlates with diseases such as asthma, COPD, emphysema, and hypertension. Therefore, the purpose of this exhibit is to highlight the clinical value of the Lung Aging Index by reviewing CT images with high and low index values that reveal key features of accelerated or decelerated lung aging.

TABLE OF CONTENTS/OUTLINE

#1 Title #2 Table of contents #3 Background: Concept of biological vs. chronological age and emerging role of biological age as a health indicator #4 Patient selection and demographics: Description of datasets - NLST, [Hospital 1] (US), [Hospital 2] (Asia) #5 Study Workflow and Model Pipeline: Data preprocessing, model architecture, ensemble prediction, Lung Aging Index calculation, disease correlation analysis #6 Comparison of AI-Predicted Biological Lung Age vs Chronological Age: Scatter plots and summary statistics across datasets #7 Disease Associations: Logistic regression analysis correlating Lung Aging Index with asthma, COPD, emphysema, and hypertension #8 Representative CT Images #8-1 CT Features of Lungs with High Lung Aging Index #8-2 CT Features of Lungs with Low Lung Aging Index #9 Clinical Implications: Application of Lung Aging Index for early disease detection, population-level risk stratification, and preventive screening #10 Take-home Messages #11 References

INEE-46 ADVANCED 3D IMAGING FOR SURGICAL GUIDANCE IN SOLID ORGAN TUMORS: A MULTIDISCIPLINARY APPROACH

Eduardo M. Araujo, MD (*Presenter*)
Salie Oliveira, MD (*Abstract Co-Author*)
Tiara Vitalino Galvao, MD (*Abstract Co-Author*)
Daniel Nunes (*Abstract Co-Author*)
Paulo Falcao, MD (*Abstract Co-Author*)
Thiago De Sousa (*Abstract Co-Author*)
Danilo Santos Silva (*Abstract Co-Author*)
Juliana Lima (*Abstract Co-Author*)
Elizabeth Maria Neves Silva Souza (*Abstract Co-Author*)
Luis Gabriel Campos Pires (*Abstract Co-Author*)
Pedro Filgueira (*Abstract Co-Author*)
Hyroan Brandell Pereira Correa (*Abstract Co-Author*)
Romulo Varella, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

- Advanced 3D imaging enhances spatial understanding of solid organ tumors and supports personalized surgical planning. - 3D reconstructions and printed models help reduce operative time, blood loss, and interobserver variability. - Integration between radiology, surgery, and biomedical engineering is critical for a successful workflow. - Radiologists play a central role in model development and interdisciplinary surgical guidance. - 3D modeling serves as an effective educational tool for trainees and surgical simulation.

TABLE OF CONTENTS/OUTLINE

Introduction: The challenge of complex solid tumors - The rise of personalized, minimally invasive surgery. - Limitations for surgeons for spatial and relational anatomical analysis of 2D imaging. 3D Imaging Workflow in Surgical Planning - Steps from image acquisition to segmentation, modeling, and 3D printing.- Software and PACS integration for clinical applications. Clinical Applications Across Solid OrgansLiver: Segmental 3D planning for Y90 radioembolization. - Pancreas: Post-chemotherapy planning with printed model validation.- Lung: Vascular/airway mapping and printing for central tumors.- Kidney: Margin-based planning for nephron-sparing surgery.- Uterus: Leiomyoma mapping for fertility-focused myomectomy.- Diaphragm: Complex hiatal hernia planning. Interdisciplinary Care and Radiology Leadership - Radiologists as coordinators of 3D workflow and tumor board discussions. Medical Education and Surgical Simulation - Resident training, anatomical teaching, and rehearsal of complex procedures. Conclusion - 3D imaging as a transformative toolEnhances safety, precision, and integration in oncologic surgical care

INEE-47 ADDING CLINICAL CONTEXT USING A VISUALIZATION TOOL FOR CO-REGISTERED PATIENT VISIBLE LIGHT IMAGES AND RADIOGRAPHS

Srini Tridandapani, MD, PhD (*Presenter*)
Carson A. Wick, PhD (*Abstract Co-Author*)
Nabile M. Safdar, MD, MPH (*Abstract Co-Author*)
Pamela T. Bhatti, PhD (*Abstract Co-Author*)

TEACHING POINTS

Point-of-care patient visible light (VL) imaging can provide missing visual context in radiology. A VL imaging system was deployed at a large academic hospital and an application created to co-register and efficiently visualize co-registered VL images with the corresponding radiographs. This application features a user interface to select a study and visualize radiographs overlayed on VL images. Opacity of the overlayed radiograph is controlled using a software slider bar in the application. The ease of transitioning back and forth between VL images and radiographs will allow interpreting radiologists to efficiently compare image content in both modalities. This will prove valuable in locating features in common but also provide a view beyond the collimation of the radiograph acquisition, providing a “mini physical exam.” This educational exhibit will highlight multiple use cases of VL images, elucidated by videos of the application allowing simultaneous viewing of these images overlayed with radiographs.

TABLE OF CONTENTS/OUTLINE

Explanation of benefits of point-of-care patient visible-light (VL) images in radiography Overview of VL system Use cases highlighting the benefits of co-registered VL images and radiographs and an application to efficiently view them Diabetic foot ulcer and osteomyelitis Soft Tissue conditions Cellulitis Subcutaneous emphysema

Ruling out free air using patient positioning Checking for presence of lines and tubes absent in radiographs Masses not seen in radiographs but visualized on the photographs

INEE-48 BEYOND EXPLAINABILITY: MECHANISTIC INTERPRETABILITY FOR UNDERSTANDING RADIOLOGY FOUNDATION MODELS FROM WITHIN

Bardia Khosravi, MD, MPH (*Presenter*)
Amirali Khosravi, MD (*Abstract Co-Author*)
Frank Li, PhD (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)

TEACHING POINTS

1. Differentiate between AI explainability (what the model did) and interpretability (how the model works), understanding their complementary roles in trustworthy radiology AI 2. Identify polysemanticity challenges in neural networks where single neurons respond to multiple unrelated concepts, complicating interpretation 3. Apply mechanistic interpretability techniques like activation patching and sparse autoencoders to dissect how radiology AI models process images and make diagnostic decisions

TABLE OF CONTENTS/OUTLINE

1. Introduction to Interpretability and Explainability in Radiology AI: (a) The black box problem and its clinical implications (b) Explainability: Post-hoc attribution methods (saliency maps, attention maps, SHAP) (c) Interpretability: Understanding the internal mechanisms 2. Challenges in Neural Network Interpretation: (a) Polysemanticity: When neurons encode multiple unrelated concepts (b) Superposition: How networks represent more features than neurons (c) Case study: Hidden biases in chest X-ray classification 3. Mechanistic Interpretability Techniques: (a) Sparse autoencoders: Disentangling features for clearer interpretation (b) Activation patching: Causal interventions in model decision-making 4. Clinical Applications and Implications: (a) Understanding racial disparities in image classification models (b) Detecting and mitigating bias through mechanistic insights (c) Using interpretability to improve clinical safety and trustworthiness 5. Future Directions: (a) Automated circuit discovery for scalable interpretability (b) Implications for regulatory frameworks and clinical implementation 6. Conclusion

INEE-49 SMARTER AI TRAINING, FEWER LABELS: THE ACTIVE LEARNING PERSPECTIVE FOR RADIOLOGISTS USING GRAND SAMPLING

Sahika Yayli, MD (*Presenter*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Radiologists and data scientists can achieve high-performing models with fewer annotations by using active learning, saving labeling time and cost. • Active learning enables selective sampling of the most informative data to improve model efficiency. • GraNd (Gradient Norm) is a simple, interpretable, and model-agnostic strategy for sample selection. • Even with simple datasets like MNIST, GraNd demonstrates the value of data prioritization.

TABLE OF CONTENTS/OUTLINE

1. Introduction: The Annotation Bottleneck in RadiologyRadiology AI models require large labeled datasets, but expert annotations are costly and time-consuming. 2. What Is Active Learning?: Active learning is a machine learning paradigm that aims to reduce the number of labeled samples needed by selecting only the most informative examples for annotation. It does so by estimating the model's uncertainty and focusing labeling efforts where the model learns the most. We introduce this concept through intuitive examples and connect it to real-world clinical relevance. 3. GraNd Sampling: Gradient Norm-Based SelectionEntropy and gradient norm-based method to identify impactful training samples. 4. Proof-of-Concept Experiment Using MNIST: MNIST used to simulate radiology data labeling. Models trained with: Small seed set Randomly added samples GraNd-selected samples Full dataset Active learning achieved similar performance to full labeling with fewer samples. 5. Clinical Implication : Active learning strategies like GraNd help radiologists and data scientists prioritize which data to label first, enabling efficient AI training in scenarios where annotations are costly or limited.

INEE-50 BENCHMARK TESTING FOR SAFER RADIOLOGY VISION-LANGUAGE AI ON ERROR DETECTION AND CORRECTION IN CT REPORTS

Sunggu Kyung, PhD (*Presenter*)
Jinyoung Seo (*Abstract Co-Author*)
Hyungbin Park (*Abstract Co-Author*)
Jimin Sung (*Abstract Co-Author*)
Jihyun Kim (*Abstract Co-Author*)
Dongyeong Kim, MD (*Abstract Co-Author*)
Wooyoung Jo (*Abstract Co-Author*)
Yoojin Nam, MD (*Abstract Co-Author*)
Sangah Park (*Abstract Co-Author*)
Taehee Kwon (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

TEACHING POINTS

• The importance of benchmarking in radiology AI for evaluating safer and more effective AI systems in clinical settings. • Categorize six common error types in CT reports and analyze clinical impact. • Discuss advances in medical large multimodal language models (MLLMs) and their clinical applicability, focusing on the technical features and CT interpretation capabilities. • Analyze the limitations of existing medical visual question answering (VQA) benchmarks (e.g., simple visual focus, limited clinical relevance) and emphasize the need for precise, clinically relevant evaluation schemes. • Highlight error detection and correction as key indicators for evaluating medical AI models and propose a new benchmark design. • Analyze performance of 3D medical MLLMs across error classification, detection, and correction to identify model characteristics and clinical selection criteria

TABLE OF CONTENTS/OUTLINE

1. Introduction The importance of benchmark tests in radiology vision-language AI Errors in CT reports: prevalence and clinical impact 2. Advances in MLLMs Overview of MLLMs in medicine Key 3D MLLM models: RadFM, M3D, CT-CHAT Comparative analysis: technical features & CT interpretation 3. Limitations of Existing Medical VQA Benchmarks 2D benchmarks: VQA-RAD, PMC-VQA, OmniMedVQA 3D benchmarks: RP3D-VQA, M3D-VQA Methodological issues: simple visual focus, limited reasoning, low clinical relevance 4. Designing a New Benchmark for Error Detection and Correction Error types: Omission, Insertion, Orientation, Size, Unit, Typo Evaluation: classification, detection, correction 5. Results and Analysis Task-wise performance metrics Model strengths and weaknesses Selection criteria for clinical use

Abstract Archives of the RSNA, 2025

IREE

Interventional Radiology Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

IREE-1 PERCUTANEOUS CT GUIDED BONE TUMOR BIOPSY: BASIC PRINCIPLES AND APPROACHES- A CASE-BASED REVIEW

Alexandra Panyukova, MD (*Presenter*)
Mishal Shahab, MBBS (*Abstract Co-Author*)
Sukrita Menon, MD (*Abstract Co-Author*)
Antonio Santana Veliz, MD (*Abstract Co-Author*)
Katsuhiro Kobayashi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. CT guidance remains the primary method for bone tumor biopsy. 2. The shortest route is not always the best: careful trajectory planning minimizes damage to vital structures and compartments. 3. Meticulous planning is essential, especially for suspected sarcomas — biopsy track contamination can significantly impact limb-salvage surgery outcomes. 4. Close communication with orthopedic oncologists is critical when sarcoma is suspected to ensure optimal surgical outcomes. 5. Procedural complications such as non-diagnostic sampling, bleeding, joint violation, nerve injury, and tumor seeding can be minimized through careful planning and technique.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. General Biopsy Principles 3. Special Considerations for Primary Bone Tumors 4. Site-Specific Biopsy Approaches 4.1 Upper extremity: 4.1.1 Humerus (Proximal to Distal) 4.1.2 Forearm (Radius and Ulna) 4.2 Lower extremity:4.2.1 Pelvis 4.2.2 Femur (Proximal, Shaft, Distal) 4.2.3 Tibia and Fibula 5. Complications and Pitfalls 6. Take Home Points 7. References

IREE-2 EVOLVING GLOBAL TRENDS IN LOCOREGIONAL TREATMENT FOR HEPATOCELLULAR CARCINOMA

Mahmoud Odeh, MD (*Presenter*)
Diana Dinh, MD, MPH (*Abstract Co-Author*)
Jeffrey L. Weinstein, MD (*Abstract Co-Author*)
Muneeb Ahmed, MD (*Abstract Co-Author*)
Ammar Sarwar, MD (*Abstract Co-Author*)

TEACHING POINTS

• Globally, the incidence of hepatocellular carcinoma (HCC) has been slowly increasing over the past two decades until it reached 6.15 in 2021 • The highest incidence and mortality rates are observed in East Asia, which account for over half of global cases • In China, TACE is the most commonly used LRT, utilized in 37% of patients in 2013, with a gradual increase in the use of radiotherapy • In Japan, the use of TACE and ablation declined between 1996 and 2017 (from 35% to 27% and 31% to 19%, respectively), in favor of surgical resection. Despite this shift, TACE remains the most frequently used LRT. TARE is not yet approved for clinical use • In South Korea, the overall use of LRTs has slightly declined in favor of increased resection. Among transarterial therapies, TACE remains dominant but has been decreasing following the introduction of TARE from 88% in 2008 to 79% in 2022, while TARE accounts for 7.7% of transarterial therapies use in 2022. • In the United States, the use of TACE reached a peak in 2010 and has since been declining, while TARE use has been increasing rapidly since 2012, becoming the most common LRT offered to HCC patients awaiting liver transplantation in 2023.

TABLE OF CONTENTS/OUTLINE

1. Overview of the global incidence and mortality of HCC 2. HCC trends outside the United States (Europe, China, Japan, South Korea)a. Incidence and mortality rates of HCC outside the United States compared to within the U.S. b. Trends in the use of locoregional therapies (LRTs) for HCC outside the United States compared to the U.S. over the past two decades c. Shifts within LRT modalities: trends in the use of ablation, transarterial chemoembolization (TACE), and transarterial radioembolization (TARE) both outside and within the United States

IREE-3 TARGETING BONE METASTASES: THE POWER OF MICROWAVE ABLATION - INSIGHTS FROM A SINGLE-CENTER EXPERIENCE WITH PRACTICAL TIPS & TRICKS FOR THE INTERVENTIONAL RADIOLOGIST

Helena Puigderrajols Vehils, MD (*Presenter*)
Igor Radalov, MD (*Abstract Co-Author*)
Claudio Pusceddu, MD (*Abstract Co-Author*)
Alberto Solano Lopez (*Abstract Co-Author*)
Jose Maria Maiques Llacer, MD (*Abstract Co-Author*)
SALVATORE MARSICO (*Abstract Co-Author*)

TEACHING POINTS

1. Practical review of the principles and equipment of microwave ablation based therapies. 2. Outline appropriate patient selection criteria, indications, contraindications and possible integration with other therapies. 3. Describe procedural planning, including CT-guided techniques, and lesion access strategies based on location. 4. Illustrate key pre- and post-ablation imaging findings and their correlation with clinical outcomes, emphasizing the role of MWA in pain palliation and local tumor control. 5. Identify potential complications and strategies for their avoidance and management.

TABLE OF CONTENTS/OUTLINE

1. Overview of bone metastases and current treatment strategies. 2. Rationale for thermal ablation, with a particular focus on MWA, and comparative analysis of MWA relative to other ablation techniques. 3. MWA technique: equipment, energy parameters, and ablation dynamics. 4. Indications and patient selection: 4.1.Pain palliation in refractory cases 4.2.Oligometastatic disease 4.3.Integration with radiotherapy and systemic treatments 4.4.Combination with cementoplasty for stabilization of bone structures (in selected cases with high risk of pathological fractures). 5. Absolute and relative contraindications. 6. Procedural approaches: 6.1.CT-guided planning 6.2.Lesion access by location 6.3.Pre-procedural biopsy 6.4.Adjunctive techniques 7. Review of the most common complications and strategies for their avoidance and management 8. Multiple combined case examples from our institution, including technical tips & tricks 9. Summarize & key points 10. Conclusion

IREE-4 A MODERN APPROACH TO HEMODIALYSIS ACCESS: ENDOVASCULAR ARTERIOVENOUS FISTULA CREATION THROUGH CLINICAL CASES

Manex Lasa, MD (*Presenter*)
Virginia Diaz (*Abstract Co-Author*)
Inigo Deba Ayarza, MD (*Abstract Co-Author*)
Carlos Jimenez Zapater (*Abstract Co-Author*)
Borja Pena (*Abstract Co-Author*)
Nicolas Perez, MD (*Abstract Co-Author*)
Mikel Merino Aboitiz, MD (*Abstract Co-Author*)
Ainhoa Urrutia Ortiz De Salazar, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the indications and patient selection criteria for endovascular arteriovenous fistula (endoAVF) creation in hemodialysis candidates.Review the step-by-step technique and essential imaging guidance for successful endoAVF creation. Recognize potential complications and strategies to manage them intra- and post-procedurally.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of dialysis access options and the role of endoAVF creation. Patient Selection: Clinical and radiological inclusion criteria. Case Planning: Arm vessel mapping using Doppler ultrasound. Technique: Step-by-step procedure with imaging guidance. Case-Based Review: Illustrative examples highlighting key technical points and variations. Complications and Management: Identification and handling of intra- and post-procedural issues; ultrasound evaluation and follow-up of fistula maturity. Conclusion: Practical insights and take-home messages.

IREE-5 MINIMALLY INVASIVE MANAGEMENT OF INTRA-ABDOMINAL LYMPHATIC PATHOLOGIES - THE "MILIEU INTERIEUR" DEMYSTIFIED

Venkata Subbaih Arunachalam, MD (*Presenter*)
Saebeom Hur, MD (*Abstract Co-Author*)

TEACHING POINTS

1) To illustrate the anatomy and physiology of hepatic, mesenteric, and retroperitoneal lymphatic system 2) To describe the pathophysiological basis of clinical manifestations of pathologies of the intra-abdominal lymphatic system 3) To systematically categorize the acquired intra-abdominal pathologies of the lymphatic system and postulate an algorithmic approach for evaluation and interventional management of chylous ascites 4) To describe the salient imaging features and interventional management of protein-losing enteropathy, Chyluria and lymphatic decompression for interventional management of Refractory ascites in patients with CLD

TABLE OF CONTENTS/OUTLINE

1) Introduction 2) Anatomy & Physiology of hepatic, mesenteric, and retroperitoneal lymphatic system 3) Pathophysiological basis of clinical manifestations - Chylous ascites, Ascites, Protein-losing enteropathy, Chyluria, Scrotal and Lower limb edema 4) Classification of intra-abdominal lymphatic pathologies - Congenital vs Acquired, Disorders of production, transit (reflux), and drainage. 5) Etiologies of chylous ascites - Congenital, Inflammatory, Neoplasm, Trauma 6) Role of imaging in the management of chylous ascites8) Endovascular approaches to manage chylous ascites - Hepatic Lymphatic deprivation, Mesenteric lymphatic deprivation, Thoracic duct angioplasty and stenting, Retroperitoneal lymphatic embolization, Endolymphatic BORALE 7) Imaging and Interventional management of protein-losing enteropathy, hepatic lymphorrhoea & Chyluria 8) Rationale of lymphatic decompression in the management of Refractory ascites 9) Complications of lymphatic interventions 10) Conclusion

IREE-6 NUMB AND NUMBER: A GUIDE TO MASTERING SEDATION, ANALGESIA, AND LOCAL ANESTHESIA

Tanya W. Moseley, MD, PhD (*Presenter*)
Mary S. Guirguis, MD (*Abstract Co-Author*)
Ronald Arthur Rauch (*Abstract Co-Author*)
Gaiane M. Rauch, MD, PhD (*Abstract Co-Author*)
Beatriz E. Adrada, MD (*Abstract Co-Author*)

TEACHING POINTS

Pain management during radiological procedures is essential for patient comfort, cooperation, and procedural success. This comprehensive guide addresses analgesia, local anesthesia, and sedation techniques in radiology, emphasizing patient safety and procedure efficacy. TEACHING POINTS Patient assessment and risk stratification prior to analgesia and sedation Pharmacology of common analgesic agents and local anesthetics Sedation techniques and monitoring requirements Procedure-specific pain management protocols

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS Introduction and Background Patient Assessment and Preparation Pharmacology of Analgesic Agents Local Anesthesia Techniques Pharmacology of Sedative Agents Monitoring and Safety Considerations Special Populations Complications and Management

IREE-7 TUMOR ACIDITY-REGULATING LIPIODOL PICKERING EMULSIONS STABILIZED BY IRON NANOPARTICLES ENABLES ENHANCED TRANSARTERIAL EMBOLIZATION THERAPY VIA SYNERGISTICALLY INDUCING FERROPTOSIS AND ACTIVATING ANTITUMOR IMMUNITY

Yang Weihao (*Presenter*)

TEACHING POINTS

1,The long-term therapeutic outcome of TACE is significantly limited by unfavorable pharmacokinetic behaviors of the loaded drug and intraarterial embolization aggravated tumor immunosuppression. 2,In this study, iron nanoparticles (FeNPs) with pH-dependent Fention catalytic ability was synthesized and utilized as particular surfactants to stabilize Lipiodol Pickering emulsion (LPE) for tumor localized delivery of cariporide in responding to the extracellular tumor acidity.3,As an inhibitor of sodium-hydrogen exchanger in plasma membrane, cariporide markedly enhanced the ferroptosis inducing ability of FeNPs via down-regulating intracellular pH, while suppressed extracellular tumor acidosis through reducing proton efflux. 4,The obtained cariporide-loaded FeNPs-stabilized LPE, abbreviated as CFe-LPE, initiated potent antitumor immunity by inducing immunogenic cell death and reversing the immunosuppressive TME through amelioration of tumor acidity. 5, CFe-LPE mediated TAE treatment exhibited significantly improved therapeutic efficacy against orthotopic N1S1 HCC in rats compared to conventional TACE treatment with the lipiodolized doxorubin emulsion.

TABLE OF CONTENTS/OUTLINE

1)Preparation and characterization of CFe-LPE2)CFe-LPE induces self-enhancing ferroptosis of cancer cells3)In vivo therapeutic efficacy of CFe-LPE on subcutaneous H22 tumors4)RNA-Sequencing5)Immune activation effect of CFe-LPE in vivo6)In vivo TACE treatment with CFe-LPE in an orthotopic N1S1 rat tumor model.

IREE-8 BEYOND PEDIATRICS: UNVEILING THE TRUE INTRAHEPATIC PORTAL SYSTEM IN CONGENITAL PORTOSYSTEMIC SHUNTS—RECLAIMING THE ROLE OF INTERVENTIONAL RADIOLOGY

Masashi Tamura, MD, PhD (*Presenter*)
Seishi Nakatsuka, MD (*Abstract Co-Author*)
Takahiro Hosokawa (*Abstract Co-Author*)
JITSURO TSUKADA (*Abstract Co-Author*)
Hiroki Yoshikawa (*Abstract Co-Author*)
YUJI FURUKAWA (*Abstract Co-Author*)
Ryo Ogawa, MD (*Abstract Co-Author*)
Yosuke Yamamoto, MD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. C ongenital portosystemic shunt (CPSS) may remain undetected in childhood and be first diagnosed in young adults with complications, highlighting their relevance even for non-pediatric radiologists. 2. Angiography with balloon occlusion (BO) reveals true intrahepatic portal system (IHPS) status in congenital portosystemic shunt (CPSS), often underestimated by conventional imaging. 3. IHPS classification (Mild/Moderate/Severe) under BO and concurrent measurement of mean portal vein pressure (mPVP) provide crucial guidance for shunt management. 4. Radiologists shold recognize CPSS-portopulmonary hypertension (PoPH) association , a leading mortality cause. 5. Interventional radiologists are key to CPSS management through angiographic evaluation, treatment planning, and percutaneous closure procedures.

TABLE OF CONTENTS/OUTLINE

1. Overview of CPSS : definition, embryology, and presentation beyond pediatrics. 2. CPSS Classification Intrahepatic, extrahepatic, persistent ductus venosus; Abernethy types . 3. IHPS assessment : Conventional imaging limitations . 4. Balloon Occlusion Test : Technique, IHPS classification, mPVP correlation. 5. Management Algorithm : Decision-making based on shunt type, complications, IHPS, mPVP. 6. CPSS-related Complications : hepatic, neurological and pulmonary disorders. 7. PoPH in CPSS : Significance, diagnosis, radiologist's role. 8. Shunt Closure Outcomes : Clinical impact in pediatric and young adult patients. 9. Case Examples : Diagnostic workup and intervention illustrations. 10. Conclusion : Reclaiming interventional radiology’s role in the evolving care of CPSS

IREE-9 STANDARDIZING THE VX2 RABBIT MODEL FOR LIVER CANCER RESEARCH IN INTERVENTIONAL RADIOLOGY: A COMPREHENSIVE HOW-TO-GUIDE TO METHODOLOGY AND APPLICATIONS

Salma A. Abosabie (*Presenter*)
Sara Abosabie (*Abstract Co-Author*)
Yubei He (*Abstract Co-Author*)
Han Xu, MSc (*Abstract Co-Author*)
Justus Ramtke (*Abstract Co-Author*)
Friederike Hesse (*Abstract Co-Author*)
Julius Chapiro, MD, PhD (*Abstract Co-Author*)
Veronica E. Prieto Ventura, MD (*Abstract Co-Author*)
Hanna Javan, MD (*Abstract Co-Author*)
Ben Sadeghi, MD (*Abstract Co-Author*)
Nadine Abi-Jaoudeh, MD (*Abstract Co-Author*)
Lynn J. Savic, MD (*Abstract Co-Author*)

TEACHING POINTS

1. The VX2 liver tumor model in New Zealand White rabbits is widely used in translational research for interventional oncology, particularly due to its size, rapid and reproducible growth, hypervascularity, and imaging features that resemble hepatocellular carcinoma. 2. The model involves intramuscular implantation of tumor fragments in donor rabbits, followed by hepatic implantation of fragments from the donor tumor into recipient rabbits. 3. Both VX2 cell suspensions or solid tumor fragments can be used, each with its advantages and limitations. 4. The animal size allows for the use of standard clinical equipment for transarterial and ablation therapies, and radiologic imaging can be performed with human-size CT or MR scanners. 5. While the model is highly reproducible, it is essential to adhere to standard operating procedures for complex interventions, accurate and consistent anesthesia and analgesia protocols, and thorough postoperative monitoring to ensure procedural success and animal welfare.

TABLE OF CONTENTS/OUTLINE

1. Introduction to VX2 rabbit liver model and its applications in IO research.. 2. Two-step tumor induction protocol including tumor inoculation in donor rabbits, and laparotomy and hepatic implantation of recipient rabbits. 3. Comparison of VX2 cell suspensions and tumor fragments, including preparation methods, advantages, and limitations. 4. Macroscopic and microscopic histopathological features of VX2 tumors and their imaging features. 5. Perioperative protocols of anesthesia and analgesia. 6. Guidelines for postoperative care and surgical complication management. 7. SOP for transarterial access and embolization and microwave ablation of VX2 liver tumors.

IREE-10 SEALING THE LEAK : FROM DIAGNOSIS TO EPIDURAL BLOOD PATCH

Jyoti Narayan, MBBS (*Presenter*)
Tanvi Gowadia, MBBS (*Abstract Co-Author*)
Shrinivas B. Desai, MD (*Abstract Co-Author*)

TEACHING POINTS

Clinical vigilance supplemented by Imaging transforms radiology into a powerful diagnostic tool in Spontanous Intracranial Hypotension (SIH). CT myelography is preferred for confirming and locating CSF leaks. Identifying resistance factors like plica dorsalis, arachnoid webs, and CSF-venous fistulas aids in treatment planning. Accurate localization supports targeted repair is preferred. When leak location is unknown, blind EBP still offers significant relief and imaging improvement. Dynamic CT myelography is especially effective. Radiologists must recognize misleading signs like the “C1-C2 sign,” which may falsely suggest craniocervical leaks. Treatment must be personalized—ranging from blood patches and fibrin glue to surgery—based on leak type and site.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of intracranial hypotension, including diagnostic tools like dynamic CT myelogram and EBP. Discusses MR myelogram, types, and causes of CSF leaks. Methods CT Myelogram Dynamic CT with contrast under fluoroscopy to locate CSF leaks. Emphasis on technique to avoid complications. Dynamic vs. conventional Needle/contrast choice Positioning, scanning, diagnostic tips Epidural Blood Patch (EBP) Blind EBP under CT/fluoroscopy. Indications, types, and approach Technical details Mechanism, positioning, care, failure reasons Cases & Discussion Highlights success of dynamic CT myelogram and EBP in SIH, with strong outcomes using blind patch technique. Conclusion Combined approach offers high effectiveness, low complication rates. Teaching Points Covers pitfalls and best practices.

IREE-11 MISSION POSSIBLE: A RADIOLOGIST’S GUIDE TO NAVIGATING THE RIGHT ADRENAL VEIN WITH CONFIDENCE

Mehreet Kaur Chahal (*Presenter*)
Ram Kishore R. Gurajala, MBBS, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Review adrenal venous anatomy and identify key fluoroscopic landmarks to facilitate precise and efficient right adrenal vein localization. Emphasize the importance of pre-procedural CT (Computed Tomography) in evaluating adrenal vascular anatomy and predicting potential obstacles. Provide a structured, stepwise approach to AVS (Adrenal Vein Sampling) . Address challenges in adrenal vein cannulation, focusing on technical difficulties, anatomical variations, and catheter selection. Discuss complications, pitfalls, and false-negative prevention through case-based learning.

TABLE OF CONTENTS/OUTLINE

Introduction :-Role of AVS in diagnosis of primary aldosteronism and guiding unilateral Vs Bilateral adrenalectomy decisions. Understanding the anatomical location of the right adrenal vein. Pre-Procedural Planning: Cross-sectional imaging for vascular anatomy and anatomic variants. Assessment of mass lesions, if any. ACTH Stimulation including preparation and importance. Challenges in Right adrenal Vein cannulation -Smaller Size of the vein. Difficulties in recognizing the typical vascular pattern. Confusion with other adjacent vessels - renal, hepatic, retroperitoneal and thus difficult fluoroscopic identification. Stepwise Algorithm for troubleshooting AVS : Flowchart Confirmation of Success : Imaging and Biochemical Analysis -How results determine success; Lateralization Index

IREE-12 HANDS UP, THIS IS A ROBBERY! SPLENIC STEAL SYNDROME IN LIVER TRANSPLANT: DIAGNOSIS AND INTERVENTIONAL MANAGEMENT

Daniel Campillo Amoros (*Presenter*)
Carolina Nieto Garcia (*Abstract Co-Author*)
Ines Bonnin, MD (*Abstract Co-Author*)
Sandra L. Barrero Varon, MD (*Abstract Co-Author*)
Raul Garcia (*Abstract Co-Author*)

TEACHING POINTS

1. Understanding the physiopathology of splenic steal syndrome (SSS), a vascular complication in liver transplant recipients, where excessive splenic artery flow compromises hepatic arterial perfusion. 2. Identify key diagnostic features and imaging findings. 3. Review interventional radiology techniques, focusing on embolization of the splenic artery to restore hepatic arterial flow and graft viability.

TABLE OF CONTENTS/OUTLINE

1. Physiopathology of SSS in liver transplant patients. 2. Clinical and analytical presentation of SSS. 3. Diagnosis of splenic steal syndrome: a. US/US-Doppler: decreased hepatic artery flow and increased splenic artery velocity. b. Computer Tomography: prominent splenic artery, early splenic hyperenhancement and hepatic artery caliber decrease. c. Digital Subtraction Angiography (DSA): Gold Standard. Confirmatory tool showing dominant splenic flow. 4. Interventional Radiology treatment: Embolization. Techniques, materials used and expected outcomes.

IREE-13 TREATMENT APPROACH FOR A PORTAL CAVERNOMA WITH BILIARY OBSTRUCTION

Ammar Jawad (*Presenter*)
Pratiik Kaushik (*Abstract Co-Author*)
Devi Preetham Veeramgari (*Abstract Co-Author*)
Calvin Nguyen (*Abstract Co-Author*)
Christopher W. Bailey, DO (*Abstract Co-Author*)

TEACHING POINTS

1. To understand the clinical presentation and complications that arise from portal cavernomas and discuss various approaches for their treatment.2. Illustrate the role of multidisciplinary consultation in the management of portal cavernomas.3. Provide trainees with a primer on associated portal cavernoma radiological findings.

TABLE OF CONTENTS/OUTLINE

Background: introduce readers to cavernous transformations of the portal vein and common treatment approaches. Pathophysiology: describe the hepatobiliary mechanisms and etiologies behind portal cavernomas, as well as their various clinical presentations and complications. Case example/imaging: review clinical findings and radiological associations corresponding with a portal cavernoma case. Treatment approaches: in depth discussion of the progression from historically used management strategies (medical therapy, endoscopic/surgical operations) to minimally invasive image-guided interventions performed by interventional radiologists with the aid of a clinical decision making flowchart. Summary: Cavernous transformations of the portal vein (CTPV), known as portal cavernomas, are a sequela of chronic portal vein thrombosis (PVT) and may result in varices and splenomegaly due to biliary obstruction and portal hypertension. These malformations present correlative radiological and clinical findings. Treatment wise, this condition was historically treated endoscopically and/or surgically; however, minimally invasive image-guided therapies performed by interventional radiologists are now becoming increasingly employed. Step-wise multidisciplinary management aids clinical decision making and understanding.

IREE-14 IMMERSIVE EDUCATION FOR INTERVENTIONAL RADIOLOGY USING SPATIAL COMPUTING AND EXTENDED REALITY: STRATEGIES FOR ENHANCING SPATIAL UNDERSTANDING

Maki Sugimoto, MD, PhD (*Presenter*)
Takuya Sueyoshi (*Abstract Co-Author*)

TEACHING POINTS

2D IVR Imaging Limits 2D (CT, MRI) image reliance in IVR hinders 3D anatomy/instrument understanding, a key learning barrier. XR for Spatial Insight XR (VR/MR) offers spatial organ visualization, improving 3D anatomical understanding over planar images & boosting education. App 1: Cerebral Coiling XR spatial vascular models aid pre-op coil shaping simulation for aneurysms, enhancing device selection & procedural learning. App 2: TAVI Planning XR simulation for TAVI allows spatial valve-coronary assessment, aiding pre-op planning & reducing complication risks (e.g., PCI). App 3: RFA Guidance XR spatial indicators (virtual paths, "Green Zones") for RFA clarify needle trajectory/angle, promoting safer, effective procedural training. App 4: Hybrid OR Navigation XR with landmarks (clips) for 3D registration improves orientation/understanding in complex hybrid OR procedures (e.g., cholangiography).

TABLE OF CONTENTS/OUTLINE

Intro Traditional IVR education challenges & XR paradigm shift. XR Fundamentals Spatial visualization benefits & immersive learning. XR Apps in IVR Cerebral Coiling: 3D simulation. TAVI: Pre-op planning. RFA: Safer puncture training. Hybrid OR: Better navigation/spatial sense. XR Education Implementation Integration & practicalities. Conclusion Future potential & impact of XR in IVR education.

IREE-15 LYMPHANGIOGRAPHY IN INTERVENTIONAL RADIOLOGY: CUTTING-EDGE TECHNIQUES FOR AN OLD-SCHOOL PROCEDURE

Pedro Vicenzo Deo Malaquini, MD (*Presenter*)
Daniel Cabrera, MD (*Abstract Co-Author*)
Fernanda Prazeres (*Abstract Co-Author*)
Soraia Damiao, MD (*Abstract Co-Author*)
Enji Y. Mallmann I (*Abstract Co-Author*)
Caio Cesar G. Amorim, MD (*Abstract Co-Author*)
Aline Cavalcante (*Abstract Co-Author*)
Charles E. Zurstrassen, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

Lymphatic interventions are increasingly relevant for managing postoperative lymphatic complications, such as refractory chylous leaks and lymphatic fistulas. Knowledge of lymphatic anatomy and access techniques—especially intranodal and thoracic duct embolization—is essential for procedural success. Image-guided lymphangiography remains a key diagnostic and therapeutic tool in interventional radiology.

TABLE OF CONTENTS/OUTLINE

Introduction to Lymphatic Interventions & General Anatomy of the Lymphatic System. Lymphangiography Techniques and Access Routes, including Intranodal Lymphangiography, Transabdominal and Transvenous Thoracic Duct Access, Peripheral and Direct Puncture Techniques. Main lymphatic pathologies, Key lymphatic intervention and example of Lymphatic fistula identified on lymphangiography in a patient who underwent a robotic prostatectomy - followed by embolization of the right inguinal lymph node. Thoracic Duct Embolization after Lobectomy and Mediastinal lymphadenectomy. Thoracic Duct Embolization by retrograde catheterization.

IREE-16 BEYOND CLOSURE: RETHINKING PULMONARY ARTERIOVENOUS MALFORMATIONS, ENDOVASCULAR THERAPY, AND PERSISTENCE MANAGEMENT

Sai Swarupa R. Vulasala, MD (*Presenter*)
Naga Sai Rasagna Mareddy, MBBS (*Abstract Co-Author*)
Lourdhu Pragna Onteddu (*Abstract Co-Author*)
Aryan Sharma (*Abstract Co-Author*)
Sanjeeva P. Kalva, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Describe the type of PAVMs and review their imaging features2. Outline the patterns of persistent PAVM despite successful embolization.3. Detail the management of the persistent PAVM depending on the pattern of persistence. Pulmonary arteriovenous malformations (PAVM) are the fistulous connections between feeding pulmonary arteries and draining pulmonary veins without intervening capillary bed. They are commonly associated with hereditary hemorrhagic telangiectasia (HHT) syndrome and are discovered incidentally on a screening transthoracic contrast-enhanced echocardiogram. Further confirmation can be obtained with computed tomographic angiography or magnetic resonance angiography. Endovascular embolization of the feeding vesels can be performed to exclude the PAVM from the pulmonary circulation. Coils and plugs are the two most employed embolization agents in the current clinical practice. Despite successful embolization, the persistence of PAVM is not uncommon. Follow up imaging demonstrates filling of venous sac or draining vein through recanalization of the feeding artery, accessory feeding pulmonary artery, systemic arteries, or retrograde pulmonary venous filling. This presentation will focus on these patterns of persistence and their management.

TABLE OF CONTENTS/OUTLINE

1. Types of PAVM2. Incidence and syndrome association3. Clinical presentation4. Imaging appearance of different types of PAVM5. Indications for intervention6. Currently employed endovascular therapies7. Types of PAVM persistence8. Various factors associated with persistence9. Management of the persistent PAVM

IREE-17 URETEROARTERIAL FISTULAS: INSTITUTIONAL EXPERIENCE IN DIAGNOSIS AND TREATMENT OF A RARE BUT INCREASINGLY COMMON HIGH MORBIDITY CONDITION

Danielle Cadoret, MD, BSc (*Presenter*)
Mohannad S. Behairy, MD (*Abstract Co-Author*)
Younes Jahangiri, MD (*Abstract Co-Author*)
Aaron Leach, MD, BA (*Abstract Co-Author*)
Chirag Patel, MD (*Abstract Co-Author*)
James J. Morrison, MD (*Abstract Co-Author*)
Bryan R. Mustert, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review the pathogenesis, clinical presentation, risk factors and diagnosis of ureteroarterial fistulas (UAFs). • Compare endovascular and surgical treatment; understand the leading role of IR in practice. The following teaching points will be demonstrated using real institutional cases from 2018-2024: • Assess patient and situational needs for optimal peri-procedural care. • Describe technical aspects of endovascular repair. • Understand common and catastrophic complications of endovascular repair. • Understand clinical followup required for UAF and what to look for. • Know the specialties involved in multidisciplinary care of UAF, what to rely on them for, and Radiology (IR and DR)'s role.

TABLE OF CONTENTS/OUTLINE

1. Introduction to ureteroarterial fistulas (UAFs). 2. Pitfalls in Diagnosis: how to not miss a UAF. 3. UAF Treatment Options and Radiology's Role. 4. Real life cases: spot the UAF. 5. Case series demonstration on endovascular repair technique. 6. Peri, procedural and post-procedural complications with case series examples. 7. Know your plan: short and long-term followup post-procedure. 8. Know your friends: players involved in the multidisciplinary care of UAFs

IREE-18 IMAGE-GUIDED PERCUTANEOUS SHARP RECANALIZATION OF CENTRAL VENOUS OCCLUSION: TECHNIQUE AND PEARLS

Alex Stevens, DO (*Presenter*)
Zac Ohs (*Abstract Co-Author*)
Mario Dervishi, MD (*Abstract Co-Author*)
Nami R. Azar, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

Central venous occlusions (CVOs) are increasingly prevalent due to chronic catheter use, dialysis access, and malignancy. When conventional wire and catheter techniques fail, cross-sectional guided sharp recanalization provides a viable salvage technique. Knowledge of the technique, tools, and imaging features is essential for radiologists involved in diagnosis, management, and post-procedural evaluation. General radiologists should be familiar with patient selection, procedural steps, potential complications, and interpretation of follow-up imaging.

TABLE OF CONTENTS/OUTLINE

Central venous occlusions (CVOs), particularly involving the thoracic central veins, are increasingly encountered in patients with chronic indwelling catheters, dialysis access, or malignancy. When conventional wire and catheter techniques fail, a cross-sectional guided sharp recanalization offers a viable and alternative option to restore venous patency and preserve critical vascular access. This educational exhibit reviews the fundamentals of sharp recanalization, with an emphasis on the cross-sectional technique, required tools, and key imaging features. Practical tips for general radiologists are provided to enhance understanding of this high-stakes technique, including recognizing candidates for referral, interpreting post-procedure imaging, and anticipating complications.

IREE-19 Y-90 OUTSIDE HCC AND MCRC: REVIEW OF Y-90 TREATMENT IN HEPATIC METASTATIC DISEASE

Steven Meng, MD (*Presenter*)
Sang Bum Lee (*Abstract Co-Author*)
June Kim (*Abstract Co-Author*)
Jamaal Benjamin, MD, PhD (*Abstract Co-Author*)
Moaz Choudhary, MD (*Abstract Co-Author*)
Seung Kwon Kim, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Overview of current indications for Y-90 and treatment types. 2) Review of literature for uses in various cancers with hepatic metastases. 3) Explore case examples of Y-90 treatment in hepatic metastases.

TABLE OF CONTENTS/OUTLINE

1) Current indications for Y-90 microspheres. 2) Treatment strategies based on tumor burden, clinical status, patient factors. 3) Overview literature for uses of Y-90 in various hepatic metastatic disease, exploring tumor response, safety profile, and overall survival. 4) Case example of breast cancer, renal cell carcinoma, and uveal melanoma with hepatic metastases. Additional cases may be added. References: 1) Feretis M, Solodkyy A. Yttrium-90 radioembolization for unresectable hepatic metastases of breast cancer: A systematic review. IREE-20 HOW TO PERFORM PERCUTANEOUS CHOLECYSTOLITHOTOMY: A REVIEW OF PROCEDURAL INDICATIONS, TOOLS AND STEPS, AND POST-PROCEDURE MANAGEMENT

Sang Bum Lee (*Presenter*)
Steven Meng, MD (*Abstract Co-Author*)
June Kim (*Abstract Co-Author*)
Akram Sadeghi, MD (*Abstract Co-Author*)
Seung Kwon Kim, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Overview procedural tools and steps commonly used in percutaneous cholecystolithotomy for calculous cholecystitis. 2) Review indications for percutaneous cholecystolithotomy based on size and number of stones. 3) Review management algorithms for percutaneous cholecystolithotomy. 4) Discuss outcomes for percutaneous cholecystolithotomy in current literature.

TABLE OF CONTENTS/OUTLINE

1) Discussion of current indications and contraindications for percutaneous cholecystolithotomy. 2) Overview cholecystolithotomy tools including Spyglass, electrohydraulic lithotripsy, laser, and stone basket. 3) Overview procedural steps, including discussion of size- and number-based approach. 4) Discuss management algorithm, including considerations and timing for re-intervention or tube removal. 5) Review case example of cholecystolithotomy. 6) Review current literature on outcomes of cholecystolithotomy. References: 1) Kim SK, Mani NB, Darcy MD, Picus DD. Percutaneous cholecystolithotomy using cholecystoscopy. Percutaneous transhepatic cholecystolithotomy by holmium laser for non-high-risk patients with symptomatic gallbladder stones. Med Arch. 2022;76(1):29-33.

IREE-21 OPTIMIZING BILIARY DRAINAGE: A TECHNICAL AND IMAGING REVIEW OF ARTICULATED PLASTIC STENT USE FOR STRICTURE MANAGEMENT

Mary Foster (*Presenter*)
Jesus Beltran-Perez, MD (*Abstract Co-Author*)
Jorge E. Lopera, MD (*Abstract Co-Author*)

TEACHING POINTS

Articulated plastic biliary stents (APBS) provide a valuable alternative for percutaneous transhepatic drainage (PTBD) of complex hilar strictures. Obstruction at the hilum is challenging due to complexity of ductal anatomy, often requiring two or more PTBD.APBS provide an advantage of achieving drainage of two or more biliary ducts using a single percutaneous access.APBS allows achieving a very large internal diameter at area of stenosis while using smaller drain externally, improving patient comfort and limiting complications.APBS may result in decreased complications associated with blockage of smaller bile ducts by large bore catheters.

TABLE OF CONTENTS/OUTLINE

Intro to APBS. Indications for APBS. Possible stent configurations (T-, Y-, and double barrel configurations) and the common applications for each. Stepwise technique and materials needed to fabricate articulated plastic biliary stents. Patient Case 1: Deployment of APBS for left-sided biliary duct. Patient Case 2: Deployment of APBS for right-sided biliary duct. Patient Case 3: Challenging stent exchange. Complications of APBS.

IREE-22 ENTERIC ACCESS: PRACTICAL GUIDE FOR THE INTERVENTIONAL RADIOLOGIST

Kenneth N. Huynh, DO (*Presenter*)

TEACHING POINTS

1. Review the relevant gastrointestinal anatomy, indications/contraindications, and equipment used for percutaneous enteric access. 2. Present different techniques to percutaneous enteric access, including push-/pull-type gastrostomy, gastrojejunostomy, direct jejunostomy, and transesophageal gastrostomy. 3. Review technical considerations, post-procedural care, and complications related to percutaneous enteric access.

TABLE OF CONTENTS/OUTLINE

Optimal nutrition is essential to the recovery and quality of life in patients whose oropharyngeal or gastrointestinal anatomy, or function, precludes safe oral intake. The prevalence of dysphagia from stroke and neurodegenerative disease, head-and-neck or upper-GI malignancies, severe gastroparesis, and post-surgical or radiation changes is rising, increasing the demand for durable access for enteral nutrition. Image-guided percutaneous techniques can circumvent the limitations of endoscopic or surgical approaches, accommodate hostile abdomens, and allow precise placement in altered anatomy. Familiarity with different enteric access options—gastrostomy, gastrojejunostomy, jejunostomy, and trans-esophageal gastrostomy—allows interventional radiologists to directly impact patient outcomes. This educational exhibit will (1) review relevant GI anatomy and indications for enteric access, (2) present different techniques for enteric access and considerations for successful placement and exchange, and (3) discuss post-procedural care such as routine tube maintenance, troubleshooting (peristomal leakage, buried bumper, clogging), and complications such as hemorrhage, aspiration, and gastric or duodenal obstruction.

IREE-23 TIPS FOR EVOH EMBOLIZATION: EVOH IN THE PORTOVENOUS SYSTEM

Alexander Weinstein, BS (*Presenter*)
Amin Golamy-Sadig (*Abstract Co-Author*)
John A. Walker, MD, PhD (*Abstract Co-Author*)
Jorge E. Lopera, MD (*Abstract Co-Author*)
Carlos B. Ortiz, MD (*Abstract Co-Author*)

TEACHING POINTS

Review imaging and technical aspects of ethylene-vinyl alcohol copolymer (EVOH) (LAVA and Onyx) embolization for the treatment of bleeding varices. Recognize cases where EVOH embolization can effectively embolize varices. Understand the importance of catheter positioning to avoid potential complications when using EVOH in the

portovenous system. Technical review of different access techniques for embolization in the portovenous system.

TABLE OF CONTENTS/OUTLINE

Introduction to EVOH embolization embolic properties, prior literature, preparation, and current use of LAVA and Onyx. Review variceal anatomy and access required for embolization gastroesophageal, coronary, splenic, gastric, splenorenal shunts, and paraumbilical veins. Technical steps to prepare for safe EVOH embolization EVOH concentration selection, proper mixing, catheter stability, and secure microcatheter position for safe embolization. Review important imaging considerations while performing EVOH embolization for proper visualization increasing fluoroscopy dose, collimation, magnification, adequate mixing of EVOH, and use of roadmaps in dense EVOH. Various cases to demonstrate teaching points, procedural steps, and imaging considerations TIPS creation with embolization, transhepatic access, percutaneous varix access, and femoral/jugular access for splenorenal shunts. Outcomes, Limitations, and Complications. Conclusion: EVOH embolization can serve as a quick and effective method for embolization of varices in the portovenous system. There are important technical and procedural considerations for application of this novel technique in the treatment of variceal bleeding.

IREE-24 MECHANICAL THROMBECTOMY FOR PE: TOOLS AND LESSONS FROM COMPLICATIONS

Matteo Conte, MD (*Presenter*)
Anne Sailer, MD (*Abstract Co-Author*)
Hamid R. Mojibian, MD (*Abstract Co-Author*)
Joshua Cornman-Homonoff, MD (*Abstract Co-Author*)

TEACHING POINTS

Mechanical thrombectomy for PE is a fast-evolving technique that delivers rapid hemodynamic improvement. As devices expand the scope of treatment, understanding their specific roles and associated risks becomes critical. This case-based exhibit follows the procedural sequence, highlighting tool selection and complication management.

TABLE OF CONTENTS/OUTLINE

(1) Tools. Mechanical thrombectomy requires selecting devices based on clot burden, location, and anatomy. Teaching points cover pros and cons of widely used tools, each designed for specific pulmonary embolism niches. (2) Access Site. Initial femoral or jugular venous access carries risks like arterial puncture, pseudoaneurysm, and retroperitoneal hematoma. Sheath insertion may dislodge iliofemoral DVT or cause vessel injury. Teaching points address recognition, prevention, and management. (3) Crossing the Heart. Passing wires and catheters through the right atrium and ventricle can cause arrhythmias, valvular trauma, or pericardial effusion. Teaching points highlight wire selection, crossing technique, and fluoroscopic or hemodynamic cues for early injury detection. (4) When the Tool Becomes the Threat. Device-related pulmonary artery complications include vessel perforation (from direct injury or aggressive aspiration) and embolic dislodgement (from incomplete aspiration or clot adhesion). Teaching points focus on recognizing, managing, and preventing such events. (5) Bleeding. Post-procedural bleeding may result from access site issues, anticoagulation mismatch, or unrecognized injuries—leading to hemoptysis, pleural effusions, or instability. Teaching points emphasize targeted imaging, and timely intervention.

IREE-25 BRIDGING VISUAL AND RADIOLOGIC GUIDANCE: THE ROLE OF ENDOSCOPES IN INTERVENTIONAL RADIOLOGY

Mehdi Siddiqui, MD (*Presenter*)
Fei Ye (*Abstract Co-Author*)
Novin Nekoui, BA (*Abstract Co-Author*)
John A. Walker, MD, PhD (*Abstract Co-Author*)
Samy Al-Bayati, MD (*Abstract Co-Author*)
Jorge E. Lopera, MD (*Abstract Co-Author*)

TEACHING POINTS

Minimally invasive techniques such as endoscope-guided interventions can be utilized in the management of a wide variety of complex conditions. By combining radiologic imaging with high-resolution endoscopic visualization, these techniques can enhance diagnostic accuracy and targeted therapy. Here, we present a series of cases highlighting the versatility of endoscope-guided interventions in the management of gastrointestinal and urologic conditions.

TABLE OF CONTENTS/OUTLINE

Endoscopic guidance can be crutial in geniturinary interventions for obtaining access to the ureter from the bladder, removal of ureteral stents that are in difficult positions or cannot be easilty retracted Using endoscopes in the hepatobiliary cases can help both in diagnosis and treatment of biliary disease In settings of necrotizing pancreatitis, endoscopes can be used to evaluate for necrotic debris that are otherwise not able to be appreciated using flouroscopy aloneIn cases where imaging is equivacal, endoscopes can be a great tool for better ellucidate a diagnosis

IREE-26 COMPLEX IVC FILTER RETRIEVAL

Zachary Fitzgerald, BS (*Presenter*)
Madison Mills, BS (*Abstract Co-Author*)
Peyton Hopkins (*Abstract Co-Author*)
Dan F. Laney IV, MD (*Abstract Co-Author*)
Alexandra H. Fairchild, MD (*Abstract Co-Author*)
Bahri Ustunsoz, MD (*Abstract Co-Author*)
Hector Ferral, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand key anatomic and technical factors that complicate inferior vena cava (IVC) filter retrieval. Review retrieval techniques and tools tailored to complex scenarios. Have a clearly defined backup strategy and recognize the 'point of no return' to safely manage challenging filter retrievals.

TABLE OF CONTENTS/OUTLINE

Overview of Complex IVC Filter Retrieval: Common complicating factors: Filter migration, Filter Tilt, IVC Invasion Fractured or damaged filters Dwelling length and presence of clot Median dwell time is 196 days for successful removal vs 375 days for failed removal Filter Classification: Identifying open vs closed cell filters Closed cell filters often require more advanced techniques for removal and certain filters are more prone to fracture Advanced Retrieval Techniques: Techniques will be demonstrated through case examples & 9;& 9;Hangman technique Loop Snare With Single Access / Realignment Technique Tilted Filter-Straightening Single Access / Stiff Wire-Displacement Technique Wire Loop-and-Forceps / A modified version of the Sling Technique Rigid Bronchoscopy Forceps, Thermal, Etc / Dissection Technique& 9;& 9; Filters that can be removed from the femoral approach Procedural Planning and post-operative management: & 9;& 9;Always have a back up plan& 9;& 9; Knowing your point of "No return" Follow suspected complications closely with imaging

IREE-27 PROJECTION-BASED APPROACH TO PULMONARY ANGIOGRAPHY: NAVIGATING EACH SEGMENT

Matteo Conte, MD (*Presenter*)
Anne Sailer, MD (*Abstract Co-Author*)
Joshua Cornman-Homonoff, MD (*Abstract Co-Author*)
Hamid R. Mojibian, MD (*Abstract Co-Author*)

TEACHING POINTS

Cutting edge pulmonary interventions have increased the need for precise pulmonary angiography over time. However, fluoroscopic interpretation is often limited by misleading 2D projections that compromise navigation and accuracy. Mastering oblique views and real-time recognition of vascular landmarks enhances catheter control,

segmental access, and procedural success. By combining multiplanar reconstructions (MPR) with live angiography, interventionalists can anticipate anatomical variation, troubleshoot deceiving views, and avoid critical errors during high-risk procedures.

TABLE OF CONTENTS/OUTLINE

(1) Mastering Projectional Imaging in Pulmonary Angiography. Proper use of oblique views resolves ambiguous fluoroscopic appearances. This section introduces "deceiving views" and demonstrates troubleshooting through C-arm rotation and image alignment. Practical examples show how to visualize hidden vessels and distinguish overlapping structures. (2) Segmental Navigation and Superselection: A Systematic Approach. A step-by-step method for consistent pulmonary segment selection is presented. Each segment is reviewed using a multimodal workflow: axial CTA, preferred-projection CTA, 3D reconstruction, and angiographic correlation. This sequence connects static imaging to live navigation using anatomical reasoning. (3) Case-Integrated Learning. Clinical cases illustrate segmental access, projection planning, and superselection across diverse pathologies (e.g., AVMs, PE, aneurysms). Selected examples highlight how missteps in planning lead to delays or suboptimal views, reinforcing the value of structured angiographic technique.

IREE-28 HOW CAN IR CONTRIBUTE TO THE MANAGEMENT OF VASCULAR COMPLICATIONS POST PANCREATICODUODENECTOMY?

Hiroaki Kato, MD, PhD (*Presenter*)
Masashi Fujimori, MD, PhD (*Abstract Co-Author*)
Yuki Yamaoka (*Abstract Co-Author*)
Ryosuke Shima, MD (*Abstract Co-Author*)
Yuki Omori (*Abstract Co-Author*)
Hikari Fukui (*Abstract Co-Author*)
Takanori Kokawa, MD (*Abstract Co-Author*)
Naritaka Matsushita, MD (*Abstract Co-Author*)
Takashi Yamanaka, MD (*Abstract Co-Author*)
Hajime Sakuma, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Vascular complication is one of the fatal complications after pancreaticoduodenectomy and surgical repair is challenging. This educational exhibit will outline the vascular complications post pancreaticoduodenectomy and discuss how IR can treat and save the patients with the vascular complications after pancreaticoduodenectomy. -To review the anatomy of abdominal organs and vessels post pancreaticoduodenectomy -To identify common vascular complications post pancreaticoduodenectomy -To discuss minimally invasive treatment options to manage vascular complications post pancreaticoduodenectomy

TABLE OF CONTENTS/OUTLINE

1. Anatomy of Abdominal Organs and Vessels post Pancreaticoduodenectomy a) Location of Reconstructed Abdominal Organs b) Anatomy of Arteries and Portal Vein c) Vessels Potentially Work as Collateral Vessels for Critical Organs 2. Arterial Complications Post Pancreaticoduodenectomy a) Symptoms b) Location of Involved Arteries c) Computed Tomography Images of Arterial Complications 3. Endovascular Treatment for Arterial Complications a) Coiling b) Stent Graft Placement c) Endovascular Treatment with Drainage for Bile/Pancreatic juice leakage 4. Venous Complications Post Pancreaticoduodenectomy a) Symptoms b) Extrahepatic Portal Venous Stenosis/Occlusion c) Computed Tomography Images of Venous Complications 5. Endovascular Treatment for Venous Complications a) Stenting i. Percutaneous Transhepatic Approach ii. Under Laparotomy b) Thromectomy c) Anticoagulant or Antiplatelet Therapy after Stenting

IREE-29 HEMOPTYSIS IN LUNG CANCER: AN OVERVIEW OF ENDOVASCULAR MANAGEMENT

Antoine Khalil, MD, PhD (*Presenter*)
Waqaas Mohammad (*Abstract Co-Author*)
Ahmed Tibaoui (*Abstract Co-Author*)
Salma Attia (*Abstract Co-Author*)
Khaled Kadri (*Abstract Co-Author*)
Valerie Gounant (*Abstract Co-Author*)

TEACHING POINTS

The knowledge of the pathophysiology and natural history of bronchial cancer provides insight into the mechanisms of hemoptysis More than identification of the BA network, the CT-angio, by showing signs in favor of an erosion of the pulmonary artery, i.e. necrosis and visualization of a false aneurysm of the PA, is the cornerstone examination in the pre-therapeutic workup Indications of endovascular treatment are guided by the rate (>200mL/24-48h), the tolerance, the presence of CT-angio signs of PA erosion, and in preventive situation in case of necrotizing large cancer before chemotherapy Covered stent is the treatment of choice of proximal PA injuries however, coils or liquid are used for distal PA The recurrencies of hemoptysis after treatment could be in relation with a different mechanism, ectopic systemic artery or progression of the disease

TABLE OF CONTENTS/OUTLINE

Introduction Lung tumor vascularization Physiopathology of hemoptysis in patients with lung cancer Role of CT-angiography in the pre endovascular treatment workup Indication of endovascular embolization Active hemoptysis: rate/24-48h; tolerance of hemoptysis Preventive treatment: lung cancer necrosis A- Systemic artery embolization: Technique (bronchial artery embolization "BAE" and systemic non bronchial artery embolization) Results of Systemic Artery Embolisation How to deal with recurrences or failures? B- Pulmonary artery management: Technique (Pulmonary artery occlusion "PAO" and Pulmonary artery stenting "PAS") Results of Pulmonary artery management How to deal with recurrences or failures? Clinical Cases Conclusion

IREE-30 WHAT TO DO WHEN "URINE" TROUBLE: GENITOURINARY CATHETER COMPLICATIONS AND THEIR MANAGEMENT

Caleb Walker, DO (*Presenter*)
Kamil Bahit, MD (*Abstract Co-Author*)
Lap-Heng Keung, MD (*Abstract Co-Author*)
Jaimin D. Shah, MD (*Abstract Co-Author*)

TEACHING POINTS

1: Genitourinary catheters are common devices to treat a number of genitourinary disorders. Because of their wide-spread use, familiarity with the types of catheters, their complications and typical presentations, as well as their management, is important to understand for both the diagnostic radiologist and interventional radiologist alike. 2: Imaging evaluation may involve a range of modalities, including ultrasound, CT, MRI, and Nuclear Medicine. Fluroroscopy is a mainstay in diagnosing and managing complications. 3: Common catheter complications may arise from catheter itself, such as malfunction, obstruction, dislodgement and malposition. Other issues may arise outside of the catheter, such as pain along the catheter track, hematuria, or infection. Additional catheter complications include injury to the collecting system which may result in urine leaks, injury to the renal vasculature resulting in pseudoaneurym or arteriovenous fistula formation, or injury to adjacent organs during placement. 4: Complications are typically managed via catheter exchange, upsizing, repositioning, or converting to alternative diversion methods.

TABLE OF CONTENTS/OUTLINE

Introduction. Types of Catheters. Indications and Contraindications for Placement. Procedure Care and Chronic Catheter Management Evaluation of Potential Complications Imaging Complications and Management Catheter Malfunction and Obstruction Malposition and Dislodgement Hemorrhage Infection Pain, Discomfort, and Urinary Symptoms Pseudoaneurysm Formation Urine LeakAdjacent Organ Injury, Fistula Formation and Pneumothorax Five Cases Illustrating Complications and Management Citations

IREE-32 TRICUSPID VALVE VEGETECTOMY USING TRANSESOPHAGEAL OR INTRACARDIAC ECHOCARDIOGRAPHY GUIDED LARGE BORE MECHANICAL ASPIRATION: AN INSTITUTIONAL EXPERIENCE UTILIZING A NOVEL TECHNIQUE AND THE EVOLVING ROLE OF IR IN THE MULTIDISCIPLINARY CARE OF PATIENTS WITH RIGHT SIDED INFECTIVE ENDOCARDITIS

Behairy, MD (*Presenter*)
Zachary T. Vandeveer, MD (*Abstract Co-Author*)
Dylan Goldsmith, MD (*Abstract Co-Author*)
Christopher D. Swenson, MD (*Abstract Co-Author*)
Jarrod MacFarlane, DO (*Abstract Co-Author*)
James J. Morrison, MD (*Abstract Co-Author*)

TEACHING POINTS

Infective endocarditis, particularly drug use associated right-sided infective endocarditis, is a condition with high rates of morbidity and mortality requiring complex multidisciplinary care For high-risk surgical patients with tricuspid valve (TV) vegetations, large-bore mechanical aspiration offers a viable, minimally invasive treatment alternative. Institutional experience demonstrates the feasibility, safety, and clinical success of echocardiography-guided endovascular tricuspid valve vegetation debulking in selected patients with right-sided IE.

TABLE OF CONTENTS/OUTLINE

Overview of Infective Endocarditis - Epidemiology, pathophysiology, and clinical presentation of right-sided IE - Risk factors and complications. Unique challenges with drug use associated IE Therapeutic Approaches - Medical and surgical management of TV vegetations - Percutaneous vegetectomy: vacuum-assisted and mechanical aspiration techniques. Indications, considerations and outcomes Institutional Experience and Case Series - Technical insights using the Inari FlowTriever system - Periprocedural considerations in patient selection - Outcomes and lessons learned from 8 patients, including special scenarios such as pregnancy, prosthetic valves and intracardiac devices Conclusions - Evolving role of interventional radiology in multidisciplinary care - The need for more robust studies evaluating short- and long-term outcomes of percutaneous vegetectomy.

IREE-33 TARGETED, MINIMALLY INVASIVE, EFFECTIVE: PROSTATIC ARTERY EMBOLIZATION FOR BENIGN PROSTATIC HYPERPLASIA

Serhat Akis, MD (*Presenter*)
Melike Z. Akis, MD (*Abstract Co-Author*)
Raif Can Yarol, MD (*Abstract Co-Author*)
Afonso Q. Fonseca, MD (*Abstract Co-Author*)
Tiago Bilhim, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand benign prostatic hyperplasia (BPH) as a common cause of bladder outlet obstruction in aging men, presenting with storage (nocturia, urgency, frequency) and voiding (hesitancy, weak stream, incomplete emptying) symptoms that require careful differentiation from other urologic conditions. Prostatic artery embolization (PAE) is a minimally invasive option for moderate to severe BPH-related symptoms with a growing role in current guidelines. Learn comprehensive pre-procedural assessment for PAE, including uroflowmetry, symptom scoring (IPSS and QoL), prostate volume, erectile function evaluation, PSA, and CT angiography for vascular mapping. Recognize the technical demands, including accurate artery identification within complex pelvic anatomy, and the role of cone-beam CT and advanced embolization techniques. PAE is a safe with fewer complications than surgery most of which resolve on their own.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of BPH pathophysiology, symptomatology, conventional treatments, and the emerging role of PAE as a minimally invasive alternative. PAE Candidacy: Patient selection criteria based on symptom severity, anatomical suitability, and surgical risk profile. Pre-procedural Evaluation Clinical, functional, and imaging assessments required for appropriate PAE planning. Techniques Detailed overview of PAE steps, vascular anatomy, image guidance, and advanced methods to enhance embolization safety and efficacy. Complications Common post-PAE adverse events, their management, and strategies to prevent non-target embolization. Comparison Clinical outcomes, complication rates, and advantages of PAE versus surgery.

IREE-34 3D DIFFERENTIABLE GAUSSIAN-BASED STRATEGY FOR CRYOABLATION PLANNING IN LIVER TUMORS

Xiaoyu Huang (*Presenter*)

TEACHING POINTS

1. A novel preoperative planning algorithm using 3D differentiable-Gaussians was developed to optimize hepatic tumor cryoablation strategies.2. The algorithm differentiates between tumors =5 cm and >5 cm, offering complete ablation plans for smaller tumors and combined complete/debulking plans for larger ones.

TABLE OF CONTENTS/OUTLINE

Purpose: This study proposes a preoperative planning algorithm for hepatic tumor cryoablation based on 3D differentiable-Gaussian-based planning strategy. The algorithm aims to provide complete or debulking ablation plans for different tumors. The safety was evaluated. Materials and Methods: A total of 47 tumors were included. Tumors with diameters =5 cm were planned for complete ablation, while those >5 cm were approached using a combined complete and debulking strategy. The algorithm automatically optimized puncture paths and generated multiple feasible plans. Clinicians rated the top five plans and selected the optimal one. The safety of these selected plans were assessed. Results: The median physician score for the selected plans was 1.50 (IQR: 1.00-1.50). For tumors <3 cm, the algorithm achieved a 100% complete ablation rate. For tumors 3-5 cm, complete coverage and complete ablation rates were 94.44% and 72.22%, respectively. For tumors >5 cm, complete coverage and complete ablation rates were 23.81% and 14.29%, respectively. Conclusion: A novel 3D differentiable-Gaussian-based planning strategy was proposed for hepatic tumor cryoablation. The algorithm-generated plans demonstrated favorable safety upon clinical evaluation.

IREE-35 IRREVERSIBLE ELECTROPORATION OF LIVER TUMORS NEAR CRITICAL STRUCTURES: A PRECISION IMAGE-GUIDED TECHNIQUE

Chris Jackel (*Presenter*)
Hunter Colson (*Abstract Co-Author*)
Andrew H. Shabila, MD (*Abstract Co-Author*)
Haseeb Ahmad (*Abstract Co-Author*)
Gaby E. Gabriel, MD (*Abstract Co-Author*)

TEACHING POINTS

Irreversible electroporation (IRE) is a non-thermal ablation technique particularly suited for liver tumors located near critical structures such as bile ducts, portal veins, and hepatic arteries. Unlike thermal methods, IRE minimizes collateral damage, making it ideal for anatomically challenging locations. Successful outcomes depend on meticulous pre-procedural imaging assessment, precise electrode placement, and ECG-gating to deliver energy safely and effectively. Familiarity with unique post-IRE imaging appearances is essential for accurately evaluating treatment response and differentiating expected changes from residual or recurrent tumors.

TABLE OF CONTENTS/OUTLINE

1. IRE mechanism and advantages over thermal ablation for challenging liver tumor locations 2. Patient selection and pre-procedural imaging assessment (Identifying tumors near vital structures using CT/MRI) 3. Technical approach: electrode configuration, parameters, and ECG-synchronization 4. Post-procedure imaging and follow-up protocols 5. Case demonstrations: Step-by-step review of complex case(s) with pre- and post-ablation imaging 6. Outcomes and complication avoidance strategies

IREE-36 CLEARLY VISUALIZING WHAT IS CHALLENGING TO SEE: THE TRANSFORMATIVE POTENTIAL OF ARTIFICIAL INTELLIGENCE-BASED SEGMENTATION IN IMAGE-GUIDED LIVER TUMOR THERAPIES

Noreen Siddiqi, MD (*Presenter*)
Jessica A. Marques Silva, MD (*Abstract Co-Author*)

McKell Woodland, PhD (*Abstract Co-Author*)
Mais M Al Taie (*Abstract Co-Author*)
Aashish C. Gupta, MS (*Abstract Co-Author*)
A. Kyle Jones, PhD (*Abstract Co-Author*)
Caleb Oconnor (*Abstract Co-Author*)
Iwan Paolucci, PhD (*Abstract Co-Author*)
Kristy K. Brock, PhD (*Abstract Co-Author*)
Bruno C. Odisio, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Liver and tumor contouring (segmentation) is essential in many aspects of image-guided liver tumor therapies within radiation, surgical, and interventional oncology. Liver tumor segmentation is particularly challenging due to tumor heterogeneity. 2. Segmentation tasks have historically entailed slice-by-slice manual contouring tumors on a medical image; a time-consuming and repetitive task for clinicians that is prone to inter-observer variation in results. 3. Artificial intelligence (AI)-based segmentation can streamline this process, enhancing both patient care and clinical workflow across specialties. Given this anticipated impact, clinicians should gain a foundational understanding of AI-based segmentation tools (models). 4. Developing AI-based segmentation models for liver tumors requires many high-quality labeled images for training, validation, and testing. 5. Before use in patient care, model performance must be assessed with quantitative, qualitative, and patient outcomes-based metrics. Continuous human oversight is required to assess for model failure. Nevertheless, this development process is worthwhile, as these models can offer high-quality, consistent outputs that enhance precision and reproducibility in image-guided therapies.

TABLE OF CONTENTS/OUTLINE

1. Exploring the World of Therapeutic Possibilities with Liver Segmentation 2. If it's not Measured, it's Just Maybe: Leveraging Segmentation to Overcome Limitations in Visual Ablative Margin Assessment 3. Know How Much You Grow: Preparing the Liver for Surgery with Portal Vein Embolization 4. The Basics of AI-Based Segmentation Model Development 5. Using Multi-Faceted Approaches to Evaluate Model Performance

IREE-37 DIRECT TO THE POINT: DIPS FOR PORTAL HYPERTENSION COMPLICATIONS IN CANCER PATIENTS: AN ALTERNATIVE APPROACH TO CONVENTIONAL INTERVENTIONS

Mohammad M. Khavandi, MD (*Presenter*)
Ketan Y. Shah, MD (*Abstract Co-Author*)
Milan N. Patel, MD (*Abstract Co-Author*)
Nariman Nezami, MD (*Abstract Co-Author*)
Bruno C. Odisio, MD, PhD (*Abstract Co-Author*)
Alda L. Tam, MD (*Abstract Co-Author*)
Steven Y. Huang, MD (*Abstract Co-Author*)
Armeen Mahvash, MD (*Abstract Co-Author*)
Joshua D. Kuban, MD (*Abstract Co-Author*)
Rahul A. Sheth, MD (*Abstract Co-Author*)
Peiman Habibollahi, MD (*Abstract Co-Author*)

TEACHING POINTS

Portal hypertension is a common complication in cancer patients, defined by an increased pressure gradient between the portal and systemic veins. Associated complications include variceal bleeding, refractory ascites, and hepatic hydrothorax. Transjugular Intrahepatic Portosystemic Shunt (TIPS) has historically been employed to manage these complications. However, conventional TIPS can be technically challenging or unfeasible in cancer patients due to anatomical variance, tumor invasion, or hepatic vein thrombosis. Direct Intrahepatic Portosystemic Shunt (DIPS), which uses ultrasound and fluoroscopic guidance to access the portal vein directly from the inferior vena cava, has emerged as an alternative in these complex scenarios. This educational exhibit shows the role of DIPS in cancer, where conventional methods are not an option.1. Recognize clinical scenarios in oncology where conventional TIPS is not feasible, and DIPS becomes the preferred approach. 2. Understand essential imaging protocols, including ultrasound and intravascular ultrasound (IVUS), for planning and performing DIPS procedures. 3. Implement a structured algorithm for screening, timely identification, and management decisions for portal hypertension in cancer patients that would require appropriate intervention (TIPS vs. DIPS) based on individual anatomical and clinical factors.

TABLE OF CONTENTS/OUTLINE

1. Introduction to DIPS: Rationale and Clinical Indications in Cancer Patients 2. Clinical Decision-Making : Identifying Candidates for DIPS vs. TIPS 3. Essential Imaging and Procedural Protocols: Ultrasound and IVUS-Guided Technique 4. Clinical Impact: Evidence from Institutional Experience

IREE-38 COMMAND AND CONTROL: NAVIGATING LIVER ABLATION WITH ARTIFICIAL INTELLIGENCE AT YOUR SIDE

Jessica A. Marques Silva, MD (*Presenter*)
Noreen Siddiqi, MD (*Abstract Co-Author*)
Iwan Paolucci, PhD (*Abstract Co-Author*)
A. Kyle Jones, PhD (*Abstract Co-Author*)
Caleb Oconnor (*Abstract Co-Author*)
Kristy K. Brock, PhD (*Abstract Co-Author*)
Bruno C. Odisio, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Thermal ablation software supports the full procedural workflow, from procedure planning to case-end margin assessment; thereby enhancing consistency, reproducibility, and treatment precision. Accurate preprocedural planning and probe placement verification are critical for effective ablation. Software-based tools offer 3D visualization and spatial feedback that help clinicians select optimal trajectories and probe positions. Software-based assessment during CT-guided thermal ablation of liver tumors significantly improves the minimal ablative margin (MAM) compared to visual inspection, as demonstrated in the COVER-ALL randomized clinical trial, supporting its potential integration as a standard component of liver ablation workflows. The minimal ablative margin (MAM) is a key predictor of local tumor progression after liver ablation. Several software platforms have been developed to quantify the MAM using (artificial intelligence) AI-enhanced auto-segmentation and image registration techniques. Minimal ablative margin computation requires pre- and post-ablation images to be spatially aligned, which is achieved through image-to-image registration. Because liver deformation is common during ablation, deformable image registration—particularly biomechanical or AI-based—offers improved accuracy and anatomical plausibility over rigid techniques.

TABLE OF CONTENTS/OUTLINE

A New Player Enters the Game: Software-based methods in Liver Ablation Planning, Targeting, and Confirming: One Software, Many Moves Planning and Targeting — Getting It Right from the Start Precision Wins: From Visual Guesswork to Quantified Coverage Summary of Evidence on 3D Software for MAM Assessment

IREE-39 PERSONALIZED YTTRIUM-90 DOSIMETRY: A PRACTICAL FRAMEWORK FOR INTENT-BASED RADIOEMBOLIZATION

Arsalan Nadeem, MBBS (*Presenter*)
Ethan P. McMoran, MD (*Abstract Co-Author*)
Kasey Helmlinger, BS (*Abstract Co-Author*)
Husameddin El Khudari, MBChB (*Abstract Co-Author*)
Venkatesh P. Krishnasamy, MD (*Abstract Co-Author*)
Aliaksei Salei, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Define personalized dosimetry and key recommendations. 2. Present a stepwise approach to Yttrium-90 (Y-90) transarterial radioembolization (TARE) based on clinical factors and treatment goals. 3. Review imaging findings and clinical scenarios with pictorial examples.

TABLE OF CONTENTS/OUTLINE

Background : TARE using Y-90 glass or resin microspheres is a standard treatment for primary liver malignancies (hepatocellular carcinoma and cholangiocarcinoma) and metastatic disease, (colorectal cancer and neuroendocrine tumors). Emerging evidence supports that personalized dosimetry improves outcomes and reduces toxicity. Recent expert guidelines emphasize the role of incorporating personalized dosimetry into treatment planning. Introduction to Personalized Y-90 Dosimetry 1. Brief history of dosimetry development in Y-90 TARE. 2. Definitions and methods for activity prescription. 3. Comparison of glass vs. resin microspheres. 4. Patient eligibility criteria, including Child-Pugh Score and ALBI grade. Treatment Intent 1. Curative a) Radiation segmentectomy. b) Radiation lobectomy. 2. Palliative a) Multifocal unilobar disease. b) Multifocal bilobar disease. c) Macrovascular invasion. Pretreatment Planning and Technique 1. Importance of multidisciplinary team evaluation prior to TARE. 2. Dosimetry thresholds tailored to microsphere type and tumor biology. 3. Technical considerations: a) Mapping angiography. b) Importance of beam CT for accurate targeting and dosimetry. c) Lung shunt fraction: planar imaging and SPECT/CT. d) Tumor-to-normal liver ratio. e) Tools for multicompartment dosimetry. Treatment Verification and Post-TARE Imaging Protocols

IREE-40 MANAGEMENT OF COMPLICATIONS POST LUNG RADIOFREQUENCY ABLATION- HOW TO FIND AND HOW TO TREAT

Yuki Yamaoka (*Presenter*)
Masashi Fujimori, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Radiofrequency ablation (RFA) has been used as a local treatment for primary and metastatic lung tumors. The complication rate has been reported up to 50%. Though most of these complications were pneumothorax, fatal complications were also reported. Pulmonary artery aneurysm, bronchopleural fistula, and air embolism are such rare but potentially fatal complications after lung RFA. This educational exhibit will outline the complications post lung RFA and discuss how to find such fatal complications and manage the patients. -To review the preprocedural preparation, treatment procedure, and post-treatment follow-up of lung RFA -To outline the complications post lung RFA -To discuss treatment options to manage complications post lung RFA, including rare but potentially fatal complications.

TABLE OF CONTENTS/OUTLINE

1. Treatment Flow of Lung RFA a) Preprocedural Preparation b) Treatment Procedure c) Post-treatment Follow-up 2. Complications post Lung RFA a) Definition of Major/Minor Complications b) Mortality Rate post Lung RFA c) Minor Complications d) Major Complications 3. Treatment for Frequently Reported Complications post Lung RFA a) Pneumothorax b) Bleeding c) Pleuritis 4. Treatment for Rare but Potentially Fatal Complications a) Pulmonary Artery Aneurysm i) Symptoms ii) Image findings iii) Treatment b) Air Embolism i) Symptoms ii) Image findings iii) Treatment

IREE-41 STATE OF THE FIELD: INTERVENTIONAL RADIOLOGY & SPACE

Orhun Davarci (*Presenter*)
Roberto R. Galuppo Monticelli, MD (*Abstract Co-Author*)

TEACHING POINTS

With NASA having plans to send a manned mission to Mars in 2030s, a significant question have arisen within the aerospace medicine and the medical community at large as to how to provide urgent and emergent medical care to the astronauts on long term missions. It has been proposed that rising field of interventional radiology (IR) would be best suited for role of being the onboard physician to address the cases that can’t be managed remotely by medical expertise on earth. However, there are still many factors to be considered with IR as well. As the field rapidly expands and increases its breadth & depth of the performed procedures, limitations caused by the spaceflight must be carefully considered. These include increased difficulty of moving objects with higher mass, and proper management of fluids due to IR catheterization to avoid contamination within the spacecraft. 1- To review recent IR related advancements with respect to space exploration.2- To investigate the qualities of IR needed for effective and versatile medical care in space.3- To understand the potential and bright future as well as limitations of IR applications in space.

TABLE OF CONTENTS/OUTLINE

1- Latest developments using image guided interventions in space, advantages & limitations.2- Assessment of space-flights that would benefit from possessing IR onboard the most.3- Space medicine considerations for IR physicians and procedures.4- Interventional procedures of US-only procedures vs X-ray only procedures in IR.5- Differences in engineering requirements between basic surgical care vs basic IR procedural care systems.6- Take home points

IREE-42 VEINS TO THE RESCUE: TRANSCATHETER ARTERIALIZATION OF DEEP VEINS FOR NO-OPTION CHRONIC LIMB-THREATENING ISCHEMIA

Kausthubh Hegde, MBBS (*Presenter*)

TEACHING POINTS

1. Understand the concept and clinical need for deep venous arterialization (DVA) in patients with no-option chronic limb-threatening ischemia (CLTI). 2. Review procedural steps and devices available for DVA - including both dedicated systems (LimFlow) and off-the-shelf/commercially available tools. 3. Compare short and long-term clinical outcomes, including amputation-free survival, limb salvage, wound healing, and cost-effectiveness. 4. Highlight the evolving evidence base and potential future directions, including health economics and broader device availability.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Peripheral Artery Disease and CLTI • Definition & burden of disease• Limitations of below-the-knee revascularization options 2. Pathophysiologic Rationale for DVA • ‘Desert foot’ physiology • Mechanism: Using venous channels to bypass arterial occlusions • Historical background • How DVA targets small artery disease 3. Techniques and Tools• Dedicated System: LimFlow device • Commercial/Off-the-shelf devices • Technical steps: AV fistula creation, valvulotomy, stent deployment• Imaging and procedural guidance pearls4. Clinical Outcomes• PROMISE I & II, ALPS study: Feasibility and efficacy with LimFlow Device•DEPARTURE study: Efficacy with non-dedicated tools• Safety, patency, and reintervention rates• Comparative effectiveness, cost effectiveness, and health system impact: TADV vs natural history (CLariTI Registry)• Implications for reducing amputation rates and healthcare burden5. Future Directions• Expanding device access and refining patient selection • Role of interventional radiologists in scaling access, ongoing trials, and next-gen device innovations

IREE-43 A GUIDE TO EMBOLIC AGENTS IN INTERVENTIONAL RADIOLOGY

Rooshi Parikh, BS (*Presenter*)
Stephen P. Reis, MD,MBA (*Abstract Co-Author*)

TEACHING POINTS

1) To understand temporary vs. permanent embolic agents. 2) To classify embolic agents: coils, particles, liquid embolics. 3) To review the mechanisms by which different embolic agents achieve vessel occlusion. 4) To identify appropriate clinical scenarios for the use of specific embolic agents.

TABLE OF CONTENTS/OUTLINE

1) Introduction to Embolic Agents: Differentiate between temporary and permanent agents, as well as coils, particles, and liquid embolics. 2) Coils: Mechanism of Action: induce thrombosis by creating a mechanical block within the vessel. Clinical Applications: used for larger, accessible vessels in bleeding and tumor embolization. Advantages and Limitations: well-established with a predictable occlusion profile, less effective for small or complex vessels due to their inability to provide dense occlusion in all cases. 3) Particulate Embolic Agents: Mechanism of Action: range from 50 to 1500 microns in size, occlude vessels by physically blocking the lumen.

Clinical Applications: Commonly used in UFEs, tumor embolization, and certain GI bleeds. Advantages and Limitations: effective for moderately sized vessels but may be associated with a higher risk of non-target embolization and ischemic complications. 4) Liquid Embolic Agents: Mechanism of Action: ability to flow through the vasculature, providing precise occlusion of small, tortuous vessels. Clinical Applications: small vessels, tumors, and AVMs. Advantages and Limitations: high precision and minimal distal migration, potential complications of non-target embolization and difficulty in control during deployment. 5) Summary of embolic agents' properties, including ideal applications, strengths, and potential drawbacks.

IREE-45 FEASIBILITY ANALYSIS OF ULTRASOUND-GUIDED PERCUTANEOUS THERMAL ABLATION FOR LIVER METASTASES BASED ON A SCORING SYSTEM

Xiaoning Yue (*Presenter*)
Xiang Zhou (*Abstract Co-Author*)

TEACHING POINTS

Purpose To analyze the differences in conspicuity and feasibility between contrast-enhanced ultrasound (CEUS) and conventional ultrasound (US) for guiding percutaneous radiofrequency ablation of liver metastases (LM). Materials and Methods: This retrospective study included patients who underwent ultrasound-guided radiofrequency ablation for LM between June 2022 and January 2024. The number of LMs, size, depth, and location were recorded. We used a 5-point scale to evaluate the conspicuity of target lesions on US and CEUS and compared score differences between the two. Feasibility of target lesions was assessed based on lesion conspicuity and the safety of the ablation path. Results A total of 68 LM patients with 203 lesions were included. CEUS significantly outperformed US in target lesion conspicuity (mean scores: 4.6 vs. 2.9, $p < 0.05$). For US, lesion size and depth affected conspicuity; for CEUS, depth and location were key factors. Tumor size was an independent risk factor for US-guided ablation feasibility, while tumor depth was an independent risk factor for CEUS-guided ablation. For tumors =3cm in size and<4cm in depth, CEUS-guided ablation feasibility was significantly higher than US-guided ablation (29.1% vs. 79.8%, $p < 0.05$; 32.0% vs. 82.8%, $p < 0.05$, respectively). Conclusion CEUS-guided percutaneous radiofrequency ablation demonstrates superior conspicuity and feasibility for LM compared to US. CEUS has notable advantages in identifying small and shallow LMs. However, for larger or deeper lesions, detection rates and feasibility of LM are comparable between US and CEUS.

Purpose Materials and Methods: .Results Conclusion

IREE-46 NEW HORIZONS FOR BRONCHIAL ARTERY EMBOLIZATION: THE EXPANDING ROLE OF LOCOREGIONAL THERAPIES IN LUNG CANCER

Gavin Wu, BA (*Presenter*)
Fereshteh Yazdanpanah, MD, MBA (*Abstract Co-Author*)
Jason C. Hoffmann, MD (*Abstract Co-Author*)
Mina S. Makary, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the potential role of locoregional therapies, including TACE, TARE, and combination approaches, in the management of advanced lung cancer. 2. Review evidence on efficacy and outcomes of these minimally invasive treatments, including tumor response rates, symptom relief, and survival benefits. 3. Recognize emerging data supporting combination therapies and identify areas where further clinical research is needed to optimize patient selection and treatment protocols.

TABLE OF CONTENTS/OUTLINE

Background Advanced-stage lung cancer carries a poor prognosis, with limited curative options. Locoregional therapies such as TACE and TARE are emerging as potential adjuncts to systemic treatment. Procedure Details and Outcomes Studies demonstrate that DEB-TACE achieves ORRs of up to 50% and median OS up to 16.5 months with minimal complications. TARE shows potential but remains investigational. Combination therapies (e.g., TACE + iodine-125 seeds or TAE + RFA) show improved response rates and survival over monotherapy. Conclusion Locoregional therapies may offer improved local control, symptom relief, and survival in select patients with advanced lung cancer. Continued research is needed to define their optimal use in clinical practice.

IREE-47 THE APPLICATIONS OF SPECTRAL CT IN INTERVENTIONAL RADIOLOGY: INNOVATIONS IN DIAGNOSIS AND INTRAOPERATIVE GUIDANCE

Milin Patel (*Presenter*)
Moaz Choudhary, MD (*Abstract Co-Author*)
Patrick D. Sutphin, MD, PhD (*Abstract Co-Author*)
Sanjeeva P. Kalva, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Spectral CT offers enhanced pre-operative planning, intraoperative precision, and post-procedural assessment in interventional radiology. Spectral CT reduces artifacts, improves contrast, and allows functional imaging such as perfusion and temperature mapping. This modality assists in detecting post-procedural complications including endoleaks, hemorrhage, and tumor recurrence with higher accuracy than conventional CT. Future innovations including AI analysis and integration into IR suites holds great promise in advancing medical imaging.

TABLE OF CONTENTS/OUTLINE

Background Spectral CT imaging overview Pre-operative Planning Tissue and lesion characterization Vascular mapping and perfusion Intraoperative Use Needle guidance and ablation mapping Functional and artifact-reduced imaging Post-procedural Applications Tumor response (e.g., post-TACE) Endoleak and hemorrhage detection Vessel recanalization Institutional examples of utility of Spectral CT Future Directions of Spectral CT Artificial intelligence algorithms that interface with spectral CT images to improve interpretation of imaging data Integration of Spectral CT into IR suite

IREE-48 INTRA-ARTERIAL TREATMENT FOR HEPATOCELLULAR CARCINOMAS : HOW TO MANAGE SHUNTING FROM THE ARTERY

Dohoon Kim, MD (*Presenter*)
Hyo-Cheol Kim, MD (*Abstract Co-Author*)

TEACHING POINTS

Intra-arterial therapy including chemoembolization and radioembolization is a workhorse for the treatment of patients with hepatocellular carcinomas. Occasionally, the operators encounter shunts from the artery (arterioportal, arteriovenous, and arteriopulmonary shunts) that prevent effective treatment. The causes of these shunts include tumor invasion to the vessels, previous percutaneous procedures, chronic inflammation, and congenital acquisition. Unless the shunt is properly occluded, embolic material can pass through the shunt and cause non-target embolization or serious complications. The purpose of this exhibit is : (1) To review radiologic appearance of arterioportal, arteriovenous, and arteriopulmonary shunts. (2) To learn how to manage these shunts with proper embolic materials. (3) To list the possible complications and their management.

TABLE OF CONTENTS/OUTLINE

1) List of shunts Arterioportal shunt (hepatic artery - portal vein), Arteriovenous shunt (hepatic artery - hepatic vein), Arteriopulmonary shunt (hepatic artery - pulmonary artery/vein), 2) Imaging findings on CT/MR and angiography according to the cause (tumorous vs non-tumorous condition) 3) Embolization strategy and materials for shunts 4) Complications related with non-target embolization and their management

IREE-49 HIGH-INTENSITY FOCUSED ULTRASOUND IN VARICOSE VEIN THERAPY

Motaz A. Daraghma, MD (*Presenter*)
Umar Hashim (*Abstract Co-Author*)
Hunaid Rana, BS (*Abstract Co-Author*)

TEACHING POINTS

*High-Intensity Focused Ultrasound (HIFU) is an emerging non-invasive technique for treating varicose veins, offering an alternative to traditional therapies such as endovenous laser treatment (EVLT) and sclerotherapy. *HIFU enables precise, extracorporeal ablation of incompetent venous structures without requiring anesthesia, incisions, or catheterization *Understanding the mechanism, clinical applications, and benefits of HIFU can improve its adoption in vascular and interventional radiology practices.

TABLE OF CONTENTS/OUTLINE

Introduction to Varicose Veins and Current Treatment Challenges Epidemiology and impact of varicose veins. Overview of standard treatment options and their limitations. Mechanism of High-Intensity Focused Ultrasound (HIFU) Principles of HIFU and targeted thermal ablation. How HIFU differs from histotripsy , a technique used in interventional oncology. Clinical Applications and Emerging Research SonoVein trials and their implications. Case studies demonstrating the effectiveness of HIFU in vein therapy. Comparison with Conventional Therapies Success rates and procedural benefits. Patient recovery time, risk factors, and potential complications. Future Directions and Impact on Radiology Practice Expanding the use of HIFU beyond vascular treatments. Considerations for radiologists and interventional specialists adopting this technology.

IREE-50 PERCUTANEOUS INTERVENTIONS FOR BENIGN BILIARY STRICTURES

Arsalan Nadeem, MBBS (*Presenter*)
Junaid Raja, MD (*Abstract Co-Author*)
Stephen R. Brown, MD (*Abstract Co-Author*)
Husameddin El Khudari, MBChB (*Abstract Co-Author*)
Aliaksei Salei, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the etiology, classification, and clinical presentation of benign biliary strictures in adults. 2. Describe the imaging modalities and diagnostic procedures used to evaluate strictures. 3. Highlight percutaneous minimally invasive techniques available for management, including evolving therapies.

TABLE OF CONTENTS/OUTLINE

Background: Benign biliary strictures account for up to 30% of biliary obstructions. Early diagnosis and effective management are essential to prevent complications such as cholangitis and liver failure. Technological advances in imaging and interventional techniques have expanded the role of percutaneous approaches, especially when endoscopic options fail. Etiology and Classification: 1. Causes: iatrogenic (post-surgical), infectious, inflammatory, ischemic, autoimmune. 2. Anastomotic vs non-anastomotic strictures. 3. Classification systems based on location and surgical relevance. Clinical Presentation and Diagnostic Modalities: 1. Symptoms and laboratory findings. 2. Noninvasive imaging: ultrasound, computed tomography (CT), magnetic resonance imaging (MRI), and magnetic resonance cholangiopancreatography (MRCP). 3. Invasive diagnostic options: endoscopic retrograde cholangiopancreatography (ERCP), percutaneous transhepatic cholangiography (PTC), and percutaneous cholangioscopy. Percutaneous Management: 1. Benign biliary protocol. 2. Percutaneous balloon cholangioplasty. 3. Percutaneous biliary stenting. a) Types of stents. b) Options of stent removal. Role of Cholangioscopy Adjunct and Emerging Techniques: 1. Sharp recanalization and rendezvous procedures. 2. Endobiliary radiofrequency ablation. 3. Evolving tools.

IREE-51 MICROWAVE THERMAL ABLATION IN BREAST CANCER: TRICKS AND TIPS FROM OUR EXPERIENCE IN 29 CASES WITHOUT COMPLICATIONS

Myriam F. Montes, MD (*Presenter*)
Maria J. Ciudad, MD (*Abstract Co-Author*)
Beatriz Lannegrand Menendez (*Abstract Co-Author*)
Carlota Garcia Baron (*Abstract Co-Author*)
Laura Escudero, MD (*Abstract Co-Author*)
Nancy Sanchez Rubio, MD (*Abstract Co-Author*)
Noelia Arevalo (*Abstract Co-Author*)

TEACHING POINTS

To describe the performance of the microwave ablation in breast cancer treatment through our experience step by step To illustrate with our cases some useful tips to performance microwave ablation minimizing complications

TABLE OF CONTENTS/OUTLINE

Ultrasound-guided microwave thermal ablation is a promising technique for treating early breast cancer. It uses high temperatures to achieve coagulative necrosis of the tumor, offering advantages such as reduced use of general anesthesia, fewer complications, shorter recovery times, and better aesthetic results. In our breast unit, this technique is proposed as a palliative treatment for patients unfit for surgery, particularly elderly and frail patients who benefit from a minimally invasive approach. We will present our experience, including the criteria for patient selection by the multidisciplinary team and some useful tips and tricks we have learned to perform the technique without complications. Although other authors recommend performing microwave ablations with general anesthesia, we have conducted all procedures using only local anesthesia, which was well tolerated by patients. In our experience, which includes 29 cases in 27 patients, the procedure is fast and safe and it was performed without complications and with a high degree of patient satisfaction.

IREE-52 BEYOND THE BASICS: ADVANCED PLUG-ASSISTED RETROGRADE TRANSVENOUS OBLITERATION (PARTO) TECHNIQUES FOR GASTRIC VARICEAL EMBOLIZATION

Yasmin Aly, MBBCh (*Presenter*)
Husameddin El Khudari, MBChB (*Abstract Co-Author*)

TEACHING POINTS

Discuss the anatomy of gastric varices (GV) and gastrorenal shunts (GRS). Review the standard PARTO Technique. Describe three novel, refined PARTO techniques, including: Fogarty-Assisted Plug-Assisted Retrograde Transvenous Obliteration (F-PARTO), Balloon and Plug-Assisted Retrograde Transvenous Obliteration (BPARTO), and Web-Straddled Plug-Assisted Retrograde Transvenous Obliteration (S-PARTO).

TABLE OF CONTENTS/OUTLINE

Outline Introduction Gastric variceal hemorrhage is one of the leading causes of mortality among patients with liver cirrhosis. PARTO, is an effective treatment of GV with GRS. We aim to review the standard PARTO technique and its limitations, and explore novel modifications designed to overcome these limitations. PARTO Techniques Standard PARTO: For shunts up to 16mm. After positioning of the vascular plug above the venous web at the GRS- left renal vein junction, the sclerosant mixture is injected through the catheter. F-PARTO: For smaller shunts (= 7mm). A Fogarty catheter is advanced into the GRS, and its balloon is inflated allowing sclerosant injection before plug placement in the standard fashion. B-PARTO: For shunts up to 16mm. A balloon guide catheter occludes flow, enabling controlled sclerosant injection before plug deployment. S-PARTO: For larger shunts (= 16 mm). The proximal nitinol mesh of the 22mm Amplatzer II plug is positioned below the venous web, ensuring secure placement of plug. Conclusion These specialized PARTO techniques allow customized treatment for effective obliteration of GV.

IREE-53 CLINICAL GUIDELINES IN TRAUMA: PICTORIAL REVIEW

Devang Srivastava (*Presenter*)
Adam P. Jacobs, MD (*Abstract Co-Author*)
Stephen R. Brown, MD (*Abstract Co-Author*)
Andrew J. Gunn, MD (*Abstract Co-Author*)
Aliaksei Salei, MD (*Abstract Co-Author*)

TEACHING POINTS

• Discuss AAST, EAST, WSES, SIR guidelines for trauma management as well as other pertinent guidelines. • Illustrate approaches to trauma imaging and current guideline recommendations for detection of vascular injury and active bleeding. • Provide case-based review of organ specific guidelines for splenic, hepatic, renal and pelvic trauma.

TABLE OF CONTENTS/OUTLINE

1 Introduction ? Epidemiology of trauma ? Expanding role of IR in trauma care 2 Guideline Overview ? Key society guidelines for trauma imaging and management 3 Organ-Specific Algorithms with Clinical and Imaging Scenarios: Splenic Trauma ? Implications of 2018 AAST scaling update ? Management considerations based on clinical presentation, other organ damage, grade of injury and presence of vascular injury ? Distal vs. proximal splenic artery embolization ? Impact on immune function Hepatic Trauma ? Implications of liver vascular anatomy on management ? Management considerations based on clinical presentation, other organ damage, and presence of vascular injury Renal Trauma ? Rationale for increased use of nonoperative management in renal injury ? Management based on clinical presentation, other organ damage, presence of vascular injury, and injury to collecting system ? Management of traumatic renal artery dissection or occlusion ? Embolization techniques in guidelines Pelvic Trauma ? Means of hemostasis in pelvic trauma (embolization, preperitoneal packing, REBOA) ? Overview of clinical and imaging scenarios ? Embolization techniques in guidelines Summary and Key Takeaways

IREE-54 SAFE AND CONTROLLED NBCA EMBOLIZATION USING A NOVEL LOW-ADHESION MICROCATHETER: A FIVE-CASE SERIES

Motoki Nakai, MD, PhD (*Presenter*)
Toru Saguchi, MD (*Abstract Co-Author*)
Takafumi Yamada (*Abstract Co-Author*)
Masanori Ishida (*Abstract Co-Author*)
Kazuhiro Saito, MD (*Abstract Co-Author*)

TEACHING POINTS

•N-butyl 2-cyanoacrylate (NBCA) rapidly polymerizes upon contact with blood, enabling emergent hemostasis but posing risks of catheter adherence to the vessel wall, necessitating prompt catheter removal. •NSX® is a novel microcatheter featuring a 3-cm PTFE tip with low adhesion to NBCA, allowing safe catheter removal even after delayed withdrawal. •NSX® enables slow, controlled injection of NBCA, achieving accurate embolization without rushed catheter removal.

TABLE OF CONTENTS/OUTLINE

Introduction •NBCA is effective for emergency embolization but requires immediate catheter removal due to strong adhesiveness, risking incomplete treatment. •This limits injection control, and delayed removal increases the risk of catheter entrapment or vascular injury. •To overcome these challenges, the NSX® microcatheter was developed with a PTFE tip that reduces adhesion to NBCA. •This exhibit highlights five representative cases demonstrating the clinical utility of NSX® in emergent settings. Case Series (5 patients) Five representative cases were treated with NSX® for: 1. postoperative bleeding, 2. gastrointestinal bleeding, 3. intraperitoneal bleeding, 4. postpartum hemorrhage, and 5. trauma. In all cases, NBCA was injected and the catheter withdrawn >1 minute after injection, with no significant adhesion or complications. Conclusion •NSX® allows safe, controlled NBCA injection in various emergent bleeding scenarios without the need for hurried withdrawal, ensuring accurate embolization. •The average time from injection to removal was 96 seconds. •A minor limitation is slightly reduced distal trackability compared to conventional microcatheters due to the PTFE tip’s stiffness.

IREE-55 APPROACH TO THE COMPLEX BILIARY TRACT USING ARTICULATED CATHETERS: A MINIMALLY INVASIVE STRATEGY

Denny Marcela P. Achicanoy I, MEd (*Presenter*)
Daniel F. Mendez Lopez I, MEd (*Abstract Co-Author*)
Diana F. Achicanoy, MD (*Abstract Co-Author*)
Ana M. Roman an Marquez, MD (*Abstract Co-Author*)
Ismael Juarez Nunez, MD (*Abstract Co-Author*)

TEACHING POINTS

The placement of percutaneous transhepatic biliary drainage (PTBD) as a treatment for biliary stenosis has gained greater relevance due to the decrease in morbidity and mortality rates, associated complications, and costs compared to invasive surgical procedures. For this reason, new techniques have been developed that surpass the advantages of PTBDs, such as Articulated Plastic Biliary Catheters (APBC). APBCs consist of one or more shorter secondary intraluminal biliary drainage catheters associated with a primary internal-external biliary drainage system facilitating drainage mainly in hilar stenosis of more than one bile duct through a single percutaneous access. The indications for APBC are specifically three: complex benign or malignant hilar stenosis requiring bilateral PTBC, benign distal biliary stenosis, and benign biliary-enteric anastomotic stenosis involving the hepatic ducts. CBPA placement can be performed in three ways: Y, T, and Tandem techniques. The first two are mainly used for hilar stenosis and the last for distal stenosis. Complications in APBC and PTBD are similar, including catheter obstruction with or without cholangitis, pericatheter biliary leak, catheter migration, among others. However, the presence of multiple PTBD increases their incidence, and larger PTBDs cause obstruction of small bile ducts, predisposing to the formation of liver abscesses. We will conduct an objective and current review of articulating plastic biliary catheters and describe several clinical cases of malignant biliary strictures that were successfully treated with APBC.

TABLE OF CONTENTS/OUTLINE

Introduction, definition, indications, technique, clinical cases, complications

IREE-56 MASTERING VASCULAR PLUGS: FROM BASIC TO ADVANCED TECHNIQUES AND STRATEGIC USE FOR EFFICIENT AND SUSTAINABLE EMBOLIZATION

Shintaro Senda, MD (*Presenter*)
Hideki Yashiro (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Vascular plugs offer numerous advantages in embolotherapy, including excellent device control, stable occlusion, low recanalization risk, and minimal imaging artifact. These features contribute to efficient procedures, reduced radiation exposure, and decreased use of embolic materials, which align with the goals of an effective and environmentally conscious practice. However, standard deployment may be inadequate in complex vascular anatomies or high-flow conditions, where mechanical instability or insufficient thrombosis can pose significant challenges. To address these, a variety of refined techniques have emerged in clinical practice. Focusing on the most widely used plugs, Amplatzer Vascular Plugs (AVPs), this exhibit provides a comprehensive overview of a wide range of techniques, spanning from basic to advanced approaches, to promote strategic and effective plug use.

TABLE OF CONTENTS/OUTLINE

(1) Introduction : Clinical utility of AVPs and their contribution to Green Radiology, along with current limitations of standard use. (2) Technique-Based Strategies and Classification : A. Deployment Stabilization : Compressing Deployment Technique, Pull-through Wire Technique, Plug Anchoring Technique B. Thrombus Formation

Enhancement : Gelfoam-Assisted Technique, Internal Coil Packing Technique, Modified Internal Coil Packing Techniques (Direct Puncture, Coil Prefilling, Preloading Catheter) C. Alternative Access and Special Situations : Candy-Plug Technique, Aortic Pseudoaneurysm Occluding Technique *Each technique will be illustrated using clinical examples, technical tips, and common pitfalls derived from real-world experience.

IREE-57 WEDGED INJECTION OF NBCA UNDER OCCLUSION WITH MICROBALLOON CATHETER: YOUR ULTIMATE TECHNIQUE FOR CHALLENGING SITUATIONS

Maki Hirao, MD (*Presenter*)
Hideki Ishimaru, MD, PhD (*Abstract Co-Author*)
Satomi Yoshimi (*Abstract Co-Author*)
Shuto Miyamura (*Abstract Co-Author*)
Oka Taiga (*Abstract Co-Author*)
Takamasa Nishimura (*Abstract Co-Author*)
Chika Somagawa, MD (*Abstract Co-Author*)
Tomoki Nakano, MD (*Abstract Co-Author*)
Ryo Toya, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The use of a microballoon catheter for wedged injection of NBCA is highly effective for embolizing a large volume of blood vessels into a mold shape. This technique allows both antegrade and retrograde injections. It is also useful when a standard microcatheter cannot be inserted into the target vessel; however, in such cases, it is necessary to obstruct the normal perfusion area using coils. Although more expensive than conventional microcatheters, the microballoon catheter enables "wedged injection" by blocking blood flow with a balloon, which also prevents NBCA from flowing back towards the catheter. When a single injection is expected to provide sufficient therapeutic results, the use of a microballoon catheter is recommended.

TABLE OF CONTENTS/OUTLINE

1) Features of NBCA 2) What are the benefits of wedged injection of NBCA? 3) Properties of microballoons (made from polyurethane and silicone) and the potential for catheter adhesion 4) Contrasting wedged injection using a microballoon with injection under flow arrest using a balloon guiding catheter 5) Balloon occluded antegrade injection versus retrograde injection 6) Various scenarios where microballoons prove beneficial (including arteriovenous malformation, arteriovenous fistula, varix, hemorrhage, and pseudoaneurysm, among others) 7) Adjunctive technique 8) Pitfall

IREE-58 PRECISION UNDER PRESSURE: A MULTI-FACETED APPROACH TO ACCESS ANY TARGET IN THE ABDOMEN

Kira Brenner, MS (*Presenter*)
Laurel Chen, MEng (*Abstract Co-Author*)
Stephanie A. Vincent-Sheldon, MD (*Abstract Co-Author*)
Brian J. Di Giacinto, DO (*Abstract Co-Author*)

TEACHING POINTS

It is possible to access almost any abdominal mass or fluid collection for diagnostic or therapeutic purposes with the correct combinations of preprocedural patient optimization and percutaneous techniques. A simple direct route is often the key to success. However, many providers are reticent to displace or traverse other organs due to overestimation of the risks involved. We provide our systematic institutional approach to complex patients and case-based reviews of underutilized percutaneous techniques to simplify accessing deep abdominal targets. All these approaches are safe and supported by literature or our institutional experience. Our educational exhibit specifically addresses risk to benefit ratio assessment, patient optimization, approach selection (e.g., trans-pleural, transpulmonary, transcaval, passage through hollow viscera), window optimization (re-positioning, bladder volume adjustment, enema, etc.), and access techniques (e.g., curved needle, blunt dissection, needle lever). For radiologists and radiology trainees, this exhibit provides real-world techniques backed by institutional examples that reinforce how deep abdominal targets can be safely accessed. We hope these techniques can equip proceduralists and trainees alike with the skills to access intraabdominal pathology.

TABLE OF CONTENTS/OUTLINE

1) Title 2) Teaching points and learning objectives 3) Specific access techniques: Choosing an approach 4) Technique A: Guide needle/catheter lever 5) Technique B: Window optimization via bladder distention 6) Technique C: Curved needle 7) Technique D: Hydrodissection 8) Key Takeaways 9) References

IREE-59 TIPS AND TRICKS FOR KIDS: REVIEW OF ENDOVASCULAR PORTAL INTERVENTIONS, INDICATIONS, AND COMPLICATIONS IN PEDIATRIC PATIENTS

Matthew Anguiano (*Presenter*)
Stuart L. Polk, MD (*Abstract Co-Author*)
Austin Glenn (*Abstract Co-Author*)
Nicholas Schreiter, MD (*Abstract Co-Author*)
Anish Kammila (*Abstract Co-Author*)
Marie Killerby, MPH (*Abstract Co-Author*)
Omar Abdalla, BS (*Abstract Co-Author*)
Atlee Witt (*Abstract Co-Author*)
Allen Luna, BEng (*Abstract Co-Author*)
Lily Gao, BA (*Abstract Co-Author*)
Devanshi Bhangle (*Abstract Co-Author*)
Christopher M. Baron, MD (*Abstract Co-Author*)
Reza Imani-Shikhabadi, MD, MS (*Abstract Co-Author*)
Nicholas Voutsinas, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to: Review normal and abnormal anatomy pertinent to the portal venous system. Discuss the options for portal interventions and indications. Emphasize differences between adult and pediatric patients in pre-, intra-, and post-procedural management of portal interventions.

TABLE OF CONTENTS/OUTLINE

Portal system anatomy Normal anatomy Variant anatomy Congenital portosystemic shunt (Abernethy malformation) Patent ductus venosus Gastrorenal shunt Spontaneous splenorenal shunt Post-liver transplant Post-Meso-Rex shunt Options for endovascular interventions Obtaining access (transhepatic, transsplenic) Transjugular intrahepatic portosystemic shunt (TIPS) Portal vein recanalization (angioplasty, thrombectomy, stent) Variceal sclerotherapy Balloon-assisted antegrade/retrograde transvenous obliteration Congenital portosystemic shunt embolization Surgical portosystemic shunt angioplasty Portal vein embolization Portal system pathologies indicating endovascular intervention The core pathogenic mechanisms Portal hypertension (prehepatic, intrahepatic, and posthepatic) Shunting Portal vein thrombosis and stenosis Gastric varices Extrahepatic portal vein obstruction Liver disease and cirrhosis Surgical complications (post-liver transplant, post-Meso-Rex shunt) Congenital portosystemic shunts (Abernethy malformations) Cavernous transformation of the portal vein Complications of endovascular interventions Bleeds Biliary fistula Thrombosis Restenosis Hepatic encephalopathy Pulmonary edema Special consideration for pediatric patients Stents Catheter size Micropuncture kit Ring set changes

IREE-60 PUSHING THE BOUNDARIES: ALL THE WAY THROUGH THE URETER

Onur Ege Tari, MD (*Presenter*)
Emre Unal, MD (*Abstract Co-Author*)

Aycan Uysal, MD (*Abstract Co-Author*)
Turkmen Ciftci (*Abstract Co-Author*)
Devrim Akinci (*Abstract Co-Author*)

TEACHING POINTS

Ureteral stenosis or leak encountered in native or transplant kidneys, can be managed percutaneously with several ways including double J, tandem or metallic stents. Obtaining ureteral access is a challenge, but an interventional radiology (IR) team is capable of achieving ureteral access either antegrade (through percutaneous nephrostomy) or retrograde (via urethra to ureter) manner. Particularly in women, retrograde ureteral access via urethral orifice can be obtained with imaging guidance and without cystoscopy. Therefore, ureteral magnetic compression anastomosis (MCA) procedure involving two magnets placed to cranial and caudal part of an occlusion, can be done in an IR unit since both antegrade and retrograde accesses are achieved with imaging guided methods. MCA can be done with a high technical success rate without cystoscopy and/or surgery in native and post-surgical ureteric occlusions, allowing patients with total ureteric occlusion to be catheter-free. At last an imaging-guided ureteroneocystostomy involving three basic steps, (1) percutaneous puncture of bladder, (2) needle course through the lumen of bladder, and (3) final puncture of caudal segment of the obstructed ureter, can be performed in an IR unit.

TABLE OF CONTENTS/OUTLINE

1. An overview of ureteral stenosis and leaks 2. Methods for imaging guided ureteral accesses a. Antegrade b. Retrograde c. Direct Puncture 3. Management of ureteral stenosis and leak in various scenarios (native-transplant kidneys and ileal conduits) a. Double J stent placement b. Tandem stent placement c. Balloon dilatation d. Metallic stent placement e. Rendezvous technique 4. Total occlusion a. Magnetic compression anastomosis b. Direct ureteral puncture

IREE-61 HISTOTRIPSY OF HEPATIC LESIONS: EARLY LESSONS FOR POST TREATMENT DIAGNOSTIC STUDIES

Anna S. McKenney, MD,PhD (*Presenter*)
Qian Yu, MD (*Abstract Co-Author*)
Andrew Navarro, MD (*Abstract Co-Author*)
Osmanuddin S. Ahmed, MD (*Abstract Co-Author*)
Christos S. Georgiades, MD, PhD (*Abstract Co-Author*)
Mikhail Silk, MD (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)
Elizabeth M. Hecht, MD (*Abstract Co-Author*)

TEACHING POINTS

Histotripsy of the liver has gained momentum for locoregional treatment, and its post-treatment findings differ from classic thermal ablation findings. Histotripsy treatment-zone findings on immediate imaging include hypoattenuation and hypoenhancement, but some treatment zones may show minimal change from hepatic parenchyma. On short- and long-term followup, hyperenhancement of margins should be interpreted with caution. Secondary signs of tissue destruction, including presence of blood products or diffusion restriction should be considered. Post treatment findings likely depend on the nature of the primary tumor. Post-histotripsy findings for hypoenhancing tumors such as metastatic colorectal lesions will differ from hyperenhancing lesions such as HCC. Acute findings and adverse events may be identified in the immediate postprocedure period. Many are asymptomatic and self-limiting, but some require treatment.

TABLE OF CONTENTS/OUTLINE

Histotripsy Technology and procedure: Potential benefits Drawbacks Adverse Events Patient selection / tumor board discussion major points Post-histotripsy Imaging Immediate postprocedure Ablation zone characteristics Identification of acute findings Short Term Findings that can be misleading including persistent peripheral enhancement Findings that may provide collateral information including hemorrhagic products and diffusion restriction Long term interpretation Contextualizing the originally ablated tumor In the setting of additional locoregional treatment

IREE-62 THYROID ARTERY EMBOLIZATION FOR BENIGN GOITER: ANATOMY, EVALUATION, AND TREATMENT TECHNIQUES

John Caniglia, MD (*Presenter*)
Josh Verhagen (*Abstract Co-Author*)
Matthew M. Niemeyer, MD (*Abstract Co-Author*)
Sean K. Golden, MD (*Abstract Co-Author*)

TEACHING POINTS

Thyroid artery embolization (TAE) is an emerging endovascular treatment for benign thyroid disease, including multinodular goiter and Graves'. Typical patients are poor surgical candidates due to substernal goiter or comorbidities. TAE is favored over thermal ablation in patients with large or substernal nodules. Pre-procedure work-up includes CTA neck to assess goiter location and arterial supply, as well thyroid function tests. TAE is performed on an outpatient basis via femoral or radial access. The thyroid gland is supplied by the bilateral inferior and superior thyroid arteries, which are branches of the thyrocervical trunk and external carotid artery, respectively. During TAE, two or three of the thyroid arteries are embolized to stasis using particles to induce ischemia of the gland, improving mass effect and/or hyperthyroidism. Non-target embolization, vessel dissection, or atheroembolism can result in stroke, a rare complication of the procedure occurring in less than 1% of patients. Intra-procedure CTA or cone-beam CT can be performed to reduce risk of non-target embolization. Understanding of common anatomic variants of the thyrocervical trunk and thyroidea ima is critical for technical success. Post-procedure, subclinical hyperthyroidism is common and can be managed conservatively. Thyroid storm, hypothyroidism, and hypoparathyroidism are uncommon but should be screened for using thyroid and parathyroid labs. Post-procedure imaging can be obtained with ultrasound or CT to quantify goiter reduction.

TABLE OF CONTENTS/OUTLINE

1. History of TAE 2. Indications 3. Pre-procedure work-up 4. Vascular anatomy and variants 5. Procedural steps 6. Complications 7. Post-procedure follow-up

IREE-63 PORTAL HYPERTENSION WITH ECTOPIC VARICES: CAUSES, COMPLICATIONS, AND MANAGEMENT

Danielle Heiser, BS (*Presenter*)
Kevin V. Curley, DO (*Abstract Co-Author*)
Kenneth S. Zurcher, MD (*Abstract Co-Author*)
Douglas S. Lewis, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Portal hypertension can result from prehepatic, hepatic, and posthepatic etiologies. 2. Ectopic varices are an uncommon, but clinically significant complication of portal hypertension, and can occur anywhere along the GI tract. 3. Management of ectopic varices requires a collaborative and interdisciplinary approach, with diagnostic and interventional radiologists playing a central role in both diagnosis and treatment. 4. Interventional treatment of ectopic varices is highly individualized, often including a combination of TIPS decompression, variceal embolization, and/or portal vein recanalization and may require alternate access such as transhepatic, transplenic, or direct stick approaches.

TABLE OF CONTENTS/OUTLINE

1. Briefly review causes, epidemiology, and complications of portal hypertension. 2. Review ectopic varix etiology, anatomic locations, complications, and prognosis. 3. Provide an overview of various interventional treatment options and approaches for ectopic varices. 4. Review a small case series of lower GI ectopic varices managed with a variety of the above interventional approaches and techniques.

IREE-65 COMMON ENDOVASCULAR AND PERCUTANEOUS IMPLANTABLE DEVICES: WHAT THE DIAGNOSTIC RADIOLOGIST NEEDS TO KNOW

Aida Haddad, MD (*Presenter*)
Juliet M. Alla, MD (*Abstract Co-Author*)
Fregenet Gichamo, MD (*Abstract Co-Author*)
Surbhi B. Trivedi, MD (*Abstract Co-Author*)
Christine E. Boone, MD,PhD (*Abstract Co-Author*)
Christopher J. Friend, MD,MBA (*Abstract Co-Author*)

TEACHING POINTS

Review the indications for use of common endovascular and percutaneous implantable devices. Delineate endovascular devices, such as inferior vena cava (IVC) filters, embolics, and vascular repair devices. Identify complications related to endovascular devices and their appropriate follow-up. Outline percutaneous devices, such as general drains, biliary drains, gastrointestinal tract tubes, and genitourinary tract tubes, as well as their respective complications and appropriate diagnosis. Provide multimodal imaging examples distinguishing indications, features, complications, and potential diagnostic pitfalls of endovascular and percutaneous devices.

TABLE OF CONTENTS/OUTLINE

Endovascular Devices Common examples of IVC filters and their potential complications. Characteristic examples of embolic agents, such as liquid embolics, glue, coils, and plugs, as well as their associated imaging artifacts. Common endovascular aneurysm repairs, including specific examples of general procedural steps, types of stent-graft devices, and short- & long-term complications (specifically, endoleaks). Drains Characteristic examples and a stepwise approach to assessing pre- and immediate post-intervention imaging, including examples of standardized approaches to identify complications, such as malpositioned or kinked drains. Biliary stricture interventional approach and the appearance of devices implemented in these treatment approaches placed by IR versus gastroenterology, and their complications. Evaluation and management after placement of a percutaneous nephrostomy tube, percutaneous nephroureteral tube, nephroureteral stent, or retrograde ureteral stent.

IREE-66 ABLATIVE RADIOEMBOLIZATION FOR LIVER TUMOR : WHEN AND HOW

Hyo-Cheol Kim, MD (*Presenter*)

TEACHING POINTS

Radioembolization has become a workhorse for the treatment of patients with unresectable hepatocellular carcinoma and metastatic liver cancers. Unlike traditional radioembolization, ablative radioembolization aims to deliver a significantly higher radiation dose, often exceeding 200 Gy, to achieve tumor ablation. This can result in complete tumor necrosis, making it a potentially curative option for selected patients, especially those who are not candidates for surgery. It is particularly effective for small- to medium-sized tumors and can serve as a bridge to liver transplantation or surgical resection. Despite its advantages, the procedure carries risks such as radiation-induced liver disease, and non-target embolization. Careful patient selection, accurate dosimetry planning, and multidisciplinary management are essential to minimize complications and maximize therapeutic outcomes. The purpose of this exhibit is : (1) To review definition and outcome of ablative radioembolization. (2) To learn how to prescribe the target tumor dose. (3) To list the technical tips and tricks of ablative radioembolization depending on tumor size and location.

TABLE OF CONTENTS/OUTLINE

1) Definition of radioembolization 2) Literature review regarding outcomes of ablative radioembolization 3) Single compartment dosimetry 4) Partition model dosimetry 5) Voxel-based dosimetry 6) Radiation segmentectomy in small tumor 7) Radiation major hepatectomy in large tumor 8) Superselective multiple injection in small future liver remnant 9) Flow diversion in central tumor

IREE-67 A JOINT VENTURE: EMBOLIZATION FOR CHRONIC JOINT DISEASE BEYOND THE KNEE

Harrison Blume (*Presenter*)
Gray R. Lyons, MD, PhD (*Abstract Co-Author*)
Clifford R. Weiss, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Explore novel applications of transarterial embolization for management of joint disease beyond the knee, including osteoarthritis, tendinopathies and adhesive capsulitis. 2. Identify clinical and imaging indications of transarterial embolization for patients with chronic joint pain. 3. Review technical considerations, highlighting target vessels for embolization, vascular access, catheter selection and choice of embolic materials. 4. Assess gaps in current literature, emphasizing innovation and long-term clinical follow-up of safety and efficacy.

TABLE OF CONTENTS/OUTLINE

1. Introduction: review of chronic joint pathologies amenable to embolization 2. Overview of general management strategies: current medical and surgical options 3. Rationale for embolization: incorporating existing literature for understanding pathophysiology 4. Indications for embolization: patient selection, key imaging findings and clinical evaluation of joint disease 5. Review of normal joint arterial anatomy with branches targeted for embolization 6. Embolization techniques for chronic joint disease a. Locations for vascular access: radial, ulnar, femoral access b. Considerations for catheter selection c. Choice of embolic materials: resorbable or permanent 7. Adverse events and contraindications, noting non-target embolization and joint ischemia 8. Future research directions: prospective studies, improving procedural materials, and broadening the scope of joint disease treated with embolization

IREE-68 THE ESTABLISHMENT AND VALIDATION OF A MODEL FOR PREDICTING OVERALL SURVIVAL IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA UNDERGOING TRANSARTERIAL CHEMOEMBOLIZATION

Tianbo Fan (*Presenter*)
Qi Wang (*Abstract Co-Author*)

TEACHING POINTS

To develop a new model to predict overall survival (OS) of patients with unresectable HCC after TACE.

TABLE OF CONTENTS/OUTLINE

I. Purpose A. Study objective: develop a nomogram to predict overall survival (OS) after TACE in unresectable HCC II. Methods A. Patient Selection 1. Inclusion criteria (unresectable HCC, TACE between Jan 2015-Dec 2019) 2. Training vs. validation cohorts (random assignment) B. Variable Assessment 1. Clinical and laboratory parameters 2. Radiologic response after first TACE C. Statistical Analysis 1. Cox proportional hazards model (identification of independent prognostic factors) 2. Model performance: a. Concordance index (C-index) b. Calibration plots c. Time-dependent ROC AUC d. Decision curve analysis (DCA) III. Results A. Cohort Characteristics and Median OS (11.2 months) B. Independent Prognostic Factors • Radiologic response • Tumor number • Vein invasion • Extrahepatic metastasis • AFP level • ALBI grade • PLR C. Nomogram Performance 1. C-index: 0.775 (training), 0.796 (validation) 2. Calibration: strong observed vs. predicted agreement 3. AUC: superior to conventional staging systems 4. DCA: demonstrated clinical net benefit D. Risk Stratification • Comparison of OS across low-, intermediate-, and high-risk groups ($P < 0.001$) IV. Conclusion A. Summary: TACE-specific nomogram enables precise OS prediction in unresectable HCC B. Clinical Implication: tool for individualized patient counseling and management V. Keywords unresectable hepatocellular carcinoma; transarterial chemoembolization; nomogram; prediction model

IREE-69 TRANSARTERIAL EMBOLIZATION OF TYPE II ENDOLEAKS USING A NOVEL QUINTET-COAXIAL CATHETER SYSTEM: OVERCOMING CHALLENGING ACCESS ROUTES

Toru Saguchi, MD, PhD (*Presenter*)
Motoki Nakai, MD, PhD (*Abstract Co-Author*)
Takafumi Yamada (*Abstract Co-Author*)
Masanori Ishida (*Abstract Co-Author*)
Kazuhiro Saito, MD (*Abstract Co-Author*)

TEACHING POINTS

• Introduce a novel quintet-coaxial catheter system for embolization of type II endoleaks associated with internal iliac artery (IIA) branches. • Demonstrate the technical feasibility of navigating tortuous lumbar and iliolumbar routes into the aneurysm sac using this system. • Highlight the procedural advantages of enhanced microcatheter support and precision in embolic delivery.

TABLE OF CONTENTS/OUTLINE

Type II endoleaks (ELs) from IIA branches can persist despite standard management. Effective transarterial embolization (TAE) requires stable access to the aneurysm sac via tortuous and narrow collateral routes. Device Description The quintet-coaxial system consists of five coaxially aligned catheters: 1. 5-F flexible guiding sheath 2. 5-F guiding catheter 3. 3.4-F large-bore distal access catheter 4. 2.7-F high-flow microcatheter 5. 1.9-F microcatheter Technique TAE was performed in five patients (mean age: 81.8 years) with persistent type II EL post-EVAR. The catheter system was introduced via the ipsilateral femoral artery and advanced through lumbar and iliolumbar arteries into the aneurysm sac. Embolization was achieved using a 20% NBCA-Lipiodol mixture, followed by coil embolization of inflow arteries. Results All procedures were successful without complications. The large-bore access catheter provided robust support, enabling precise microcatheter navigation. Mean procedure time was 166 minutes; mean fluoroscopy time was 71 minutes. Six-month CT follow-up showed sac shrinkage or stability in all cases. Conclusion The quintet-coaxial catheter system facilitates safe and effective TAE for IIA-related type II ELs, especially via challenging vascular routes.

IREE-70 OPTIMISATION OF ULTRASOUND FOR INTERVENTIONAL RADIOLOGISTS: A CASE-BASED COMPREHENSIVE REVIEW

Nanda Venkatanarasimha, FRCR, FRANZCR (*Presenter*)

TEACHING POINTS

1.Interventional Radiologists should be familiar with the numerous features commonly available on ultrasound (US) machines including advanced technical features that can play a valuable role in ultrasound guided interventions.2.Optimisation of US can improve detection of target tissue, minimise artefacts, reduce procedural times &increase application of this technology across a variety procedures. 3.Thorough understanding of basics &nuances of the functionality of US machine will translate into greater operator confidence, safer &successful procedure.

TABLE OF CONTENTS/OUTLINE

1.Required equipment- Mandatory: Multiple linear &curvilinear probes of varying frequency, greyscale with harmonic imaging &spatial compounding, color, power &spectral Doppler. Desirable, not mandatory: Bedside table &adjustable stool, dual screen capability, advanced techniques (e.g. Fusion, contrast-enhanced ultrasound, techniques to enhance acoustic window, microvascular imaging, B-flow).2.Using a side-by-side illustration we will present a case based discussion of ultrasound equipment parameters that can maximise image quality to improve practical applications during interventions - frequency, gain, depth, dynamic range, compound &harmonic imaging etc.3.Provide functional information illustrating correct optimisation of ultrasound images to increase the likelihood of performing ultrasound guided interventions confidently, safely &effectively. 4.Review relevant pitfalls/artefacts &provide tips to minimise these to improve diagnostic & therapeutic outcomes.5.Discuss general considerations - ergonomics, ambient lighting, infection prevention including lessons from pandemic.

IREE-71 VARIANT HEPATIC ARTERY ANATOMY: IMPLICATIONS FOR LIVER-DIRECTED THERAPY

Lily Gao, BA (*Presenter*)
Stuart L. Polk, MD (*Abstract Co-Author*)
Nicholas Schreiter, MD (*Abstract Co-Author*)
Austin Glenn (*Abstract Co-Author*)
Omar Abdalla, BS (*Abstract Co-Author*)
Atlee Witt (*Abstract Co-Author*)
Marie Killerby, MPH (*Abstract Co-Author*)
Devanshi Bhangle (*Abstract Co-Author*)
Allen Luna, BEng (*Abstract Co-Author*)
Matthew Anguiano (*Abstract Co-Author*)
Anish Kammila (*Abstract Co-Author*)
Andrew J. Marsala II, MD (*Abstract Co-Author*)
Meaghan Dendy Case, MD (*Abstract Co-Author*)
Tony Borgmann (*Abstract Co-Author*)
Reza Imani-Shikhabadi, MD, MS (*Abstract Co-Author*)
Nicholas Voutsinas, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is 1) to review normal and variant hepatic artery anatomy and 2) to discuss the clinical implications of variant arterial anatomy for liver-directed therapy, with a focus on Transarterial Chemoembolization (TACE) and Transarterial Radioembolization (TARE).

TABLE OF CONTENTS/OUTLINE

1. Normal Mesenteric and Hepatic Arterial Anatomy a. Celiac Trunk b. Superior Mesenteric Artery c. Hepatic Arteries and their branches 2. Variant Hepatic Arterial Anatomy a. Replaced vs Accessory b. Michels' Classification (Types I-X) c. Extrahepatic Tumoral Arterial Supply i. Phrenic ii. Gastroduodenal iii.Gastric 3. Overview of Arterial-Based Liver-Directed Therapy a. TACE b. TARE c. Bland Embolization 4. Implications of Variant Anatomy on Liver-Directed Therapy a. Mechanisms of Failure i. Vascular injury ii. Catheter misplacement iii. Variant downstream anatomy despite correct catheter placement iv. Accessory tumor supply b. Off-Target Effects i. Delivery of embolic to extrahepatic organs ii. Ischemia of extrahepatic organs c. Decreased Treatment Efficacy i. Chemotherapy or radiation bypasses tumor ii. Accessory tumor supply results in residual viable tumor d. Additional Procedures i. Repeat Embolization ii. Adjunct Liver Directed Therapy (Microwave of Residual Disease) iii. Protective Arterial Embolization 5. Pre-procedural Imaging a. Technetium-99m-labeled macroaggregated albumin (MAA) mapping i. Hepatopulmonary Shunt b. CT & MR Angiography c. 3D Reconstruction

IREE-72 BLEOMYCIN ELECTROSCLEROTHERAPY (BEST) FOR VASCULAR ANOMALIES - A PRIMER FOR INTERVENTIONAL RADIOLOGISTS

Kevin K. Fung, MBBS, FRCR (*Presenter*)
Moritz Wildgruber, MD, PhD (*Abstract Co-Author*)
Roberto Luigi Cazzato, MD (*Abstract Co-Author*)
Premal A. Patel, MBBS, FRCR (*Abstract Co-Author*)
Kishore Minhas, FRCR,MBChB (*Abstract Co-Author*)
Martin Krauss (*Abstract Co-Author*)
Alessandro Zanasi (*Abstract Co-Author*)
Afshin Gangi, MD, PhD (*Abstract Co-Author*)
Walter A. Wohlgemuth, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Using the principle of reversible electroporation, bleomycin electrosclerotherapy (BEST) is an emerging image-guided treatment for patients with vascular anomalies, particularly effective in cases which are refractory to conventional sclerosants or surgical resection. 2. The large molecular size of bleomycin limit its ability to cross cell membranes and exert its effect of disrupting DNA inside the cytosol. The application of short, intense electric pulses potentiates the effect of bleomycin sclerotherapy through 1) "reversible electroporation", i.e. transient increase in cell membrane permeability, which increases the intracellular bioavailability of bleomycin; and 2) "vascular lock effect", i.e. temporary vasoconstriction of dysplastic vasculature, to increase the retention of bleomycin. 3. BEST has a role in treatment of slow flow vascular malformations with considerable stromal component, such as microcystic lymphatic malformations (LM) and extensive venous malformations (VM), and

arteriovenous malformations (AVM) with challenging angioarchitecture for embolization. 4. Successful BEST treatment requires careful case selection, pre-procedural planning, bleomycin instillation, electrode placement and post-procedural care. Common complications include cutaneous hyperpigmentation, post-procedural swelling and pain. Nerve palsy and vasospasm are rare. Preventive strategies include limitation of adhesive use, placement of electrode away from nerves and post-BEST analgesic plan.

TABLE OF CONTENTS/OUTLINE

1. Mechanism of BEST; 2. Equipment and planning; 3. Peri-procedural optimization; 4. Cases to illustrate the role of BEST ; 5. Complications and preventive strategies

IREE-73 RADIOLOGIC ASSESSMENT AFTER RADIOEMBOLIZATION: EXPECTED CHANGES AND COMPLICATIONS

Nai-Wen Chang, MD (*Presenter*)
Yin Chen Y. Tsai, MD (*Abstract Co-Author*)
Chien An Liu, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize normal post-TARE findings : Common tumor changes include thin rim enhancement, internal hemorrhage; liver parenchyma may show edema, fibrosis, capsular retraction or compensatory hypertrophy at contralateral lobe. Be aware of post-TARE complications : These include rare but significant events such as radiation pneumonitis, radioembolization-induced liver disease (REILD), complication related to non-target embolization, and lymphopenia, etc. Use enhancement-based criteria for tumor response assessment : EASL, modified RECIST, and LI-RADS TRA focus on viable tumor enhancement, providing more accurate post-TARE evaluation than size-based criteria alone.

TABLE OF CONTENTS/OUTLINE

Outline1. The tumor (1) Common early and late findings (2) Complete necrosis, or not (3) Evaluating tools- EASL, modified RECIST, LI-RADS2. The liver (treated and untreated)- common early and late findings, radioembolization induced liver disease (REILD)3. The lung - radiation induced lung disease4. The non-target organs - gastroduodenal, falciform ligament and cystic arteries5. Post embolization syndrome

IREE-74 ULTRASOUND-GUIDED THORACIC PROCEDURES: INDICATIONS, TECHNIQUES AND COMPLICATIONS REVIEW

Silvia Revuelta Gomez, MD (*Presenter*)
Alejandra Somoano Marfull (*Abstract Co-Author*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Rodrigo Sutil, MD (*Abstract Co-Author*)
Ana Berasategui Criado, MD (*Abstract Co-Author*)
Victor Fernandez Lobo (*Abstract Co-Author*)

TEACHING POINTS

1. To review the basic concepts of ultrasound-guided thoracic interventions.2. To describe the advantages and limitations of ultrasound as a procedural guidance tool.3. To discuss the main indications and complications associated with pleural and pulmonary interventional procedures.

TABLE OF CONTENTS/OUTLINE

1. INTRODUCTION. Thoracic interventional procedures represent a rapidly expanding field, with numerous thoracic pathologies requiring image-guided interventions for both diagnostic and therapeutic purposes.Radiologists must therefore be familiar with each procedure's indications, complications, and technical aspects. 2. GENERAL CONSIDERATIONS. 2.1. Thoracic ultrasound. 2.2. Interventionism 3. PLEURAL INTERVENTIONS: indications, technique and complications 3.1. Thoracocentesis. 3.2. Pleural drainage. 3.3. Pleural biopsy 4. PULMONARY INTERVENTIONS: indications, technique and complications. 4.1. Pulmonary biopsy. 4.2. Drainage of pulmonary abscesses. 5. CONCLUSIONS. Due to its accessibility, low cost, and safety profile, ultrasound is an excellent tool for guiding various thoracic interventional procedures:- At the pleural level, ultrasound represents the ideal technique for performing thoracentesis, pleural drainage, and pleural biopsies, with a very low complication rate.- In the lung , the role of ultrasound is more limited, as only lesions in contact with the parietal pleura are accessible using this technique.6. BIBLIOGRAPHY.

IREE-75 POSTPARTUM HEMORRHAGE EMBOLIZATION ESSENTIALS: COMMON AND UNCOMMON BLEEDING SOURCES, PELVIC COLLATERALS, AND FERTILITY OUTCOMES

Sakiko Kageyama, MD (*Presenter*)
Kei Takase, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-Postpartum hemorrhage (PPH) includes both uterine atony-related bleeding from the endometrial cavity and traumatic bleeding from the cervix, vaginal wall, or perineum. -Depending on the hemorrhage site, bleeding may arise not only from uterine arteries but also from extra-uterine branches . Awareness of these sources is vital for selecting access and achieving effective embolization. -This exhibit reviews bleeding sources by location, including normal anatomy, variants, collateral pathways, and relevant anastomoses. -Understanding potential complications and reproductive outcomes is essential for optimal care.

TABLE OF CONTENTS/OUTLINE

1) Introduction: Overview of postpartum hemorrhage (PPH) subtypes, including uterine atony and traumatic bleeding, and the importance of anatomical understanding in interventional planning. 2)Pelvic Vascular Anatomy and Collateral Circulation Comprehensive review of pelvic arteries involved in PPH, including the uterine artery, cervicovaginal artery, vaginal artery, round ligament artery, ovarian artery, internal and external pudendal arteries, and superior, medium and inferior rectal arteries. Includes normal anatomy, common variants, collateral pathways, and clinically significant anastomoses. 3)Case-Based Presentation of Hemorrhage Patterns: Imaging and angiographic examples categorized by bleeding type and location, including uterine atony, vaginal hematoma, perineal hematoma, and other complex scenarios. 4)Complications and Reproductive Outcomes: Summary of potential ischemic complications following embolization and current evidence regarding fertility preservation and reproductive outcomes.

IREE-76 RADIOLOGY'S ROLE IN MANAGEMENT OF METASTATIC NEUROENDOCRINE TUMOR: CURRENT GUIDELINES AND RECOMMENDATIONS

Marie Killerby, MPH (*Presenter*)
Jeffrey Bodner, MD (*Abstract Co-Author*)
Nicholas Schreiter, MD (*Abstract Co-Author*)
Austin Glenn (*Abstract Co-Author*)
Stuart L. Polk, MD (*Abstract Co-Author*)
Omar Abdalla, BS (*Abstract Co-Author*)
Allen Luna, BEng (*Abstract Co-Author*)
Lily Gao, BA (*Abstract Co-Author*)
Devanshi Bhangle (*Abstract Co-Author*)
Matthew Anguiano (*Abstract Co-Author*)
Anish Kammila (*Abstract Co-Author*)
Atlee Witt (*Abstract Co-Author*)
Heather A. Cole, MD (*Abstract Co-Author*)
Andrew J. Marsala II, MD (*Abstract Co-Author*)
Reza Imani-Shikhabadi, MD, MS (*Abstract Co-Author*)
Nicholas Voutsinas, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this presentation is: 1) Review the role of interventional radiology and nuclear medicine in the treatment of metastatic neuroendocrine tumors. 2) Review recommendations as to when radiologic interventions are optimally applied, based on guidelines and recommendations from appropriate organizations

TABLE OF CONTENTS/OUTLINE

1) Introduction a. Neuroendocrine Tumor (NET) types, progression, mortality b. Treatment options for metastatic NET: i. Systemic therapy ii. Liver directed therapy. 2) Relevant society guidance and recommendations a. National Comprehensive Cancer Network (NCCN) b. The North American Neuroendocrine Tumor Society (NANETS) c. European Neuroendocrine Tumor Society (ENETS) d. Society for Interventional Radiology (SIR) e. Society of Nuclear Medicine and Molecular Imaging (SNMMI). 3) Interventional radiology and nuclear medicine management options a. Peptide Receptor Radionuclide Therapy (PRRT): i. Patient selection ii. Treatment Protocol b. Intra-arterial Embolization: i. Patient selection ii. Choice of transarterial embolization (TAE) vs. transarterial chemoembolization (TACE) vs. transarterial radioembolization (TARE) iii. Procedural Technique c. Percutaneous Therapy: i. Patient selection ii. Procedural Technique 1. Microwave Ablation 2. Cryoablation 3. Radiofrequency Ablation 4. Irreversible Electroporation 5. Histotripsy. 4) Medical Management of side effects post treatment a. Dependent on subtype of tumor, but often involving somatostatin analogs.

IREE-77 PROPTOSIS? EYE'M ON IT: A PARACAVERNOUS DAVF MIMICKING INDIRECT CCF - A DIAGNOSTIC AND THERAPEUTIC ODYSSEY

Devahuti Shalley, MD (*Presenter*)
Vivek Murumkar (*Abstract Co-Author*)
Priscilla Joshi, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Para-cavernous dural arteriovenous fistulas are rare lesions that mimic indirect carotid-cavernous fistulas (CCFs) in clinical presentation and imaging. Key differences in venous drainage and shunt location influence management. When conventional transvenous access (eg- the inferior petrosal sinus (IPS), facial vein) is not feasible, multidisciplinary approach by direct superior ophthalmic vein (SOV) access provides a safe alternative.

TABLE OF CONTENTS/OUTLINE

Clinical Presentation: A 56 year old hypertensive female presented with right eye proptosis, redness, watering, lid swelling and ptosis. Exam showed non-pulsatile, non-reducible, tender proptosis with chemosis, corneal opacities, conjunctival congestion and restricted eye movements. Imaging Findings: MRI: T1 DIXON: Right eye proptosis, enlarged SOV, swollen extraocular muscles, retrobulbar fat stranding. T2WI: Tortuous flow voids in right cavernous region. DSA & Endovascular Management DSA showed a Barrow type D indirect CCF with feeders from ICA & ECA. The right IPS was hypoplastic; embolization attempts via right superior petrosal sinus & left IPS failed. An anatomic variant of the right SOV lacked communication with the angular/ facial vein. Diagnosis revised to paracavernous fistula . Treatment & Outcome Direct SOV access with oculoplastic surgeon assistance enabled embolization. SOV was exposed and punctured using 21G Gelco cannula with Y-connector and hemostatic valve. 0.4 ml Onyx injected into fistulous sac via microcatheter, achieving complete occlusion. Post-procedure, congestion, chemosis and proptosis reduced significantly. Extraocular movements and visual acuity improved from 6/36 (pinhole) to 6/12 (p).

Abstract Archives of the RSNA, 2025

Sub-Events

MKEE-1 COMPLICATIONS AFTER SPINE SURGERY: UPDATED IMAGING CONCEPTS AND A STRUCTURED CLASSIFICATION APPROACH

Joao P. Ferreira, MD (*Presenter*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Provide a didactic classification and systematization of postoperative complications following spinal surgeries. 2. Categorize complications according to etiology (iatrogenic or not), time of onset (immediate, early, late), related to the instrumentation hardware, and anatomical location (bone, soft tissues, disc, dural sac, spinal cord, nerve roots). 3. Present a comprehensive list of complications, including direct iatrogenic events (such as wrong site injection and gossypiboma), hematoma, hardware malpositioning, fistula, infection, disc herniation recurrence, incomplete disc resection, periradicular fibrosis, adjacent segment disease, pseudarthrosis, hardware loosening or fracture, nerve root injury, radiculitis, arachnoiditis, myelopathy and pseudomeningocele. 4. Describe the imaging findings of each complication and recommend the most appropriate imaging modalities for evaluating each of them.

TABLE OF CONTENTS/OUTLINE

1. Review of applied and practical spinal anatomy. 2. Overview of common spinal surgical techniques and their indications. 3. Didactic systematization and listing of postoperative complications. 4. Management strategies for each complication. 5. Future perspectives and emerging techniques (such as endoscopic spine surgery). 6. Final didactic flowchart summarizing all complications and their classifications.

MKEE-2 MAKE THE JUICE WORTH THE SQUEEZE: TIPS AND TACTICS FOR SUCCESSFUL ARTHROCENTESIS

Jeremiah R. Long, MD (*Presenter*)
Alecio F. Lombardi, MD (*Abstract Co-Author*)
Logan Haug, MD (*Abstract Co-Author*)
David M. Melville, MD (*Abstract Co-Author*)
Jonathan A. Flug, MD, MBA (*Abstract Co-Author*)
Rupert O. Stanborough, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Common Procedure : Arthrocentesis is a frequently performed diagnostic procedure in many radiology settings.2. Widely Performed by Radiologists : Trainees, general radiologists and those with subspecialty musculoskeletal (MSK) training routinely perform arthrocentesis.3. Multiple Imaging Modalities Fluoroscopy, ultrasound, and computed tomography (CT) are all utilized for image-guided arthrocentesis.4. Factors Influencing Success : The technical success of arthrocentesis, defined as obtaining fluid, depends on multiple factors, including operator experience.5. Importance of Knowledge : Understanding site-specific and modality-specific tips and tactics can significantly enhance the technical success rate of arthrocentesis in different settings.

TABLE OF CONTENTS/OUTLINE

This educational exhibit will review the procedure of arthrocentesis with attention to consistent procedural steps, image guidance modality selection, native versus prosthetic joints and tips and tactics to help increase aspiration yields. The following outline will be utilized:• Indications for joint aspiration• Preprocedural imaging• Patient preparation• Needle selection• Specimen handling• Image guidance modality selection including pros and cons• Native joint versus prosthetic joint• General arthrocentesis tips and tactics to help improve technical success rate• Anatomic site-specific recommendations to help improve technical success rate

MKEE-3 TWIST AND TORQUE: UNRAVELING THE DISTAL BICEPS BRACHII TENDON

Lorena Brandao, MD (*Presenter*)
Gustavo O. Watanabe, MD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Luiz Ribas (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

Distal biceps brachii tendon (DBBT) ruptures have nearly doubled in the last decade, driven by an aging, active male population and better imaging. Ruptures occur when a 90° flexed, supinated elbow is forcefully extended, with hypovascularity, smoking, and steroids increasing risk. Nontraumatic issues include bursitis, tendinopathy, and chronic rupture; tenosynovitis doesn’t occur in this sheathless tendon. The DBBT’s long head enhances supination, while its short head flexes the elbow at 90°. The tendon twists 90° as it inserts, using the radial tuberosity’s apex as a cam to maximize torque. The lacertus fibrosus aponeurosis stabilizes the tendon and a teardrop-shaped bicipitoradial bursa cushions both heads during rotation. X-rays and CT detect bone injuries and postoperative changes but can’t show the tendon. MRI with the FABS view (84% sensitivity, 86% specificity) is the gold standard despite cost and limited availability. US is more accessible but requires multiple windows and dynamic maneuvers. Surgery restores strength through single or double-incision techniques with fixation options from suture buttons to interference screws but is contraindicated in patients with poor soft tissue or major comorbidities. Although complications such as rerupture, infection, heterotopic ossification, and nerve injury are uncommon, radiologists must recognize normal postoperative imaging appearances by timing and clinical context to distinguish true complications.

TABLE OF CONTENTS/OUTLINE

Anatomy Biomechanics Image evaluation CR and CT MRI (FABS) Ultrasound techniques Acute tear Degenerative lesion Miscellany Surgical Techniques Normal postoperative findings and complications of surgical repair

MKEE-4 NO STRESS WITH STRESS FRACTURES: A CASE-BASED GUIDE TO ACCURATE DIAGNOSIS

Erica D. Cruz, MD (*Presenter*)
Arthur H. Godeiro, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Stress fractures result from the repeated and excessive application of force on the bone and are classified into two types: fatigue fractures and insufficiency fractures. Fatigue fractures occur when a healthy bone is subjected to repetitive stress that exceeds its capacity for remodeling. They are more common in young athletes, particularly females, and typically affect the lower limbs. In contrast, insufficiency fractures develop when routine activities cause injury to bones that are already weakened, most often seen in elderly individuals with preexisting bone diseases. X-ray is the most commonly used initial imaging method due to its wide availability; however, other techniques such as computed tomography (CT), bone scintigraphy, and magnetic resonance imaging (MRI) play a crucial role in the diagnosis and prognosis of stress fractures.

TABLE OF CONTENTS/OUTLINE

Review and analysis of stress fracture cases from both personal and institutional archives, aiming to define fundamental concepts and correlate them with imaging findings, with an emphasis on magnetic resonance imaging. The cases are organized according to a previously established classification. Topics are structured to facilitate understanding and support further study.

MKEE-5 DECIPHERING HIP PROSTHESIS: A RADIOLOGIC GUIDE FOR BETTER EVALUATION AND DESCRIPTION

Erica D. Cruz, MD (*Presenter*)
Mateus Oliveira Gloria, MD (*Abstract Co-Author*)
Jose Lucas S. Galvao I, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

The analysis of hip orthopedic materials through imaging studies presents a challenge for radiologists, requiring specialized knowledge due to its critical role in postoperative evaluation and in identifying potential complications associated with these devices. Plain radiography is typically the initial imaging modality of choice, as it is widely available, cost-effective, and provides a general overview of implant positioning, bone condition, and joint alignment. However, advanced imaging techniques such as computed tomography (CT) and magnetic resonance imaging (MRI) are often recommended for a more detailed assessment of the prosthesis-bone interface, surrounding soft tissues, and possible pathological changes. The integrated use of these imaging modalities enables a more comprehensive and accurate evaluation, contributing to the proper interpretation of hip orthopedic devices.

TABLE OF CONTENTS/OUTLINE

Analysis of hip prosthesis cases from both personal and institutional archives, reviewing aspects such as anatomical landmarks, prosthetic components, techniques, measurements and angles, complications, and special cases. Additionally, correlations between different imaging modalities are performed.

MKEE-6 NO UNION, NO GLORY: IMAGING THE DOWNFALL OF AN UNHEALED SCAPHOID

Giulia Caroline Paes Scopel, MD (*Presenter*)
Rodrigo Zancanaro, MD (*Abstract Co-Author*)
Daniel C. Oliveira, MD (*Abstract Co-Author*)
Tereza Souto, MD (*Abstract Co-Author*)
Mariana Faria Amaral, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to provide an educational overview of scaphoid non-union.A) To recognize key imaging findings across radiography, CT, and MRI for accurate diagnosis and differentiation from anatomical variants.B) To identify critical complications such as avascular necrosis (AVN) and patterns of carpal instability, including the progression to scapholunate advanced collapse (SLAC) wrist. This exhibit aims to improve diagnostic accuracy and confidence among radiologists in formation and musculoskeletal imaging specialists in evaluating scaphoid non-union and its complications.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of scaphoid anatomy and vascular supply, emphasizing the retrograde intraosseous blood supply to the proximal pole and its implications for non-union. Discussion of scaphoid fracture patterns and mechanisms of injury, with a focus on fractures prone to non-union. Definition of scaphoid non-union and its clinical consequences. Imaging Techniques: Radiography. Computed Tomography (CT). Magnetic Resonance Imaging (MRI). Interpreting Imaging Findings (case based review): Avascular Necrosis (AVN). Carpal instability patterns. Scapholunate advanced collapse (SLAC) wrist. Conclusion: Summary of Key Imaging Features. Importance of Accurate Diagnosis and Imaging-Guided Management.

MKEE-7 FIRST CARPOMETACARPAL OSTEOARTHRITIS: BIOMECHANICS, IMAGING, AND OPERATIVE TREATMENT

Jayesh Gupta, MD (*Presenter*)
Conner Beyersdorf, MD (*Abstract Co-Author*)
Brandon Ritchie, DO (*Abstract Co-Author*)
Vijaya K. Kosaraju, MD (*Abstract Co-Author*)
Navid Faraji, MD (*Abstract Co-Author*)

TEACHING POINTS

The carpometacarpal (CMC) joint is a complex joint of two perpendicular, saddle-shaped bones stabilized by ligaments. This unique anatomy enables the thumb's wide range of motion, including various forms of adduction, abduction, opposition, and retropulsion. The CMC joint is the second most common site of hand arthritis and the most frequently operated joint in the upper extremity. Arthritis here can significantly impair function and quality of life. While nonsurgical treatments may be tried, surgery is often required, with multiple techniques available. This educational exhibit aims to: 1) Review CMC joint anatomy, 2) Outline the Eaton-Littler classification, and 3) Present surgical treatment options with postoperative imaging.

TABLE OF CONTENTS/OUTLINE

CARPOMETACARPAL ANATOMY• Understanding the biomechanics of the joint and the stabilizing ligaments involved • EPIDEMIOLOGY/RISK FACTORS • IMAGING • Reviewing Eaton-Littler classification and identifying pertinent negative findings • Using MRI for further evaluation • TREATMENT • Surgical options available such as volar ligament reconstruction, tendon interposition, arthroplasty • Identifying patients who have received surgical treatment for CMC arthritis and associated postoperative complications

MKEE-8 DEMYSTIFYING THE DRUJ: POSTOPERATIVE IMAGING OF THE DISTAL RADIOULNAR JOINT

Parker Brown, MD (*Presenter*)
Lana Elcic, MD (*Abstract Co-Author*)
Logan Haug, MD (*Abstract Co-Author*)
Anisha Shetty, MD (*Abstract Co-Author*)
Jeremiah R. Long, MD (*Abstract Co-Author*)
Aaron J. Wyse, MD (*Abstract Co-Author*)
Jonathan A. Flug, MD, MBA (*Abstract Co-Author*)
David M. Melville, MD (*Abstract Co-Author*)

TEACHING POINTS

Present the anatomic complexity of the distal radioulnar joint (DRUJ) and how its complex structure is essential for forearm rotation and upper extremity weight bearing. Introduce common pathologies involving the DRUJ, specifically highlighting the impact on osseous anatomy by focusing on osteoarthritis and post-traumatic instability. Present cases of various DRUJ pathology with emphasis on the spectrum of interventions employed to treat DRUJ injuries while demonstrating the post-operative appearances. When applicable, spotlight post-operative complications associated with these interventions, such as: Recurrent or persistent subluxation/widening of the DRUJ at the sigmoid notch after ligamentous reconstruction, loosening or infection, Aptis arthroplasty component failure.

TABLE OF CONTENTS/OUTLINE

Introduction : Anatomic and functional overview of the DRUJ, Imaging techniques for DRUJ evaluations, Common DRUJ pathologies and their imaging appearances. Surgical Interventions for DRUJ Pathology : Adams-Berger ligamentous reconstruction, Sauve-Kapandgi, Darrach, Wrist arthrodesis and bone graft with pronator quadratus stabilization, Bowers procedure, Matched distal ulnar resection, Extensor retinaculum for DRUJ instability, Aptis arthroplasty, Hemiresection with pronator quadratus interposition and volar stabilization. Postoperative Complications Conclusion : Summary of key points, highlighting common pathology and most frequent surgical interventions.

MKEE-9 IMAGING OF DESMOID FIBROMATOSIS: A COMPREHENSIVE REVIEW

Shuji Nagata, MD (*Presenter*)
Hiroshi Nishimura, MD (*Abstract Co-Author*)
Miyuki Sawano (*Abstract Co-Author*)
Yuki Shouji (*Abstract Co-Author*)
Seiji Kurata, MD (*Abstract Co-Author*)
Yusuke Uchiyama, MD (*Abstract Co-Author*)
Shuichi Tanoue, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

To illustrate the clinical and radiologic features of desmoid fibromatosis (DF) in extra-abdominal, intra-abdominal, and abdominal wall sites. To compare MRI findings with pathological features of DF in various phases (e.g., growth phase, plateau phase, and regression phase). To highlight characteristic MRI findings of DF (e.g., band sign, fascial tail sign, flame sign, Yin-yang sign, and staghorn sign). To discuss MRI findings for predicting tumor growth in DF (e.g., Black fiber sign and T2 ratio). To describe soft tissue tumors that may mimic DF on MRI (e.g., schwannoma, SFT, leiomyosarcoma).

TABLE OF CONTENTS/OUTLINE

Desmoid fibromatosis (DF) is a rare, deep-seated myofibroblastic tumor characterized by infiltrative growth and a high rate of local recurrence. Its variable imaging features and clinical behavior often make diagnosis challenging. MRI is the imaging modality of choice, and a systematic approach is essential to distinguish DF from malignant soft-tissue tumors. Radiologists should recognize key imaging signs and patterns to accurately suggest the diagnosis. In addition, we discuss MRI findings for predicting tumor growth in DF, including the black fiber sign and T2 ratio.

MKEE-10 FROM TACKLE TO TINGLING: A RADIOLOGIC APPROACH TO SPORTS-RELATED PERIPHERAL NERVE INJURIES

Maria Lua Gulde (*Presenter*)
Paulo Victor P. Helito, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)
Renata T. Fernandes, MD (*Abstract Co-Author*)
Eduardo L. Bizetto, MD (*Abstract Co-Author*)
Raul O. Martins, MD (*Abstract Co-Author*)
Marcelo Bordalo, MD (*Abstract Co-Author*)
Elisabet Hagert (*Abstract Co-Author*)

TEACHING POINTS

Sports-related peripheral nerve injuries are an important source of pain and often present a diagnostic challenge, as symptoms frequently overlap with those of other conditions. These injuries may result from acute trauma but more commonly arise from chronic repetitive stress. Radiologists play a key role in diagnosing neuropathies, either by being the first to identify an unsuspected injury or by confirming and staging a suspected pathology. This exhibit aims to promote awareness of peripheral nerve injuries in athletes by outlining a practical imaging-based diagnostic approach. We present a comprehensive review of peripheral nerve pathologies associated with sports, focusing on examination protocols, anatomy, imaging findings, and relationship with sport modalities. Emphasis is given to high-resolution ultrasonography (US) and MR-neurography (MRN). This exhibit integrates imaging findings with patient history and, when applicable, surgical correlation. It addresses both compressive and post-traumatic neuropathies, involving abdominal wall, upper and lower limb nerves.

TABLE OF CONTENTS/OUTLINE

1. General overview of sports-related peripheral nerve injuries. 2. Mechanisms of nerve injury and the association with sport-specific movements. 3. Imaging protocols and assessment of the peripheral nerves using 3D MRN and high-resolution US. 4. Case-based review from our institutional database with sport-specific examples. 5. Correlation with imaging findings, clinical implications, surgical planning, and intraoperative findings.

MKEE-11 IMAGING FINDINGS AND TREATMENTS FOR OF MUSCULOSKELETAL VASCULAR ANOMALIES: WHAT RADIOLOGIST SHOULD KNOW

Miyuki Sawano (*Presenter*)
Shuji Nagata, MD (*Abstract Co-Author*)
Shohei Mizushima (*Abstract Co-Author*)
Tomoko Kugiyama (*Abstract Co-Author*)
Asako Kuhara (*Abstract Co-Author*)
Yusuke Uchiyama, MD (*Abstract Co-Author*)
Masamichi Koganemaru (*Abstract Co-Author*)
Shuichi Tanoue, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the spectrum of vascular anomalies (VAs) and relevant syndromes. 2. To present the characteristics and roles of each imaging modality. 3. To illustrate the imaging appearances of various musculoskeletal VAs related to treatment.

TABLE OF CONTENTS/OUTLINE

The musculoskeletal system is one of most common sites involved by VAs. The VAs are basically categorized based on the classification established by International Society for the Study of Vascular Anomalies (ISSVA) . For the safe and effective treatments, accurate imaging diagnosis is essential, in addition, the correct understanding of angioarchitecture and hemodynamics of the lesion may help making appropriate treatment strategy. 1). Classification and terminology of VAs according to the ISSVA 2). Characteristics and clinical applications of imaging modalities: US, CT, MRI, Angiography 3). Clinical manifestations and imaging features of VAs: Infantile hemangioma, Congenital hemangioma, Tufted angioma, Kaposiform hemangioendothelioma, Kaposi sarcoma, Angiosarcoma 4). Clinical features and treatment strategies based on the angiographic classification of vascular malformations: Arteriovenous malformation, Venous malformation, Lymphatic malformation, Capillary malformation 5). Clinical manifestations and imaging findings of vascular malformations associated with other anomalies: Klippel-Trenaunay syndrome, Parks Weber syndrome 6). Clinical manifestations and imaging findings of unclassified VAs: Fibro adipose vascular anomaly (FAVA)

MKEE-12 PEARLS AND PITFALLS OF TOTAL KNEE ARTHROPLASTIES

Yujie Qiao, MD (*Presenter*)
Josephina A. Vossen, PhD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit will review surgical indications of total knee arthroplasties, normal and abnormal postoperative imaging appearance, and the most common short and long-term complications. Increased knowledge and improved detection of complications can prevent delays in treatment that could result in long-term disability.

TABLE OF CONTENTS/OUTLINE

Review the indications and contraindications of total knee arthroplasties. Describe and illustrate the expected imaging appearance of total knee arthroplasties. Teach the difference between unconstrained (posterior-cruciate retaining, posterior-cruciate substituting), constrained (nonhinged, hinged) and fixed versus mobile bearing. Describe short and long-term complications and their imaging appearance, including prothesis malalignment, prosthesis loosening, periprosthetic fractures, polyethylene liner dislodgement, extensor mechanism rupture and infection.

MKEE-13 IMAGING CARPAL LIGAMENT INSTABILITY AND INJURIES: CLINICAL INSIGHTS THROUGH CASE-BASED LEARNING

Ligia C. Germek, MD (*Presenter*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Camila Tabosa, MD (*Abstract Co-Author*)
Rafael Omena, MD (*Abstract Co-Author*)
Roberto Froeder Oliveira, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Carpal ligament instability is a complex diagnostic challenge requiring detailed anatomical knowledge and clinical-radiological correlation. Understanding instability patterns (CID, CIND, adaptive, complex) is essential for accurate interpretation and management. A multimodality imaging approach improves detection and characterization of ligamentous injuries.

TABLE OF CONTENTS/OUTLINE

We begin with a review of the functional anatomy of carpal ligaments, categorized as intrinsic and extrinsic, emphasizing their three-dimensional arrangement and their fundamental role in both dynamic and static carpal stability. We then explore the classification of carpal instabilities, focusing on the main patterns: dissociative (CID), non-dissociative (CIND), adaptive, and complex types. This framework is key for interpreting imaging findings and guiding management.A range of imaging modalities—including radiographs, CT, and MRI—are discussed with emphasis on their strengths and limitations in evaluating ligamentous injuries. Real clinical cases are used to illustrate different instability patterns, highlighting clinical-radiological correlation and key diagnostic features. Schematic illustrations are incorporated to clarify key concepts, particularly in angular assessment and progression of injury patterns.

MKEE-14 OSTEOID OSTEOMA. A RADIOLOGICAL REVIEW

Marta Granados Baltuille, MD (*Presenter*)
Xiaqun Xuzhu (*Abstract Co-Author*)

TEACHING POINTS

The aim of this article is to present the main radiological findings of one of the most common bone tumors, the osteoid osteoma. This is the third most common bone tumor, after enchondroma and non-ossifying fibroma. Typically, it occurs in males between 10 and 35 years old and clinically manifests as nocturnal pain that relieves with salicylates. This tumor consists of a nidus, or the tumor itself, which appears as a cortical lytic lesion in the diaphysis of the long bones such as the femur and tibia, accompanied by sclerosis and surrounding corticoperiosteal thickening. Less common locations include the carpal and tarsal bones, the spine, the upper limbs, or even intra-articular sites in up to 10-13% of cases, presenting as joint effusion and synovitis, for which MRI is the imaging modality of choice. The gold standard imaging technique is Computed Tomography (CT), which demonstrates a highly specific sign called "the vascular groove sign" in up to 80% of cases. Furthermore, CT guides treatment, which consists of radiofrequency ablation of the nidus, with success rates of 94-95%. However, it is a lesion that requires a high degree of suspicion to diagnose, as it can present in multiple forms depending on the degree of calcification of the nidus, as well as a wide range of differential diagnoses, such as Brodie's abscess, osteoblastomas, stress fractures, or septic arthritis, among others.

TABLE OF CONTENTS/OUTLINE

The article presents the following outline: Introduction Epidemiology Classification and Locations Diagnostic imaging techniques and main radiological findings Treatment Differential Diagnosis Conclusions

MKEE-15 THE SILENT INFECTION: MRI CLUES TO TUBERCULAR SACROILIITIS

Sapna Katyal, MD (*Presenter*)
Sapna Singh (*Abstract Co-Author*)
Anjali Prakash, DMRD (*Abstract Co-Author*)

TEACHING POINTS

Imaging features of tubercular sacroiliitis and differentiating features of tubercular sacroiliitis from seronegative spondyloarthropathy.

TABLE OF CONTENTS/OUTLINE

Tuberculosis is a major cause of musculoskeletal infection particularly in immunocompromised patients most commonly involving the spine. Tubercular sacroiliitis however, is an uncommon infection which may present insidiously, making early MRI-based diagnosis essential for appropriate management. The exhibit will illustrate the MRI features of tubercular sacroiliitis structured under specific imaging parameters including bone and cartilage changes in the form of bone marrow edema, intraosseous abscesses and erosions; joint and synovial changes in the form of synovitis, enthesitis, capsulitis, sclerosis; juxta-articular soft tissue changes including perimuscular edema, presacral abscesses, sinus tract formation and neurovascular bundle involvement. Key imaging differences from seronegative spondyloarthropathy (SpA) will also be highlighted. Imaging findings favoring tubercular sacroiliitis include bone marrow edema with sacral predominance and asymmetric distribution, deep erosions with sacral dominance, intraosseous and presacral abscesses, muscle edema, sinus tract formation and neurovascular involvement whereas features favoring seronegative spondyloarthropathy include iliac-dominant, symmetrical bone marrow edema, typically smaller (<1 cm) and iliac-predominant erosions, inflammation confined to the joint without muscular or neurovascular involvement.

MKEE-16 COMPREHENSIVE IMAGING REVIEW OF ELBOW TRAUMA: ANATOMY AND KEY INJURIES

Danilo Amaral, MD (*Presenter*)
Livia Reis, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Elbow trauma demands a thorough understanding of the joint's complex anatomy and the mechanisms underlying common injury patterns. Accurate assessment relies on a structured approach to imaging interpretation, supported by knowledge of anatomical landmarks and normal variants. Multimodality imaging—including radiography, CT, and MRI—plays a central role in detecting both osseous and soft tissue injuries. Early recognition of subtle findings is essential to avoid misdiagnosis and guide appropriate clinical management. This exhibit aims to enhance diagnostic accuracy and reporting clarity through focused anatomical review and case-based learning.

TABLE OF CONTENTS/OUTLINE

The exhibit begins with an overview of the clinical relevance of elbow trauma and the imaging modalities employed in its evaluation. It then transitions into a detailed review of elbow anatomy, highlighting osseous structures, musculature, and ligamentous complexes. Key anatomical variants are briefly discussed to support accurate interpretation. Common traumatic injuries are presented next, including fractures of the distal humerus, radial head, coronoid process, and olecranon, along with typical patterns of elbow dislocation. A case-based section reinforces key learning points and illustrates complex injuries, concluding with diagnostic strategies and their clinical implications.

MKEE-17 POSTERIOR MENISCAL MYSTERIES-IMAGING KEYS TO UNLOCKING RAMP TEAR DIAGNOSIS

Pranav K. Udupi, MD,MBBS (*Presenter*)
Amit K. Sahu, MBBS, MD (*Abstract Co-Author*)
VIKASH K. GUPTA, MD (*Abstract Co-Author*)
Anuradha Sural, MD (*Abstract Co-Author*)
Bharat Aggarwal, MD (*Abstract Co-Author*)
Anjali Sharma (*Abstract Co-Author*)
Vikas Gupta (*Abstract Co-Author*)

TEACHING POINTS

Recognize the spectrum of Ramp lesions (posterior medial meniscal tears) using the Grief classification system, demonstrated through case examples and custom illustrations.Understand clinical significance: RAMP tears frequently accompany ACL injuries (10-40%) and may contribute to anterolateral rotatory instability when overlooked, potentially compromising ACL reconstruction outcomes. Recognize clinical implications: Identification and repair of RAMP tears leads to improved knee stability, better functional outcomes, and reduced ACL graft stress. Missed RAMP lesions remain a significant cause of persistent instability following ACL reconstruction.

TABLE OF CONTENTS/OUTLINE

Definition of RAMP tear and its classification by Grief et all. Includes custom made illustration of types.Case example of type 1 RAMP tear.Case example of type 2 RAMP tear.Case example of type 3A and 3B RAMP tears.Example of type 4A RAMP tear and custom illustration of type 4B tear.Illustration of Type 5 tear and clinical significance with differential diagnosis.

MKEE-18 THE SILENT SIGNALS-THE SOFT TISSUE FINDINGS THAT SPEAKS VOLUMES

Pranav K. Udupi, MD,MBBS (*Presenter*)
Amit K. Sahu, MBBS, MD (*Abstract Co-Author*)
VIKASH K. GUPTA, MD (*Abstract Co-Author*)
Anuradha Sural, MD (*Abstract Co-Author*)
Bharat Aggarwal, MD (*Abstract Co-Author*)
Akshay Tiwari (*Abstract Co-Author*)

TEACHING POINTS

Recognize characteristic imaging patterns of Pellegrini-Stieda lesion, representing post-traumatic ossification of the medial collateral ligament, which appears as linear calcification along the medial femoral condyle. Identify calcific tendinitis and myositis ossificans with case example Appreciate the arcuate sign as a reliable indicator of posterolateral corner injury, representing avulsion of the arcuate ligament complex - a finding often overlooked but critical for surgical planning. Distinguish phleboliths in vascular malformations from other calcifications based on their characteristic lamellated appearance and association with soft tissue masses showing diagnostic vascular features. Interpret periosteal reaction patterns (solid, lamellated, sunburst, Codman triangle) as valuable clues to underlying pathology, from benign processes to aggressive malignancies. Recognize distinctive matrix patterns in bone tumors that guide differential diagnosis, including chondroid, osteoid, and fibrous matrices.

TABLE OF CONTENTS/OUTLINE

Case example of Pelligrini Steida lesion and Arcuate sign.Case of calcific tendinitis and Vascular malformation.Slide about Myositis ossificans with examples and CT correlation.Slide about different periosteal reaction.Different types of matrix of bone lesions with example for chondroid matrix.

MKEE-19 APPLICATIONS OF DIGITAL TOMOSYNTHESIS IN THE MUSCULOSKELETAL SYSTEM

Nogah Shabshin, MD (*Presenter*)
Mor Armoni (*Abstract Co-Author*)
Yotam Kimmel (*Abstract Co-Author*)
Guy Yoskovitz (*Abstract Co-Author*)
Yael S. Schiffenbauer, PhD (*Abstract Co-Author*)
Ophir Robenpour (*Abstract Co-Author*)
Sigal Tal, MD, DMD (*Abstract Co-Author*)
Yiftah Beer, MD (*Abstract Co-Author*)

TEACHING POINTS

Digital tomosynthesis (DTS) is a well-established imaging technique that has become the gold standard in breast mammography. In recent years its benefits in musculoskeletal (MSK) imaging have gained recognition, and along with the growing availability at lower costs resulted in a rapid increase in its utilization. Although this is a radiographic technique, reading a DTS study is different than reading a conventional radiograph, and requires just a short learning curve. The purpose of this exhibit is to enhance the readers knowledge and confidence on the technology, and explore a range of clinical cases and applications. Key benefits of DTS in MSK include: 1. Enhanced visualization of overlapping bones and articular surfaces; 2. Improved sensitivity of radiographically occult fracture diagnosis; 3. Better anatomical localization of both normal bony structures and abnormal findings; 4. Elimination of radiographic pseudo findings such as pseudo fractures caused by overlapping structures; 5. Provision of sufficient diagnostic information for surgical planning, with significantly lower radiation, cost, and reading time compared to CT; 6. Reduced dependency of image quality on optimal patient positioning; 7. Significantly improved imaging of the bones and joints in patients with casts, splints and bracing; 8. Improved imaging in the presence of metal.

TABLE OF CONTENTS/OUTLINE

1) Purpose of the Educational Session. 2) Background on DTS. 3) Radiation considerations. 4) How to read a DTS study. 5) Enhance the readers knowledge and confidence in DTS. 6) Applications and Clinical cases. 7) Take home messages

MKEE-21 PREOPERATIVE IMAGING OF ACUTE KNEE DISLOCATION: WHAT THE SURGEON WANTS TO KNOW

Dyan V. Flores, MD (*Presenter*)

TEACHING POINTS

Acute knee dislocation (AKD) refers to complete disruption of the integrity of the tibiofemoral articulation. It is a potentially limb-threatening injury with long-term dysfunction and even amputation. Though an overall rare condition with a reported incidence of less than 0.5%, actual incidence is likely underestimated due to spontaneous reduction or missed diagnosis in the setting of polytrauma. In some instances, the radiologist may even be the first physician to suggest the diagnosis of a traumatic knee dislocation. Given its significant morbidity, the radiologist plays a crucial role in accurate depiction of the extent of injury for appropriate preoperative planning. The objectives of this educational exhibit are: -To review definitions and classifications in AKD -To discuss imaging considerations and associated injuries -To outline imaging findings that the surgeon wants to know before operative management

TABLE OF CONTENTS/OUTLINE

Definitions •Dislocation •Subluxation •Multiligament knee injury Classifications •Kennedy •Schenck Imaging Considerations Associated Injuries •Posterolateral corner •Popliteal artery •Common peroneal nerve •Dislocations in the rest of the knee What The Surgeon Wants to Know 1.Findings that affect treatment decision-making (operative versus conservative) •Location of ligament tears •Presence of osseous avulsion •Peroneal nerve injury 2.Findings that may affect timing of surgery •Which ligaments are injured (staged approach) •Popliteal artery injury •Meniscus tear •Chondral damage 3.Findings that may affect the surgical technique •Reconstruction versus repair •Status of the iliotibial band

MKEE-22 BONE VOYAGE: SCANNING THROUGH OSTEOPOROSIS WITH DXA

Matheus Alpaccino Vale De Castro (*Presenter*)
Livia Vasconcelos, MD (*Abstract Co-Author*)
Raul N. Pigatto, MD, MBA (*Abstract Co-Author*)
Paulo Ferreira, MD (*Abstract Co-Author*)
Andre S. Kamogari Nakamura, MD (*Abstract Co-Author*)
Ricardo Caracante, MD (*Abstract Co-Author*)
Joao Pedro d. Costa, MD (*Abstract Co-Author*)
Renato Fujiki, MD (*Abstract Co-Author*)
Paulo R. Moreira, MD (*Abstract Co-Author*)
Henrique A. Lino, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Osteoporosis is a progressive, silent disease that increases fracture risk and demands early and accurate diagnosis. DXA (dual-energy X-ray absorptiometry) is the gold standard for assessing bone mineral density. Quantitative criteria as T-score and Z-score are essential but can be influenced by qualitative factors. Artifacts such as patient positioning, vertebral fractures, vascular calcifications, and degenerative changes can alter DXA interpretation.The physician plays a critical role in interpreting DXA results, similar to a flight commander who adjusts the coordinates according to the conditions.

TABLE OF CONTENTS/OUTLINE

Introduction - epidemiology and impact of osteoporosis and importance of early diagnosis;Imaging Method - DXA - technical principles and quantitative assessment and T-score interpretation;Qualitative factors influencing DXA - commom artifacts and anatomical variations,- degenerative changes, fractures,- calcifications,- positioning errors and their consequencesThe physician’s role: avoiding misdiagnosis through qualitative evaluation).

MKEE-23 CRACKING THE SIDE STRAIN PEARLS: RADIOLOGIC INSIGHTS INTO A RARE ELITE ATHLETIC INJURY

Omar Ashour, MD, MRCS (*Presenter*)
Kieran Pandey (*Abstract Co-Author*)
Aditya R. Daftary, MBBS (*Abstract Co-Author*)
Leanne K. Singh, MBBS, FRCR (*Abstract Co-Author*)
Prof. Janani Pillai, MBBS,FRCR (*Abstract Co-Author*)

TEACHING POINTS

Side strain is an uncommon tear of the lateral abdominal wall muscle commonly seen in cricketers, presenting as acute lateral trunk pain. MRI is the gold standard, accurately delineating and grading the extent of injury, predicting recovery time, and aiding safe return-to-play decisions.These injuries can get missed without appropriate imaging, which can delay recovery or increase the risk of recurrence. Radiologists play a pivotal role in diagnosis but also in guiding management, recovery and influencing long-term outcomes. Given the limited literature and low awareness, a radiology led multidisciplinary approach is essential for recognising and managing this underdiagnosed sports injury, improving outcomes.

TABLE OF CONTENTS/OUTLINE

What is side strain and why it matters in elite-level cricket? Mechanism of Injury: Rotational biomechanics and anatomical vulnerability of the internal oblique. Clinical Features: Epidemiology, presentation (acute lateral trunk pain on non-dominant side), and clinical assessment. Imaging: MRI findings (oedema, partial tears, avulsion); ultrasound’s adjunct role in dynamic assessment and guided interventions; excluding other diagnoses. Management: Conservative treatment (rest, analgesia, physiotherapy) as mainstay; role of corticosteroid or PRP injections; rarely surgery. Return-to-Play: Criteria for safe return, typical recovery timeline and re-injury prevention. Radiology-Led Teaching Value: call for awareness, imaging protocols and multidisciplinary approach to make time sensitive decisions. Conclusion: Gaps in literature and radiologist’s crucial role to confirm diagnosis, management, and outcomes for this rare injury.

MKEE-24 WHOLE-BODY MAGNETIC RESONANCE IMAGING FOR NEUROMUSCULAR DISORDERS: APPLICATIONS, NEW PERSPECTIVES AND CASE-BY-CASE REVIEW

Renato Fujiki, MD (*Presenter*)
Amr Kalander, MD (*Abstract Co-Author*)
Joao S. Pais, MD (*Abstract Co-Author*)
Paulo Ferreira, MD (*Abstract Co-Author*)
Livia Vasconcelos, MD (*Abstract Co-Author*)
Paulo R. Moreira, MD (*Abstract Co-Author*)
Ricardo Caracante, MD (*Abstract Co-Author*)
Raul N. Pigatto, MD, MBA (*Abstract Co-Author*)
Andre S. Kamogari Nakamura, MD (*Abstract Co-Author*)
Renan Oliveira De Carvalho Caminha (*Abstract Co-Author*)
Henrique A. Lino, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)

TEACHING POINTS

Whole-body magnetic resonance imaging (WB-MRI) is well established in medical practice in oncologic screening and staging. There are new perspectives for musculoskeletal evaluation, especially for inflammatory arthropathies and myopathies. Despite being rare, neuromuscular disorders (NMD) can benefit from the radiologic evaluation of specific patterns of muscular fatty atrophy (MFA). The purpose of this exhibition is to: - Review the role of WB-MRI in musculoskeletal evaluation, focusing on NMD. - Review the specific patterns of MFA related to NMD and highlight when this diagnosis should be suspected. - Discuss the new perspectives for WB-MRI in this scenario. - Describe the technique of image acquisition within a resumed protocol.

TABLE OF CONTENTS/OUTLINE

Introduction Physical and clinical aspects of WB-MRI Currently available WB-MRI options Epidemiology, physiopathology and clinical aspects of NMD in general. Perspectives in WB-MRI for NMD evaluation Review the importance of the patterns of MFA and why this protocol could be helpful in NMD assessment New perspective and protocol suggestion for NMD evaluation with examples. Case-by-case discussion and review Specific patterns of MFA and its correlation with NMD: desminopathy, collagen-VI related dystrophies, metabolic dystrophies, mitochondrial myopathies and others. Differential diagnosis: myositis, fasciitis and other conditions. Conclusions & "take-home messages"

MKEE-25 FOLLOW THE FAT AND YOU WILL FIND THE ANSWER: MRI PATTERN RECOGNITION OF GENETIC MYOPATHIES

Benjamin M. Pizarro-Galleguillos, MD (*Presenter*)
Maria Fernanda Galleguillos, MD (*Abstract Co-Author*)
Axel I. Aranguiz Aranda, MD (*Abstract Co-Author*)
Diana G. Lopez Alvarez, MD (*Abstract Co-Author*)
Jorge A. Bevilacqua (*Abstract Co-Author*)
Jorge Diaz, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Genetic myopathies are caused by mutations in genes involved in muscle structure or function and are characterized by selective muscle involvement.2. MRI is the imaging gold standard for the assessment of myopathies. Standard protocols include T1w and STIR: T1w allows assessment of muscle fatty replacement, while STIR identifies edema.3. Fatty replacement patterns help to differentiate genetic myopathies and support genetic testing.4. Key imaging features include selective muscle involvement (e.g. tongue in Pompe), sparing (e.g. sartorius in dysferlinopathy), asymmetry (e.g. facioscapulohumeral dystrophy), cephalocaudal gradients (e.g. sarcoglycanopathies), and specific signs (e.g. peripheral involvement with central sparing in COL6A).5. MRI reports should quantify fatty replacement for each muscle group, highlighting affected and spared muscles. Conclusions should indicate whether the findings are consistent with a myopathy, support a genetic etiology, and, if possible, suggest a specific diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Introduction: pathophysiology and genetics.2. MRI protocols: recommended sequences.3. Myopathy imaging findings: fatty replacement and edema.4. Diagnostic approach: systematic analysis and diagnostic algorithms5. Disease-specific patterns: a) Dystrophic: Limb-girdle muscular dystrophies, dystrophinopathies, and others. b) Non-dystrophic: Congenital myopathies and channelopathies. c) Metabolic: Pompe and mitochondriopathies.6. How to report: a recommended template.7. Conclusions.

MKEE-26 BEYOND THE USUAL SUSPECTS: UNCOVERING CHOPART SPRAINS ON MRI

Grace Wang, MD, MPH (*Presenter*)
Mickael Tordjman, MD, MS (*Abstract Co-Author*)
Kevin Pham, MD (*Abstract Co-Author*)
Bronte Balon, MD (*Abstract Co-Author*)
Mingqian Huang, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Identify normal anatomy of the Chopart (midtarsal) joint complex on MRI, including the calcaneocuboid and talonavicular ligaments 2) Use case-based imaging review to demonstrate MRI features of mid-ankle (Chopart) sprains, which are often under recognized in routine ankle trauma workups 3) Recognize classic injury mechanisms and associated bone contusion patterns that suggest midtarsal ligament injury 4) Distinguish pitfalls 5) Highlight the clinical consequences of missed Chopart sprains 6) Emphasize the role of MRI in guiding and discuss when further orthopedic evaluation is warranted

TABLE OF CONTENTS/OUTLINE

Introduction: a) Epidemiology of midtarsal injuries in ankle trauma b) Clinical presentation in ED and outpatient settings Anatomy and biomechanics of injuries: a) Normal anatomy of the talocalcaneonavicular and calcaneocuboid joints b) Mechanisms of Chopart injury Case-Based Review of Chopart Sprains: a) For example, classic acute inversion-type sprain, chronic sequalae of remote midtarsal sprain, and complex combined ligamentous injury Pitfalls and Variants: a) Differentiating true ligament injury from normal thickening or chronic scarring b) Accessory ossicles vs. avulsion fragments c) Commonly missed bone marrow edema patterns in Chopart injuries Surgical and Clinical Correlation: a) Overview of conservative vs. surgical management b) Role of imaging in guiding orthopedic referral c) Outcomes of untreated Chopart instability

MKEE-27 PAINFUL SKIN TUMORS UNDER THE PROBE: HIGH-FREQUENCY ULTRASOUND AS A KEY DIAGNOSTIC TOOL

Sofia Skaf (*Presenter*)
Damaris V. Goncalves, MD (*Abstract Co-Author*)
Claudia B. Camara, MD (*Abstract Co-Author*)
Fernanda A. Cavallieri, MD (*Abstract Co-Author*)
Maria Issa (*Abstract Co-Author*)
Leila Riedel (*Abstract Co-Author*)
Andrezza Sarli, MD (*Abstract Co-Author*)
Caroline Skaf, MD (*Abstract Co-Author*)

TEACHING POINTS

High-frequency ultrasonography (HFUS) has become a key diagnostic tool for dermatologists and plastic surgeons due to its availability, safety, and cost-effectiveness. It also offers higher spatial resolution than earlier imaging modalities like magnetic resonance imaging (MRI). As demand for specialized sonographic evaluation grows, radiologists must recognize dermatologic lesions and their imaging features. Although asymptomatic skin lesions are often underestimated—delaying cancer diagnoses—patients tend to seek faster evaluation when lesions are palpable, painful, or cause dysesthesia. These arise from various etiologies grouped under the acronym ENGLAND (eccrine spiradenoma, neuroma, glomus tumor, leiomyoma, angiolipoma, neurilemmoma, and dermatofibroma). Expanded acronyms like LEND AN EGG also include endometrioma and granular cell tumor. However, many other conditions, such as foreign bodies, may similarly present with pain and cutaneous alterations. This educational exhibit highlights their key clinical and sonographic features, particularly on HFUS, and aims to serve as a practical guide for radiologists in differentiating these entities and improving diagnostic report quality.

TABLE OF CONTENTS/OUTLINE

1) Introduction: overview of painful skin lesions and presentation of the acronym LEND AN EGG. 2) HFUS: technical aspects of imaging of skin lesions with high-frequency probes and low-scale Color and Power Doppler imaging. 3) Demonstration of each painful skin lesion and its imaging aspect: Leiomyoma, Eccrine spiradenoma, Neuroma, Dermatofibroma, Angiolipoma, Neurilemmoma (Schwannoma), Endometrioma, Glomus tumor, Granular cell tumor, Miscellanea. 4) Conclusion

MKEE-28 STRAIGHT TALK ON A TWISTED SPINE: NAVIGATING SCOLIOSIS IMAGING

(*Presenter*)
Lucas K. Miyahara, MD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: 1. To review scoliosis definition, etiology and classification. 2. To discuss when to use imaging techniques such as CT and MRI to evaluate patients with scoliosis. 3. To analyze multimodality imaging associated findings in patients with scoliosis. 4. To assess the ability to predict postoperative correction. 5. Scoliosis surgical treatment.

TABLE OF CONTENTS/OUTLINE

1. Scoliosis definition. 2. Scoliosis etiology and biomechanics. 3. Imaging evaluation: Role of radiography, computed tomography, and magnetic resonance imaging. 4. Cobb angle. 5. Lenke Scoliosis Classification. 6. Spinal flexibility assessment in preoperative scoliosis. 7. Imaging findings associated regarding each scoliosis etiology. 8. Indications, main techniques, imaging findings, and complications in scoliosis surgery treatment.

MKEE-29 HIGH-FREQUENCY ULTRASOUND IN THE EVALUATION OF NON-TRAUMATIC PERIPHERAL NEUROPATHIES: PEARLS AND PITFALLS

Enzo Calheiros, MD (*Presenter*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Cesar Gabriel Rocha Da Costa Paloschi, MD (*Abstract Co-Author*)
Debora Mayumi Takamune, MD (*Abstract Co-Author*)
Roddie Moraes Neto, MD (*Abstract Co-Author*)
Alex Dias, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Gabriela R. Camerin, MD (*Abstract Co-Author*)
Regiany Alessandra Garcia Jureidini, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

High-frequency ultrasound (HFUS) is a valuable modality for evaluating non-traumatic peripheral neuropathies, including compressive and inflammatory etiologies. HFUS provides real-time, high-resolution imaging of nerve morphology and pathology. It is faster, more accessible, and more cost-effective than MRI, with the added advantage of bedside use and suitability for serial monitoring and image-guided interventions. In compressive neuropathies, HFUS allows accurate localization of entrapment sites, visualization of nerve compression, displacement, and associated lesions. In inflammatory neuropathies, HFUS identifies hallmark features of nerve involvement, aiding the diagnosis of disorders like CIDP, Lewis-Sumner syndrome, and multifocal motor neuropathy.

TABLE OF CONTENTS/OUTLINE

1. Introduction- Peripheral neuropathies: types and classification- Role of imaging in diagnosis and management2. HFUS in nerve imaging: an overview- Technical Considerations- Comparison with MRI and other modalities3. Compression neuropathies- Common Sites of Entrapment (e.g., carpal tunnel, ulnar groove)- Dynamic Assessment Techniques- HFUS-Guided Interventions4. Inflammatory neuropathies- Key sonographic findings- Role in monitoring disease progression and treatment response5. Other non-traumatic neuropathies: metabolic, post-infectious, autoimmune and inflammatory causes6. Pitfalls and Diagnostic Challenges7. Future Directions and Emerging Technologies8. Summary and take-home messages

MKEE-30 LIKE THE BACK OF YOUR HAND: A PRACTICAL GUIDE TO ULTRASONOGRAPHIC EVALUATION OF THE HAND AND WRIST

Luana Paschoal, MD (*Presenter*)
Janaina Moreira (*Abstract Co-Author*)
Arthur H. Godeiro, MD (*Abstract Co-Author*)
Ana Gomes, MD (*Abstract Co-Author*)
Marcos Antonio Tebet Filho (*Abstract Co-Author*)
Danilo Amaral, MD (*Abstract Co-Author*)
Caio P. Martinel, MD (*Abstract Co-Author*)
Jose Lucas S. Galvao I, MD (*Abstract Co-Author*)

TEACHING POINTS

Ultrasound is an essential tool for evaluating the musculoskeletal structures of the hand and wrist, offering high resolution and real-time dynamic assessment. It provides detailed visualization of tendons, ligaments, muscles, joints, nerves, and superficial vascular structures. The most common findings include tenosynovitis, tendinopathies, tendon tears, synovial cysts, inflammatory and degenerative changes, nerve compressions such as carpal tunnel syndrome, soft tissue masses, and foreign bodies. Additionally, ultrasound is useful for guiding interventional procedures such as injections and aspirations, contributing to early diagnosis and therapeutic monitoring of various conditions.

TABLE OF CONTENTS/OUTLINE

This work begins by highlighting the benefits of ultrasound in evaluating the hand and wrist, followed by a brief anatomical review. It then discusses examination techniques, including patient positioning and dynamic maneuvers. The main detectable pathologies are presented, such as tendon inflammation, tears, cysts, joint changes, nerve compressions, and traumatic injuries. The role of ultrasound in guiding therapeutic procedures is also addressed. The content concludes with clinical applications and case examples that demonstrate its relevance in medical practice.

MKEE-31 HIT THE TARGET: A PRACTICAL GUIDE TO PET/CT-GUIDED BIOPSY

Margrit E. Muller, MD (*Presenter*)
Caio Nunes, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Rodrigo Gobbo (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Eduardo N. Kihara, MD (*Abstract Co-Author*)

TEACHING POINTS

- Demonstrate the role of PET/CT imaging in guiding biopsies of metabolically active bone lesions, particularly in oncology patients. - Provide a step-by-step practical guide for performing PET/CT-guided bone biopsies with high diagnostic accuracy and safety. - Highlight the advantages of PET/CT-guided biopsies compared to conventional CT-guided techniques.

TABLE OF CONTENTS/OUTLINE

Clinical Context and Clinical Indications: - Overview of clinical scenarios where PET/CT-guided bone biopsy is valuable Imaging Integration and Lesion Selection - PET/CT combines metabolic and anatomic imaging to localize lesions with high FDG or PSMA uptake (SUV), enabling accurate selection of biopsy targets. Step-by-Step

Technique 1. Image Acquisition: Initial PET/CT scan identifies the metabolically active lesion. 2. Biopsy Planning: Lesions are selected based on highest radiotracer uptake and anatomical accessibility. 3. Patient and Equipment Positioning: Patient is positioned to optimize access to the lesion, and biopsy materials are prepared. 4. Confirmation of needle positioning: A second PET/CT scan ensures accurate needle placement at the metabolic hotspot. 5. Tissue Sampling: Multiple core samples are collected to improve diagnostic yield. 6. Histopathological Analysis: Results guide final diagnosis and influence treatment planning. Diagnostic Yield and Safety - PET/CT-guided biopsies show higher diagnostic accuracy and lower complication rates than conventional CT-guided techniques. Case Illustrations - Selected clinical cases demonstrate the technique's effectiveness and impact on patient management

MKEE-32 BEHIND THE CURTAIN: DANCE-RELATED PATELLOFEMORAL INJURIES ON MRI

Bronte Balon, MD (*Presenter*)
Kevin Pham, MD (*Abstract Co-Author*)
Grace Wang, MD, MPH (*Abstract Co-Author*)
Mickael Tordjman, MD, MS (*Abstract Co-Author*)
Adriano Cuadros (*Abstract Co-Author*)
Mingqian Huang, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Describe the unique biomechanical demands of dance on the patellofemoral joint and extensor mechanism 2) Case-based introduction of the injuries and their presentation patterns 3) Highlight patellar anatomy and key MRI measurements crucial for accurate assessment of these injuries 4) Discuss the clinical implications of early diagnosis, including prevention of chronic dysfunction and impact on athletic performance

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of common dance movements and associated biomechanics Imaging of the Knee in Dancers: a) Anatomy Review b) Important measurements (TT-TG distance, patellar tilt angle) Case-Based Review of Patellofemoral Injuries in dancers: a) Chondromalacia Patellae b) Patellar Osteochondral Injury c) Patellar Maltracking and Instability Case-Based Review of Patellar Tendon Injuries in dancers: a) Patellar Tendinopathy ("Jumper's Knee") b) Partial Patellar Tendon Tears c) Sinding-Larsen-Johansson Syndrome Clinical Impact: a) Importance of early diagnosis in preventing chronic disability b) Conservative vs. surgical management implications based on imaging Summary: a) Early-stage patellofemoral and tendon pathologies are common but often under- recognized in dancers b) The critical role MRI plays in diagnosing these changes

MKEE-33 QUANTITATIVE MR FINGERPRINT IN SARCOPENIA. MORE THAN THE RADIOLOGIST'S EYE MEETS

Alfonso Iglesias, MD, PhD (*Presenter*)
Ana Blanco Bugueiro (*Abstract Co-Author*)
Mercedes Arias Gonzalez, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

To know the applications of texture analysis in medical image analysis and their challenging problems in image processing due to the fact that textures have a huge variability To illustrate the MRI data preparation: preprocessing and region of interest for the extraction of textures features whose aim to characterize muscle tissue structure To know the different texture descriptors such as Gray-Level Co-occurrence Matrix (GLCM), Gray-Level Run Length Matrix (GLRLM), Discrete Wavelet Transform (DWT), and Fractal Dimension (FD) that allows to extract texture findings from T2-weighted-images that help in identifying texture patterns associated with sarcopenia. To evaluate how these metrics capture complexity, homogeneity, and variability in muscle structures, providing quantitative biomarkers relevant to detect sarcopenia.

TABLE OF CONTENTS/OUTLINE

Review key concepts and the strengths and weaknesses of texture analysis in medical image analysis Application of different texture analysis methods on T2-weighted-images to characterize healthy muscle and to be able to differentiate it from sarcopenic muscle To explain how these methods support the development of automated, objective systems for diagnostic imaging, offering helpful tools to assist in the identification of sarcopenia

MKEE-34 HIGH-FREQUENCY ULTRASOUND IN MUSCULOSKELETAL RADIOLOGY: MAIN INDICATIONS AND CASE REVIEW

Roddie Moraes Neto, MD (*Presenter*)
Debora Mayumi Takamune, MD (*Abstract Co-Author*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Eduardo L. Bizetto, MD (*Abstract Co-Author*)
Marcos Felippe D. Correa, MD (*Abstract Co-Author*)
Viviane S. Yamachira (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)
Luciana C. Zattar, MD (*Abstract Co-Author*)

TEACHING POINTS

Learn how to perform high-frequency ultrasound and understand its specific technical features; Understand the clinical applications of high-frequency ultrasound in the musculoskeletal system; Structure the diagnostic approach to common pathologies and differential diagnoses involving skin, nails, cutaneous appendages, and the musculoskeletal system

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of high-frequency ultrasound; Technical guide on how to perform it and key considerations; Anatomy and ultrasound anatomy of the skin, subcutaneous tissue, and appendages; Applications in the musculoskeletal system and related pathologies; High-Frequency Ultrasound - Musculoskeletal System: Case-Based Review: Cutaneous tumors; Nail lesions; Cutaneous appendage lesions Inflammatory and infectious conditions; Vascular lesions;Nerve injuries; Soft tissue injuries; Summary; Take-Home Messages

MKEE-35 ULTRASOUND-GUIDED BARBOTAGE IN THE TREATMENT OF CALCIFIC ROTATOR CUFF TENDINOPATHY: TECHNIQUE, CHALLENGES AND PRACTICAL INSIGHTS

Roberts Naglis (*Presenter*)
Matilde Goncalves, MD (*Abstract Co-Author*)
Maria Pilar Aparisi Gomez, FRANZCR,MBChB (*Abstract Co-Author*)
Alberto Bazzocchi, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the indication and create a practical flow-chart with the steps for ultrasound guided barbotage in rotator cuff calcific tendinopathy. To analyze diagnostic and technical challenges and strategies for complication prevention and management.

TABLE OF CONTENTS/OUTLINE

When conservative treatment of calcific tendinopathy of the rotator cuff fails, ultrasound-guided barbotage (UGB) offers a minimally invasive and effective alternative. Understanding deposit morphology and location on ultrasound is essential for procedural planning, as it guides needle placement, technique selection, and directly influences barbotage success. UGB requires adequate equipment selection, patient positioning, sterile preparation and administration of local and bursal anaesthesia. Both single and two-needle approaches have specific advantages depending on the calcification's characteristics. Repeated cycles of lavage are used to fragment and evacuate the calcium. Completion of UBG is based on analysis of fragmentation and changes in morphology. A bursal infiltration with a corticosteroid is typically done

post-barbotage, followed by passive or active mobilization of the shoulder. Partially successful procedures or large deposits must be recognized and considered for follow-up procedures. Technical challenges like needle placement, along with potential complications, require precise technique to ensure safe and effective outcomes.

MKEE-36 ACQUISITION OF A MUSCULOSKELETAL MRI: FROM PHYSICS TO PRACTICAL TROUBLESHOOTING - A COMPREHENSIVE GUIDE

Paulo Ferreira, MD (*Presenter*)
Paulo R. Moreira, MD (*Abstract Co-Author*)
Andre S. Kamogari Nakamura, MD (*Abstract Co-Author*)
Gabriel Da Silva Eli, MD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Matheus Alpaccino Vale De Castro (*Abstract Co-Author*)
Joao Henrique Barros Penteado Furlan, MD (*Abstract Co-Author*)
Renato Fujiki, MD (*Abstract Co-Author*)
VINICIUS R. BRAMBILLA, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Magnetic Resonance Imaging (MRI) is the modality of choice for several musculoskeletal conditions as it is a safe, reliable and reproductive method. Its image acquisition, however, may pose a significant challenge due to patients' diverse body habitus, comorbidities, hardware, among many others. The purpose of this exhibit is to: - Provide MRI physics concepts useful for understanding imaging acquisition. - Review main MRI artifacts and how to overcome them. - Provide insights in unexpected situations: additional findings, large or restless patients. - Discuss imaging parameters and optimization in specific situations: tumors, whole-body protocols.

TABLE OF CONTENTS/OUTLINE

1. Introductiona. Applied MRI physics reviewb. "Hands on" of the MRI interface and acquisitionc. Primary MRI adjustments (average, TR, TE, concatenation, FOV etc.) 2. MRI artifacts a. Physics behind MRI artifacts b. How to avoid and solve MRI artifacts3. Specific situations:a. Slice programming in the setting of an unexpected findingb. Uncooperative patients c. Metal artifactsd. Signal and resolution balancing 4. Conclusions & "take-home messages"

MKEE-37 SPORT MUSCLE INJURIES OF THE TRICEPS SURAE: WHAT, HOW, WHY AND WHERE

Agustin M. Marrero SR, MD (*Presenter*)
Ricardo H. Trueba, MD (*Abstract Co-Author*)
Jaime Isern-Kebschull, PhD, MD (*Abstract Co-Author*)
Leandro A. Mazza, MD (*Abstract Co-Author*)
Nicolas Cedola, MD (*Abstract Co-Author*)
Rafael Barousse, MD (*Abstract Co-Author*)
Tomas A. Pascual, MD (*Abstract Co-Author*)
Ricardo Cobenas, MD (*Abstract Co-Author*)
Cecilia M. Velez, MEd (*Abstract Co-Author*)
Micaela A. Rabino, MBBS (*Abstract Co-Author*)
Maria F. Neville, MEd (*Abstract Co-Author*)
Javier Michienzi (*Abstract Co-Author*)
Pablo A. Eivers (*Abstract Co-Author*)
Augusto Napoli, MD (*Abstract Co-Author*)

TEACHING POINTS

To understand the anatomy, function, and biodynamic aspects of triceps surae muscle complex. To recognize the spectrum of tearing of these muscles, myotendinous junctions and tendons during sports practice analyzing their mechanism of injury. To evaluate the imaging methods in the different gastrocnemius, soleus and plantaris lesions and describe the precise location and characteristics. To describe ultrasound and magnetic resonance signs of these tears, emphasizing the prognostic criteria for recovery, return to play, and re-injury.

TABLE OF CONTENTS/OUTLINE

The posterior muscles of the leg are arranged in two compartments, one superficial and the other deep. The superficial muscle group, or triceps surae, includes medial and lateral gastrocnemius, soleus and the plantaris which are inserted distally into the calcaneus. Its primary function is plantar flexion of the foot, with a secondary role in knee flexion. This muscle complex plays a crucial role in propulsion during walking and sprinting.Triceps surae muscle complex injuries generally affect the medial gastrocnemius and soleus muscles, and the most common injury mechanism is during the sprint or high-speed running with knee extension and foot dorsiflexion. The injuries of gastrocnemius, soleus and plantaris were included in the category of calf injuries.Ultrasound is commonly employed as an initial imaging technique. To assess deeper anatomical structures MR imaging is the diagnostic gold standard.The evolution of injuries and the return to play can be estimated depending on its extent and location.Additionally, we will include some injuries of the deep muscle group.

MKEE-38 MUSCULOSKELETAL IMAGING IN DIABETIC FOOT COMPLICATIONS: A PRACTICAL APPROACH

Roberts Naglis (*Presenter*)
Matilde Goncalves, MD (*Abstract Co-Author*)
Domenico Romeo (*Abstract Co-Author*)
Maria Pilar Aparisi Gomez, FRANZCR,MBChB (*Abstract Co-Author*)
Alberto Bazzocchi, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the role of the different imaging techniques on assessing diabetic foot complications. To provide a logical algorithm for diagnosis of the different possible complications, based on the capabilities of the different techniques

TABLE OF CONTENTS/OUTLINE

Foot complications are a leading cause of non-traumatic amputations. The global prevalence has been calculated to be approximately 6.3%. The delayed diagnosis of complications poses an additional risk for patients and may lead to amputations. Early and accurate diagnosis in high-risk patients is crucial to prevent progression and preserve the limb. Radiographs are a first line tool for detecting fractures, osteolysis and joint destruction, but lack sensitivity for early-stage changes. Ultrasound allows assessment of soft tissue infections and aids in performing targeted interventions. MRI is the gold standard for detecting early osteomyelitis and distinguishing infection from non- infectious Charcot neuroarthropathy. CT lacks sensitivity for the assessment of early infectious or neuroarthropathic changes, but may be useful in the assessment of progression and with surgical planning. Nuclear imaging aids in the challenging differentiation of early osteomyelitis from Charcot arthropathy by detecting increased bone metabolism.

MKEE-39 IMAGING EVALUATION OF PERIPHERAL NERVE INJURIES IN CHILDREN

Thiago Jose Pinheiro Lopes, MD (*Presenter*)
Vitor D. Bichuette, MD (*Abstract Co-Author*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Raul O. Martins, MD (*Abstract Co-Author*)
Eduardo L. Bizetto, MD (*Abstract Co-Author*)
Catherina Zadeh, MD, FRCR (*Abstract Co-Author*)
Ben Walker, MD (*Abstract Co-Author*)
Lillian M. Lai, MD (*Abstract Co-Author*)
Marcos Felippe D. Correa, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)

TEACHING POINTS

1) The evolution of high-frequency ultrasound transducers and the development of specific magnetic resonance imaging sequences have made it feasible to visualize peripheral nerves and diagnose abnormalities in radiological studies. 2) The assessment of peripheral nerves in the pediatric population must consider age-related differences, anatomical particularities, and technical challenges, in order to guide the choice of imaging modality and ensure accurate interpretation of the findings. 3) Our purpose is to illustrate, based on real cases from our institution, the main imaging findings to look for in the evaluation of nerves in children, focusing on traumatic, inflammatory, and tumor-related conditions. 4) Understanding the mechanism of neuropathy, as well as the extent and location of the injury, can aid in selecting an appropriate treatment strategy—whether surgical or conservative—and in predicting the child's recovery potential.

TABLE OF CONTENTS/OUTLINE

1) Introduction to the imaging assessment of peripheral nerves. 2) Particularities of the pediatric age group. 2) Advantages, limitations and applications of each imaging method. 4) Normal appearance of peripheral nerves vs. general abnormal findings. 5) Case-based review of nerve injury mechanisms. 5.1) Traumatic injuries. 5.2) Inflammatory neuropathies. 5.3) Peripheral nerve tumors. 5.4) Postoperative injuries. 6) Challenges, pearls and pitfalls in interpreting peripheral nerve images. 7) Take-home messages.

MKEE-40 SURFACE ECHOES: SONOGRAPHY OF SUPERFICIAL NON-NEOPLASTIC LESIONS

Hari Nath, MD (*Presenter*)
Daniel Kowal, MD (*Abstract Co-Author*)

TEACHING POINTS

Non-neoplastic superficial palpable abnormalities encompass a wide range of pathologies that present as apparent masses, often causing significant distress for patients. Sonography is an excellent, and frequently first-line, modality for evaluating these abnormalities. Effective use of ultrasound can expedite diagnosis, alleviate patient anxiety, and reduce the need for unnecessary imaging studies, specialist consultations, and procedures.We will discuss how factors such as patient demographics, lesion location, and chronicity can be combined with imaging findings to develop an appropriate differential diagnosis for a given palpable abnormality. The sonographic features of common superficial non-neoplastic entities, including vascular and lymphatic malformations as well as cystic lesions, will be reviewed. Additionally, we will explore superficial pseudo-masses, including but not limited to hematomas, fat necrosis, scar endometriomas, abscesses, and bursal disease. Common pitfalls and mimics to be aware of in the diagnostic process will also be highlighted. Finally, we will provide an overview of relevant treatments and management strategies for these conditions.

TABLE OF CONTENTS/OUTLINE

• Introduction • Objectives • Review of relevant presentations and the pathophysiology of various nonneoplastic entities • Key sonographic features and examples • Additional diagnostic considerations, review of common pitfalls, and mimics of nonneoplastic entities • Review of treatment/management • Summary and conclusions • References

MKEE-41 LESSER EVIL: IMAGING AND DISEASES OF THE LESSER TOES

Abdullah Alkorbi (*Presenter*)
Tatiane C. Rodrigues, MD (*Abstract Co-Author*)
Aline Serfaty Sr, MD, PhD (*Abstract Co-Author*)
Dyan V. Flores, MD (*Abstract Co-Author*)

TEACHING POINTS

Forefoot pain arises from various conditions. While numerous articles have detailed the anatomy and imaging of hallux abnormalities, there is scarcity of literature on lesser toe disorders despite their considerable morbidity. The lesser toes enhance the weight-bearing surface area and support a significant portion of body weight during walking, making them susceptible to greater stresses and unique disorders. The lesser toe plantar plate features a single fibrocartilaginous capsular thickening, which can lead to attritional deficiency. The second and third metatarsals are typically longer and more slender, bearing the most force during push-off, increasing their risk for stress fractures and Freiberg's infraction. The narrower intermetatarsal spaces between the second and fourth toes may compress and irritate the plantar digital nerves, resulting in Morton's neuroma. This educational exhibit will concentrate on forefoot pain associated with lesser toe disorders emphasizing relevant anatomy mechanisms and imaging findings

TABLE OF CONTENTS/OUTLINE

PLANTAR PLATE TEAR •Single fibrocartilaginous capsular thickening predisposes to attritional deficiency •MTPJ synovitis may cause plantar plate degeneration over time and MTPJ instability STRESS FRACTURE The longer, thinner MT2 and MT3 bear greatest impact in push off IMPINGEMENT Morton's neuroma Narrower 2nd-4th intermetatarsal spaces predispose to nerve irritation Adventitial bursitis Foot is supported at the heel, MT1 and MT5 (tripod) increasing risk for bursitis HAMMERTOE, MALLET, CLAWTOE Longer, thinner 2nd toe predisposes to compression FREIBERG'S INFRACTION Longer, thinner 2nd toe predisposes to altered joint biomechanics

MKEE-42 UPDATE ON CHRONIC LATERAL ANKLE INSTABILITY - WHAT RADIOLOGISTS NEED TO LOOK FOR AND HOW TO REPORT IT

Matheus Marcelino Dias, MD (*Presenter*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

Ankle sprains are among the most common musculoskeletal injuries, particularly in athletic populations. A substantial proportion of these injuries progress to Chronic Lateral Ankle Instability (CLAI), which is characterized by the presence of residual symptoms and repeated ankle sprains, sensations of instability, and mechanical laxity persisting after an initial significant lateral ankle sprain. Given the clinical overlap and subjective nature of symptoms, radiologists play a crucial role in the accurate diagnosis of CLAI. The purposes of this exhibit are: Make a multimodality-based didactic review of the main topics of the Chronic Lateral Ankle Instability with multiple imaging methods. Make a practice guide with schematic fluxogram explaining the decision make. Propose a didactic categorization of these topics by radiology method: x-ray with and without stress ultrasound tomography resonance arthroscopy Illustrate those conditions based on cases from our radiology group.

TABLE OF CONTENTS/OUTLINE

MKEE-43 TINY TROUBLES: IMAGING CHALLENGES IN NEONATAL AND SMALL CHILDREN BONE AND SOFT TISSUE TUMORS

Pedro Mecate Prada, MD (*Presenter*)
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*)
Lisa Suzuki, MD, PhD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)

TEACHING POINTS

- Recognize the clinical relevance of early detection and accurate diagnosis of common and uncommon bone and soft tissue tumors in neonates and small children. - Emphasize the role of ultrasound as a first-line imaging tool, complemented by CT and MRI for comprehensive evaluation and surgical planning. - Review a wide spectrum of tumor types and their differential diagnoses, distinguishing benign from malignant entities. - Present illustrative cases to demonstrate diagnostic challenges, typical imaging features, and treatment strategies.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Overview of epidemiology, anatomy, and clinical impact 2. Imaging Modalities Ultrasound: Initial assessment tool. CT/MRI: Define lesion extent, guide biopsy, surgical planning. 3. Types of Tumors and Conditions - Case Based Review Bone/Soft Tissue Tumors: Rhabdomyosarcoma Infantile fibrosarcoma Rhabdoid tumor Lipoblastoma / Lipoma Fibrous tumors Vascular Lesions: Infantile and congenital hemangiomas Klippel-Trénaunay syndrome Lymphoproliferative/Histiocytic Disorders: Langerhans cell histiocytosis Lymphoma Other Conditions: Congenital torticollis Neuroblastoma Teratoma Skeletal dysplasias Dysraphism Bone malformations Chronic recurrent osteomyelitis Metabolic bone disorders Hematoma Cystic lesions 4. Differential Diagnoses: Key imaging features to distinguish malignant from benign and pseudotumoral entities. 5. Treatment and Follow-Up: Imaging role in staging, planning, and monitoring. 6. Diagnostic Flowchart: Structured algorithm to support accurate reporting.

MKEE-44 CRACKING THE CODE: IMAGING PATTERNS OF OSTEOID OSTEOMA ACROSS MRI

Tatiana M. Fazecas, MD (*Presenter*)
Flavia M. Costa, MD, PhD (*Abstract Co-Author*)
Juliana Da Trindade (*Abstract Co-Author*)
Sergio F. Junior SR, MD (*Abstract Co-Author*)
Flavia P. Lopes, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. To understand the pathophysiology and clinical presentation of osteoid osteoma. 2. To identify characteristic conventional and advanced MRI features of osteoid osteoma. 3. To recognize potential pitfalls and mimicries in MRI interpretation. 4. To improve diagnostic confidence and accuracy in identifying osteoid osteoma using MRI systematic aprroach.

TABLE OF CONTENTS/OUTLINE

Introduction: OO is a benign osteogenic tumor affecting children and young adults, characterized by a small radiolucent nidus surrounded by reactive bone sclerosis. While CT is traditionally considered the gold standard for diagnosis, MRI is increasingly used for its superior soft tissue contrast, ability to detect marrow and soft tissue edema, and lack of ionizing radiation. However, MRI findings can sometimes be nonspecific or misleading, making a thorough understanding of MRI features critical for accurate diagnosis. Objective: To review the etiopathogenesis ,conventional and advanced MRI characteristics in detecting the nidus of OO with a systematic approach, that will be proposed to differentiate from inflammatory, infectious, traumatic, and tumoral lesions. An understanding of the applicability and limitations of MRI tecniques is necessary to make accurate diagnosis and potentially the right treatment for our patients.TABLE OF CONTENTS AND OUTLINE 1) The value of each conventional and advanced MRI techniques(DIXON T1 (inand out phase) , DCEperfusion and, DWI) in diagnosis. 2) Case discussion to demonstrate the ultility in differentiate OO from : · Lymphoma · Inflamatory diseases · Infection (Brodie abscess) · CRMO · Stress Fractures

MKEE-45 BEYOND THE SHEATH: DIAGNOSTIC CHALLENGES AND PITFALLS IN PERIPHERAL NERVE TUMORS

Debora Mayumi Takamune, MD (*Presenter*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Raul O. Martins, MD (*Abstract Co-Author*)
Eduardo L. Bizetto, MD (*Abstract Co-Author*)
Eduarda C. Bernal, MD (*Abstract Co-Author*)
Leonardo Rosolen Iunes, MD (*Abstract Co-Author*)
Roddie Moraes Neto, MD (*Abstract Co-Author*)
Marcos Felippe D. Correa, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)

TEACHING POINTS

Clinical and epidemiological approach to peripheral nerve sheath tumors, with emphasis on less common and diagnostically challenging subtypes. Most commonly affected nerves and associated functional implications. Role of magnetic resonance imaging and ultrasound in the diagnosis and characterization of these lesions. Imaging criteria to differentiate benign from malignant tumors, including red flags for malignant transformation. Typical and differential imaging features of less common tumors such as intraneural perineuriomas, lipofibromatous hamartoma and malignant tumors such as malignant peripheral nerve sheet tumor and malignant triton tumor, in addition to schwannomas and neurofibromas. Recognition of secondary expansive lesions affecting peripheral nerves (cystic nerve lesions, perineurial spread of malignancy and inflammatory pseudotumors) Recognition of common pitfalls that may mimic nerve sheath tumors: radiation-induced neuropathy, post-traumatic neuromas, and inflammatory neuropathies. Illustrative cases with key diagnostic insights.

TABLE OF CONTENTS/OUTLINE

Overview of peripheral nerve sheath tumors: origin, epidemiology, and clinical relevance. Role and imaging protocol of MRI and ultrasound in the assessment of these lesions. Imaging differences between benign and malignant tumors. Less common and diagnostically challenging tumors, as intraneural perineurioma and malignant triton tumor. Pitfalls and how to identify them. Illustrative case discussions highlighting diagnostic challenges, key learning points, pitfalls and secondary expansive lesions affecting peripheral nerve.

MKEE-46 ANTERIOR CRUCIATE LIGAMENT INJURIES AND REPAIR: ADVANCES IN IMAGING AND INTERPRETATION

Lavinia Dias, MD (*Presenter*)
Gabriel Figueiredo, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)

Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Frederico C. Miranda, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

This case-based review provides an in-depth exploration of the anatomy and biomechanics of anterior cruciate ligament (ACL) injuries, encompassing, injury types, surgical indications, surgical techniques and expected imaging findings, postoperative complications, prognosis, and future advancements, with a focus on magnetic resonance imaging (MRI).

TABLE OF CONTENTS/OUTLINE

AnatomyTypical MRI appearance Biomechanics Main mechanisms of injury Injuries: MRI appearance of partial lesion, degeneration, complete lesion.Associated injuries such as Segond fracture, ramp lesion, posteromedial corner injury of the knee, meniscocapsular separation, O'Donoghue unhappy triad (anterior cruciate ligament tear, medial collateral ligament injury and medial meniscal tear (lateral compartment bone bruise) Management Conservative and surgical treatment criteria;When to re-address lesions in cases that have already undergone surgeryNew surgical techniques: Internal Brace or Ligament Augmentation and BEAR - Bridge-Enhanced ACL Repair Postoperative Findings Imaging features of conventional reconstruction, different graft options, ligament suturing, double-bundle reconstruction, and single-bundle reconstruction.Expected postoperative imaging results.Identification of complications through MRI as tunnel enlargement/malpositioning, friction, arthrofibrosis, tunnel cysts, infection, loosening of material and re-rupture Teaching Flowchart: A schematic flowchart will be prepared to guide the report

MKEE-47 POSTOPERATIVE IMAGING OF LUMBAR SPINE ENDOSCOPIC DECOMPRESSION SURGERY - WHAT THE RADIOLOGIST NEEDS TO KNOW

Gabriel B. Barbosa, MD (*Presenter*)
Adham A. Castro, MD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Marcello H. Nogueira-Barbosa, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Chronic low back pain, defined as pain persisting for more than three months, is a leading musculoskeletal complaint.• Endoscopic lumbar decompression is a minimally invasive technique using endoscopic and microscopic tools via small incisions, reducing complications while ensuring effective neural decompression.• MRI is the modality of choice in low back pain context, particularly for suspected radiculopathy or disc herniation, playing a key role in both preoperative planning and postoperative evaluation.• Postoperative complications are uncommon and include hematoma, seroma, infection and recurrent herniation.• Hematomas are most frequent (up to 86%) but rarely symptomatic. Symptomatic cases may present with pain, paresthesia and dysuria.• Granulation tissue and epidural fibrosis are common and must be distinguished from recurrent herniation, often requiring contrast-enhanced MRI.• Interlaminar and transforaminal are the main surgical routes, selected based on preoperative imaging and herniation type.• Postoperative findings are often subtle, demanding careful image interpretation and clinical correlation.

TABLE OF CONTENTS/OUTLINE

• Overview of lumbar spine anatomy on MRI, with focus on findings relevant to surgical planning.• Comparison between open and endoscopic spine surgery, including different endoscopic approaches - key imaging features, advantages, disadvantages and criteria guiding surgical choice.• Postoperative MRI and CT findings, including expected appearance and complications, illustrated with clinical cases.• Future directions, the role of AI and a practical flowchart to support radiologists in interpreting endoscopic spine surgery imaging.

MKEE-48 HIGH-FREQUENCY ULTRASOUND IN SKIN CANCER - A COMPREHENSIVE IMAGING APPROACH

Fernanda Philadelpho, MD, PhD (*Presenter*)
Carolina A. Almeida, MD (*Abstract Co-Author*)
Ana Carina Silva (*Abstract Co-Author*)
Flavia M. Costa, MD, PhD (*Abstract Co-Author*)
Simone Guarconi (*Abstract Co-Author*)
Flavio Luz (*Abstract Co-Author*)
Clarissa C. Moraes Do Carmo, MD (*Abstract Co-Author*)

TEACHING POINTS

High-frequency ultrasound (HFUS) is a valuable, noninvasive imaging tool for evaluating non-melanoma skin cancers, especially basal cell carcinoma (BCC) and squamous cell carcinoma (SCC) . HFUS enables precise measurement of tumor thickness and delineation of tumor margins , aiding in surgical planning and risk stratification. Sonographic patterns differ between BCC and SCC, allowing imaging-based differentiation and potentially influencing clinical management. HFUS can be used to detect recurrence , assess treatment response , and guide biopsies in complex or ambiguous lesions. Combining HFUS with clinical and dermoscopic evaluation enhances diagnostic accuracy in dermatologic oncology.

TABLE OF CONTENTS/OUTLINE

Introduction to High-Frequency Ultrasound (HFUS) in Dermatology Overview of HFUS technology and resolution Advantages over conventional ultrasound in skin imaging Clinical relevance in cutaneous oncology Ultrasound Technique and Protocols Transducer selection (15-70 MHz) Patient positioning and scanning planes Use of gel standoff pads and minimal pressure Role of color and power Doppler Sonographic Appearance of Basal Cell Carcinoma (BCC) Typical HFUS features: hypoechoic, well-defined, intradermal/subdermal Patterns by histologic subtype (nodular, infiltrative, superficial) Preoperative depth and margin assessment Sonographic Appearance of Squamous Cell Carcinoma (SCC) HFUS features: heterogeneous, irregular margins, deep infiltration Doppler findings and vascular flow patterns Detection of aggressive behavior Comparative Sonographic Features: BCC vs SCC Morphologic and vascular differences Practical tips for differentiation Case-based examples with images

MKEE-49 KEY SPINE MEASUREMENTS: A RADIOGRAPHIC GUIDELINE

Paulo Eduardo Borher Moreira, MD (*Presenter*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Francisco Rocha (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

Spine radiographs, in frontal and lateral views, offer valuable quantitative data beyond visual analysis. These images enable key measurements essential for diagnosis, therapeutic planning, and postoperative follow-up in spinal disorders. Sagittal balance evaluation relies on the relationship between spinal curvatures and pelvic parameters. Pelvic incidence defines the ideal spinal curves for global alignment, while pelvic tilt, sacral slope, and SVA complete the assessment. In coronal deformities, key parameters are Cobb angle, vertebral rotation, apex position, and compensatory clavicle/pelvic obliquity. Clavicle and pelvic obliquity indicate compensatory adjustments. Morphological evaluations, including vertebral body and intervertebral disc heights, pedicle dimensions, and foraminal widths, aid in structural assessment.

Dynamic radiographs improve instability detection. Flexion-extension views better identify segmental instability, while lateral bending radiographs distinguish structural from non-structural scoliosis. This guide consolidates essential radiographic parameters for objective, biomechanically grounded spine evaluation.

TABLE OF CONTENTS/OUTLINE

1Frontal View Scoliosis definition, Key measures; Dynamic evaluation (bending) ; Post-treatment follow-up 2Lateral View Spinopelvic curvatures, Pelvic parameters, Sagittal balance measurements; Cervicothoracic balance key parameters; Scheuermann Disease evaluation; Dynamic Evaluation for Segmental Instability (Flexion/extension); Structural findings (Foraminal stenosis, Disc space narrowing, Vertebral body height loss); Post-treatment follow-up.

MKEE-50 ULTRASOUND-GUIDED PERINEURAL AND INTRAMUSCULAR INJECTIONS FOR NEURALGIAS OF THE HEAD, NECK, AND UPPER CHEST

Tanya L. Tivorsak, MD (*Presenter*)
Joseph C. Giaconi, MD (*Abstract Co-Author*)
George R. Matcuk JR, MD (*Abstract Co-Author*)

TEACHING POINTS

Perineural and intramuscular injections in the head, neck, and upper chest can be performed under real-time ultrasound guidance for diagnostic and therapeutic purposes. These injections can be used to evaluate and/or treat pain related to occipital neuralgia, prior trauma or surgery, or neurogenic thoracic outlet syndrome. This exhibit will review the sonoanatomy of certain nerves and muscles from the head to the upper chest and topographic anatomy correlation with MRI and provide a guide for specific perineural and muscle injections.

TABLE OF CONTENTS/OUTLINE

1. Introduction and indications for perineural and intramuscular injections - diagnose and confirm specific neuropathy prior to surgery, relieve nerve pain 2. Procedure preparation- ultrasound transducers, needle size, amount of anesthetic or steroid/anesthetic mixture 3. Anatomy, techniques, and imaging examples of certain perineural and muscle injections, including the greater occipital nerve, lesser occipital nerve, greater auricular nerve, interscalene brachial plexus, and the anterior and middle scalene muscles and pectoralis minor muscle for neurogenic thoracic outlet syndrome. 4. Risks and side effects

MKEE-51 BEYOND BONES AND MUSCLES: THE RADIOLOGIST'S GUIDE TO MUSCULOSKELETAL LYMPHNODES

Myrian Linhares, MD (*Presenter*)
Vitor Verlangieri Carmo Machado, MD (*Abstract Co-Author*)
Thaina d. Rodrigues, MD (*Abstract Co-Author*)
Italo Ueno SR, MD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the imaging appearance of normal, reactive, and involved musculoskeletal lymph nodes. Recognize histopathologic correlations and immunohistochemical profiles in lymph node assessment. Identify diagnostic challenges and pitfalls in nodal interpretation during musculoskeletal imaging.

TABLE OF CONTENTS/OUTLINE

Musculoskeletal lymph nodes, although clinically significant, are frequently overlooked in routine imaging. This pictorial review highlights pertinent nodal stations—including axillary, inguinal, external iliac, and popliteal chains—and explores their relevance in inflammatory, infectious, and neoplastic conditions. Morphologic criteria such as size, cortical thickness, and hilum preservation, alongside advanced imaging techniques like DWI, assist in distinguishing benign from malignant nodes. Two histologically confirmed cases are presented: one demonstrating complete nodal replacement by metastatic rhabdomyosarcoma with positive myogenic markers (Desmin, Myogenin, MyoD1, CD56), and another showing a reactive lymphoid pattern with interfollicular expansion and eosinophils, supported by preserved B and T-cell profiles, high germinal Ki-67 index, and absence of CD30 expression. Understanding lymph node behavior in musculoskeletal imaging not only aids in diagnosis but also enhances staging accuracy and patient management, especially in oncology and inflammatory diseases.

MKEE-52 IMAGING IN JUVENILE IDIOPATHIC ARTHRITIS: HOW RECENT ADVANCES ARE REDEFINING CLINICAL CARE

Karina Hayama, MD (*Presenter*)
Adham A. Castro, MD (*Abstract Co-Author*)
Daisy T. Kase (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Ana Lara Almeida Da Silva, MD (*Abstract Co-Author*)
Jose Flavio De Oliveira Neto (*Abstract Co-Author*)
Lucas K. Miyahara, MD (*Abstract Co-Author*)
Stefanie Basilio Medeiros, MD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Highlight the latest advancements in imaging modalities for JIA diagnosis and monitoring. Demonstrate how these techniques enable early detection of inflammation and structural damage. Emphasize the role of standardized imaging protocols in improving diagnostic accuracy and patient outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction: Definition, classification, and diagnostic challenges of JIA. Role of Imaging: Importance of imaging for early detection, differential diagnosis, and disease monitoring. Conventional Radiography: Structural assessment and limitations. Musculoskeletal Ultrasound: Accessibility, utility in joint evaluation, and standardized scoring. Magnetic Resonance Imaging: High sensitivity, evolving criteria, and international standardization efforts. Criteria for disease remission and how imaging exams can assist Treatment Future Perspectives: Standardization needs, protocol improvements, and integration of artificial intelligence.

MKEE-53 FROM TRADITIONAL TO MODERN MENISCAL REPAIR: IMAGING CHALLENGES AND INSIGHTS

Gabriel Figueiredo, MD (*Presenter*)
Lavinia Dias, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the main and new surgical techniques used in meniscal treatment, including partial meniscectomy, meniscal repair and meniscal replacement; To present expected imaging findings and diagnostic pitfalls in the postoperative meniscus; To demonstrate the role of multimodal imaging — especially MR and MR arthrography —

in the differentiation between postoperative changes and recurrent meniscal tears; To illustrate common postoperative scenarios with imaging examples and highlight the importance of clinical correlation

TABLE OF CONTENTS/OUTLINE

1 - Meniscal anatomy and physiology relevant to surgery and healing Anatomical zones (red vs. white zone) and vascularity; Structural function of the meniscus and its implications in surgery; Healing potential and cellular differences by meniscal region; 2 - Surgical techniques and postoperative expectations (indications, surgical approach, and expected postoperative findings) Partial meniscectomy; Meniscal repair: repairable tear patterns, fixation techniques including meniscal suture and meniscal root repair; Meniscal transplantation; 3 - Imaging strategies in the postoperative evaluation Role of conventional MR imaging and its limitations; MR arthrography and CT arthrography: clinical utility in specific contexts, and advantages in detecting recurrent tear; 4 - Most common postoperative imaging findings and diagnostic challenges 5 - Practical Tips for Radiology Reporting and How to Communicate Relevant Findings 6 - Future Perspectives and Innovations 7 - Decision-Making Flowchart for Radiologists: visual algorithm to guide image interpretation;

MKEE-54 METATARSALGIA OF THE LESSER RAYS:A MULTICAUSAL APPROACH TO FOREFOOT PAIN

Isabella Torres de Lima, MD, MD (*Presenter*)
Marilia Da Cruz Fagundes, MD (*Abstract Co-Author*)
Lucas N. Silva, MD (*Abstract Co-Author*)
Thiago A. Rizzetto, MD (*Abstract Co-Author*)
Caio Nery (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

Metatarsalgia refers to pain in the metatarsal region, a frequent complaint affecting about 10% of the population and up to 85% of foot pain in middle-aged women. Its causes are diverse and often clinically indistinct, making imaging essential for accurate diagnosis. The forefoot can be divided into the first ray and the lesser rays—the latter being the focus of this review. Foot biomechanics play a key role in load distribution and gait stability. Alterations can lead to second ray syndrome with plantar plate rupture, Morton's neuroma, stress fractures, and Freiberg's infraction. Non-mechanical causes must also be considered, including plantar vein thrombosis, rheumatoid arthritis, gout, osteoarthritis, infections, and tumors. A multimodal imaging approach enhances diagnostic accuracy. Radiographs and CT are helpful for detecting osseous abnormalities, such as stress and subchondral fractures. MRI and ultrasound provide superior soft tissue assessment, crucial for evaluating plantar plate injuries and Morton's neuroma. Treatment ranges from conservative management—rest, orthotics—to surgery in cases of persistent pain or joint instability. This study discusses the biomechanical, structural and systemic causes of metatarsalgia, the role of imaging in diagnosis, and therapeutic outcomes.

TABLE OF CONTENTS/OUTLINE

Anatomy. Normal e altered biomechanics. Assessment of imaging methods: X-ray, Ultrasound, CT, MRI. Differential diagnosis of metatarsalgias: Mechanical causes and Non mechanical causes. Post-surgical treatment.

MKEE-55 STICK, SEAL, HEAL: IMAGING CHARACTERISTICS AND THE EVOLVING LANDSCAPE OF CHONDRAL REPAIR TECHNIQUES

Gabriel Da Silva Eli, MD (*Presenter*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Frederico C. Miranda, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: 1. To review the anatomy, microstructure of articular cartilage and the imaging characteristics of chondral defects.2. To discuss the treatment of chondral lesions using various surgical techniques with particular emphasis on the use of autologous matrix-induced chondrogenesis and their imaging features.3. To demonstrate the role of imaging in postoperative evaluation, illustrated with cases showing expected postoperative findings and the most common complications.

TABLE OF CONTENTS/OUTLINE

1 - Anatomy of the chondral surfaces, including imaging characteristics of normal cartilage.2 - Imaging characteristics of the most common chondral defects.3 - Treatment of chondral lesions using multiple surgical techniques, with an overview of indications, advantages, and limitations, illustrated with clinical cases: Debridement and Chondroplasty (Shaving / Lavage);Microfracture; Drilling; Osteochondral autograft transplantation (OATS / Mosaicplasty);Osteochondral allograft transplantation; Autologous Chondrocyte Implantation (ACI / MACI); 4 - Focused discussion on the treatment of chondral lesions using autologous matrix-induced chondrogenesis and its imaging features.5 - A practical guide for radiologists to identify postoperative MRI features of chondral repair, differentiate normal healing patterns from complications, and deliver accurate reports.6 - Use of advanced T2 mapping sequences and the MOCART score in postoperative evaluation.7 - Future perspectives, emerging techniques, and trends in chondral repair.

MKEE-56 FIBROUS AND (SOMETIMES) FURIOUS: MULTI-MODALITY REVIEW FOR DIAGNOSING, MANAGING, AND TREATMENT RELATED IMAGING CHANGES OF DESMOID TUMORS

Brandon Ritchie, DO (*Presenter*)
Kennedy Sparling (*Abstract Co-Author*)
Navid Faraji, MD (*Abstract Co-Author*)

TEACHING POINTS

• Identify subtypes and pathologic behavior of desmoid fibromatosis • Review a spectrum of indolent to more aggressive imaging features of desmoid tumors across multiple modalities • Outline current management strategies while describing how imaging can be used to assess treatment response and disease recurrence

TABLE OF CONTENTS/OUTLINE

Background & Classification: Overview of extra-abdominal, abdominal wall, and intra-abdominal subtypes. Pathophysiology Sporadic vs. FAP-associated; ß-catenin and APC gene involvement. Clinical Features: Locally aggressive with no metastatic potential; high recurrence risk. Imaging Evaluation MRI (preferred): T2 signal intensity reflects tumor activity; fascial tail, band, and whorled signs CT/US: Variable attenuation/echogenicity; useful for intra-abdominal lesions. Management: Active surveillance for stable tumors Surgery, radiotherapy for select cases Systemic therapy (NSAIDs, anti-estrogens, TKIs, chemo) Interventional approaches (e.g., cryoablation) Monitoring: MRI T2 signal, changes in lesion density, and lesion size help assess treatment response

MKEE-57 CHARTING THE CARTILAGE COURSE: A RADIOLOGIST'S GUIDE TO CHONDRAL BONE LESIONS

Myrian Linhares, MD (*Presenter*)
Thaina d. Rodrigues, MD (*Abstract Co-Author*)
Italo Ueno SR, MD (*Abstract Co-Author*)
Vitor Verlangieri Carmo Machado, MD (*Abstract Co-Author*)
Taisa M. Guarilha, MD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)

Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the imaging spectrum of chondral bone tumors, from benign to malignant. Recognize key radiologic features that help distinguish ACT from high-grade chondrosarcomas. Integrate imaging findings with clinical context and histopathology to support diagnosis and management.

TABLE OF CONTENTS/OUTLINE

Chondral bone tumors represent a diverse group of osseous lesions sharing a chondroid matrix and exhibiting variable biological behavior. These lesions range from benign enchondromas to aggressive, therapy-resistant high-grade chondrosarcomas. Imaging features such as flocculent or comma-shaped mineralization, endosteal scalloping, cortical destruction, and periosteal reaction assist in diagnosis and risk stratification. Special attention is given to atypical cartilaginous tumors (ACTs), classified as low-grade chondrosarcomas with locally aggressive behavior. The main diagnostic challenge lies in distinguishing ACTs from high-grade chondrosarcomas, which are resistant to chemotherapy and radiotherapy. Case-based examples are presented, including pathological fractures associated with ACT and misclassified lesions evolving into higher-grade tumors. Osteochondromas and multiple hereditary exostoses are also reviewed, with attention to cartilage cap thickness and syndromic patterns. Differential diagnosis must account for lesion location, multiplicity, and patient age, incorporating mimics such as metastasis, plasmacytoma, fibrous dysplasia, and bone infarction. A structured diagnostic approach is key for radiologic evaluation and guiding management.

MKEE-58 'DISPUTED' THORACIC OUTLET SYNDROME (DTOS): BEYOND BONE- RETHINKING MUSCULAR AND SOFT TISSUE IMPINGEMENT

Marcos Felippe D. Correa, MD (*Presenter*)
Jose Carlos Garcia (*Abstract Co-Author*)
Eduardo L. Bizetto, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)

TEACHING POINTS

Disputed Thoracic Outlet Syndrome (DTOS) might represent up to 99% of neurogenic TOS cases, yet it's often missed because standard MRI and electromyography typically show normal results. We believe DTOS isn't truly "disputed," but rather frequently overlooked due to subtle muscular compressions and mild, variable symptoms. Bilateral dynamic positional MRI (2D/3D sequences) can catch these hidden compressions and subtle asymmetries missed by routine exams. In our patient series, we found impingements caused by muscles such as the scalenes, pectoralis minor, anterior serratus, and subclavius, as well as fibrous bands, anomalous nerve trajectories, and muscle variants. Spotting these subtle anatomical details greatly improves diagnosis and allows precise, minimally invasive endoscopic treatments. It's time to rethink DTOS!

TABLE OF CONTENTS/OUTLINE

* Introduction * Key MRI Signs of Compression * DTOS: Emerging Evidence (4 Cases): 1. Subclavius 2. Middle Scalene 3. Anterior Serratus 4. Pectoralis Minor * Beyond Bone (Anatomical Variants): Muscular and Soft-Tissue Impingement (4 Cases): 5. Scalenus Minimus 6. Subclavius Posticus 7. Anomalous Nerve Trajectories 8. Fibrous Band

MKEE-59 NOT EVERY HOT SPOT IS BONE INFECTION: UNMASKING MIMICKERS THROUGH MULTIMODAL IMAGING

Julio B. Guimaraes, MD, PhD (*Presenter*)
Paulo Eduardo Borher Moreira, MD (*Abstract Co-Author*)
Damaris V. Goncalves, MD (*Abstract Co-Author*)
Mariana Batista Rosa Pinto, MD (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

Bone lesions that simulate infection represent a recurrent challenge in radiology, often leading to misdiagnosis, unnecessary antibiotic use, and delays in identifying the actual underlying cause. The clinical and imaging overlap between infectious and non-infectious bone lesions necessitates a careful and structured approach. Among non-infectious inflammatory mimics, chronic nonbacterial osteitis (CNO/CRMO) and SAPHO syndrome are key conditions, especially in children and young adults. Complex regional pain syndrome (CRPS) may also resemble osteomyelitis. Some neoplastic entities and benign lesions can exhibit cortical disruption, periosteal reaction, or surrounding edema features commonly associated with infection. Other vascular and mechanical causes of bone changes add to the diagnostic complexity. This review discusses multimodal imaging findings related to bone infection and non-infectious bone changes, highlighting key features useful for discriminating these non-infectious entities. Incorporating these clues into radiologic assessment can improve diagnostic accuracy and guide appropriate management.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Mimickers of Osteomyelitis. 2. Non-infectious Inflammatory Conditions 3. Neoplastic (benign and malignant) 4. Vascular and Hematologic Lesions 5. Developmental and Mechanical Conditions 6. Imaging Approach & Differential Clues

MKEE-60 IMAGING FINDINGS OF DERMATOFIBROSARCOMA PROTUBERANS: A CASE-BASED EDUCATIONAL EXHIBIT

Luciana C. Zattar, MD (*Presenter*)
Renata V. Leao, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Dermatofibrosarcoma protuberans (DFSP) is a rare soft tissue tumor, a dermal sarcoma known for its locally aggressive nature, that presents a diagnostic challenge due to its variable clinical and histological features. Accurate imaging plays a crucial role in the diagnosis and management of DFSP, by characterizing lesions, assessing tumor extent, and guiding treatment planning. This educational exhibit will delve into the nuances of DFSP and aims to explore the imaging findings of DFSP using various modalities, highlighting key features that aid in accurate diagnosis and management, through a series of case-based discussions, with: 1. Overview of Dermatofibrosarcoma Protuberans 2. Imaging Modalities for DFSP Evaluation 3. Typical Imaging Features of DFSP 4. Differential Diagnosis and Pitfalls 5. Role of Imaging in Treatment Planning 6. Follow-up Imaging and Surveillance

TABLE OF CONTENTS/OUTLINE

I. Introduction to Dermatofibrosarcoma Protuberans II. Imaging Modalities in DFSP Evaluation III. Case Studies IV. Differential Diagnosis and Imaging Pitfalls V. Treatment Planning and Imaging Guidance VI. Follow-up Strategies and Surveillance Imaging This exhibit aims to equip radiologists, oncologists, and other healthcare professionals with the knowledge and skills necessary to accurately interpret imaging findings of DFSP, ultimately improving patient outcomes through timely diagnosis and appropriate management.

MKEE-61 CROSSROADS OF RECOVERY: POSTOPERATIVE INSIGHTS OF ANTERIOR CRUCIATE LIGAMENT

Rafael Omena, MD (*Presenter*)
Felipe Batista Rodrigues, MD (*Abstract Co-Author*)
Camila Tabosa, MD (*Abstract Co-Author*)
Ligia C. Germek, MD (*Abstract Co-Author*)
Roberto Froeder Oliveira, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review key aspects of postoperative evaluation of ACL reconstruction, focusing on graft positioning and integrity. • Highlight the role of imaging modalities in assessing surgical outcomes. • Recognize common complications. • Distinguish expected postoperative changes from pathological findings.

TABLE OF CONTENTS/OUTLINE

Postoperative imaging assessment of anterior cruciate ligament (ACL) reconstruction is essential to confirm graft positioning and integrity, monitor healing-related changes, and identify complications. X-ray and CT help evaluate tunnel positioning, fixation devices, and bone structures, with CT also detecting early tunnel widening. MRI is the most sensitive modality for assessing graft signal and integrity, typically showing low signal on T1 and T2 sequences, and evaluating intra-articular structures. Common complications include motion limitation (e.g., impingement, arthrofibrosis, ganglion cysts), graft laxity or rupture, infection, fixation failure, and tunnel enlargement. Clear distinction between expected postoperative findings and complications is crucial for appropriate patient management and timely intervention to avoid surgical failure and long-term dysfunction.

MKEE-62 SAGITTAL BALANCE AND JOINT INTERACTIONS: FROM SPINE TO HIP AND BEYOND

Italo Ueno SR, MD (*Presenter*)
Myrian Linhares, MD (*Abstract Co-Author*)
Thaina d. Rodrigues, MD (*Abstract Co-Author*)
Vitor Verlangieri Carmo Machado, MD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

Present the key parameters of spinopelvic alignment (PI, PT, SS, LL, PI-LL mismatch) and their functional significance. Emphasize how alterations in spinopelvic alignment affect postural compensation, surgical outcomes, and joint overload. Highlight the value of standing and sitting radiographs to evaluate functional pelvic mobility before surgery. Show how imaging supports surgical planning in both spine fusion and hip arthroplasty to prevent complications like impingement, dislocation, or sagittal decompensation.

TABLE OF CONTENTS/OUTLINE

Introduction: Spinopelvic balance as a central axis of musculoskeletal alignment — not just a spinal concern.Understanding the Parameters: Defining and correlating pelvic incidence, tilt, sacral slope, lumbar lordosis, and PI-LL mismatch.Postural Compensation and Alignment: How the body adapts through pelvic retroversion, hip flexion, and knee positioning.Imaging Approach: The role of lateral standing and seated radiographs in evaluating functional spinopelvic dynamics.Surgical Planning Integration: Using imaging to guide decision-making in spine fusion and hip arthroplasty, especially in rigid or decompensated patients.Clinical Consequences: How poor alignment affects implant positioning, risk of dislocation, joint degeneration, and patient-reported outcomes.Interdisciplinary Insight: The importance of shared understanding between radiologists, spine surgeons, and hip surgeons to ensure optimal results.

MKEE-63 "BONE TO BE WILD": A RADIOLOGIC JOURNEY THROUGH SCLEROSING DYSPLASIAS

Thaina d. Rodrigues, MD (*Presenter*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Myrian Linhares, MD (*Abstract Co-Author*)
Italo Ueno SR, MD (*Abstract Co-Author*)
Stefanie Basilio Medeiros, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Jose Flavio De Oliveira Neto (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: A. Define sclerosing bone dysplasias, highlighting their relevance findings in radiologic practice and differing from mimics conditions; B. Present the objectives of the pictorial essay, such as reviewing the main imaging patterns and differential diagnoses; C. To simplify how to look the findings and become in a imaging diagnostic.

TABLE OF CONTENTS/OUTLINE

1. Classification and diagnostic challenges; 2. Radiographic, CT, MRI findings of each sclerotic dysplasias and sclerotic conditions that mimic dysplasias, including: 2a. pyknodisostosis 2b. osteopetrosis 2c. osteopoikilosis 2d. osteophatia striata 2e. hyperostosis corticalis generalisata (van buchem disease) 2f. progressive diaphyseal dysplasia (ribbing disease) 2g. overlap syndromes 2h. melorheostosis 2i. intramedullary sclerosis 2j. progressive diaphyseal dysplasia (camurati-engelmann disease) 2k. mielofibrosis 2l. DISH 2m. metastases 2n. paget disease 2o. sicke-cell disease 2p. erdheim-chester disease 2q. tuberous sclerosis 2r. chronic osteomyelitis; 3. Educational diagnostic algorithm designed to refine diagnostic reasoning and facilitate radiologists' understanding of the differential diagnoses of sclerosing bone dysplasias.

MKEE-64 STEP BY STEP: A RADIOLOGIC AND SURGICAL WALKTHROUGH OF FEET DEFORMITIES

Thaina d. Rodrigues, MD (*Presenter*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Myrian Linhares, MD (*Abstract Co-Author*)
Vitor Verlangieri Carmo Machado, MD (*Abstract Co-Author*)
Italo Ueno SR, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: A. Divide foot deformities by anatomical division (forefoot, midfoot and hindfoot), define which are the most common, their findings, what is important to report about; B. Reviewing the main imaging patterns and differential diagnoses; C. To simplify how to look the findings and become in a imaging

diagnostic; D. Provide images and surgical techniques used in the treatments of the cases presented.

TABLE OF CONTENTS/OUTLINE

1. Definition, classification, and diagnostic challenges about feet deformities; 2. Radiographic, CT, MRI findings of each feet deformities, including: 2a. hallux valgus, 2b. hammer toe, 2c. claw toe, 2d. mallet toe, 2e. pes cavus, 2f. midfoot collapse, 2g. lisfranc injuryx, 2h. charcot foot, 2i. pes planus, 2j. tarsal coalition, 2k. achilles insertional deformities, 2l. deformities due to inflammatory artrhropaties; 3. Ortopaedics surgical imaging; 4. Educational diagnostic algorithm designed to refine diagnostic reasoning and facilitate radiologists' understanding of the differential diagnoses of feet deformities; 5. Future perspectives, such as new diagnostic methods and application of artificial intelligence.

MKEE-65 CHONDRAL AND OSTEOCHONDRAL LESIONS IN CHILDREN: MAPPING THE CHALLENGES IN THE IMMATURE SKELETON

Isabella Torres de Lima, MD, MD (*Presenter*)
Bruno Grande Da Cunha (*Abstract Co-Author*)
Marilia Da Cruz Fagundes, MD (*Abstract Co-Author*)
Paulo de Tarso K. Perez, MD (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)

TEACHING POINTS

The immature skeleton, still undergoing growth and ossification, exhibits distinct biomechanical and histological characteristics that influence the type and pattern of injuries sustained during childhood. With the increasing involvement of children in sports activities—often at competitive intensities—there has been a notable rise in osteochondral injuries resulting from both acute trauma and repetitive microtrauma. These stressors place considerable mechanical demand on the developing osteochondral unit, particularly in skeletally immature joints. Early and accurate recognition of such injuries is essential not only to prevent progression to secondary osteoarthritis but also to avoid misinterpreting normal variants of physiological ossification as pathological alterations. A precise diagnosis that guides the appropriate selection of treatment, combined with thorough post-treatment monitoring via imaging studies, is essential for achieving a favorable outcome. This study aims to describe the development of the osteochondral unit in children, identify the main etiological factors involved in pediatric osteochondral injuries, highlight their distinctions from adult skeletal injuries, and outline strategies for post-treatment evaluation using advanced imaging techniques.

TABLE OF CONTENTS/OUTLINE

Developmental process of the osteochondral unit. Imaging evaluation of osteochondral lesions.Patterns of osteochondral injury in children. Differences between osteochondral lesions in pediatric and adult populations. What to report in the pre- and post-treatment imaging assessment. Post-surgical evaluation of osteochondral lesions.

MKEE-66 UPDATED BEST PRACTICES FOR IMAGING AND REPORTING OF LOWER LIMB INJURIES IN YOUNG ATHLETES

Laura Macedo, MD (*Presenter*)
Adham A. Castro, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Frederico C. Miranda, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the pediatric anatomy applied to musculoskeletal imaging exams with the particularities of children's development. 2. To highlight the importance of a structured approach and evaluation of the lower limb injuries in young athletes. 3. To discuss and to illustrate the different mechanisms and presentations of the main lower limb injuries in childhood across different imaging modalities. 4. Discuss key points to address in the report in cases of sports injuries. 5. Discuss the spectrum of changes involving sports injuries in young athletes: Apophysitis and avulsion fractures Physeal injuriesOsteochondral injuries Overuse injuries / stress fractures Muscle and tendon injuries Impingement syndromes Instability Ligament injuries Accessory bones and coalition Other findings and pitfalls

TABLE OF CONTENTS/OUTLINE

Introduction: Common pediatric MSK injuries in the emergency room are related to sports activities. Epidemiology and distribution of fractures and soft-tissue lesions in pediatric athletic group More frequent findings before and after the growth spurt Emerging perspectives in the diagnosis of pediatric sports-related disorders. Imaging: Multimodality imaging techniques: radiography (XR), magnetic resonance imaging (MR), ultrasound (US) and computerized tomography (CT) Imaging evaluation: Bone evaluation of pediatric sports injuries, including the apophyses and growth plates Importance of imaging in diagnosis of sports injuries in childhood Structured reporting templates highlighting the essential findings for each pediatric hip disorder. Treatment: Correlate the medical and sports history with the accurate imaging diagnosis and treatment.

MKEE-67 WHAT IS THAT? A RADIOLOGIST'S GUIDE TO LESS COMMON ORTHOPEDIC PROCEDURES AND DEVICES

Mary E. Buchanan, MD (*Presenter*)
Jade A. Anderson, MD (*Abstract Co-Author*)
Bethany Ho, MD (*Abstract Co-Author*)
Rolando Gerena, MD (*Abstract Co-Author*)
Nicole C. Sztuk, DO, MS (*Abstract Co-Author*)
Lily Gibson (*Abstract Co-Author*)

TEACHING POINTS

Many radiologists are familiar with the expected post-operative appearances of common orthopedic surgeries and interventions. The number of orthopedic surgeries in the United States has steadily increased in recent years and new technologies are increasingly employed. This exhibit aims to elucidate the expected appearance of several newer and less ubiquitous orthopedic procedures to increase familiarity among radiologists.

TABLE OF CONTENTS/OUTLINE

MISHA knee system, SpineJack Osseointegration prosthesis, Antibiotic spacers, Meniscal transplant, Corpectomy cages, Silicone joint prosthesis, Thumb CMC suspensionplasty, Osteochondral Allograft Transplantation (OATS), Latarjet procedure, MAGEC rods, Four corner wrist fusion, Proximal row corpectomy, Scheker prosthesis, Knee rotationplasty, Ulnar nerve transposition , Latissimus dorsi tendon transfer for subscapularis repair, IcoTec carbon fiber fusion rods, Subacromial balloon spacer, TOPS device

MKEE-68 NOT JUST A FRACTURE - A PERIOSTEAL PLOT TWIST

Fabio Yoshimura, MD (*Presenter*)
Thiago Munoz Ruiz, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

Frederico C. Miranda, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)

TEACHING POINTS

Review fracture complications unique to the pediatric population, where growth plate involvement requires special attention. Emphasize the importance of follow-up imaging in suspected growth plate injuries to avoid long-term sequelae. Recognize periosteal interposition in the physis as a rare but critical complication that can lead to growth disturbances. Understand how to apply the Salter-Harris classification system for precise diagnosis and communication. Guide treatment planning and surgical decision-making based on imaging findings and classification.

TABLE OF CONTENTS/OUTLINE

Introduction Pediatric fractures: why they are different The clinical relevance of periosteal interposition Case-Based Review Illustrative cases from our institution highlighting periosteal entrapment Clinical presentation and radiologic findings Imaging Evaluation Comparative role of radiographs, ultrasound, CT, and MRI Advantages of each modality for detecting soft tissue and physeal involvement Fracture Classification Detailed application of Salter-Harris types I-V Correlation with prognosis and complications Management and Treatment Conservative versus surgical approaches How imaging findings influence treatment strategy and follow-up

MKEE-70 FROM CLIVUS TO SACRUM: IMAGING OF CHORDOMAS

Harshini Victor, MBBS, MD (*Presenter*)
Amit Janu, MBBS, MD (*Abstract Co-Author*)
Amit J. Choudhari, FRCR,MBBS (*Abstract Co-Author*)
Kunal B. Gala, MBBS, MD (*Abstract Co-Author*)
Nitin S. Shetty, MBBS, MD (*Abstract Co-Author*)
Jose Siju, MBBS (*Abstract Co-Author*)
SUYASH KULKARNI (*Abstract Co-Author*)
Manish Pruthi, MD (*Abstract Co-Author*)
Siddhartha Laskar, MD (*Abstract Co-Author*)
Nehal Khanna (*Abstract Co-Author*)

TEACHING POINTS

1. Review the embryologic origin and typical anatomical distribution of chordomas along the axial skeleton, emphasizing common locations including the clivus, mobile spine, and sacrococcygeal region.2. Describe the characteristic CT and MRI imaging features of chordomas, highlighting their appearance on different sequences and the role of each modality in diagnosis and surgical planning.3. Differentiate chordomas from imaging mimics such as chondrosarcoma, metastases, and other spinal and skull base lesions, using location, signal characteristics, and enhancement patterns.4. Discuss current management strategies for chordomas, including the roles of surgery, external beam radiation therapy (EBRT), and proton beam therapy, with attention to indications, challenges, and long-term outcomes.

TABLE OF CONTENTS/OUTLINE

1. Introduction, definition, incidence, and clinical relevance of chordomas.2. Anatomical locations and imaging characteristics on CT and MRI.3. Pathological subtypes of Chordoma and basic histological appearance.4. Imaging patterns and key differentials of various tumor mimics on multimodality imaging.5. Challenges in the management of Chordoma and the role of imaging.

MKEE-71 EWING-LIKE, BUT NOT QUITE: IMAGING OF CIC-REARRANGED AND BCOR-ALTERED SARCOMAS

Swetha M. Nair, MBBS, MD (*Presenter*)
Amit Janu, MBBS, MD (*Abstract Co-Author*)
Nithin Krishnan, MBBS, MD (*Abstract Co-Author*)
Amit J. Choudhari, FRCR,MBBS (*Abstract Co-Author*)
Raksha P. Algeri (*Abstract Co-Author*)
Mukta Ramadwar (*Abstract Co-Author*)
SUYASH KULKARNI (*Abstract Co-Author*)
Nitin S. Shetty, MBBS, MD (*Abstract Co-Author*)
Nehal Khanna (*Abstract Co-Author*)
Manish Pruthi, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Describe the spectrum of undifferentiated round cell tumours, including classic Ewing sarcoma and emerging Ewing-like entities.2. Understand the pathologic and molecular features of CIC-rearranged, BCOR-altered sarcomas and their diagnostic significance.3. Identify imaging features characteristic of Ewing sarcoma and recognise patterns that may raise suspicion for Ewing-like sarcomas.4. Review CIC-rearranged and BCOR-altered sarcomas through a case-based, multimodality imaging approach. 5. Recognise the radiologist’s role in guiding appropriate molecular testing in cases with atypical imaging findings.

TABLE OF CONTENTS/OUTLINE

1. WHO Classification of Undifferentiated Round Cell Sarcomas: Overview of Ewing sarcoma and emerging Ewing-like entities (CIC-rearranged, BCOR-altered, and EWSR1 non-ETS fusion sarcomas). 2. Pathologic Review and Clinical Presentation, including histopathologic features, immunohistochemistry, molecular alterations, and clinical demographics of each subgroup. 3. Multimodality Imaging Features and Diagnostic Clues to distinguish Ewing-like sarcomas from the classic Ewing sarcoma. 4. Case-Based Review of CIC and BCOR-Altered Sarcomas, integrating radiological and pathological findings.

MKEE-72 BEYOND THE BEAR ESSENTIALS: UPDATES TO HARDWARE AND NEW OPERATIVE TECHNIQUES IN THE KNEE

Eddy Zandee van Rilland, MD (*Presenter*)
Sepideh Abdi, MD (*Abstract Co-Author*)
Seth Sherman (*Abstract Co-Author*)
Geoff Abrams (*Abstract Co-Author*)
Robert D. Boutin, MD (*Abstract Co-Author*)
Kathryn J. Stevens, MBBS, FRCR (*Abstract Co-Author*)

TEACHING POINTS

• 1. Post-operative imaging in the knee is challenging due to the complexity and variety of surgical techniques and hardware, as well as hardware-related artifacts that may further degrade image quality and obscure surrounding tissues. • 2. Metal artifact reduction techniques are essential for minimizing image distortion from metallic implants, improving visualization of the surrounding bone and soft tissues, and for identifying potential complications such as infection, loosening, or hardware failure. • 3. New and evolving surgical techniques and orthopedic hardware in the knee pose potential diagnostic challenges for radiologists who are unfamiliar with their imaging appearances. • 4. Understanding the imaging characteristics of these new surgical techniques and hardware enables radiologists to differentiate between normal postoperative changes from hardware complications, enhancing diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

• Introduction • Diagnostic challenges of hardware imaging • Metal artifact reduction o Techniques: 1.5T where possible, FSE, increase bandwidth, increase matrix, STIR or IDEAL for uniform fat suppression o Sequences: Multi-Acquisition Variable-Resonance Image Combination (MAVRIC), Multi-Acquisition with Variable Resonance Image Combination SeLective (MAVRIC SL), Slice-Encoding for Metal Artifact Correction (SEMAC), and Orthopedic Meal Artifact Reduction (O-MAR). • Case-based review including: o Medial Implantable Shock Absorber (MISHA) o Bridge-Enhanced Anterior Crucial Ligament Restoration (BEAR) Implant o Lateral Extra-articular Tenodesis o BioBrace Implant o Matrix-induced autologous chondrocyte implantation (MACI) • Discussion/conclusion

MKEE-73 IMAGING FINDINGS OF DESMOID TUMORS UNDERGOING MEDICAL AND ABLATION THERAPIES AND THEIR COMPLICATIONS: A CASE-BASED REVIEW

Gary Yu, PhD (*Presenter*)
Benjamin E. Northrup, MD (*Abstract Co-Author*)
Mariam A. Malik, MD (*Abstract Co-Author*)
Kelby B. Napier, MD, PhD (*Abstract Co-Author*)
Resten Imaoka, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand imaging characteristics of extra-abdominal desmoid tumors and the differential diagnosis of similar soft tissue masses Recognize changes in imaging characteristics associated with post-treatment changes of desmoid tumors and imaging features concerning for disease recurrence

TABLE OF CONTENTS/OUTLINE

- Overview of imaging characteristics of desmoid tumors - Brief imaging-based differential diagnosis for desmoid tumor - Case-based review of desmoid tumors undergoing various types of treatment and corresponding post-treatment imaging findings o Wide local excision with resulting scar formation o Cryoablation o Medical management with new therapeutic agents (sorafenib, niregacestat) o Identifying disease recurrence in patients who have undergone multiple types of treatment o Combinations of therapies o Complications of desmoid tumors after treatment

MKEE-74 AXIAL COMPRESSION OF THE LUMBAR SPINE: HOW TO PERFORM, INDICATE AND INTERPRET

Danilo Amaral, MD (*Presenter*)
Livia Reis, MD (*Abstract Co-Author*)
Luana Paschoal, MD (*Abstract Co-Author*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)

TEACHING POINTS

Lumbar spine imaging performed in the supine position may underestimate the severity of spinal canal narrowing, as this posture alleviates symptoms and removes the gravitational load present in standing. Axial loading simulates upright physiology, providing a more accurate depiction of dynamic changes. This exhibit illustrates the value of axial loading in CT and MRI, highlighting its role in detecting critical findings such as dural sac compression and symptomatic stenosis. Understanding the appropriate indications, technical execution, and imaging interpretation under load enhances diagnostic accuracy and clinical decision-making in patients with suspected lumbar canal stenosis.

TABLE OF CONTENTS/OUTLINE

The exhibit begins by explaining how lumbar canal dimensions vary with posture, emphasizing the limitations of conventional supine imaging. Axial loading is introduced as a method to replicate the effects of weight-bearing during imaging. The technique involves applying a supine axial load equivalent to 50% of body weight using a calibrated compression device with an acoustic alert for patient movement. Key findings include reduction in dural sac cross-sectional area (with thresholds for relative and absolute stenosis), focal deformities, and symptom reproduction. The case-based review highlights typical appearances and pitfalls, concluding with practical criteria for when to request dynamic lumbar spine imaging under load.

MKEE-75 TOTAL ELBOW ARTHROPLASTY: WHAT RADIOLOGISTS SHOULD KNOW

Youngjune Kim, MD (*Presenter*)
Yusuhn Kang, MD, PhD (*Abstract Co-Author*)
Choong Guen Chee, MD (*Abstract Co-Author*)

TEACHING POINTS

1) To understand the anatomy of the elbow and the indications for total elbow arthroplasty 2) To learn about the common types and components of prostheses used in total elbow arthroplasty 3) To review the common complications that can occur after total elbow arthroplasty

TABLE OF CONTENTS/OUTLINE

1. Anatomy and physiologic movement of elbow 2. Indications for total elbow arthroplasty 3. Representative procedure during total elbow arthroplasty 4. Common types and components of total elbow arthroplasty - Linked total elbow arthroplasty - Unlinked total elbow arthroplasty 5. Complications after total elbow arthroplasty - Infection - Bushing wear and osteolysis - C-ring failure - Periprosthetic fracture

MKEE-76 CORTICAL IS CRITICAL: WHAT DOES A BENIGN BONE LESION LOOK LIKE?

Roberto Froeder Oliveira, MD (*Presenter*)
Ligia C. Germek, MD (*Abstract Co-Author*)
Camila Tabosa, MD (*Abstract Co-Author*)
Rafael Omena, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Benign bone lesions typically present as well-defined, non-aggressive findings on imaging, often with preserved bone architecture, absence of periosteal reaction, and no associated soft tissue mass. These features reflect their indolent biological behavior and allow confident differentiation from more aggressive or malignant processes. Radiographs serve as the initial diagnostic tool, but advanced modalities such as CT and MRI offer complementary detail when lesion extent, matrix characteristics, or surrounding structures require further evaluation. MRI, in particular, helps assess marrow involvement and soft tissue response, enhancing diagnostic certainty. Recognizing imaging patterns consistent with benignity helps avoid unnecessary procedures, reduces patient anxiety, and contributes to more efficient and accurate care pathways. Radiologists play a critical role in this process, providing diagnostic clarity through pattern recognition and clinical correlation.

TABLE OF CONTENTS/OUTLINE

This educational display presents a schematic overview of the imaging characteristics commonly seen in benign bone lesions, emphasizing their typical features on MRI. It includes illustrative cases that highlight key patterns such as margin definition, internal signal characteristics, and absence of aggressive findings. The goal is to reinforce recognition of benign imaging features through visual correlation and case-based learning.

MKEE-77 IMAGING OF POST-ABLATION MUSCULOSKELETAL NEOPLASMS

Grant Yoneoka, MD (*Presenter*)
Maria Ly (*Abstract Co-Author*)

Benjamin E. Northrup, MD (*Abstract Co-Author*)
Kelby B. Napier, MD, PhD (*Abstract Co-Author*)
Mariam A. Malik, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to:*Review various ablation techniques and the pre-ablation assessment.*Review the expected post-ablation appearance in various musculoskeletal neoplasms using multimodal imaging techniques.*Provide examples of recurrent disease following ablation and review ablation-related complications.

TABLE OF CONTENTS/OUTLINE

*Introduction and epidemiology*Overview of common and emerging ablation techniques*Preprocedural assessment, pre-procedural imaging, and technical considerations*Post-ablation appearance of benign tumors*Post-ablation appearance of malignant tumors*Post-ablation augmentation techniques*Recurrent disease and ablation-related complications*Conclusion

MKEE-78 IMAGING-GUIDED STRATIFICATION OF HYPERVASCULAR SOFT TISSUE TUMORS: A DIAGNOSTIC FRAMEWORK BEYOND FLOW VOIDS

Shingo Omata, MD (*Presenter*)
Hiroki Kato (*Abstract Co-Author*)
Masaya Kawaguchi (*Abstract Co-Author*)
Masashi Asano, MD (*Abstract Co-Author*)
Yuki Arita, MD, PhD (*Abstract Co-Author*)
Masayuki Matsuo, MD (*Abstract Co-Author*)

TEACHING POINTS

Due to overlapping imaging features, hypervascular soft tissue tumors pose diagnostic challenges. We present a structured, three-step imaging-based framework to support pre-biopsy assessment.Hypervascular soft tissue tumors can be effectively stratified by evaluating flow void prominence, T2 signal characteristics, and enhancement patterns. Recognizing early-diagnosable entities aids confident image-based triage before histologic confirmation. Step 1: Early recognition of six tumors with specific traits: - Hibernoma (fat-rich) - Alveolar soft part sarcoma (numerous intra/peritumoral vessels) - Glomus tumor (subungual, painful, enhancing) - Epithelioid hemangioendothelioma (ill-defined, brush-like margins) - Kaposiform hemangioendothelioma and Kaposi sarcoma (cutaneous, HIV-related). These often suggest a confident presumptive diagnosis prior to biopsy. Step 2: Ten others—Perivascular epithelioid cell tumor, solitary fibrous tumor, infantile fibrosarcoma, angiosarcoma, paraganglioma, myopericytoma, infantile hemangioma, synovial sarcoma, leiomyosarcoma, and angioleiomyoma—are categorized by flow void prominence: prominent, limited, or absent. Step 3: Final refinement integrates T2 signal, enhancement, and clinical features (e.g., age, pain, depth) to narrow the differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Background: Diagnostic complexity in hypervascular tumors Step 1 - Early Diagnosable Tumors (n=6): Specific imaging traits Step 2 - Flow Void-Based Classification (n=10): Prominent, limited, absent Step 3 - Refinement by T2 signal, enhancement, and clinical features Educational Value: Structured visual approach before pathology

MKEE-79 MRI OF CARTILAGE: A PRACTICAL GUIDE FOR RADIOLOGY RESIDENTS

Ligia C. Germek, MD (*Presenter*)
Luis Eduardo Jordao Ravazi, MD (*Abstract Co-Author*)
Roberto Froeder Oliveira, MD (*Abstract Co-Author*)
Rafael Omena, MD (*Abstract Co-Author*)
Camila Tabosa, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Diego A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Cartilage injuries are common and clinically significant, especially in young and active patients. MRI plays a crucial role in diagnosis but often presents subtle findings that may be overlooked by residents. A practical and image-rich approach can enhance confidence and accuracy in cartilage evaluation.

TABLE OF CONTENTS/OUTLINE

This exhibit aims to provide a practical and didactic review of articular cartilage assessment using MRI, specifically targeted at radiology residents. It begins with a discussion of the basic anatomy and biomechanics of hyaline cartilage, followed by the main imaging patterns of cartilage injury and their clinical implications, including pain, subchondral bone marrow edema, and synovial reaction. Real case examples from our institution are extensively used to illustrate the full spectrum of cartilage involvement—from subtle superficial defects to deep lesions with subchondral exposure—focusing on visual recognition of common imaging findings. Additionally, the key points that should be included in the radiological report are addressed, with emphasis on clarity, clinical relevance, and impact on orthopedic decision-making. By integrating theoretical background, imaging features, and practical application, this presentation seeks to strengthen the resident's foundation and confidence in evaluating articular cartilage.

MKEE-80 FIGHT CALCIUM WITH WATER: EVERYTHING YOU NEED TO KNOW ABOUTULTRASOUND-GUIDED PERCUTANEOUS IRRIGATION OF CALCIFIC TENDINOPATHY (US-PICT) OF THE SHOULDER:

Irene Toniolo, MD (*Presenter*)
Andrea De Grandis, MD (*Abstract Co-Author*)
Carlo D'Alessandro, MD (*Abstract Co-Author*)
Giulia Beggiato, MD (*Abstract Co-Author*)
Giacomo Negro, MD (*Abstract Co-Author*)
Giovanni Sussan, MD (*Abstract Co-Author*)
Francesco Fusco, MD (*Abstract Co-Author*)
Emilio Quaia, MD (*Abstract Co-Author*)
Filippo Crimi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Rotator cuff calcific tendinopathy (RCCT) is a common condition, mainly affecting the supraspinatus tendon, that can cause pain and a certain degree of disability. There are different treatment for this condition. Ultrasound-guided percutaneous irrigation (US-PICT) is a safe, effective, and minimally invasive treatment for RCCT. US-PICT represents a valuable alternative to more invasive therapies, with rapid symptom relief and minimal recovery time. This procedure can be performed with various techniques with different advantages. Proper technique, especially using the double-needle approach and closed-circuit irrigation, enhances efficacy and safety. Radiologists should be familiar with procedural nuances to ensure optimal results.

TABLE OF CONTENTS/OUTLINE

RCCT: physiopathology Imaging findings and classifications US-PICT indications and contraindications Single- vs. double-needle technique: pros and cons Procedural steps, tips and tricks Role of post-procedural steroid injection in the subacromial-subdeltoid bursa Additional post-treatment care: cryotherapy and oral analgesics Outcomes: clinical efficacy, safety profile, and complication rate

MKEE-81 LATERAL ANKLE INSTABILITY: A COMPREHENSIVE REVIEW AND NEW CONCEPTS

Bruna Carvalho (*Presenter*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Gustavo O. Watanabe, MD (*Abstract Co-Author*)
Lucas N. Silva, MD (*Abstract Co-Author*)
Mauro Cesar Mattos E Dinato (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

Lateral ankle sprain is the most common orthopedic injury in emergency care, leading to significant functional impairment and socioeconomic impact. Although most sprains resolve with conservative management, their high incidence and clinical-economic impact demand a detailed diagnostic evaluation, to prevent chronic pain, instability, and secondary sequelae. In this review, we evaluate standard and advanced imaging modalities for lateral ankle instability, highlighting their strengths and limitations in acute and chronic settings, and demonstrating how these techniques impact clinical management and surgical planning. We also highlight emerging insights into ATFL microinstability—isolated tears of the intra-articular superior fascicle—which often elude conventional assessment and may underlie persistent symptoms. Finally, we discuss current surgical indications, main anatomic repair techniques (most notably Broström-type reconstructions), and their possible complications, providing a review on what the radiologist should report in a post-operative scenario.

TABLE OF CONTENTS/OUTLINE

Introduction & Biomechanics of Injury Classical Imaging Evaluation: • Radiography: Conventional and Stress Radiographs • Ultrasound • Computed Tomography • Magnetic Resonance Imaging New Concepts in Anatomy & Microinstability: • Detailed ATFL Anatomy: Superior vs. Inferior Fascicle • Imaging Features of Microinstability Associated Lesions Clinical Management, Surgical Techniques & Postoperative Imaging: • Conservative Treatment • Surgical Indications & Candidate Selection • Anatomic Repair Techniques (Broström-Gould, Retinacular Augmentation) • Postoperative Imaging

MKEE-82 COMMON WRIST AND HAND SURGERIES - A MULTIMODALITY GUIDE OF NORMAL FINDINGS AND COMPLICATIONS

Alex Dias, MD (*Presenter*)
Roddie Moraes Neto, MD (*Abstract Co-Author*)
Gabriela R. Camerin, MD (*Abstract Co-Author*)
Raul O. Martins, MD (*Abstract Co-Author*)
Eduarda C. Bernal, MD (*Abstract Co-Author*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Denise T. Amaral (*Abstract Co-Author*)
Marcos Felippe D. Correa, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review common lesions of tendons and ligaments of the wrist and fingers (traumatic, degenerative), such as gamekeeper thumb and Stener lesion, scapholunate ligament injury, extensor and flexor tendon injuries. • Summarize usual techniques for surgical repair of tendons and ligaments in hand surgery and their imaging findings on radiographs, CT, ultrasound and MRI. • Highlight complications in tendon repair: recurrent rupture, hardware failure, fibrosis, tenosynovitis, infection, neuroma. • Review scapholunate ligament repair complications: loss of graft integrity, residual instability, hardware failure, SLAC wrist, fibrosis. • Review Stener lesion repair complications: hardware failure, recurrent rupture, laxity and fibrosis/ ossification. • Discuss less frequent ligament lesions, their repair surgeries and complications.

TABLE OF CONTENTS/OUTLINE

• Introduction and epidemiology of hand and wrist ligament and tendon lesions and their mechanism. • Review of surgical repair techniques and imaging findings, as well as protocols and technical aspects of post operative evaluation. • Imaging findings and complications: o Tendon repair (flexors and extensors). o Scapholunate ligament repair. o Stener lesion repair. o Other ligaments lesions and repair. • Challenging cases and take-home points

MKEE-83 VASCULAR TUMORS AND PSEUDOTUMORS OF THE MUSCULOSKELETAL SYSTEM

Gabriel Pianowski Pajanoti, MD (*Presenter*)
Raifran Neto, MD (*Abstract Co-Author*)
Juliana Lie Taya (*Abstract Co-Author*)
Bruno C. Carneiro (*Abstract Co-Author*)
Marcio A. Ishida, MD (*Abstract Co-Author*)
Adriano Silveira Moreira Novaes, MD (*Abstract Co-Author*)
Bruno B. Cardoso, MD (*Abstract Co-Author*)
Luiz T. Nehme, MD (*Abstract Co-Author*)

TEACHING POINTS

Review vascular tumors/pseudotumors of the musculoskeletal system, emphasizing radiological findings and diagnostic approaches using multimodality imaging.

TABLE OF CONTENTS/OUTLINE

Vascular tumors/pseudotumors range from benign (hemangiomas, malformations) to aggressive (angiosarcomas). MRI, CT, and Doppler US are key for assessing vascularization and behavior, aiding differentiation and management. Review epidemiology, clinical features, and imaging characteristics of musculoskeletal vascular lesions for educational purposes.Hemangiomas, the most common benign vascular tumors, typically exhibit hyperintensity on T2-weighted MRI and homogeneous contrast enhancement, often with venous flow on Doppler and signs of spontaneous involution. In contrast, hemangioendotheliomas can display varying aggressiveness, presenting as infiltrative lesions with heterogeneous enhancement and perilesional edema. Angiosarcomas, the most malignant, appear as poorly defined masses with necrosis and may mimic hematomas or inflammatory processes.Vascular malformations, though non-neoplastic, can mimic tumors. Venous malformations show T2 hyperintensity, phleboliths on CT, and lack arterial flow. Lymphatic malformations are cystic and may contain fluid-fluid levels, while arteriovenous malformations demonstrate high-flow vessels, early arterial enhancement, and shunting. Syndromic associations, such as Klippel-Trenaunay syndrome, combine vascular anomalies with soft tissue and bone overgrowth.Accurate imaging interpretation is crucial for diagnosis and management, avoiding unnecessary interventions and optimizing care.

MKEE-84 IMAGE-GUIDED EPIDURAL BLOOD PATCH - TECHNIQUE, TIPS AND BEST PRACTICES

Ariadne Obrigon (*Presenter*)
Eduardo N. Kihara Filho, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
DURVAL BARROS SANTOS, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Indications and contraindications; Prep an patch material; Procedure: patching;Patch types by indication; Post-patch restrictions and complication.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION · Review what the procedure is, its indications and contraindications .· How to prepare the material and the patient for the procedure. PATCHING GUIDED BY CT · Step by step. PATCH TYPES BY INDICATION · Unseen leaks and chronic orthostatic headaches; · Post dural puncture headache;· Indwelling devices; · Surgical durotomy; · Ventral dural tear and sleev leak; · Cerebral fluid venous fistula. POST-PROCEDURE MANAGEMENT · What the patient should and shouldn't do and what complications the doctor needs be aware of.

MKEE-85 MRI ARTHROGRAPHY AND SHOULDER MICROINSTABILITY: WHAT THE RADIOLOGIST NEEDS TO KNOW

Adriano Magna, MD (*Presenter*)
Leonardo Kazunori Tsuji, MD (*Abstract Co-Author*)
Lucas K. Miyahara, MD (*Abstract Co-Author*)
Vitor N. Sato, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Present an overview of the anatomy of the shoulder, with stability factors and the association with the concept of shoulder microinstability and its predisposing factors. Discuss the applicability of magnetic resonance arthrography, with its sensitivity to subtle structures among other advantages, which allow for early and accurate identification of abnormalities. To illustrate the main findings in magnetic resonance arthrography in shoulder microinstability, as well as normal findings that mimic labral lesions.

TABLE OF CONTENTS/OUTLINE

Introduction and overview of shoulder anatomy, presenting stability factors (static and dynamic) and relationship with the causal factors of shoulder microinstability. Presentation of magnetic resonance imaging, both conventional and arthrography as a tool for evaluating injuries, presenting advantages and drawbacks common to both and the arthrography related. Identifying the main safety concerns involving magnetic resonance imaging and arthrography. Technique and parameters of the shoulder MRI (conventional and arthrography) protocol, including additional positioning. Main findings in magnetic resonance arthrography in labral, ligamentous and rotator cuff injuries, anterior and posterior impingements in shoulder microinstability. Warning and illustrations with examples of some pitfalls that should not be confused with injuries.

MKEE-86 DIGIT CLUES RADIOLOGIC INSIGHTS INTO COMMON FINGER DEFORMITIES

Vitor Verlangieri Carmo Machado, MD (*Presenter*)
Italo Ueno SR, MD (*Abstract Co-Author*)
Myrian Linhares, MD (*Abstract Co-Author*)
Thaina d. Rodrigues, MD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to: Provide a structured, imaging-based overview of the most frequent congenital and acquired finger deformities. Highlight key imaging findings that support diagnosis, classification, and surgical planning. Emphasize the importance of radiologic evaluation in sports-related finger injuries. Reinforce the role of multimodality imaging in differentiating deformities and guiding clinical management.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview and clinical impact of finger deformities. Congenital Deformities: Polydactyly: Classification, imaging patterns, and surgical relevance. Syndactyly: Soft tissue vs. osseous fusion and preoperative imaging role. Acquired Deformities: Rheumatoid Arthritis-related changes: Ulnar deviation, swan-neck, and boutonnière deformities. Dupuytren's Contracture: Fascial thickening and flexion deformity on imaging. Sports-Related Finger Deformities: Mallet Finger, Jersey Finger, Skier’s Thumb: Mechanisms, imaging features, and clinical implications. Imaging Modalities: Contributions of radiography, ultrasound, and MRI to diagnosis and management. Conclusions: Importance of radiologic expertise in recognizing patterns and supporting therapeutic decisions.

MKEE-87 ARTHROGRYPOSIS AND IT'S POSTOPERATIVE FINDINGS: WHAT THE RADIOLOGIST SHOULD KNOW

Juliana Lie Taya (*Presenter*)
Caio Kumassaka Kamikoga (*Abstract Co-Author*)
Gabriel Pianowski Pajanoti, MD (*Abstract Co-Author*)
Raifran Neto, MD (*Abstract Co-Author*)
Bruno C. Carneiro (*Abstract Co-Author*)
Marcio A. Ishida, MD (*Abstract Co-Author*)
Adriano Silveira Moreira Novaes, MD (*Abstract Co-Author*)
Bruno B. Cardoso, MD (*Abstract Co-Author*)
Luiz T. Nehme, MD (*Abstract Co-Author*)

TEACHING POINTS

- Explain the importance of radiological imaging at Arthrogryposis evaluation.- Demonstrate the efficacy of x ray and ultrasound analising the different muscles and joints affected.- Describe different surgical treatment and radiological results in between the patients with Artrhogryposis.

TABLE OF CONTENTS/OUTLINE

1. Brief overview of Arthrogryposis (definition, clínical manifestations and epidemiology).2. Why imaging is important in patients with Arthrogryposis.3. Explain the usage of multimodality imaging (ultrasound and x-ray) in patients with Arthrogryposis.5. Discuss briefly the different possible manifestations and each surgical treatment.4. Provide image-rich examples and descriptions of different manifestations and its post operative findings with Arthrogryposis who underwent radiological imaging.5. Point out the importance of radiological imagins in patients with Arthrogryposis.6. Conclusion and Take Home Message.

MKEE-88 OFF TRACK: A VISUAL REVIEW OF PATELLOFEMORAL JOINT INSTABILITY

Brandon Ritchie, DO (*Presenter*)
Kennedy Sparling (*Abstract Co-Author*)
Navid Faraji, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize subtypes and risk factors of patellofemoral joint instability. 2. Understand clinical presentation and underlying pathophysiology. 3. Discuss both conservative and surgical treatment options. 4. Review key multimodality imaging findings for diagnosis, assessment, and post-surgical changes.

TABLE OF CONTENTS/OUTLINE

Background Spectrum includes subluxation, dislocation, and chronic instability. Subtypes Lateral (most common), medial, and multidirectional instability. Etiology/Risk Factors : Trochlear dysplasia, patella alta, malalignment, prior trauma, connective tissue disorders . Clinical Features : Instability, pain, mechanical symptoms; risk of chondral injury and early OA. Evaluation Imaging : Radiographs for initial eval; MRI is gold standard. Key Findings : Trochlear dysplasia: Sulcus angle, facet asymmetry Patellar height: Insall-Salvati, Caton-Deschamps indices Lateralization: Congruence angle, TT-TG distance Patellar tilt: Lateral PF angle, Fulkerson angle. Management Non-Surgical: PT, bracing, NSAIDs Surgical: MPFL reconstruction, tibial tubercle osteotomy, trochleoplasty Post-op Imaging: MRI/CT for assessment.

MKEE-89 LOW-ENERGY TRAUMA BUT HIGH IMPACT: A REVIEW OF THE ANATOMY, PATHOLOGY, AND IMAGING OF SUBTLE LISFRANC INJURIES

Matthew Oleksak, MD (*Presenter*)
Bryan Chan, MD (*Abstract Co-Author*)
Geoffrey Phillips (*Abstract Co-Author*)
Pamela J. Walsh, MD (*Abstract Co-Author*)
Mobeen Farooq, MD (*Abstract Co-Author*)

TEACHING POINTS

Subtle Lisfranc injuries occur with low-energy trauma and result in instability at the midfoot/Lisfranc joint complex · Lisfranc injuries can be classified as transverse or longitudinal and simple or complex based on which ligaments are involved and if there is extension into additional joints · Subtle Lisfranc injuries continue to be underdiagnosed, secondary to their atypical imaging features and due to the lack of familiarity with variant Lisfranc injury patterns · A missed or delayed diagnosis can lead to increased patient morbidity and a decline in quality of life · Weightbearing films and/or CT/MRI are often necessary to arrive at the correct diagnosis and identify other accompanying osseous and soft tissue injuries · Certain patient characteristics (i.e. young age, athlete) can be used to raise index of suspicion for a subtle Lisfranc injury

TABLE OF CONTENTS/OUTLINE

Brief introduction to the Lisfranc joint/midfoot· Review the osseous and ligamentous anatomy of the Lisfranc joint · Discuss the direct (high-energy) and indirect (low-energy) mechanisms of Lisfranc injury, with emphasis on the indirect mechanism · Illustrate some of the patterns of subtle Lisfranc injuries caused by low-energy trauma (transverse, longitudinal etc.) · Describe the role of different imaging modalities (Radiographs, CT and MRI) in evaluation of subtle Lisfranc injuries · Use case examples to review imaging findings in subtle Lisfranc injuries · Highlight clinical features useful in raising index of suspicion for a subtle Lisfranc injury

MKEE-90 RADIOLOGICAL ASPECTS OF MARFAN SYNDROME

Juliana Lie Taya (*Presenter*)
Caio Kumassaka Kamikoga (*Abstract Co-Author*)
Narriman P. Hazime, MD (*Abstract Co-Author*)
Felipe Correa Brito, MD (*Abstract Co-Author*)
Bruno B. Cardoso, MD (*Abstract Co-Author*)
Adriano Silveira Moreira Novaes, MD (*Abstract Co-Author*)
Bruno C. Carneiro (*Abstract Co-Author*)
Marcio A. Ishida, MD (*Abstract Co-Author*)
Luiz T. Nehme, MD (*Abstract Co-Author*)

TEACHING POINTS

- Explain the importance of radiological imaging at Marfan syndrome patients- Demonstrate the efficacy of x ray, ultrasound, MRI and CT analising Marfan syndrome patients - Describe different manifestations and radiological results in between the patients with Marfan syndrome

TABLE OF CONTENTS/OUTLINE

1. Brief overview of Marfan syndrome (definition, clínical manifestations and epidemiology)2. Why imaging is important in patients with Marfan syndrome3. Explain the usage of multimodality imaging (x ray, ultrasound, MRI and CT) in patients with Marfan syndrome4. Provide image-rich examples and descriptions of different manifestations with Marfan syndrome who underwent radiological imaging 5. Point out the importance of radiological imagins in patients with Marfan syndrome 6. Conclusion and Take Home Message

MKEE-91 HOW ABOUT A LITTLE HAND? POSTOPERATIVE FINDINGS OF THE HAND AND WRIST

Andre Y. Aihara, MD, PhD (*Presenter*)
Filipe Costa Toledo, MD (*Abstract Co-Author*)
Lucas K. Miyahara, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: 1. Provide a comprehensive radiologic overview of the most common surgical procedures involving the hand and wrist. 2. Highlight the radiologic features associated with common complications. 3. Familiarize radiologists and trainees with the normal imaging appearances of various surgical interventions, including osteosynthesis, arthroplasty, arthrodesis, and tenorrhaphy.

TABLE OF CONTENTS/OUTLINE

1. Introduction: objectives of postoperative imaging, a brief review of the main indications for hand and wrist surgery with illustrations of selected surgical procedures, and an overview of imaging modalities (X-ray, CT, MRI).2. Osteosynthesis: Indications, techniques, expected imaging findings, and potential complications. 3. Triangular fibrocartilage complex repair: review and illustrative case. 4. Trapeziectomy vs. total thumb arthroplasty: indications, differences, and illustrative case. 5. Four-Corner Arthrodesis: difference between SLAC and SNAC. 6. Tenorrhaphy: review and illustrative case. 7. Osteotomy: review and illustrative case. 8. Conclusion. 9. Bibliographical references.

MKEE-92 BRACE FOR THE IMPACT: THE TIP OF THE ICEBERG AND THE DEEP IMPACT OF EXOPHYTIC TUMORS - A VISUAL GUIDE TO PROGNOSIS ACROSS VARIOUS HISTOLOGIES

Livia Vasconcelos, MD (*Presenter*)
Renato Fujiki, MD (*Abstract Co-Author*)
Matheus A. Vale De Castro, MD (*Abstract Co-Author*)
Paulo Ferreira, MD (*Abstract Co-Author*)
Raul N. Pigatto, MD, MBA (*Abstract Co-Author*)
Paulo R. Moreira, MD (*Abstract Co-Author*)
Henrique A. Lino, MD (*Abstract Co-Author*)
Alberto P. Bambirra, MD (*Abstract Co-Author*)
Ricardo Caracante, MD (*Abstract Co-Author*)
Andre S. Kamogari Nakamura, MD (*Abstract Co-Author*)
Mozart Liessi, MD (*Abstract Co-Author*)
Joao Pedro d. Costa, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Superficial soft tissue tumors are defined as lesions originating within or above the muscular fascia. The term exophytic describes their outward growth from the surface of origin, distorting skin contours. These tumors have distinct characteristics, including a significant psychological impact on patients. While most exophytic tumors are benign, excluding malignancy is critical, particularly in lesions exceeding 5 cm in diameter, located at a deep level, or demonstrating rapid growth.Superficial lesions are typically detected earlier than deep-seated ones. However, relying solely on size for superficial tumors risks underdiagnosis or delayed diagnosis, as it may overlook key prognostic features such as fascial contact/invasion. Additional imaging findings like fascial edema, cutaneous contact/thickening, and tumor necrosis also hold diagnostic and prognostic significance.This presentation will illustrate, through clinical cases of an oncological reference center, how exophytic masses of diverse histologies share similar imaging appearances. Additionally, it will serve as a visual guide to the most relevant prognostic factors and essential radiological reporting points.

TABLE OF CONTENTS/OUTLINE

A. Definition and ClassificationB. Role of Imaging and Rationale for MRIC. Recommended MRI protocolsD. Essential Elements of the Standardized Report and Classification Proposals such as ST-RADSE. Differentiating Benign and Malignant Lesions on MRIF. The Different Histologies of Common Exophytic Superficial Tumors and Their MimickersG. Key Prognostic and Diagnostic Factors for the ReportH. Common Pitfalls in the Imaging Diagnosis of Exophytic Tumors

MKEE-93 NO ARCH ENEMY: NEW INSIGHTS INTO PROGRESSIVE COLLAPSING FOOT DEFORMITY (PCFD) USING MULTIMODAL IMAGING

Livia Vasconcelos, MD (*Presenter*)
Adham A. Castro, MD (*Abstract Co-Author*)
Carlos F. Teixeira Lobo, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Rodrigo Vivas Cardoso, MD (*Abstract Co-Author*)
Mozart Liessi, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Alexandre L. Santos (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Paulo R. Moreira, MD (*Abstract Co-Author*)

TEACHING POINTS

Progressive Collapsing Foot Deformity (PCFD) is a complex 3D deformity with significant clinical impact, resulting from the sequential failure of static and dynamic stabilizers of the medial longitudinal arch. Accurate diagnosis and staging are essential for optimal management, requiring a multimodal imaging approach.This paper analyzes radiography, magnetic resonance imaging and weight-bearing computed tomography (WBCBCT) in the evaluation of PCFD discussing the advantages and disadvantages of each method.

TABLE OF CONTENTS/OUTLINE

Understand the progressive failure sequence of both static and dynamic stabilizers in the medial longitudinal arch that leads to PCFD development.Recognize essential radiographic measurements for PCFD assessment while being aware of their limitations in evaluating dynamic deformities.Appreciate conventional CT's complementary role in detecting associated conditions such as arthropathy and tarsal coalitions.Grasp the critical importance of WB-CBCT as the gold standard for 3D PCFD assessment.Identify characteristic MRI findings of soft tissue pathology. Understand the current consensus classification system for PCFD and how imaging findings guide surgical decision-making. Learn postoperative imaging evaluation protocols for assessing alignment correction and detecting potential complications like undercorrection or recurrence.Explore our proposed imaging algorithm that strategically integrates radiography, MRI, CT, and WB-CBCT based on deformity severity.Examine future artificial intelligence applications that can help in the analysis of images related to PCFD

MKEE-94 POST-OP SPINE: DON'T MISS THESE IMAGING SIGNS

Michelle Caroline Ferreira Dos S Cortez, MD (*Presenter*)
Amanda Martins E. Ribeiro Dos Santos, MD (*Abstract Co-Author*)
Roberto Freitas, MD (*Abstract Co-Author*)
Fabio D. Salles, MD (*Abstract Co-Author*)
Marco de Andrade Bianchi (*Abstract Co-Author*)
Jose Claudio N. Junqueira, MD (*Abstract Co-Author*)
Faissal M. Saad, MD (*Abstract Co-Author*)
Almir A. Urbanetz, MD (*Abstract Co-Author*)
Danielle B. Rumi, MD (*Abstract Co-Author*)
Pedro Henrique R. Silva, MD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Breno Trindade (*Abstract Co-Author*)

TEACHING POINTS

- Spinal surgeries have become increasingly common and can be divided into decompressive procedures, stabilization-fusion procedures and various others.- The different surgical materials used and their surgical approaches should be known by radiologists.- It is essential to differentiate expected postoperative changes from complications.- Early and late postoperative spine complications recogntition and imaging (related to the procedure itself and materials used, infectious, non infectious).- By knowing expected changes, radiologists can provide more assertive reports which can play a crucial role for postoperative complication management by the referring physician.

TABLE OF CONTENTS/OUTLINE

- Review of the main spinal surgeries and materials used.- Expected postoperative changes.- Didactic division of the main postoperative complications of the spine.- Imaging of postoperative complications.- Imaging recognition of postoperative complications typical findings.

MKEE-95 MR NEUROGRAPHY: STEP-BY-STEP APPROACH TO INTERPRETATION - A PRIMER FOR RADIOLOGISTS

Vitor D. Bichuette, MD (*Presenter*)
Thiago Jose Pinheiro Lopes, MD (*Abstract Co-Author*)
Maria Vitoria Ludwig, MD (*Abstract Co-Author*)
Enzo Calheiros, MD (*Abstract Co-Author*)
Eduardo L. Bizetto, MD (*Abstract Co-Author*)
Raul O. Martins, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)
Marcelo Bordalo, MD (*Abstract Co-Author*)
Marcos Felippe D. Correa, MD (*Abstract Co-Author*)
Paulo Victor P. Helito, MD (*Abstract Co-Author*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)

TEACHING POINTS

• Understand MR neurography protocols and optimal sequence selection (e.g., STIR-SPAIR, high-resolutionT2 FS)• Recognize imaging patterns of neuropathies and muscle denervation• Apply a systematic approach to interpretation for improved diagnostic confidence

TABLE OF CONTENTS/OUTLINE

Introduction:• Definition, indications, and advantages of MR neurography• Technical considerations and protocol highlightsNerve Evaluation• Assess nerve caliber and asymmetry• Evaluate signal alterations and contrast enhancement• Confirm continuity and identify neuromas or transections• Analyze fascicular architecture for signs of fibrosis, infiltration, or edema• Observe morphological changes and assess surrounding fat planesMuscle Evaluation• Identify denervation edema on fluid-sensitive sequences• Detect fatty infiltration on T1-weighted images for chronic changesSummaryTake-Home Messages

MKEE-96 IMAGING THE SOLE: A COMPREHENSIVE SONOGRAPHIC EVALUATION OF THE PLANTAR FAT PAD

Alejandra Somoano Marfull (*Presenter*)
Silvia Revuelta Gomez, MD (*Abstract Co-Author*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Rodrigo Sutil, MD (*Abstract Co-Author*)
Celia Cantolla, MD (*Abstract Co-Author*)
Elena A. Gallardo, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

To review the unique histological and anatomical features of the plantar fat pad. To identify the sonoanatomy of the subcalcaneal and submetatarsal regions. To recognize a broad spectrum of mechanical and non-mechanical fat pad pathologies. To apply an anatomic and etiologic classification to improve diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

The plantar fat pad is a specialized structure critical for shock absorption and load distribution. Its complex multilobular architecture and regional differentiation make ultrasound an ideal tool for high-resolution, dynamic evaluation. Histologic and Anatomical Overview : We discuss the structural differences between the subcalcaneal and submetatarsal fat pads, including septal organization, and biomechanical function. Normal Sonoanatomy : Ultrasound appearance of plantar fat compartments, with emphasis on echotexture and compressibility. Pathologies by Etiology and Location : Mechanical Causes: • Cutaneous: Hyperkeratosis, and corns (helomas). • Subcutaneous: Adventitial bursitis and fat pad contusion syndrome. Non-Mechanical Causes : • Cutaneous: Papillomas. • Dermo-hypodermic: Plantar vein thrombosis, epidermal inclusion cyst, piezogenic papules. • Subcutaneous: Foreign bodies, abscesses, subcutaneous rheumatoid nodules, lipomas. • Deep-structure-related: Morton’s neuroma, plantar fibromatosis. This poster presents a comprehensive ultrasonographic approach to plantar fat pad pathology using an anatomically and etiologically driven framework with illustrative cases from our institution.

MKEE-97 FREEZE, BURN OR BUZZ: BONE TUMOR ABLATION IN DAILY RADIOLOGIC PRACTICE

Fabio D. Salles, MD (*Presenter*)
Amanda Martins E. Ribeiro Dos Santos, MD (*Abstract Co-Author*)
Michelle Caroline Ferreira Dos S Cortez, MD (*Abstract Co-Author*)
Roberto Freitas, MD (*Abstract Co-Author*)
Marco de Andrade Bianchi (*Abstract Co-Author*)
Breno Trindade (*Abstract Co-Author*)
Jose Claudio N. Junqueira, MD (*Abstract Co-Author*)
Pedro Henrique R. Silva, MD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Ablation of bone tumors has become more accessible and is now the first line of treatment for many common and uncommon lesions found in our daily practice. There are some considerations that involve the decision of ablating a bone tumor: refractory pain, associated pathological fracture, length of the lesion. Ablation can be performed by several techniques: radiofrequency ablation, cryoablation and microwave ablation are the more commonly used methods and the choice of therapy relies on availability, location and tumor specific characteristics. While performing the ablation itself, care must be taken regarding near noble structures, such as nerves and vascular structures. Isolating the target structure by performing hydro and pneumodissection is a common strategy.

TABLE OF CONTENTS/OUTLINE

Review of the most common imaging characteristics of bone tumors that are submitted to ablation. Demonstrate the material used in different types of ablations at our institution. Explain the technique used in different types of ablations, focusing on radiofrequency ablation, cryoablation and microwave ablation. Post-procedure imaging and patient follow up.

MKEE-98 ULTRASOUND IMAGING OF NAIL PATHOLOGIES: ESSENTIALS FOR RADIOLOGISTS

Humberto A. Rivera Gonzalez, MD (*Presenter*)
Maria J. Veloza Vega, MD (*Abstract Co-Author*)
Laura Olarte Bermudez (*Abstract Co-Author*)
Ana M. Rendon-Garavito (*Abstract Co-Author*)
Oscar Rivero SR, MD (*Abstract Co-Author*)
Javier A. Romero, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

Recognize and understand different pathologies and noxas, such as onychodystrophy, leukonychia, onychomycosis and subungual glomus tumor, among others can affect the nail and surrounding structures, and how this alteration of the anatomy can present in ultrasound imaging, from real life cases with various presentations of the same disease. Learn the key elements to document in an ultrasound report, including reservation of the trilaminar nail structure, thickness of the nail bed, vascularization of the nail folds, and integrity of the surrounding bone structures, taking into account clinical findings, for an accurate diagnosis. Develop a comprehensive review of the normal anatomy and ultrasound presentation of the nail plate, nail bed, matrix, and surrounding structures, as well as the nail growth, allowing for correct identification and differentiation of normal and abnormal findings.

TABLE OF CONTENTS/OUTLINE

1. Normal Anatomy and Ultrasound Findings 2. Infectious Nail Disorders: Onychomycosis, Paronychia, Onychocryptosis3. Nail dystrophies: Onychodystrophy, Onycholysis, Leukonychia, Onychomadesis, Onychorrhexis, Melanonychia4. Cysts: Synovial Cyst Myxoid-mucoid cyst 5. Tumors and Cancers: Koenen's Tumor, Glomus Tumor,Subungual Exostosis, Bowen's Disease6. Others:Psoriasis 7. Correct Radiological Report and Key points

MKEE-99 BONE CLUES: A RADIOLOGIST’S DETECTIVE GUIDE TO LONG BONE OSTEOSYNTHESIS

Mariana Laranjeira Pierotti, MD (*Presenter*)
Andreza Melloni, MD (*Abstract Co-Author*)
Jose Alvaro Nascimento Paixao, MD (*Abstract Co-Author*)
Camila N. Oliveira (*Abstract Co-Author*)
Atilio Teixeira, MD (*Abstract Co-Author*)
Alexandre Bialowas, MD (*Abstract Co-Author*)
Taise T. da Silva (*Abstract Co-Author*)

TEACHING POINTS

Many long bone fractures require surgical treatment using various fixation devices, including Kirschner wires, intramedullary nails, plates, and screws. It is the radiologist's responsibility to assess the progression of fracture healing, identify the types of osteosynthesis materials, and detect potential complications. This work presents and illustrates both normal and pathological healing processes, including hypertrophic callus formation, non-union (pseudoarthrosis), and both acute and chronic osteomyelitis. Additionally, it addresses hardware-related complications such as loosening and fracture of fixation devices.

TABLE OF CONTENTS/OUTLINE

Bone Clues: Radiologic Evaluation of Long Bone Osteosynthesis Introduction Radiologists must assess bone healing and fixation integrity after surgery. Step 1: Fixation Type: Identify hardware: Kirschner wires, nails, plates, screws. Step 2: Hardware Evaluation: Check for loosening, deviation, fracture. Compare with baseline images. Step 3: Healing: Assess callus, alignment, signs of malunion or non-union. Step 4: Infection: Look for osteomyelitis or soft tissue abscess. Conclusion: A structured, stepwise approach improves diagnosis and patient outcomes.

MKEE-100 DDH AND ITS COMPLICATIONS: FROM NEWBORN SCREENING TO ADULT PRESENTATION AND MANAGEMENT

Arash Azhideh, MD, MPH (*Presenter*)
Farhad Pishgar, MD, MPH (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Hyun Su Kim, MD, PhD (*Abstract Co-Author*)
Ezekiel Maloney, MD (*Abstract Co-Author*)
Maryam Yousefiasl, MPH (*Abstract Co-Author*)
Bahar Mansoori, MD (*Abstract Co-Author*)
Pramod Kamalapathy, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

TEACHING POINTS

Ultrasound, particularly Graf’s method for measuring the a-angle, is essential for detecting DDH in newborns, offering a non-invasive, reliable, and widely accessible imaging technique. As the child ages, radiography becomes crucial for assessing acetabular index and femoral head displacement, aiding in accurate classification and treatment planning of DDH. MRI and CT are pivotal for post-treatment evaluation, assessing femoral head positioning after reduction, and detecting complications such as avascular necrosis or joint over-coverage.

TABLE OF CONTENTS/OUTLINE

• Introduction to DDH, Screeningo DDH spectrumo Barlow and Ortolani maneuvers, limitationso Risk factorso Flowchart of screening• Anatomyo Hip joint anatomy on US and X-rayo US timing, screening protocols• Ultrasoundo Graf US, landmarks, and a-angleo Normal findings: a = 60°o Mild dysplasia: a 50-59°, management by ageo Dislocated hips: a < 43°, labral elevation• Radiographso Switch from US to radiography.o Describes Hilgenreiner’s, Perkin’s, Shenton’s lineso Acetabular index• Radiographic Classificationo Subtle acetabular shallownesso High-riding femoral headO Grades I-IVo Uses H-point• Treatment and Follow-Upo Treatment planning and decisionso MRI§ Used post-reduction to confirm hip positioning§ Soft tissue visualization, femoral head vascularity§ Concentric reduction in spica cast on MRIo CT and Arthrography§ CT inication§ Used during reduction to assess obstacles§ Arthrogram• Complicationso Potential long-term and treatment-related issueso AVNo Persistent acetabular shallowness despite treatmento Later OA• Case Studieso Symmetric dislocationso Early treated and resolved DDH• Conclusion

MKEE-101 PREOPERATIVE TO POSTOPERATIVE IMAGING FEATURES OF PEDIATRIC FOOT DEFORMITIES. HOW RADIOGRAPHS MATTER!!

Jainam A. Doshi, MBBS, MD (*Presenter*)
Pushpa Bhari Thippeswamy, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

• Reporting checklist for assessing pediatric foot deformities on radiograph that warrant surgical intervention.• Systematic method for evaluating postoperative radiographs in patients with pediatric foot deformity. • Flow chart to address deformities in report to aid clinicians in management.

TABLE OF CONTENTS/OUTLINE

Pediatric foot deformities affect the quality of life for both child and parent. Prevalence varies from 1/1,000 live births for clubfoot to 1 /10,000 for congenital vertical talus. These deformities are primarily diagnosed clinically but preoperative imaging helps assess bone development and alignment. Various lines and angles help to assess the degree of deformity and guide management strategy. Pediatric foot deformities are treated either by conservative or surgical approach. Conservative approach includes serial manipulation and casting, special orthosis, & physiotherapy. The resistant cases may require surgical management, which includes soft tissue release, tendon transfers, osteotomies and arthrodesis. In certain deformities like congenital vertical talus and neglected clubfoot, surgery is the only option for management. Radiographs are the most common modality used for post-operative assessment in pediatric foot deformities. Radiographs play critical role in evaluation of success of surgical correction, implant placement, implant-related complications and detecting recurrence. Hence, radiologists should be aware of postoperative imaging features of routine surgical interventions. This educational exhibit focuses on the common pediatric foot deformities, surgical strategies and postoperative radiographic appearance.

MKEE-102 NEURAL SHEATH TUMORS: A PICTORIAL REVIEW

Gabriela Fernanda Riboli Favaro (*Presenter*)
Wankler Dias Canhadas Junior (*Abstract Co-Author*)
Sarah De Menezes (*Abstract Co-Author*)
Narriman P. Hazime, MD (*Abstract Co-Author*)
Leticia Ikedo, MD (*Abstract Co-Author*)
Felipe Correa Brito, MD (*Abstract Co-Author*)
Bruno B. Cardoso, MD (*Abstract Co-Author*)
Adriano Silveira Moreira Novaes, MD (*Abstract Co-Author*)
Marcio A. Ishida, MD (*Abstract Co-Author*)
Bruno C. Carneiro (*Abstract Co-Author*)
Rafael B. Jorge, MD (*Abstract Co-Author*)
Luiz T. Nehme, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the main subtypes of neural sheath tumors and their imaging characteristics. Identify findings that suggest malignancy, such as undefined margins, necrosis, hemorrhage, and invasion of adjacent structures. Understand the importance of observation with neurofibromatosis type 1 (NF1) as a risk factor for malignant transformation. Differentiate benign from malignant tumors based on imaging patterns, contributing to early diagnosis and appropriate management. Appreciate the role of imaging in diagnostic suspicion, even when it is not possible to define with certainty benignity or malignancy without biopsy.

TABLE OF CONTENTS/OUTLINE

Introduction Definition and origin of neural sheath tumors Clinical relevance and association with NF1 Retrospective institutional analysis with histological confirmation Imaging modalities used: MRI, CT and radiography Classification and Subtypes Schwannoma (typical and atypical) Neurofibroma (localized, diffuse, plexiform) Malignant neural sheath tumors Perineurioma and rare variants Imaging findings: T1, T2 signal, enhancement pattern, necrosis, hemorrhage Features suggesting malignancy Correlation with symptoms and location Differential Diagnosis Soft tissue sarcomas Myogenic tumors and pseudotumoral lesions Discussion of Cases Illustrative examples with images Clinical and anatomopathological Conclusion

MKEE-103 ACHILLES TENDON: STATE OF THE ART IN TENDON INJURIES AND POSTOPERATIVE FINDINGS

Guilherme B. Rocha, MD (*Presenter*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the anatomy of the achilles tendon and the pathophysiology and types of injuries 2. To correlate the type of injury with imaging findings, focusing in ultrasound and MRI 3. To review the main surgical treatments and their corresponding findings in radiographs, ultrasound and MRI

TABLE OF CONTENTS/OUTLINE

1. Anatomy and pathophysiology of the achilles tendon 2. Correlate the injury mechanism with the type of injury found 3. Main achilles tendon injuries 3.1 Tendinosis 3.2 Achilles tendon tears 3.3 Paratendinitis 3.4 Insertional tendinopathy 3.5 Haglund's deformity 3.6 Bursitis 3.7 Systemic disease 4. Treatments and corresponding imaging findings 4.1 Conservative - Functional bracing/casing in resting equinus 4.2 Non-conservative - Reinsertion repair (open) : single row and double row techniques - Mid-tendon repair: minimally invasive (achillion) and open (Kessler; Bunell; Krackow); complementary autologous tendon reinforcement or halo grafting 5. Pos-operated achilles injuries 5.1 Re-rupture 5.2 Infection

MKEE-104 LABRAL TEARS UNVEILED: MRI CLUES AND ARTHROSCOPIC CONFIRMATION

Ira Agrawal (*Presenter*)
Amit K. Sahu, MBBS, MD (*Abstract Co-Author*)
Bharat Aggarwal, MD (*Abstract Co-Author*)
Vikas Gupta (*Abstract Co-Author*)
Akram Jawed (*Abstract Co-Author*)
Vikas Kumar Shukla (*Abstract Co-Author*)

TEACHING POINTS

Identify normal MRI anatomy of the glenoid labrum across anterior, posterior, and superior regions. 1. Describe MRI features of common labral tears (SLAP, Bankart, posterior). 2. Correlate MRI findings with arthroscopy for accurate diagnosis. 3. Differentiate true tears from variants (sublabral recess, foramen, Buford complex). 4. Discuss diagnostic pitfalls and MRI limitations. 5. Review clinical relevance for treatment decisions.

TABLE OF CONTENTS/OUTLINE

Anterior Labral Tears: Bankart: Anteroinferior avulsion; unstable. ALPSA: Medialized labrum; chronic injury. Perthes: Detached labrum with intact periosteum. GLAD: Superficial tear + cartilage damage; stable. HAGL: IGHL avulsion from humerus; not a labral tear. Superior Labral Tears (SLAP): Ten types based on location and biceps involvement. Posterior Labral Tears: Reverse Bankart: Posteroinferior avulsion. Posterior Peel: Lifted labrum, intact periosteum. Kim Lesion: Incomplete tear; subtle. Posterior HAGL: IGHL avulsion from humerus. Posterior SLAP Extension: SLAP tear extending posteriorly. Labral Tear Mimickers: Sublabral Recess: Normal variant at 12-1 o'clock. Sublabral Foramen: Gap at anteroinferior labrum. Buford Complex: Absent anteroinferior labrum + thick MGHL. Magic Angle: Signal artifact on short TE. Partial Volume Averaging: Pseudotear from thick slices or oblique plane.

MKEE-105 ORTHOPEDIC PHOTODYNAMIC FIXATION

Kyle Robbins (*Presenter*)
Kelby B. Napier, MD, PhD (*Abstract Co-Author*)
Mariam A. Malik, MD (*Abstract Co-Author*)
Benjamin E. Northrup, MD (*Abstract Co-Author*)

TEACHING POINTS

Introduce the technology of photodynamic fixation for prophylactic and fracture fixation Understand the surgical approaches and operative technique of photodynamic fixation Recognize the normal imaging findings after photodynamic fixation Identify potential complications including extraosseous fixation and periprosthetic fracture

TABLE OF CONTENTS/OUTLINE

Outline Introduction Indications including prophylactic fixation as well as benign and pathologic fixation Surgical approach and technique Case based review of expected imaging findings and complications Normal postoperative appearance of fixation at different site Potential complications including extraosseous extension and periprosthetic fracture Outcomes after fixation

MKEE-106 ULTRASHORT TIME TO ECHO (UTE) SEQUENCES IN IMAGING OF THE CORTICAL BONE - CAN THE "INVISIBLE" BE FINALLY "VISIBLE" ON MRI: AN INITIAL EXPERIENCE

Rakhee Kumar Paruchuri, FRCR, MBBS (*Presenter*)

TEACHING POINTS

• Ultrashort Echo Time (UTE) MRI is a newer sequence available on 3T machines. It utilizes ultrashort TE to capture signal on tissues with short T2 / T2* values. • This makes "invisible" structures such as cortical bone, tendons, ligaments & menisci "visible". • High contrast morphological imaging of the cortical bone results in images that have similar contrast to CT images. • The images can be "inverted" to give an appearance similar to CT images or radiographs. • This MR technique can potentially reduce radiation exposure with CT. It also aids in avoiding multiple investigations to assess cortical abnormalities and replacing the traditional use of CT to assess the cortical bone.

TABLE OF CONTENTS/OUTLINE

1. Physiology of normal bone and its appearance on conventional MRI sequences. 2. Key features of UTE sequences, understanding the physics behind this sequence, technical specifications and utilization. 3. Benefits of UTE sequences. 4. Illustrative examples demonstrating the use of UTE sequences in depicting cortical abnormalities. 5. Understanding its limitations. 6. Future role of UTE.

MKEE-107 EMERGING ROLE OF ZERO ECHO TIME (ZTE) MRI IN EVALUATING BENIGN AGGRESSIVE BONE NEOPLASMS

Amit Janu, MBBS, MD (*Presenter*)
Pranjal Rai, MBBS (*Abstract Co-Author*)
SUYASH KULKARNI (*Abstract Co-Author*)
Nitin S. Shetty, MBBS, MD (*Abstract Co-Author*)
Kunal B. Gala, MBBS, MD (*Abstract Co-Author*)
Amit J. Choudhari, FRCR,MBBS (*Abstract Co-Author*)
Vivek Dhomane, MBBS (*Abstract Co-Author*)

TEACHING POINTS

? Understand the technical principles of ZTE MRI and its advantages in bone imaging. ? Explore the role of ZTE in evaluation of matrix mineralisation, margins and periosteal reaction in evolution of benign aggressive bone neoplasm. ? Recognize ZTE imaging patterns to know how the radiograph and CT findings like sclerosis, different matrix, lytic changes appear on ZTE sequence. ? Compare ZTE with conventional radiography and MRI in benign aggressive bone neoplasms.

TABLE OF CONTENTS/OUTLINE

1. Introduction ? Overview of benign aggressive bone tumors ? Current imaging Techniques ? Principle of ZTE MRI 2. Benign aggressive bone tumor- Chondroblastoma 3. Benign aggressive bone tumor- Giant cell tumor 4. Benign aggressive bone tumor- Osteoid Osteoma and others 5. Conclusion ? Summary and clinical impact6. Overall review: Benign aggressive bone neoplasms often present with overlapping features that challenge conventional imaging modalities. While the zone of transition and periosteal reaction are better assessed on radiograph, CT offers excellent cortical detail and matrix mineralization, its ionizing radiation burden remains a concern, particularly in young and adolescent patients. Zero Echo Time (ZTE) MRI, enables direct cortical bone visualization with minimal susceptibility artifacts, can act as an emerging promising alternative with emphasis on 3D accessibility of bone tumors over plane radiographs. ZTE offers CT-like contrast for bone while retaining the soft tissue resolution inherent to MRI, facilitating comprehensive lesion evaluation in a single modality. Through case-based examples we demonstrate how ZTE improves diagnostic confidence and management of these tumors.

MKEE-108 MAGNETIC RESONANCE IMAGING RESPONSE EVALUATION AFTER NEOADJUVANT TREATMENT IN SOFT TISSUE SARCOMAS: WHERE DO WE STAND?

Jose A. Narvaez, MD (*Presenter*)

TEACHING POINTS

1. To review the current role of neoadjuvant treatment in soft tissue sarcomas (STS). 2. To recognize that MR Imaging depict various changes induced by neoadjuvant therapies in the treatment of STS, but these changes are poorly correlated with histology and clinical outcomes.3. To recognize the usefulness of Choi's criteria, together with information from functional magnetic resonance imaging (DWI AND DCE-MRI), to improve the efficacy of response criteria such as RECIST 1.1 in identifying good responders based on tumor cell necrosis and viability after neoadjuvant treatment.

TABLE OF CONTENTS/OUTLINE

A. Review the current role of Neoadjuvant Therapy in soft-tissue (ST) sarcomas, emphasizing the more common indications. B. MR imaging protocols for assessment response to Neoadjuvant Theraphy in ST sarcomas. Conventional pulse sequences, Diffusion (b values, ADC, IVIM), Dynamic Contrast-enhanced images. C. Spectrum of Pathologic Changes in ST sarcomas after Neoadjuvant Therapy. Necrosis, Granulation Tissue, Fibrotic Tissue, Viable Tumor, Peripheral changes and Pseudocapsule. D. MR imaging/Pathologic correlation of changes after Neoadjuvant Therapy in ST sarcomas. Histologic subtypes with specific imaging/pathologic changes (Synovial Sarcoma, Myxoid Liposarcoma). Changes in conventional MR pulse sequences, Difussion, Dynamic Contrast-enhanced images. E. Imaging response criteria: RECIST 1.1, Choi Criteria, usefulness of functional MRI. F. Prognostic value of good response to neoadjuvant therapy in ST sarcomas.

MKEE-109 NARRATIVE NEEDLEWORK: DOCUMENTING THE ORAL TRADITION OF MUSCULOSKELETAL INTERVENTION TRAINING TO MAXIMIZE PROCEDURAL SUCCESS

Brian Y. Chan, MD (*Presenter*)

TEACHING POINTS

1. Create an enduring resource containing procedural knowledge that has been acquired largely via oral tradition.2. Suggest guidelines for maximizing patient comfort and opportunity for technical success.3. Provide tips for troubleshooting commonly encountered procedural pitfalls.

TABLE OF CONTENTS/OUTLINE

1. Before the procedure- Allergies- Managing barriers to moderate sedation- Consent- Room setup- Equipment selection- Planning the approach- Patient positioning- Role of intraprocedural pathology consultation2. During the procedure- Pain management- Navigating around sensitive structures- How to sample difficult lesions- Removing the sample3. After the procedure- Specimen handling and transport media- Dealing with complications4. Modality-specific considerations- FL- US- CT

MKEE-110 WHAT LASTS OF THEM: FUNGAL INFECTION IN MUSCULOSKELETAL IMAGING

Vitor Nascimento, MD (*Presenter*)
Lucas Nogueira, MD (*Abstract Co-Author*)
Ricardo Caracante, MD (*Abstract Co-Author*)
Henrique A. Lino, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Fungal infections have multiple forms of musculoskeletal presentation and are often a neglected differential diagnosis. MRI is the most sensitive modality for early detection, while CT provides detail on cortical destruction and calcifications. Recognition of imaging patterns and correlation with clinical risk factors is critical for suggesting a fungal etiology and guiding biopsy or treatment.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of fungal musculoskeletal infections and its diagnostic challenges. Objectives: To describe imaging features of fungal infections, highlight key pathogens, and discuss diagnostic strategies. Methods: Illustrative case-based review using MRI, CT, and plain radiographs from confirmed fungal infections. Discussion: Review of dissemination pathways (hematogenous, direct inoculation, contiguous spread), typical imaging findings, and pathogen-specific clues. Conclusion: Fungal infections should be considered in indolent, atypical musculoskeletal presentations. High clinical suspicion and targeted imaging play a central role in early diagnosis and improved outcomes.

MKEE-111 PSORIATIC ARTHRITIS FROM A TO Z: A GUIDE TO RADIOLGY

Hugo Franco, MD (*Presenter*)
Damaris V. Goncalves, MD (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

Psoriatic arthritis (PsA) is a systemic inflammatory disease that affects peripheral and axial joints, tendons, ligaments, and their insertions, present in around 30% of patients with the cutaneous disease and in up to 90% of the patients with nail psoriatic changes. Although the diagnosis of psoriasis is eminently clinical, imaging exams play a fundamental role in assessment of PsA, as well as for monitoring disease progression and response to treatment. X-rays have traditionally been used to document structural joint damage, such as bone erosions, joint space narrowing, bone proliferation, and typical deformities (e.g. "pencil-in-cup"), having a greater role in the chronic phase. Ultrasound (US) and magnetic resonance imaging (MRI) are particularly useful in detecting inflammatory changes in the soft tissues, such as synovitis and enthesitis. US, for example, can identify specific abnormalities of PsA, such as perientheseal microvascular flow detected by Power Doppler and has good sensitivity for detection of bone erosions. MRI provides a detailed view of inflammatory and structural changes, such as bone marrow edema and synovitis, being useful for both

peripheral and axial disease. The appropriate use of various imaging modalities and accurate interpretation of the findings add significant value to the diagnostic and treatment of patients with PsA, contributing to prevention of joint destruction and reduction of disease burden.

TABLE OF CONTENTS/OUTLINE

1. Introduction: psoriasis and PsA 2. The Enthesis Organ Concept 3. Epidemiology & Clinical Features of PsA 4. Multimodality imaging 5. Key Findings in PsA 6. Differential Diagnosis 7. Conclusion

MKEE-112 ENTHESIS IN HEALTH AND DISEASE: A PRIMER FOR RADIOLOGISTS

Irem Togrul, MD (*Presenter*)
Ahmet Gurkan Erdemir (*Abstract Co-Author*)
Sevtap Arslan (*Abstract Co-Author*)
Ustun Aydingoz, MD (*Abstract Co-Author*)
Adalet E. Yildiz, MD (*Abstract Co-Author*)

TEACHING POINTS

Entheses are structures that attach tendons, ligaments, capsules, or fasciae to bones. They may exist in the form of fibrous or fibrocartilaginous entheses, the latter further subdivided into classic, functional, and articular types. Entheses consist of various types of cartilage and synovial tissue, collectively referred to as the "synovioentheseal complex" (SEC). The SEC can be affected by many rheumatic diseases, foremost among them psoriatic arthritis, the most common subtype of peripheral spondyloarthritis, as well as traumatic or overuse injuries like Osgood-Schlatter disease and metabolic conditions such as X-linked hypophosphatemia. This educational exhibit aims to provide essential information about the structure of various forms of healthy entheses and the spectrum of diseases and conditions that can lead to their inflammation or disruption.

TABLE OF CONTENTS/OUTLINE

1. Enthesis in health: synovioentheseal complex and enthesis subtypes 2. Imaging modalities for enthesitis and/or enthesopathies 3. Case examples of enthesis in disease including Arthritis (a) Psoriatic arthritis, reactive arthritis, inflammatory bowel disease-related arthritis(b) Rheumatoid arthritis(c) Ankylosing spondylitis(d) Juvenile idiopatic arthritis (enthesitis-related arthritis)(e) Diffuse idiopathic skeletal hyperostosis (DISH)(a) Crystal arthropathy (gout arthritis)(f) Systemic lupus erythematosus(g) Synovitis, acne, pustulosis, hyperostosis, osteitis syndrome (SAPHO)(h) Chronic non-bacterial osteomyelitis (CNO) Metabolic Diseases (b) X-linked hypophosphatemia Trauma-Overuse Related (a) Osgood-Schlatter disease(b) Haglund deformity(c) Pulley injury4. Summary 5. Conclusion

MKEE-113 STAYING AFLOAT IN MUSCULOSKELETAL TRAUMA: AN OVERVIEW OF CONDITIONS WITH FAT FLOATING ON BLOOD

Ahmet Gurkan Erdemir (*Presenter*)
Omer Cakir, MD (*Abstract Co-Author*)
Sevtap Arslan (*Abstract Co-Author*)
Ece I. Akduman, MD (*Abstract Co-Author*)
Stephen B. Huebner, MD (*Abstract Co-Author*)
Adalet E. Yildiz, MD (*Abstract Co-Author*)
Ustun Aydingoz, MD (*Abstract Co-Author*)

TEACHING POINTS

Fat-blood interface, whereby fat and blood come into direct contact and less dense fat floats within more dense serum and hematocrit, has unique imaging characteristics that point to specific pathophysiological patterns of musculoskeletal system. Lipohemarthrosis is a pathognomonic feature of intra-articular fractures, which result in a mixture of marrow fat and blood with synovial fluid within joint space. When gas is also introduced, as with certain surgeries, gunshots or other forms of trauma, pneumolipohemarthrosis occurs. Lipohematomas can be seen adjacent to fractures, whereby the hematoma is composed of marrow blood mixed with fat. Bursal or tendon sheath lipohematomas may also occur. Morel-Lavallée (ML) lesions are seen in subcutaneous fat tissue (usually deeper to superficial fascia) over a bony promontory when a shear injury disrupts vessels, into which floating globules from the surrounding fat or ruptured lymphatics may be introduced. Foci of coalesced extracellular fat within marrow may be seen in bone contusions and fractures, as well as in osteomyelitis.

TABLE OF CONTENTS/OUTLINE

Radiographic shades of grey and how they pertain to fat floating on or in serum/blood on radiographs or CT. Pathophysiology of fat floating within a blood-filled cavity. Case examples of lipohemarthrosis, pneumolipohemarthrosis, bursal lipohematoma, floating fat within tendon sheaths, ML lesions, and coalesced extracellular fat globules within marrow in bone contusions, fractures and, as a differential consideration, osteomyelitis. How "saline-solution load test? may result in an erroneous diagnosis of pneumolipohemarthrosis in a "challenged joint?, if chart review is not duly performed by radiologist.

MKEE-114 ASSESSMENT OF T2-WEIGHTED MRI-DERIVED SYNTHETIC CT FOR THE DETECTION OF SUSPECTED LUMBAR FACET ARTHRITIS: A COMPARATIVE ANALYSIS WITH CONVENTIONAL CT

Gan Cao (*Presenter*)
Jun Xia (*Abstract Co-Author*)
Shanghuang Xie (*Abstract Co-Author*)
Jiandong Guo (*Abstract Co-Author*)
Keliang Ye (*Abstract Co-Author*)

TEACHING POINTS

1.Deep learning-based sCT using Pix2Pix GAN with ResNet-9 transforms T2-weighted MRI into CT-equivalent images, enabling radiation-free bone evaluation. 2.sCT shows strong correlation with conventional CT (axial/sagittal SSIM: 0.889/0.858; PSNR: 24.56/23.75dB; MAE: 0.031/0.038; DSC: 0.935/0.876). 3.For lumbar facet pathology, sCT outperforms T2-weighted MRI in detecting bone erosions (sensitivity: 57.9%vs.5.3%; specificity: 98.8%vs.84.6%), osteosclerosis and joint alterations. 4.Bland-Altman analysis confirms high agreement between sCT and CT across 15 spinal parameters with excellent inter/intra-reader reliability (ICC: 0.839-0.983/0.953-0.995). 5.Integrating sCT into MRI protocols provides "one-stop" spinal assessment, potentially eliminating need for additional CT while maintaining diagnostic confidence. 6.Limitations include reduced performance with severe degeneration, metal artifacts, or anatomical variants, requiring further technical refinement.

TABLE OF CONTENTS/OUTLINE

I. IntroductionA. Lumbar facet arthropathy significanceB. Imaging limitations: CT vs. MRIC. Need for MRI-derived synthetic CT II. Technical FrameworkA. Pix2Pix-GAN architecture with ResNet-9B. Custom loss functionsC. Dataset and validation approach III. Image AnalysisA. Modality comparison (CT/sCT/T2WI)B. Normal vs. pathological facet jointsC. Multi-planar reconstruction accuracy IV. Validation ResultsA. Quality metrics (SSIM, PSNR, MAE, DSC)B. Bland-Altman analysis of key measurementsC. Diagnostic performance for facet pathologies V. Clinical ImpactA. Radiation reduction benefitsB. Diagnostic workflow enhancementC. Limitations and future directions

MKEE-115 UPDATE ON IMAGING OF ROTATOR CUFF TEARS: WHAT WE KNOW SO FAR AND WHAT LIES AHEAD

Dyan V. Flores, MD (*Presenter*)

TEACHING POINTS

Rotator cuff (RC) tears affect 20%-50% of individuals aged 60 years or older. The RC repair is the second most common orthopedic soft tissue repair procedure and more than 250 000 repairs are performed annually in the United States alone. Imaging plays a crucial role in diagnosing and evaluating rotator cuff tears. Multiple modalities are used, each with its own strengths and applications. Rapid advances in imaging, along with updates on anatomy and arthroscopy have provided opportunities for improved treatment strategies, based on a better understanding of the various patterns of RC tears. In this educational exhibit, we review the latest on

rotator cuff tears specifically imaging modalities, radiologic reporting and interpretation, and treatment. We also highlight controversies, gaps in literature, burning questions and future directions.

TABLE OF CONTENTS/OUTLINE

1. IMAGING MODALITIES What We Know So Far •Common US pitfalls •Common MRI pitfalls What Lies Ahead •3D MRI •Novel sequences 2. RADIOLOGIC INTERPRETATION AND REPORTING What We Know So Far •Lack of MRI grading system •ISAKOS classification •Non-ISAKOS tears: Thinning, Delamination, MTJ tear •Hard to diagnose areas: subscapularis, rotator interval •Measurements: tendon retraction and muscle atrophy What Lies Ahead •AI-driven measurements 3. POSTOPERATIVE IMAGING What We Know So Far •When to use US, MRI or MRA •Appearances of conventional repairs What Lies Ahead •Biologic and structural augmentation •Tendon transfers •Superior capsular reconstruction

MKEE-117 LEPROSY REVISITED: AN IMAGING REVIEW OF MUSCULOSKELETAL ABNORMALITIES

Marcelo Amaral, MD (*Presenter*)
Vitor Verlangieri Carmo Machado, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Leonor G. Savarese, MD, PhD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Artur Da Rocha Correa Fernandes, MD, PhD (*Abstract Co-Author*)
Marcello H. Nogueira-Barbosa, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to: Highlight the characteristics of neural and musculoskeletal imaging findings associated with leprosy. Demonstrate the role of ultrasonography and magnetic resonance imaging (MRI) in the early detection, diagnosis and disease monitoring, as well as management of leprosy-related complications. Emphasize the importance of global diagnostic awareness and the radiologist’s role in improving outcomes through timely imaging evaluation.

TABLE OF CONTENTS/OUTLINE

Introduction: Definition of leprosy, clinical relevance and current diagnostic challenges. Public Health: Increasing relevance in developed countries due to global migration and delayed recognition of atypical cases in non-endemic settings. Role of Imaging: Importance of imaging in early detection, differential diagnosis and disease monitoring. Ultrasonography: Accessibility, utility in nerve evaluation and neural complications, standardized measurement. MRI: Use for joint evaluation and its importance for differential diagnosis. Future Perspectives: Imaging protocols standardization, investigation of potential role of MR neurography/tractography and ultrasound elastography in leprosy neuropathy.

MKEE-118 EPONYMOUS FRACTURES: REFLECTING ON THE HISTORY, MECHANISM, AND RADIOLOGICAL FEATURES

Nour Lababede (*Presenter*)
Mahmoud Omar, MD (*Abstract Co-Author*)
Vijaya K. Kosaraju, MD (*Abstract Co-Author*)
Navid Faraji, MD (*Abstract Co-Author*)

TEACHING POINTS

Many common musculoskeletal eponyms are named after 18th and 19th century physicians whose original descriptions laid the foundation for modern fracture classification. Eponymous fractures demonstrate characteristic imaging findings based on mechanistic patterns. Knowledge of eponymous fractures facilitates active review of imaging and recognition of secondary findings.

TABLE OF CONTENTS/OUTLINE

Background: Accuracy of eponym use in clinical practice. Advantages and limitations of eponym usage. Eponymous Fractures: Le Fort, Jefferson, Hangman, and Chance (craniofacial and spinal). Bankart and Hill-Sachs (shoulder). Colles, Galeazzi, Monteggia, Gamekeeper's, Bennett, Rolando, and Boxer (upper extremity). Lisfranc, Segond, Schatzker Classification, Maisonneuve, Pilon, Tillaux, Chopart, and Jones (lower extremity).

MKEE-119 THE BIG NERVE PROBLEM: IMAGING OF SCIATIC NERVE PATHOLOGIES FROM COMMON TO RARE !!

Aruna R. Patil, MD, FRCR (*Presenter*)
Rajesh V. Helavar, MBBS,MD (*Abstract Co-Author*)
Kartik Revanappa (*Abstract Co-Author*)

TEACHING POINTS

Sciatic nerve as it spans a long course can be affected by focal or diffuse pathologies at various levels. Many disease processes spread along the nerve and present with confusing clinical picture. Awareness of the typical and atypical imaging features of common and1. rare abnormalities is vital for any practicing radiologist. This exhibit will focus on :1.Radiological anatomy of Sciatic nerve - USG, CT, MRI 2. Approach on localisation of sciatic nerve pathologies 3. Multiple focal and diffuse abnormalities of the nerve with pertinent imaging features

TABLE OF CONTENTS/OUTLINE

The exhibit will cover: 1. The anatomy of the sciatic nerve (illustration) and radiological anatomy 2. Variant anatomy and landmarks 3.Motor supply of the nerve and denervation patterns 4. Focal lesions: Benign: Schwannoma, neurofibroma, intraneural ganglion cyst, intraneural lipoma . Malignant: neurofibrosarcoma, in NF-1, lymphoma, chloroma 5.Diffuse: Guillian Barre, chronic idiopathic inflammatory polyneuropathy, Charcot Marie Tooth disease, Hansens disease, neuritis secondary to compression (Ischiofemoral impingement, bed sores , persistent sciatic artery), radiation plexitis / neuritis, vasculitis related neuritis, malignant extension 6. Trauma - neuropraxia due to complete transection , posterior hip dislocation 7. Extrinsic compression - by tumors, osteochondroma, labral cysts 8.Secondary involvement - by vascular malformation, endometriosis, tumors, abscess (perianal fistula) , fibromatosis 9. Sciatic nerve interventions - image guided injections - tips to avoid iatrogenic injury 10.Advances - MR neurography and DTI

MKEE-120 THE FAT LABYRINTH: NAVIGATING PITFALLS IN FAT-CONTAINING SOFT TISSUE TUMORS

Takahiro Kitayama, MD, PhD (*Presenter*)
Yuka Takahashi (*Abstract Co-Author*)
Yudai Asano (*Abstract Co-Author*)
Fumiyo Higaki (*Abstract Co-Author*)
Katsuhide Kojima (*Abstract Co-Author*)
Yoshiyuki Ayada (*Abstract Co-Author*)
Hidetaka Yamamoto (*Abstract Co-Author*)
Takao Hiraki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Fat is a distinctive imaging feature and plays a crucial role in the differential diagnosis of soft tissue tumors. However, adipocytic tumors span a broad spectrum from benign to malignant, and radiologists often encounter benign lipoma subtypes that may be challenging to differentiate from liposarcomas, as well as liposarcomas that closely mimic benign lesions. Additionally, various neoplastic and non-neoplastic fat-containing masses can act as mimickers of adipocytic tumors, occasionally leading to diagnostic uncertainty among radiologists. The purpose of this exhibit is to: 1. Explore the spectrum of adipocytic tumors based on the latest WHO Classification of Soft

Tissue Tumors, with a focus on their imaging characteristics. 2. Highlight key mimickers, emphasizing pitfalls, diagnostic challenges, and differential considerations. 3. Present a structured diagnostic framework that integrates imaging features, clinical information and anatomical distribution to aid in the differentiation of fat-containing soft tissue tumors.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Case-based review of adipocytic tumors following the WHO Classification of Soft Tissue Tumors, 5th Edition, covering both benign and malignant subtypes, with a focus on imaging characteristics and diagnostic challenges.3. Overview of neoplastic and non-neoplastic fat-containing masses that mimic adipocytic tumors, emphasizing key imaging pitfalls and differential considerations.4. A structured diagnostic flowchart integrating imaging features, clinical information and anatomical distribution to guide the differentiation of fat-containing soft tissue tumors.5. Summary

MKEE-121 NON-EXTREMITY MUSCLE INJURIES: A FRONT-TO-BACK OVERVIEW

Ethan Porter, BA (*Presenter*)
Muhayman Sadiq, MBBS (*Abstract Co-Author*)
Manickam Kumaravel, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Identify all non-extremity muscles and provide examples of commonly imaged and injured muscles in this group. Highlight MRI techniques most useful for diagnosing non-extremity muscle injuries, associated injuries, and complications. Detail MRI techniques for detecting edema and hematoma in non-extremity muscle injuries. Compare T2-weighted and T1-weighted imaging findings. Outline grading methods for strains and tears in non-extremity muscles, with MRI examples of each. Discuss intraoperative and postoperative appearances of these muscles, including common postoperative complications.

TABLE OF CONTENTS/OUTLINE

Introduction Diagnosis of non-extremity muscle injury. MRI findings: qualitative and quantitative. Relevant muscles and MRI injury examples. MRI Techniques MRI techniques for edema qualification. Strengths of different MRI techniques. T1 vs. T2 contrasts, with side-by-side MRI examples. Measurement and distinction of fluid areas, edema, and hematoma on MRI. Grading Comparing grading patterns for different muscles with respective imaging. Criteria for surgical vs medical management of tears. Management Pre-op, intra-op, and post-op imaging with illustration. Postoperative complications imaging appearance. Conclusion Suggest a report template with key information to include. Key imaging pitfalls and techniques to avoid them. Key takeaways. References

MKEE-122 FROM SPINE TO SYNOVIUM: A COMPREHENSIVE REVIEW OF SKELETAL TB FOR THE LEARNING RADIOLOGIST

Janardhana Ponnatapura, MD (*Presenter*)
Praveen Shastry (*Abstract Co-Author*)

TEACHING POINTS

Musculoskeletal TB is a diagnostic challenge due to its protean manifestations and overlap with other pathologies. Musculoskeletal TB represents 10-15% of extrapulmonary TB. Spine, hip, and knee are the most commonly affected sites. MRI is the most sensitive modality for early detection, assessment of disease extent, and treatment response. Recognizing characteristic imaging patterns (e.g., paradiscal involvement, Phemister's triad, cold abscesses, spina ventosa) is critical to early and accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

Overview of musculoskeletal tuberculosis• Pathophysiology and routes of skeletal TB spread• Classification of spinal TB patterns Paradiscal Anterior subligamentous Central Posterior element involvement • Extraspinal manifestations of TB Tuberculous arthritis and Phemister's triad Tuberculous osteomyelitis TB dactylitis (Spina ventosa) Tenosynovitis and myositis • Characteristic imaging features on radiographs, CT, and MRI• Key differentiating features from mimics Pyogenic infections Metastatic disease Inflammatory arthritis • Role of imaging in diagnosis, biopsy planning, and monitoring response• Radiologic signs of active vs. healing disease• Diagnostic tips and red flags for early recognition• Educational value for trainees: case-based quiz and pattern-recognition pearls

MKEE-123 IDENTIFYING COMMON BLIND SPOTS IN SPINE MRI: WHAT SETS RADIOLOGISTS APART FROM OTHER CLINICIANS

Hyun Su Kim, MD, PhD (*Presenter*)
Peyman Mirghaderi, MD, MPH (*Abstract Co-Author*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

TEACHING POINTS

• Spine MRI routinely captures a broader anatomical landscape than the immediate clinical target. • Clinically significant pathologies may lurk in overlooked regions, escaping detection without a vigilant review. • Radiologists possess the unique expertise to identify subtle but actionable findings invisible to most clinicians. • A comprehensive, anatomy-wide approach elevates diagnostic precision and directly impacts patient outcomes. • Cultivating awareness of blind spots and implementing structured search patterns amplifies the radiologist's diagnostic value

TABLE OF CONTENTS/OUTLINE

Introduction - Expanding the radiologist's role beyond focused interpretation - Risks of missing high-impact findings in non-targeted areas Why Blind Spots Matter - Incidental findings with major clinical consequences - Missed diagnoses, delayed treatment, and avoidable morbidity Anatomical Regions Often Overlooked - Craniocervical junction - Thoracic cavity and pulmonary apex - Retroperitoneum and psoas compartment - Pelvis and extraspinal soft tissues Illustrative Case Examples - Aneurysms, deep-seated tumors (sellar, retroperitoneal, muscular, costovertebral), abscesses, insufficiency fractures, osteonecrosis - Multimodality correlation (CT, PET-CT, enhanced MRI) for definitive diagnosis Recommendations for Practice - Structured interpretive strategies to minimize oversight - Imaging or biopsy recommendations when suspicion arises Conclusion - What sets radiologists apart is their vigilance—making the invisible, visible.

MKEE-124 SEEING BETWEEN THE LINES: MR AND CT ARTHROGRAMS MADE CLEAR FOR RADIOLOGISTS

Fabio Yoshimura, MD (*Presenter*)
Eduardo N. Kihara Filho, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Compare the technical execution, clinical indications, and diagnostic advantages of MR and CT arthrography in musculoskeletal imaging. Provide guidance on appropriate modality selection based on clinical scenarios. Review intra-articular injection techniques, including fluoroscopy- and ultrasound-guided approaches. Identify key imaging findings for accurate diagnosis. Discuss potential complications associated with arthrography. Emphasize strategies to enhance diagnostic confidence and improve patient care.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of arthrography in musculoskeletal radiology Clinical value and growing role of MR and CT arthrograms Technical Considerations Intra-articular injection techniques Fluoroscopy-guided Ultrasound-guided Contrast agents and protocols Modality Comparison MR Arthrography: strengths, limitations, and clinical

applications CT Arthrography: strengths, limitations, and clinical applications Choosing the right modality Common Complications Infection Adverse contrast reactions Neurovascular injury Joint-Specific Applications Shoulder Elbow Wrist Hip Knee Ankle Conclusion Importance of technical proficiency and anatomical knowledge Role of arthrography in improving diagnostic accuracy and patient outcomes

MKEE-125 PEARLS AND PITFALLS IN TFCC IMAGING: FACT VERSUS ARTIFACT

Dyan V. Flores, MD (*Presenter*)

TEACHING POINTS

The triangular fibrocartilage complex (TFCC) is a complex arrangement of delicate structures that plays a crucial role in wrist stability. Its radiologic appraisal can be challenging due the small size of its components, subtle imaging characteristics, variable imaging criteria for injury to each component, and lack of imaging-surgical correlation in existing literature. This educational exhibit aims to present the latest information regarding the imaging characteristics of each component, highlight common pitfalls in imaging assessment, and provide practical strategies to address these pitfalls.

TABLE OF CONTENTS/OUTLINE

CENTRAL DISC Fact : • Palmer type IA lesion appears as a thin perforation in the central disc Artifact : •The disc can appear thin on wrist rotation mimicking a perforation DISTAL RADIOULNAR LIGAMENTS (DRULs) Fact : •The ligamentum subcruentum (LS) is a vascular fissure that represents the deep/foveal layer of the DRULs •The DRULs attach to the ulnar fovea and styloid Artifact : •The bright signal of the LS can be confused for a tear on MRI •Supinated positioning of the wrist can distort the appearance of the ulnar insertions of the DRULs, limiting evaluation ULNOMENISCAL HOMOLOGUE (UMH) Fact : •The UMH is a synovium-like structure that lies just ulnar to the prestyloid recess Artifact: •The appearance of the UMH is highly variable and often affected by the imaging parameters and the position of the wrist at the time of scanning ULNAR COLLATERAL LIGAMENT (UCL) Fact: •The UCL arises from the ulnar aspect of the ulnar styloid and merges with fibers of the rest of the TFCC Artifact: •The normal UCL can appear injured on radiocarpal compartment arthrography

MKEE-126 CRIMPS, PULLEYS, AND BOWSTRINGS: ULTRASOUND AND MAGNETIC RESONANCE IMAGING EVALUATION OF FLEXOR PULLEY INJURIES FROM ROCK CLIMBING

David Lee, MD (*Presenter*)
Steven R. Kussman, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Finger pulley injury is well-known and dreaded among rock climbers, developing from persistent overuse and heavy loading of the finger flexors, the flexor digitorum, in a crimp position. 2. Finger pulley is a localized thickening of the synovial tendon sheath, which stabilizes the flexor digitorum by maintaining its close distance to the phalanx, and allows for efficient force transfer in finger flexion. 3. A2 and A4 pulleys, located volar to the proximal and middle phalanges, respectively, are most commonly injured, which leads to 'bowstringing' of the flexor tendon away from the phalanx. 4. Ultrasound and magnetic resonance imaging enable efficient and effective evaluation of bowstringing based on increased tendon-phalanx distance, which correlates with the severity of pulley injury, ranging across the spectrum of sprain, partial rupture, complete rupture, and complete ruptures of multiple pulleys. 5. Imaging-guided evaluation of pulley injury guides management, with varied timelines of conservative medical management through immobilization, rehabilitation, versus surgical management.

TABLE OF CONTENTS/OUTLINE

1) Anatomy of the finger pulley system. 2) Biomechanics of pulley injury in rock climbing. 3) Ultrasound evaluation of the severity of pulley injury, with tendon-phalanx distance as a measure of 'bowstringing' of the flexor digitorum away from the phalanx. 4) Additional ultrasound signs of finger flexor overuse: tenosynovitis and synovial cyst. 5) Clinical grading for management and rehabilitation: sprain, partial rupture, complete rupture, and multiple pulley complete ruptures. 6) Advanced evaluations using MRI.

MKEE-127 DECT POST PROCESSING IN SPINAL HERNIATION AND DEGENERATION

Levent A. Solim, MD (*Presenter*)
Scherwin Mahmoudi, MD (*Abstract Co-Author*)
Vitali Koch, MD (*Abstract Co-Author*)
Christian Booz, MD (*Abstract Co-Author*)
Simon Bernatz, MD (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)
Ibrahim Yel, MD (*Abstract Co-Author*)

TEACHING POINTS

Dual-Energy CT (DECT) enables advanced material differentiation by acquiring datasets at two different energy levels, allowing post-processing techniques such as Virtual Non-Calcium (VNCa) imaging and Collagen Mapping to highlight specific tissue changes beyond what conventional CT can offer. VNCa imaging suppresses the calcium signal from vertebral bodies and endplates, improving visualization, which serves as a non-invasive marker of degenerative spinal disease and disc herniation. Collagen mapping, a relatively novel DECT application, enhances the depiction of the intervertebral disc structure, allowing improved evaluation of annular tears, disc degeneration, and facet joint changes by quantifying collagen content and distribution. The application of VNCa and collagen mapping in thoracic and lumbar spine demonstrates promising added value in diagnosing spinal pathologies, contributing to a more nuanced assessment of spine disorders using CT.

TABLE OF CONTENTS/OUTLINE

1. Intervertebral herniation 2. Vertebral degeneration 3. DECT post-processing 4. Virtual noncalcium reconstruction (VNCa) 5. Collagen mapping

MKEE-128 PREGNANCY-RELATED MUSCULOSKELETAL DISORDERS AND TUMORS

Peyman Mirghaderi, MD, MPH (*Presenter*)
Sara Haseli, MD (*Abstract Co-Author*)
Kevin Oommen, MD (*Abstract Co-Author*)
Hyun Su Kim, MD, PhD (*Abstract Co-Author*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Nastaran Hosseini (*Abstract Co-Author*)
Bahar Mansoori, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

TEACHING POINTS

• Classify Musculoskeletal (MSK) disorders by pregnancy stage: prenatal, peripartum, postpartum • Recognize pregnancy-specific MSK pathology and exacerbations of preexisting disease • Understand the impact of pregnancy on tumor growth/presentation • Identify a safe/effective imaging approach across trimesters

TABLE OF CONTENTS/OUTLINE

A wide range of MSK disorders in pregnancy are often underdiagnosed due to overlapping symptoms and imaging hesitancy. Pregnancy-related MSK pathology can be generally categorized as pregnancy-induced, pregnancy-exacerbated, childbirth-induced, or neoplastic (benign and malignant). We review multimodality imaging, safety, and clinical pearls using real cases to develop a practical framework for navigating MSK disorders in pregnancy. Table of Contents • Pregnancy Induced o Pelvic Girdle Syndrome o Osteoporosis o Stress Fractures o Hip Subchondral Bone Disease o Disk Herniation o Sciatica o Carpal Tunnel Syndrome o Meralgia Paresthetica • Exacerbated preexisting conditions o Vascular malformation o Deep MSK Fibromatosis o Rheumatoid Arthritis, etc. • Childbirth-related / Postpartum o Lumbosacral Plexopathy o Pubic Symphysis Disorder o Sacrococcygeal Dislocation o Coccygodynia o Septic Arthritis o De Quervain tenosynovitis (Baby Wrist) o Osteitis Condensans

Ilii o Joint pain/remodeling/hypermobility/instability o Ligamentous Laxity o Diastasis Recti o Varicose Veins o Pes Planus • Benign/malignant tumors o Giant Cell Tumor o Hemangioma o Desmoid Tumor o Aggressive Angiomyxoma o Metastases (primarily breast cancer) o Angiosarcoma • Imaging modality use and safety Case-based imaging algorithms

MKEE-129 STRUCTURED REPORTING OF PROXIMAL HUMERUS FRACTURES: A CHECKBOX-BASED TOOL FOR CONSISTENCY AND SURGICAL COMMUNICATION

Ignacio Cavaller, MD (*Presenter*)
Cristina Casado Perez, MD (*Abstract Co-Author*)
Andres Abellan Albert, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the different classification systems used for proximal humerus fractures. To explain the key factors to assess in shoulder CT imaging for accurate diagnosis and treatment planning. To detail Hertel's criteria for predicting avascular necrosis. To optimize the synthesis of these critical data points through a structured tool for systematic evaluation. To demonstrate how checkbox-based templates can be translated into clear, concise, and standardized written radiology reports.

TABLE OF CONTENTS/OUTLINE

Epidemiology and fracture patterns. Neer’s classification and special fracture configurations. Hertel’s criteria for vascular risk stratification. Introduction and walkthrough of the structured reporting form, showing different images to illustrate each item. Nine clinical cases from our institution, illustrated through both the form and the corresponding structured report.

MKEE-130 BEYOND THE BIG TOE: ATYPICAL PRESENTATIONS OF GOUT IN MUSCULOSKELETAL IMAGING

John Cerne, MD, BS (*Presenter*)
Vanessa M. Zayas-Colon, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Tophi generally enhance and have low T2 signal, but look for juxta-articular location and associated bone erosion, to increase specificity. 2. The earliest sign of gout is joint effusion. 3. Dual-energy CT can help to clarify urate crystal presence. 4. Certain characteristics of erosions support a diagnosis of gout. These include: (a) sparing the joint space (until late in the disease) and (b) juxta-articular location 5. Focal nodular synovitis in gout is a manifestation of chronic urate deposition and can mimic synovial tumors.

TABLE OF CONTENTS/OUTLINE

Introduction [a] Brief overview of gout as a common crystalline arthropathy [b] Emphasis on classic presentation vs under-recognized atypical manifestations, on MRI [c] Avoiding misdiagnosis Pathophysiology [a] Urate crystal deposition [b] Mechanisms: i. Tophus formation ii. Erosions iii. Inflammation Atypical Gout [a] Tophi, not at the big toe [b] Enthesopathy [c] Bursitis [d] Erosions, not at the big toe [e] Focal nodular synovitis Clinical Pearls for Radiologists [a] Teaching points for recognizing unusual patterns [b] Importance of correlating imaging with clinical and laboratory data [c] Reporting language to suggest gout when features are ambiguous Case Gallery from our institution (8 examples) Conclusion [a] Recap the importance of recognizing gout beyond its typical presentation [b] Emphasize the radiologist’s role in guiding correct diagnosis and management [c] Suggest follow-up actions: biopsy avoidance, DECT confirmation, and collaboration with rheumatology

MKEE-131 THE EXPANDING ROLE OF VIRTUAL NON-CALCIUM IMAGING IN AN AGING SOCIETY: BEYOND FRACTURE DETECTION

Hirotaka Nakashima, MSc, RT (*Presenter*)

TEACHING POINTS

1. VNCa imaging has been demonstrated to enhance the detection of subtle fractures in osteoporotic bone.2. This technology facilitates the estimation of bone density and the analysis of marrow fat.3. The vendor-neutral implementation of these systems has been shown to facilitate widespread clinical adoption.4. It has been demonstrated that VNCa may contribute to the prevention of fractures and support healthy aging.

TABLE OF CONTENTS/OUTLINE

This exhibit introduces the concept of Virtual Non-Calcium (VNCa) imaging, a derivative of Dual-Energy CT (DECT), emphasizing its multifaceted role in an aging population. A total of 178 cases were analyzed for the purpose of detecting fractures, 228 patients were examined for correlation with bone mineral density, and 563 patients were analyzed for age-related intramedullary fat composition.Case studies will illustrate the efficacy of VNCa in visualizing subtle fractures, estimating bone fragility through marrow density, and detecting fatty marrow conversion associated with aging. These findings are particularly salient in the context of Japan, a nation that has become a paradigm of a super-aged society. VNCa has the potential to serve as a valuable instrument in the early detection of fragility signs and the prevention of fractures in elderly populations. The educational value of the images is maximized through the use of annotated images, correlation charts, and visual comparisons with conventional CT.

MKEE-132 IMAGING-BASED CLASSIFICATION AND CHARACTERIZATION OF SPINAL DYSRAPHISM: INSIGHTS FROM A TERTIARY CARE EXPERIENCE

Gurubharath Ilangovan, MD (*Presenter*)
Anand N. Parimalai, MD (*Abstract Co-Author*)
Amarnath Chellathurai, MD, FRCR (*Abstract Co-Author*)
Murali K. Logudoss, MBBS, MD (*Abstract Co-Author*)
Rahul Thangavel (*Abstract Co-Author*)

TEACHING POINTS

1. Spinal dysraphism requires detailed imaging for accurate diagnosis. 2. MRI is best for soft tissue and neural evaluation; CT excels in bony detail. 3. Open types present early with severe deficits; closed types present later with variable signs. 4. Multimodal imaging and clinical correlation are essential for diagnosis, planning, and prognosis.

TABLE OF CONTENTS/OUTLINE

Spinal dysraphism comprises congenital neural tube defects arising between the 2nd-6th gestational weeks, often linked with vertebral segmentation anomalies. MRI is optimal for evaluating neural and soft tissue structures, while CT is valuable for assessing vertebral anatomy. This study assessed imaging's role in detecting and characterizing spinal dysraphism in 24 clinically suspected patients over one year using MRI (1.5T Siemens Magnetom Essenza) and CT (128-slice Siemens Somatom Scope). Closed dysraphism was more prevalent (67%) and more common in females (58%). Open types, mainly myelomeningocele, were often diagnosed prenatally and had severe neurological deficits. Closed types, like diastematomyelia, often presented later with signs such as hypertrichosis and variable symptoms. MRI was superior for neural tissue assessment; CT excelled in identifying vertebral anomalies. A multimodal approach improved diagnostic accuracy, classification, and clinical management.

MKEE-133 STRATEGIES TO EXTEND QUANTITATIVE INFORMATION FROM LOW-DOSE CHEST CT EXAMINATION

Xinyu Li (*Presenter*)

TEACHING POINTS

1. To point out relevant additional quantitative Information from low-dose chest CT that may interest people. 2. To propose a no-dose-increase way to obtain these Information from low-dose chest CT by using quantitative CT (QCT) software 3. To demonstrate the advantages of extending quantitative information from low-dose chest CT

TABLE OF CONTENTS/OUTLINE

1. Additional quantitative Information in low-dose CT • Bone mineral density (BMD) • The fat content of Liver and muscle • The area of total soft tissue, visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) 2. Strategies to obtain these quantitative Information using QCT without dose increase • Perform standard low-dose chest CT commonly covers the first and second lumbar vertebra and a part of upper liver • Calculate BMD of the first and second lumbar vertebra using QCT software • The fat content of liver, area of total soft tissue, VAT and SAT could be measured with QCT software, and the image slice containing main portal vein is recommended • The fat content of muscle could be measured depended on clinical needs 3. The advantages of extending quantitative information using low-dose CT • Extend application value of low-dose chest CT screening, provide comprehensive assessment for patient health in one-stop CT • Additional parameters are quantitative instead of qualitative • No additional scan required

MKEE-134 PERI-PROSTHETIC OSTEOMYELITIS: IMPROVING RECOGNITION OF A CHALLENGING ENTITY ON MRI

Alan Campbell, MBBCHIR (*Presenter*)
Danielle Forster (*Abstract Co-Author*)
Rikin Hargunani, FRCR, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Periprosthetic osteomyelitis (PPO) poses a diagnostic challenge on imaging as traditional approaches of diagnosis are limited in the presence of a prosthetic joint. 2. When present, cloacae and collections are very useful in diagnosis. 3. Metal artefact reduction is vital: In biopsy proven PPO, the surrounding marrow tends to return decreased signal intensity on T1w imaging and increased signal intensity on fluid-sensitive (particularly STIR) imaging and thus optimisation is key to detect subtle changes. 4. Periostitis or surrounding soft tissue oedema are not sufficiently specific in isolation for osteomyelitis in the presence of a prosthetic joint. 5. When present in combination, bone marrow oedema, periostitis and soft tissue oedema, together with raised inflammatory markers, are useful in positively predicting PPO and guiding decisions to proceed to more extensive bone sampling.

TABLE OF CONTENTS/OUTLINE

This educational exhibit will: -Describe PPO - background, epidemiology and clinical presentation -Demonstrate typical, uncommon and challenging appearances primarily on MRI: --Signal characteristics --Biopsy proven cases, supported by examples --Morphologically useful features including cloacae, collections and periostitis --Limitations, including artefact, which can be challenging --Pearls and pitfalls to avoid in improving accurate detection of cases -Discuss correlating data and their utility: --Microbial culture results from aspiration, needle biopsy, open sampling --Inflammatory markers and use in challenging cases The reader will refresh their understanding of MRI features of PPO and build confidence in combining data in deciding when to proceed to sampling and/or surgery.

MKEE-136 OSSEOINTEGRATION: A MULTIMODALITY IMAGING UPDATE FOR THE RADIOLOGIST

Muhayman Sadiq, MBBS (*Presenter*)
Saagar Patel, MD (*Abstract Co-Author*)
Manickam Kumaravel, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to: 1. Describe what Osseointegration is and its unique benefits. 2. Outline the movement biomechanics with socket-based prosthetic and Osseointegrated limbs. 3. Discuss different Osseointegration techniques and their benefits. 4. Explain the role of radiographs, CT, MRI, ultrasound, and nuclear medicine scans in evaluating Osseointegrated limbs. 5. Overview of the considerations/measurements used in preoperative planning and postoperative monitoring. 6. Review the normal intraoperative and postoperative findings. 7. Identify the imaging findings of postoperative failure and different postoperative complications. 8. Discuss potential pitfalls when evaluating Osseointegration and how to avoid them.

TABLE OF CONTENTS/OUTLINE

1. Introduction. a. Outline Osseointegration and its benefits. b. Biomechanics of socket-based prosthetics and Osseointegrated limbs. c. Indications and contraindications to Osseointegration and their imaging appearance. 2. Osseointegration. a. Types of Osseointegration and their pros/cons. b. Stages of the procedure, including preoperative planning and measurement. c. Surgical technique with intraoperative illustration and imaging. d. Steps to optimize imaging. 3. Postoperative imaging. a. Normal appearance on radiographs, CT, and MRI. b. Postoperative complications and their imaging appearance. c. Early signs of hardware failure. d. Potential pitfalls and techniques to avoid them. 4. Conclusions. a. Suggest a report template with key information to include. b. Key takeaways. 5. References.

MKEE-137 RADIOLOGIC ASSESSMENT OF KNEE ARTHROPLASTY: A STRUCTURED REPORTING APPROACH FROM PREOPERATIVE PLANNING TO POSTOPERATIVE SURVEILLANCE

Javier Azpeitia Arman, MD (*Presenter*)
Rosa M. Lorente-Ramos, MD, PhD (*Abstract Co-Author*)
Paz Azpeitia Hernandez (*Abstract Co-Author*)
Javier Azpeitia-Hernandez, MD (*Abstract Co-Author*)
Teresa Lago Munoz, MD (*Abstract Co-Author*)
Antonio-David Murillo Vizuete (*Abstract Co-Author*)
Maria Juan Porter, MD (*Abstract Co-Author*)

TEACHING POINTS

-To review the different types of knee prostheses. -To analyse normal and abnormal postoperative imaging findings and signs of complications -To review the role of imaging techniques (plain radiograph, CT, MR, US, scintigraphy) in pre- and postoperative evaluation of the knee. -To illustrate image analysis and interpretation of knee replacement studies, emphasizing useful parameters that should be described in radiological reports.

TABLE OF CONTENTS/OUTLINE

We review the image of knee replacement, highlighting variables that should be included in radiological reports, and correlating images with clinical considerations and functional outcomes. We present: 1. A review of types of replacement. 2. Surgery. Aims. 3. Imaging. Plain radiographs, CT, US, and scintigraphy. 4. Image analysis and interpretation. - Parameters that should be evaluated: alignment of femoral and tibial components, position (flexion/extension), rotation, patellar assessment, joint line height. -Imaging complications: Aseptic loosening, infections, instability, disassembly, dislocation, subluxation, periprosthetic fractures, mechanical failure of prosthetic components, and ectopic bone formation 5. Proposed report for knee replacements in the pre- and postoperative settings.

MKEE-138 OSTEOID OSTEOMA: THE NIGHT OWL OF BONE TUMOURS

Hasaam Uldin, BSC,MBChB (*Presenter*)
Ali Shah, FRCR, MBBS (*Abstract Co-Author*)
Shashank Chapala, MD,MBBS (*Abstract Co-Author*)
Devpriyo Pal, MD,FRCR,MBBS (*Abstract Co-Author*)
Sameer B. Raniga, MD, FRCR (*Abstract Co-Author*)
Rajesh Botchu, MBBS (*Abstract Co-Author*)

TEACHING POINTS

• To describe essential imaging features of untreated osteoid osteomas (OO) • To raise awareness of the atypical features of OO • To enable differentiation between OO and imaging mimics • To discuss treatment approaches and follow-up of OO

TABLE OF CONTENTS/OUTLINE

CONTENTS : • Meet the Menace: Introduction to OO • Know Your Tools: Multimodality Imaging of OO • When It's Not Textbook: Atypical Presentations • Masquerades and Mimics: What Else Could It Be? • Pictorial Parade: Typical and Atypical Cases • Treated but Hurting? Post-Treatment Imaging • Pearls and Pitfalls: Read Between the Lesions • Final Diagnosis: Take-Home Messages OUTLINE : Osteoid osteoma is common, representing approximately 10% of benign bone neoplasms and encountered by virtually all radiologists over a career. Radiographs and CT classically show dense, fusiform, sclerotic bone around a lone central nidus. MRI typically shows accompanying marked edema. However, atypical features can muddle the diagnosis. Multicentric (two nidi in a single lesion), multifocal (two or more nidi in the same bone), synchronous (multiple lesions in different bones at one time), and metachronous (lesions separated in time) OO can occur. Rare etiologies such as iatrogenesis also cause diagnostic uncertainty. Diagnostic mimics include other tumors, infection, and trauma. Similarly, an OO alongside pre-existing pathology needs a sound understanding of both conditions for confident diagnosis. We discuss clinical and imaging features of typical and atypical lesions through unique cases. Methods to differentiate atypical OO from salient mimics are covered. Difficulties in managing these lesions and strategies for optimal treatment and followup are also reviewed.

MKEE-139 GOING VIRAL: THE MUSCULOSKELETAL MANIFESTATIONS YOU SHOULD'T MISS

Aline Serfaty Sr, MD, PhD (*Presenter*)
Dyan V. Flores, MD (*Abstract Co-Author*)
Tatiane C. Rodrigues, MD (*Abstract Co-Author*)

TEACHING POINTS

Viral infections can leave behind distinctive, yet often overlooked, musculoskeletal (MSK) manifestations. These include inflammatory arthropathies, myositis, neuritis, and bone marrow involvement, which may mimic autoimmune, neoplastic, or bacterial diseases. Imaging—particularly MRI—plays a critical role in detecting these viral footprints, aiding in early diagnosis, appropriate management, and the avoidance of unnecessary interventions.

TABLE OF CONTENTS/OUTLINE

• Overview and Clinical Spectrum Define the scope of MSK involvement in viral infections. Highlight the potential for underdiagnosis due to overlap with autoimmune and septic conditions. Include epidemiologic insights on common viral agents such as Parvovirus B19, Chikungunya, Dengue, HIV, Herpes Zoster, and SARS-CoV-2. • Mechanisms of Injury Describe the main pathways of MSK involvement, including direct viral invasion, immune-mediated injury, and post-viral inflammatory responses. Imaging Modalities Discuss the roles of radimaging in evaluating viral MSK disease, with emphasis on MRI. • Case-Based Imaging Patterns Case-based imaging patterns of viral musculoskeletal involvement. • Red Flags and Mimics Discuss diagnostic pitfalls and key features that help differentiate viral etiologies from autoimmune and bacterial conditions. Include imaging clues favoring viral origin. • Conclusion and Clinical Impact Reinforce the value of imaging in the diagnostic workup of suspected viral MSK disease, particularly in the setting of an outbreak or in high-risk individuals. Highlight the importance of pattern recognition and clinical correlation for timely and accurate diagnosis.

MKEE-140 LIPOSARCOMA UPDATE—RADIOLOGIC-PATHOLOGIC CORRELATION BASED ON THE WHO 2020 CLASSIFICATION (5TH EDITION) SUBTYPES, PRACTICAL DIAGNOSTIC APPROACH, AND DIFFERENTIAL CONSIDERATIONS—

Koichiro Mori, MD (*Presenter*)
Ryo Kurokawa, MD, PhD (*Abstract Co-Author*)
Mariko Kurokawa, PhD, MD (*Abstract Co-Author*)
Shu Suzuki, MD (*Abstract Co-Author*)
Yasunobu Takaki (*Abstract Co-Author*)

TEACHING POINTS

Comprehend the diverse clinical and imaging features of liposarcoma subtypes according to WHO 2020 Classification (5th edition) Recognize both typical and atypical imaging features of liposarcomas, and understand the characteristic findings that help differentiate them from benign lipomatous tumors that may mimic liposarcoma Recognize the role of molecular markers such as MDM2 and CDK4 in radiological interpretation and diagnosis Provide site-specific differential diagnostic approaches for various anatomical locations Present a diagnostic flowchart for MRI evaluation of fat-containing soft tissue masses useful for everyday clinical practice

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology and clinical significance of liposarcoma Overview of WHO 2020 Classification (5th edition) updates Radiological-Pathological Correlation by Subtype Atypical lipomatous tumor/Well-differentiated liposarcoma Dedifferentiated liposarcoma Myxoid liposarcoma Pleomorphic liposarcoma Myxoid pleomorphic liposarcoma (new entity) Role of Molecular Markers in Radiological Diagnosis Integration of molecular information into imaging interpretation Site-Specific Features and Differential Diagnosis Extremity liposarcomas Retroperitoneal liposarcomas Other anatomical locations Post-Treatment Imaging Local recurrence patterns Dedifferentiation: imaging characteristics Metastatic disease assessment Practical Approach: MRI Diagnostic Flowchart Systematic evaluation of fat-containing soft tissue masses Decision points and diagnostic criteria Imaging pearls and pitfalls Conclusion

MKEE-141 TOTAL TALUS REPLACEMENTS: AN EDUCATIONAL OVERVIEW

Muhayman Sadiq, MBBS (*Presenter*)
Tiffany A. Kumala (*Abstract Co-Author*)
Saagar Patel, MD (*Abstract Co-Author*)
Manickam Kumaravel, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to: 1. Outline what a total talus replacement is and it's indications. 2. Understand the anatomy and biomechanics of the talus and associated ligaments. 3. Overview the role of radiographs, CT, MRI, and ultrasound in evaluating total talus replacements. 4. Identify key imaging findings in pathologies necessitating total talus replacement. 5. Learn about various types of replacements and prosthetics used in clinical practice. 6. Understand the pre-operative planning and measurements for total talus replacement (including AI-generated automated measurements). 7. Discuss intraoperative and postoperative imaging findings in non-complicated cases. 8. Recognize common postoperative complications and their imaging findings.

TABLE OF CONTENTS/OUTLINE

1. Introduction. a. Talus and hindfoot anatomy and biomechanics. b. Indications for total talar replacement (pathologies of the talus) and their imaging appearance. 2. Total Talus Replacement procedure. a. Types of prostheses. b. Preoperative planning and measurements. c. Surgical techniques with intraoperative illustrations and imaging. d. Associated benefits and risks. 3. Post-operative imaging. a. Radiographs: views, technique, standard image acquisition, and parameters that should be evaluated. b. CT: technique, parameters which should be evaluated. c. Imaging appearance of normal post-operative findings and associated complications (with illustrations). 4. Conclusions. a. Suggest a report template highlighting key information for an orthopedic surgeon. b. Key takeaways 5. References.

MKEE-142 ULTRASOUND-GUIDED SPINAL AND SACROILIAC MUSCULOSKELETAL PROCEDURES: KEY CONCEPTS AND PRACTICAL GUIDE FOR RADIOLOGISTS

Matilde Goncalves, MD (*Presenter*)
Roberts Naglis (*Abstract Co-Author*)
Sebastiano Inturri (*Abstract Co-Author*)
Domenico Romeo (*Abstract Co-Author*)

Miguel O. Castro, MD (*Abstract Co-Author*)
Maria Pilar Aparisi Gomez, FRANZCR,MBChB (*Abstract Co-Author*)
Alberto Bazzocchi, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the sonographic anatomy of the spine and sacroiliac (SI) joints. To review the technical aspects and applications of various spine and SI joint ultrasound-guided procedures.

TABLE OF CONTENTS/OUTLINE

Neck and lowback pain represent illnesses with a substantial burden. Facet joints and SI joint pathology contribute significantly to back pain. Spinal and SI injections are effective for both diagnostic and therapeutic purposes, aiding in surgical planning and as a supplement to conservative management. Ultrasound-guided interventions are increasingly utilized due to their lack of ionizing radiation, portability, reliability, and cost-effectiveness compared to fluoroscopy and computed tomography. The success rates for ultrasound-guided spinal and SI joint injections have been reported to be comparable to fluoroscopic guidance, with significant reduction in pain. However, degenerative spine changes and anatomical conditions can pose challenges to spine ultrasound-guided procedures. This educational exhibit will review the indications and illustrate step-by-step the technique for cervical and lumbar facet injections, spinal nerve blocks and SI joint injections.

MKEE-143 PERSONALIZED VERTEBRAL FRACTURE RISK PREDICTION: A TEACHING EXHIBIT ON THE APPLICATION OF GENDER- AND AGE-SPECIFIC BMD ANALYSIS USING QUANTITATIVE CT

Wei Duan (*Presenter*)

TEACHING POINTS

1.To explain the interaction effects between gender, age, and bone mineral density (BMD) on vertebral fragility fracture risk. 2.To illustrate the development and clinical utility of an individualized fracture risk prediction model using quantitative CT (QCT) measurements. 3.To demonstrate how ROC analysis, calibration, and nomogram visualization can enhance personalized risk stratification and early preventive intervention.

TABLE OF CONTENTS/OUTLINE

1) Introduction to Vertebral Fragility Fractures (a) Epidemiology and clinical significance (b) Importance of early individualized risk prediction 2) Methodology Overview (a) Role of Quantitative CT (QCT) in assessing volumetric BMD. (b) Constructing predictive models using logistic regression with interaction terms (BMD × Gender, BMD × Age Group). (c) Development of a scoring system and nomogram for clinical application. 3) Model Performance and Visualization Techniques (a) ROC curve analysis demonstrating excellent discrimination (AUC = 0.921). (b) Calibration curve analysis indicating good predictive consistency. (c) Decision curve analysis (DCA) evaluating clinical net benefit. 4) Risk Stratification and Clinical Translation (a) Stratifying patients into low, intermediate, and high fracture risk groups based on prediction scores (b) Application of a nomogram for individualized clinical decision-making. 5) Clinical Implications and Future Directions (a) Improving early identification of high-risk populations for vertebral fractures. (b) Integrating BMD, gender, and age factors into personalized osteoporosis management strategies. (c) Potential for multi-center validation and AI integration to enhance predictive performance.

MKEE-144 ULTRASONOGRAPHIC FINDINGS IN MYCOBACTERIAL INFECTIONS AFTER AESTHETIC PROCEDURES: IMPORTANCE OF EARLY RECOGNITION

Cibelle Melo, MD (*Presenter*)
Luara Boson, MD (*Abstract Co-Author*)
Estevao Vargas (*Abstract Co-Author*)
Evelyn Rubin (*Abstract Co-Author*)

TEACHING POINTS

The rising incidence of non-tuberculous mycobacterial, particularly rapidly growing mycobacteria, infections following aesthetic and other invasive procedures represents a growing public health concern. In Brazil alone, nearly 3,000 cases were reported between 1998 and 2022, with a notable predominance in women undergoing cosmetic interventions. Due to their indolent clinical course, these infections are frequently underdiagnosed or misdiagnosed, often after unsuccessful empirical antibiotic treatments. This diagnostic delay can compromise therapeutic efficacy, extend treatment duration, and result in poor aesthetic outcomes. This educational exhibit, based on illustrative clinical cases, emphasizes the role of high-frequency ultrasound in the early recognition of cutaneous mycobacterial infections. It highlights the typical clinical and sonographic features of these infections and the critical role of ultrasound-guided sampling for microbiological confirmation.

TABLE OF CONTENTS/OUTLINE

1. Overview of cutaneous mycobacterial infections following aesthetic procedures. 2. Clinical manifestations and diagnostic challenges. 3. Ultrasonographic findings: a. Small abscesses with dense internal content b. Hypoechoic, irregular, and heterogeneous soft-tissue areas c. Increased perilesional vascularity on Doppler d. Fistulous tracts 4. Role of ultrasound in guiding sample collection for microbiological culture. 5. Conclusion and take-home messages.

MKEE-145 DEEP LEARNING-BASED EARLY DETECTION OF LUMBAR SPONDYLOLYSIS IN X-RAY IMAGES WITH SELF-SUPERVISED PRETRAINING

Sho Maruyama, PhD (*Presenter*)
Haruyuki Watanabe, PhD (*Abstract Co-Author*)

TEACHING POINTS

This presentation explores the applicability of deep learning-based diagnostic support systems in the orthopedic field for young athletes and underscores the importance of future research based on the following educational points. Lumbar spondylolysis is a common cause of low back pain in young athletes, and early diagnosis is essential to prevent long-term disability. X-ray imaging is recommended for initial assessment, but it has limited sensitivity for early-stage cases. A detection system for lumbar spondylolysis focusing on X-ray images demonstrates promising classification performance for early detection. Deep learning models with self-supervised pretraining improve model generalizability in limited-data scenarios. Visualization of classification rationale using Grad-CAM not only helps interpret model behavior but also suggests the potential utility of attention to non-defect regions for risk assessment.

TABLE OF CONTENTS/OUTLINE

1 Introduction - Overview of lumbar spondylolysis - Limitations of current imaging diagnosis - Motivation for computer-aided diagnosis for X-ray image. 2 Materials and Methods - Self-supervised pretraining strategy - Overview of deep learning model architecture - Application of ResNet as a comparison benchmark - Dataset description - Evaluation metrics. 3 Results - Assessment of model performances across imaging direction (AP vs. lateral) - Grad-CAM analysis. 4 Discussion - Impact of X-ray imaging direction - Effectiveness of self-supervised pretraining - Applicability to risk assessment beyond lesion localization - Potential and limitations for screening young athletes - Future directions. 5 Summary of key findings

MKEE-146 NOOKS & CRANNIES: A SONOGRAPHIC GUIDE TO JOINT RECESSES AND THEIR SYNOVIAL COMMUNICATIONS

Lisa Billone, BSc (*Presenter*)
Andrew J. Grainger, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Ultrasound is a first-line tool for detecting joint effusions and intra-articular pathology, but lesser-known recesses and synovial communications may be overlooked, leading to missed or misinterpreted findings. 2. The sonoanatomy of normal joint recesses and their physiologic communications with bursae and tendon sheaths will be demonstrated, supported by MRI correlation. 3. Case-based examples, featuring images and cine clips, will demonstrate how joint recess anatomy and synovial

connections impact the detection of pathology on ultrasound. 4. Optimal patient positioning and dynamic scanning techniques will be reviewed to improve sensitivity and avoid common diagnostic pitfalls. 5. Clinically relevant recesses for US-guided injection and aspiration will be highlighted.

TABLE OF CONTENTS/OUTLINE

A. Introduction B. Anatomy, sonographic technique and case examples of the: a) Shoulder girdle: glenohumeral joint recesses; biceps tendon sheath; subacromial-subdeltoid bursa; acromioclavicular & sternoclavicular joint recesses b) Elbow: coronoid, olecranon & annular recesses; bicipitoradial bursa c) Wrist: distal radioulnar, radiocarpal & midcarpal joint recesses d) Hand: carpometacarpal & interphalangeal joint recesses e) Hip: femoroacetabular joint recesses; iliopsoas & obturator externus bursae f) Knee: anterior, parameniscal & posterior joint recesses; semimembranosus-medial gastrocnemius bursa; popliteus tendon sheath; proximal tibiofibular joint recess g) Ankle: tibiotalar & subtalar joint recesses; flexor hallucis longus tendon sheath h) Foot: midtarsal, tarsometatarsal, metatarsophalangeal & interphalangeal joint recesses C. Take Home Points

MKEE-147 HOLY COW! THAT CALF HURTS - LET'S SCAN IT

Madeline Stever, MD (*Presenter*)
Daniel Kowal, MD (*Abstract Co-Author*)

TEACHING POINTS

• Ultrasound plays a pivotal role in the evaluation of calf pain from musculoskeletal etiologies. • Standardized ultrasound scanning protocols are essential for ensuring a comprehensive and systematic musculoskeletal evaluation. Standardization enhances diagnostic accuracy, facilitates reproducibility, and minimizes the risk of overlooking subtle but clinically significant findings. • Ultrasound allows for dynamic evaluation of muscles, tendons, and peritendinous structures. This dynamic imaging is unique to ultrasound and may be used to aid in the diagnostic evaluation for calf pain. • The portability, cost-effectiveness, and accessibility of ultrasound makes it especially valuable in sports medicine, emergency, and outpatient clinical settings.

TABLE OF CONTENTS/OUTLINE

• Introduction • Learning objectives • Scanning techniques and relevant ultrasound anatomy evaluating calf pain • Imaging cases & causes of pain - Mechanism of injury, imaging findings, differential diagnoses/imaging pitfalls o Muscle & tendons: gastrocnemius tear, Achilles tendon injury (acute vs. chronic tendinosis, partial vs. full thickness tear), Achilles paratenonitis, plantaris tendon injury (normal vs. abnormal) o Soft tissues: shin muscle hernia, bursitis o Masses: lipomas, hematomas, shin sarcomas, lower calf/ankle nerve sheath tumors o Vascular: soleal vein thrombosis • Summary • References

MKEE-148 SOUND APPROACH TO ACHING TENDONS: A GUIDE TO US-GUIDED TREATMENTS OF TENDON DISEASE

Sultan M. Alamro, MBBS (*Presenter*)
Dyan V. Flores, MD (*Abstract Co-Author*)

TEACHING POINTS

Tendinopathy is a broad term used to describe a wide spectrum of pathologies in and around tendons. Tenosynovitis refers to inflammation of the synovial membrane surrounding a tendon. It may be seen with or without tendinosis/tendinitis. Tendinosis refers to disorganized collagen architecture due to a primarily degenerative, noninflammatory process, and can occur after aging or overuse. Conversely, tendinitis is inflammation of the tendon after acute overload from excessive or sudden tensile force. Several US-guided percutaneous tendon treatments are now available and continue to develop rapidly. The objectives for treating each tendon disease may vary. For example, the goal for tendinosis is to stimulate collagen repair, in contrast to the goal for tendinitis, which is to reduce inflammation. Some treatments to reduce inflammation in tendinitis and tenosynovitis, such as corticosteroid therapy, are counterintuitive in tendinosis. In this educational exhibit, we will emphasize US techniques, controversies and current evidence in the three most common treatments: peritendinous injection, calcific tendinopathy barbotage and tenotomy.

TABLE OF CONTENTS/OUTLINE

1. Peritendinous injection • Technique • Common tendons: De Quervain's, long head of the biceps • Burning questions: - Indications - Interval and number of session 2. Barbotage • Technique • Common tendons: rotator cuff, gluteus • Burning questions: - Does the size of the calcification change treatment effectivity? 3. Tenotomy/Fenestration • Mechanical - Dry needling only • Chemical - PRP, stem cell, hyaluronate • Common tendons: common extensor, common flexor • Burning questions: - Effectivity of various substances in chemical fenestration

MKEE-149 KEEP YOUR HANDS WHERE WE CAN SCAN THEM: USING ULTRASOUND TO EVALUATE MASSES AND PSEUDOMASSES OF THE WRIST AND HAND

Madeline Stever, MD (*Presenter*)
Daniel Kowal, MD (*Abstract Co-Author*)

TEACHING POINTS

• Ultrasound effectively characterizes common wrist and hand masses allowing for differentiation between solid and cystic lesions, vascular vs. avascular structures, and inflammatory vs. neoplastic processes. • Color Doppler and microvascular flow imaging adds valuable information by evaluating the vascularity of a lesion, which can aid in differentiating between benign and potentially malignant or inflammatory masses. • Dynamic ultrasound assessment provides a unique advantage, allowing evaluation of mass mobility, compressibility, and interaction with surrounding tendons, joints, and neurovascular structures. • The accessibility, cost-effectiveness, and portability of ultrasound make it especially useful in outpatient clinics, hand surgery practices, sports medicine, and emergency settings, where quick and accurate assessment is essential.

TABLE OF CONTENTS/OUTLINE

• Introduction • Learning objectives • Imaging cases & causes of pain - Pathophysiology, imaging findings, differentials/imaging pitfalls o Masses: ganglion cyst, giant cell tumor, fibromatosis, epidermal inclusion cyst, intramuscular myxoma, lipomas o Pseudomasses: tenosynovitis (inflammatory vs. infectious), intersection syndrome, de Quervains tenosynovitis, accessory muscles, vascular malformations • Summary • References

MKEE-150 MUSCULOSKELETAL REPORTING AND DATA SYSTEM (MSK-RADS): EXPANDING APPLICATIONS, SCOPE, AND CLASSIFICATION FRAMEWORKS

Hyeyun Lee, MD (*Presenter*)
Chankue Park, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Review the different musculoskeletal reporting and data system (RADS) • Illustrate the imaging finding of bone tumor, soft tissue tumor, infection and neuropathy with exemplary application of RADS • Identify the different scope and intended use of RADS

TABLE OF CONTENTS/OUTLINE

Reporting and data systems (RADS) standardize radiologic terminology, reduce interpretive variability, and enhance clinical management and interdisciplinary communication. In musculoskeletal imaging, however, each RADS differs in modality, target population, evidence base, and required expertise. It is important for radiologists to know the characteristics to appropriately use RADS according to different scenarios. In this exhibit, we will review 8 different RADS; five RADS for bone tumor assessment(• American College of Radiology Bone-RADS • Radiological Evaluation Score for Bone Tumor • CT and MR Bone-RADS by Society of Skeletal Radiology • Osseous Tumor-RADS • Solitary bone tumor imaging-RADS Bone tumor), Soft tissue tumor(ST)-RADS, musculoskeletal infection(MSKI)-RADS, and neuropathy score(NS)-RADS with examplery cases and applications.1.1. RADS related to bone tumor assessment: • Lipoma • Enchondroma • Giant cell tumor • Osteosarcoma • Metastasis, 1.2 ST-RADS: •Fibroma •Peripheral nerve sheath tumor •Myxoma •Sarcoma, 1.3MSKI-RADS •Abscess •Necrotizing fasciitis •Possible osteomyelitis

•Osteomyelitis •Septic arthritis, 1.4 NS-RADS •Injury •Neoplasm •Entrapment •Diffuse neuropathy •Post-intervention 2. Characteristics •Structure •Modality • Intended use •Target population •Use of clinical information •Number of lesions Finally, we will explore the strengths and weaknesses to identify optimal use.

MKEE-151 DIFFERENTIALS FOR STERNOCLAVICULAR JOINT SWELLING

Sakib Kazi, MD (*Presenter*)
Dyan V. Flores, MD (*Abstract Co-Author*)

TEACHING POINTS

The sternoclavicular (SC) joint, the osseous articulation between the axial and appendicular skeleton, is an essential component of the shoulder girdle. It allows limited motion but plays a vital role in shoulder movement including clavicular elevation and depression; protraction and retraction; and rotation. Given the potential for significant morbidity and functional impairment associated with various SC joint disorders, accurate radiologic assessment using a systematic approach is necessary for appropriate diagnosis and management. A vast majority of SC joint disorders present with swelling and are most commonly due to traumatic, typical atraumatic, and atypical atraumatic causes. This exhibit aims to enhance radiologist awareness of the diverse pathologies that affect the SC joint. The objectives of this educational exhibit are: • To review the normal anatomy and variants of the SC joint • To discuss pearls and pitfalls in the various imaging modalities for evaluating the SC joint • To discuss the role of various imaging techniques (radiography, CT, MRI, ultrasound) in the evaluation of SC joint pathology • To outline the differentials for swelling of the SC joint based on three common etiologies: traumatic, atraumatic - typical, and atraumatic - atypical

TABLE OF CONTENTS/OUTLINE

ANATOMY AND VARIANTS 1. Osseous components 2. Ligaments and musculature IMAGING 1. Radiography • Serendipity view • Hobbs view 2. CT 3. MRI 4. Ultrasound DIFFERENTIALS FOR SWELLING 1. Traumatic 2. Atraumatic - Typical • Degenerative • Inflammatory • Infectious 3. Atraumatic - Atypical • SAPHO • Friedrich's • Tietze's syndrome • Condensing osteitis • Neoplasms

MKEE-152 IMAGING INTERPRETATION OF MORPHEA: PEARLS AND PITFALLS

Parham Pezeshk, MD (*Presenter*)
Majid Chalian, MD (*Abstract Co-Author*)
Oganes Ashikyan, MD (*Abstract Co-Author*)
Alireza Eajazi, MD (*Abstract Co-Author*)

TEACHING POINTS

- Determining the activity and extent of soft tissue involvement in localized scleroderma (morphea) can be clinically challenging. - Deep soft tissue involvement in morphea may lead to irreversible sequelae, including functional and cosmetic impairment. Therefore, an accurate assessment of the extent of soft tissue involvement is crucial. - MRI has shown promise in providing detailed information for clinicians; however, optimal interpretation remains a challenge due to a lack of standardized key elements to report.

TABLE OF CONTENTS/OUTLINE

- Briefly review the pathophysiology of morphea. - Discuss the clinical grading system used by dermatologists, the Localized Scleroderma Assessment Tool (LoSCAT), for evaluating morphea. - Review an optimized MRI protocol for imaging morphea. - Establish a structured MRI reporting approach incorporating key elements from LoSCAT, including skin thickness, involvement of the fascia, subcutaneous fat, muscle, and joints, as well as perfusion and enhancement. - Present case studies with key MRI findings and interpretations.

MKEE-153 WRIST MRI UNLOCKED: A SYSTEMATIC APPROACH TO ULNAR, RADIAL, AND DORSAL PAIN SYNDROMES

Akhileshwar R. Ginnaram, MBBS (*Presenter*)
Suryansh Bajaj, MD (*Abstract Co-Author*)

TEACHING POINTS

MRI is the gold standard for evaluating complex wrist pain due to its ability to visualize soft tissues, ligaments, cartilage, and bone marrow. A clinically relevant, region-based classification of wrist pain—ulnar, radial, dorsal (interosseous ligament), and miscellaneous—enhances diagnostic precision and management. Ulnar-sided wrist pain is the most frequent and diagnostically challenging subtype, with high-resolution MRI essential for evaluating TFCC injuries, ECU tendon disorders, ulnocarpal impaction, and other mimics. Understanding the imaging-pathologic correlation of wrist biomechanics and injury patterns is key to recognizing subtle but clinically significant lesions.

TABLE OF CONTENTS/OUTLINE

Introduction Clinical importance of MRI in wrist pain evaluation Biomechanical context for pathology Wrist Pain Classification Framework Anatomical approach: Ulnar, Radial, Dorsal, Miscellaneous Ulnar-Sided Wrist Pain TFCC Anatomy and Palmer Classification MRI patterns of traumatic vs. degenerative lesions Ulnotriquetral ligament pathology Ulnar impaction syndromes (ulnolunate, styloid, hamato-lunate) ECU tendon disorders Ulnar-sided fractures (hook of hamate, triquetral) Pisotriquetral osteoarthritis Radial-Sided Wrist Pain Scaphoid and trapezial fractures Triscaphe arthritis De Quervain's and distal intersection syndrome EPL and FCR tendon tears Dorsal Wrist Pain Interosseous ligament injuries (scapholunate, lunotriquetral) MRI features of instability and SLAC progression Miscellaneous Conditions Radioulnar abutment syndrome Madelung deformity Conclusion Emphasis on structured MRI interpretation aligned with clinical findings

MKEE-154 IMAGING EVALUATION OF MENISCAL TRANSPLANTATION FROM INDICATION TO INTEGRATION

Shrey Derasari (*Presenter*)
Muhayman Sadiq, MBBS (*Abstract Co-Author*)
Saagar Patel, MD (*Abstract Co-Author*)
Manickam Kumaravel, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to: 1. Evaluate the role of the menisci through anatomical position, vascular supply, and biomechanical load distribution. 2. Discuss indications for transplantation, including symptomatic meniscal deficiency, post-meniscectomy syndrome, and concomitant ligamentous/chondral pathology. 3. Review clinical and imaging preoperative evaluation criteria and necessary measurements to assess cartilage, axis alignment, and meniscal extrusion. 4. Overview of various surgical fixation methods and postoperative MRI appearances. 5. Discuss patient-reported functional outcome measures and longitudinal MRI monitoring. 6. Identify imaging findings of early & late-stage postoperative complications of transplantation.

TABLE OF CONTENTS/OUTLINE

1. Introduction. a. Overview of meniscal anatomy and vascular supply. b. Biomechanics of menisci and related load distribution schematics. 2. Meniscal Transplantation. a. Indications of meniscal transplantation. b. Initial injury, post-meniscectomy, and concurrent knee pathology imaging. c. Preoperative assessment and key imaging measurements for surgical planning. d. Surgical techniques illustrations and postoperative imaging 3. Postoperative Evaluation. a. Normal MRI postoperative appearance. b. Functional outcome monitoring with imaging and clinical tools. c. Postoperative complications imaging, including graft extrusion and failure, with subsequent cartilage and joint degeneration. 4. Conclusions a. Key takeaways b. Key imaging pitfalls and how to avoid them. 5. References.

MKEE-155 WHEN FAT SPEAKS: INTERPRETING FAT WITHIN BONE LESIONS

Ali Shah, FRCR, MBBS (*Presenter*)
Sonal Saran, MBBS (*Abstract Co-Author*)

Sai Niharika Gavvala, MD, MBBS (*Abstract Co-Author*)
Devpriyo Pal, MD,FRCR,MBBS (*Abstract Co-Author*)
Sameer B. Raniga, MD, FRCR (*Abstract Co-Author*)
Rajesh Botchu, MBBS (*Abstract Co-Author*)

TEACHING POINTS

To learn how to recognize classic and atypical fat-containing bone lesions. To learn how to differentiate benign from malignant marrow lesions using macroscopic and microscopic fat. To learn the principles and diagnostic value of Chemical Shift Imaging (CSI) in bone lesion evaluation. To learn practical imaging tips for lesion characterization in oncologic and non-oncologic patients. To learn when fat is a reassuring finding and when it warrants further work-up.

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS Fat Fables : Classic lesions with macroscopic fat - lipomas, haemangiomas, infarcts Imaging Tools : Detecting fat on radiographs, CT, MRI Shift Focus - CSI : Physics, technique and interpretation utilising 20% signal drop out rule Curveballs Ahead : Atypical cases and how to avoid VOMIT 1 Rare Cases : Unusual fat-rich tumours and fat-mimicking lesions, and collision lesions Clinical Pearls : Tips to distinguish benign from malignant; guidance for radiologists reporting in high-risk populations OUTLINE Bone lesions can pose diagnostic challenges and uncertainty, especially in patients at risk for metastases or marrow-based malignancies. Recognising fat within bone lesions can help differentiate benign from malignant marrow lesions using macroscopic and microscopic fat. We demonstrate typical and atypical fat-containing bone lesions, describing imaging pearls using radiographs, CT, MRI, and chemical shift imaging (CSI), emphasizing when fat indicates benignity and when further work-up is warranted. Imaging pitfalls with aggressive haemangiomas and collision lesions are also reviewed. 1. Victim of modern imaging techniques

MKEE-156 ULNAR WRIST PAIN - THE DARK SIDE OF THE WRIST

Andreas Kunz, MD (*Presenter*)
Jan P. Grunz, MD (*Abstract Co-Author*)

TEACHING POINTS

Ulnar wrist pain describes a complex clinical situation with a variety of underlying causes, the differential diagnosis of which requires a detailed understanding of anatomy, biomechanics and pathophysiology. While radiological assessment plays a decisive role in ulnar wrist pain, close cooperation with hand surgeons is key for optimal patient care. Cross-sectional imaging techniques with high spatial resolution can be supplemented by dynamic procedures such as ultrasound and fluoroscopy. Injuries to the ulnocarpal complex (TFCC) represent the most common cause of instability in the distal radioulnar joint. Multicompartmental injection of contrast medium followed by CT or MR arthrography is the imaging reference standard for TFCC lesions.

TABLE OF CONTENTS/OUTLINE

1. Anatomy of the ulnar wrist a) Biomechanical propertiesb. Vascularization 2. Imaging a) MRI with and without intravenous contrast enhancement b) CT and MR arthrography c) Dynamic imaging with fluoroscopy and ultrasound 3. Pathologies a) TFCC injuries b) Distal radioulnar joint instability c) Extensor carpi ulnaris tendon pathologies d) Impaction syndromes e) Radioulnar impingement f) Lunotriquetral instability g) Pisotriquetral pathologies h) TILT syndrome 4. Therapy a) Surgery versus conservative treatment b) Overview of surgical procedures 5. Discussion

MKEE-157 PERCUTANEOUS TREATMENT OF ANEURYSMAL BONE CYSTS: INTRALESIONAL CALCITONINE AND CORTICOID INJECTION

Laura Tello Arnas (*Presenter*)
Mar Tapia Vine (*Abstract Co-Author*)
Jorge Guisandez (*Abstract Co-Author*)
Remedios De Frutos (*Abstract Co-Author*)
Jorge Rey Porras (*Abstract Co-Author*)
Pablo Lama (*Abstract Co-Author*)
Angel Romero Guzman (*Abstract Co-Author*)

TEACHING POINTS

The main objectives are to describe the percutaneous treatment of aneurysmal bone cysts using radiological guidance, focusing on intralesional injection of calcitonin and corticosteroids in selected cases, and to show imaging findings during follow-up.

TABLE OF CONTENTS/OUTLINE

Aneurysmal Bone Cysts (ABC) are non-malignant bone lesions composed of blood-filled channels, primarily affecting children and adolescents. While traditional treatments include surgery and curettage, these can be incomplete and lead to recurrence. Promising alternatives, particularly in high-risk patients or difficult locations, are percutaneous treatments, alone or in combination, with a primary focus on intralesional injection of calcitonin and corticosteroid. This minimally invasive technique is performed under general anesthesia, using CT guidance to locate the cyst. The patient is positioned to facilitate easy access, and a coaxial needle is inserted. The procedure involves breaking the thin internal partitions, aspirating contents, and injecting methylprednisolone and calcitonin. Methylprednisolone has anti-inflammatory effects; calcitonin promotes new bone formation. In our hospital, this procedure has been performed in five patients, two with prior embolization—one received three injections, the others two. Iodinated contrast may be used to ensure no vascular communication. This method reduces lesion volume and induces ossification with no significant complications. Follow-up CT is recommended at three months; repeat procedures may be needed at six months. Overall, it is a safe, effective alternative to surgery.

MKEE-158 COMPREHENSIVE ASSESSMENT OF BONE METASTASES USING DUAL-ENERGY CT: FROM DETECTION TO TREATMENT RESPONSE

Hirotaka Nakashima, MSc, RT (*Presenter*)

TEACHING POINTS

1. Dual-energy computed tomography (DECT) improves the detection, characterization, and assessment of treatment efficacy of bone metastases.2. Virtual Non-Calcium (VNCa) imaging improves sensitivity for detecting early bone marrow invasion by highlighting fat loss and tumor replacement.3. Iodine maps in bone allow evaluation of tumor perfusion and vascular changes before and after treatment.4. DECT is a non-invasive, rapid and quantitative tool for longitudinal monitoring and may reduce reliance on biopsy and MRI.5. Correlation with MRI or PET/CT may further improve diagnostic accuracy and clinical decision making.

TABLE OF CONTENTS/OUTLINE

This educational exhibit presents a comprehensive approach to the evaluation of bone metastases using DECT. First, the clinical importance of accurate assessment of bone lesions in oncology patients will be outlined and the basic principles of DECT will be presented, including imaging techniques such as material degradation, VNCa, and iodine mapping in bone. It will then explore how DECT improves early detection of metastatic lesions by visualizing subtle bone marrow changes not seen with conventional CT, and how quantification of fat loss and contrast enhancement patterns can help differentiate malignant from benign lesions. In addition, how DECT facilitates objective monitoring of treatment response through changes in iodine uptake and bone densitometry indices is supported by illustrative clinical cases comparing pre- and post-treatment findings. Finally, we highlight the clinical value of integrating DECT into routine practice and its potential role as a noninvasive, reproducible tool for personalized cancer treatment.

MKEE-159 THE MANY FACES OF PES ANSERINE BURSITIS

Nagore Siles, MD (*Presenter*)
James Teh, MD (*Abstract Co-Author*)
Huw Walters, MA,MBBCHIR (*Abstract Co-Author*)

TEACHING POINTS

1. To describe the anatomy of the pes anserine bursa.2. To introduce the concept of the enthesis organ, using the pes anserine as an example of a "functional enthesis organ". 3. To illustrate the imaging manifestations of the pes anserine bursitis, emphasizing concurrent pathologic conditions.

TABLE OF CONTENTS/OUTLINE

1. Anatomy of the pes anserine bursa. 2. The enthesis organ: beyond the focal insertion. 3. Radiological features of various causes of pes anserine bursitis: a) Overuse. b) Chronic enthesopathy. c) Inflammatory arthritis. d) Infection. e) Synovial chondromatosis. f) Tenosynovial giant cell tumour (TSGCT), aka pigmented villonodular synovitis (PVNS). g) Osteochondroma associated.

MKEE-160 UNCOMMON BUT CRITICAL: RADIOLOGIC RECOGNITION AND CLINICAL IMPLICATIONS OF SKELETAL MUSCLE AND SUBCUTANEOUS FAT METASTASES

Hyun Su Kim, MD, PhD (*Presenter*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Peyman Mirghaderi, MD, MPH (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

TEACHING POINTS

• Soft tissue metastases (STM) are rare but meaningful indicators of aggressive disease and possible therapeutic targets. • CT and US show characteristic but nonspecific findings; awareness of patterns is key. • Radiologists should consider STM in new soft tissue lesions in cancer patients. • Biopsy should be recommended when STM is suspected based on imaging and clinical context. • Greater recognition of STM may improve outcomes and support future treatment strategies.

TABLE OF CONTENTS/OUTLINE

1. Purpose: STM to skeletal muscle and subcutaneous fat are rare but clinically important. As cancer survival improves and use of PET-CT, CT, and whole-body MRI expands, STM are increasingly recognized. This exhibit highlights key imaging features, diagnostic challenges, and the radiologists' role. 2. Overview • Often accompanied by other metastases; however, isolated STM do exist. • Lung cancer - most common primary source 3. Imaging Findings • CT: Central low attenuation with rim enhancement or homogeneous enhancement • US: Hypoechoic with well-defined margins and vascularity • PET-CT: Strong FDG uptake • MRI: Ill or well-defined lesions with peritumoral edema, non-enhancing T2 hyperintensity 4. Mimickers: Epidermoid cysts, abscesses, fibromatosis, endometriosis 5. Clinical and Imaging Considerations • CT : more commonly used, may miss subtle lesions. • PET-CT: greater sensitivity but comes with limitations (radiation, access). • Imaging alone is rarely definitive—image-guided biopsy is essential. 6. Impact • Recognition of STM can support early diagnoses and guide locoregional treatments. • Familiarity may lead to accurate diagnosis and contribute to future research and treatment protocols.

MKEE-161 NONINVASIVE ASSESSMENT OF INTRAMUSCULAR PHOSPHATE METABOLISM USING ^{31}P-MR SPECTROSCOPY ON CLINICAL MRI SYSTEMS: PRINCIPLES, PROTOCOLS, AND CLINICAL APPLICATIONS

Koji Takumi, MD, PhD (*Presenter*)
Hiroaki Nagano, MD, PhD (*Abstract Co-Author*)
Ryota Nakanosono, MD (*Abstract Co-Author*)
Tsubasa Nakano (*Abstract Co-Author*)
Fumitaka Ejima (*Abstract Co-Author*)
Masanori Nakajo, MD (*Abstract Co-Author*)
Kiyohisa Kamimura, MD, PhD (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Multi-nuclear MRI is gaining attention as a powerful tool for noninvasive metabolic assessment. Intramuscular phosphate metabolism reflects mitochondrial function and plays a key role in physiological adaptation, aging, and diseases like diabetes and heart failure. 31 P-MRS allows noninvasive, in vivo quantification of high-energy phosphate metabolites (PCr, Pi, ATP) and intracellular pH. Once mainly a research tool, clinical implementation of 31 P-MRS is now feasible. This exhibit introduces the principles and clinical utility of 31 P-MRS for evaluating intramuscular metabolism and mitochondrial function. The purposes of this exhibit are: 1) To explain the principles of 31 P-MRS and phosphate metabolite quantification, 2) To outline clinical MRI protocols for 31 P-MRS, 3) To demonstrate applications through skeletal and cardiac muscle cases, emphasizing post-exercise PCr recovery and pH monitoring

TABLE OF CONTENTS/OUTLINE

1) Overview of intramuscular phosphate metabolism and clinical significance: Energy metabolism, roles of PCr, Pi, ATP, and pH, 2) Principles of 31 P-MRS and clinical implementation: Basics of acquisition and spectral analysis; protocol optimization, 3) Clinical and research applications: PCr recovery as an oxidative biomarker; pH changes in aging, heart failure, and diabetes, 4) Take-home messages: 31 P-MRS as a clinical metabolic biomarker; future integration with multiparametric MRI

MKEE-162 PAINFUL KNEE ARTHROPLASTY: A RADIOLOGIST'S SURVIVAL GUIDE FOR RESIDENTS

Zoe G. Winston, MBBS, FRCR (*Presenter*)
Michelle W. Ooi, MBBS, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the complementary roles of various imaging modalities in the assessment of a painful knee arthroplasty.2. Review the spectrum of common causes of prosthetic knee failure, including aseptic loosening, subsidence, dislocation, periprosthetic fractures, arthrofibrosis, and tendon ruptures.3. Illustrate key complications through multimodality case examples, highlighting characteristic imaging findings.

TABLE OF CONTENTS/OUTLINE

Total knee arthroplasty (TKA) is a common procedure for managing advanced osteoarthritis, with excellent outcomes in most cases. However, persistent or recurrent post-operative pain can present a significant diagnostic challenge due to the wide range of potential complications. This pictorial review highlights key imaging findings in common causes of knee arthroplasty failure, with an emphasis on a multimodality approach. Cases will demonstrate pathologies including prosthesis component dislocation and subsidence, aseptic loosening, septic loosening (periprosthetic joint infection), periprosthetic fracture, arthrofibrosis, extensor mechanism injury and instability. Radiographs, CT, and MRI will be used to illustrate the diagnostic value of each modality. The review is designed to support radiology trainees in recognising important post-operative complications and to aid in clinical decision-making through accurate image interpretation.

MKEE-163 REVOLUTIONIZING DIAGNOSIS: SCREENING OPPORTUNITIES TRANSFORMING PIXELS TO PROGNOSIS

Robert D. Boutin, MD (*Presenter*)
Eddy Zandee van Rilland, MD (*Abstract Co-Author*)
Andrew Johnston, MD, MBA (*Abstract Co-Author*)
Jennifer A. Padwal, MD, MS (*Abstract Co-Author*)
Akshay Chaudhari, PhD (*Abstract Co-Author*)
Leon Lenchik, MD (*Abstract Co-Author*)

TEACHING POINTS

[1] Muscular, skeletal, and fatty tissues are seen on all musculoskeletal imaging exams; each of these tissues contains modifiable biomarkers that can be used to gauge biological health/aging. [2] Sarcopenia, osteoporosis, and adiposity can be treated; disease screening is important because each condition is an independent risk factor for poor clinical outcome. [3] Routine imaging exams provide an opportunity for screening of underdiagnosed and undercoded diseases, including osteosarcopenia, sarcopenic obesity, and other related conditions.

TABLE OF CONTENTS/OUTLINE

[I] DEFINITIONS & PATHOGENIC LINKS: Sarcopenia; Osteoporosis; Adiposity [II] PATIENT IMPACT & UNMET DIAGNOSTIC NEED: Sarcopenia; Osteoporosis; Adiposity [III] IMAGING: TECHNICAL CONSIDERATIONS & CORRECTIONS: Radiography; CT; MRI; Sonography [IV] IMAGING APPROPRIATENESS & CLINICAL IMPLEMENTATION: Reporting; Clinical Practice Guidelines; Coding; Billing [V] AI & Multimodal Foundation Models: What's Ready; What's Coming

MKEE-164 FROM DIAGNOSIS TO FOLLOW-UP: IMAGING AND MANAGEMENT OF LOCALIZED AND DIFFUSE TENOSYNOVIAL GIANT CELL TUMORS

Raul N. Pigatto, MD, MBA (*Presenter*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Pedro Henrique R. Silva, MD (*Abstract Co-Author*)
Ricardo Caracante, MD (*Abstract Co-Author*)
Renato Fujiki, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Illustrate the TGCT multimodality signature : nodular extremity masses (L-TGCT) versus extensive large-joint synovial proliferation (D-TGCT) - with exemplar XR, CT, US and MRI cases. Recognize the MRI fingerprint : low-to-intermediate T1/T2 signal with blooming on GRE/SWI/T2*. Distinguish TGCT from mimickers : using blooming, calcifications, post-contrast behavior and a side-by-side comparison table chart. Apply an evidence-based management & follow-up flow-chart : marginal excision followed by less stringent MRI control for L-TGCT. Partial synovectomy, total synovectomy ± radiotherapy and CSF1R inhibition for D-TGCT, with more stringent MRI follow-up. Equip readers with a structured checklist to ensure all key findings are reported.

TABLE OF CONTENTS/OUTLINE

Epidemiology Classification: L-TGCT vs D-TGCT Imaging workflow & hallmarks Differentials & mimickers Treatment roadmap Follow-up flow-chart & recurrence detection Structured checklist

MKEE-165 MELANOMA IN MOTION - MUSCULOSKELETAL METASTASES UNVEILED

Flavia M. Costa, MD, PhD (*Presenter*)
Carolina A. Almeida, MD (*Abstract Co-Author*)
Clarissa C. Moraes Do Carmo, MD (*Abstract Co-Author*)
Flavia P. Lopes, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

To evaluate the performance of conventional and advanced MRI techniques in the diagnosis and to differentiate them from other soft tissue tumors. Illustrate many cases of MSK metastasis of melanoma demonstrating their dissemination, leading to compression and invasion of adjacent structures. To be aware of the conditions and the mechanisms by which false positive and negative results (hematomas, ossificans myositis and thrombosis). Make a pictorial essay of the main differential diagnosis. An understanding of the applicability and limitations of MRI tecniques is necessary to making accurate diagnosis and potentially the right treatment for our patients.

TABLE OF CONTENTS/OUTLINE

1) The value of each conventional and advanced MRI techniques(DIXON T1, T2*, SWI, DCEperfusion and TIC, DWI) in diagnosis and follow-up.2) Case discussion to demonstrate the ultility in differentiate this tumors from : Sarcomas Lymphoma Hematoma Tenosynovial Giant Cell Tumor Hemosiderotic neurogenic tumor Desmoid Chondral tumors 3) Common pittfalls

MKEE-166 COMPREHENSIVE IMAGING ATLAS OF NEUROMUSCULAR DISEASES: DIAGNOSTIC PATTERNS AND EDUCATIONAL INSIGHTS

Hiroki Miyazaki, MD (*Presenter*)
Hiroki Mukai (*Abstract Co-Author*)
Hajime Yokota, MD (*Abstract Co-Author*)
Jun Hashiba (*Abstract Co-Author*)
Takashi Uno (*Abstract Co-Author*)

TEACHING POINTS

•Advances in genetic testing and identification of disease-specific autoantibodies have reduced the reliance on muscle biopsy, making non-invasive imaging with CT and MRI increasingly essential in the diagnosis and management of neuromuscular diseases. •Some neuromuscular diseases, such as facioscapulohumeral muscular dystrophy (FSHD), cannot be diagnosed by exome sequencing and often show only nonspecific muscle pathology, highlighting the importance of radiologists in recognizing disease-specific imaging patterns. •Muscle imaging supports diagnosis by evaluating key features such as atrophy, fatty replacement, edema, asymmetry, distribution, and extramuscular findings. •This exhibit presents a structured, pattern-based imaging approach to representative neuromuscular diseases, providing radiologists with practical diagnostic tools and a systematic understanding of disease classification for immediate clinical application.

TABLE OF CONTENTS/OUTLINE

•Background and Significance of Imaging in Neuromuscular Diseases •CT and MRI Evaluation of Neuromuscular Diseases •Pattern-Based Imaging Approach •Disease-Specific Imaging Approach A. Acquired Myopathies • Inflammatory myopathies: - PM/DM - IMNM - IBM - Muscular sarcoidosis B. Inherited Myopathies • Muscular dystrophies: - Dystrophinopathies - Myotonic dystrophy - LGMD - FSHD - OPMD/OPDM • Distal myopathy C. Neurogenic Diseases • Motor neuron diseases: - ALS - SMA - SBMA • Peripheral neuropathies: - Charcot-Marie-Tooth disease •Diagnostic Pearls and Pitfalls •Summary and Diagnostic Algorithm • Imaging-based diagnostic flowchart

MKEE-167 MR NEUROGRAPHY PLAYBOOK: ESSENTIAL IMAGING SIGNS FOR THE DIAGNOSIS OF PERIPHERAL NERVE PATHOLOGY

Ali S. Tejani, MD (*Presenter*)
Amelie M. Lutz, MD (*Abstract Co-Author*)
Mahesh Prakash, MD, MBBS (*Abstract Co-Author*)
Avneesh Chhabra, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

1. Review role of MR Neurography (MRN) for diagnosing peripheral nerve pathology 2. Discuss optimal MRN protocol 3. Provide a visual review of typical diagnostic signs for common etiologies of peripheral nerve pathology

TABLE OF CONTENTS/OUTLINE

1. Introduction a. Clinical paradigms for peripheral nerve evaluation b. Role for MR neurography (MRN) c. Optimal MRN protocol for peripheral nerve evaluationd. Neuropathy Score Reporting Data System (NS-RADS) for consistent and reproducible reporting of findings 2. Imaging signs a. Nerve tumors/tumor-like lesions i. Spaghetti - lipomatosis of nerve ii. Target- peripheral nerve sheath tumors iii. Honeycomb - perineuroma, idiopathic hypertrophic mononeuropathy, CIDP and hereditary motor and sensory neuropathy iv. Garland - intraneural ganglion cyst v. Bag of worms - plexiform neurofibroma/schwannoma vi. Dripping hose - neurolymphoma, perineural spread of malignacy or non-malignant disease like infection or active inflammation b. Nerve injury i. Gudgeon (fresh water fish) - neuroma in continuity ii. Yarn and string - terminal neuroma iii. Loner - brachial plexus avulsion injury iv. White out - post-radiation fatty change, intraneural hemorrhage from injury, endometriosis, or sarcoma v. Black out - scarring from severe injury or regional ablation, ischemic neuropathy from severe compression, graft degeneration c. Nerve entrapment/inflammation i. Mount Fuji - neurogenic thoracic outlet syndrome ii. Meandering - nerve inflammation like brachial neuritis iii. Zig-zag - multifocal post-traumatic or iatrogenic scarring iv. Hourglass - nerve root torsion or severe constriction v. Triple B sign - severe constriction at entrapment

MKEE-168 DIAGNOSIS AND TREATMENT OF TRAUMATIC PERONAL TENDON DISORDERS

Raquel Prada, PhD (*Presenter*)
Juan Manuel Gomez Canedo (*Abstract Co-Author*)
Maria Costas, MD (*Abstract Co-Author*)
Montserrat Novoa Ferro, MD (*Abstract Co-Author*)
Selma d. Estepar, BMBS (*Abstract Co-Author*)

TEACHING POINTS

Understand pathogenesis of traumatic peroneal tendons injuries. Describe the US and MR finding of peroneal tendinopahy, peroneal instability and peroneal tendón tears and predisposing anatomical variants .Explain the different therapeutic approaches and illustrate surgical procedures .

TABLE OF CONTENTS/OUTLINE

Although traumatic injuries to peroneal tendons are uncommon, they are a common cause of chronic lateral ankle pain and may lead to ankle instability.There are three traumatic disorders; peroneal tendinopathy, peroneal subluxation, and peroneal tendon tears. The most common associated pathologies are also described: lateral collateral ligament sprain, osteochondral injury to talar dome, and calcaneal and peroneal fractures. Initial diagnosis is difficult and often underdiagnosed. Imaging techniques, primarily ultrasound and MRI, play an important role in diagnosis. For peroneal tendons instabiliy Eckert and Davis/Oden classification is used and for tendon tears Sobel classification is used. The first treatment option is conservative maneuvers. The next therapeutic approach for peroneal instability is open or endoscopic repair of superior peroneal retinaculum, with or without endoscopic or open fibular groove deepening. For tendinopthy the surgical options include debridement and synovectomy and for tendon tears, debridement and tubularization, resection and tenodesis. The most common postoperative complications are tendon retears and tenosynovitis. US and MRI findings as well as predisposing anatomical variants are illustrated. The different surgical procedures and posoperative complications are also described.

MKEE-169 IMAGING OF MUSCLE INJURY COMPLICATIONS

Stefano Fusco, MD (*Presenter*)
Fernando Idoate, MD (*Abstract Co-Author*)
Alexeys Perez, MD (*Abstract Co-Author*)
Luis Cerezal, MD (*Abstract Co-Author*)
Eva Llopis, MD (*Abstract Co-Author*)

TEACHING POINTS

Muscle injuries are a major concern in sports medicine, and imaging plays a key role not only in diagnosis but also in follow-up, aiding in the detection of potential complications. Normal healing may result in restitutio ad integrum or scar formation, whereas abnormal healing can lead to excessive fibrosis, potentially impairing function and increasing the risk of reinjury, one of the most challenging complications. Nerve involvement can occur in acute muscle strains due to stretch injury, with nerve thickening, edema, and loss of the fascicular pattern. Acute nerve disruption may also occur, especially in hamstring avulsions, often involving small motor sciatic branches, with MRI usually showing only indirect signs. Chronically, nerve injury may result from entrapment within scar tissue or from disruption. MRI signs are muscle edema and, if unresolved, fatty atrophy. Other complications include calcifications, which can occur during the healing process, and myositis ossificans, consisting of heterotopic bone formation, typically following hematomas after direct trauma. Rarely, residual fascial defects may cause herniation of muscle belly, best assessed by dynamic US. Deep vein thrombosis is another potential complication, detectable on US and MRI. It mainly occurs in calf injuries, particularly involving intramuscular veins. Awareness of these complications is essential, as they significantly impact prognosis and return-to-play.

TABLE OF CONTENTS/OUTLINE

1.Excessive scarring and reinjury; 2.Nerve injury - 2a.Acute (stretching / disruption) - 2b.Chronic (secondary to fibrosis or disruption); 3. Calcifications & myositis ossificans; 4.Muscle hernia; 5.Deep vein thrombosis

MKEE-170 PLAY-D'OHN'T BE FOOLED: IDENTIFYING DISPLACED MENISCAL TEARS AND THEIR MIMICKERS

Natalia Eugene, MD (*Presenter*)
Sanjum Singh, MD (*Abstract Co-Author*)
David Cornwell (*Abstract Co-Author*)
Matthew Rae (*Abstract Co-Author*)
Tetyana A. Gorbachova, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review the current classification of meniscal tears and typical locations of displaced meniscal tears. • Utilize original 3D printed and Play-Doh models as well as clinical MRI images to illustrate meniscal anatomy and tear configurations. • Highlight anatomic findings, variants and artifacts that may mimic displaced meniscal tears. • Emphasize the importance of accurate tear characterization for both radiologists and orthopedic surgeons in guiding management.

TABLE OF CONTENTS/OUTLINE

1. Current classification of meniscal tears with emphasis on displaced tears. 2. MRI signs of displaced meniscal tears and their pitfalls (e.g., comma or boomerang sign, meniscus in the notch, double PCL) 3. Common Locations for displaced meniscal fragments a. Medial Meniscus b. Lateral Meniscus c. Search patterns and diagnostic pitfalls d. Treatment implication depending on tear morphology and fragment location 4. Mimickers of displaced meniscal tears a. Transverse meniscal ligament b. Meniscofemoral and meniscotibial ligaments c. Oblique meniscomeniscal ligaments d. Anteromedial capsulofemoral band e. Semimembranosus tendon f. Popliteus tendon g. Popliteomeniscal fascicles h. Discoid meniscus 5. MRI Artifacts that may mimic tears (e.g., vacuum phenomenon) 6. Treatment Strategies a. Treatment options (e.g., meniscectomy, arthroscopic repair—including different techniques based on location—and meniscal allograft transplantation) b. Indications for urgent Intervention (fragment location and salvageability) c. Prognostic factors d. Special treatment considerations (pediatric vs adult patients)

MKEE-171 NERVE-WRACKING: HIGH-RESOLUTION ULTRASOUND OF TRAUMATIC PERIPHERAL NERVE INJURIES

Tania A. Toma, MBChB (*Presenter*)
Melissa Berwick, mbbs (*Abstract Co-Author*)
Dyan V. Flores, MD (*Abstract Co-Author*)
Linda Probyn, MD (*Abstract Co-Author*)
Angela Atinga, MBBChir, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Traumatic peripheral nerve injury (TPNI) can result in profound sensory and motor deficits as well as chronic neuropathic pain, impacting on function and quality of life. High-resolution sonography (US) offers excellent sensitivity and spatial resolution with dynamic capabilities and is a valuable adjunct to nerve conduction studies (NCS), electromyography (EMG) and magnetic resonance imaging (MRI), in diagnosis, prognosis and treatment selection. It is especially beneficial in the setting of severe trauma where longer acquisition times of MRI with marked edema and hemorrhage may limit overall image quality. The teaching objectives are as follows: 1. Review the normal anatomy and US appearances of peripheral nerves 2. Discuss different types of TPNIs and review current grading classification systems 3. Demonstrate cases of TPNIs emphasizing their US appearances and extraneural findings, and how this relates to prognosis and implications for treatment

TABLE OF CONTENTS/OUTLINE

1. Normal peripheral nerve anatomy and US appearances 2. Imaging considerations (including timing of imaging) 3. Mechanisms and types of nerve trauma 4. Seddon and Sunderland Classification system for TPNI 5. US scanning techniques including pearls and pitfalls 6. TPNI cases emphasizing US appearances and extraneural findings 7. Prognostication and treatment implications

MKEE-172 HIDDEN STRENGTH: OPPORTUNISTIC BONE HEALTH ASSESSMENT IN ROUTINE IMAGING

Margrit E. Muller, MD (*Presenter*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Akemi Osawa, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

- To explain the concept and clinical relevance of opportunistic bone health assessment in medical imaging. - To explain the concept and importance of Dual-energy X-ray Absorptiometry (DXA) in assessing bone health. - To review the main imaging modalities that allow bone mineral density (BMD) estimation beyond Dual-energy X-ray absorptiometry (DXA). - To highlight emerging techniques and technologies, including AI algorithms. - To illustrate with clinical cases where opportunistic screening made a significant difference in patient outcomes. - To encourage radiologists to integrate bone assessment into routine imaging to support early diagnosis and prevention of osteoporosis-related fractures.

TABLE OF CONTENTS/OUTLINE

- Definition and value of opportunistic bone health assessment. - DXA as the gold standard: strengths and limitations. - Alternative imaging modalities: CT, radiography, ultrasound, and MRI. - Advances in quantitative imaging: quantitative CT (QCT), AI-based tools, quantitative ultrasound (QUS), and ultrashort echo magnetic resonance imaging (UTE MRI). - Case examples illustrating potential impact on patient care.

MKEE-173 PELVIC BONE TUMORS : A COMPREHENSIVE IMAGING AND INTERVENTIONAL GUIDE FOR THE RADIOLOGIST

Felipe A. Sulla Lupinacci, MD (*Presenter*)
Flavia F. Araujo, MD (*Abstract Co-Author*)
VINICIUS R. BRAMBILLA, MD (*Abstract Co-Author*)
Marco Gonzalez (*Abstract Co-Author*)
Pedro H. Arruda, MD (*Abstract Co-Author*)
Isabela A. Da Cruz, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Alipio Ormond Filho, MD (*Abstract Co-Author*)
Marcelo A. Nico, MD (*Abstract Co-Author*)

TEACHING POINTS

Pelvic bone tumors represent a diagnostic and therapeutic challenge given the complex anatomy and the broad pathological spectrum—ranging from benign to malignant, primary to metastatic lesions. The limitations of physical examination due to deep location and proximity to vital pelvic structures underscore the indispensable role of imaging. Radiography is frequently suboptimal owing to overlapping anatomy and thin cortical bone in regions such as the iliac wing. MRI is the modality of choice for evaluating marrow infiltration, soft-tissue extension, and peritumoral edema, although reconversion or persistence of hematopoietic marrow may mimic pathology. The sacroiliac joint, with limited cartilage coverage and frequent tumor invasion, and the hip joint, commonly affected by degenerative changes, require meticulous assessment. Interventional radiology is integral to management, with CT-guided biopsy, thermal ablation, and cementoplasty offering minimally invasive options. High-resolution CT enables precise localization relative to critical neurovascular landmarks, including iliac vessels, femoral/sciatic nerves, and the sacral plexus. This review discusses imaging hallmarks, introduces a structured diagnostic algorithm, and outlines image-guided interventions tailored to lesion type and location.

TABLE OF CONTENTS/OUTLINE

Introduction Multimodality Evaluation Classification of Pelvic Bone Tumors 3.1 Benign 3.2 Malignant 3.3 Metastatic Imaging-Based Diagnostic Algorithm Interventional Radiology Considerations 5.1 Different approaches 5.2 Structures to avoid 5.3 Possible complications

Abstract Archives of the RSNA, 2025

MSEE-1 SEEING WHAT WAS INVISIBLE: SPECTRAL AND UHR IMAGING WITH PHOTON COUNTING DETECTOR CT

Kota Yokoyama, MD, PhD (*Presenter*)
Yusuke Kawasaki, MD (*Abstract Co-Author*)
Hirofumi Yamada (*Abstract Co-Author*)
Tomoki Imokawa, MD (*Abstract Co-Author*)
Jun Oyama (*Abstract Co-Author*)
Akane Ozawa (*Abstract Co-Author*)
Junichi Tsuchiya, MD, PhD (*Abstract Co-Author*)
Ukihide Tateishi, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Photon-counting detector CT (PCD-CT) introduces a paradigm shift in radiology with ultra-high resolution (UHR) and spectral imaging. - PCD-CT enables detailed visualization of small vessels, tissue characterization, and lesion delineation. - It broadens the utility of contrast-enhanced CT across cardiovascular, neurovascular, oncologic, and inflammatory diseases. - Spectral data such as iodine and extracellular volume (ECV) maps support functional assessment comparable to MRI. - PCD-CT advances “Green Radiology” by reducing the need for MRI, lowering radiation dose, and potentially replacing invasive procedures.

TABLE OF CONTENTS/OUTLINE

Introduction - Overview of PCD-CT and comparison with energy-integrating detector CT (EID-CT) - Key innovations: direct photon conversion, spectral binning, noise reduction Ultra-High Resolution Imaging - Non-contrast imaging: temporal bone, trabecular bone, lung - Contrast imaging: in-stent lumen, small vessels, dural defects, pancreaticobiliary ducts Spectral Imaging Applications - Iodine and ECV mapping for myocardial fibrosis - Lesion conspicuity in cancer imaging - Inflammatory disease evaluation - Bone marrow imaging Clinical Impact & Future Directions - Toward replacing MRI and invasive angiography - Dose reduction and sustainability - Practical needs: kernel tuning, software, data management Conclusion - PCD-CT redefines CT by integrating structural and functional imaging.

MSEE-2 KEY FINDINGS: CRACKING OPEN THE SKULL VAULT’S DIAGNOSTIC TREASURE

Andressa C. Kuzma, MD (*Presenter*)
Mariana Carmo, MD (*Abstract Co-Author*)
Rodrigo Zancanaro, MD (*Abstract Co-Author*)
Enzo Fatuch (*Abstract Co-Author*)
Bruno Coghi (*Abstract Co-Author*)
Sebastiao B. de Araujo Neto, MD (*Abstract Co-Author*)
Stenio Burlin, MD (*Abstract Co-Author*)
Luis T. Tibana, MD (*Abstract Co-Author*)
Gustavo D. Gomez, MD (*Abstract Co-Author*)

TEACHING POINTS

A wide spectrum of calvarial lesions and malformations can be identified on imaging, ranging from congenital and developmental anomalies to neoplastic, metabolic, infectious, vascular, and traumatic causes. Understanding their underlying pathophysiology helps radiologists establish a diagnostic approach. In this exhibit we present a didactic review of skull vault abnormalities according to etiology, as a teaching aid with causes ranging from commonest to rare, aiming to both stimulate the young resident as well as review and remember experts of rarer differential diagnoses.

TABLE OF CONTENTS/OUTLINE

Congenital causes include inclusion cysts, leptomeningeal cysts, congenital skull depressions, meningoencephaloceles, and syndromic conditions such as Apert syndrome and cleidocranial dysplasia. Other developmental and genetic disorders like fibrous dysplasias and tuberous sclerosis are also explored. Metabolic disorders such as renal osteodystrophy, Paget disease, and hyperparathyroidism are included, along with endocrine causes like acromegaly and also drug-related hyperostosis. Infectious and inflammatory diseases, including osteomyelitis and Langerhans cell histiocytosis, are presented. Neoplastic conditions range from benign (osteoma and meningioma variants) to malignant (metastases, multiple myeloma, and malignant bone tumors). The exhibit addresses hematologic disorders and idiopathic causes such as Gorham disease, but also more common iatrogenic changes including burr holes. Normal variants such as prominent foramina and arachnoid granulations are also considered as potential pitfalls.

MSEE-3 OLD SCHOOL, STILL COOL CONVENTIONAL CONTRAST STUDIES IN ACTION

Pablo Nahuel Montalto, MD (*Presenter*)

TEACHING POINTS

Highlight the continued relevance of conventional contrast studies in modern radiologic practice. Identify clinical scenarios where these studies outperform or complement modern cross-sectional imaging. Demonstrate key imaging findings in gastrointestinal tract, genitourinary, and airway pathologies using real cases. Emphasize the value of dynamic fluoroscopy in visualizing functional abnormalities that static imaging may miss.

TABLE OF CONTENTS/OUTLINE

Introduction: Revisiting conventional contrast imaging Technical overview: Equipment and acquisition principles Gastrointestinal applications: Achalasia, reflux, Zenker's diverticulum Genitourinary cases: Ureterocele, vesicoureteral reflux, urethral strictures Airway relevance: Swallowing studies and tracheoesophageal fistulas Advantages, limitations, and reporting pearls Educational conclusions and take-home messages

MSEE-4

Koji Takumi, MD, PhD (*Presenter*)

EXTRACELLULAR VOLUME FRACTION ASSESSMENT IN ONCOLOGY USING DUAL-ENERGY AND PHOTON-COUNTING CT: TECHNIQUES, INTERPRETATION, AND CLINICAL APPLICATIONS

Ryota Nakanosono, MD (*Abstract Co-Author*)
Tsubasa Nakano (*Abstract Co-Author*)
Fumitaka Ejima (*Abstract Co-Author*)
Masanori Nakajo, MD (*Abstract Co-Author*)
Kiyohisa Kamimura, MD, PhD (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Extracellular volume fraction (ECV) is a promising imaging biomarker in oncology, with clinical utility across multiple organs. It enables non-invasive evaluation of tumor microenvironment features such as fibrosis and extracellular matrix, which correlate with tumor subtype, aggressiveness, and treatment response. Radiologists should understand the principles, technical aspects, and clinical value of ECV to improve diagnostic accuracy and guide treatment. Advances in dual-energy CT (DECT) and photon-counting CT (PCCT) have simplified and enhanced ECV quantification, especially via iodine-based imaging. The purposes of this exhibit are: 1) To review the principles and methods of ECV quantification using DECT and PCCT. 2) To illustrate the interpretation of ECV maps in various oncologic entities with pathological correlation. 3)To discuss the clinical applications of ECV in tumor characterization, staging, and treatment monitoring, with examples from thoracic and abdominopelvic tumors.

TABLE OF CONTENTS/OUTLINE

1) Overview of ECV Quantification in Oncology; 1: Definition and biological significance of ECV. 2: Technical overview of ECV measurement using DECT and PCCT, 2) Techniques; 1: Acquisition protocols: equilibrium phase imaging and dual-energy/spectral techniques, 2: Mathematical calculation and required inputs (hematocrit, attenuation value or iodine concentration, 3) Clinical Applications; 1: Role of CT-derived ECV in differentiating tumor subtypes as a biomarker for tumor aggressiveness, 2: Case-based interpretation: lung cancer subtypes, mediastinal tumors, liver and pancreatic lesions, gastric cancers, rectal tumors, etc.

MSEE-5 MULTIMODALITY IMAGING OF VASCULAR GRAFT AND ENDOGRAFT INFECTION

Sophie Canham, BSC,MBChB,FRCR (*Presenter*)
Mitesh Naik, FRCR (*Abstract Co-Author*)
Namir Asmar, MBBCHIR (*Abstract Co-Author*)
Elika Kashef, FRCR (*Abstract Co-Author*)
Oliver Lyons (*Abstract Co-Author*)
Tara D. Barwick, FRCR, MSc (*Abstract Co-Author*)

TEACHING POINTS

• To discuss the pathogenesis, clinical presentation and management of vascular graft and endograft infection (VGEI) • To provide an overview of imaging features of VGEI for the general reporting radiologist • To highlight strengths and limitations of imaging modalities used to diagnose VGEI, including ultrasound, CT angiography, white blood cell scintigraphy (WBC) with SPECT/CT and [18 F]FDG PET/CT • To review international guidance on the workup of suspected VGEI

TABLE OF CONTENTS/OUTLINE

Background • Pathogenesis • Presentation - clinical/radiological/laboratory features (including MAGIC [Management of Aortic Graft infection Collaboration] criteria) • Management and follow up Review of imaging features • Ultrasound - perigraft fluid/collections, mural thickening, edema, thrombus • CT angiography - perigraft fluid/gas/soft tissue inflammation/collections • [18 F]FDG PET/CT - visual analysis (level and pattern of tracer uptake with grading) and semi-quantitative analysis (standardized uptake value and target-to-background ratios) • WBC scintigraphy with SPECT/CT - visual analysis (level and pattern of tracer uptake incrementing across two time-points) • Advantages and disadvantages of each modality Review of international imaging guidance Multimodality case examples with interpretive pearls and pitfalls • Typical cases • Unusual presentations and complex scenarios • Complications Summary

MSEE-6 MULTIMODALITY IMAGING OF COSMETIC FILLERS AND BIOSTIMULATORS: PATTERNS, PEARLS AND PITFALLS

Heytor Jose De Oliveira Cabral, MD (*Presenter*)
Marilia A. Tavares, MD (*Abstract Co-Author*)
Israel Missrie, MD (*Abstract Co-Author*)
Alexandre M. Silva, MD (*Abstract Co-Author*)
Luciana C. Zattar, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Julia Capobianco, MD (*Abstract Co-Author*)

TEACHING POINTS

• The increasing demand for percutaneous aesthetic procedures has led to a growing variety of injectable materials, including non-resorbable synthetic fillers, autologous fat grafts, and resorbable agents.• These substances often exhibit distinct imaging features across modalities. However, patients may be unaware of the specific material used, complicating clinical and radiologic assessment.• Recognizing the imaging characteristics of different fillers is essential to avoid misdiagnosis, false-positive findings, and unnecessary invasive procedures

TABLE OF CONTENTS/OUTLINE

• Illustrate, through institutional case examples, the imaging appearances of various fillers and biostimulatory agents—including free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite, and autologous fat—across multiple imaging modalities.• Review common injection sites and discuss potential local and systemic complications associated with each type of injectable material.• Help radiologists recognize the typical imaging features of these materials to reduce misinterpretation, avoid false-positive diagnoses, and prevent unnecessary interventions.

MSEE-7 HYDATIDOSIS BEYOND THE LIVER: A SYSTEMATIC REVIEW BASED IN A SERIES OF CASES

Isabel Fonseca Buelga, MD (*Presenter*)
Sara Siguenza-Gonzalez, MD (*Abstract Co-Author*)
Claudia Viescas Huerta, MD (*Abstract Co-Author*)
Diego Alejandro Garcia Paredes, MD (*Abstract Co-Author*)
Sergio Sintes (*Abstract Co-Author*)
Antonio Michael-Fernandez, MD (*Abstract Co-Author*)
Raquel Garcia Latorre, MD (*Abstract Co-Author*)
Abel Gonzalez Huete, MD (*Abstract Co-Author*)

TEACHING POINTS

Brief review of the current situation, epidemiology and life cycle of the Echinococcus granulosus. Description of the radiographic findings comparing different imaging modalities (US, CT and MRI). To recall the classification of hydatidic cysts. Review extraabdominal hydatidosis manifestations by using illustrative cases and remarking the differential diagnosis in each location Talk about the possible complications of the disease and their diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Introduction. Current Situation and Cycle. 1.1 Epidemiology and distribution of Echinococcus granulosus 1.2 Cycle 2. Imaging Features 2.1 Ultrasound (US) 2.2 Computed Tomography (CT) 2.3 Magnetic Resonance Imaging (MRI). Hepatic Echinococcosis. 3. Classification of hydatidic cysts Ethiopathogenesis. Classification of

Ghaarby. 4. Extrahepatic Hydatidosis. 4.1 Intra-abdominal cysts . 4.2 Extra-abdominal dissemination . 4.3 Illustrating cases. 5. Musculoskeletal hydatidosis 5.1 Imaging findings. 5.2 Differential diagnosis 6. Complications . 6.1 Etiopathogenesis . 6.2 Imaging features .7. Summary

MSEE-8 VISUALIZATION&INTERVENTION:BASICS OF LYMPHATIC SYSTEM RADIOLOGY

Wei Meng, MD (*Presenter*)
Yosuke Yamamoto, MD (*Abstract Co-Author*)
Taiki Nozaki, MD (*Abstract Co-Author*)
Jitsuro Tsukada (*Abstract Co-Author*)
Yuko Tsujioka, MD, PhD (*Abstract Co-Author*)
Yu Iwabuchi (*Abstract Co-Author*)
Shigeyoshi Soga, MD (*Abstract Co-Author*)
Masanori Inoue, MD (*Abstract Co-Author*)
Yoshitake Yamada, MD, PhD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purposes of this exhibit are 1)To demonstrate the function, anatomy, and anatomical variations of the lymphatic system. 2)To present various imaging modalities for visualizing the lymphatic system and compare their advantages and disadvantages. 3)To illustrate Interventional Radiology treatment options for lymphatic disorders along with representative imaging findings.

TABLE OF CONTENTS/OUTLINE

1)Introduction 2) The function, anatomy, and anatomical variations of the lymphatic system 3) Visualization of the lymphatic system: modalities including scintigraphy, lymphangiography and MR lymphangiography(Non-contrast MR lymphangiography and Dynamic contrast MR lymphangiography) 4) Interventional Radiologic of lymphatic disorders including Retrograde transvenous thoracic duct embolization and Percutaneous thoracic duct embolization

MSEE-9 HAIRY KIDNEYS AND FIBROTIC SURPRISES: RADIOLOGIC ADVENTURES IN MULTISYSTEM DISEASE

Shayan Saeed (*Presenter*)
Jasmine Zhao, MD (*Abstract Co-Author*)
Syed Ibrahim (*Abstract Co-Author*)
Star Lopez (*Abstract Co-Author*)
Jadyn Lontoc (*Abstract Co-Author*)
River Wolf (*Abstract Co-Author*)
Mohammad Helmy, MD (*Abstract Co-Author*)
James Shi, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Multisystem diseases such as IgG4-related disease, sarcoidosis, amyloidosis, Behçet's disease, and Erdheim-Chester disease present with diverse, often non-specific symptoms that can mimic more common conditions. 2. Radiologic imaging is essential for early identification, with certain diseases exhibiting hallmark signs such as retroperitoneal fibrosis (IgG4-RD) and the "hairy kidney" and coated aorta signs (Erdheim-Chester disease). 3. MRI, CT, and PET/CT facilitate detection of multisystem involvement, often revealing subtle findings before clinical symptoms fully manifest. 4. Early recognition through imaging can guide targeted biopsy, inform differential diagnosis, and enable prompt initiation of appropriate multidisciplinary therapy.

TABLE OF CONTENTS/OUTLINE

1. Learning objectives 2. 5 Must-Know Multisystem diseases: Case-Based Examples 2. i) Clinical Presentation 2. ii) Epidemiology 2. iii) Histopathogenesis 2. iV) Understand Disease-specific Imaging Modalities 2. V) Key Imaging features and Diagnostic challenges 3. Summary and Key Takeaways

MSEE-10 RECOGNIZING IGG4-RELATED DISEASE: IMAGING INSIGHTS INTO A COMPLEX DIAGNOSIS

Vitor Soares, MD (*Presenter*)
Andrey Ribeiro, MD (*Abstract Co-Author*)
Luiza Chimeli-Ormonde, MD (*Abstract Co-Author*)
Mateus Pereira Dos Santos Gomes, MD (*Abstract Co-Author*)
Andre Ferreira, MD (*Abstract Co-Author*)
Felipe C. Ribeiro, MD (*Abstract Co-Author*)
Anna P. Riello, MD, MSc (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

IgG4-related disease (IgG4-RD) is a rare, immune-mediated condition with diverse clinical presentations, that can affect virtually any organ. Imaging plays a crucial role in detecting organ involvement and guiding diagnosis.Familiarity with characteristic imaging patterns across multiple organs is essential for radiologists.

TABLE OF CONTENTS/OUTLINE

I. Purpose To review the multisystemic imaging manifestations of IgG4-RD and highlight key radiologic findings that support early and accurate diagnosis. II. Multisystemic Manifestations and Key Imaging Features ? Type 1 Autoimmune Pancreatitis The pancreas is the most frequently involved organ. Image is useful for distinguishing between the acute and chronic phases. ? Retroperitoneal Fibrosis Presents as a soft-tissue mass encasing the abdominal aorta and its branches. It often involves the ureters, potentially leading to hydronephrosis. ? Sclerosing Cholangitis The biliary system is the second most commonly affected site. Imaging typically reveals fibrosis of the intra- and extrahepatic bile ducts, accompanied by upstream biliary dilatation. ? Pulmonary Involvement May present with nodules or masses, ground-glass opacities, and interstitial or peribronchovascular changes. ? Sialadenitis Characterized by typically painless, bilateral glandular swelling. III. Future Perspectives ^{18}F-Fluorodeoxyglucose positron emission computed tomography has shown promise in assessing multiorgan involvement in a single scan. IV. Conclusion Imaging modalities, particularly CT and MRI, play a pivotal role in the diagnosis and follow-up of IgG4-RD. Nuclear medicine techniques may further enhance diagnostic accuracy and disease monitoring soon.

MSEE-11 BONE MARROW PATHOLOGICAL MODIFICATIONS OF HEMATOLOGICAL MALIGNANCIES

Mickael Tordjman, MD, MS (*Presenter*)
Fadila Mihoubi Bouvier (*Abstract Co-Author*)
Seoung-Oh Yang, PhD (*Abstract Co-Author*)
Mohamed Jarraya, MD (*Abstract Co-Author*)
Bachir Taouli, MD (*Abstract Co-Author*)
Ali Guermazi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Bone marrow (BM) evaluation is central to the diagnosis, staging, and response assessment of hematological malignancies.• Specific imaging and pathological patterns help differentiate between various hematological malignancies such as multiple myeloma, bone lymphoma, leukemia, and myelofibrosis.• Recognizing focal, diffuse, variegated, and patchy BM infiltration patterns is key to the diagnosis, prognosis and guiding appropriate treatment strategies.• Advanced imaging techniques (Dixon,

PET/CT, whole-body MRI, PET/MRI) increasingly complement histopathological analysis in detecting early or residual disease.• Understanding post-therapeutic BM remodeling (e.g., reconversion, fibrosis, necrosis) is crucial for differential diagnosis and accurate longitudinal assessment.

TABLE OF CONTENTS/OUTLINE

1. Normal Bone Marrow Architecture. 2. Imaging Techniques of Bone Marrow Evaluation. o MRI signal changes, Dixon characteristics, PET uptake. 3. Pathological Patterns of Marrow Infiltration. o Focal, diffuse, and mixed patterns. o Cell lineage-specific features (e.g., plasma cells, blasts, lymphocytes). 4. Hematological Malignancies Imaging Features Overview. o Multiple Myeloma and Plasmacytoma. o Acute and Chronic Leukemiaso Lymphoma. o Aplastic Anemia. o Myelofibrosis. 5. Therapy-Induced Marrow Changes. o Treatment response patterns. o Complications: fibrosis, necrosis. o Reconversion. 6. Diagnostic Pitfalls and Mimics. o Reactive changes, infections, and marrow reconversion. 7. Integrating Imaging and Histopathology for Diagnosis and Monitoring

MSEE-12 PEDIATRIC VITAMIN DEFICIENCIES AND MALNUTRITION: WHAT THE RADIOLOGIST NEEDS TO KNOW

Dora Chen, MD (*Presenter*)
Asha Sarma, MD (*Abstract Co-Author*)
Yu Luo, MD,PhD (*Abstract Co-Author*)
Elizabeth J. Snyder, MD (*Abstract Co-Author*)
Rekha S. Krishnasarma, MD (*Abstract Co-Author*)

TEACHING POINTS

Consequences of pediatric vitamin deficiencies range from mild to devastating. Deficiencies can have specific imaging findings, and therefore imaging plays an essential role in early and accurate diagnosis. Early diagnosis is important because prompt supplementation can prevent, halt, or even reverse consequences. Causes of vitamin deficiencies in pediatric patients are wide-ranging and include: no Vitamin K administration, prematurity, self-restricted diet/anorexia, metabolic disease, and renal disease. Radiologists should be familiar with the various ways each vitamin deficiency can present and its appearance across modalities.

TABLE OF CONTENTS/OUTLINE

Series of curated cases of pediatric patients who presented with specific deficiencies, organized by vitamin. Each vitamin, in addition to its cases, will have accompanying slides dedicated to explaining the functional role of that vitamin as well slides dedicated to describing the manifestations/disease states that can occur.

MSEE-13 SICKLE CELL DISEASE ON IMAGING: WHAT RADIOLOGISTS SHOULD KNOW

Marcella Brandao, MD, MEd (*Presenter*)
Igor Amorim, MSc (*Abstract Co-Author*)
Daniel Sa Ribeiro (*Abstract Co-Author*)
Paulo H. Fujita (*Abstract Co-Author*)
Dilton Mendonca (*Abstract Co-Author*)
Paulo Mariz Filho, MD (*Abstract Co-Author*)

TEACHING POINTS

To showcase a broad range of real patient cases, highlighting the clinical and radiologic heterogeneity of sickle cell disease. To provide a structured overview of acute and chronic complications, reinforcing the radiologist’s role in diagnosis and management. To emphasize key imaging features and potential diagnostic pitfalls that may influence patient outcomes.

TABLE OF CONTENTS/OUTLINE

Sickle cell disease is a multisystem hematologic disorder with diverse and characteristic imaging manifestations. This case-based review is organized by organ systems: Musculoskeletal: H-shaped vertebrae, bone infarcts, osteonecrosis, osteomyelitis, and deep vein thrombosis. Neurological: Stroke, silent infarcts, moyamoya syndrome, posterior reversible encephalopathy syndrome (PRES), and labyrinthine hemorrhage. Cardiopulmonary: Chronic (pulmonary artery dilatation, cardiomegaly, concentric left ventricular hypertrophy, and chronic parenchymal lung changes) and acute (variable CT presentations of acute chest syndrome). Abdominal: Iron overload (hepatic, splenic, and renal iron deposition), hepatobiliary (cholelithiasis, choledocholithiasis, and morphological liver changes), splenic (autosplenectomy, splenic infarcts, and Gamna-Gandy bodies) and renal (bilateral cortical necrosis, renal vein thrombosis and pyelonephritis).

MSEE-14 GENETIC SYNDROMES WITH INCREASED RISK OF GASTROINTESTINAL AND GENITOURINARY CANCERS: ROLE OF IMAGING IN SCREENING

Komal A. Chughtai, MD (*Presenter*)
Amar Shah, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Roman Shrestha, MD (*Abstract Co-Author*)
Kumaresan Sandrasegaran, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review major hereditary cancer syndromes affecting the gastrointestinal (GI) and genitourinary (GU) systems. 2. Understand current imaging-based screening protocols for these high-risk populations 3. Explore emerging research and discuss controversies regarding screening and surveillance in high-risk populations.

TABLE OF CONTENTS/OUTLINE

Contents/Outline This exhibit highlights the role of radiologists in screening patients with cancer-predisposing germline mutations affecting GI and GU systems. Discussed symptoms include: • Familial Adenomatous Polyposis • Lynch Syndrome • Peutz-Jeghers • Juvenile Polyposis Syndrome • BRCA1 and BRCA2 • Li-Fraumeni • Multiple Endocrine Neoplasia Types 1 and 2• ATM, PALB2 • PRSS1 • Von Hippel-Lindau• Hereditary Leiomyomatosis Renal Cell Carcinoma• Hereditary Papillary Renal Cell Carcinoma • Birt-Hogg-Dubé • Cowden Syndrome (PTEN Hamartoma Syndrome) Clinical features, associated GI and GU tumors, recommended imaging screening strategies, and representative radiologic cases will be presented for each syndrome highlighting practical imaging pearls. Novel directions in cancer surveillance, including the use of whole-body MRI for radiation-free multi-organ screening and advances in radiomics for early lesion characterization, will be discussed. Additionally, we review areas of controversy regarding oncologic screening and surveillance in certain high-risk populations. Summary Familiarity with syndrome-specific screening protocols, characteristic imaging findings, and emerging tools empowers radiologists to directly impact patient outcomes. Early, tailored imaging can be life-saving for high-risk individuals.

MSEE-15 NEUROENDOCRINE TUMORS: GET IT STRAIGHT

Cecilia Vieira Leite (*Presenter*)
Sandra Baleato Gonzalez, MD, PhD (*Abstract Co-Author*)
Roberto Garcia Figueiras, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Neuroendocrine tumors are an heterogeneous group of tumors occurring at various anatomic sites and with a wide range of appearance in imaging studies. They represent around 1% of all malignancies, but with an increasing incidence worldwide.Understanding these tumors, their possible locations, imaging characteristics and how the radiological findings can impact the treatment approach are of key importance for a correct management.

TABLE OF CONTENTS/OUTLINE

- - Get the best out of your resources. Learn how to use different imaging techniques and how each of them can be useful for your diagnosis- - Be aware of where to look for. Describing the most typical locations and presentation forms, but also atypical locations and uncommon situations. - - Measure what matters. Knowing what and why describe tumor size, ADC values, SUV, texture. How they can correlate with prognosis and how they will impact management.- - See beyond. The behavior behind imaging. What the presence of necrosis, cystic degeneration, the vascularity, and what tumor margins can tell you. - - Game changing. Assessing resectability, embolization and theragnostics indications. Which criteria is important when considering surgical approach, vascular information, number of lesions, and how the presence of molecular and nuclear markers can influence treatment decisions.- - Getting the puzzle together. A radiological report with all the critical information your multidisciplinary team needs to know.

MSEE-16 GOT YOU UNDER MY SKIN: ULTRASOUND EVALUATION OF POST-FILLER NODULES

Rosa Maria Silveira Sigrist, MD (*Presenter*)
Matheus Fritzen, MD (*Abstract Co-Author*)
Julia D. Zavariz, MD (*Abstract Co-Author*)
Mateus Esmeraldo, MD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

To describe the ultrasound characteristics of different dermal fillers and post-filler nodules To distinguish non-inflammatory from inflammatory post-filler nodules using HFUS. To demonstrate the role of Doppler imaging in identifying active inflammation and vascularity.

TABLE OF CONTENTS/OUTLINE

A. Imaging Technique and Normal Skin Anatomy Use of =15-20 MHz HFUS for layered visualization Protocol for scanning face and subcutaneous compartments Importance of Doppler in evaluating vascularity B. Types of Fillers and Sonographic Patterns Hyaluronic Acid (HA): Pseudocystic anechoic, well-defined, typically avascular Calcium Hydroxyapatite (CaHA): Coalescent hyperechoic foci with acoustic shadowing Poly-L-lactic acid (PLLA): Hyperechoic deposits that become subtle after 15 days PMMA, Silicone, polycaprolactone (PCL), Hydrogel: Varying echogenicity and artifact signatures C. Non-inflammatory Nodules Product Redistribution: maintains the intrinsic sonographic aspects of the filler, but are in a different region than injectedInaccurate Placement: filler deposits are placed in an unintended layer (SMAS, intramuscular) Accumulation: Localized filler pooling D. Inflammatory Nodules and Reactions Granulomatous Inflammation: Abscess: Panniculitis E. Clinical Impact and Management Guidance Diagnostic clarification to avoid biopsy or surgery Ultrasound-guided therapy (e.g., hyaluronidase injection) Monitoring resolution and treatment response

MSEE-17 WHEN BEAUTY SPREADS: ULTRASOUND EVALUATION OF LYMPH NODE ALTERATIONS AFTER COSMETIC PROCEDURES

Rosa Maria Silveira Sigrist, MD (*Presenter*)
Matheus Fritzen, MD (*Abstract Co-Author*)
Julia D. Zavariz, MD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Cosmetic materials such as silicone, PMMA, calcium hydroxyapatite, and tattoo pigment can migrate to lymph nodes and mimic malignant or infectious conditions on ultrasound. High-frequency ultrasound enables identification of echogenic foci, posterior artifacts, and vascular patterns that help distinguish reactive from suspicious nodes. Clinical correlation with prior aesthetic procedures is essential to avoid misdiagnosis and unnecessary biopsy or alarm. Radiologists must recognize the specific sonographic appearances associated with each material to accurately interpret lymph node alterations.

TABLE OF CONTENTS/OUTLINE

Introduction - Overview of lymph node changes after filler injections and cosmetic procedures. Normal Lymph Node Anatomy on Ultrasound - Key criteria and baseline appearance. Sonographic Findings of Migrated Materials a. Silicone: snowstorm artifact b. PMMA: hyperechoic foci with comet-tail artifacts c. Tattoo pigment: punctate foci and mild cortical thickening d. Calcium hydroxyapatite: reactive lymphadenopathy Case Examples - Ultrasound images and histologic correlations. Differentiating Benign from Malignant Patterns - Tips to avoid pitfalls. Conclusion - The importance of aesthetic history and sonographic expertise in lymph node evaluation.

MSEE-18 ONE DISEASE TO RULE THEM ALL? : THE MANY FACES OF IGG4-RELATED DISEASE AND RECENT TRENDS

Mandeep S. Virk, MBBS, MD (*Presenter*)
Mahesh Chaudhary, MD (*Abstract Co-Author*)
Steven S. Chua, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize different presentations of IgG-4 related disease in various body organs. • Understanding how early diagnosis is important to prevent multi-organ failure. • Knowledge about common mimickers of IgG-4 related disease. • Correlating radiological features with serological and histopathological findings. • Recent trends and advancements in disease diagnosis.

TABLE OF CONTENTS/OUTLINE

• Introduction • Epidemiology and Pathophysiology • Diagnostic criteria • Common organ involvement with radiological images: 1. Pancreas 2. Biliary tree 3. Renal 4. Retroperitoneum 5. Lymph nodes 6. Orbits 7. Prostate 8. Hepatic pseudotumor 9. Vasculitis 10. Pulmonary • Pitfalls and atypical presentation. • Management and prognosis of disease. • Recent advances and future perspective • Summary

MSEE-19 IMAGING OF DERMATOLOGIC LESIONS ASSOCIATED WITH SYNDROMIC DISEASES

Peyman Mirghaderi, MD, MPH (*Presenter*)
Clarissa C. Moraes Do Carmo, MD (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Nastaran Hosseini (*Abstract Co-Author*)
Chankue Park, MD, PhD (*Abstract Co-Author*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize characteristic Imaging findings (ultrasound, MRI, DTI-tractography, etc) of skin lesions associated with syndromic diseases.• Understand how imaging differentiate dermatologic lesions in syndromic diseases from other soft-tissue masses, aiding in accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

Cutaneous lesions are critical early biomarkers for over 30% of syndromic disorders, offering radiologists a unique opportunity to diagnosis syndromic disease before severe complications arise. For instance, xanthomas signal familial hyperlipidemia, a precursor to cardiovascular events, while neurofibromas in neurofibromatosis type 1 (NF1) precede malignant peripheral nerve sheath tumors (MPNSTs). Goals include (1) empower radiologists to recognize syndromic skin lesions through modality-specific hallmarks, (2) bridge imaging patterns to genetic disorders (e.g., desmoid tumors in FAP, lymphangiomas in Turner syndrome): Neurofibroma (NF1) Schwannoma (Neurofibromatosis Type 2 [NF2], Schwannomatosis) Desmoid Tumor (Familial Adenomatous Polyposis/Gardner Syndrome) Xanthoma (Familial

Hyperlipidemia) Lymphangioma (Turner/Noonan Syndrome) Angiofibroma (Tuberous Sclerosis Complex [TSC], MEN1) Calcinosis Cutis (CREST Syndrome, Dermatomyositis) Lupus Pernio (Sarcoidosis) Telangiectasia (CREST Syndrome) Erythema Nodosum (Sarcoidosis, Inflammatory Bowel Disease) Basal Cell Carcinoma (Gorlin Syndrome) MPNST (NF1) Angiokeratoma (Fabry Disease) Collagenoma (Multiple Endocrine Neoplasia Type 1 [MEN1]) Ehlers-Danlos Skin Features (Vascular Ehlers-Danlos Syndrome) § Scleroderma Skin Thickening (Systemic Sclerosis)

MSEE-20 FROM MALIGNANCY TO AESTHETICS: A COMPREHENSIVE APPROACH TO SKIN ASSESSMENT WITH ELASTOGRAPHY

Luciana C. Zattar, MD (*Presenter*)
Renata V. Leao, MD (*Abstract Co-Author*)
Gabrielle A. Zattar (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Elastography is an advanced ultrasound-based technique that assesses skin elasticity or stiffness, aiding in the evaluation of both pathologic and aesthetic conditions. - In dermatology, elastography provides important data and details, enhancing diagnosis, treatment planning, and monitoring across a range of conditions. - Applications include tumor characterization, fibrosis assessment, scar evaluation, identification and monitoring of filler or collagen biostimulation and it complications or outcomes.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Elastography - Strain vs. Shear Wave Elastography 2. Applications: clinical, US and Elastography characteristics in: 2.1. Anatomic evaluation - Skin and anatomical layers, superficial musculoaponeurotic system, ligaments 2.2. Oncology : - Lesion identification: subtypes and characterization (melanona, basal cell carcinoma, squamous cell carcinoma, dermatofibrosarcoma protuberans, others) - Treatment: pre-operative mapping, margin, invasion, lymph nodes 2.3. Inflammatory Disorders - Scleroderma, psoriasis, hidradenitis suppurativa, lipedema 2.4. Scar and Keloid Assessment - Objective staging and treatment monitoring 2.5. Aesthetic Dermatology - Filler and collagen biostimulators identification, follow-up and complications 3. Advantages and Limitations - Functional, real-time, and non-invasive - Considerations: probe frequency, site variability, learning curve 4. Conclusion

MSEE-21 ISOMERISM EXPOSED: A STEPWISE ATLAS OF HETEROTAXY ANOMALIES

Mikel Isla-Jover, MD (*Presenter*)
Martin Santamaria Boado, MD (*Abstract Co-Author*)
Marta Alaia Montes Zubia, MD (*Abstract Co-Author*)
Inigo Alcaraz Hernando, MD (*Abstract Co-Author*)
Udane Perez Ibarrondo, MD (*Abstract Co-Author*)
Sara Garcia, MD (*Abstract Co-Author*)
Maria I. Berastegui, MD (*Abstract Co-Author*)
Armando Gozalo Garcia (*Abstract Co-Author*)
Nerea Hormaza, MD (*Abstract Co-Author*)

TEACHING POINTS

Isomerism encompasses a spectrum from situs solitus to complete situs inversus, with situs ambiguous subdivided into right and left heterotaxy. It can be approached using a dual framework: i) Situs spectrum : solitus, total inversus, partial inversus, ambiguous (right/left isomerism); (ii) Organ-system compartments : thoracic, abdominal, extra-visceral. Recognition of atrial isomerism via atrial appendage morphology refines cardiac classification and guides sequential segmental analysis. Multimodality imaging is essential for comprehensive assessment and management planning.

TABLE OF CONTENTS/OUTLINE

Introduction Definition Embryological overview, etiopathological considerations and epidemiology Educational goals Clinical implications and management Role of imaging Spectrum and Classification Situs solitus and situs inversus totalis Partial inversus Situs ambiguous (heterotaxy) Right isomerism (asplenia) Left isomerism (polysplenia) Thoracic Compartment Bronchial isomerism and lung lobation Cardiac anomalies: Atrial isomerism Atrioventricular canal defects Conotruncal defects Vacular anomalies Systemic veins Pulmonary veins Arteries Abdominal Compartment Splenic variants: asplenia, polysplenia spectrum. Gastrointestinal anomalies Other visceral anomalies Extra-Visceral Systems Neurological anomalies Skeletal anomalies Diagnosis and Management Algorithmic framework for diagnosis 7. Take home lessons 8. References

MSEE-22 NEUROENDOCRINE TUMORS IN PLACES YOU WOULD NOT EXPECT

Darcy F. Carabantes Garcia, MD (*Presenter*)

TEACHING POINTS

Neuroendocrine tumor (NET) that arises from the enterochromaffin (or Kulchitsky) cells and can affect virtually any organ system in the body. A possible explanation for this association is the growth factors or mitogens secreted by carcinoid tumors, which may promote phenotypic changes in susceptible cells Several histologic types of malignant tumors can coexist with carcinoid and have been reported in up to 25% of cases. Multifocal or multiple carcinoid tumors can also be seen in the same patient at the time of presentation (described as synchronous) or at a later time (described as metachronous)after prolonged stimulation, inducing The most frequent sites for carcinoids are the gastrointestinal tract (73.7%) and the bronchopulmonary system (25.1%). However, almost any organ of the body can be involvedneoplastic transformation

TABLE OF CONTENTS/OUTLINE

- Know what neuroendocrine tumors are. -Identify the radiological characteristics and components of neuroendocrine tumors. - Exemplify in a didactic way the key points found from a series of cases of our institution

MSEE-23 HIGH FREQUENCY ULTRASOUND AT YOUR FINGERTIPS: A PRACTICAL GUIDE TO FOCAL LESIONS

Thiago Munoz Ruiz, MD (*Presenter*)
Lara Quiche, MD (*Abstract Co-Author*)
Matheus Cruz Ferraro, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Caio Nunes, MD (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Roberta Linhares, MD (*Abstract Co-Author*)
Lavinia Dias, MD (*Abstract Co-Author*)
Roberto A. Kobayashi (*Abstract Co-Author*)
Sandro C. Mandaloufas (*Abstract Co-Author*)
Stephanie C. Castro, MD (*Abstract Co-Author*)
Victor A. Jabour, MD (*Abstract Co-Author*)
Miguel J. Francisco Neto, MD, PhD (*Abstract Co-Author*)
Erika T. Koshimura (*Abstract Co-Author*)
Andrea G. Leite, MD (*Abstract Co-Author*)

Marcelo R. Silva, MD (*Abstract Co-Author*)
Marcos R. Queiroz, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

The purposes of this exhibit are: To emphasize the importance of ultrasound for assessing pathologies of the hand and fingers To provide a visual guide for the diagnosis and differentiation of these lesions. To reduce the need for invasive tests.

TABLE OF CONTENTS/OUTLINE

To review the finger anatomy in ultrasound Illustrated teaching cases from our department showing the main differential diagnoses: Cystic lesions, Solid lesions, Inflammatory lesions, Tumor lesions, Nail apparatus Main lesions illustrated: Synovial cyst, Schwannoma, Foreign body, Myofibroma, Hemangioma, Subungual exostosis, Pyogenic Granuloma

MSEE-24 IMAGING CHAGAS DISEASE: A MULTIMODALITY MULTISYSTEMIC REVIEW FOR RADIOLOGISTS

Matheus Tonholo Ikedo, MD (*Presenter*)
Iuri Shen De Lacerda, MD (*Abstract Co-Author*)
Thiago Matheus Santos Rios, MD (*Abstract Co-Author*)
Luiza A. Oliveira Gatto, MD (*Abstract Co-Author*)
Juliana Helena Manso Brandao, MD (*Abstract Co-Author*)
Artemis D. Alves, MD (*Abstract Co-Author*)
Cinthia D. Ortega, MD,PhD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)
Natalia K. Fujiwara, MD (*Abstract Co-Author*)
Ralph R. Tavares, MD (*Abstract Co-Author*)
Manoel S. Rocha, MD, PhD (*Abstract Co-Author*)
Leandro T. Lucato, MD, PhD (*Abstract Co-Author*)
Izaely R. Prates, MD (*Abstract Co-Author*)
Shri Krishna Jayanthi, MD (*Abstract Co-Author*)

TEACHING POINTS

1.To review the pathophysiology of Chagas disease, including the life cycle of Trypanosoma cruzi and its effects on key organ systems. 2. To identify the clinical manifestations of Chagas disease, distinguishing between the acute and chronic phases, with emphasis on cardiovascular, gastrointestinal, and neurological involvement. 3. To analyze the roles of various imaging modalities, including echocardiography, CT, MRI, and scintigraphy, in the diagnosis and monitoring of Chagas disease. 4. To evaluate clinical scenarios where multimodality imaging is essential for accurate diagnosis and effective management of Chagas disease, particularly in endemic regions. 5. To compare Chagas disease with other conditions that present with similar imaging findings, enhancing differential diagnosis skills.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Overview of Chagas disease, its pathophysiology, parasitic life cycle, epidemiology, and clinical significance. 2. Radiological Manifestations: Imaging findings across key systems—cardiovascular, gastrointestinal, neurological, abdominal, and pulmonary. 3. Radiological Differential Diagnosis: Key radiological features distinguishing Chagas disease from other conditions with similar imaging presentations. 4. Take Home Messages: Key points for radiologists in diagnosing and managing Chagas disease, focusing on the multimodality approach and imaging insights.

MSEE-25 UPDATES ON IMAGING FOR SCREENING AND SURVEILLANCE FOR ABDOMINOPELVIC NEUROENDOCRINE NEOPLASMS

Ajaykumar C. Morani, MD (*Presenter*)
Linda C. Chu, MD (*Abstract Co-Author*)
Mayur K. Virarkar, MD (*Abstract Co-Author*)
Ritu Shah (*Abstract Co-Author*)
Ashni Terapalli (*Abstract Co-Author*)
Sai Vasa (*Abstract Co-Author*)
Priya R. Bhosale, MD (*Abstract Co-Author*)

TEACHING POINTS

Neuroendocrine neoplasms (NENs) have shown a significant increase in incidence and prevalence in the recent decades, primarily due to improved cross-sectional imaging, expanded use of endoscopic procedures and advanced genetic analysis. However, detection of the hereditary NENs is still a challenge due to heterogeneity in their presentation, variety of neoplastic locations and associated syndromes. Long term (or may be lifelong) follow-up imaging is needed not only for screening of these hereditary NENs, but also for surveillance of hereditary as well as sporadic NENs. This is because some of the hereditary NENs may even be detected in late adult life and, recurrence or metastatic disease may occur even up to or after 10 years after the curative treatment for prior NENs. Early detection and timed management can significantly reduce morbidity and mortality in these cases, for which comprehensive screening and surveillance programs centered around anatomic and functional imaging are needed in addition to biochemical tests, genetic counseling and testing for at-risk relatives to identify carriers.

TABLE OF CONTENTS/OUTLINE

1) Introduction: Hereditary and sporadic NENs 2) National Comprehensive Cancer Network (NCCN) guidelines for: A) Screening of Hereditary NENs a) Hereditary Gastroenteropancreatic (GEP) NENs (e.g. MEN1, NF1, tuberous sclerosis, etc.) b) Hereditary GU NENs (e.g. VHL, MEN2, NF1, pheochromocytoma/paragangliomas, etc.) B) Surveillance guidelines for hereditary and sporadic NENs a) GEP NENs b) GU NENs 3) Role of anatomic and functional Imaging including CT, MRI, PET-CT with different tracers including FDG & somatostatin analog tracers like DOTATATE with illustrations 4) Conclusion

MSEE-26 UNDER PRESSURE: HOW RADIOLOGY REDEFINES THE DIAGNOSTIC AND THERAPEUTIC PATH IN SECONDARY HYPERTENSION

Giulia Beggiato, MD (*Presenter*)
Andrea De Grandis, MD (*Abstract Co-Author*)
Carlo D'Alessandro, MD (*Abstract Co-Author*)
Irene Toniolo, MD (*Abstract Co-Author*)
Giacomo Negro, MD (*Abstract Co-Author*)
Giovanni Sussan, MD (*Abstract Co-Author*)
Francesco Fusco, MD (*Abstract Co-Author*)
Teresa Maria Seccia (*Abstract Co-Author*)
Gian Paolo Rossi (*Abstract Co-Author*)
Emilio Quaia, MD (*Abstract Co-Author*)
Filippo Crimi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Hypertension is one of the principal risk factors for cardiovascular diseases, with a large role in overall death and disability. Secondary hypertension (SH) is due to an identifiable and treatable cause. Hypertension with renovascular origin can be identified with radiological imaging. Also renovascular disorder can be treated with interventional radiology (IR) procedures, that may be life saving in emergency situations like the Pickering syndrome. Primary Aldosteronism (PA) as a cause of SH uses both radiological imaging and IR for diagnostic purposes, and to lead the surgical therapy. Soon radiomic analysis will provide insight into the activity of adrenal

adenomas (AA). IR may also increase its importance in SH treatment thanks to percutaneous ablation as a mean to treat pheochromocytomas and functioning adenomas (FA) as causes of SH.

TABLE OF CONTENTS/OUTLINE

1. Characteristics suggestive of SH and its types 2. Renovascular hypertension (RVH): fibromuscular dysplasia and atherosclerosis as a cause and their physiopathology 3. RVH diagnosis: renal arterial duplex ultrasound technique, anatomical pitfalls and data interpretation; renal arteries CT and MRI study 4. RVH interventional radiology treatment: indication and technical application of renal angioplasty and stenting; emergency management and Pickering syndrome 5. PA: radiology role in diagnosis, CT and MRI characterization of AA, 6. Radiomics and AI: predictive models for subclinical FA 7. IR to lead the correct treatment: adrenal veins sampling objective, preparation and technique 8. Percutaneous ablation of AA and pheochromocytomas with curative intent: indications, risk and prevention of hypertensive crisis, ablation methods

MSEE-27 MULTIMODALITY IMAGING OF MEDIAN ARCUATE LIGAMENT SYNDROME

Grant Yoneoka, MD (*Presenter*)
Katerina Konstantinoff, MD (*Abstract Co-Author*)
Malak Itani, MD (*Abstract Co-Author*)
Sharlene A. Teefey, MD (*Abstract Co-Author*)
Mark J. Hoegger, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to: *Illustrate normal anatomy and pathophysiology of median arcuate ligament syndrome (MALS) using multimodality imaging, including CT, MR, ultrasound, and conventional angiography. *Describe a clinical framework for the diagnostic and therapeutic evaluation of MALS. *Review expected post-operative findings and complications.

TABLE OF CONTENTS/OUTLINE

*Epidemiology and presentation *Anatomy: normal celiac trunk and median arcuate ligament anatomy *Clinical approach to MALS: diagnostic and therapeutic framework for MALS, election considerations between imaging modalities *CT angiography: CTA technique and protocol, normal CTA appearance, and CTA findings of MALS *Ultrasound assessment: ultrasound technique, normal grayscale and Doppler appearance, and contrast-enhanced ultrasound *MR angiography: MRA technique and protocol, normal MRA appearance, and MRA findings of MALS *Conventional angiography *Treatment approaches: median arcuate release, adjunct procedures such as angioplasty, stenting, ganglia block, and celiac bypass *Post-operative imaging and complications *Imaging pitfalls: variant anatomy and mimics

MSEE-28 SKIN DEEP INSIGHTS: HIGH-FREQUENCY ULTRASOUND IN DERMATOLOGIC TUMOR ASSESSMENT

Andrea G. Leite, MD (*Presenter*)
Caio Nunes, MD (*Abstract Co-Author*)
Jacqueline Nascimento, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Victor Arthur Ohannesian (*Abstract Co-Author*)
Youssef Bazzoun (*Abstract Co-Author*)
Victor A. Jabour, MD (*Abstract Co-Author*)
Roberto A. Kobayashi (*Abstract Co-Author*)
Eliane E. Dutenhefner, MD, BDS (*Abstract Co-Author*)
Erika T. Koshimura (*Abstract Co-Author*)
Miguel J. Neto (*Abstract Co-Author*)
Marcelo R. Silva, MD (*Abstract Co-Author*)
Marcos R. Queiroz, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

Highlight the increasing role of high-frequency dermatologic ultrasound (HFUS) for non-invasive, high-resolution imaging of skin tumors and metastases. Demonstrate how HFUS surpasses computed tomography (CT) and magnetcic resonance imaging (MRI) in detailed visualization of key malignancy features (invasion depth, thickness, irregular margins, microcalcifications, vascularity). Emphasize the correlation between HFUS imaging findings and histopathological results in a case series from a referral center. Illustrate the crucial role of HFUS in diagnosis, clinical management, surgical planning, locoregional evaluation, and follow-up of skin tumors. Present characteristic HFUS features of basal cell carcinoma (BCC), squamous cell carcinoma (SCC), metastasis, Merkel cell carcinoma, and melanoma to aid radiologist identification. Underscore HFUS as a promising method complementing dermatologic diagnosis despite challenges in differentiating benign/malignant and histopathological types.

TABLE OF CONTENTS/OUTLINE

Epidemiology and main features of skin cancer The emerging role of HFUS in evaluating dermatological lesions Skins neoplasms ultrasound correlation with histopathology Representative cases from a dermatologic ultrasound service in a specialized hospital Imaging Findings: characteristics of BCC, SCC, metastasis, Merkel cell carcinoma and melanoma Conclusion and take-home messages

MSEE-29 THE DARK SIDE OF AESTHETIC ENHANCEMENT: A RADIOLOGIST'S GUIDE TO FOREIGN MODELING AGENT REACTIONS

Montserrat M. Cuadra, MD (*Presenter*)
Daniela Briones, MD (*Abstract Co-Author*)
Mario Calva, MD (*Abstract Co-Author*)
Hugo A. Cervantes Flores, MD (*Abstract Co-Author*)
Maria F. Ortiz Haro y Nasar, MEd (*Abstract Co-Author*)
Yeni Fernandez de Lara Barrera, MD (*Abstract Co-Author*)
Johnatan Rubalcava Ortega, MD (*Abstract Co-Author*)

TEACHING POINTS

• Illustrate the appearance of a wide range of foreign modeling agents used in cosmetic procedures across imaging modalities (US, CT, PET-CT, MRI). • Present case-based examples of Foreign Modeling Agent Reactions (FMAR) from mild to severe. • Define and visualize iatrogenic allogenosis — foreign-body-induced tissue responses to non-biocompatible materials. • Integrate radiological, surgical, and histopathological correlations to explain FMAR mechanisms. • Highlight key findings and red flags to suspect adverse reactions across imaging modalities (US, CT, PET-CT, MRI).MeMention the main differentials and potential pitfalls of FMAR.

TABLE OF CONTENTS/OUTLINE

Introduction and background Definition of iatrogenic allogenosis and foreign modeling agent reactions (FMAR) Pathophysiology of foreign-body induced tissue responses. Case presentation of reactions from mild to severe including: - Edema - Granulomas - Infection - Fat Necrosis - Systemic siliconosis - Myositis and compartment syndrome Main differentials and potential pitfalls of FMAR Conclusions and Take home points.

MSEE-30 TINY PATIENTS, TANGLED VESSELS: DIAGNOSING PEDIATRIC VASCULITIS

Eugene Nishi, MD (*Presenter*)
Yuko Tsujioka, MD, PhD (*Abstract Co-Author*)
Gen Nishimura (*Abstract Co-Author*)
Tatsuo Kono, MD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Pediatric vasculitis encompasses a diverse group of disorders characterized by inflammation of blood vessels, leading to multi-organ dysfunction. Early diagnosis is essential to initiate therapy and prevent irreversible morbidities. As with viral infection, affected children present with non-specific inflammatory symptoms, such as fever, fatigue, and rash, making clinical diagnosis challenging. Distinct childhood-specific vasculitic phenotypes exist. IgA vasculitis is the most common, while Kawasaki disease ranks second in prevalence. Genetic defects in interferon metabolism cause infantile-onset chilblain vasculitis. Other pediatric vasculitides overlap with adult-onset forms, though prevalence and outcomes differ between these groups. Pediatric-specific diagnostic strategies are essential when evaluating affected children. Radiologists should recognize the broad spectrum of imaging findings across vasculitis subtypes to support multidisciplinary management. This presentation aims to summarize the current imaging perspectives of pediatric vasculitis.

TABLE OF CONTENTS/OUTLINE

Introduction—Large vessel vasculitis (Takayasu arteritis)—Medium sized vessel vasculitis (Kawasaki disease, childhood polyarteritis nodosa, etc.)—Small vessel granulomatous vasculitis (granulomatosis with polyangiitis, eosinophilic granulomatosis with polyangiitis)—Small vessel granulomatous vasculitis (IgA vasculitis, microscopic polyangiitis, etc.)—Others (Behcet disease, Cogan syndrome, vasculitis associated with connective tissue diseases, isolated vasculitis of the CNS, inteferonopathy-related vasculitis)

MSEE-31 BEHÇET'S DISEASE: A REVIEW OF MULTI-SYSTEM IMAGING FINDINGS

Amar Shah, MD (*Presenter*)
Matthew T. Stib, MD (*Abstract Co-Author*)
Nicholas G. Matthees, MD (*Abstract Co-Author*)
Kalen Riley, MD, MBA (*Abstract Co-Author*)
David M. Melville, MD (*Abstract Co-Author*)
Cole P. Thompson, MD (*Abstract Co-Author*)
Roman Shrestha, MD (*Abstract Co-Author*)
Sedat G. Kandemirli, MD (*Abstract Co-Author*)
Darpan R Thakare (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)

TEACHING POINTS

Behçet’s Disease (BD) is a variable vessel vasculitis with multisystem clinical presentation. Imaging plays a role in diagnosis, management & surveillance. * BD presents as venous thrombosis and arterial pseudoaneurysms across various systems. Mucocutaneous and vascular systems are most commonly affected while the central nervous system and thorax are the most common sites of imaging findings. Other involved sites include gastrointestinal and musculoskeletal systems. * Management is individualized according to organs involved, severity of leading manifestations, age, and sex. * Imaging predicts prognosis. Increased mortality is associated with vascular and neurologic involvement.

TABLE OF CONTENTS/OUTLINE

Epidemiology * Pathology * Diagnosis * Clinical Features * Role of Radiology * Imaging Manifestations: Mucocutaneous: Oral and genital ulcers, folliculitis, erythema nodosum-like lesions, superficial thrombophlebitis. Ocular: Posterior or panuveitis, retinal vessel occlusion. Cardiovascular: Deep vein thrombosis, arterial narrowing, aneurysm, and occlusion, pericarditis, ruptured sinus of Valsalva, intracardiac thrombosis, periaortic pseudoaneurysm. Pulmonary: Recurrent pneumonia, subpleural alveolar infiltrates, pulmonary infarction, and hemorrhage. Gastrointestinal: Ulcers and complications, postoperative ulcer recurrence, downhill esophageal varices, Budd-Chiari syndrome due to thrombosis, pancreatitis. Mimicker of IBD. Central Nervous System: Parenchymal lesions, venous thrombosis, arterial aneurysm, occlusion, and dissection. Musculoskeletal: Arthritis, enthesopathy, avascular necrosis, myositis. * Prognosis * Treatment.

MSEE-32 MULTISYSTEM IMAGING FINDINGS AND COMPLICATIONS OF GLP-1 RECEPTOR AGONISTS: WHAT RADIOLOGIST SHOULD KNOW

Arash Mahdavi, MD (*Presenter*)
Negar Firoozeh, MD (*Abstract Co-Author*)
Farhad Pishgar, MD, MPH (*Abstract Co-Author*)
Antonio C. Westphalen, MD, PhD (*Abstract Co-Author*)
Dushyant Sahani, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the expanding use of GLP-1 receptor agonists (e.g., Semaglutide) and their growing relevance in radiology practice.2. Review multisystem imaging findings involving adipose tissue, muscle, liver, bone, gastrointestinal tract, and CNS.3. Recognize imaging features of key complications, including pancreatitis, gastroparesis, and thyroid malignancy risk.4. Identify drug-specific challenges in nuclear medicine, PET imaging, and gastric emptying studies.5. Equip radiologists with tools to interpret and manage imaging variability related to GLP-1 agonist therapies.

TABLE OF CONTENTS/OUTLINE

With Semaglutide use rapidly expanding, what should radiologists expect across imaging modalities? This exhibit reviews organ-specific changes, including reduced visceral and subcutaneous fat, improved hepatic steatosis, and evolving data on bone density and muscle composition. Can CT scan, ultrasound, or MRI reliably capture these changes?What are the imaging clues for GLP-1-related complications such as pancreatitis, gastroparesis, bowel obstruction, retinopathy, and thyroid cancer risk? How do we adjust for altered gastric emptying on scintigraphy or increased muscle uptake on FDG PET?We also address practical considerations: How long should GLP-1 agonists be withheld before functional imaging? Are new protocol standards needed? This exhibit empowers radiologists to recognize drug-related patterns, avoid interpretation pitfalls, and adapt practice to this fast-changing therapeutic landscape.

MSEE-33 THE SUBSTANCE! IMAGING COMPLICATIONS OF THE “PERFECT” BODY CREATED BY ANABOLIC ANDROGENIC STEROIDS

Beatriz Oliveira, MD (*Presenter*)
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*)
Mariana A. Rodrigues, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)
Thiago M. Baraviera, MD (*Abstract Co-Author*)

TEACHING POINTS

- Discuss the raise in abuse of anabolic steroids - Provide an overview of the side effects caused by the use of anabolic androgenic steroids. - Describe the imaging findings of potential complications related to steroid use, organized by body system. - Contribute to raise awareness of complications of anabolic steroids in imaging evaluation.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION - Define Anabolic Androgenic Steroids - Recognize the increasing trend of misuse, especially among individuals seeking enhanced athletic and aesthetic performance. - Discuss that the misuse of anabolic androgenic steroids leads to serious complications that affect multiple organs and tissues. OBJECTIVE - Highlight the importance of imaging exams in identifying and assessing complications related to anabolic androgenic steroids use. - Describe imaging findings of these potential complications by organ system ->Cardiovascular and Thoracic: cardiomegaly, myocarditis, asymmetric hypertrophic cardiomyopathy with fibrosis, pulmonary thromboembolism, septic embolism. ->Central Nervous System: venous thrombosis, intraparenchymal hematoma. ->Musculoskeletal: myositis and pyomyositis, fasciitis. ->Gastrointestinal system: hepatic adenoma, peliosis, sinusoidal alterations. CONCLUSION - Contribute to accurate diagnosis and early treatment through proper imaging interpretation. - Reinforce the central role of radiologist in diagnosis of anabolic steroids complications, since in some cases patients may deny the use of any substances at first.

MSEE-34 EXTRAMEDULLARY HEMATOPOIESIS: A COMMON ENTITY WITH VARIABLE IMAGING PRESENTATIONS

Anthony Sposato, MD (*Presenter*)
Ashwin Panda, MD (*Abstract Co-Author*)
Marta Braschi Amirfarzan, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the causes of Extramedullary hematopoiesis (EMH), including hematopoiesis deficiencies such as myelofibrosis, anemia, and thalassemia, in the setting of immunosuppressive medication and secondary to hematological malignancies 2. Review the pathophysiology of EMH 3. Review the variable imaging appearance of EMH (radiographs, CT, PET/CT) 4. Present EMH in multiple body parts

TABLE OF CONTENTS/OUTLINE

- Definition and causes of EMH - Review the imaging features of EMH in multiple body parts utilizing a case-based approach: 1. Paraspinal EMH suspected on radiograph, characterized on CT scan, and confirmed by biopsy 2. Giant paraspinal EMH causing symptomatic respiratory distress 3. Perirenal EMH seen on PET/CT in a patient with relapsed lymphoma 4. Presacral EMH in the setting of anticancer medication use

MSEE-35 MELANOMA'S GREAT ESCAPE: THE PATHWAYS OF DISSEMINATION

Nicole Diaz, MD (*Presenter*)
Andreas Rubilar, MD (*Abstract Co-Author*)
Javiera Saldano, MD (*Abstract Co-Author*)
Catalina Ramirez, MD (*Abstract Co-Author*)
Felipe Allendes, MD (*Abstract Co-Author*)
Jaime Recasens, MD (*Abstract Co-Author*)

TEACHING POINTS

-Know the Breslow classification as a prognostic variable. -To understand the pathways of melanoma dissemination. -Know the different forms of presentation of melanoma metastasis in different organs.

TABLE OF CONTENTS/OUTLINE

Relevance and main challenges for radiologist in the staging of metastatic melanoma - Illustrated review of local staging of melanoma. - Review the different dissemination pathways of melanoma, including illustrations ofthe three proposed models: the "stepwise step" model, the "simultaneous spread" model and the "differential spread" model. - Overview of inmune escape and metastasis mechanisms in melanoma. - Pictorial review of the main metastatic sites and their organ-specific imaging presentations, through different imaging techniques. Melanoma is one of the most aggressive and lethal skin neoplasms, with a marked tendency to metastasize to multiple organs via both lymphatic and hematogenous routes. Emerging theories on metastatic dissemination, including the concept of immune escape, highlight the need for a refined diagnostic approach. In this context, radiologists play a key role in actively detecting metastases and recognizing organ-specific imaging patterns, which are reviewed in this presentation.

MSEE-36 ONE DELETION, MANY HITS: A RADIOLOGIC ATLAS OF SMARCB1-DEFICIENT TUMOURS ACROSS THE BODY

Swetha M. Nair, MBBS, MD (*Presenter*)
Nithin Krishnan, MBBS, MD (*Abstract Co-Author*)
Amit Janu, MBBS, MD (*Abstract Co-Author*)
Vasundhara Smriti, MD (*Abstract Co-Author*)
Arpita A. Sahu, MBBS, MD (*Abstract Co-Author*)
Munita Bal, MBBS (*Abstract Co-Author*)
Nitin S. Shetty, MBBS, MD (*Abstract Co-Author*)
Suyash Kulkarni, DDS, DMRD (*Abstract Co-Author*)
Deepa Nair (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the role of the SMARCB1 gene and the SWI/SNF chromatin remodelling complex as a tumour suppressor. 2. Explore the spectrum of SMARCB1-deficient tumours across multiple organ systems. 3. Appreciate the diversity of histomorphological appearances (carcinoma/sarcomas) of tumours resulting from this shared genetic alteration. 4. Recognise the diverse imaging appearances of these tumours across various sites. 5. Assess the prognostic and therapeutic relevance of identifying SMARCB1 loss in clinical practice.

TABLE OF CONTENTS/OUTLINE

1. Genetics: The role of the SWI/SNF chromatin remodelling complex and its SMARCB1 subunit in tumour suppression 2. Spectrum of SMARCB1-Deficient Tumours: Overview of tumours with reduced, mosaic, or absent SMARCB1 expression across organ systems 3. Anatomic Distribution and Imaging Characteristics: A region-wise radiological review of SMARCB1-deficient neoplasms 4. Prognostic and Clinical Implications: The impact of identifying SMARCB1 loss on diagnosis, treatment, and outcomes

MSEE-37 WHAT TO KNOW FOR FEMALE DYNAMIC PELVIC FLOOR MR IMAGING

Man B. Dai, MD (*Presenter*)

TEACHING POINTS

1) Understand normal female pelvic floor anatomy and appearance on MR imaging. 2) Develop a systemic approach for interpreting dynamic pelvic floor MR imaging. 3) Recognize and effectively report female pelvic floor pathologies on dynamic pelvic floor imaging.

TABLE OF CONTENTS/OUTLINE

1) Overview of female pelvic floor prolapse - epidemiology, clinical significance, presentation and treatment. Role of MRI. 2) Normal pelvic floor anatomy. 3) Dynamic pelvic floor MRI protocol. 4) Pictorial review of pelvic floor pathologies on dynamic pelvic floor MRI Quantifications of findings: pubococcygeal line (PCL), H-line, M-line, anorectal angle. Anterior compartment pathologies - cystocele, urethral hypermobility. Middle compartment pathologies - uterine/vaginal prolapse. Posterior compartment pathologies - rectocele, rectoanal intussusception with Oxford Grading scale, peritoneocele, enterocele, sigmoidocele. Spastic pelvic floor syndrome. 5) Sample reporting. 6) Summary and take-home points.

MSEE-38 HERE AND THERE... SYNOVIAL SARCOMAS EVERYWHERE!

Marycarmen E. Flores Duenas, MD (*Presenter*)
Yanet Y. Torres Maza (*Abstract Co-Author*)
Alejandra M. Bonilla Ruiz I, BDS (*Abstract Co-Author*)
Ruth Pareja Maldonado, MD (*Abstract Co-Author*)
Dory Guerrero (*Abstract Co-Author*)
Juan Jose Giron Ramirez (*Abstract Co-Author*)

TEACHING POINTS

Synovial sarcoma (SS) is a rare type of soft tissue sarcoma accounting for 5-10% of cases. It mainly affects adolescents and young adults (mean age 39 years). They originate in primitive mesenchymal cells and not in the synovial membrane. The etiologic cause of SS is believed to be a chromosomal abnormality that is usually present in more than 90% of cases, known as T(x; 18) (P11.2; q11.2). Histologically, it presents in three types: monophasic (most common), biphasic, and poorly differentiated (worse prognosis). It usually occurs near the joints (frequently in the lower extremities, around the knee). However, it can be located in other regions of the body, although much less frequently, in the intra-abdominal or intra-thoracic cavity, or at the level of the head and neck, which is much rarer. As for imaging studies, magnetic resonance imaging is the technique of choice, as it shows areas of hyperintensity, isointensity, and hypointensity, indicating the mixture of cystic and hemorrhagic areas with a signal intensity three times higher. In some cases, tomography may contribute to the identification of calcifications. However, histological confirmation is necessary for diagnosis and treatment. The five-year survival rate is 75%. For this, locoregional (surgery or radiotherapy) or systemic management are available.

TABLE OF CONTENTS/OUTLINE

Intra-thoracic synovial sarcoma.Intra-abdominal synovial sarcoma.Synovial sarcoma in the head and neck.

MSEE-39 PARADIGM SHIFT TOWARD A PATIENT-CENTERED MRI SCREENING STRATEGY FOR GENETIC AND FAMILIAL HIGH-RISK ADULTS

Sarah Eid, MD (*Presenter*)
Katherine M. Krajewski, MD (*Abstract Co-Author*)
Jyothi Priya Jagannathan, MD (*Abstract Co-Author*)
Abdullah S. Al-Yousef, MD (*Abstract Co-Author*)
Kyung Won Kim, MD (*Abstract Co-Author*)

TEACHING POINTS

• MRI screening is increasingly used for early cancer detection in individuals with hereditary cancer syndromes, offering a high-sensitivity imaging tool. • Growing shift to gene-based, multi-organ MRI strategies tailored to individual genetic and familial risk. • Radiologists must be familiar with hereditary cancer syndromes, associated gene mutations, and current MRI screening recommendations to interpret risk-adapted imaging protocols.

TABLE OF CONTENTS/OUTLINE

1) Introduction to MRI-Based Screening and the Radiologist's Role Increasing incorporation of MRI screening for hereditary cancer syndromes Paradigm shift toward gene-based, multi-organ MRI screening Radiologists' role: integrating genetic/familial risk into personalized protocols 2) Summary of Cancer-Based Screening Strategies Using MRI Importance of radiologist familiarity with MRI screening guidelines MRI screening recommendations now span a range of cancers and associated gene mutations: including breast, ovarian, prostate, pancreatic, hereditary colorectal, and renal cancers, as well as Li-Fraumeni syndrome, neurofibromatosis types 1 and 2, pheochromocytoma/paraganglioma, and multiple endocrine neoplasia types 1 and 2. 3) Clinical Cases MRI representative cases illustrating early cancer detection. Emphasis on the impact of personalized, precision screening in high-risk individuals

MSEE-41 NEXT-GENERATION T-CELL ENGAGING ANTI-CANCER THERAPIES: CAR-T, BISPECIFIC ANTIBODIES, AND T-CELL ENGAGERS: WHAT RADIOLOGISTS SHOULD KNOW?

Kyung Won Kim, MD (*Presenter*)
Jimi Huh, MD (*Abstract Co-Author*)
Chong Hyun Suh, MD, PhD (*Abstract Co-Author*)
Nari Kim (*Abstract Co-Author*)
Sarah Eid, MD (*Abstract Co-Author*)
Saurabh Pallod, MD,DMRD (*Abstract Co-Author*)
Katherine M. Krajewski, MD (*Abstract Co-Author*)

TEACHING POINTS

To provide radiologists with a comprehensive understanding of next-generation T-cell engaging immunotherapies, specifically CAR-T cells, bispecific antibodies (BsAbs), and bispecific T-cell engagers (BiTEs), highlighting their mechanisms, clinical applications, imaging findings, and immune-related adverse events, enabling improved interpretation and multidisciplinary care in cancer imaging.

TABLE OF CONTENTS/OUTLINE

1. Overview of T-cell Engaging Therapies - Mechanisms of action of CAR-T, BiTEs, and BsAbs. - Comparison of structural design and immunologic synapse formation. 2. Current Clinical Applications and Agents - FDA-approved agents: Axicabtagene ciloleucel, Blinatumomab, Teclistamab, etc. - Indications in hematologic and solid malignancies. 3. Imaging Patterns of Treatment Response - Usual response pattens including early dramatic response - Atypical response patterns including pseudoprogression and hyperprogression. - Limitations of RECIST and LUGANO and the role of iRECIST and LYRIC. 4. Imaging of Immune-related Toxicities - Cytokine Release Syndrome (CRS), Immune effector Cell-Associated Neurotoxicity Syndrome (ICANS), and opportunistic infections. - Radiologic clues for early identification. 5. What Radiologists should know? - Suggested imaging protocols and timepoints in clinical trials. - Checklist for structured reporting and communication tips in tumor boards.

MSEE-42 "NINJA TUMORS": THE RADIOLOGIST'S CHALLENGE IN DETECTING TUMORS OF UNKNOWN PRIMARY

Kyohei Tsuchida, MD (*Presenter*)
Masashi Asano, MD (*Abstract Co-Author*)
Kaneko You (*Abstract Co-Author*)
Shingo Omata, MD (*Abstract Co-Author*)
Yoshifumi Noda, MD, PhD (*Abstract Co-Author*)
Nobuyuki Kawai, MD, PhD (*Abstract Co-Author*)
Tetsuro Kaga, MD, PhD (*Abstract Co-Author*)
Yukiko Takai (*Abstract Co-Author*)
Hiroki Kato (*Abstract Co-Author*)
Masayuki Matsuo, MD (*Abstract Co-Author*)

TEACHING POINTS

- To demonstrate the imaging features of tumors of unknown primary origin, including those with regressed, masked, or ectopic primaries.- To outline a systematic diagnostic approach that integrates imaging findings with clinical and laboratory data.- To emphasize the radiologist's role in localizing and characterizing elusive primaries, impacting patient care.

TABLE OF CONTENTS/OUTLINE

1. Concept - Definition and clinical importance of tumors with elusive or undetectable primaries2. Case-Based Imaging Review of "Ninja Tumors" by Pathophysiologic Categories - Regressed/small primaries: burned-out testicular tumor, occult thyroid tumor, occult breast cancer, AFP-producing gastric carcinoma- Lack of tumor markers: small cell prostate carcinoma with low PSA- Extensive metastasis obscuring origin: primary peritoneal carcinoma, low-grade appendiceal mucinous neoplasm- Ectopic origin: papillary carcinoma in ectopic thyroid tissue, cryptorchidism-related seminoma3. Diagnostic and Management Strategy - Recognition of metastatic pathways (lymphatic, hematogenous, transcoelomic)- Integration of tumor markers (AFP, pro-GRP, CA-125, PSA, etc.) with imaging- The impact of identifying the primary tumor on treatment decisions and prognosis4. Conclusion Awareness of these "Ninja Tumors" and recognition of imaging and clinical patterns can guide appropriate diagnostic testing and improve patient outcomes.

MSEE-43 FROM HEAD TO TOE: ROLE OF WHOLE-BODY MRI IN LI-FRAUMENI SYNDROME

Maria Eduarda De Oliveira Fernandes (*Presenter*)
Alexandre S. Morgado (*Abstract Co-Author*)
Matheus Martins de Andrade, MD (*Abstract Co-Author*)
Gabriel Alves, MD (*Abstract Co-Author*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Li-Fraumeni Syndrome (LFS) is an autosomal dominant hereditary cancer syndrome caused by a mutation in the TP53 tumor suppressor gene and development of multiple neoplasms. Whole-Body MRI (WB-MRI) is a highly sensitive method for screening for surveillance in LFS patients, without ionizing radiation exposure. This study aims to discuss the role of WB-MRI in the surveillance of patients with LFS, including international protocols recommendations, highlighting its importance in the multidisciplinary management of this genetic condition.

TABLE OF CONTENTS/OUTLINE

Introduction:LFS is a genetic disorder caused by a mutation in a tumor suppressor gene. Approximately 50% of affected individuals develop at least one LFS-associated cancer before the age of 30.Therefore, the implementation of screening and surveillance strategies is essential to identify and treat potential malignancies at an early stage, improving both survival and quality of life. In this context, imaging takes a central role in the follow-up of these patients, with emphasis on WB-MRI, which offers high sensitivity for detecting suspicious lesions without the use of ionizing radiation. Development:Description and discussion of LFS and its most up-to-date follow-up and surveillance protocols, with a focus on the role of imaging studies—particularly WB-MRI—including illustrative case examples from a tertiary public healthcare institution.

MSEE-44 NON-VASCULAR MALFORMATION DISEASES MIMICKING AND MISDIAGNOSED AS COMMON VASCULAR MALFORMATIONS: A PICTORIAL REVIEW

Taiga Matsumoto, MD (*Presenter*)
Hiro Kiyosue, MD (*Abstract Co-Author*)
Hidetaka Hayashi, MD (*Abstract Co-Author*)
Goh Sasaki, PhD, MD (*Abstract Co-Author*)
Yoshitaka Tamura (*Abstract Co-Author*)
Hiroyuki Uetani, PhD (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Vascular malformations are relatively common conditions encountered in everyday clinical practice. Common vascular malformations are classified into low-flow (venous and lymphatic) and high-flow (arteriovenous) malformations based on their hemodynamic characteristics. These malformations arise from errors in the process of vascular development and can present with a variety of clinical manifestations. Some tumors and tumor-like lesions can mimic these common vascular malformations clinically and radiologically, increasing the diagnostic challenge and the possibility of misdiagnosis. Accurate differentiation of vascular malformations from those nonvascular malformation lesions is crucial, as the natural history, treatment strategies, and prognosis of each condition are fundamentally different. Misdiagnosis can lead to inappropriate interventions and delayed treatment, which may adversely affect patient outcomes, especially in the case of potentially malignant diseases. In this exhibition, we will review imaging and clinical features of a variety of diseases that can mimic common vascular malformations with illustrative cases and discuss several points to reduce the risk of misdiagnosis.

TABLE OF CONTENTS/OUTLINE

1.General clinical and imaging features of the common vascular malformations2.Diseases mimicking arteriovenous malformation3.Diseases mimicking venous malformation4.Diseases mimicking lymphatic malformation

MSEE-46 FROM THE GARDEN TO THE READING ROOM: SOME NATURAL RADIOLOGY SIGNS

Catalina Alarcon Del Campo, MD (*Presenter*)
Javier Suarez, MD (*Abstract Co-Author*)
Pablo A. Cikutovic SR, MD (*Abstract Co-Author*)
Carlos R. Riquelme, MD (*Abstract Co-Author*)
Francisco J. Garrido Cisterna, MD (*Abstract Co-Author*)
Alvaro Huete Garin, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Many radiologic signs are named after fruits, flowers, or plant-like forms due to visual resemblance, aiding in recognition and recall. 2. Understanding the clinical significance of these nature-inspired signs is essential for accurate diagnosis and appropriate patient management

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Learning objectives 3. Radiologic signs: Neuroradiology: palm tree sign Abdomen and pelvis: apple core sign, cloverleaf sign, lotus flower sign, nutcracker syndrome, coffee bean sign, onion skin appearance, staghorn calculi, cauliflower morphology Chest: tree-in-bud pattern, ginkgo leaf sign MSK: bamboo spine, rice bodies Pediatrics: greenstick fracture, fallen lily sign 4. Conclusions

MSEE-47 WHOLE-BODY MRI IN ONCOLOGY: FROM FUNDAMENTALS TO CLINICAL PRACTICE

Anna F. Garcia Herrmann, MD (*Presenter*)
Veronica Alarcon, MD (*Abstract Co-Author*)
Mariana C. Kucharczyk, MD (*Abstract Co-Author*)
Fernando D. Losada Lopez, MD (*Abstract Co-Author*)
Lisandro Paganini, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the expanding role of whole-body MRI (WBMRI) in oncologic imaging, from initial detection and staging to treatment response assessment. Review technical fundamentals and standardized acquisition protocols essential for accurate interpretation. Emphasize the importance of structured reporting systems such as MY-RADS

and MET-RADS in response evaluation. Demonstrate, through real-world case examples, how WBMRI provides both functional and anatomical insights into marrow and extramedullary disease in various solid and hematologic malignancies.

TABLE OF CONTENTS/OUTLINE

Introduction "Why Whole-Body MRI?": Overview and limitations of traditional imaging. Whole-Body MRI basics: Key sequences (DWI, Dixon), technical parameters, and acquisition strategies for protocol optimization and workflow efficiency. Clinical applications: Marrow and extramedullary disease detection in various cancers, both solid and hematologic. Interpretation and response assessment criteria: Standardized criteria using MY-RADS and MET-RADS systems. Case-Based review: Imaging examples illustrating typical findings and practical interpretation challenges

MSEE-48 THORACIC DISORDERS WITH MUSCULOSKELETAL SYSTEM INVOLVEMENT

Babina Gosangi, MD, MPH (*Presenter*)

TEACHING POINTS

Numerous medical conditions have multiorgan imaging findings. Here, we review specifically thoracic disorders involving the musculoskeletal system. These correlations are meant to remind the astute clinician that certain thoracic disorders with MSK involvement should trigger a careful evaluation for multisystemic processes.

TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Examples of cases: a. Connective tissue disorders- Rheumatoid arthritis, Raynaud's syndrome, SLE, Dermatomyositis b. Hereditary conditions: Marfan, Ehlers Danlos, sickle cell disease c. Metabolic- Hyperparathyroidism, Renal failure with osteodystrophy and metastatic calcification in the lungs d. Infectious conditions: Tuberculosis, septic embolism e. Neoplastic conditions: lung cancer, melanoma. 3. Conclusion.

MSEE-49 DECODING IGG4-RELATED DISEASE: A MULTISYSTEMIC ABDOMINAL AND PELVIC PERSPECTIVE

Aylen Gonzalez Gonzalez, MD (*Presenter*)
Sofia Pividori, MD (*Abstract Co-Author*)
Mariana Ines Tompkins Palmier, MD (*Abstract Co-Author*)
Julio R. Coronil, MD (*Abstract Co-Author*)
Nicolas Roccatagliata, MD (*Abstract Co-Author*)
Teresa A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

IgG4-related disease (IgG4-RD) is a chronic immune-mediated condition with multisystemic involvement, characterized by fibroinflammatory infiltration of various organs induced by plasma cells that express (immunoglobulin G subclass 4). Radiologic findings are often characteristic and, when correlated with clinical and histopathologic criteria, can avoid unnecessary interventions. Familiarity with organ-specific patterns and key differential diagnoses is essential for radiologists. In this exhibit we will: - Review the typical findings of the IgG4-related abdomen and pelvis. - Classify them according to their location. - Review the keys for diagnosis and their main differential diagnosis.

TABLE OF CONTENTS/OUTLINE

1) Introduction, Clinical and Histopathological findings. 2) Diagnosis and Classification criteria. 3) Role of different modalities. 4) Entities based on location Pancreatic disease Pancreas - Autoimmune Pancreatitis Extrapancreatic disease Bile duct - Sclerosing cholangitis and Gallbladder disease. Kidney and Ureter- Tubulointerstitial nephritis Retroperitoneum - Retroperitoneal fibrosis, lymphoplasmacytic aortitis Mesentery - Sclerosing mesenteritis Prostate - Prostatitis Lymph node - Lymphadenopaty 5) Differential diagnosis Infections Inflammatory Neoplasms 6) Conclusions 7) Summary

MSEE-50 STATE-OF-THE-ART IMAGING BIOMARKERS IN SCREENING OF CARDIOVASCULAR DISEASE

Prabhakar Rajiah, MD, FRCR (*Presenter*)

TEACHING POINTS

Cardiovascular disease (CVD) is the leading cause of morbidity and mortality. Atherosclerosis is a long, progressive, silent process that may manifest first as an acute event. 1. To discuss categories of cardiovascular risk 2. To discuss the goals of screening for CVD in asymptomatic individuals. 3. To review the current clinical strategy for screening CVD. 4. To explore the state-of-the-art imaging tools available for screening CVD.

TABLE OF CONTENTS/OUTLINE

A. Introduction B. Strategies for CVD screening C. Risk prediction tool - ASCVD calculator-age, gender, race, smoking blood tests (lipids, glucose), BP - SCORE 2, SCORE 2-OP D. Lab biomarkers- ApoA, ApoB, hs-CRP, BNP, lipoprotein (a) [Lp(a)], cholesterol remnants, LDL particles, etc E. Early tests - Stress ECG, exercise testing F. Imaging tests and biomarkers used for screening CVD- Discussion with case examples i. Coronary artery calcium score ii. Calcium score from routine chest CT, x ray iii. Coronary plaque characterization iv. Plaque quantification- Qualitative, semi-quantitative, quantitative v. Peri-coronary adipose tissue attenuation (PCAT)- vi. Epicardial adipose tissue (EAT) quantification vii. Coronary artery stenosis assessment viii. Radiomics ix. Other calcium- aortic valve, mitral annulus, thoracic aorta, abdominal aorta x. Carotid-intimate media thickness xi. Carotid MRI xii. Aortic arterial stiffness xiii. Aortic MRI xiv. Ankle brachial index xv. Breast arterial calcification xvi. Brain white matter hyperintensities G. Imaging for risk assessment and secondary prevention i. CT-fractional flow reserve ii. Myocardial perfusion iii. Extracellular volume iv. Late iodine enhancement v. Bone mineral density, liver attenuation

MSEE-51 MULTIMODALITY IMAGING OF COMPLICATIONS OF DIABETES MELLITUS

Prabhakar Rajiah, MD, FRCR (*Presenter*)
Kevin R. Kalisz, MD (*Abstract Co-Author*)
Sudhakar K. Venkatesh, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. To review the pathophysiology of diabetesmellitus (DM).2. To discuss the complications related to DM. 3. To describe the role of imaging in theevaluation of DM complications. 4. To illustrate the imaging appearances of variouscomplications of DM.

TABLE OF CONTENTS/OUTLINE

1. DM- Pathophysiology 2. Role of Imaging- Radiograph, ultrasound,CT, MRI, nuclear medicine, echocardiography3. Discussion and illustration of thefollowing complications of DM with case examples A. Cardiac - Coronary artery disease- CardiomyopathyB. Vascular - Peripheral arterial disease- Medial arterial sclerosisC. Thoracic - InfectionsD. Gastrointestinal - Fatty liver- Emphysematous cholecystitis- Pancreatitis- Pancreatic atrophy- Actue necrotizing esophagus- Pneumatosis cystoides intestinalisE. Genitourinary - Xanthogranulomous pyelonephritis- Emphysematous pyelonephritis/cystis- Renal papillary necrosis- Medullary nephrocalcinosis- Renal papillary necrosis- Renal abscess- Renal disease- Polycystic oveary- Vascular erectile dysfunction- Calcified vas defernsF. Musculoskeletal - Neuroarthropathy- Myopathy- Necrotizing fasciitis- Fournier's gangrene- Amyloid deposits- Spinal epidural abscess- Osteomyelitis- Spondylodiscitis- Muscle denervation- Insulin ballG. Breast - MastopathyH. Neurologic - Stroke- Non-ketotic hyperglycemia hemichorea- Dementia- Malignant otitis externa- Hyperostotosis frontalis interna- Neuropathy

MSEE-52 STATE-OF-THE-ART PHOTON COUNTING CT IN MULTISYSTEM VASCULAR IMAGING

Prabhakar Rajiah, MD, FRCR (*Presenter*)

TEACHING POINTS

To review the benefits of photon-counting detector (PCD) CT in vascular imaging To discuss the parameters to be optimized for PCD-CT in vascular imaging To illustrate the clinical applications of PCD-CT in vascular imaging

TABLE OF CONTENTS/OUTLINE

PCD CT TECHNOLOGIES Single source, Dual-source BENEFITS OF PCD-CT -a) Ultra-high spatial resolution b)Multi energy (ME) imaging c)K-edge imaging- multi/novel contrast media d) High vascular signal e) Low electronic noise & artifacts f)Lower radiation & contrast doses TECHNICAL ASPECTS FOR VASCULAR IMAGING a)Scan modes- Ultra-high resolution (UHR), multi-energy, UHR-ME, Flash-ME, gated/ungated b)Kernels- Smooth, Sharp c) Collimation, matrix d) Images - Single energy (T3D), VMI, Material-specific (iodine, Virtual non contrast, virtual non calcium) e) Radiation doses, CARE keV VASCULAR APPLICATIONS OF PCD CT WITH CASE SAMPLES a)UHR - Improved small vessel visualization (Perforator flaps; Artery of Adamkiewicz; arteries of hand, feet, head), calcified plaques, small stents b)High iodine CNR (low-energy VMIs)- Low contrast dose studies, salvage of suboptimal-enhanced studies c) Decreased artifacts - Calcium blooming, beam hardening, metal d)ME calcium separation Improved lumen visualization e)ME bone subtraction - Rapid and accurate f)ME lesion characterization hematoma vs active bleed vs calcification g) Vascular perfusion - Lung, myocardium, extremities h) Multi-contrast,novel contrast media - e.g. iodine and gadolinium i)Advanced material separation - Calcium j) Radiation dose reduction - VNC in multiphasic studies, lower noise profile LIMITATIONS, PITFALLS a) Image storage and transfer issues b)Noise in UHR c) Artificial-looking images

MSEE-53 NOW SCREENING: THE ROLE OF IMAGING IN SURVEILLANCE OF PATIENTS WITH CANCER PREDISPOSITION SYNDROMES

Victoria Chernyak, MD, MS (*Presenter*)
Milana Flusberg, MD (*Abstract Co-Author*)
Mariya Kobi, MD (*Abstract Co-Author*)
Lyndon Luk, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review various cancer predisposition syndromes, including genetic mutations and associated cancers 2. To learn about imaging surveillance recommendations for various cancer predisposition syndromes3. To learn the recommended imaging modalities for various surveillance strategies

TABLE OF CONTENTS/OUTLINE

1. Background: a. Objectives of surveillance b. Imaging modalities for cancer surveillance 2. Breast Cancer a. BRCA1/2 mutation, Li Frumeni, PALB2/CHEK2/ATM/CDH1 mutations, Cowden syndrome, Hereditary Diffuse Gastric Cancer, Peutz-Jeghers Syndrome b. Annual breast MRI in addition with annual mammography with tomosynthesis 3. Ovarian cancer a. BRCA1/2 mutation, Lynch syndrome b. Transvaginal ultrasound with serum CA-125 4. Pancreatic Cancer a. Familial pancreatic cancer syndrome, Peutz-Jeghers syndrome, hereditary pancreatitis, Lynch syndrome, BRCA1/BRCA2/PALB2/ATM/ CDKN2A mutations b. MRI/magnetic resonance cholangiopancreatography and endoscopic ultrasound 5. Colorectal cancer a. Lynch syndrome, familial adenomatous polyposis, Peutz-Jeghers syndrome, juvenile polyposis syndrome b. Screening with colonoscopy; the age at initial screening varies by syndrome 6. Thyroid cancer a. Multiple endocrine neoplasia type 2, PTEN hamartoma syndrome, familial adenomatous polyposis type 1 b. Thyroid ultrasound 7. Renal cancer a. Von Hippel-Lindau syndrome, Hereditary Leiomyomatosis and Renal Cell Cancer syndrome, Birt-Hogg-Dubé syndrome, tuberous sclerosis b. Annual CT or MRI 8. Li-Fraumeni Syndrome (TP53 mutation): a. Close to 100% lifetime cancer risk b. Whole-body MRI for annual surveillance

MSEE-55 CUSHING SYNDROME

Benjamin Srivastava (*Presenter*)
James Hwang, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Khaled M. Elsayes, MD, PhD (*Abstract Co-Author*)
Rachita Khot, MD (*Abstract Co-Author*)
Ajay Malhotra, MD, MMM (*Abstract Co-Author*)
Shehbaz M. Ansari, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. MRI plays an essential role in the diagnosis of Cushing's disease caused by an ACTH-secreting pituitary adenomas2. Dedicated adrenal imaging with CT or MRI differentiates ACTH-independent Cushing’s syndrome3. Integration of imaging findings of Cushing’s disease and syndrome with clinical and laboratory values helps to avoid misdiagnosis4. Ectopic ACTH Syndrome and adrenal tumors may also result in the development of Cushing’s Syndrome5. Early detection and appropriate management of Cushing's disease are vital to prevent complications and improve patient outcomes.

TABLE OF CONTENTS/OUTLINE

1. Pathophysiology of Cushing’s syndrome spectrum- differentiation and clinical/laboratory presentation2. Exogenous causes, associated conditions and role of imaging CT/MR/US:o prolonged use of corticosteroid medications (prednisone, ect) in pts with asthma, lupus, or rheumatoid arthritis.?3. Endogenous causes and role of imaging CT/MR/US: Pituitary Adenomas (Cushing's Disease) Benign tumors of the pituitary gland that secrete excess adrenocorticotropic hormone (ACTH), stimulating cortisol production. Ectopic ACTH Syndrome (Paraneoplastic syndrome) ACTH is produced by tumors located outside the pituitary gland, such as in the lungs or pancreas. Adrenal Tumors Benign (adrenal adenoma and hyperplasia) or malignant tumors of the adrenal glands (Adrenocortical carcinoma) that produce excess cortisol independently 4. Complications: adrenal hyperplasia, osteoporosis/fractures, avascular necrosis, brain atrophy, cardiovascular changes (LV hypertrophy).5. Most common management and treatment options

MSEE-56 SOMETHING DOES NOT BELONG: ABC’S OF FOREIGN BODIES

Claudia M. Muns, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Gabriel Frattallone, MD (*Abstract Co-Author*)
Larry M. Alejandro Vargas, MD (*Abstract Co-Author*)
Zofia Marrero (*Abstract Co-Author*)
Paola Berrios Jimenez (*Abstract Co-Author*)
Andrea M. Ruiz Mojica, MD (*Abstract Co-Author*)
Amanda P. Marrero-Gonzalez, MD, BS (*Abstract Co-Author*)

TEACHING POINTS

1. Provide a comprehensive review of frequent and uncommon foreign bodies (FB), emphasizing their key imaging features. 2. Review types of FB by location 3. Understanding the expected attenuation of different materials on imaging modalities 4. Discuss the advantages and limitations of various imaging techniques in detecting FB 5. Use a glossary for visual representation, facilitate study, and recognition of FB.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Objectives 3. Anatomy review 4. Expected attenuation of the different foreign body material in US, CT and X-ray (metal, plastic, wood, glass, bones, etc). 5. Review of foreign bodies by etiology: = Arising from ingestion or introduction through natural orifices - Eye, ear - Gastrointestinal and genitourinary tracts - Airway - Vagina = Iatrogenic / post-surgical = Traumatic = Others: Fistula (peritoneal cavity) 6. Complications 7. Structured radiology report 8. Conclusion Abstract: FBs are common in emergency medicine,often presenting diagnostic and management challenges. The management of FBs involves three key considerations: accurate characterization of the material, detection of complications, and effective documentation. This exhibit simplifies FB evaluation through a creative glossary analogy, reviews imaging techniques, and provides guidance on thorough radiology reporting. It aims to educate medical students, residents, and imaging specialists.

MSEE-57 LOCKED, LOADED, AND READY TO SCAN: TRY NOT TO MISS THESE RADIOLOGY SIGNS

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Jorge Machicote, MD, MSc (*Abstract Co-Author*)
Ana Ayala (*Abstract Co-Author*)
Carlos J. Perez, MD (*Abstract Co-Author*)
Jose A. Lara, MD (*Abstract Co-Author*)

TEACHING POINTS

Learn to recognize important radiological findings inspired by weapons and munitions. Use real cases from our institution to apply knowledge to clinical scenarios and improve diagnostic acumen. Participate in a detective-style narrative to investigate radiological signs, for a creative memorable way to remember these signs.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Anatomy Review IV. Weapon signs and imaging findings Suspect Weapon Clues Crime Scene Case Summary VII. Conclusion This exhibit explores over 15 weapon-themed radiologic signs, which aid diagnosis but may be unfamiliar to modern radiologists. Using a detective-themed approach, it presents visual examples, real clinical cases, and a crime-solving narrative to enhance learning. Participants will analyze "clues" and "crime scenes" (imaging modality and anatomical regions), "weapons" (signs/radiologic findings), and identify "suspects" (pathologies) across different imaging modalities from our institution. By integrating creativity with critical thinking, this exhibit improves pattern recognition and diagnostic confidence.

MSEE-58 SEE YOU LATER, RADIO-GATOR! ZOO OF ANIMAL-INSPIRED RADIOLOGY SIGNS

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
John Melendez Moreno (*Abstract Co-Author*)
Amanda P. Marrero-Gonzalez, MD, BS (*Abstract Co-Author*)

TEACHING POINTS

Discuss the most common radiological signs inspired by animals. Explain the background, etiology, and radiological uses of each of the discussed signs. Describe the signs through example cases and illustrations using various imaging modalities.

TABLE OF CONTENTS/OUTLINE

I. Educational Objectives and Introduction II. Discuss signs with imaging examples of the following animal categories: fish and marine life, mammals, birds, arthropods and reptilesIV. Importance in recognitionV. Conclusion ??In this pictorial review, we will showcase a series of classic animal signs inspired by different animal categories, such as fish and marine life, mammals, birds, arthropods and reptiles. These signs, visible across various imaging modalities, will be illustrated with drawings, a public domain image of the animal that inspired its name, and example cases from our institution. Additionally, a concise explanation of the underlying pathology and pertinent information for the referring physician will be provided. A total of 25 radiological signs will be reviewed, including manta ray, fish vertebra, lobster claw, bear paw, beaver tail, camel hump, staghorn calculus, anteater, pig nose, scotty dog, tigroid pattern, butterfly vertebra, cobra, moth eaten, bag of worms, crocodile pancreas, caterpillar, bird's beak, owl eyes, pooping duck and seagull sign. With these animal based signs, we aim to enhance the recognition and understanding of various pathologies.

MSEE-59 THE MSK EPONYM ALPHABET: LETTERS WITH A FRACTURE

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Christopher Quintana (*Abstract Co-Author*)
Ana Ayala (*Abstract Co-Author*)
Elizabeth Trullenque, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review common musculoskeletal fractures and pathologies, emphasizing clinical features and historical relevance. 2. Use a glossary with visuals to help recognize eponyms commonly seen at our institution. 3. Showcase key imaging findings using X-rays, CT, 3D reconstructions, and artwork to support diagnosis and treatment.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Glossary of Terms IV. Cases with Anatomy Diagram and Institutional Case V. Pioneer/Author Image VI. History and Clinical Relevance VII. QuizThis exhibit reviews common musculoskeletal fractures and pathologies, focusing on clinical presentation, historical relevance, and key imaging signs. It includes joint and long bone fractures, common classifications, and osteochondrosis. A glossary of musculoskeletal eponyms is provided, with definitions, and brief history. Imaging features are highlighted through X-rays, CT, and 3D reconstructions of real cases from our institution. By combining clinical, historical, and radiologic perspectives, the exhibit aims to improve recognition, diagnosis, and management of musculoskeletal conditions, while providing a visual learning experience for radiologists, residents, and medical students.

MSEE-60 NEEDLE IN THE CASE STACK: APPROACH TO RADIOGRAPHS FOR RETAINED SURGICALLY PLACED FOREIGN BODIES, TIPS & TRICKS FOR BOOSTING RADIOLOGIST CONFIDENCE

Selin Ocal, MD (*Presenter*)
John Eng, MD (*Abstract Co-Author*)

TEACHING POINTS

• Images obtained to rule out unintentionally retained surgically placed foreign bodies (SFBs) are an anxiety-provoking study type for radiologists. • SFBs are a rare occurrence, and specialized exposure to this topic may not be provided in residency and fellowship programs. These factors contribute to a lack of significant experience and confidence when these studies are interpreted. •Given that positive studies for retained SFBs are uncommon, we provide examples of radiographs that depict SFBs of various levels of "difficulty" to demonstrate the wide range of pitfalls that can occur when interpreting these images. • To improve detection of SFBs and boost confidence, we provide a special framework for radiologists to consider utilizing, in addition to their usual radiographic search pattern.

TABLE OF CONTENTS/OUTLINE

• Unintentionally retained surgically placed foreign bodies (SFBs): what they are, how often they occur, and how different institutions utilize radiography to detect them • The evolving role of the radiologist in identifying SFBs—how culpability extends from the operating room to the reading room • Lack of radiology trainee exposure to these unique studies • Is your existing search pattern enough? Tips and tricks to evaluate these images • Spectrum of difficulty with case examples: positive radiographs with SFBs that were detected by the radiologist (considered "routine" or simpler to detect) and some that were missed by the radiologist (considered "difficult" or harder to detect) • General principles and patterns of "difficult" cases that made detection of SFBs in those instances harder, and what we can learn from them

MSEE-61 IMAGING IN HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH)

Yashant Aswani, MD (*Presenter*)
Pranjal Rai, MBBS (*Abstract Co-Author*)
Shehbaz M. Ansari, MD, MBBS (*Abstract Co-Author*)
Ananya Panda, MD, MBBS (*Abstract Co-Author*)
Mohamad Kayali, MBBCh (*Abstract Co-Author*)

Shreyas Reddy Kankara, MBBS, MD (*Abstract Co-Author*)
Hiba G. Narvel, MBBS (*Abstract Co-Author*)
Chetan Saini, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening condition of excessive immune activation with widespread systemic inflammation & multiorgan dysfunction. This exhibit discusses the following teaching points: 1. Identification of imaging patterns that, in the appropriate clinical context, can provide crucial early diagnostic clues to suspect HLH.2. Radiologic findings in HLH are often nonspecific but can provide early diagnostic clues & help assess complications.3. While radiology is not part of the diagnostic criteria, which is mainly based on clinical findings & laboratory analysis, imaging certainly aids in identifying biopsy sites, monitoring treatment response, and ruling out mimics such as sepsis or lymphoma.4. As awareness of HLH increases, radiologists play a vital role in timely recognition & management.

TABLE OF CONTENTS/OUTLINE

Epidemiology Types Primary HLH Secondary HLH Etiologies Familial HLH (type 1-5) Association with immunodeficiency syndromes Associated viral etiologies (EBV, CMV, HSV, VZV, HIV) Associated malignancies (T or NK cell lymphoma/leukemia & B-cell lymphoma) Associated rheumatological disease (systemic JIA, SLE) Role of radiology Imaging manifestations CNS (multifocal T2 hyperintensities, enhancing parenchymal lesions, brainstem/cerebellar predominant or non-specific atrophy) Pulmonary (ground glass opacities, consolidation, interstitial infiltrates, pleural effusion, ARDS-like) Gastrointestinal (hepatosplenomegaly, lymphadenopathy, ascites, liver focal hypodensities, gallbladder wall thickening) MSK (Osteonecrosis, metaphyseal lucencies, osteopenia, intramuscular hematoma) Prognostication Treatment response

MSEE-62 ULTRASONOGRAPHIC EVALUATION OF HIDRADENITIS SUPPURATIVA: ALL YOU NEED TO KNOW

Delfina Lotti, MD (*Presenter*)
Fatima A. Lezcano Sticchi SR, MD (*Abstract Co-Author*)
Constanza San Miguel, MD (*Abstract Co-Author*)
Micaela Sturnigh, MD (*Abstract Co-Author*)
Joaquin Martinez Pereira, MD (*Abstract Co-Author*)
Jonathan Rosenvasser, MD (*Abstract Co-Author*)

TEACHING POINTS

- To provide an introduction about hidradenitis suppurativa, clinical background, historical aspects, and pathophysiology.- To highlight the importance of an early diagnosis in order to provide an effective treatment.- To learn the main ultrasonographic findings which will allow the initial diagnosis. - To review staging criteria of Hidradenitis Suppurativa and their role in treatment response evaluation. - To enhance the importance of the radiologists role in diagnosis and follow-up of this entity.

TABLE OF CONTENTS/OUTLINE

- Introduction to this underdiagnosed disease.- Normal skin ultrasound and optimal US settings.- Imaging evaluation of Hidradenitis Suppurativa: the importance of ultrasound. * Examination Technique * US Findings: Dermal thickening; Pseunododule/pseudocyst; Fluid collection; Fistulas. - Sonographic Scoring. * Modified sonographic scoring of hidradenitis suppurativa (mSOS-HS). * Activity Scoring (US-HSA)

MSEE-63 FERUMOXYTOL-ENHANCED MRI/MRA OF ABDOMEN, PELVIS, AND PERIPHERAL VASCULATURE

Daniel R. Ludwig, MD (*Presenter*)
Richard Tsai, MD (*Abstract Co-Author*)
Nathan P. Skinner, MD, PhD (*Abstract Co-Author*)
Benjamin S. Strnad, MD (*Abstract Co-Author*)
Anup S. Shetty, MD (*Abstract Co-Author*)

TEACHING POINTS

-Ferumoxytol is an FDA-approved IV iron preparation composed of superparamagnetic iron oxide nanoparticles which is used to treat iron-deficiency anemia. Also a safe and effective off-label MRI contrast agent which may benefit patients with clinical indications for contrast-enhanced MRI/MRA but who have contraindications to gadolinium-based contrast agents (GBCAs) -Due to its long intravascular half-life (~15 hours), steady-state imaging with intense vascular enhancement can be performed up to a day after infusion -Ferumoxytol is taken up by the mononuclear phagocyte system (MPS) 24-72 hours after infusion, accurately differentiating tumor from splenule with delayed imaging -FDA issued a black box warning on ferumoxytol about potential acute hypersensitivity reactions, though the rate of severe allergic reactions is likely similar to GBCAs. Diluted ferumoxytol can be administered safely as either slow infusion or bolus but requires additional clinical monitoring

TABLE OF CONTENTS/OUTLINE

-Background on use of ferumoxytol as off-label imaging agent -Steps needed for institutional approval to use ferumoxytol as an imaging agent -Advantages and disadvantages of ferumoxytol over gadolinium -Discussion and illustration of use cases including applications for bolus injection in scanner and steady-state imaging after slow infusion: MRA of renal and hepatic transplant vasculature; MRA of abdominal aorta and peripheral vasculature (AIF); diagnosis of placenta accreta spectrum pathology; dynamic lesion characterization in a patient unable to receive GBCA; staging or restaging known or suspected malignancy during pregnancy; differentiation of peri-pancreatic splenule from tumor

MSEE-64 PICTORIAL REVIEW OF ABDOMINOPELVIC DISEASES WITH ELEVATED ALPHA-FETOPROTEIN: FROM DIAPHRAGMATIC DOME TO GENITAL AREA

Jian Guan, MD, PhD (*Presenter*)
Shulin Ma (*Abstract Co-Author*)
Guanglei Tang, MBBS (*Abstract Co-Author*)
Rulin Xu (*Abstract Co-Author*)
Yang Peng (*Abstract Co-Author*)

TEACHING POINTS

1. To review the basic knowledge of alpha-fetoprotein (AFP).2. To know normal AFP levels in different age populations and physiological variations. 3. To explore the relationship between various abdominopelvic diseases and AFP elevation. 4. To learn the spectrum of abdominopelvic diseases with elevated AFP in various organs.

TABLE OF CONTENTS/OUTLINE

1. Basic knowledge of alpha-fetoprotein (AFP) (1) Definition and physiological function of AFP;(2) Biosynthesis, production and metabolic pathways of AFP;(3) Normal AFP levels in different age populations and physiological variations 2. Case reviews by organ system: imaging features and clinical relevance(1) Diseases of liver (hepatocellular carcinoma and recurrence, combined hepatocellular and cholangio- carcinoma, hepatoblastoma, acute hepatitis, chronic active hepatitis, cirrhosis, etc) ; (2) Diseases of gallbladder and bile duct (intrahepatic cholangiocarcinoma, hepatoid adenocarcinoma differentiated intrahepatic cholangiocarcinoma, ectopic hepatocellular carcinoma, biliary atresia, etc);(3) Diseases of pancreas (pancreatoblastoma, pancreatic hepatoid carcinoma, neuroendocrine tumor, etc);(4) Diseases of gastrointestinal tract (hepatoid adenocarcinoma);(5) Diseases of kidney (Wilms tumor, eg. teratoid nephroblastoma) and retroperitoneal space (malignant degeneration of retained testicle, immature teratoma, etc);(6) Diseases of reproductive system (Yolk sac tumor, seminoma, immature teratoma, dysgerminoma, mixed germ cell tumor, Sertoli-Leydig cell tumors, etc).3. Summary of abdominopelvic diseases with elevated alpha-fetoprotein.

MSEE-65 AN APPROACH TO MRI FOR CHRONIC PELVIC PAIN

Arjuna Somasundaram, MBBS (*Presenter*)
Tam Tran (*Abstract Co-Author*)

Craig Buchan, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Recognise the radiologist's role in the evaluation of chronic pelvic pain (CPP), a complex multidisciplinary condition. 2. Review the strengths and weaknesses of magnetic resonance imaging (MRI) to identify structural causes of CPP. 3. Review diseases that can cause CPP, their imaging findings and potential diagnostic pitfalls on MRI.

TABLE OF CONTENTS/OUTLINE

Chronic pelvic pain (CPP) is a debilitating condition that affects 15 - 25% of women. 1,2 It is defined as non-malignant pain below the level of the umbilicus that is continuous or intermittent for a minimum of six months duration. 4 The aetiology is complex and multifactorial, contributing to an average time to diagnosis of seven years. 3 MRI provides an effective, non-invasive tool for diagnosing structural causes of CPP. This educational exhibit is a review of MRI for chronic pelvic pain. 1. Definition of CPP. 2. Causes of CPP. 3. Systematic approach to diagnosing CPP, with imaging findings and pitfalls. Gynaecological: Endometriosis, Adenomyosis, Pelvic congestion, Fibroids, Ovarian remnant syndrome, Pelvic inflammatory disease Urological: Urethral diverticula, Cystitis, Prostatitis Anorectal & Pelvic Floor: Perianal disease, Hypertrophic myopathy of the internal anal sphincter, Sigmoid/rectal inflammation, Pelvic floor dysfunction Musculoskeletal & Neurological: Hernias, Neuropathy, Pubic symphysis pathology, Rectus abdominis/adductor pathology, Sacroiliitis, Hip pathology Postoperative complications: Surgical material infection, Hernia recurrence, Malpositioned tacks, Perimesh fibrosis, Nerve impingement

MSEE-66 START FROM SCRATCH! IMAGING FINDINGS OF SPOROTRICHOSIS

Matheus Taborda, MD (*Presenter*)
Nathalia Bonmann, MD (*Abstract Co-Author*)
Regielly Cognialli (*Abstract Co-Author*)
Bruna M. Sarolli, MD (*Abstract Co-Author*)
Bernardo C. Teixeira, MD, PhD (*Abstract Co-Author*)
Dante L. Escuissato, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

- To outline the main clinical and epidemiological characteristics of sporotrichosis.- To understand physiopathological and immunological aspects of Sporothrix infection. - To review imaging findings of sporotrichosis in multiple systems, including osteoarticular, central nervous system, and pulmonary sporotrichosis.

TABLE OF CONTENTS/OUTLINE

This presentation aims to provide a comprehensive overview of the main features of sporotrichosis, including epidemiology, pathology, radiographic features, prognosis, differential diagnosis, and treatment. Using an organ-based approach, we will explore the classic and uncommon imaging manifestations of sporotrichosis, including lymphocutaneous, osteoarticular, central nervous system, and pulmonary sporotrichosis, as well as miscellaneous findings. The presentation will be subdivided in the following categories: 1. Introduction 2. Epidemiology 3. Physiopathology and Immune Response 4. Lymphocutaneous Form 5. Osteoarticular Form 6. Central Nervous System Sporotrichosis 7. Pulmonary Sporotrichosis 8. Miscelaneous 9. Conclusion

MSEE-67 "NEUROTHORACICS" - THORACIC DISEASES WITH NEURO-RADIOLOGICAL MANIFESTATIONS AND VICE VERSA

Alexandre Semionov, MD, PhD (*Presenter*)

TEACHING POINTS

There exist a number of pathological entities with thoracic and neuro-radiological manifestations. When considered separately, imaging findings could be nonspecific. However integration of radiological findings from both body systems can lead to a specific diagnosis based on imaging alone. As a corollary, certain neuroimaging findings should prompt screening of the thorax and vice versa. The purpose of this exhibit is a review of several pathological entities that can have both chest and neuro-radiological manifestations.

TABLE OF CONTENTS/OUTLINE

Each case will be presented as image(s) of thoracic abnormality and image(s) of CNS abnormality. The combination of the thoracic and CNS findings should lead to fairly specific diagnosis. Explanation of the findings and brief review of the pathological entity will be provided. The pathological entities included in the presentation: 1. Tuberous sclerosis 2. Cowden syndrome 3. Langheran's cell histiocytosis 4. TB 5. Sarcoidosis 6. Erdheim-Chester disease 7. Limbic encephalitis 8. AIDS 9. Breast cancer 10. NF1 11. Alcohol abuse 12. Osler-Weber-Rendu 13. IgG4 disease 14. Takayasu's arteritis 15. PRES - preeclampsia 16. Klippel-Feil syndrome 17. Amyloidosis 18. Hyperparathyroidism 19. Septic emboli 20. Granulomatosis with polyangitis.

MSEE-68 ULTRASONOGRAPHIC FINDINGS IN HIDRADENITIS SUPPURATIVA: A GUIDE FOR THE RADIOLOGIST

Cibelle Melo, MD (*Presenter*)
Luara Boson, MD (*Abstract Co-Author*)
Estevao Vargas (*Abstract Co-Author*)
Thiago Lopes (*Abstract Co-Author*)

TEACHING POINTS

Hidradenitis suppurativa (HS) is a chronic, inflammatory skin disorder characterized by recurrent nodules, abscesses, and sinus tracts, predominantly in intertriginous areas such as the axillae and groin. Ultrasound plays a critical role in detecting subclinical anatomical changes and in revealing the often underestimated clinical severity of HS, which is essential for appropriate therapeutic decision-making. The main ultrasonographic features include follicular dilatation, dermal thickening, pseudocysts, fluid collections, sinus tracts, and hair tract remnants. The presence of three or more of these findings has been proposed as a diagnostic criterion for HS. Doppler ultrasound further aids in identifying subclinical fistulous tracts and assessing inflammatory activity. This educational exhibit presents a standardized ultrasound protocol for the evaluation of HS, illustrated through representative clinical cases. The proposed protocol aims to improve diagnostic consistency and enhance patient management by guiding radiologists in the systematic assessment of HS using grayscale and Doppler imaging.

TABLE OF CONTENTS/OUTLINE

1. Overview of hidradenitis suppurativa. 2. Ultrasonographic evaluation protocol and key imaging findings. 3. Educational materials including annotated images and flowcharts derived from a comprehensive literature review. 4. Take-home messages.

MSEE-69 BEYOND THE BONE MARROW: MULTI-MODALITY IMAGING OF EXTRAMEDULLARY DISEASE IN ACUTE MYELOID LEUKEMIA

Shu Suzuki, MD (*Presenter*)
Koichiro Mori, MD (*Abstract Co-Author*)
Yasunobu Takaki (*Abstract Co-Author*)
Mizuka Suzuki, MD (*Abstract Co-Author*)
Noriko Doki (*Abstract Co-Author*)

TEACHING POINTS

•Multimodal imaging approachA comprehensive imaging strategy incorporating CT, MRI, PET/CT and US is essential for the accurate detection and characterization of extramedullary disease (EMD) in acute myeloid leukemia (AML). •Case-based insights into diagnostic challengedsA case-based review highlights the diverse manifestations of EMD in AML, recognizing imaging features to avoid misdiagnosis. •Distinguishing EMD from lymphoma: the significance of ADC valuesAlthough the

imaging findings of EMD are similar to those of lymphoma, the lesion tends toshow lower ADC values, which may be useful for differential diagnosis. incorporating CT, MRI, PET/CT and US is essential for the accurate detection and characterization of extramedullary disease (EMD) in acute myeloid leukemia (AML).

TABLE OF CONTENTS/OUTLINE

•Present classification and epidemiology of AML •General treatment of AML •Case presentation of relatively common sites of extramedullary leukemia; Lymphadenopathy, Hepatomegaly, Splenomegaly •Case presentation of various sites of extramedullary leukemia; Central nervous system, middle ear, lung, bone, skin, gastrointestinal tract, orbit etc. •Comparison of ADC values: extramedullary disease in AML and malignant lymphoma •Diagnostic pitfalls; infection and other malignancy

MSEE-70 IMAGING IN TSUTSUGAMUSHI DISEASE (SCRUB TYPHUS)

Yashant Aswani, MD (*Presenter*)
Galib Mirza Nasirul Islam, MBBS (*Abstract Co-Author*)
Shreyas Reddy Kankara, MBBS, MD (*Abstract Co-Author*)
Nishant Aswani (*Abstract Co-Author*)
Shravan Reddy K, MBBS (*Abstract Co-Author*)
Simmi Kumari, MBBS (*Abstract Co-Author*)

TEACHING POINTS

• Scrub typhus (ST) is a common rickettsial zoonosis endemic to Asia-Pacific region & is transmitted by bite of chigger mites infected with Orientia tsutsugamushi. In the US, it is primarily encountered among travellers • Presents as acute febrile illness with non-specific features. Eschar at site of mite bite & positive serology clinches the diagnosis • Multisystemic involvement is the rule. Underlying pathology is vasculitis & perivasculitis in multiple organs • Imaging features are nonspecific. However, awareness about common features like a combination of gallbladder wall edema, hepatosplenomegaly & reticulonodular lung opacities is crucial to raise suspicion of ST in those at risk & thus prompt specific diagnostic testing. Imaging features are particularly useful in flagging cases of early disease with negative serology or those without the characteristic eschar • ST responds promptly to antirickettsial antibiotics. Delayed institution of antibiotics carries an adverse prognosis; hence early diagnosis is important • Imaging helps with prognostication & early detection of complications like myocarditis & ARDS

TABLE OF CONTENTS/OUTLINE

• Epidemiology • Life cycle of mite • Pathogenesis • Clinical features • Diagnosis o Role of imaging o Imaging manifestations o Pulmonary (reticulonodular opacities, pleural effusion, hilar lymph nodes, ARDS) o Cardiac (reversible cardiomegaly) o CNS (encephalitis & or meningitis, microhemorrhages, PRES, myelitis, ADEM) o Abdomen (gallbladder wall edema, periportal inflammation, hepatosplenomegaly, splenic infarct, lymphadenopathy, hemorrhage, acute renal failure) • Treatment & prognosis • Control measures for mite

MSEE-71 OPPORTUNISTIC CT SCREENING: WHAT, WHY, AND HOW?

Siddhant Dogra, MD (*Presenter*)
Malte Westerhoff (*Abstract Co-Author*)
Soterios Gyftopoulos, MD, MBA (*Abstract Co-Author*)
Ehizokha Ihionkhan, MD (*Abstract Co-Author*)
Miriam A. Bredella, MD, MBA (*Abstract Co-Author*)
Michael P. Recht, MD (*Abstract Co-Author*)
Bari Dane, MD (*Abstract Co-Author*)

TEACHING POINTS

Opportunistic CT screening refers to standardized extraction of imaging biomarkers from routinely acquired CT scans for early risk stratification and proactive intervention. By leveraging imaging data that would otherwise be overlooked, opportunistic screening can deliver measurable patient- and population-outcome benefits without extra radiation, repeat scans, or cost to the patient. AI enables automatic extraction of quantitative data, making opportunistic screening feasible at scale and seamlessly integrable into existing clinical workflows. Common examples of opportunistic screening include assessment of bone mineral density, vascular calcification, body-composition (adiposity, sarcopenia), and hepatic steatosis. Deliberate implementation is key to success, including aligning sensitivity and specificity with institutional priorities, integrating screening into the radiologist workflow, and seamlessly communicating findings to primary-care and specialty referrers

TABLE OF CONTENTS/OUTLINE

1) What is opportunistic screening? (Definition, Historical context and growing clinical interest). 2) Value of opportunistic screening (Patient outcomes, Cost-effectiveness). 3) Common opportunistic screening examples (Body composition [sarcopenia, adiposity]), Bone mineral density, Liver steatosis, Vascular calcifications). 4) Workflow (PACS integration, Dissemination and implementation pathways to primary care providers and specialty referrers). 5) Institutional experience (Adoption timeline, QI metrics, Pitfalls and mitigation strategies). 6) Future directions (Improved AI-assisted quantification, Potential quality measures and reimbursement pathways).

MSEE-72 BODY OF EVIDENCE: RADIOLOGIC MANIFESTATIONS OF KAPOSI SARCOMA FROM HEAD TO TOE

Amir Imanzadeh, MD (*Presenter*)
Shayan Saeed (*Abstract Co-Author*)
Anh-Tho Nguyen (*Abstract Co-Author*)
Malak Itani, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)

TEACHING POINTS

Despite a decreasing incidence of Kaposi Sarcoma (KS), geographic and racial disparities in incidence and survival persist. It is therefore imperative for radiologists to remain aware of KS and raise suspicion in the appropriate clinical context. Although imaging findings are nonspecific, radiologists often identify the presence of visceral disease. Imaging facilitates the diagnosis, staging, and follow-up of KS. KS may be complicated by immune reconstitution syndrome (IRS); in cases of pulmonary KS, IRS may be differentiated by more widespread disease in the latter. This exhibit will present the typical and atypical imaging manifestations of KS in multiple organ systems, and showcase imaging findings and patterns that favor KS

TABLE OF CONTENTS/OUTLINE

1. Epidemiology2. Pathology3. KS variants 4. Role of imaging 5. Imaging Manifestations: Head and Neck: Mucosal thickening or enhancing masses in the palate, tongue, or pharynx; Hyperenhancing cervical adenopathy. Thoracic: Enhancing peribronchovascular and subpleural pulmonary nodules; Flame shaped interstitial opacities. GI: Hypervascular mural/submucosal lesions; Polypoid lesions. GU: Bladder or urethral masses; External genital lesions. Musculoskeletal: Enhancing intramuscular or subcutaneous nodules; Lytic or mixed osseous lesions 6. Diagnostic Challenges and Solutions: Mimics and differential considerations on imaging Disease progression versus opportunistic co-infection7. Complications and Disease Monitoring The role of imaging in staging, treatment response assessment, and longitudinal disease monitoring KS-associated immune reconstitution syndrome: imaging hallmarks Prognostic factors

MSEE-73 LESS NOISE, MORE INSIGHT: CASE-BASED IMAGING WITH B-FLOW

Vitor Amorim Falcao, MD (*Presenter*)
Nikhil Gupta (*Abstract Co-Author*)
Eunhae Yeo, MD (*Abstract Co-Author*)
Terri A. Williams-Weekes, MD (*Abstract Co-Author*)

TEACHING POINTS

Comprehend the physical principles and imaging mechanism of B-Flow. Identify normal B-Flow appearances in different organs. Recognize the added diagnostic value of B-Flow in detecting vascular and parenchymal pathology through illustrative case examples. Appreciate the complementary role of B-Flow to enhance traditional color and spectral Doppler and the limitations of the technique.

TABLE OF CONTENTS/OUTLINE

Introduction to B-Flow Technology • Overview, physics, and clinical rationale Normal B-Flow Studies • Neurosonography (e.g., neonatal brain) • Hepatic Imaging (e.g., liver vasculature) • Renal Imaging (e.g., native and transplant kidneys) Pathologic Applications • Neurologic Pathologies (e.g., thalamic infarct, periventricular leukomalacia) • Renal Pathologies (e.g., proteinaceous cyst, vs solid mass, perfusion of renal transplant) • Hepatic Disorders (e.g., left portal vein thrombus) • Vascular disorders (e.g., internal jugular vein thrombosis) Comparative Imaging: B-Flow vs Color Doppler • Side-by-side image analysis • Strengths and limitations of each modality Limitations and Technical Considerations • Artifacts, motion sensitivity, and operator dependence • When and where B-Flow may be suboptimal Summary and Future Applications • Key takeaways • Potential areas for expansion of clinical and research applications of the technique

MSEE-74 RECOGNIZING HEPATIC AND EXTRAHEPATIC MANIFESTATIONS IN HEREDITARY LIVER DISEASES

Sung-Hua Chiu, MD (*Presenter*)
David Bingham (*Abstract Co-Author*)
Aya Kamaya, MD (*Abstract Co-Author*)
Justin Tse, MD (*Abstract Co-Author*)

TEACHING POINTS

Patients with hereditary liver diseases require frequent imaging to monitor disease and identify complications. This education exhibit will also provide an overview of five more commonly encountered hereditary liver diseases: glycogen storage disease, alpha-1-antitrypsin deficiency, cystic fibrosis, Wilson's disease, and primary hemochromatosis. For example, deficient activity of the glucose 6-phosphatase enzyme in glycogen storage disease results in excess glycogen and fat deposition in the liver. Hepatocellular adenomas are extremely common, most commonly inflammatory and ß-catenin-mutated exon 7/8 subtypes. While the pathophysiology is unclear, the association between GSD I and Moyamoya disease has been reported for decades.

TABLE OF CONTENTS/OUTLINE

Genetics, hepatic manifestations, and extrahepatic manifestations of the following disease processes: 1. Glycogen storage disease 2. Alpha-1-antitrypsin deficiency 3. Cystic fibrosis 4. Wilson's disease 5. Primary hemochromatosis

MSEE-75 PHAKOMATOSES IN THE ERA OF MOLECULAR TARGET THERAPIES: REVISITED

Shunsuke Nakamura, MD (*Presenter*)
Yuko Tsujioka, MD, PhD (*Abstract Co-Author*)
Gen Nishimura (*Abstract Co-Author*)
Tatsuo Kono, MD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Phakomatoses, synonymously termed neurocutaneous disorders, comprise a diverse group of genetic skin disorders with pigmentary or vascular cutaneous lesions and/or skin tumors, complicated by hamartomatous proliferation or vascular malformation in other organs, most commonly in the nervous system. The term "phakomatoses" was proposed by a Dutch ophthalmologist (Jan van der Hoeve) in the early 20th century. The term was initially referred to as lenticular retinal changes in neurofibromatosis (NF1) and tuberous sclerosis (TS), and named after the old Greek word, meaning "lentil". The morphological concept was applied to extraocular lesions in NF1 and TS, and extended to other disorders, e.g., von Hippel-Lindau disease (VHL) and Sturge-Weber syndrome (SWS). Recent molecular investigations have revealed that phakomatoses share the common pathogenic mechanism with cancers, i.e., aberrant signaling in the cell cycle, e.g., RAS/MAPK and PI3K/Akt/mTOR pathways. Therefore, molecular target therapies are currently feasible in phakomatoses. In general, diseases of the same pathway share common clinical and imaging features. Radiologists should be aware of the current status of pathophysiology linked to imaging findings and the therapeutic strategy of phakomatoses. From this perspective, we attempt to review imaging findings in the group of disorders.

TABLE OF CONTENTS/OUTLINE

Introduction - RAS/MAPK pathway-related (NF1, Neurocutaneous melanosis, Parkes-Weber syndrome, CM-AVM, etc.) - PI3K/Akt/mTOR pathway-related (TS, VHL, PI3K-related overgrowth syndromes, etc.)- Other pathways (SWS, hereditary hemorrhagic telangiectasia, PHACE syndrome, Nevoid Basal Cell Carcinoma Syndrome, etc.)

MSEE-76 WHY IS IT DARK ON T2 AND BRIGHT ON CT? A PATHOPHYSIOLOGIC APPROACH TO CROSS-ORGAN PATTERN-BASED DIAGNOSIS

Orito Ikeda (*Presenter*)
Hirotaka Akita (*Abstract Co-Author*)
Yoshitake Yamada, MD, PhD (*Abstract Co-Author*)
Yuko Tsujioka, MD, PhD (*Abstract Co-Author*)
Junya Tsuzaki (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

•Lesions with low signal on T2-weighted MRI and high attenuation on unenhanced CT can be categorized into six pathophysiologic groups based on fundamental tissue characteristics, such as the presence of paramagnetic substances, dense material accumulation, or reduced free water content. •These imaging features result from high atomic number substances attenuating X-rays (CT hyperdensity) and paramagnetic or dense tissues shortening transverse relaxation times (T2 hypointensity). •Recognizing these cross-organ signal patterns enhances diagnostic confidence and refines differential diagnoses by focusing on fundamental tissue characteristics, offering critical clues across diverse clinical scenarios, from acute hemorrhage to chronic fibrosis and malignancy. •Understanding the relationship between physical properties, disease mechanisms, and imaging appearances fosters a more comprehensive, mechanism-based diagnostic approach applicable across organ systems and patient populations.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Background and rationale for focusing on T2 hypointensity and CT hyperattenuation 2. Fibrous, Collagenous, and Muscular Lesions with Dense Stromal Architecture 3. Lesions Characterized by High-Protein, Mucinous, or Colloidous Material (e.g., Thyroid Tissue) 4. Lesions Associated with Melanin or Heavy Metal Deposition 5. Hypercellular Tumors with Dense Cellular Proliferation 6. Lesions Associated with Hemorrhage and Iron Deposition 7. Calcified Lesions Characterized by Prominent Mineralization 8. Conclusion

MSEE-77 CHIMERIC ANTIGEN RECEPTOR (CAR) T-CELL THERAPY. A PRACTICAL GUIDE FOR RADIOLOGISTS

Silvia Revuelta Gomez, MD (*Presenter*)
Alejandra Somoano Marfull (*Abstract Co-Author*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Rodrigo Sutil, MD (*Abstract Co-Author*)
Marta Drake Perez, MD (*Abstract Co-Author*)
Enrique Marco de Lucas (*Abstract Co-Author*)

TEACHING POINTS

1.To review the basic principles of CAR T-cell therapy.2.To describe the clinical and imaging findings of therapy-related toxic effects.

TABLE OF CONTENTS/OUTLINE

1. Introduction. CAR T-cell therapy is a recently approved immunotherapy that has revolutionized the treatment of hematologic malignancies. 2. Principles of CAR T-cell therapy. 2.1. CAR structure. 2.2. Steps in therapy process. 3. Indications. 4. Complications. Because of their nature as a cellular product that amplifies the patient's immune system, CAR T-cell therapies have a toxicity profile that differs from toxicities observed in other immunotherapies. 4.1. Cytokine release syndrome (CRS). 4.2. Immune effect cell-associated neurotoxicity syndrome (ICANS). 4.2.1. Pathogenesis. 4.2.2. Grading. 4.2.3. Clinical features. 4.2.4. Imaging. 4.3. Hemophagocytic lymphohistiocytosis (HLH). 4.4. Immunosuppression and infection risk. 4.4.1. Bacterial pneumonia. 4.4.2. Viral respiratory tract infections. 4.4.3. Fungal pulmonary infections. 5. Conclusion. With the expected increase in the use of CAR T-cell therapy in the near future, it is important for radiologists to become familiar with this breakthrough treatment. This includes being able to identify radiologically evident adverse events that require prompt diagnosis and intervention. 6. Bibliography.

NMMIEE

Nuclear Medicine & Molecular Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

NMMIEE-1 BASICS OF THERANOSTICS DOSIMETRY: OPTIMIZING SAFETY AND EFFICACY IN RADIOPHARMACEUTICAL THERAPIES

Jennifer J. Kwak, MD (*Presenter*)
Michael Silosky, MS (*Abstract Co-Author*)
Wendy Siman (*Abstract Co-Author*)

TEACHING POINTS

Great excitement in theranostics radiopharmaceuticals with the capability to image and treat tumors has been accompanied by a growing interest in the optimization of radiopharmaceutical therapies with dosimetry. The goal of this educational exhibit is to explain in simple terms and illustrate with figures and image rich case examples, the basic concepts of dosimetry, dosimetry methods, and utilization of dosimetry to optimize radiopharmaceutical therapies. Learning objectives are to discuss the role of dosimetry in radiopharmaceutical therapy, describe key steps in the performance of dosimetry, and review clinical applications and challenges of utilizing dosimetry.

TABLE OF CONTENTS/OUTLINE

I. Introduction : Theranostics and theranostic pair in nuclear medicine; Radiopharmaceutical dosing regimens II. Important Terms and Concepts in Dosimetr y: Dosimetry; Radionuclide; Radioactive decay; Count rate; Activity; Absorbed Dose; Prescribed Activity III. Key Steps in Dosimetry Data collection : Measurement of radiopharmaceutical biodistribution and clearance; Imaging methods; Defining the regions of interests Calculations : Absorbed dose calculations 1. Conversion of count rate to activity 2. Calculation of time integrated activity 3. Conversion of activity to absorbed dose Biological assessment : Assessing the biological effects of absorbed dose; Other factors affecting biological effects of radiation Prescribed activity recommendation IV. Clinical Implementation : Current challenges and potential solutions V. Case examples

NMMIEE-2 PRECISION IMAGING IN ESTROGEN RECEPTOR (ER)- POSITIVE BREAST CANCER: ^{18}F-FLUOROESTRADIOL (^{18}F-FES) PET-DRIVEN DECISION MAKING ACROSS CLINICAL SCENARIOS

Saurabh Jindal, MD,MBBS (*Presenter*)
Nusayba Bagegni (*Abstract Co-Author*)
Cynthia Ma (*Abstract Co-Author*)
Barry A. Siegel, MD (*Abstract Co-Author*)
Farrokh Dehdashti, MD (*Abstract Co-Author*)
Ashwin Singh Parihar, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Patients with 18 F-FES-negative disease are unlikely to benefit from endocrine therapies, despite ER-positive disease on pathology. 2. 18 F-FES PET can show the true extent of the disease in 18 F-FDG-negative cases with high clinical suspicion.

TABLE OF CONTENTS/OUTLINE

Section 1: Introduction Mechanism of ER-targeted PET imaging Comparison with 18 F-FDG PET Section 2: Appropriate Use Criteria-Based Clinical Scenarios. Sub-section includes illustrative cases and clinical rationale. [Scores 1-3: Rarely Appropriate; 4-6: May be appropriate; 7-9: Appropriate] Diagnosis Scenario 1: Primary breast cancer diagnosis (Score: 2) Scenario 2: Unknown primary malignancy, biopsy not feasible (Score: 5) Staging Scenario 3: T staging of primary tumor (Score: 1) Scenario 4: Axillary node staging (Score: 3) Scenario 5: Distant metastasis staging (Score: 5) Scenario 6: Staging invasive lobular/low-grade ductal carcinoma (Score: 5) Biopsy Assessment Scenario 7: Lesions accessible to biopsy (Score: 5) Scenario 8: Lesions difficult to biopsy (Score: 8) Therapy Selection Scenario 9: After disease progression, for considering 2 nd -line endocrine therapy (Score: 8) Scenario 10: At initial diagnosis of metastases, for considering endocrine therapy (Score: 8) Scenario 11: At primary diagnosis of primary cancer, for considering endocrine therapy (Score: 1) Other Uses Scenario 12: Measuring therapy response (Score: 1) Scenario 13: Suspected/known recurrent/metastatic disease (Score: 5) Scenario 14: Other imaging tests are equivocal or suggestive (Score: 8) Section 5: Limitations and Future Directions Monitoring response to SERM/D with 18 F-FDG PET Assessment of hepato-biliary disease Research needs for rare use cases

NMMIEE-3 MOLECULAR IMAGING FOR BREAST CANCER: CLINICAL IMPACT AND CORRELATION WITH OTHER IMAGING MODALITIES

Marcelo A. Queiroz, MD (*Presenter*)
Priscilla R. Dreyer, MD (*Abstract Co-Author*)
Rafael F. Nunes, MD (*Abstract Co-Author*)
Larissa B. Costa, MD (*Abstract Co-Author*)
Poliana Zampieri, MD (*Abstract Co-Author*)
Carolina Mautoni, MD (*Abstract Co-Author*)
Matheus Waitman, MD (*Abstract Co-Author*)
Artur M. Coutinho, MD,DSc (*Abstract Co-Author*)
Carlos A. Buchpiguel, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Describe clinical applications of FDG-PET/CT in breast cancer, including primary staging, therapeutic response, and recurrence detection. Discuss strengths and limitations of FDG-PET/CT compared to MRI, US, mammography, CT, bone scan, and FES PET. Recognize common interpretative pitfalls of FDG-PET/CT in breast cancer, including low FDG uptake in invasive lobular carcinoma, flare phenomenon, and challenges with sclerotic bone lesions. Review imaging criteria for treatment response and advances in molecular imaging, including novel PET tracers (e.g., FES, HER2-targeted agents) and hybrid techniques like PET/MRI and PET mammography.

TABLE OF CONTENTS/OUTLINE

1. Tumor biology and metabolism 1.1. Imaging features across different tumor subtypes 1.2. Patterns of spread according to tumor site and histology 2. Primary staging 2.1. Tumor (T) 2.1.1. Correlation with Breast MRI, US, MMG and FES PET/CT 2.2. Nodal (N) 2.2.1. Correlation with MRI, US and PLS 2.3. Metastasis (M) 2.3.1.

Correlation with CT, MR/DW, BS and FES PET/CT 3. Therapeutic response assessment 3.1. After neoadjuvant treatment - PET imaging as a tool for guiding therapeutic decision-making 3.2. After surgery 3.3. After systemic therapy 3.3.1. Flare phenomenon 3.3.2. Correlation with CT, MR/DW, BS and FES PET/CT 3.3.3. Imaging criteria (RECIST1.1 vs. others) 4. Recurrence detection 4.1. Local / distant recurrence 4.2. Differentiation from post-treatment changes (recurrence vs. inflammation) 5. New developments 5.1. New PET/CT tracers (ex.: FES, HER2) 5.2. PET/MRI and PET/mammography

NMMIEE-4 FDG-PET/CT IMAGING IN ESOPHAGEAL AND ESOPHAGOGASTRIC JUNCTION CANCER: A PRACTICAL GUIDE FOR CLINICAL DECISION-MAKING

Poliana Zampieri, MD (*Presenter*)
Priscilla R. Dreyer, MD (*Abstract Co-Author*)
Rafael F. Nunes, MD (*Abstract Co-Author*)
Artur M. Coutinho, MD,DSc (*Abstract Co-Author*)
Carolina Mautoni, MD (*Abstract Co-Author*)
Matheus Waitman, MD (*Abstract Co-Author*)
Marcelo A. Queiroz, MD (*Abstract Co-Author*)
Carlos A. Buchpiguel, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Describe the clinical applications of FDG-PET/CT in esophageal and EJC cancers, including initial staging, restaging after neoadjuvant therapy, and detection of recurrence. Explain the diagnostic value of FDG-PET/CT, particularly its specificity for locoregional lymph node involvement, sensitivity for distant metastases, and its ability to detect incidental and synchronous findings. Interpret key quantitative PET parameters (e.g., SUVmax, MTV, TLG) and discuss their prognostic relevance for patient stratification and treatment planning. Recognize the importance of structured reporting and explore emerging advances such as novel PET tracers and radiomics for future precision imaging.

TABLE OF CONTENTS/OUTLINE

FDG PET imaging for esophageal cancer Primary staging TNM classification: assessing tumor (T), nodes (N), and metastases (M) Detection of synchronous malignancies Incidental and unexpected findings Impact on treatment selection Restaging after neoadjuvant treatment Identification of interval progression or response Guiding surgical and therapeutic decisions Detection of recurrence Differentiating post-treatment changes from true recurrence Patterns of disease relapse: where to look for? Locoregional (anastomosis and lymph nodes) Visceral PET quantitative parameters Tumor volume and metabolic burden: what to measure? Prognostic value of PET-derived metrics Perspectives Structured report: What do oncologists need to know? Emerging PET tracers (e.g., FAPI, HER2-targeted agents) Radiomics

NMMIEE-5 A CLEAR VISION FOR TEAR MANAGEMENT: THE ROLE OF DACRYOSCINTIGRAPHY IN EPIPHORA DIAGNOSIS

William Denton, BA, MA (*Presenter*)
Hunter Colson (*Abstract Co-Author*)
Haseeb Ahmad (*Abstract Co-Author*)
Katherine Manning (*Abstract Co-Author*)
Ahmed Elsayed, MD (*Abstract Co-Author*)
Chris Jackel (*Abstract Co-Author*)
Johnson Deshommes, MD (*Abstract Co-Author*)
Mohamed Tarek S. Ahmed, MD, PhD (*Abstract Co-Author*)
Xingyu Nie (*Abstract Co-Author*)
Blaine T. Mischen, MD (*Abstract Co-Author*)
Riham H. El Khouli, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Epiphora is a common ophthalmologic problem. - It is typically caused by nasolacrimal duct obstruction (NLDO), but in many cases no structural obstruction exists and functional obstruction is identified instead. - Dacryoscintigraphy is a sensitive, non-invasive nuclear medicine technique evaluating the physiological drainage of the lacrimal system and its patency.- It plays an important role in differentiating functional from anatomical NLDO, and aids in identifying the level of obstruction, impacting management decisions.- Dynamic imaging capability helps assess pre- and post-surgical outcomes, particularly in patients with persistent symptoms.- Understanding normal and abnormal transit patterns can refine patient selection for procedures such as dacryocystorhinostomy (DCR).

TABLE OF CONTENTS/OUTLINE

I. Anatomy and physiology of nasolacrimal ductal system.II. Pathophysiology and clinical presentation of NLDO.III. Dacryoscinitigraphy protocol: Radiopharmaceutical, positioning, image acquisition.IV. Discuss quantitative tear duct drainage rate assessment and correlation to physiologic and pathological drainage.V. Multiple representative cases* will include: a. Patent bilateral nasolacrimal system b. Bilateral and/or unilateral partial obstruction at different levels c. Overflow tearing.VI. Take-home highlights and key points.VII. Selected references.*Each case will include: clinical history, relevant anatomy, key images, quiz questions & answers, diagnosis, discussion, and diagnostic pearls.

NMMIEE-6 BREAKING DE PSMA PET (CT/MRI) CODE: WHEN MORE DATA DOES NOT MEAN MORE CLARITY

Roberto I. Lemus Mendez, MD, MSc (*Presenter*)
Mary E. Arevalo Molina, MD (*Abstract Co-Author*)
Jose L. Criales, MD (*Abstract Co-Author*)

TEACHING POINTS

-Assess which patients are appropriate candidates for PSMA-PET imaging.-Understand the clinical implications of staging and risk stratification with PSMA-PET.-Evaluate the strengths and limitations of current PSMA-PET reporting systems.-Apply structured frameworks to reduce interobserver variability when interpreting PSMA-PET.

TABLE OF CONTENTS/OUTLINE

-Brief overview of PSM-PET.-When is the use of PSMA-PET appropriate?-PSMA-PET staging and risk stratification.-Best practices for reporting PSMA-PET in prostate cancer (PCa): Optimizing clinical decision-making.-Current reporting tools: Are we communicating effectively with the attending physician? (case review)-What is the path forward?

NMMIEE-7 PAGET'S DISEASE OF THE BONE: AN UPDATE

Alexander D. Zhang, MD, BA (*Presenter*)
Prem P. Batchala, MD (*Abstract Co-Author*)

TEACHING POINTS

Paget's disease (PD) of the bone is a well-recognized, common disorder characterized by abnormal, excessive bone remodeling. It is relatively more common in the elderly. Although well-recognized clinically and on imaging, the etiology is poorly understood. In this update, we review the following: 1) Genetic basis for PD including SQSTM1 mutations that regulate osteoclast activity; appearance on pathology, 2) Clinical presentation and diagnosis of PD, 3) Imaging appearance on conventional imaging (radiographs, CT, MRI, bone scan) including characteristics signs, 4) Imaging appearance in non-conventional modalities such as PET/CT (FDG, DOTATATE, PSMA), 5) Diagnostic pitfalls and mimics, 6) Summary of clinical implications, treatment/management and follow-up

TABLE OF CONTENTS/OUTLINE

1) Introduction to Paget's Disease of Bone- Definition and epidemiology. 2) Pathogenesis/Genetics- Abnormal remodeling process- Role of SQSTM1 mutations in osteoclast regulation. 3) Histopathologic features- Clinical Presentation and Diagnosis. 4) Conventional Imaging Modalities- Radiographs, CT, MRI, Bone scintigraphy. 5) Non-Conventional Imaging- FDG PET/CT, DOTATATE PET/CT, PSMA PET/CT. 6) Imaging Pitfalls and Mimics- Differentiating PD from metastatic disease. 7) Management and Follow-Up- Clinical indications for treatment- Medical therapy (e.g., bisphosphonates)- Imaging and clinical surveillance strategies. 8) Conclusion- Key clinical implications and interdisciplinary considerations.

NMMIEE-8 IS PROSTATE MRI ALWAYS NECESSARY? EXPLORING PSMA PET/CT AS A STANDALONE MODALITY IN PROSTATE CANCER IMAGING

Jacob Teigen, BA, BA (*Presenter*)
Erica L. Martin-Macintosh, MD (*Abstract Co-Author*)
Allison J. Clapp, MD (*Abstract Co-Author*)

TEACHING POINTS

Imaging in Prostate Cancer Diagnosis Describe the biological and clinical basis of PSMA PET/CT Compare PET's diagnostic value with MRI Identify scenarios favoring PSMA PET/CT alone Discuss advantages, limitations, and future directions Purpose To evaluate whether PSMA PET/CT can serve as a comprehensive imaging modality for prostate cancer staging, potentially replacing MRI in select scenarios. This exhibit explores comparative performance, workflow benefits, and situations where PSMA PET/CT may be sufficient alone. Content Summary PSMA PET/CT enables high sensitivity, whole-body imaging in prostate cancer. Studies such as ProPSMA and F-18 PSMA-1007 Phase II show superior or equivalent performance to MRI for staging, particularly in nodal and distant metastasis detection. PET/CT offers streamlined workflow, improved access for MRI-ineligible patients, and reduces multiple imaging modalities. While MRI remains essential for assessing local, PSMA PET/CT is increasingly favored in preoperative staging, recurrence evaluation, and treatment planning. PET/MRI and theranostics are expanding with evolving guidelines supporting PET's broader use.

TABLE OF CONTENTS/OUTLINE

Introduction to PSMA PET/CT Comparative Evidence: PSMA PET/CT vs. Prostate MRI Scenarios Favoring PSMA PET/CT Alone Advantages Over MRI Limitations and Considerations Future Outlook Conclusion: PSMA PET/CT demonstrates diagnostic accuracy that can rival and even surpass prostate MRI—especially in staging and biochemical recurrence. While MRI remains valuable, selected patients may benefit from imaging using PSMA PET/CT alone, supporting a potential shift in imaging pathways for prostate cancer management.

NMMIEE-9 NOT ALL THAT'S HOT IS LYMPHOMA: IDENTIFYING INFECTIOUS, INFLAMMATORY, AND BENIGN MIMICS ON FDG PET/CT

Kristina Yancey, MD (*Presenter*)
Evani Patel (*Abstract Co-Author*)
Clifford Shin, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Recognize key non-malignant diseases that can mimic lymphoma on FDG PET/CT. Understand typical imaging patterns and distinguishing features of infectious, inflammatory, autoimmune, and benign lymphoproliferative mimics. Apply clinical and imaging correlation to reduce misdiagnosis and unnecessary biopsy or treatment.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Overview of FDG PET/CT in lymphoma evaluation - Limitations and common false positives 2. Infectious Mimics - HIV, tuberculosis, infectious mononucleosis, toxoplasmosis - Imaging patterns and systemic correlation 3. Inflammatory and Autoimmune Mimics - Sarcoidosis, lupus, rheumatoid arthritis, Still's disease, mesenteric panniculitis - Symmetric nodal involvement and organ-specific signs 4. Benign Lymphoproliferative Disorders and Drug Reactions - Kikuchi-Fujimoto, Castleman's disease, Rosai-Dorfman, CAR-T therapy - Key imaging and histologic differentiators 5. IgG4-Related Disease and Overlapping Patterns - Imaging features and systemic fibrosing patterns - Use of serum markers and biopsy criteria 6. Diagnostic Approach - Structured checklist to evaluate FDG-avid nodes - Red flags for mimics vs true lymphoma - Case-based learning with histopathologic correlation (where available)

NMMIEE-10 ADVANCED CANCER IMAGING WITH HYPERPOLARIZED CARBON-13 MAGNETIC RESONANCE IMAGING: TECHNIQUES AND APPLICATIONS

Gigin Lin, MD (*Presenter*)
Ying-Chieh Lai (*Abstract Co-Author*)
Ching-Yi Hsieh, PhD (*Abstract Co-Author*)
Kuan-Ying Lu, MS (*Abstract Co-Author*)

TEACHING POINTS

Hyperpolarized carbon-13 magnetic resonance imaging (HP 13C-MRI) is an advanced metabolic imaging technique that enables noninvasive, real-time assessment of dynamic metabolic flux using dynamic nuclear polarization (DNP), which increases signal-to-noise ratio by up to 50,000-fold. [1-13C]pyruvate, highlights metabolic reprogramming in cancer and immune cells by tracing its conversion to lactate, alanine, and bicarbonate—revealing glycolytic and mitochondrial activity. HP 13C-MRI has demonstrated clinical potential in various cancers (e.g., prostate, brain, renal, breast) for tumor characterization, early therapy response, and immune activation assessment.

TABLE OF CONTENTS/OUTLINE

Introduction to Hyperpolarized 13C-MRI Principles of metabolic imaging Comparison with conventional MRI and PET Fundamentals of Dynamic Nuclear Polarization (DNP) Physics of carbon-13 hyperpolarization Signal amplification and polarization decay Imaging Techniques and Acquisition Model-based imaging (IDEAL CSI) Metabolite-specific imaging with spectral-spatial pulses Data Analysis Kinetic modeling (e.g., kPL) Model-free metrics (e.g., AUC ratios) Clinical Applications Prostate cancer: grading, biopsy targeting, treatment response Brain tumors: IDH mutation, gliomas, pediatric CNS tumors Renal and breast cancer: metabolic phenotyping and therapy monitoring Immune imaging: spleen activation, lymph node assessment Future Directions Emerging tracers beyond pyruvate Copolarization for multiplex metabolic and perfusion imaging Conclusion Clinical translation and research outlook

NMMIEE-11 ATOMIC CONTROL AGAINST CANCER: THE DIRECTED POWER OF YTTRIUM-90

Abigail Arriaga Contreras, MD (*Presenter*)
Rodrigo Hernandez Ramirez, MD (*Abstract Co-Author*)
Juan P. Chavez Torres, MD (*Abstract Co-Author*)
Miguel Angel Corza Ayala, MD (*Abstract Co-Author*)
Francisco Jesus Solano Caballero, MD (*Abstract Co-Author*)

TEACHING POINTS

Hepatocellular carcinoma (HCC) is the most common primary liver cancer and a leading cause of cancer-related deaths worldwide. Transarterial radioembolization (TARE) with Yttrium-90 (90 Y), also known as selective internal radiation therapy (SIRT), has emerged as a key LRT. It is a form of brachytherapy in which microspheres impregnated with the radioactive isotope Yttrium-90 are administered directly into the hepatic arteries supplying the tumor. TARE with 90 Y has become established as a valuable therapeutic option for patients with HCC in various clinical situations: Unresectable HCC Bridge to Transplant (BTT) or Resection Portal Vein Thrombosis (PVT) The pre-treatment evaluation and planning phase is a critical part of the procedure. It is a detailed workup that dictates the safety and potential efficacy of 90 Y treatment. It comprises: diagnostic angiography (1-3 weeks before 90 Y infusion) and 99m Tc-MAA simulation. Post-procedure imaging is a crucial quality assurance

step. Post-radioembolization adverse effects are common in 20-70% of patients. Symptoms may include fatigue (most frequent). Serious complications can occur (1-5%) and can include radioembolization-induced liver disease (REILD).

TABLE OF CONTENTS/OUTLINE

Introduction (general aspects of hepatocellular carcinoma). Clinical case presentation and imaging archive. What is hepatic radioembolization? Indications and contraindications. Treatment planning: angiography, simulation with 99m Tc-MAA, calculation of hepatopulmonary shunt and dose calculation. Administration of yttrium-90 treatment. Post-treatment imaging with PET/CT. Follow-up imaging. Adverse effects of the therapy. Conclusions

NMMIEE-12 THE CLINICAL UTILITY OF PET-CT IN HEREDITARY CANCER SYNDROMES. "ADVANCING SCREENING, DIAGNOSIS AND MANAGEMENT"

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Ayman H. Gaballah, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. Hereditary Cancer Syndromes: Genetic, imaging and Pathologic Foundations 2. Comprehensive Whole-Body Surveillance 3. Early Detection and Risk Stratification 4. Improved Diagnostic Accuracy and Lesion Characterization on PET/CT using F-18 FDG or Ga-68 DOTATATE improves the ability to differentiate between benign and malignant lesions4. Evaluation in Post-Surgical and Altered Anatomy In patients with prior surgeries or anatomical distortion (e.g., from metallic implants or surgical clips), PET/CT can visualize areas obscured or limited on MRI or CT, facilitating the detection of residual or recurrent disease.5. Post-Treatment Surveillance 6. Tailored Imaging Based on Tumor Biology o Ga-68 DOTATATE PET/CT is ideal for neuroendocrine tumor surveillance in syndromes such as VHL, MEN, TS, and SDHB mutations.o F-18 FDG PET/CT is better suited for evaluating aggressive or dedifferentiated malignancies, including malignant transformation in NF1-related tumors.

TABLE OF CONTENTS/OUTLINE

Provide an overview of key hereditary cancer syndromes including NF1, NF2, VHL, MEN, SDHB, TS, BRCA mutations, Lynch syndrome, FAP, and Turcot syndrome . Review the molecular, imaging and genetic mechanisms that predispose these patients to multifocal, multi-organ neoplasms. Demonstrate the clinical utility of PET/CT , Present illustrative cases with multimodality imaging and pathology correlation

NMMIEE-13 BREAST CANCER MOLECULAR IMAGING: STATE OF THE ART

Mary E. Arevalo Molina, MD (*Presenter*)
Osvaldo Garcia-Perez, MD (*Abstract Co-Author*)
Mary C. Herrera-Zarza, MD (*Abstract Co-Author*)

TEACHING POINTS

- To describe the molecular and histopathological aspects of breast cancer.- To review the recent PET/CT indications for breast cancer.- To describe the main molecular imaging in clinical scenarios.- To understand how to evaluate breast cancer through different radiotracers.

TABLE OF CONTENTS/OUTLINE

- Introduction- Breast cancer molecular aspects and mutations- Breast cancer immunophenotype - PET/CT indications- PET/CT FDG according to clinical scenario- PET/CT other tracers- Take-home points- References

NMMIEE-14 CLINICAL APPLICATIONS OF DUAL-TRACER PET IMAGING: BENEFITS, LIMITATIONS, AND EMERGING OPPORTUNITIES

Bahar Ataeinia, MD, MPH (*Presenter*)
Sophia R. O'Brien, MD, MEd (*Abstract Co-Author*)
Austin Pantel, MD (*Abstract Co-Author*)

TEACHING POINTS

• Multiple dual tracer pairs are currently clinically available that can contribute to more accurate cancer phenotyping and guide patient management. • Dual tracer imaging can better evaluate indeterminate lesions on FDG PET and guide the choice of biopsy targets for improved metastatic burden evaluation and staging. • Indeterminate FDG avid lesions that are favored to be of inflammatory or infectious nature can be better characterized by dual tracer imaging to prevent additional invasive diagnostic approaches and unnecessary treatment. • Dual tracer imaging can characterize heterogeneous lesions and detect tumor progression toward poorly differentiated phenotypes that can have suboptimal responses to targeted therapies. • Current protocols require imaging on separate days to avoid radioactive interference. This separation burdens patients, increases costs and radiation exposure, and creates logistical inefficiencies that delay care. New protocols are needed to image two tracers in the same imaging session for optimal patient care.

TABLE OF CONTENTS/OUTLINE

1. Introduction to dual-tracer PET, available combinations, and clinical indications: • Breast cancer (FES + FDG) • Prostate cancer (PSMA + FDG) • Neuroendocrine tumors (DOTATATE + FDG) 2. Case-based applications: • Tumor phenotyping and staging adjustment • Malignancy and inflammation dilemma • Treatment planning and response assessment 3. Technical limitations, and future directions: • Limitations of the current dual tracer protocols • Moving toward same-day whole-body protocols

NMMIEE-15 WHEN PSMA MISLEADS: FALSE POSITIVES ON PSMA PET/CT IN NON-PROSTATIC CASES

Shayan Saeed (*Presenter*)
Ozivefueshe Dimowo, MD, MPH (*Abstract Co-Author*)
Lawrence Wang, DO (*Abstract Co-Author*)
Arash Anavim, MD, MBA (*Abstract Co-Author*)
Joseph E. Burns (*Abstract Co-Author*)
Anderanik Tomasian, MD (*Abstract Co-Author*)
Maryam Golshan Momeni, MD (*Abstract Co-Author*)
Peter H. Pham, MD (*Abstract Co-Author*)

TEACHING POINTS

[1] To review the biodistribution of prostate specific membrane antigen (PSMA) [2] To review the indications for PSMA PET/CT in prostate cancer [3] To provide own institution cases of false positives on PSMA PET/CT

TABLE OF CONTENTS/OUTLINE

[1] Learning Objectives [2] Biodistribution of PSMA [3] Indications for PSMA in Prostate Cancer (i) PSMA PET CT is sensitive for prostate cancer metastasis but can show false positives, while bone MRI provides high-resolution images of bone marrow and lesions, often missing soft tissue uptake. [4] Bone MRI in Prostate Cancer Management (i) Bone MRI excels at detecting marrow involvement and subtle bone changes that PSMA/PET CT might miss, providing complementary information in metastatic assessment. [5] Discrepancies Between PSMA/PET CT and Bone MRI Findings (i) Common discrepancies occur with benign bone lesions or post-treatment changes, where PSMA/PET CT may show activity that MRI does not correlate with, leading to potential misinterpretation. [6] Summary and Key Takeaways (i) A multimodal approach, combining PSMA/PET CT with bone MRI, ensures more accurate diagnoses and reduces the risk of misdiagnosis.

NMMIEE-16 CAUSES OF ALTERED BIODISTRIBUTION OF F-18 FDG PET MIP IN MULTIPLE MYELOMA

(*Presenter*)
Stephanie Lewis (*Abstract Co-Author*)
McKenzie House (*Abstract Co-Author*)
Tarik Alfayyomi (*Abstract Co-Author*)
Ghaith Hashem (*Abstract Co-Author*)
Riyan Siddiqui (*Abstract Co-Author*)
Logan Lamar (*Abstract Co-Author*)
Vani Vijayakumar, MD (*Abstract Co-Author*)

TEACHING POINTS

Discuss the role of F-18 FDG in PET MIP, especially when imaging patients with multiple myeloma. Distinguish physiologic from pathologic causes of altered F-18 FDG uptake in skeletal muscles. Assess F-18 FDG uptake in precancerous plasma cell disorders, such as smoldering multiple myeloma. Correlate F-18 FDG uptake with lab findings to determine significant PET scan findings post monoclonal antibody treatment.

TABLE OF CONTENTS/OUTLINE

Multiple myeloma is a malignant plasma cell cancer often characterized by various biomaterials, including monoclonal immunoglobulins and free light chains, that lead to destruction of bone marrow. F-18 fluorodeoxyglucose (FDG) is a radioactive tracer used in positron emission tomography maximum intensity projection (PET MIP) that collects in metabolically active areas of the body, namely those impacted by malignant cancers. Use of this technology allows for anatomic and pathological classification of disease and has proved useful in diagnosing and staging hematologic cancers like multiple myeloma. This exhibit will examine several cases of multiple myeloma in which the F-18 FDG PET MIP scans demonstrated altered distribution of this radioactive tracer in conjunction with disease traits. These include skeletal muscle uptake, staging of disease, physiological uptake, and comparison with lab values attributed to multiple myeloma.

NMMIEE-17 VARIANTS OF PRIMARY PROGRESSIVE APHASIA: DETECTION AND PREDICTION OF CLINICAL COURSE ON ^{18}FDG-PET/CT

Reema Goel, MD (*Presenter*)
Anson L. Thaggard, MD (*Abstract Co-Author*)
Zachariah Burns, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To clarify the value of 2-deoxy-2-[18F]fluoro-D-glucose (FDG)-positron emission tomography (PET) in the detection and diagnosis of the 3 variants of Primary Progressive Aphasia (PPA) 2. To predict the clinical course of PPA with FDG-PET, illustrated by multiple cases with corresponding clinical and MRI/CT findings.PPA is a rare neurodegenerative disorder characterized by language-predominant deficits involving the frontal and temporal regions of the left hemisphere with 3 characteristic subtypes. Often it leads to development of dementia, specifically semantic dementia (SD) for frontotemporal dementia (FTD) and logopenic progressive aphasia (LPA) as an atypical presentation of Alzheimer's disease (AD). Among the imaging-supported diagnostic criteria for the PPA variants, it appears FDG- PET has better diagnostic performance compared with Magnetic Resonance (MR) imaging, particularly for the LPA and Nonfluent/agrammatic Variant PPA (nfvPPA). Although the three PPA subtypes show distinct regions of glucose hypometabolism on FDG PET, there is significant overlap amongst hypometabolic areas complicating differential diagnosis. Furthermore, it seems PET imaging data could help predict the clinical course of PPA, which differs according to each variant. It has been shown that left anterior temporal and frontal medial hypometabolism in agrammatic variant is linked to motor neuron disease and atypical parkinsonism, respectively. It has also been shown to progress to fronto-temporal degeneration with tau pathology. As mentioned previously SD evolves to behavioral disorder; and LPA to AD.

TABLE OF CONTENTS/OUTLINE

5 cases with legends presented in the PDF file illustrating the above teaching points

NMMIEE-18 RECENT ADVANCES IN MOLECULAR IMAGING INPROSTATE CANCER STAGING:PROMISE V2 AND THE PRIMARY SCORE

Glaucia Oki, MD, MSc (*Presenter*)
Eduardo Bote (*Abstract Co-Author*)
Kamila S. Albuquerque, MD (*Abstract Co-Author*)
Graziela C. Bernardo, MD (*Abstract Co-Author*)
Fabio Lewin, MD (*Abstract Co-Author*)
Marina M. Costa (*Abstract Co-Author*)
Carolina P. Abud, MD (*Abstract Co-Author*)
Roberta Morgado F. Zuppani, MD (*Abstract Co-Author*)
Maria Helena N. Pedroso (*Abstract Co-Author*)
Ana Claudia Vincenzi Raduan Uski (*Abstract Co-Author*)

TEACHING POINTS

PROMISE V2 and the PRIMARY ScoreProstate cancer, the most prevalent malignancy in men, demands precise diagnostic strategies. Molecular imaging with PSMA PET/CT has transformed disease staging and monitoring. The PROMISE V2 framework standardizes findings in molecular imaging, enhancing multicenter evaluations and supporting evidence-based decisions. Meanwhile, the PRIMARY score assesses intraprostatic patterns in PSMA PET/CT, classifying uptake intensity and location to differentiate malignant from benign lesions, thus improving diagnostic accuracy. This integration promotes personalized, evidence-based prostate cancer management.Despite technological progress, conventional imaging faces challenges in objective measurements and reproducibility. PROMISE V2 and the PRIMARY score address the need for standardized protocols, reducing interobserver variability and ensuring reliable interpretations of PSMA PET/CT images, crucial for clinical practice and research.

TABLE OF CONTENTS/OUTLINE

In conclusion, the collaboration between PROMISE V2 and the PRIMARY score has improved diagnostic precision and personalized care in prostate cancer. Future efforts should focus on validating these systems in diverse populations and training multidisciplinary teams, aiming for broader clinical applications and health equity.

NMMIEE-19 SPECT/CT IN PSMA THERANOSTICS: INTERPRETATION GUIDELINES, RESPONSE PATTERNS, PITFALLS, AND STRUCTURED REPORTING

Alireza Ghodsi, MD (*Presenter*)
Ridvan A. Demirci, MD (*Abstract Co-Author*)
Delphine L. Chen, MD (*Abstract Co-Author*)
Amir Iravani, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the role of SPECT/CT in PSMA theranostics, particularly for treatment response assessment. Identify common pitfalls in SPECT/CT interpretation, using teaching cases to highlight potential nuances. Explore the development of structured reporting guidelines for SPECT/CT in PSMA theranostics, focusing on creating a standardized reporting method to harmonized communication among physicians. Recognize treatment response patterns in SPECT/CT.

TABLE OF CONTENTS/OUTLINE

I. Introduction Overview of SPECT/CT in PSMA theranostics and its growing role in clinical practice. II. Systematic approach to SPECT/CT interpretation Detailed body map segmentation by organ system. Differentiating physiological from pathological uptake. III. Common pitfalls in SPECT/CT imaging Misinterpretation of benign vs. malignant lesions. Artifacts and technical limitations. IV. Structured reporting proposal Proposed framework for structured reports in SPECT/CT.Key elements to include in the report. Importance of standardization to enhance reproducibility and communication. V. Response patterns in SPECT/CT Favorable response patterns : Case

examples of significant imaging changes, including complete and partial responses. Progression patterns : Imaging examples showing disease progression, new lesions, and increasing PSMA uptake. Mixed response patterns : Examples where some lesions show a response while others progress, demonstrating the heterogeneity of disease. VI. Clinical application and impact How proper interpretation and structured reporting guide therapy and optimize outcomes.Real-world examples demonstrating the use of SPECT/CT to influence treatment decisions.

NMMIEE-21 ENABLING PRECISION MEDICINE: ACHIEVING MULTIPLEXED PET (MPET) FOR IMAGING-BASED MOLECULAR CHARACTERIZATION OF DISEASE

Hinesh Patel, MD,PhD (*Presenter*)
Kip E. Guja, MD, PhD (*Abstract Co-Author*)
Craig Levin, PhD (*Abstract Co-Author*)
Hong Song, MD, PhD (*Abstract Co-Author*)
Andrei Iagaru, MD (*Abstract Co-Author*)
Farshad Moradi, MD (*Abstract Co-Author*)
Jagruti Shah, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Positron Emission Tomography (PET) enables non-invasive in vivo assessment of disease-related physiological and molecular processes. Conventional PET detects same-energy 511 keV annihilation photons, hindering energy-based discrimination and largely restricting PET to single-tracer studies. Disease heterogeneity, involving disruptions in multiple molecular pathways, presents a significant challenge for traditional PET. Multiplexing PET (mPET), or the detection of =2 molecular targets within a single imaging session offers a richer non-invasive molecular characterization of disease. This educational exhibit aims to explore the approaches to achieving mPET, highlighting advantages, disadvantages, and technical aspects associated with each. Ultimately, this exhibit will discuss the potential of mPET and imaging-based molecular expression data in driving precision medicine.

TABLE OF CONTENTS/OUTLINE

1. Highlight disease heterogeneity and role of PET imaging. 2. Discuss advantages/disadvantages and technical aspects of various mPET methods: a) Sequential injection: imaging distinct radiotracers separated in time. b) Multi-tracer injection protocols and kinetic modeling: multi-tracer compartment modeling (MTCM) with acquired arterial input functions and dynamic PET. c) Multi-Isotope PET: distinct radiotracer half-lives or biodistribution. d) Detector technologies: Triple coincidences (prompt gammas), silicon photomultipliers (SiPMs) and large axial field of view (LAFOV) scanners. e) Deep learning/computational approaches to enabling mPET 3. Present imaging-based non-invasive molecular insights for detecting therapeutic targets and facilitating precision medicine.

NMMIEE-22 ADIPOSE TISSUE: NORMAL VARIANTS AND PATHOLOGIC INSIGHTS ON ^{18}F-FDG PET/CT

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Ahmed K. Elsayes (*Abstract Co-Author*)
Gabriel C. Fine, MD (*Abstract Co-Author*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Ayman H. Gaballah, MD, FRCR (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Devaki Shilpa S. Surasi, MD (*Abstract Co-Author*)

TEACHING POINTS

Adipose tissue, a major metabolically active endocrine organ, is traditionally classified into white adipose tissue (WAT) and brown adipose tissue (BAT). F-18 FDG PET-CT has become an essential tool in distinguishing normal physiologic activity within adipose tissue from other pathological conditions. This exhibit will examine the role of F-18 FDG PET/CT in identifying and interpreting adipose metabolism, differentiating normal adipose tissue from other abnormal pathologies, and recognizing the limitations of imaging in this context

TABLE OF CONTENTS/OUTLINE

1- Overview of Normal Fat Distribution and types of Adipose tissue including brown and white fat 2- FDG PET-CT Protocol at Our institution-:A review of imaging techniques and acquisitions parameters 3. Case studies of Normal physiologic Fat uptake: Recognizing normal variants and how to reduce it4. Common Fat Grafts: Imaging characteristics and clinical significance 5. Post -Surgical Adipose changes: PET/CT findings post operative patients6. Adipose pathology: Case based review of fat related pathologies including , lipomas, liposarcoma, teratomas , fatty tumor metaplasia and other conditions 7 Conclusion: Key takeaways and clinical implications.

NMMIEE-23 WHERE THE LIGHT BETRAYS. IMMUNOTHERAPY-RELATED ADVERSE EVENTS (IRAES) ON F-18 FDG PET-CT

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Motaz A. Daraghma, MD (*Abstract Co-Author*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Mohamed Issa, MD (*Abstract Co-Author*)
Gabriel C. Fine, MD (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Ayman H. Gaballah, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Immunotherapy Role in Cutaneous Malignancies Immune checkpoint inhibitors are a cornerstone in the management of advanced and high-risk cutaneous malignancies , used in both metastatic and adjuvant settings. Metabolic Pitfalls: irAEs on FDG PET/CT Immune-related adverse events (irAEs) are FDG-avid and can mimic tumor progression or other inflammatory/infectious processes. Differentiation is key: Known sites of tumor usually remain stable or improve , while new findings may reflect inflammatory toxicity rather than disease progression. Common irAEs on PET/CT Sarcoid-like lymphadenitis : Symmetric or isolated FDG-avid lymphadenopathy (e.g., hilar, mediastinal). Hypophysitis : FDG uptake in the pituitary region, may correlate with endocrine symptoms. Pneumonitis : Focal or diffuse FDG-avid pulmonary opacities, often without clear infectious etiology. Hepatitis : Diffuse hepatic uptake or hepatomegaly. Pancreatitis : Focal or diffuse pancreatic uptake. Colitis : Diffuse or segmental bowel uptake with or without wall thickening. Clinical Importance Recognizing irAEs helps prevent misdiagnosis of progression , avoids unnecessary changes in cancer therapy , and guides timely supportive treatment for toxicity.

TABLE OF CONTENTS/OUTLINE

1. The rise of Immunotherapy in clinical oncology2. The paradox: Efficacy vs immune related events3. The Role of F18 FDG PET-CT in monitoring immune activation4. Mechanism of immune activation5.Distinguishing tumor response from immune relate event6.Spectrum of immune related events7. Challenges in interpretation 8.Clinical implications and future directions

NMMIEE-24 THE BLOOD'S NEW ALPHABET " CRITICAL INSIGHTS FOR RADIOLOGISTS IN UNDERSTANDING THE NEW WHO LYMPHOMA CLASSIFICATION”

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Mahmoud S. Diab, MSc,MBBCh (*Abstract Co-Author*)
Mohamed Issa, MD (*Abstract Co-Author*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Gabriel C. Fine, MD (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Khaled M. Elsayes, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Hematologic malignancies (HM) represent a diverse spectrum of disorders characterized by varying incidence rates, clinical outcomes, and underlying causes. These conditions originate from either hematopoietic progenitor cells in the bone marrow or immune-related cells. Broadly, they are categorized into: - Mature B-cell neoplasms** (encompassing B-cell lymphomas and plasma cell dyscrasias) -Mature T-cell and natural killer (NK) cell lymphomas - Hodgkin lymphoma (HL)** - Post-transplantation lymphoproliferative disorders (PTLD) - Dendritic cell neoplasms The latest classification system for hematologic malignancies integrates cutting-edge advancements in hematology and oncology, introducing novel subtypes that reflect deeper biological insights. Modern diagnostic approaches increasingly rely on molecular and genomic markers, which guide targeted therapy selection and clinical trial eligibility. As research progresses, these molecular signatures are expected to further refine potentially redefine the classification of lymphomas and other hematologic cancers in the years ahead.

TABLE OF CONTENTS/OUTLINE

1. F18 FDG PET-CT protocol for different lymphoma cases2. Updates from 5th edition of WHO classification 3. New entities and subtypes4. Imaging findings for common lymphoma types5. Imaging findings for uncommon/rare lymphoma types 6. Role of F18 FDG in management of lymphomas 7. Future directions

NMMIEE-25 BEYOND OSSEOUS METASTASIS: DEEP DIVE INTO BONE SCINTIGRAPHY

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Mohammed Mousa, MSc (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Devaki Shilpa S. Surasi, MD (*Abstract Co-Author*)
Mohamed Issa, MD (*Abstract Co-Author*)
Beth Chasen, MD (*Abstract Co-Author*)
Gabriel C. Fine, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Clinical Utility of Bone Scintigraphy • Sensitivity in detecting metabolic bone activity compared to anatomic detail.• Applications in oncology, trauma, infection, and metabolic disorders.2. Pitfalls & Pearls • Differentiating true pathology from artifacts or normal anatomy.• Overcoming limitations to minimize false positives and negatives.3. Beyond Metastases • Emphasizing non-malignant conditions (e.g., AVN, metabolic diseases, trauma).4. Multidisciplinary Impact • The role of accurate interpretation in guiding patient management.

TABLE OF CONTENTS/OUTLINE

Introduction •• Objectives: Pitfalls, variants, and uncommon findings.2. Mechanism of Bone Scintigraphy • Tc-99m MDP uptake (hydroxyapatite binding, blood flow).• Reflects osteoblastic activity.3. Protocol & Technical Aspects • Patient prep (hydration, timing).• Imaging phases: flow, blood pool, delayed.• SPECT/CT value.4. Pitfalls & Challenges • Tracer-related : Poor labeling, free pertechnetate.• Artifacts : Non-uniformity, motion, attenuation, drug related • Anatomic variants : Accessory ossicles, rib variants, deltoid insertion 5. Soft Tissue Uptake • Lungs : Metastatic calcification, amyloidosis, metastasis • Liver/Spleen : Iron overload, sickle cell, metastasis • Muscles : Rhabdomyolysis, injections• Node : Intralymphatic injection6. Drug & Metabolic Effects • Bisphosphonates, G-CSF, chemotherapy (flare phenomenon).• Super Scan : Metastatic vs. metabolic causes (hyperparathyroidism, Paget's).7. NAT & AVN • NAT : Classic pediatric patterns.•Renal : Obstruction, absent kidney.• **Sacroiliitis, osteomyelitis, fibrous dysplasia. 9.. Conclusion

NMMIEE-26 V/Q SCINTIGRAPHY "MORE THAN A PE SCAN —KNOW THE PATTERNS, AVOID THE TRAPS!"

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Amr Mohammed, MD (*Abstract Co-Author*)
Mohamed Issa, MD (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Sanjit O. Tewari, MD (*Abstract Co-Author*)
Matthew F. Covington, MD (*Abstract Co-Author*)
Gregory C. Ravizzini, MD (*Abstract Co-Author*)

TEACHING POINTS

Versatility of V/Q Imaging V/Q scintigraphy extends far beyond PE diagnosis—it can also evaluate intracardiac and intrapulmonary shunts , pulmonary hypertension , vasculitis , and other non-thromboembolic vascular pathologies . Optimizing Technique to Reduce Pitfalls SPECT/CT fusion , appropriate patient positioning, and protocol modifications can improve anatomical localization , reduce false positives, and distinguish true defects from technical or physiologic artifacts . Pitfalls vs. True Pathology Recognize common pitfalls such as free Tc-99m (renal or gastric activity) , clumping of radiotracer , or suboptimal aerosol deposition , and distinguish these from true pathology such as pulmonary vein occlusion or vasculitis. Unexpected Tracer Distribution as Diagnostic Clues Extrapulmonary uptake (e.g., in the liver or kidneys) or asymmetric lung perfusion may indicate systemic disease , including right-to-left shunts, hepatopulmonary syndrome, or cardiac dysfunction. .

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Protocol & Technique • Patient Prep :• Ventilation : Technegas vs. DTPA aerosols (avoid swallowing artifact).• Perfusion : Supine injection, monitor for clumping/free Tc-99m3. Pitfalls & Technical Challenges 4. Beyond PE: Key Diagnoses • Pulmonary Hypertension (PH), Right-to-Left Shunts, Pulmonary Vein Occlusion, Air Trapping Unexpected Soft Tissue Uptake • Liver/Spleen, 6. Vascular & Inflammatory Conditions, Vasculitis (e.g., GPA): Pulmonary Sarcoma :• Focal perfusion defect with mass on CT.5. Conclusion

NMMIEE-27 CARDIAC TRANSTHYRETIN AMYLOIDOSIS FOR RESIDENTS: FUNDAMENTALS AND FUTURE DIRECTIONS OF 99MTC-PYP SCINTIGRAPHY

Taku Takaishi (*Presenter*)
Masaya Kisohara, MD, PhD (*Abstract Co-Author*)
Naohide Hotta (*Abstract Co-Author*)
Susumu Kobayashi (*Abstract Co-Author*)
Masanori Kitase (*Abstract Co-Author*)
Misugi Urano, MD, PhD (*Abstract Co-Author*)
Akio Hiwatashi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-Transthyretin cardiac amyloidosis (ATTR-CM) has been a fatal disease, but disease-modifying therapies, such as tafamidis (a transthyretin stabilizer), offer hope for improved prognosis. Early and accurate detection of ATTR-CM is crucial for better patient outcomes. - 99mTc-PYP scintigraphy is recognized as the gold standard for ATTR-CM screening. We will review conventional metrics based on planar imaging, such as the H/CL ratio and the visual Perugini score. We will also discuss their disadvantages, including susceptibility to contamination from other structures such as the blood pool and ribs. -We will then revisit the underlying mechanism of SPECT/CT and how this ensemble technique works. Thanks to its better anatomical localization and attenuation correction, SPECT/CT offers advantages compared to planar-imaging for ATTR-CM diagnosis. -In the future prospects section, we will summarize the several promising quantitative SPECT/CT metrics. We will also share our institutional experience with a SPECT/CT-based metric for ATTR-CM diagnosis. -Through this educational exhibit, we hope to provide a comprehensive understanding of ATTR-CM and the future direction of SPECT/CT-based quantitative imaging.

TABLE OF CONTENTS/OUTLINE

1) Overview of ATTR-CM: Pathology and Epidemiology 2) Treatment: Advent of Disease-Modifying Drugs 3) Diagnosis: Role of 99mTc scintigraphy 4) Modality: Planar imaging vs. SPECT-CT 5) Future Prospects: Potential of Quantitative SPECT-CT including our institutional experience

NMMIEE-28 THE FORGOTTEN TERRITORY " THE BRAIN'S BLIND SPOT IN ONCOLOGIC PET/CT" WHY OVERLOOKED?"

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Marwah Algodi, MD (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Mohamed Issa, MD (*Abstract Co-Author*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Khaled M. Elsayes, MD, PhD (*Abstract Co-Author*)
Mohamed-Ihab S. Reda, MD (*Abstract Co-Author*)

TEACHING POINTS

Up to 20% of significant brain findings on PET/CT are non-malignant , yet they can critically impact oncologic management, staging, and prognosis. Neurologic conditions such as HIV-related encephalopathy, stroke, autoimmune encephalitis, and paraneoplastic syndromes may mimic brain metastases or primary CNS tumors on PET/CT, complicating diagnosis. Differentiating malignant from non-malignant brain uptake Oncology-specific diagnostic pearls : In lung cancer and melanoma : Brain metastases are common, but immune-related encephalitis and paraneoplastic limbic encephalitis should be considered Assessing brain findings can guide accurate classification of lymphoma , primary CNS lymphoma (PCNSL) from secondary CNS involvement , which differ in chemotherapy regimens and prognosis. treatment intensity, intrathecal therapy decisions, and long-term outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction: Why the Brain Is Overlooked in Oncologic PET/CT Missed Malignant Lesions: Oncology-Relevant Brain Findings Brain metastases from solid tumors Primary brain tumors detected on whole-body PET/CT Help differentiate primary vs. secondary CNS lymphoma , which have vastly different therapeutic approaches Non-Malignant Brain Conditions Uncovered During Staging PET/CT Infectious and inflammatory (e.g., encephalitis, HIV-related changes) Vascular pathologies (e.g., infarcts, paraneoplastic vasculitis) Neurodegenerative changes (e.g., Parkinsonian patterns, Alzheimer's-like uptake) Incidental benign findings (e.g., demyelinating disease) Why Non-Oncologic Brain Findings Matter in Cancer Patients Toward a More Systematic Brain Review on PET/CT Takeaway

NMMIEE-29 NAVIGATING NEURODEGENERATION: HOW PET IMAGING GUIDES DIAGNOSIS AND TREATMENT

Joseph M. Moirano, MD (*Presenter*)
Divya Yadav, MBBS (*Abstract Co-Author*)
Joseph R. Osborne, MD, PhD (*Abstract Co-Author*)
Anna Nordvig (*Abstract Co-Author*)
Gloria C. Chiang, MD (*Abstract Co-Author*)
Jana Ivanidze, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. PET imaging can provide valuable insight into the underlying biological processes of neurodegenerative diseases (NDs). 2. Recently, several PET radiotracers have become available in clinical practice, aiding in accurate diagnosis of common NDs. 3. Early detection of NDs allows for optimized management as novel therapeutics become available, leading to better patient outcomes.

TABLE OF CONTENTS/OUTLINE

PET plays a pivotal role in the diagnosis and management of NDs. The ability to visualize/quantify key molecular changes in the brain with PET helps to improve diagnostic accuracy for NDs, particularly Alzheimer's (AD) and Parkinsons (PD). Accurate and early detection allows for tailored therapeutics. We will outline the use and utility of FDG-PET, amyloid PET, FDOPA PET and Tau PET. [F18]Fluorodeoxyglucose (FDG)-PET: Visualizes brain glucose metabolism. FDG PET is often the first brain PET for patients with cognitive impairment. Region-specific patterns of decreased cortical FDG avidity can help in the diagnosis of common NDs. Amyloid PET: There are 3 FDA-approved amyloid PET tracers. Amyloid PET confirms suspected AD diagnoses and assesses eligibility for amyloid-targeted therapies (ex. Lecanemab). Centiloid scores can also be calculated. Tau PET: [F18]Flortaucipir is currently the only FDA approved PET radiotracer visualizing Tau neurofibrillary tangles. As Tau burden correlates better with disease stage than amyloid burden, Flortaucipir is emerging as a useful clinical tool in the staging of AD. [F18]Fluorodopa (FDOPA) PET: FDOPA PET allows visualization of dopaminergic neurons, allowing more accurate diagnosis of Parkinsonian syndromes compared to [I123]Iodoflupane SPECT (DATSCAN).

NMMIEE-30 TAU PET IMAGING IN NEURODEGENERATIVE DISORDERS: A TAILORED APPROACH TO DIAGNOSIS AND MANAGEMENT

Michelle Chen, MD (*Presenter*)

TEACHING POINTS

1. Tau, a microtubule-associated protein essential for neuronal stability, aggregates into pathologic neurofibrillary tangles (NFTs) when hyperphosphorylated. 2. NFTs are a hallmark of Alzheimer's disease (AD) and other tauopathies (ex: PSP, CBD). 3. Tau PET uses radiolabeled tracers to selectively bind to tau aggregates in vivo, enabling visualization of regional tau deposition and correlation with Braak staging. 4. First-generation tracers demonstrate more off-target binding in subcortical regions whereas second-generation tracers show improved specificity for AD-type tau. 5. Baseline tau PET uptake predicts future cognitive decline and neurodegeneration in AD, independent of amyloid-ß status. 6. Tau PET is recommended for young-onset dementia, atypical AD, and amyloid-positive cases with unclear phenotypes. 7. Tau PET optimizes anti-tau therapies by monitoring tau burden reduction in Braak-defined regions (ex: temporal cortex) to assess therapeutic efficacy. 8. Emerging applications include integrating AI-driven quantification to automate Braak staging. 9. Tau PET bridges biomarker-driven diagnosis and therapeutic innovation to optimize individualized patient care.

TABLE OF CONTENTS/OUTLINE

1. Tau biology and pathophysiology 2. Principles of Tau PET imaging 3. Appropriate use criteria 4. Evolution of tau PET tracers 5. Clinical and research applications 6. Future Directions

NMMIEE-31 MULTIMODALITY EVALUATION OF CARDIAC SARCOIDOSIS: PEARLS AND PITFALLS OF HYBRID IMAGING

Luis O. Tierradentro-Garcia, MD (*Presenter*)
Katerina H. Lee, MD (*Abstract Co-Author*)
Paco E. Bravo, MD (*Abstract Co-Author*)

TEACHING POINTS

- CMR, especially late gadolinium enhancement (LGE), is the gold standard modality in diagnosis and prognosis of cardiac sarcoidosis.- Chronic granulomatous inflammation leads to scar tissue formation, which can be visualized as LGE.- FDG-PET has a high sensitivity for detection of active inflammation in cardiac sarcoidosis.- Abnormal FDG-PET uptake is associated with increased risk of major adverse events.- CMR and FDG-PET are complementary modalities for diagnosis and monitoring of cardiac sarcoidosis.- Ga-DOTATATE PET/CT has demonstrated a potential role in diagnosing cardiac sarcoidosis

TABLE OF CONTENTS/OUTLINE

- Pathophysiology and genetic factors associated with cardiac sarcoidosis.- Discuss common patterns of cardiac sarcoidosis imaging using CMR and FDG-PET.- Presentation of cases from a tertiary academic institution.- Propose a diagnostic algorithm for the interpretation of suspected cases of cardiac sarcoidosis.- Pearls and pitfalls: prognostic value of imaging, quantitative assessment, surveillance, dietary mechanisms (ketosis), SGLT2 inhibitors- Potential use of spatial proteomics in cardiac sarcoidosis.

NMMIEE-32 TRACERS IN TEST TUBES: IN VITRO TECHNIQUES FOR THE NUCLEAR RADIOLOGIST

Jonathan Porter, MD (*Presenter*)
Bryce Nelson (*Abstract Co-Author*)
Mariusz Bereznicki (*Abstract Co-Author*)
Adeline Le (*Abstract Co-Author*)
Jan Andersson (*Abstract Co-Author*)

TEACHING POINTS

A solid understanding of radiopharmaceutical production techniques is essential for clinicians, especially when unexpected production outcomes hinder accurate diagnostic interpretation. This exhibit will showcase several common radiopharmaceutical production techniques, providing an overview of their practical applications and synthesis steps, while illustrating cases from our institution where unexpected production results impacted clinical use. We explore solutions to these production challenges and conclude with future directions for improvement with implications for clinical practice. 1) White blood cell labeling: Covers the production technique used at our institution, including separation of white blood cells, labeling with 99m Tc, isolation and re-suspension, labeling efficiency determination, and reasons for poor labeling. 2) Red blood cell labeling: Focuses on labeling the Ultratag TM kit with 99m Tc, outlining production steps, pharmacology, labeling efficiency determination, and reasons for poor labeling. 3) GFR measurement: Discusses radiotracers developed for GFR evaluation such as 51 Cr-EDTA and 99m Tc-DTPA, basic principles of GFR evaluation, plasma sampling methods such as the Russell two-sample method, and the Gates camera-based method. 4) Urea breath test: Outlines the method of 14 C administration, activity measurements, and potential reasons for false negative or false positive results.

TABLE OF CONTENTS/OUTLINE

1) Introduction; 2) White blood cell labeling; 3) Red blood cell labeling; 4) GFR measurement; 5) Urea breath test; 6) Future improvements and implications for clinical practice; 7) Conclusions; 8) References

NMMIEE-33 ^{68Ga}-DOTATATE PET IN MENINGIOMA: PATTERNS, PITFALLS, AND POST-TREATMENT PEARLS

Anna Giarratana, MD, PhD (*Presenter*)
Abhinav Patel, MBBS (*Abstract Co-Author*)
Michael C. Veronesi, MD, PhD (*Abstract Co-Author*)
Matthew E. Larson, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

Initially utilized for imaging neuroendocrine tumors, DOTATATE PET is now increasingly applied in meningioma due to high expression of somatostatin receptor subtype 2 (SSTR) on tumor cells. [1-3] We review the clinical utility of DOTATATE PET in meningioma evaluation, beginning with a brief overview of tumor biology and the role of SSTR2 in enabling targeted imaging. [4] We describe typical avidity patterns, with emphasis on common features and locations. [5] We review common pitfalls, including physiologic uptake. [2] We explore post-treatment interpretation through cases showing persistent uptake in surgical beds and irradiated tissue, highlighting the importance of MRI and serial imaging for distinguishing recurrence. [6] Additionally, we highlight DOTATATE's emerging role for peptide receptor radionuclide therapy (PRRT). [7] This exhibit incorporates our institution's experience with DOTATATE PET for meningioma, including representative cases and utilization trends. This real-world perspective may aid others facing implementation challenges and foster practical discussion.

TABLE OF CONTENTS/OUTLINE

Introduction Meningioma characteristics and SSTR expression DOTATATE PET use in primary and recurrent disease Typical DOTATATE Avidity Patterns Imaging features Common sites: convexity, parasagittal region, skull base Pitfalls and Off-Target Uptake Physiologic uptake: pituitary gland, choroid plexus, nasal mucosa Benign inflammatory uptake Post-Treatment Imaging Challenges Persistent uptake MRI correlation/Serial Imaging Emerging Role for PRRT Utilization Trends and Practical Insights Real-world exam experience and utilization trends

NMMIEE-34 WHERE ARE MY BLINDSPOTS? A FDG-PET/CT SEARCH PATTERNS FEEDBACK TOOL VIA EYE-TRACKING AND NNUNET

Joy T. Wu, MBChB, MPH (*Presenter*)
Daniel Beckmann (*Abstract Co-Author*)
Sarah Miller, MD (*Abstract Co-Author*)
Stephan Altmayer, MD, PhD (*Abstract Co-Author*)
Ken Chang, MD,PhD (*Abstract Co-Author*)
Alexander C. Lee, MBChB (*Abstract Co-Author*)
Elizabeth Theng, BA, MD (*Abstract Co-Author*)
David Kersting (*Abstract Co-Author*)
Tomoaki Otani, PhD (*Abstract Co-Author*)
Brittany Z. Dashevsky, MD, DPhil (*Abstract Co-Author*)
Hye Lim Park (*Abstract Co-Author*)
Matteo Novello, MD (*Abstract Co-Author*)
Kip E. Guja, MD, PhD (*Abstract Co-Author*)
Benjamin Risse (*Abstract Co-Author*)
Daniel Gruhl (*Abstract Co-Author*)
Guido A. Davidzon, MD (*Abstract Co-Author*)

TEACHING POINTS

Compared to experienced radiologists, in training radiologists on average spent more time evaluating anatomy. Becoming familiar with normal and variant anatomy is an important factor to becoming an efficient and thorough radiologist. We have many interesting examples from our dataset that attendings do alter their search patterns to pay more attention to areas related to cancer specific metastatic pathways. Real time and aggregate retrospective feedback on search patterns and blind spots could be a useful tool for training radiologists. Benefit to trainee learning will need to be further tested in practice.

TABLE OF CONTENTS/OUTLINE

FDG-PET/CT is the standard of care for staging and follow-up of a wide range of cancers. There is increasing demand to read more of these complex studies rapidly. Fatigue, distractions and/or less experience are common factors contributing to higher errors, which can lead to suboptimal oncological care. We have built an interactive eye-tracking enabled PET/CT viewer that proposes lesion candidates for radiologists to efficiently validate or correct while their search patterns are collected at 60 Hz. With this viewer, search patterns for 318 studies were each collected from a trainee and a board certified attending. All original de-identified images were obtained from the public Tubingen FDG-PET/CT dataset. For this educational exhibit, we present the exploratory analyses and a prototype educational feedback tooling, which utilizes a deep learning 3D nnUNet anatomy segmentation model to provide a quantitative analysis of readers' search patterns. We will also be able to demonstrate our eye-tracking and Unet enabled PET/CT read feedback tool life at the exhibit.

NMMIEE-35 VORICONAZOLE-INDUCED FLUOROSIS AND PERIOSTEITIS: MULTIMODALITY IMAGING AND DIFFERENTIAL DIAGNOSIS

Ba D. Nguyen, MD (*Presenter*)
Alecio F. Lombardi, MD (*Abstract Co-Author*)
Paul Chroneos, MD (*Abstract Co-Author*)
Taejung Song (*Abstract Co-Author*)
Mackenzie Bartkus (*Abstract Co-Author*)
Felipe Martinez (*Abstract Co-Author*)

TEACHING POINTS

Voriconazole is a medication with high content in fluoride, administered as a preventive antifungal drug to oncologic patients. The high dose or long-term therapy of this medication could trigger fluorosis and periosteitis with bone pain symptomatology and characteristic radiologic and scintigraphic features. The teaching points of this educational exhibit are (1) to familiarize the viewers with its pharmacologic characteristics and side effects of fluorosis and periosteitis, (2) to present and illustrate the imaging features of voriconazole-induced fluorosis and periosteitis, and (3) to discuss the clinical entities constituting its differential diagnosis with imaging comparison.

TABLE OF CONTENTS/OUTLINE

This educational exhibit has three components: (1) the description of the characteristic features of Voriconazole-induce fluorosis and periosteitis, consisting of curvilinear, amorphous or bulky periosteal deposits with radiopharmaceutical avidity, depicted by radiographs, CT, bone scintigraphy, SPECT/CT and 18F FDG PET/CT, (2) the presentation of the timing of occurrence of induced periosteitis under Voriconazole therapy and the timing of its resolution after discontinuation of the drug, and (3) the imaging comparison of other clinical entities resembling Voriconazole-induced fluorosis and periostitis such as primary and secondary hypertrophic osteoarthropathy, computer duster huffing addiction with difuoroethane, venous stasis, shin splints, thyroid acropachy , and tea consumption-induced fluorosis.

NMMIEE-36 "MISGUIDED MISSILES" WHEN RADIOTRACERS WANDER OFF COURSE

Ahmed H. Ebada Salem, MBBCh, PhD (*Presenter*)
Reham M. Ellessy, MBBCh (*Abstract Co-Author*)
Akram M. Shaaban, MBBCh (*Abstract Co-Author*)
Kathryn A. Morton, MD (*Abstract Co-Author*)
Ayman H. Gaballah, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Know Your Radio-tracer : Understanding the mechanism of action is key to predicting both normal and abnormal biodistribution for both PET and non PET tracers Physiology vs. Pathology : Some patterns may mimic disease; correlating with clinical context and other imaging is essential. Technical Errors Can Mimic Disease : Radiotracer QC failures can result in misleading biodistribution—always check the basics. Systemic Conditions Matter : Cardiac failure, endocrine disorders, and autoimmune diseases can significantly alter tracer uptake. Patient Prep Is Critical : Improper preparation can derail scan interpretation (e.g., insulin before FDG PET, no Lugol before Ioflupane). Recognize Common Pitfalls : Patterns like brown fat, rhabdomyolysis, or post-therapy inflammation have typical appearances but may be misread. Correlate and Confirm : Use multimodality imaging and follow-up to confirm atypical findings when in doubt.

TABLE OF CONTENTS/OUTLINE

Introduction Basics Refresher Commonly used radiotracers (FDG, PSMA, FES, MIBG, PYP, MAA, MDP, Ioflupane, etc.) Normal biodistribution patterns Mechanisms of action (molecular targets and physiological uptake) Mechanisms of Altered Distribution Technical factors, Physiological and pathological conditions or patient-related factors Case-Based Review Categories of Atypical Uptake Extravascular leakage (e.g., rhabdomyolysis, edema) Shunting and altered flow (e.g., MAA in brain from ASD) Off-target binding (e.g., PSMA in stroke or inflammation) Technical artifacts and QC failures (e.g., free F-18 in blood pool) Physiologic mimics (e.g., brown fat, muscle uptake) Strategies to Reduce or Avoid Pitfall

NMMIEE-37 FDG PET/CT IN DECIPHERING THE CAUSES OF FEVER OF UNKNOWN ORIGIN: A PICTORIAL REVIEW

Nana Fujita (*Presenter*)
Masatoshi Hotta, MD, PhD (*Abstract Co-Author*)
Takeyuki Watadani, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Fever of Unknown Origin (FUO) represents a significant diagnostic challenge, encompassing a wide spectrum of potential etiologies. As an advanced imaging modality, FDG PET/CT plays a central role in the diagnostic workup of FUO, providing critical insights into its underlying causes. This educational exhibit aims to: 1) Highlight the diagnostic utility of FDG PET/CT in FUO compare to other modalities such as Ga-citrate scintigraphy. 2) Present illustrative cases where FDG PET/CT contributed to the successful diagnosis of FUO. 3) Describe characteristic FDG PET/CT findings associated with various FUO etiologies to aid differential diagnosis.

TABLE OF CONTENTS/OUTLINE

? Overview - Definition and diagnostic challenges of FUO. - Role of FDG PET/CT in the diagnosis of FUO. ? FDG PET/CT of underlying conditions of FUO 1. Infection: infective endocarditis, occult abscess, bone and joint infection, soft-tissue infection, tuberculosis, syphilis, fungal infections (e.g., histoplasmosis). 2. Non-Infectious Inflammatory Diseases (NIID): polymyalgia rheumatica (PMR), adult-onset Still's disease (AOSD), systemic lupus erythematosus (SLE), sarcoidosis (Lofgren syndrome), inflammatory bowel disease (e.g., Crohn's disease), vasculitis (e.g., Takayasu arteritis, giant cell arteritis, polyarteritis nodosa, granulomatosis with polyangiitis, eosinophilic granulomatosis with polyangiitis). 3. Neoplasm: lymphoma (e.g., intravascular lymphoma), Castleman disease, TAFRO syndrome. 4. Miscellaneous: thyroiditis, hyperthyroidism, necrotizing lymphadenitis (Kikuchi-Fujimoto disease).

NMMIEE-38 EMBRACING DIFFERENCES: UNDERSTANDING DISCREPANCIES BETWEEN PROSTATE MRI AND PSMA PET AND THEIR IMPLICATIONS

Susan Dhamala, MD (*Presenter*)
Lilja B. Solnes, MD, MBA (*Abstract Co-Author*)
Katarzyna J. Macura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-Prostate MRI and PSMA PET play a crucial and complementary role in the management of prostate cancer. -Prostate MRI is currently the initial imaging modality of choice in the diagnostic pathway of prostate cancer to identify suspicious areas, guide targeted biopsies, and aid in treatment planning and active surveillance decisions. -Given that prostate cancer has a wide range of aggressiveness, interpretation of prostate MRI relies on combining information from multiparametric sequences and assigning a PI-RADS assessment category intended to represent the lesion's likelihood of clinically significant prostate cancer (Grade Group 2 and above). -In conjunction with MRI, PSMA PET has emerged as an important staging tool in patients with newly diagnosed intermediate and high-risk disease. -PSMA PET imaging uses a radioactive tracer that binds to PSMA proteins, which is overexpressed in most prostate cancer cells, allowing detection of both local and distant disease spread. -Growing number of patients undergo combined assessment with prostate MRI and PSMA PET/CT leading to questions regarding discrepant findings between the two modalities. -Understanding the principles behind these imaging modalities and varying histology of prostate cancer can help explain their different presentation on imaging. -Discrepancies between prostate MRI and PSMA PET/CT also can impact treatment decisions in prostate cancer and PSMA theranostics.

TABLE OF CONTENTS/OUTLINE

1. Introduction to prostate cancer 2. Basis of prostate MRI and PSMA PET 3. Cases of prostate MRI and PSMA PET/CT concordance and discordance 4. Reasons for discrepant findings between imaging modalities 5. Clinical implications for treatment decisions

NMMIEE-39 Surprise Hotspots: A Quality Initiative in Nuclear Medicine QC

Bhargavi S. Sovani, MD,MBBS (*Presenter*)
Jerold W. Wallis, MD (*Abstract Co-Author*)
Maria R. Ponisio, MD (*Abstract Co-Author*)

TEACHING POINTS

Quality Control (QC) in nuclear medicine is a crucial skill that may have been impacted during the pandemic. Effective QC in nuclear medicine necessitates a comprehensive understanding of normal tracer biodistribution and the potential causes of deviations, which can be due to technical issues, contamination, or unexpected findings. Maintaining high standards in QC ensures reliable diagnostic outcomes. 1. Purpose: This educational exhibit aims to illustrate common misleading events through cases that can lead to incorrect image interpretations. 2. Methods: Review and analysis of case studies where QC issues led to image misinterpretation. Identification of the types of errors, such as technical faults, contamination, and unexpected tracer distribution. Documentation of corrective actions taken and recommendations for future QC practices. 3. Results: Compilation of case studies showing common QC errors and their impact on image interpretation. Detailed analysis revealing the root causes of the identified errors. Recommendations for improving QC protocols to prevent similar issues in the future. 4. Conclusion Through methodical examination of case studies and identification of common QC errors, this exhibit highlights the importance of rigorous QC processes in nuclear medicine. It is an educational resource to better train radiology with the knowledge and skills to ensure accurate image interpretation and diagnostic reliability.

TABLE OF CONTENTS/OUTLINE

Studies Included Bone scans, I-131, In-111 Pentetreotide (OctreoScan), VQ, renal, sestamibi, brain, Meckel, PET scans. The following will be reviewed: Common indications, Expected biodistribution, History to look for, Practical QC checklist

NMMIEE-40 DECODING PARKINSONIAN SYNDROMES WITH MOLECULAR IMAGING: A PRIMER FOR RESIDENTS

Andres Guillermo Tarra Romero, MD (*Presenter*)
Shahin Soltani Darani, MD (*Abstract Co-Author*)
Santiago Carrillo, MD (*Abstract Co-Author*)
Julian Rodriguez Cely, MD (*Abstract Co-Author*)

TEACHING POINTS

• The uptake of presynaptic radiotracers, such as 6-[¹8F]FDOPA, is decreased in conditions like Parkinson's disease and atypical parkinsonian syndromes.• In drug-induced parkinsonism, essential tremor, Alzheimer's disease, and other conditions, presynaptic radiotracer concentration is typically preserved. • Postsynaptic radiotracer concentration generally remains normal in Parkinson's disease, but shows variable alterations in atypical parkinsonian syndromes. • The lateralized pattern helps differentiate DCB from other parkinsonian syndromes, which typically show more symmetric involvement.

TABLE OF CONTENTS/OUTLINE

Introduction Anatomy Normal Brain Glucose and Dopamine Metabolism Imaging in Parkinson's Disease Imaging of Atypical Parkinsonian Syndromes Take-Home Messages Conclusions References

NMMIEE-41 TO DOSE OR NOT TO DOSE: PET-CT IN PREGNANCY-ASSOCIATED CANCERS

Amy Maduram, MD (*Presenter*)
Michael Hansen, MD (*Abstract Co-Author*)
Sarah Imran, MD (*Abstract Co-Author*)
Andrea N. Saldana, MD (*Abstract Co-Author*)
Lilian Wang, MD (*Abstract Co-Author*)
Vidushani S. Perera, MD (*Abstract Co-Author*)

TEACHING POINTS

Pregnancy-associated cancers (PAC), affecting 1 in 1000 pregnancies, present a complex clinical challenge at the intersection of radiology, oncology, and maternal-fetal medicine. These patients are often diagnosed at more advanced stages, as delays hinder early detection in evaluation and treatment. PET/CT offers clear clinical benefits for staging and recurrence detection, but its use during pregnancy is controversial as FDG crosses the placenta. Fetal radiation exposure concerns, limited counselling on risk-benefit trade-offs, and medicolegal concerns have limited its application. Furthermore, although PET-CT is not absolutely contraindicated during pregnancy per ACR guidelines, recent NCCN guidelines for pregnancy-associated breast cancers notably contraindicate nuclear imaging, and ASCO practice management guidelines discourage 18FDG PET-CT to assess for distant metastases. This exhibit will demonstrate the multidisciplinary approach and rationale for using PET-CT during pregnancy and how it can significantly influence clinical management and outcomes of PAC.

TABLE OF CONTENTS/OUTLINE

1. Review the role of PET/CT in staging and evaluating treatment response. 2. Discuss the risks, benefits, and safety considerations of PET/CT in pregnant patients, including fetal radiation exposure. 3. Identify patterns of physiologic FDG uptake in lactating breast tissue and potential mimics or obscuration of pathology. 4. Cases of PET/CT performed during pregnancy for patients with breast and lung cancer. 5. Cases of PET/CT contributing to detecting more extensive metastatic disease in PAC. 6. Self-assessment quiz.

NMMIEE-42 USING 18F-FET PET/MR FOR DETECTION OF RECURRENT DISEASE IN HIGH-GRADE GLIOMAS: TIPS AND TRICKS FOR INTERPRETATION

Timothy L. Chen, MD (*Presenter*)
Javier Villanueva-Meyer, MD (*Abstract Co-Author*)
Robert R. Flavell, MD, PhD (*Abstract Co-Author*)
Nancy Ann Oberheim Bush (*Abstract Co-Author*)
Thomas A. Hope, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the difficulties of differentiating recurrent disease from treatment effect in imaging of high-grade gliomas with current standard of care MRI-based techniques 2. Understand the key advantages of FET PET compared to other radiotracers in imaging of the gliomas 3. Learn how to interpret FET PET using a semi-quantitative approach 4. Recognize limitations of FET PET and pitfalls in interpretation

TABLE OF CONTENTS/OUTLINE

1. The dilemma: treatment effect vs. progressive disease in gliomas 2. A review of current and historic approaches to follow up of high-grade gliomas: MRI, PET, and SPECT 3. Introduction to FET PET imaging a. What is FET b. Advantages and disadvantages of FET to resolve treatment effect vs progressive disease compared to other radiotracers such as FDG and F-DOPA 4. FET PET/MRI imaging protocol 5. Semi-quantitative interpretation approach for FET PET 6. Case series: positive, negative, and ambiguous examples 7. Summary of challenges and pitfalls in interpretation

NMMIEE-43 ONCOLOGY AND TOXICOLOGY INTERSECT: THE ROLE OF NUCLEAR MEDICINE IN DETECTING CHEMOTHERAPY-INDUCED ADVERSE EFFECT

Ryogo Minamimoto, MD, PhD (*Presenter*)
Yumi Abe (*Abstract Co-Author*)
Rintaro Ito, MD, PhD (*Abstract Co-Author*)
Ryota Asai, MD (*Abstract Co-Author*)
Katsuhiko Kato, MD, PhD (*Abstract Co-Author*)
Shinji Naganawa, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Nuclear medicine has been widely utilized to guide treatment strategies in oncologic patients; however, it also provides important insights into chemotherapy-related adverse effects. This presentation explores the role of nuclear medicine in identifying treatment-induced toxicities across various organ systems. Chemotherapy can elicit inflammatory, infectious, or immune-mediated changes that manifest as abnormal radiotracer uptake, sometimes mimicking disease progression. Recognizing these incidental findings is critical to avoid diagnostic pitfalls and ensure appropriate patient management. Characterization of abnormal uptake patterns can aid in differentiating adverse events from tumor recurrence or metastasis, facilitate early detection of complications, and support timely therapeutic interventions. Increased awareness among radiologists and nuclear medicine physicians of these imaging patterns contributes to improved diagnostic accuracy and optimized care pathways for oncology patients. Incorporating the assessment of chemotherapy-induced changes into nuclear medicine imaging interpretation is becoming an essential component of comprehensive oncologic evaluation.

TABLE OF CONTENTS/OUTLINE

- Drug-induced pneumonitis in testicular cancer patient receiving BEP (Bleomycin, etoposide and platinum) - Gemcitabine induced vasculitis - Immune-related adverse events (irAEs) from immune checkpoint inhibitors - Fat Necrosis during the R-CHOP therapy in lymphoma - G-CSF (pegfilgrastim) induced side effect

NMMIEE-44 AMYLOID PET IN ALZHEIMER'S DISEASE: CURRENT EVIDENCE, CLINICAL UTILITY, QUANTITATIVE ADVANCES, AND THERAPEUTIC IMPLICATIONS

Shir Hazut Krauthammer, MHA,MD (*Presenter*)
Jeremy N. Ford, MD,MBA (*Abstract Co-Author*)
Hina Shah, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the evolution of amyloid PET tracers, their technical characteristics, interpretation criteria, and clinical value in Alzheimer's disease (AD).2. Understand the complementary roles of visual interpretation and quantitative analysis in amyloid PET imaging.3. Learn how the Centiloid scale enables standardized assessment of amyloid burden and supports clinical decision making.4. Highlight the need for a structured synthesis of growing evidence and propose practical, context-of-use recommendations for the Centiloid scale.5. Recognize real-world clinical applications of quantitative amyloid PET in diagnosis, longitudinal monitoring, and clinical trial design.

TABLE OF CONTENTS/OUTLINE

1. Background and Pathologic Basis 1.1. AD pathophysiology and ß-amyloid role 1.2. Dementia continuum and staging definitions 1.3. Histopathology to in vivo imaging 1.4. Anti-amyloid therapy landscape 1.5. Diagnostic integration of amyloid PET 2. Amyloid PET Imaging 2.1. FDA-approved [^{18}F] tracers 2.2. Tracer kinetics and positivity thresholds 2.3. Case examples of positive and negative scans 3. Quantitative Tools in Amyloid PET 3.1. Visual vs. quantitative assessment 3.2. Key metrics and Centiloid scale 3.3. Software reproducibility and thresholds 4. Updated Appropriate Use Criteria (AUC 2025) 4.1. Expanded diagnostic indications 4.2. PET's role in therapeutic planning 4.3. Representative clinical scenarios with case examples 5. Special Considerations 5.1. CAA and implications for imaging 5.2. ARIA in anti-amyloid treatment monitoring 5.3. Complementary use of FDG and amyloid PET

NMMIEE-45 MULTIMODALITY IMAGING FOR NEUROFIBROMATOSIS TYPE 1-ASSOCIATED PERIPHERAL NERVE SHEATH TUMORS

Ryota Asai, MD (*Presenter*)
Ryogo Minamimoto, MD, PhD (*Abstract Co-Author*)
Rintaro Ito, MD, PhD (*Abstract Co-Author*)
Tomohiro Komada (*Abstract Co-Author*)
Shinji Naganawa, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Malignant peripheral nerve sheath tumors (MPNSTs) are highly aggressive sarcomas that represent a major cause of mortality in individuals with neurofibromatosis type 1 (NF1). These tumors develop in approximately 8-13% of NF1 patients over their lifetime, making early detection and accurate diagnosis crucial for improving outcomes. Historically, the classification of nerve sheath tumors with atypical features but lacking definitive malignancy was challenging, often grouped under the ambiguous term "atypical neurofibroma". A significant advancement occurred with the 2017 consensus statement, which introduced standardized criteria and the concept of atypical neurofibromatous neoplasm of uncertain biologic potential (ANNUBP) to better define these intermediate lesions, particularly in the context of NF1. These refined classifications have since been incorporated into the WHO Classification of Tumours, 5th Edition. Given the limitations and risks associated with invasive biopsies, non-invasive diagnostic methods are essential for surveillance and clinical decision-making. This review focuses on the role of multimodality imaging for evaluating NF1-associated peripheral nerve sheath tumors.

TABLE OF CONTENTS/OUTLINE

1. Proposed nomenclature for NF1-associated peripheral nerve sheath tumors, 2. Neurofibroma and ANNUBP, 3. Cellular neurofibroma, 4. ANNUBP, 5. MPNST, high-grade

NMMIEE-46 MOLECULAR IMAGING OF SOFT-TISSUE SARCOMAS: PEARLS, PITFALLS, AND CLINICAL UTILITY OF FDG PET

Se-Young Yoon, MD (*Presenter*)
Jagruti Shah, MD, MBBS (*Abstract Co-Author*)
Geoffrey M. Riley, MD (*Abstract Co-Author*)
Kip E. Guja, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Soft tissue sarcomas are a rare and heterogeneous group of tumors requiring multimodality imaging and multidisciplinary management. Molecular imaging with FDG PET can provide metabolic information that is unique and complementary to conventional anatomic imaging techniques. FDG PET imaging often correlates with tumor grade, can help guide biopsy, and frequently detects additional sites of disease compared to conventional imaging in patients being considered for definitive or salvage therapy. Traditional size-based evaluation of treatment response is often inadequate in soft tissue sarcoma and changes in metabolic activity can add significant value to interim and end of treatment imaging for high-grade sarcomas. FDG PET can be used for detection of recurrence or malignant transformation and thus play a vital role in surveillance. The use of FDG PET for low-grade subtypes is more limited, and studies should be interpreted cautiously, with attention to potential false negative and false positive results.

TABLE OF CONTENTS/OUTLINE

Topics include: Current role of FDG PET in soft tissue sarcoma diagnosis and management with illustrative case examples of various sarcoma subtypes, benign versus malignant features, false positives and false negatives, added value of FDG PET in staging and restaging, and potential role for quantitative FDG PET metrics such as total lesion glycolysis and total metabolic tumor volume.

NMMIEE-47 HOT SPOTS AND COLD TRUTHS: A TRAINEE'S GUIDE TO PATTERN AND PITFALLS ON BONE SCANS

Ronald Gathagan, MD (*Presenter*)
Caroline Merriam, DO (*Abstract Co-Author*)
Manroop Kaur, MD (*Abstract Co-Author*)
Ming-Kai Chen, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Bone scintigraphy remains a vital component of musculoskeletal imaging, particularly in the evaluation of skeletal abnormalities and metabolic bone disease. While cross-sectional modalities such as MRI and CT provide detailed anatomic information, bone scans offer high sensitivity for detecting conditions including metastatic disease, occult fractures, infection, and arthropathy. Recognizing characteristic patterns of radiotracer uptake allows radiologists to identify both normal variants and pathologic findings with confidence. The objective of this presentation is to provide radiology trainees with a structured framework for understanding and interpreting Tc-99m MDP bone scans. Topics will include the basic principles of radiotracer selection and image acquisition, patterns of normal and abnormal distribution, interpretation of increased and decreased uptake, the utility of triple-phase imaging, and common diagnostic pitfalls.

TABLE OF CONTENTS/OUTLINE

1. Basic principles -- a. Radiotracer selection -- b. Properties of MDP -- c. Imaging protocol 2. Normal distribution 3. Abnormal distribution 4. Findings with increased uptake -- a. Fractures -- b. Benign bone lesions -- c. Bone malignancies -- d. Soft tissue lesions 5. Findings with decreased uptake -- a. Avascular necrosis, infarction, multiple myeloma 6. Three-phase bone scan 7. Common pitfalls -- a. Artifacts -- b. Post-surgical material -- c. Degenerative joint disease -- d. Radiation osteonecrosis

NMMIEE-48 BEYOND THE OBVIOUS: PET/CT DETECTION OF CUTANEOUS AND SUBCUTANEOUS METASTASES AS EARLY INDICATORS OF SYSTEMIC MALIGNANCY

Antonio Santana Veliz, MD (*Presenter*)
Gilberto J. Aquino, MD (*Abstract Co-Author*)
Garrett Depalma, DO (*Abstract Co-Author*)
Arwa Elsamny, MBBCh (*Abstract Co-Author*)
Andrij R. Wojtowycz, MD (*Abstract Co-Author*)
David J. Lubin, MD (*Abstract Co-Author*)
Michal Kawzowicz, MD (*Abstract Co-Author*)
Alexandra Panyukova, MD (*Abstract Co-Author*)

TEACHING POINTS

Cutaneous and subcutaneous metastases are rare but critical manifestations of visceral malignancies. Early radiologic recognition is essential, as these lesions may be the first indicator of metastatic disease. PET/CT imaging, particularly true whole-body PET/CT, enhances detection and characterization of soft tissue metastases, guiding diagnosis and management. Distinguishing these from benign mimics like post-surgical changes or inflammation is vital to avoid misdiagnosis.

TABLE OF CONTENTS/OUTLINE

1-Introduction to cutaneous and subcutaneous metastases.Epidemiology and clinical relevance.Imaging modalities with a focus on 18F-FDG PET/CT. 2-Common primary tumors associated with cutaneous spread Breast, lung, melanoma, esophageal, colorectal, bladder, renal. 3-Radiologic patterns and pitfalls: differentiating metastases from benign lesions. 4-Institutional Case Series Illustrative cases from our PACS archiveEmphasis on PET/CT findings, clinical correlation, and management impact. 5-Role of true whole-body PET/CT in comprehensive assessment. 6-Conclusion: Implications for practice and patient outcomes

Abstract Archives of the RSNA, 2025

Noninterpretive Skills (Beyond Imaging) Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

NPMEE-1 COGNITIVE CARTOGRAPHY: ENHANCING RADS MASTERY THROUGH RIGHT-BRAIN VISUALIZATION AND WHOLE-BRAIN LEARNING

Sean Cassingham (*Presenter*)
Aryan Ahuja (*Abstract Co-Author*)
Zhiyun Yang, MD (*Abstract Co-Author*)

TEACHING POINTS

1. RADS are cognitively demanding, difficult to retain and recall using traditional rote (table-based) methods alone, which predominantly engage the left brain. 2. Right-brain visual memory techniques can transform abstract concepts into memorable, intuitive symbols/ figures. 3. Our study investigates the efficacy of a novel, right-brain learning tool—using color, imagery, emotion, and metaphor—for improving grasp and recall of the RADS systems 4. Whole-brain learning (table + figures) improves both recall time and accuracy by engaging both logic and imagination. 5. Crossover study results attest to the benefit of adding right-brain visual tools, especially for visual learners. 6. This approach is adaptable for broader radiology education helping overcome cerebral overload in complex classification systems.

TABLE OF CONTENTS/OUTLINE

1.Introduction & Learning Challenge 1A.Why RADS are challenging to master 1B. Cognitive overload in traditional approaches2.Whole-Brain Learning Framework 2A.Left-brain vs. Right-brain memory processing 2B.Four-step method: Read ? Identify ? Visualize ? Recall3.Visual Tools for RADS Mastery - Part 1 3A.Mind map overview of 9 RADS systems 4.Visual Tools for RADS Mastery - Part 2 4A.Right-brain principles: connection, color, exaggeration, cartoon, and emotion 5.Study Design, Results & Educational Impact 5A.Crossover study design and participant methods 5B.Score and time comparisons (Figures 1-3) 5C.Survey feedback and learner preference (Figure 4) 5D.Educational takeaways and implications for future radiology training

NPMEE-3 IMPLEMENTATION OF LUNG CANCER SCREENING AND MULTIDISCIPLINARY CARE IN RURAL SETTINGS: BARRIERS AND OPPORTUNITIES

Diego Collazo-Irizarry, BSc (*Presenter*)
Kyle Burton (*Abstract Co-Author*)
Noelle K. LoConte, MD (*Abstract Co-Author*)
Anand K. Narayan, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1) Introduction a. Lung Cancer Outcomes in Rural Populations b. Role of Multidisciplinary Care in Lung Cancer Outcomes 2) Unique Barriers in Rural Practice Settings a. Geographic access b. Connections between local and referral centers c. Lack of common electronic medical record systems d. Insurance coverage and reimbursement issues 3) Unique Assets in Rural Practice Settings a. Strong community cohesion and connections b. Opportunity for Radiologists and Radiation Oncologists to Make a Difference i. Care Coordination ii. Reducing Health Disparities 4) Models of Multidisciplinary care in Rural Practice Settings a. Tumor boards/Meetings b. Co-localization in multidisciplinary clinics c. Refer-as-you-go 5) Innovations in Rural Radiology and Radiation Oncology Care a. Kentucky Community Engagement Terminate Lung Cancer Study b. Multi-disciplinary Remote Tumor Boards c. Mobile Lung Cancer Screening Units

TABLE OF CONTENTS/OUTLINE

This educational exhibit describes barriers to the implementation of lung cancer screening and multidisciplinary care models in rural practice settings. To solve these problems, this exhibit describes current and proposed innovative care models to improve access to radiology and radiation oncology services in rural practice settings.

NPMEE-4 MORE THAN JUST DYE: WHAT EVERY RADIOLOGIST SHOULD KNOW ABOUT CONTRAST SAFETY

Koju Nakai, MD (*Presenter*)
Jay Starkey, MD (*Abstract Co-Author*)

TEACHING POINTS

Differentiate types and characteristics of iodinated and gadolinium-based contrast agents, including safety implications Understand mechanisms of contrast-related adverse reactions across acute, delayed, and very late phases Clarify evolving concepts around contrast-associated acute kidney injury and its risk Identify patient-specific risk factors for contrast reactions and injury Apply evidence-based strategies to prevent, manage, and mitigate contrast-related complications

TABLE OF CONTENTS/OUTLINE

Introduction Rise in contrast media use and importance of safety in imaging Types and Characteristics of Contrast Agents Iodinated contrast: LOCM vs. IOCM, route-specific AKI risks, cost considerations Gadolinium-based contrast: Linear vs. macrocyclic; safety in renal impairment Mechanisms of Adverse Reactions Acute: Mast cell activation, complement, chemical toxicity Late: T-cell mediated hypersensitivity Very Late: NSF due to gadolinium retention Contrast-Associated Acute Kidney Injury (CA-AKI) Redefined concepts: CA-AKI vs. CI-AKI; limited causality evidence Patient Risk Factors Prior reactions, asthma, low eGFR, sex, age, autoimmune or allergic conditions Management and Prevention Severity-based treatment: antihistamines to epinephrine Hydration and premedication for high-risk patients

NPMEE-5 CLOSING THE REPORTING GAP: AN AI-ENHANCED DICTATION PRACTICE TOOL FOR MEDICAL STUDENTS

Ethan Vyhmeister (*Presenter*)
Mei Carter (*Abstract Co-Author*)
Amanda Aguilera, MD (*Abstract Co-Author*)

TEACHING POINTS

Radiology is underrepresented in medical school curricula, limiting early exposure to imaging interpretation and clinical communication. Traditional electives often face barriers to dictation practice, including restricted imaging software access, IT challenges, and billing constraints. This project introduces an AI-powered platform that addresses these challenges by providing medical students with a flexible, self-directed way to practice dictation. Students engage with curated radiology cases selected from institutional standard reports, dictating findings via integrated voice-to-text tools to simulate real-world workflows. An AI chatbot compares each dictation to an attending radiologist's report, offering immediate feedback on structure, clarity, and completeness. A progress tracker summarizes strengths and weaknesses, while an instructor dashboard enables faculty oversight and longitudinal assessment. By combining interactive dictation, case-based learning, and AI feedback, this platform offers an innovative, scalable approach to teaching structured reporting and communication skills in radiology.

TABLE OF CONTENTS/OUTLINE

Rationale and Program Overview Platform Features and Structure Sample Case Walkthrough Faculty Oversight and Platform Flexibility Future Work: Curriculum Development, Pilot Testing, and Outcome Tracking

NPMEE-6 MAGNETIC PERSONALITY, DANGEROUS ATTRACTION: SAFETY IN THE MRI SUITE

Koju Nakai, MD (*Presenter*)
Jay Starkey, MD (*Abstract Co-Author*)

TEACHING POINTS

MRI accidents arise from projectile, thermal, and mechanical injuries due to the magnet's powerful forces. Staff education is essential to prevent fatal incidents involving ferromagnetic objects. Thermal injuries can occur without direct contact with metal, requiring attention to patient positioning and leads. Image quality can be preserved by understanding and mitigating artifact sources. MRI-specific risks like acoustic noise and claustrophobia must be actively managed to ensure patient safety.

TABLE OF CONTENTS/OUTLINE

Introduction Scope of MRI-related safety concerns Brief overview of accident case studies Magnetic Environment and Risk Without Metal Static, gradient, and RF field interactions Risks from patient position, motion, and non-metal sources Projectile Events Force dynamics and magnet proximity Examples of common projectiles (e.g., oxygen tanks, wheelchairs) Fatal cases and prevention strategies Torque and Mechanical Injuries Physics of torque on implants and tools Real-life cases of torque-induced accidents Thermal Injuries Mechanism of RF-induced heating Loop formation and patient positioning risks Safe wire and electrode practices Artifact Recognition and Reduction Types and causes of artifacts Techniques to minimize artifacts in challenging scenarios Non-Magnetic Hazards Acoustic damage and use of ear protection Managing claustrophobia: sedation, open MRI, and patient communication

NPMEE-7 HOT TAKES ON THE HOT SEAT: EXPLORING TEACHING STRATEGIES IN THE GEN-Z AND MILLENNIAL ERA

Hannah Conley, MD (*Presenter*)
Amanda C. Gibson, DO (*Abstract Co-Author*)
Katherine Copely, MD (*Abstract Co-Author*)
Fara Y. Shikoh, MD (*Abstract Co-Author*)
Andres R. Ayoob, MD (*Abstract Co-Author*)

TEACHING POINTS

With the impending return of oral boards, a hot topic in radiology education is defining the most effective teaching strategies for both board preparation and real-life practice. For many years, the classic style of teaching was considered the "hot-seat" case-based conference in which a resident discusses an unknown case in the presence of their peers and the presenting radiologist. More recently, with the transition to multiple choice examinations in lieu of an oral examination and to virtual lectures during the COVID-19 pandemic, programs saw a significant increase in non-interactive didactic lectures. With the reappearance of an oral board examination, it is natural to assume a return to the "hot-seat" conference as the predominate teaching style. However, given the ever-evolving educational landscape, it is more important than ever to consider other factors, including new generations of learners and high rates of resident burnout and feelings of isolation. Educational research indicates effective teaching strategies promote active engagement, critical thinking, and clinical reasoning and can be achieved through various approaches. This project aims to discuss evidenced-based advantages and challenges of different teaching strategies to guide programs in creating safe, collaborative, and effective teaching sessions for learners.

TABLE OF CONTENTS/OUTLINE

1. Description of different teaching strategies 2. Discussion of the advantages and challenges of these methods, including their association with resident isolation, burnout, and wellness 3. Summary of published survey literature on residents' perception of various teaching styles

NPMEE-8 "JUST SIGN HERE?": RETHINKING INFORMED CONSENT IN RADIOLOGY

Jay Starkey, MD (*Presenter*)
Shoichi Maeda (*Abstract Co-Author*)
Eri Ishikawa (*Abstract Co-Author*)

TEACHING POINTS

Informed consent is an ethical and legal obligation grounded in patient autonomy. Radiologists must understand which procedures require consent and how to obtain it appropriately. Consent must be tailored to patient age, mental status, language, and procedure risk. The difference between consent and assent is essential in pediatric and adolescent imaging. Failure to obtain adequate informed consent can result in ethical violations and legal liability.

TABLE OF CONTENTS/OUTLINE

Introduction What is informed consent? Historical and ethical foundations Informed Consent in Radiology When consent is required: diagnostic vs. interventional procedures Contrast media: when and how to disclose risks Documentation and communication strategies Ethical and Legal Dimensions Respect for autonomy and decision-making capacity Consent vs. coercion Legal precedents and malpractice risk Special Populations and Situations Informed consent vs. assent in minors Patients with cognitive impairment or language barriers Emergency exceptions and surrogate decision-makers Best Practices and Pitfalls Elements of a well-conducted informed consent Common errors and how to avoid them Case examples: negligence, misunderstanding, and communication failures

NPMEE-9 THE WEIGHT OF SITTING: LOWER BODY WORK MUSCULOSKELETAL DISORDERS AMONGST DIAGNOSTIC RADIOLOGISTS AND PROPHYLAXIS

Matthew Phillipi (*Presenter*)
Shayan Saeed (*Abstract Co-Author*)
Erwin Ho, BS (*Abstract Co-Author*)
Roozbeh Houshyar, MD (*Abstract Co-Author*)

TEACHING POINTS

The transition from film to picture archiving and communication systems (PACS) has led to an increase in computer-based work for radiologists. In addition, case volume has also increased, effectively expanding radiologist's workload and time spent at PACS stations. While PACS has increased radiologist efficiency, the sedentary nature of PACS stations elevates radiologists' risk for work musculoskeletal disorders (WMSD) and repetitive stress injuries (RSI). A study on a PACS-based radiology department found that 58% of radiologists experience RSI symptoms and 38% of them are diagnosed with an RSI. To combat the risk for WMSDs and RSIs, ergonomic and prophylactic interventions can be utilized by the radiologist. While there is extensive research about upper body WMSDs, there is limited information about the lower

body. In this comprehensive review, we aim to educate radiologists on potential lower body WMSDs resulting from PACS stations. Additionally, we will advise on ergonomic and prophylactic interventions to prevent and manage lower body WMSDs.

TABLE OF CONTENTS/OUTLINE

1. Radiologist Risk for Lower Body Work Musculoskeletal Disorders (WMSD) 2. Lumbar Spine Stiffness 3. Hollowing Technique Exercise 4. Dynamic Lumbar Extension Exercise 5. Lumbar Disc Herniation 6. Body Weight Planks Exercise 7. Body Weight Bridges Exercise 8. Cat Cow Stretching Pose 9. Decreased Passive Hip Extension 10. Standing Hip Flexor Stretch 11. Modified Kneeling Lunge Stretch 12. Deep Vein Thrombosis 13. Weight Transfer Maneuver Exercise 14. Knee Osteoarthritis 15. Seated Knee Extensions Exercise 16. Wall Sit Exercise 17. Body Weight Squats Exercise 18. Standing Lunges Exercise 19. Conclusion

NPMEE-10 FRAMEWORK FOR INTEGRATING EDI INTO THE AI CURRICULUM OF RADIOLOGY RESIDENCY PROGRAMS

Nicole Bodnariuc (*Presenter*)
Sonali Sharma, BSc (*Abstract Co-Author*)
Charlotte J. Yong-Hing, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Describe current gaps in equity, diversity, and inclusion (EDI) representation in AI-related radiology education. Analyze barriers and enablers to integrating EDI content into formal AI education in Canadian residency programs. Evaluate strategies for equitable access to AI education, especially for underrepresented or marginalized learners. Identify actionable recommendations for curriculum developers to promote inclusivity and fairness in AI education.

TABLE OF CONTENTS/OUTLINE

Introduction Without inclusive education, AI may perpetuate healthcare inequities. Trainees from underrepresented groups face systemic barriers to engaging in AI learning (e.g., lack of mentors, digital literacy gaps, resource access). Data from radiology literature shows underrepresentation of women in AI research. National Survey Survey launched to assess how EDI principles (algorithmic bias, fairness, data diversity) are taught in AI education in Canadian residency programs. Data explores teaching formats, institutional barriers, and recommendations for inclusive AI training. Barriers Limited faculty expertise Lack of formal teaching on fairness, representation, or ethics Lack of interdisciplinary collaboration. Time constraints. Proposed Framework Adapt a model to foster fairness and inclusion in AI education. Advocate for peer learning, mentorship, interdisciplinary collaboration, and faculty development around bias and fairness in AI. Recommendations and Implications Develop educational resources and toolkits for program directors and curriculum developers. Incorporating EDI in AI curricula prepares residents to critically engage with technology and deliver more equitable care.

NPMEE-11 ROOTING FOR EXCELLENCE: MOCK RCA EVENTS TO CULTIVATE QUALITY EDUCATION IN RESIDENCY

Jonathan A. Flug, MD, MBA (*Presenter*)
Cathy Hannafin, MBA, BSN (*Abstract Co-Author*)
Lisa Ponce, RT (*Abstract Co-Author*)

TEACHING POINTS

1. The ACGME requires annual resident participation in a safety event review 2. A Mock Root Cause Analysis (RCA) can be an effective resident centered approach to meet this requirement 3. Utilizing an interdisciplinary review with the principles of a fair and just culture can lead to real practice improvements and engender a culture of improvement within residents and allied health staff 4. Mock RCA events are easily replicated and can be modified to meet organizational and departmental needs.

TABLE OF CONTENTS/OUTLINE

1. Background of ACGME requirements 2. Elements of fair and just culture and case discussion 3. Designing a case appropriate for resident review 4. Identifying team members for the review 5. Examples of Mock RCA cases used in our department 6. Fishbone diagrams and action plan generation 7. Lessons learned and future directions

NPMEE-12 ACTIVE LEARNING IN RADIOLOGY: STRATEGIES TO ENHANCE EDUCATIONAL OUTCOMES

Francisco J. Garrido Cisterna, MD (*Presenter*)
Catalina Alarcon Del Campo, MD (*Abstract Co-Author*)
Javier Suarez, MD (*Abstract Co-Author*)
Carlos R. Riquelme, MD (*Abstract Co-Author*)
Alvaro Huete Garin, MD (*Abstract Co-Author*)

TEACHING POINTS

1. University teaching often relies on passive learning strategies that are teacher-centered and involve little student participation in their learning process. 2. Active learning is defined as teaching-learning strategies that rely on student motivation, attention, and active engagement, promoting higher-order cognitive processes. 3. The integration of these strategies into radiology education promotes deeper student learning and is applicable in both undergraduate and residency settings.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Passive vs. active learning 3. Teaching strategies to enhance radiology learning: Flipped classroom, Team-based learning and cooperative learning, Case-based learning, Problem-based learning, Simulation, Gamification, Virtual learning strategies 4. What to do in the reading room? 5. Conclusions

NPMEE-13 BIAS BUSTERS: COUNTERING COMMONLY SEEN EPIDEMIOLOGICAL BIASES IN RADIOLOGY RESEARCH

Arissa Milton, BS (*Presenter*)
Christoph I. Lee, MD,MS (*Abstract Co-Author*)
Ruth C. Carlos, MD, MS (*Abstract Co-Author*)
Farouk Dako, MD, MPH (*Abstract Co-Author*)
Randy C. Miles, MD, MPH (*Abstract Co-Author*)
Efren J. Flores, MD (*Abstract Co-Author*)
Anand K. Narayan, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Epidemiology is the study of why and how often diseases occur in different groups of people • Selection and information biases represent two major categories of epidemiological biases that impact clinical research studies • Selection bias occurs when the participants in the research study are not representative of the population of interest to the study authors • Information bias occurs when there are errors in the measurement of study variables • Understanding types of epidemiological biases can help to improve the design and evaluation of radiology research studies

TABLE OF CONTENTS/OUTLINE

This educational exhibit reviews epidemiological biases that influence the design and evaluation of radiology research studies. The exhibit emphasizes commonly seen issues in radiology journal submissions and describes standardized approaches to mitigating these biases. At the end of this exhibit, radiology researchers will be able to identify the major types of biases in epidemiology that influence radiology research studies and implement proactive strategies to address these biases. 1) Introduction to Epidemiology a) Definition b) Applications of Epidemiology in Radiology Research 2) Selection Bias a) Non-response bias b) Loss to follow-up bias c) Volunteer bias d) Incidence-prevalence bias e) Berkson's bias f) Healthy Worker bias g) Control selection h) Length-time bias i) Sampling bias 3) Information Bias a) Recall bias b) Misclassification c) Observation bias d) Interviewer bias e) Measurement error f) Surveillance bias g) Lead-time bias 4) Confounding 5) Test Your Knowledge

NPMEE-14 RETHINKING THE FUTURE OF RADIOLOGY: ELEVATING THE ENTIRE IMAGING EXPERIENCE WITH CONVENIENCE, COMMUNICATION, AND CARE

Karthika Devi D S, MBBS (*Presenter*)
Manjiri K. Dighe, MD (*Abstract Co-Author*)
Gulnoor Sheriff, RT (*Abstract Co-Author*)
Domenico Mastrodicasa, MD (*Abstract Co-Author*)
Sarabjeet Singh, MD, MBA (*Abstract Co-Author*)
Dushyant Sahani, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Discuss ways to improve patients' perceptions & experience of radiology services. 2. Crafting digital patient journey to be more seamless, integrated, & customized to patients' needs. 3. Apply best practices from custom-centered industries & leverage AI integrated tools to support a patient-centric, AI-enabled imaging vision.

TABLE OF CONTENTS/OUTLINE

1. Changing volume to value: • Current trends - review literature on patient's imaging experience. • Identify problems affecting patient experience (fishbone diagram). • Create an overview with overlapping concepts of general principles governing & enriching patient experience. 2. Appropriate exam ordering: • Imaging order appropriateness determination based on the clinical indication. • Using clinical data to estimate pre-test probability and guide imaging orders. 3. Exam scheduling & customization: • Appointment location & time based on zip code & preference. • Synchronous/asynchronous scheduling with clinical visits. • Automated digital instructions delivery for imaging appointment. • Digital check-in and screening forms - integrated into EHR. 4. Seamless scanning environment: • Customized patient experience: scenery selection, name display. • Cloud-based protocol management. 5. Post-scanning AI: • Detection & triage of critical findings (PE, fracture). • Automate report generation using a disease-focused lexicon. 6. Collaboration & Communicating results. Provider=• Effective result communication - Digital • Structured disease-specific report. Patient=• Report summaries using patient-friendly language. 7. Solicit feedback. • Embedded hyperlink in image report- solicit feedback from patient for continuous quality improvement.

NPMEE-15 BUILDING A BREAST IMAGING EDUCATIONAL COLLABORATION IN JAKARTA, INDONESIA

Stefanie A. Woodard, DO (*Presenter*)
Eniola T. Oluyemi, MD, MPH (*Abstract Co-Author*)
Sidhvi Reddy (*Abstract Co-Author*)
Wei T. Yang, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

• Subspecialty breast imaging training is limited in Jakarta, Indonesia. • A structured international collaboration between U.S. breast radiologists and Ciptomangunkusumo National Referral Hospital radiology department was developed under the RSNA Global Learning Center (GLC). • The partnership emphasized curriculum based on local needs, multimodal delivery and sustainability. • Learner performance was tracked and programs established to measure educational outcomes via pre/post-lecture testing. • This model can serve as a replicable framework for global radiology education, particularly in low- and middle-income countries.

TABLE OF CONTENTS/OUTLINE

I. Introduction a. Breast cancer epidemiology in Indonesia b. Educational and clinical infrastructure gaps c. Rationale for international academic partnership II. Program Design a. Needs assessment methodology and stakeholder input b. Curriculum planning and topic selection c. Virtual lectures and hybrid delivery d. In-person workshops and procedural training e. VR-based breast biopsy simulation f. Multidisciplinary tumor boards and journal clubs III. Content Highlights a. Mammography and ultrasound basis b. MRI indications and protocols c. Post-treatment imaging d. Interventional procedures e. Quality metrics IV. Assessment and Outcomes a. Quiz-based pre/post strategy b. Hypothesis: i. Improvements in test scores by topic ii. Increased engagement over time c. Feedback-driven changes V. Conclusion a. Educational impact and sustainability b. Lessons learned and scalability c. Future directions toward a breast imaging fellowship

NPMEE-16 GENERATIVE AI IN RADIOLOGY EDUCATION: EMERGING TOOLS, USE CASES, AND LIMITATIONS

Samantha Leech, MD (*Presenter*)
Scott J. Adams, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Define generative AI and its growing relevance in radiology education. • Demonstrate how GenAI supports curriculum development, teaching and learning, and learner assessment. • Explain how GenAI enables exposure to rare cases, adapts to learner level, and reduces educator workload. • Identify key risks and limitations of GenAI in radiology education. • Explore future integration of GenAI into radiology workflows to support radiology education.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Generative AI in Radiology Education • What GenAI is, how it works, and why it matters for radiology education 2. Opportunities for Learners and Educators • Curriculum development • Teaching and learning • Learner assessment 3. Key Challenges and Limitations • Risk of hallucinations, factual drift, or vague language in outputs • Data privacy, transparency, and academic integrity concerns • Bias and equity risks related to model training and user interaction 4. Future Integration and Implementation • Workflow embedding into PACS

NPMEE-17 CORE COMMUNICATION SKILLS FOR PATIENT ENCOUNTERS IN RADIOLOGY: A TOOLKIT

Amina Karage, MD (*Presenter*)
Anand K. Narayan, MD, PhD (*Abstract Co-Author*)
Victoria L. Mango, MD (*Abstract Co-Author*)
Jade A. Anderson, MD (*Abstract Co-Author*)

TEACHING POINTS

• Patient Centered Care is associated with improved patient satisfaction, improved health outcomes, and reduced burnout among healthcare providers • Common patient encounters in radiology departments, such as delivering cancer diagnoses, represent some of the most impactful encounters across the healthcare continuum • Radiologists and technologists can improve patient centered communication skills using evidence-based formal and informal resources adapted from other subspecialties

TABLE OF CONTENTS/OUTLINE

Effective patient centered communication between radiologists and patients improves patient safety, health outcomes, and improves professional satisfaction and engagement. However, there are limited formal educational resources available for radiologists to provide high quality, patient centered care during imaging encounters. This communication toolkit adapts educational resources from the American Association of Family Practitioners to provide discrete tools and resources for radiologists to provide high quality, patient centered care during imaging encounters. 1) Sequence for Imaging Encounter a) Introduce and Build Report i) Verbal Communication Skills ii) Non-Verbal Communication Skills b) Elicit Patient's Agenda c) Discuss Patient's Concerns d) Empathize (e.g. NURSE mnemonic) e) Summarize f) Engage in Shared Decision Making 2) Evidence Based Recommendations for Practice a) Avoiding Interruptions b) Elicit Patient's Agenda c) Patient Centered Communication Training Courses i) Improvement in Communication Skills ii) Improvements in Patient Outcomes 3) Case Scenarios in Radiology Departments a) Delivering Bad News b) Informed Consent c) Trauma Informed Health Care

NPMEE-18 ¨BEYOND THE MAGNET-MASTERING MRI SAFETY¨

Mariam Vargas Gonzalez, MD (*Presenter*)

TEACHING POINTS

MRI is a powerful imaging tool, its strong magnetic fields pose significant safety risks. This guide covers key safety aspects, from magnetic force control to emergency preparedness and emerging innovations. • Invisible Forces, Real Dangers MRI magnets are always active, generating strong, invisible fields that can turn metal objects into dangerous projectiles. • First Line of Defense Proper screening is critical. Missing a single implant can turn a routine scan into a disaster. • Zones of Safety or Risk The four-zone MRI safety model separates order from chaos, shielding patients and staff from magnetic hazards. • Preparing for the Unthinkable Regular emergency drills and cutting-edge training prevent severe incidents like burns and RF injuries. • The Future of MRI Safety As MRI tech advances, so must safety strategies. AI-driven screening and real-time patient monitoring promise a safer tomorrow.

TABLE OF CONTENTS/OUTLINE

Introduction - The Magnetic Frontier Why MRI safety is more than a protocol,it's a mission. The Hidden Force - Understanding the Magnetic Beast The unyielding power of a 3 T field, always on, always dangerous. Red Zones - Navigating the Magnetic Battlefield The Four-Zone Model, from open spaces to high-risk areas. First Line of Defense - Human Vigilance Beyond the checklist - the critical role of human awareness and AI in proactive safety. Emergencies - When Things Go Wrong Real life incidents and lessons learned - from projectile injuries to life saving drills. The Next Frontier - Pioneering a Safer Tomorrow Innovations shaping the future of MRI safety, from smart algorithms to automated screening. Conclusion - Beyond the Magnet, Beyond the Risk The ongoing quest for 0 harm in the age of powerful fields.

NPMEE-19 TRANSFORMATIONAL LEADERSHIP IN THE DIGITAL AND HEALTHCARE ERA

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Juan Cruz Gallo, MD, MD (*Abstract Co-Author*)
Carlos Capunay, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the evolution of leadership in the digital and healthcare sectors, emphasizing the transition from hierarchical models to adaptive, high-performance leadership approaches. Explore the principles of transformational leadership. Examine the role of digital transformation in leadership, focusing on data-driven decision-making, agile structures, and technology adoption. Identify key strategies for leading through change and uncertainty. Apply leadership principles in healthcare and medical imaging.

TABLE OF CONTENTS/OUTLINE

The Four Key Factors of Leadership Success Simplifying complexity and operationalizing strategic goals. Encouraging ambition and alignment across the organization. Understanding and promoting effective teamwork. Developing future leaders through mentorship and empowerment. Leadership in the Digital Age The shift from hierarchical structures to networked, agile organizations. The role of data-driven decision-making and technological adoption. Balancing operational efficiency with innovation and flexibility. Leading Through Change and Uncertainty Adaptive leadership as a key competency in fast-evolving industries. The importance of resilience and emotional intelligence. Strategies for fostering a culture of continuous learning and collaboration. Application in Healthcare and Medical Imaging Leadership strategies for managing cross-functional teams in radiology and diagnostics. Implementing digital transformation while maintaining clinical excellence. The role of leadership in driving AI adoption and operational efficiency.

NPMEE-20 KEY INGREDIENTS FOR BUILDING A RESILIENT RADIOLOGY PRACTICE

Jonathan B. Kruskal, MBChB (*Presenter*)
Jeffrey L. Weinstein, MD (*Abstract Co-Author*)
James V. Rawson, MD (*Abstract Co-Author*)
Muneeb Ahmed, MD (*Abstract Co-Author*)
Jonathan G. Goldin, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Describe why radiology practice resilience has become so important for preserving and advancing our tripartite missions. 2. Describe what practice resilience is and looks like. 3. Illustrate what are considered the essential requirements and building blocks of a resilient practice. 4. Describe contemporary approaches for addressing and implementing each of these components

TABLE OF CONTENTS/OUTLINE

Structural and functional elements that ensure and sustain a resilient radiology practice; Building a learning and improvement culture - fostering a growth mindset; Keep your blinkers wide open: know the headwinds; Over enunciate the progress towards prioritized annual goals, and your mission and vision; Optimize workflow, workplace and workforce efficiency; Reimagine and prioritize service delivery; Retain your excellent team members - retention strategies that work; clear job descriptions prevent mission creep; The due process and accountability practices; Develop the skills to advance your staff; Be nimble; Effective financial stewardship; Manage all risk proactively; Anticipate and manage staff concerns and anxiety; all staff have heard voices; communicate strategically and effectively; foster an inclusive culture; Build a peak performing team (address the building blocks for such a team); Know then address all barriers to effective team function; preserve the reputation of your practice; build and sustain a resilient workforce

NPMEE-21 APPLYING QUALITY IMPROVEMENT TOOLS TO ENHANCE RADIOLOGY RESIDENTS EDUCATION

Omar Msto Hussain Nasser, MD (*Presenter*)
Sophia R. O'Brien, MD, MEd (*Abstract Co-Author*)
Scott A. Simpson, DO, MEd (*Abstract Co-Author*)
James V. Rawson, MD (*Abstract Co-Author*)

TEACHING POINTS

• The quality improvement (QI) tools used to improve clinical performance can also be used to improve radiology resident education. • The seven basic quality improvement tools provide radiology educators with a structured, data-driven framework to analyze and improve training for more efficient, targeted learning. Ishikawa noted these simple methods can address ~95% of quality issues. • These and other QI tools can be used to identify high yield changes in resident education. • QI tools also foster a culture of continuous improvement in graduate medical education.

TABLE OF CONTENTS/OUTLINE

1. Introduction to the seven basic quality improvement tools other QI tools and their relevance to educational processes: a. 1) Check Sheets: Encourage standardized skill evaluation and checklist-based learning i. 1) Check sheets, 2) histograms, and 3) control charts improve performance tracking and identify trends and gaps. b. 4) Pareto analysis and 5) fishbone diagrams help identify key drivers and diagnose root causes of training challenges. c. 6) Scatter diagrams and 7) stratification uncover correlations and hidden trends in learning outcomes. d. Scripted Education: Use concise, structured teaching scripts to support efficient point-of-care instruction. e. Microlearning: Deliver brief, high-yield content in asynchronous formats to reinforce learning in limited time. f. Pre-work Strategies: Use structured orientation tools to reduce cognitive load and accelerate learning at rotation start. 2. Benefits and limitations. 3. Conclusions.

NPMEE-22 NEURODIVERSITY IN RADIOLOGY EDUCATION: RETHINKING HOW WE TRAIN AND ASSESS NON-NEUROTYPICAL LEARNERS

Waqas Ahmad I, MBBS (*Presenter*)

TEACHING POINTS

Neurodiversity includes a range of cognitive profiles—such as ADHD, autism spectrum disorder (ASD), and dyslexia—that affect how radiology trainees perceive, process, and communicate information. Standard radiology training and assessment methods may unintentionally disadvantage neurodiverse learners, leading to performance

disparities unrelated to competence. Inclusive educational strategies—such as visual-based learning, chunked instruction, flexible assessments, and sensory-adapted workspaces—can significantly improve engagement, performance, and well-being for neurodiverse trainees. Faculty awareness and training are essential to recognize neurodiversity not as a limitation but as a strength, unlocking unique diagnostic talents and creative problem-solving approaches in radiology. Redesigning radiology education to support neurodiverse learners contributes to broader goals of equity, diversity, and innovation within academic medicine.

TABLE OF CONTENTS/OUTLINE

Introduction Why neurodiversity matters in radiology education Common Neurodiverse Profiles ADHD, ASD, dyslexia, and their relevance to radiology training Challenges in Current Training Models Barriers in teaching, assessment, and clinical environments Inclusive Educational Strategies Practical adaptations for teaching, feedback, and support Rethinking Assessments Alternatives to time-based evaluations and rigid formats Faculty and Institutional Recommendations Awareness, mentorship, and systemic change Conclusion Summary and actionable roadmap

NPMEE-24 STATE OF THE FIELD: DIAGNOSTIC RADIOLOGY & SPACE

Orhun Davarci (*Presenter*)
Roberto R. Galuppo Monticelli, MD (*Abstract Co-Author*)

TEACHING POINTS

Currently, the only officially clinically employed medical imaging modality in space is the ultrasound system in the International Space Station. Although it's one of the most portable imaging systems, it's well known that some diseases are not well suited to be evaluated via ultrasound. Astronauts go through extensive medical work-up for a variety of diseases before launch. However, many medical conditions can arise quickly & endanger the health of an astronaut, jeopardizing mission objectives. In the past, NASA guidelines have focused on returning the astronauts to Earth in case of severe medical problem. However, with manned missions to Mars in the horizon, there's a severe need to develop extensive on-board medical imaging systems capable of generating high-quality images. Real progress have been made within the last 2 decades, as miniaturized systems are now capable of taking diagnostic-level X-ray images in space. In the future, we expect to see the development of newer technologies and radiology workflows.1- To review the recent advancements in diagnostic radiology related in space medicine.2- To understand the limitations facing the diagnostic radiology applications in space.3- To recognize the potential ways into increase adoption of diagnostic radiology in space medicine.

TABLE OF CONTENTS/OUTLINE

1- The latest developments of using medical imaging in space and the cursory specifications. 2- The speed at which the X-ray systems are being developed for uses in imaging procedures. 3- US capable pathologies for diagnostics and added value of x-rays in diagnostics. 4- Telemedicine vs Radiology-on-board approaches to incorporate medical imaging into clinical-decision making in space. 5- Take home points

NPMEE-26 YOU'LL PROBABLY BE SUED, BUT THAT'S OK: A REVIEW OF MEDICAL MALPRACTICE LIABILITY & INSURANCE FOR RADIOLOGISTS

Shailin Thomas, MD (*Presenter*)

TEACHING POINTS

After completion of this presentation, the reader will be able to:• Understand the prevalence of malpractice litigation in the field of radiology• Identify the four elements of a malpractice action and describe the concepts of standard of care, proximate cause, and but-for cause• Describe the different types of damages available to plaintiffs in a malpractice action• Understand the scope of their liability, whether they are an attending or a trainee• Describe the common types of malpractice insurance and determine in what situations they may need tail insurance coverage

TABLE OF CONTENTS/OUTLINE

• Backgroundo Many radiologists are sued over the course of their careers, but many radiologists and radiology trainees do not know the basics of medical malpractice claims or insurance o Data on percentage of radiologists sued over their career, payouts, and settlements • Elements of a malpractice case o Duty — Standard of care o Breach— Failure to adhere to standard of care o Causation — Defendant's breach must cause plaintiff's injury (proximate cause & but-for cause) o Damages— Many types: Economic, non-economic, and punitive • Who is liable? — Mostly attendings, but trainees are not free from liability • Malpractice insurance o Occurrence— ACGME requires occurrence malpractice insurance for trainees o Claims-Made o Tail coverage

NPMEE-28 THE WEIGHT WE CARRY: A REVIEW OF RADIATION PROTECTION AND ERGONOMICS FOR INTERVENTIONAL RADIOLOGY TEAMS

Vandilson dos Santos Galdino, MD (*Presenter*)
Luiz Ybarra (*Abstract Co-Author*)
Leandro Cardarelli Leite, MD (*Abstract Co-Author*)

TEACHING POINTS

Review traditional and advanced radiation shielding technologies used in interventional radiology. Explain and compare the advantages and ergonomic limitations of radiation shielding technologies. Summarize current evidence supporting the use of traditional and advanced shielding systems. Discuss the ergonomic aspects and musculoskeletal risks associated with prolonged PPE use and strategies to mitigate them, focusing on practical considerations.

TABLE OF CONTENTS/OUTLINE

1. Introduction Radiation safety and the physical burden of protection. 2. Foundations Review of traditional protective equipment including caps, glasses, thyroid shields, aprons, and gloves. 3. Innovation Overview of advanced radiation shielding technologies such as ceiling-mounted systems, robotic and portable barriers, and integrated shielding platforms. 4. Solutions: Highlights of additional shielding options such as rolling shields, lead curtains, disposable scatter shields, and vertical attenuation pads. 5. Evidence Review What does the literature say about effectiveness and adoption of these tools? 6. Looking Ahead Practical recommendations, upcoming trends in radiation safety, and ergonomic considerations to minimize occupational injury.

NPMEE-29 EYE-OPENER: WHY THE LENS NEEDS PROTECTION FROM RADIATION

Koju Nakai, MD (*Presenter*)
Jay Starkey, MD (*Abstract Co-Author*)

TEACHING POINTS

The crystalline lens is one of the most radiosensitive organs, with cataract formation being a critical occupational risk in imaging. The threshold dose for radiation-induced cataract has been revised downward, now as low as 0.5 Gy, with a 20 mSv annual limit. Fluoroscopic and interventional procedures result in high cumulative dose to the lens, especially without protective gear. Radiation protection for the lens should follow time, distance, and shielding principles, with lead goggles and ceiling shields being highly effective. Awareness, policy, and equipment design improvements are necessary to increase compliance with lens protection.

TABLE OF CONTENTS/OUTLINE

Introduction The radiosensitivity of the crystalline lens Historical context and recent ICRP dose limit revisions Pathogenesis of Radiation-Induced Cataracts Oxidative stress and DNA damage in lens epithelial cells Impaired repair mechanisms and accumulation of damaged cells High-Risk Procedures and Exposure Estimates Fluoroscopy-guided surgery, interventional cardiology, ERCP Radiation dose estimates per procedure and per unit time Protective Strategies: Time, Distance, Shielding Fluoroscopy time/frame rate reductions Distance: inverse square law and operator positioning Shielding: beam collimation, lead goggles, and ceiling-mounted shields Barriers and Solutions to Lead Goggle Use Access, comfort, and integration with prescription eyewear Institutional mandates and ergonomic equipment improvements Conclusion Lens protection is vital for long-term safety of imaging professionals Combined use of all protective principles allows for safer and more sustainable procedural practice

NPMEE-30 FROM LIKES TO PATIENTS: THE ROLE OF SOCIAL MEDIA TO IMPROVE BREAST RADIOLOGISTS AND PATIENTS RELATIONSHIP

Myriam F. Montes, MD (*Presenter*)
Noelia Arevalo (*Abstract Co-Author*)
Nancy Sanchez Rubio, MD (*Abstract Co-Author*)
Beatriz Lannegrand Menendez (*Abstract Co-Author*)
Maria J. Ciudad, MD (*Abstract Co-Author*)
Laura Escudero, MD (*Abstract Co-Author*)
Carlota Garcia Baron (*Abstract Co-Author*)

TEACHING POINTS

To understand how social media can be our social stethoscope to diagnose the doubts and needs of our patients. To demonstrate the usefulness and impact of social media in: 1) Providing the population with scientific evidence translated into colloquial language. 2) To counteract the dissemination of false myths and fake news about breast radiology. To acknowledge why social media can be a powerful tool that allows breast radiologists to get closer to our patients, improving our communication and interaction.

TABLE OF CONTENTS/OUTLINE

Although radiologists are using social media more and more, we still undermine the potential of social media in improving our relationship with our patients. Social media in medicine is here to stay and SM in health, matters Social media offers us opportunities for social interaction and plays a role in several medical services, particularly regarding patients. We will review several key aspect of social media that can help us to improve our relatioship with patients by knowing our patients' needs and feelings better, like our social stethoscope. We will show also different estrategies to improve our visibility and interact with patients being part of support networks that empower people, and influence health awareness at the societal level.

NPMEE-31 STRATEGIES TO INCREASE ACCESS AND EQUITY IN IMAGING: LESSONS FROM AND FOR RURAL AND REMOTE COMMUNITIES

Samantha Leech, MD (*Presenter*)
Ivar Mendez, MD,PhD (*Abstract Co-Author*)
Brent E. Burbridge, MD, FRCPC (*Abstract Co-Author*)
Scott J. Adams, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Identify disparities in access to medical imaging in rural and remote communities. • Identify operational, technological, and workforce strategies to expand access to imaging in rural and remote settings. • Describe real-world examples of community-driven and technology-enabled solutions that have improved imaging access. • Apply tools and metrics to measure progress toward improved imaging access and equity.

TABLE OF CONTENTS/OUTLINE

1. Understanding Imaging Inequities in Rural and Remote Settings • Social determinants of health and imaging access • Structural barriers and system-level inequities, including geographic, logistical, and sociocultural challenges in rural and remote communities • A conceptual model for equitable imaging 2. Strategies to Improve Imaging Access in Rural and Remote Communities 2.1 Operational and delivery innovations • Remote scanning • Mobile imaging units • Fly-in and pop-up clinics • Regional hub-and-spoke models • AI-augmented acquisition and triage 2.2 Workforce development and support • Cross-training and task-shifting • Tele-education and mentorship • Retention and incentive programs for imaging personnel. 2.3 Culturally safe and community-led models • Co-design with local communities • Cultural safety training 3. Case Examples • Telerobotic ultrasound • Remote scanning (CT and MRI) • Low-field MRI 4. Data, Evaluation, and Advocacy • Measuring progress and outcomes • Radiologist-led advocacy and innovation 5. Resources and References • Toolkits, sample workflows, and further reading

NPMEE-32 INNOVATIVE EDUCATIONAL APPROACH TO IMPROVE PROBLEM SOLVING SKILLS: AN EXPERIENCE FROM DEPARTMENT OF ALLIED HEALTH PROFESSIONS OF CAREGGI UNIVERSITY HOSPITAL

Andrea Lastrucci (*Presenter*)
Nicola Iosca (*Abstract Co-Author*)
Angelo Barra, RT (*Abstract Co-Author*)
Cinzia Bastida (*Abstract Co-Author*)
Yannick Wandael (*Abstract Co-Author*)
Renzo Ricci (*Abstract Co-Author*)

TEACHING POINTS

The Department of Allied Health Professions at Careggi University Hospital has developed a series of innovative educational courses for radiographers and radiation therapists, aimed at strengthening their clinical reasoning and problem solving skills. These courses use a blended educational approach that integrates virtual reality (VR), gamification and the teach-back method.

TABLE OF CONTENTS/OUTLINE

Last year, these training courses were organized and delivered using a mixed and innovative approach:Total Body Irradiation (TBI) training course in Virtual Reality involved 30 radiation therapists. The program included theoretical lessons on the proper use of Virtual Reality tools, as well as asynchronous modules covering clinical and physical principles and the delivery of all TBI procedures within a virtual environment. The primary aim of the course was to enhance memory retention of the procedural steps involved in TBI delivery."Escape from the control Room" was a gamification learning method involved 18 radiation therapist. This educational escape room set whitin a radiotherapy scenario. The primary focus of this training course was related to improve the knowledge and recognizition of potential error in a risk free offline environment.At the end of each training course, an interactive teach-back session was conducted in which participants completed a real-time questionnaire to assess improvement in knowledge and confidence. This session provided an opportunity to openly discuss participants' perspectives and feedback on the training methods.

NPMEE-33 IMPROVING WOMEN'S EXPERIENCE IN DIAGNOSTIC EXAMS: HOW RADIOLOGISTS CAN FOSTER EMPATHY AND MAKE A DIFFERENCE

Marcela C. Lauar, MD (*Presenter*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Ana Luisa A. De Nicola, MD (*Abstract Co-Author*)
Carla C. Benetti, MD (*Abstract Co-Author*)
Aline C. Oliveira (*Abstract Co-Author*)
Cinthia C. Barbisan, MD (*Abstract Co-Author*)

Gabriela Lauar, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Although traditional radiology models have not emphasized interaction between patients and radiologists, patient-centered care requires a more active role from radiologists, with increased engagement and processes centered around patients' needs and preferences. Effective communication, emotional support, physical comfort, and alleviation of fear are essential components. Women's imaging exams—such as mammography, pelvic MRI, or transvaginal ultrasound—are often associated with high levels of anxiety and physical discomfort. Many patients arrive already distressed due to fears of diagnoses like breast cancer, infertility, or endometriosis, or due to concerns about body exposure and pain. Patient satisfaction and trust are directly linked to better adherence and outcomes. Empathy and a welcoming approach can reduce stress and pain perception. This work highlights how diagnostic exams may become distressing for female patients and presents strategies to humanize the experience.

TABLE OF CONTENTS/OUTLINE

1- Importance of patient-centered care in diagnostic imaging.2- Communication strategies for women's imaging exams.3- Best practices for delivering bad news.4- How environment, scheduling, and post-exam care affect experience.5- Writing sensitive and clear radiology reports.6- Role of AI in patient communication.

NPMEE-34 SHOULD I PURCHASE THIS AI SOFTWARE? A TOOLKIT FOR DEPARTMENT LEADERS TO DETERMINE RETURN ON INVESTMENT

Anand K. Narayan, MD, PhD (*Presenter*)
Robert K. Bour, MD (*Abstract Co-Author*)
Dania Daye, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

• Radiology department leaders are frequently asked to consider purchasing new software and equipment, such as artificial intelligence algorithms. • Examining the financial implications of proposed initiatives can help radiology department leaders make informed decisions when prioritizing new initiatives. • A return on investment (ROI) analysis estimates the net financial gains (or losses) for new initiatives by assessing potential changes in costs and revenues. • ROI analyses can support ongoing monitoring of the financial benefits and costs after implementation.

TABLE OF CONTENTS/OUTLINE

This toolkit provides step-by-step methods, resources, and case studies to calculate the ROI for new imaging initiatives. The toolkit has been adapted from the Agency for Healthcare Research and Quality (AHRQ) toolkit designed to evaluate the ROI for quality improvement initiatives. 1) Return on Investment (ROI) a) Definition b) ROI vs Cost Effectiveness Analyses 2) Core Design Considerations a) Definition of Scope b) Implementation Timeline (Inflation, Discounting, Depreciation of Equipment) c) Comparison Group d) Financial Contributors 3) Costs (Denominator) a) Categories (Personnel, Supplies, Equipment and Depreciation, Training, Information Systems, Outreach and Communication, External Consultant Costs) b) Phases of Improvement Actions (Planning and Development, Training, Startup, Ongoing Operation and Maintenance, Shutdown) 4) Financial Changes (Numerator) a) Hospitalizations b) Payments from Insurance Companies c) New Services Provided d) Avoidance of Penalties from Payers e) Changes in Service Operating Costs f) Liability Costs g) Productivity Changes h) Other 5) Case Examples 6) Resources

NPMEE-35 SIMPLIFYING QUALITY IMPROVEMENT MODELS IN RADIOLOGY

Niyati Hansaria (*Presenter*)
Dhiraj Baruah, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

- Quality improvement (QI) is an important component of healthcare and different models can be utilized within radiology- Root Cause Analysis is a retrospective process which analyzes contributing factors to an event and targets each of these factors for improvement.- Failure Mode and Effect Analysis (FMEA) is a prospective process to identify potential issues and prevent negative events.- Plan Do Study Act (PDSA) incorporates a team approach to troubleshooting errors and can be a continuous process to improving practice.- Lean Management, through waste reduction, and Six Sigma, through variation reduction, can be utilized within radiology to improve quality.

TABLE OF CONTENTS/OUTLINE

Introduction: importance of QI in radiology history of QI requirements related to QI Terminologies Measurement of improvement Models/ Tools for QI with examples Root Cause Analysis Retrospective process best completed as soon as possible after the event Identify possible causes or contributions to event occurring and formulate risk reduction strategies and improvement actions related to each cause Failure Mode and Effect Analysis Prospective process to proactively identify and prevent incidents from happening Define topic, assemble team, develop process map, conduct hazard analysis, develop action and measures Plan Do Study Act Trial and learning approach, continuous process which can be repeated multiple times Lean Management Continuous process; group involvement in sustained improvement Defining value, mapping stream value, creating flow, establishing pull, pursuing perfection A3 tool Six Sigma Quality standard- reducing variability Steps: define, measure, analyze, improve, change Conclusions

NPMEE-36 HOW IS THE MEDICAL COMMUNITY USING SOCIAL MEDIA FOR RADIOLOGY EDUCATION? RESULTS OF A GLOBAL SURVEY

Lilly Kauffman, BA (*Presenter*)
Elliot K. Fishman, MD (*Abstract Co-Author*)

TEACHING POINTS

- The medical community is using social media for radiology education.- Over half of respondents from our survey use social media for radiology education every day- YouTube is the most actively used, and the preferred, platform for radiology education- Most respondents use social media to learn more about radiology or to keep abreast of current events- Over 75% of respondents say they find social media "extremely useful" or "very useful" and over 47% indicate they find social media more useful than traditional resources such as textbooks

TABLE OF CONTENTS/OUTLINE

- An introduction to social media in the realm of radiology education- The results of our survey: demographics- The results of our survey: social media--- What social media platforms are popular--- What individuals' goal is by using social media- Indications for radiology educators

NPMEE-37 RADBOARDSAI: VOICE-INTERACTIVE AI PLATFORM FOR DIAGNOSTIC RADIOLOGY ORAL-BOARD SIMULATION

Rohit Reddy, MD (*Presenter*)
Nicholas Ott, MD (*Abstract Co-Author*)
Nicolas Litardo (*Abstract Co-Author*)
Nicole O. Brofman, MD (*Abstract Co-Author*)
Katharine Lampen-Sachar, MD (*Abstract Co-Author*)

TEACHING POINTS

1. ABR's 2028 of the oral exam reinstatement requires scalable methods for case-based diagnostic reasoning practice.2. Voice-interactive AI that is built on siloed speech-text-speech (STS) model logic can emulate realistic ABR board-style cases.3. Cloud-hosted micro-services (voice gateway, moderator, scoring) can be replicated and shared, giving residents in small or rural programs the same high-fidelity practice opportunities traditionally available only at large academic centers.4. Evidence-based design and rubric-based longitudinal feedback allow trainees and program leadership to track competency.

TABLE OF CONTENTS/OUTLINE

Background & Need : ABR oral exam return; faculty time constraints limit mock oral boards simulations. Current Landscape: Early pilots do not cover DR's full subspecialty breadth and layered knowledgebase. System & Deployment Architecture : Docker/Kubernetes micro-services (voice gateway, moderator, scoring, PACS, UI) with tenant isolation and tested API connectors for multi-center use. Case Pipeline & Prompt Engineering: ABR based templates ? automated prompt synthesis with case-metadata overlays, phase state-machine, and safety guardrails refined through iterative testing.Evidence-Based Design : self-paced practice, immediate feedback, spaced repetition, and adaptive reinforcement.Interactive Examination Workflow : case selection ? image review ? voice dialogue ? multilayer cases ? real-time feedback.Validation Data : multi-cohort metrics, resident uptake, rubric consistency, 99.5 % service uptime.Next Steps multilingual guidance already built to support non-native speakers; federated model updates protect resident data.

NPMEE-38 WILL AI REPLACE RADIOLOGISTS? THE TRUTH BEHIND LARGE LANGUAGE MODELS

Jose Ignacio Debes, MD (*Presenter*)
Pilar Navarro Azurmendi, MD (*Abstract Co-Author*)
Sofia D. Gambetta I, MD (*Abstract Co-Author*)

TEACHING POINTS

- Understand the capabilities and limitations of Large Language Models (LLMs) in radiology.- Recognize practical applications of LLMs in clinical reporting, education, and workflow optimization. - Learn basic prompt engineering strategies to maximize the effectiveness of LLMs. - Reinforce the indispensable role of radiologists in the AI era.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION - The growing impact of AI and LLMs in radiology. - Debunking myths about AI "replacing" radiologists. -WHAT ARE LLMS?: - How LLMs transform unstructured text into clinical assistance. - Large language models developed for general medical tasks, clinical prompting, and biomedical text analysis. -APPLICATIONS IN RADIOLOGY: - Drafting clinical reports. - Supporting education and research. - Optimizing workflow processes. -PROMPT ENGINEERING FOR RADIOLOGISTS: - Simple strategies to craft effective prompts. - Examples of clinical, educational, and research-oriented prompts. -CHALLENGES, ETHICAL CONSIDERATIONS, AND FUTURE PERSPECTIVES: - Managing hallucinations, bias, and privacy risks. - Augmented radiology: human expertise enhanced—not replaced—by AI.

NPMEE-39 THE DUAL DIAGNOSIS: MOTHERHOOD AND RESIDENCY IN RADIOLOGY

Zohaib Mallick, MBBS (*Presenter*)
Amal Mahmood (*Abstract Co-Author*)
Uffan Zafar, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit addresses the multifaceted challenges and triumphs of navigating motherhood during radiology residency. It explores the impact of this "dual diagnosis" on training, professional development, and personal well-being. The exhibit will examine strategies for balancing clinical responsibilities, academic pursuits, and family life, and highlight institutional support systems that facilitate success. It will also discuss the evolving landscape of parental leave policies and the importance of mentorship in fostering a supportive environment for resident mothers. Identify the primary challenges faced by radiology residents who are mothers.

TABLE OF CONTENTS/OUTLINE

I. Introduction: The Intersections of Motherhood and Residency A. Unique challenges faced by resident mothers B. Impact on training, well-being, and career trajectory II. Time Management and Work-Life Integration Strategies A. Effective scheduling and prioritization techniques B. Utilizing technology and support systems C. Strategies for managing on-call duties and unpredictable hours III. The Role of Institutional Support A. Parental leave policies: Current status and best practices B. Flexible training options and childcare resources C. Creating a supportive and inclusive work environment IV. Mentorship and Networking A. The importance of mentorship for resident mothers B. Building a professional network C. Finding role models and peer support V. Conclusion: Fostering a Sustainable and Supportive Future A. Recommendations for residency programs and institutions B. Future directions for research and advocacy

NPMEE-40 STRATEGIES FOR SURVEILLANCE AND CARE OF VULNERABLE AND UNDERSERVED POPULATIONS AT RISK FOR CHRONIC LIVER DISEASE AND HCC

Ania Z. Kielar, MD, FRCPC (*Presenter*)
Tasneem A. Lalani, MD (*Abstract Co-Author*)
James T. Lee, MD (*Abstract Co-Author*)
Satheesh Krishna, MD (*Abstract Co-Author*)
James V. Rawson, MD (*Abstract Co-Author*)

TEACHING POINTS

Prevalence of chronic liver disease is increasing in North America with risk factors including increasing rates alcohol, and metabolic dysfunction-associated steatotic liver disease (MASLD), and decreasing rates of virus-related liver disease (such as hepatitis B and C).. Often, individuals do not realize they have liver disease until their health is significantly compromised, yet in many cases, especially MASLD, there are modifiable factors which can help reduce their risk of developing cirrhosis and HCC. Patients at risk for chronic liver disease and HCC include those who are underserved and often considered to be vulnerable due to their socioeconomic status as well as other factors. Finding ways to identify, stratify and treat this group of patients can help reduce health care costs, as well as patient suffering, down the road.

TABLE OF CONTENTS/OUTLINE

Identifying vulnerable and underserved populations associated with development of chronic liver disease and HCC.Role of opportunistic screening in identifying patients at risk for chronic liver disease and HCC..Compare and contrast current worldwide MASLD guidelines, include EASL, AASLD, Worldwide gastroenterology, and Canadian Association of Radiologist guidelines. . Develop potential ideas to screen and stratify vulnerable patients at risk for chronic livers disease. Creation of multidisciplinary clinics (MDC) to provide all aspects of care in as few visits as possible for patients who live remotely or have low SES with risk factors for "no shows". This includes key members of MDC ClinicsDescribing the role of MDC clinics in ensuring best patient care

NPMEE-41 HOW CAN WE EARN TRUST? OPTIMIZING MEDIA CHANNELS FOR RADIOLOGY MARKETING AND PUBLIC RELATIONS CAMPAIGNS

Vilert A. Loving, MD, MMM (*Presenter*)

TEACHING POINTS

1. Marketing and public relations strategies serve two critical roles for radiology practices: a) attract and retain imaging service utilization; b) educate community members and providers regarding radiology-related topics. 2. Radiology marketing and public relations teams communicate to patients and providers via four media channel categories: paid, earned, shared, and owned. 3. Media channels facilitate patients' and referring providers' progression through the marketing communication lifecycle: awareness, interest, desire, and action. Awareness = knowledge that a service/topic exists. Interest = curiosity to learn more about the messaged service/topic. Desire = intent to pursue the service or develop deeper understanding about the educational topic. Action = actual follow through with the imaging service or to study/propagate the educational content. 4. Measuring a media campaign's success is important to determine if the chosen media channel warrants additional resource investment or should be abandoned.

TABLE OF CONTENTS/OUTLINE

1. Why do radiology practices need marketing and public relations? 2. Identifying the target audience: patients, providers, journalists, and influencers 3. The four media channel categories 4. Advantages and disadvantages of the four media channel categories 5. Introduction to the marketing communication lifecycle 6. Media channel

selection and their impact on marketing communication lifecycle 7. Measuring media campaign success

NPMEE-42 RADIOLOGY WITHOUT BORDERS: YOUTUBE'S IMPACT ON GLOBAL LEARNING

Zohaib Mallick, MBBS (*Presenter*)
Reyan Hussain Shaikh (*Abstract Co-Author*)
Uffan Zafar, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit will explore YouTube's transformative role in democratizing radiology education, highlighting its potential to bridge global disparities in access to learning resources. Specifically, the exhibit will: Showcase exemplary channels Analyze content effectiveness Discuss the platform's limitations and ethical considerations, including issues of quality control and misinformation. Delve into the use of YouTube for subspecialty training and continuing medical education (CME) Provide strategies for effective use in radiology education Emphasize YouTube's potential to foster a global community of practice.

TABLE OF CONTENTS/OUTLINE

I. Introduction: YouTube as a Global Educational ResourceII. Democratization of Radiology Education: Bridging the GapIII. Exemplary YouTube Channels in Radiology: A Curated SelectionIV. Content Analysis: Effectiveness and Limitations, including Quality ControlV. Ethical Considerations and Best Practices: Addressing MisinformationVI. Strategies for Effective Use in Radiology Education: A Practical GuideVII. Case Studies: Impact on Learning Outcomes and Skill DevelopmentVIII. The Future of Radiology Education on YouTube: Innovation and TrendsIX. Conclusion: Harnessing YouTube's Potential for a Global Community of Practice

NPMEE-43 PRACTICAL SHOWCASE FOR RADIOLOGY RESIDENT LEADERS IN COMMUNITY ENGAGEMENT NATIONWIDE THROUGH "COMMUNITIES CRUSHING CANCER"

Liz Z. Lin, MD, BA (*Presenter*)
Somiah Almeky, MD (*Abstract Co-Author*)
Carlos D. Aramayo, MD (*Abstract Co-Author*)
Madhurya Amirapu, MBBS (*Abstract Co-Author*)
Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

1. The "Communities Crushing Cancer (CCC)" initiative, a nationwide resident-led event focusing on patient education, can serve as a model for outreach efforts. 2. Residents and trainees are most powerful when working together, in collaboration with community partnerships and organized medicine. 3. Stepwise progression to statewide, and national expansion requires a network. A designated liaison for expansion efforts at each site are essential. 4. Social media outreach efforts are invaluable for both identifying new sites for engagement but also to support solidarity.

TABLE OF CONTENTS/OUTLINE

Identify a cause Formulate an intervention Identify stakeholders Verify content Understand current practice and contexts Start locally Secure buy-in Human capital Department support Apply for internal/external grants Identify existing collaborators Expand statewide Find quality liaisons Build a Toolkit for success Centralize information Lower barriers to access Expand nationwide What makes a good partnership or coalition? Secure buy-in Funding opportunities via organized medicine and other sponsorships Marketing and Outreach Social media Establish platforms, recruit superusersEngage with short form content and videos, challenges Sustainability Prioritize recruitment of junior residents and trainees Collect data Reflect

NPMEE-44 SUSTAINABLE DEVELOPMENT IN RADIOLOGY: STRATEGIES FOR ENVIRONMENTALLY RESPONSIBLE IMAGING CENTERS

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Juan Cruz Gallo, MD, MD (*Abstract Co-Author*)
Carlos Capunay, MD (*Abstract Co-Author*)
Patricio J. Sita (*Abstract Co-Author*)
Valeria Szymanowski (*Abstract Co-Author*)

TEACHING POINTS

Environmental Impact of Radiology - Understanding the carbon footprint of imaging modalities, including energy-intensive MRI and CT scanners, and the waste generated from contrast media and consumables. Energy-Efficient Radiology Practices - Strategies to reduce electricity consumption through smart scheduling, AI-powered image reconstruction, and energy-efficient equipment. Waste Management and Recycling - Implementation of contrast media recycling programs, paperless workflows, and proper disposal of radiological materials. Economic and Social Sustainability - The role of cost-effective digital solutions, telemedicine, and patient-centered approaches in promoting sustainability. Green Certification and Policies - Overview of sustainable healthcare certifications (e.g., LEED, Energy Star) and policy frameworks to promote eco-friendly radiology practices.

TABLE OF CONTENTS/OUTLINE

Introduction - The need for sustainability in radiology and its impact on healthcare systems. Energy Consumption in Medical Imaging - Analysis of power usage in different imaging modalities and potential savings with energy-efficient practices. Strategies for Sustainable Imaging Centers - Practical steps, including AI integration, energy-efficient scanner utilization, and eco-friendly facility design. Case Studies and Best Practices - Examples of radiology departments successfully implementing green initiatives. Challenges and Future Directions - Addressing barriers to sustainability adoption and exploring technological advancements that will shape eco-friendly radiology.

Abstract Archives of the RSNA, 2025

NREE-2 CRACKING THE CODE: IMAGING CLUES TO DISTINGUISH LONG-TERM EPILEPSY-ASSOCIATED TUMOR (LEAT) SUBTYPES

Julian Rodriguez Cely, MD (*Presenter*)
Andres Guillermo Tarra Romero, MD (*Abstract Co-Author*)
David F. Loaiza Ramirez SR, MD (*Abstract Co-Author*)
Rodrigo Arrieta Darras, MD (*Abstract Co-Author*)

TEACHING POINTS

LEATs (Long-term Epilepsy-Associated Tumors) are low-grade glioneuronal or glial neoplasms often causing pharmacoresistant epilepsy in young patients. MRI plays a key role in detecting, characterizing, and localizing these tumors, essential for surgical planning. Recognizing MRI patterns (e.g., bubbly multivesicular appearance in DNET, cystic-solid mural nodules in gangliogliomas or PXAs) improves diagnostic confidence and distinguishes LEATs from mimics. Correlation with histopathology and molecular markers (e.g., FGFR1, BRAF V600E) refines prognostic assessment. Awareness of rare LEAT entities (PGNT, PLNTY, MVNT, angiocentric gliomas) broadens the diagnostic scope.

TABLE OF CONTENTS/OUTLINE

Introduction Definition of LEATs Clinical significance in epilepsy surgery Imaging Features by Tumor Type Dysembryoplastic Neuroepithelial Tumor (DNET) Ganglioglioma (GG) Pleomorphic Xanthoastrocytoma (PXA) Papillary Glioneuronal Tumor (PGNT) Isomorphic Glioma Molecular and Histopathological Correlation WHO Classification updates Common genetic mutations (FGFR1, BRAF) Clinical and Surgical Relevance Role of MRI in localizing epileptogenic zones Importance of identifying cortical dysplasia Summary and Take-Home Messages

NREE-3 IMAGING INSIGHTS OF THE OPTIC NERVE IN MS DIANGOSIS: HOW TO USE THE FIFTH ELEMENT PRESERVING SPECIFITY

Tamara Hernandes Ricci, MD (*Presenter*)
Manoel Barbosa, MD (*Abstract Co-Author*)
Tatiana Iutaka, BDS (*Abstract Co-Author*)
Beatriz D. Prado, MD (*Abstract Co-Author*)
Ana Paula A. Fonseca, MD (*Abstract Co-Author*)
Felipe T. Pacheco, MD, PhD (*Abstract Co-Author*)
Felipe Scortegagna SR, MD (*Abstract Co-Author*)
Renato Hoffmann Nunes, MD, MBA (*Abstract Co-Author*)
Antonio Carlos M. Maia JR (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The objectives of this exhibit are to: ? Introduce the optic nerve as a fifth region for Dissemination in Space (DIS) in the upcoming 2024 revision of the McDonald criteria for Multiple Sclerosis. This addition aims to enhance the sensitivity of the diagnostic process while maintaining high specificity.? Highlight the clinical significance of including the optic nerve in the early diagnosis of Multiple Sclerosis, emphasizing how this can lead to earlier detection and better patient outcomes.? Review the underlying principles and current recommendations for incorporating the optic nerve as a diagnostic criterion, providing a comprehensive understanding of its role in the diagnostic framework.? Discuss the differential diagnosis of optic neuritis in Multiple Sclerosis and explore their respective MRI findings. It aims to provide a comprehensive understanding of how to distinguish MS-related optic neuritis from other conditions with similar clinical presentations, highlighting key imaging features that aid in accurate diagnosis."

TABLE OF CONTENTS/OUTLINE

? Introduction and initial considerations? Principles and recommendations for including the optic nerve as a diagnostic criterion? Optic neuritis as the first manifestation of multiple sclerosis? Differential diagnostics between demyelinating and non-demyelinating diseases with didactic illustrations? Final remarks

NREE-4 WHITE MATTER WHISPERS: NEUROIMAGING FEATURES OF PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY

Lara Mori, MD (*Presenter*)
Diogo G. Correa, MD (*Abstract Co-Author*)
Tomas Freddi, MD (*Abstract Co-Author*)
Celso Hygino, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Progressive multifocal leukoencephalopathy (PML) is an infection caused by a human polyomavirus John Cunningham (JC) virus. In immunocompromised hosts, its reactivation causes an often fatal disease characterized by direct involvement of oligodendrocytes.Most patients with PML are HIV-positive, or use monoclonal antibodies.The clinical presentation usually includes paresis, sensory deficit, hemianopia, cognitive dysfunction, aphasia, and gait difficulties.Typically, imaging shows lesions involving mainly the subcortical white matter, without mass effect, hypodense on CT and with hyperintense signal on T2-weighted imaging and FLAIR, on MRI.Lesions are usually non-enhancing or with mild peripheral enhancement, bilateral but asymmetrical, or unilateral.In some cases, diffusion restriction may be observed in the periphery of the lesion.When associated with immune reconstitution inflammatory syndrome, PML is associated with atypical findings, such as marked contrast enhancement and mass effect.Important differential diagnosis are:HIV encephalitis, which generally affects the periventricular white matter and spares the subcortical white matter, unlike PML.Lymphoma: Some findings, such as contrast enhancement, restricted diffusion and hyperperfusion, suggest lymphoma. Other opportunistic infections: cytomegalovirus and toxoplasmosis, although characterized by areas of enhancement.

NREE-5 THE MYSTERIOUS MESH: EXPLORING RETE-LIKE CONFIGURATIONS OF THE MIDDLE CEREBRAL ARTERY

Pedro Mecate Prada, MD (*Presenter*)
Marcelo Z. Bringel Martins, MD (*Abstract Co-Author*)
Carlos Felipe D. Reyna, MD (*Abstract Co-Author*)
Juarez Pimentel, MD (*Abstract Co-Author*)
Marcos V. Camargo, MD (*Abstract Co-Author*)
Frederico Adolfo B. Silva, MD (*Abstract Co-Author*)
Flavia I. Cevasco, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Caio Nunes, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

- To review the embryology and pathophysiology of the Rete-like configurations of the Middle Cerebral Artery. - To recognize the imaging features of the Rete-like configurations of the Middle Cerebral Artery, and to review the differential diagnosis, highlighting the key diagnostic features. - To understand the hemodynamic repercussions of the Rete-like configurations of the Middle Cerebral Artery, including on the perfusion imaging. - To recognize complications associated with the Rete-like configurations of the Middle Cerebral Artery, particularly its relation to ischemic and hemorrhagic stroke. - Emphasize the importance of recognizing Rete-like configurations of the Middle Cerebral Artery to prevent diagnostic errors and inappropriate interventions.

TABLE OF CONTENTS/OUTLINE

- Definition, embryological basis, and hemodynamic repercussions - Clinical considerations and management strategies - Imaging features, and Complications, with teaching cases - Perfusion assessment - Differential diagnoses - Take Home Messages - References

NREE-6 READING BETWEEN THE PEAKS SPECTROSCOPY IN CHALLENGING NEURO-ONCOLOGY CASES

Pablo Nahuel Montalto, MD (*Presenter*)

TEACHING POINTS

Introduce the clinical indications and added value of MR spectroscopy in neuro-oncologic imaging. Recognize metabolic patterns in complex neuro-oncologic cases where spectroscopy can aid diagnosis. Understand the significance of key metabolites: NAA, Choline, Creatine, Lipids, and Lactate. Illustrate how spectroscopy findings correlate with treatment response and pathology. Emphasize how MRS complements conventional MRI, improving diagnostic confidence.

TABLE OF CONTENTS/OUTLINE

The role of MR spectroscopy in complex neuro-oncology cases Technical principles of MR spectroscopy and metabolic interpretation Spectroscopic findings in high-grade vs. low-grade gliomas Differentiation between tumor recurrence and radiation necrosis Spectroscopy in pseudoprogression and treatment-related changes Summary of clinical cases illustrating diagnostic impact Conclusion: MRS as a non-invasive tool to support decision-making in neuro-oncology

NREE-7 SHEDDING LIGHT ON ACUTE SPINAL CORD INFARCTION: IMAGING PEARLS, PITFALLS & DIFFERENTIAL DIAGNOSIS

Dhruti J. Maisuri, MD, MBBS (*Presenter*)

TEACHING POINTS

1.) Case based review that demonstrates the key MRI findings of acute spinal cord ischemia (ASCI) in both adults and children.2.) Review the vascular anatomy of the spinal cord as it pertains to imaging findings in ASCI.3.) Common and uncommon etiologies of ASCI and radiological differential diagnosis of ASCI.

TABLE OF CONTENTS/OUTLINE

Acute spinal cord ischemia (ASCI)is an uncommon diagnosis that requires a high index of suspicion by both the referring clinician and neuroradiologist interpreting the spinal MRI. Diagnosis can be especially challenging in the pediatric patient. This educational exhibit will present case based review of ASCI in pediatric and adult patients from our tertiary care center with an emphasis on the MRI findings including the importance of DWI. For example "Owl's eye " appearance is pathognomic for anterior spinal cord infarct. Based on our experience, diffusion weighted imaging (DWI) is highly recommended in all cases of acute myelopathy when possible. The STIR sequence is essential for detection of associated bone infarcts. The cases will demonstrate and discuss, a variety of etiologies of ASCI including atherosclerotic disease, thoracoabdominal dissection/ aneurysm repair, trauma, bronchial artery embolization for hemoptysis, sports related injury and fibrocartilaginous emboli. Examples of anterior and posterior spinal artery infarcts will be shown. The exhibit will also review spinal cord vascular anatomy as it pertains to the MRI findings of ASCI. Finally, we will discuss the radiological differential diagnosis(like tumour, infection/inflammation, demyelination).

NREE-8 NOT JUST A STROKE OF BAD LUCK: OVERVIEW OF SICKLE CELL NEUROVASCULAR COMPLICATIONS AND VENOUS HYPERINTENSITIES

Alejandro Gonzalez, BS (*Presenter*)
Kamish Marrero (*Abstract Co-Author*)
Manus Donahue, PhD (*Abstract Co-Author*)
Sumit Pruthi, MBBS (*Abstract Co-Author*)
Lori Jordan (*Abstract Co-Author*)

TEACHING POINTS

- 1. Sickle cell disease (SCD) is an inherited hemoglobinopathy causing RBC sickling and chronic anemia - 2. Neurologic complications include stroke , silent cerebral infarcts (SCIs) , moyamoya disease , and cerebral aneurysms - 3. Elevated cerebral blood flow (CBF) reflects impaired cerebral hemodynamics - 4. Neuroimaging is key for diagnosis of neurologic complications

TABLE OF CONTENTS/OUTLINE

- I. SCD pathophysiology and neurological complications - II. Neuroimaging findings of complications - III. Advanced neuroimaging techniques and treatments - IV. Conclusion SCD is associated with neurovascular complications such as SCIs, overt stroke, and cerebral vasculopathy. SCIs increase with age, affecting ~50% of patients by age 30, appearing on FLAIR as = 3mm white matter hyperintensities in border zones of CBF. Ischemic strokes, often involving the MCA territory, occur in early childhood. Hemorrhagic strokes are more frequent in the 3 rd -4 th decades of life. Both stroke types are linked to vasculopathy. MRA in moyamoya vasculopathy often reveals ICA occlusion/stenosis with lenticulostriate collaterals. Aneurysms occur often in atypical locations across anterior/posterior circulation. Elevated CBF, detected via advanced MRI techniques, compensates for reduced O 2 delivery due to chronic anemia but can result in cerebral capillary shunting and impaired O 2 extraction. Shunting appears as hyperintense signals in dural sinuses on arterial spin labeling MRI and is quantified by venous hyperintensity score (VHS). These findings

may serve as non-invasive markers of cerebrovascular dysfunction. Notably, stem cell transplant has been shown to significantly decrease CBF and reduce venous hyperintensities.

NREE-9 MYELINATION AND BEYOND: DEVELOPMENTAL MILESTONES, MOLECULAR GATEKEEPERS, AND MRI TOOLS FOR ACCURATE RECOGNITION OF HYPOMYELINATING AND DELAYED MYELINATION SYNDROMES

Mario Mahecha, MD (*Presenter*)
Camilo Perdomo, MD (*Abstract Co-Author*)
Fabricio G. Goncalves, MD (*Abstract Co-Author*)
Matt T. Whitehead, MD (*Abstract Co-Author*)

TEACHING POINTS

• Compare myelination patterns with standardized, age-matched MRI atlases to reduce diagnostic bias. • When findings are inconclusive, schedule follow-up MRI every 3-6 months to assess for progression versus stability. • Look for ancillary abnormalities that may suggest specific genetic or metabolic syndromes.

TABLE OF CONTENTS/OUTLINE

Objectives Review normal myelination milestones and their appearance on T1- and T2-W MRI. Differentiate key radiologic and clinical features of hypomyelination versus delayed myelination. Provide a visual key of each disorder using clearly labeled diagrams for rapid recognition and comparison. Introduction Myelination follows a predictable pattern reflecting neurodevelopment and depends on coordinated genetic and molecular signaling, which may be disrupted by leukodystrophies, hypothyroidism or environmental factors. Key Imaging Features Delayed Myelination: Evolving T1 and T2 shortening over time, consistent with age-adjusted norms. Hypomyelination: Stable T2 hyperintensity and lack of age-appropriate T1 shortening beyond expected developmental windows. Advanced Imaging Strategies Use inversion recovery sequences, diffusion tensor imaging (DTI), and myelin water fraction mapping. Common Pitfalls Confusing gliosis, edema, or volume loss with hypomyelination; missing early progression due to inadequate follow-up. Conclusion Distinguishing hypomyelination from delayed myelination requires integrating imaging, neurodevelopmental context and genetics to guide diagnosis and management.

NREE-10 DON’T BE BLIND: ORBITAL AND OCULAR PATHOLOGIES IN TRAUMA

Stephanie McClintock-Batista, MD, BS (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Pedro Collazo-Ornes, MD (*Abstract Co-Author*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Ana Davila Rodriguez (*Abstract Co-Author*)
Neian Contreras Alvarado (*Abstract Co-Author*)

TEACHING POINTS

1. Identify normal orbital anatomy using a space-themed visual analogy. 2. Recognize and classify orbital fractures and mechanisms of injury. 3. Use a structured CT search pattern to assess injury extent and guide clinical decisions. 4. Detect critical findings such as retrobulbar hemorrhage, globe rupture, optic nerve injury, or air tracking.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Anatomy Review IV. Mechanisms of Injury and Symptoms V. Imaging Search Pattern and CT Findings: 1. Orbital Wall Fractures 2. Globe Injury, Rupture, Intraorbital Hemorrhage 3. Retina, Muscles, Extraconal Soft Tissue VI. Management and Clinical Decision-Making VII. Conclusion Abstract: Orbital trauma is a common scenario for radiology residents, demanding swift and accurate CT interpretation. Given the complex anatomy and risk of multiple concurrent injuries, a systematic approach is vital. This exhibit guides learners in identifying key structures and trauma patterns, integrating mechanisms of injury and red flags to support timely clinical action. A creative space analogy enhances anatomical understanding: the lens is a hologram, the globe a fragile blue glass ball, muscles as robotic arms, optic foramen as a projection system, and the optic nerve as a power cable. CT cases from our institution illustrate critical findings, aiding learners in producing relevant, management-oriented reports. This engaging educational tool supports students, residents, and imaging specialists alike.

NREE-11 PUT A RING ON IT, DR. MAGIC: LET'S DISCUSS RING ENHANCING LESIONS OF THE BRAIN

Stephanie McClintock-Batista, MD, BS (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Noralys E. Pagan (*Abstract Co-Author*)
Lina Mercedes Bernier Colon (*Abstract Co-Author*)
Pedro Collazo-Ornes, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Provide an anatomical review of the relevant structures involved in ring enhancing lesions. 2. Discuss the mechanism and subtypes of ring enhancing lesions. 3. Explain characteristic imaging findings and their correlation with specific subtypes. 4. Use engaging imagery and the mnemonic of Dr. MAGIC to create visual associations that improve memory and understanding of ring enhancing pathologies.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Anatomy Review IV. Ring enhancing lesions. 1. Subtypes- MAGICDR M: Metastasis A: Abscess G: Glioblastoma I: Infarct (subacute phase) or Inflammatory (neurocysticercosis) C: Contusion D: Demyelinating disease R: Radiation necrosis or resolving hematoma VII. Conclusion Abstract: Ring-enhancing brain lesions can result from various pathological processes. These lesions often remain undiagnosed during initial presentation, particularly in patients managed conservatively or with subtle clinical symptoms. Accurate imaging interpretation using CT and MRI is essential but challenging due to overlapping enhancement patterns, diffusion characteristics, and associated features. This exhibit introduces the mnemonic Dr. MAGIC, which represents etiologies, such as infectious, neoplastic, inflammatory/autoimmune, vascular, and others aiming to provide a structured approach to evaluating ring enhancing lesions.

NREE-12 LAYER BY LAYER - A DEEP DIVE INTO CERVICAL AND INTRACRANIAL ARTERIAL DISSECTION

Lucas Aquino (*Presenter*)
Rafael Docema, MD (*Abstract Co-Author*)
Vitor C. Romano, MD (*Abstract Co-Author*)
Carlos Felipe D. Reyna, MD (*Abstract Co-Author*)
Tatiana L. Arcanjo, MD (*Abstract Co-Author*)
Renata Bertanha, MD (*Abstract Co-Author*)
Rogerio Iquizli, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

- To review the pathophysiology of cervical and intracranial arterial dissection - To review the imaging technique and protocols for the evaluation of cervical and intracranial arterial dissection - To recognize the imaging features of cervical and intracranial arterial dissection and to review the differential diagnosis and mimics, highlighting the key diagnostic features - To be familiarized with the evolution of arterial dissection and mural hematoma - To recognize the complications associated with the cervical and intracranial arterial dissection

TABLE OF CONTENTS/OUTLINE

- Introduction and pathophysiology - Imaging technics and protocols - Imaging features with teaching cases: - Doppler US, CT and CTA, MRI and MRA, VWI - Evaluation of the mural hematoma - Evolution and complications, with teaching cases - Differential diagnosis / Mimics, with teaching cases - Take home messages - References

NREE-13 UNDERSTANDING SELLAR AND PARASELLAR LESIONS: AN APPROACH BASED ON SELLAR DISPLACEMENT

Jordan Hughes, MD (*Presenter*)
Anish Neupane, MBBS, MD (*Abstract Co-Author*)
Amit Mahajan, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Lesions of the sella and parasellar regions are not uncommonly encountered by radiologists with a variety of etiologies including congenital, inflammatory, vascular and neoplastic. We will provide a brief review of the embryology and anatomy of the parasellar region as it can appear on imaging. Additionally, we will present a schema that can be useful in formulating a differential diagnosis for anterior and middle cranial fossa lesions focusing on how these lesions displace the sellar contents. We aim to demonstrate this approach using imaging examples and clinical correlates from our institution. Our suggested approach can be supplemental to CT and MRI characteristics thereby guiding the radiologist to an appropriate and comprehensive differential diagnosis. This as a result may allow for more targeted clinical management.

TABLE OF CONTENTS/OUTLINE

1. Introduction and background a. Clinical presentation b. Displacement as guiding tool 2. Anatomy and embryology 3. Inferior displacement a. Craniopharyngioma b. Dermoid/epidermoid c. Germinoma 4. Superior displacement a. Chondrosarcoma b. Clival plasmacytoma 5. Lateral displacement a. Meningioma b. Schwannoma c. Aneurysm 6. Intrinsic sellar lesions a. Pituitary adenoma b. Chloroma c. LCH 7. Discussion/conclusion 8. References

NREE-14 FROM SCAN TO SCALPEL: DECODING MENINGIOMAS THROUGH RADIOLOGY AND RESECTION

Mariana Carmo, MD (*Presenter*)
Andressa C. Kuzma, MD (*Abstract Co-Author*)
Enzo Fatuch (*Abstract Co-Author*)
Miguel Lins Quintella (*Abstract Co-Author*)
Bruno Coghi (*Abstract Co-Author*)
Sebastiao B. de Araujo Neto, MD (*Abstract Co-Author*)
Stenio Burlin, MD (*Abstract Co-Author*)
Luis Antonio Tobaru Tibana, MD (*Abstract Co-Author*)
Gustavo D. Gomez, MD (*Abstract Co-Author*)

TEACHING POINTS

To understand the imaging characteristics, mainly in preoperative planning. Radiologists must assess tumor relationships with cortex, and neural/vascular structures to guide surgical approach and outcomes. To study the radiological features suggesting specific histological subtypes. These findings can raise suspicion for a higher-grade tumor and prompt more aggressive surgical planning and consideration of adjuvant therapies. Understanding these correlations aids neurosurgeons in predicting tumor behavior. To assist in risk stratification and help determine the frequency of follow-up imaging and whether adjuvant treatment is warranted, even after gross total resection. Larger tumor size, presence of peritumoral edema, irregular shape, dural tail extending a long distance, and heterogeneous enhancement have all been linked to higher-grade meningiomas (WHO Grade II or III) and increased recurrence rates.

TABLE OF CONTENTS/OUTLINE

Meningiomas, common extra-axial intracranial tumors, require accurate radiology for effective neurosurgical planning. While definitive grading requires histology, radiologists should comment on features suggestive of higher-grade lesions (e.g., irregular margins, heterogeneous enhancement, brain invasion, peritumoral, and restricted diffusion). The WHO classification (Grades I, to III) reflects increasing aggressiveness. We will correlate radiological and histopathological findings from surgical specimens across 15 meningioma classification types. Neurosurgeons rely on radiologists for a comprehensive "roadmap" of anatomical relationships, aggressiveness, and complications, enabling safe surgery and complication anticipation.

NREE-15 ADVANCES IN NEUROIMAGING IN THE ASSESSMENT OF MENINGIOMAS - SURGICAL IMPLICATIONS AND MOLECULAR MARKERS

Rafael Docema, MD (*Presenter*)
Luiz R. Uchoa, MD (*Abstract Co-Author*)
Youssef Bazzoun (*Abstract Co-Author*)
Lavinia Dias, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Eduardo C. Ribas, MD,PhD (*Abstract Co-Author*)
Guilherme C. Ribas, MD,PhD (*Abstract Co-Author*)
Fabiana D. Hirata, MD (*Abstract Co-Author*)
Renata Bertanha, MD (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)

TEACHING POINTS

- Understanding the pathophysiology of meningiomas, risk factors and relation with genetic syndromes - Understanding the dual arterial supply of meningiomas, the contribution of pial arteries and the relation with subjacent brain parenchyma edema - Understanding and classifying the degree of dural sinuses invasion and the implications for tumor resection - Discussing molecular markers and updates in the classification of meningiomas - Understanding the relation between meningioma's imaging aspects and the degree of aggressiveness and prognostic impact - Discussing mimics and red flags of meningiomas

TABLE OF CONTENTS/OUTLINE

- Introduction - Arterial supply - Pial arteries and edema - Dural sinuses - Molecular markers and classification updates - Imaging aspects and correlation with aggressiveness and prognosis - Teaching cases - Red flags / Mimics - Take home messages - References - Authors

NREE-16 NEURODEGENERATION IN FOCUS: IMAGING THE HIDDEN PATTERNS OF MOVEMENT DISORDERS

Motaz A. Daraghma, MD (*Presenter*)
Qays Abu-Saymeh (*Abstract Co-Author*)
Ayman Nada, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

After completing this exhibit, the viewer will be able to:*Understand the key pathogenesis of Parkinson’s disease and Parkinson syndromes*Correlate between the pathogenesis and the imaging techniques*Learn about the clinical significance of imaging biomarkers and their role in diagnosis, planning of treatment, and management of patients.*Identify the specific findings of Parkinsonian syndromes on MRI*Differentiate between Parkinson’s disease and atypical Parkinsonian disorders, such as: progressive supranuclear palsy, corticobasal degeneration, and multiple system atrophy.*Avoid common diagnostic pitfalls by correlating clinical features with neuroimaging patterns.*Recognize new MRI techniques and their potential future clinical applications.

TABLE OF CONTENTS/OUTLINE

*Introduction and overview of movement disorders and the role of imaging*The key mechanisms of disease development and how these help in developing specific imaging techniques*Clinical Correlations and Diagnostic Pitfalls*Imaging workup for a suspected cases of Parkinson's disease or syndrome*MRI Findings in Parkinsonian Syndromes*Impact of various imaging findings on patients' outcomes*Rule of the imaging biomarkers in treatment evaluation, and monitoring disease progression*Clinical Implications and Future Directions

NREE-17 IDENTIFYING ORBITAL MASSES AND MASS-LIKE LESIONS

Jo Ann Sun (*Presenter*)
Tausif Siddiqui (*Abstract Co-Author*)
Akm Rahman, DO (*Abstract Co-Author*)

TEACHING POINTS

1. Orbital masses present with overlapping clinical symptoms such as proptosis, vision changes, or pain. Multimodal imaging and pathologic correlation are critical for accurate diagnosis. 2. Understanding orbital compartmental anatomy (intraconal vs. extraconal) provides a systematic approach to lesion localization and diagnosis. 3. Characteristic imaging signs, such as "tram-tracking" in optic nerve sheath meningioma, provide diagnostic clues. 4. Awareness of emergent entities like orbital compartment syndrome is critical due to the risk of vision loss and intracranial complications. 5. Non-neoplastic mimics, including inflammatory conditions like orbital pseudotumor or thyroid eye disease, can manifest similarly to tumors and should be considered in the differential.

TABLE OF CONTENTS/OUTLINE

1. Background 2. Orbital Anatomy Overview 3. Common Orbital Lesions 3a. Orbital Lymphoma 3b. Pleomorphic Adenoma 3c. Optic Pathway Glioma 3d. Rhabdomyosarcoma 3e. Optic Nerve Sheath Meningioma 3f. Schwannoma 3g. Orbital Cavernous Venous Malformation 3h. Arteriovenous Malformation (AVM) 4. Emergent and Inflammatory Conditions 4a. Orbital Compartment Syndrome 4b. Orbital Pseudotumor 5. Miscellaneous Orbital Lesions 5a. Retinoblastoma 5b. Phthisis Bulbi 5c. Thyroid Eye Disease 6. Key Points

NREE-18 IMAGING FINDINGS OF COMPLICATIONS FROM MIDDLE MENINGEAL ARTERY EMBOLIZATION

Zack Nigogosyan, MD (*Presenter*)
Uma Mani, MD (*Abstract Co-Author*)
Noor Alnazal, DO (*Abstract Co-Author*)
Sarah Alnazal, DO (*Abstract Co-Author*)
Ayman Nada, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Describe indications and pathophysiology of middle meningeal artery embolization? 2. Understand anatomy of the middle meningeal artery? 3.Recognize possible complications related to middle meningeal artery embolization ? 4. At the completion of this presentation, the participant will be able to: ? Understand the middle meningeal artery origin and its variant anatomy? Determine possible complications related to middle meningeal artery embolization ? Comprehend procedural techniques that can be used to reduce risk of complications? Describe imaging that can be performed to detect and prevent potential complications?

TABLE OF CONTENTS/OUTLINE

Introduction to middle meningeal artery embolization? Pathophysiology of middle meningeal artery embolization in chronic subdural hematoma ? Anatomy of the middle meningeal artery? Case-based study of complications of middle meningeal artery embolization ? Embolic? Middle meningeal artery perforation ? Off target embolizationDevice complications (ex. retained catheter after glue)?

NREE-19 CLINICAL UTILITIES OF SUPER-SELECTIVE ARTERIAL SPIN LABELING

Takashi Katsube, MD (*Presenter*)
Aiko Gobara, MD (*Abstract Co-Author*)
Hiroya Asou (*Abstract Co-Author*)
Makoto Obara (*Abstract Co-Author*)
Takeshi Yoshizako, MD (*Abstract Co-Author*)
Yasushi Kaji, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The application of super-selective arterial spin labeling (SS-ASL) has made it possible to acquire vascular-selective cerebral perfusion images and vascular-selective 4D-MR angiography (4D-S-PACK), which were previously difficult to obtain. Importantly, SS-ASL enables the evaluation of cerebral blood flow information that cannot be assessed with conventional ASL or MR angiography. These images can be acquired alongside routine MRI scans using a non-invasive method without radiation exposure. 1. SS-ASL provides novel imaging information by generating vascular-selective perfusion images in brain axial sections. This section will discuss the clinical utility of SS-ASL in visualizing changes in cerebral blood flow distribution due to vascular lesions and characterizing blood flow patterns in brain tumors. 2. 4D-S-PACK is a non-invasive imaging technique that provides dynamic vascular information closely resembling digital subtraction angiography (DSA). This section will highlight the clinical utility of 4D-S-PACK in assessing various vascular pathologies, including moyamoya disease, arteriovenous malformations, and dural arteriovenous fistulas.

TABLE OF CONTENTS/OUTLINE

A. Principles of SS-ASL technique 1. SS-ASL: vascular-selective pseudo-continuous ASL image 2. 4D-S-PACK: vascular-selective 4D-MR angiography B. Limitations and Accuracy of SS-ASL and 4D-S-PACK 1. Diffiulti in selecting blood vessels 2. Artifacts and pitfalls C. Clinical Utilities of SS-ASL and 4D-S-PACK 1. Moyamoya disease, Cerebral vascular stenoses 2. Superficial temporal artery-middle cerebral artery bypass evaluation 3. Arteriovenous malformations, Arteriovenous fistulas 4. Brain tumors

NREE-20 NEUROLYMPHOMATOSIS IMAGING: UNVEILING THE INVISIBLE — A CASE-BASED REVIEW

Greg Pommier (*Presenter*)
Seulah Choi, MD (*Abstract Co-Author*)
Sasicha Manupipatpong, MD (*Abstract Co-Author*)
Jake Schick, BS, MD (*Abstract Co-Author*)
Francis Deng, MD (*Abstract Co-Author*)
Majid A. Khan, MD (*Abstract Co-Author*)

TEACHING POINTS

Neurolymphomatosis (NL) is a rare but serious manifestation of lymphoma, characterized by infiltration of cranial and/or peripheral nerves by malignant lymphocytes. Clinical presentation is highly variable and may mimic neuropathies or cranial nerve palsies, making diagnosis particularly challenging—especially when NL is the initial manifestation of lymphoma. MRI and [^{18}F]FDG-PET are key imaging modalities, frequently demonstrating nerve thickening, contrast enhancement, and/or FDG avidity. Definitive diagnosis often requires nerve biopsy; however, this is invasive and may be deferred when imaging and clinical features are strongly suggestive. Treatment typically involves systemic chemotherapy and/or radiation therapy. While the overall prognosis is poor, early recognition and aggressive management may improve outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction: definition and epidemiology of NL; clinical significance and diagnostic challenges. Case Series: composed of five cases corresponding to Figures 1-5 (attached). Pathophysiology and Disease Spectrum: mechanisms of lymphomatous nerve infiltration; central vs. peripheral nervous system involvement; common lymphoma subtypes associated with NL. Diagnostic Workup: clinical features and differential diagnosis; imaging modalities (MRI and [^{18}F]FDG-PET/CT); importance and limitations of nerve biopsy. Management Strategies: systemic chemotherapy regimens; indications for radiation therapy; supportive care and symptom management. Clinical Implications and Future Directions: importance of early recognition; challenges in diagnosis and treatment; ongoing research into targeted therapies and biomarkers.

NREE-21 BRIDGING THE GAP: DECODING CORPUS CALLOSAL ABNORMALITIES WITH FETAL MRI

Kranthi K. Marathu, MD, MBBS (*Presenter*)
Shehbaz M. Ansari, MD, MBBS (*Abstract Co-Author*)
Okan Ince, MD (*Abstract Co-Author*)
Kapil Semalti, MBBS, MD (*Abstract Co-Author*)
Aysha Lamis Vattoth, MD (*Abstract Co-Author*)
Sumeet G. Dua, MD (*Abstract Co-Author*)
Santhosh Gaddikeri, MD (*Abstract Co-Author*)
Miral D. Jhaveri, MD, MBA (*Abstract Co-Author*)
Surjith Vattoth, MD, FRCR (*Abstract Co-Author*)
Sharon E. Byrd, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Outline the current classification system for fetal corpus callosal abnormalities 2. Familiarize the audience with the embryological development process of corpus callosum 3. To illustrate and discuss fetal MRI images with corpus callosal abnormalities and associated central nervous system (CNS) and non-CNS anomalies

TABLE OF CONTENTS/OUTLINE

Corpus callosal abnormalities (CCA) encompass a range of structural malformations that can occur in isolation or with other CNS and non- CNS anomalies. While these abnormalities have been frequently described in the literature, a universally accepted classification system remains absent. Historically, prenatal diagnosis relied heavily on ultrasound, which, despite its accessibility, has limitations in detecting subtle brain malformations and associated syndromic features. Fetal MRI has emerged as a superior modality enabling more accurate characterization of CCA subtypes, assessing the severity and in identifying associated anomalies. This detailed imaging aids in recognition of genetic syndromes, supporting early diagnosis, assessing the potential neurodevelopmental prognosis, guiding parental counseling. For radiologists and clinicians, fetal MRI also provides valuable information about the expected findings at different gestational ages and informs both prenatal management and postnatal follow-up. This pictorial essay presents illustrative embryological diagrams detailing the development of the corpus callosum. Additionally, we introduce the latest classification of CCA, accompanied by representative fetal MRI findings highlighting associated midline anomalies, cortical malformations, and posterior fossa abnormalities.

NREE-22 SUBACUTE AND CHRONIC CEREBRAL VENOUS THROMBOSIS: A RADIOLOGIC ROADMAP TO DIAGNOSIS AND FOLLOW-UP

Griselda T. Romero Sanchez, MD (*Presenter*)
Michelle Y. Gonzalez Putoy SR, MD (*Abstract Co-Author*)
Angela M. Sosa, MD, MSc (*Abstract Co-Author*)
Kristina Ramirez Garcia, MD (*Abstract Co-Author*)
Jason R. Shewchuk, MD (*Abstract Co-Author*)
Mahmud Mossa-Basha, MD (*Abstract Co-Author*)

TEACHING POINTS

Describe the cerebral venous system anatomy and its relevance in cerebral venous drainage. Understand the pathogenesis and risk factors associated with subacute and chronic venous thrombosis (CVT). Review the optimal imaging modalities for diagnosing and monitoring CVT, including CTV, MRI, and MRV. Highlight the importance of follow-up imaging in determining prognosis and guiding patient management. Identify key imaging findings in acute, subacute and chronic settings of CVT.

TABLE OF CONTENTS/OUTLINE

1 . Introduction: -Cerebral Venous Anatomy:- Dural venous sinuses: Superior and Inferior Dural Sinuses. -Cerebral veins: Cortical veins, deep venous system, and transcerebral anastomoses. - Anatomical Pitfalls: Hypoplasia, high-riding bifurcations, septi, and Arachnoid granulations. 2. Imaging Approach for Diagnosis and Follow-Up: - Role of CT, CTV, MRI, MRV and VW-MRI in diagnosis. - Strengths and limitations of each modality- Follow-up imaging protocols and interpretation. 3. Imaging Findings Across Disease Phases: Case-Based Review. -Acute CVT: Direct signs: Dense triangle sign, cord sign, empty delta sign. Indirect signs: Venous infarction, cerebral edema, subarachnoid/subdural hemorrhage. - Subacute CVT: Thrombus propagation, evolving infarction or hemorrhage, and early recanalization.- Chronic CVT and Complications: Imaging of dural arteriovenous fistulas (dAVFs), signs of intracranial hypertension, and veno-occlusive patterns. 4. Prognostic and Management Implications: - Clinical relevance of imaging follow-up.- Correlation with outcomes and decision-making regarding anticoagulation, or endovascular therapy.

NREE-23 AN UPDATED REVIEW OF THE IMAGING FINDINGS OF THE FULL SPECTRUM OF CNS LYMPHOMA

Mana Shams, MD (*Presenter*)
Keon Mahmoudi, MD (*Abstract Co-Author*)
Ameera F. Ismail, MD (*Abstract Co-Author*)

TEACHING POINTS

CNS lymphoma is the second most frequent primary brain malignancy in adults after gliomas. Historically the literature has described the radiological features of the most typical imaging appearances of CNS lymphoma without accounting for rarer presentations or subtypes encountered in the real world. Classification of CNS lymphoma is evolving and has been updated in the World Health Organization Classification of CNS tumors 2021 and Hematolymphoid Tumors 2022. Knowledge of the full spectrum of disease is essential for the radiologist to avoid misdiagnosis and for early detection and initiation of treatment.

TABLE OF CONTENTS/OUTLINE

CNS lymphoma is the second most common primary brain malignancy in adults. Early suspicion of the disease and initiation of treatment has a favorable impact on survival. Radiologists play a key role in its diagnostic workup, and failure to suggest its possibility carries negative clinical impact. The radiological features most often described in the literature pertain to the characteristics of primary diffuse large B-cell lymphoma (DLBCL) of the CNS negative for Epstein-Barr virus. However, rarer presentations of DLBCL and other specific subtypes with their own distinct imaging features are infrequently described in the literature, yet regularly encountered in real practice. We will provide the radiologist an updated review of the full spectrum of CNS lymphoma through a range of neuroradiological cases reflecting typical and atypical presentations. Cases of primary DLBCL of the CNS, immunodeficiency-associated lymphoma, mucosa associated lymphoid tissue lymphoma, intravascular lymphoma, and lymphomatosis cerebri will be reviewed, among other cases of secondary lymphoma.

NREE-24 ORBITAL APEX DISORDERS: FROM ANATOMY TO IMAGING — A COMPREHENSIVE REVIEW FOR IMPROVING CLINICAL OUTCOMES

Aiko Gobara, MD (*Presenter*)
Takashi Katsube, MD (*Abstract Co-Author*)
Takeshi Yoshizako, MD (*Abstract Co-Author*)
Yasushi Kaji, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Orbital Apex Disorders (OADs), including Orbital Apex Syndrome, Superior Orbital Fissure Syndrome, and Cavernous Sinus Syndrome, share overlapping features due to intricate, contiguous anatomy. This complexity presents diagnostic challenges, making accurate imaging crucial for outcomes. This exhibit provides a structured review correlating anatomy, clinical symptoms, and pathology to improve diagnostic accuracy and guide management. 1. To describe the detailed anatomy of the orbital apex and surrounding structures.2. To correlate OADs symptoms with the precise anatomical location of the lesions.3. To recognize characteristic imaging findings of various diseases affecting the orbital apex.4. To identify optimal imaging techniques and protocols for evaluating suspected OADs.5. To integrate clinical and imaging findings for differential diagnoses and appropriate patient management.

TABLE OF CONTENTS/OUTLINE

A. Anatomy: Detailed review of the orbital apex and related structures. B. Clinical Syndromes: OAD presentation; linking symptoms to affected structures. C. Pathology & Imaging: Overview of OADs with imaging examples: Inflammatory/Infectious, Neoplastic (Benign & Malignant), Vascular, Traumatic/Iatrogenic, Endocrine & Miscellaneous. D. Imaging Techniques: CT and MRI protocols for OADs; role of advanced MR sequences. E. Diagnostic Algorithm & Management: Systematic approach integrating clinical presentation, imaging findings, and management considerations.

NREE-25 SUPRATENTORIAL PEDIATRIC BRAIN TUMORS: INSIGHTS FROM THE WHO 2021 CLASSIFICATION AND RECENT UPDATES

Mariko Kurokawa, PhD, MD (*Presenter*)
Ryo Kurokawa, MD, PhD (*Abstract Co-Author*)
Aristides A. Capizzano, MD (*Abstract Co-Author*)
Osamu Abe, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. pHGGs are classified into four molecular subtypes:DMG-H3K27a, DHG-H3G34m, H3/IDH-wildtype, and IHG differ in genetics and clinical features. 2. MRI helps predict tumor subtype noninvasively:Findings like T2-FLAIR mismatch (DMG-H3K27a) or well-defined enhancement (MYCN-subtype) aid diagnosis.3. Imaging and molecular data enable radiogenomic prediction:Radiomics and AI can detect mutations such as H3K27M or G34R/V. 4. Prognosis and therapy differ by subtype:IHG has better outcomes; DHG-H3G34m and MYCN-subtype are more aggressive. 5. WHO CNS5 stresses age- and mutation-based diagnosis:Molecular tests (e.g., methylation, NGS) guide classification and targeted treatment.

TABLE OF CONTENTS/OUTLINE

Pediatric-type high-grade gliomas (pHGGs) are aggressive tumors classified into four WHO CNS5 subtypes: DMG-H3K27a, DHG-H3G34m, pediatric-type HGG (H3/IDH-wildtype), and IHG. These differ in age, location, imaging, genetics, and prognosis. MRI offers key non-invasive clues: DMG-H3K27a shows midline location, T2-FLAIR mismatch, and minimal enhancement; DHG-H3G34m presents as large hemispheric masses with necrosis and hemorrhage. MYCN subtype appears well-circumscribed with solid enhancement. IHG occurs in infants as large cystic tumors with enhancing walls. Radiogenomic tools such as radiomics and AI help predict mutations like H3K27M or G34R/V, especially when biopsy is limited. Prognosis varies—IHG often has better outcomes, while DMG-H3K27a and DHG-H3G34m are more aggressive. Molecular diagnostics and targeted therapies (e.g., NTRK, EGFR, ALK inhibitors) are essential. Integrating imaging and molecular data is key to personalized care in pediatric neuro-oncology.

NREE-28 CT-GUIDED PERCUTANEOUS BIOPSY FOR DISCITIS-OSTEOMYELITIS; A PRIMER

Josephina A. Vossen, PhD (*Presenter*)
Yujie Qiao, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit will review indication, techniques and potential complications of CT-guided percutaneous biopsy for discitis-osteomyelitis. CT-guided disc/endplate sampling is a minimally invasive, safe and accurate procedure for tissue diagnosis.

TABLE OF CONTENTS/OUTLINE

- Discuss the indications and contraindications of CT-guided percutaneous biopsy for discitis-osteomyelitis, including review of current Infectious Diseases Society of America guidelines. - Review of the commonly used approaches to access the disc and/or vertebral body endplate. This includes pre-procedural planning, patient positioning, needle angulation and identification of vital structures. - Describe and illustrate the expected imaging appearance during CT-guided percutaneous vertebral biopsies and discuss techniques to maximize sampling success. - Describe complications and their imaging appearance.

NREE-29 SELLARCRANIAL CYST CONUNDRUM: CAN YOU SPOT THE DIFFERENCE?

Zeshan Tariq (*Presenter*)
Hrishikesh A. Kale, MD, MBBS (*Abstract Co-Author*)
Hussam Abou-al-Shaar (*Abstract Co-Author*)
Paul Gardner (*Abstract Co-Author*)
Vikas Agarwal, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

Sellar cystic lesions encompass a broad, differential (Rathke cleft cyst (RCC), arachnoid cyst (AC), cystic pituitary adenomas (CPA), epidermoid cyst, dermoid cyst, craniopharyngiomas, xanthogranulomas, and others) each of which require different surgical treatments thereby providing impetus for specific identification. Of particular importance is the ability to differentiate between the easily misidentified RCC, AC, and CPA. Our specific teaching points are as follows : 1. Review the imaging characteristics of the sellar region on CT and MRI 2. Provide representative clinical presentations and imaging characteristics of RCC, AC, CPA 3. Highlight differences in pathological mechanisms of each entity and correlate them to radiological modalities 4. Practice differentiation between all three entities and the usage of a decision tree cognitive aid 5. Describe neurosurgical management and approaches for each entity.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Mechanism, clinical presentation, imaging characteristics, treatment a. RCC b. AC c. CPA 3. Decision Tree Overview 4. Case Challenge with highlights of common pitfalls 5. Conclusion

NREE-30 RADIOLOGIC ATLAS OF CRANIAL NERVE NEOPLASMS: DIAGNOSTIC STRATEGIES, IMAGING INSIGHTS, AND KEY MIMICS ALONG ANATOMICAL PATHWAYS

Naman Gupta, MD (*Presenter*)
Ankita Gupta, MBBS, MD (*Abstract Co-Author*)
Parul Gupta, MBBS, MD (*Abstract Co-Author*)
Divyansh Gupta, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

An imaging-first, anatomy-guided approach allows accurate identification of cranial nerve tumors and distinction from mimics. Advanced MRI sequences aids in lesion localization and characterization. Case-based learning highlights the importance of recognizing atypical presentations and maintaining high clinical suspicion.

TABLE OF CONTENTS/OUTLINE

. Introduction • Overview of cranial nerve anatomy and clinical relevance• Diagnostic challenges: rarity, symptoms, complex anatomy• Imaging's central role in localization and differential diagnosis 2. Imaging Strategy & Workflow • MRI (T1, T2, FLAIR, contrast, DWI, CISS/FIESTA), CT for bony detail• Structured approach: nerve origin, course, morphology, enhancement, skull base changes• Malignancy clues: red flags, atypical features 3. Case-Based Tumor Spectrum • CN I: Meningioma vs esthesioneuroblastoma• CN II: Sheath meningioma vs glioma• CN III: Schwannoma, rare pediatric ATRT• CN V: V1/V3 schwannomas • CN VI: Intraorbital abducens schwannoma• CN VII-VIII: Bilateral schwannomas , facial pseudocysts• CN IX-XI: Jugular schwannoma (NF2) vs paraganglioma• CN X: Vagal schwannoma vs paraganglioma• CN XII: Hypoglossal palsy from breast cancer metastasis 4. Mimics & Differentiation • Imaging distinctions: cranial nerve tumors vs meningiomas• Common mimics: metastases, infections, perineural spread• Key signs: dural tail, calcification, bone changes 5. Teaching Pearls • Annotated imaging with key takeaways• Localization strategy and diagnostic pitfalls• Checklist: nerve-based vs dural-based lesions 6. Conclusion • Radiologist's role in early, accurate diagnosis• Importance of a structured approach• Impact on surgical planning and outcomes

NREE-31 UNLOCKING THE SINUS: IMAGING INSIGHTS INTO INTRACRANIAL HYPERTENSION AND STENTING

Guilherme Swerts Pereira (*Presenter*)
Thiago G. Abud, MD (*Abstract Co-Author*)
Fabiana D. Hirata, MD (*Abstract Co-Author*)
Tatiana L. Arcanjo, MD (*Abstract Co-Author*)
Renata Bertanha, MD (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

To discuss the association between transverse sinus stenosis and intracranial hypertension, and to emphasize the importance of neuroimaging in the diagnostic, especially when clinical suspicion is low. To review the imaging technique and protocols for the evaluation of transverse sinus stenosis and intracranial hypertension. To recognize the imaging features of the transverse sinus stenosis and intracranial hypertension. To discuss the role of endovascular stenting in the treatment of transverse sinus stenosis and intracranial hypertension. To be familiarized with the post-angioplasty imaging features. To present follow-up strategies to evaluate stent patency and monitor for signs of intracranial hypertension.

TABLE OF CONTENTS/OUTLINE

Introduction; Anatomy and pathophysiology; Imaging features of transverse sinus stenosis and intracranial hypertension, with teaching cases; Dural sinus angioplasty, with teaching cases; Post-angioplasty imaging evaluation, with teaching cases. Take home messages; References.

NREE-32 MRI CHANGES IN CLIVAL CHORDOMAS FOLLOWING ADJUVANT PROTON THERAPY

Marina Siesto Marcos, MD (*Presenter*)
Maria Teresa Corbalan Sevilla (*Abstract Co-Author*)
Jose Maria Lara Torres, PhD (*Abstract Co-Author*)
Eva E. Romo (*Abstract Co-Author*)
Oscar Felipe Gutierrez Arteaga (*Abstract Co-Author*)
Pagliarani Gil Pablo, MD (*Abstract Co-Author*)
Maria Castillo (*Abstract Co-Author*)
David Amo Calzas, MD (*Abstract Co-Author*)

TEACHING POINTS

The main objective of this study is to evaluate the MRI findings of skull base chordomas and the changes following adjuvant treatment with proton therapy.

TABLE OF CONTENTS/OUTLINE

1. Purpose or Learning Objective: The main objective of this study is to evaluate the MRI findings of skull base chordomas and the changes following adjuvant treatment with proton therapy. 2. Methods: We performed a retrospective review of the clivus chordomas and their treatments, and we describe a case of clivus chordoma diagnosed at our centre that was treated with proton therapy as adjuvant therapy. 3. Results: MRI scans after adjuvant proton therapy showed some of the characteristic findings associated with this type of therapy. 4. Conclusion: Total resection of skull base chordomas is often not possible due to the involvement of surrounding neurovascular structures. Therefore, residual tumors must be treated with adjuvant therapy, with proton therapy playing an increasingly prominent role in recent years. The neuroradiologist has a key role in identifying the initial and/or residual disease, recurrence, and treatment complications.

NREE-33 NEUROIMAGING IN YOUNG STROKE : A PICTORIAL REVIEW

Divya Saikumar, MBBS, MD (*Presenter*)

TEACHING POINTS

1. To review the etiology of young stroke, their characteristic imaging findings and classic signs 2. To explore the role of advances in neuroimaging in the timely diagnosis and management of young stroke 3. To develop an algorithmic approach to young stroke based on their imaging features and to differentiate them from common mimics. We did a retrospective review of 63 cases of young stroke of various etiologies which came to our institution during a one year period for teaching purposes. We present a pictorial review of the above cases highlighting their differentiating imaging features and formulate an algorithmic approach to the diagnosis of young stroke. We explore the role of various diagnostic neuroimaging techniques and interventional radiology in the timely diagnosis and management of young stroke.

TABLE OF CONTENTS/OUTLINE

A. Learning Objectives B. Background C. Role of imaging D. Imaging modalities in stroke - Non-contrast CT and MRI, Cross sectional angiography, Perfusion imaging, Vessel wall imaging, Catheter angiography E. Causes of young stroke, various imaging signs and management 1. Cardioembolic causes 2. Dissection and vasculitis 3. Prothrombotic causes 4. Reversible cerebral vasoconstriction syndrome (RCVS) 5. Monogenic causes like cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) 6. Moya Moya disease 7. Mitochondrial Encephalopathy, Lactic Acidosis and Stroke like episodes (MELAS) 8. Rare genetic causes like Adenosine deaminase 2 deficiency (DADA2) F. Conclusion

NREE-34 EXTRAOCULAR INVOLVEMENT OF RETINOBLASTOMA: IMAGING FINDINGS

Mariana Faria Amaral, MD (*Presenter*)
Giulia Caroline Paes Scopel, MD (*Abstract Co-Author*)
Tereza Souto, MD (*Abstract Co-Author*)
Carolina Albernaz Henriques, MD (*Abstract Co-Author*)
Jose Lucas De Araujo Rabelo (*Abstract Co-Author*)
Gabriel Tizey (*Abstract Co-Author*)
Luiz Paulo Faria Renzi, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: To provide a general education review of some of the most common types of extraocular involvement of retinoblastoma. Teaching points: A) Understanding general aspects of retinoblastoma such as definition, epidemiology and diagnostic methods. B) Highlighting the importance of extraocular involvement as a marker of poor prognosis and of significantly increased risk of distant metastasis. C) Pointing out the role of orbit and neuroaxis MRI in the diagnosis and

monitoring of patients with extraocular retinoblastoma. D) Presenting MRI findings of extraocular involvement that radiologists should know in order to report these cases, such as trilateral involvement, leptomeningeal spread and tumor recurrence in ocular implants after enucleation for treatment of primary involvement.

TABLE OF CONTENTS/OUTLINE

A) Retinoblastoma definition, epidemiology and diagnostic. B) Extraocular involvement of retinoblastoma and imaging features: 1- local extraocular dissemination; 2- trilateral retinoblastoma; 3- leptomeningeal involvement and 4- tumor recurrence in ocular implant. C) Treatment and prognosis. D) Take home messages.

NREE-35 PRACTICAL APPROACH TO NEUROIMAGING OF EPILEPTOGENIC TUMORS: A COMPREHENSIVE REVIEW

Max Yunior Orsi Salazar, MD (*Presenter*)
Ana Paula A. Fonseca, MD (*Abstract Co-Author*)
Larissa A. Martins, MD (*Abstract Co-Author*)
Tatiana Iutaka, BDS (*Abstract Co-Author*)
Felipe T. Pacheco, MD, PhD (*Abstract Co-Author*)
Felipe Scortegagna SR, MD (*Abstract Co-Author*)
Renato Hoffmann Nunes, MD, MBA (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This article provides a comprehensive overview of neuroimaging protocols and diagnostic approaches for epileptogenic tumors.The purposes of this exhibit are to:? Discuss the MRI protocol, including the International League Against Epilepsy-endorsed Harmonized Neuroimaging of Epilepsy Structural Sequences (HARNESS)? Address Long-term Epilepsy-Associated Tumors (LEATs), their diagnostic characteristics, and different representatives: gangliogliomas, dysembryoplastic neuroepithelial tumors (DNETs), pilocytic astrocytomas, angiocentric gliomas, and the recently included tumors, such as diffuse astrocytoma MYB or MYBL1 altered, polymorphous low-grade neuroepithelial tumor of the young (PLNTY), and multinodular and vacuolating neuronal tumor (MVNT)? Discuss the differential diagnoses of epileptogenic lesions, such as focal cortical dysplasia, encephalitis, other tumors, vascular malformations, and post-ictal changes? Propose a flowchart for the practical approach to epileptogenic tumors"

TABLE OF CONTENTS/OUTLINE

? Introduction? MRI Protocolo Including the HARNESS protocol? Long-term Epilepsy-Associated Tumors (LEATs)o Required characteristics for LEATso LEATs:? Gangliogliomas? DNET? Pilocytic astrocytomas? Angiocentric gliomas? Diffuse astrocytoma MYB or MYBL1 altered? PLNTY? MVNT? Differential diagnosiso Focal cortical dysplasiao Encephalitiso Other tumorso Vascular malformationso Post-ictal changeso Other? Flowchart of the practical approach to epileptogenic tumors? Conclusion and key points

NREE-36 BEYOND STENOSIS: INTRACRANIAL VESSEL WALL MRI IN RESIDENT PRACTICE

Daniel Ignacio Lira Munoz, MD (*Presenter*)
Patricio M. Latorre Brajovic, MD (*Abstract Co-Author*)
Andres R. Miranda Merchak, MD (*Abstract Co-Author*)
Andrea Maldonado, MD (*Abstract Co-Author*)
Salvador Camelio (*Abstract Co-Author*)

TEACHING POINTS

Intracranial vessel wall imaging (VWI) MRI can provide diagnostic insights beyond conventional lumen-based imaging techniques, allowing direct visualization of arterial wall pathology and detection of subtle or angiographically occult lesions. Distinctive wall features on VWI, including vessel wall thickness, remodeling pattern, and contrast enhancement, may help differentiate specific intracranial vascular pathologies. Awareness of common artifacts and interpretation pitfalls during acquisition and interpretation can help minimize diagnostic errors.

TABLE OF CONTENTS/OUTLINE

Introduction to VWI MRI as a complement to conventional vascular imaging techniques. Fundamental imaging techniques: Resolution, sequences, and contrast enhancement. Structured pictorial review using a standardized VWI analysis framework with representative pathological cases. Clinical case-based examples: Intracranial atherosclerosis, vasculitis, inflammatory vasculopathies, moyamoya disease, intracranial aneurysms, intracranial arterial dissections, non-atherosclerotic intracranial stenosis, post-endovascular treatment evaluation and reversible cerebral vasoconstriction syndrome. Common interpretation pitfalls and artifact management. Summary emphasizing clinical relevance and diagnostic impact of VWI in routine practice.

NREE-37 STRUCTURAL MRI BIOMARKERS OF OLFACTORY DYSFUNCTION IN NEURODEGENERATIVE DEMENTIAS

Omar Rodriguez-Mendoza, MD, MSc (*Presenter*)
Laura M. Sanchez, MD (*Abstract Co-Author*)
Johnatan Rubalcava Ortega, MD (*Abstract Co-Author*)

TEACHING POINTS

Olfactory dysfunction is a frequent prodromal symptom across multiple neurodegenerative dementias, including Alzheimer's disease, Parkinson's disease and progressive supranuclear palsy. Structural MRI enables the detection of early morphological alterations in olfactory structures, particularly in the olfactory bulb, piriform cortex, entorhinal cortex, and orbitofrontal regions. Quantitative MRI techniques, such as olfactory bulb volumetry and cortical thickness analysis, provide non-invasive imaging biomarkers that may facilitate the early diagnosis and risk stratification of dementias.

TABLE OF CONTENTS/OUTLINE

Clinical Overview of Early-Stage Dementias (Alzheimer's Disease, Parkinson's Disease, Progressive Supranuclear Palsy) The Prodromal Phase: Hyposmia as an Early Clinical Marker Structural MRI Anatomy of the Olfactory System (Olfactory bulb, tract, piriform cortex, amygdala, entorhinal and orbitofrontal cortices) MRI Acquisition Protocols and Volumetric Assessment Techniques Key Structural MRI Findings Across Dementias 5.1. Olfactory Bulb Atrophy Patterns in Neurodegenerative Diseases 5.2. Morphological Alterations in Olfactory-Related Cortical Regions Quantitative Imaging and Volumetry for Early Diagnosis Emerging Applications of Machine Learning in Olfactory MRI Biomarkers Conclusion: Structural MRI as a Non-Invasive Tool for Early Diagnosis and Risk Stratification

NREE-38 REVIEW OF IMAGING MANIFESTATIONS OF MYELIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY-ASSOCIATED DISORDERS (MOGAD)

Shreyas Reddy Kankara, MBBS, MD (*Presenter*)
Ankit Arora, MBBS, MD (*Abstract Co-Author*)
Sabha Ahmed, MD, FRCR (*Abstract Co-Author*)
Shravan Reddy K, MBBS (*Abstract Co-Author*)
Unnathi Nayak, MBBS (*Abstract Co-Author*)

TEACHING POINTS

• Myelin oligodendrocyte glycoprotein antibody-associated disorders (MOGAD) are a relatively new neuroinflammatory demyelinating disorder. • They are characterised by the presence of serum antibodies to MOG, which is an extracellular myelin protein. • Key imaging characteristics include ill-defined, T2/FLAIR hyperintense lesions affecting white and grey matter, frequently involving the basal ganglia, thalamus, and brainstem. • In the spinal cord, central grey matter and conus medullaris involvement are typical, while hallmark optic pathway findings include longitudinally extensive optic neuritis, retrobulbar segment involvement, optic disc oedema, and

optic perineuritis. • Though there is significant overlap with other demyelinating diseases, the present immunological, laboratory and imaging evidence demonstrated MOGAD as a distinct disease entity.

TABLE OF CONTENTS/OUTLINE

• Overview of the pathophysiology and clinical presentation of MOGAD. • Comprehensive review of neuroimaging features of MOGAD, emphasising key findings. o Brain - ADEM-like, meningitis, brainstem and cortical encephalitis. o Optic nerves - Retrobulbar and bilateral involvement, optic disc swelling, perineuritis o Spinal cord - Transverse myelitis, conus involvement, and leptomeningitis. • Description of unusual and atypical imaging phenotypes - Leukodystrophy-like pattern, acute haemorrhagic leukoencephalitis, cranial nerve palsies, FLAIR-hyperintense lesions in anti-MOG associated encephalitis with seizures (FLAMES), tumefactive demyelination, perivascular enhancement, limbic encephalitis. • Comparison imaging analysis of MOGAD with Multiple Sclerosis and Neuromyelitis optica.

NREE-40 FROM NECK TO BRAIN: KEY INSIGHTS INTO VASCULAR IMAGING IN ACUTE ISCHEMIC STROKE

Lavinia Dias, MD (*Presenter*)
Gabriel Figueiredo, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Lucas Aquino (*Abstract Co-Author*)
Rogerio Iquizli, MD (*Abstract Co-Author*)
Tatiana Marques, BSc (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

-Tips and Challenges in the Evaluation of Cervical and Intracranial Vascularization in Acute Ischemic Stroke (AIS). -Recognize key imaging features of acute arterial occlusion, and demonstrate a systematic approach to initial evaluation of the vascularization in the acute stroke scenario. -Discuss frequent pitfalls and unusual vascular syndromes that may impact diagnostic interpretation and management. -Emphasize the importance of an active search for the underlying etiologic factor/mechanism in AIS.

TABLE OF CONTENTS/OUTLINE

Introduction Relevance of vascular imaging in AIS. Systematic CTA Evaluation Structured approach improves detection of occlusions and emboli, including calcified emboli mimicking artifacts. Pitfalls & Collaterals Diagnostic tips, importance of assessing distal collaterals, and avoiding satisfaction of search errors. Vascular Syndromes Imaging of Moyamoya, MCA rete-like pattern, and ICA agenesis. Cervical/Intracranial Findings Carotid web, unstable plaques, intraluminal thrombi, and heavily calcified plaques or valves. Dissections & Stenosis High-grade and multisegmental stenoses; distinguishing vasculitis, atherosclerosis, and vasoconstriction. Etiology & Workflow Integrating imaging with clinical data for etiologic classification and treatment planning.

NREE-41 FROM BABIES' HEADS TO DOCS' BRAINS: THE ULTRASOUND THAT REVEALS IT ALL

Eva S. Lemus Palma, MD (*Presenter*)

TEACHING POINTS

- review neuroanatomy and transfontanellar ultrasound techniques.- advantages of this technique such as the absence of ionizing radiation, availability, portability, and low cost. - know the normal and pathologic anatomy in neonates including premature and term infants. - know its limitations in the evaluation of complex malformations, and in the assessment of damage to white matter. - use in diagnosis and follow up for congenital and acquired neurological conditions.

TABLE OF CONTENTS/OUTLINE

- Review the normal neuroanatomy and its variants-Transfontanellar ultrasound techniques for anterior fontanelle assessment. - Review the different spectrums of neurological diseases in neonates. -Review its limitations in the evaluation of complex malformations, and in the assessment of damage to white matter. -Demonstration of a variety of institutional neurological cases.

NREE-42 CHOOSING YOUR WORKHORSE: CONTRAST-ENHANCED T1-WEIGHTED SEQUENCES IN NEURORADIOLOGY

Elena Luque, MD (*Presenter*)
Ester Carballo, MD (*Abstract Co-Author*)
Maria del Carmen A. Polidura, MD (*Abstract Co-Author*)
Maria Natividad Gomez Ruiz (*Abstract Co-Author*)
Manuela M. Jorquera (*Abstract Co-Author*)
Miguel Yus Fuertes, MD (*Abstract Co-Author*)

TEACHING POINTS

• To review the technical principles of MRI T1-weight sequences (T1ws). • To examine contrast-enhanced (CE) T1ws used in neuroimaging, differentiating them by technical aspects and applications, and comparing their strengths and limitations.

TABLE OF CONTENTS/OUTLINE

• Introduction to T1ws. T1ws are typically acquired using short repetition and echo times. Pulse sequences are categorized into Spin-Echo (SE), which offer high signal-to-noise ratio (SNR), robust tissue contrast, and reduced field inhomogeneity sensitivity; and Gradient-Echo (GRE), which provide faster acquisition but are more prone to susceptibility artifacts. Volumetric (3D) acquisition offers isotropic resolution, improved SNR, and reduced partial volume effects (enhancing small lesion detectability), but their sensitivity to motion artifacts is increased due to longer scan times. • Review the different CE-T1ws used in neuroimaging . Gadolinium agents shorten T1 relaxation times, enhancing tissue contrast. They are essential for assessing blood-brain barrier integrity and detecting pathological enhancements. Depending on the clinical context, the chosen sequence may vary, considering the advantages and limitations of each. CE T1ws can be classified based on pulse sequence type, acquisition method (2D vs 3D), use of inversion-recovery pulses (e.g. MPRAGE), dynamic vs static imaging (e.g. LAVA) and the use of innovative black-blood enhancement techniques (e.g. MSDE). While CE T1w FSE offers superior sensitivity compared to GRE for detecting pathological enhancements (meningeal, cranial nerve, etc.), GRE sequences provide higher anatomical detail and are more suitable for evaluating vessel lumen.

NREE-43 THE RADIOLOGIC FACES OF NEUROMELIOIDOSIS: INSIGHTS INTO IMAGING PHENOTYPES

Sabha Ahmed, MD, FRCR (*Presenter*)
Shreyas Reddy Kankara, MBBS, MD (*Abstract Co-Author*)
Ankit Arora, MBBS, MD (*Abstract Co-Author*)
Shravan Reddy K, MBBS (*Abstract Co-Author*)
Jitender Saini, MD,MBBS (*Abstract Co-Author*)

TEACHING POINTS

1.Neuromelioidosis is caused by Burkholderia pseudomallei, seen in endemic tropical regions, commonly in immunocompromised patients.2.CNS dissemination occurs following aspiration, inhalation or inoculation via the hematogenous or transneural routes.3. Key imaging features consistent of T2/FLAIR hyperintense lesions that maydemonstrate diffusion restriction, ring enhancement, or haemorrhagic changes, most commonly affecting the basal ganglia, brainstem, and corticospinal tracts.4. Linear white matter tract involvement is called the 'Tunnel sign'.5.Cranial nerve involvement, myelitis, osteomyelitis, meningeal enhancement, epidural and subdural collections are also frequently observed.6. Rarely, cerebral venous sinus thrombosis (CSVT) and haemorrhage can also occur.7. Given its ability to mimic other infectious and inflammatory diseases, a high index of suspicion and correlation with systemic findings are crucial for early diagnosis.

TABLE OF CONTENTS/OUTLINE

& 3; Overview of the pathophysiology and clinical presentation of neuromelioidosis.& 3; Review of imaging findings in neuromelioidosis, with emphasis on key radiologicalpatterns.o Brain involvement: Cerebritis, microabscesses, white matter and cranialnerve involvement, leptomeningeal/pachymeningeal enhancement.o Spinal cord: Transverse myelitis, epidural or subdural collections,osteomyelitis and discitis.o Description of atypical presentations and complications: Intracerebralhaemorrhage, CSVT. & 3; Differential diagnosis and comparison with other infectious, inflammatory andneoplastic mimics.

NREE-44 ABCS OF THE PARANASAL SINUSES: WHAT RADIOLOGISTS NEED TO KNOW

Sarvani Uppati (*Presenter*)
Ilkyu D. Oh, MD (*Abstract Co-Author*)
Runail Ratnani, MD (*Abstract Co-Author*)
Nikhil Kapil (*Abstract Co-Author*)
Fabricio S. Feltrin, MD (*Abstract Co-Author*)
Marco C. Pinho, MD (*Abstract Co-Author*)
Kirang Patel, MD (*Abstract Co-Author*)

TEACHING POINTS

Radiologists play a vital role in detecting causes of sinonasal diseases as well as providing pre-operative CT planning for various surgeries such as Functional Endoscopic Sinus Surgery (FESS) or transsphenoidal surgeries for sellar tumors. Understanding and recognizing the major sinonasal drainage pathways, key anatomic variants and bony landmarks in a systematic approach can give radiologists the essential information to help diagnose causes of various sinusitis and help prevent serious surgical complications. The primary purpose of this educational exhibit is to use the mnemonic "ABCs" as a systematic and easy way to approach and evaluate the paranasal sinuses which can in turn optimize patient care. The purpose of this exhibit is to: Provide a systematic approach using the ABCs method Discuss critical anatomic variants Provide imaging examples of these variants Highlight clinical relevance and potential surgical complications related to these pitfalls

TABLE OF CONTENTS/OUTLINE

-Review of normal sinonasal anatomy -Introduce systematic approach for evaluating sinonasal anatomy using "ABCs" method which includes Aeration, Bony landmarks, and Cells and variants. -Imaging manifestations of sinonasal variants and examples of relevant pathology. -Describe the role of radiologists in preoperative planning and relevant surgical complications with undiagnosed anatomic variants. - Aeration Nasal cavity Osteomeatal complex (OMC) Sphenoethmoidal recess - Bony Landmarks Cribriform plate Lamina paprycea Sella/Clivus Sphenoid sinus septations Skull base - Cells and Variants Onodi cell Agger Nasi cell Haller cell Supraorbital cell Concha bullosa Paradoxical turbinate

NREE-45 DECODING MULTINODULAR AND VACUOLATING NEURONAL TUMOR (MVNT) AND ITS MIMICKERS

Alisa Trundaeva, MD (*Presenter*)
Marta Mazuque Mancilla (*Abstract Co-Author*)
Albina Polianskaia, MD, MD (*Abstract Co-Author*)
Eva Gimenez Comet, MD (*Abstract Co-Author*)

TEACHING POINTS

- MVNT typically appears as "bubbly" subcortical lesions, most often in the temporal lobes, and are usually asymptomatic. -On MRI, it shows high T2/FLAIR signal without diffusion restriction or contrast enhancement. - Key differential diagnoses include dysembryoplastic neuroepithelial tumor (DNET), focal cortical dysplasia type II, and enlarged perivascular spaces.

TABLE OF CONTENTS/OUTLINE

MVNT represents a newly recognized cytoarchitectural pattern recently added to the revised 2016 edition of the WHO classification of CNS tumors. Although most cases are asymptomatic, depending on the location, they may be associated with epileptic seizures or other neurological symptoms. Being frequently an incidental finding, they can be easily misinterpreted or underestimated by radiology specialists. On MRI, MVNT typically appears as multiple small subcortical nodules, most commonly located in the temporal lobes. These lesions show high signal intensity on T2-weighted sequences and remain hyperintense on FLAIR, with no diffusion restriction on DWI or enhancement on the post-contrast sequences. The main differential diagnoses include DNET, focal cortical dysplasia type II, and enlarged perivascular spaces. Awareness of this entity and the description of new cases contributes to a better understanding of their radiological features, improving the clinical management of these patients and avoiding aggressive treatment approaches.

NREE-46 NON-CONTRAST MRI EVALUATION OF PEDIATRIC MOYAMOYA BEFORE AND AFTER EDAS SURGERY: A MULTIPARAMETRIC APPROACH WITH TOF, VENOGRAPHY, 4D TRANCE AND ASL PERFUSION

Albina Polianskaia, MD, MD (*Presenter*)
Marta Gomez-Chiari, MD (*Abstract Co-Author*)
Jaroslaw M. Smiechowicz (*Abstract Co-Author*)
Monica Rebollo Polo, MD (*Abstract Co-Author*)
Monica Ruiz Moreno (*Abstract Co-Author*)
Mariana C. Planells, MD (*Abstract Co-Author*)
Emilio Inarejos Clemente, MD (*Abstract Co-Author*)
Diego Preciado, MD (*Abstract Co-Author*)
JORDI MUCHART LOPEZ (*Abstract Co-Author*)

TEACHING POINTS

-Moyamoya vasculopathy (MMV) leads to progressive intracranial arterial stenosis, requiring surgical revascularization to optimize cerebral perfusion.-Encephaloduroarteriosynangiosis (EDAS) is a surgical procedure in which a segment of the superficial temporal artery is transposed onto the brain surface to promote collateral blood flow in children with MMV.-Non-contrast MRI techniques enable comprehensive evaluation of cerebral morphology, vascular anatomy, hemodynamics, cerebral blood flow (CBF) and collateralization in MMV.-Cerebrovascular reserve (CVR) assessment with an acetazolamide test is useful for evaluating cerebral hemodynamics before and after EDAS.

TABLE OF CONTENTS/OUTLINE

Moyamoya vasculopathy (MMV) is characterized by progressive stenosis of the intracranial arteries, often necessitating surgical revascularization to improve CBF. Evaluation of CBF and CVR is essential both pre- and post-operatively to assess cerebral hemodynamics. Although EDAS is a commonly used indirect revascularization technique, few studies have assessed its impact on CBF and CVR in pediatric patients. In this article, we present our initial experience using a non-contrast MRI cerebrovascular protocol, which includes TOF and phase contrast venography, 4D TRANCE and ASL perfusion to evaluate vascular anatomy, filling pattern, CBF and CVR before and after EDAS surgery in children with MMV. We observed encouraging post-surgical changes in both CBF and CVR, suggesting improved hemodynamic status. This novel multiparametric MRI protocol proved to be a valuable and reproducible tool for surgical planning and outcome assessment in pediatric MMV patients undergoing EDAS revascularization.

NREE-47 NORMAL PRESSURE HYDROCEPHALUS: BEYOND VENTRICULOMEGALY

Florencia D. Vespa SR, MD (*Presenter*)
Stefania Solanot, MD (*Abstract Co-Author*)
Luis A. Miquelini, MD (*Abstract Co-Author*)
Manuel S. Perez Akly, MD (*Abstract Co-Author*)
Cristina H. Besada SR, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1) Diagnostic imaging criteria include Evans' index >0.3, callosal angle =80°, absence of macroscopic CSF flow obstruction, and enlarged temporal horns not solely attributable to hippocampal atrophy. 2) In Alzheimer's disease the subarachnoid space and cortical parietal sulci of the brain are enlarged due to atrophy. DESH findings may be useful for differentiating TNH from Alzheimer's disease. 3) Callosal angle is an accepted parameter to differentiate iNPH from atrophic hydrocephalus and a predictor of prognosis. 4) Early diagnosis and CSF shunting intervention in iNPH yield more favorable outcomes, emphasizing the importance of timely identification and treatment. 5) Asymptomatic ventriculomegaly with iNPH features on MRI (AVIM) may represent a preclinical stage of iNPH with an estimated annual progression rate of 17%.

TABLE OF CONTENTS/OUTLINE

1) Introduction to Normal Pressure Hydrocephalus2) Pathophysiology: CSF Dynamics and Pulse Distribution3) Imaging Criteria and DESH Findings 4) Differential Diagnosis from Alzheimer's Disease and Atrophic Hydrocephalus5) AVIM: Preclinical Stage and Progression Rate 6) AI Applications in iNPH Diagnosis

NREE-48 MOGAD : DECODING THE MRI SPECTRUM OF A NEUROIMAGING CHAMELEON

Abhijit D. Pawar, MD (*Presenter*)
Aparna H. Chandorkar, MBBS,MD (*Abstract Co-Author*)
Suyog P. Somkuwar, MD (*Abstract Co-Author*)

TEACHING POINTS

1. MOGAD mimics multiple demyelinating disorders. Differentiation from MS and NMOSD is crucial. 2. MRI patterns in MOGAD are diverse involving the brain, spinal cord and optic nerves. 3. MRI findings to be correlated with history, presentation, CSF analysis and serologic testing for anti-MOG antibody. 4. Use of radiologic algorithm enhances diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

1. What is MOGAD? New Face in the Demyelination family: Brief history, clinical relevance and pathophysiology 2. MOGAD Vs the usual suspects (MS, NMOSD, ADEM): Key differentiating clinical and imaging features 3. Master of Disguise: MOGAD's many faces on MRI: MRI spectrum in MOGAD: brain, spine (not just your typical LETM), optic nerves. 4. Mimics and misdiagnoses: How MOGAD masquerades as other pathologies on imaging: Red-flags, pitfalls and mimickers. 5. The Missing Links: Clinical clues, CSF, and Anti-MOG antibodies 6. Cases from clinical practice 7. MOGAD decoded: A radiologic roadmap: Diagnostic algorithm for radiologic diagnosis of MOGAD. 8. Management implications: How imaging influences treatment decisions. 9. Key takeaways: Key imaging pearls. 10. References.

NREE-49 CIRCUMSCRIBED GLIOMAS: LIKE PEAS IN A POD, YET WORLDS APART!

Francesco Schimperna, MD (*Presenter*)
Matia Martucci, MD (*Abstract Co-Author*)
Francesca Lisi, MD (*Abstract Co-Author*)
Giovanni Pentassuglia (*Abstract Co-Author*)
Giuliana Tattaresu (*Abstract Co-Author*)
Giuseppe Varcasia, MD (*Abstract Co-Author*)
Rosellina Russo (*Abstract Co-Author*)
Simona Gaudino (*Abstract Co-Author*)

TEACHING POINTS

- Describe the common features of this new group, made up of tumors that differ in epidemiology, site, MRI characteristics and grading, and with an overview of their molecular alterations, that may be therapeutic targets. - Describe MRI characteristics of each tumor and their differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Background: the new WHO CNS5 classification, considering recent discoveries in molecular genetics of brain tumors and its increasingly central role in patient care, has made some changes regarding the previous subdivisions and has introduced new entities. Notably, it introduced a new group named "Circumscribed Astrocytic Gliomas", including Pilocytic Astrocytoma, Pleomorphic Xanthoastrocytoma, Subependymal Giant Cell Astrocytoma, Chordoid Glioma and two new entities, High-grade Astrocytoma with Piloid Features and Astroblastoma, MN1-Altered. Cases presentation: to describe their features, including epidemiology, site, neuroradiological findings, genetic alterations, grading/prognosis and differential diagnosis. Underline of common characteristics: 1- They are circumscribed, with a good distinction between healthy and pathological tissue, both radiologically and histologically. 2- They lack IDH mutation, but a broad spectrum of other mutations that may be therapeutic targets, like BRAF or TSC.

NREE-50 INFECTION-RELATED ENCEPHALOPATHY SYNDROMES: A RADIOLOGIC PATTERN-BASED DIAGNOSTIC APPROACH

Naman Gupta, MD (*Presenter*)
Ankita Gupta, MBBS, MD (*Abstract Co-Author*)
Divyansh Gupta, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Infection-triggered encephalopathy syndromes (ITES) are acute neuroinflammatory disorders following systemic infections, often without direct CNS involvement. Syndromes like AESD, ANE, FIRES, HHE, and MERS have overlapping but distinct imaging features. A pattern- and anatomy-based approach helps differentiate ITES from autoimmune, metabolic, or toxic encephalopathies. MRI, especially DWI, is key for early detection and guiding management, particularly in pediatric, post-viral, or immunocompromised patients. Epidemiologic awareness and age-specific patterns improve diagnostic accuracy. ITES offer radiology trainees valuable integration of clinical context and imaging.

TABLE OF CONTENTS/OUTLINE

I ntroduction : Definition, pathophysiology, symptoms (AMS, seizures), risk factors (immunocompromised, elderly), radiology's role Imaging Modalities : MRI (T2, FLAIR, DWI) preferred; CT in acute settings Syndromes & Patterns :• AESD: Biphasic, subcortical DWI• ANE: Bilateral thalami, hemorrhage• MERS: Transient splenial lesion• FIRES: Delayed hippocampal/cortical changes• HHE: Unilateral DWI, later atrophy Interpretation Strategy : Stepwise, pattern-based; identify edema, cortical-subcortical and deep structure involvement Mimics & Red Flags : Differentiate from stroke, metabolic causes; watch for mass effect, asymmetry Management Impact : Imaging guides antivirals, steroids, detects complications; aids prognosis Pitfalls & Pearls : Early DWI clues, missed CT signs, mimics Conclusion : Summarize key findings, stress clinical context Case-Based Learning : Interactive, annotated cases with highlighting diagnostic strategies

NREE-51 I'M STILL HERE: MYCOBACTERIUM TUBERCULOSIS SPECTRUM OF DISEASE

Bruno Rigonato (*Presenter*)
Bruno Matos (*Abstract Co-Author*)
Gustavo Yamada, MD (*Abstract Co-Author*)
MATHEUS KRAUSE (*Abstract Co-Author*)
Pedro Tiradentes (*Abstract Co-Author*)
Adolfo Souza (*Abstract Co-Author*)
Matheus Ruffini (*Abstract Co-Author*)
Lillian Goncalves Campos (*Abstract Co-Author*)
Lais Cordeiro (*Abstract Co-Author*)

Juliana Duarte (*Abstract Co-Author*)
Fabiano Reis (*Abstract Co-Author*)

TEACHING POINTS

Tuberculosis is an infectious disease caused by the Mycobacterium tuberculosis complex, a group of aerobic, bacilli species bacteria, characterized by their mycolic acid cell wall. It can lead to a variety of clinical and radiological manifestations, depending mainly on the immunological status of the patients. Represents a poverty-related disease, with a higher burden in lower-income countries and groups. The infection was responsible for an estimated 10.8 million new cases in 2023. Concurrent with its high incidence values, tuberculosis represents the leading infectious cause of death globally and the tenth leading cause of death in 2021. THEACHING POINTS Review and illustrate the imaging findings of tuberculosis, their correlation with pathological images and the differential diagnoses. Describe through illustrative presentations the benefits of the multimodality imaging approach to the diagnosis of neurocysticercosis. Establish the characteristic findings and how they can help the radiologist reach the correct diagnosis.

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS - Introduction - Epidemiology of tuberculosis - Natural history of the disease and stages - Clinical manifestations - Diagnostic clues - Imaging investigation (characteristic imaging findings) - Differential diagnoses - Pitfalls Final Remarks

NREE-52 WHEN THE WALL SPEAKS: WHAT VWI TELLS US ABOUT VASCULITIS

Roberta Linhares, MD (*Presenter*)
Andre F. Formiga, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Nicole Lambrakos, MD (*Abstract Co-Author*)
Marcos V. Camargo, MD (*Abstract Co-Author*)
Tatiana L. Arcanjo, MD (*Abstract Co-Author*)
Rogerio Iquizli, MD (*Abstract Co-Author*)
Mariana A. Rodrigues, MD (*Abstract Co-Author*)
Fabiana D. Hirata, MD (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the principles and technical aspects of Vessel Wall Imaging (VWI) in the evaluation of central nervous system vasculitis To review the normal and abnormal imaging findings of cervical and intracranial vessel walls, emphasizing key patterns seen in vasculitis To differentiate vasculitis from its main mimics using VWI characteristics and clinical context To illustrate the clinical relevance of VWI in diagnosis, treatment guidance, and follow-up of vasculitis

TABLE OF CONTENTS/OUTLINE

Introduction Principles of MRI and Vessel Wall Imaging in the Evaluation of Vasculitis Normal vs. Abnormal Vessel Wall Appearance VWI Features of CNS Vasculitis: Typical Patterns and Teaching Cases Differential Diagnoses Clinical Applications and Impact on Management Take Home Messages References

NREE-53 THE RADIOLOGIC FACE OF HISTONE MUTATIONS: DECODING PEDIATRIC DIFFUSE HIGH-GRADE GLIOMAS

Andrey Ribeiro, MD (*Presenter*)
Luiza A. Nahoum, MD (*Abstract Co-Author*)
Nina Ventura, MD (*Abstract Co-Author*)

TEACHING POINTS

- Explain the recent molecular characterization of pediatric-type diffuse high-grade gliomas. - Describe the key imaging features of histone-related pediatric-type diffuse high-grade gliomas on magnetic resonance imaging (MRI).

TABLE OF CONTENTS/OUTLINE

I. Introduction Pediatric-type diffuse high-grade gliomas (pHGGs) were included in the 2021 WHO Classification and account for most high-grade gliomas in children. They are defined by specific molecular alterations, particularly those related to histone mutations, including diffuse midline gliomas (DMGs) and diffuse hemispheric gliomas (DHGs). DMGs arise in midline structures such as the brainstem, thalami, and spinal cord, and are classically associated with H3 K27M mutations in the H3.1 or H3.3 variants. They exhibit an infiltrative and expansile pattern. More recently, cases with EGFR alterations have also been included. DHGs , in contrast, occur in the cerebral hemispheres and are defined by a G34 mutation in histone H3.3. They share aggressive imaging features, such as diffusion restriction, heterogeneous enhancement, and frequently leptomeningeal contact. II. Imaging Findings Magnetic resonance imaging (MRI) is essential for evaluation, revealing a spectrum of findings ranging from low-enhancing infiltrative lesions to necrotic, hyperenhancing and diffusion restricted masses. Recognizing these radiologic patterns supports early diagnosis and correlates strongly with molecular subtypes, playing a crucial role in clinical and therapeutic management. III. Conclusion: Imaging techniques, particularly magnetic resonance imaging (MRI), offer strong correlation with molecular diagnoses and play a key role in early detection.

NREE-54 FROM ANATOMY TO DIAGNOSIS: A COMPREHENSIVE REVIEW OF SPINAL CORD INFARCTION IMAGING

Eiko Yamamori, MD (*Presenter*)
Hidenobu Takagi, MD, PhD (*Abstract Co-Author*)
Mirei Abe (*Abstract Co-Author*)
Hinano Anaba (*Abstract Co-Author*)
Erina Kato (*Abstract Co-Author*)
Chiaki Maeda (*Abstract Co-Author*)
Yohei Morishita (*Abstract Co-Author*)
Atsushi Umetsu, MD (*Abstract Co-Author*)
Hideki Ota, PhD (*Abstract Co-Author*)
Kei Takase, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Spinal cord infarction (SCI) is a rare condition that is often misdiagnosed due to the lack of standardized diagnostic criteria and specific imaging findings. Recognizing its symptoms, clinical course, and imaging findings can help avoid unnecessary tests and invasive procedures. A better understanding of spinal cord vascular anatomy and its typical infarct distribution patterns enhances diagnostic accuracy. It is also important to recognize the temporal evolution of imaging findings. Radiologists must recognize the various underlying conditions and disease processes that can cause SCI and be familiar with key differential diagnoses.

TABLE OF CONTENTS/OUTLINE

1. Clinical features of SCI : Epidemiology, typical symptoms, diagnostic criteria, clinical course, and clinical impact of misdiagnosing. 2. Normal Vascular Anatomy of the Spinal Cord : Vertical perfusion of the spinal cord varies by level, arterial territories of anterior spinal artery and posterior spinal arteries, and origins of the artery of Adamkiewicz. 3. Imaging of SCI : MR imaging protocols, typical findings on DWI, T2WI and contrast enhanced T1WI, lesion distribution patterns, and temporal evolution. 4. Case presentation, Differential Diagnoses and Mimics : including surgery-related SCI and SCI with aortic dissection/occlusion.

NREE-55 THE MANY FACES OF HISTIOCYTOSES IN THE CENTRAL NERVOUS SYSTEM: AN IMAGING ATLAS

Marina Nori Hilario, MD (*Presenter*)
Carolinny Cruvinel Maia, MD (*Abstract Co-Author*)
Vinicius Martins, MD (*Abstract Co-Author*)
Paula Cristina Amaral, MD (*Abstract Co-Author*)
Guilherme L. Gaiotto, MD (*Abstract Co-Author*)
Camila Almeida, MD (*Abstract Co-Author*)
Felipe Cintra Valentin (*Abstract Co-Author*)
Leonardo Lima (*Abstract Co-Author*)
Bruno S. Inada, MD (*Abstract Co-Author*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)
Fernanda B. Assuncao, MD (*Abstract Co-Author*)

TEACHING POINTS

To present the main subtypes of histiocytoses affecting the central nervous system (CNS). To illustrate the characteristic radiological findings of the major CNS histiocytoses through clinical case examples. To discuss the diagnostic challenges in imaging differentiation, particularly on magnetic resonance imaging (MRI).

TABLE OF CONTENTS/OUTLINE

Central Nervous System (CNS) histiocytoses are rare diseases characterized by the proliferation of abnormal cells of the monocyte-macrophage system. They are divided into two major groups: Langerhans cell histiocytosis (LCH), which is more common, and non-Langerhans histiocytoses, primarily represented by Erdheim-Chester disease and Rosai-Dorfman disease. In Langerhans cell histiocytosis (LCH), the main findings include lytic bone lesions, loss of the normal spontaneous T1 hyperintensity of the neurohypophysis (often associated with diabetes insipidus), and signal intensity changes during the degenerative phase. Erdheim-Chester disease typically presents with extra-axial masses in the sellar or retro-orbital regions and persistent, delayed post-gadolinium enhancement lasting up to 8 days. Rosai-Dorfman disease may manifest with painless cervical lymphadenopathy and extra-axial masses showing homogeneous contrast enhancement. Recognition of these imaging patterns, particularly through magnetic resonance imaging (MRI), is essential for accurate diagnosis and appropriate management.

NREE-56 LOW PRESSURE, HIGH IMPACT: UNDERSTANDING SPONTANEOUS INTRACRANIAL HYPOTENSION

Guilherme Swerts Pereira (*Presenter*)
Gustavo Zoega Salles Bueno, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Murilo Prevital Correia, MD (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the pathophysiology and complications of cerebrospinal fluid fistulas and cerebral hypotension. To review the typical imaging findings, highlighting the key diagnostic features, as well as the role of myelotomography. To recognize the main types of treatment and post-treatment monitoring.

TABLE OF CONTENTS/OUTLINE

Introduction. Pathophysiology and complications of cerebrospinal fluid fistulas and cerebral hypotension. Typical Imaging Features, Complications, Types of treatment and Evolution, with teaching cases. The role of myelotomography. Take Home Messages. References.

NREE-57 UNMASKING ACUTE LEUKEMIA: IMAGING INSIGHTS INTO HEAD & NECK INVOLVEMENT

Mostafa A. Shehata, MD (*Presenter*)
Selin Ocal, MD (*Abstract Co-Author*)
Ezana E. Lulseged, MD (*Abstract Co-Author*)
Francis Deng, MD (*Abstract Co-Author*)

TEACHING POINTS

Define updated diagnostic and classification terminology for acute leukemia and related hematopoietic neoplasms, including recent updates from the WHO 2022 hematolymphoid tumor classification Identify the imaging manifestations of acute leukemia lesions in extracranial and intracranial head & neck structures with an emphasis on advanced imaging techniques Recognize infectious, inflammatory, vascular and neoplastic complications of acute leukemia and its therapies, with diagnostic pearls to distinguish these entities

TABLE OF CONTENTS/OUTLINE

1. Introduction to Acute Leukemia and Innovations in Diagnosis o Overview of acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) o 2022 WHO classification updates for hematopoietic tumors and imaging relevance 2. Intracranial and Extracranial Imaging Manifestations of Leukemia o Extramedullary disease manifestations (myeloid sarcoma and lymphoblastic lymphoma) o Bone marrow and adjacent soft tissue infiltration (e.g., calvarium, spine, sinonasal, oral cavities) o Neuroleukemiosis and orbital involvement with diagnostic MRI features o Vascular manifestations 3. Complications of Leukemia and Associated Treatment in the Head & Neck, including Vascular, Infectious, & Neoplastic Complications 4. Advanced Imaging Techniques in the Evaluation of Head & Neck Leukemia o Integration of PET/MRI for functional and anatomical assessment o DWI in evaluating acute leukemia, particularly in assessing treatment response and detecting complications 5. Case-Based Education o Cases highlighting imaging manifestations, pitfalls, & multidisciplinary management o Rare neoplastic mimics (ie Small Round Blue Cell Tumors, Histiocytic Sarcoma)

NREE-58 CT PERFUSION: BEYOND ISCHEMIA. TECHNICAL CONSIDERATIONS, SOURCES OF ERROR, AND MIMICS

Juliana Alarcon Jaramillo, MD (*Presenter*)
Daniela Florez, MD (*Abstract Co-Author*)
Nicolas Herrera Parra (*Abstract Co-Author*)
David Ortigoza (*Abstract Co-Author*)
Ana M. Granados, MD (*Abstract Co-Author*)
Juan C. Marquez, MD (*Abstract Co-Author*)

TEACHING POINTS

Brain perfusion computed tomography (CTP) is a non-invasive technique that evaluates capillary blood flow and parenchymal blood delivery by tracking contrast medium passage. Currently, its primary indication is the diagnosis of ischemic stroke , identifying and quantifying infarcted tissue (core) and salvageable tissue (penumbra) to guide therapeutic decisions.This poster aims to describe the key technical considerations radiologists must know when performing these studies—crucial for obtaining high-quality images and preventing inaccurate parameter estimations. Topics include contrast injection protocols, image acquisition, post-processing techniques, and potential sources of technical errors.We will present essential tools for interpreting perfusion in ischemic events. Additionally, this technique can detect stroke mimics ; their key imaging findings will also be highlighted.

TABLE OF CONTENTS/OUTLINE

Introduction Definition and Overview of Perfusion Technical Considerations 3.1. Contrast Injection 3.2. Image Acquisition 3.3. Post-Processing Sources of Error 4.1. Arterial Input and Venous Output Curve Evaluation 4.2. Arterial Input Selection 4.3. Venous Output Selection 4.4. Patient Motion Acute Ischemia on Perfusion Imaging and Interpretation Pitfalls Ischemic Stroke Mimics 6.1. Seizures 6.2. Migraine 6.3. Infections 6.4. Tumors 6.5. Vascular Malformations 6.6. Brain Death 6.7. Anatomical Variants Conclusions The accompanying slides include original work by the authors and images acquired at the authors' institution.

NREE-59 LANDMARK OF LOSS: A COMPREHENSIVE GUIDE TO MRI STRUCTURED REPORTING FOR DEMENTIA

Jimin Lee (*Presenter*)
Benjamin M. Pizarro-Galleguillos, MD (*Abstract Co-Author*)
Paula Alcaide, MD (*Abstract Co-Author*)

TEACHING POINTS

A standardized imaging protocol and comprehensive structured report template are essential tools to ensure consistency in the imaging assessment of patients with cognitive complaints. Evaluation of dementia should include isotropic 3D T1-weighted imaging with specific multiplanar reconstructions to enable accurate application of visual and quantitative scales of brain atrophy. Brain atrophy can be assessed using validated rating scales such as the Global Cortical Atrophy scale and the Medial Temporal Atrophy scale. Blood-sensitive sequences are critical for detecting microbleeds and superficial siderosis, which are relevant for determining eligibility for Alzheimer's disease-modifying treatments. Vascular pathology is evaluated using T2-weighted FLAIR and blood-sensitive sequences to identify infarcts, cerebral microbleeds, and microangiopathic white matter changes, rated using the Fazekas scale. Structured dementia reports should incorporate these key scales to support a thorough and standardized assessment.

TABLE OF CONTENTS/OUTLINE

Introduction: dementia from pathophysiology to imaging MRI protocol: a standardized proposal Grading scales how, when, and why (Key anatomy landmarks for reproducible measurements, MTA Scale, GCA Scale, Fazekas scale) Disease-specific MRI patterns (AD, FTLD, PSP, MSA, CBD) A quick overview of standardized reporting Structured report in dementia: a proposal Dementia structured report in the AD modifying treatment era

NREE-60 BLEED IT OUT: NEUROIMAGING SPECTRUM OF HEMATOLOGICAL DISEASES

Milena Yonamine (*Presenter*)
JEAN LEVI RIBEIRO DE PAIVA (*Abstract Co-Author*)
Gustavo Yamada, MD (*Abstract Co-Author*)
Raissa Cabral Pili, MD (*Abstract Co-Author*)
Fabiano Reis (*Abstract Co-Author*)

TEACHING POINTS

Highlight the key features of imaging in CNS involvement of several hematological conditions, including lymphoma, multiple myeloma, leukemic infiltration, mastocytosis, immune thrombocytopenia, and aceruloplasminemia. Furthermore, our objective is to delineate the diagnostic challenges, differential diagnoses, and complications associated.

TABLE OF CONTENTS/OUTLINE

Central nervous system involvement in hematological diseases is rare and denotes a guarded prognosis when it occurs. In this educational study, we will demonstrate the imaging patterns observed in computed tomography and magnetic resonance imaging of the aforementioned hematological conditions, based on cases from a tertiary care institution. The study aims to clarify the main imaging features and diagnostic challenges. When patients develop neurological symptoms, it is recommended to investigate potential neurological involvement through both imaging and laboratory assessments, as imaging findings can often assist in diagnosis and refine differential considerations. The malignant status of hematological diseases renders patients susceptible to complications such as opportunistic infections, cerebrovascular events, and other treatment-related conditions, particularly those associated with chemotherapeutic regimens. These conditions are discussed in this study, highlighting their specific imaging characteristics, which are of paramount importance given their high mortality rates.

NREE-61 POSTOPERATIVE IMAGING IN ANTERIOR SKULL BASE SURGERY

Griselda T. Romero Sanchez, MD (*Presenter*)
Eduardo Ortega Matute, MD (*Abstract Co-Author*)
Kristina Ramirez Garcia, MD (*Abstract Co-Author*)
Angela M. Sosa, MD, MSc (*Abstract Co-Author*)
Michelle Y. Gonzalez Putoy SR, MD (*Abstract Co-Author*)
Lindsay A. Milroy, MD (*Abstract Co-Author*)
Almudena Perez-Lara, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

? Describe the normal radiological anatomy of the anterior skull base and the imaging characteristics of common lesions, including tumors, trauma, and infection. ? Illustrate the expected post-surgical imaging findings, including the appearance of surgical materials and normal healing patterns. ? Identify potential complications of anterior skull base surgery using CT, CT myelography and MRI. ? Emphasize key aspects for an accurate and structured postsurgical radiological report.

TABLE OF CONTENTS/OUTLINE

Overview of anterior skull base anatomy Summary of lesions of the anterior skull base Tumors (Esthesioneuroblastoma, meningiomas of the olfactory groove) Trauma Infectious processes Congenital lesions Imaging techniques in preoperative planning Key imaging modalities (CT, MRI) Preoperative findings in common tumors Surgical approaches to anterior skull base pathology Endoscopic Endonasal Approach (EEA) and Functional Endonasal Sinus Surgery (FESS) Craniofacial resection Craniotomies and craniectomies Surgical materials and their imaging appearance Synthetic grafts (Duramatrix, Tisseel, DuraGen, Neuro-Patch) Autologous fascia lata Fat grafts Acellular dermal matrix (AlloDerm) Hydroxyapatite cement Post-Surgical imaging of the anterior skull base Normal post-surgical findings Appearance of adjacent brain, bone, and mucosa Imaging techniques for follow-up Post-Surgical complications and their imaging features CSF leaks Infections Tumor recurrence

NREE-62 DECODING BRAINSTEM LESIONS: A VISUAL GUIDE TO ANATOMICAL-IMAGING-CLINICAL CORRELATION

Thiago Costa Haiter, MD (*Presenter*)
Gustavo Yamada, MD (*Abstract Co-Author*)
Luiz Borella (*Abstract Co-Author*)
Sofia Marchi (*Abstract Co-Author*)
Fabio Montico (*Abstract Co-Author*)
Elaine Minatel (*Abstract Co-Author*)
Fabiano Reis (*Abstract Co-Author*)

TEACHING POINTS

Brainstem lesions require a deep understanding of anatomy and imaging to correlate with clinical symptoms. This exhibit aims to explore how to: - Identify key neuroanatomical structures of the midbrain, pons, and medulla on MRI (T1, T2, FLAIR, DWI). - Correlate specific imaging findings with clinical symptoms in brainstem lesions. - Diagnose complex brainstem syndromes (e.g., Dejerine Syndrome - Parinaud Syndrome, Wallenberg Syndrome) using a structured, case-based approach. - Understand key imaging signs, including MRI findings and histologic correlations, to enhance diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

Introduction Importance of understanding brainstem lesions for accurate diagnosis. Anatomy of the Brainstem Overview of the midbrain, pons, and medulla oblongata structures relevant for lesion identification. MRI Imaging Modalities in Brainstem Lesions Discussion of MRI techniques (T1, T2, FLAIR, DWI) and their role in visualizing brainstem lesions. Case Studies :Locked-In Syndrome;Wallenberg Syndrome;Millard-Gubler Syndrome;Benedikt Syndrome;Middle Cerebellar Peduncle;DegenerationHypertrophic;Olivary Degeneration;Dejerine Syndrome;Parinaud Syndrome;Facial Colliculus Syndrome; Correlating Imaging with Clinical

Symptoms Case-based analysis linking MRI findings to clinical presentation. Differential Diagnoses and Common Pitfalls Common misdiagnoses and how to avoid them. Diagnostic Challenges and Solutions Strategies for overcoming diagnostic challenges in brainstem lesions.

NREE-63 FRAGMENTED GAIT, FOCUSED VIEW: MRI GENOTYPE-PHENOTYPE CORRELATES IN HEREDITARY ATAXIC DISORDERS

Benjamin M. Pizarro-Galleguillos, MD (*Presenter*)
Claudio A. Lema Olivares, MD (*Abstract Co-Author*)
Marcelo Miranda (*Abstract Co-Author*)
M.Leonor Bustamante (*Abstract Co-Author*)
Roberta La Piana (*Abstract Co-Author*)
Ana Patricia P. Orellana, MD (*Abstract Co-Author*)

TEACHING POINTS

1 . Hereditary ataxias are a heterogeneous group of inherited neurodegenerative disorders characterized by progressive unsteadiness of gait, dysmetria, and dysarthria. 2. MRI serves as a valuable diagnostic tool, complementing genetic studies by excluding alternative causes and revealing distinctive neuroimaging patterns. 3. Two main imaging patterns are recognized: ataxias with and without global cerebellar atrophy. 4. Characteristic findings include the hot cross bun sign in Spinocerebellar Ataxia (SCA), the middle cerebellar peduncle sign in Fragile X-associated Tremor/Ataxia Syndrome (FXTAS), bilateral hyperintensity of the dentate nuclei in Spastic Paraplegia Type 7 (SPG7) and Cerebrotendinous Xanthomatosis (CTX), and T2 hyperintensity in the pons in Autosomal Recessive Spastic Ataxia of Charlevoix-Saguenay (ARSACS). 5. The recently proposed CHARON algorithm supports a structured MRI-based approach to the diagnosis of hereditary ataxias.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Clinical and Genetic Overview of Hereditary Ataxias. 2. Classification of Hereditary Ataxias: Subtypes and Inheritance Patterns. 3. MRI protocols: Recommended Sequences. 4. Imaging Features: Characteristic Signs and Patterns. 5. The CHARON Algorithm: A Practical Diagnostic Framework: a) Ataxias with global cerebellar atrophy. b) Ataxias without global cerebellar atrophy. 6. Genotype-Imaging Correlations: a) SCA. b) Ataxia-Telangectasia. c) ARSACS. d) FXTAS. e) SPG7. f) CTX. 7. Structured Reporting of Hereditary Ataxias on MRI. 8. Future Directions in Imaging of Hereditary Ataxias. 9. Conclusions.

NREE-64 CENTRAL AND EXTRAVENTRICULAR NEUROCYTOMAS: RADIOLOGIC-PATHOLOGIC CORRELATION AND HISTORICAL PERSPECTIVES

Robert Y. Shih, MD (*Presenter*)

TEACHING POINTS

1. Central neurocytoma is a rare neuronal tumor (<1% of primary brain tumors) of the ventricular system that usually presents in young adults (20-40 years old) with symptoms related to elevated intracranial pressure. 2. While rarely encountered in the reading room, central neurocytomas typically present as an avidly enhancing mass with a bubbly appearance on T2-weighted imaging within the anterior half of the lateral ventricles. 3. Histopathologically, central neurocytomas typically present with monotonous neoplastic cells with round nuclei (salt & pepper chromatin) in a fibrillary matrix that stain positive for synaptophysin (neuronal marker). 4. Gross total resection, or maximal safe resection when not possible, is the main treatment modality. Adjuvant radiation may be used to reduce risk of recurrence for subtotal resection or atypical tumors (elevated Ki-67). 5. Extraventricular neurocytomas are similar to central neurocytomas on imaging and histopathology but are located outside the ventricles, usually in the cerebral hemispheres (FGFR1-TACC1 fusion is a molecular feature).

TABLE OF CONTENTS/OUTLINE

1. What is a Central Neurocytoma? = case presentation of central neurocytoma, brief history of central neurocytoma 2. Clinical Features of Central Neurocytoma: discuss typical clinical presentation, transcortical vs transcallosal surgery 3. Radiologic Features of Central Neurocytoma: discuss typical imaging features, illustrate with panel of select images 4. Pathologic Features of Central Neurocytoma: discuss typical histopathology plus immunohistochemical features 5. What is an Extraventricular Neurocytoma? = present case of extraventricular neurocytoma (FGFR1-TACC1 fusion)

NREE-65 UNDERSTANDING MESIAL TEMPORAL LOBE LESIONS: DIFFERENTIAL DIAGNOSES AND GUIDING CARE

Kyle Sporn (*Presenter*)
Kevin Thomas, BS (*Abstract Co-Author*)
Shannon Chu (*Abstract Co-Author*)
Markus Lammle, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review normal anatomy, landmarks, and functions of the mesial temporal lobe. 2. Review various etiologies of mesial temporal lobe lesions, including mesial temporal sclerosis, neoplasms, inflammatory, autoimmune, and infectious disorders, and their classic MRI imaging features.

TABLE OF CONTENTS/OUTLINE

1. Normal anatomy and landmarks of the mesial temporal lobe. 2. Differential diagnosis of mesial temporal lobe lesions and classic MR imaging features. a. Mesial temporal sclerosis. b. Neoplasms: Low-grade Gliomas, Pleomorphic Xanthoastrocytoma, Glioblastoma, Primary CNS Lymphoma, and Dysembryoplastic Neuroepithelial. c. Inflammatory/Infectious: Postictal Edema, HSV Encephalitis, Tuberculosis, Neurocysticercosis, and Toxoplasmosis. d. Autoimmune: Autoimmune Limbic Encephalitis. e. Genetic: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL). 3. Management considerations. 4. Summary

NREE-66 GLIONEURONAL TUMORS AND THEIR MIMICS: NEUROIMAGING REVIEW WITH PATHOLOGY AND GENETIC ASSOCIATIONS

Smily Sharma, MD, FRCR (*Presenter*)
Venkata Subbaih Arunachalam, MD (*Abstract Co-Author*)
Bejoy Thomas (*Abstract Co-Author*)
Chandrasekharan Kesavadas, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To study the classification and imaging features of common and rare glioneuronal tumors along with their pathological associations, using a case-based review. 2. To study genetic associations of glioneuronal tumors, such as BRAF with gangliogliomas, FGFR1 and PDGFRA with dysembryoplastic neuroepithelial tumor. 3. To define an imaging protocol for the evaluation of glioneuronal tumors. 4. To study features differentiating glioneuronal tumors from common mimics like polymorphous low grade neuroepithelial tumor of the young (PLNTY) and pilocytic astrocytomas 5. To provide a systematic approach for the imaging evaluation of glioneuronal tumors

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Imaging Protocol 3. WHO 2021 Classification of Brain Tumors: Glioneuronal and Neuronal Tumors 4. Genetic Associations of Glioneuronal Tumors 5. Radiology-Pathology features of Various Glioneuronal Tumors i. Ganglioglioma, common and rare manifestations ii. Desmoplastic Infantile Ganglioglioma iii. Dysembryoplastic Neuroepithelial Tumor iv. Papillary Glioneuronal Tumor v. Rosette Forming Glioneuronal Tumor vi. Diffuse Leptomeningeal Glioneuronal Tumor vii. Dysplastic cerebellar gangliocytoma viii. Neurocytoma ix. Newly recognized tumor types: DGONC, MGNT, MVNT 6. Mimics of Glioneuronal Tumors 7. Systematic imaging approach for evaluation of glioneuronal tumors 8. Take Home Points

NREE-67 SPINAL VASCULAR MALFORMATIONS: COMPREHENSIVE INSIGHTS FROM ANATOMY TO ENDOVASCULAR MANAGEMENT

Radhika More, MBBS (*Presenter*)
Sharath Kumar G G (*Abstract Co-Author*)

Payal Agrawal I, MD (*Abstract Co-Author*)
Savith Kumar, MBBS, MD (*Abstract Co-Author*)
Satya Narayana Mandalapu (*Abstract Co-Author*)

TEACHING POINTS

Overview of spinal vascular anatomy and SVM classification. Pathophysiology and clinical features of SVM. Imaging features with case illustrations. Endovascular management strategies with examples.

TABLE OF CONTENTS/OUTLINE

OUTLINE: Spinal vascular malformations (SVMs) are rare lesions with variable clinical presentations due to differences in anatomy and angioarchitecture. A solid understanding of spinal vascular anatomy and pathophysiology is essential for accurate diagnosis and treatment. Various classification systems exist, based on lesion location and flow characteristics—high-flow, low-flow, and no-shunt types. High-flow shunts may cause hemorrhage, mass effect, or be incidental findings. Low-flow SVMs, often acquired, typically affect older men and present with progressive myelopathy due to venous hypertension. MRI is useful for initial diagnosis; spinal DSA remains the gold standard for detailed evaluation and treatment planning. Endovascular embolization is the preferred treatment in most cases, aiming for complete occlusion with preservation of normal vasculature or targeted therapy at weak points if full occlusion is not feasible. Table of Contents: Spinal arterial and venous anatomy. Case-based clinical and imaging features of SVM. MRI features and feeder identification. Angioarchitecture and types of SVM. Endovascular embolization techniques.

NREE-68 CNS EMBRYONAL TUMORS AND THEIR MIMICS: WHAT A RADIOLOGIST SHOULD KNOW?

Smily Sharma, MD, FRCR (*Presenter*)
Venkata Subbaih Arunachalam, MD (*Abstract Co-Author*)
Chandrasekharan Kesavadas, MD (*Abstract Co-Author*)
Bejoy Thomas (*Abstract Co-Author*)

TEACHING POINTS

1. To study clinical presentation and imaging features of common and rare embryonal tumors, using an illustrative case-based review. 2. To study the pathology correlations of embryonal tumors. 3. To study syndromic associations of common embryonal tumors like medulloblastoma 4. To study imaging features of common mimics like ependymomas and infantile hemispheric gliomas, and discuss the differentiating features from embryonal tumors 5. To discuss the imaging protocol and derive a systematic approach for the evaluation of embryonal tumors

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Classification of embryonal tumors 3. Imaging protocol 4. Medulloblastoma: general and molecular subtype-specific features 5. Other embryonal tumors: 5A. Atypical teratoid/rhabdoid tumor (AT/RT) 5B. Embryonal tumor with multilayered rosettes (ETMR) 5C. CNS Neuroblastoma, FOXR2-activated 5D. CNS tumor with BCOR internal tandem duplication 6. Syndromic associations of embryonal tumors (with emphasis on medulloblastoma) 7. Mimics of embryonal tumors: 7A. Mimics of medulloblastoma (posterior fossa ependymoma, pilocytic astrocytoma, metastasis) 7B. Mimics of other embryonal tumors (Supratentorial ependymoma, infant-type hemispheric glioma) 8. Systematic approach for evaluation of CNS embryonal tumors 9. Take home points

NREE-69 DIAGNOSIS AND TREATMENT OF DEGENERATIVE SPINAL CYSTS

Khoi Nguyen (*Presenter*)
Linda Lu (*Abstract Co-Author*)
Jay Acharya, MD (*Abstract Co-Author*)

TEACHING POINTS

Symptomatic spinal cysts are an uncommon cause of severe back pain that may be definitively managed with non-invasive image-guided interventions. Intraspinal synovial cysts arise from degenerative facet joints and appear as extradural T2W hyperintense cysts with possible nerve compression. Image-guided cyst rupture, aspiration, and fenestration have shown significant improvement in symptoms and disability. Discal cysts are thought to arise from annular fissures and epidural venous plexus rupture. Case series report that CT-guided aspiration or fenestration may lead to complete symptom resolution. Ligamentous cysts arise from the ligamentum flavum or posterior longitudinal ligament and appear as a midline extradural T2W hyperintense cyst that can result in nerve compression. Transforaminal epidural injections can be used for pain management. Finally, interspinous pseudarthroses can lead to interspinous bursitis and extension of the bursa between the ligamentum flavum, creating an extradural cyst. Imaging shows communication between the cyst and interspinous bursa. Surgical management includes decompression or interspinous fusion to address degenerative changes. Alternatively, patients may undergo image-guided steroid injections for symptomatic management or aspiration/fenestration. Overall, image-guided interventions can provide symptomatic relief for a variety of degenerative spinal cysts and should be considered prior to surgical management.

TABLE OF CONTENTS/OUTLINE

Background, Intrapsinal Synovial Cysts, Ligamentous Cysts, Discal Cyst, Interspinous Bursitis (Baastrup's disease), Conclusion

NREE-72 FROM SYMPTOMS TO SCANS: BRIDGING CLINICAL INSIGHTS, IMAGING FINDINGS, AND ROLE OF INTERVENTIONAL RADIOLOGY IN INTRACRANIAL DURAL ARTERIOVENOUS FISTULAS ACROSS COGNARD GRADES

Sudhan Rackimuthu, MBBS (*Presenter*)
Elango Swamiappan, MBBS, MD (*Abstract Co-Author*)
Devanand Balalakshmoji, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the clinical variability of intracranial dural arteriovenous fistulas (dAVFs), focusing on symptoms such as pulsatile tinnitus, headaches, and visual disturbances. Understand the Cognard grading system for classifying dAVFs based on venous drainage patterns and their correlation with clinical risk. Learn the role of multimodal imaging techniques (CT, MRI, DSA) in diagnosing and characterizing dAVFs, with an emphasis on differentiating between Cognard grades. Identify critical imaging findings in different Cognard grades, particularly in relation to venous reflux, ectasia and sequestered sinus Explore the role of interventional radiology in managing dAVFs and how treatment strategies vary based on anatomy and Cognard grades.

TABLE OF CONTENTS/OUTLINE

Introduction to Intracranial Dural Arteriovenous Fistulas (dAVFs) Definition, pathophysiology, and clinical presentation. Cognard Grading System Grading dAVFs based on venous drainage patterns and clinical risk. Differentiating between Cognard grades I-V. Imaging Modalities CT: Initial evaluation, detecting venous congestions, hemorrhage, and osseous changes MRI/MR Angiography: Identifying venous reflux and ectasia. DSA: Final classification of dAVFs and assessing venous drainage. Use of a structured algorithm for multimodality imaging integration Case Studies Example cases for each Cognard grade, with detailed and annotated imaging findings. Interventional Radiology in dAVF Management Management strategies for different Cognard grades, focusing on embolization and surgical options. Pitfalls and Pearls Key imaging and diagnostic challenges in grading dAVFs.

NREE-73 UPDATED INSIGHTS IN MULTIPLE SCLEROSIS NEUROIMAGING AND NEW MCDONALD CRITERIA: PRACTICAL RADIOLOGICAL IMPLICATIONS

Max Yunior Orsi Salazar, MD (*Presenter*)
Tatiana Iutaka, BDS (*Abstract Co-Author*)
Beatriz D. Prado, MD (*Abstract Co-Author*)
Larissa A. Martins, MD (*Abstract Co-Author*)

Ana Paula A. Fonseca, MD (*Abstract Co-Author*)
Felipe Scortegagna SR, MD (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This article provides a comprehensive overview of neuroimaging in Multiple Sclerosis (MS) New McDonald Criteria review: 1. Optic Nerve Integration: Now include optic nerve lesions as a fifth dissemination-in-space site.2. Paramagnetic Rim Lesions (PRLs): Hypointense T2* rings at lesion edges enhance specificity for MS (96% vs. mimics). These correlate with chronic active lesions and disability progression.3. Central Vein Sign (CVS): =40% periventricular lesions with central veins on SWI/FLAIR improve diagnostic accuracy (sensitivity 88%, specificity 93%).

TABLE OF CONTENTS/OUTLINE

1. McDonald Criteria Evolution (2010 - 2017 - 2024):• 2024 revisions eliminate dissemination-in-time requirements for radiologically isolated syndrome (RIS) and integrate optic nerve lesions as a fifth anatomical site for dissemination-in-space.2. Optic Nerve Specificity:• Optic nerve lesions require T2 fat-sat/STIR sequences for detection; =3 mm lesions with perineural enhancement increase specificity for MS (89%).3. No longer require dissemination in time (DIT):• DIS (Dissemination in Space) revised: Five anatomical areas.• Radiologically Isolated Syndrome (RIS): can be diagnosed without clinical symptoms4. High-Specificity Biomarkers:• Central Vein Sign (CVS): =40% periventricular lesions with central veins on SWI/FLAIR (specificity 93% vs. mimics).• Paramagnetic Rim Lesions (PRLs): Hypointense T2* rings (specificity 96%) correlate with chronic active lesions.5. MS mimics• Microangiopathy• Leuconcefalopatia (AARS 2)• Other demyelinating diseases (MOGAD, NMOSD)• PRESS6. Possible treatment complications• LEMP• Fingolimod-related pseudotumoral lesion

NREE-74 IMAGING THE VASCULAR REPERCUSSIONS: INTRACRANIAL VASCULAR COMPLICATIONS OF RHINO-ORBITO-CEREBRAL MUCORMYCOSIS

Reeta Kanaujiya, MBBS, MD (*Presenter*)
Charu Paruthi, MD,MBBS (*Abstract Co-Author*)
Swarna Gupta, MBBS (*Abstract Co-Author*)
M Sarthak Swarup, MD,MBBS (*Abstract Co-Author*)
Geetika Sindhwani, MBBS (*Abstract Co-Author*)
Megha Jain, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. To review the pathophysiology of ROCM and its predilection for intracranial vascular involvement 2. Illustrate the imaging spectrum of vascular complications including subtle vessel wall changes, presence of intraluminal fungal hyphae to aneurysm formation and infarctions 3. To identify the early radiographic signs of vascular involvement on routine CEMRI 4. Establish a standardised imaging protocol and reporting checklist emphasising the critical role of routine contrast-enhanced MRI (CE-MRI) for early detection of vascular complication

TABLE OF CONTENTS/OUTLINE

Rhino-Orbito-Cerebral Mucormycosis (ROCM) is a life threatening fungal infection with increasing incidence in post-COVID-19 era and in immunocompromised patients. Due to its angio-invasive behaviour it can spread directly through vascular lumen or perivascular and perineural route. Intracranial vascular complications include vessel wall inflammation, thrombosis, infarction, and aneurysm formation. We present 130 cased of ROCM, of which 17 cases had intracranial vascular complications. Illustrative cases demonstrate: 1. Key vascular territories involved include the cavernous segment of the ICA, anterior cerebral circulation, posterior communicating artery, and dural venous sinuses. 2. Early signs : vessel wall thickening, enhancement (post-contrast MRI) and presence of intra-luminal fungal hyphae 3. Stenotic and Thrombotic phase : luminal narrowing, stenosis, and thrombosis 4. Advanced complications : mycotic aneurysms, pseudo-aneurysms, infarctions 5. Patterns and route of spread : from cavernous sinus, orbital apex, to ICA involvement

NREE-75 FRACTURES IN FOCUS: WHAT MAKES PEDIATRIC ORBITS DIFFERENT? A DEEP DIVE INTO UNIQUE INJURY PATTERNS AND ASSOCIATED COMPLICATIONS

V. Michelle Silvera, MD (*Presenter*)
Lynsey Ploenzke, BS (*Abstract Co-Author*)
Erica Allen (*Abstract Co-Author*)
Ian T. Mark, MD (*Abstract Co-Author*)
Norbert G. Campeau, MD, MSc (*Abstract Co-Author*)
Paul J. Farnsworth, DO (*Abstract Co-Author*)
Laurence J. Eckel, MD (*Abstract Co-Author*)
Julie B. Guerin, MD (*Abstract Co-Author*)

TEACHING POINTS

Introduction:Pediatric orbital fractures differ from adult patterns due to unique craniofacial anatomy and biomechanics. The pliable nature of pediatric bone predisposes children to trapdoor fractures with soft tissue entrapment and minimal bony displacement. Classic entities such as a white-eyed blowout fracture (WEBOF) can be missed. Rare post -traumatic complications such as orbitocele and blepharocele mimic more common findings such as orbital hematomas leading to diagnostic uncertainty. This exhibit highlights key imaging and clinical features of pediatric orbital trauma to improve diagnostic accuracy and guide management. Teaching Points1. Pediatric orbital trauma includes linear, blow out, and trapdoor fractures.2. Trapdoor fractures, most common in children, may involve fat and/or muscle entrapment, with minimal displacement.3. WEBOF presents with minimal periorbital bruising but significant risk of long-term deficits, if unrecognized.4. Prompt diagnosis of muscle entrapment is critical to avoid muscle ischemia, fibrosis and permanent motility issues.5. Rare complications such as orbitocele and blepharoceles will be illustrated.

TABLE OF CONTENTS/OUTLINE

• Pediatric orbital anatomy• Common pediatric orbital fracture types: linear, blowout, trapdoor, WEBOF• Imaging pearls and pitfalls: reformats, teardrop sign, muscle changes• Complications: diplopia and enophthalmos, orbitocele, blepharocele• Management: surgical timing vs facial growth considerations.• Case-based examples: classic, subtle findings, and complication driven findings.

NREE-76 WHEN NERVES LIGHT UP: CRANIAL AND PERIPHERAL NERVE ENHANCEMENT ON MRI, WHY A MULTIDISCIPLINARY PERSPECTIVE MATTERS

Paula Munoz Carrasco, MD (*Presenter*)
Antonio Barbosa, MD (*Abstract Co-Author*)
Maria Elena Capilla, MD (*Abstract Co-Author*)

TEACHING POINTS

- To review cranial and peripheral nerves enhancement patterns on MRI.- To illustrate different cases where a multidisciplinary approach was key.

TABLE OF CONTENTS/OUTLINE

Abnormal enhancement of cranial and peripheral nerves on MRI is a common and challenging finding and can indicate a wide range of pathologies, from inflammatory to neoplastic processes. Interpretation requires not only radiological expertise but also integration with clinical, neurological, neurophysiological, and laboratory findings. A multidisciplinary approach is key to timely diagnosis and optimal patient management.This presentation reviews imaging patterns of cranial and peripheral nerve enhancement, emphasizing their diagnostic significance and differential diagnoses.We illustrate key cases where collaboration between radiologists, neurologists, and other specialists was essential for accurate interpretation and treatment decisions. By highlighting the complexity and diversity of nerve enhancement findings, we advocate for multidisciplinary teamwork in addressing these often subtle but clinically critical signs.

NREE-77 UNWANTED TENANTS. INFECTIOUS GRANULOMATOUS DISEASES OF THE CENTRAL NERVOUS SYSTEM

Mauricio Pedreira, MD (*Presenter*)
Henrique Scalet (*Abstract Co-Author*)
Manoel Barbosa, MD (*Abstract Co-Author*)
Narriman P. Hazime, MD (*Abstract Co-Author*)
Leticia Victorazzo Louzada, MD (*Abstract Co-Author*)
Beatriz Helena Maia Tourao (*Abstract Co-Author*)
Isis Prado (*Abstract Co-Author*)
Felipe Correa Brito, MD (*Abstract Co-Author*)
Angelo C. Duarte, MD (*Abstract Co-Author*)
Felipe T. Pacheco, MD, PhD (*Abstract Co-Author*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)
Antonio Carlos M. Maia JR (*Abstract Co-Author*)

TEACHING POINTS

Review the epidemiology, clinical presentation, and imaging findings of infectious granulomatous diseases affecting the CNS Recognize the key imaging patterns in MRI and CT that suggest these diagnoses Highlight imaging-based diagnostic clues to differentiate infectious granulomatous diseases from neoplastic or other inflammatory lesions

TABLE OF CONTENTS/OUTLINE

Granulomatous infections of the CNS represent a major diagnostic challenge in endemic and immunocompromised populations. Multiple pathogens—including Mycobacterium tuberculosis , Taenia solium , Toxoplasma gondii , Cryptococcus neoformans , and Paracoccidioides spp. —can cause similar imaging patterns. Understanding their radiologic signatures is essential for appropriate diagnosis and management. Infectious granulomatous diseases of the CNS are diverse and can present with overlapping imaging features. A compartmental and etiological approach based on radiologic patterns, combined with clinical and epidemiological data, is crucial for accurate diagnosis and targeted therapy. Recognizing key signs—such as the eccentric target sign in toxoplasmosis or gelatinous pseudocysts in cryptococcosis—may help avoid unnecessary invasive procedures.

NREE-78 BRAIN DAMAGE: AN ACID METABOLIC TRIP ON THE NEUROIMAGING SPECTRUM

Bruno Rigonato (*Presenter*)
Gustavo Yamada, MD (*Abstract Co-Author*)
MATHEUS KRAUSE (*Abstract Co-Author*)
Matheus Ruffini (*Abstract Co-Author*)
Adolfo Souza (*Abstract Co-Author*)
Juliana Duarte (*Abstract Co-Author*)
Fabiano Reis (*Abstract Co-Author*)

TEACHING POINTS

Understand the neurotoxic impact of rare inherited metabolic disorders classified as organic acidurias. Recognize distinctive MRI patterns, including basal ganglia involvement, frontotemporal atrophy, and white matter abnormalities. Appreciate the role of advanced imaging techniques—such as diffusion-weighted imaging and magnetic resonance spectroscopy—in detecting early metabolic disturbances. Correlate neuroimaging findings with clinical and biochemical data to guide diagnosis and therapeutic decisions in pediatric patients.

TABLE OF CONTENTS/OUTLINE

1. Overview of organic acidurias and pathophysiological mechanisms of neurotoxicity. 2. Imaging hallmarks of glutaric aciduria types one and two. 3. Neuroimaging spectrum of propionic acidemia, methylmalonic acidemia, and isovaleric acidemia. 4. Characteristic findings in Canavan disease and its diagnostic reliance on MR spectroscopy. 5. Diffusion-weighted imaging and spectroscopy as tools for early detection. 6. Pictorial review of representative clinical cases with multimodal MRI. 7. Diagnostic pitfalls and mimics in metabolic encephalopathies. 8. Integrating clinical, biochemical, and radiologic data for improved diagnostic accuracy.

NREE-79 FROM IMAGE TO INCISION: THE ROLE OF T2 SPACE-MRA FUSION IN BRAINSTEM VASCULAR COMPRESSION

Vishnu Sankar T S, MD (*Presenter*)
Bhagyashree Chavan, MBBS (*Abstract Co-Author*)
Kapil Jhamnani, MBBS (*Abstract Co-Author*)
Hrishikesh A. Kale, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

• Fusion imaging with 3D T2 SPACE and modified 3D TOF MR sequences can enhance visualization of neurovascular compression in trigeminal neuralgia (TN) and hemifacial spasm (HFS). • It offers more accurate preoperative identification of offending vessels than conventional MR, aiding neurosurgical planning. • Integrating fusion imaging into diagnostic workflows can improve surgical outcomes by reducing complications and enhancing precision.

TABLE OF CONTENTS/OUTLINE

• TN and HFS are characterized by episodic facial pain or spasms, often caused by neurovascular compression of CN V or CN VII. Accurate identification of the offending vessel is key for surgical success. • T2 SPACE and 3D TOF MRA images of patients with unilateral TN or HFS was fused using Syngovia software. TOF sequences were modified for improved arterial visualization. Findings were compared with intraoperative results to assess the accuracy of fused vs. conventional imaging. • T2 SPACE delineates nerves but not arteries/veins. TOF highlights arteries but lacks nerve detail. Fusion resolves both limitations. The degree of T2 SPACE and TOF MRA overlap can be digitally adjusted to optimize visualization of both nerve and artery. • Fused imaging improved preoperative localization of neurovascular contact, aiding targeted decompression and reducing uncertainty. This lowers operative time and complications, and improves outcomes. • Intraoperative correlation of imaging findings will be provided.

NREE-80 THE HIDDEN CAVE: A RADIOLOGIC ATLAS OF MECKEL'S CAVE PATHOLOGIES

Abdulla Al-Hashemi, MD (*Presenter*)
Shahd Mohammedain (*Abstract Co-Author*)
Syeda Shabistan Intekhab, MBBS (*Abstract Co-Author*)
Mohammad Mohsin Arshad, MD (*Abstract Co-Author*)
Devendra Kumar, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

1-Review Meckel's Cave anatomy and relevant adjacent structures.2-Recognize key imaging features of lesions in the differential diagnosis.3-Differentiate Meckel's Cave lesions based on imaging and location.Background:Meckel's Cave is a dural recess in the middle cranial fossa that contains the trigeminal ganglion and proximal portions of the trigeminal nerve divisions. It lies at a critical anatomical junction bordered by the cavernous sinus, petrous apex, internal carotid artery, and the superior and inferior petrosal sinuses. Despite its small size, Meckel's Cave is frequently involved by a range of pathologies, both intrinsic and extrinsic, which can be challenging to identify radiologically. This educational exhibit begins with a focused review of Meckel's Cave anatomy and adjacent neurovascular structures using high-resolution MRI. Through a case-based approach, we illustrate normal and abnormal appearances of Meckel's Cave, emphasizing patterns of involvement, signal intensity, enhancement,

lesion morphology, and anatomical distortion. The primary objective of this exhibit is to enable radiologists to confidently diagnose Meckel's Cave lesions by identifying abnormal imaging findings and differentiating potential diagnoses through integration of imaging characteristics, anatomical localization, and lesion behavior.

TABLE OF CONTENTS/OUTLINE

1- Introduction to Meckel's Cave2- Review of anatomical importance and structural relationships3- Key imaging features of normal versus abnormal Meckel's Cave4- Case-based presentation of pathologies affecting Meckel's Cave5- Summary and differentiation between Meckel's Cave lesions

NREE-81 IMAGING PATTERNS OF BILATERAL GLOBUS PALLIDUS ABNORMALITIES: A PICTORIAL REVIEW

Leticia Victorazzo Louzada, MD (*Presenter*)
Isis Prado (*Abstract Co-Author*)
Manoel Barbosa, MD (*Abstract Co-Author*)
Henrique Scalet (*Abstract Co-Author*)
Narriman P. Hazime, MD (*Abstract Co-Author*)
Mauricio Pedreira, MD (*Abstract Co-Author*)
Beatriz Helena Maia Tourao (*Abstract Co-Author*)
Angelo C. Duarte, MD (*Abstract Co-Author*)
Felipe T. Pacheco, MD, PhD (*Abstract Co-Author*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)
Antonio Carlos M. Maia JR (*Abstract Co-Author*)

TEACHING POINTS

Review the anatomy and vulnerability of the globus pallidus, highlight key MRI findings in bilateral lesions, and propose an imaging-based classification to guide differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Introduction Highlight the globus pallidus's anatomical relevance, high metabolic demand, and vulnerability to systemic, toxic, metabolic, and genetic insults.Methods Retrospective multicenter review of brain MRIs with bilateral globus pallidus abnormalities, correlated with clinical data to define imaging phenotypes.Imaging Patterns and Etiologic Correlation T1 Hyperintensity Common in manganese intoxication and chronic liver disease. T2 Hyperintensity Observed in acute toxic encephalopathies Seen in inborn errors of metabolism. Associated with hypoxic-ischemic injury. T2 Hypointensity Related to iron or calcium deposition. Diffusion Restriction Seen in uremic encephalopathy, hypoxic injury, and vigabatrin toxicity. Mixed Patterns Associated with complex metabolic syndromes or overlapping etiologies. Additional Findings Involvement of adjacent white matter or other basal ganglia nuclei can help differentiate systemic vs. localized processes. Diagnostic Approach Proposal Imaging flowchart integrating clinical context with radiologic pattern to narrow differential diagnosis. ConclusionRecognition of typical imaging patterns involving the globus pallidus allows radiologists to narrow the differential diagnosis effectively. When integrated with clinical and laboratory data, this approach contributes to early and accurate diagnosis, guiding appropriate treatment while minimizing unnecessary investigations.

NREE-82 NEURO-DENGUE: A RADIOLOGICAL PERSPECTIVE

Zohaib Mallick, MBBS (*Presenter*)
Muhammad Abdullah (*Abstract Co-Author*)
Uffan Zafar, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit will illustrate the spectrum of neuroimaging findings in dengue encephalitis, emphasizing key differentiating features. We will review typical and atypical manifestations, including characteristic MRI patterns, to improve radiologic diagnosis and understanding of this emerging complication.

TABLE OF CONTENTS/OUTLINE

Introduction to Dengue Encephalitis Pathophysiology and Clinical Presentation Typical Imaging Findings MRI Sequences (T2, FLAIR, DWI, SWI) Commonly Affected Areas (Thalami, Basal Ganglia, Brainstem, Cerebellum) Characteristic Patterns (e.g., symmetrical involvement) Atypical Imaging Findings Uncommon Locations (e.g., cortical involvement, spinal cord) Variations in Presentation (e.g., hemorrhage, edema) Differential Diagnosis Other Viral Encephalitides ADEM Vascular Complications Case Examples Representative cases with imaging and clinical correlation Conclusion References

NREE-83 FLOW DIVERTER IMPLANTATION: EARLY PROCEDURAL COMPLICATIONS AND IMAGING CORRELATES

Laura Peter, MD (*Presenter*)
Felix Gallo, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review the clinical and radiologic findings associated with neurological symptoms during flow diverter implantation.- Identify complications related to device implantation and correlate them with device location and procedural technique.- Illustrate how retrospective case analysis contributes to improving clinical practice and follow-up protocols in interventional neuroradiology.

TABLE OF CONTENTS/OUTLINE

Flow diverters are endovascular devices primarily used to treat large, wide-necked, or fusiform intracranial aneurysms. We reviewed 29 patients with brain aneurysms who underwent flow diverter treatment and developed neurological complications during or within the first few hours after implantation. Clinical presentation, aneurysm location, device type, imaging features, and outcomes were evaluated. Early neurological complications following flow diverter implantation are uncommon but clinically significant. Prompt recognition and imaging evaluation are essential to guide management and improve patient outcomes. Retrospective analysis of such events can help refine procedural techniques and enhance safety in future interventions.

NREE-84 A SYRINX IS JUST THE BEGINNING: DIAGNOSTIC CLUES, PITFALLS, AND MANAGEMENT

Donna Parizadeh, MD,MPH (*Presenter*)
Ahmed W. Moawad, MBBch (*Abstract Co-Author*)
Gabriel Virador, MD (*Abstract Co-Author*)
Abiel B. Habtezghi, MD (*Abstract Co-Author*)
Adam Averbuch, DO (*Abstract Co-Author*)
Christian Pedersen, MD (*Abstract Co-Author*)

TEACHING POINTS

We will use a combination of interactive image-based questions, radiologic illustrations, and flowcharts to:1-Differentiate central canal dilatation, hydromyelia, and syringomyelia. 2- Identify underlying causes of syrinx formation with interactive case examples. 3-Discuss the current theories on pathophysiology of syrinx. 4-Understand the role of different imaging techniques in management. 5-Apply a stepwise diagnostic and management algorithm incorporating diagnosis and treatment techniques

TABLE OF CONTENTS/OUTLINE

1-Introduction-Imaging Spectrum and Terminology: Demonstrates imaging examples and definition of normal central canal, mild dilatation, hydromyelia, and syringomyelia on MRI. 2- Pathophysiology and Etiologies: Reviews current theories of syrinx formation. 3-Explores common and uncommon causes including Chiari malformation, arachnoiditis, spinal cord tethering, tumors, trauma, and rare causes such as CSF venous fistulas. 4. Case-Based Learning: Presents multiple interactive MRI cases simulating real-world diagnostic challenges. 5. Diagnostic Algorithm: Integrates findings into a diagnostic and management algorithm that incorporates clinical symptoms, imaging clues, MRI with contrast, cine MRI, CT myelogram, and decision points for surgical referral vs observation. 6. Key Takeaways: Concludes with a synthesis of pearls and pitfalls, emphasizing the importance of recognizing imaging red flags that necessitate further workup or neurosurgical referral, and conditions that may be safely monitored

NREE-85 NEUROLOGICAL JANUS: EXPLORING THE TWO-FACED NATURE OF MOGAD WITH INFECTIONS - SIMILARITIES AND DIFFERENCES

Manoel Barbosa, MD (*Presenter*)
Narriman P. Hazime, MD (*Abstract Co-Author*)
Felipe Correa Brito, MD (*Abstract Co-Author*)
Angelo C. Duarte, MD (*Abstract Co-Author*)
Felipe T. Pacheco, MD, PhD (*Abstract Co-Author*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)
Renato Hoffmann Nunes, MD, MBA (*Abstract Co-Author*)
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*)
Antonio Carlos M. Maia JR (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This educational exhibit provides a comprehensive overview of neuroimaging in Myelin Oligodendrocyte Glycoprotein Antibody-associated Disease (MOGAD). A review of MOGAD imaging phenotypes: FLAMES , ADEM-like , Myelitis , Neuritis/Perineuritis , and Infratentorial Syndromes . Key imaging-based similarities and differences between MOGAD and various infectious diseases , organized according to each MOGAD phenotype.

TABLE OF CONTENTS/OUTLINE

1. Introduction and overview of MOGAD 2. FLAMES - T2 and FLAIR hyperintensity affecting the cortex, usually unilateral, often with cortical and leptomeningeal enhancement Main differential : Viral encephalitis 3. ADEM-like phenotype - Extensive T2 and FLAIR hyperintensities in the subcortical white matter and deep gray nuclei Main differential : Progressive Multifocal Leukoencephalopathy (PML) 4. Myelitis - Longitudinally extensive spinal cord lesions (=3 vertebral segments), often involving the central gray matter Main differential : Tuberculous myelitis 5. Optic neuritis/perineuritis - Long-segment involvement of the optic nerves, often bilateral, with perineural enhancement Main differential : Syphilitic neuroretinitis and perineurinitis. 6. Infratentorial involvement - T2 hyperintensity in the brainstem and middle cerebellar peduncles Main differential : JC virus-associated granule cell neuronopathy and HIV encephalopathy

NREE-86 WHEN THROMBECTOMY GOES WRONG: A RADIOLOGIC REVIEW OF PROCEDURAL COMPLICATIONS

Laura Peter, MD (*Presenter*)
Felix Gallo, MD (*Abstract Co-Author*)

TEACHING POINTS

- Mechanical thrombectomy is a life-saving intervention in acute ischemic stroke, yet procedural complications remain a significant concern. - A systematic analysis of real-world complications can guide interventional radiologists in preventing, recognizing, and managing adverse events. - Technique selection (aspiration vs stent retriever vs combined) and number of device passes may influence complication rates and angiographic outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of thrombectomy in ischemic stroke and clinical relevance of procedure-related complications. Materials and Methods Retrospective review of patients undergoing thrombectomy at a tertiary care center. Data includes demographics, thrombectomy technique, number of passes, angiographic outcome (TICI), and complications. Results Common complications included new territory embolism and vessel perforation. Most procedures used a combined technique. Higher number of passes showed a trend toward increased complications. Imaging Examples Radiologic cases highlighting the most frequent and severe complications. Discussion Interpretation of findings, correlation with literature, and procedural considerations to minimize risks. Conclusion Awareness of complication patterns and risk factors can enhance safety and outcomes in stroke thrombectomy.

NREE-87 HIDDEN CONNECTIONS: NEUROVASCULAR LESIONS IN HEREDITARY HEMORRHAGIC TELANGIECTASIA

Ayelen Leao, MD (*Presenter*)
Kevin Kurt Mac Allister (*Abstract Co-Author*)
Stefania Solanot, MD (*Abstract Co-Author*)
Manuel S. Perez Akly, MD (*Abstract Co-Author*)
Cristina H. Besada SR, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1) Hereditary Hemorrhagic Telangiectasia can manifest with a variety of neurovascular lesions such as arteriovenous malformations (AVMs), capillary malformations and developmental venous anomalies. 2) Primary neurologic complications include stroke, intracerebral hemorrhage, cerebral edema, seizure, and migraines. 3) Silent lesions such as AVMs are underrecognized and often underreported 4) MRI is widely used as a primary screening tool for detecting cerebral AVMs, while Digital Subtraction Angiography remains the gold standard for the definitive diagnosis of cerebral AVMs due to its superior spatial resolution and ability to provide dynamic vascular flow information.5) Genotype-phenotype correlation in HHT can guide surveillance strategies.

TABLE OF CONTENTS/OUTLINE

HHT is a rare autosomal dominant disorder characterized by vascular malformations throughout multiple organ systems. CNS manifestations pose significant diagnostic and management challenges due to their potential for serious complications. The spectrum of neurovascular anomalies include brain AVM, arteriovenous fistulas, and capillary malformations, each with distinct imaging features. Many CNS lesions remain asymptomatic and are incidentally discovered during screening, early detection is essential for risk stratification and prevention of catastrophic events. This educational exhibit explores the spectrum of CNS manifestations in HHT, key radiological features, diagnostic approaches, and interventional management strategies. 1) Introduction to HHT 3) Spectrum of radiological findings and differential diagnosis. 4) Recommended Imaging Protocols 5) Surveillance Recommendations 6) Treatment 7) Conclusions

NREE-88 CLIPS (CLINOIDAL, LATERAL, INFERIOR, POSTERIOR, SUPERIOR): DEVELOPMENT OF A MAGNETIC RESONANCE GRADING SYSTEM TO PREDICT PITUITARY ADENOMA INVASION OF CAVERNOUS SINUS COMPARTMENTS

Maverick Jubane, MD (*Presenter*)
Johannes H. Decker, MD,PhD (*Abstract Co-Author*)
Nancy J. Fischbein, MD (*Abstract Co-Author*)
Felipe Constanzo (*Abstract Co-Author*)

TEACHING POINTS

Advances in Endoscopic Endonasal Approach (EEA) to Pituitary adenoma resection allow for better access to the cavernous sinuses and increase chances of gross total resection. Existing imaging based classification systems of pituitary adenoma invasion were developed without the advanced access that EEA provides, leading neurosurgeons to consider new anatomic based classification systems to aid them in surgical planning. CLIPS is a new MR based classification system of cavernous sinus compartment invasion by pituitary adenoma that takes into account the advances in EEA and neurosurgical anatomic classification. CLIPS stands for Clinoidal, Lateral, Inferior, Posterior, and Superior, referring to the 4 cavernous sinus compartments (superior, inferior, lateral, and posterior) and the clinoid venous space beyond the proximal dural ring, which are relevant sites of invasion that are accessible to EEA. CLIPS has high sensitivity, specificity, and inter-rater reliability

TABLE OF CONTENTS/OUTLINE

Review anatomy of pituitary, sella, and surrounding structures. Review pituitary lesions, with emphasis on pituitary adenomas. Review surgical approaches to the sella (Transcranial, Transsphenoidal Microsurgery, and Endoscopic Endonasal Approach). Review Knosp MR classification and limitations (Original study, Modification, and Inter-rater reliability). Introduction to CLIPS MR Classification System.Illustration of examples of invasion into each compartment (Figure 1).Binary grading for each of the 5 compartmentsSingle bisecting line using anatomic planes.Examples w/ illustration of each compartment (Figures 2-4).Summary statistics and inter-rater agreement (Tables 1 and 2).

NREE-89 NEURORADIOLOGY OF THE VENTRICLES: DECIPHERING TUMOR PATHOLOGY

Daniel Santiago Ramirez Amaya, MD (*Presenter*)
Cesar Andres Rodriguez Pulido, MD (*Abstract Co-Author*)
Carolina Tramontini (*Abstract Co-Author*)

TEACHING POINTS

• Understand the intricate ventricular anatomy and its embryological origin, emphasizing the diverse tissue formations and cell lineages implicated in intraventricular tumorigenesis. • Recognize, via magnetic resonance imaging (MRI), the distinctive radiologic features of intraventricular lesions by evaluating their location, morphology, and contrast enhancement patterns. • Implement a systematic approach, incorporating patient age and anatomical localization, to effectively differentiate intraventricular masses. • Integrate epidemiologic and anatomical data into a diagnostic algorithm that enhances precise clinical decision-making.

TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Objectives.3. Classification.4. Tumor approach.5. Key Messages.

NREE-90 DECIPHERING THE EPILEPTIC BRAIN: AN ATLAS OF IMAGING FINDINGS

Oreanna Quintero, MD (*Presenter*)
Andres F. Caliz Cabrales, MD (*Abstract Co-Author*)
Julian M. Gandur, MD (*Abstract Co-Author*)
Sara Gomez Milanes, MD (*Abstract Co-Author*)
Jesus Eduardo Barreto Fernandez (*Abstract Co-Author*)
Luz A. Unigarro, MD (*Abstract Co-Author*)
Alejandro Blanco Rojas, MD (*Abstract Co-Author*)
Carolina Tramontini (*Abstract Co-Author*)

TEACHING POINTS

Imaging's Crucial Role: Neuroimaging is vital for identifying epilepsy's underlying causes, going beyond seizure description and EEG. Specific imaging findings strongly suggest distinct etiologies. MCDs: Developmental Disruptions: FCD Polymicrogyria Schizencephaly MTS: Temporal Lobe Epilepsy Hallmark Neoplastic Origins: DNET: Low-Grade Tumors: Astrocytomas: Variable (solid to cystic), slow growth, subtle mass effect. Gangliogliomas: Cystic with enhancing nodule, linked to chronic epilepsy. Oligodendrogliomas: Calcifications, well-defined borders, often frontal or temporal. Vascular Anomalies: Cavernomas Temporal Evolution: Imaging shows progression in conditions like MTS and tumor growth, crucial for understanding disease course. Interpretation & Accuracy: Strengths and limits of MRI, CT, PET for specific causes. Expert interpretation is key to avoid pitfalls. Visual Atlas Value: Aids clinicians/trainees in accurate image interpretation, pattern recognition, and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

I. Introduction: Imaging in Epilepsy Etiology A. Beyond Semiology and EEG B. Imaging Modalities Overview C. Atlas GoalsII. Malformations of Cortical Development (MCDs) A. Focal Cortical Dysplasia (FCD) B. Neuronal Migration Disorders: Heterotopias C. Polymicrogyria D. SchizencephalyIII. Mesial Temporal Sclerosis (MTS) IV. Neoplastic Origins A. Dysembryoplastic Neuroepithelial Tumor (DNET) B. Other Low-Grade Tumors V. Vascular Malformations A. CavernomasVI. Temporal Evolution of Imaging VII. Principles of Interpretation & Accuracy A. Modality Strengths & Limitations VIII. Visual Atlas of Imaging Findings IX. Conclusion: Empowering Diagnosis & Management.

NREE-91 HIGH-GRADE GLIOMAS OF THE YOUNG ADULT: CONVENTIONAL AND ADVANCED NEUROIMAGING WITH HISTOLOGICAL CHARACTERISTICS

Bernardo C. Teixeira, MD, PhD (*Presenter*)
Joao Nadal (*Abstract Co-Author*)
Joao V. de Oliveira Souza, MD (*Abstract Co-Author*)
Leonardo Kami, MD (*Abstract Co-Author*)
James H. Yared, MD (*Abstract Co-Author*)
Bruno A. Telles, MD (*Abstract Co-Author*)
Marcela Santos Cavalcanti (*Abstract Co-Author*)
Erasmo Barros Da Silva Junior (*Abstract Co-Author*)
Ricardo Ramina (*Abstract Co-Author*)

TEACHING POINTS

High-grade gliomas in adolescents and young adults are aggressive diffusely infiltrating brain tumors. Under the 2021 WHO classification, adult-type diffuse gliomas include astrocytomas (IDH-mutant) and glioblastomas (IDH-wildtype), as well as oligodendrogliomas (IDH-mutant, 1p/19q-co-deleted). In young adults, On MRI these tumors are T1-hypointense, T2/FLAIR-hyperintense, often with irregular enhancement, necrosis and surrounding edema. A classic MRI clue is the T2-FLAIR mismatch sign which is highly specific for IDH-mutant, 1p/19q non-codeleted astrocytoma.

TABLE OF CONTENTS/OUTLINE

1. Advanced MRI Perfusion shows elevated rCBV in high-grade regions, reflecting neovascularity. DWI often reveals the foci of restricted diffusion in densely cellular tumor areas. Spectroscopy shows markedly increased choline and reduced N-acetylaspartate in high-grade tumors, often with lactate/lipid peaks; a high Cho/Cr ratio and presence of lactate/lipid peak strongly favor anaplastic glioma over low-grade. 2. Histological/Molecular Features IDH1/2 mutation is a hallmark of “lower-grade” adult gliomas; IDH-mutant astrocytomas often harbor concurrent ATRX loss and TP53 mutation, while 1p/19q co-deleted tumors have intact ATRX and TERT promoter mutations. IDH-wildtype high-grade gliomas frequently show EGFR amplification, +7/-10 and methylated MGMT promoter. 3. Diagnostic/Prognostic Relevance Diffuse midline gliomas with H3 K27-alteration occur in midline structures of younger patients. Overall, IDH-mutant gliomas have significantly longer survival than IDH-wildtype; for example, IDH-mutant “glioblastomas” fare much better than true IDH-wild glioblastoma.

NREE-92 DECODING STROKE MIMICS: WHEN IMAGING TELLS A DIFFERENT STORY

Zainab Salman, MD (*Presenter*)
Jasmina Boban, MD,PhD (*Abstract Co-Author*)
Sarah Salman Siddiqui (*Abstract Co-Author*)

TEACHING POINTS

1. Revise the imaging findings in acute, subacute and chronic ischemic stroke on non enhanced CT and MRI. 2. Understand the variety of pathologies that may present as stroke mimics. 3. Classify stroke mimics based on imaging patterns and recognize their key imaging findings. 4. To improve the performance of the Radiologist in stroke mimic scenarios.

TABLE OF CONTENTS/OUTLINE

Imaging Pattern-Based Approach Through Cases: 1. Regional gray and white matter: Seizures and post ictal deficits, Migraine, HSV encephalitis, Venous thrombosis, Hypoglycemia, Tumor, MELAS 2. Cortical and deep gray matter: HIE, Hepatic encephalopathy, CJD, Wernicke's encephalopathy. 3. Deep gray matter: CO poisoning, extrapontine myelinolysis, CJD, Nonketotic Hyperglycemia, Venous thrombosis, Wernicke's. 4.White matter: CADASIL, Susac's, demyelination, metronidazole toxicity, Heroin leukoencephalopathy. 5.Watershed zones: RCVS, PRES, Moya-Moya. 6.Scattered Foci: Fat emboli, Diffuse axonal injury, Embolic infarcts, Metastasis. 7.Corpus Callosum: CLOCCs, Seizures, Marchiafava-Bignami.

NREE-93 THE CEREBELLAR PATHWAYS: DIFFERENTIAL DIAGNOSES OF MIDDLE CEREBELLAR PEDUNCLE ABNORMALITIES

Manoel Barbosa, MD (*Presenter*)
Beatriz Helena Maia Tourao (*Abstract Co-Author*)
Leticia Victorazzo Louzada, MD (*Abstract Co-Author*)
Narriman P. Hazime, MD (*Abstract Co-Author*)
Mauricio Pedreira, MD (*Abstract Co-Author*)
Henrique Scalet (*Abstract Co-Author*)
Isis Prado (*Abstract Co-Author*)
Angelo C. Duarte, MD (*Abstract Co-Author*)
Felipe T. Pacheco, MD, PhD (*Abstract Co-Author*)
Thiago Luiz P. Scoppetta, MD (*Abstract Co-Author*)
Lazaro F. Amaral, MD (*Abstract Co-Author*)
Renato Hoffmann Nunes, MD, MBA (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)
Antonio Carlos M. Maia JR (*Abstract Co-Author*)

TEACHING POINTS

This educational exhibit aims to provide a comprehensive review of conditions affecting the middle cerebellar peduncles (MCPs) and their neuroimaging characteristics.- To review the anatomy and function of the middle cerebellar peduncle. - To present the neuroimaging features and specific aspects of various differential diagnoses involving the MCPs.

TABLE OF CONTENTS/OUTLINE

Anatomy and function of the middle cerebellar peduncle. 1. Degenerative Diseases a. Multiple system atrophy - cerebellar type (MSA-C) b. Spinocerebellar ataxias (SCAs) c. Fragile X-associated tremor/ataxia syndrome (FXTAS) 2. Demyelinating conditions a. Myelin Oligodendrocyte Glycoprotein Antibody-associated Disease (MOGAD) b. Multiple Sclerosis (MS) c. Adrenoleukodystrophy (ALD) d. Behçet’s Disease 3. Infectious diseases a. Neurotuberculosis b. Progressive multifocal Leukoencephalopathy (PML) c. Granule cell neuronopathy caused by JC virus 4. Neoplastic conditions a. Gliomas b. Medulloblastoma c. Lymphoma d. Metastases 5. Vascular conditions a. Posterior reversible encephalopathy syndrome (PRES) b. Inflammatory vasculopathy c. Ichemia 6. Toxic and metabolic alterations a. Wilson’s Disease b. Marchiafava-Bignami c. Chemotherapic neurotoxicity

NREE-94 INTRATUMORAL ONCOLYTIC VIROTHERAPY FOR DIFFUSE PEDIATRIC HIGH-GRADE GLIOMAS

Carmen Mbongo, MD (*Presenter*)
Marta Calvo-Imirizaldu, MD (*Abstract Co-Author*)
Pablo D. Dominguez, MD (*Abstract Co-Author*)
Reyes M. Garcia-Eulate (*Abstract Co-Author*)

TEACHING POINTS

• Oncolytic viruses selectively replicate within tumor cells, promoting immunogenic cell death and stimulating antitumor immune responses.• This therapeutic approach offers a promising strategy for diffuse pediatric high-grade gliomas , which are characterized by infiltrative growth, limited treatment options, and unfavorable prognosis.• MRI plays a critical role in identifying and characterizing treatment-related changes and tumor response assessment in patients undergoing intratumoral oncolytic virotherapy.

TABLE OF CONTENTS/OUTLINE

Oncolytic virotherapy is an emerging treatment for diffuse pediatric high-grade gliomas , aggressive tumors with limited response to standard therapies. Intratumoral delivery , performed via neuronavigation-guided injection, enhances local viral concentration and bypasses systemic barriers. MRI is central to evaluating treatment response and post-infusion changes . This exhibit reviews the rationale and imaging considerations of intratumoral oncolytic virotherapy, focusing on adenoviral-based agents. A dedicated MRI protocol includes baseline scans, immediate post-infusion imaging, and serial follow-up every four weeks with T2, FLAIR, DWI, and contrast-enhanced T1 sequences. Response is assessed using iRANO/RAPNO criteria, based on T2/FLAIR signal in non-enhancing tumors.Common findings include stable or decreasing hyperintensity, tumor volume reduction, and transient enhancement along the cannula tract. Accurate interpretation is essential to avoid misclassification of expected post-treatment changes. MRI thus plays a key role in guiding clinical decisions in this context.

NREE-95 GREEN MRI FOR NEUROIMAGING: FOLLOW-UP OF BRAIN TUMORS BY NON-CONTRAST SEQUENCES

Kazuhiro Tsuchiya, MD, PhD (*Presenter*)
Miho Gomyo (*Abstract Co-Author*)
Shichiro Katase (*Abstract Co-Author*)
Kenichi Yokoyama, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To learn the basic concepts of “green” MRI. 2. To learn whether contrast agents are needed when using MRI to follow-up brain tumors. 3. To know what kinds of brain tumors can be followed up by non-contrast MRI and their recommended scan protocols.

TABLE OF CONTENTS/OUTLINE

1. Basic issues of green MRI, including reduced use of Gd-based contrast agents (GBCAs), reduced electric power consumption, reduced waste materials, and so on. 2. Currently known issues of negative environmental impacts of GBCAs. 3. What kinds of brain tumors can be followed up with non-contrast MRI and what are their recommended scan protocols? 4. Presentation of clinical cases followed up by non-contrast MRI. 5. Additional discussion on current limitations as well as future directions.

NREE-96 ASSESSMENT OF HEMODYNAMICS OF VARIOUS INTRACRANIAL VASCULAR AND NEOPLASTIC LESIONS BY SUPER-SELECTIVE PSEUDO-CASL TECHNIQUE

Kazuhiro Tsuchiya, MD, PhD (*Presenter*)
Miho Gomyo (*Abstract Co-Author*)
Keita Fukushima (*Abstract Co-Author*)
Kenichi Yokoyama, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To learn the basic concepts and technical aspects of the super-selective pseudo-continuous arterial spin labeling (ss-pCASL) technique. 2. To learn the clinical significance of assessing hemodynamics of cerebral vascular and neoplastic lesions supplied by multiple arterial systems. 3. To learn through case studies what types of cerebrovascular and neoplastic lesions can benefit from ss-pCASL.

TABLE OF CONTENTS/OUTLINE

1. Basic technical issues of CASL and ss-pCASL. 2. What kinds of cerebral vascular lesions develop arterial blood supply by different flow systems from normal status? 3. What kinds of brain tumors develop arterial blood supply by multiple blood flow systems? 4. Presentation of clinical cases whose hemodynamic status is effectively visualized by ss-pCASL. 5. Additional discussion on current limitations as well as future directions.

NREE-97 BEYOND FEVER: MRI INSIGHTS INTO SCRUB TYPHUS-RELATED CNS MANIFESTATIONS

Shalini Bangalore Suresh JR, MBBS, MD (*Presenter*)

TEACHING POINTS

1.Scrub typhus is a significant but often underrecognized cause of CNS infection in endemic regions, presenting with varied neurological symptoms and imaging patterns. 2.Scrub typhus typically presents with fever and altered sensorium, often accompanied by thrombocytopenia (low platelet count), elevated liver transaminases (LFT derangement), splenomegaly, and sometimes pleural effusions. 3.Key MRI findings include: Leptomeningeal enhancement (55%), Cerebellitis (16), White matter changes, Rhombencephalitis, encephalitis, Cranial nerve enhancement and Acute Necrotising Encephalopathy (ANE) like presentation. 4.CT scan findings (where available) shows diffuse cerebral edema, hypodensities in white matter regions and cerebellum, subtle meningeal enhancement (best appreciated post-contrast). 5.Early recognition of these patterns, alongside supportive lab findings, allows prompt initiation of doxycycline, substantially reducing morbidity and mortality.

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology & diagnostic challenges of scrub typhus neuroinfection. Methods Retrospective review of 36 seropositive cases (mean age 30 y) using 1.5T/3T MRI and CT. Imaging Spectrum Leptomeningitis Cerebellitis (DWI & ASL hyperperfusion) Deep white matter hyperintensities Rhombencephalitis (pons/MCP) Cranial nerve enhancement Acute necrotizing encephalopathy Case Gallery Annotated high-yield MRI examples. Radiologist’s Pearls Key diagnostic tips & pitfalls. Conclusion MRI’s crucial role in febrile encephalopathy; one of the largest scrub typhus neuroimaging cohorts

NREE-98 COLOR-CODED MULTIPHASIC CTA OF THE BRAIN: WHAT THE RADIOLOGIST NEEDS TO KNOW

Saravana Kumar Swaminathan, MBBS, FRCR (*Presenter*)

TEACHING POINTS

Color-coded multiphase CT angiography (mCTA) is an innovative software tool that synthesizes information from all mCTA phases into a unified dataset and provides color-coded visualization based on contrast arrival timing in the intracranial vasculature. Through carefully selected case illustrations the author will provide multiple color-coded mCTA examples demonstrating their various clinical applications. Corresponding digital subtraction angiograms and follow-up MR images will also be included to enhance understanding.

TABLE OF CONTENTS/OUTLINE

The purpose of this exhibit is to demonstrate: The fundamental principles of acquisition, processing and interpretation of color-coded multiphasic CTA images of the brain The clinical applications of this imaging modality in stroke assessment including, a. Rapid detection of large vessel occlusions and multifocal occlusions across different vascular territories, b. Enhanced detection of medium and distal vessel occlusions, c. Efficient assessment of the collateral status and d. Differentiation acute thrombotic occlusions from chronic atherosclerotic stenotic occlusions The primary limitations of color-coded multiphasic CTA and compare with other imaging modalities used in acute stroke assessment such as routine CT angiogram and CT perfusion

NREE-99 ADVANCED NEUROVASCULAR EVALUATION WITH BLACK BLOOD MRI: DIAGNOSTIC APPLICATIONS OF VESSEL WALL IMAGING AND CURVED MULTIPLANAR RECONSTRUCTION

Elham Tavakkol, MD (*Presenter*)
Laura A. Ocasio, MD, MSc (*Abstract Co-Author*)
Konstanze Guggenberger, MD (*Abstract Co-Author*)
Juan Ricardo, MD (*Abstract Co-Author*)
Roy Riascos, MD, MBA (*Abstract Co-Author*)
David E. Timaran Montenegro, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the use of Black Blood MRI (BB-MRI) in vessel wall imaging (VWI) for neurovascular evaluation. Demonstrate clinical applications in intracranial and extracranial distinguishing vascular pathologies. Highlight curved multiplanar reconstruction as a valuable postprocessing technique. Recognize common pearls and pitfalls in image interpretation of BB-MRI.

TABLE OF CONTENTS/OUTLINE

1. Introduction to BB-MRI: Introduce BB-MRI as a key tool for neurovascular imaging. Emphasize technical aspects such as 3D acquisition, effective flow suppression, optimized contrast weighting, high spatial resolution, and compressed sensing to improve image quality. 2. Differentiation of Vascular Pathologies with VWI: Illustrate diagnostic utility in identifying intracranial atherosclerotic disease, vasculitis, arterial dissection, Moyamoya disease, saccular aneurysms, vasospasm, and giant cell arteritis. 3. New MRI Techniques: Describe 3 curved multiplanar reconstructions as a postprocessing method for quantitative analysis of vessel wall remodeling. Demonstrate its use with fly-through technique for visualization of vessel morphology. 4. Pitfalls and Pearls in Interpretation: Review common challenges, including flow artifacts, venous and vasa vasorum enhancement, post-treatment changes, leptomeningeal enhancement, organized thrombus with recanalization, and findings mimicking pathology in Moyamoya disease.

NREE-100 SPONTANEOUS INTERNAL CAROTID ARTERY DISSECTION: FROM PATHOPHYSIOLOGY TO CTA/MRI FINDINGS — A PRACTICAL GUIDE

Sergio Colomer Rosell, MD (*Presenter*)

TEACHING POINTS

Spontaneous internal carotid artery (ICA) dissection affects the arterial wall, potentially causing local symptoms or neurological deficits. Although uncommon, it accounts for up to 20% of strokes in young adults. It can occur in any ICA segment, but is more frequent in the extracranial portion. Two main mechanisms are described: intramural hematoma from vasa vasorum rupture, or intimal tear with blood entering the wall, both resulting in arterial wall layer separation. Based on blood location,

dissection is classified as subintimal—stenotic and eccentric lumen—or subadventitial—dissecting aneurysm. Historically, digital subtraction angiography (DSA) was the diagnostic gold standard. Currently, CT angiography (CTA) and MRI are preferred due to their non-invasive nature and better availability. CTA plays a key role in acute settings with high-resolution vessel wall assessment. MRI, particularly T1 fat-saturated sequences, directly depicts intramural hematoma.Imaging findings often reflect pathophysiology. The most frequent finding is an irregular, stenotic, and eccentric lumen which -when identified in its typical location- allows for a confident diagnosis. Other findings include the intimal flap, double lumen, or "target sign". Therefore, understanding the pathophysiology is essential for accurate recognition on CTA and MRI, the most commonly used modalities in clinical practice.

TABLE OF CONTENTS/OUTLINE

Introduction. Risk Factors and symptoms. Pathophysiology: - Dissection. - Stroke. Imaging Findings and Correlation: - CTA. - MRI. Imaging Evolution. Differential Diagnosis.

NREE-101 REVEALING THE LANGUAGE NETWORK OF THE HUMAN BRAIN AND ASSOCIATION WHITE MATTER PATHWAYS WITH DUAL LANGUAGE AND LIMBIC FUNCTIONS

Nithya Narayana (*Presenter*)
Anusha Gandhi, MD (*Abstract Co-Author*)
Arash Kamali, MD (*Abstract Co-Author*)

TEACHING POINTS

The purposes of the exhibit are: 1. Expanding beyond the dual-stream model of language processing as advances in fMRI and DTI have revealed a more interconnected system. 2. Presenting a seven-language center-based approach to illustrate the integration of language and cognitive processing. 3. Association of the language pathways with the limbic system may explain language disorders with emotional comorbidities. 4. Visualizing neural connections highlights the importance of integrating language, executive function, and emotion in understanding speech related disorders.

TABLE OF CONTENTS/OUTLINE

1. Background a. Dual-stream model b. Advances in neuroimaging and white matter mapping. 2. Introduction a. Justification for a center-based approach in language processing. b. Bridging language and limbic system functions 3. Language Centers 4. Association White Matter Tracts 5. Implications for Language Disorders a. Impact of white matter integrity on language recovery (stroke-induced aphasia and rehabilitation). 6. Future Directions and Clinical Applications a. The interwoven nature of language and emotion points towards a more holistic approach to understand and treating language disorders.

NREE-102 RADIOLOGIC ASSESSMENT OF POSTOPERATIVE LUMBAR SPINE

Laura Oleaga, MD, PhD (*Presenter*)
Camilo Pineda Ibarra, MD (*Abstract Co-Author*)
Miren L. Olondo, MD (*Abstract Co-Author*)
Carlos Cardenal (*Abstract Co-Author*)
Valeria Richart Sierra, MD (*Abstract Co-Author*)
Nuria Bargallo, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

To review the fundamental principles in the evaluation of the postoperative spine, including key anatomical and radiological findings. To understand and optimize the assessment of the instrumented spine, focusing on imaging modalities, hardware positioning, and alignment. To identify and analyze common postoperative complications, including infection, hardware failure, pseudarthrosis, and adjacent segment disease.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of lumbar spine surgeryImportance of postoperative evaluation Surgical Techniques Decompressive procedures (herniated disc, spinal stenosis)Deformity correction (degenerative disc disease, spondylolisthesis, trauma)Vertebral body replacement (tumour, trauma, infection) Postoperative Findings in Lumbar Spine Surgery Normal Postoperative Changes Soft Tissue Changes Edema in paraspinal muscles or surgical planes Enhancement of the annulus fibrosus Bone Changes Vertebral endplate enhancement Bone remodeling around screw tracts or fusion sites Presence of bone graft material Surgical Hardware Screws, rods, interbody cages (expected appearance) Instrumented Spine Complications Early Complications Implant malpositioning Postoperative collections (hematoma, seroma) Pseudomeningocele Discitis, osteomyelitis, epidural abscess Late Complications Implant loosening or fracture Sterile radiculitis or arachnoiditis Recurrent disc herniation Epidural fibrosis Spondylolysis and spondylolisthesis Degenerative changes at adjacent segments Spondylodiscitis Conclusion Crucial role of imaging in the management of treated patients

NREE-103 WHEN NEURONS MISFIRE: MAPPING A PICTORIAL JOURNEY OF SEIZURE PATHOLOGIES

Gabriel Frattallone, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Ricardo Vargas Figueroa, MD (*Abstract Co-Author*)
Joaquin Ruiz-Lopez, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review key anatomical structures involved in epilepsy - Use a map analogy with engaging imaging to illustrate seizure causes and locations - Discuss causes, imaging findings (MRI/CT), and clinical relevance in intractable epilepsy

TABLE OF CONTENTS/OUTLINE

- Introduction - Objectives - Anatomy Review - Cases: Developmental, Epileptogenic Tumors, Gliosis/Scarring, Neurocutaneous Syndromes, Miscellaneous - Conclusion Epilepsy is a complex disorder with varied causes. Intractable epilepsy often stems from identifiable developmental or structural abnormalities that may be subtle and easily missed. This exhibit uses a visual map analogy —brain parenchyma as land, cerebrospinal fluid as sea—to enhance comprehension and memory of seizure-related pathologies. We will present real cases from our institution, categorized as: - Developmental Focal cortical dysplasia, heterotopia, polymicrogyria, hemimegalencephaly, schizencephaly - Epileptogenic Tumors Ganglioglioma, DNET, pleomorphic xanthoastrocytoma, hypothalamic hamartoma - Gliosis and Scarring - Neurocutaneous Syndromes: Sturge-Weber, tuberous sclerosis, neurofibromatosis 1, Von Hippel-Lindau - Miscellaneous: Rasmussen encephalitis, cavernous hemangioma By recognizing these entities, radiologists can improve diagnostic accuracy and patient outcomes.

NREE-104 BRAINS BEHIND THE NAMES: EPONYMS IN NEURORADIOLOGY

Gabriel Frattallone, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Christopher Quintana (*Abstract Co-Author*)
Maria Dossantos Torres (*Abstract Co-Author*)
Joaquin R. Ortiz-Cruz, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Provide a comprehensive review of frequently encountered neurology pathologies emphasizing their clinical presentation, historical significance, and key imaging features. 2. Use a timeline for visual representation, and facilitate the study and recognition of commonly used eponyms in neurology medicine encountered at our

facility. 3. Illustrate the critical imaging features of these pathologies, focusing on the role of different modalities (X-rays, CTs, and MRIs) in accurately diagnosing and documenting these pathologies for effective treatment and management.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Timeline IV. Cases - Etiology and historical context, clinical manifestation, focused anatomical diagrams V. Conclusion Eponyms are common in medical language, though there is debate—some advocate for their abandonment—others believe eponyms enhance memorability, encapsulate complex concepts, and foster appreciation for medical history. This exhibit presents a timeline of over 20 neuroradiology-related eponyms encountered at our institution, illustrated through real cases using X-rays, CTs, and MRIs. Each eponym and associated pathology is discussed to emphasize its clinical relevance and educational impact. By combining history with diagnostic imaging, this timeline-based approach aims to engage medical students, residents, and imaging specialists, reinforcing key concepts and advancing radiologic education.

NREE-105 THE DEEP GRAY… MATTERS: A PUZZLE WORTH SOLVING

Gabriel Frattallone, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Santiago A. Saldana Mendez, MD, BS (*Abstract Co-Author*)
Maria Dossantos Torres (*Abstract Co-Author*)
Andrea Natalia Viruet Pantoja, MD (*Abstract Co-Author*)
Carlos I. Llorens, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review deep gray matter anatomy - Describe common pathologies using a puzzle piece analogy to aid visual learning - Illustrate key findings with CTs and MRIs from our institution

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Anatomy of the deep gray matter IV. Cases - Toxic : Carbon Monoxide, Ethylene Glycol - Vascular : Hypoxic-Ischemic Injury, Infarct, Internal Cerebral Vein Thrombosis - Infectious : Toxoplasmosis - Metabolic/Genetic Propionic Acidemia, Pyruvate Dehydrogenase Deficiency, MSUD, Fahr Disease, Hypoparathyroidism, Iron deposition - Hemorrhagic V. Imaging: CT, MRI VI. Pathophysiology VII. Clinical Features VIII. Treatment IX. Conclusion --- The deep gray matter—basal ganglia and thalami—is central to motor, sensory, and cognitive functions. This exhibit uses a puzzle analogy, presenting each nucleus as a key piece of the brain's framework. We review toxic, vascular, infectious, metabolic, and hemorrhagic pathologies using CT and MRI cases from our institution. This integrated approach aids trainees and radiologists in practice in mastering anatomy, pathology, and imaging findings to improve diagnostic accuracy.

NREE-106 ARTERIAL DETOURS: A COMPREHENSIVE LOOK AT INTRACRANIAL VASCULAR VARIANTS

Gabriel Frattallone, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Juan Gonzalez, MD (*Abstract Co-Author*)
Lyan Cabello Ballester (*Abstract Co-Author*)
Emilio Cepeda (*Abstract Co-Author*)
John Melendez Moreno (*Abstract Co-Author*)
Mario J. Polo, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review the anatomy of the intracranial arterial system. - Use a road analogy to explain arterial variants and their embryological development. - Present real case examples of variants using CTA, MRA, and DSA.

TABLE OF CONTENTS/OUTLINE

- Introduction - Objectives - Anatomy Review - Intracranial Arterial Variants: - Aberrant, fenestration, azygos, accessory, persistent primitive, duplication, and extracranial location (anterior & posterior circulation) - Imaging Modalities - Conclusion Intracranial artery variants result from deviations in embryologic development and vascular remodeling. Often asymptomatic, their detection is key for accurate diagnosis and avoiding complications. This exhibit reviews common and rare variants using real cases imaged with CTA, MRA, and DSA. A road network analogy is used for clarity: persistent primitive arteries are like old roads still in use; fenestrations and duplications act like bridges rerouting traffic. By blending real imaging and relatable analogies, we offer a practical and memorable approach to understanding these variants.

NREE-107 FAT EMBOLISM SYNDROME VS ITS MIMICS: A DIAGNOSTIC APPROACH

Diana Kokash, MD (*Presenter*)

TEACHING POINTS

Fat Embolism Syndrome (FES) should be suspected in patients presenting with acute pulmonary, neurological, or cutaneous symptoms within 12 to 72 hours following traumatic skeletal injuries. While imaging plays a supportive role, diagnosis requires integration of clinical context—specifically recent trauma and signs of respiratory or neurologic compromise. Initial CT brain may appear normal; follow-up MRI within 24-48 hours is often necessary to detect evolving findings. Differentiating cerebral fat embolism from other differentials such as diffuse axonal injury relies heavily on clinical history and injury mechanism. Imaging findings in FES may be transient, underscoring the importance of early recognition to improve patient outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction, pathophysiology, and diagnostic challenges. Chest imaging findings, brain MRI patterns and its subtypes. case examples, chest differentials (ARDS, septic emboli) and brain differentials (diffuse axonal injury, septic emboli, hypoxic-ischemic and hypoglycemic encephalopathy, toxic and delayed hypoxic leukoencephalopathy). A comparative summary table highlights distinguishing imaging features. Diagnostic criteria including Gurd's and Schonfeld's systems are reviewed, concluding with management strategies and key learning points.

NREE-108 AMYLOID RELATED IMAGING ABNORMALITIES (ARIA): NEUROIMAGING INSIGHTS IN ALZHEIMER'S DISEASE-MODIFYING THERAPEUTICS

Michelle Chen, MD (*Presenter*)

TEACHING POINTS

1. Anti-amyloid (Aß) monoclonal antibodies may slow early Alzheimer's disease (AD) progression, but they can pose significant risks, often identified on MRI as amyloid related imaging abnormalities (ARIA). 2. Anti-Aß therapies disrupt vascular permeability and exacerbate inflammatory responses, which serves as the underlying pathophysiology of ARIA-E (edema) and ARIA-H (microhemorrhage) subtypes. 3. Certain risk factors are associated with ARIA-E and ARIA-H development, such as APOE e4 status and baseline cerebral amyloid angiopathy (CAA) or multiple microhemorrhages, necessitating MRI-based pre-treatment risk stratification to exclude high-risk patients. 4. Radiologists play a pivotal role in the safe and effective use of anti-Aß therapies, from baseline risk assessment and protocol optimization to early ARIA detection, standardized reporting, and multidisciplinary care coordination. 5. Familiarity with ARIA mimics (ex: subarachnoid hemorrhage, posterior reversible encephalopathy) and potential pitfalls is essential to avoid misdiagnosis and inappropriate therapy discontinuation. 6. Emerging AI tools can automate ARIA grading, reducing interobserver variability.

TABLE OF CONTENTS/OUTLINE

1. Overview of ARIA as a critical adverse event in AD therapies 1a) Pathophysiology and risk factors 1b) Features of ARIA subtypes 2. Imaging protocols 2a) MRI sequences and timing 2b) Grading severity 3. Clinical management and multidisciplinary collaboration 4. Emerging AI integration for automated ARIA detection

NREE-109 AUTOSOMAL DOMINANT HEREDITARY SMALL VESSEL DISEASES: A RADIOLOGIC REVIEW WITH ILLUSTRATIVE CASES OF CADASIL AND CARASAL

Maria J. Redondo, MD (*Presenter*)
Marina Daniela Sarmiento, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit's purpose is to review the spectrum of hereditary small vessel diseases (hSVDs), a heterogeneous group of disorders that affects the microvasculature, leading to leukoencephalopathy, lacunar infarcts and cognitive decline. With a description on its phenotype, genotype, pathogenesis and imaging methods and diagnoses, doing emphasis on imaging patterns of each lesion involving cerebral small vessel disease and white matter lesions.

TABLE OF CONTENTS/OUTLINE

CADASIL - CARASAL - HTRA1-SVD - Pathogenesis - Cerebral imaging - Neuropathology - Leukoencephalopathy - Stoke- Microangiopathy - Hereditary small vessel disease- Genotype - Diagnosis- Differential diagnosis

NREE-110 DUAL ENERGY CT (DECT) IN THE ASSESSMENT OF HEMORRHAGIC COMPLICATIONS AFTER ENDOVASCULAR THROMBECTOMY (EVT)

Giovanni Furlan, MD (*Presenter*)
Manuel Belgrano, MD (*Abstract Co-Author*)
Maria A. Cova, MD (*Abstract Co-Author*)

TEACHING POINTS

To illustrate the role of Dual Energy Computed Tomography (DECT) in detecting hemorrhagic complications after endovascular thrombectomy (EDT).

TABLE OF CONTENTS/OUTLINE

DECT is an advanced CT technique that allows the identification of structures presenting different elemental compositions that may have similar attenuation values at conventional unenhanced CT scans. One of its major applications is its role in distinguishing blood and iodine contrast, both of which appear hyperattenuating at standard unenhanced CT scans. In absence of contraindications and when performable, EDT is the treatment of choice in patients with acute ischemic stroke. Considering its invasiveness, EDT has a significant risk of hemorrhagic complications. Still, at CT scans performed after EDT, it is not unusual to observe non-hemorrhagic hyperattenuating areas representing iodine contrast extravasation due to hematoencephalic barrier damage; these two conditions are not easily distinguishable at conventional CT scans, while they can be easily differentiated at DECT since blood and iodine contrast agents show different attenuation characteristics at different energy values. The capability of obtaining early differentiation between hemorrhagic complications and iodine contrast extravasation in patients who underwent EDT can help the neurologist in the correct clinical management of the patient (e.g., to allow early administration of antiplatelets or anticoagulants in order to reduce the risk of reocclusion). A wider use of DECT in patients who underwent EDT is therefore desirable both to obtain early diagnosis of hemorrhagic complications and not to postpone antiplatelet/anticoagulant treatment.

NREE-111 INTERPRETING COMPUTED TOMOGRAPHY PERFUSION OF THE BRAIN - A COMPREHENSIVE GUIDE FOR STROKE MIMICS AND PITFALLS

Otavio Augusto Ferreira Dalla Pria, MD (*Presenter*)
Laiz Godoy, MD (*Abstract Co-Author*)
Nitesh Shekhrajka, MD,MBBS (*Abstract Co-Author*)
Daniel Gewolb, MD (*Abstract Co-Author*)
Daniella Karassawa Zanoni, MD (*Abstract Co-Author*)
Thomas Reith, MD (*Abstract Co-Author*)
Joan E. Maley, MD (*Abstract Co-Author*)
Robert Kurtz (*Abstract Co-Author*)
Minako Hayakawa, MD (*Abstract Co-Author*)

TEACHING POINTS

Stroke affects hundreds of thousands of Americans every year and is considered a medical emergency due to its time-sensitive therapeutic plan. In this setting, proper imaging evaluation is crucial to determine the appropriateness of interventional treatment. Radiologists play a pivotal role in this scenario by analyzing cerebral hemodynamics and helping neurologists/neuro-interventionists select patients with at-risk but still viable brains through advanced imaging techniques. In this context, Perfusion computed tomography (CTP) of the brain is a reliable method of evaluating acute stroke. Sometimes, CTP is the first brain imaging in the patient's life, and considering that time is vital for decision-making, it's essential to be aware of potential pitfalls and differentials for CTP findings. Knowledge of imaging patterns and potential pitfalls of this technique is essential to the radiologist since not all perfusion abnormalities happen due to stroke.

TABLE OF CONTENTS/OUTLINE

1. Summary of the basics of the imaging technique and applicability of CTP. 2. Potential pitfalls with imaging acquisition and underlying patient conditions that may affect results. 3. Illustration of several cases demonstrating the use of CTP in the evaluation of acute stroke. 3. Case series showing differential diagnosis that caused abnormal CTP findings to mimic or mask stroke, and 4. Conclusion and take-home messages.

NREE-112 2024 UPDATED CRITERIA FOR MULTIPLE SCLEROSIS: KEY TAKEAWAYS FOR RADIOLOGISTS

Edgar A. Zamora, MD (*Presenter*)
Angela M. Sosa, MD, MSc (*Abstract Co-Author*)
Carlos Zamora, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Review key imaging updates in the 2024 McDonald Criteria for multiple sclerosis (MS). Describe the inclusion of the optic nerve as a fifth topography for dissemination in space (DIS). Highlight the emerging roles of the central vein sign (CVS) and paramagnetic rim lesions (PRLs). Outline new diagnostic pathways for radiologically isolated syndrome (RIS). Summarize the use of kappa free light chains (kFLCs) and oligoclonal bands (OCBs).

TABLE OF CONTENTS/OUTLINE

The 2024 McDonald Criteria improve diagnostic sensitivity for early and atypical MS by incorporating advanced imaging and CSF biomarkers. The optic nerve is now the fifth region for demonstrating DIS. Diagnosis can be made with DIS and either OCBs or kFLCs, without requiring dissemination in time (DIT). RIS may fulfill MS criteria when DIS is present with DIT, positive CSF, or =6 CVS-positive lesions. Criteria apply to both relapsing and progressive forms, with added consideration for age and vascular risk. CVS (=6 lesions) and PRLs (=1 lesion) improve diagnostic confidence. SWI or T2* sequences at =3T are recommended. RIS refers to incidental MS-typical lesions in asymptomatic individuals. Radiologists must recognize key imaging features and apply optimized protocols, as the revised criteria place greater diagnostic emphasis on imaging and fluid biomarkers.

NREE-113 IMAGING OF VISUAL DISORDERS: CORRELATION OF RADIOLOGIC AND SURGICAL FINDINGS

Fumiyo Higaki (*Presenter*)
Jun Haruma (*Abstract Co-Author*)
Masafumi Hiramatsu (*Abstract Co-Author*)
Joji Ishida (*Abstract Co-Author*)
Shota Tanaka (*Abstract Co-Author*)
Takao Hiraki, MD, PhD (*Abstract Co-Author*)
Takahiro Kitayama, MD, PhD (*Abstract Co-Author*)
Yusuke Matsui, MD, PhD (*Abstract Co-Author*)
Yoshihiro Otani (*Abstract Co-Author*)
Yuka Takahashi (*Abstract Co-Author*)

TEACHING POINTS

Objective This study provides an overview of visual disorders by correlating radiologic imaging findings with surgical perspectives, focusing on lesions along the visual pathway. Diseases are classified into three regions: Optic Nerve Level, Optic Chiasm and Tract Level, and Optic Radiation and Occipital Lobe Level. For each lesion, characteristic MRI and CT findings are described. In addition, angiographic findings and surgical observations are presented to enhance diagnostic and therapeutic understanding. Representative diseases for each region are selected to illustrate key imaging characteristics and surgical correlations, facilitating a comprehensive understanding of visual pathway disorders. The integration of radiologic and surgical findings provides valuable insights into the diagnosis and management of a wide spectrum of visual disorders.

TABLE OF CONTENTS/OUTLINE

Optic Nerve Level Disorders Inflammatory: NMOSD(Neuromyelitis Optica Spectrum Disorder)MOGAD (Myelin Oligodendrocyte Glycoprotein Antibody- Associated Disease)Tumors : Optic nerve sheath meningioma, Optic nerve sheath schwannoma,glioma, malignant lymphoma Vascular: Ophthalmic artery aneurysm, venous malformations Bone lesions: Fibrous dysplasia, Osteosarcoma Other: IgG4-related disease Optic Chiasm and Tract Level Disorders Tumors: Pituitary Neuroendocrine Tumor, Craniopharyngiomas, Meningioma , Metastatic TumorVascular: Cerebral aneurysms and post-treatment complications Optic Radiation and Occipital Lobe Level Disorders Vascular: infarctions Tumors: gliomas, metastasisOther: PRES(posterior reversible encephalopathy syndrome)

NREE-114 FROM CLINIC TO PHYSICS: UNPACKING PERFUSION MRI IN DEPTH

Zhongwei Zhang, MD, PhD (*Presenter*)
Matthew F. Glasser, MD,PhD (*Abstract Co-Author*)
Liang Wang, MD (*Abstract Co-Author*)
Cyrus A. Raji, MD, PhD (*Abstract Co-Author*)
Tammie S. Benzinger, MD, PhD (*Abstract Co-Author*)
Joshua S. Shimony, MD, PhD (*Abstract Co-Author*)
Robert C. McKinstry III, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Perfusion MRI is a cornerstone in studying cerebral hemodynamics. This exhibit serves as a comprehensive bridge between clinical practice and the underlying physics, guiding learners through real-world cases to explore the full workflow of perfusion MRI—from image acquisition and post-processing to advanced analysis and clinical interpretation. We delve into state-of-the-art techniques, unpacking their physical foundations, mathematical models, and practical applications, while addressing common challenges with actionable solutions. Participants will deepen their understanding of key concepts such as contrast agent dynamics, deconvolution techniques, T1 and T2* relaxation effects, and non-contrast arterial spin labeling (ASL), ultimately enhancing their diagnostic acumen in neuroimaging.

TABLE OF CONTENTS/OUTLINE

1. Overview of Perfusion MRI 2. Introduction to Perfusion MRI in Brain Studies 3. Clinical Relevance and Applications 4. Perfusion MRI methods and their added value 5. Dynamic Susceptibility Contrast (DSC)-MRI (T2*-Weighted) 1) Case-Based Learning & Discussion: Clinical Applications and Challenges 2) Physical Principles: Contrast Agents and Administration, Signal-to-Concentration Relationships, Deconvolution, GBCA Leakage effect and Correction 6. Arterial Spin Labeling (ASL)-MRI 1) Case-Based Learning & Discussion: Clinical Applications and Challenges; 2) Physical Principles: Non-Contrast ASL Techniques (PASL, CASL, PCASL, VS-ASL), Technical Considerations, and Data Acquisition; 3) Qualitative and Quantitative interpretation; 4) Emerging Techniques and Future Directions

NREE-117 IMAGING STRATEGIES FOR SELLAR ,SUPRASELLAR AND RARE SUPRASELLAR LESIONS RAD-PATH CORRELATION

Reefath Jabaraj, DMRD,MBBS (*Presenter*)
Krishnaveni V. Pillai, MBBS (*Abstract Co-Author*)
Madhura P. Ghate, MD,MD (*Abstract Co-Author*)

TEACHING POINTS

Rare sellar and suprasellar lesions, its imaging approach and how to differentiate familiarity with uncommon conditions may help clinician and radiologist in arriving at correct diagnosis imaging approach to common sellar and suprasellar pathologies

TABLE OF CONTENTS/OUTLINE

introduction learning objectives anatomy of sella and suprasellar regioncommon pathologies involving sella and suprasellar region Brief description of uncommon pathologies Imaging approach: what radiologist and clinician wants to knowdifferential diagnosis case based approach take home points conclusion

NREE-118 PERSONALIZED TARGETING OF MR-GUIDED FOCUSED ULTRASOUND VIM THALAMOTOMY FOR ESSENTIAL TREMOR: OVERVIEW AND HOW WE DO IT

Toshio Yamaguchi, MD, PhD (*Presenter*)

TEACHING POINTS

1. Provide a comprehensive review of the targeting methods of MR imaging-guided focused ultrasound VIM thalamotomy (MRgFUS) for essential tremor (ET) 2. Describe how we plan and measure individually towards personalized targeting and lesion prediction at our site. 3. Increase awareness among radiologists to promote safe informed use of this relatively newer incisionless treatment in the brain

TABLE OF CONTENTS/OUTLINE

1. What is ET? incidence, etiology, dentatorubrothalamic tract (DRTT) loop (Fig. 1) 2. Surgical treatment: radio-frequency (RF) ablation, MRgFUS and DBS. 3. MR neuroanatomy: Vim and cortico-spinal tract (CST) (Fig. 2) 4. Indirect targeting (Fig. 3) 5. Direct (image navigated) targeting (Fig.3) 1) VIM segmentation (THOMAS), 2) Tract-based targeting (DRTT, CST) 3) Use of CST as an anatomic landmark 6. Basic strategy at our site: Relieve distal tremor initially (posterolateral ventral area of VIM) followed by proximal tremor relief with consideration of VIM somatotopy (Fig.4) 7. How we do it towards personalized targeting 1) Obtain precise CST-weighted T2 orthogonal MR image individually (Fig. 5) 2) Measure posterior CST at AC-PC plane 3) Simulate tentative targeting on 3-D planes 4) And target using fusion tract with CST weighted image: on DRTT and off medial lemniscus (ML) 5) Evaluate real-time clinical response 8. Predict temperature raise and lesion shape with segmental CT analysis individually 9. Take-home messages: tailored therapy along with imaging the individual

NREE-119 THE SELLAR-SUPRASELLAR CONUNDRUM: IMAGING CLUES AND DIAGNOSTIC CHALLENGES OF UNUSUAL LESIONS

Suman T. Prabhakar, MD, FRCR (*Presenter*)
Nerses Nersesyan, MD (*Abstract Co-Author*)
Sushmitha Puttappa Shivagange, MBBS (*Abstract Co-Author*)
Paulo C. Puac Polanco, MD, MSc (*Abstract Co-Author*)
Maria Lucia Brun, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review rare atypical lesions of the sellar and suprasellar regions. 2. Highlight key CT and MRI imaging features that aid in narrowing differential diagnoses. 3. Discuss each pathology briefly with histopathological correlation

TABLE OF CONTENTS/OUTLINE

The complex sellar-suprasellar region encompasses wide spetrum of pathologies. While pituitary adenomas remain the most commonly diagnosed lesion, other rare pathologies can mimic these benign masses both clinically and radiologically, leading to potential diagnostic challenges. MRI is the preferred imaging modality for accurate characterization of these lesions. This pictorial review presents a selection of histopathologically confirmed, rare sellar and suprasellar lesions using a structured, case-based approach. Each case is introduced with key imaging findings, followed by a discussion of relevant differential diagnoses, the final diagnosis, and a concise description of the pathology. Lesions Discussed Include Infectious/Inflammatory Lesions Tuberculosis Granulomatous hypophysitis Rosai-Dorfman disease Neoplastic Lesions Benign Tumors Pituicytoma Granular cell tumor Chordoid glioma Gangliocytoma Angiolipoma Choristoma Chordoid meningioma Malignant Tumors Glioblastoma multiforme SummaryRare sellar-suprasellar lesions, though accounting for less than 1% of cases, can closely mimic common pathologies like pituitary adenomas. This exhibit presents illustrative cases with key imaging features and histopathological correlations to aid accurate diagnosis. Recognizing imaging red flags and atypical patterns is essential to avoid misdiagnosis and ensure appropriate clinical management.

NREE-120 CLINICALLY RELEVANT ANATOMY OF THE BRAINSTEM, CEREBELLUM, AND THALAMUS: AN INTERACTIVE WEBSITE

Frank Salamone, MD (*Presenter*)
Noriko Salamon, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

We present a free neuroanatomy website designed to introduce clinically relevant anatomy of the brainstem, cerebellum, and thalamus using unique illustrations, annotated cross-sectional images, practice questions, and clinical cases with interactive components. Material is inspired by neuroanatomy lectures that have been refined over 20 years by a board certified neuroradiologist and delivered to medical students and trainees in radiology, neurology, and neurosurgery. The content is designed to build in complexity from a baseline of minimal pre-existing knowledge. For example, brainstem anatomy is organized in five levels of increasing complexity, beginning with the gross divisions of the brainstem and ending with more intricate and difficult to appreciate nuclei. Pathophysiology and functional surgical techniques, like deep brain stimulation, are used to reinforce the structure and location of clinically relevant structures. We hope that a motivated user who reviews the material will find value for both their understanding of neuroanatomy and the interpretation of neuroradiological studies.

TABLE OF CONTENTS/OUTLINE

1. Thalamus a. Relevant nuclei b. Function c. Functional neurosurgery d. Vascular anatomy e. Clinical cases, bilateral thalamic lesions 2. Brainstem a. Levels 1-5 of brainstem sectional anatomy b. Clinical cases 3. Cerebellum a. Surface anatomy b. Nuclei c. Function d. Vascular anatomy f. Clinical cases

NREE-121 IMAGING THE EFFICACY AND SIDE EFFECTS OF CAR T-CELL THERAPY IN PEDIATRIC CANCER PATIENTS

Zahra Shokri Varniab, MD (*Presenter*)
Iryna Vasyliv, MD (*Abstract Co-Author*)
Sneha Ramakrishna (*Abstract Co-Author*)
Heike E. Daldrup-Link, MD (*Abstract Co-Author*)

TEACHING POINTS

CAR T-cell therapy is a transformative immunotherapy for pediatric patients with relapsed or refractory malignancies. Imaging plays a crucial role in evaluating treatment efficacy and detecting complications such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Familiarity with characteristic imaging patterns allows radiologists to support clinical decision-making and optimize patient care.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of CAR T-cell therapy, FDA-approved indications, and timeline from apheresis to infusion. Emphasis on radiologic checkpoints, including pseudoprogression and hyperprogression, typically seen on imaging within 6-12 weeks post-infusion. Imaging Efficacy: Role of imaging in identifying treatment response in hematologic malignancies and solid tumors, with emphasis on bone marrow and visceral organ changes. Imaging Side Effects: Imaging correlates of ICANS, including white matter changes and cerebral edema, as well as thoracic findings associated with CRS such as pleural effusions, atelectasis, cardiac inflammation. Management and Outcomes: Radiologic assessment supports decisions regarding escalation of therapy, and identification of treatment-related sequelae. Conclusion: Radiologists play a pivotal role in detecting complications and confirming therapeutic response to CAR T-cell therapy. Knowledge of imaging biomarkers can improve outcomes in pediatric cancer care.

NREE-122 NEXT-GEN MS IMAGING: CENTRAL VEIN SIGN AND PARAMAGNETIC RIM LESIONS IN THE UPDATED 2024 MCDONALD CRITERIA

Priscilla Stecher, MD, MBA (*Presenter*)
Yin-Chen Hsu, MD, MS (*Abstract Co-Author*)
Pascal Sati (*Abstract Co-Author*)
Daniel Ontaneda (*Abstract Co-Author*)
Daniel S. Reich, MD, PhD (*Abstract Co-Author*)
Marcel M. Maya, MD (*Abstract Co-Author*)
Quy Cao (*Abstract Co-Author*)
Matthew Schindler (*Abstract Co-Author*)
Russell Shinohara (*Abstract Co-Author*)
Jae W. Song, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

The diagnosis of multiple sclerosis (MS) is undergoing a transformative evolution. In 2024, revisions to the McDonald criteria redefined how clinicians will diagnose MS. The new criteria move beyond traditional temporal dissemination and incorporate new imaging biomarkers: the Central Vein Sign (CVS) and Paramagnetic Rim Lesions (PRLs). In this educational exhibit, we will discuss the central role of neuroimaging for MS and equip you with the knowledge to identify and report these diagnostic criteria with confidence. We will discuss how to use these criteria to enhance diagnostic accuracy, reduce misdiagnosis, and predict disease trajectory in patients with MS. The learning objectives are: 1. Key updates in the 2024 McDonald Criteria 2. Primer for recognizing the CVS and PRLs on MRI 3. Technical considerations and requirements (imaging protocols, pulse sequence parameters and magnet strength) 4. Role of neuroimaging in MS prognostication

TABLE OF CONTENTS/OUTLINE

1: Reimagining MS Diagnosis: From 2017 to 2024 a. Addressing diagnostic uncertainty, overdiagnosis, therapeutic delay b. Review of 2017 Criteria and Proposed 2024 Criteria 2: Central Vein Sign (CVS): Signature of Perivenular Demyelination a. Radiology-pathology correlation b. CVS on MRI c. Optimizing pulse sequences and field strength considerations d. Diagnostic strategies: "Select 3" vs "Select 6" rules e. Pitfalls and mimics 3: Paramagnetic Rim Lesions (PRLs): Chronic Inflammation Visualized a. Radiology-pathology correlation: Iron-laden microglia b. PRLs on MRI c. Using susceptibility-based imaging (SWI/QSM) d. Interpretive pitfalls 4: Imaging Biomarkers and MS Prognosis a. Emerging evidence on CVS/PRLs and MS progression

NREE-123 NEUROIMAGING OF CEREBRAL SMALL VESSEL DISEASE: A COMPREHENSIVE REVIEW WITH CURRENT PERSPECTIVES

Tatiana Iutaka, BDS (*Presenter*)
Leticia Costa (*Abstract Co-Author*)
Larissa A. Martins, MD (*Abstract Co-Author*)
Felipe Scortegagna SR, MD (*Abstract Co-Author*)
Renato Hoffmann Nunes, MD, MBA (*Abstract Co-Author*)
Antonio J. Da Rocha, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Esta apresentação fornecerá uma visão geral abrangente da Doença Cerebral de Pequenos Vasos (DCVS). Os objetivos desta exposição são: - Elucidar a fisiopatologia do DCVS e os marcadores de neuroimagem padronizados definidos sem consenso STRIVE. -Explorar as duas principais formas esporádicas de DCVS: Arterioloesclerose (DCVS hipertensiva) e Angiopatia Amilóide Cerebral (AAC), destacando seus achados característicos distintos em ressonância magnética. - Discutir os Critérios de Boston 2.0 atualizados para o diagnóstico de DCVS, enfatizando as principais modificações da versão 1.5. - Revisar as variantes da DCVS, incluindo DCVS inflamatória e amiloidoma, e examinar a relação entre DCVS e Doença de Alzheimer. - Discutir a nova terapia para Doença de Alzheimer e Anormalidades de Imagem Relacionadas à Amiloide (ARIA). - Abordar as causas genéticas da DCVS, destacando suas características clínicas e de imagem únicas. - Discutir os avanços recentes em técnicas de neuroimagem para detecção e monitoramento de DCVS, discutindo direções futuras em pesquisa e manejo clínico.

TABLE OF CONTENTS/OUTLINE

Introdução Fisiopatologia e biomarcadores de RM Arteriolosclerose e CAA Resultados de ressonância magnética Critérios de Boston 2.0 CAA inflamatório, amiloidoma e doença de Alzheimer CAA vs. arteriolosclerose Nova terapia para doença de Alzheimer e anormalidades de imagem relacionadas a amiloide (ARIA) Causas genéticas da DCV Mutação CADASIL, CARASIL, doença de Fabry, MELAS, APP, COL4A1/COL4A2, FOXC1/FOXC2 e TREX1 Avanços em imagem e perspectivas atuaisConclusão e pontos-chave

NREE-124 MULTIMODAL STRATEGIES FOR NEUROFLUID ASSESSMENT: FROM INDIVIDUAL BIOMARKERS TO AN INTEGRATED NEUROFLUID PROFILE

Toshiaki Taoka, MD, PhD (*Presenter*)
Rintaro Ito, MD, PhD (*Abstract Co-Author*)
Rei Nakamichi (*Abstract Co-Author*)
Toshiki Nakane (*Abstract Co-Author*)
Shinji Naganawa, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Cognitive impairment has been increasingly linked to dysfunction of the glymphatic system, which plays a crucial role in clearing metabolic waste from the brain and is implicated in neurodegenerative diseases. 2. Imaging techniques such as diffusion tensor image analysis along the perivascular space (DTI-ALPS), choroid plexus volumetry (CPV), free water imaging (FWI), arterial spin labeling (ASL), and intrathecal gadolinium-based contrast agent (IT-GBCA) each target different aspects of this complex system, with varying degrees of invasiveness, repeatability, and clinical feasibility. 3. A multimodal approach enhances understanding by integrating the complementary strengths of individual modalities, as visualized via radar charts.

TABLE OF CONTENTS/OUTLINE

1. Clinical Significance: The glymphatic system, proposed as a brain-wide waste clearance mechanism, is implicated in a wide range of neurological disorders. 2. Imaging Biomarkers: DTI-ALPS provides a noninvasive index of perivascular diffusion, while PVS volumetry and CPV reflect structural features linked to fluid stasis. FWI and ASL further offer physiological insights into free water content and perfusion. 3. Complementarity of Methods: No single modality captures the full spectrum of neurofluid dynamics. Integration is essential for a holistic evaluation. 4. Educational Visualization: A radar chart highlights the strengths and limitations of each method. Multimodal assessment approaches a balanced, circular profile, reinforcing their complementarity. 5. Future Directions: Combining structural, functional, and dynamic metrics may advance our understanding of neurofluid dysregulation in aging and disease.

NREE-125 PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY — MRI FINDINGS AS A BIOMARKER FOR EARLY DIAGNOSIS —

Koichiro Mori, MD (*Presenter*)
Mariko Kurokawa, PhD, MD (*Abstract Co-Author*)
Masafumi Harada, MD, PhD (*Abstract Co-Author*)
Yasunobu Takaki (*Abstract Co-Author*)
Yoshiharu Miura (*Abstract Co-Author*)

TEACHING POINTS

PML is generally a disease with poor prognosis, however early diagnosis in the asymptomatic stage, particularly in natalizumab-associated cases, significantly improves survival outcomes. This highlights the need for reliable biomarkers in addition to JCV PCR testing of cerebrospinal fluid. Understanding the typical MRI findings and progression patterns of PML lesions in correlation with pathological findings is essential fundamental knowledge. Natalizumab-associated PML can often present with atypical clinical symptoms and imaging features. Characteristic MRI findings in early PML include "Punctate Pattern" and "Milky Way appearance," which have been reported as useful imaging findings for detection of PML lesions in early and asymptomatic stages. Susceptibility-weighted imaging (SWI) demonstrates potential value in early PML diagnosis through identification of low signal abnormalities. MRI can serve as a useful biomarker for early PML diagnosis.

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology of PML Impact of early diagnosis on survival outcomes Limitations of current diagnostic methods Fundamental Aspects of MRI Findings in PML Established MRI features of PML in correlation with pathological findings Imaging Characteristics for Early PML Diagnosis: Natalizumab-Associated PML and Low CSF JCV Cases Early imaging biomarkers: "Punctate Pattern" and "Milky Way appearance" Value of susceptibility-weighted imaging (SWI) in early diagnosis Other important imaging features for early diagnosis and differential diagnosis Key differential points between MS relapse and PML Towards establishing optimal MRI surveillance protocols and intervals Conclusion

NREE-126 BEHIND THE SMOKE AND MIRRORS-UNRAVELING THE VARIOUS FACETS AND MIMICS OF CNS LYMPHOMA

Meghana Kancharla, MBBS, MD (*Presenter*)
Clyde Richard Menezes (*Abstract Co-Author*)
Dhanush Jayanna (*Abstract Co-Author*)

TEACHING POINTS

Diagnostic uncertainty regarding Primary CNS lymphoma (PCNSL) arises particularly in atypical variants, immunocompromised states, or rare subtypes. This pictorial review aims to: Review classic & atypical imaging features of CNS lymphoma, including rare subtypes. Highlight the role of advanced imaging in diagnosis Outline a practical imaging-based framework for distinguishing CNS lymphoma from its mimics.

TABLE OF CONTENTS/OUTLINE

Background: PCNSL is intra-axial with an angiocentric growth pattern. Diagnostic Features Classic radiologic signs include "snowball", "notch", "reef", "T2 pseudonecrosis","peritumoral leukomalacia" signs to name a few. Atypical features include ring enhancing or non-enhancing lesions, necrosis, hemorrhage, calcifications. Advanced Imaging: Contrast-enhanced MRI with DWI/ADC, DSC perfusion, MR spectroscopy, SWI act as a surrogate for histopathology by assessing cellularity, vascularity, tumor microenvironment. This review highlights imaging clues to differentiate PCNSL from special subtypes —Primary Dural Lymphoma, Secondary CNS Lymphoma, and Intravascular Lymphoma and imaging mimics —glioblastoma, metastases, demyelination, abscesses, toxoplasmosis Clinical Relevance Imaging enables early diagnosis, track treatment response, detect recurrence. Steroid therapy before biopsy may obscure characteristic imaging features. Low ADC, rCBV values are associated with poor prognosis, aggressive disease. Conclusion: Awareness of classic & atypical features of CNS lymphoma, with advanced imaging facilitates differentiation from mimics & management. Given its wide radiological spectrum, CNS lymphoma remains a master of disguise in neuro-oncology.

NREE-127 GUIDE TO CAROTID PLAQUE-RADS FOR REAL WORLD APPLICATION

Sriharsha Voleti, MD (*Presenter*)
Ronald L. Wolf, PhD (*Abstract Co-Author*)
Brett Cucchiara (*Abstract Co-Author*)
Scott Kasner (*Abstract Co-Author*)
Joseph S. McNally, MD (*Abstract Co-Author*)
Chun Yuan, PhD (*Abstract Co-Author*)
Elias Johansson (*Abstract Co-Author*)
Tobias Saam, MD (*Abstract Co-Author*)
Luca Saba, MD (*Abstract Co-Author*)
Jae W. Song, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Carotid artery atherosclerosis is a well-established risk factor for cerebrovascular events. While luminal stenosis has traditionally guided clinical management, growing evidence highlights the importance of plaque composition and morphology for more accurate risk stratification. To support standardized evaluation, the Carotid Plaque Reporting and Data System (Plaque-RADS) was recently introduced, providing a structured framework for assessing cervical carotid plaque across imaging modalities. Given its recent development, clinicians and trainees may not be familiar with its application in clinical practice. We focus on how to apply Plaque-RADS to CTA neck or Carotid Vessel Wall MR exams. In this educational exhibit, we aim to: 1. Review Carotid Plaque-RADS classification system and criteria 2. Provide a guide to assist learners in easily applying Plaque-RADS to neck CTA or carotid vessel wall MRA exams 3. Share CTA and MRI examples of Plaque-RADS 4. Identify potential pitfalls in Plaque-RADS application based on imaging modality

TABLE OF CONTENTS/OUTLINE

1. Carotid plaque introduction a. Anatomy b. Plaque composition/morphology c. Overview of CT/MRI high-risk plaque features 2. Carotid Plaque-RADS scoring system overview a. Description and example cases of each Plaque-RADS classification (1-4) 3. Practical considerations for applying Plaque-RADS a. CTA neck algorithm b. Limitations of using CT c. Carotid Vessel Wall MRA algorithm d. Limitations of MR/MRI e. Recommendation of additional imaging 4. Potential limitations/pitfalls of Plaque-RADS a. CTA b. MR/MRA 5. Inter-modality (MRA/MRI vs CTA) and intra-modality differences (MRA vs MRI; energy integrating detector CTA vs photon counting CTA)

NREE-128 DEMYSTIFYING HEMATOLYMPHOID TUMORS OF THE CENTRAL NERVOUS SYSTEM (CNS), LYMPHOPROLIFERATIVE DISORDERS, AND THEIR MIMICS

Lidia Guzhva, MD (*Presenter*)
Tyler Richards, MD (*Abstract Co-Author*)
Blair A. Winegar, MD (*Abstract Co-Author*)
Joe Mendez (*Abstract Co-Author*)
Karen L. Salzman, BS, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Hematolymphoid tumors of the CNS are distinct entities as defined by the 2021 WHO 5th edition of CNS Tumors, with key imaging features that can lead to an accurate pre-operative diagnosis. 2. Though primary CNS lymphoma does have a classic imaging appearance, due to disease and patient factors, its presentation may be more variable. This is why it is known as a great mimicker. 3. Due to the diverse and overlapping imaging characteristics of CNS lymphomas and lymphoproliferative disorders, the differential diagnosis should include a broad spectrum of malignant, infectious, and inflammatory conditions. The patient's immunocompetence should also be considered.

TABLE OF CONTENTS/OUTLINE

All listed pathologies will include local radiologic examples. Distinguishing imaging and patient characteristics, pathologic features, and molecular markers will be discussed. CNS Lymphomas - Primary diffuse large B-cell lymphoma of the CNS - Immunodeficiency-associated CNS lymphoma - Lymphomatoid granulomatosis - Intravascular large B-cell lymphoma - Histiocytic tumors: Erdheim-Chester disease, Rosai-Dorfman disease, Langerhans Cell Histiocytosis, Juvenile xanthogranuloma Malignancy Mimics - Glioblastoma, IDH-wildtype - Metastases Mimics in immunocompromised patients - Toxoplasmosis - Progressive Multifocal Leukoencephalopathy (PML)/Immune-reconstitution Inflammatory Syndrome (IRIS) - Post-transplant lymphoproliferative disorder (PTLD) Infectious or inflammatory Mimics - Tumefactive demyelination - Sarcoidosis - Vasculitis - Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) - Abscess - Tuberculosis - Lyme disease

NREE-129 TRAUMATIC BRAIN INJURY: CURRENT GUIDELINES AND EVOLVING MODALITIES

Jo Ann Sun (*Presenter*)
Akm Rahman, DO (*Abstract Co-Author*)
Tausif Siddiqui (*Abstract Co-Author*)

TEACHING POINTS

1. Discuss the epidemiology of traumatic brain injury (TBI), as well as the mechanism of injury and pathophysiology of TBI: TBI has an estimated annual global incidence of 69 million and a diverse etiology including falls, contact sports, and motor vehicle accidents. Its physiology is complex, demanding precise diagnostic and prognostic tools to guide clinical decisions. 2. Summarize current TBI imaging guidelines and discuss the utility and limitations of various imaging modalities: First-line management of TBI involves non-contrast head CT, which is a rapid, cost-effective assessment for triage. However, CT is limited in detecting certain TBI pathologies, for which MRI sequences such as gradient echo (GRE), FLAIR, and susceptibility-weighted imaging (SWI) may be more sensitive. Diffusion tensor imaging (DTI) and functional MRI (fMRI) are able to provide further functional information about the brain’s post-injury white matter integrity and metabolic activity. 3. Describe the potential for novel tools in TBI imaging, including proton magnetic resonance spectroscopy (1H-MRS), perfusion computed tomography, new DTI modalities, and convolutional neural networks.

TABLE OF CONTENTS/OUTLINE

1. Overview and Epidemiology 2. Mechanism of Injury 3. Imaging Guidelines 4. Overview of Current Modalities: FLAIR, DWI, SWI, DTI, fMRI 5. Novel Imaging Modalities 6. Deep Learning Models 7. Key Points

NREE-130 THE BRAIN UNDER SIEGE: DECODING NEUROINVASION BY HISTIOCYTIC DISORDERS

Gauri Bornak, MD,MBBS (*Presenter*)
Jitender Saini, MD,MBBS (*Abstract Co-Author*)
Sabha Ahmed, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

The histiocytoses are rare disorders characterized by the accumulation of macrophage, dendritic cell or monocyte-derived cells in various tissues and organs of children and adults. More than 100 different subtypes have been described, with a wide range of clinical manifestations, presentations, and histologies. Neurological manifestations of Langerhans' cell histiocytosis (LCH) has been widely studied and it known to radiologists and clinicians. Non-Langerhans cells histiocytosis (NLCH), which includes entities such as hemophagocytic lymphohistiocytosis (HLH), Erdheim-Chester disease (ECD) and Rosai-Dorfman disease (RDD) also show CNS involvement to variable extent. The aim of this review is to describe the imaging spectrum of the histiocytic disorders affecting the central nervous system and to simplify the plethora of findings associated with this entity.

TABLE OF CONTENTS/OUTLINE

Table of contents: 1) Introduction 2) Aims and objectives 3) WHO classification of Histiocytic disorders 4) Case Illustrations: Langerhans cell histiocytosis, Rosai-Dorfman disease, Erdheim-Chester Disease, Hemophagocytic Lymphohistiocytosis and ALK positive histiocytosis. 5) Overview of the neurological and systemic manifestations of the histiocytoses 6) Conclusion

NREE-131 THE PRICE OF SURVIVAL: IMAGING MANIFESTATIONS OF CNS TUMOR TREATMENT COMPLICATIONS

Ilkyu D. Oh, MD (*Presenter*)
Runail Ratnani, MD (*Abstract Co-Author*)
Nikhil Kapil (*Abstract Co-Author*)
Sarvani Uppati (*Abstract Co-Author*)
Kirang Patel, MD (*Abstract Co-Author*)
Fabricio S. Feltrin, MD (*Abstract Co-Author*)
Karuna M. Raj, MD (*Abstract Co-Author*)
Marco C. Pinho, MD (*Abstract Co-Author*)

TEACHING POINTS

To review common CNS tumor treatments and recognize typical post-treatment imaging findings, including manifestations of treatment-related neurotoxicity. To identify key imaging pitfalls following CNS tumor treatment and distinguish them from true tumor recurrence. To recognize atypical imaging patterns of treatment-related toxicity and emphasize the radiologist's role in early detection of life-threatening complications.

TABLE OF CONTENTS/OUTLINE

Review of current therapeutic strategies for CNS tumors, including both traditional approaches and newly emerging techniques.•Surgical resection, including indications and impact on prognosis.•Radiation therapy, including whole brain, stereotactic, and proton beam therapies.•Pharmacotherapy, including chemotherapy and targeted molecular and immunotherapies.•Other emerging and experimental therapies, including novel agents and gene therapies. Imaging Manifestations in the Post-Treatment Setting:• Review of benign, non-pathologic, and expected post-treatment changes.• Review of radiologic features of post-treatment complications: vascular, infection, autoimmune, metabolic, iatrogenic, neoplastic, drug-effect. Diagnostic pearls and pitfalls in distinguishing true tumor recurrence from atypical post-treatment imaging manifestation.• Pseudo-progression• SMART syndrome• ICANS• PRES• Radiation injuries• Medication-induced neurotoxicity. Review of advanced MRI techniques in challenging cases: The role of techniques such as diffusion, perfusion, and spectroscopy in improving diagnostic accuracy and guiding clinical management.

NREE-132 PROTEAN YET PREDICTABLE? A CONTEMPORARY IMAGING TAKE ON NEUROSARCOIDOSIS

Kapil Semalti, MBBS, MD (*Presenter*)
Surjith Vattoth, MD, FRCR (*Abstract Co-Author*)
Okan Ince, MD (*Abstract Co-Author*)
Kranthi K. Marathu, MD, MBBS (*Abstract Co-Author*)
Romessa Shaikh (*Abstract Co-Author*)
Alaa Radaideh, MD (*Abstract Co-Author*)
Santhosh Gaddikeri, MD (*Abstract Co-Author*)
Miral D. Jhaveri, MD, MBA (*Abstract Co-Author*)
Shehbaz M. Ansari, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. To review the clinical symptoms and updated Neurosarcoidosis Consortium Consensus Committee (NCCC) diagnostic criteria (2018) 2. To illustrate the spectrum of imaging manifestations of neurosarcoidosis in the brain, spine, and orbits. 3. To discuss common imaging differentials for various imaging manifestations of neurosarcoidosis.

TABLE OF CONTENTS/OUTLINE

Patients with systemic sarcoidosis have imaging manifestations of CNS involvement in 10% cases. Given the broad spectrum of clinical and imaging manifestations of neurosarcoidosis, a strong knowledge of the imaging spectrum of neurosarcoidosis is vital for a structured diagnostic approach. Neuroimaging is pivotal in establishing the diagnosis of neurosarcoidosis along with integration of clinical information, CSF analysis and histopathological results. We will commence the discussion with an outline of the clinical manifestations and updated NCCC Diagnostic Criteria for Neurosarcoidosis, along with illustrations showing imaging spectrum of neurosarcoidosis. Subsequent slides will systematically delineate the myriads of MRI and CT imaging findings in patients of neurosarcoidosis from our institution, along with discussion of common differentials for various imaging findings. We will first highlight the diverse intracranial manifestations including meningeal and brain parenchymal involvement followed by other intracranial findings including involvement of various cranial nerves, hydrocephalus, vascular complications and sellar/suprasellar involvement. We will then outline calvarial and orbital involvement and conclude by outlining the spectrum of spinal involvement.

NREE-133 TRACING TOXIC AND METABOLIC ENCEPHALOPATHIES

Zainab Salman, MD (*Presenter*)
Noor Badrawi, MBBS (*Abstract Co-Author*)
Shaikh Sayeed Iqbal, FRCR (*Abstract Co-Author*)
Ayoub A. Abedzadeh (*Abstract Co-Author*)

TEACHING POINTS

• Identify the imaging features in various common and uncommon toxic and metabolic brain disorders.• Develop a pattern-based approach to help narrow down the differential diagnosis. • Understand the underlying pathophysiology of various disorders. • Recognize the myriad of etiologies that can mimic toxic and metabolic brain disorders.

TABLE OF CONTENTS/OUTLINE

Background Toxic and metabolic encephalopathies comprise a heterogeneous group of disorders that present with a spectrum of neurological symptoms, ranging from mild confusion to critical conditions such as coma.Developing a pattern-based approach helps narrow the differentials and aids in timely patient management. Introduction Diagnosis is often a puzzle which requires a combination of clinical, imaging and laboratory features. Imaging Pattern-Based Approach Through CasesCortical grey patterns CHANTER syndrome, Hepatic encephalopathy, Hypoglycemic encephalopathy, MDMA induced encephalopathy. Pattern mimic - hypoxic ischemic encephalopathy White matter patterns Acute heroin induced leukoencephalopathy, PRES, Osmotic demyelination syndrome, CLOCC, Marchiava Bignami . Pattern mimic: Progessive multifocal leukoencephalopathy, Acute disseminated encephalomyelitis, CADASIL, Metachromatic leukodystrophy. Deep grey patterns Wernickes encephalopathy, Carbon monoxide poisoning, Methanol poisoning, Uremic encephalopathy, Diabetic striatopathy, Pattern mimic - Artery of Percheron infarct. Summary table highlighting anatomical based approach to various toxic and metabolic disorders with distinguishing imaging features.

NREE-134 DIFFUSION TENSOR MR IMAGING : A STALWART TOOL FOR PREOPERATIVE MAPPING OF BRAIN TUMOURS

Mahitha Jujjavarapu, MBBS, MD (*Presenter*)
Babu Peter S (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: 1. To discuss the applications and techniques of diffusion tensor magnetic resonance imaging in brain tumours. 2. Learn to identify the brain white matter tracts using Diffusion tensor imaging (DTI) and 3D fibre tractography. 3. Illustrate a series of cases of brain tumours and interpret the patterns of white matter involvement 4. To review utility of the technique in clinical and surgical management of brain tumours.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Diffusion Tensor imaging (DTI) of the brain2. Techniques and parameters.4.Methodology - Preoperative contrast-enhanced MRI and DTI examinations were conducted in 3T Magnetic Resonance imaging (MRI) on brain tumour patients. Patients underwent conventional MRI, followed by DTI and 3D fibre tractography.3. Brief review of normal DTI and fibre tractographic white matter anatomy4. Classification of Patterns of effect on white matter tracts in brain tumours5. Case-based illustration of brain tumours including interpretation of patterns of white matter involvement6. Discussion on clinical and surgical impact of imaging findings on management of brain tumours7. Summary and conclusions

NREE-135 AMYLOID-RELATED IMAGING ABNORMALITY (ARIA) REPORTING MADE EASY: A GUIDE TO STRUCTURED REPORTING

Ali S. Tejani, MD (*Presenter*)
Matthew Barkovich, MD (*Abstract Co-Author*)
Kambiz Nael, MD (*Abstract Co-Author*)
Javier Villanueva-Meyer, MD (*Abstract Co-Author*)
Andreas M. Rauschecker, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Review challenges for consistent and reproducible reporting of Amyloid-Related Imaging Abnormalities (ARIA) 2. Introduce reporting templates to guide structured ARIA reporting 3. Provide a visual review of best practices when using structured reporting, including challenging scenarios

TABLE OF CONTENTS/OUTLINE

1. Introductiona. Brief review of ARIA findings i. Impact of reports on treatment adjustments b. Review of MRI Protocol for ARIA assessment i. Technical considerations (GRE versus SWI, 2D versus 3D T2/FLAIR) ii. Value of protocol standardization c. Introduce structured reporting templates for ARIA i. Example templates ii. Improving multidisciplinary communication d. Challenges i. Consistent and appropriate use of report fields 2. Visual guide for reporting templates a. Baseline studies i. History and Technique ii. Findings 1. Microhemorrhages (number and location) 2. Superficial siderosis (defining “focal areas” and locations)3. Recommendations on reporting discrepancies between T2* versus SWI sequences iii. Impression b. Follow-up studies i. History and Technique ii. Findings 1. Prior versus new ARIA-E 2. Distinguishing “pre-treatment baseline,” “treatment emergent,” and “new” microhemorrhages using examples a. Which microhemorrhages are “incident?” 3. When should studies reset after initial worsening ARIA-E or ARIA-H? How is this reported? 4. When do we stop additional follow-up? iii. Impression 1. Challenging scenarios a. Follow-up continued to assess worsening ARIA-E, but stable treatment emergent ARIA-H, or vice versa. How is severity reported? b. T2* shows mild ARIA-H, but SWI shows moderate ARIA-H. What should the impression report?

NREE-136 INTRACRANIAL MENINGIOMAS: ASSESSMENT BY IMAGING TECHNIQUES

Eva Taibo Gimenez, MD (*Presenter*)
ALEJANDRO MANUEL DIAZ GARCIA (*Abstract Co-Author*)
Andres Vega Chaves, MD,MD (*Abstract Co-Author*)

TEACHING POINTS

- Updates for meningiomas in the 5th edition of the WHO classification of CNS tumors. - Review of the imaging features of typical, atypical, and anaplastic meningiomas. - Pictorial review through cases from our center.

TABLE OF CONTENTS/OUTLINE

Meningiomas are primary tumors of the central nervous system and stand as the most frequent extra-axial neoplasm, representing one third of all of them. The majority are benign and indolent lesions, with typical (grade 1) meningiomas accounting for around 90-95% of the total. However, there are more aggressive histological subtypes (WHO grades 2-3) with a higher risk of dissemination and recurrence. The aim of this text is to review the typical imaging features, the locations (both characteristic and less frequent) and, with special emphasis, the radiological signs that suggest atypical and anaplastic variants. Imaging techniques (CT and MRI) provide us with useful tools for the correct identification and characterization of meningiomas, which is essential for early diagnosis and proper management. In addition, the different subtypes are exemplified through the presentation of cases from our center.

NREE-137 OUT OF SIGHT, OUT OF MIND: AGENESIS AND HYPOPLASIA OF THE INTERNAL CAROTID ARTERY

Margrit E. Muller, MD (*Presenter*)
Lavinia Dias, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Caio Nunes, MD (*Abstract Co-Author*)
Nicole Lambrakos, MD (*Abstract Co-Author*)
Mariana A. Rodrigues, MD (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)
Renata Bertanha, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

- To review the embryology and pathophysiology of the internal carotid artery (ICA) agenesis and hypoplasia. - To review the clinical presentation and image assessment of the ICA agenesis and hypoplasia. - To recognize the imaging features of the ICA agenesis and hypoplasia, highlighting the key diagnostic features. - To recognize the complications associated with the ICA agenesis and hypoplasia, particularly its relation to ischemic and hemorrhagic stroke.

TABLE OF CONTENTS/OUTLINE

1. Definition and Pathophysiology - Embryological basis and classification of the ICA anomalies. 2. Clinical and Imaging Presentation - Symptoms, incidental findings, and potential complications. 3. Key Diagnostic Features - Imaging modalities and distinguishing criteria. 4. Perfusion assessment - Hemodynamic repercussions in the ICA agenesis and hypoplasia. 5. Teaching cases - Didactic case examples, including cases with adverse outcomes. 6. Take Home Messages 7. References

NREE-138 IMAGING THE OPERATED SPINE: KEY FINDINGS AND COMPLICATIONS FOR GENERAL RADIOLOGISTS

Silvia Revuelta Gomez, MD (*Presenter*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)

Alejandra Somoano Marfull (*Abstract Co-Author*)
Rodrigo Sutil, MD (*Abstract Co-Author*)
Marina Arroyo Olmedo, MD (*Abstract Co-Author*)
Marta Drake Perez, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To describe the different types of spinal surgical procedures. 2. To illustrate the typical postoperative imaging findings in patients who have undergone spine surgery. 3. To highlight the key postoperative complications that can be detected through imaging.

TABLE OF CONTENTS/OUTLINE

1. Introduction Back pain is a prevalent reason for medical consultation. The use of imaging studies to detect potentially treatable pathologies has significantly increased, along with the rise in surgical procedures aimed at alleviating patient symptoms. The interpretation of postoperative findings can sometimes be challenging for general radiologists. Therefore, we aim to provide a basic overview of the main spine surgeries and their potential complications, supported by representative cases from our hospital. 2. Surgical procedures 2.1. CERVICAL SPINE 2.1.1. Anterior cervical discectomy and fusion (ACDF). 2.1.2. Corpectomy. 2.1.3. Odontoid fractures. 2.2. LUMBAR SPINE 2.2.1. Spinal fusion surgeries: anterior lumbar interbody fusion (ALIF) and direct lateral interbody fusion (DLIF)/oblique lumbar interbody fusion (OLIF). 2.2.2. Spinal simple decompressive surgeries (without fusion): discectomy, laminectomy/hemilaminectomy/facetectomy and interspinous device. 2.2.3. Special cases: combination of transpedicular screws and possible vertebroplasty (by interventional radiology). 3. Complications. 3.1. Implant-related complications: implant rupture, implant movement and malposition. 3.2. Adjacent level syndrome. 3.3. Pseudoarthrosis. 3.4. Postoperative collections: seroma/abscesses and hematoma. 3.5. Complications related to the procedure: CSF fistula. 4. Conclusions. 5. Bibliography.

NREE-139 WHAT THE EYES DON'T SEE, BUT FEEL: CAROTID-CAVERNOUS FISTULAS

Margrit E. Muller, MD (*Presenter*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Rafael Docema, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Caio Nunes, MD (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Mariana A. Rodrigues, MD (*Abstract Co-Author*)
Fabiana D. Hirata, MD (*Abstract Co-Author*)
Luis F. Godoy, MD (*Abstract Co-Author*)
Renata Bertanha, MD (*Abstract Co-Author*)
Breno A. Matos, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review the pathophysiology and classification of carotid-cavernous fistulas (CCFs). - Identify key imaging features of CCFs on CTA, MRA, and DSA. - Highlight imaging techniques that aid in diagnosis, including early arterial-phase CT angiography, time-of-flight (TOF) MRA, venous-phase MRA, the time-resolved imaging of contrast kinetics (TRICKS) sequence, and arterial spin labeling (ASL) perfusion. - Discuss the imaging assessment of CCF-related complications. - Correlate imaging findings with clinical presentation to enhance early diagnosis and guide multidisciplinary management.

TABLE OF CONTENTS/OUTLINE

Definition and Pathophysiology - Classification based on Barrow types and flow dynamics (high-flow vs. low-flow). Key Diagnostic Features - Role of CTA and MRA in detecting indirect and direct signs of CCFs. - DSA as the gold standard for confirmation, classification, and treatment planning. Classification and Hemodynamic Assessment - Importance of identifying flow direction and venous drainage patterns. - Hemodynamic implications for symptom severity and complication risk. Complication Assessment - Imaging evaluation of complications such as venous thrombosis, orbital congestion, and intracranial hypertension. Teaching cases - Pictorial review of didactic cases with multimodal imaging (CTA, MRA, DSA). - Examples demonstrating diagnostic challenges and emphasizing the value of combining imaging modalities. Take-home messages References

NREE-140 APPROACH TO MOTOR DISORDERS THROUGH PET. CAN I COMPLEMENT THE MRI?

Tatiana Lopez Sandoval, MD (*Presenter*)
Pedro Dib Hoyos, MD (*Abstract Co-Author*)
Sebastian Pelaez SR, MD (*Abstract Co-Author*)
Valentina Munera Orozco, MD (*Abstract Co-Author*)

TEACHING POINTS

Movement disorders are often evaluated using MRI to identify structural, but PET-CT, can detect early stages of disease before anatomical changes, also helping with differential diagnosis where clinical features overlap. The diagnosis of Parkinson's disease (PD) through 18F-DOPA PET imaging, is capable of quantifying dopamine synthesis and storage deficiencies in the presynaptic striatal nerve terminals. PET primarily focus on assessing dopaminergic function, in the striatum, which includes the caudate nucleus and putamen. Also, a significant reduction in Dopamine Transporter Density, particularly in the putamen, and decline in presynaptic terminal function and loss of pigmented dopaminergic neurons using ligands that bind to neuromelanin in the substantia nigra, are the hallmarks of PD. In Atypical parkinsonisms (AP), 18F-FDG PET, PSP shows hypometabolism in frontal and midbrain regions; MSA shows decreased putamen, cerebellum and brainstem; DLB is characterized by occipital hypometabolism; and CBD by asymmetric alterations in the frontoparietal cortex and basal ganglia contralateral to the most clinically affected side. And, in Creutzfeldt-Jakob disease (CJD), PET-CT using FDG provides functional value, revealing patterns of hypometabolism that correlate with prion distribution in autopsies, especially in the thalamus and frontoparietal cortex. The combination of DWI and FDG-PET improves diagnostic sensitivity, especially in atypical presentations or when MRI is negative.

NREE-141 SMALL PATIENTS, BIG CLUES: RECOGNIZING PEDIATRIC CNS CANCER PREDISPOSITION SYNDROMES ON IMAGING

Trisha Mukherjee (*Presenter*)
Alok I. Jaju, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Up to 15% of pediatric central nervous system (CNS) tumors are associated with an underlying cancer predisposition syndrome (CPS). 2. Early recognition is essential, enabling individualized screening, targeted therapies, radiation avoidance, and genetic counseling for family members. 3. While family history may be absent, certain tumor types, locations, and imaging features can suggest a syndromic diagnosis.

TABLE OF CONTENTS/OUTLINE

1. This exhibit aims to familiarize radiologists with the imaging manifestations of both common and rare pediatric CPSs involving the CNS, including neoplastic and non-neoplastic findings. We also highlight key clinical features and management considerations. 2. The 2021 WHO classification of CNS tumors (WHO CNS5) identifies 19 relevant CPSs—8 newly added—underscoring the evolving recognition of genetic drivers in pediatric neuro-oncology. 3. We present illustrative cases from the following syndromes: NF1, NF2, schwannomatosis, von Hippel-Lindau, tuberous sclerosis, Li-Fraumeni, Cowden, constitutional mismatch repair deficiency (CMMRD), nevoid basal cell carcinoma syndrome (Gorlin syndrome), rhabdoid tumor predisposition syndrome, DICER1, familial retinoblastoma, BAP1 tumor predisposition syndrome, and ELP1-

medulloblastoma syndrome. 4. Emphasis is placed on tumor type, location, patient age, and characteristic imaging clues that should prompt genetic evaluation. 5. Syndrome-specific surveillance is discussed. 6. Radiologists play a central role in identifying CPSs and guiding timely diagnosis, surveillance, and family management.

NREE-142 ADVANCED BRAIN HEALTH IMAGING: PRACTICAL CASE-BASED PEARLS FOR THE GENERAL RADIOLOGIST

Cyrus A. Raji, MD, PhD (*Presenter*)
Somayeh Meysami (*Abstract Co-Author*)
Yosef G. Chodakiewitz, MD (*Abstract Co-Author*)
Sean S. London, MD (*Abstract Co-Author*)
Sam Hashemi, MSc (*Abstract Co-Author*)
Alex Exuzides (*Abstract Co-Author*)
Daniel J. Durand, MD (*Abstract Co-Author*)
Amar P. Patel, MD (*Abstract Co-Author*)

TEACHING POINTS

A brain MRI protocol combining volumetric T1 (Neuroreader®) and arterial spin labeling (ASL) perfusion can enhance evaluation of brain aging and cognitive decline when added to conventional sequences (FLAIR, SWI). Characteristic MRI patterns: Alzheimer's: Hippocampal and parietal atrophy with posterior cingulate and precuneus hypoperfusion. Parkinson's dementia: Loss of midbrain "swallow tail" sign with diffuse cortical hypoperfusion and spared hippocampi. Multiple sclerosis: Central vein sign, deep gray hypoperfusion, and preserved global volume in early/asymptomatic stages. Recognizing normal variants (e.g. pituitary ASL hotspot) and MR volumetry segmentation errors helps avoid misdiagnosis.

TABLE OF CONTENTS/OUTLINE

Introduction Brain health imaging overview and key MRI sequences: 3D T1, ASL, FLAIR, SWI. Normal Aging Brain Normal brain volumes and perfusion in a healthy older adult, with delineated precuneus anatomy on T1 and ASL. Alzheimer's Pattern Hippocampus, temporal and parietal atrophy; posterior cingulate and precuneus hypoperfusion. Parkinsonian Dementia Midbrain "swallow tail" sign loss on SWI, frontal and parietal hypoperfusion, spared hippocampal volume. Multiple Sclerosis Perivenular lesion with central vein sign; reduced caudate and thalamic perfusion; normal brain volume in early stages. Quality Control & Pitfalls Volumetry segmentation errors and ASL variants (e.g. pituitary bright signal on ASL) that can mimic pathology. Conclusion Integrating volumetric and perfusion imaging into routine practice improves early detection and differentiation of neurodegenerative diseases.

NREE-143 NOT EVERYTHING IS WHAT IT SEEMS: NEUROCYSTICERCOSIS AND ITS MIMICS - A PICTORIAL REVIEW OF CASES

Luiza Suman, MD (*Presenter*)
Gabriela Ramos Ribeiro, MD (*Abstract Co-Author*)
Vinicius Siessere Gugelmin, MD (*Abstract Co-Author*)
Tiago Bertoncini, MD (*Abstract Co-Author*)
Cilmario L. da Silva Junior, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Understand the life cycle and pathological features of neurocysticercosis. Identify the imaging characteristics of neurocysticercosis through its four stages: vesicular, colloidal vesicular, granular nodular, and calcified. Characterize lesion morphology, distribution, and associated features to help distinguish neurocysticercosis from its mimics.

TABLE OF CONTENTS/OUTLINE

Neurocysticercosis (NCC) is the most common helminthic infection of the central nervous system (CNS) and a leading cause of acquired and preventable epilepsy in endemic regions, particularly in low-resource countries. It results from the ingestion of Taenia solium eggs, which hatch in the gut, enter the bloodstream, and reach the CNS. NCC commonly affects the cerebral parenchyma, but can also occur in extra-axial compartments. Most cases are asymptomatic, diagnosed incidentally by calcifications on neuroimaging. The diagnosis is made mainly through neuroimaging, especially magnetic resonance imaging (MRI) and computed tomography (CT). Imaging also helps to stage the disease: the vesicular stage shows a thin-walled cyst with a visible scolex; the colloidal stage presents a proteinaceous cyst with wall enhancement and edema due to inflammation; late stages show cyst shrinkage and granuloma formation. MRI is more sensitive than CT for detecting small parenchymal, intraventricular, and cisternal lesions. Main differential diagnoses include tuberculosis, tuberculoma, neurocryptococcosis, abscess, and metastasis. These lesions often present with peripheral enhancement, mimicking NCC. The goal of this presentation is to show the imaging findings of NCC and its mimics.

NREE-144 KEEP THEM STRAIGHT: A REVIEW OF OSSEOUS DESTRUCTIVE PATHOLOGIES OF THE SPINE

Tyler Morgan, MD (*Presenter*)
Sally J. Choi, MD (*Abstract Co-Author*)
Sonal Jha, MD (*Abstract Co-Author*)
Achint K. Singh, MD (*Abstract Co-Author*)
Manoj Kumar, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

This presentation focuses on classic appearances and differentiating features of multiple types of osseous destructive pathologies, as many of these have overlapping features making them tricky to differentiate, especially for trainees and junior faculty. Destructive spinal pathologies of metabolic, infectious, degenerative, primary tumor, and metastatic etiologies are discussed in this presentation. Though there have been prior published reviews of various spinal arthropathies and pathologies, this is the first to provide as extensive a review of the categories and etiologies responsible for specifically osseous destructive spinal findings.

TABLE OF CONTENTS/OUTLINE

Outline: Metabolic: Dialysis-related spondyloarthropathy, Charcot spine, Hyperparathryoidism. Infectious: Discitis-osteomyelitis, Tuberculous spondylitis, Fungal Osteomyelitis. Degenerative: Intervertebral osteochondrosis, Schmorl Node. Primary tumor: Chordoma, Osteoblastoma, Aneurysmal Bone Cyst, Giant Cell Tumor, Langerhans Cell Histiocytosis. Metastatic: Multiple Myeloma, Lymphoma, Breast, Lung, Renal Cell Carcinoma

NREE-145 UNRAVELING THE IMAGING OF LANGERHANS CELL HISTIOCYTOSIS IN THE CENTRAL NERVOUS SYSTEM

Lara Mori, MD (*Presenter*)
Diogo G. Correa, MD (*Abstract Co-Author*)
Gabriela A. Ribas, MD (*Abstract Co-Author*)
Luciane De Oliveira (*Abstract Co-Author*)
Tomas Freddi, MD (*Abstract Co-Author*)
Celso Hygino, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Langerhans Cell Histiocytosis (LCH) is a rare neoplastic disorder characterized by monoclonal proliferation and tissue infiltration of pathological dendritic cells, often associated with abnormal MAPK pathway activation and BRAF V600E mutation. It affects different age groups, being more prevalent in children up to 3 years. Diagnosis relies on clinical, radiological and histopathological evaluation. LCH may involve several organs, especially the bones, skin and hypothalamic-pituitary axis. CNS involvement evaluation includes parenchymal and non-parenchymal structures including the craniofacial bones, hypothalamic-pituitary axis, and meninges. Lesions may present in tumoral or neurodegenerative forms, with symptoms varying by the affected region. Tumoral lesions usually affect craniofacial bones and hypothalamic-pituitary axis. On MRI, they are tipically hypointense on T1- and T2-weighted imaging, with contrast enhancement. Pituitary involvement may result in endocrinopathies,

especially diabetes insipidus, evidenced by findings such as pituitary stalk thickening and loss of neurohypophyseal T1 hypersignal. The neurodegenerative form manifests with progressive clinical, neurological and/or radiological deterioration, mainly involving the cerebellar nuclei.

TABLE OF CONTENTS/OUTLINE

Introduction: Definition, etiology, epidemiology, classification and histopathological findings of LCH; Imaging: Role of each imaging modality; Bone Presentation: Craniofacial and vertebral assessment, including differentials; Intracranial Presentation: Types and differential diagnoses; Conclusion: Imaging relevance and radiologist's role in diagnosis and prognosis.

NREE-146 ADVANCES IN SODIUM (^{23}NA) MRI AND CEST IMAGING FOR BRAIN TUMORS: METHODOLOGICAL INNOVATIONS AND EVOLVING CLINICAL UTILITY

Aashim Bhatia, MD, MS (*Presenter*)
Lina Chihoub (*Abstract Co-Author*)
Hannah Nguyen (*Abstract Co-Author*)
Apoorva Kotha, MBBS (*Abstract Co-Author*)
Luke Bloy, PhD (*Abstract Co-Author*)
Akinbanji Afolabi (*Abstract Co-Author*)
Mohammad Haris (*Abstract Co-Author*)
Blake Benyard (*Abstract Co-Author*)
Neil Wilson (*Abstract Co-Author*)
Em Triolo (*Abstract Co-Author*)
Fernando E. Boada, PhD (*Abstract Co-Author*)
Ravinder Reddy, PhD (*Abstract Co-Author*)
Timothy Roberts, PhD (*Abstract Co-Author*)

TEACHING POINTS

Conventional 1 H MRI (Diffusion weighted imaging, Fluid-Attenuated Inversion Recovery, post-contrast T1) remains the clinical gold standard for evaluating human brain tumors, but recent advances suggest that 23 Na MRI & advanced 1 H MRI such as chemical exchange saturation transfer (CEST) imaging can provide novel insights into tumor biology by quantifying sodium concentrations & metabolites elevated in brain tumors. Though historically limited by low signal to noise ratio, poor resolution, & long scan times, technological innovations have improved their clinical viability. They hold promise for more detailed characterization of tumor biology & treatment response. 1. Educate on potential role of 23 Na MRI & CEST in brain tumor evaluation 2. Describe technical advancements enabling their clinical use 3. Summarize literature demonstrating 23 Na MRI MRI & CEST in tumor characterization & monitoring 4. Present pediatric cases of 23 Na MRI MRI & CEST from Children’s Hospital of Philadelphia (CHOP)

TABLE OF CONTENTS/OUTLINE

Intro Limitations of 1 H imaging in pediatric brain tumors Fundamentals of 23 Na/CEST imaging 23 Na/CEST MRI background Biological relevance & imaging principles Historical technical barriers Imaging technique advancement Hardware Pulse sequence 23 Na MRI compartment differentiation techniques Figure 1: Technical advancements of 23 Na MRI at CHOP (flowchart) Brain tumor applications Evolution from feasibility to clinical utility (characterize & stratify tumors, monitor treatment response & progression) Figures 2-3: Literature on clinical studies of 23 Na & CEST imaging (tables) Figures 4-5: 23 Na MRI & CEST in pediatric cases at CHOP (images)

Abstract Archives of the RSNA, 2025

OBEE

OB/Gynecology Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

OBEE-1 MRI-BASED MORPHOLOGY OF OVARIAN CLEAR CELL CARCINOMAS

Nobuyuki Takeyama, MD (*Presenter*)
Yuki Tashiro, MD (*Abstract Co-Author*)
Jiro Munechika (*Abstract Co-Author*)
Yoshimitsu Ohgiya, MD (*Abstract Co-Author*)
Kota Watanabe, MD (*Abstract Co-Author*)

TEACHING POINTS

Ovarian clear cell carcinomas (CCCs) are pathologically characterized by cysts and glands lined with cuboidal, hobnail, or flattened cells containing clear or eosinophilic cytoplasm. While most patients are diagnosed at an early stage, advanced-stage CCC has a worse prognosis than serous or endometrioid carcinomas due to its relative insensitivity to platinum-based chemotherapeutic agents. When CCC is suspected preoperatively, gynecologic oncologists may make maximal efforts to achieve complete cytoreduction with no residual disease. MRI-based morphological patterns can be classified into seven types: an entirely solid mass with central edema exhibiting a renal cortico-medullary appearance; an entirely solid mass with central necrosis; a solid and cystic mass demonstrating a black sponge appearance; a solid and cystic mass with a broad-based, multifocal, or concentric growth pattern of the solid component containing internal cystic areas; a solid and cystic mass with a polypoid, focal, or eccentric growth pattern of the solid component containing internal cystic areas; an entirely cystic mass with multiple septations and a small solid component; and an entirely cystic mass with internal septations and small mural nodules. We will present cases focusing on the correlation between pathological features and MRI findings, which may facilitate preoperative identifications of CCC during image interpretation.

TABLE OF CONTENTS/OUTLINE

1. Etiology of ovarian CCCs and other epithelial carcinomas. 2. Pathology of CCC. 3. MRI findings of CCC. 4. Classification of 7 types of MRI-based morphological pattern. 5. Case-based review correlated between pathological and MRI findings. 6. Conclusion. 7. References.

OBEE-2 BUYER BEWARE: COMPLICATIONS OF CONTRACEPTION

Nabeal Aljabban, MD (*Presenter*)
Sepand Moalej, DO, BSc (*Abstract Co-Author*)
Emily Rooney, MD (*Abstract Co-Author*)
Gurinder Singh, MD (*Abstract Co-Author*)
Susan J. Frank, MD (*Abstract Co-Author*)
Monika Misra, MD (*Abstract Co-Author*)
Sharon Gordon, MD (*Abstract Co-Author*)
Barak Friedman, MD (*Abstract Co-Author*)
Rona J. Orentlicher Fine, MD (*Abstract Co-Author*)

TEACHING POINTS

Several contraceptives are commonly used in the United States, each with its own potential complications depending on the method. Intrauterine device (IUD)-proper positioning is critical to prevent complications. Malpositioning is common and can include partial or complete migration and expulsion. IUD arms may become embedded in the myometrium and lead to uterine perforation. Incorrect IUD placement can lead to IUP and raises the likelihood of ectopic pregnancy. Tubal Ligation/Essure-permanent contraceptive methods. Malposition can lead to unintended pregnancy or ectopic pregnancy. May become embedded in uterus or ovary resulting in perforation and peritoneal migration. Hydrosalpinx can also result. Oral contraceptive pills (OCP)-associated with increased risk of deep vein thrombosis (DVT), pulmonary emboli (PE), and hepatic adenomas. May elevate risk of stroke and myocardial infarction (MI) in those people with additional risk factors. Vasectomy-associated with postop hematoma/infection. Can form spermatoceles, tubular ectasia, sperm granuloma and “dancing mega sperm” which reflect obstructed sperm flow.

TABLE OF CONTENTS/OUTLINE

Overview of Female and Male Contraception. Summary of types and their frequency of use. Review common complications by contraceptive type including IUD, Permanent Methods such as Tubal Ligation, Essure and Vasectomy and Oral contraception. Review imaging evaluation of contraceptive complications including US, CT & MRI. Discuss clinical presentation and risk factors of complications. Evaluate various treatments, patient management and efficacy.

OBEE-3 MR IMAGING OF ABDOMINAL PAIN IN PREGNANT WOMEN: A PRACTICAL GUIDE OF COMMON OBSTETRIC AND NON-OBSTETRIC PATHOLOGIES

Roberta V. Ninkova, MD (*Presenter*)
Marco Gennarini (*Abstract Co-Author*)
Claudia Cutonilli, MD (*Abstract Co-Author*)
Federica Curti, MD (*Abstract Co-Author*)
Carlo Catalano, MD (*Abstract Co-Author*)
Lucia Manganaro, MD (*Abstract Co-Author*)

TEACHING POINTS

- MRI is a safe, non-ionizing modality for assessing abdominal pain during pregnancy, especially when ultrasound results are inconclusive. - Proper MRI protocols in pregnant patients avoid gadolinium and utilize rapid sequences like T2-weighted, T1 in-phase/out-of-phase, and diffusion-weighted imaging (DWI) to reduce fetal motion artifacts and optimize diagnostic yield. - Understanding both obstetric and non-obstetric causes of abdominal pain is essential . Obstetric causes include placental abruption, uterine rupture, and retained products of conception, while non-obstetric causes include appendicitis, bowel obstruction, ovarian torsion, and urinary tract complications. - Radiologists must differentiate pathological findings from normal anatomical and physiological changes of pregnancy , such as organ displacement, gestational hydronephrosis, and altered bowel motility, to prevent false positives. - Tailoring interpretation by trimester improves diagnostic accuracy and supports appropriate clinical management.

TABLE OF CONTENTS/OUTLINE

1. Introduction Clinical context and diagnostic challenges in pregnant women. 2. MRI Safety and Protocols Guidelines for non-contrast imaging and patient positioning. 3. Obstetric and Gynecologic Causes MRI features of uterine rupture, ovarian torsion, and more. 4. Gastrointestinal and Urinary Pathologies Imaging findings in appendicitis, bowel obstruction, and pyelonephritis. 5. Interpretative Tips and Pitfalls Avoiding confusion with normal pregnancy-related changes. 6. Conclusion Role of MRI in improving maternal and fetal outcomes.

OBEE-4 LOST IN TRANSIT: NAVIGATING EXTRA-TUBAL ECTOPIC PREGNANCIES

Gurinder Singh, MD (*Presenter*)
Emily Rooney, MD (*Abstract Co-Author*)
Nabeal Aljabban, MD (*Abstract Co-Author*)
Sepand Moalej, DO (*Abstract Co-Author*)
Jay G. Hochsztein, MD (*Abstract Co-Author*)
Kathryn D. Solomon, MD (*Abstract Co-Author*)
Sharon Gordon, MD (*Abstract Co-Author*)
Monika Misra, MD (*Abstract Co-Author*)
Barak Friedman, MD (*Abstract Co-Author*)
Rona J. Orentlicher Fine, MD (*Abstract Co-Author*)

TEACHING POINTS

Ectopic Pregnancy(EP)-Under 2% of all pregnancies, but medical emergency requiring rapid diagnosis to lower morbidity & mortality Up to 10% in extra-tubal sites: Interstitial: Implants in cornual portion of fallopian tube; eccentric sac with thin overlying myometrium. High bleeding risk, presents later than tubal EP. Need to differentiate with rudimentary horn EP and angular pregnancy (not EP) C-section Scar: implant in scar with thin overlying myometrium leads to rupture risk; measurements aid in diagnosis Cervical: implants in cervical wall; negative sliding sign on US. Positive fetal cardiac activity differentiates from early pregnancy loss Ovarian: implants in/on ovarian tissue. May mimic hemorrhagic cyst Abdominal: Rare, often caused by tubal rupture w/ reimplantation in abdominal cavity (ex. bowel, liver, and omentum). High risk of internal bleeding Rudimentary horn: Implant in communicating/non-communicating undeveloped uterine horn; late diagnosis with rupture risk Diagnostic Methods: US (mainstay) & MRI (problem-solving) Focus: Emphasis on subtle imaging differences, clinical signs & management

TABLE OF CONTENTS/OUTLINE

Overview of extra-tubal ectopic pregnancy (EP) Discuss diagnostic imaging features of each type emphasizing role of US & MRI Compare interstitial, angular & rudimentary horn pregnancies Discuss measurements of C-section Scar EP to aid diagnosis Differentiate cervical EP & early pregnancy loss Review risk factors, presentation, complications, prevention and prognosis Discuss management and compare treatment options

OBEE-5 POST-RADIOTHERAPY MRI IN CERVICAL CANCER: DISTINGUISHING EXPECTED FROM PATHOLOGIC FINDINGS

Igara Tavares, MD (*Presenter*)
Rita d. Matheus (*Abstract Co-Author*)

TEACHING POINTS

Cervical cancer is the fourth most commonly diagnosed malignancy in women worldwide and remains a leading cause of cancer-related mortality. Approximately 30% of patients are diagnosed with advanced disease, for which the standard therapeutic approach involves chemoradiotherapy, followed by intracavitary brachytherapy. Post-treatment magnetic resonance imaging (MRI) is generally performed 3-6 months after the completion of chemoradiotherapy. The restoration of the cervical stroma's low-signal intensity on T2-weighted imaging (T2WI) is indicative of a complete therapeutic response. However, post-treatment changes may persist for up to 9 months, complicating the differentiation between residual tumor and post-treatment edema, as both can present with intermediate signal intensities on T2WI. The use of diffusion-weighted imaging (DWI) becomes essential, as tumors typically show restricted diffusion, unlike edema. Post-radiotherapy complications can be classified into acute and chronic categories. Acute toxicities predominantly affect the pelvic organs, particularly the bladder and bowel and chronic complications are mainly attributed to fibrotic changes in irradiated tissues.

TABLE OF CONTENTS/OUTLINE

1. Overview of cervical cancer;2. Outlining the 2018 FIGO staging system;3. Detection of tumors in MRI;4. Differentiating residual tumor from post-radiotherapy edema;5. Other common findings (e.g., fatty marrow replacement);6. Acute complications (e.g., radiation proctitis);7. Chronic complications (e.g., cervical stenosis, fibrotic bladder, fistula formation, and insufficiency fractures).8. Summary of key concepts.

OBEE-6 ENDOMETRIOSIS AND CONGENITAL MüLLERIAN ANOMALIES: A CASE-BASED REVIEW

Nadia Rios, MD (*Presenter*)
Mariana c. Linares, MEd, MEd (*Abstract Co-Author*)
Lorena I. Arrieta (*Abstract Co-Author*)
Lilian Fazzion (*Abstract Co-Author*)
Virginia Robles (*Abstract Co-Author*)
LUCIANO GANZER (*Abstract Co-Author*)
MONICA BONIN (*Abstract Co-Author*)
Ezequiel Barbero (*Abstract Co-Author*)
Carolina Etel Torres (*Abstract Co-Author*)

TEACHING POINTS

1-The association between congenital Müllerian anomalies and endometriosis has been a debatable research topic in the last years. 2-Congenital uterine anomalies, resulting from malformations of Müllerian ducts during embryonic development, have a prevalence of: 5.5% in the general population 8% in women with infertility 13.3% in women with a history of miscarriage. 3-A strong positive association between non-obstructive Müllerian anomalies and endometriosis would support the embryonic remnants/ celomic metaplasia hypothesis. 4-Women with Congenital Uterine Anomalies and endometriosis are more likely to suffer from severe endometriosis and dysmenorrhea. 5- Three-dimensional (3D) TV US or MRI may help to visualize the external uterine fundal contour and internal indentation of the endometrial cavity, two key morphological characteristics in the diagnosis of congenital uterine anomalies. 6-MRI helps to characterize and allows assessment for ectopic ureters, abnormally positioned ovaries, or associated deep infiltrative endometriosis.

TABLE OF CONTENTS/OUTLINE

Title Introduction Objectives Clinical Presentation MR and TV US: Protocol and Report Considerations Case Reports with Discussion/s of Imaging in Each Treatment Conclusion References

OBEE-7 BEHIND THE SHADOWS: MRI INSIGHTS INTO T2 HYPOINTENSE OVARIAN MASSES AND ITS DIFFERENTIAL DIAGNOSIS

Helena Font, MD (*Presenter*)
Lledo Cabedo Esteve, MD (*Abstract Co-Author*)
Carlos Nicolau, MD (*Abstract Co-Author*)
Olatz Saenz De Argandona, MD (*Abstract Co-Author*)
Meritxell Munmany (*Abstract Co-Author*)
Adela Saco (*Abstract Co-Author*)
Carmen Sebastia Cerqueda, MD (*Abstract Co-Author*)

TEACHING POINTS

1)To review the MRI features of adnexal lesions that show low signal intensity on T2-weighted images, highlighting their histopathologic correlates. 2)To identify key imaging criteria that help differential diagnosis between benign, borderline, and malignant T2-hypointense adnexal masses. 3)To propose a structured, MRI-based diagnostic algorithm for accurate lesion characterization and appropriate clinical management. 4)To introduce the potential of radiomics as a complementary tool in pelvic MRI.

TABLE OF CONTENTS/OUTLINE

1) Introduction: Epidemiology of adnexal masses and diagnostic challenges. Role of MRI and T2-weighted sequences in the evaluation of adnexal lesions. Clinical relevance of identifying T2-hypointense lesions. Overview of O-RADS classification. 2) Anatomic and pathologic correlates: Review of normal pelvic and ovarian anatomy on MRI. How to differentiate a peritoneal from an extraperitoneal lesion. Pathologic correlates of T2-hypointensity. 3) MRI features and key differential diagnoses: Benign lesions (ovarian fibroma, fibrothecoma, endometrioma, hemorrhagic cysts, cystadenofibroma and others). Malignant or borderline lesions (brenner tumor, ovarian M1, malignant transformation of endometrioma, borderline serous cystadenomas and others). Mimics and other considerations. 4) MRI-Based Diagnostic Algorithm. 5)Role of Radiomics in Pelvic MRI: Potential in improving the identification of normal ovaries, distinguishing myomas from fibromas, and enhancing diagnostic precision in differentiating benign from malignant adnexal masses. 6) Conclusion.

OBEE-8 ENDOMETRIOSIS IN ADOLESCENTS A CASE-BASED REVIEW

Pamela I. Causa Andrieu, MD (*Presenter*)
Ana Villanueva, MD (*Abstract Co-Author*)
Nadia Rios, MD (*Abstract Co-Author*)
Mariana c. Linares, MEd, MEd (*Abstract Co-Author*)
Carolina R. Chacon, MD (*Abstract Co-Author*)
Ayelen Leao, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)
Liina Poder, MD (*Abstract Co-Author*)
Wendaline M. VanBuren, MD (*Abstract Co-Author*)
Marjan Attaran (*Abstract Co-Author*)
Myra K. Feldman, MD (*Abstract Co-Author*)

TEACHING POINTS

Endometriosis is highly prevalent in adolescents with chronic pelvic pain, but diagnosis is often delayed due to limited awareness among clinicians and the general public. Adolescents with endometriosis have unique clinical presentations, diagnostic approaches, disease phenotypes, and treatment options. Most frequently, it appears as mild deep disease which is often associated with superficial disease, with features of glandular activity (T1WI hyperintensity on MRI). Early active subtle lesions may be associated with more severe symptoms than bigger and more fibrotic lesions. Torus uterinus and uterosacral ligament are the most affected in <15 years. However, rectosigmoid lesions and anterior compartment involvement are rare. Endometrioma mainly occurs in = 18 years; the ovarian reserve should be assessed if a cystectomy is considered. Coexistence with adenomyosis (approximately 20%) and Mullerian anomalies (particularly the obstructive ones). Minimal literature on disease progression in adolescents. Initial approach is a transabdominal US and transvaginal if possible. Dedicated pelvic MRI with endovaginal gel (if possible) and IV contrast helps establish the diagnosis and guide treatment.

OBEE-9 THE LAST CHAPTER OF PREGNANCY: WHAT ULTRASOUND TELLS US IN THE THIRD TRIMESTER

Roddie Moraes Neto, MD (*Presenter*)
Alex Dias, MD (*Abstract Co-Author*)
Dario Nascimento Ferreira Alves, MD (*Abstract Co-Author*)
Debora Mayumi Takamune, MD (*Abstract Co-Author*)
Enzo Calheiros, MD (*Abstract Co-Author*)
Leonardo Rosolen Iunes, MD (*Abstract Co-Author*)
Maria Vitoria Ludwig, MD (*Abstract Co-Author*)
Regiany Alessandra Garcia Jureidini, MD, MBA (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Sergio Kobayashi, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the purpose of third-trimester ultrasound and how to perform it correctly while avoiding common pitfalls; Recognize and know how to identify the main fetal anomalies detectable in the third trimester; Know the applications and recommendations that can influence medical decision-making with the aid of third-trimester ultrasound

TABLE OF CONTENTS/OUTLINE

Introduction : Why perform obstetric ultrasound in the third trimester? How to perform obstetric ultrasound in the third trimester? Evidence related to third-trimester ultrasound; Examination Technique Standard fetal biometry to be evaluated; Common pitfalls in assessment and how to avoid them; Doppler in the third trimester: how to perform and interpret it; Fetal anomalies Head/brain; Heart; Urinary system; Thorax; Applications and Recommendations in Third-Trimester Ultrasound Placenta previa; Placenta accreta spectrum; Vasa previa; Amniotic fluid disorders; Fetal growth disorders (large for gestational age and small for gestational age); Case-based review ; Summary ; Take home messages

OBEE-10 ENDOMETRIOSIS UNPLUGGED: UNUSUAL LOCATIONS AND UNEXPECTED MANIFESTATIONS

Isabel Fonseca Buelga, MD (*Presenter*)
Alba Salgado Parente, MD (*Abstract Co-Author*)
Carmen Sebastia Cerqueda, MD (*Abstract Co-Author*)
Blanca Pano Brufau, MD (*Abstract Co-Author*)
Pamela I. Causa Andrieu, MD (*Abstract Co-Author*)
Vanessa Murad, MD (*Abstract Co-Author*)
Ana Villanueva, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the pathophysiology and imaging features of endometriosis in atypical locations throughout the body, using multiple imaging modalities including ultrasound, CT, MRI, and PET. 2. To identify the imaging findings of atypical presentations of endometriosis, with the aim of reducing delayed or missed diagnoses. 3. To propose a systematic approach for evaluating nonspecific lesions in both premenopausal and postmenopausal women, in order to determine whether endometriosis should be considered as a potential diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Background. Epidemiology and pathophysiology 2. Unusual Locations of endometriosis a. Intra-abdominal extrapelvic: GI and GU tract, peritoneum b. Thoracic: pericardium, diaphragm, pleura c. MSK: abdominal wall, cesarean section scar, episiotomy d. Neural involvement 3. Unusual Manifestations a. Malignant transformation

b. Infection c. Decidualization during pregnancy 4. Systematic Approach: What is the differential diagnosis of atypical presentations of endometriosis? 5. Conclusions and take home points 6. References

OBEE-11 IMAGING THE INVISIBLE: ULTRASOUND IN THE DIAGNOSIS AND MANAGEMENT OF UROGYNECOLOGIC SLING COMPLICATIONS

Viviane B. Scattolini, MD (*Presenter*)
Caio Nunes, MD (*Abstract Co-Author*)
Laura Macedo, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Claudia C. da Silva, MD (*Abstract Co-Author*)
Isadora Calixto, MD (*Abstract Co-Author*)
Andrea G. Leite, MD (*Abstract Co-Author*)
Tatiana F. Guimaraes, MD (*Abstract Co-Author*)
Miguel J. Neto (*Abstract Co-Author*)
Marcelo R. Silva, MD (*Abstract Co-Author*)
Marcos R. Queiroz, MD, MBA (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to: - Review the relevant pelvic anatomy and the types of mid-urethral slings (retropubic vs. transobturator). - Describe the ultrasound techniques used to assess sling positioning and functional integrity. - Identify common and uncommon complications of urogynecologic slings as seen on ultrasound. - Correlate sonographic findings with clinical outcomes and long-term management strategies.

TABLE OF CONTENTS/OUTLINE

- Feminine pelvic anatomy relevant to sling placement - Overview of surgical techniques for sling insertion - Ultrasound evaluation methods: transperineal and transvaginal approaches - Normal sonographic appearance of slings - Key ultrasound parameters for sling assessment - Common and uncommon sling-related complications - Clinical relevance and management based on imaging findings - Representative clinical case studies.

OBEE-12 WOULD YOU HAVE SUSPECTED THIS? RARE GYN TUMORS AND MIMICKERS THAT BREAK THE RULES

Valesca B. Monteiro, MD (*Presenter*)
Pedro Naime B. Araujo I, MD (*Abstract Co-Author*)
Andrea d. Aranha, MD (*Abstract Co-Author*)

TEACHING POINTS

Not all pelvic tumors follow the typical rules of gynecologic oncology. This educational exhibit presents a series of rare and unexpected gynecologic malignancies—including melanoma, lymphoma, sarcoma, and metastasis—that defy common imaging patterns. Through a case-based format, radiologists will explore imaging clues that help distinguish these unusual entities, understand potential diagnostic pitfalls, and expand their differential diagnoses beyond the conventional. Recognizing these rare tumors can lead to earlier diagnosis, appropriate referral, and optimized patient outcomes.

TABLE OF CONTENTS/OUTLINE

* Introduction: The importance of recognizing rare gynecologic malignancies and their mimickers. * When the presentation defies expectations: clinical and imaging red flags. * Pattern recognition beyond the typical: how rare tumors break the rules. * Mimickers and misdiagnoses: what to avoid in interpretation. * Imaging strategies across modalities (MRI, CT, US): choosing the right tool. * Case-based quiz: can you spot what doesn't fit? * Diagnostic pearls and reporting tips for unusual GYN tumors. * Key pitfalls and how to avoid them. * Summary: expanding your differential in pelvic oncology

OBEE-13 UNVEILING THE HIDDEN: AN ICONOGRAPHIC EXPLORATION OF VAGINAL PATHOLOGIES THROUGH IMAGING

Luiza Suman, MD (*Presenter*)
Gabriela Ramos Ribeiro, MD (*Abstract Co-Author*)
Luana Silva (*Abstract Co-Author*)
Mayra V. Soares, MD (*Abstract Co-Author*)

TEACHING POINTS

•? ?Understand normal vaginal anatomy on MRI •? ?Review key MRI findings in congenital anomalies•? ?Recognize MRI features of common and rare benign and malignant vaginal lesions and their differential diagnoses

TABLE OF CONTENTS/OUTLINE

The vagina is a fibromuscular structure between the vulva and uterine cervix and can be affected by rare benign and malignant conditions. Accurate imaging characterization requires knowledge of vaginal anatomy. Among benign conditions, congenital anomalies resulting from Müllerian duct malformations—such as vaginal agenesis, seen in Mayer-Rokitansky-Küster-Hauser syndrome—are best evaluated by MRI.Inflammatory and infectious vaginal diseases are common. Vaginitis, often of infectious origin, can be challenging to characterize on imaging.Benign tumors include cystic and solid lesions such as Gartner duct cysts and leiomyomas. Malignant lesions may be primary or, more commonly, secondary to cervical or vulvar cancer.Primary vaginal cancer is rare, accounting for 1-2% of all gynecologic malignancies and 10% of vaginal malignancies. The most common subtype is squamous cell carcinoma (90%), followed by adenocarcinoma (8-10%). Lymphomas, sarcomas, and melanomas are exceedingly rare.Due to its superior soft tissue contrast, MRI is the modality of choice for evaluating these tumors. PET-CT is complementary for distant staging.

OBEE-14 TOO YOUNG FOR ENDOMETRIOSIS? THE POWER OF IMAGING IN EARLY DETECTION DURING ADOLESCENCE

Ana Carolina Gaetan Afonso, MD (*Presenter*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Arthur H. Godeiro, MD (*Abstract Co-Author*)
Yasmin Fattah, MD (*Abstract Co-Author*)
Lhuanna Maria Barbosa Teixeira, MD (*Abstract Co-Author*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Carolina L. Travassos (*Abstract Co-Author*)
Cinthia C. Barbisan, MD (*Abstract Co-Author*)

TEACHING POINTS

Endometriosis is a chronic inflammatory condition that may begin in the early years following menarche, yet it is frequently underdiagnosed in adolescents due to its nonspecific clinical presentation, such as acyclic pelvic pain. These vague symptoms often lead to misdiagnosis with other common conditions, including primary dysmenorrhea, irritable bowel syndrome, and recurrent urinary tract infections. In adolescents, lesions are typically superficial, making detection through conventional

imaging particularly challenging. Moreover, the psychosocial burden of endometriosis during adolescence is substantial, with a marked impact on quality of life. These factors highlight the critical need for radiologists to be trained in recognizing the subtle imaging features of early-stage disease to enable timely and accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

This study explores the key aspects of endometriosis in adolescence, using clinical cases that illustrate the diagnostic challenges and imaging findings characteristic of this age group. The pathophysiology, epidemiology, and clinical presentation of the disease in adolescents will be discussed, with emphasis on the distinct features when compared to the adult population. The review will also cover imaging aspects, focusing on the advantages and limitations of various modalities, including ultrasound and magnetic resonance imaging (MRI).

OBEE-15 SURFING THE PERITONEUM: A PICTORIAL ESSAY ON SUPERFICIAL ENDOMETRIOSIS

Izabela P. Franco, MD (*Presenter*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Ana Paula C. Moura, MSc (*Abstract Co-Author*)
Isabelle Thomassin-Naggara, MD (*Abstract Co-Author*)
Anuradha S. Shenoy-Bhangle, MD (*Abstract Co-Author*)
Kristine S. Burk, MD (*Abstract Co-Author*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Luciana G. Matteoni-Athayde, MD (*Abstract Co-Author*)
Cicilia F. Pontes Fernandez, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Superficial endometriosis is the most common form of the disease, accounting for approximately 80% of all cases, yet it remains significantly underdiagnosed.Normal imaging does not exclude the diagnosis. Despite frequent false-negative imaging results, diagnostic accuracy can be improved through advanced knowledge of pelvic anatomy and the application of high-resolution magnetic resonance imaging (MRI) protocols and dedicated ultrasound(US). This strategy supports more accurate diagnosis and tailored treatment planning.Transvaginal US can detect subtle, nonspecific findings suggestive of superficial endometriosis, which gain diagnostic value when correlated with the patient's clinical history. MRI provides superior anatomical detail, particularly for hemorrhagic lesions.3D MRI sequences in T1- and T2-weighted images, combined with careful evaluation of peritoneal fluid and subtle peritoneal defects, can enhance the detection of lesions.Hormonal treatments may temporarily suppress disease visibility, posing challenges to accurate imaging diagnosis

TABLE OF CONTENTS/OUTLINE

Introduction 1.1 Definition and epidemiology of Superficial Endometriosis 1.2 Clinical Relevance Pathophysiology and Clinical Presentation 2.1 Peritoneal Involvement 2.2 Histological Features 2.1 Clinical implications and anatomical correlation Imaging Techniques and Findings 3.1 Ultrasonographic Features 3.2 MRI features and 3D Volumetric Sequences Diagnostic Challenges 4.1 Limitations of Imaging Methods 4.2 Effect of Hormonal Therapy Clinical Management and Implications 5.1 Diagnostic Algorithm 5.2 Implications for Fertility and Pain Management Teaching Points and Practical Considerations

OBEE-16 CESAREAN SCAR AND FIRST TRIMESTER PREGNANCY: LESSONS FROM INTER-DISCIPLINARY COLLABORATIVE CASE REVIEW

Deepashri Basavalingu, MD,MBBS (*Presenter*)
Garvit D. Khatri, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Cesarean delivery rates have continued to rise globally from 7% in 1990 to 21% in recent years. 2. Cesarean scar ectopic pregnancy occurs when an early pregnancy implants in the scar from previous cesarean delivery. Cesarean scar pregnancy presents significant risk of severe maternal morbidity and mortality as it can lead to complications including uterine dehiscence, uterine rupture, placenta accrete spectrum, hemorrhage, premature delivery and cesarean hysterectomy.3. Growing evidence that early first trimester transvaginal ultrasound screening may be indicated in patients with history of previous cesarean delivery to identify cesarean scar pregnancy.4. Cesarean scar pregnancy is a continuum of abnormal implantation ranging from partial implantation over cesarean scar to implantation within the scar niche.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Rising rates of cesarean delivery and cesarean scar ectopic pregnancies.2. Cesarean scar ectopic pregnancy: Definition, incidence and case examples demonstrating the continuum of cesarean scar implantation ranging from partial implantation to implantation within the niche. 3. Complications of cesarean scar ectopic pregnancy with case examples.4. Role of first trimester ultrasound in identifying cesarean scar pregnancy.5. Lessons learned from inter-disciplinary collaborative case review with case examples: a. Implantation over the cesarean scar versus within the scar niche. b. Ultrasound findings of cesarean scar implantation.c. Location of early placenta with respect to the cesarean scar.d. Early pregnancy loss and cesarean scar.6. Management of cesarean scar pregnancy. 7. Take home points.

OBEE-17 GLOWBUSTERS: CHASING THE INTRAMYOMETRIAL CYSTS

Leonela Panaccio (*Presenter*)
Paula Hernandez Garrigo (*Abstract Co-Author*)
Sofia Pividori, MD (*Abstract Co-Author*)
Bruno Miguel Manzanares, MD (*Abstract Co-Author*)
Silvia E. Gimenez, MS (*Abstract Co-Author*)
Diego Saez, MD (*Abstract Co-Author*)
Teresa A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Ultrasound serves as the primary diagnostic method for assessment of uterine cystic lesions due its accessibility, non-invasiveness, and cost-effectiveness. Understanding the imaging characteristics of uterine cystic lesions is essential to differentiate benign conditions—such as accessory and cavitated uterine mass (ACUM), adenomyosis, or uterine fibroids with cystic degeneration—from more complex or malignant entities like uterine sarcomas. Endometrial stromal tumors (ESTs) primarily arise in the myometrium and/or endometrium but may occasionally be found in extrauterine locations such as the ovaries or peritoneal surfaces. Preoperative diagnosis of low-grade endometrial stromal sarcoma (LGESS) is challenging due to highly variable imaging findings, often leading to confusion with benign uterine masses, such as degenerative leiomyomas. Recognizing imaging patterns specific to each differential diagnosis and its mimics is crucial for appropriate diagnosis and management.

TABLE OF CONTENTS/OUTLINE

Comprehensive Description of Imaging Findings in Intramyometrial Cysts. Comparative Analysis of Intramyometrial Cystic lesions: Ultrasound Characteristics with MRI Correlation. Role of Imaging in the Early Detection and Diagnosis of Intramyometrial Cystic Lesions. Pitfalls and Mimics: Case Examples.

OBEE-18 UNRAVELING THE SPECTRUM OF PLACENTA ACCRETA DISORDERS: WHAT EVERY RADIOLOGIST NEEDS TO KNOW

Khatya Gonzales de Holanda, BMedSc (*Presenter*)
Alessandro B. Alla, MD (*Abstract Co-Author*)
Daniella Martins, MD (*Abstract Co-Author*)
Atilio Teixeira, MD (*Abstract Co-Author*)
Flavia M. Augusto, MD (*Abstract Co-Author*)

TEACHING POINTS

Identify MRI features of placenta accreta spectrum (PAS) disorders: accreta, increta, and percreta. Recognize imaging signs that distinguish different degrees of placental invasion. Apply MRI to complement ultrasound, especially in complex or inconclusive cases. Understand the clinical impact of timely and accurate diagnosis on maternal outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction to PAS: Definition, prevalence, and clinical importance; relevance of early diagnosis. MRI Technique: Recommended sequences and protocols; value of multiplanar evaluation. Imaging Features by Type: MRI signs of accreta, increta, and percreta; correlation with depth of invasion. Key MRI Findings: T2-dark bands, abnormal placental vascularity, myometrial thinning, retroplacental interface loss, uterine contour changes, and bladder interface disruption. Diagnostic Pitfalls: Avoiding misinterpretation and artifacts; common challenges in assessment. Clinical Relevance: Role of imaging in planning delivery and surgical approach; importance of multidisciplinary coordination. Conclusion: Radiologists play a critical role in PAS diagnosis, and MRI is essential in comprehensive prenatal care.

OBEE-19 IMAGING AND STAGING OF UTERINE CANCER: PRACTICAL INSIGHTS FROM THE LATEST FIGO AND CLINICAL GUIDELINES

Sofia B. Maksoud, MD (*Presenter*)
Rubia Vanceta (*Abstract Co-Author*)
Patricia P. Cardia, MD, PhD (*Abstract Co-Author*)
Ana Paula C. Moura, MSc (*Abstract Co-Author*)
Rafaela S. Argones (*Abstract Co-Author*)
Luiza L. Soares, MD (*Abstract Co-Author*)
Giovanna S. Torre (*Abstract Co-Author*)
Kamila S. Albuquerque, MD (*Abstract Co-Author*)

TEACHING POINTS

Endometrial cancer (EC) is the second most prevalent gynecologic malignancy, with rising incidence and mortality, particularly among younger women. In 2023, over 66,000 new cases and 13,000 deaths were estimated in the U.S. The revised FIGO 2023 staging system represents a paradigm shift, integrating anatomical, pathological, and molecular features to better define prognosis and guide management. MRI remains essential preoperatively, offering key insights into prognostic factors such as myometrial invasion, cervical stromal involvement, and lymph node status. Histologically, EC subtypes include low-grade endometrioid carcinomas—considered non-aggressive—and high-grade tumors such as grade 3 endometrioid, serous, clear cell, carcinosarcomas, and others. Molecular profiling, introduced by The Cancer Genome Atlas (TCGA), categorizes tumors into four subtypes: POLEmut, MMRd, p53abn, and NSMP. These categories outperform histologic classification in prognostic stratification and are now incorporated into FIGO 2023. The updated system, supported by WHO and ESGO/ESTRO/ESP guidelines, allows for more precise sub-staging, refining treatment strategies and improving patient outcomes.

TABLE OF CONTENTS/OUTLINE

To review and illustrate the key imaging findings in uterine cancer staging and to demonstrate how recent updates in the FIGO classification and clinical protocols impact diagnostic interpretation and clinical decision-making in everyday radiologic practice.

OBEE-20 THE HIDDEN HIGHWAYS OF THE PELVIS: UNLOCKING FASCIAL ANATOMY TO GUIDE NERVE-SPARING SURGERY

Marcela C. Lauar, MD (*Presenter*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Izabela P. Franco, MD (*Abstract Co-Author*)
Karina d. Giassi, MD,PhD (*Abstract Co-Author*)
Luciana G. Matteoni-Athayde, MD (*Abstract Co-Author*)
Cicilia F. Pontes Fernandez, MD (*Abstract Co-Author*)
PENELOPE ANDRADE (*Abstract Co-Author*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Duarte M. Ribeiro, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Neural endometriosis is clinically significant, causing visceral and somatic pain, such as bladder hyperactivity/sensitivity, incontinence, dysuria, rectal pain, as well as sciatica and gluteal pain, numbness, muscle weakness and rarely foot drop. Untreated cases may progress to chronic inflammation, fibrosis, adhesions, and permanent nerve damage. Surgical excision is the standard treatment, with nerve-sparing techniques improving postoperative function and quality of life. Nerve-sparing techniques aim to reduce iatrogenic injuries, using surgically developed 'virtual spaces' which provide access to deep neurovascular structures and enable safe mobilization and separation of pelvic tissues, minimizing tissue trauma. Comprehensive pelvic fascial anatomy knowledge is vital for nerve-sparing surgery, as pelvic fascia delimit the pelvic spaces and the nerves traverse between fascial sheets. Using standardized, intuitive terms improves communication between surgeons and radiologists, ensuring precise dissection and safer procedures.

TABLE OF CONTENTS/OUTLINE

1- Female Pelvic Fascia Anatomy, including endopelvic fascia and its respective parietal, visceral and extraperitoneal subdivisions. 2- Female Pelvic avascular spaces, prevesical, and their anatomical landmarks. 3- Pelvic Neural Anatomy related to fascial planes are frequently involved in deep endometriosis. 4- Key Imaging Findings that radiologists should recognize to guide preoperative planning and help avoid complications. 5-Postoperative Imaging Appearances and potential complications associated with these procedures.

OBEE-21 A COMPREHENSIVE REVIEW OF CONDITIONS FOUND ON HYSTEROSALPINGOGRAM

Mark J. Hoegger, MD, PhD (*Presenter*)
Amanda L. Mehrsheikh, MD (*Abstract Co-Author*)
Katharina Feister, MD (*Abstract Co-Author*)
Grant Yoneoka, MD (*Abstract Co-Author*)
Douglas M. Rogers, MD (*Abstract Co-Author*)
Cary L. Siegel, MD (*Abstract Co-Author*)
Grace G. Zhu, MD (*Abstract Co-Author*)

TEACHING POINTS

Hysterosalpingogram (HSG) is a commonly performed imaging study for the evaluation of subfertility and infertility. However, the breadth of normal and disease conditions may be unfamiliar to practicing radiologists. This educational exhibit aims to: 1. Describe the technical considerations for performing diagnostic HSG. 2. Illustrate the HSG appearance of normal anatomic features of the female reproductive tract. 3. Provide a comprehensive case-based review of Müllerian duct anomalies and uterine, tubal, and peritoneal conditions identifiable with HSG.

TABLE OF CONTENTS/OUTLINE

1. Technique: patient preparation, procedural timing, cervical identification, cannulation, and patient positioning. 2. Equipment: speculum, contrast, and catheters. 3. Normal anatomy and variants: female reproductive tract anatomy with HSG, flexion, version, and normal peritoneal findings. 4. Müllerian duct anomalies: arcuate, septate, unicornuate, didelphys, and hypoplasia. 5. Tubal Conditions: pelvic inflammatory disease (PID), salpingitis isthmica nodosa (SIN), tuberculosis, and tubal

polyps. 6. Uterine Conditions: fibroids, polyps, adhesions, intravasation, adenomyosis, and iatrogenic conditions. 7. Peritoneal Conditions: loculated peritoneal collections, ovarian enlargement, uterine enlargement, and pelvic floor disorders.

OBEE-22 BEYOND THE BASICS: ADVANCED PELVIC ANATOMY IN ENDOMETRIOSIS

Martin Horwarth, MD (*Presenter*)
Eduardo Gomes de Menezes JR, MD (*Abstract Co-Author*)
Ruggeri B. Guimaraes, MD (*Abstract Co-Author*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)
Glaucy L. Neme, MD (*Abstract Co-Author*)

TEACHING POINTS

Endometriosis can infiltrate peritoneal and extraperitoneal spaces, pelvic nerves (both autonomic and somatic), fascias and vascular structures, which can be challenging for conventional image interpretation. Understanding pelvic anatomy is essential for accurately detecting and describing endometriotic lesions, as well as improving interdisciplinary communication and preoperative surgical planning. Understanding the complex anatomy of the parametrium and its adjacent avascular spaces, which are accessed during surgical dissection, is crucial for surgical planning, preventing complications and improving outcomes. Superficial endometriosis may appear as subtle peritoneal defects with associated extraperitoneal fluid, requiring careful evaluation and understanding of these spaces.

TABLE OF CONTENTS/OUTLINE

- Introduction - Pelvic anatomy and compartmentalization - Pelvic fascias - Extraperitoneal pelvic spaces - Pelvic nerves - Take home messages - References

OBEE-23 CHALLENGES IN MATERNAL IMAGING: UNVEILING PREGNANCY AND POSTPARTUM COMPLICATIONS THROUGH RADIOLOGY

Luciana Ramacho Rolim Araujo, MD (*Presenter*)
Eduardo Gomes de Menezes JR, MD (*Abstract Co-Author*)
Joao Manoel M. Santos, PhD (*Abstract Co-Author*)
Fernanda G. Velloni, MD (*Abstract Co-Author*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)
Glaucy L. Neme, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review MRI and CT features of pregnancy-related complications, from pre-conception through the postpartum period. • Highlight imaging manifestations of conditions that challenge radiologic assessment, including assisted reproduction complications, gynecologic emergencies, and postpartum disorders. • Provide practical diagnostic tips and emphasize the need for multidisciplinary collaboration in maternal care.

TABLE OF CONTENTS/OUTLINE

1. Physiologic Imaging Findings in Pregnancy and Postpartum: overview of normal MRI/CT appearances and imaging protocols during and after pregnancy.2. Complications of Assisted Reproduction: imaging features of ovarian hyperstimulation syndrome and oocyte retrieval-related issues.3. Maternal Emergencies During Pregnancy includes pelvic masses, adnexal torsion, red degeneration of fibroids, appendicitis, internal hernia, ureterolithiasis, bowel inflammation, and vascular complications.4. Postpartum Disorders: covers imaging of cesarean scar complications (dehiscence, hematoma, abscess, endometrial implants), ovarian vein thrombosis, puerperal hematoma, and hepatic adenoma rupture.5. Diagnostic Pearls and Management Considerations: practical guidance for accurate interpretation and early intervention, with a focus on teamwork across specialties.

OBEE-24 UTERINE SYNECHIAE: WHY RADIOLOGISTS SHOULD PAY ATTENTION—IMAGING INSIGHTS AND MANAGEMENT RELEVANCE

Luciana G. Matteoni-Athayde, MD (*Presenter*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Cicilia F. Pontes Fernandez, MD (*Abstract Co-Author*)
Izabela P. Franco, MD (*Abstract Co-Author*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Karina d. Giassi, MD,PhD (*Abstract Co-Author*)
PENELOPE ANDRADE (*Abstract Co-Author*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Caroline De Nicola (*Abstract Co-Author*)
Ana Luisa A. De Nicola, MD (*Abstract Co-Author*)
Bernardo Lasmar (*Abstract Co-Author*)
RICARDO LASMAR (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Uterine synechiae are intrauterine adhesions (IUAs) that distort the endometrial cavity and impair endometrial function, significantly compromising fertility .2. They are commonly developed after intrauterine procedures, trauma, or infections. Clinical manifestations may include menstrual irregularities, infertility, and recurrent pregnancy loss. 3. This condition is frequently underdiagnosed; therefore, radiologists must be familiar with its imaging features across multiple modalities to enable early detection. 4. The location and depth of intrauterine adhesions are critical factors that must be clearly assessed through imaging, as they directly influence therapeutic planning and patient counseling. 5. Accordingly, developing a reproducible and standardized imaging language to describe the site, extent, and characteristics of IUAs across various modalities is essential to guide clinical decision-making and improve patient outcomes.

TABLE OF CONTENTS/OUTLINE

Overview of Uterine Synechiae: Pathophysiology and clinical implications. Updated Classification Systems: Adhesion grading based on site and depth of injury. Multimodality Imaging Approach: · 2D Transvaginal Ultrasound (TVUS) · 3D Ultrasound · Saline Infusion Sonohysterography (SIS) · Hysterosalpingography (HSG)· Magnetic Resonance Imaging (MRI). Imaging Pitfalls and Differential Diagnosis. Correlation with Hysteroscopic Findings. Case-Based Review: From imaging diagnosis to hysteroscopic confirmation. Summary: Key imaging features and management implications.

OBEE-25 NO, IT IS NOT JUST MENSTRUAL CRAMPS! IMAGING FEATURES OF TEENAGE ENDOMETRIOSIS

Brenda Hernandes dos Santos Teixeira, MD (*Presenter*)
Martin Horwarth, MD (*Abstract Co-Author*)
Andrea d. Aranha, MD (*Abstract Co-Author*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)
Glaucy L. Neme, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Improve the knowledge of endometriosis in young patients focused on prevalence, clinical presentation, anatomy and imaging techniques using a didactic approach. 2. Highlight the importance of noninvasive diagnostic methods for early detection of endometriosis in adolescents and young adults, minimizing delays in diagnosis and improving patient outcomes. 3. Improve the understanding of imaging techniques, particularly the role of magnetic resonance imaging (MRI) as a key tool in detecting endometriotic lesions. 4. Describe biomarkers and clinical symptomatology that can be used as a support to imaging findings.

TABLE OF CONTENTS/OUTLINE

1. Definition and epidemiology of endometriosis in adolescents and young adults: importance of early diagnosis and challenges in noninvasive detection. 2. Imaging protocols for endometriosis in young patients: recommended MRI protocols and technical considerations for optimal evaluation, including the role of bowel preparation, sequence selection, and US complementation. 3. Clinical and imaging findings in young patients: common symptoms and differences from adult endometriosis presentations. 4. Noninvasive diagnostic methods focused on Magnetic Resonance Imaging (MRI) and ultrasound (US): utility in detecting deep infiltrating endometriosis. 5. Biomarkers and Laboratory Tests: current limitations and future perspectives in biomarker-based diagnosis. 6. Conclusions and "take home messages": consolidate the acquired knowledge.

OBEE-26 FROM PIXELS TO PATHOLOGY: DECODING ENDOMETRIAL CANCER SUBTYPES

Sofia Pividori, MD (*Presenter*)
Leonela Panaccio (*Abstract Co-Author*)
Lenny Paloma Ticona Pereira (*Abstract Co-Author*)
Laura L. Cardona Diaz SR (*Abstract Co-Author*)
Maria Toscano, MD (*Abstract Co-Author*)
Silvia E. Gimenez, MS (*Abstract Co-Author*)
Teresa A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Endometrial tumors include multiple histologic subtypes with varying prognosis, metastatic potential, and MRI features. Accurate characterization requires evaluating T2 signal intensity, diffusion behavior and enhancement patterns. Imaging findings were reviewed from current literature and correlated with pathology. Epithelial tumors (endometrioid carcinoma) range from low-grade polypoid to high-grade infiltrative forms, with hypovascular enhancement. Serous and clear cell carcinomas show early myometrial invasion and intense, heterogeneous enhancement. Mesenchymal tumors vary by grade: low-grade endometrial stromal sarcoma shows subtle, worm-like myometrial infiltration; high-grade stromal sarcoma forms bulky, necrotic masses with extrauterine implants. Mixed tumors have distinct MRI patterns, for example adenosarcoma shows a "Swiss cheese" architecture. While ultrasound is commonly used, it lacks specificity. MRI more effectively assesses myometrial invasion, extrauterine spread, and suspicious lymph nodes, key for staging and treatment. Radiologic-pathologic correlation improves diagnostic accuracy and supports individualized treatment.

TABLE OF CONTENTS/OUTLINE

1. Introduction. Overview of Endometrial Tumor Types. Importance of MRI. 2. MRI Findings and Pathological Confirmation: i) Epithelial Tumors: Endometrioid Carcinoma. Serous Carcinoma. Clear Cell Carcinoma. Carcinosarcoma (Malignant Mixed Müllerian Tumor). ii) Mesenchymal Tumors: Low-Grade Endometrial Stromal Sarcoma. High-Grade Endometrial Stromal Sarcoma. Undifferentiated sarcoma. iii) Mixed Tumors: Adenosarcoma 3. Discussion: Pitfalls in MRI Interpretation.4. Summary: Table.5. Conclusion

OBEE-27 CT ROLE IN GYNECOLOGIC EMERGENCIES

Valentina Garralda (*Presenter*)
Maria Candela Nieves, MD (*Abstract Co-Author*)
Lis T. Silvestri, MD,PhD (*Abstract Co-Author*)
Martina Aineseder, MD (*Abstract Co-Author*)
Mara L. Gomez, MD (*Abstract Co-Author*)
Carolina R. Chacon, MD (*Abstract Co-Author*)

TEACHING POINTS

- Gynaecological emergencies often present with non-specific abdominal symptoms, requiring a high index of suspicion for accurate diagnosis. - CT can reveal critical gynaecological findings such as ovarian torsion, pelvic inflammatory disease, hemorrhagic follicles, and ovarian vein thrombosis. - Ovarian torsion should be suspected with ovarian edema and abnormal positioning, while tubo-ovarian complexes on CT suggest pelvic inflammatory disease. - Familiarity with gynaecological pathologies on urgent CT scans improves diagnostic accuracy, speeds up treatment, and enhances interdisciplinary collaboration, ultimately helping preserve reproductive health.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Epidemiology 3. CT technique 4. Description of the characteristic CT findings of different pathologies a. Ovarian torsion b. Pelvic inflammatory disease (PID) c. Hemorrhagic follicle d. Ovarian vein thrombosis e. Ectopic tubal pregnancy f. Endometritis g. Others 5. Differential diagnosis 6. Pitfalls 7. Conclusions

OBEE-28 SURGICAL FOOTPRINTS: CLINICAL RELEVANCE OF POSTOPERATIVE UTERINE IMAGING FINDINGS

Brunna C. Oliveira, MD, MSc (*Presenter*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Izabela P. Franco, MD (*Abstract Co-Author*)
Lavinia Dias, MD (*Abstract Co-Author*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Anuradha S. Shenoy-Bhangle, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The rising average maternal age has increased the frequency of conservative uterine surgeries in scenarios where hysterectomy was previously standard. Radiologists must be aware of these procedures to accurately identify postoperative anatomy, detect complications, and recognize findings that may impact fertility or gestational outcomes.

TABLE OF CONTENTS/OUTLINE

Uterine Zonal Anatomy: Normal appearance of the endometrium, junctional zone, and myometrium on MRI and ultrasound Surgical Procedures & Imaging Features: Endometriosis resection; use of hemostatic agents (e.g., oxidized cellulose) Myomectomy, adenomyomectomy, myometrectomy Cone biopsy, trachelectomy, supracervical/total hysterectomy Cesarean section and scar assessment Curettage and manual uterine aspiration (MUA) Hysteroscopic procedures (e.g., myomectomy, polypectomy, ablation) Postoperative Complications: Myometrial thinning, uterine rupture, perforation, fistulas Secondary adenomyosis Uterine niche Vaginal vault dehiscence Pelvic adhesions Infections Didactic Cases: Multimodal imaging of normal and abnormal postoperative findings Structured Reporting: Checklist of key elements to guide clinical decisions and avoid missed findings

OBEE-29 CONGENITAL PULMONARY MALFORMATIONS: PRENATAL MRI ROLE

Mariano Lorea (*Presenter*)
Guadalupe Comadran (*Abstract Co-Author*)
Maria Agustina Vargas (*Abstract Co-Author*)
Martina Aineseder, MD (*Abstract Co-Author*)
Irene Spektor (*Abstract Co-Author*)
Horacio Aiello (*Abstract Co-Author*)
Marcelo A. Pietrani, MD (*Abstract Co-Author*)

TEACHING POINTS

Congenital chest malformations (CCM) include a group of different entities in which making a correct diagnosis is essential MRI plays a key role in characterizing pulmonary malformations Usefulness in the diagnosis and treatment of such injuries, essential in the management of these patient Evaluates neoadjuvant therapy response on changes in FDG uptake

TABLE OF CONTENTS/OUTLINE

1- Introduction a) General aspects b) Classification 2- Congenital diaphragmatic hernia (CDH) a) Epidemiological scenario b) Imaging findings c) Total fetal lung volume (TFLVo) and percentage of herniated liverd) Differential diagnosis e) Treatment3- Congenital pulmonary airway malformations (CPAM) a) Classification b) Key imaging findings. Macrocystic vs microcystic4- Bronchopulmonary sequestration (BPS) a) Classification b) Key imaging findings. Distinction between intralobar and extralobar5- Other congenital malformations a) Congenital pulmonary lymphangiectasiab) Bronchial atresia c) Bronchogenic cysts d) Congenital lobar emphysema 5- Conclusions

OBEE-30 OVARIAN SEX CORD-STROMAL TUMORS: RADIOLOGIC-PATHOLOGIC CORRELATION

Fatmaelzahraa A. Denewar, MD, PhD (*Presenter*)
Misugi Urano, MD, PhD (*Abstract Co-Author*)
Mitsuru Takeuchi, MD, PhD (*Abstract Co-Author*)
Amany Hassan (*Abstract Co-Author*)
Kazuma Murai, MD (*Abstract Co-Author*)
Ahmed Eladl (*Abstract Co-Author*)

TEACHING POINTS

Ovarian sex cord-stromal tumors are a group of neoplasms originating from primitive sex cord and stromal cells, representing 7-8% of ovarian tumors. These tumors can occur in women of all ages, exhibiting diverse clinical manifestations. Unlike epithelial ovarian tumors, sex cord-stromal tumors often present early and have a favorable prognosis with surgical treatment. Although some sex cord-stromal tumors, like fibromas, have distinct imaging features, changes such as increased cellularity, necrosis, or degeneration can pose diagnostic challenges. Other rare subtypes are particularly more confusing due to varied morphology. The rarity of these tumors also lowers suspicion, increasing the likelihood of misdiagnosis as more common epithelial ovarian cancers. Our focus is on the imaging characteristics of ovarian sex cord-stromal tumors, comparing their features to other ovarian tumors. We'll explore ultrasound, CT, and MRI findings with radiologic-pathologic correlation.

TABLE OF CONTENTS/OUTLINE

1. Introduction including the incidence and recent WHO classification of ovarian sex cord-stromal tumors. 2. Case-based review focusing on radiologic-pathologic correlation of sex-cord stromal tumors, highlighting clinical manifestations, key pathologic features, and MRI characteristics. 3. Discussion for treatment planning and prognosis.

OBEE-31 KEY INSIGHTS AND PITFALLS IN MRI OF UTERINE AND CERVICAL LESIONS

Alice Schuch, MD (*Presenter*)
Camila B. Visconti, MEd (*Abstract Co-Author*)
Natalia H. Concatto, MD (*Abstract Co-Author*)
Ariane Giovanaz (*Abstract Co-Author*)
Patricia Leal, MD (*Abstract Co-Author*)
Debora Koltermann Da Silva (*Abstract Co-Author*)
Aline S. Casagrande (*Abstract Co-Author*)
Henrique M. Guerra, MD (*Abstract Co-Author*)
Caroline L. Ghezzi (*Abstract Co-Author*)
Rubia Vanceta (*Abstract Co-Author*)

TEACHING POINTS

Uterine and cervical lesions are common in clinical practice, and MRI is pivotal for their evaluation due to its superior soft-tissue contrast and multiplanar capability. Recognizing diagnostic pearls and avoiding pitfalls is essential for optimal patient care.

TABLE OF CONTENTS/OUTLINE

Key Considerations High-quality MRI protocols (T2/T1-weighted, DWI, dynamic contrast-enhanced) are critical. Challenges include anatomical variants, pathological changes, and intrinsic lesion features (size, degeneration, hemorrhage). Poorly angled images, small/extensive lesions, and overlapping conditions (adenomyosis, leiomyomas, endometriosis) complicate diagnosis. Atypical benign or inflammatory lesions may mimic malignancy. Objective Through a case series, this study highlights common pitfalls and clarifies key doubts in uterine/cervical lesion assessment, empowering radiologists to apply MRI pearls, avoid errors, and ensure precise, clinically impactful interpretations.

OBEE-32 ENDOMETRIAL OR CERVICAL CANCER? IMAGING CLUES AND DIAGNOSTIC CHALLENGES

Camila N. Oliveira (*Presenter*)
Jose Alvaro Nascimento Paixao, MD (*Abstract Co-Author*)
Atilio Teixeira, MD (*Abstract Co-Author*)
Mariana Laranjeira Pierotti, MD (*Abstract Co-Author*)
Andreza Melloni, MD (*Abstract Co-Author*)
Flavia M. Augusto, MD (*Abstract Co-Author*)
Fabricius A. Traple SR, MD (*Abstract Co-Author*)

TEACHING POINTS

Magnetic resonance imaging (MRI) is the modality of choice for the initial evaluation of cervical and endometrial cancers , providing essential information on tumor location, size, depth of invasion, and nodal status for staging and treatment planning. Differentiating between these two entities can be challenging , especially in large pelvic tumors where anatomical landmarks are distorted. Morphologic features - such as tumor epicenter, shape, and pattern of spread - along with functional imaging (contrast enhancement and diffusion-weighted sequences) offer valuable clues to the tumors site of origin. Although histopathology remains definitive, radiologists play a key role in preoperative evaluation and management guidance.This education exhibit aims to highlight MRI features that help distinguish between cervical and endometrial cancer and to reinforce the importance of imaging in accurate staging and diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Epidemiology of endometrial and cervical cancer and the importance of accurate diagnosis for treatment planning. 2. MRI protocol: Recommended MRI sequences and their diagnostic relevance. 3. Typical Imaging Features: Key MRI characteristics of primary cervical and endometrial cancers, including tumor location, shape, stromal invasion, and pattern of locoregional spread. 4. Challenging cases: Diagnostic pitfalls and examples of tumor with overlapping features or ambiguous origin. 5. Conclusion.

OBEE-33 ENDOMETRIOSIS SCREENING IN AN ENRICHED POPULATION: ASPIRATIONAL OR ACHIEVABLE?

Soumyadeep Ghosh, MBBS, MD (*Presenter*)
Priyanka Jha, MBBS (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)
Liina Poder, MD (*Abstract Co-Author*)

Leo L. Tsai, MD, PhD (*Abstract Co-Author*)
Shravya Srinivas Rao, MD (*Abstract Co-Author*)
Avinash R. Kambadakone, MD, FRCR (*Abstract Co-Author*)
Mukesh G. Harisinghani, MD (*Abstract Co-Author*)
Anuradha S. Shenoy-Bhangle, MD (*Abstract Co-Author*)

TEACHING POINTS

Why Consider Screening? High Prevalence: Endometriosis affects approximately 1 in 10 premenopausal women Significant Morbidity: It contributes to chronic pelvic pain, infertility, and reduced quality of life Prolonged Diagnostic Delays There is a multifactorial diagnostic delay by 7-10 years How Can We Screen? Current Tools Transvaginal ultrasound (TVUS) is the most commonly used imaging modality for evaluating female pelvic symptoms and presents an opportunity to detect endometriosis during routine imaging Enhanced Techniques Maneuvers like the sliding sign and posterior cul-de-sac imaging improve detection on TVUS (SRU Consensus Statement, 2024) Who Should Be Screened? Targeted Approach: Given the high specificity but lower sensitivity of current imaging modalities (TVUS and MRI), screening should be directed at pre- or perimenopausal women with clinical symptoms or examination findings suggestive of endometriosis

TABLE OF CONTENTS/OUTLINE

A. Criteria for Effective Endometriosis Screening Disease related Screening test related Management related B. Framework for a Successful Screening Program Define the enriched population Promote awareness among patients, technologists, and radiologists Utilize TVUS as a primary screening tool Employ advanced imaging modalities (e.g., bowel-prepped TVUS and/or pelvic MRI) when needed Foster communication with referring clinicians through standardized templates C. Rationale for Screening High disease prevalence Unacceptable diagnostic delays Economic and emotional burden on patients and healthcare systems Improved outcomes with timely intervention Potential prevention of long-term complications, including malignant transformation

OBEE-34 IMPLANTATION MISSION: IMPOSSIBLE — WHEN BEING IN THE UTERUS IS NOT ENOUGH

MARTIN CALVO (*Presenter*)
Marcela Cimmino (*Abstract Co-Author*)
Ana Maria Javadi Nia (*Abstract Co-Author*)
Mailen Sarobe, MD (*Abstract Co-Author*)
Diego Saez, MD (*Abstract Co-Author*)
Silvia E. Gimenez, MS (*Abstract Co-Author*)

TEACHING POINTS

Always suspect an intrauterine ectopic pregnancy when the gestational sac is low, eccentric, or immobile. Evaluate vascularization with color Doppler: intense peritrophoblastic flow suggests active trophoblastic tissue. Use MRI when ultrasound findings are atypical or inconclusive. Avoid dilation and curettage (D&C) if there is any suspicion of an ectopic implantation within the uterus — the risk of life-threatening hemorrhage is high. Look for specific signs: Interstitial line sign ? Interstitial pregnancy Fixed sac below the internal os ? Cervical pregnancy Sac implanted in anterior lower segment scar ? Cesarean scar pregnancy Sac fully surrounded by myometrium, no endometrial connection ? Intramural pregnancy

TABLE OF CONTENTS/OUTLINE

Introduction Definition and relevance of ectopic uterine pregnancies Interstitial Pregnancy Ultrasound and MRI findings - surgical compatibility. Cervical Pregnancy Ultrasound and MRI characteristics - therapeutic implications. Pregnancy in Cesarean Section Scar Image presentation and treatment options. Intramural Pregnancy Ultrasound diagnosis and surgical considerations. Diagnostic Pitfalls Differentiation between ongoing miscarriage and other entities. Conclusions References and Acknowledgments

OBEE-35 SEEING THE WHOLE PICTURE: MUSCULOSKELETAL FINDINGS IN FEMALE PELVIC IMAGING

Luis R. Ferreira de Souza, MD, PhD (*Presenter*)
Patricia P. Cardia, MD, PhD (*Abstract Co-Author*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
Isadora Balderama Canedo, MD (*Abstract Co-Author*)
Marcelo Amaral, MD (*Abstract Co-Author*)
Thalyne Lima (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)
Marcello H. Nogueira-Barbosa, MD, PhD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

With relative frequency, patients undergoing pelvic imaging exams present musculoskeletal findings that may raise diagnostic uncertainties and pose challenges for the abdominal radiologist. These findings can be physiological and act as potential pitfalls in image interpretation, such as perineural cysts. Alternatively, they may reflect underlying disease processes or previously undiagnosed symptomatic conditions, including infiltrative bone marrow lesions, avascular necrosis, osteomyelitis, and bursitis, among others.Given this scenario, the abdominal radiologist plays a crucial role in recognizing and accurately describing these findings, as they may significantly impact patient management and clinical decision-making.The primary objective of this exhibit is to review the most relevant musculoskeletal findings and pathologies that may be incidentally detected in pelvic imaging studies, aiming to provide practical diagnostic tips to aid radiologists in accurate identification and differentiation of these entities, thereby enhancing diagnostic confidence and avoiding common interpretative pitfalls.

TABLE OF CONTENTS/OUTLINE

Introduction; Objectives; Main musculoskeletal pathologies found on pelvic imaging exams illustrated by cases from our institutions; Diagnostic approach; Conclusion

OBEE-36 POST-RADIATION THERAPY CHANGES AND COMPLICATIONS IN CERVICAL CANCER

Camila N. Oliveira (*Presenter*)
Jose Alvaro Nascimento Paixao, MD (*Abstract Co-Author*)
Atilio Teixeira, MD (*Abstract Co-Author*)
Andreza Melloni, MD (*Abstract Co-Author*)
Mariana Laranjeira Pierotti, MD (*Abstract Co-Author*)
Mateus Rodrigues De Lima (*Abstract Co-Author*)
Fabricius A. Traple SR, MD (*Abstract Co-Author*)

TEACHING POINTS

Cervical cancer remains a significant global health issue, and radiation therapy plays a central role in its treatment , particularly in locally advanced stages. As survival rates improve, post-treatment imaging has become essential for assessing therapeutic response, detecting recurrence, and identifying complications. Magnetic resonance imaging (MRI) is the modality of choice for post-radiation follow-up due to its excellent soft tissue contrast and multiplanar capability. However, interpretation can be challenging. Radiation induces a spectrum of expected changes in pelvic organs - including the cervix, uterus, bladder, rectum, and bone marrow - that may mimic tumor recurrence or obscure early complications. This educational exhibits reviews the typical MRI appearances of the post-treatment pelvis and highlights common post-radiation complications such as fistulas, fibrosis and strictures. Differentiating expected post-therapy changes from true pathological findings is essential for accurate diagnosis, avoiding pitfalls, and guiding management.

TABLE OF CONTENTS/OUTLINE

1. Introduction: overview of cervical cancer, female pelvis anatomy, and the role of MRI in post-treatment follow-up. 2. MRI protocol key sequences for post-treatment pelvic MRI evaluation. 3. Expected Post-Radiation Findings typical imaging appearances of the cervix, uterus, bladder, rectum, and bone marrow. 3. Radiation-related complications common and uncommon findings such as fistulas, fibroses and strictures. 4. Tumor recurrence imaging clues suggestive of recurrence. 5. Conclusion practical tips to improve diagnostic confidence and avoid pitfalls.

OBEE-37 NAVIGATING THE NUANCES: A COMPARATIVE STUDY OF NORMAL AND ABNORMAL PREGNANCY LOCATIONS - A PICTORIAL REVIEW

Alexandra M. Davis, MD (*Presenter*)
Chris N. Gu, MD (*Abstract Co-Author*)
Janelle Santos (*Abstract Co-Author*)
Ann Packard, MD (*Abstract Co-Author*)

TEACHING POINTS

1. First trimester ultrasound (US) is key in establishing pregnancy viability, number, and location. 2. Normal pregnancy implantation includes intrauterine and intrauterine eccentric variants 3. Locations of ectopic pregnancy implantation includes cervical ectopic, cesarean scar ectopic, intramural ectopic, interstitial ectopic, tubal ectopic, ovarian ectopic, and abdominal ectopic, which are sometimes mistaken for normal implantation or other pathologies.

TABLE OF CONTENTS/OUTLINE

1. Review the indications for first trimester US including the importance of ß-hCG and pregnancy of unknown location. 2. Recognize the normal appearance of an intrauterine pregnancy (IUP) of the first trimester. 3. Review the non-ectopic locations for pregnancy implantation including intrauterine and eccentric variant IUP and helpful radiologic signs such as double decidual sac sign and intradecidual sign. 4. Review a common pitfall comparing and contrasting eccentric IUP and interstitial ectopic pregnancy. 5. Examination of a case of cesarean section scar ectopic and potential complications. 6. Comparison of ultrasound evaluation of adnexal ectopic pregnancy versus a corpus luteum.

OBEE-38 ENDOMETRIOSIS IMPOSTORS CLUB: WHO'S FOOLING RADIOLOGISTS?

Talessa Cometi De Oliveira, MD (*Presenter*)
Cristiane R. Costa (*Abstract Co-Author*)
Martin Horwarth, MD (*Abstract Co-Author*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)
Glaucy L. Neme, MD (*Abstract Co-Author*)

TEACHING POINTS

Not all T1-hyperintense or fibrotic lesions in the pelvis and abdomen represent endometriosis and recognizing key mimics is essential to avoid misdiagnosis. Correlating lesion morphology, signal intensity, location, and patient demographics is crucial to differentiate endometriosis from look-alike entities such as tumors, abscesses, and benign fibrous lesions. A systematic imaging approach, combined with clinical suspicion and knowledge of typical mimics, enhances diagnostic accuracy and prevents unnecessary surgical interventions.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Pelvic mimics of endometriosis 3. Abdominal wall and extraperitoneal mimics 4. Uncommon and surprising mimics 5. Take-home messages 6. References

OBEE-39 GYN CANCERS UNDER THE KNIFE: A RADIOLOGIC QUIZ FOR SURGICAL DECISION-MAKING

Andrea d. Aranha, MD (*Presenter*)
Valesca B. Monteiro, MD (*Abstract Co-Author*)
Pedro Naime B. Araujo I, MD (*Abstract Co-Author*)

TEACHING POINTS

Accurate imaging interpretation is essential for the surgical management of gynecologic malignancies. This educational exhibit uses a quiz-based format to highlight imaging features that directly impact surgical decisions in cancers of the endometrium, cervix, ovary, and vulva. Learners will identify key imaging questions surgeons need answered, recognize common diagnostic pitfalls, and understand the implications of FIGO staging updates and the expanding role of MRI and CT in preoperative planning.

TABLE OF CONTENTS/OUTLINE

Introduction. Overview of gynecologic oncology staging and surgical goals. Imaging questions that guide surgery by tumor site: *• Endometrium: depth of invasion, cervical stromal involvement *• Cervix: parametrial invasion, pelvic sidewall, vaginal extension *• Ovary: peritoneal disease, resectability criteria *• Vulva: tumor extension, urethral involvement. * Lymph node status and the new role of imaging in FIGO staging. * Quiz-based case review. *Imaging pitfalls and pearls. *Prognostic factors. Take-home messages.

OBEE-40 ROLE OF ULTRASOUND IN PREOPERATIVE ASSESSMENT AND SURGICALPLANNING OF ENDOMETRIOSIS

Eduardo A. Soares, MD (*Presenter*)

TEACHING POINTS

Transvaginal ultrasound (TVUS) is the preferred, minimally invasive imaging technique to detect and map endometriosis, with high sensitivity and specificity for ovarian and deep infiltrating lesions. Accurate preoperative TVUS enables identification of lesion location and extent, prediction of surgical complexity, and involvement of multidisciplinary teams (e.g., colorectal or urological surgeons when bowel or bladder are affected). Ultrasound-based staging systems and techniques like the sliding sign and posterior compartment assessment enhance detection of adhesions and deep lesions, improving surgical completeness and patient outcomes. Findings support personalized therapeutic planning, including risk counseling, fertility preservation, and referral to specialized centers.

TABLE OF CONTENTS/OUTLINE

Importance of Preoperative Imaging Techniques and Diagnostic Accuracy Mapping and Staging of Ovarian and Deep Endometriosis Predicting Surgical Complexity and Team Planning Counseling and Individualized Management New Protocols and Consensus Guidelines

OBEE-41 DEEP PELVIC ENDOMETRIOSIS INDEX MAGNETIC RESONANCE IMAGING SCORE (DPEI): WHAT THE RADIOLOGIST NEEDS TO KNOW?

Ana Claudia Vincenzi Raduan Uski (*Presenter*)
Marilia P. Ferreira, MD (*Abstract Co-Author*)
Maria Helena N. Pedroso (*Abstract Co-Author*)
Marina M. Costa (*Abstract Co-Author*)
Virginia d. Goncalves, MD (*Abstract Co-Author*)
Hilton M. Leao Filho, MD, PhD (*Abstract Co-Author*)

Ananda P. Araujo, MD (*Abstract Co-Author*)
Filipe Chaves, BMedSc (*Abstract Co-Author*)
Lhuanna Maria Barbosa Teixeira, MD (*Abstract Co-Author*)
Gustavo Hoff Ussami (*Abstract Co-Author*)
Carolina P. Abud, MD (*Abstract Co-Author*)

TEACHING POINTS

Pelvic endometriosis is a chronic inflammatory gynecologic disorder that may lead to chronic pelvic pain, dysmenorrhea, dyspareunia, gastrointestinal or urinary dysfunction, and infertility. Magnetic resonance imaging (MRI) plays a pivotal role in detecting and assessing the extent of disease. The Deep Pelvic Endometriosis Index (dPEI) classification assists in surgical risk stratification. In brief, the pelvis is divided into nine anatomically defined compartments. One point is assigned for each deep endometriosis (DE) lesion identified per compartment, regardless of lesion size. An additional point is given if the lesion extends beyond the parietal fascia in the lateral compartment. Based on the final score, the disease is classified as mild, moderate, or severe.This review aims to familiarize radiologists with the routine application of the dPEI score, which demonstrates good accuracy and reproducibility, and supports preoperative planning and the prediction of potential postoperative complications.

TABLE OF CONTENTS/OUTLINE

Introduction;Objectives;Radiologic cases with clinical and/or surgical correlation;Conclusion / take home messageReferences

OBEE-42 PLACENTAL PATHOLOGY THROUGH LENS OF IMAGING DIAGNOSTIC INSIGHTS AND CLINICAL IMPLICATIONS

Flaminia Frezza, MD (*Presenter*)
Valentina Miceli, MD (*Abstract Co-Author*)
Marco Gennarini (*Abstract Co-Author*)
Sandrine Riccardi (*Abstract Co-Author*)
Roberta V. Ninkova, MD (*Abstract Co-Author*)
Chiara Amoroso (*Abstract Co-Author*)
Federica Curti, MD (*Abstract Co-Author*)
Claudia Cutonilli, MD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize key MRI features of common and critical placental disorders, as Placenta Previa, Placenta Accreta Spectrum, Placental Abruption and Tumors• Appreciate the role of MRI in patients management • Placenta PreviaClassification based on distance from OCI (lateral, marginal and central partial or complete)Ultrasound is the gold standard for the diagnosis. • Placenta Accreta Spectrum Includes: accreta (adherence to myometrium), increta (invasion into myometrium), percreta (penetration beyond serosa) MRI evaluates depth of invasion and assist in the delivery planningContrast agent in same cases can be used.• Placental Abruption: In the majority of cases it can lead hemorrhage and compromise fetal blood supply.Classified as mild and sever.Ultrasound is the gold standard for diagnosis, as it can identify retroplacental hematoma. • Placental TumorsBenign, as chorioangioma and hydatidiform mole and malignant as the gestational trhophoblastic neoplasia (choriocarcinoma).

TABLE OF CONTENTS/OUTLINE

1. Introduction Overview of Common Placental Disorders Role of Radiology2. Placenta previa Classification Imaging Techniques and Diagnostic Criteria3. Placenta Accreta Key imaging Findings for Radiologists Implications for Delivery Planning and Management4. Placental Abruption Role of Ultrasound and MRI in Diagnosis5. Placental Tumors Benign Tumorso Malignant Tumors Imaging Features in the Hydatidiform Mole6. Conclusions Summary of Imaging's Role in Placental Disorders

OBEE-43 ENZIAN AND THE CHOCOLATE FACTORY. AN ENDOMETRIOSIS 2025 MUST

Sandra Victoria Servin Baltierra, MD (*Presenter*)
Yeni Fernandez de Lara Barrera, MD (*Abstract Co-Author*)
Maria Jose Becerril Barrientos, MD (*Abstract Co-Author*)

TEACHING POINTS

1.Highlight the endometriosis phenotypes; 2.Demonstrate the value of the ENZIAN system in describing deep endometriosis; 3.Detail the ENZIAN classification with numerous real cases with imaging and surgical correlation; 4.Establish the recommendations of laparoscopy (no longer the gold standard for diagnosis) in whose patients have negative imaging results and/or where empirical treatment has failed or has been inappropriate.

TABLE OF CONTENTS/OUTLINE

1.Introduction to endometriosis phenotypes; 2.Diagnostic paradigm shift; 3.ENZIAN Classification: A radiologist´s guide; 4.MRI Endometriosis Mapping Protocol; 5.Imaging Findings and ENZIAN correlation by case-based learning; 6.Pitfalls & mimics; 7.Multidisciplinary impact.

OBEE-44 MISSION IMPOSSIBLE. WHY CAN'T I GET PREGNANT? DECODING THE HIDDEN FINDINGS IN FEMALE INFERTILITY IMAGING

Sandra Victoria Servin Baltierra, MD (*Presenter*)
Omar A. Gamboa Abundis, MD (*Abstract Co-Author*)

TEACHING POINTS

1.Infertility is becoming a public health issue in developed countries; 2.Infertility in females is multifactorial in origin. The pelvic causes are: tubal, uterine and ovarian; 3.The imaging findings help direct subsequent patient care; 4.The selected imaging methods to assess this are hysterosalpingography, pelvis ultrasound, hysterographic ultrasound and pelvic magnetic resonance imaging; 5.Illustrated examples of each of the infertility imaging findings as fallopian tube abnormalities, endometriosis, intrauterine filling defects, uterine contour irregularities, mullerian duct anomalies, cervical and ovarian abnormalities; 6.Imaging methods represent the pathway to assess female infertility; 7.This pictorial review shows multiple imaging findings while evaluating female infertility.

TABLE OF CONTENTS/OUTLINE

1.Introduction to female infertility; 2.Imaging modalities and clinical utility; 3.Anatomical causes; 4.Imaging pathway for infertility; 5.Illustrated imaging findings; 6.Pitfalls and limitations; 7.Different imaging method findings correlation; 8.Take home messages.

OBEE-45 ABDOMINOPELVIC COMPLICATIONS OF GYNECOLOGIC MALIGNANCY: ESSENTIALS FOR RADIOLOGISTS

Sara Hassanzadeh, MD (*Presenter*)
Yuliya Lakhman, MD (*Abstract Co-Author*)
Elizabeth A. Sadowski, MD (*Abstract Co-Author*)
Atul B. Shinagare, MD (*Abstract Co-Author*)
Stephanie Nougaret, MD, PhD (*Abstract Co-Author*)
Benedetta Gui, MD (*Abstract Co-Author*)
Lucia Manganaro, MD (*Abstract Co-Author*)
Katherine E. Maturen, MD, MS (*Abstract Co-Author*)
Stefania Rizzo, MD, PhD (*Abstract Co-Author*)
Evis Sala, MD, PhD (*Abstract Co-Author*)
Pamela I. Causa Andrieu, MD (*Abstract Co-Author*)
Aradhana Venkatesan, MD (*Abstract Co-Author*)

TEACHING POINTS

?To recognize pre-therapy tumor-related abdominopelvic complications of gynecologic malignancy, including those related to: locoregional invasion, tumor rupture, hypercoagulability, and secondary infection ?To identify the post-therapy abdominopelvic complications encountered in gynecologic cancer patients, specific to treatment modality, and to distinguish these from expected post-treatment sequelae: oPost-operative complications (e.g., postoperative ileus, fistulas, lymphocele, wound infection) oPost radiation complications (e.g., radiation enteritis, bladder dysfunction, pelvic insufficiency fractures) oComplications following systemic chemotherapy? Cytotoxic chemotherapy? Targeted therapies (e.g., myelosuppression, neutropenic enterocolitis, bowel perforation, nephrotoxicity) oComplications of immunotherapy (e.g., colitis, enteritis, hepatitis, pancreatitis) ?CT is a first-line modality due to its accessibility and high accuracy. MRI is superior for fistulas, tumor recurrence, and radiation-related changes. US is helpful for hydronephrosis, lymphoceles, and pelvic collections. PET/CT aids in distinguishing recurrence from post-therapy effects.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of gynecologic malignancies and their abdominopelvic complications Role of radiology Pre-treatment tumor-related Complications Post-therapy Complications Conclusion Summary of imaging insights and impact on patient care Methodology: Case-Based illustrative exhibit highlighting classic and uncommon complications and interpretive challenges.

OBEE-46 ROUND LIGAMENT OF UTERUS - A ROPE WALK !!

Aruna R. Patil, MD, FRCR (*Presenter*)
Harshita Ramamurthy (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)

TEACHING POINTS

The round ligaments of the uterus are a pair of fibromuscular cord-like structures derived from the gubernaculum and serve as a secondary support system for the uterus. The round ligaments have varied clinical and surgical implications which are underestimated and underutilized in clinical practice. This exhibit will review: • Embryology of round ligaments and related structures • Surgical and Imaging anatomy of the round ligaments • Pathologies affecting the round ligaments • Imaging features of pertinent conditions

TABLE OF CONTENTS/OUTLINE

The involvement of round ligaments by pathological processes is underestimated. They are involved in spreading diseases, as sites for primary neoplasms, and serve as landmarks in differentiating lesions. The exhibit aims to include: • Embyrology • Surgical anatomy • Surgical implications - plication, oophoropexy • Imaging anatomy - USG, CT, MR • Round ligaments as landmark - differentiate interstitial from angular pregnancy, true and pseudo broad ligament fibroids, ACUM, rudimentary horns, aid in diagnosis of unicornuate uterus, differentiate appendicular and tubo-ovarian abscess • Pathologies of Round ligaments: infection, endometriosis (with details on compartmentalisation and scoring systems), varices, benign tumors - leiomyoma, mesothelial cyst, lipoma, malignant tumors - leiomyosarcoma, secondary spread of endometrial, cervical, ovarian, gastric, and gallbladder carcinomas • Canal of Nuck pathologies - hydrocele (different types and imaging manifestations), hernias - infantile/ adult - ovarian and intestinal contents

OBEE-48 PATTERNS OF RECURRENCE FOR CERVICAL, ENDOMETRIAL AND OVARIAN CANCER: WHAT THE RADIOLOGIST NEEDS TO KNOW

Aradhana Venkatesan, MD (*Presenter*)
Anugayathri Jawahar, MD (*Abstract Co-Author*)
Ekta Maheshwari, MD (*Abstract Co-Author*)
Stephanie Nougaret, MD, PhD (*Abstract Co-Author*)
Yuliya Lakhman, MD (*Abstract Co-Author*)
Benedetta Gui, MD (*Abstract Co-Author*)
Melissa J. McGettigan, MD (*Abstract Co-Author*)
Aki Kido, MD, PhD (*Abstract Co-Author*)
Lucia Manganaro, MD (*Abstract Co-Author*)
Atul B. Shinagare, MD (*Abstract Co-Author*)
Katherine E. Maturen, MD, MS (*Abstract Co-Author*)
Elizabeth A. Sadowski, MD (*Abstract Co-Author*)
Stefania Rizzo, MD, PhD (*Abstract Co-Author*)
Rosemarie Forstner, MD (*Abstract Co-Author*)
Teresa M. Cunha, MD (*Abstract Co-Author*)
Evis Sala, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Overview: • Recognize common and atypical recurrence patterns for the top 3 most common gynecologic malignancies: cervical, endometrial and ovarian cancers. • Understand how histology and treatment impact recurrence patterns, using case-based examples. Cervical and Endometrial Cancer: • Recurrence is often local (cervix, vaginal apex) or locoregional (pelvic sidewall, pelvic/para-aortic nodes). • Histology and prior treatment influence recurrence pattern and salvage therapy. • Higher recurrence risk with advanced stage, adjacent organ invasion or nodal involvement. Ovarian Cancer: • Recurs in pelvis or peritoneal recesses, along pathways of normal peritoneal fluid flow. • Pattern varies with primary therapy: upfront cytoreduction vs. neoadjuvant chemo and interval debulking. • Maintenance therapy influences recurrence: bevacizumab linked to nodal, liver, lung recurrences; PARP inhibitors linked to peritoneal, nodal, hepatic recurrences. • Bevacizumab-related toxicity associated with extensive bowel involvement, muscularis invasion and rectovaginal tumor. • Oligometastatic recurrences: Evaluate organ/vascular involvement to assess suitability for secondary cytoreduction. Imaging: MRI and PET are vital to cervical and endometrial cancer recurrence detection; CT or MRI for ovarian cancer recurrence detection. PET aids in whole body staging and distinguishing recurrence from post-therapy changes.

TABLE OF CONTENTS/OUTLINE

Introduction Overview of recurrence patterns Role of imaging Cervical Cancer Patterns of Recurrence Endometrial Cancer Patterns of Recurrence Ovarian Cancer Patterns of Recurrence Salvage Therapies and Imaging Considerations Reporting Essentials Conclusion

OBEE-49 SCAN AND UNDERSTAND: THE LANGUAGE OF EARLY PREGNANCY LOSS

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Alejandro Gonzalez, BS (*Abstract Co-Author*)
Larry M. Alejandro Vargas, MD (*Abstract Co-Author*)
Karla Martin Ortiz (*Abstract Co-Author*)
Wilma Rodriguez-Mojica, MD (*Abstract Co-Author*)

TEACHING POINTS

Provide an anatomical review of the uterus and early pregnancy findings. Review how ultrasound plays a crucial role in differentiating between early pregnancy loss (EPL) types based on first-trimester findings. Explain how each type of EPL, and ectopic pregnancy presents unique ultrasound characteristics. Discuss the proper use of first-trimester ultrasound terminology and how it fosters clearer communication and reduces patient distress.

TABLE OF CONTENTS/OUTLINE

Introduction Objectives Anatomy Review Normal pregnancy findings Ultrasound Features of EPL Concerning for EPL Diagnostic EPL In progress EPL Incomplete EPL Complete EPL Ectopic pregnancy findings Preferred vs. Avoided Terminology Conclusion EPL, also referred to as miscarriage, is the loss of pregnancy during the first 13

weeks of pregnancy, and a complex and emotionally charged medical condition requiring precise and sensitive terminology. Accurate identification and description of EPL types are critical for proper diagnosis, management, and communication. This presentation focuses on standardizing first-trimester ultrasound terminology to avoid stigma and confusion. It also reviews ultrasound features of normal early pregnancy, different EPL types, and ectopic pregnancy to aid radiologists and clinicians in delivering accurate care.

OBEE-50 DIAGNOSTIC VALUE OF OPTIMIZED ADDITIONAL MRI SEQUENCES TO GET CLOSER TO THE TRUE NATURE OF GYNECOLOGIC DISEASES

Mayumi Takeuchi, MD, PhD (*Presenter*)
Kenji Matsuzaki, MD, PhD (*Abstract Co-Author*)
Masafumi Harada, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. MRI is a crucial problem-solving tool for diagnosing gynecologic disorders, however, routine protocols may not always provide sufficient diagnostic accuracy. This exhibit reviews case-based strategies for optimizing additional MRI sequences to characterize gynecologic diseases better. 2. Various advanced MRI techniques provide key insights: 1) 3D-T2WI: High spatial resolution and multiplanar capability reveal internal structures of pathologies and relationships with adjacent organs. 2) Reduced FOV DWI (FOCUS) /Multi-shot DWI (MUSE): High spatial resolution with minimal distortion enables precise assessment of tumor size and extent, enhances the detection of small malignant foci, and minimizes the T2 shine-through effect when combined with high b-value computed DWI. 3) Dynamic MRI: Highlights hypervascular features of malignancies, functional tumors, and gestational lesions. TIC analysis is helpful for risk stratification of tumors. 4) Contrast-enhanced (CE) Subtraction: Aids in evaluating malignant foci or clots in T1-high cysts such as endometrioma or mucinous cystadenoma. 5) Dixon Method: Useful for assessing both fat-rich and fat-poor pathologies. 6) (T2*-based) Susceptibility-WI (SWI): Sensitive to hemorrhagic necrosis in high-grade malignancies, hemosiderin deposits in endometriosis, and thrombus in adnexal torsion or red degeneration of leiomyomas. 7) MR Spectroscopy (MRS): Provides metabolic information, including proliferative activity, necrosis, mucin content, and anaerobic infection contributing to tissue-specific diagnosis.

TABLE OF CONTENTS/OUTLINE

3D-T2WI; Reduced FOV DWI /Multi-shot DWI; Computed DWI; Dynamic MRI; CE subtraction; SWI; Dixon method; MRS

OBEE-51 INTERSTITIAL ECTOPIC PREGNANCY: DIAGNOSIS, DILEMMAS, DANGERS

Mindy M. Horrow, MD (*Presenter*)
Maria Grigovich, MD (*Abstract Co-Author*)
Shuchi K. Rodgers, MD (*Abstract Co-Author*)

TEACHING POINTS

1. IEP is an implantation in the interstitial fallopian tube which extends from the tubal ostium through the myometrial wall 2. IEP accounts for 2-5% of all ectopic pregnancies 3. IEP has a higher morbidity and mortality than tubal EP since the greater capacity of the interstitial tube to accommodate the sac and rich myometrial vascularity may result in a more advanced pregnancy that can rupture with catastrophic hemorrhage 4. Early eccentric IUPs can be mistaken for an IEP possibly resulting in mistreatment 5. Later IEPs can be mistaken for the common tubal EPs. 6. Signs for the diagnosis of IEP include claw sign, myometrial bar, interstitial line sign 7. Helpful techniques for the diagnosis of IEP: coronal reformat, cine clip, sliding sign

TABLE OF CONTENTS/OUTLINE

1. Background a. Demographics b. Terminology c. Importance of differentiating interstitial ectopic pregnancy (IEP) from more common tubal ectopic pregnancy (EP) 2. Anatomy and appearance of interstitial fallopian tube a. On routine pelvic US with 3D, HSG and saline infusion sonohysterography with intracavitary CEUS b. With Essure device c. Interstitial hydrosalpinx 3. Diagnosis of IEP a. Interstitial line sign b. Thickness of overlying myometrium c. Myometrial bar d. Claw sign e. Techniques i. 3D coronal reformat, cine clip ii. Color Doppler: Vascularity arising from myometrium iii. Sliding technique 4. US appearances of IEP through 1st trimester a. Early b. Late 5. Ruptured IEP 6. How to differentiate IEP from other diagnoses with similar appearances a. Eccentric intrauterine pregnancy (IUP) vs early IEP b. Tubal EP vs later IEP c. IUP in uterus with Mullerian duct anomaly d. Subserosal myoma e. Eccentric corpus luteum 7. Treatment a. Surgical b. Medical c. Other

OBEE-52 DON'T LET YOUR DIAGNOSTIC SKILLS GO DOWN THE TUBES: A REVIEW OF FALLOPIAN TUBE PATHOLOGY

Erika Pianin, DO (*Presenter*)
Justin S. Alpert, MD (*Abstract Co-Author*)

TEACHING POINTS

The fallopian tubes play an integral role in female reproductive health and fertility, yet are frequently overlooked in imaging studies, primarily because they are difficult to visualize when normal. This can make identification of fallopian tube pathology particularly challenging. This educational exhibit aims to strengthen understanding of normal and abnormal appearances of the fallopian tubes, with the following teaching points: (a) Understand the anatomy and function of the fallopian tubes. (b) Understand the importance of recognizing fallopian tube pathology. (c) Gain familiarity with the imaging modalities commonly used in diagnosing fallopian tube pathologies. (d) Learn how to diagnose various fallopian tube pathologies using radiologic imaging.

TABLE OF CONTENTS/OUTLINE

(a) Fallopian tube anatomy and function. (b) Importance of recognizing fallopian tube pathology in regards to reproductive and overall health. (c) Pertinent imaging modalities used to identify various fallopian tube pathologies. (d) Definition, common symptoms, and imaging findings of various fallopian tube pathologies, including: Hydrosalpinx and hematosalpinx, Tubal ectopic pregnancy, Salpingitis isthmica nodosa, Tubal occlusion, Tubal endometriosis, Pelvic inflammatory disease (tubo-ovarian abscess and pyosalpinx), Neoplasm (tubal leiomyoma and tubal carcinoma), Congenital anomalies (agenesis and unicornuate uterus). (e) Conclusion. (f) References.

OBEE-53 ENHANCED MYOMETRIAL VASCULARITY: WHAT, WHERE AND WHEN TO TREAT?

Maria Grigovich, MD (*Presenter*)
Anna S. McKenney, MD,PhD (*Abstract Co-Author*)
Mindy M. Horrow, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Enhanced myometrial vascularity is the presence of abundant tortuous myometrial vessels with high-velocity flow, observed during or after completion of a pregnancy at any gestational age. 2. The terms EMV and acquired AVM should not be used interchangeably as the management might differ. While the sonographic appearance of both entities is similar, early venous drainage is typical for AVM and absent in EMV. 3. In setting of bleeding, prior intervention and focal area of markedly increased EMV on US, MRA and DSA may be suggested for further evaluation. 4. EMV management is variable and depends on the degree of bleeding, presence of associated RPOC or ectopic pregnancy. 5. Number of conditions/lesions may mimic EMV.

TABLE OF CONTENTS/OUTLINE

1. Controversy of the term "enhanced myometrial vascularity" (EMV) in literature 2. Proposed definition 3. Diagnostic ultrasound criteria 4. Peak systolic velocity as a potential predictor of bleeding risk and management 5. EMV and acquired arteriovenous malformation (AVM) - is there a difference? Role of MRI/MRA. 6. EMV in normal pregnancy/normal physiologic remodeling of placental bed 7. EMV associated with RPOC 8. EMV associated with uterine ectopic pregnancy (EP): - Cesarean section EP - Cervical EP - Interstitial EP 9. Differential diagnosis and mimics: - Gestational trophoblastic disease - Pseudoaneurysm - Fibroids/neoplasms - Adenomyosis - Endometritis - Varices 10. Management: - Expectant - Medical - IR embolization - Surgery 11. Conclusion and proposed terminology for radiology reports

OBEE-54 REPORTING NON-GYNECOLOGICAL PELVIC MASS: HOW TO DO IT

de Souza, MD, PhD (*Presenter*)
Patricia Leal, MD (*Abstract Co-Author*)
Caroline L. Ghezzi (*Abstract Co-Author*)
Ana Paula C. Moura, MSc (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Provide a concise review of female pelvic anatomy.Outline a systematic approach for assessing non-gynecological pelvic lesions in women. Emphasize optimal imaging modality selection and precise lesion localization within pelvic compartments.Describe the characteristic imaging features of common non-gynecological pelvic tumors and key differential diagnoses.Correlate MRI findings with histopathological diagnoses to enhance diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

Introduction Accurate assessment of large pelvic lesions requires careful consideration of the anatomical positioning of pelvic organs within these compartments, as this spatial understanding is crucial for establishing or narrowing the differential diagnosis through imaging. Pelvic Compartments and Common Non-Gynecological Lesions Extraperitoneal Compartment Anterior Leiomyoma/Bladder cancer/Urethral diverticulum and fibroid/Posterior Rectal cancer/Teratoma/Myelolipoma/Tailgut cyst/Neurogenic tumors/ Bone tumors -Intraperitoneal Compartment Appendiceal mucocele/Pelvic abscess/Abdominal tuberculosis/Pseudomyxoma peritonei/ Peritoneal inclusion cyst/Lymphocele Conclusion : A structured approach to evaluating large pelvic masses is essential for radiologists to reach an accurate diagnosis. Recognizing compartmental anatomy and selecting the appropriate imaging modality are critical for narrowing the differential diagnosis and guiding clinical management. By focusing on specific imaging characteristics and their correlation with potential pathologies, clinicians can better inform treatment plans and patient outcomes.

OBEE-55 EXPLORING UNUSUAL SITES OF ENDOMETRIOSIS

Hideyuki Fukui, MD, PhD (*Presenter*)
Takahiro Tsuboyama, MD (*Abstract Co-Author*)
Hiromitsu Onishi, MD, PhD (*Abstract Co-Author*)
Takashi Ota, MD, PhD (*Abstract Co-Author*)
Toru Honda, MD (*Abstract Co-Author*)
Kengo Kiso (*Abstract Co-Author*)
K. Kaketaka (*Abstract Co-Author*)
Takumi Tanigaki, MD (*Abstract Co-Author*)
Eriko Yoshidome, MD (*Abstract Co-Author*)
Masatoshi Hori, MD, PhD (*Abstract Co-Author*)
Mitsuaki Tatsumi, MD, PhD (*Abstract Co-Author*)
Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

* Recognize the imaging features of endometriosis beyond common ovarian and pelvic locations* Understand the pathophysiological basis for the unusual anatomical distribution of extragenital endometriosis* Identify characteristic MRI and CT findings of endometriosis in various anatomical sites including thoracic, abdominal wall, urinary tract, gastrointestinal, and other rare locations* Learn the significance of specific imaging findings (T1/T2 signal characteristics, enhancement patterns) in the diagnosis of deep infiltrative endometriosis at unusual sites* Apply systematic reporting approaches for endometriosis to improve pre-operative planning and management

TABLE OF CONTENTS/OUTLINE

1. Introduction and Anatomical Distribution of Endometriosis - Common and uncommon sites - Pathophysiological mechanisms 2. Gastrointestinal Endometriosis - Rectosigmoid colon (mushroom cap sign) - Small bowel and cecum - Appendix 3. Thoracic Endometriosis - Diaphragmatic endometriosis (right-sided predominance) - Pulmonary endometriosis 4. Abdominal Wall Endometriosis - Scar endometriosis - Umbilical endometriosis - Inguinal/round ligament endometriosis 5. Urinary Tract Endometriosis - Bladder endometriosis - Ureteral endometriosis (extrinsic vs. intrinsic) - Prevesical space 6. Other Rare Locations - Cervical endometriosis - Vaginal and vaginal vault endometriosis - Omental endometriosis 7. MRI Reporting Recommendations for Unusual Sites - Structured approach to evaluation - Key elements for surgical planning 8. Conclusion

OBEE-56 MISPLACED BUT NOT TO BE MISSED: NAVIGATING ECTOPIC PREGNANCY SUBTYPES, MIMICS, AND DIAGNOSTIC PITFALLS

Ziyu Xian, MD (*Presenter*)
Daniel Kowal, MD (*Abstract Co-Author*)

TEACHING POINTS

Ectopic pregnancy is a time-sensitive and potentially life-threatening diagnosis in which radiologists play a pivotal role in early detection. Imaging findings can be subtle, as the gestational sac may implant in various locations and mimic normal ovarian structures or other pathologies, posing significant diagnostic challenges. Accurate identification is essential, as a missed diagnosis may compromise a viable intrauterine pregnancy or lead to life-threatening complications such as rupture. This exhibit will review the spectrum of ectopic pregnancy subtypes, including cervical, cesarean scar, interstitial, tubal, ovarian, and abdominal ectopics. For each subtype, we will discuss characteristic locations, imaging features, and potential complications, using both ultrasound and MRI. Common mimics such as corpus luteum cysts, eccentrically located intrauterine pregnancies, and early pregnancy loss will be examined in context, with emphasis on imaging clues that help to distinguish them from true ectopic gestations. Less common mimics such as accessory and cavitated uterine masses will also be discussed, along with the appearance of ectopic pregnancy in the setting of Mullerian anomalies. Finally, we will highlight critical diagnostic pitfalls, including heterotopic pregnancy, to ensure this rare but life-threatening condition is not overlooked.

TABLE OF CONTENTS/OUTLINE

• Introduction• Epidemiology and risk factors • Imaging characteristics of each ectopic subtype and mimics (cervical, cesarean scar, interstitial, tubal, ovarian, abdominal)• Complications• Pitfalls• Management• Summary• References

OBEE-57 A WOLF IN SHEEP'S CLOTHING IN THE UTERINE CERVIX: ALL ABOUT CERVICAL ADENOCARCINOMA, GASTRIC-TYPE

Yumiko Oishi Tanaka, MD, PhD (*Presenter*)
Akiko Tonooka, MD (*Abstract Co-Author*)
Makiko Omi (*Abstract Co-Author*)
Tomohiro Chiba (*Abstract Co-Author*)
Hidetaka Nomura (*Abstract Co-Author*)
Hiroyuki Kanao (*Abstract Co-Author*)

TEACHING POINTS

1. To know the clinico-pathological characteristics of cervical adenocarcinoma, gastric type (GAS), including: i) multistep carcinogenesis from the lobular endocervical glandular hyperplasia (LEGH), ii) poor prognosis due to difficulty in early diagnosis and metastatic tendency. 2. To know the imaging characteristics of LEGH as a precursor of GAS, comparing its mimickers. 3. To know the variety of imaging characteristics of GAS.

TABLE OF CONTENTS/OUTLINE

WHO classification of the epithelial tumors of the uterine cervix (Squamous cell vs adenocarcinoma, HPV-related vs HPV-independent, adenocarcinoma, NOS vs mucinous adenocarcinoma) - History of adenoma malignum to GAS (Detecting gastric-type mucin, establishment of histopathological disease entity of LEGH and GAS)-

Imaging characteristics of LEGH comparing its mimickers (Nabothian cysts, chronic cervicitis etc.)-Imaging characteristics of early detection of the carcinoma (Especially the role of DWI and dynamic contrast enhancement)- Imaging findings that suggests poor prognosis (Rapid growing, ill-defined margin, tendency of ovarian metastasis and intraperitoneal dissemination, high recurrence rate).

OBEE-58 BEYOND DELIVERY: RADIOLOGIC INSIGHTS INTO POSTPARTUM AND POST-CESAREAN COMPLICATIONS

Marta Mazuque Mancilla (*Presenter*)
Marta Vera Cartas, MD (*Abstract Co-Author*)
Eva Gimenez Comet, MD (*Abstract Co-Author*)
Alisa Trundaeva, MD (*Abstract Co-Author*)
Marta Bonfill Garcin (*Abstract Co-Author*)

TEACHING POINTS

1. Understand anatomical and physiological changes during pregnancy and postpartum. 2. Identify and categorize main postpartum complications based on radiologic findings. 3. Analyze the most appropriate imaging modalities for diagnosis.

TABLE OF CONTENTS/OUTLINE

Pregnancy causes significant anatomical and physiological changes—such as hemodynamic shifts, hypercoagulability, hydronephrosis, and organ displacement—that often persist postpartum. Awareness of these changes is essential to avoid misinterpretation in imaging. Postpartum complications can be organized into five main categories, illustrated with institutional clinical cases: 1. Iatrogenic complications . Frequently related to C-section, including uterine bleeding, ureteral injuries, and retained surgical materials (e.g., gossypiboma). 2. Infectious complications . Infections such as endometritis are leading causes of maternal morbidity. 3. Thromboembolic complications . The postpartum hypercoagulable state predisposes to venous thrombosis, especially in the ovarian veins or as pulmonary embolism. 4. Hemodynamic changes . Elevated cardiac output can trigger events like intracranial hemorrhage or reversible cerebral vasoconstriction syndrome. 5. Miscellaneous and other . Includes conditions like spontaneous uterine rupture (in scarred uteri), retained products of conception, and coexisting non-obstetric pathologies. A precise radiologic diagnosis has significant clinical implications, as complications can be severe and rapidly progressive.

OBEE-59 FROM SPOKE WHEELS TO PEARL NECKLACES: ULTRASOUND OF NON-NEOPLASTIC CYSTIC ADNEXAL DISEASES

Emily Van Antwerp, DO (*Presenter*)
Daniel Kowal, MD (*Abstract Co-Author*)

TEACHING POINTS

Non-neoplastic cystic adnexal disease refers to cystic lesions arising from the ovary or surrounding adnexal structures that are not related to tumors or neoplasms. Patients may be asymptomatic or present with pelvic pain, menstrual irregularities, or infertility. Ultrasound is the first-line imaging modality, offering real-time, noninvasive assessment of disease morphology, vascularity, and other associated features. We delve into the ultrasound image characteristics and underlying pathophysiology of peritoneal inclusion cyst, ovarian hyperstimulation syndrome (OHSS), hyperreactio luteinalis, polycystic ovarian syndrome (PCOS), endometrioma, pyosalpinx/hydrosalpinx, tubo-ovarian abscess (TOA), and massive ovarian edema with peripheral follicles. Each entity has distinct sonographic features and underlying pathophysiology. For example, peritoneal inclusion cysts result from adhesions that entrap peritoneal fluid around a normal ovary, often producing a multiloculated, spider-on-a-web appearance. OHSS and hyperreactio luteinalis are both associated with markedly enlarged, multicystic ovaries with "spoke-wheel" configuration but differ in etiology, with OHSS typically iatrogenic following fertility treatment and hyperreactio luteinalis arising spontaneously during pregnancy. Accurate identification and differentiation of these lesions is essential to avoid unnecessary interventions and ensure appropriate management. Pitfalls will be reviewed as well.

TABLE OF CONTENTS/OUTLINE

· Table of Contents · Introduction · Ultrasound imaging characteristics and pathophysiology of non-neoplastic adnexal diseases · Pitfalls and mimics · Summary · References

OBEE-60 DIAGNOSTIC CHALLENGE IN PLACENTAL DISORDERS: CASE-BASED CORRELATION BETWEEN US AND MRI FINDINGS

Noriko Tanio, MD (*Presenter*)

TEACHING POINTS

Placental disorders can lead to life-threatening conditions for both the mother and fetus due to complications such as massive hemorrhage. Therefore, accurate evaluation of placental disorders is essential for the management of pregnancy and delivery. Ultrasonography (US) is the first-line imaging modality for evaluating placental abnormalities, while magnetic resonance imaging (MRI) is often performed for further assessment. Familiarity with both US and MRI findings along with a thorough understanding of the risk factors associated with placenta accreta spectrum (PAS) disorders, is essential to enhance diagnostic accuracy and improve clinical outcomes.

TABLE OF CONTENTS/OUTLINE

1. Basics of the Placenta•Embryological and physiological features•Normal anatomy and size2. Ultrasound (US) and Magnetic Resonance Imaging (MRI) Findings •US and MRI findings of normal placenta and its variations•MRI indications, imaging protocols, and the role of MRI in evaluating placental disorders •Definition, risk factors, significance, and management of abnormal placentation3. Case-Based Review of US and MRI findings of Placental Disorders and their results •Abnormal placental location-Placenta previa (complete/partial/marginal placenta previa or low-lying placenta)•Placenta accreta and associated risk factors-Placenta accreta-Postoperative state-History of cesarean section-Uterine surgeries, such as myomectomy or adenomyomectomy -Other associative factors-Hemorrhagic complications in the mother and fetal ischemia during delivery associated with abnormal placenta -Vasa previa -Cesarean section due to coexisting uterine fibroids and adenomyosis

OBEE-61 MULTIMODAL IMAGING OF POSTPARTUM COMPLICATIONS: WHAT THE RADIOLOGIST NEEDS TO KNOW

Noriko Tanio, MD (*Presenter*)

TEACHING POINTS

Imaging is frequently required in the evaluation of postpartum complications, which includes life-threatening conditions. As radiologists play a crucial role in the timely diagnosis of these conditions, they should be familiar with key imaging findings associated with postpartum emergencies and diseases that impact daily life after childbirth. In this review, we categorize several important postpartum conditions and highlight the imaging features and diagnostic points .

TABLE OF CONTENTS/OUTLINE

1.Basics of the Postpartum Period Etiology Pathophysiology Causes and risk factors Clinical significance 2.Imaging Features and Diagnostic Points •Severe bleeding(Postpartum hemorrhage) -Uterine atony Cervical Retroperitoneal hemorrhage -Retained products of conception (RPOC) -Obstetric disseminated intravascular coagulation (DIC) -Amniotic fluid embolism •Infections Postpartum pelvic infections •Pregnancy-Induced Hypertension -Thrombosis Cerebral venous sinus thrombosis (CVST) -Deep vein thrombosis Pulmonary embolism (PE) -Ovarian vein thrombosis -High Blood Pressure (Pre-eclampsia and Eclampsia) -Posterior reversible encephalopathy syndrome (PRES) -Reversible cerebral vasoconstriction syndrome (RCVS) -Cerebrovascular disease -Vascular permeability Pulmonary edema •Other Systemic Effects and Complications -Central nervous system -Cerebrovascular disease -Pituitary disorders (central diabetes insipidus and Sheehan syndrome) -Cardiovascular system -Heart failure/volume overload - Mammary gland Puerperal mastitis -Bone system Public symphysis, -diastasis/sacral osteomyelitis Transient osteoporosis during pregnancy -Insufficiency fracture

OBEE-62 THE PREGNANT BELLY: INTERPRETING PREGNANCY NIGHTMARES WITH MRI

Charis Bourgioti, MD (*Presenter*)
Marianna Konidari, MD (*Abstract Co-Author*)
Lia A. Moulopoulos, MD (*Abstract Co-Author*)

TEACHING POINTS

• Diagnosis and management of abdominal pathology in pregnant women is challenging; pregnancy related anatomical and physiological changes may induce symptoms like abdominal discomfort, vomiting or fatigue, mimicking variable abdominal diseases. • Many common and less common abdominal conditions may complicate pregnancy; discrimination between obstetrical and non-obstetrical causes as well as early identification of conditions which require surgical vs conservative treatment is pivotal for a successful maternal and fetal outcome. • Sonographic evaluation of the pregnant belly may be limited, especially in the third trimester, due to the enlarged gravid uterus and small field of view; MRI serves as a problem-solving tool in complex cases, especially when ultrasound findings are inconclusive. • Familiarity with the main MRI findings of different abdominal pathologies which may occur during pregnancy could help radiologists provide more accurate diagnoses, thus optimizing patient care.

TABLE OF CONTENTS/OUTLINE

• Introduction to normal pregnancy-related anatomical and physiological changes • Familiarization with causes of abdominal pain during pregnancy including obstetric, gynecological, gastrointestinal, hepatobiliary, urinary or extra-abdominal pathologies • The use of MRI in diagnosis and management of abdominal pain during pregnancy: A routine or an adjunct assessment tool? • MRI protocols for evaluation of gravid population: Conventional protocols and special considerations • Case-based discussion of challenging life-threatening obstetrical and non-obstetrical pathologies related to abdominal pain with radiologic-pathologic correlation

OBEE-63 US AND MRI FINDINGS OF ENDOMETRIOSIS WITH DEEP EXTERNAL MYOMETRIAL INFILTRATION (DEMI) SUGGESTING SEVERE DISEASE

Sara Hassanzadeh, MD (*Presenter*)
Pamela I. Causa Andrieu, MD (*Abstract Co-Author*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Izabela P. Franco, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• DEMI refers to ectopic endometrial tissue extending into the external layer of the myometrium, which is facilitated by the rich vascularization and muscular composition of the myometrium. Most frequently, it affects the posterior myometrium. • DEMI prevalence is approximately 15% in Deep Endometriosis. • DEMI represents an important imaging indicator of severe disease, often accompanied by extensive pelvic adhesions, bilateral endometriomas, decreased ovarian reserve, and involvement of the viscus and shallow organs.• Recognizing DEMI on preoperative imaging is helpful in treatment planning, including surgical and fertility considerations.

TABLE OF CONTENTS/OUTLINE

1- Introduction• Overview of DEMI as a diagnostic entity and differentiation from related conditions such as internal adenomyosis. 2. Case-based review: • Typical TVUS and MRI findings • Compartmental evaluation strategy. • Clinical, Surgical, and Obstetrics Implications 3. Conclusions 4. Suggested literature

OBEE-64 REVIEW OF MÜLLERIAN DUCT ANOMALIES: COMBINED PERSPECTIVES FROM RADIOLOGY AND GYNECOLOGIC SURGERY

Molly Pantelic, MD, MS (*Presenter*)
Erica B. Stein, MD (*Abstract Co-Author*)
Kate McCracken, MD (*Abstract Co-Author*)
David Mortensen, MD (*Abstract Co-Author*)
Maria F. Ladino Torres, MD (*Abstract Co-Author*)
Michelle D. Sakala, MD (*Abstract Co-Author*)
Katherine E. Maturen, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

1. Müllerian duct anomalies (MDAs) comprise a wide spectrum of pathology, ranging from atresia to duplication. 2. Clinical presentations of MDAs vary widely; while many patients are asymptomatic, others may experience infertility, amenorrhea, or dysmenorrhea. 3. Ultrasound is the first-line diagnostic modality for MDAs in the pediatric population, while MRI is used for definitive characterization and preoperative planning. 4. MDAs are associated with renal anomalies. Imaging plays a key role in screening for concomitant renal abnormalities. 5. Treatment strategies are dependent on the patient's underlying anatomy, aimed at alleviating symptoms, managing comorbid anomalies, and optimizing fertility.

TABLE OF CONTENTS/OUTLINE

1. Introduction to MDAs a. Pathogenesis, pictorial review of embryogenesis b. Categorizing MDAs: disruption of organogenesis, fusion, or resorption. c. Clinical presentations 2. Imaging evaluation of MDAs a. Ultrasound b. MRI 3. Clinical considerations in diagnosis, treatment of MDAs a. Management of menstrual outflow obstruction, dysmenorrhea b. Contraception in MDAs c. Infertility and MDAs d. Associated renal anomalies 4. Case examples, highlighting important surgical considerations a. Müllerian agenesis (Mayer-Rokitansky-Küster-Hauser syndrome) b. Unicornuate uterus c. Accessory cavitated uterine mass d. Septate uterus e. Didelphys uterus f. Bicornuate uterus g. Obstructed hemivagina and ipsilateral renal anomaly (OHVIRA) 5. Conclusion with summary of key teaching points

OBEE-65 PELVIC VENOUS DISEASE: THE CENTRAL ROLE OF RADIOLOGISTS IN DIAGNOSIS, MANAGEMENT, AND INTERDISCIPLINARY COLLABORATION

Inbar Friedman (*Presenter*)
Tiffany Ni (*Abstract Co-Author*)
Andrew D. Brown, MD (*Abstract Co-Author*)

TEACHING POINTS

Learning Objectives 1. Define pelvic venous disease (PeVD) and its significance in chronic pelvicpain (CPP).2. Introduce the SVP classification system.3. Discuss non-invasive imaging modalities in PeVD.4. Highlight the role of interventional radiology in management. Teaching points summary PeVD is an often underdiagnosed cause of CPP, especially inpremenopausal parous women with varicosities.High suspicion is needed after ruling out other diagnoses.Vascular imaging is essential for evaluation.Refer to interventional radiology colleagues if medical managementfails or is not an option.

TABLE OF CONTENTS/OUTLINE

Learning ObjectivesWhat is Pelvic Venous Disease (PeVD)?A Difficult Diagnosis - table of disorders with similar symptomsSymptoms of PeVDThe Symptoms-Varices-Pathophysiology (SVP) ClassificationOverview of the SVP classification system of PeVDRole of Ultrasound in PeVD Diagnosis (Transabdominal ultrasound imaging of prominent left periuterine vein)Role of CT Imaging in PeVD Diagnosis (CT images)Role of MRI and Magnetic Resonance Venography (MRV) in PeVD DiagnosisDiagnostic Laparoscopy in PeVD (MRI images)Summary of key investigations for assessment of PeVDConservative Management of PeVDMedical Management of PeVDSurgical Management of PeVDEndovascular Embolization of PeVDCase Study: Endovascular Embolization of PeVD (images of endovascular embolization)Summary of key treatment strategies for PeVDConclusion

OBEE-66 A HEARTLESS APPROACH TO THE FETAL CHEST

Anne M. Kennedy, MBBCh (*Presenter*)
Mai Le, MD (*Abstract Co-Author*)
April M. Griffith, MD (*Abstract Co-Author*)
Susan Dalton (*Abstract Co-Author*)
Paula J. Woodward, MD (*Abstract Co-Author*)

TEACHING POINTS

The standard anatomic survey only requires documentation of cardiac structures. The detailed survey requires documentation of the diaphragm, lungs, and ribs. Many disease processes involve the fetal lungs, airways, pleura, mediastinum, esophagus, thoracic spine, and chest wall soft tissues. The first step in evaluation of an abnormal thoracic finding is to localize it anatomically; this narrows the differential diagnosis. Accurate diagnosis is critical for management planning especially in the era of fetal intervention and fetal surgery.

TABLE OF CONTENTS/OUTLINE

Characterize the finding - Cystic, solid, mixed, feeding vessel, diffuse perfusion, avascular? Where is it? A mediastinal mass extends superior to inferior and displaces the lungs out and back. A lung mass displaces the mediastinum away from the lesion. Lung hypoplasia/aplasia causes mediastinal shift toward the abnormal side. Pleural fluid surrounds the lung, pericardial fluid displaces the lungs. Chest wall abnormalities include skin edema, excess fat deposition, lymphatic malformations, and sternal defects. Thoracic spine and rib abnormalities are important in differential diagnosis of perinatal lethal skeletal dysplasia. Fetal intervention : Thoracoamniotic shunts can be placed for tension hydrothorax or to drain large multicystic masses. FETO may be offered for diaphragmatic hernia. EXIT to ECMO and EXIT to resection may be considered for large masses.

OBEE-67 MAPPING DEEP INFILTRATING ENDOMETRIOSIS: MR FINDINGS, SURGICAL INSIGHTS AND WHAT GYNECOLOGISTS CARE TO KNOW

Mandeep S. Virk, MBBS, MD (*Presenter*)
Swathi Kisara, MD (*Abstract Co-Author*)
Sadina Shrestha, MD, MBBS (*Abstract Co-Author*)
Randa Jalloul (*Abstract Co-Author*)
Varaha Tammisetti, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the importance of accurate pre-operative mapping of Deep Infiltrating endometriosis (DIE) for optimal patient care. Illustrate anatomic lexicon and MR findings of ENDOVALIRM 9-compartment-based approach to map Deep pelvic infiltrating endometriosis using the MR. Illustrate common and uncommon MRI findings of Deep Infiltrating Endometriosis.Understand how the MRI findings correlate with surgical findings and outcomes.Identify surgical implications of MR based mapping in each of the 9 compartments that include medial and lateral compartments and how this helps gynecologists prepare in terms of surgical planning and outcomes.

TABLE OF CONTENTS/OUTLINE

Epidemiology, Pathogenesis and Histological phenotypes of Deep Infiltrating Endometriosis.Comparison, limitations and understanding of current scoring and mapping systems: Enzian, Revised American Society for Reproductive Medicine (rASRM), Deep Pelvic Endometriosis Index (dPEI) scoring system by ENDOVALIRM groupMR anatomic lexicon and MR findings of mapping deep pelvic infiltrating endometriosis in each of the 9 compartments including middle and lateral compartments using case based approach. Impact of MR based mapping on surgical implications and outcomes using case based approach and surgical correlation.Proposal of ENDO-QUAL to assess image quality of MR for mapping DIE.Future considerations and Conclusions.

OBEE-68 FROM CELLS TO CORTEX - MAPPING FETAL BRAIN MILESTONES THROUGH THE MRI PIXELS

Nitin P. Ghonge, MD, MBBS (*Presenter*)
Nidhi Goyal, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Fetal brain development progresses through three key milestones -proliferation, migration, and organization. These milestones follow specific timelines with recognizable MRI correlates. Neuronal Proliferation zones appear as T2 hypointense rim along ependymal surface of the lateral ventricles. Abnormal appearance of germinal matrix is an important predictor of abnormal brain development. Neuronal Migration produces 5-layered cerebrum visible on MRI. Abnormal telencephalic lamination is an important predictor of abnormal brain development. Neuronal Organization is reflected in the appearance of cortex and sulci. Abnormal sulcation and gyration is an important predictor of abnormal brain development. Fetal MRI allow critical insights into fetal brain maturation by mapping these milestones.

TABLE OF CONTENTS/OUTLINE

Fetal brain development follows a highly organized sequence: neuronal proliferation, migration, and cortical organization. Fetal MRI enables mapping and evaluation of these stages. Neuronal proliferation [8-16 weeks], involves the generation of immature neurons in the germinal matrix. Persistence of these zones later in gestation may suggest delayed maturation. Neuronal migration[12-24 weeks], is seen as 5-layered cerebrum. Abnormalities may indicate conditions such as lissencephaly or heterotopia. Cortical organization [>24 weeks], involves the formation of gyral and sulcal patterns, in a predictable sequence. Delayed or abnormal sulcation patterns may point to cortical dysplasia. Radiologists should be aware of the appropriate MR imaging protocols and sequences. Correct interpretation and mapping of the brain development needs correlation with the gestational age.

OBEE-69 SKULL AND SPINE UNDER CONSTRUCTION: CRANIAL TO CAUDAL RADIOLOGIC JOURNEY AND INSIGHTS OF NEURAL TUBE DEFECTS

Ramya R. Yegurla, MBBS, MD (*Presenter*)
Bathula Venkata Durga Ashok, MBBS (*Abstract Co-Author*)
Anjali Vadakanti, MD (*Abstract Co-Author*)
Shreeya Devatha, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand embryological development of the neural tube and mechanisms underlying neural tube defects (NTDs) Appreciate the role of Antenatal ultrasound, MRI, in diagnosis, preoperative planning, and post-treatment follow-up Recognize imaging features of NTDs on prenatal and postnatal studies Differentiate common NTD subtypes (e.g., anencephaly, myelomeningocele, encephalocele, lipomyelomeningocele etc) Review current management strategies and multidisciplinary care implications for affected patients

TABLE OF CONTENTS/OUTLINE

Introduction & Embryology of Neural Tube Classification of NTDs: Cranial vs Caudal(Open vs closed) Defects Prenatal Imaging (Ultrasound, Fetal MRI) Postnatal Imaging and Diagnosis (MRI) Illustrative Cases with Multimodality Imaging Associated Anomalies and Syndromic Correlations Treatment, Prognosis & Follow-Up Imaging Summary and Learning Pearls

OBEE-70 THE VULVA: ANATOMY AND PATHOLOGIES ALL GU RADIOLOGISTS SHOULD KNOW

Colby Foster, MD (*Presenter*)
Erica B. Stein, MD (*Abstract Co-Author*)
Nikita Consul, MD (*Abstract Co-Author*)
Anum Aslam, MD (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)

Hero K. Hussain, MD, FRCR (*Abstract Co-Author*)
Katherine E. Maturen, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

1. Define vulvar anatomy and outline female erectile tissue anatomy. 2. Differentiate female perineal pathologies based on anatomic location e.g. Bartholin vs Gartner vs Skene's gland cysts. 3. Demonstrate the diversity of vulvar pathologies including: benign and malignant lesions, infectious/inflammatory, and posttraumatic etiologies. 4. Recognize the role of MRI as the modality of choice for the vulva/perineum, while appreciating a multi-modality imaging approach in diagnosis. 5. Describe how MRI can locally stage squamous cell carcinoma and differentiate among other malignancies such as melanoma and mesenchymal tumors. 6. Differentiate disease processes that mimic vulvar pathologies.

TABLE OF CONTENTS/OUTLINE

I. Introduction a. Exhibit goals: sharpen radiologists' anatomic knowledge and diagnostic skills to improve patient care b. Incidence/prevalence of general vulvar pathology categories c. Role of the radiologist in overall management of patients with vulvar pathologies II. Vulvar anatomy a. Defining the vulva, and vulvar anatomy at MRI b. Illustration comparing female and male erectile tissue III. Vulvar pathologies a. Congenital i. Lymphatic malformation ii. Hemangioma b. Infectious/Inflammatory i. Bartholin's abscess ii. Vulvar endometriosis iii. Vulvar varicosities c. Neoplastic i. Vulvar melanoma ii. Squamous cell carcinoma iii. Leiomyoma iv. Lipoma v. Metastases d. Traumatic/Iatrogenic i. Post-partum hematoma ii. Laceration e. Mimics i. Cystocele ii. Tailgut cyst f. Conclusions/Clinical Implications i. Importance of MRI in imaging the vulva ii. More robust education of vulvar anatomy and pathologies by radiologists can benefit the radiologic/gynecologic communities.

OBEE-71 THE UNEXPECTED WHEN YOU ARE EXPECTING: CAUSES OF ABDOMINAL PAIN IN PREGNANCY

Pouya Entezari, MD (*Presenter*)
Suzanne Czerniak (*Abstract Co-Author*)
Mahan Mathur, MD (*Abstract Co-Author*)

TEACHING POINTS

Acute abdominal and pelvic pain during pregnancy presents a unique diagnostic challenge. Many pathologies may mimic signs and symptoms attributed to maternal physiologic adaptations, physical examination findings can be confounded by the gravid uterus, and computed tomography (CT) is of limited utility in pregnant patients. Etiologies are variable and include obstetric-gynecologic disorders as well as other common entities such as gastrointestinal (including hepatobiliary), genitourinary, or even vascular causes. Prompt diagnosis plays a crucial role in appropriate treatment to ensure optimal maternal and fetal outcomes. This presentation will explore the depth and breadth of acute abdominopelvic pathologies during pregnancy. At the conclusion of the module, the learner should be able to do the following: • Elucidate common etiologies of abdominal and pelvic pain during pregnancy. • Describe appropriate imaging approaches to accurately diagnose pathologies during pregnancy. • Recognize the imaging appearance of a variety of causes of acute abdominal pain in the pregnant patient.

TABLE OF CONTENTS/OUTLINE

• Challenges of accurate diagnosis in the pregnant patient. • Benefits/drawbacks of different imaging modalities during pregnancy. • Obstetric/gynecologic causes. • Gastrointestinal causes. • Genitourinary causes. • Vascular causes.

OBEE-72 FROM REPORT TO RESECTION: RADIOLOGIC ASSESSMENT OF ENDOMETRIOSIS GUIDING A PERSONALIZED SURGICAL APPROACH

Ishwariya Rajendran, FRCR (*Presenter*)
Janette Smith, MBBChir (*Abstract Co-Author*)
Amreen Shakur, MBBS (*Abstract Co-Author*)
Helen C. Addley, FRCR, BMBCh (*Abstract Co-Author*)
Susan Freeman, MRCP, FRCR (*Abstract Co-Author*)

TEACHING POINTS

MRI is considered highly accurate for assessing the extent of deep infiltrating endometriosis due to its superior soft tissue contrast. Structured imaging reports improve multidisciplinary communication and guide surgical planning. Radiologic evaluation should include lesion location, depth, and relationship to critical structures. Recognition of extrapelvic disease sites (e.g., small bowel, abdominal wall, diaphragm, pleura) is essential for accurate planning. Collaboration between radiologists and surgeons using a multidisciplinary approach improves outcomes involving appropriate teams (robotics, gynaecology, colorectal, and urology).

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of endometriosis. Surgical challenge in extensive disease. Imaging Modalities: MRI protocol. Role of ultrasound and multidisciplinary meeting. Radiologic Findings: Uterus, ovaries and tubes. Rectal, sigmoid and small bowel involvement. Pelvic sidewall and parametrial disease. Ureteric endometriosis (intrinsic vs. extrinsic). Bladder, appendix, and nerve involvement. Abdominal wall, diaphragmatic, and pleural disease. Structured Reporting: Standardised template with key descriptors. Surgical Implications with intra-operative/post-operative images. Fertility conserving- oocyte cryopreservation or fertility-sparing surgery. Imaging impact on type of bowel surgery- shave, discectomy or bowel resection. Decisions on ureterolysis, ureterostomy, nephrectomy or partial cystectomy. Role of imaging in nerve-sparing surgery. Preoperative identification of extrapelvic disease. Conclusion: Radiologist's role in providing improved outcomes through tailored, imaging-guided surgery

OBEE-73 DECODING FETAL BODY MRI: A TRAINING GUIDE FOR IDENTIFYING NORMAL AND PATHOLOGICAL ANATOMY

Luis Ramirez, MD (*Presenter*)
Guadalupe Castro Nolasco, MD (*Abstract Co-Author*)

TEACHING POINTS

Fetal MRI provides a valuable, complementary view of complex fetal anatomy when ultrasound findings are limited or inconclusive. This exhibit presents a structured, segmental approach beginning with renal and urinary evaluation, followed by thoracic, gastrointestinal, central nervous system, and limb assessments. Learners will gain confidence in identifying renal anomalies, bladder enlargement, pulmonary hypoplasia, cardiac axis deviations, abdominal wall defects, and brain abnormalities.

TABLE OF CONTENTS/OUTLINE

Introduction The role of fetal MRI when sonographic evaluation is limited.Emphasis on a reproducible segmental assessment. Renal Evaluation Normal kidney location and laterality.Pelviectasis, duplication anomalies, agenesis. Bladder and Urinary Tract Bladder size and signal.Megacystis and bladder outlet obstruction. Thoracic Structures Lung signal, size, and homogeneity.Cardiac axis and mediastinal positioning.Pulmonary pathologies (e.g., CDH, CPAM, sequestration). Gastrointestinal System and Wall Defects Bowel dilatation, position, and stomach location.Omphalocele vs gastroschisis. Central Nervous System Ventricular size and midline structures.Posterior fossa and cortical development. Extremity Evaluation Limb presence, symmetry, and movement.Pathologies such as clubfoot. Clinical Integration Prognostic implications of imaging findings. Contribution to postnatal planning and counseling. Conclusion Reinforces a practical step-by-step MRI review of fetal anatomy. Educational utility for radiologists and multidisciplinary fetal care teams.

OBEE-74 INSIDE OUT: FETAL MRI IMAGING IN ABDOMINAL WALL DEFECTS - GASTROSCHISIS VS OMPHALOCELE AND BEYOND

Guadalupe Castro Nolasco, MD (*Presenter*)
Luis Ramirez, MD (*Abstract Co-Author*)
Valeria Morales, MD (*Abstract Co-Author*)
Genier Fabian Castano Lizarazo, MD (*Abstract Co-Author*)

TEACHING POINTS

Fetal MRI is a valuable adjunct to ultrasound in the evaluation of abdominal wall defects (AWDs), particularly in cases with equivocal findings or complex anatomy. Precise prenatal characterization of the fetal features can greatly affect the outcome. Differentiating gastroschisis from omphalocele and recognizing rare but severe conditions such as body-stalk anomaly or cloacal exstrophy, is critical for perinatal planning. MRI provides key diagnostic features including presence of a sac, umbilical cord insertion site, associated anomalies, and bowel signal/intensity characteristics. Understanding normal fetal bowel development on T1- and T2-weighted sequences aids in distinguishing physiological from pathological findings. Structured MRI assessment enhances interdisciplinary communication and improves counseling for expecting families.

TABLE OF CONTENTS/OUTLINE

Introduction and Clinical Importance Overview of abdominal wall defects Role of MRI in prenatal diagnosis and management Normal Fetal Abdominal Wall and Bowel Development Physiological herniation timeline MRI features of normal bowel at different gestational ages Gastroschisis vs. Omphalocele Key distinguishing MRI features Clinical implications and prognosis Common diagnostic pitfalls Beyond the Basics: Rare and Complex AWDs Body-stalk anomaly Cloacal exstrophy Pentalogy of Cantrell Associated findings on MRI Case-Based Review and Teaching Pearls Illustrated examples with corresponding MRI images Structured approach for interpretation Conclusion Summary of take-home messages Impact of precise prenatal MRI on patient outcomes

OBEE-75 PELVIC GAS IN WOMEN: CT-BASED DIAGNOSTIC APPROACH TO INTRAUTERINE AND ADNEXAL AIR

EITO KOZAWA, MD, PhD (*Presenter*)
Kaiji Inoue, MD (*Abstract Co-Author*)
Keita Nagawa (*Abstract Co-Author*)

TEACHING POINTS

1. Gas in the uterus or adnexa detected on CT is an important imaging finding that may reflect a wide spectrum of pathologies, ranging from benign transient conditions to life-threatening infections or necrotic tumors. 2. CT can characterize gas patterns and associated findings such as enhancement, fluid collections, and fat stranding, allowing for etiologic classification into infectious, ischemic/necrotic, fistulous, and iatrogenic origins. 3. Familiarity with typical imaging appearances and key differentiating features is essential for accurate diagnosis, guiding clinical management, and avoiding misinterpretation in postpartum or postprocedural settings.

TABLE OF CONTENTS/OUTLINE

1. Introduction- Importance of detecting pelvic gas on CT- Clinical implications and diagnostic pitfalls 2. Pathophysiologic Categories of Pelvic Gasa. Infectious gas formation (e.g., tubo-ovarian abscess, pyometra) b. Ischemic/necrotic gas (e.g., endometrial carcinoma with necrosis, carcinosarcoma) c. Fistulous entry of gas (e.g., colon-uterine fistula due to diverticulitis) d. Iatrogenic/postpartum air (e.g., after vaginal delivery, IUD insertion, hysteroscopy) 3. CT Imaging Features and Key Differentiators- Gas location (uterine cavity vs adnexal structures)- Enhancement pattern of adjacent tissue- Presence of associated findings (fluid collections, fistula tract, inflammation)- Clinical context (fever, discharge, post-procedure history) 4.Case-Based Imaging Review- Annotated CT examples illustrating each category- Emphasis on diagnostic clues and mimics 5.Summary and Practical Diagnostic Algorithm- Stepwise approach to interpreting intrauterine/adnexal gas on CT

OBEE-76 C-SECTION SCARS: NOT JUST A NICHE TOPIC

Komal A. Chughtai, MD (*Presenter*)
Jamal Mourad (*Abstract Co-Author*)
Quinn Baker, MD (*Abstract Co-Author*)
Scott W. Young, MD (*Abstract Co-Author*)
Kumaresan Sandrasegaran, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Focus on identifying, characterizing, and reporting uterine niches (isthmoceles) across imaging modalities 2. Step-by-step approach to include what the surgeon wants to know. 3. Provide case-based review of different subtypes of niches, their complications, and treatment approaches, including intraoperative photographs.

TABLE OF CONTENTS/OUTLINE

Contents/Outline Uterine niches are increasingly encountered due to rising cesarean rates and are associated with complications such as abnormal bleeding, infertility, and cesarean scar ectopic pregnancy. This exhibit presents a structured, multimodality approach—featuring ultrasound, MRI, hysterosalpingography, sonohysterography, and CT—to evaluate niches and differentiate them from normal post-cesarean anatomy. A stepwise guide for radiologists outlines key preoperative findings required by surgeons, including niche dimensions, complexity, and internal contents. A case-based review demonstrates imaging characteristics of simple, complex, and branched niches, associated complications (e.g., endometriosis, retained products), and expected versus abnormal postoperative appearances. Management strategies are reviewed, emphasizing the impact of symptoms and fertility goals. Surgical options include hysteroscopic, laparoscopic, and vaginal repair, each with specific preoperative imaging considerations. Summary Uterine niches are under-recognized chronic complications of cesarean delivery. Radiologists play a pivotal role in guiding surgical planning through accurate, comprehensive imaging evaluation and reporting, ultimately supporting better clinical and reproductive outcomes.

Pediatric Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

PDEE-1 DIAGNOSTIC PEARLS: NEUROIMAGING FINDINGS IN PEDIATRIC NON-HERPETIC VIRAL ENCEPHALITIS REVISITED

Santiago Martinez-Correa, MD (*Presenter*)
Taisa M. Guarilha, MD (*Abstract Co-Author*)
Sara R. Teixeira, MD, PhD (*Abstract Co-Author*)
Savvas Andronikou, MBBCh, PhD (*Abstract Co-Author*)
Luis T. Tibana, MD (*Abstract Co-Author*)
Maria Clara Piazza (*Abstract Co-Author*)
Patricia P. Rafful, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Provide an overview of the current understanding of non-Herpetic viral encephalitis in children - Describe the characteristic imaging features and patterns associated with each condition - Correlate imaging findings with clinical characteristics, highlighting the relationship between imaging and clinicopathologic processes

TABLE OF CONTENTS/OUTLINE

• Epidemiology and regional predilection of pediatric viral encephalopathy • Diagnostic approach • Categorize characteristic imaging findings of each of the following viral encephalopathies: 1. Influenza A: Acute necrotizing encephalopathy with symmetric lesions affecting bilateral thalami, brainstem and cerebellum 2. Influenza B: Cytotoxic edema in the middle cerebellar peduncles and dentate nuclei 3.Human Parechovirus: White matter "sunburst type" injury pattern 4. Enterovirus: Rhombencephalitis with involvement of the pontine tegmentum, medulla, midbrain, and dentate nuclei 5. Arboviruses: -Japanese encephalitis: thalamic and basal ganglia involvement -Easter Equine encephalitis: Basal ganglia involvement 6. Acute Cytomegalovirus: White matter injury often localized to the periventricular region 7. Dengue: Bilateral thalamic involvement associated with hemorrhagic changes 8. Measles: Acute disseminated encephalomyelitis (ADEM) vs. subacute sclerosing panencephalitis (SSPE) 9. Varicella-zoster: Cerebellitis and multifocal lesions 10. Epstein-Barr Virus: Widespread cortical and splenial lesions 11. HIV encephalopathy: Confluent periventricular white matter signal abnormality with volume loss vs multifocal lesions • Conclusion and take home points.

PDEE-2 IT COMES WITH BAGGAGE! ANCILLARY FINDINGS IN PEDIATRIC PULMONARY VENOUS OBSTRUCTION

Maria Segev, MD (*Presenter*)
Kenneth K. Cheung, FRCR, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the distinct characteristics of pulmonary venous stenosis (PVO) in the pediatric population compared to adults and recognize the clinical scenarios that should prompt suspicion and investigation for this condition 2. Recognize secondary imaging findings that can support the diagnosis of PVO and increase suspicion during image interpretation 3. Understand the pathophysiology underlying the various imaging findings 4. Address the technical challenges in imaging PVO in children and understanding the unique strengths and limitations of each modality

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Why pediatric PVO differs and when to suspect it 3. Pathophysiology of underlying imaging findings 4. Plain radiograph findings 5. Computed tomography findings 6. Dual-energy CT findings 7. Magnetic resonance imaging findings 8. Optimizing PVO evaluation and follow-up

PDEE-3 NEURAL TUBE TO FETAL THERAPY: HOW MRI SHAPES DIAGNOSIS, INTERVENTION, AND PROGNOSIS

Luiz Rodrigues Santos, MD (*Presenter*)
Igor J N Leite, MD (*Abstract Co-Author*)
Karen Peixoto, MD (*Abstract Co-Author*)
Tatiana M. Fazecas, MD (*Abstract Co-Author*)
Pedro T. Castro (*Abstract Co-Author*)
Heron Werner JR, MD (*Abstract Co-Author*)

TEACHING POINTS

The radiologist must be familiar with the embryological development and normal anatomy of the fetal spine and posterior fossa, and should apply a systematic approach to assess critical features on every fetal MRI. Identifying the level and extent of the spinal defect, associated Chiari II malformation, ventriculomegaly, and supratentorial anomalies is essential, as these findings directly impact surgical eligibility and long-term neurological prognosis.Fetal surgery for myelomeningocele has emerged as a potential intervention to improve postnatal outcomes, but appropriate patient selection is crucial and relies heavily on accurate MRI interpretation. This presents a unique challenge for the multidisciplinary team, reinforcing the importance of the radiologist's role in therapeutic planning.This pictorial essay will provide a comprehensive overview of neural tube closure defects on fetal MRI, including myelomeningocele and other forms of spinal dysraphism, with pre- and post-operative imaging examples, and correlation with surgical criteria and postnatal outcomes. The objectives of this pictorial essay are: 1 - To review the embryology and normal anatomy of the fetal spine and posterior fossa; 2 - To identify key imaging features of open and closed neural tube defects on fetal MRI; 3 - To discuss the MRI criteria for fetal surgery candidacy and illustrate pre- and postnatal imaging findings.

TABLE OF CONTENTS/OUTLINE

- Cervical spine and posterior fossa anatomy;- Open and closed spinal dysraphisms;- Meningocele;- Myelomeningocele;- Myelocele;- Pre and posoperative findings in In utero repair;- Fetal MRI findings and prognostic correlation.

PDEE-4 MANY FACES OF ABDOMINAL INVOLVEMENT OF BURKITT'S LYMPHOMA IN CHILDREN

Irem Togrul, MD (*Presenter*)
H. Nursun Ozcan, MD (*Abstract Co-Author*)
Berna Oguz, MD (*Abstract Co-Author*)
Mithat Haliloglu, MD (*Abstract Co-Author*)

TEACHING POINTS

Burkitt's lymphoma is the most common form of non-Hodgkin's lymphoma in children. It has a rapid doubling time of about 24 hours, which makes it an aggressive type of cancer. Despite its aggressive nature, Burkitt's lymphoma responds very well to chemotherapy and early diagnosis is crucial to improving the prognosis of patients. It can be localized or disseminated and can involve various sites. The aim of this exhibit is to highlight the abdominal and pelvic radiological findings in Burkitt's lymphoma and help the reader recognize these early signs on imaging to make the correct diagnosis and improve the patient's outcome.

TABLE OF CONTENTS/OUTLINE

1. An overview of Burkitt's lymphoma 2. Clinical features of Burkitt's lymphoma 3. Imaging work-up 4. The spectrum of abdominal and pelvic involvement of Burkitt's lymphoma a. Gastrointestinal involvement (stomach, intestine) b. Intraabdominal solid organs (liver, spleen, kidney, pancreas, gallbladder) c. Mesenteric and retroperitoneal disease d. Gonadal involvement 5. Summary 6. Conclusion

PDEE-5 THIRD WINDOW ANOMALIES IN CHILDREN: A COMPREHENSIVE OVERVIEW

Melike Z. Akis, MD (*Presenter*)
Serhat Akis, MD (*Abstract Co-Author*)
Fatma C. Sarioglu, MD (*Abstract Co-Author*)
Handan Guleryuz (*Abstract Co-Author*)

TEACHING POINTS

Third-window anomalies are bony defects of the inner ear that allow abnormal communication with the middle ear and/or cranial cavity. Normally, the inner and middle ear interact via the oval (first) and round (second) windows. A third window causes dissipation of acoustic energy, resulting in mixed hearing loss. Radiologists are key in detecting these lesions on imaging to avoid unnecessary surgery. This exhibit showcases the full spectrum of pediatric third-window anomalies using CT cases from our institution, supported by original medical illustrations, to improve recognition and diagnostic confidence. Accurate assessment of third-window anomalies requires effective multiplanar reconstruction (MPR). The exhibit also aims to enhance radiology residents' skills in using MPR to detect subtle bony defects.

TABLE OF CONTENTS/OUTLINE

Normal anatomy of the inner ear - Knowledge of inner ear structures and familiarity with normal anatomy is essential for detecting subtle third-window changes. Classification of third-window anomalies - Lesions are classified by location and include bony dehiscences in the semicircular canals, vestibular aqueduct, and cochlea. • Semicircular canals: Dehiscences • Vestibule: Enlarged vestibular aqueduct; inner ear malformations causing a dehiscence between vestibule and non-vestibule sites • Cochlea: Cochlear dehiscences; inner ear malformations • Other rare defects Case-based approach - Each subtype of third-window anomaly is exemplified through pediatric CT cases, enabling step-by-step visual recognition of the entire lesion spectrum.

PDEE-6 FROM IMAGING TO DIAGNOSIS: A RADIOLOGIC GUIDE FOR NEONATAL FLUOROSCOPY AND BASIC PATHOLOGICAL CONDITIONS

Stacey Danica L. Gosiaco, MD (*Presenter*)
Rafael Maria Benjamin Echevarria, MD (*Abstract Co-Author*)
Randall S. Teh, MD (*Abstract Co-Author*)
Lourdjeanne Luces, MD (*Abstract Co-Author*)
Nathan David P. Concepcion, MD (*Abstract Co-Author*)

TEACHING POINTS

The neonatal period, defined as the first 28 days of life, represents a critical window marked by an inherent increased susceptibility to various congenital conditions. Fluoroscopy plays a vital role in evaluating structural and functional abnormalities during this period. However, there remains a lack of consensus on how to perform and interpret fluoroscopic studies solely for this population, which is notable for its physiological fragility and sensitivity to ionizing radiation. This exhibit aims to provide radiologists and trainees with a comprehensive, approach to performing neonatal fluoroscopy, with emphasis on procedural execution, patient safety, and diagnostic interpretation highlighting characteristic imaging features of common pathologies encountered in clinical practice. The objectives are: 1) Explain the physics and fundamental principles of fluoroscopy as applied to neonatal imaging, 2) Discuss strategies for radiation protection and dose minimization in neonates, 3) Outline the indications, contraindications, and protocols for key fluoroscopic procedures, 4) Detail proper patient preparation, positioning, and technical considerations for safe and effective imaging, 5) Demonstrate hallmark radiologic findings of common neonatal pathologies assessed by fluoroscopy.

TABLE OF CONTENTS/OUTLINE

I. Introduction on the Basic Principles of Fluoroscopy and application of ALARA principle in neonatal fluoroscopic studies II. Fluoroscopy Procedures and Basic Common Clinical Pathologies i. Airway Fluoroscopy ii. Esophagoram and Upper Gastrointestinal Series iii. Small Intestinal Series iv. Contrast Enema and Distal Colonogram v. Voiding Cystourethrography III. Conclusion

PDEE-7 SCALP SCRATCHES AND SKULL SURPRISES: WHAT'S HIDING BENEATH?

Caroline Rutten, MD (*Presenter*)
Daniel Schlam (*Abstract Co-Author*)
Anthea Lafreniere (*Abstract Co-Author*)
Samantha K. Gerrie, MD, FRCPC (*Abstract Co-Author*)
Elka Miller, MD, FRCPC (*Abstract Co-Author*)
Vivek B. Pai, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Pediatric scalp and skull lesions encompass a broad spectrum of pathologies, ranging from common and benign to rare and potentially malignant. Accurate imaging evaluation is crucial for distinguishing between these lesions and guiding management.This poster provides a comprehensive review of the imaging characteristics of various scalp and skull lesions, highlighting key radiologic features that aid in differentiation and diagnosis.

TABLE OF CONTENTS/OUTLINE

Congenital/developmental lesions- Dermoid- Epidermoid- Meningocele- Encephalocele- Sinus pericraniiVascular lesions - Hemangioma- Arteriovenous malformationInflammatory/infectious - Lymph node- Tuberculosis- Osteomyelitis- Potts puffy tumorBenign scalp lesions - Neurofibroma- Schwannoma- Pigmented melanocytoma- Calcifying epithelioma- Lymphoma- Nodular fasciitis- CholesteatomaBenign skull lesions - Osteoma- Osteoblastoma- Ossifying fibroma- Meningioma- Langerhans cell histiocytosis- Rosai Dorfman- Intraosseous hemangiomaMalignant skull lesions - Ewing sarcoma- OsteosarcomaPost-traumatic - Growth fracture

PDEE-8 TINY LIVERS, BIG INSIGHTS: ELASTOGRAPHY IN PEDIATRIC HEPATIC IMAGING

Larissa Falkenstein, MD (*Presenter*)
Isadora Shiota (*Abstract Co-Author*)

Camila Gomes Barbosa, MD (*Abstract Co-Author*)
Amanda Alves Tavares, MD (*Abstract Co-Author*)
Deborah Y. Otto (*Abstract Co-Author*)
Fabiana Gual, MD (*Abstract Co-Author*)
Osmar C. Saito, MD,PhD (*Abstract Co-Author*)
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*)
Silvia Maria S. Rocha (*Abstract Co-Author*)
Lisa Suzuki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Ultrasound remains a cornerstone imaging modality in pediatric practice, playing a crucial role in both the initial diagnosis and longitudinal monitoring of a wide range of clinical conditions. Among recent technological advancements, elastography has emerged as a promising technique, offering a noninvasive and quantitative approach to tissue characterization. This modality is gaining traction as a valuable adjunct to conventional ultrasound, with the potential to replace invasive procedures such as liver biopsies.This study aims to provide a comprehensive review of elastography techniques applied to liver assessment in the pediatric population, with an emphasis on identifying the available modalities, standardizing acquisition methodology, and critically analyzing the reference values considered normal in children. Additionally, the study seeks to illustrate the clinical applicability of elastography through the presentation of representative cases, highlighting its role in diagnosis, follow-up, and therapeutic decision-making across various clinical scenarios.

TABLE OF CONTENTS/OUTLINE

Review of elastography techniques: point SWE, 2D SWE and transient elastography; Imaging Diagnosis and normal values; Indications in pediatrics and confounders; Use and example in cases: Chronic liver disease, Biliary atresia, Cystic fibrosis-associated liver disease, liver transplantation, cholangiopathy, Metabolic dysfunction-associated fatty liver disease (MAFLD), Sinusoidal obstruction syndrome (SOS).

PDEE-9 PEDIATRIC SENSORINEURAL HEARING LOSS - WHAT A RADIOLOGIST NEEDS TO KNOW

Alka Gupta, MD (*Presenter*)
Saurabh Gupta, MD (*Abstract Co-Author*)
Mark Halverson, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Sensorineural hearing loss is a major cause of childhood disability. Early identification and determination of etiology are essential for ensuring early intervention.2. A comprehensive understanding of inner ear and vestibulocochlear nerve anatomy, along with systematic evaluation with a checklist is essential for detecting and describing an abnormality.3. Familiarity with varied etiologies of sensorineural hearing loss, their imaging characteristics is critical for deciding management and predicting outcome.

TABLE OF CONTENTS/OUTLINE

Multimodality imaging with high resolution CT and MRI, now with added advantage of photon counting CT are essential for comprehensive diagnostic evaluation of sensorineural hearing loss and pre-operative assessment. Familiarity with anatomy and normal variants of the temporal bone and inner ear structures is essential for diagnosing congenital malformations and acquired abnormalities implicated in hearing impairment. Through this review, the authors will illustrate the imaging features of inner ear malformations and its classification utilizing different modalities including temporal bone CT, photon counting CT and brain MRI. This presentation will provide readers with a anatomic review of inner ear with emphasis on key anatomic structures including basal, middle and apical turns of cochlea, osseous spiral lamina/basilar membrane complex within the basal and middle turns, first and second ridges of interscalar septum, modiolus, cochlear aperture and vestibular aqueduct. Additional acquired pathologies of labyrinth, including traumatic, infectious/inflammation, autoimmune, neoplastic or drug induced will be included in this comprehensive review.

PDEE-10 FETAL MRI FOR GENITOURINARY ANOMALIES: KEY CONDITIONS, FINDINGS, AND DIAGNOSTIC VALUE

Mika Shapira Rootman, MD, PhD (*Presenter*)
Ron Beloosesky (*Abstract Co-Author*)
Goni Merhav (*Abstract Co-Author*)
RON BARDIN (*Abstract Co-Author*)
Shirley Pollack (*Abstract Co-Author*)
Sharon Perlman (*Abstract Co-Author*)

TEACHING POINTS

Enhanced Diagnostic Accuracy with MRI : Illustrate MRI's complementary role alongside prenatal ultrasound, particularly in complex scenarios. Functional Assessment Capabilities of MRI : Discuss the significance of diffusion-weighted imaging and ADC mapping in evaluating renal parenchyma. Review of Major Genitourinary Pathologies : Demonstrate MRI's capability to detail pathologies and correlate prenatal findings with postnatal outcomes when available.

TABLE OF CONTENTS/OUTLINE

• Introduction to MRI in Genitourinary Imaging Overview of Genitourinary Anatomy : Discuss the normal anatomy of the genitourinary system as visualized on fetal MRI. Technical Aspects of MRI : Explanation of MRI techniques relevant to fetal imaging, including diffusion-weighted imaging and ADC mapping, along with a discussion on the advantages of MRI over ultrasound in specific scenarios. • Major Abnormalities Discussed Urinary Tract Dilatation and Obstruction Conditions such as lower urinary tract obstruction, unilateral urinary tract obstruction. Other conditions like vesico-ureteric reflux. Megacystis, with emphasis on megacystis microcolon hypoperistalsis syndrome. Assessment of Cystic Renal Disease Assessment of Urinomas : A marker of urinary tract obstruction. Fusion Anomalies Renal Agenesis, Ectopic Kidney Mullerian Anomalies • Conclusion and Future Directions Summarize key insights and practical applications derived from the exhibit. Discuss potential advancements in MRI technology and their implications for prenatal diagnostics.

PDEE-11 THE BIG BRAIN THEORY: DIAGNOSING THE HEMISPHERE THAT WENT ROGUE

Anna C. Silva (*Presenter*)
Marcela Mazzetto Cavalcante, MD (*Abstract Co-Author*)
Cristian Lima Duarte, MD (*Abstract Co-Author*)
Caroline Pereira, MD (*Abstract Co-Author*)
Roberto Bastos, MD (*Abstract Co-Author*)
Matheus Luis Silva (*Abstract Co-Author*)

TEACHING POINTS

1. Characterize the morphological features of the pediatric brain via magnetic resonance imaging, we emphasis on supratentorial structures. 2. Present the characteristic imaging findings of hemimegalencephaly. 3. Recognize the pivotal role of MRI in the evaluation and differential diagnosis of major causes of pediatric cerebral hemispheric asymmetry. 4. Propose a logical diagnostic approach flowchart for cases of pediatric brain asymmetry. 5. Understand the significance of early detection of pediatric brain asymmetry in shaping tailored management and intervention protocols.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Embryology 3. Pathophysiology of hemimegalencephaly 4. Main differential diagnoses of pediatric cerebral hemispheric asymmetries, with MRI findings that aided in accurate diagnosis 4.1 Hemimegalencephaly 4.2 Physiological cerebral asymmetry 4.3 Cerebral edema 4.4 Schizencephaly 4.5 Trephine syndrome 4.6 Encephalomalacia 4.7 Unilateral craniosynostosis 4.8 Dyke-Davidoff-Masson (DDMS) 4.9 Sturge-Weber (SWS) 4.10 Rasmussen encephalitis 5. Proposed Diagnostic Approach Algorithm 6. Take home messages

PDEE-12 UNFOLDING THE PEDIATRIC PERITONEUM

Camila Gomes Barbosa, MD (*Presenter*)
Isadora Shiota (*Abstract Co-Author*)
Larissa Falkenstein, MD (*Abstract Co-Author*)
Regina Tchicuata, MD (*Abstract Co-Author*)
Amanda Alves Tavares, MD (*Abstract Co-Author*)
Deborah Y. Otto (*Abstract Co-Author*)
Silvia Maria S. Rocha (*Abstract Co-Author*)
Lisa Suzuki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The peritoneum is a semipermeable membrane of mesodermal origin that lines the peritoneal cavity and its organs, contributing to their structural support, immune defense and sensory function. It comprises two layers — parietal and visceral —, the latter covering the organs and forming mesenteric folds and omenta through its continuity with the parietal layer. Although typically not visible under normal conditions, these layers are essential in the early detection of certain pathologies. In pediatric radiology, peritoneal diseases such as congenital anomalies, neoplasms, and inflammatory/infectious conditions, though uncommon, may be encountered. Awareness and understanding of these conditions are crucial for prompt and accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

A review of the anatomy, embryology, and peritoneal function. Illustrative cases of congenital peritoneal diseases. Examples of neoplasms of the peritoneum, including primary and secondary tumors. Illustrative cases of Inflammatory/infectious involvement of the peritoneum.

PDEE-13 CYSTIC LUNG DISEASE IN CHILDREN: A PATTERN-BASED IMAGING AND HISTOPATHOLOGIC CORRELATION ACROSS DIVERSE ETIOLOGIES

Stephanie El Omeiri, MD (*Presenter*)
Ankita Chauhan, MD, MBBS (*Abstract Co-Author*)
Marcus Otavio Silva de Campos Meneses, MD (*Abstract Co-Author*)
Jenny Pogoriler, MD,PhD (*Abstract Co-Author*)
Joice C. Prodigios, MD (*Abstract Co-Author*)
Hansel J. Otero, MD (*Abstract Co-Author*)
David M. Biko, MD, MBA (*Abstract Co-Author*)
Jordan B. Rapp, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Overview the spectrum of cystic lung diseases in children encompassing congenital malformations, genetic syndromes, neoplastic, inflammatory, and infectious etiologies 2. Describe distinctive imaging appearances across this spectrum, with a pattern-based approach emphasizing CT features that aid in diagnosis and differentiation 3. Correlate radiologic findings with histopathologic characteristics and clinical context to guide accurate diagnosis, workup, and management

TABLE OF CONTENTS/OUTLINE

Introduction • Define cysts, bullae, cavities, and their distinguishing features • Highlight the importance of accurately diagnosing cystic lung disease in pediatric populations • Overview of imaging modalities, with emphasis on CT technique and pediatric-specific protocols Diagnostic Approach • Stepwise evaluation by age, clinical context, and imaging pattern • Indications for imaging, biopsy, and genetic testing Imaging and Histopathologic Patterns by Etiology o Congenital Lung Lesions: Congenital Pulmonary Airway Malformation (CPAM) o Neoplastic: Langerhans Cell Histiocytosis (LCH), Pleuropulmonary Blastoma (PPB) o Genetic/Syndromic: Birt-Hogg-Dubé (BHD), Lymphangioleiomyomatosis (LAM), Trisomy 21, Marfan syndrome o Infectious and post-infectious o Diffuse Lung Disease: Inborn errors of surfactant Differential Diagnosis Considerations and Mimics • Cystic fibrosis, bronchogenic cysts, pneumatoceles, and others • Radiologic clues to distinguish mimics from true parenchymal cystic pathology Conclusion Take-home points and future directions in imaging

PDEE-14 BEYOND THE MATRIX: IMAGING SPECTRUM OF PEDIATRIC CARTILAGINOUS TUMORS

Emilio Inarejos Clemente, MD (*Presenter*)
Maria Navallas, MD (*Abstract Co-Author*)
Jaime Isern-Kebschull, PhD, MD (*Abstract Co-Author*)
Enrique Ladera (*Abstract Co-Author*)
Ferran Torner, MD (*Abstract Co-Author*)
David Moreno Romo, MD,MD (*Abstract Co-Author*)
Ignasi Barber, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

After reviewing this exhibit, the learner should: - Understand the clinical and biological behavior of chondrogenic tumors in children - Describe the radiologic features of common benign and malignant cartilaginous tumors, with emphasis on radiography and MRI - Review current classification systems and their implications for diagnosis and management - Recognize atypical presentations and pitfalls in interpretation - Correlate radiologic findings with histopathology and, in some cases, arthroscopic appearances

TABLE OF CONTENTS/OUTLINE

1. Introduction to Pediatric Cartilaginous Tumors, including definition and spectrum 2. Epidemiology, clinical presentation, and natural history with key pathological features 3. Review of imaging techniques: - Radiography as first-line - MRI as the modality of choice for local staging and tissue characterization - Role of CT and bone scintigraphy in selected cases 4. Classification and staging: Review of WHO and Enneking classification systems, with focus on their radiologic correlation and implications for management: - Benign tumors: Enchondroma, paraosteal chondroma, osteochondroma, chondroblastoma, chondromyxoid fibroma, synovial chondromatosis - Malignant tumors: Chondrosarcoma, chondroid cordoma 5. Review of imaging findings, including radiography and conventional and advanced MRI techniques, such as DWI and DCE-MRI. Correlation with histopathology and arthroscopy 6. Diagnostic challenges and mimickers (infection, other benign tumors) and strategies to avoid misdiagnosis 7. Summary: key takeaways reinforcing the importance of an integrated clinical, radiologic, and pathologic approach in the evaluation of pediatric cartilaginous tumors.

PDEE-15 MAIN DIFFERENCES BETWEEN PEDIATRIC MEDIASTINAL MASSES: DIAGNOSTIC TIPS

Ana Lara Almeida Da Silva, MD (*Presenter*)
Luis Fernando Freitas De Sousa (*Abstract Co-Author*)
Rodrigo Ragazzini, PhD (*Abstract Co-Author*)

TEACHING POINTS

To highlight the main characteristics and to identify imaging features that help in the differential diagnosis of pediatric mediastinal masses.

TABLE OF CONTENTS/OUTLINE

Introduction Mediastinal masses in children have a varied embryological origin and may present similar symptoms. A rigorous assessment of the location of the tumor (anterior, middle or posterior mediastinum), its radiological characteristics and the patient's age are essential for an adequate diagnosis. In this summary, we will

highlight the main characteristics that help in the differential diagnosis of these masses. Findings and procedure details- Lymphoma (Hodgkin's and Non-Hodgkin's Lymphoma).- Tuberculosis- Germ cell tumors- Thoracic neuroblastoma

PDEE-16 DON'T JUMP TO EBSTEIN'S! NAVIGATING VARIED CAUSES OF NEONATAL AND INFANTILE CARDIOMEGALY

Maria Segev, MD (*Presenter*)
Kenneth K. Cheung, FRCR, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize the importance of chest radiography: utilize it as an initial tool in the diagnostic workup for cardiomegaly. 2. Identify key radiographic features: note specific findings on chest radiographs that contribute to establishing a diagnosis. 3. Broaden the differential for right heart enlargement: remember that conditions beyond Ebstein's anomaly can cause increased right heart blood volume and result in structural changes. 4. Consider pseudocardiomegaly in your assessment: be aware that non-cardiac factors can mimic true cardiac enlargement on radiographs. 5. Review the diverse causes of cardiomyopathy: familiarize yourself with the various etiologies of neonatal and infantile cardiomyopathy.

TABLE OF CONTENTS/OUTLINE

Introduction Challenges in Assessing Heart Size on Chest Radiograph Influence of Thymus and Inspiration causing pseudocardiomegaly Advantages of Lateral View Causes of True Cardiomegaly in Neonates and Infants with examples and key radiographic features Structural Heart Disease: Cardiomyopathy High-Output Cardiac Failure Miscellaneous

PDEE-17 FROM IMAGING TO INTERVENTION: THE ROLE OF ULTRASONOGRAPHY IN URINARY TRACT INFECTIONS AND SURGICAL MANAGEMENT OF VESICOURETERAL REFLUX

Vitor C. Romano, MD (*Presenter*)
Rafaela F. Palhares, MD (*Abstract Co-Author*)
Renata M. Copetti, MD (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Fabiana Gual, MD (*Abstract Co-Author*)
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*)
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Ultrasound is the first-line imaging modality for postoperative assessment following surgical or endoscopic correction of vesicoureteral reflux (VUR). 2. Recognizing normal postoperative anatomy—such as submucosal ureteral tunnels and altered ureteral jet dynamics—is essential to avoid misinterpretation. 3. Key findings to evaluate include ureteral insertion site, presence of hydronephrosis, ureteral caliber, bladder wall changes, and ureteral jets on Doppler. 4. Understanding the surgical technique (e.g., Cohen, Lich-Gregoir, or Deflux injection) is crucial for proper interpretation and reporting.

TABLE OF CONTENTS/OUTLINE

1. Overview of VUR and Treatment Options - Surgical (ureteral reimplantation) vs. endoscopic (Deflux). 2. Ultrasound Technique & Protocols - Bladder filling, color Doppler, dynamic assessment. 3. Normal Postoperative Findings - Submucosal ureteral course, ureteral jets, bladder wall thickening. 4. Abnormal/Postoperative Complications - Persistent hydronephrosis, obstruction, Deflux migration, scarring. 5. Reporting Recommendations - Standardized descriptors, key structures to assess, correlation with clinical history.

PDEE-18 HAND RADIOGRAPHY IN PEDIATRICS: DECIPHERING FINGERPRINTS TO REVEAL DIAGNOSES

Oscar Felipe Gutierrez Arteaga (*Presenter*)
Maria L. Lorente, MD (*Abstract Co-Author*)
Francisco Garrido Enjamio, MD (*Abstract Co-Author*)
Marina Siesto Marcos, MD (*Abstract Co-Author*)

TEACHING POINTS

- To evaluate the diagnostic utility of hand radiography in the detection of congenital skeletal malformations, dysplasias and systemic diseases (hematologic and metabolic conditions).- To describe classic radiographic features associated with congenital and systemic diseases in pediatrics. - To provide a visual atlas of the most representative cases, useful for the radiologist.

TABLE OF CONTENTS/OUTLINE

1. Anatomic variants: 1.1. Ivory epiphyses.1.2. Pseudo-epiphyses. 1.3. Cone-shaped epiphyses.2. Congenital bone fusions.3. Disorders of Bone Remodeling (Osteoclast Dysfunction).3.1. Pyknodysostosis.3.2. Osteopetrosis. 4. Skeletal Dysplasias (Cartilage/Bone Growth Defects).4.1. Achondroplasia. 4.2. Chondrodysplasia punctata, brachytelephalangic subtype (CDP-BT).4.3. Hereditary Multiple Exostosis4.4. Ollier disease (multiple enchondromas). 4.5. McCune-Albright syndrome.4.6. Acrodysostosis. 4.7. Multiple epiphyseal dysplasia.5. Metabolic/Enzymatic Diseases.5.1. Mucopolysaccharidosis.6. Overgrowth Syndromes (Tissue Hyperplasia).6.1. Macrodystrophia lipomatosa. 6.2. Proteus syndrome. 7. Connective Tissue Disorders.7.1. Marfan syndrome.8. Endocrine Disorders (Hormonal Dysregulation).8.1. Pseudohypoparathyroidism/pseudopseudohypoparathyroidism. 9. Hematologic Diseases9.1. Thalassemia.9.2. Sickle cell disease.10. Autoimmune. 10.1. Juvenile idiopathic arthritis. 11. Genetic Syndromes.11.1. Turner syndrome.

PDEE-19 BEYOND THE MIDLINE: NAVIGATING THE SPECTRUM OF SEPTO-OPTIC DYSPLASIA

Ashvin Kumar (*Presenter*)
Rajath Ramegowda, MBBS, MD (*Abstract Co-Author*)
Sanjay P. Prabhu, MBBS, FRCR (*Abstract Co-Author*)

TEACHING POINTS

To review evolving nomenclature, imaging features, and MRI protocol optimization strategies for septo-optic dysplasia (SOD) across fetal, neonatal, and pediatric stages.

TABLE OF CONTENTS/OUTLINE

1. Introduction and Nomenclature Classic triad: optic nerve hypoplasia, hypothalamic-pituitary anomalies, midline brain abnormalities. Expanded definition: "SOD spectrum" to reflect broader phenotypic variability. 2. Etiology and Genetics Key genes: HESX1, SOX2/SOX3, OTX2, SHH . Consideration of environmental and vascular disruption factors. 3. Imaging Features Across Development Fetal/Neonatal Optic nerve hypoplasia, absent septum pellucidum, associated malformations. Ocular Pathway Optic nerve/chiasmal hypoplasia, achiasmia, retinal fiber anomalies. Pituitary Ranges from stalk thinning to agenesis, ectopic posterior pituitary, anterior hypoplasia. Midline Brain Callosal anomalies, septal agenesis, hypothalamic changes, falcine hypoplasia. Associated Findings Schizencephaly, polymicrogyria, olfactory bulb agenesis, Chiari I malformation. 4. Differential Diagnosis Isolated septal deficiency Holoprosencephaly spectrum Secondary septal loss from hydrocephalus 5. Optimized MRI Protocol Sagittal volumetric T1 (e.g., MPRAGE) High-res T2 axial/coronal (brain/orbits) Heavily T2 (CISS/FIESTA) for optic nerves DWI/DTI for tract evaluation Coronal T1 and sagittal T2 for pituitary/hypothalamus 6. Diagnostic Checklist Hypothalamic-pituitary axis Optic nerves/chiasm Midline structures (septum, corpus callosum) Associated cortical/anatomical anomalies

PDEE-20 A SYSTEMATIC APPROACH TO PEDIATRIC SCROTAL PATHOLOGIES: THE WHIRLPOOL AND BEYOND

William Pryor (*Presenter*)
Carolina V. Guimaraes, MD (*Abstract Co-Author*)
Lynn A. Fordham, MD (*Abstract Co-Author*)
Lane F. Donnelly, MD (*Abstract Co-Author*)
Rebecca N. Hansen, MD (*Abstract Co-Author*)
Marcelo S. Takahashi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1) Children can present with unique pediatric scrotal pathologies that radiologist should accurately diagnose. 2) Demonstrate how a systematic approach to image evaluation is key to accurate diagnosis and the role of other factors such as age, clinical history, lab values and histology. 3) Discuss the importance of imaging in guiding patient management, especially in the acute settings (testicular torsion vs appendage torsion vs epididymitis/orchitis OR presence or absence of testicular rupture in traumatic lesions) 4) Discuss important imaging features suggesting benign vs malignant, intra-testicular vs extra-testicular or emergent vs non-emergent cases and potential pitfalls.

TABLE OF CONTENTS/OUTLINE

1) Introduction and presentation of a flow chart on how to approach pediatric scrotal pathologies systematically 2) Nonpalpable testis: A) Inguinal or retractile testis B) Cryptorchidism C) Intrauterine torsion 3) Painful Swelling A) Acute: I) Testicular Torsion: a) Complete vs Intermittent b) Testicular Infarct II) Torsed Appendix Testis III) Epididymitis/Orchitis IV) Testicular ischemia secondary to inguinal hernia B) Chronic: Varicocele 4) Painless Swelling: A) Hydrocele B) Inguinal Hernia C) Spermatic cord cyst and spermatocele D) Paratesticular Mass: Rhabdomyosarcoma, IgG4 related lesion, splenogonadal E) Intratesticular Lesion: Microlithiasis, TART, Dermoid/Epidermoid, F) Primary malignancy, lymphoma / leukemia 5) Trauma: A) Hematocele B) Hematoma C) Testicular Rupture 6) Scrotal Wall abnormalities: A) Infectious: cellulitis, abscess, necrotizing fasciitis B) Vascular malformation C) Acute idiopathic scrotal edema 7) Conclusion

PDEE-21 BONES, HORMONES, AND BEYOND: THE RADIOLOGIST'S GUIDE IN EARLY PUBERTAL DEVELOPMENT EVALUATION

Roberta Linhares, MD (*Presenter*)
Fernanda G. Bolsi, MD (*Abstract Co-Author*)
Fabio Yoshimura, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Carolina Ramos (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*)

TEACHING POINTS

• To provide radiologists with a structured approach to imaging in early pubertal development, integrating clinical and hormonal data; • To review imaging protocols and findings in bone age assessment, pelvic ultrasound, and brain MRI in the pediatric population; • To distinguish imaging features of central vs. peripheral precocious puberty, including uncommon and incidental findings; • To discuss key differential diagnoses in early pubertal development, such as hypothalamic hamartoma, adrenal tumors, McCune-Albright syndrome, and normal variants; • To explore future directions in pediatric imaging, highlighting the role of artificial intelligence in bone age assessment and pattern recognition, advances in MR and ultrasound techniques, and the integration of imaging with clinical and hormonal data to enable more precise, personalized, and earlier diagnoses; • To reinforce the role of imaging in multidisciplinary decision-making and longitudinal follow-up in pediatric patients.

TABLE OF CONTENTS/OUTLINE

• Introduction • Overview of Normal Pubertal Physiology in Children • Imaging Techniques in Pediatrics • Typical and Atypical Imaging Patterns in Precocious Puberty • Central vs. Peripheral Causes: Radiologic Clues • Differential Diagnoses • Case-Based Review with Teaching Points • Future Perspectives: Artificial Intelligence, Evolving Imaging Modalities, and Multidisciplinary Integration

PDEE-22 HIDDEN HAZARDS: A RADIOLOGIC GUIDE TO PEDIATRIC FOREIGN BODY INGESTION AND ASPIRATION

Nagore Siles, MD (*Presenter*)
Lucia Riaza Martin, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To understand how to select and apply the appropriate imaging modality in cases of pediatric foreign body ingestion and aspiration. 2. To describe the characteristics and radiologic appearance of various foreign bodies, with emphasis on key warning signs of high-risk foreign bodies. 3. To recognize imaging patterns of airway obstruction and gastrointestinal complications to guide timely intervention.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Epidemiology and Clinical Relevance. 2. Role of Imaging Techniques. 3. Airway Foreign Bodies. a) Imaging approach and findings. b) Management . 4. Gastrointestinal Foreign bodies with Special Considerations. a) Disk and Cylindrical Batteries. b) Coins. c) Magnets. d) Sharp objects. e) Radiolucent Foreign Bodies. f) With hazardous chemical composition. 5. Imaging Pitfalls.

PDEE-23 INVISIBLE THREADS: PEDIATRIC TUBERCULOSIS ACROSS THE SPECTRUM

Igor J N Leite, MD (*Presenter*)
Tatiana M. Fazecas, MD (*Abstract Co-Author*)
Luiz Rodrigues Santos, MD (*Abstract Co-Author*)
Karen Peixoto, MD (*Abstract Co-Author*)
Pedro Daltro, MD (*Abstract Co-Author*)
Elazir Mota, BMedSc (*Abstract Co-Author*)
Heron Werner JR, MD (*Abstract Co-Author*)
Pedro T. Castro (*Abstract Co-Author*)
Luiz Lima, MD (*Abstract Co-Author*)
Nara Vedoveli (*Abstract Co-Author*)

TEACHING POINTS

Think Lymph First In children, nodal enlargement is the earliest and most consistent radiographic clue—look for hilar or mediastinal adenopathy even when the lung fields seem clear. Pattern Predicts Pathway Parenchymal consolidation without cavitation favors progressive primary TB, whereas innumerable uniform micronodules signal hematogenous (miliary) spread ; matching the pattern to the pathophysiology streamlines diagnosis and management. Age Drives Risk Infants and toddlers are at highest risk for rapid dissemination to the CNS, skeleton, and pleura—maintain a low threshold for brain MRI, spine radiographs, and ultrasound of large joints in this age group. Use Multimodality Wisely Start with chest radiography, escalate to HR-CT for subtle miliary disease or airway compression, and reserve MRI/US for CNS and musculoskeletal assessment—minimizing radiation while maximizing lesion characterization. Beware the Mimics Atypical infections, Langerhans-cell histiocytosis, and malignancy can imitate pediatric TB; key discriminators are lymph-node necrosis, "tree-in-bud" spread, and vertebral body collapse with a paraspinal abscess.

TABLE OF CONTENTS/OUTLINE

Scope & Learning Objectives Pathogenesis & Age-related Risk Factors Imaging Algorithms in Suspected Pediatric TB Primary Complex Progressive Primary Disease Complicated Progressive TB Miliary (Hematogenous) TB Extrapulmonary TB - CNS Extrapulmonary TB - Musculoskeletal Extrapulmonary TB - Pleural & Lymphatic Multimodality Pearls & Protocol Tips Treatment Response & Follow-Up Imaging Key Differential Diagnoses (Quick-look Table) Interactive Quiz / Audience Engagement Slides References & Suggested Reading

PDEE-24 PEDIATRIC RENAL TUMORS: A SYSTEMATIC APPROACH AND CASE REVIEW

Marcelo S. Takahashi, MD, PhD (*Presenter*)
Lane F. Donnelly, MD (*Abstract Co-Author*)
William Pryor (*Abstract Co-Author*)
Rebecca N. Hansen, MD (*Abstract Co-Author*)
Carolina V. Guimaraes, MD (*Abstract Co-Author*)
Forrest Wilke (*Abstract Co-Author*)
Lynn A. Fordham, MD (*Abstract Co-Author*)

TEACHING POINTS

Pediatric renal tumors, while relatively uncommon, are significant childhood malignancies where imaging is crucial for diagnosis, treatment planning, treatment response evaluation and surveillance. This educational exhibit will focus on: - Review the imaging findings for common, uncommon and rare pediatric tumors, relevant differential diagnosis and essential reporting elements. - Review the role of other clinical factors in both diagnosis, prognosis and management of pediatric renal tumor patients (age, comorbidities and genetic syndromes). - Review the main staging criteria used by European and north American groups.

TABLE OF CONTENTS/OUTLINE

Introduction to Pediatric Renal Tumors • Epidemiology and Significance Common and Key Pediatric Renal Tumors (with pathology correlation when available): • Wilms Tumor • Congenital Mesoblastic Nephroma • Clear Cell Sarcoma of the Kidney • Malignant Rhabdoid Tumor of the Kidney • Renal Cell Carcinoma Other Renal Masses and Mimics (with pathology correlation when available): • Nephrogenic rests/Nephroblastomatosis • Cystic Nephroma • Angiomyolipoma • Renal Lymphoma/Leukemia • Renal Abscess/Infection • Normal Variants Imaging Modalities and Protocols Staging, Surgical Planning, Treatment Response and Surveillance Advanced and Functional Imaging Techniques Diagnostic Challenges and Future Directions

PDEE-25 FOLLOWING THE CLUES: HOW RADIOLOGY HELPS US TRACE RICKETS ACROSS AGES

Ingrid Galvis, MD, MS (*Presenter*)
Camilo Perdomo, MD (*Abstract Co-Author*)
Jenny Vo-Phamhi, MS (*Abstract Co-Author*)
Ola F. Kvist, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Rickets is a pediatric metabolic bone disorder characterized by imaging features that change according to the patient's age and underlying cause. Some conditions may mimic rickets due to similar radiologic features; therefore, accurate recognition of hallmark radiographic signs is critical for timely diagnosis and appropriate management. Nutritional rickets remains the most prevalent cause, particularly among exclusively breastfed infants without adequate vitamin D supplementation. However, older children with rickets frequently have genetic and systemic causes, such as renal and phosphate metabolism disorders. Although radiographs remain the principal imaging modality for evaluation, MRI may provide enhanced diagnostic precision in challenging or unclear cases.

TABLE OF CONTENTS/OUTLINE

Introduction - Clinical relevance of rickets and its identification in specific pediatric populations Pathophysiology and Classification - Role of vitamin D, calcium, phosphate, and renal function in bone metabolism - Nutritional, hereditary, and systemic causes Core Imaging Features - Differences between active and healing rickets Age-Specific Imaging Patterns - Infants: nutritional rickets predominance - Toddlers and older children: systemic and genetic etiologies Radiologic Mimics of Rickets - Differentiating features and clinical context Advanced Imaging Considerations - Role of MRI in equivocal or complex cases Conclusion and Clinical Pearls - Integrating clinical, lab, and imaging data - Recognizing overlapping features, avoiding misdiagnosis - Age-tailored interpretation of radiologic findings

PDEE-26 HEADS UP: KEY HEAD AND NECK FETAL MRI ANATOMY AND ABNORMALITIES YOU CAN'T MISS

Ana Bucci, MD (*Presenter*)
Mariana R. Defreitas, MD (*Abstract Co-Author*)
Selima Siala, MD (*Abstract Co-Author*)
Carolina V. Guimaraes, MD (*Abstract Co-Author*)

TEACHING POINTS

1) It is important to know normal fetal anatomy and to follow a systematic approach of evaluation when reading fetal MRI 2) Many head and neck fetal pathologies can be subtle on imaging, yet they are clinically significant as they may indicate a syndromic diagnosis, influence the mode of delivery, and offer prognostic information to clinicians and families.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Approach to Head & Neck Anatomy A. Skull and Scalp 1) Normal morphology and proportions 2) Scalp integrity 3) Masses B. Face 1) Nasal bone 2) Nasal passages and choana 3) Ocular globes 4) Jaw 5) Palate/ lip 6) Airway 7) Masses C. Ear 1) Pinna 2) Middle ear 3) Inner ear D. Neck 1) Neck symmetry 2) Airway 3) Vascular anatomy 4) Normal thyroid 5) Masses III. Abnormalities Not to Miss A. Skull/Scalp 1) Craniosynostosis 2) Chiari II 3) Aplasia Cutis 4) Masses: Encephaloceles, Atretic Parietal Cephalocele, Dermoid Cyst, Sinus Pericranii, Lipoma, Hemangioma, Lymphatic malformation, Malignancies 5) Skull base mass: Ethmoid Cephalocele B. Facial 1) Orbital: microphthalmia, anophthalmia, persistent vasculature, coloboma 2) Nasal abnormalities 3) Micrognathia: Inferior Facial Angle and Jaw Index measurements 4) Cleft lip and palate 5) Facial mass: Congenital Epulis, Epignathus, Lipoma C. Ear 1) Microtia/Anotia 2) Low-lying ears 3) Inner ear abnormalities D. Neck 1) Lymphatic malformation 2) Teratoma 3) Goiter 4) Congenital Hemangioma 5) Cysts: Thymic, Dermoid, Duplication, Thyroglossal, Branchial Cleft IV. Conclusion Comprehensive evaluation of fetal head and neck is essential for detecting abnormalities that can significantly affect fetal morbidity, survival, delivery planning, and the need for surgical intervention.

PDEE-27 COMPREHENSIVE REVIEW OF NONSYNDROMIC AND SYNDROMIC CRANIOSYNOSTOSES

Kevin Hu, BA (*Presenter*)
Shannon Chu (*Abstract Co-Author*)
Kevin Thomas, BS (*Abstract Co-Author*)
Markus Lammle, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the various types of nonsyndromic and syndromic craniosynostoses and their characteristic anatomic presentations. 2. Discuss the clinical features, clinical associations, and imaging findings on head CT and 3D reconstruction. 3. Describe surgical treatment approaches and postoperative outcomes in patients with craniosynostoses.

TABLE OF CONTENTS/OUTLINE

1. Review normal anatomy of the newborn skull. 2.Various nonsyndromic and syndromic craniosynostoses: their associated clinical features and 3D reconstruction of head CT. 2a. Nonsyndromic craniosynostoses: scaphocephaly, trigonocephaly, brachycephaly, anterior plagiocephaly, and posterior plagiocephaly. 2b. Syndromic craniosynostoses: Crouzon, Apert, Pfeiffer, and Muenke syndromes. 3. Case presentations of patients with various craniosynostoses: relevant history, operative management, and surgical outcomes. 4. Summary

PDEE-28 CONDITIONS INVOLVING THE DENTATE NUCLEUS IN THE PEDIATRIC POPULATION

Vivek B. Pai, MBBS, MD (*Presenter*)
Caroline Rutten, MD (*Abstract Co-Author*)
Moath Alsaiady, MBBS (*Abstract Co-Author*)
Christopher G. Filippi, MD (*Abstract Co-Author*)
Suzanne Laughlin, MD (*Abstract Co-Author*)
Pradeep Krishnan, MD (*Abstract Co-Author*)
Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*)

TEACHING POINTS

The dentate nucleus (DN) is the largest of the deep cerebellar nuclei. It is involved in planning, initiating, and modifying various voluntary movements while playing a key role in cognition. The DN may be involved in a wide range of diseases, the knowledge of which helps identify or narrow down a diagnosis, thus guiding further investigations and management.

TABLE OF CONTENTS/OUTLINE

1. Artistic renditions of the anatomy and connections of the DN.2. Pictorial essay of the DN pathologies, broadly divided into the following subgroups:A. Vascular: Hypoxic ischemic encephalopathyB. Leukodystrophy: Krabbe disease, Alexander disease, Canavan disease, Megalencephalic leukoencephalopathy with subcortical cystsC. Metabolic: Glutaric aciduria, L-2-hydroxy glutaric aciduria, Leigh syndrome, Maple syrup urine disease, Cockayne, MucopolysaccharidosesD. Toxic: Vigabatrin-associated brain abnormalities, Gadolinium deposition, Isoniazid toxicityE. Neurodegenerative: Pantothenate kinase-associated neurodegeneration (PKAN), Aceruloplasminemia, Giant axonal neuropathy, Membrane-bound O-acyltransferase 7 (MBOAT7)F. Inflammatory: Langerhans cell histiocytosis, Multiple sclerosis, Myelin oligodendrocyte glycoprotein antibody disease (MOGAD)G. Phacomatoses: Neurofibromatosis type 1

PDEE-29 IMAGING OF PEDIATRIC SKULL BASE MASSES

Vivek B. Pai, MBBS, MD (*Presenter*)
Gokalp Cikman (*Abstract Co-Author*)
Caroline Rutten, MD (*Abstract Co-Author*)
Manohar M. Shroff, MD, FRCPC (*Abstract Co-Author*)
Birgit B. Ertl-Wagner, MD, PhD (*Abstract Co-Author*)
Elka Miller, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Lesions of the skull base are common in clinical pediatric neuroradiology. These are often difficult to treat due to the complexity of their location, constraints of the developing skull and the small habitus. Radiology plays a key role in detection, characterization and estimation of extent of these lesions to enable a better surgical approach and prognostication.

TABLE OF CONTENTS/OUTLINE

1. Review the embryology of the skull and anatomy of the skull base.2. Describe imaging features of pediatric skull base massesa. Development: Fronto-nasal dysplasia, nasal glioma, cephalocele, dermoidb. Non-neoplastic bone lesions: Fibrous dysplasia, Langerhans cell histiocytosis, aneurysmal bone cystc. Neoplastic bone lesions: Osteosarcoma, metastasis (neuroblastoma, leukemia)d. Dural lesions: Meningioma (NF-2)e. Neurogenic lesions: Schwannoma, neurofibromaf Sellar masses: Macroadenoma, craniopharyngioma, Rathke's cystg. Notochordal origin: Ecchordosis physaliphora, chordomah. Sinonasal / nasopharyngeal lesions: Juvenile Nasopharyngeal Angiofibroma, Squamous cell carcinoma, lymphoma, rhabdomyosarcomai. Vascular origin: Paraganglioma, hemangioma (PHACES)j Miscellaneous: Infection, cholesteatoma

PDEE-30 PRECISION MEDICINE DRIVEN BY GENETICS ADVANCES AND MOLECULAR SIGNALING PATHWAYS: WHAT A PEDIATRIC RADIOLOGIST NEEDS TO KNOW?

Govind B. Chavhan, MD (*Presenter*)
Diana Veiga Canuto, PhD, MD (*Abstract Co-Author*)

TEACHING POINTS

1. New advances and understanding in genetics combined with ability of AI to analyze and process large amount of data is driving the clinical practice towards precision medicine. 2. Learning the basic concepts of precision medicine, genetics and molecular pathways can help radiologists to have a better understanding of diseases and their imaging characteristics, and help decide imaging workup and screening protocols. 3. In this primer, we aim to provide basic concepts and terminology in genetics, precision medicine and molecular pathways to familiarize radiologists with different types of genetic testing and to understand the impact of these concepts in different groups of pediatric diseases including cancers and cancer predisposition syndromes, skeletal dysplasia, vascular anomalies and others.

TABLE OF CONTENTS/OUTLINE

Introduction Basic concepts and terminology in genetics : Gene expression and regulation: from DNA to mRNA to amino acids to protein Gene inheritance, transmission and genetic imprinting Genetic dominance: genotype-phenotype relationships, phenotype variability Genetic mutations Genes and diseases. Genetic testing Molecular test (target single variant, single gene, gene panel, whole genome sequence) Chromosomal microarray Gene expression test Biochemical tests Concept of Precision Medicine and role of radiologist Genetics in cancer predisposition syndromes Tumor suppressor genes Proto oncogenes Radiological screening in cancer predisposition syndromes. Genetics in skeletal dysplasia Skeletal dysplasia panel Implications on imaging Genetics in vascular malformations RAS/ MEK/ERK and PI3 kinase/mTOR signaling pathway Summary

PDEE-31 A LEGG UP ON PERTHES: COMPLETE RADIOLOGIST GUIDE

Daisy T. Kase (*Presenter*)
Adriano Magna, MD (*Abstract Co-Author*)
Leonardo Kazunori Tsuji, MD (*Abstract Co-Author*)
Lucas R. Medeiros (*Abstract Co-Author*)
Lucas K. Miyahara, MD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Overview of Legg-Calve-Perthes disease including clinical and imaging findings in a multimodality approach. • Recognize the imaging appearances and complications of LCPD and their prognosis and treatment implications. • To present a radiologist guide of LCPD disease, including a structural MRI report, identifying imaging findings that can help orthopedists to predict outcomes and complications.

TABLE OF CONTENTS/OUTLINE

Introduction and overview of Legg-Calve-Perthes, including epidemiology, pathophysiology and clinical manifestation. Typical imaging findings of necrotic and revascularization phases in a multimodality approach. Complementary MRI sequences: how contrast-enhanced MRI and diffusion-weighted MRI may quantify the severity of ischemic lesion of the femoral head to improve the treatment guidance. Highlight the imaging findings related to poor prognosis that must be reported. Demonstrating with didactic cases LCPD complications and follow-up evaluation. Association between the Stulberg classification and the corresponding treatment. Elaborating a structural MRI report for early and late phases of the disease. Differential Diagnosis of Legg-Calvé-Perthes, like septic arthritis, transient synovitis of the hip and epiphyseal dysplasia, highlighting its difference on imaging findings, preventing misdiagnosis.

PDEE-32 THROUGH THE ULTRASOUND WAVES: A PEDIATRIC ATLAS OF RENAL PARENCHYMA FROM NORMAL TO PATHOLOGY

Laith E. Abandeh, MD (*Presenter*)

TEACHING POINTS

To emphasize the importance of comprehensive renal ultrasound technique tailored to pediatric patients. To distinguish normal variants from true renal pathology. To identify and differentiate common sonographic features of pediatric renal parenchymal diseases. To enhance diagnostic confidence by correlating sonographic findings with clinical scenarios and adjunct imaging when needed. To appreciate the role of sonography in the longitudinal follow-up of renal pathologies and congenital anomalies. To highlight common pitfalls and technical artifacts in pediatric renal ultrasound interpretation and strategies to avoid them.

TABLE OF CONTENTS/OUTLINE

Learning Objectives Background Ultrasound Technique and Optimization Probe Selection: Convex vs Linear Focal Zone and Magnification Dynamic Scanning Tips Normal Anatomy and Variants Normal Pediatric Renal Sonographic Appearance Normal Variants Mimicking Pathology Junctional Parenchymal Defect Fetal Lobulation Column of Bertin Dromedary Hump Persistent Fetal Echogenicity Transient Pyramidal Echogenicity Prominent Medullary Pyramids Sinus Lipomatosis Cortical-Medullary Band Incomplete Duplex System Pseudolesions from Bowel Gas or Ribs Congenital and Pathologic Renal Parenchymal Conditions Syndromic Associations Zellweger, Joubert, Tuberous SclerosisDenys-Drash, DiGeorge, TurnerBardet-Biedl, Meckel-Gruber, VACTERLAlport, Nephronophthisis, Schinzel-GiedionTrisomy 13, 18Beckwith-Wiedemann, Williams, Lowe Syndrome Pitfalls Summary Summary Table: Variants vs. PathologySyndromic Associations Quick GuideTechnical Checklist for Optimal Renal UltrasoundReferences

PDEE-33 CRANIOVERTEBRAL JUNCTION ABNORMALITIES IN CHILDREN: WHAT THE RADIOLOGIST NEEDS TO KNOW

Ryoko Asahara, MD (*Presenter*)
Yuko Tsujioka, MD, PhD (*Abstract Co-Author*)
Mikako Enokizono, MD, PhD (*Abstract Co-Author*)
Tatsuo Kono, MD (*Abstract Co-Author*)

TEACHING POINTS

Craniovertebral junction (CVJ) abnormalities in pediatric patients encompass a broad spectrum of etiologies. Although often asymptomatic, CVJ abnormalities carry significant risks, such as severe neurological sequelae and sudden death, making it essential to recognize conditions associated with these abnormalities. CVJ abnormalities may present with mild symptoms, such as neck pain, torticollis, or restricted neck movement, and may also lead to the discovery of previously undiagnosed systemic diseases. Radiologists play a vital role in ensuring comprehensive evaluation of the CVJ, and active imaging assessment with attention to age-appropriate developmental landmarks is required. In this educational presentation, learners will understand: (1) the etiology, clinical features, and imaging findings of pediatric CVJ abnormalities; (2) the association between CVJ abnormalities and underlying conditions; and (3) the appropriate timing and imaging protocols for radiological intervention in the comprehensive evaluation of pediatric CVJ lesions.

TABLE OF CONTENTS/OUTLINE

Introduction - Anatomy - Congenital malformations (Chiari malformation, Atlantooccipital assimilation/subluxation, Os odontoideum, Basilar invagination, Klippel-Feil malformation, Chromosome 22q11.2 microdeletion syndrome) - Inflammatory diseases (Juvenile idiopathic arthritis, Kawasaki disease, Retropharyngeal inflammation) - Skeletal dysplasias (Achondroplasia, Spondyloepiphyseal dysplasia, Mucopolysaccharidosis, Chondrodysplasia puncata, Osteogenesis imperfecta) - Neoplasms (Langerhans Cell Histiocytosis, Chordoma, Osteoblastoma, Ewing sarcoma) - Trauma

PDEE-34 RADIATION-DOSE OPTIMIZATION IN PEDIATRIC CT FOR CONGENITAL HEART DISEASE: PRINCIPLES, TECHNOLOGIES, AND PROTOCOL IMPLEMENTATION

Takanori Masuda, PhD (*Presenter*)
Yoshinori Funama, PhD (*Abstract Co-Author*)
Takeshi Nakaura, MD (*Abstract Co-Author*)
Atsushi Ono (*Abstract Co-Author*)
Kazuo Awai, MD (*Abstract Co-Author*)

TEACHING POINTS

Children with congenital heart disease, being both highly radiosensitive and subject to frequent follow-up imaging, require rigorously justified examinations and pediatric-optimized low-dose CT protocols with cumulative dose tracking to minimize lifetime radiation risk. Pediatric CT dose is minimized by strict clinical justification; size-specific low-kVp protocols with real-time tube-current/voltage modulation; high-pitch or prospectively triggered acquisition and tight collimation; iterative or deep-learning reconstruction; precise centring without unnecessary shielding; continuous dose tracking (CTDI_{vol}, DLP, SSDE); and ongoing ALARA-focused, multidisciplinary education.

TABLE OF CONTENTS/OUTLINE

- Fundamentals of Radiation Dose in Pediatric CT - Biological sensitivity of children - Dose metrics (CTDI, DLP, SSDE, effective dose) - Regulatory and guideline frameworks (Image Gently, ICRP 138) Dose-Reduction Technologies and Techniques - Automatic tube current modulation (ATCM) - Automatic tube voltage selection (ATVS) - Low-kVp protocols with iodine optimisation - High-pitch spiral & prospective ECG triggering - Iterative and deep-learning reconstructions - Dynamic bow-tie filtration and couch-height compensation

PDEE-35 ONE LUNG, ONE CLUE: DIAGNOSTIC APPROACH TO UNILATERAL WHITE LUNG IN PEDIATRICS

Vilma J. Varela George SR, MEd (*Presenter*)
Laura L. Sosa Munoz, MEd (*Abstract Co-Author*)
Sofia Arizaga, MD (*Abstract Co-Author*)

TEACHING POINTS

Complete opacification of a hemithorax indicates the presence of a significant disease, as there shall be loss of physiological functions on the involved side. The differential diagnosis of opaque hemithorax may include congenital anomalies, inflammatory and neoplastic disorders, and even postsurgical cause. Lung agenesis is a rare congenital abnormality that is defined as the absence of lung tissue along with the absence of bronchi. It is a rare phenomenon with the incidence from one report of 1.22 cases per 100,000 live births. Primary lung tumors in children are rare, with a narrow range of diagnostic considerations. However, the overlapping imaging appearances of these tumors necessitate attention to key discriminating imaging and pathologic features. In the neonate and infant, the important considerations include pleuropulmonary blastoma, infantile fibrosarcoma, and fetal lung interstitial tumor.

TABLE OF CONTENTS/OUTLINE

1.Systematic Approach 1.1 Acronym: "A-B-C-D-E" 2. Pattern of mediastinal involvement 2.1 Displacement of the mediastinum to the same opaque side. 2.1 .1. Pulmonary agenesia. 2.1.2Congenital pulmonary hypoplasia. 2.1.3 Congenital pulmonary airway malformation 3. Displacement of the mediastinum to the contralateral side 3.1 Large lung or pleural tumor 3.1.1 Mediastinal germ cell tumor 3.1.2 Fusiform rhabdomyosarcoma of the posterior thoracic wall. 3.1.3 Pleuropulmonary blastoma 3.2 Pneumonia complicated by extensive empyema 4. No evident mediastinal displacement to the contralateral side 4.1 Extensive pneumonia (complete consolidation of one lung) 4.2 Diaphragmatic hernia (Morgagni). 4.3 Diffuse alveolar hemorrhage.

PDEE-37 SOLVING THE PUZZLE: IMAGING EVALUATION OF PEDIATRIC RENAL MASSES: A GUIDE FOR THE RADIOLOGY RESIDENT

Sofia Arizaga, MD (*Presenter*)
Vilma J. Varela George SR, MEd (*Abstract Co-Author*)
Arnoldo Hernandez Frausto, MD (*Abstract Co-Author*)
Sara A. Solorzano-Morales, MD (*Abstract Co-Author*)
Marco Antonio Sarmiento, MD (*Abstract Co-Author*)
Isabel Beristain, MD (*Abstract Co-Author*)

TEACHING POINTS

- To Identify the different features of benign renal tumors children and adolescents.- To Identify the different features of malignant renal tumors children and adolescents.

TABLE OF CONTENTS/OUTLINE

- Introduction- To review the different benign renal masses in children: cystic nephroma, mesoblastic nephroma and angiomyolipoma.- To evaluate the different benign renal masses in children: Wilms tumor, nephrobastomatosis, rhabdoid tumor, clear cell sarcoma, renal cell carcinoma and lymphoma.- To make accurate differential diagnosis with the different renal lesiones.- To evaluate the renal masses with different imaging modalities- Cases.- Summary.- Take home points.

PDEE-38 PEDIATRIC ISCHEMIC STROKE

Cesar Gabriel Rocha Da Costa Paloschi, MD (*Presenter*)
Isabela D. Alves, MD (*Abstract Co-Author*)
Jose Eduardo Mourao Morais, MD (*Abstract Co-Author*)
Camila T. Amancio (*Abstract Co-Author*)
Marcos F. Docema, MD, PhD (*Abstract Co-Author*)
Daniel Delgado (*Abstract Co-Author*)
Cesar Augusto P. Alves SR, MD, PhD (*Abstract Co-Author*)
Hae W. Lee, MD, PhD (*Abstract Co-Author*)
Claudia D. Leite, MD, PhD (*Abstract Co-Author*)
Maria Martin, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This educational exhibition provides a comprehensive overview of the imaging evaluation of pediatric patients with ischemic stroke. Specific imaging patterns, differential diagnoses, and potential pitfalls in imaging interpretation will be addressed, as well as etiology categorization, classification grading systems, and treatment modalities, aiming at a broad review of the subject. The purpose of this exhibition is to:- Present multiples etiologies of pediatric arterial stroke;- Present classical imaging findings;- Highlight points of interest regarding treatment and rapid identification of complications.

TABLE OF CONTENTS/OUTLINE

Definition and imaging indication in pediatric stroke. • Overview of the classic definition and urgent brain imaging criteria in pediatric stroke.Ischemic stroke: main etiologies • Highlight main etiologies of pediatric stroke. Genetic causes • Imaging findings of the main genetic causes of ischemic stroke. Perfusion deficit study • Comprehensive evaluation of cerebral perfusion in children with suspected strokeManagement • Explore the therapeutic window and treatment modalities of ischemic stroke in the pediatric population.

PDEE-39 "CRACKING THE CODE": PEDIATRIC JAW LESIONS MADE SIMPLE FOR RADIOLOGISTS

Mario Ruben Paz Campos, MD (*Presenter*)
Arturo Gross, MD (*Abstract Co-Author*)
Michelle Estefania Gonzalez Cordova, MD (*Abstract Co-Author*)
Rocio Gutierrez Rodriguez, MD (*Abstract Co-Author*)
Elena Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the most common pediatric jaw lesions, emphasizing their characteristic imaging features and clinical relevance. To develop a simple, systematic approach for the evaluation and description of pediatric jaw lesions, facilitating accurate and efficient diagnosis.

TABLE OF CONTENTS/OUTLINE

Pediatric jaw lesions pose unique challenges due to active growth plates, developing teeth, and bone remodeling. These factors blur distinctions between normal variants, benign processes, and aggressive pathology. Though most lesions are benign and nonodontogenic, imaging features often overlap infections, inflammation, and malignancy, requiring systematic evaluation. Radiologists refine the differential using lesion margins, location, and tooth displacement. Imaging guides biopsy decisions and helps preserve function and aesthetics through timely intervention. A structured approach starts with age, history, and lesion position relative to teeth and the inferior alveolar canal—odontogenic lesions lie above, nonodontogenic below. Key imaging traits include density, borders, locularity, growth pattern, and adjacent effects. Benign lesions show well-defined margins, narrow transition zones, cortical remodeling, and directional root resorption. Malignant lesions demonstrate ill-defined margins, wide zones, cortical destruction, soft tissue invasion, and nondirectional resorption. Aggressive infections can mimic malignancy with similar invasive features. This work reviews common odontogenic and nonodontogenic lesions, both cystic and tumoral, applying radiologic patterns to streamline interpretation and expedite accurate diagnosis in clinical practice.

PDEE-40 ECHOES OF PRESSURE: THE ROLE OF ULTRASOUND IN MANAGING INTRACRANIAL HYPERTENSION IN NEONATES AND INFANTS

Vitor C. Romano, MD (*Presenter*)
MARCIA W. MATSUOKA, MD (*Abstract Co-Author*)
Renata M. Copetti, MD (*Abstract Co-Author*)
Fabiana Gual, MD (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Rafaela F. Palhares, MD (*Abstract Co-Author*)
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Ultrasound is a non-invasive, bedside technique that enables real-time monitoring of intracranial pressure through transfontanelar assessment of the brain and optic nerve sheath measurements. 2. Ventricular-Hemisphere Index (VHI) can help identify hydrocephalus and other intracranial conditions. An elevated VHI suggests

abnormal ventricular enlargement, which can be a marker of intracranial pressure (ICP) elevation. 3. Doppler Ultrasound for Cerebral Hemodynamics: Doppler ultrasound of the cerebral arteries can reflect changes in ICP. The Resistive Index (RI) can give insights of the intracranial pressure and blood flow repercussions. 4. Thickening of the optic nerve sheath can be used as a marker of increased ICP. 5. The ability to perform ultrasound in postoperative settings (e.g., after surgery for craniosynostosis or neuroglial tumors) makes this a vital tool for detecting complications related to intracranial hypertension.6. The combination of optic nerve sheath measurement and Doppler ultrasound aids in decision-making processes, such as when to initiate or adjust interventions like ventriculoperitoneal shunting or pharmacological management.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Intracranial Hypertension in Neonates and Infants 2. The Role of Ultrasound in Managing Intracranial Hypertension 3. Ultrasound Technique and Methodology 4. Key Findings and Data 5. Clinical Applications and Case Studies 6. Discussion and Teaching Points 7. Conclusion and Future Directions

PDEE-41 UNLOCKING THE MYSTERIES OF PAEDIATRIC ESOPHAGEAL PATHOLOGIES: ESSENTIAL INSIGHTS FOR RADIOLOGISTS

Taruna Yadav, MD (*Presenter*)
Manav Shah, MBBS (*Abstract Co-Author*)
Pawan K. Garg, MD (*Abstract Co-Author*)
Rengarajan Rajagopal, MBBS (*Abstract Co-Author*)
Binit Sureka, MBBS, MD (*Abstract Co-Author*)
Pushpinder S. Khera (*Abstract Co-Author*)

TEACHING POINTS

1. To learn about the imaging clues to identify esophageal pathologies from the fetal stage to childhood.2. To study the role of barium swallow and CT/MRI for the assessment of various pediatric esophageal pathologies.3. Using state of the art cases, to learn about myriad of pediatric esophageal abnormalities for early detection, management and their follow up (whenever available). 4. Syndromic associations with esophageal disorders.

TABLE OF CONTENTS/OUTLINE

1. Introduction to embryology, developmental considerations and pathologies of fetal and pediatric esophagus.2. To learn the role of different radiological investigations along with advantages/disadvantages of various imaging modalities in evaluation of pediatric esophagus.3. Depiction of imaging features of various esophageal pathologies (congenital - atresia with and without fistula/short esophagus with and without CDH and acquired - foreign bodies with and without perforation and mediastinitis, fungal infection, inflammation, congenital and acquired strictures with balloon dilation, achalasia, duplication cyst, neoplasms) in children.4. Few syndromic associations of esphageal disorders (VACTERL, down syndrome - GERD and motility disorder, congenital short esophagus, Allgrove syndrome).5. Conclusion.

PDEE-42 PEDIATRIC URINARY TRACT DILATION: A GUIDE FOR RADIOLOGISTS

Luisa L. Faria, MD (*Presenter*)
Ana Paula Martins Nascimento (*Abstract Co-Author*)
Amanda Campos (*Abstract Co-Author*)
Jackson Borges Sarmento (*Abstract Co-Author*)
Camilla Calil (*Abstract Co-Author*)
Tales Alvarenga (*Abstract Co-Author*)

TEACHING POINTS

The evaluation of urinary tract dilation in children is part of the radiologist's daily routine and is becoming increasingly frequent with the increase in the number of obstetric ultrasounds performed during prenatal care. However, most dilations observed in the prenatal period will resolve spontaneously, without the need for additional imaging evaluation. Therefore, it is crucial for the radiologist to distinguish and adequately report what is normal, what is abnormal, and when to trigger additional imaging evaluation. Effective communication with neonatologists and specialist pediatricians is also essential so that the findings are correctly understood and unnecessary examinations are avoided. The objective of this presentation is to review the radiological evaluation of urinary tract dilation in the pediatric population through selected cases, rich in images with high educational content, focusing on appropriate reporting, adequate classification of findings, and prevention of the most frequent errors.

TABLE OF CONTENTS/OUTLINE

(1) Radiology of the kidneys and urinary tract: what is normal in newborns, infants and children?(2) How to evaluate a child's urinary system through ultrasound?(3) Case-based approach to UTD classification system: how to use it and how to avoid the most common mistakes?(4) Differential diagnoses of urinary tract dilation that every radiologist should be familiar with.(5) Guiding the next steps: what are the roles of other imaging methods (fluoroscopy, computed tomography, magnetic resonance imaging and nuclear medicine)?

PDEE-43 FETAL MRI: STEP-BY-STEP ASSESSMENT OF CORTICAL DEVELOPMENT MALFORMATIONS

Patricia Oliveira-Szejnfeld, MD (*Presenter*)
Mariana Cerdeira Machado, MD (*Abstract Co-Author*)
Marcos V. Camargo, MD (*Abstract Co-Author*)
Caroline Victorino Felix De Lima, MD (*Abstract Co-Author*)
Adriana De Oliveira, MD (*Abstract Co-Author*)
Luciane De Oliveira (*Abstract Co-Author*)
Fernanda Tovar-Moll, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

Demonstrate the protocol for proper image acquisition in fetal MRI and the sequences required to analyze cortical development. Study the current classification of MDC based on the disturbance of one of the three phases of cortical development: proliferation, migration, or organization.Illustrate the morphological aspects of the fetal cortex malformations in a fetal MRI. Recognize the early signs of cortical development abnormalities between 22 and 28 gestational weeks through fetal MRI. Be careful to assess the abnormalities of the infratentorial structures! These guide the genetic diagnosis in many cases.

TABLE OF CONTENTS/OUTLINE

To demonstrate the morphological aspects of the fetal cerebral cortex in malformations of cortical development (MCD) using fetal MRI, we will briefly discuss cortical development (neuronal proliferation, migration, and organization) and explore anatomic landmarks and normal cortical morphology from 22 to 34 gestational weeks.We will conduct a thorough literature review, including radiological diagnosis consensus of CMD in the postnatal period and the currently accepted classification, notions of embryological processes, and potential limits and challenges when extrapolated for the evaluation of imaging findings in fetal MRI.

PDEE-44 CONGENITAL HEART DISEASE MADE EASY: CARDIAC CT-BASED APPROACH OF SEGMENTAL SEQUENTIAL ANALYSIS

Harold Goerne, MD (*Presenter*)
Prabhakar Rajiah, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. To understand the segmental sequential analysis for congenital heart disease (CHD)2. To apply this method systematically using cardiac CT angiography3. To identify and categorize simple and complex congenital cardiac anomalies based on atrial, ventricular, and great vessel relationships

TABLE OF CONTENTS/OUTLINE

• Introduction• Importance of structured approaches in CHD imaging• Previous segmental approaches- Van Praagh• Segmental Sequential Analysis overview- Anderson's approach• Review of segmental sequential analysis using illustrative case examples- Venoatrial connections- Atrial arrangement- Atrioventricular valves- Atrioventricular connections- Ventriclular topology- Ventriculoarterial connections- Great arterial relations- Infundibular morphology- Associated malformations• Integration into structured reporting templates• Role in surgical planning and follow-up• Conclusion

PDEE-45 PEDIATRIC CARDIAC THERAPEUTIC AND MONITORING DEVICES: WHAT ARE THEY? WHERE ARE THEY? AND HOW DID THEY GET THERE?

Ankita Chauhan, MD, MBBS (*Presenter*)
Jordan B. Rapp, MD (*Abstract Co-Author*)
David M. Biko, MD, MBA (*Abstract Co-Author*)
Ammie M. White, MD (*Abstract Co-Author*)
Hansel J. Otero, MD (*Abstract Co-Author*)
Erica Riedesel, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Discuss therapeutic and monitoring cardiac devices in the pediatric age group.2. Illustrate the normal and abnormal imaging appearances of cardiovascular devices in children.3. Understand the radiologist's role in initial assessment and follow-up of the cardiovascular devices.

TABLE OF CONTENTS/OUTLINE

Goals and objectives Background information • Radiographic Anatomy, normal and abnormal• Indication for surgery and device placements• Radiologist's role in determining initial device positioning and surveillance Discussion of devices• Pacemaker devices (e.g. epicardial pacing wires, lead fracture, malposition of leads, abandoned leads) • Implantable cardioverter-defibrillators (ICDs) • Left ventricular assist device (e.g. Berlin cannulas) • Prosthetic valves (mitral, tricuspid, aortic, and pulmonary) • Closure devices (e.g. ductus occlusion and atrial septal defect closure) • Vascular stents (e.g. aortic, pulmonary arterial stents, ductus arteriosus) • Postsurgical support devices (e.g. mediastinal drains and intracardiac catheters)• Catheters (e.g. Port-a-Cath and Swan-Ganz) • Cardiovascular surgical clips and embolization coils Conclusion: Radiologists should be familiar with the radiographic appearances of the therapeutic and monitoring pediatric cardiovascular devices and how they correlate with cross-sectional imaging. Knowledge of normal appearance will help detect abnormalities in a timely manner and avoid potential complications.

PDEE-46 PHOTON-COUNTING DETECTOR CT: THE SCIENCE AND CRAFT OF PEDIATRIC PROTOCOLING IN THE NEW AGE OF CT

Anushree M. Burade, MBBS (*Presenter*)
Seyedehelaheh Hosseini, MD (*Abstract Co-Author*)
Javier Contreras Yametti, MD (*Abstract Co-Author*)
Chelsea Dunning, PhD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)
Michael S. Gee, MD, PhD (*Abstract Co-Author*)
Pallavi Sagar, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Understand multivendor photon-counting detector CT technology (PCD-CT) and the key differences from energy-integrating detector CT scanners (EID-CT)2. Learn unique scan acquisition and reconstruction factors of PCD-CT: their impact on diagnostic quality and radiation dose3. Analyze pediatric-specific PCD-CT applications and diagnostic applications: Fitting pediatric clinical needs to pediatric acquisition protocols4. Balancing multi-resolution aspects of pediatric PCD-CT: Finding the right mix of spatial, spectral, and temporal resolution

TABLE OF CONTENTS/OUTLINE

. Counting photons: pediatric-friendly overview of the differences between EID-CT and PCD-CT technologies2. Distributing photons: radiologist-friendly explanation of PCD-CT-specific scan and reconstruction factors3. Baby-fitting photons: Crafting evidence- and need-based PCD-CT protocols for children4. Making each photon count: Getting pediatric task-specific image types from spectral and spatial resolution.5. Understanding applications of pediatric PCD-CT6. Mitigating limitations of pediatric PCD-CT: Understanding that too many or too thin images do not always equal too much diagnostic information!

PDEE-47 RINGS AND SLINGS: THE ROLE OF MDCT IN EVALUATING CONGENITAL VASCULAR ANOMALIES

Uffan Zafar, MD (*Presenter*)
Zohaib Mallick, MBBS (*Abstract Co-Author*)
Naila Nadeem, MBBS (*Abstract Co-Author*)
Muhammad Abdullah (*Abstract Co-Author*)

TEACHING POINTS

This case-based educational exhibit demonstrates how multidetector CT (MDCT) is pivotal for diagnosing congenital vascular rings and slings. Participants will learn pediatric and adult MDCT protocols, post-processing techniques (MinIP, MIP, VRT, MDCTA), and evidence-based imaging guidelines. Through illustrative cases, we'll review clinical presentations, study planning, key imaging findings, interpretive pitfalls, and reporting pearls that guide management and surgical planning.

TABLE OF CONTENTS/OUTLINE

What Are "Rings" and "Slings," and How Do They Come to Be? 1.1. Embryologic origins of double aortic arch, right aortic arch with aberrant subclavian 1.2. Pulmonary artery sling and associated anomalies 1.3. Pathophysiology of tracheoesophageal compression Clinical Presentation & Initial Workup Ideal Imaging Strategies for Vascular Structures Introduction to MDCT Protocols & Guidelines Key Imaging Findings on MDCT 5.1. Double aortic arch: characteristic "ring" encircling trachea/esophagus 5.2. Right aortic arch with aberrant left subclavian: Kommerell's diverticulum 5.3. Pulmonary artery sling: aberrant left pulmonary artery course MDCT Post-Processing Techniques Case-Based Discussions Case 1 Neonatal Double Aortic Arch Presenting with Stridor Case 2 Known case of TOF presenting with respiratory distress Case 3 Teenager with Dysphagia due to Aberrant Right Subclavian Artery Review of Complications & Surgical Planning Reporting Templates & Pearls Future Directions & Emerging Applications Conclusion and Take-Home Messages

PDEE-48 NAVIGATING PEDIATRIC PULMONARY NODULES: CURRENT STATE OF KNOWLEDGE AND FUTURE DIRECTIONS

Aki Tanimoto, MD (*Presenter*)
Andrew T. Trout, MD (*Abstract Co-Author*)
Jonathan R. Dillman, MD, MSc (*Abstract Co-Author*)
Andrew Schapiro, MD (*Abstract Co-Author*)

TEACHING POINTS

Pulmonary nodules are frequently detected in patients with and without malignancy. While small pulmonary nodules detected in patients without malignancy are typically of little clinical significance, small pulmonary nodules in children with malignancy are clinically relevant as possible metastatic foci. As the lung is one of the most common sites of metastatic disease, the accurate detection of nodules is crucial for correct staging and therapy optimization. While the detection and characterization of pulmonary nodules is essential in pediatric cancer patients, this task can be challenging and time-consuming for radiologists to perform, in part due to the small size of some metastatic foci. Computer-aided detection systems and deep learning algorithms have been shown to improve sensitivity for nodule detection in adult patients, and recent research has investigated the use of these applications in children. This educational exhibit aims to provide a comprehensive review of the literature surrounding pediatric pulmonary nodules, summarizing the current state of knowledge and future directions for research.

TABLE OF CONTENTS/OUTLINE

This educational exhibit will review: • The definition and potential causes of a pulmonary nodule • Imaging modalities for evaluation of pulmonary nodules • Imaging features of pulmonary nodules in healthy children and children with cancer • Imaging features of primary pediatric pulmonary malignancy • Use of artificial intelligence (AI) for evaluation of pediatric pulmonary nodules

PDEE-49 NEUROIMAGING FINDINGS IN PEDIATRIC COCCIDIOIDOMYCOSIS: FROM HYPHAE TO MRI

Ana Geraldo, MD,MSc (*Presenter*)
Marine Moeremans (*Abstract Co-Author*)
Bruno P. Soares, MD (*Abstract Co-Author*)
Mark Halverson, MD (*Abstract Co-Author*)
Hisham Dahmoush, MBBCh (*Abstract Co-Author*)

TEACHING POINTS

1. Coccidioides species are endemic to the Southwestern region of the USA2. Symptomatic patients present with primary (flu-like) and/or secondary/disseminated infection3. Pediatric cases (~10%) are associated with a higher rate of dissemination (usually affecting the bone) and mortality4. CNS involvement may also occur and represents the most serious complication5. Imaging of the spine, brain and head and neck structures plays a pivotal role in suggesting the diagnosis as well as in excluding complications, guiding biopsy and evaluating treatment response6. The most common neuroimaging patterns of pediatric Coccidioidomycosis are a TB-like osteomyelitis of the spine/craniofacial bones or a TB-like basal cistern meningitis which may be complicated by vasculitis, infarcts, and/or hydrocephalus as well as spinal extension7. Other possible neuroimaging findings in children include conglomerate of cervical lymphadenopathy, retinitis, brain abscess/empyema, multiple small parenchymal and/or sulcal contrast-enhancing lesions

TABLE OF CONTENTS/OUTLINE

1. Overview of endemic mycosis in the USA2. Mycology, epidemiology, pathogenesis and clinical presentation of Coccidioidis species3. Role of neuroimaging in the diagnosis of Coccidioidomycosis4. Pictorial review of the characteristic neuroimaging findings of Coccidioidomycosis infection in children involving the brain, head and neck and spine (from 13 confirmed cases from a tertiary pediatric center based on an endemic region) and tips for suggesting the diagnosis5. Systematization of the most common neuroimaging patterns of pediatric Coccidioidomycosis and comparison with the adult population6. Key-points7. Conclusion

PDEE-50 IMAGING DIAGNOSIS IN CANCER PREDISPOSITION SYNDROMES IN CHILDHOOD

Paula Romero, MD (*Presenter*)

TEACHING POINTS

Cancer predisposition syndromes in childhood are increasingly recognized and carry significant clinical and imaging implications. Early identification of these syndromes enables tailored surveillance and early tumor detection, improving prognosis. Imaging, particularly ultrasound and whole-body MRI, plays a central role in screening and monitoring these high-risk patients.

TABLE OF CONTENTS/OUTLINE

Introduction to Pediatric Cancer Predisposition Syndromes Definition and epidemiology Importance of early identification Genetic Mechanisms and Molecular Basis Germline vs. mosaic mutations Tumor suppressor genes vs. proto-oncogene involvement Overview of Major Syndromes Neurofibromatosis type 1 Down syndrome Li-Fraumeni syndrome Gorlin syndrome Beckwith-Wiedemann syndrome Fanconi anemia Other mutations: MEN 2A/2B, DICER1, APC, SMARCB1, RB Role of Radiology in Surveillance and Diagnosis Imaging indications and protocols Use of ultrasound and whole-body MRI Institutional Experience and Case Examples Imaging features and clinical evolution of selected cases Current Guidelines and Follow-up Strategies Recommendations for imaging-based surveillance Summary of national and international protocols Conclusions and Clinical Implications Key imaging findings Role of radiologists in multidisciplinary care

PDEE-51 LOOK DOWN! WHEN PEDIATRIC BODY IMAGING HOLDS THE KEY TO NEUROLOGIC DIAGNOSIS

Caroline Rutten, MD (*Presenter*)
Kevin K. Fung, MBBS, FRCR (*Abstract Co-Author*)
Govind B. Chavhan, MD (*Abstract Co-Author*)
Elka Miller, MD, FRCPC (*Abstract Co-Author*)
Helen M. Branson, MBBS, FRCR (*Abstract Co-Author*)
Birgit B. Ertl-Wagner, MD, PhD (*Abstract Co-Author*)
Vivek B. Pai, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

In an era of increasing subspecialization, pediatric radiologists often focus on specific organ systems. However, many genetic and multisystemic diseases affect both the brain and body, with certain body pathologies being the cause of secondary neurological manifestations. Recognizing body imaging findings can provide key diagnostic clues to neurological disorders.This poster highlights cases where body imaging findings provide important clues for neurological diseases, emphasizing the importance of a holistic, cross-specialty approach in pediatric radiology.

TABLE OF CONTENTS/OUTLINE

- IDH mutant astrocytoma and Ollier disease- Pituitary thickening and lytic lesions in Langerhans cell histiocytosis- Macrocephaly and skeletal findings in Hurler syndrome- Optic pathway glioma and congenital pseudarthrosis in neurofibromatosis type 1- Cervical spine stenosis and other skeletal findings in chondrodysplasia punctata- Speckled brain lesions and skin lesions in incontinenta pigmenti- Fibrous dysplasia and Leydig cell hyperplasia in McCune Albright syndrome- Anti-NMDA receptor encephalitis and ovarian teratoma- Brain findings and acute liver failure in Wilson's disease- Intracranial caseating granulomas in miliary tuberculosis- Hemangioblastoma and pancreatic lesions in Von Hippel-Lindau disease- Leukodystrophy and gallbladder findings in metachromic leukodystrophy- Skull metastasis and adrenal mass in metastatic neuroblastoma- Opsoclonus-myoclonus syndrome with neuroblastoma- Septic embolic infarcts in endocarditis- Intracranial arteriopathy and supravalvular stenosis in Williams syndrome

PDEE-52 UNVEILING THE LEGACY OF SKELETAL DYSPLASIAS IN PRE-COLUMBIAN CERAMICS

Amalia P. Ojeda, MD (*Presenter*)
Tatiana Rodriguez Ojeda (*Abstract Co-Author*)
Laura Rodriguez Alba, MD (*Abstract Co-Author*)
Hugo Sotomayor Tribin (*Abstract Co-Author*)

TEACHING POINTS

Pre-Columbian ceramics dating between 400 BCE and 400 CE exhibit morphological traits of skeletal dysplasias including achondroplasia, Morquio disease, congenital femoral deficiency, hemimelia, and Mermaid Syndrome.Several practices in indigenous societies regarding individuals with skeletal dysplasias were identified, ranging from infanticide to the use of their worldviews and the assignment of specific tasks based on their abilities. Dwarfs were associated with sexuality and vitality due to their ability to generate life. They were considered protectors of Mother Earth and masters of the animals. They were respected and honored with offerings.The integration of radiology and archaeological studies provides a bridge between the past and modern scientific tools to understand the physical and cultural diversity of ancient societies.The morphological findings of the pre-Columbian ceramics match the radiological findings of contemporary patients diagnosed with skeletal dysplasias. This suggests that these conditions were recognized and represented in pre-Columbian cultures, opening new avenues for investigating the social, cultural, and medical perceptions of bone anomalies in ancient times

TABLE OF CONTENTS/OUTLINE

Introduction, Objectives, Materials and Method, History of Archaeo-medicine,Timeline of Archaeoradiology, Indigenous Culture, Dwarfism and Pre-Columbian Cultural Beliefs, Radiological Approach to Skeletal Dysplasias, Cases Morquio Disease, Achondroplasia, Spondylometaphyseal Dysplasia Type Kozlowsk, Congenital Femoral Deficiency, Tibial Hemimelia and Sirenomelia, Results and Conclusions

PDEE-53 FROM FULL-SPINE X-RAY TO HERITABLE CONNECTIVE TISSUE DISORDERS: WHEN PEDIATRIC SCOLIOSIS IS MORE THAN JUST A CURVE

Clara De Arriba Heras, MD (*Presenter*)
Claudia Moreno, MD (*Abstract Co-Author*)
Audena Maria Garcia Kempf, MD (*Abstract Co-Author*)
Ignacio Cavaller, MD (*Abstract Co-Author*)
Irene Navas Fdez-Silgado, MD (*Abstract Co-Author*)
Raquel Sanz de Lucas, MD (*Abstract Co-Author*)
Maria Pont, MD (*Abstract Co-Author*)
Carmen Gallego, MD (*Abstract Co-Author*)

TEACHING POINTS

- Recognize the radiologist's critical role in early identification, characterization, and follow-up of Heritable Connective Tissue Disorders (HCTDs) in pediatric scoliosis. - Detect imaging findings on full-spine radiographs that may raise suspicion for an underlying HCTD, and correlate with radiologic clues across other imaging and clinical referrals to guide differential diagnosis. - Illustrative cases from our institutional database highlight imaging features that aid in distinguishing among different HCTDs.

TABLE OF CONTENTS/OUTLINE

Introduction: HCTDs is a wide and heterogeneous group of syndromes with genetic variability, multisystemic involvement and significant phenotypic overlap; it can present with scoliosis, as well as many other comorbidities. Diagnosing the precise mutation is challenging but crucial for management and counseling. Clinical and imaging findings can guide genetic testing. Pediatric radiologists play a pivotal role in detecting suspicious signs, assessing multisystem involvement, and monitoring musculoskeletal and cardiovascular conditions. 1. When to suspect HCTDs on Full-Spine Radiographs - Checklist: early-onset/progressive scoliosis, spondylolysis, spondylolisthesis, acetabular protrusion, pectus deformities, vascular anomalies, and more. 2. In the setting of a scoliosis with concerning features: look for more - There may be additional clues in previous radiological or clinical records. 3. Case-Based Learning of HCTDs - Marfan Syndrome, Ehlers-Danlos Syndrome, Loeys-Dietz Syndrome, Shprintzen-Goldberg Syndrome, Arterial Tortuosity Syndrome, and Osteogenesis Imperfecta.

PDEE-54 MASTERING PEDIATRIC NEUROMETABOLIC IMAGING: A PATTERN-BASED APPROACH TO 25 ESSENTIAL DISORDERS FOR TRAINEES

Vinay V. Kandula, MBBS (*Presenter*)
Yashasvi Shukla (*Abstract Co-Author*)
Rithika Sriram, MBBS (*Abstract Co-Author*)
Rupali Jain, MD,MBBS (*Abstract Co-Author*)
Arnav Shah (*Abstract Co-Author*)

TEACHING POINTS

Neurometabolic disorders represent a complex and challenging group of conditions often encountered in pediatric neuroradiology. Early and accurate diagnosis is critical, and neuroimaging, particularly MRI, plays a pivotal role. This exhibit aims to provide radiology trainees with a practical, pattern-based approach to recognizing the imaging findings of 25 essential inherited neurometabolic diseases. Familiarity with characteristic imaging patterns, distribution of abnormalities, specific radiological signs, and key MRS findings is essential for diagnosing inherited neurometabolic disorders.

TABLE OF CONTENTS/OUTLINE

We present a curated selection of 25 "must-know" neurometabolic disorders for trainees, including conditions such as Maple Syrup Urine Disease (MSUD), Nonketotic Hyperglycinemia (NKH), Urea Cycle Disorders (UCD), Canavan Disease, Zellweger Spectrum Disorders, Pantothenate kinase-associated neurodegeneration (PKAN), leukodystrophies [Metachromatic (MLD), Krabbe, Adreno (ALD), Alexander, vanishing white matter (VWM), Pelizaeus-Merzbacher disease (PMD), Hypomyelination with Atrophy of the Basal Ganglia and Cerebellum (H-ABC), Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL), Megalencephalic leukoencephalopathy with subcortical cysts (MLC)], mitochondrial disorders (Leigh syndrome, MELAS, MERRF), Tay-Sachs, Pseudohypoparathyroidism (PHP) and others. Utilizing a case-based format, we systematically review the characteristic imaging findings on conventional MRI and MR Spectroscopy (MRS) in narrowing the differential diagnosis. Emphasis is placed on pattern recognition.

PDEE-55 THE GREAT PRETENDERS: DISTINGUISHING TUMORS AND NON-NEOPLASTIC MIMICS IN PEDIATRIC NEUROIMAGING

Vinay V. Kandula, MBBS (*Presenter*)
Yashasvi Shukla (*Abstract Co-Author*)
Rithika Sriram, MBBS (*Abstract Co-Author*)
Rupali Jain, MD,MBBS (*Abstract Co-Author*)
Arnav Shah (*Abstract Co-Author*)

TEACHING POINTS

Accurate characterization of intracranial and spinal lesions in children is critical for guiding appropriate management, which differs vastly between neoplastic and non-neoplastic conditions. However, significant overlap exists in imaging appearances, leading to diagnostic challenges. This exhibit aims to illustrate these diagnostic pitfalls using a case-based approach, highlighting key imaging features that aid in differentiating pediatric tumors from their mimics and vice versa.

TABLE OF CONTENTS/OUTLINE

We retrospectively reviewed challenging pediatric neuroimaging cases from our institutional archives. Cases were selected to represent two main categories: Pathologies Mimicking Tumors Examples include Lhermitte-Duclos disease (dysplastic cerebellar gangliocytoma), posterior fossa epidermoid/dermoid/teratoma cysts, tuber cinereum hamartoma, 3rd ventricular cavernoma, tumefactive MS, CNS sarcoidosis, lymphocytic hypophysitis, tumefactive perivascular spaces, post-radiation cavernomas of the spine, MOGAD lesions, NF1 associated spinal cord spongiform changes, and cerebellar AVF. Tumors Mimicking Other Pathologies Examples include DNET mimicking neurocysticercosis, gastric cancer metastases presenting atypically, glioneuronal tumors causing raised intracranial pressure without obvious mass, multinodular and vacuolating neuronal tumor (MVNT), infiltrating low-grade astrocytoma, basal ganglia germinoma, astroblastoma mimicking intracerebral hematoma, diffuse midline glioma/diffuse pediatric high-grade glioma with infiltrative patterns, and medulloblastoma presenting with symmetric cerebellar or brainstem involvement.

PDEE-56 PEDIATRIC PARAMEDIASTINAL MASSES: A RADIOLOGIC GUIDE

Achala Donuru, MD (*Presenter*)
Yashasvi Shukla (*Abstract Co-Author*)
Rupali Jain, MD,MBBS (*Abstract Co-Author*)
Vinay V. Kandula, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Paramediastinal masses in children encompass a wide range of pathologies, creating a diagnostic challenge for radiologists. This exhibit provides a comprehensive pictorial review of common and uncommon paramediastinal lesions, highlighting key imaging features for accurate diagnosis. Cases will illustrate characteristic findings

of neuroblastoma, schwannoma, duplication cyst, leukemia/lymphoma, hematoma, extramedullary hematopoiesis, and other relevant entities. Each case will emphasize clinical presentation, multi-modality imaging characteristics (CT, MRI, and potentially PET), and pathological correlation where available. This exhibit aims to enhance radiologists' ability to confidently differentiate these lesions, enabling timely and appropriate management.

TABLE OF CONTENTS/OUTLINE

Introduction Definition and overview of paramediastinal masses in children Importance of accurate diagnosis for appropriate management Imaging Modalities Strengths and weaknesses of radiography, CT, MRI, ultrasound, and PET/CT in evaluating paramediastinal masses Case Presentations Neuroblastoma, Schwannoma, Duplication Cyst (Esophageal and Bronchogenic), Leukemia/Lymphoma, Hematoma, Extramedullary Hematopoiesis, Teratoma Origin, imaging characteristics, and clinical presentation Illustrative cases with multi-modality imaging and pathology correlation Conclusion Summary of key teaching points Algorithm or decision tree for approaching paramediastinal masses in children Importance of multidisciplinary collaboration for optimal patient care

PDEE-57 PEDIATRIC MUSCULOSKELETAL SPORTS INJURIES: A HEAD-TO-TOE APPROACH

Emily Cao (*Presenter*)
Rebekah Julie Park (*Abstract Co-Author*)
Muhayman Sadiq, MBBS (*Abstract Co-Author*)
Saagar Patel, MD (*Abstract Co-Author*)
Manickam Kumaravel, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. Appreciate unique anatomic considerations in pediatric musculoskeletal sports injuries, including the impact of skeletal immaturity, growth plates, and biomechanical factors. 2. Outline key imaging findings of common pediatric sports injuries across different anatomical regions and their clinical significance. 3. Review the roles of radiographs, CT, MRI, and ultrasound when evaluating such injuries. 4. Discuss key imaging pitfalls and tips to avoid them. 5. Provide a structured approach to reporting injuries to ensure key findings are effectively communicated.

TABLE OF CONTENTS/OUTLINE

1. Introduction. a. Outline unique pediatric anatomical considerations, including the impact of open growth plates and skeletal immaturity. 2. Upper Extremity Injuries. a. Coracoid Stress Injury. b. Labral and Cartilage Injury. c. Little League Shoulder. d. Periostitis. e. Serratus Anterior injury. f. Avulsion fracture of the humeral lesser tuberosity. g. Little League Elbow. h. UCL Elbow Injury. i. Elbow OCD (Osteochondritis Dissecans). j. Scaphoid Injury/Wrist Bone Edema. k. Gymnast's Wrist. 3. Pelvic and Lower Extremity Injuries. a. Slipped Capital Femoral Epiphysis. b. Hip Labrum Injury. c. Rectus Femoris Avulsion. d. Patellar Dislocation. e. Patellar Avulsion Fracture. f. Knee OCD. g. Osgood-Schlatter Disease. h. Tibial Stress Edema. i. Spondylosis. j. PDEE-58 BRIGHT BUT MISPLACED: THE ECTOPIC NEUROHYPOPHYSIS ON PEDIATRIC MRI

Karine Coelho Rodrigues, MD (*Presenter*)
Ingrid Eckert, MD (*Abstract Co-Author*)
Vitoria Lima Beltrao Vieira de Melo, MD (*Abstract Co-Author*)
Jose Alberto Moraes Neto, MD (*Abstract Co-Author*)
Jose Flavio De Oliveira Neto (*Abstract Co-Author*)
Soraya Monteiro (*Abstract Co-Author*)

TEACHING POINTS

Ectopic neurohypophysis (ENH) denotes a developmental malformation where the neurohypophysis is abnormally positioned, most often situated at the level of the median eminence or infundibular recess. It is frequently associated with interruption of the pituitary stalk and hypoplasia of the anterior pituitary lobe. MRI is the preferred imaging method for identifying these alterations, especially in pediatric patients with isolated growth hormone deficiency.This exhibit aims to: Demonstrate the principal MRI signs that support the diagnosis of ectopic neurohypophysis; Review the typical anatomy and embryologic development of the hypothalamic-pituitary axis; Discuss clinical and anatomical associations observed in patients with ENH; Highlight potential diagnostic pitfalls and differential diagnoses relevant to radiologic interpretation.

TABLE OF CONTENTS/OUTLINE

Anatomical and embryological overview of the hypothalamic-pituitary axis correlating with imaging features of normal and ectopic neurohypophysis on sagittal T1 MRI; Series of pediatric cases with different clinical presentations and hormonal correlation in patients with ENH, highlighting the imaging characteristics for diagnosis; Differential diagnosis and interpretation pitfalls, teaching pearls to improve early recognition and avoid misdiagnosis.

PDEE-59 NEONATAL HEAD ULTRASOUND EMERGENCIES: WHAT THE ON-CALL RADIOLOGIST SHOULD KNOW

Hunter R. Carlock, MD (*Presenter*)
Brian Nguyen, MD (*Abstract Co-Author*)
Pavan Kottamasu, MD, MBA (*Abstract Co-Author*)
Rahim Ismail, MD (*Abstract Co-Author*)
Sankarsh N. Jetty, MD (*Abstract Co-Author*)
Shehanaz K. Ellika, MBBS, MD (*Abstract Co-Author*)
Apeksha Chaturvedi, MD (*Abstract Co-Author*)

TEACHING POINTS

Neonatal head ultrasound is an inexpensive imaging modality for assessment of intracranial abnormalities. This can be performed at the bedside without radiation or sedation, which has the advantage over CT or MRI. Limitations of neonatal head ultrasound include varying patient anatomy (relying on adequate windows), user variation, and lack of familiarity for some radiologists - particularly non-pediatric subspecialty trained. While neonatal head ultrasounds are commonly used for screening premature infants for germinal matrix hemorrhages, evaluation for other etiologies is often performed including infarction, trauma, infection, and developmental anomalies. Through this educational exhibit, we intend to provide an overview of imaging techniques of neonatal head ultrasound and normal anatomy/embryology along with various pathologies that can be seen including infection, cerebrovascular injuries, and developmental anomalies. Teaching Objectives 1. Discuss imaging techniques and normal anatomy for neonatal head ultrasound. 2. Review cerebrovascular pathology including germinal matrix hemorrhage, other intra- and extra-axial hemorrhage, and infarcts. 3. Review infectious pathology including meningitis, abscess, and ventriculitis. 4. Review embryology and development anomalies that can be seen on neonatal head ultrasounds. 5. Describe other findings that may mimic disease such as artifact and variant anatomy.

TABLE OF CONTENTS/OUTLINE

1. Introduction/Background 2. Neonatal head ultrasound techniques and normal anatomy 3. Intracranial hemorrhages 4. Cerebral infarcts 5. Intracranial infection 6. Developmental Anomalies 7. Other findings 8. Closing points

PDEE-60 IMAGING FEATURES OF PEDIATRIC AORTIC DISEASE

Izabella Necula Moculescu, MD (*Presenter*)
Flavio Zuccarino (*Abstract Co-Author*)
Maria Navallas, MD (*Abstract Co-Author*)
Juan Carretero (*Abstract Co-Author*)
Ignasi Barber, MD,PhD (*Abstract Co-Author*)
Mariana C. Planells, MD (*Abstract Co-Author*)

Jose Maria Maiques Llacer, MD (*Abstract Co-Author*)
Emilio Inarejos Clemente, MD (*Abstract Co-Author*)

TEACHING POINTS

Thoracic aortic pathology in pediatric and adult populations requires precise imaging for diagnosis, surgical planning, and post-treatment surveillance.This educational review focuses on optimized computed tomography (CT) and magnetic resonance imaging (MRI) protocols specifically tailored for the assessment of aortic diseases in the pediatric population. Key imaging techniques, including multiplanar and 3D reconstructions, are highlighted for their diagnostic value in identifying common and complex entities. The main imaging findings for each pathology are discussed, emphasizing protocol adjustments tailored to children to maximize diagnostic yield while minimizing risks. This overview aims to provide radiologists with practical guidance for selecting and implementing advanced imaging strategies in pediatric aortic disease. With this exhibit we will:

TABLE OF CONTENTS/OUTLINE

- Discuss strategies for protocol optimization in CT angiography and MRI, emphasizing techniques to reduce radiation and contrast doses and shorten acquisition times. These adjustments enable high-quality imaging while minimizing risks, and in some cases, allow for optimal studies without the need for sedation.- Review of the key imaging findings of congenital aortic malformations (coarctation, hypoplasia, vascular rings, etc).- Review the key imaging findings of aortopathies, classifying them as congenital and non congenital: - Congenital (connective tissue disorders such as Marfan syndrome, Loeys-Dietz, or Ehlers-Danlos, middle aortic syndrome, etc.). - Non-congenital (Takayasu arteritis).

PDEE-61 APOPHYSEAL INJURIES IN YOUNG ATHLETES: IMAGING CLUES FROM DIAGNOSIS TO HEALING

Jaime Isern-Kebschull, PhD, MD (*Presenter*)
Sandra Mecho Meca, PhD (*Abstract Co-Author*)
MINDAUGAS GUDELIS (*Abstract Co-Author*)
Ara Kassarjian, MD, FRCPC (*Abstract Co-Author*)
Agustin M. Marrero SR, MD (*Abstract Co-Author*)
Alvaro Bartolome Solanas, MD (*Abstract Co-Author*)
Xavier Alomar (*Abstract Co-Author*)
Ana Isabel Garcia, MD (*Abstract Co-Author*)
Gil Rodas Font (*Abstract Co-Author*)
Emilio Inarejos Clemente, MD (*Abstract Co-Author*)

TEACHING POINTS

- Present the anatomical features and normal anatomical variants of ossification centers in pediatric and adolescent athletes. - Review the pathophysiological mechanisms and clinical correlation of apophyseal injuries. - Illustrate the radiological spectrum of apophyseal injuries, ranging from apophysitis to avulsion fractures. - Differentiate apophyseal injuries from their main radiological mimics. - Demonstrate the expected imaging findings during the healing process following conservative and surgical treatment, and their correlation with return-to-play (RTP) timelines.

TABLE OF CONTENTS/OUTLINE

1. Anatomical characteristics and normal variants of ossification nuclei in children and young athletes. 2. Pathophysiology and clinical correlation of apophyseal injuries. 3. Imaging spectrum of apophyseal injuries, from apophysitis to avulsion fractures , highlighting key imaging features to avoid misinterpretation . 4. Differential diagnosis, with emphasis on r adiological mimics of apophyseal injuries. 5. Healing process and imaging-based risk assessment for clinical Return to Play (RTP) decisions.

PDEE-62 PEDIATRIC LIVER TRANSPLANT: INDICATIONS AND FOCUS ON ANATOMIC ASSESSMENT. A REPORT FROM THE PEDIATRIC LIRADS WORKING GROUP

Michael R. Acord, MD (*Presenter*)
Amy B. Kolbe, MD (*Abstract Co-Author*)
Geetika Khanna, MD, MS (*Abstract Co-Author*)
Cara E. Morin, PhD (*Abstract Co-Author*)
Haithuy N. Nguyen, MD (*Abstract Co-Author*)
Andrew S. Phelps, MD (*Abstract Co-Author*)
Mitchell Rees, MD (*Abstract Co-Author*)
Gary R. Schooler, MD (*Abstract Co-Author*)
Judy H. Squires, MD (*Abstract Co-Author*)
Alex Towbin, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Indications for pediatric liver transplant differ from those in adults. 2. Knowledge and reporting of critical anatomy, including sectional anatomy, vascular and volumetric assessment is essential to guide split and whole liver transplant. 3. Liver transplant is the only treatment option for unresectable liver malignancies in children and the anatomic definitions of PRETEXT group assignment and annotation factors are essential for reporting.

TABLE OF CONTENTS/OUTLINE

• Brief review of several pediatric liver pathologies requiring resection or transplant o Neoplasms o Cholestatic syndromes o Metabolic disease • Presurgical imaging modalities o Complementary role of sonography, CT and MRI for liver transplant planning • Tumor staging (PRETEXT/POSTTEXT) o Anatomic definitions of liver sections o Annotation factors with a focus on challenges identifying vascular involvement • Recipient anatomic assessment o Native liver volume and size of patient o Impact of prior surgeries (e.g. Kasai) o Risk prohibitive characteristics for transplant (i.e. extent of vascular tumor involvement, tumor type, institutional practice patterns) • Living donor anatomic assessment with attention to relevant anatomy and important information for reporting o Segmentation, liver volumes o Variant anatomy: venous, arterial, biliary • A brief review of complications after resection/transplant relating to anatomy o Biliary: leak, strictures, excluded system/orphan ducts o Vascular: stenosis, thrombosis

PDEE-63 NONINVASIVE 4D MRI ASSESSMENT OF FETAL FORAMEN OVALE FLOW WITH DOPPLER ULTRASOUND GATING

Jochen Gerstner, MD (*Presenter*)
Takashi Fujiwara (*Abstract Co-Author*)
Sungho Park, MD (*Abstract Co-Author*)
Erin K. Englund, PhD (*Abstract Co-Author*)
Lorna Browne, MD, FRCR (*Abstract Co-Author*)
Ilham Essafri (*Abstract Co-Author*)
Alex Barker (*Abstract Co-Author*)

TEACHING POINTS

Doppler ultrasound (DUS)-gated 4D flow MRI enables in vivo visualization of fetal foramen ovale (FO) shunting without sedation, contrast, or retrospective synchronization. This technique enhances physiologic assessment of fetal intracardiac flow using standard clinical MRI equipment. Physiologic gating and online image reconstruction provide a framework for broader clinical implementation in fetal cardiovascular imaging. This exhibit will a. Describe the technical approach of DUS-gated 4D flow MRI for fetal cardiac evaluation b. Demonstrate direct visualization of right-to-left atrial shunting via the foramen ovale c. Review the clinical and physiologic relevance of FO flow in fetal circulation d. Compare this approach with existing fetal echocardiography and MRI techniques e. Discuss future directions, including potential for flow quantification and clinical translation

TABLE OF CONTENTS/OUTLINE

Background Fetal circulation and the functional role of the foramen ovale Imaging Methods a. MRI hardware and acquisition sequence b. Doppler ultrasound gating setup c. Online image reconstruction and offline post-processing Case Presentation a. Clinical background and fetal status b. Acquisition parameters and gating signals c. Visualization of FO-directed blood flow Discussion a. Technical advantages and disadvantages over traditional methods b. Comparison with prior 4D flow techniques in fetal imaging c. Limitations and future applications (including flow quantification potential) Conclusion Feasibility and clinical relevance of noninvasive intracardiac fetal flow assessment using physiologic gating

PDEE-64 PEDIATRIC ACCIDENTAL HEAD TRAUMA: WHAT THE ON-CALL RESIDENT MUST KNOW

Aldo Mijail Pacheco Carrillo, MD (*Presenter*)
Claudia Y. Rodriguez Garza, MD (*Abstract Co-Author*)
Alejandra I. Castillo Cervantes, MD (*Abstract Co-Author*)
Daniel Chavez, MD (*Abstract Co-Author*)
Erwin J. Narvaez Garcia, MD (*Abstract Co-Author*)
Guillermo Elizondo-Riojas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Understand key anatomical differences between pediatric and adult skulls that influence trauma patterns. Identify critical imaging features of common intra-axial, extra-axial, and skull injuries in pediatric head trauma. Apply age-appropriate imaging strategies and modality selection in the radiologic assessment of pediatric TBI.

TABLE OF CONTENTS/OUTLINE

Teaching Points - Core educational objectives of the exhibit. Introduction - Epidemiology, relevance, and clinical context of pediatric head trauma. Pathophysiology - Mechanisms of injury. Anatomical Differences - Key skull and brain distinctions between children and adults. Imaging Modalities - Role of CT, MRI, and ultrasound in pediatric head trauma. Skull Fractures and Scalp Injuries - Linear, depressed (“ping pong”), diastatic, complex ("burst") fractures, and soft tissue/subgaleal injuries. Extra-axial Injuries - Subdural, epidural, and subarachnoid hemorrhages. Intra-axial Injuries - Intraparenchymal hematoma and diffuse axonal injury (DAI). Uncommon Mechanisms - Penetrating trauma and atypical causes (e.g., arrows, pencils, firearms). Complications and Differential Diagnosis - Sequelae, mimics, and clinical-radiologic pitfalls. Take-Home Messages - Final summary of key radiologic concepts for the on-call resident.

PDEE-65 PEDIATRIC STROKE CLASSIFICATION: ARTERIOPATHY, CARDIOEMBOLISM AND BEYOND

Stephen B. Little, MD (*Presenter*)
Asha Sarma, MD (*Abstract Co-Author*)
Alexandra M. Foust, DO (*Abstract Co-Author*)
Laura L. Hayes, MD (*Abstract Co-Author*)
Darragh Brady, MD (*Abstract Co-Author*)
Sumit Pruthi, MBBS (*Abstract Co-Author*)
Lori Jordan (*Abstract Co-Author*)
Bryan Philbrook (*Abstract Co-Author*)

TEACHING POINTS

1. CASCADE is a consensus-based anatomic classification system, providing uniform nomenclature for childhood arterial ischemic stroke. 2. In children with arterial ischemic stroke, most cases of small vessel arteriopathy (SVA) are diagnosed based on infarct characteristics (MRI) and clinical data. 3. There is no true ‘gold standard’ for the diagnosis of most childhood arteriopathies, and the distinction between arteriopathy and thromboembolism is not always clear. 4. In children with stroke and large vessel occlusion, arteriopathy is more likely than cardioembolism when there is no cardiac disease, and thrombus is accompanied by arterial stenosis or irregularity. 5. Strong vessel wall enhancement may be associated with progressive arteriopathy, but this is controversial. 6. Perfusion failure may trigger stroke in children with steno-occlusive arteriopathy and limited cerebrovascular reserve, even in the absence of thrombotic arterial occlusion. 7. One of the limitations of CASCADE is the variable sensitivity of different modalities (e.g., to stenoses and basal collaterals).

TABLE OF CONTENTS/OUTLINE

1. Introduction: Pediatric stroke and the importance of stroke classification. 2. Childhood AIS (arterial ischemic stroke) Standardized Classification And Diagnostic Evaluation - CASCADE: Description of the CASCADE system, including strengths and limitations. 3. Cases: Application of the CASCADE criteria in clinical practice - Small vessel arteriopathy of childhood. Unilateral focal cerebral arteriopathy. Bilateral cerebral arteriopathy. Aortic/cervical arteriopathy. Cardio-embolic. Other (including cryptogenic). Multifactorial. 4. Prognostic value of the CASCADE system 5. Conclusions

PDEE-66 A RADIOLOGIST'S GUIDE TO CLEFT LIP AND PALATE CT REPORTING- WHAT THE CRANIOFACIAL TEAM WANTS TO KNOW

Alexandra M. Foust, DO (*Presenter*)
Jarred T. Todd, DO (*Abstract Co-Author*)
Lindsey Pelissier, MD (*Abstract Co-Author*)
Stephen B. Little, MD (*Abstract Co-Author*)
Sumit Pruthi, MBBS (*Abstract Co-Author*)
Dann Martin, MD, MS (*Abstract Co-Author*)
Asha Sarma, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Neuro/pediatric radiologists are underutilized, but important members of craniofacial teams. 2. Familiarity with the embryology and anatomy of cleft lip and palate improves understanding and interpretation of maxillofacial CT in cleft patients. 3. Understanding of expected cleft related surgical changes improves accuracy in identifying complications (i.e. oronasal fistula, failed bone graft incorporation or resorption, hardware failure or infection).

TABLE OF CONTENTS/OUTLINE

Cleft lip and/or palate is a common congenital malformation of the head and neck with an incidence of approximately 0.33 per 1,000 live births. Affected patients undergo staged repairs over the course of childhood, often customized to the individual patient’s needs by a dedicated craniofacial team. A team-based approach to these complex patients has been shown to improve patient outcomes and streamline patient care leading to improved efficiency and cost savings. The role of the neuro/pediatric radiologist is often under-utilized on these teams, however can prove invaluable for initial diagnosis, surgical planning, and post-treatment monitoring and surveillance. This education exhibit will first review pertinent embryology and nomenclature related to cleft lip and palate, highlighting related maxillofacial anatomy abnormalities where appropriate. Subsequently, the stages (and timing) of surgical repair and expected imaging findings will be discussed, with attention to areas where the radiologist can “add value” in reports. Finally, imaging findings that may be encountered related to treatment failure/complication (oronasal fistula, failed graft incorporation) will be discussed through case-based examples.

PDEE-67 IMAGING DIAGNOSIS FOR FETAL AND NEONATAL EMERGENCY ABDOMINAL DISEASES

Chihiro Tani, MD (*Presenter*)
Shogo Maeda, MD (*Abstract Co-Author*)
Haruka Higashibori (*Abstract Co-Author*)
Fuminari Tatsugami, MD (*Abstract Co-Author*)
Yuko Nakamura, MD, PhD (*Abstract Co-Author*)
Kazuo Awai, MD (*Abstract Co-Author*)

TEACHING POINTS

Ultrasonography (US) and plain radiography are the first-choice imaging methods for neonatal emergency abdominal imaging. Many emergency abdominal diseases are diagnosable by US and plain radiography. The demand for diagnostic fetal imaging studies is increasing because they can detect emergency abdominal anomalies early.We present US and plain radiography findings made in major emergency abdominal diseases in neonates as well as MRI results for fetuses that every radiologist should know.

TABLE OF CONTENTS/OUTLINE

(1) US and Plain radiography findings in neonates- Gastrointestinal diseasesmidgut volvulus, hypertrophic pyloric stenosis, necrotizing enteritis, focal intestinal perforation- Hepatobiliary system diseases- biliary atresia, congenital biliary dilatation(2) MRI findings in fetuses- Gastrointestinal obstruction- duodenal atresia, jejuno-ileal atresia, meconium peritonitis, anorectal anomaly- Abdominal wall defects- omphalocele, gastroschisisDiagnostic US-, plain radiography-, and MRI findings that are important when fetal- or neonatal emergency abdominal anomalies are suspected.

PDEE-68 PEDIATRIC MUSCULOSKELETAL INFECTION: A RADIOLOGICAL EVALUATION TO AVOID MISINTERPRETATION

Emilio Inarejos Clemente, MD (*Presenter*)
Maria Navallas, MD (*Abstract Co-Author*)
Enrique Ladera (*Abstract Co-Author*)
Ignasi Barber, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

After reviewing this exhibit, the learner should Understand the pathophysiology of pediatric MSK infections and their impact on imaging appearances. Describe the imaging techniques, with emphasis on US and advanced MRI techniques. Recognize classical imaging findings of osteomyelitis, septic arthritis, and soft tissue infections. Describe the role and added value of advanced MRI techniques (DWI and DCE MRI), in challenging cases. Identify mimickers of MSK infection and discuss key imaging features that help differentiate them.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Common infections (osteomyelitis, septic arthritis, pyomyositis). 3. Pathophysiology and Impact on Imaging: Discussion of infection pathways and their influence on radiological findings. 4. Imaging Techniques and Findings - Classical techniques: x-rays, US, CT, MRI and nuclear medicine.- Advanced techniques: DWI and DCE-MRI. 5. Classical Imaging Findings of osteomyelitis, septic arthritis ans soft tissue infections, with its potential complications. 6. Role of Advanced MRI Techniques to Avoid Misinterpretation - DWI: detection of abscess and differentiating infection from sterile inflammation or tumors by using ADC as a biomarker.- DCE MRI: evaluation of perfusion patterns to distinguish infection from neoplastic processes (time intensity curves) and for therapy monitoring. 7. Mimickers of Infection - Neoplastic: Ewing sarcoma, LCH, leukemia. - Inflammatory: CNO, JIA, transient synovitis.- Others: stress fracture, bone infarcts. 8. Summary: key points reinforcing the importance of integrating clinical, laboratory, and imaging findings for accurate diagnosis.

PDEE-69 DON'T MISFLAG THE IFAG: ULTRASOUND IN THE DIAGNOSIS OF IDIOPATHIC FACIAL ASEPTIC GRANULOMA

Rodrigo Sutil, MD (*Presenter*)
Alejandra Somoano Marfull (*Abstract Co-Author*)
Silvia Revuelta Gomez, MD (*Abstract Co-Author*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Alvaro Sanchez Mulas (*Abstract Co-Author*)
Marta Pelaz Esteban (*Abstract Co-Author*)
Alexandra de Diego Diez (*Abstract Co-Author*)
Vanesa Gomez Dermit (*Abstract Co-Author*)
Elena A. Gallardo, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

- Highlight the clinical and ultrasonographic features of idiopathic facial aseptic granuloma (IFAG). - To propose a differential diagnosis with other skin lesions that can be confused with idiopathic facial aseptic granuloma. - To show images from our institution illustrative of this dermatologic condition.

TABLE OF CONTENTS/OUTLINE

Idiopathic facial aseptic granuloma (IFAG) is a self-limiting inflammatory process, typical of pediatric age, which manifests as a cutaneous nodule in the facial region, typically in the malar area.IFAG is a recently described entity with few cases published in the literature. However, its incidence is thought to be relatively high and it is largely underdiagnosed.Histologically it shows an inflammatory infiltrate with the presence of multinucleated gigantic cells.High-frequency probe ultrasound is a very useful tool for diagnosis due to its image resolution, availability and safety. The imaging findings, together with the clinical presentation, make it possible to reach a certain diagnosis without the need for biopsy.On ultrasound a solid, ovoid intradermal lesion with a hypoechogenic appearance, with well delimited borders, without capsule or calcific deposits is observed. Generally, there is no intralesional Doppler flow except in the case of complications. Doppler also allows inferring the time of evolution of the nodule, since the perile-sional flow disappears in the resolution phase.The differential diagnosis includes cutaneous abscesses, epidermoid cyst, pilomatrixoma and pyogenic granuloma among others.

PDEE-70 MOVE, TWIST, KINK, RELAX: A MULTIMODALITY GUIDE TO PEDIATRIC ORGAN HYPERMOBILITY

Katsutoshi Horiuchi, MD (*Presenter*)
Ryosuke Taiji, MD (*Abstract Co-Author*)
Hotaka Doi (*Abstract Co-Author*)
Shunsuke Taniguchi (*Abstract Co-Author*)
Minako Wada (*Abstract Co-Author*)
Ippei Morisawa (*Abstract Co-Author*)
Toshihiro Tanaka, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to Classify organ motion into four dynamic patterns—Move (wander), Twist (torsion), Kink, Relax (laxity)—on dynamic ultrasound. Correlate these sonographic signs with CT/MRI findings and propose an imaging algorithm that prioritises emergencies and identifies underlying connective-tissue phenotypes.

TABLE OF CONTENTS/OUTLINE

Pediatric organ hypermobility represents a spectrum of motion anomalies produced by lax or variant ligaments, redundant mesenteries, and heritable connective-tissue disorders. Unrecognised hypermobility can lead to acute ischemia, obstructive crises, or delayed diagnosis of systemic disease. Real-time ultrasound “freezes” the critical movement, while CT and MRI provide the anatomic road-map required for surgical decision-making and genetics referral. Move (Wander) Wandering thymus on phonation, Mobile cecum, Abdominal undescended testis, Organo-axial gastric volvulus Twist (Torsion) Intermittent intravaginal testicular torsion (Bell-Clapper), Ovarian torsion, Mid-gut volvulus (SMA/SMV whirlpool), Torsed wandering spleen Kink (Kink / Dynamic Compression) Iliac-artery endofibrosis in athletes, Nutcracker phenomenon, Median arcuate ligament syndrome (MALS)—celiac-artery indentation, Tracheobronchomalacia—expiratory airway collapse Relax (Heritable Connective-Tissue Laxity) Nail-Patella syndrome ,Down syndrome, Marfan syndrome, Ehlers-Danlos spectrum This pictorial review unifies multisystem pediatric hypermobility within a four-pattern, multimodality framework, streamlining differential diagnosis, expediting treatment of torsion/volvulus, and uncovering genetic disorders before complications arise.

PDEE-71 IMAGING OF ABDOMINAL AND PELVIC TUMORS IN THE NEONATE AND YOUNG INFANT

Diana Veiga Canuto, PhD, MD (*Presenter*)
Roberto Llorens Salvador (*Abstract Co-Author*)
Oscar M. Navarro, MD (*Abstract Co-Author*)

TEACHING POINTS

Neonatal and congenital tumors present unique diagnostic challenges; understanding their peculiarities in behavior, prognosis an associations with other congenital anomalies is key for an appropriate approach. Accurate imaging characterization, integrated with age, location, clinical and laboratory findings, is essential for differentiating neoplasms from non-neoplastic entities

TABLE OF CONTENTS/OUTLINE

INTRODUCTION Terminology Epidemiology Challenges of tumor behavior Associations with congenital anomalies DIAGNOSTIC APPROACH Role of imaging Diagnostic approach based on prenatal vs postnatal detection, location, appearance, clinical and laboratory findings ABDOMINAL MASSES LIVER Age distribution Differential diagnosis solitary lesions: Congenital hemangioma vs hepatoblastoma, Mesenchymal hamartoma Other liver lesions: vascular anomalies, umbilical venous line-related complications Differential diagnosis of multiple liver lesions: Neuroblastoma metastases vs infantile hemangiomas, Multifocal hepatoblastoma SUPRARENAL Normal adrenal gland in fetus and neonates Adrenal masses Neuroblastoma vs hemorrhage Other suprarenal region lesions: Intraabdominal extralobar bronchopulmonary sequestration, Enteric duplication cyst, Upper pole renal malformations RENAL Mesoblastic nephroma and subtypes Neonatal Wilms tumor: predisposing genetic conditions, nephrogenic rests, bilateral tumors Rhabdoid renal tumor Renal pseudomasses Column of Bertin Pyelonephritis Multicystic dysplastic kidney OTHER ABDOMINAL CYSTIC LESIONS Choledocal cyst Antenatal ovarian torsion Meconium peritonitis Enteric duplication cyst PELVIC LESIONS Sacrococcygeal teratoma CONCLUSION

PDEE-72 DOUBLE-EDGED SWORD EFFECT OF CANCER THERAPY: SECOND MALIGNANT NEOPLASMS (SMNS) IN PEDIATRIC CANCER SURVIVORS

Rhea A. Morani (*Presenter*)
Ritu Shah (*Abstract Co-Author*)
Sireesha Yedururi, MBBS (*Abstract Co-Author*)
Ishan Arora (*Abstract Co-Author*)
Cynthia Herzog (*Abstract Co-Author*)
Priya R. Bhosale, MD (*Abstract Co-Author*)

TEACHING POINTS

1) The cancer mortality rate in the pediatric population has rapidly declined with the advent of modern therapies in oncology; however, long term effects of treatment pose significant challenges. 2) One of the most dreaded complications of cancer therapy is the risk of second malignant neoplasms (SMNs), which are histologically different primary neoplasms that occur at least two months after the end of prior cancer treatment. 3) Risk factors for SMNs can be divided into therapy-related factors (chemotherapy, radiation, stem-cell transplant), patient characteristics (genetic predisposition, age), and environmental/behavioral factors. 4) Treatment protocols should be tailored by considering data on treatment outcomes, toxicities, cumulative doses, and genetic predispositions to reduce SMN risks without compromising the efficacy of primary therapy. 5) Vigilant, potentially lifelong surveillance should also be emphasized, and radiologists must remain aware to ensure timely diagnosis and management of these cases.

TABLE OF CONTENTS/OUTLINE

A) Introduction. B) Epidemiology, etio-pathogenesis, clinical findings and pathology of SMNs in pediatric cancer survivors. C) Classification with multimodality cross-sectional imaging illustrations: 1) Therapy related SMNs a) Chemotherapy-related SMNs b) Radiation-related SMNs c) Stem cells transplant related SMNs 2) SMNs due to genetic or hereditary predisposition (e.g. RB1, TP53, BRCA1/2, NF1, MLH1, MSH2, MSH6, and DICER1 mutations). D) Strategies to mitigate risk of SMNs (e.g. chemotherapy modifications, alternating therapies, radiation adjustments, advancing radiation delivery). E) Surveillance and screening. F) Conclusion.

PDEE-73 MIND THE LIMP: KEY INSIGHTS IN PEDIATRIC HIP IMAGING FROM PRACTICAL TIPS TO EMERGING DIAGNOSES

Laura Macedo, MD (*Presenter*)
Ariadne Obrigon (*Abstract Co-Author*)
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)
Vitor T. Paula, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the anatomy applied to imaging exams with the particularities in childhood. 2. To discuss and illustrate the most common paediatric hip and proximal lower limb pathologies and their presentation in the different imaging modalities. 3. To discuss updates in the pathophysiology and imaging propaedeutics of paediatric hip diseases. 4. To discuss and propose structured reporting templates highlighting the essential findings for each pediatric hip disorder. 5. To discuss the most common hip and proximal lower limb diseases in childhood, including: Congenital disorders: Developmental dysplasia of the hip, congenital short femur, proximal femoral focal deficiency Development disorders: Legg-Calvé-Perthes disease, coxa valga and vara, femoroacetabular impingement Infectious disorders: Transient synovitis, septic arthritis Mechanical disorders: Slipped Capital femoral epiphysis, avulsion fracture, stress fracture, apophyseal injury, acetabular labral tear, athletic pubalgia Tumors: benign and malignant: Osteoid osteoma, osteochondromas, osteosarcoma, Ewing sarcoma, leukemia

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of hip and proximal lower limb anatomy in children. Main hip and proximal lower limb pathologies in children. Emerging perspectives in the diagnosis of pediatric hip disorders. Imaging: Multimodality imaging techniques, such as plain radiography (XR), magnetic resonance imaging (MRI) and ultrasonography (US) Imaging evaluation: Importance of imaging in diagnosis of diseases affecting the hip and proximal lower limb in children. Structured reporting templates highlighting the essential findings for each pediatric hip disorder.

PDEE-74 CHOLESTEATOMA IN THE PEDIATRIC POPULATION; WHAT THE SURGEON WANTS TO KNOW

Saba Moghimi, MD (*Presenter*)
Adrian James (*Abstract Co-Author*)
Caroline Rutten, MD (*Abstract Co-Author*)
Manohar M. Shroff, MD, FRCPC (*Abstract Co-Author*)
Birgit B. Ertl-Wagner, MD, PhD (*Abstract Co-Author*)
Vivek B. Pai, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

1. When reporting findings in the setting of cholesteatoma, knowledge of key anatomical landmarks and variants can inform surgical management. 2. Careful description of facial recess, anterior epitympanic recess, sinus tympani, mastoid antrum, and mastoid air cells is important as it is challenging to remove disease from these areas increasing the risk of recurrence. 3. The level of the lateral dura is relevant in informing the surgical approach. The location of the sinodural plate and whether there is involvement/erosions by disease is useful for safe intraoperative navigation. 4. Anatomical variants including a low lying tegmen or a high/dehiscent jugular bulb are important to highlight. 5.Multiple pathologies can mimic cholesteatoma including mastoiditis, cholesterol granuloma, and teratoma. 6. Potential complications related to cholesteatoma including Labyrinthine fistulisation, otomastoiditis, and CSF leakage are important to recognize.

TABLE OF CONTENTS/OUTLINE

1. Review the imaging technique including standard CT, MRI, and photon counting CT 2. Present an approach to cholesteatoma. 3. Review relevant anatomy and key structures. 4. Review specific findings that are relevant for surgical management and planning. 5. Discuss pathologies that can mimic cholesteatoma.

PDEE-75 CHILDHOOD TUMORS AND OTHER CONDITIONS ASSOCIATED WITH DICER1 SYNDROME: AN IMAGING REVIEW

Jessie Huang (*Presenter*)
Shehanaz K. Ellika, MBBS, MD (*Abstract Co-Author*)
Apeksha Chaturvedi, MD (*Abstract Co-Author*)

TEACHING POINTS

1. DICER1 syndrome is a rare genetic condition associated with hereditary cancers that commonly affect infants and young children. Tumors arise due to germline mutations in the DICER1 gene, affecting processing of microRNA. 2. Associated tumors include pleuropulmonary blastoma, ovarian Sertoli-Leydig cell tumor, embryonal rhabdomyosarcomas, pineoblastoma, cystic nephroma, and multinodular goiter. 3. US, CT, MRI, and fluorodeoxyglucose PET/CT and PET/MRI play an important role in initially identifying and evaluating these diverse tumors in addition to surveilling carriers with known variants.

TABLE OF CONTENTS/OUTLINE

1. Introduction and Genetics 2. WHO Classification of the Associated Tumors 3. DICER1 Syndrome and Surveillance 4. Clinical and Imaging Features with Pathologic Correlation a) Pleuropulmonary blastomas b) Embryonal rhabdomyosarcomas c) Ovarian tumors d) Renal tumors d) Thyroid conditions 2) Pineoblastoma f) Genetically related conditions 5. Conclusion

PDEE-76 PEDIATRIC BOWEL OBSTRUCTION IN CHILDREN BEYOND THE NEONATAL PERIOD: RECOGNIZING THE URGENT AND THE UNEXPECTED

Silvia Revuelta Gomez, MD (*Presenter*)
Alejandra Somoano Marfull (*Abstract Co-Author*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Marta Pelaz Esteban (*Abstract Co-Author*)
Vanesa Gomez Dermit (*Abstract Co-Author*)
Carmen Gonzalez-Carrero Sixto, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the various etiologies of bowel obstruction and their underlying pathophysiological mechanisms. 2. To describe the hallmark imaging findings. 3. To assess whether additional imaging is required based on basic radiograph and ultrasound (US) results: guidelines for optimizing the computed tomography (CT) protocol.

TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Imaging techniques. Pediatric bowel obstruction can be a challenging diagnosis and often manifests with nonspecific symptoms such as abdominal pain, distention, and vomiting. Imaging techniques are necessary to identify the cause, location, and severity of the obstruction. 2.1. Conventional radiography. 2.2. US. 2.3. CT protocol. 3. Causes of bowel obstruction. Bowel obstruction in older children can be due to a variety of congenital and acquired causes, often different from the causes of bowel obstruction in neonates or adults. To present the topic in a practical way, cases from our hospital will be used as an example of the different pathologies. 3.1. Malrotation and midgut volvulus. 3.2. Appendicitis. 3.3. Intussusception. 3.4. Meckel diverticulum. 3.5. Sigmoid volvulus. 3.6. Internal hernia. 3.7. Inflammatory bowel disease. 3.8. Gastrointestinal duplication cysts. 3.9. Ingested foreign body. 3.10. Distal intestinal obstruction syndrome. 4. Conclusion. A clear knowledge of the common causes of pediatric bowel obstruction, an understanding of the appropriate choice of imaging modality and recognition of the key imaging features can lead to early diagnosis and appropriate treatment, optimizing the management of children with this condition. 5. Bibliography.

PDEE-77 ADVANCING PEDIATRIC INTERVENTIONAL ONCOLOGY - CAN WE OFFER MORE THAN BIOPSIES?

Kevin K. Fung, MBBS, FRCR (*Presenter*)
Prakash Muthusami, MBBS, MD (*Abstract Co-Author*)
Premal A. Patel, MBBS, FRCR (*Abstract Co-Author*)
Fernando Gomez Munoz (*Abstract Co-Author*)
Kishore Minhas, FRCR,MBChB (*Abstract Co-Author*)
Raja Shaikh, MD (*Abstract Co-Author*)
Anne Gill, MD (*Abstract Co-Author*)
C. Matthew Hawkins, MD, MBA (*Abstract Co-Author*)
Michael J. Temple, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Interventional radiologists should be aware of the important differences between pediatric and adult neoplasms in terms of tumor biology, natural history of disease, treatment options and follow-up strategies. Pediatric-specific technical modifications should be made. 2. Compared to adults, a significantly larger amount of tissue is required for molecular profiling and risk stratification for pediatric tumors, e.g. the N-myc status in neuroblastoma and CTTNB1 in hepatoblastoma. 3. Endovascular interventions have improved outcome in specific tumors types, e.g. intra-arterial chemotherapy has improved globe salvage rate in advanced retinoblastoma to 70 - 80%; trans-arterial radioembolization can downstage hepatoblastoma to bridge to surgical resection or liver transplantation; bland embolization is a life-saving measure for ruptured tumor. 4. Percutaneous thermal or non-thermal ablation can be an effective treatment in many benign and malignant pediatric tumors, including desmoid fibromatosis, primary liver tumors or metastatic lesions to lungs, liver, soft tissue and bones. 5. Image-guided interventions can improve the child's quality of life by symptomatic palliation. Indwelling tunneled catheter can alleviate dyspnea and discomfort from malignant effusion and allow home care. Cryoablation is an opioid-free alternative for durable pain control, especially in patients with bone metastases.

TABLE OF CONTENTS/OUTLINE

1. Introduction; 2. Biopsy recommendation with reference to Children's Oncology Group; 3. Endovascular and ablative therapies for different tumors; 4. Palliative interventions; 5. Complications and preventive measures

PDEE-78 CANCER PREDISPOSITION SYNDROMES IN CHILDREN - WHO, WHEN AND HOW TO SCREEN?

Kevin K. Fung, MBBS, FRCR (*Presenter*)
Caroline Rutten, MD (*Abstract Co-Author*)
Vivek B. Pai, MBBS, MD (*Abstract Co-Author*)
Yin Ting Chiu (*Abstract Co-Author*)
Elaine Y. Kan, MBChB (*Abstract Co-Author*)
Eman E. Marie, MD, MSc (*Abstract Co-Author*)
David Malkin (*Abstract Co-Author*)
Andrea S. Doria, MD, PhD (*Abstract Co-Author*)
Mary-Louise C. Greer, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Although rare, at least 15-20% of pediatric cancer patients harbor a germline pathogenic variant related to cancer predisposition syndrome (CPS). In general, screening is recommended when there is an age-specific 5% or greater chance of developing childhood cancer. 2. Clinical features suggestive of CPS include: 1) family

history of same or related cancer; 2) bilateral, multifocal or multiple cancers; 3) tumor being diagnosed at an earlier age than usual; 4) physical findings or tumor type associated with specific CPS. 3. Surveillance imaging in pediatric CPS aims to detect primary malignancy in asymptomatic children and secondary neoplasm in those with a known cancer. Screening protocols continue to evolve, guided by evidence and expert opinion, with modality and timing determined by tumor type, age of onset and interval of tumor occurrence. 4. Whole-body MRI (WBMRI) is recommended in a subset of CPS, including Li-Fraumeni syndrome, neurofibromatosis type I & II, constitutional mismatch repair deficiency, hereditary paraganglioma and pheochromocytoma syndrome, rhabdoid tumor predisposition syndrome, and more recently, enchondromatosis & hereditary multifocal osteochondromatosis. 5. Optimization of WBMRI scan acquisition supplemented by regional MRI as warranted, and use of standardized reporting terminology can help reduce false positive results, which can lead to unnecessary investigations, higher healthcare cost and patient/parental anxiety.

TABLE OF CONTENTS/OUTLINE

1. Common types of pediatric CPS; 2.Updates in pediatric CPS screening; 3.WBMRI in CPS (a. Role, b. scan optimization, c. strategies to reduce false negative and positive results); 4.Tips for a successful CPS screening program

PDEE-79 LOOKING AT LITTLE BUMPS AND LUMPS: IMAGING OF SUPERFICIAL SOFT TISSUE LESIONS IN PEDIATRICS

Noah M. Seymore, MD (*Presenter*)
Houman Alizadeh, MD (*Abstract Co-Author*)
Azadeh Eslambolchi, MD (*Abstract Co-Author*)
Maria R. Ponisio, MD (*Abstract Co-Author*)

TEACHING POINTS

Palpable superficial “lumps and bumps” are an extremely common reason for presentation of pediatric patients and can be a cause of significant anxiety for parents. While the majority of these lesions are benign and many can be clinically identified via history and exam, a considerable number require further evaluation with imaging to solidify the diagnosis or narrow the differential. High-resolution ultrasound is the first step of imaging evaluation due to its accessibility, lack of ionizing radiation, and ability to provide detailed information of lesion composition, and will reliably identify or narrow the differential in most cases. Lesions that can be reliably characterized via ultrasound include causes of scalp swelling in the newborn, inclusion cysts, ganglion cysts, and vascular lesions (such as hemangiomas or vascular malformations), among many other causes. When ultrasound characteristics are nonspecific or difficult to categorize or history and exam are not reassuring of benign features, further evaluation with MRI, CT, or tissue sampling may be pursued to evaluate for rare but more aggressive or malignant pathologies, or to further characterize lesions that may require intervention such as vascular malformations. Recognizing diagnostic sonographic features and integrating them with clinical data are valuable skills to provide patient and parent relief and guide the appropriate use for more invasive and expensive testing.

TABLE OF CONTENTS/OUTLINE

Please refer to Teaching Points.

PDEE-80 LET'S GET PHYSEAL - MUSCULOSKELETAL PATHOLOGY IN THE ACTIVE ADOLESCENT

Jamie Jacobs, DO (*Presenter*)
Melkamu D. Adeb, MD (*Abstract Co-Author*)
Eric P. Eutsler, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize the most common musculoskeletal pathologies in active adolescents and which sports they are associated with 2. Understand the mechanism of these injuries 3. Understand the preferred imaging modality for accurate diagnosis 4. Identify the imaging findings characteristic of each pathology 5. Recognize commonly associated injuries and complications 6. Understand preferred treatments and indications

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Learning Objectives III. Pathologies A. Bennett Lesion B. Little Leaguer's Shoulder C. Little Leaguer's Elbow D. Gymnast's Wrist E. Osteochondritis Dissecans F. Jumper's Knee G. Sub-Events

PHEE-1 UNTAPPED POTENTIAL: ADDING VALUE THROUGH IMAGE-BASED OPPORTUNISTIC IMAGING

Matthew H. Lee, MD (*Presenter*)
John W. Garrett, PhD (*Abstract Co-Author*)
Joshua D. Warner, MD,PhD (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Opportunistic screening is the purposeful practice of leveraging imaging data unrelated to the clinical indication for patient benefit. 2. Opportunistic screening is a cost-saving and clinically effective approach to cardiometabolic screening compared with strategies that ignore these data. 3. AI tools can be applied to existing imaging examinations without the need for additional specialized testing, cost, radiation exposure, or time. 4. Successful clinical implementation of image-based opportunistic screening will require buy-in from the various stakeholders (patients, radiologists, and ordering providers). 5. Opportunistic screening has potential for improved personalized risk assessment and population/public health impact.

TABLE OF CONTENTS/OUTLINE

1. Overview of imaging based opportunistic screening efforts.-Describe the origins and purpose of imaging based opportunistic screening. 2. Review early applications of image-based opportunistic screening. -Opportunistic screening can be done with any modality, but CT has received the most attention. 3. Discuss AI applications to opportunistic screening. -AI tools can be prospectively or retrospectively applied to existing data. 4. Examine the role of opportunistic imaging in public health. 5. Describe novel applications of opportunistic screening for risk modeling with examples. -CT biological age, MRI age, cardiovascular risk, metabolic syndrome, fibrosis, fragility fracture risk. -Early experiences with opportunistic screening programs. 6. Discuss ethical considerations for successful implementation of opportunistic screening. 7. Future directions -Describe future applications and barriers to opportunistic screening.

PHEE-2 HOW U-NET CAN IMPROVE BLOOD VESSEL SEGMENTATION BY EMPLOYING ADDITIONAL LOSS FUNCTION?

Kensaku Mori, PhD (*Presenter*)
Masahiro Oda, PhD (*Abstract Co-Author*)
Yuichiro Hayashi, PhD (*Abstract Co-Author*)

TEACHING POINTS

- To understand what a fully convolutional neural network is - To understand how FCNs work for multi-organ information from 3D CT images - To understand how distance information is essential in multi-organ segmentation - To understand how distance information-embed loss function improves multi-organ segmentation using FCNs

TABLE OF CONTENTS/OUTLINE

Introduction - The importance of medical image segmentation in computer-aided diagnosis systems. - The various applications of multi-organ segmentation in different body areas. - The use of Fully Convolutional Networks (FCNs) for organ segmentation from medical images, including CT images. FCNs and loss function - The significance of loss function design for achieving improved segmentation performance. - The critical role of embedding auxiliary information into the loss function to enhance segmentation performance. - The potential of distance information on organ boundaries to increase segmentation accuracy. Multi-organ segmentation using new loss function - Training FCNs, including U-net and V-net with newly designed loss functions, using 300 cases of 3D abdominal CT images and testing with 100 cases of 3D images. - The distance information-embedded loss function achieves higher segmentation accuracy in both U-net and V-net. - Presentation of segmentation results by U-net and V-net with the new loss function. - Successful segmentation of thin organs, including blood vessels, by introducing new information criteria. Discussion - Designing loss functions with consideration for target organs is essential. - Multi-organ segmentation serves as a crucial component in computer-aided diagnosis systems.

PHEE-3 EMERGING APPLICATIONS OF VISION-LANGUAGE MODELS IN CT RADIOLOGY: AGENTIC ASSISTANCE FOR REPORT GENERATION

Kensaku Mori, PhD (*Presenter*)
Masahiro Oda, PhD (*Abstract Co-Author*)
Yuichiro Hayashi, PhD (*Abstract Co-Author*)

TEACHING POINTS

- To understand what the vision language (VLM) model is - To understand what a large-language model (LLM) is - To understand how VLM works - To understand how VLM generates radiology findings report - To understand how agentic VLM can help radiologists write radiology reports - To understand what problems remain in using VLM in the radiology area

TABLE OF CONTENTS/OUTLINE

Introduction - What is a vision-language model (VLM) that combines visual understanding with natural language processing? - What kind of VLMs are proposed, including CLIP, BioMed CLIP, CT2Rep, or LLaVA? - What is a large language model (LLM)? - How is LLM trained and combined with LLM?- What kind of applications are expected in the radiology VLM area? Methods - What is the core technology behind VLM? - What are the tokenizers of text and image information? - Mechanism of CLIP and its application to the biomedical area - Mechanism of CT2Rep for CT diagnostic report generation - Mechanism of LLaVA and its application to the radiology area - How does VLM for follow-up CT scan work for report generation? - How are VLM models trained on a supercomputer platform? Demonstration - Demonstration of VLM models for follow-up CT volume scan reading - Demonstration of agentic assistance for radiological report generation - Demonstration of the hallucination occurrence of VLMs Discussion - Future direction of VLM for agentic assistance of CT image report writing in the radiology area - Contribution to workload reduction to radiologists and junior radiologists' performance enhancement - Hallucination mitigation, regulation, and integration into PACS workflows

PHEE-4 APPLICATION OF HYDROXYAPATITE IMAGING TO QUANTITATIVE CORONARY PLAQUE EVALUATION: A NEW APPROACH TO USE INFORMATION FROM PHOTON COUNTING CT

Mana Mitani, BSc, RT (*Presenter*)
Takashi Asahara, PhD (*Abstract Co-Author*)
Yusuke Morimitsu (*Abstract Co-Author*)
Noriaki Akagi, RT (*Abstract Co-Author*)
Tomohiro Inoue (*Abstract Co-Author*)
Toru Miyoshi (*Abstract Co-Author*)
Mitsugi Honda (*Abstract Co-Author*)
Toshihiro Iguchi, MD (*Abstract Co-Author*)
Natsumi Kimoto, PhD (*Abstract Co-Author*)
Rina Nishigami (*Abstract Co-Author*)
Hiroaki Hayashi, PhD (*Abstract Co-Author*)

TEACHING POINTS

[1] Hydroxyapatite (HAP) image generated by photon-counting CT (PC-CT) enables quantitative evaluation of coronary calcified plaques. [2] Virtual monoenergetic images (VMIs) can generate HAP images, which can be produced by solving equations based on the radiation physics. [3] Analysis of several clinical images suggested that HAP imaging allows for a more detailed quantitative analysis of plaques.

TABLE OF CONTENTS/OUTLINE

[1] The Agatston score, which can be applied to coronary CT images, has been widely used for cardiovascular risk assessment. In this presentation, we will show that our HAP density images generated using PC-CT have the potential to enable a more detailed quantitative assessment. [2] A procedure to generate HAP density images from VMI images was presented, which could be performed with an in-house program. [3] The optimal VMI combination (70 keV & 100 keV) was determined by a phantom experiment. Our algorithm has an accuracy of ±10% in HAP quantification. [4] Our method was applied to patient analysis. Although patients have similar conventional Agatston scores, they indicated different densities in the HAP image. [5] A flow chart for risk assessment of heart disease using photon-counting CT was proposed. In addition to conventional qualitative assessment, quantitative assessment using "HAP images" is available.

PHEE-5 ADVANCING CT IMAGE QUALITY ASSESSMENT WITH DEEP LEARNING: FROM TRADITIONAL METRICS TO CLINICALLY INFORMED AI EVALUATION

Jie Zhang, PhD (*Presenter*)
Gary Y. Ge, PhD (*Abstract Co-Author*)
Abdullah-Al-Zubaer Imran, PHD (*Abstract Co-Author*)

TEACHING POINTS

Understand the evolution from traditional CT image quality metrics to deep learning-based approaches. Learn how AI-driven metrics align better with clinical interpretation and diagnostic needs. Explore emerging clinical applications, including QA automation and protocol optimization.

TABLE OF CONTENTS/OUTLINE

As CT technology advances, so does the need for robust and clinically meaningful image quality evaluation. Traditional image quality metrics, such as image noise, have long served as technical standards. However, they often fall short of capturing the diagnostic utility of an image as perceived by human observers or as required in specific clinical scenarios. Recent innovations in deep learning (DL) provide new avenues to bridge this gap by incorporating context-aware and perceptually informed evaluations. This education exhibit is organized into four key sections: Traditional Metrics : Subjective (reader studies, VGA) and objective (SNR, CNR, NPS, MTF, SSIM) Perceptual Metrics : PIQE, NIQE, BRISQUE, and task-based assessments (e.g., CHO) DL-Based Metrics : Tools like LPIPS, DISTS, and models trained on radiologist scoring or diagnostic performance Clinical Applications : DL metrics for protocol tuning, iterative reconstruction, automated QA, and scanner harmonization Deep learning-based CT image quality metrics represent a promising frontier in radiologic quality assurance. By aligning technical evaluations with clinical interpretability, these methods can improve diagnostic consistency, optimize acquisition protocols, and streamline imaging workflows. As these models mature, they are poised to become integral to both research and real-world clinical practice.

PHEE-6 TRANSCATHETER AORTIC VALVE IMPLANTATION: RADIATION DOSE RECEIVED BY PATIENTS AND PHYSICIANS

Masahiro Sota, MSc, RT (*Presenter*)
Koichi Chida, PhD (*Abstract Co-Author*)

TEACHING POINTS

- To understand the need for reducing the radiation dose to the physician in transcatheter aortic valve implantation (TAVI). - To emphasize the importance of managing/monitoring the radiation dose in TAVI. - To understand the utility of TAVI in patient with aortic valve stenosis. - To understand that the virtual 3D-CT pre-operative planning was very helpful when choosing an interventional strategy.

TABLE OF CONTENTS/OUTLINE

- The physician doses, dose area product (DAP), fluoroscopic time, air-kerma (AK), and number of acquisitions were investigated in numerous TAVI. - In chronological order, the physician radiation dose during TAVI was evaluated using real-time monitoring system. - Reducing the radiation dose in TAVI. - Comparison of the radiation dose in TAVI: Self-Expandable valve vs. Balloon-Expandable valve, Physician (operator) vs. Anesthesiologist vs. Radiologic technologist. Outline : TAVI is newly effective procedure. Patients were assessed using, transesophageal echocardiography, multidetector CT, and angiography of the aortic root and ilio-femoral vessels for detailed assessment of the aortic valve as well as aortic root anatomy. We explored the radiation doses delivered during TAVI. Radiation exposure during TAVI cannot be ignored. The radiation dose during TAVI increase with procedural complexity. Generally, the methods for reducing/optimizing the radiation dose in TAVI will be the same as those typical for interventional radiology. Additionally, 3D virtual pre-operative planning for TAVI using 3D-CT provided significant help with regard to the interventional strategy. Thus, it can be a helpful way to reduce/optimize the radiation dose in TAVI.

PHEE-7 PITFALLS AND LIMITATIONS OF AI IN THORACIC IMAGING: LESSONS FROM REAL-WORLD IMPLEMENTATION

Seonhye Chae (*Presenter*)
Taehee Lee, MD (*Abstract Co-Author*)
Hongseok Ko, MD (*Abstract Co-Author*)

TEACHING POINTS

Identify key limitations of AI in chest radiography: high false positive rates, suboptimal performance in diffuse lung diseases and bone lesions, improved outcomes in AP views and interval change detection, and limited applicability in pediatric imaging. Recognize potential pitfalls in AI-assisted CT nodule detection, such as overreferral of benign lesions and increased healthcare costs. Understand technical constraints in current thoracic imaging AI systems, including information loss due to bit-depth reduction and the lack of machine-readable data utilization. Explore strategies to optimize AI performance through effective implementation, provider education, and imaging protocol refinement. Anticipate future developments aimed at overcoming current barriers, including standardized machine-readable data and collaborative radiologist-AI workflows.

TABLE OF CONTENTS/OUTLINE

Introduction: Current Landscape of AI in Thoracic Imaging Adoption trends and clinical applications Regulatory environment Chest Radiography AI Limitations False positive burden Performance gaps in diffuse lung diseases and osseous lesions Projection-specific performance challenges (PA vs. AP) Limitations in detecting interval

changes Challenges in pediatric imaging CT Imaging AI Limitations Over-referral of benign nodules Errors in quantitative pattern recognition Technical Obstacles Human vs. machine-readable imaging data Impact of bit-depth reduction (in CXR) Biases in training datasets Implementation Strategies and Future Directions AI Integration into clinical workflows Educational needs for interpreting providers Development of collaborative radiologist-AI interpretation models

PHEE-8 UNDERSTANDING IODINATED CONTRAST MEDIA: PRINCIPLES, PROTOCOLS, AND SAFETY IN CT EXAMINATIONS

Toru Higaki, PhD (*Presenter*)
Yuko Nakamura, MD, PhD (*Abstract Co-Author*)
Fuminari Tatsugami, MD (*Abstract Co-Author*)
Wataru Fukumoto, MD, PhD (*Abstract Co-Author*)
Kazuo Awai, MD (*Abstract Co-Author*)

TEACHING POINTS

This presentation offers a comprehensive explanation of contrast-enhanced CT examinations, covering a wide range of topics from both technical and clinical perspectives. It begins with an overview of the physicochemical properties of iodine contrast medium, followed by detailed discussions on administration techniques and the pharmacokinetics of contrast agents within the body. The principles underlying contrast enhancement and the methodology for simulating enhancement patterns are also addressed. Furthermore, the presentation explores how to determine optimal contrast protocols tailored to clinical objectives. Finally, it examines the potential adverse reactions associated with iodine contrast medium, including both immediate and delayed responses, thereby providing a well-rounded understanding essential for safe and effective CT imaging.

TABLE OF CONTENTS/OUTLINE

1. Physicochemical Properties of Iodine Contrast Medium 2. Methods of Iodine Contrast Medium Administration 3. Pharmacokinetics and Contrast Enhancement Simulation 4. Theoretical Basis of Contrast Enhancement 5. Determining Optimal Contrast Protocols 6. Adverse Reactions to Iodine Contrast Medium 6.1 Immediate Adverse Reactions 6.2 Delayed Adverse Reactions

PHEE-9 A PRACTICAL GUIDE TO SELECTING THE RIGHT TECHNOLOGY FOR METAL ARTIFACT REDUCTION ON PHOTON-COUNTING-DETECTOR AND ENERGY-INTEGRATING-DETECTOR CT

Joseph R. Swicklik, RT, BS (*Presenter*)
Michael R. Bruesewitz, RT (*Abstract Co-Author*)
Felix E. Diehn, MD (*Abstract Co-Author*)
Ian T. Mark, MD (*Abstract Co-Author*)
Francis I. Baffour, MD (*Abstract Co-Author*)
Joel G. Fletcher, MD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Lifeng Yu, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Multiple options exist on photon-counting-detector (PCD)-CT and energy-integrating-detector (EID)-CT for metal artifact reduction (MAR), including iterative MAR (iMAR) software, virtual monochromatic imaging (VMI) at high energy, Threshold high images acquired at high tube voltage with Sn filter, and combined iMAR+high keV. Which technology to choose for reducing metal artifacts depends on specific task and availability of scanner technology. 2. On PCD-CT, no significant difference between standard resolution (SR) and ultra-high-resolution (UHR) mode for MAR was identified across different methods. 3. On PCD-CT, high threshold energy "H" acquired at high tube voltage with Sn filter can reduce metal artifact compared to routine threshold low images, but still suboptimal in comparison with iMAR+high keV. 4. VMI at 90 keV is a good tradeoff between artifact reduction and bone contrast for bones; VMI at 110 keV is a good tradeoff for soft tissue. 5. No clear advantages on MAR were shown for PCD-CT over EID-CT in a phantom experiment.

TABLE OF CONTENTS/OUTLINE

1. Describe the 4 options for metal artifact reduction on PCD-CT and EID-CT: a. Iterative MAR (iMAR) software b. Virtual monochromatic imaging (VMI) at high keV c. Threshold high images acquired at high tube voltage with Sn filter (e.g., "H" at 140Sn) d. Combined iMAR and high keV 2. Provide a comparison among these options on PCD-CT, considering both standard resolution (SR) and ultra-high-resolution (UHR) modes and threshold high images. 3. Provide a comparison between PCD-CT and EID-CT for these options. 4. Provide a practical guide on how to choose the right technology for MAR.

PHEE-10 PHOTON COUNTING TECHNIQUE ENABLES NOVEL QUANTITATIVE X-RAY IMAGING: BREAKING THROUGH CHALLENGES IN CLINICAL APPLICATION

Natsumi Kimoto, PhD (*Presenter*)
Rina Nishigami (*Abstract Co-Author*)
Takashi Asahara, PhD (*Abstract Co-Author*)
Daiki Kobayashi, MD (*Abstract Co-Author*)
Sota Goto (*Abstract Co-Author*)
Yuki Kanazawa, PhD (*Abstract Co-Author*)
Akitoshi Katsumata, DDS, PhD (*Abstract Co-Author*)
Shuichiro Yamamoto (*Abstract Co-Author*)
Hiroaki Hayashi, PhD (*Abstract Co-Author*)

TEACHING POINTS

[1] The analysis of X-ray attenuation information obtained from energy-resolving photon counting detectors (ERPCDs) makes it possible to perform quantitative X-ray image diagnosis. [2] Comprehensively solving distortion factors such as beam hardening, detector response function, and counting loss enables the clinical use of quantitative images.

TABLE OF CONTENTS/OUTLINE

[1] Compared to conventional energy-integrating detectors, in which information on X-ray energy is lost, ERPCDs allow the analysis of X-ray attenuation for each X-ray energy, which is promising for novel quantitative X-ray imaging. [2] Although the advantages of ERPCD, such as high spatial resolution and low radiation dose, are widely known, quantitative imaging is also attractive. Accurate quantitative images will be obtained only when spectrum distortion factors such as beam hardening, detector response, and count loss are completely solved. [3] Counting loss caused by pulse pile-up and dead time should be solved. Since it relates to the shape of the energy spectrum, the correction should take into account both X-ray penetration in the objects having various effective atomic numbers (Z eff s) and the detector response. [4] We proposed a novel Z eff determination algorithm with counting loss correction. The novelty is to perform an appropriate counting loss correction with considering the object's Z eff . [5] Experimental verification was performed. The counting loss correction is essential for precise quantitative analysis using ERPCD.

PHEE-11 OPTIMIZING CT IMAGE QUALITY IN THE HEAD: BASICS AND BEYOND

William F. Sensakovic, PhD (*Presenter*)
Joseph Ausmus (*Abstract Co-Author*)
Emily M. James, MD (*Abstract Co-Author*)
Robert G. Paden, MS (*Abstract Co-Author*)
Justin Cramer, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Apply adjustments of basic CT parameters to optimize image quality 2) Understand the role advanced parameters may play in image quality 3) Examine advantages and disadvantages of photon counting and deep learning 4) Understand artifacts associated with newer postprocessing algorithms and strategies for mitigation

TABLE OF CONTENTS/OUTLINE

1) The basics of acquisition 1.1) Acquisition: mA, kV, positioning, and pitch 1.1.1) Contrast, Spatial Resolution, Temporal Resolution, and Noise 1.1.2) Artifacts 1.2) Reconstruction: Iterative reconstruction strength, matrix size, and reconstruction filter/kernel 1.2.1) Contrast, Spatial Resolution, Temporal Resolution, and Noise 1.2.2) Artifacts2) Beyond the basics 2.1) Under the hood parameters: Getting vendor specific 2.1.1) Examples 2.2) Photon counting 2.2.1) Unique considerations 2.2.2) Examples of the good 2.2.3) Examples of the bad 2.3) Deep learning reconstruction 2.3.1) Advantages 2.3.2) Disadvantages 2.3.3) Artifacts

PHEE-12 CREATING PHANTOMS FOR DUAL-ENERGY CT: MORE THAN THE EYE CAN SEE?

Nina Hagen, BSc (*Presenter*)
Robin Duteweert (*Abstract Co-Author*)
Laura Deden, MSc (*Abstract Co-Author*)
Carla Meeuwis (*Abstract Co-Author*)
Niels R. Van der Werf, MS (*Abstract Co-Author*)
Ioannis Sechopoulos, PhD (*Abstract Co-Author*)

TEACHING POINTS

Spectral data from dual or multi-energy computed tomography (MECT) is becoming more widely available. With different vendors offering different MECT techniques, it is important to perform cross-vendor comparisons with a validated phantom, as indicated by the AAPM Task Group Report 299. Although various CT phantoms are commercially available, not all phantoms are appropriate for MECT applications. During our in-house study, we compared a breast phantom to clinical data. Although at first the conventional reconstructions show similar images, spectral analysis showed inconsistencies within the iodine concentrations/inserts in the phantom. This educational exhibit will outline theoretical properties and common pitfalls when using phantoms for MECT studies, and will substantiate these points with an in-house study.

TABLE OF CONTENTS/OUTLINE

1) Physics of MECT and the energy attenuation for different human tissues, tissue differentiation and quantification of iodine concentration; 2) Mimicking attenuation properties of human tissues in a phantom: example of a breast phantom; 3) Validation process of a MECT-reliable phantom; 4) What to keep in mind when designing a phantom used for MECT? 5) In-house study: cross-vendor comparison of MECT of a breast phantom.

PHEE-13 INTO THE INVISIBLE: WHERE CONVENTIONAL DOPPLER REACHES ITS LIMITS, MICROVASCULAR DOPPLER SHINES

Nadine Santos, MD (*Presenter*)
Matheus Fritzen, MD (*Abstract Co-Author*)
Rudolph Octaviano Kogima, MD (*Abstract Co-Author*)
Julia D. Zavariz, MD (*Abstract Co-Author*)
Lucca Faria, MD (*Abstract Co-Author*)
Peter C. Francolin (*Abstract Co-Author*)
Mateus Esmeraldo, MD (*Abstract Co-Author*)
Andrea Cavalanti, MD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Microvascular Doppler ultrasound techniques—such as SMI, MVI, and UMA—overcome the limitations of conventional Doppler by preserving low-velocity flow signals while effectively filtering out tissue motion artifacts. These advanced technologies enhance the visualization of small-caliber vessels and microvascular flow, contributing to improved diagnostic accuracy across a wide range of clinical scenarios. This exhibit highlights the practical applications of microvascular Doppler. To illustrate how microvascular Doppler improves detection of slow-flow and small-vessel signals; To compare conventional, microvascular Doppler, and B-flow imaging performance in real clinical cases; To demonstrate the added diagnostic value across multiple organs and pathologies; To discuss practical considerations and limitations in applying microvascular Doppler.

TABLE OF CONTENTS/OUTLINE

Introduction: Physics behind conventional vs. microvascular Doppler; Commercial technologies and their principles (SMI, MVI, UMA, etc.). Post-transplant monitoring cases. Inflammatory conditions. Tumor vascular assessment. Protocol Optimization: Settings for high-resolution imaging. Summary: Clinical relevance and future perspectives.

PHEE-14 HYPERPOLARIZED XENON AND CARBON-13 MAGNETIC RESONANCE IMAGING: WHAT IS IT, HOW CAN WE USE IT IN CLINICAL RESEARCH?

James Grist (*Presenter*)
Stefan Neubauer (*Abstract Co-Author*)
Damian Tyler (*Abstract Co-Author*)
Fergus V. Gleeson, FRCR,MBBS (*Abstract Co-Author*)

TEACHING POINTS

• An introduction to the physics and theory of hyperpolarized xenon and carbon-13 magnetic resonance imaging will be provided.• Current hardware and software requirements for their incorporation into clinical research will be presented.• The emerging utility of each technique will be covered.• Clinical challenges and potential pitfalls of each technique will be reviewed.• Future directions and opportunities for the technologies will be discussed.

TABLE OF CONTENTS/OUTLINE

This exhibit will focus on emerging technologies: hyperpolarized xenon and carbon-13 MRI. It will provide a comprehensive overview of the current status of both technologies in clinical research. Firstly, the exhibit will cover the necessary theory to understand each technique, including MR physics, lung function, and metabolism (Figure 1). After this, the current methods and hardware requirements, such as broadband amplifiers and specialist coils, for clinical data collection and analysis will be presented. This will include common MRI sequences used in research studies, and image post-processing techniques for kinetic modelling, including consensus recommendations (Figure 2). Next, the current literature demonstrating potential clinical utility of each method will be discussed, including latest clinical trial results assessing acute response to therapy and early diagnosis (Figure 3). Subsequently, limitations and pitfalls of each technique, such as scanner sequence calibration errors and confounding physiological processes such as perfusion, will be considered (Figure 4). Finally, the future directions of travel for the technologies, such as clinical adoption and next generation studies, will be presented (Figure 5).

PHEE-15 THE BREAST IMAGING RADIOLOGIST WANTS TO READ FROM HOME - NOW WHAT?

Ingrid Reiser, PhD (*Presenter*)
Katie Hulme, MS (*Abstract Co-Author*)
David A. Scaduto, PhD (*Abstract Co-Author*)
Adrian A. Sanchez, MD, PhD (*Abstract Co-Author*)
Steven Lafontaine, MS (*Abstract Co-Author*)

Karli McMahan, BS (*Abstract Co-Author*)
Laura B. Shepardson, MD (*Abstract Co-Author*)

TEACHING POINTS

• Mammography workstations are subject to unique requirements relative to standard radiology workstations, and thus clear communication between Informatics, Medical Physicists, Radiologists, and Quality Control Technologists is essential. • Deploying mammography stations to radiologist homes poses additional logistical and regulatory complexities, particularly if the station is located out of state, reads for multiple institutions, or reads for units on different QC manuals. • Traditional delegation of QC responsibilities must be reassessed in the home environment, with radiologists assuming tasks formerly completed by the technologist. • Completion and documentation of QC for home workstations is one of the most common weak points for regulatory compliance; anticipating reasons for non-compliance can help with the development of solutions to prospectively address them. • Clear guidance and accountability regarding the home reading environment - such as network connectivity, speed, desk space, and reading conditions - prior to workstation deployment can help prevent many common issues.

TABLE OF CONTENTS/OUTLINE

1. Introduction: (a) Considerations and requirements (b) Getting set up (c) Maintaining compliance (d) Preventing problems and pitfalls. 2. Case-based tutorials: Scenario 1 - Deploying home workstations for occasional work from home. Scenario 2 - Starting to read for an additional practice. Scenario 3 - Reading from vacation home in different state, with moonlighting for multiple practices. 3 . Resources (a) Radiologists home readiness questionnaire and attestation; (b) Ongoing compliance checklist; (c) When is a physicist needed?

PHEE-16 TROUBLESHOOTING TIPS FOR OVERCOMING ARTIFACTS IN CURRENT CLINICAL CT: WHAT THE RADIOLOGIST AND RADIOLOGY TECHNOLOGIST NEED TO KNOW

Shingo Harashima (*Presenter*)
Haruhiko Machida, MD (*Abstract Co-Author*)
Rika Fukui (*Abstract Co-Author*)
Toshiya Kariyasu (*Abstract Co-Author*)
Makiko Nishikawa, MD (*Abstract Co-Author*)
Hidenori Yamaguchi (*Abstract Co-Author*)
Etsuko Tate, MD (*Abstract Co-Author*)
Wakana Samejima (*Abstract Co-Author*)
Yuta Hirose, MSc (*Abstract Co-Author*)
Isao Tanaka (*Abstract Co-Author*)
Yun SHEN (*Abstract Co-Author*)

TEACHING POINTS

1. To review image appearance & related factors of CT artifacts. 2. To introduce current imaging technologies & operator-dependent techniques for overcoming artifacts. 3. To illustrate troubleshooting tips for clinically overcoming artifacts.

TABLE OF CONTENTS/OUTLINE

1. Image appearance & related factors: a) Beam-hardening (BH) artifact: high-attenuating materials, congested contrast media (CM), b) Metallic artifact: metallic implants, c) Motion artifact: respiration, cardiac pulsation, d) Blooming artifact: high-attenuating materials, e) Others: oil-painting texture caused by iterative reconstruction (IR), pseudoenhancement; 2. Imaging technologies & operator-dependent techniques: a) Imaging technologies: fast pitch & rotation speed/ECG-gated scan/high-kV scan/high-resolution scan & reconstruction kernel/gantry tilt/virtual monochromatic image (VMI)/material decomposition image (MDI)/motion correction algorithm (MCA)/metallic artifact reduction software (MARS)/IR/deep-learning reconstruction (DLR), b) Operator-dependent techniques: adequate patient positioning/breathold instruction/CM injection technique/ß-blocker premedication; 3. Troubleshooting tips: a) BH artifact vs. high-kV scan/high-keV VMI/gantry tilt, adequate patient positioning/CM injection technique, b) Metallic artifact vs. high-kV scan/gantry tilt/high-keV VMI/MDI/MARS, c) Motion artifact vs. fast pitch & rotation speed/ECG-gated scan/MCA/breathold instruction/ß-blocker premedication, d) Blooming artifact vs. high-resolution scan & reconstruction kernel, e) Oil-painting texture vs. DLR, f) Pseudoenhancement vs. high-resolution scan & reconstruction kernel/VMI/MDI.

PHEE-17 WHAT IS VISION FOUNDATION MODEL AND HOW IT USED TO DEVELOP CAD

Masahiro Oda, PhD (*Presenter*)
Hirotsugu Takabatake, MD,PhD (*Abstract Co-Author*)
Masaki Mori, MD (*Abstract Co-Author*)
Hiroshi Natori, MD, PhD (*Abstract Co-Author*)
Kensaku Mori, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purposes of our exhibit are: 1. To learn what vision foundation model is and how it is different from conventional AI models 2. To learn how vision foundation model changes AI development 3. To learn how vision foundation models are used to develop CAD systems 4. To learn applications of foundation model in CAD

TABLE OF CONTENTS/OUTLINE

Vision Foundation Model - What is vision foundation model - Difference between vision foundation models and conventional AI models - Advantages of using vision foundation models in AI development: develop high performance AI even from small dataset, significantly reduces load on AI development How to Develop Vision Foundation Model - How to train vision foundation models: self-supervised learning (annotations are not necessary) is used while conventional AIs are trained using supervised learning (annotations are necessary) - Training method: masked autoencoder, contrastive learning Applications of Vision Foundation Model - Image-based CAD development : Foundation models are applicable to develop AI CADs in many applications - Image-and-language-based CAD development : Vision-language AI models are commonly developed using both vision foundation model and language foundation model Application of Vision Foundation Model in CAD - CAD system development for many applications - Radiology report generation assistance based on image - Automated disease assessment - Improve explainability of AI by text explanation

PHEE-18 DUAL-ENERGY CT IODINE OVERLAY MAPS TO IDENTIFY SILICONE FILLERS AND IMPLANTS

Olga Sliwicka, MD, PhD (*Presenter*)
Khanin Khanungwanitkul, MD (*Abstract Co-Author*)
Fides Schwartz, MD (*Abstract Co-Author*)
Aaron D. Sodickson, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

DECT characterizing silicone fillers and implants may assist in identifying complications such as migration, granulomas, infection/fluid collectionSilicone mimics iodine and color-codes on DECT iodine overlay images but disappears on VNC, unlike calciumExtent of silicone implant rupture can be visualized on DE iodine overlay

TABLE OF CONTENTS/OUTLINE

Purpose: To familiarize radiologists with imaging of silicone-based medical products (polydimethylsiloxane (PDMS)) used in reconstructive/cosmetic procedures. To emphasize role of Dual-Energy-CT (DECT) with iodine overlay and virtual-non-contrast(VNC) reconstructions to differentiate silicone from pathology 1.Introduction: Overview of silicone-based products in medical practice-cosmetic/reconstructive surgery 2.Silicone-Based Medical Products: Silicone Gel: Semi-solid crosslinked PDMS used in breast implants, soft-tissue fillers—soft, cohesive, and widely applied Silicone Elastomer: Vulcanized silicone used for outer shells and solid implants(chin, cheek, jaw, nasal, pectus excavatum, ear, calf, testicular) Silicone Oil: Used in ophthalmology for retinal detachment repair; historically in soft-tissue augmentation Saline-filled implants with silicone sheath 3.Principles of DECT, iodine overlay and VNC in clinical evaluation 4.Key Imaging Findings: Silicone vs native soft tissue. Spectral signatures

on DECT 5.Case Examples of soft (breast, gluteal), and solid implants (penile, testicular); where DECT aids interpretation (granulomas, implant rupture, infection/fluid collection) 6.Clinical Impact: Potentially improved accuracy in distinguishing silicone materials and complications

PHEE-19 CLINICAL PRACTICE OF DIXON METHOD IN BREAST MRI: UNDERSTANDING THE BENEFITS AND ARTIFACTS

Huimin Wu, PhD (*Presenter*)

TEACHING POINTS

To understand the advantages of DIXON method over traditional fat suppression techniques (e.g., CHESS, STIR, SPIR, SPAIR) in breast MRI protocol To recognize global or local water/fat swap artifacts associated with DIXON method. To analyze the cause of DIXON artifacts under different scenarios and properly select alternative techniques.

TABLE OF CONTENTS/OUTLINE

1. Fat suppression is an essential part of clinical breast MRI protocol. a. Lesions that are bright on T2 weighted images could be masked by bright fat. b. Fat is bright on T1 weighted images that could mask enhancing lesions in dynamic contrast enhanced (DCE) scan. 2. Why is fat suppression challenging in breast MRI? a. Sensitivity to B0 and B1 field inhomogeneity b. Consideration of scan time penalty in dynamic CE sequence c. Comparison of major fat suppression techniques 3. Review of DIXON methods. a. How does DIXON work to separate water and fat? b. Improved sensitivity to B0 and B1 field inhomogeneity c. SNR benefits d. Time efficiency 4. Water/fat swap artifacts of DIXON method a. Global swap b. Local swap happened on one side of the breast c. Local swap happened in the heart and surrounding structures d. Local swap artifacts that is lesion-mimicking e. Breast implants add additional challenges to DIXON 5. What to do when DIXON artifacts happen a. T2W scan: i. Shimming and frequency tuning ii. Scan each side of the breasts separately iii. Switch to STIR b. T1W DCE scan: i. Subtraction of in-phase series ii. Switch to SPIR/SPAIR 6. Looking ahead to emerging techniques such as deep learning

PHEE-20 PHOTON-COUNTING CT: CLINICAL APPLICATIONS ACROSS MUSCULOSKELETAL, CARDIAC, AND NEURO IMAGING

Tricia Ng, MBBS (*Presenter*)
Kang Ren Yong, MBBS (*Abstract Co-Author*)
Srujana Ganti, MBChB, FRCR (*Abstract Co-Author*)
Phey Ming Yeap, MBChB, FRCR (*Abstract Co-Author*)
Mohammad T. Bin Mohamed Shah, MD (*Abstract Co-Author*)
Parag R. Salkade, FRCR,MMed (*Abstract Co-Author*)
Chi Long Ho, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Photon-counting CT (PCCT) represents a next-generation imaging technology using direct-conversion detectors that count individual x-ray photons and assign energy values. Compared to conventional CT, PCCT offers improved spatial resolution, reduced artifacts, and inherent spectral imaging without additional radiation dose. This exhibit highlights its clinical advantages across musculoskeletal, cardiac, and neuroimaging subspecialties, using side-by-side comparisons with conventional CT.

TABLE OF CONTENTS/OUTLINE

1) Musculoskeletal Imaging: - Reduction of beam-hardening and streak artifacts near metallic implants - Visualization of bone-implant interfaces - Potential role in bone marrow edema detection 2) Cardiac Imaging: - Improved delineation of coronary arteries and stents - Reduced blooming from coronary calcium - High-pitch, single-heartbeat acquisition with motion artifact reduction 3) Neuroradiology: - High-resolution imaging of temporal bone structures - Reduced beam-hardening from dense bone - Improved visualization of fine anatomic detail (e.g., cochlea, ossicles) This educational exhibit provides radiologists an overview of PCCT’s practical advantages and pictorial comparisons that underscore its transformative potential in diagnostic imaging.

ROEE-2 LUGANO PROTOCOL ON CT AND MRI: EVERYTHING THE RADIOLOGIST NEEDS TO KNOW

Lucas Da Silva Costa, MD (*Presenter*)
Caio Nunes, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*)
Rodrigo C. Chate, MD (*Abstract Co-Author*)
Thais Mussi, MD, PhD (*Abstract Co-Author*)
Bruna M. Loureiro, MD (*Abstract Co-Author*)
Murilo M. Silva, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review the fundamental principles of the Lugano Classification used for lymphoma evaluation, including staging and treatment response assessment. - Understand the imaging workflow and define the role of each modality — particularly CT and PET/CT — according to the metabolic profile of the lymphoma. - Identify typical imaging features and measurement strategies used in the assessment of target and non-target lesions, including splenic involvement. - Recognize the relevance of integrating clinical context and selecting the appropriate imaging approach based on the FDG avidity of the disease. - Present a structured and practical reporting framework to support radiologic staging and follow-up in alignment with the Lugano guidelines.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION Understanding what the Lugano Classification is and how to apply it. HOW TO IDENTIFY TARGET LESIONS Presenting the criteria that define target lesions and the importance of computed tomography for lymphoma staging. MEASURING TARGET LESIONS Presenting the standard methodology for measuring target lesions and the importance of product calculation for treatment response assessment. SPLENIC MEASUREMENT Understanding the specific aspects of splenic measurement and the criteria evaluated during restaging. IDENTIFYING AND DESCRIBING NON-TARGET LESIONS Understanding the concept and assessment of non-target lesions.

ROEE-3 CHILDHOOD EXPOSURE TO DIAGNOSTIC X-RAY IONIZING RADIATION AND LEUKEMIA RISK: A RAPID SYSTEMATIC REVIEW OF LITERATURE AND META-ANALYSIS

Guilherme Oberto Rodrigues (*Presenter*)

TEACHING POINTS

IntroductionLeukemia is the most common cancer in children, and many studies have suggested a possible causal relationship with childhood exposure to x-ray ionizing radiation.ObjectiveTo assess the risk of developing leukemia in pediatric patients exposed to diagnostic x-ray ionizing radiation.Methods: A systematic review of the literature was conducted. Electronic databases searched included PubMed, EMBASE, Web of Science. We included peer-reviewed publications of cohort and case-control studies involving pediatric patients exposed to diagnostic x-ray ionizing radiation, evaluating the risk of these patients developing leukemia.Two reviewers analyzed the selected abstracts and full-text articles,performed data extraction,and evaluated the methodological quality of the selected articles.The methodological quality was assessed according to the Newcastle- Ottawa Scale. A meta-analysis was conducted using RevMan.ResultsOut of the 330 citations screened, 8 publications were included, representing 6,721 cases and 12,730 controls.All studies were designed as case-control.Age varied from 0 to 14 years,with a predominance of boys.The studies presented good methodological quality, but the results from individual studies were controversial.The summary of results demonstrated significant positive associations for being exposed to one or more, and three or more x-rays and the subsequent development of leukemia. No significant association was identified when considering four or more x-rays.

TABLE OF CONTENTS/OUTLINE

ConclusionIdentified a positive association between postnatal exposure to one or more, and three or more x-rays and the development of leukemia.

ROEE-4 MULTIORGAN MUCINOUS NEOPLASMS: A RADIOLOGIC REVIEW OF DIAGNOSTIC PATTERNS AND IMAGING BIOMARKERS

Michelle Narvaez (*Presenter*)
Christian A. Armijos, MD (*Abstract Co-Author*)
Gloria E. Zamora, MD (*Abstract Co-Author*)

TEACHING POINTS

Mucinous neoplasms exhibit distinctive imaging features due to their high extracellular mucin content, which influences signal intensity and attenuation across modalities. Characteristic imaging patterns can aid early diagnosis, especially when correlated with clinical and anatomical context. Cross-sectional imaging plays a pivotal role in detecting, staging, and guiding management of mucinous tumors in the pancreas, liver, ovary, colon and kidney. Recognition of organ-specific differences in appearance is crucial to avoid misdiagnosis, especially in borderline or deceptively benign presentations.

TABLE OF CONTENTS/OUTLINE

1. Introduction Definition and pathological basis of mucinous tumors 2. Imaging Characteristics of Mucinous Content CT: hypoattenuating regions, calcifications MRI: high T2 signal, variable T1 signal, diffusion behavior US: anechoic to hypoechoic patterns PET-CT: challenges in mucinous lesions (low FDG uptake) 3. Organ-Based Review 3.1 Pancreas and Liver IPMN, IPMN-B and MCN: morphology, ductal communication, enhancement patterns. 3.2 Ovary Benign vs borderline vs malignant mucinous tumors 3.3 Colorectal Mucinous colorectal cancer and peritoneal spread 3.5 Kidney Mucinous Tubular and Spindle cell carcinoma (MTSCC), a well demarcate, exophytic or parenchymal masses. 4. Differential Diagnosis and Pitfalls Overlap with non-mucinous cystic tumors Inflammatory and infectious mimics Underrecognition

due to benign appearance 5. Multimodality Imaging Strategy How to integrate US, CT, MRI and PET-CT. 6. Conclusion Summary of key patterns. The importance of radiologist familiarity with mucinous tumors

ROEE-5 RADIOLOGIC EVALUATION OF LATTICE RADIATION THERAPY IN BODY SOFT TISSUE SARCOMAS: MAPPING MORPHOLOGIC RESPONSE

Daniel Selva, MD (*Presenter*)
Katka Majerkakova (*Abstract Co-Author*)
Nicolas Martinez, MD (*Abstract Co-Author*)
Xenia Codo, BDS (*Abstract Co-Author*)
Silvia Bague (*Abstract Co-Author*)
Jose Gonzalez (*Abstract Co-Author*)
Juan Carlos Pernas, MD (*Abstract Co-Author*)
Diana Hernandez (*Abstract Co-Author*)

TEACHING POINTS

Spatially fractionated LATTICE radiation therapy (LRT) delivers high radiation doses to specific intratumoral subvolumes while sparing surrounding healthy tissues, offering a promising treatment alternative for large, inoperable high-grade soft tissue sarcomas where conventional therapies are often limited or ineffective. Imaging, particularly contrast-enhanced CT and MRI, plays a central role throughout the LRT workflow—from initial patient selection and detailed treatment planning to monitoring therapeutic response and guiding follow-up strategies. Radiologists must look beyond traditional size-based response criteria and identify imaging biomarkers such as central necrosis, intratumoral calcifications, and changes in CT attenuation (Hounsfield units), which may provide earlier and more accurate indicators of treatment efficacy.

TABLE OF CONTENTS/OUTLINE

Introduce the clinical rationale, technical principles, and therapeutic potential of LATTICE radiation therapy, illustrated through a 14-patient case series of high-grade soft tissue sarcomas. Emphasize key radiological findings observed after LRT, including reductions in CT density, development of central necrosis, appearance of intratumoral calcifications, and progressive fibrosis—features that may precede or occur independently of size changes. Discuss the limitations of conventional response criteria based solely on tumor size, and propose integrating structural and functional imaging parameters into more comprehensive assessment strategies. Selected cases highlight the heterogeneity of imaging response and the role of radiologists in guiding clinical decisions.

ROEE-6 CT/MR ASSESSMENT IN RADIATION THERAPY FOR PROSTATE CANCER USING A PERIRECTAL HYDROGEL SPACER: WHAT RADIATION ONCOLOGISTS AND RADIOLOGISTS NEED TO KNOW

Etsuko Tate, MD (*Presenter*)
Haruhiko Machida, MD (*Abstract Co-Author*)
Hiromasa Kurosaki (*Abstract Co-Author*)
Kenta HIRAYAMA (*Abstract Co-Author*)
Toshiya Kariyasu (*Abstract Co-Author*)
Rika Fukui (*Abstract Co-Author*)
Shingo Harashima (*Abstract Co-Author*)
Wakana Samejima (*Abstract Co-Author*)
Yuta Hirose, MSc (*Abstract Co-Author*)
Yukihiro Hama, MD, PhD (*Abstract Co-Author*)
Yun Shen, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. To introduce evolution of radiation therapy (RT) for prostate cancer and clinical role of a perirectal hydrogel spacer (PHS). 2. To describe CT/MR assessment for the RT planning with PHS. 3. To illustrate CT/MR assessment during/after the RT with PHS.

TABLE OF CONTENTS/OUTLINE

1. Evolution of RT & clinical role of PHS: a) Evolution of RT: two-dimensional RT, three-dimensional conformal RT, intensity-modulated RT (IMRT), image-guided RT (IGRT); b) Clinical role of PHS: physical separation between the prostate and rectum to reduce rectal radiation dose/toxicity, visibility by CT/MR as water density/signal intensity. 2. CT/MR assessment for RT planning: a) CT/MR scan technique: a flat couch top, patient immobilization, reproducible bladder distension, rectal emptying, field of view encompassing the outer body contour, thin-slice (e.g., 2-3 mm) axial section; for CT , metallic artifact reduction (e.g., hip prostheses); for MR , mainly T2-weighted sequences, additional sagittal section for PHS verification; b) CT/MR image fusion& contouring: organ-at-risk (OAR) assessment, anatomical contouring of the entire prostate as clinical target volume (CTV). 3. CT/MR assessment during/after RT: a) Daily checkpoints in IGRT: planning target volume (PTV) & rectum-prostate separation/PHS verification, rectal gas assessment for rectal enema indication; b) Temporal change after PHS placement: maintained PHS volume for at least 11 weeks by our clinical data; c) CT/MR-assessable PHS-related complications: rectal wall infiltration by PHS, rectal erosion/fistula formation; prostate subcapsular infiltration by PHS, perineal abscess; PHS migration into the venous plexus/pulmonary artery; bladder stone formation.

ROEE-7 BLADDER NEOPLASIA: FAR BEYOND UROTHELIAL HISTOLOGY

Andre De Freitas Secaf, MD (*Presenter*)
Yan V. Natal Gouvea, MD (*Abstract Co-Author*)
Eduarda Paro (*Abstract Co-Author*)
Francisco Jose De Queiroz Thome (*Abstract Co-Author*)
Pamela Grazielle Correa De Oliveira (*Abstract Co-Author*)
David F. Vieira, MD (*Abstract Co-Author*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
Gabriel L. Gouvea, MD (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Urothelial carcinoma (UC) is the most common histologic type of bladder cancer. Urothelial cells, being pluripotent, have the ability to differentiate into a variety of histologic variants. Approximately 80% of UC cases present with conventional pure urothelial histology, while the remaining 20% involve differentiated histologic variants. These variants have garnered increasing interest, as some are associated with poorer prognoses, impacting disease progression and requiring distinct therapeutic approaches.

TABLE OF CONTENTS/OUTLINE

Magnetic resonance imaging (MRI) is the most effective tool for soft tissue characterization, allowing detailed evaluation of the bladder wall, perivesical region, and pelvic organs. It offers significant advantages in the staging of bladder tumors. While urothelial carcinoma is the most common histologic type of bladder neoplasia, other types may also affect the bladder, often presenting with distinct features that can influence prognosis and treatment decisions. The main histologic variants of urothelial carcinoma include: pure (conventional), papillary, plasmacytoid, sarcomatoid, clear cell, lipid-rich cell, giant cell, micropapillary, squamous differentiation, and glandular differentiation.The aim of this study is to review bladder lesions that present histology other than the conventional urothelial form, with emphasis on the imaging characteristics observed, especially on magnetic resonance imaging (MRI).Radiologists should be familiar with the imaging characteristics of these less common and rare bladder lesions, as their management and prognosis may differ significantly from those of the most prevalent subtype—pure urothelial carcinoma.

VAEE

Vascular Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

VAEE-1 CT ANGIOGRAPHY OF CONGENITAL AORTIC AND AORTIC VALVE ANOMALIES IN ADULTS: A RADIOLOGIST´S GUIDE

Lhuanna Maria Barbosa Teixeira, MD (*Presenter*)
Rhillary S. Sa, MD (*Abstract Co-Author*)
Camila P. Reifegerste, MD (*Abstract Co-Author*)
Bruna B. Libanio, MD (*Abstract Co-Author*)
Cintia Melo (*Abstract Co-Author*)
Augusto K. Medeiros, MD (*Abstract Co-Author*)

TEACHING POINTS

Congenital anomalies of the aorta and aortic valve are frequently diagnosed in childhood, but many cases persist undetected into adulthood—often discovered during imaging for unrelated symptoms. It is essential for radiologists to recognize the major anatomic variants and congenital malformations that can have significant clinical implications, including vascular rings, valvular dysfunction, or progressive aortopathy. The purpose of this article is to:• Highlight the characteristic CT angiographic findings of congenital anomalies of the aorta and aortic valve in adults.• Discuss the embryologic and anatomic basis of these anomalies to aid in image interpretation.• Emphasize the role of computed tomographic angiography in classification, detection of complications and surgical planning.• Provide actionable teaching points for accurate diagnosis and reporting.

TABLE OF CONTENTS/OUTLINE

1. Introduction; 2. Embriology; 3. Aortic Arch Variants; 4. Aortic Coarctation; 5. Aortic valve anomalies; 6. Imaging Approach and Pitfalls; 7. Take-Home Messages.

VAEE-2 MORE THAN JUST PIPES: ABDOMINOPELVIC VENOUS PATHOLOGY WITH RAD-PATH CORRELATION

David Mortensen, MD (*Presenter*)
Erica B. Stein, MD (*Abstract Co-Author*)
Aaron M. Udager, MD, PhD (*Abstract Co-Author*)
Benjamin Mervak, MD (*Abstract Co-Author*)
Molly Pantelic, MD, MS (*Abstract Co-Author*)
Reve Chahine, MD, FRCR (*Abstract Co-Author*)
Katherine E. Maturen, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

1. It matters what’s in the vein: sterile or infected thrombus, benign or malignant tumor - all have different management implications. 2. Prepared radiologists can often distinguish these based on imaging features. 3. Septic thrombophlebitis, and specifically pylephlebitis, are feared sequelae of abdominopelvic infection with a high rate of mortality, up to 25%. Inflammatory changes are often distinctive. 4. Renal cell carcinoma, hepatocellular carcinoma, and adrenocortical carcinoma have a predilection for venous invasion, and these thrombi will usually enhance. Extent and location are critical to surgical technique. 5. Venous leiomyosarcoma is a rare primary tumor of smooth muscle origin that can arise from the wall of any vein, most commonly the IVC. Surgical treatment requires interposition grafts. 6. Intravenous leiomyomatosis is a rare, benign pathology that is locally aggressive, but can often be treated surgically, leaving veins intact. 7. Renal angiomyolipomas occasionally invade the renal veins and IVC and characteristically show evidence of intraluminal fat.

TABLE OF CONTENTS/OUTLINE

1. Anatomical overview of venous histology and anatomy a. Radiologic and histologic examples of normal and abnormal 2. Case examples a. Multiplanar, multimodality imaging of various venous pathologies with corresponding pathology b. Benign pathologies: bland thrombus, infected thrombus, fatty thrombus c. Neoplastic pathologies: tumor thrombus, leiomyosarcoma, intravenous leiomyomatosis 3. Discuss how understanding of radiology-pathology correlation can enhance understanding of disease state and clinical course 4. Summary of key concepts

VAEE-3 BEYOND THE GROIN: CT ASSESSMENT OF FEMORAL VASCULAR ACCESS-SITE COMPLICATIONS AFTER CARDIAC CATHETERIZATION

Andres Guillermo Tarra Romero, MD (*Presenter*)
Jhan Fonseca, MD (*Abstract Co-Author*)
Hugo Torres Rodriguez, MD (*Abstract Co-Author*)

TEACHING POINTS

CT is the modality of choice for assessing suspected femoral access-site complications after cardiac catheterization, providing accurate anatomical detail of vascular and perivascular structures. Pseudoaneurysms appear as contrast-filled, saccular outpouchings communicating with the femoral artery via a narrow neck, best visualized on arterial phase imaging and multiplanar reformats. Arteriovenous fistulas are identified as abnormal early venous opacification or direct communication between femoral artery and vein. Active bleeding is seen as extravasation of contrast outside the vascular structures, often increasing in size or density between arterial and venous phases. Multiplanar and 3D reconstructions improve detection and characterization of vascular complications, enhancing communication with the referring team. In patients with a history of surgical intervention or physical trauma, a post-traumatic aneurysm of the great saphenous vein should be considered as a potential cause of a non-pulsatile subcutaneous mass.

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology Normal Anatomy CT Angiography Technique Key Imaging Findings: What to Report Complications • Cellulitis • Hematoma • Active Extravasation • Cutaneous Fistula • Pseudoaneurysm • Arteriovenous Fistula • Venous Aneurysms • Cavo-mesenteric Fistula Take-Home Messages Conclusions References

VAEE-4 ENHANCING POST-ENDOVASCULAR AORTIC REPAIR ENDOLEAK DIAGNOSIS: CT IMAGING TIPS USING CUTTING-EDGE TECHNOLOGIES AND KEY INTERPRETATION POINTS

Takatoshi Higashigawa, MD (*Presenter*)
Yasutaka Ichikawa, MD (*Abstract Co-Author*)
Yuki Yamaoka (*Abstract Co-Author*)
Hiroaki Kato, MD, PhD (*Abstract Co-Author*)
Noriyuki Kato (*Abstract Co-Author*)
Hajime Sakuma, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit provides a comprehensive overview of advanced CT imaging techniques to improve the detection and characterization of endoleaks after endovascular aortic repair. Specifically, we highlight: 1) The utility of low-keV virtual monochromatic imaging (VMI) combined with deep learning image reconstruction (DLIR) to enhance endoleak conspicuity. 2) The role of photon-counting detector CT (PCD-CT) in providing high-quality iodine maps. 3) Strategies to optimize image quality and reduce artifacts for precise diagnosis. 4) Key interpretation points that bridge imaging findings with clinical decision-making for endoleaks

TABLE OF CONTENTS/OUTLINE

1) DLIR vs. hybrid iterative reconstruction (HIR): DLIR significantly reduces image noise compared to conventional HIR. DLIR is particularly beneficial at low keV VMI, where image noise increases dramatically. 2) Low-keV VMI for improved contrast enhancement: Lower energy VMI increases iodine contrast. Combined with DLIR, this approach allows clearer visualization of subtle endoleaks. 3) Metal artifact reduction with iodine maps (PCD-CT): PCD-CT-derived iodine maps reduce metallic artifacts caused by stent grafts, aiding in the differentiation of true endoleaks from pseudoenhancement or beam-hardening artifacts. 4) Key points in CT interpretation of endoleaks: Important interpretation points for diagnosing endoleaks on CT —considering treatment strategy— will be presented in a clear and accessible manner. 5) Conclusion: Advanced CT techniques, including low-keV VMI with DLIR and PCD-CT iodine mapping, enhance the accuracy of endoleak diagnosis. Applying key interpretation points further supports appropriate clinical decision-making.

VAEE-5 CLINICAL APPLICATIONS OF UPRIGHT MDCT IN CARDIOVASCULAR IMAGING

Yoshitake Yamada, MD, PhD (*Presenter*)
Minoru Yamada, RT (*Abstract Co-Author*)
Yoichi Yokoyama, MD (*Abstract Co-Author*)
Ryoma Fukuoka (*Abstract Co-Author*)
Orito Ikeda (*Abstract Co-Author*)
Fumiko Yagi, MD (*Abstract Co-Author*)
Yuki Iwaita (*Abstract Co-Author*)
Mohammed Alshahri (*Abstract Co-Author*)
Takehiro Nakahara (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The objectives of this exhibit are: (1) To explain the development, technological background, and features of upright multi-detector computed tomography (MDCT), including 320-detector upright CT and multi-position MDCT for whole-body imaging. (2) To describe posture-induced anatomical changes in the heart and vascular system due to gravitational effects. (3) To demonstrate the clinical applications and diagnostic value of upright MDCT in cardiovascular diseases through representative clinical cases.

TABLE OF CONTENTS/OUTLINE

(1) Development and advantages of upright MDCT for whole-body imaging (2) Technical performance of upright MDCT: Physical characteristics, workflow efficiency, safety, and remote operability during infectious disease pandemics (3) Influence of gravity on systemic vascular structures: Aiming to elucidate the principles and dynamics of "phlebology" (4) Clinical applications of upright MDCT, including: •Noninvasive estimation of right atrial pressure and pulmonary arterial wedge pressure (PAWP) compared with right heart catheterization •Evaluation of posture-related worsening of cardiopulmonary symptoms in various diseases •Preoperative assessment of graft vessels in coronary artery bypass grafting (CABG) (5) Limitations (6) Summary and Conclusion

VAEE-6 HEMODYNAMIC QUANTITATIVE ANALYSIS OF FEMOROPOPLITEAL ARTERY WITH 4D FLOW MRI

Xueyan Zhang (*Presenter*)

TEACHING POINTS

1) To show the femoropopliteal artery on time-resolved three-dimensional phase contrast magnetic resonance imaging (4D-flow MRI). 2) Using the 4D flow MRI to measure the hemodynamic parameters of the femoropopliteal artery. This non-invasive measurement technique provides the possibility to derive comprehensive information about the occlusion of the femoropopliteal artery.

TABLE OF CONTENTS/OUTLINE

1. The principle and characteristics of the 4D flow MRI 2. An initial three-plane localizing scan was followed by a 2D phase contrast (PC) MRI and 4D flow scans. a) For optimization of the velocity encoding (VENC) setting, the 2D PC MRI was designed to estimate the maximum flow velocity. The 2D PC MRI labeling plane was positioned perpendicular to the target artery in the coronal and sagittal images. b) After the 2D PC MRI sequence has been scanned, the next step is blood flow velocity analysis. The maximum flow velocity value of target vessel was obtained from the velocity-time curve. c) For the 4D flow acquisition, the velocity encoding (VENC) setting was set to 120% of the maximum flow velocity value of the target vessel. 3. Upon scan completion, the 4D flow MRI images were exported offline for hemodynamic quantitative analysis. a) Different blood flow patterns of femoropopliteal artery. b) The wall shear stress (WSS) distribution map with different orientations and alteration trend of WSS over one cardiac cycle. c) The energy loss and pressure difference of blood flow.

VAEE-7 VENOUS CONTRAST MIXING ON CT: A CLOSER LOOK TO AVOID MISDIAGNOSIS

Burak Kaplan, MD (*Presenter*)
Niharika Praveen, MBBS (*Abstract Co-Author*)
Mounika Pusa (*Abstract Co-Author*)
Aditi Bhanushali (*Abstract Co-Author*)
Yajurvendrasinh Chudasama (*Abstract Co-Author*)
Philip A. Araoz, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize venous contrast mixing patterns that can mimic thrombosis. Understand the importance of assessing vessel continuity and contrast dynamics in multiple planes.

TABLE OF CONTENTS/OUTLINE

Introduction Venous structures can exhibit a wide range of contrast enhancement patterns on CT imaging, particularly during early or mixed phases of contrast administration. These physiologic variations in venous opacification can mimic true vascular pathologies such as thrombosis or stenosis. Misinterpretation of these findings can lead to unnecessary further workup or inappropriate treatment. Therefore, distinguishing physiologic venous contrast mixing from true pathology is essential for accurate diagnosis. This presentation includes illustrative cases demonstrating commonly encountered sites of contrast mixing artifacts, including the

inferior mesenteric vein, renal veins, internal jugular vein, left brachiocephalic vein, and gastroepiploic vein. It also outlines practical diagnostic strategies, such as assessing vessel continuity, using multiplanar reconstructions, and correlating imaging findings with clinical and procedural context. Case Presentations Inferior Mesenteric Vein mixing with the Splenic Vein Renal veins mixing into the Inferior Vena Cava Internal Jugular Vein contrast mixing after right-arm injection Left Brachiocephalic Vein mixing from Internal Jugular and Subclavian veins Gastroepiploic Vein mixing with the Superior Mesenteric Vein Diagnostic Strategies Importance of evaluating vessel continuity, using multiplanar reformats, and correlating with clinical context.

VAEE-8 STATE-OF-THE-ART IMAGING AND MANAGEMENT OF ENDOLEAKS

Drew Maclean, MBChB, MRCS (*Abstract Co-Author*)
Chris R. Williams, MBBCh, MRCS (*Abstract Co-Author*)
Wiliam R. Thomas (*Abstract Co-Author*)
Ghali Salahia, MD (*Abstract Co-Author*)
Richard D. White, MBChB, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1) Demonstrate the importance of recognising and appropriately categorising endoleak following EVAR.2) Highlight the pros and cons of various imaging modalities used for the detection of endoleaks after EVAR, including advanced ultrasound techniques, multiphase CT and MRI as well as conventional plain radiographs and angiography.3) Categorise endoleaks which develop following both standard EVAR and fenestrated / branched EVAR, with discussion of risk factors for their development and the evidence for preventative measures for each type.4) Illustrate the spectrum of endoleaks following EVAR using schematic illustrations and case examples from a tertiary vascular centre, with treatment rationale discussed.

TABLE OF CONTENTS/OUTLINE

1) Imaging modalities 2) Follow-up strategies 3) Endoleaks a. Type I b. Type II c. Type III d. Type IV e. Type V f. Additional endoleak considerations following fenestrated / branched EVAR g. Special scenarios: i. Endoleak in the context of AV fistula ii. Surgical “endoleak”

VAEE-9 MYCOTIC AORTIC ANEURYSMS FROM EARLY SIGNS TO RUPTURE: AN EVOLUTION OVER TIME

Tushar Kumar, MBBS, MD (*Presenter*)
Nandakumar Patnam Gopal Chetty, MD (*Abstract Co-Author*)
Madhvi Yadav, MBBS (*Abstract Co-Author*)
Rajat Bhargava, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Awareness of pathophysiology, clinical features and laboratory tests are key to suspect mycotic aortitis. 2. Indistinct aortic wall and periaortic soft tissue in the clinical setting of pain should be viewed with concern. 3. Venous phase CT is insensitive for diagnosis of small pseudoaneurysm, and urgent CTA should be performed. 4. Rapid progress of pseudoaneurysm is a sign of infectious etiology, hence close clinical and imaging follow up is required.

TABLE OF CONTENTS/OUTLINE

1. Aortic mycotic aneurysm: a) Definition b) Epidemiology c) Etiology d) Pathophysiology e) Clinical features; 2. CT imaging findings of aortic mycotic aneurysm: a) Early CT findings b) Temporal evolution c) Case based review; 3. Differential diagnosis: a) Intramural hematoma b) Impending aortic aneurysm rupture c) Inflammatory aortitis/vasculitis d) Penetrating atherosclerotic ulcer; 4. Complications; 5. Management and prognosis.

VAEE-10 RED FLAGS IN THE VEINS! WHEN THROMBOSIS TELLS A DIFFERENT STORY: IMAGING CLUES TO IDENTIFY VENOUS TUMOR THROMBUS IN ABDOMINOPELVIC MALIGNANCIES

Delfina Linares, MD (*Presenter*)
Maria S. Fernandez Castillo Odena, MD (*Abstract Co-Author*)
Federico G. Diaz Telli, MD (*Abstract Co-Author*)
Miriana E. Mariussi, MD (*Abstract Co-Author*)
Juan P. Perotti, MD (*Abstract Co-Author*)
Antonella Pierina Ruiz (*Abstract Co-Author*)
Inaki Eztala, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the pathophysiologic mechanisms of venous tumor thrombus formation in abdominopelvic malignancies. - Identify key imaging features that differentiate tumor thrombus from bland thrombus across CT, MRI, and ultrasound. - Recognize the typical imaging appearance of tumor thrombus according to the affected venous territory and the organ of origin. - Review common and uncommon abdominopelvic tumors associated with venous invasion, including renal, hepatic, adrenal, pancreatic, and rectal malignancies. - Recognize imaging mimics and artifacts that may simulate venous tumor thrombus. - Appreciate the clinical and prognostic significance of venous tumor thrombus in staging and therapeutic decision-making.

TABLE OF CONTENTS/OUTLINE

Introduction Definition and clinical importance of tumor thrombus Epidemiology and diagnostic impact Pathophysiology of Tumor Venous Invasion Mechanisms of direct and indirect invasion Role of angiogenesis and metastatic cascade Imaging Modalities and Diagnostic Criteria CT, MRI, and ultrasound features How to differentiate tumor thrombus vs bland thrombus Role of diffusion and enhancement patterns Anatomical and Case-Based Review Inferior Vena Cava Portal Venous System Splanchnic and Mesenteric Veins Pelvic Venous Involvement Pitfalls and Mimics Flow artifacts Bland thrombus Cavernous transformation Pseudolesions (e.g., pseudolipoma) Clinical Implications Impact on staging and treatment Surgical planning and contraindications Conclusion

VAEE-12 DEMYSTIFYING THE CIRCUIT: A RADIOLOGIC GUIDE TO ECMO IMAGING

Samuel Castillo, MD (*Presenter*)
Mariana Madrid, MD (*Abstract Co-Author*)
Regina De La Mora Cervantes, MD (*Abstract Co-Author*)
Genier Fabian Castano Lizarazo, MD (*Abstract Co-Author*)

TEACHING POINTS

- Differentiate ECMO cannulation strategies (veno-arterial, veno-venous, and veno-pulmonary) including both peripheral and central variants. - Recognize CTA flow-relate artifacts (e.g., watershed zones, mixing artifacts) that may mimic thromboembolism, dissection, or vascular occlusion. - Apply tailored CTA protocols by adjusting ECMO flow rates, contrast injection sites, and acquisition phases to improve diagnostic accuracy. - Present real clinical cases where ECMO-related artifacts mimic pathology, highlighting key diagnostic pitfalls.

TABLE OF CONTENTS/OUTLINE

1. Introduction to ECMO cannulation Overview of cannulation, indications, and ECMO circuit components. 2. Cannulation strategies Imaging-based analysis of ECMO cannulation approaches, highlighting central vs peripheral access through clinical case examples. 3. CTA Protocol Optimization: a. Contrast injection approaches (peripheral, central, or ECMO circuit). b. Bolus tracking, test bolus and phase timing techniques. c. ECMO circuit adjustments to enhance image acquisition. d. Special considerations for pulmonary, aortic, and cerebral vascular evaluations. 4. Artifacts and Diagnostic Pitfalls: a. Aortic and cardiac artifacts. b. Lower extremities

evaluation. c. Abdominal imaging challenges. d. Head and neck vascular pitfalls. 5. Conclusion A thorough understanding of ECMO cannulation techniques and protocol adjustments—and their importance in avoiding misinterpretation.

VAEE-13 UNMASKING VASCULAR CRISES: THE PIVOTAL ROLE OF CT ANGIOGRAPHY IN LOWER LIMB EMERGENCIES

Victor Costa, MD (*Presenter*)
Alexandre M. Pereira, MD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Daniel L. Cardoso, MD (*Abstract Co-Author*)
Mariana Costa, MD (*Abstract Co-Author*)
Thiago Vieira, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Understand that emergencies in lower limb computed tomography angiography (CTA) primarily involve acute vascular conditions with high risk of limb loss and systemic complications, necessitating rapid diagnosis and immediate intervention.Recognize the need to categorize lower limb vascular emergencies into traumatic injuries and non-traumatic injuries, which include ischemic and hemorrhagic types.Know the main benefits of CT angiography like detailed information of the entire vascular bed; offers fast, non-invasive imaging; achieves isotropic submillimetric resolution for precise anatomical assessment.

TABLE OF CONTENTS/OUTLINE

1 - Introduction: an overview of the vascular emergencies;2 - Arterial tromboembolism: main features and what the the imaging studyneed to include;3 - Key findings of chronic peripheral occlusive arterial disease;4 - Aneyrism rupture: Key findings and therapeutic decisions;5 - The speed and accuracy of CT angiography in trauma.

VAEE-14 IGG4-RELATED CARDIOVASCULAR DISEASE (IGG4-CVD): CASE PRESENTATIONS AND DIFFERENTIAL DIAGNOSES

Yusuke Kobayashi, MD (*Presenter*)
Kentaro Ohara (*Abstract Co-Author*)
Tomoro Morikawa, MD (*Abstract Co-Author*)
Takaaki Hosokawa (*Abstract Co-Author*)
Tomohisa Okada (*Abstract Co-Author*)
Kazuki Yoshida, MD, PhD (*Abstract Co-Author*)
Yuki Tanabe (*Abstract Co-Author*)
Naoto Kawaguchi, MD (*Abstract Co-Author*)
Teruhito Kido, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

IgG4-related disease is the systematic disease characterized by tissue infiltration of IgG4-positive plasma cells and perivascular fibrosis. It can involve extensive organ involvement; pancreas, bile duct, gallbladder, salivary glands and even aorta and coronary arteries. Cardiovascular involvement, observed in up to 41% of patients with IgG4-RD, may result in life-threatening complications such as aortic dissection or coronary artery occlusion, and has been associated with sudden death. Given the risks associated with cardiovascular biopsy, radiologists should have a thorough understanding of its imaging manifestations.

TABLE OF CONTENTS/OUTLINE

Slide1: Teaching point. Slide2:the case of IgG4-CVD?. Slide3:the case of IgG4-CVD?. Slide4:Differential diagnosis (Takayasu's Disease, Giant Cell Arteritis). Slide4:Differential diagnosis (Malignant lymphoma).

VAEE-15 ACUTE AORTIC DISEASES

Cesar Gabriel Rocha Da Costa Paloschi, MD (*Presenter*)
Daniel L. Cardoso, MD (*Abstract Co-Author*)
Mariana Costa, MD (*Abstract Co-Author*)
Fabiana Campos, MD (*Abstract Co-Author*)
Rafael R. Santos Ferreira, MD (*Abstract Co-Author*)
Enzo Calheiros, MD (*Abstract Co-Author*)
Davi D. Romao, MD (*Abstract Co-Author*)
Rodrigo Azambuja, MD (*Abstract Co-Author*)
Alexandre M. Pereira, MD (*Abstract Co-Author*)
Thiago Vieira, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Acute Aortic Syndrome (AAS) represents a group of life-threatening conditions involvingthe aorta, characterized by a sudden onset and rapid progression. Early recognition and prompt intervention are critical to improve outcomes and reduce mortality. The three principal entities classified as AAS are: aortic dissection, penetrating atherosclerotic ulcer and intramural hematoma. Other acute aortic diseases include aortic aneurysm rupture and traumatic aortic injury. This educational exhibition provides a comprehensive overview of the imaging evaluation of the main acute aortic diseases. Specific imaging patterns, differential diagnoses, and potential pitfalls in imaging interpretation will be addressed, as well as etiology categorization, classification grading systems and treatment modalities, aiming at a broad review of the theme. The purpose of this exhibition is to:- Present multiples etiologies of acute aortic diseases.. - Present classical imaging findings- Highlight points of interest regarding treatment and rapid identification these life threatening conditions

TABLE OF CONTENTS/OUTLINE

Definition of Acute Aortic Syndrome, as well as other acute aortic diseases.Aortic dissection classification and what should we report in the main imaging modalities.Aortic dissection case in a 51 years old malePenetrating atherosclerotic ulcer and intramural hematoma imaging findings. Aortic aneurysm classification, primary and secondary signs of rupture.

VAEE-16 IMAGING EVALUATION OF SYSTEMIC VEINS

Animan Randhawa, MD (*Presenter*)
Anushri Parakh, MBBS, MD (*Abstract Co-Author*)
Sadia Sultana, MRCP,FRCR (*Abstract Co-Author*)
Vinit Baliyan, MD,MBBS (*Abstract Co-Author*)
Sandeep S. Hedgire, MD (*Abstract Co-Author*)

TEACHING POINTS

· To foster a comprehensive understanding of the anatomy of systemic veins to provide a foundation for recognizing normal venous anatomy. · Venous conditions extend beyond thrombosis, and these may be overlooked if a radiologist is unaware of the disease spectrum. · Assessing asymmetry as well as utilizing multiplanar imaging can be the key in diagnosing certain conditions. · Special emphasis on underscoring the key imaging figures associated with each abnormality, enabling confident identification and interpretation of these findings across various imaging modalities (ultrasound, CT, and MR).

TABLE OF CONTENTS/OUTLINE

• Conventional venous anatomy as well as congenital anomalies. • Pictorial examples of venous thromboses, and review importance of multiphase, prior imaging, and multiplanar imaging for accurate diagnoses. • Illustrate common and uncommon venous primary and secondary pathologies (inflammatory, compression syndromes, iatrogenic, and tumor)

VAEE-17 NAVIGATING THE NARROWS: A MULTIMODALITY JOURNEY THROUGH THORACIC OUTLET SYNDROME

Laleska Garcia, MD (*Presenter*)
Felipe L'Hotellier (*Abstract Co-Author*)
Igor R. Oliveira, MD (*Abstract Co-Author*)
Andre P. Romualdo (*Abstract Co-Author*)
Andrei S. Albuquerque, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the anatomy of the spaces involved in thoracic outlet syndrome. Doppler ultrasound technique with different provocative maneuvers for dynamic assessment during the examination. Technical protocols for image acquisition in CT angiography and MR angiography. Case-based approach to imaging findings in each modality, with clinical correlation. Review of fundamental information essential for the radiologist’s report.

TABLE OF CONTENTS/OUTLINE

Introduction with the main causes of thoracic outlet syndrome. Detailed anatomical review of the scalene triangle, costoclavicular space, and subcoracoid spaces. Doppler ultrasound technique. CT angiography protocol. MRI angiography protocol (with and without contrast). Review of the affected anatomical spaces. Diagnostic criteria. Use of provocative maneuvers to identify dynamic vascular compressions and differentiate between fixed and positional stenoses. Case-based review of imaging findings. Post-treatment evaluation and complications. Multimodality reporting guidelines. Conclusion.

VAEE-18 OUTSIDE THE LUMEN: A RADIOLOGIST'S GUIDE TO PERIVASCULAR DISEASES

Laleska Garcia, MD (*Presenter*)
Felipe L'Hotellier (*Abstract Co-Author*)
Igor R. Oliveira, MD (*Abstract Co-Author*)
Alan D. Hummel (*Abstract Co-Author*)
Andrei S. Albuquerque, MD (*Abstract Co-Author*)

TEACHING POINTS

• Diagnostic approach algorithm to access perivascular diseases • Review of perivascular acute and chronic fluid collections • Review of neoplasms and masses that presente with vascular encasing or dissemination • Review common and uncommon inflamattory diseases with perivascular envolvement • Case based review the main computed tomography findings of the differential diagnoses of perivascular diseases.

TABLE OF CONTENTS/OUTLINE

• Introduction • CTA and MRA technique to access the perivascular space • Imaging findings based algorithm • Perivascular acute and chronic collection • Neoplasms and masses • Primary vacular inflamatory disorders • Inflamatory diseases with perivascular involvement • Definition of perivascular collections • Reporting tips • Conclusion

VAEE-20 MAKING THE TINY VISIBLE: INSTITUTIONAL EXPERIENCE WITH CENTRAL AND PERIPHERAL MR LYMPHANGIOGRAPHY

Lavinia Dias, MD (*Presenter*)
Gabriel Figueiredo, MD (*Abstract Co-Author*)
Tomas M. Lacerda, MD (*Abstract Co-Author*)
Lucas T. Amaral, MD (*Abstract Co-Author*)
Renata Emy Ogawa, MD (*Abstract Co-Author*)
Adriano Tachibana, MD, MBA (*Abstract Co-Author*)
Murilo M. Silva, MD (*Abstract Co-Author*)
Marcelo A. Rocha, MD (*Abstract Co-Author*)

TEACHING POINTS

- Highlights clinical applications, protocols, and diagnostic patterns of both central and peripheral Lymphangiography by Magnetic Resonance Imaging (MRL), based on institutional experience. -Emphasizes the technique’s role in identifying lymphatic leaks, obstructions, lymphatic malformations, lymphedema, preoperative mapping of peripheral venous lymphatic anastomosis microsurgery, and its advantages over traditional methods.

TABLE OF CONTENTS/OUTLINE

Overview of central and peripheral lymphatic anatomy Protocol and imaging parameters for MRL Technique for intranodal and interdigital contrast administration Clinical applications of central MRL: detection of leaks, obstructions, and malformations Clinical applications of peripheral MRL: lymphedema assessment and surgical planning Comparison with complementary modalities (e.g., lymphoscintigraphy) Suggested structured report template for MRL studies

VAEE-22 POPLITEAL ARTERY ENTRAPMENT SYNDROME. A REVIEW BASED ON OUR EXPERIENCE: 2013-2025

Elena Luque, MD (*Presenter*)
Sara Gomez Pena, MD (*Abstract Co-Author*)
Ester Carballo, MD (*Abstract Co-Author*)
Lorena Martinez Fontanet, MD (*Abstract Co-Author*)
Marco Leyva Vasquez Caicedo (*Abstract Co-Author*)
Ana M. Fernandez Tamayo, MD (*Abstract Co-Author*)
Javier E. Armijo, MD (*Abstract Co-Author*)
Jose Mendez Montero (*Abstract Co-Author*)

TEACHING POINTS

To review popliteal artery entrapment syndrome (PAES), epidemiological and clinical aspects, differential diagnosis and treatment possibilities. To describe PAES subtypes and imaging findings, as well as the main angiographic techniques used in its diagnostic process, based on our cohort of patients from 2013 to 2025.

TABLE OF CONTENTS/OUTLINE

• Introduction . PAES is an infrequent but debilitating condition typically seen in young adults, in which PA is compressed by surrounding structures in the popliteal fossa. As chronic arterial compression may lead to irreversible vascular damage, early diagnosis is essential. Symptoms reported are exertional calf pain, intermittent claudication, etc. • Differential diagnosis . Main differential diagnosis includes chronic popliteal artery thrombosis, chronic exertional compartment syndrome, adventitial cyst, etc. • Imaging techniques . Angio-CT, angio-MR, and conventional angiography can be used in the diagnosis of PAES, being mandatory to include both static and dynamic acquisition with active plantarflexion. • Classification . PAES is categorized as anatomical (APAES), when structural anomalies are present in the popliteal fossa, and as functional when it is secondary to hypertrophy of the gastrocnemius muscle. At the same time, it’s divided into six subtypes: 1 to 5 constitute APAES and type 6 is functional. At our center, 10 confirmed cases of PAES were identified from 01/01/23 and 01/04/25, most of whom were men (n=6), with a mean age of 32 years. 5

patients were diagnosed with APAES, while the remaining cases were classified as type 6 • Treatment . It depends on the subtype and symptoms (conservative measure, botulinum toxin injection, surgical intervention).

VAEE-23 INDUCTIVE ANALYSIS OF FACTORS INFLUENCING THE DIAMETER OF THE INFERIOR VENA CAVA

Martin M. Pesce, MD (*Presenter*)
Rodrigo S. Loto, MD (*Abstract Co-Author*)
Victorio Del Casale, MD (*Abstract Co-Author*)
Luciano B. Lovotti, MD (*Abstract Co-Author*)
Roberto E. Elias, MD (*Abstract Co-Author*)
Leandro J. Pacini (*Abstract Co-Author*)

TEACHING POINTS

-Review the anatomy and pathologies affecting the inferior vena cava.-Review the pathophysiology and radiological characteristics of common and uncommon diseases.-Main determinants affecting the inferior vena cava diameter.

TABLE OF CONTENTS/OUTLINE

The inferior vena cava (IVC) is a dynamic vascular structure whose diameter can vary significantly based on physiological and pathological conditions. Accurate interpretation of IVC size and collapsibility is essential in multiple clinical scenarios, including fluid status assessment, right heart function evaluation, and critical care management. This educational exhibit provides a comprehensive overview of the main determinants that influence IVC diameter, categorized into six domains: thoracic pressure, cardiac function, abdominal pressure, parietal compliance, blood volume, and anatomical variants. Additionally, a broad spectrum of miscellaneous conditions —such as pulmonary embolism, pericardial effusion, ARDS, abdominal compartment syndrome, and vascular interventions—is addressed for their impact on IVC morphology as seen on imaging. The content is supported by schematic illustrations and selected imaging examples that clarify the effects of these factors on IVC appearance. The aim is to enhance the radiologist's ability to recognize normal variability and distinguish it from true pathological changes. Understanding these determinants is key to avoiding misinterpretation and improving diagnostic confidence in both routine and emergency settings. By the end of this exhibit, viewers will be equipped with practical knowledge to assess the IVC as a reliable marker in systemic and cardiovascular evaluation.

VAEE-24 DIAGNOSTIC IMAGING KEYS AND APPROACH TO ENDOVASCULAR MANAGEMENT IN ACUTE AORTIC SYNDROMES

Jorge Guisandez (*Presenter*)
Gonzalo Garzon Moll (*Abstract Co-Author*)
Milagros Marti de Gracia, MD, PhD (*Abstract Co-Author*)
Teresa de Jesus Hernandez Cabrero (*Abstract Co-Author*)

TEACHING POINTS

Acute aortic syndrome (AAS) comprises dynamic entities like acute aortic dissection (AAD), intramural hematoma (IMH), and penetrating aortic ulcer (PAU), all involving weakened aortic wall integrity and predisposition to rupture. Angio-CT is the preferred method for urgent AAS diagnosis; cardiac gating enhances accuracy. Transesophageal echocardiography (TEE) supports endovascular procedures by confirming access to the true lumen and evaluating entry tear closure, though it only visualizes the thoracic aorta. Stanford type A AAS requires surgery due to high complication risks. Uncomplicated Stanford type B cases are treated conservatively, while complications such as persistent pain, malperfusion syndrome, and progression warrant endovascular intervention. Mural thrombus and IMH may appear crescent-shaped, but thrombus has irregular borders within intimal calcification, while IMH shows smooth borders outside it. In AAD, signs like cobweb, beak, windsock, Mercedes-Benz help differentiate true and false lumens. The true lumen is typically smaller, more attenuated, and bordered by calcifications; tracing from the aortic root aids uncertain cases. Favorable aortic remodeling after TEVAR, is more frequent in acute/subacute dissections (<90 days); chronic ones carry higher risk of distal aneurysm.

TABLE OF CONTENTS/OUTLINE

This exhibit will present the imaging hallmarks of each AAS entity using angio-CT and TEE. Imaging criteria guiding treatment decisions will be discussed, including indications for TEVAR. Case-based examples from a tertiary care center will illustrate typical and atypical presentations, diagnostic pitfalls, and post-treatment imaging follow-up.

VAEE-25 CHALLENGING VISCERAL ARTERY PATHOLOGIES: WHAT NOT TO MISS ON CT ANGIOGRAPHY

Manuel Rafael Lopez De La Torre Carretero, MD (*Presenter*)
Carmen Mbongo, MD (*Abstract Co-Author*)
Daniel A. Zambrano Andrade, MD (*Abstract Co-Author*)
Adolfo Manuel Delgado Brito, MD (*Abstract Co-Author*)
Miguel Barrio Piqueras I, MD (*Abstract Co-Author*)
Isabel Vivas Perez, MD (*Abstract Co-Author*)

TEACHING POINTS

- To review uncommon and diagnostically challenging visceral artery pathologies. - To highlight key CT angiography technical considerations and imaging findings, including how to perform high quality studies and avoid interpretation errors. - To provide case-based learning through real clinical scenarios.

TABLE OF CONTENTS/OUTLINE

CT Angiography Essentials Protocol tips: Acquisition and reconstruction technique and tips, contrast timing. Post-processing techniques: MPR, MIP, VRT, CPR. Case-Based Review Visceral artery dissections: real vs pseudo-lesions. Splanchnic aneurysms and pseudoaneurysms: subtle clues. When invasive treatment is crucial Segmental arterial mediolysis. Compressive vascular syndromes: Diagnostic tips, treatment and follow-up imaging. Incidental thrombosis: red flags in oncology patients. Iatrogenic vascular injuries: what to expect after intervention. Anatomical variants: normal structures simulating disease. Diagnostic Toolbox Key imaging signs. Common traps and how to avoid them. Use of indirect signs (fat stranding, ischaemia). Summary & Take-Home Messages Case-based insights. Reporting tips.

VAEE-26 UNMASKING THE HIDDEN: EXPLORING THE ANEURYSMAL SPECTRUM OF THORACIC VEINS THROUGH IMAGING

Andita D. Hidayati, MD (*Presenter*)
Daniel Vargas, MD (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)
Ameya J. Baxi, MBBS,DMRD (*Abstract Co-Author*)
Vijay K. Aggarwal, MBBS (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)

TEACHING POINTS

Raise radiologist awareness and recognize the Spectrum Thoracic venous aneurysms can occur in multiple venous territories—SVC, innominate veins, azygos/hemiazygos, IVC, and pulmonary veins—each with distinct anatomical and clinical implications. Know the Imaging Clues Cross-sectional imaging (especially CT and MRI) is key to identifying aneurysmal dilatation, distinguishing it from solid or cystic mediastinal masses, and detecting complications such as thrombosis or mass effect. Don't Miss the Associations Be aware of associated anomalies like cystic hygroma, persistent left SVC, congenital heart disease (TAPVR, ASD), and syndromes like Osler-Weber-Rendu—which may point to underlying vascular malformations or systemic conditions.

TABLE OF CONTENTS/OUTLINE

- Introduction - Normal thoracic venous anatomy and epidemiology of venous aneurysms - Case-based review of types thoracic venous aneurysms with imaging approach by location: innominate vein, SVC, IVC, and pulmonary venous aneurysms, aneurysms - Common clinical associations and potential complications - Clinical implications and guidance for optimal reporting - Management

VAEE-27 MESENTERIC ISCHEMIA: FROM ACUTE EMERGENCIES TO CHRONIC CONDITIONS

Abel Gonzalez Huete, MD (*Presenter*)
Montilla Jose (*Abstract Co-Author*)
Agustina Vicente Bartulos, MD (*Abstract Co-Author*)
Esther Garcia Casado (*Abstract Co-Author*)
Claudia Viescas Huerta, MD (*Abstract Co-Author*)
Diego Alejandro Garcia Paredes, MD (*Abstract Co-Author*)
Isabel Fonseca Buelga, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To provide a comprehensive overview of mesenteric ischemia, highlighting both acute and chronic forms. 2. To describe the clinical and imaging features of different types of acute mesenteric ischemia, including arterial occlusive (embolic, thrombotic), non-occlusive, and veno-occlusive ischemia. 3. To discuss chronic mesenteric ischemia, its diagnostic challenges and its treatment. 4. To illustrate the imaging findings through case from our hospital.

TABLE OF CONTENTS/OUTLINE

1. Definitions: Acute Mesenteric Ischemia, Chronic Mesenteric Ischemia. 2. Anatomy: abdominal arterial and venous anatomy. 3. Embolic Acute Mesenteric Ischemia: definition, clinical presentation, imaging findings. 4. Arterial Occlusive Acute Mesenteric Ischemia: definition, clinical presentation, imaging findings. 5. Non-occlusive Mesenteric Ischemia (NOMI): definition, clinical presentation, imaging findings. 6. Venous Acute Mesenteric Ischemia: definition, clinical presentation, imaging findings. 7. Chronic Mesenteric Ischemia (CMI): definition, clinical presentation, imaging findings, treatment. 8. Conclusion. 9. References.

VAEE-28 ARTERIAL ARM-AGEDDON: CASE-BASED IMAGING REVIEW OF UPPER EXTREMITY ARTERIAL DISEASES

Supriya Bhupathy, MD (*Presenter*)
Margaret H. Lee, MD (*Abstract Co-Author*)
Brian D. Quinn, MD (*Abstract Co-Author*)
Richard A. Reed, MD (*Abstract Co-Author*)
Aram J. Lee, MD (*Abstract Co-Author*)
Thomas Le (*Abstract Co-Author*)
Miriam Thomas, MD (*Abstract Co-Author*)
Karoly Viragh, MD (*Abstract Co-Author*)

TEACHING POINTS

Arterial imaging of the upper extremities is less commonly performed than of the lower extremities, torso, or head/neck. Although there are many similarities in arterial anatomy, pathology and imaging techniques, important differences exist. The goal of the current educational exhibit is to (1) describe the clinically relevant upper extremity normal and variant anatomy; (2) discuss the relevant multimodality imaging technical considerations with emphasis on differences compared to other body parts; (3) provide a case-based, image-rich, multimodality review of the major arterial pathologies with interventional radiologic considerations and clinico-pathologic correlation where available. In addition, interactive (board-exam type) pointers will be included to emphasize major learning points.

TABLE OF CONTENTS/OUTLINE

1. Anatomy - arterial normal and variant anatomy (high origin of radial/ulnar branches, duplicated segments, fetal remnants, palmar arch variants). 2. Technique - CT/MR/US/catheter angiography pearls and pitfalls (optimal positioning vs maneuvers to diagnose thoracic outlet obstruction or steal; optimal CT enhancement by contrast bolus shape/timing/radiation variations; contrast vs non-contrast MRA techniques; sonographic waveforms; arterial access considerations). 3. Pathology - Illustrative cases include trauma (iatrogenic vs non-iatrogenic - including hypothenar hammer syndrome), atherosclerosis and thromboembolism (including limb ischemia), vasculitis (including Raynaud syndrome), steal syndromes, thoracic outlet obstruction, as well as their manifestations (spasm, compression, aneurysm/pseudoaneurysm, dissection, rupture, occlusion, AV fistula).

VAEE-29 HOW TO CREATE HIGH-QUALITY ANGIOGRAPHIES OF THE PERIPHERAL RUNOFF USING THE PHOTON COUNTING DETECTOR CT: TIPS, TRICKS AND PITFALLS OF PROTOCOL SELECTION AND POST-PROCESSING

Philipp Gruschwitz, MD (*Presenter*)
Henner Huflage, MD (*Abstract Co-Author*)
Kristina Krompass, MD (*Abstract Co-Author*)
Jan-Lucca Hennes, MD (*Abstract Co-Author*)
Viktor Hartung (*Abstract Co-Author*)
Jan P. Grunz, MD (*Abstract Co-Author*)

TEACHING POINTS

This Educational is intended to summarize possible adaptations of scan protocols, image reconstruction settings and post-processing applications leading to image optimization of CT angiography using photon-counting CT (PCD-CT) and possibilities to upgrade suboptimal images to a diagnostic quality. The aim is to summarize the most relevant adjustment screws to improve peripheral PDC-CT angiography in clinical routine.

TABLE OF CONTENTS/OUTLINE

The following modifiers and their influences will be explained: a) pitch factor; tube voltage and tube current settings b) PCD-CT scan mode (standard resolution vs. ultra-high resolution), collimation c) reconstruction kernel, slice thickness and pixel matrix d) "intrinsic" spectral imaging (PCD-CT) and virtual image reconstruction • virtual monoenergetic imaging for contrast agent reduction or correction of a lack of contrast • virtual native for bleeding detection or repeated administration of contrast agent • virtual calcium-free imaging for severe arteriosclerotic arteries e) quantum iterative reconstruction for optimization of contrast-to-noise ratio The influence of these parameters and the applied radiation dose on the measurable image quality parameters, in particular contrast-to-noise ratio and image noise, will be explained in more detail and illustrated with representative image comparisons.

VAEE-30 NAVIGATING THE WAVES OF TEMPORAL ARTERY DOPPLER: A RESIDENT'S GUIDE TO DIAGNOSING GIANT CELL ARTERITIS

Andres Guillermo Tarra Romero, MD (*Presenter*)
Laura M. Garcia Ramirez, BMedSc, BMedSc (*Abstract Co-Author*)
Jhan Fonseca, MD (*Abstract Co-Author*)
Julian Rodriguez Cely, MD (*Abstract Co-Author*)

TEACHING POINTS

Doppler ultrasound of the temporal arteries is recommended as the first-line imaging modality in patients with suspected temporal arteritis and cranial symptoms. Both superficial temporal arteries should be thoroughly examined in transverse and longitudinal planes, including their frontal and parietal branches. Spectral Doppler allows confirmation that the evaluated vessel is an artery rather than a vein. The persistence of a hypoechoic halo, despite compression of the temporal artery with the ultrasound probe—known as the compression sign—is a highly specific finding for giant cell arteritis (GCA). Temporal artery biopsy is considered the gold standard for

diagnosing GCA in suspected cases. In patients with a high clinical suspicion of GCA and a positive imaging test, the diagnosis can be established without the need for additional tests or biopsy.

TABLE OF CONTENTS/OUTLINE

Tabla de contenido. • Introduction. • Epidemiology. • Functional Anatomy. • Clinical approach. • Image Acquisition Protocol: Step-by-Step Ultrasound Approach. • Ultrasound Findings in Giant Cell Arteritis. • Advantages and Limitations of the Temporal Artery Doppler. • Take Home Messages. • Conclusions • Bibliography

VAEE-31 ULTRASOUND DIAGNOSTIC IMAGING IN LIPEDEMA: A GUIDE FOR THE RADIOLOGIST

Cibelle Melo, MD (*Presenter*)
Luara Boson, MD (*Abstract Co-Author*)
Estevao Vargas (*Abstract Co-Author*)
Thiago Lopes (*Abstract Co-Author*)

TEACHING POINTS

Lipedema is a chronic disorder characterized by symmetrical enlargement of painful, nodular, and fibrous adipose tissue, predominantly affecting the limbs while sparing the hands and feet. It is estimated to affect up to 10% of the female population, although its etiology remains unclear. Diagnosis is typically clinical, based on history and physical examination. However, ultrasound imaging of adipose tissue is a simple, reproducible method that assists in evaluating disease severity and monitoring progression or therapeutic response over time. Amato et al. established ultrasound thickness cut-off values for the diagnosis of lipedema in the lower limbs: 11.7 mm for the pretibial region, 17.9 mm for the thigh, and 8.4 mm for the lateral leg. The supramalleolar threshold was 7.1 mm, though diagnostic accuracy was lower at this site. Marshall et al. proposed an ultrasound-based classification for lipedema severity by measuring dermis and subcutaneous tissue thickness 6-8 cm above the medial malleolus: 12 to 15 mm, lipohyperplasia or mild lipedema; 15 to 20 mm, moderate lipedema; > 20 mm, indisputable lipedema; and > 30 mm, severe lipedema. In contrast, normal individuals typically measure approximately 2.1 mm at this location. This exhibit aims to present a practical ultrasound protocol for assessing lipedema, supported by representative imaging cases.

TABLE OF CONTENTS/OUTLINE

1. Overview of lipedema. 2. Ultrasound assessment protocol and key imaging findings. 3. Educational content with annotated images and flowcharts based on literature review. 4. Take-home messages.

VAEE-32 SPOTLIGHT ON IVC LEIOMYOSARCOMA: DIAGNOSTIC VALUE OF ADVANCED CT IMAGING

Zahra Rahmatullah, MD (*Presenter*)
Mohammad Yasrab (*Abstract Co-Author*)
Linda C. Chu, MD (*Abstract Co-Author*)
Satomi Kawamoto, MD (*Abstract Co-Author*)
Elliot K. Fishman, MD (*Abstract Co-Author*)

TEACHING POINTS

Leiomyosarcoma is a rare primary tumor of the inferior vena cava (IVC). An IVC leiomyosarcoma is challenging to diagnose on imaging as it can be confused with a thrombus, other primary IVC tumors, retroperitoneal masses, lymphomas, renal, adrenal or hepatic carcinomas. CT is pivotal in assessing its origin, invasion, metastasis and for surgical planning. Detection is dependent on scan protocols and both 2D CT (non-contrast, arterial and venous phase) and 3D CT imaging (volume rendering, maximum intensity projection, cinematic rendering) can help reach the diagnosis through various specific features. Early detection is critical due to potential for metastasis and poor prognosis.

TABLE OF CONTENTS/OUTLINE

Demographics and presentations of IVC leiomyosarcomas. Multiple case studies highlighting the various imaging characteristics of IVC leiomyosarcomas. How various CT techniques, including 2D and 3D imaging, can aid in distinguishing IVC leiomyosarcomas from other tumors with the help of case examples. Use of various CT techniques to follow and plan treatment for IVC leiomyosarcomas. Challenges when using CT to diagnose and follow IVC leiomyosarcomas.

VAEE-33 IMPORTANCE OF INVASIVE DIAGNOSIS IN THE PREPARATION OF PATIENTS FOR ANKLE RECONSTRUCTIVE SURGERY

Antonio Pulido Bonillo, MD (*Presenter*)

TEACHING POINTS

- Review the diagnostic utility of arteriography in the preoperative assessment of ankle reconstructive surgeries. - Illustrated anatomical analysis of the vascular supply to the tibiotalar joint and associated structures. - Descriptive review of lower limb angiographic examinations performed at our hospital under this indication.

TABLE OF CONTENTS/OUTLINE

Total ankle arthroplasty has experienced significant growth in recent years, driven by advancements in implant design that have improved durability and facilitated its adoption in a greater number of centers. Proper preoperative evaluation is essential to optimize outcomes and select ideal candidates for the procedure. In this context, diagnostic arteriography has become a key tool in surgical planning, as peripheral arterial disease has been identified as an independent risk factor for postoperative complications, including acute infection, the need for surgical debridement, and implant failure. Early detection of vascular abnormalities through invasive studies allows for the implementation of strategies to mitigate these risks. Moreover, the tibiotalar joint presents unique vascular characteristics that can be assessed through selective arteriography of the lower limb arteries. The talus, in particular, relies on a tripartite blood supply, whose preservation is essential to prevent complications that may compromise implant integration and affect the functional outcome of the prosthesis.

M2-SPBR-1 PREDICTIVE CAPACITY OF DKI-BASED HABITAT ANALYSIS FOR LYMPH NODE METASTASIS IN BREAST CANCER PATIENTS: A PRELIMINARY STUDY

Ziyi Mao (*Presenter*)
Hui Liu (*Abstract Co-Author*)
Haifa Liu (*Abstract Co-Author*)
Mengzhu Wang (*Abstract Co-Author*)
Yang Song (*Abstract Co-Author*)

PURPOSE

The aim of this study was to investigate the performance of first-order radiomics features derived from DKI-based habitat analysis in predicting the status of lymph node metastasis.

METHODS AND MATERIALS

This study included 45 patients with invasive ductal carcinoma of the breast, comprising 30 cases without lymph node metastasis (LNM) and 15 cases with LNM. All patients underwent 3.0T breast MRI with diffusion kurtosis imaging (DKI) using a single-shot spin-echo echo-planar imaging sequence (6 b-values: 0, 1200, 1600, 2000, 2400, and 3000 s/mm 2 ; repetition time (TR)/echo time (TE) = 6000/61 ms; field of view (FOV) = 340 × 180 mm 2 ; matrix size = 128 × 128). Mean diffusivity (MD) and mean kurtosis (MK) were calculated using the vendor-specific software (version 1.4.0). Volumes of interest (VOIs) were manually delineated on baseline b0 images using 3D Slicer (version 5.2.2). These three metrics of DKI were located in each voxel, and a consensus clustering (K-means) algorithm was applied to divide the tumor into subregions with different structural complexity and diffusion levels: subregion 1(MK moderate MD moderate), subregion 2(MK moderate MD high), subregion 3(MK high MD moderate), and subregion 4(MK low MD low). First-order radiomics features of these four subregions were then extracted using an in-house developed software and analyzed using Mann-Whitney U test, with significant features ($p < 0.05$) used to develop a logistic regression predictive model. The predictive performance was evaluated using the area under the receiver operating characteristic curve (AUC) and the calibration curve.

RESULTS

Significant features existed in MK moderate MD moderate and MK moderate MD high subregions between the two groups ($p < 0.05$). The logistic regression model demonstrated robust predictive performance, achieving an AUC of 0.856 (95% CI: 0.733-0.978), accuracy of 82.2%, sensitivity of 86.7%, specificity of 80.0% and F1-score of 76.5%. The calibration curve of the model exhibited satisfactory consistency between predicted and observed outcomes, supported by a Brier Score of 0.129 and a Hosmer-Lemeshow (HL) test statistic of 0.564 (? 2 =6.75, df=8).

CONCLUSION

This study shows that a DKI-MRI-based predictive model, leveraging radiomics features from MK moderate MD moderate and MK moderate MD high subregions, accurately discriminates lymph node metastasis in breast cancer, indicating its promise as a non-invasive diagnostic tool.

CLINICAL RELEVANCE/APPLICATION

This approach has substantial potential in clinical applications, aiding in early identification of metastatic risk and guiding personalized treatment strategies.

M2-SPBR-2 THE VALUE OF BREAST ULTRAFAST DCE-MRI IN DIAGNOSING AXILLARY LYMPH NODE METASTASIS IN MASS-TYPE INVASIVE DUCTAL CARCINOMA OF THE BREAST

Lijia Wang (*Presenter*)
Yang Li (*Abstract Co-Author*)
Qian Xu (*Abstract Co-Author*)
Feng Hui (*Abstract Co-Author*)
Haiyun Wang (*Abstract Co-Author*)
Wang Mengzhu (*Abstract Co-Author*)
Qi Wang, BSc (*Abstract Co-Author*)

PURPOSE

This study aimed to explore the relationship between preoperative ultrafast dynamic contrast-enhanced magnetic resonance imaging (UF-DCE MRI) parameters and axillary lymph node (ALN) metastasis in patients with mass-type invasive ductal carcinoma (IDC) of the breast. In addition, the study aimed to construct a nomogram model for predicting ALN metastasis.

METHODS AND MATERIALS

Preoperative UF-DCE MRI images and medical records of 96 IDC patients (38 with ALN metastasis, 58 without) confirmed by pathology were retrospectively analyzed. Conventional MRI features, UF-DCE MRI parameters, DCE parameters, and clinical features were evaluated. ROC curves and nomograms were constructed for univariate parameters and combined diagnostic efficacy.

RESULTS

Time to enhancement , time to peak after enhancement (TTP), and time to center of max. slope were significantly lower in the metastasis group (all p -values < 0.05). The tumor length was significantly smaller in the non-metastasis group ($p < 0.001$). TTP had the best diagnostic efficacy for lymph node metastasis, with an area under the curve (AUC) of 0.865 (CI: 0.794-0.937). A combined predictive model was constructed using Logistic regression with TTP, ADC value, and size, with an AUC of 0.919 (CI: 0.864-0.974). The nomogram indicated that metastasis probability = e score /1+e score , with a score = 0.70 * size - 2.49 * ADC - 0.03 * TTP + 3.78.

CONCLUSION

Multiple UF-DCE MRI parameters TTE, TTP, TMS could predict ALN metastasis in patients with mass-like IDC before surgery.The nomogram model combined with clinical and UF-DCE MRI parameters could better assist clinicians in making personalized treatment plans for patients.

CLINICAL RELEVANCE/APPLICATION

Preoperative multiparametric UF-DCE MRI could support the prediction of axillary lymph node metastasis in breast cancer, and combining the clinical features could help assess the risk of lymph node metastasis in breast cancer.

M2-SPBR-3 IMPROVED 3-YEAR BREAST CANCER RISK PREDICTION BY COMBINING ANATOMICAL NOISE POWER EXPONENT AND MIRAI: A LARGE CLINICAL STUDY

Yile Fang, PhD (*Presenter*)
Jiefei Wei (*Abstract Co-Author*)
Nathaniel D. Mercaldo (*Abstract Co-Author*)
Leslie Lamb, MD, MSc (*Abstract Co-Author*)
Kai Yang, PhD (*Abstract Co-Author*)

PURPOSE

Recent studies have shown breast parenchymal texture may reflect tissue-level risk for breast cancer. MIRAI is a deep learning (DL) model trained on screening mammograms to assess future breast cancer risk. This study aims to validate the anatomical noise power exponent (ß), derived from mammographic breast tissue texture, as an independent, quantitative biomarker for breast cancer risk and assess its incremental value when combined with MIRAI using a large clinical dataset.

METHODS AND MATERIALS

This study selected patients undergoing bilateral screening mammography at two sites (Oxford and Imperial) from the UK OPTIMAM mammography image database (OMI-DB). We included examinations that had the standard four-view 2D mammographic images and confirmed cancer status after 3 years. Women were included in the control group if they remained cancer-free for at least 3 years after screening, while into the target group with a confirmed breast cancer diagnosis within three years of screening. After quality control, the final cohort included 7,540 women (1,885 with cancer, 5,655 age-matched healthy control) with a total of 30,328 screening mammograms. A novel algorithm automatically segmented breast tissue regions and computed the anatomical noise power exponent ß, for each image as a single-value breast parenchyma descriptor. Each woman's 3-year cancer risk score was calculated via the MIRAI model. Six mathematical models were explored to combine MIRAI scores with ß, including logistic regressions and optimized weighted sums. Discriminative performance was assessed using odds ratios (OR)and receiver operator curve (ROC) analysis.

RESULTS

ß was significantly higher ($p<0.01$) for the cancer group (0.3088 ± 0.0057) as compared to the control group (0.3007 ± 0.0055). For every 0.1-unit increase in ß, the odds of breast cancer increased by 13.4% (OR=1.134, 95% CI: 1.110-1.158, $p <0.01$). ROC analysis yielded area-under-the-curve (AUC) values of 0.700 (95% CI: 0.687-0.714) for MIRAI alone. Among combination methods, the optimized weighted sum model (weight factor: 0.05) yielded the highest AUC (0.704, 95% CI: 0.691-0.718). These findings hold across clinical cancer subgroups, highlighting ß's potential as a robust, image-based cancer risk biomarker.

CONCLUSION

ß independently discriminates future breast cancer cases from controls and enhances 3-year breast cancer risk prediction when combined with MIRAI scores. The optimized weighted sum model provided the best predictive performance.

CLINICAL RELEVANCE/APPLICATION

Incorporating ß into existing DL-based risk prediction models like MIRAI can improve the accuracy of image-based breast cancer risk assessment, potentially leading to better patient stratification and targeted screening strategies.

M2-SPBR-4 USE OF AI CAD TO TRIAGE REAL-TIME VS OFFLINE READING OF SCREENING MAMMOGRAMS WITH SUBSEQUENT SAME-DAY AUTOMATED SCREENING BREAST ULTRASOUND (AUS)

Madeleine Gurney, MD (*Presenter*)
Jessica K. Peterson, MD (*Abstract Co-Author*)
Diamond Brunt (*Abstract Co-Author*)
Tuqa Asedi (*Abstract Co-Author*)
Lauren Clark, MS (*Abstract Co-Author*)
Lindsay Miner, MD (*Abstract Co-Author*)
Hannah L. Singhal, MD (*Abstract Co-Author*)

PURPOSE

To project how transitioning from full offline interpretation to AI CAD-driven triage of real-time vs offline interpretation of screening mammograms scheduled for subsequent same-day AUS would affect radiologist workflow in an academic breast imaging department.

METHODS AND MATERIALS

This retrospective review analyzed screening mammograms with same-day AUS from a single academic institution from 12/1/2023-11/30/2024. At the time of interpretation, nearly all exams were read offline. Screening mammogram BI-RADS assessment and AI CAD Transpara exam score (1-10) were collected. Exams were divided into projected real-time versus offline reading using differing Transpara exam score cutoffs, with scores less than the cutoff assigned to offline reading.

RESULTS

Among the 1,499 screening mammograms, 41 (2.7%) were assigned BI-RADS 0 assessment, requiring additional imaging evaluation, also known as a callback. Using a Transpara exam score cutoff of 8, 987 (65.8%) exams remained as offline interpretation. This would result in 15 (36.6%) callbacks not identified until after AUS was performed. Of the 512 (34.2%) mammograms transitioned to real-time interpretation, 26 (63.4%) callbacks would have been identified prior to performing AUS. Using a Transpara exam score cutoff of 9, 1,177 (78.5%) exams continued as offline interpretation, resulting in 22 (53.7%) callbacks needing diagnostic workup after AUS was performed. Of the 322 (21.5%) exams converted to real-time interpretation, 19 (46.3%) callbacks would have been identified prior to AUS. Using a Transpara exam score cutoff of 10, 1,337 (89.2%) exams stayed as offline interpretation, with 25 (61.0%) callbacks requiring further evaluation after AUS. Of the 162 (10.8%) exams changed to real-time interpretation, 16 (39.0%) callbacks would be identified prior to AUS.

CONCLUSION

Applying differing AI CAD score cutoffs results in variable degrees of real-time versus offline interpretation, with the lowest exam score cutoff resulting in the highest real-time interpretation rate and subsequent greatest number of callbacks identified prospectively. The cutoff for real-time versus offline interpretation could be customized to fit varying practice preferences.

CLINICAL RELEVANCE/APPLICATION

AI CAD can help prospectively triage screening mammograms needing real-time interpretation, to identify patients needing further evaluation before performing same-day AUS, ensuring proper exam utilization.

M2-SPBR-6 MULTIMODAL DEEP LEARNING TO PREDICT RISK OF FUTURE BREAST CANCER BASED ON SCREENING MRI FEATURES IN WOMEN WITH DENSE BREASTS

Suleeporn Sujichantararat, PhD (*Presenter*)
Anum S. Kazerouni, PhD (*Abstract Co-Author*)
Wesley Surento (*Abstract Co-Author*)
Yu-Tzu Kuo (*Abstract Co-Author*)
Isabella Li (*Abstract Co-Author*)
Daniel S. Hippe, MS (*Abstract Co-Author*)
Felipe Oviedo, PhD (*Abstract Co-Author*)
Habib Rahbar, MD (*Abstract Co-Author*)
Savannah C. Partridge, PhD (*Abstract Co-Author*)

PURPOSE

Breast cancer risk prediction models can help optimize screening strategies for earlier detection. Mammographic density is a widely accepted imaging marker that helps increase performance of risk models, but is non-specific since approximately half of US screening-aged women have dense breasts. Background parenchymal enhancement (BPE) on MRI is an emerging risk marker that may further refine risk stratification. Many state-of-the-art risk prediction models either utilize only image data or non-image clinical data. Combining multimodal data can improve model performance. This study aimed to refine the prior classification model into a multimodal risk prediction model utilizing both breast MR images and clinical data in women with dense breasts.

METHODS AND MATERIALS

After IRB approval, we retrospectively identified women with mammographically dense breasts who underwent high risk screening with breast MRI at our medical center (2005 to 2015), excluding those with prior breast cancer or contemporaneous breast cancer (diagnosed =12 months after MRI). Clinical data and cancer outcomes were extracted from the medical record and regional SEER cancer registry. Multimodal deep learning models to predict 5-year risk of breast cancer were constructed using three fusion strategies: probability, feature, and learned feature fusion. Deep learning model training data included subtraction maximum intensity projection (MIP) images from DCE-MRI, age, BPE, and density. We developed the model using grouped 5-fold cross validation and report mean performance across folds.

RESULTS

We identified 706 women (mean age 46 ± 11 years) with dense breasts who underwent screening MRI and met criteria for final analysis, of which 31 (4.4%) developed breast cancer (median 2.5 years after MRI, range 1 to 5 years). Multimodal deep learning with learned-feature-fusion-concatenation and feature-fusion strategies both achieved higher AUCs than the probability-fusion strategy (AUC 0.71, 0.70 and 0.56, respectively) for predicting 5-year risk of breast cancer. Deep learning models based on images only or clinical data only achieved lower performance than the top two fusion strategies (AUC 0.65 and 0.58, respectively).

CONCLUSION

Our results demonstrate that fusing of images and clinical data can boost risk model performance compared with using only one feature type in women with dense breasts. Different fusion strategies can also affect model performance, and the best strategy depends on characteristics of the dataset.

CLINICAL RELEVANCE/APPLICATION

This multimodal deep learning model could be deployed in clinical settings to complement traditional risk models that do not include MRI and aid physicians in assessing a patient's risk of developing a future breast cancer.

M2-SPBR-7 ACCESSING AI MAMMOGRAPHY REPORTS IMPACTS PATIENT FOLLOW-UP BEHAVIORS: THE UNINTENDED CONSEQUENCES OF INCLUDING AI IN PATIENT PORTALS

Elizabeth Song (*Presenter*)
Michael H. Bernstein, PhD (*Abstract Co-Author*)
Elizabeth H. Dibble, MD (*Abstract Co-Author*)
Ana P. Lourenco, MD (*Abstract Co-Author*)
Grayson L. Baird, PhD, MS (*Abstract Co-Author*)

PURPOSE

To investigate how follow-up behaviors are impacted by providing contextual information about an AI-interpreted imaging report in the patient portal regarding a hypothetical screening mammogram.

METHODS AND MATERIALS

English-speaking US women with 1+ prior mammogram were recruited via Prolific and randomized to one of thirteen conditions. All participants were shown a vignette asking them to imagine receiving a BI-RADS 1 (Negative) radiologist report from their patient portal. Participants in twelve conditions also received an AI report with one of four AI abnormality scores (not flagged: 0, 29; flagged: 31, 50) and 0-2 accompanying features (nothing; a only; a & b): (a) an abnormality cutoff threshold; (b) the AI tool's False Discovery Rate (FDR) or False Omission Rate (FOR). Participants indicated whether they would consider a lawsuit if a one-year follow-up found evidence of Stage 3 breast cancer. Secondary outcomes included hypothetical decisions regarding follow-up (e.g., second opinions), concern for breast cancer, and desire for additional imaging.

RESULTS

Participants (n=1,623) were more likely to consider a lawsuit when AI was (versus was not) provided, especially when AI abnormality scores were higher, $p<0.05$. However, for most AI abnormality scores, providing the cutoff threshold and FDR/FOR reduced lawsuit consideration relative to the AI abnormality score alone. Concern for breast cancer, desire for additional imaging, and follow-up requests (same radiologist, different radiologist, and ordering physician) increased as the AI abnormality score increased, though this was also often mitigated by providing the FDR (and sometimes FOR).

CONCLUSION

Disclosing AI feedback used for medical decision-making will impact patients' perceptions and behaviors pertaining to malpractice and follow-up.

CLINICAL RELEVANCE/APPLICATION

Best practices are needed to engage and inform patients about the application of AI tools in their care while minimizing its unintended consequences.

M2-SPBR-8 NAVIGATING THE DEBATE: INSIGHTS AND STRATEGIES ON REMOTE DIAGNOSTIC BREAST IMAGING FROM U.S. BREAST RADIOLOGISTS

Ria Dawar, MD (*Presenter*)
Lars J. Grimm, MD (*Abstract Co-Author*)
Reema Dawar (*Abstract Co-Author*)
Emily B. Sonnenblick, MD (*Abstract Co-Author*)
Brian N. Dontchos, MD (*Abstract Co-Author*)
Kristen Coffey, MD (*Abstract Co-Author*)
Sally Goudreau, MD (*Abstract Co-Author*)
Beatriu Reig, MD, MPH (*Abstract Co-Author*)

Sarah Jacobs, BS, RT (*Abstract Co-Author*)
Zeeshan A. Shah, MD (*Abstract Co-Author*)
Lisa A. Mullen, MD (*Abstract Co-Author*)
Vandana M. Dialani, MD (*Abstract Co-Author*)
Katerina Dodelzon, MD (*Abstract Co-Author*)
Jay R. Parikh, MD, FRCPC (*Abstract Co-Author*)
Hannah Milch, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the benefits and challenges of remote diagnostic breast imaging and propose strategies to optimize its use for radiologists, technologists, and patients.

METHODS AND MATERIALS

As part of a larger 43-question survey on remote breast imaging, breast radiologists with experience or knowledge of remote diagnostic breast imaging answered 11 multiple-choice and free-response questions. The survey was distributed to Society of Breast Imaging members (July 6-August 2, 2023). Descriptive statistics were used for multiple-choice responses, while free responses were systematically coded based on the thematic similarities.

RESULTS

Among 424 respondents (response rate: 13%, 424/3244), 40% (169/424) had experience with remote diagnostics. Of those with experience, most believed patients were either unaware of an in-person alternative (32%, 54/169) or preferred in-person exams (15%, 25/169). The majority (60%, 101/169) felt less effective at establishing patient rapport remotely, citing video calls (41%, 36/88) as the best communication method (Note: denominators vary due to skipped questions). Nearly half (48%, 81/169) felt remote work weakened rapport with technologists, suggesting strategies such as frequent communication (30%, 28/93), periodic in-person interactions (24%, 22/93), and strong communication skills (23%, 21/93). Most (63%, 74/117) relied on technologists to report physical exam findings, and when real-time scanning was needed, 53% (61/116) had patients return when a radiologist was on-site. Despite concerns—some calling it “malpractice” or “substandard care”—others saw remote diagnostics as valuable for improving patient access to fellowship-trained breast radiologists.

CONCLUSION

Remote diagnostic breast imaging remains controversial; while some radiologists view it as a valuable tool to expand access to fellowship-trained breast radiologists, others raise concerns about patient care quality, liability risks, and reduced effectiveness in building patient and technologist rapport. Respondents recommended strategies to optimize remote breast imaging, including frequent communication with technologists, periodic in-person interactions, strong interpersonal skills, and having patients return for real-time scanning when needed. Standardized guidelines incorporating these elements may improve outcomes for radiologists, technologists, and patients.

CLINICAL RELEVANCE/APPLICATION

Remote diagnostic breast imaging can expand access to specialized care but presents challenges in communication and clinical assessment. Enhanced training for technologists and strong collaborations between technologists and breast radiologists can optimize patient care in the setting of remote reading.

M2-SPCA-1 ASSOCIATION OF LEFT VENTRICULAR MYOCARDIAL STRAIN DERIVED FROM CARDIAC COMPUTED TOMOGRAPHY WITH ADVERSE CARDIAC EVENTS IN PATIENTS WITH SEVERE AORTIC STENOSIS

Jing Yi Xing (*Presenter*)
Hidenobu Takagi, MD, PhD (*Abstract Co-Author*)
Hideki Ota, PhD (*Abstract Co-Author*)
Kiyotaka Hao (*Abstract Co-Author*)
Jun Takahashi (*Abstract Co-Author*)
Kei Takase, MD, PhD (*Abstract Co-Author*)

PURPOSE

Severe aortic stenosis alters cardiac wall stress and structure, leading to left ventricular dysfunction, and increased mortality. Strain imaging quantifies myocardial deformation and aids in clinical assessment. This study evaluates the prognostic value of CT-derived left ventricular myocardial strain for risk stratification in patients with severe aortic stenosis.

METHODS AND MATERIALS

This single-center retrospective study included patients with severe aortic stenosis who underwent cardiac CT to assess TAVR eligibility from 2014 to 2023. Exclusion criteria were no valve replacement, missing baseline data, or incomplete CT images. All cardiac CT images were reconstructed at 10% intervals of the RR interval throughout the cardiac cycle (0-90%). CT strain was analyzed using research software (Ziostation REVORAS ver. 5.3.0.0; Ziosoft Inc. Tokyo, Japan). Left ventricular epi- and endo-myocardium were automatically segmented and manually corrected as needed. Myocardial strain was calculated using the feature-trucking method. Global radial (GRS) and circumferential strain (GCS) were calculated as the average of five short-axis plane from the base to the apex. Global longitudinal (GLS) was calculated as the average of long 2-, 3-, and 4-chamber views. The primary endpoint was major adverse cardiac events (MACE), defined as a composite of cardiovascular (CV) death or hospitalization due to heart failure (HF). Secondary endpoints were CV death and HF hospitalization. Cutoff values for peak GRS, GCS, and GLS to discriminate MACE, based on the Youden index, were 28.4%, -15.0%, and -10.3%, respectively.

RESULTS

A total of 324 patients (mean age 83 ± 6 years, 104 [32%] male) were included. During a median follow-up of 1.3 years, 53 MACEs were observed. Reduced peak GLS was associated with MACE (hazard ratio [HR], 2.3; 95% confidence interval [CI], 1.3-4.1; p = 0.003), while GRS (HR 0.89 [95% CI 0.5-1.6]; p = 0.70) and GCS (HR 0.96 [95% CI 0.5-1.6]; p = 0.90) were not. After adjusting for age, sex, STS risk score, left ventricular ejection fraction, presence of coronary artery disease, and history of myocardial infarction, these results remained (HR [95% CI] of GLS, 2.2 [1.1-4.6]; GRS, 0.67 [0.3-1.3], and GCS, 0.71 [0.3-1.3], respectively). The association between peak GLS and MACE was primary driven by HF hospitalization (adjusted HR 2.5 [95% CI 1.1-6.2]), not CV death (adjusted HR 1.4 [95% CI 0.4-4.8]).

CONCLUSION

CT-derived GLS independently predicts heart failure events in patients with severe aortic stenosis, offering incremental prognostic value beyond traditional biomarkers.

CLINICAL RELEVANCE/APPLICATION

GLS from routine pre-TAVR cardiac CT may serve as a non-invasive biomarker for risk stratification and guide early clinical decision-making.

M2-SPCA-2 A LASSO-BASED MODEL FOR PREDICTING LATE RECURRENCE AFTER ATRIAL FIBRILLATION ABLATION AND ITS CLINICAL UTILITY

Xiaoyan Lei (*Presenter*)
Kehui Liu (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)
Xiaohua Zhang (*Abstract Co-Author*)
Shikuan Li (*Abstract Co-Author*)
Weiyuan Huang (*Abstract Co-Author*)
Feng Chen, MD, PhD (*Abstract Co-Author*)

PURPOSE

Late recurrence (LR) following atrial fibrillation (AF) ablation compromises long-term therapeutic success. This study aimed to develop a straightforward, clinically applicable model utilizing pre-ablation clinical and laboratory data to identify individuals at elevated risk of LR and inform personalized follow-up strategies.

METHODS AND MATERIALS

A retrospective analysis was conducted on 168 patients (73.2% male) who underwent radiofrequency ablation for AF between January 2020 and October 2024. Data collected included demographic factors (e.g., age, BMI), comorbidities, and laboratory indicators (e.g., NT-proBNP, HbA1c, CRP). LR was defined as atrial arrhythmia lasting =30 seconds and occurring beyond 90 days post-procedure. Participants were randomly divided into training and testing cohorts in a 7:3 ratio. Initial variable screening involved Mann-Whitney U and chi-square tests, followed by univariate logistic regression. Key predictors were selected through least absolute shrinkage and selection operator (LASSO) regression. Model performance was assessed via receiver operating characteristic (ROC) analysis and decision curve analysis (DCA).

RESULTS

Out of the total cohort, 56 patients (33.3%) experienced LR. The final model incorporated three predictors: early recurrence post-ablation, HbA1c =6.0 %, and BMI >25 kg/m². The model achieved robust discriminative ability, with an AUC of 0.809 (95% CI: 0.723-0.888) in the training set, and an AUC of 0.824 (95% CI: 0.695-0.941) in the testing set. Sensitivity and specificity were 89.7% and 61.5% in training, and 76.5% and 82.4% in testing, respectively. Optimal cutoff points were 0.272 and

0.313, yielding Youden indices of 0.513 and 0.588. DCA demonstrated clear clinical benefit when predicted LR risk fell between 15% and 35%, with the model potentially reducing unnecessary interventions by up to 70.6% in the test cohort while preserving the identification of high-risk patients.

CONCLUSION

A concise, three-variable model incorporating early recurrence, elevated HbA1c, and increased BMI effectively forecasts late recurrence after AF ablation. It presents a practical framework for risk stratification and tailored follow-up. Future validation through prospective, multicenter research is warranted, with potential for model enhancement via integration of imaging or novel biomarkers.

CLINICAL RELEVANCE/APPLICATION

This model underscores the value of metabolic assessment and early recurrence detection in post-ablation care, offering a data-driven approach to improve long-term outcomes in AF patients.

M2-SPCA-3 FEASIBILITY OF 2D-MULTISEGMENT LATE GADOLINIUM ENHANCEMENT COMBINED WITH ARTIFICIAL INTELLIGENCE RECONSTRUCTION DEEP LEARNING NOISE REDUCTION ALGORITHM

Makoto Orii (*Presenter*)
Tsuyoshi Sugawara (*Abstract Co-Author*)
Jumpei Fujiwara, MD (*Abstract Co-Author*)
Jun Obara, MD (*Abstract Co-Author*)
Kunihiro Yoshioka, MD (*Abstract Co-Author*)

PURPOSE

Although 2D-single segmented late gadolinium enhancement sequences (2D-SSLGE) in which each myocardial slice is acquired during multiple heart beats and within a single breath-hold are considered the gold standard for LGE acquisition, they are time consuming. In 2D-multi segmented LGE sequences (2D-MSLGE), each slice is acquired in a single heart beat and the entire left ventricular stack is acquired in a few breath-holds. Recently, an artificial intelligence reconstruction deep learning noise reduction (NR) tool was developed in order to improve image quality and reduce scan time. The purpose of study is to assess the feasibility and comparison of 2D-MSLGE reconstructed with NR versus 2D-SSLGE reconstructed with NR.

METHODS AND MATERIALS

Between September 2023 and November 2024, a total of 60 patients (39 [65%] men, mean age 58 ± 17 years, body surface area 1.7 ± 0.2 m 2) with suspected cardiomyopathy at Iwate Medical University Hospital were prospectively enrolled. LGE imaging was performed using a 1.5 T scanner (SIGNA Artist, GE HealthCare) 10 min after the injection of contrast agent. 2D-MSLGE reconstructed with NR was performed just before 2D-SSLGE reconstructed with NR. Subjective overall image quality was evaluated using a 5-point Likert scale (1, poor, 2, fair, 3, moderate, 4, good, 5 excellent) that overall image impression. The visibility of artifacts (1, severe image artifacts, 2, moderate to severe image artifacts, 3, moderate image artifacts, 4, mild image artifacts, 5, no image artifacts) was also scored. LGE mass was manually quantified using a semi-automated greyscale thresholding using a cut off value of 5 standard deviations.

RESULTS

The median actual time of acquisition of 2D-MSLGE reconstructed with NR (112 ± 44 s) was significantly reduced compared with 2D-SSLGE (515 ± 145 s, p = 0.001). Overall image quality of 2D-MSLGE reconstructed with NR (3.1 ± 0.6) was non-inferior compared with 2D-SSLGE reconstructed with NR (3.2 ± 0.8, p = 0.106). Image noise was significantly reduced in 2D-MSLGE reconstructed with NR (3.4 ± 0.6) compared with 2D-SSLGE reconstructed with NR (3.0 ± 0.8, p = 0.002). There was no significant difference for LGE mass between 2D-MSLGE reconstructed with NR (17.0 ± 10.6 %) and 2D-SSLGE reconstructed with NR (17.4 ± 11.2 %, p = 0.155).

CONCLUSION

The use of 2D-MSLGE reconstructed with NR would provide shorter scan times and accurate LGE in clinical settings.

CLINICAL RELEVANCE/APPLICATION

The application of NR reconstruction may represent a reliable approach to reach a robust diagnostic performance with 2D-MSLGE compared to standard 2D-SSLGE.

M2-SPCA-5 CLINICAL APPLICATION STUDY OF ECGLESS TECHNOLOGY IN CORONARY COMPUTED TOMOGRAPHY ANGIOGRAPHY

Yongwei Zhao (*Presenter*)

PURPOSE

To evaluate the clinical application value of ECGless technology in coronary computed tomography angiography (CCTA) and explore the feasibility of its widespread adoption.

METHODS AND MATERIALS

A randomized controlled trial was conducted, enrolling 30 patients with suspected coronary artery disease who were randomly divided into an ECGless group (n=15) and a conventional ECG-gated group (using prospective ECG-gated tube current modulation technique) (n=15). Both groups received iodinated contrast medium (Iopromide, 370 mgI/mL) administered at a flow rate of 5.0 mL/s with a total volume of 40-60 mL, followed by a 30 mL saline flush. Image quality was evaluated using a double-blind method, comparing subjective vascular segment scores, objective signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and dose-length product (DLP) converted to effective dose (ED).

RESULTS

No significant difference in BMI or heart rate were observed between the non-ECG-gated group and the conventional ECG-gated group (both P >0.05). Subjective evaluation of 15 vascular segments revealed significantly higher scores in the ECGless group compared to the conventional ECG-gated group (4.36±0.65 vs. 3.72±0.12, P<0.05). Objective analysis demonstrated significant improvements in the ECGless group for SNR in the left anterior descending artery (LAD) (16.99±11.2 vs. 10.9±3.2) and CNR in both the LAD (58.31±23.8 vs. 33±14.2) and left circumflex artery (LCX) (58.31±23.8 vs. 33±14.1) (all P<0.05). Although the effective dose in the ECGless group was slightly higher than that in the conventional ECG-gated group (4.16 mSv ± 0.74 vs. 2.9 ± 1 mSv), the difference was not statistically significant (P=0.65).

CONCLUSION

ECGless technology achieves high-quality coronary imaging during free breathing without ECG monitoring, controls radiation exposure, and streamlines workflows, showing particular promise for critically ill patients.

CLINICAL RELEVANCE/APPLICATION

The ECGless technology eliminates the need for ECG monitoring, overcoming the reliance of conventional coronary CT imaging on stable heart rates and breath-holding compliance. This innovation is particularly advantageous for critically ill patients (e.g., those with acute chest pain, heart failure, or inability to follow breathing instructions), enabling rapid acquisition of high-quality coronary images during free breathing. By streamlining workflows (avoiding electrode placement and ECG synchronization) and minimizing repeat scans due to motion artifacts, it accelerates diagnostic evaluation for urgent clinical decisions . Additionally, it reduces clinical risks and healthcare costs in critically ill populations while maintaining diagnostic reliability.

M2-SPCA-6 MYOCARDIAL FIBROSIS PREDICTS SUDDEN CARDIAC DEATH IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY AFTER CARDIAC ELECTRONIC DEVICE IMPLANTATION:INSIGHTS FROMCARDIOVASCULAR MAGNETIC RESONANCE IMAGING

Xinqiao Lian (*Presenter*)
Bingqi Fu (*Abstract Co-Author*)
Minjie Minjie, PhD (*Abstract Co-Author*)

PURPOSE

We aimed to determine whether the location, pattern, and quantification of myocardial fibrosis predicts sudden cardiac death (SCD) in Hypertrophic cardiomyopathy (HCM) patients after cardiac implantable electronic device (CIED) implantation.

METHODS AND MATERIALS

This study included HCM patients who completed cardiovascular magnetic resonance (CMR) and received CIED between June 2017 and January 2023, and followed up until January 2025. The primary outcome was SCD or SCD-equivalent events, defined as the composite of SCD, resuscitated cardiac arrest, sustained ventricular tachycardia or ventricular & 7;brillation, or appropriate ICD therapy (shock or anti-tachycardia pacing).

RESULTS

Eighty-eight patients were included (age 52.3 ± 15.3 years; 67.0% male). Over a median follow-up period of 38.1 months, 27 (30.6%) SCD events were recorded. Through multivariate Cox regression analyses, inferior wall involvement, transmural pattern of fibrosis, total fibrosis (TF), and gray zone fibrosis (GZF) were all significantly associated with SCD risk. Stepwise regression analyses identified the transmural fibrosis pattern (HR = 2.87, 95% CI: 1.10-7.46, P = 0.031) and gray zone fibrosis =18.91% (GZF 5SD =18.91%; HR = 2.89, 95% CI: 1.16-7.17, P = 0.022) as independent predictors of SCD risk. Incorporating both transmural fibrosis and GZF 5SD =18.91% into the HCM 5-year SCD risk model significantly improved predictive performance (AUC = 0.76, 95% CI: 0.62-0.90, P = 0.017; NRI = 0.72, P = 0.004; IDI = 0.08, P < 0.001).

CONCLUSION

Myocardial fibrosis with transmural pattern, and elevated GZF 5SD are potential predictors of SCD in HCM patients after CIED implantation and provide additional value to existing risk scoring system.

CLINICAL RELEVANCE/APPLICATION

HCM patients face increased risk of SCD, and myocardial fibrosis is predictive of ventricular arrhythmias. ICD can prevent SCD effectively, however, it was noted that only a small fraction of patients receiving ICD for primary prevention actually benefit from the device over its operational lifespan, while facing a high risk of receiving device-related complications, and inappropriate shock. Therefore, there remains a need to optimize SCD prediction. Through this retrospective cohort study of HCM patients with CIED implantation, we found that transmural fibrosis and gray zone fibrosis =18.91% are independent predictors of SCD risk. Incorporating both these two predictors into the HCM 5-year SCD risk model significantly improved predictive performance. This study provides new evidence to support a fibrosis phenotype-guided approach for refining ICD implantation strategies in HCM patients.

M2-SPCA-7 PROGNOSTIC UTILITY OF CORONARY CALCIFICATION IN THE CONSIDERATION OF UNDERLYING NON-CALCIFIED PLAQUE BURDEN

Parth Patel (*Presenter*)
Tyler Coombes (*Abstract Co-Author*)
Yashaswi Joshi (*Abstract Co-Author*)
Alexander R. van Rosendael, MD (*Abstract Co-Author*)
Ibrahim Danad (*Abstract Co-Author*)
Jisuk Park (*Abstract Co-Author*)
Kashif Shaikh (*Abstract Co-Author*)

PURPOSE

Coronary artery calcium (CAC) scoring is the backbone of cardiovascular (CV) risk assessment. Concurrently, calcium density is inversely related to adverse CV events, and non-calcified plaque volume (NCPV) has a strong link with adverse CV events and is the modifiable component of atherosclerosis. Novel AI-enabled quantitative computed tomography (AI-QCT) allows for more accurate quantification of NCPV. Treatments for coronary artery disease (CAD) transform plaque by increasing calcified plaque (CP) density and promoting stability, thus CAC based models may create opportunity for overestimation of risk for future CV events, while also underestimating risk when CAC is low or 0 and NCPV is high. Our primary aim is to assess the added prognostic value of CAC when the NCPV is known.

METHODS AND MATERIALS

A post-hoc analysis of patients with CAC scores and NCPV % by AI-QCT from the CONFIRM2 registry undergoing a clinically indicated coronary CT angiography. The primary endpoint was composite MACE (adjudicated death, myocardial infarction, cerebrovascular accident, site-reported congestive heart failure, unstable angina, or 90-day revascularization within a 3-year period). Secondary endpoints included all-cause death and myocardial infarction (MI).

RESULTS

2,394 patients (median age 58 years, 49.7% female) were evaluated. Risk factors for CAD included hypertension, hyperlipidemia, and smoking in 51%, 43.7%, and 15.7% of patients, respectively. Statin use was present in 37.8%. Regarding CAC scoring, 41.7% scored 0, 30.8% scored 1-99, 13.5% scored 100-299, 10.7% scored 300-999, and 3.2% scored =1000. MACE occurred in 121 patients (5%). MACE occurred at increasing rates of CAC scores, with 21 events occurring in those with a CAC of 0. NCPV demonstrated a linear relationship in events with increasing NCPV%, with the largest predictor of future events being a NCPV of >7.5%; these findings were consistent after adjusting for additional risk factors including age, sex, diabetes, hypertension, smoking, and hyperlipidemia (HR 7.8 (95% CI 4.12-14.76, p = 0.008) of MACE compared to all CAC categories (HR 1.03 up to 1.33 across all CAC category ranges). When utilizing the NCPV model, the addition of the CAC score did not improve the area under the operating curve (AUC) (p=0.061); however, when utilizing the CAC score based-model, addition of NCPV showed superiority and improved AUC compared to the CAC-only model (p=0.0002).

CONCLUSION

NCPV has independent prognostic utility when considered alongside CP burden and is a better predictor of MACE than CAC alone.

CLINICAL RELEVANCE/APPLICATION

NCPV improves risk prediction independent of CAC scores. When considering CV risk based on a CAC score, addition of NCPV could further guide treatment strategies.

M2-SPCA-8 4D CARDIAC QUANTITATIVE SUSCEPTIBILITY MAPPING WITH IMPROVED TEMPORAL-DIRECTION REGULARIZED RECONSTRUCTION

Dave Tailor (*Presenter*)
Gowtham Baskar (*Abstract Co-Author*)
Myat Pwint Thein (*Abstract Co-Author*)
Martin R. Prince, MD, PhD (*Abstract Co-Author*)
Yi Wang, PhD (*Abstract Co-Author*)
Alexey Dimov, PhD (*Abstract Co-Author*)
Keigo Kawaji, PhD (*Abstract Co-Author*)

PURPOSE

To implement and evaluate a 4D cardiac QSM framework that incorporates temporal regularization for phase-resolved susceptibility mapping, enabling physiologically accurate quantification of myocardial tissue magnetic properties.

METHODS AND MATERIALS

Cardiac QSM data from N=10 swine were acquired on a 3.0T Philips Ingenia system using a free-breathing, ECG-gated 4D multi-echo SPGR sequence (TR/TE = 16-20/2.1 ms, ?TE = 1.9 ms, 6-8 echoes, 1.25×1.25×5 mm resolution, 40 slices, CS-SENSE R = 3.5, 8-11 phases). Each dataset (7-11 phases, ~7 echoes/phase) underwent phase correction, noise normalization, IDEAL-based fat-water separation, and background field removal. Custom extraction of echo times and magnitude-phase pairs enabled 4D stacking. Local field maps (RDFs) were reconstructed via (i) 3D MEDI per phase and (ii) 4D MEDI with temporal continuity and sparsity constraints. Zero referencing used longissimus dorsi ROIs. RV/LV susceptibility was quantified from QSM-mDIXON overlays; heatmaps aided visualization.

RESULTS

Zero-referencing across N=10 subjects using longissimus dorsi ROIs demonstrated low inter-phase susceptibility variance (0.0001-0.002 ppm for 3D; 0.0004-0.002 ppm for 4D), confirming stability of the reference region. Mean and variance differences between 3D and 4D reconstructions were statistically non-significant (P=0.3-0.5), validating consistency across methods. Shapiro-Wilk tests confirmed normality for 4D reconstructions (W=0.96, p=0.7). RV/LV myocardial susceptibility quantification showed mean values of 0.131 ppm (RV) and 0.0082 ppm (LV) for 3D, and 0.149 ppm (RV) and -0.0026 ppm (LV) for 4D. The RV-LV difference increased from 0.123 ppm (3D) to 0.151 ppm (4D), surpassing previously reported QSM benchmarks (0.12 ppm). A paired t-test yielded a statistically significant enhancement of RV-LV susceptibility contrast with 4D temporal regularization (P=0.04). Visual inspections of QSM-mDIXON overlays confirmed anatomical accuracy of ROI delineations. Mean RV/LV values were extracted using a Python tool; t-tests compared reconstruction methods.

CONCLUSION

Temporally-regularized 4D cardiac QSM improved myocardial muscle delineation, yielding greater RV-LV contrast and consistent zero referencing compared to 3D. These results demonstrate its feasibility for quantitative cardiac muscle tissue and ventricular oxygenation assessment.

CLINICAL RELEVANCE/APPLICATION

4D temporally-regularized cardiac QSM enables non-invasive, quantitative assessment of myocardial oxygenation, supporting its potential as a biomarker for cardiac function and ischemic evaluation.4o

M2-SPCA-11 CARDIAC MAGNETIC RESONANCE STRAIN TRAJECTORY CHANGES IN LATE GADOLINIUM ENHANCEMENT NEGATIVE POPULATION OF DUCHENNE MUSCULAR DYSTROPHY AND ITS PREDICTIVE VALUE FOR THE OCCURRENCE OF LGE:A LONGITUDINAL STUDY

Ting Xu (*Presenter*)
Ziqi Zhou, MD,BMBCh (*Abstract Co-Author*)
Huayan Xu (*Abstract Co-Author*)

PURPOSE

Duchenne muscular dystrophy (DMD) is a common X-linked recessive muscle degenerative disease that leads to progressive cardiac complications, particularly myocardial fibrosis. Myocardial strain can sensitively reflect myocardial structural and functional abnormalities. This study aims to evaluate dynamic changes in myocardial strain and their predictive value for the occurrence of late gadolinium enhancement (LGE) in patients with DMD.

METHODS AND MATERIALS

This study retrospectively collected longitudinal data of DMD patients from August 2019 to December 2024, including cardiac magnetic resonance (CMR) parameters of DMD patients at baseline and at 1, 2, 3, and 4 years. Nonlinear mixed effects model and least square method were used to analyze and compare the changes of myocardial strain parameters in different subgroups. Cox proportional hazard model and survival curve were used to analyze the predictive value of myocardial strain parameters for LGE.

RESULTS

A total of 140 participants underwent multiple CMR examinations and were included in the analysis. Among them, 40 subjects (28.6%) had LGE. Rate of decline in basal radial strain (BRS) and basal circumferential strain (BCS) was faster in LGE+ than LGE- subjects (P<0.05), while other CMR and strain parameters were not significantly different. Patients with BRS lower than 36.81% were more likely to develop myocardial fibrosis.

CONCLUSION

LGE in DMD is related to the rate change of basal radial and circumferential strain. Early dynamic monitoring of radial strain, can be used to stratify the risk and timely intervene in DMD patients. By delaying the rate of strain reduction, the occurrence of myocardial fibrosis in this patient population may be reduced.

CLINICAL RELEVANCE/APPLICATION

The dynamic monitoring of myocardial strain can serve as a non-invasive early assessment tool for DMD patients, aiding in the identification of high-risk individuals who may develop myocardial fibrosis. Through early intervention, it is possible to delay the progression of myocardial fibrosis and the decline in cardiac function.

M2-SPCA-12 INCREMENTAL DIAGNOSTIC VALUE OF CT MYOCARDIAL PERFUSION AND CT-FFR FOR HEMODYNAMIC RELEVANCE OF CORONARY ARTERY DISEASE: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Shan Huang, MD (*Presenter*)
Lu Zhang, MD (*Abstract Co-Author*)
Xinyuan Zhang (*Abstract Co-Author*)
Ran Sun (*Abstract Co-Author*)

PURPOSE

To compare the diagnostic performance of integrated coronary computed tomography angiography (CCTA) combined with CT-derived fractional flow reserve (CT-FFR) versus CCTA plus CT myocardial perfusion (CTP), as well as the combined use of CCTA, CT-FFR, and CTP for detecting hemodynamically significant coronary artery disease (CAD), using invasive angiography-derived fractional flow reserve (FFR) as the reference standard.

METHODS AND MATERIALS

A comprehensive literature search was conducted to identify studies published before March 31, 2025. Two reviewers independently screened and selected studies that compared the diagnostic performance of CCTA + CT-FFR, CCTA + CTP, and CCTA + CT-FFR + CTP for detecting hemodynamically relevant CAD, with invasive FFR as the reference standard. Data on true positives, false positives, false negatives, and true negatives were extracted to assess diagnostic accuracy. Pooled sensitivity, specificity, diagnostic odds ratios (DORs), and 95% confidence intervals (CIs) were calculated using a Bayesian network meta-analysis ANOVA model. Summary receiver operating characteristic (SROC) curves were constructed to compare the area under the curve (AUC) across modalities. Statistical analyses were performed using R Studio (v4.4.2) and STATA (MP v18.0).

RESULTS

A total of 19 studies with 1550 patients and 3959 vessels were finally included. A network plot illustrating direct comparisons among modalities is shown. Bayesian network meta-analysis revealed that the combination of CCTA + CTP + CT-FFR achieved the highest specificity (0.90 [0.85-0.93]), DOR (44.80 [20.54-83.57]), and superiority index (3.05 [1.00-5.00]). CCTA alone ranked highest in sensitivity (0.91 [0.86-0.94]), followed by CCTA + CT-FFR (0.84 [0.76-0.90]), CCTA + CTP + CT-FFR (0.82 [0.73-0.89]), and CCTA + CTP (0.80 [0.73-0.85]). The SROC analysis demonstrated that CCTA + CT-FFR + CTP yielded the highest AUC. Compared to CCTA alone, the addition of CTP, CT-FFR, or both increased specificity by 1.42-, 1.32-, and 1.5-fold, respectively, and improved overall diagnostic accuracy by 1.19-, 1.16-, and 1.25-fold.

CONCLUSION

The integration of CCTA with both CT-FFR and CTP demonstrated superior diagnostic performance for detecting hemodynamically significant CAD, as validated by invasive FFR. While CCTA alone exhibited high sensitivity, the addition of CT-FFR and/or CTP significantly enhanced specificity and overall diagnostic accuracy for functionally relevant CAD.

CLINICAL RELEVANCE/APPLICATION

Combining CCTA, CT-FFR, and CTP into a unified diagnostic strategy improves the identification of hemodynamically significant CAD, potentially reducing unnecessary invasive procedures and optimizing patient management.

M2-SPCA-13 ACCELERATED CARDIAC MRI WITH AI: A PARADIGM SHIFT IN IMAGING SPEED AND PATIENT TOLERANCE

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Macarena De Zan (*Abstract Co-Author*)
Enrique Sodor (*Abstract Co-Author*)
Carlos Capunay, MD (*Abstract Co-Author*)

PURPOSE

Artificial Intelligence (AI) in Cardiac Magnetic Resonance (CMR) through deep learning (DL)-based reconstruction, enables higher k-space under-sampling, allowing for acceleration rates of up to 12 times and scan time reductions of up to 83%. The aim of this study is to evaluate the impact of AI-driven deep learning (DL) reconstruction in CMR by comparing it to conventional balanced steady-state free precession (bSSFP) sequences in terms of scan duration, image quality, and patient experience.

METHODS AND MATERIALS

A total of 18 patients (12 men, mean age 46 years) underwent CMR on a 3T scanner using DL-based acceleration. The study included functional short-axis imaging of the whole heart and 2-, 3- and 4-chamber views, acquired with both AI-enhanced and conventional (C) sequences. Acquisition time, image quality, and functional parameters were compared. Image quality was assessed by two independent observers using a 5-point Likert scale. Interobserver agreement was measured using kappa coefficient (?). A control group of 18 patients undergoing conventional CMR was included to assess patient experience.

RESULTS

The most common clinical indications for CMR were suspected hemochromatosis, pectus excavatum, cardiomyopathy, atypical chest pain, and arrhythmia. Of the 18 patients, 10 had normal findings, while diagnoses included hypertrophic cardiomyopathy (n=3), paradoxical septal motion (n=3), hypertrabeculation (n=1), and adaptive myocardial changes due to athletic training (n=3). Scan time was significantly reduced with AI compared to conventional sequences. The mean acquisition time for functional imaging was 51 seconds with AI vs. 2 minutes 11 seconds with C sequences. The total scan time including breath-holds was 3 minutes with AI vs. 7 minutes with C imaging. Image quality was slightly higher with AI (mean Likert score: 4.1 vs. 3.9, $p > 0.05$). No significant differences were found between AI and C sequences in biventricular volumetric and functional parameters ($p > 0.05$), with excellent interobserver agreement (? = 0.9). Patient experience ratings strongly favored AI-driven imaging. In the AI group, 88% of patients rated the exam duration as short and 12% as very short. In contrast, 83% of the control group found the exam prolonged, while 16% rated it as normal.

CONCLUSION

AI-powered CMR enables faster acquisitions while maintaining diagnostic integrity and image quality. The substantial reduction in scan times significantly enhances patient experience, making CMR more feasible for non-cooperative patients or those with limited breath-hold capacity.

CLINICAL RELEVANCE/APPLICATION

As AI-driven imaging continues to evolve, it is expected to further improve workflow efficiency and broaden the clinical utility of cardiac MRI.

M2-SPCA-15 ASSOCIATION OF MAXIMUM PRINCIPAL STRAIN DERIVED FROM COMPUTED TOMOGRAPHY WITH ADVERSE CARDIAC EVENTS IN PATIENTS WITH SEVERE AORTIC STENOSIS

Jing Yi Xing (*Presenter*)
Hidenobu Takagi, MD, PhD (*Abstract Co-Author*)
Hideki Ota, PhD (*Abstract Co-Author*)
Kiyotaka Hao (*Abstract Co-Author*)
Jun Takahashi (*Abstract Co-Author*)
Kei Takase, MD, PhD (*Abstract Co-Author*)

PURPOSE

Three-dimensional maximum principal strain (MPS) represents a scalar metric derived from 3D strain tensor analysis, reflecting the largest local myocardial deformation in any direction. The aim of this study was to investigate the association between computed tomography (CT)-derived left ventricular (LV) MPS and adverse cardiac events.

METHODS AND MATERIALS

This was a single center, retrospective study, and included patients with severe aortic stenosis (AS) who underwent cardiac CT to assess eligibility for transcatheter aortic valve replacement between 2014 and 2023. Patients were excluded for incomplete transthoracic echocardiography or CT images, missing baseline clinical data, technical failure during imaging, or not undergone aortic valve replacement. All cardiac CT image data set were reconstructed at 10% intervals of the RR interval throughout the cardiac cycle (0-90%). MPS was analyzed using a prototype version of the software (Ziostation 2, Ziosoft Inc. Tokyo, Japan), Epi- and endo-myocardium of the left ventricle were automatically delineated and manually corrected if needed. LV segmental MPS was analyzed based on the 16-segment model, and global MPS was calculated as the average across all segments per patient. The optimal cutoff value of global peak LV MPS for discriminating MACE was derived using the Youden index. Patients were categorized into preserved (MPS =0.295) and reduced (MPS <0.295) myocardial strain groups based on MPS values. Primary endpoint was major adverse cardiac events (MACE) defined as a composite of cardiovascular (CV) death or hospitalization due to heart failure (HF). Secondary endpoints were each CV death or HF hospitalization.

RESULTS

A total of 331 eligible patients (mean age 83 ± 6 years, 108 [33%] male) were included. During a median follow-up of 1.3 years, 53 MACEs were observed. Reduced global peak MPS showed higher risk of MACE (hazard ratio [HR], 4.1 [95% confidence interval {CI}: 2.3-7.0, $p <0.001$), CV death (HR, 3.3 [95% CI: 1.3-8.4], $p = 0.01$), and HF hospitalization (HR 4.0 [95% CI: 2.0-8.3], $p <0.001$) compared with preserved MPS. After adjusting age, sex, LV ejection fraction, STS score, and history of myocardial infarction, reduced global peak MPS remained associated with MACE (HR: 4.0 [95% CI: 1.9-8.5], $p <0.001$), CV death (HR: 4.1 [95% CI: 1.2-13.3], $p =0.02$), and HF hospitalization (HR: 3.6; 95% CI: 1.5-9.0, $p = 0.01$).

CONCLUSION

Global peak LV MPS has prognostic value for adverse cardiac events after aortic valve replacement in patients with severe aortic stenosis.

CLINICAL RELEVANCE/APPLICATION

CT-derived MPS holds promise as a biomarker for stratifying adverse cardiac events in patients with severe AS who undergo aortic valve replacement. It may enhance risk assessment and guide patient management.

M2-SPCH-1 MACROVASCULAR BIOMARKERS FOR PERSONALIZED PREDICTION OF CHEMOTHERAPY RESPONSE IN LUNG CANCER

Xin Meng (*Presenter*)
Lucy Pu (*Abstract Co-Author*)
Emrah Duman, MD (*Abstract Co-Author*)
Jiantao Pu, PhD (*Abstract Co-Author*)
David Wilson (*Abstract Co-Author*)

PURPOSE

To evaluate whether individualized macrovascular features from pre-treatment CT scans can serve as novel imaging biomarkers for predicting response to neoadjuvant chemotherapy (NACT) in patients with non-small cell lung cancer (NSCLC), with the ultimate goal of supporting precision treatment planning.

METHODS AND MATERIALS

This retrospective study included 84 patients with NSCLC who underwent CT imaging before and after NACT. Advanced AI-based algorithms were employed to segment and quantify tumors and their surrounding macrovasculature. Tumor characteristics assessed included volume, mean and maximum diameter, solidness, and shape irregularity. Macrovascular metrics included vessel volume, number, and tortuosity, each normalized by tumor size to isolate vascular contributions. Treatment response was defined as a =30% reduction in mean tumor diameter, aligning with RECIST 1.1 criteria and optimized for robust, automated measurement. Univariate logistic regression was used to evaluate associations between imaging features and response to NACT. Multivariable models integrated tumor and vascular features. Predictive performance was assessed using the area under the curve (AUC), with 5-fold cross-validation to ensure generalizability.

RESULTS

Among the vascular features, vessel volume emerged as a significant predictor of partial response ($p = 0.013$). Vessel number and tortuosity also demonstrated predictive value, albeit with lower statistical significance. The AUCs were: vessel volume 0.70 (95% CI: 0.59-0.82), vessel number 0.65 (CI: 0.54-0.77), and tortuosity 0.62 (CI: 0.50-0.74). A combined vascular model improved the AUC to 0.77. Tumor features alone achieved an AUC of 0.72, while integration of tumor and vascular features significantly boosted predictive performance to an AUC of 0.81 (95% CI: 0.70-0.89, $p < 0.01$). Although clinical covariates (e.g., gender, lesion type, time interval between pre-NACT and post-NACT within each lesion) were modestly associated with response, they were less predictive than imaging-derived biomarkers.

CONCLUSION

Quantitative macrovascular features extracted from routine pre-treatment CT scans, especially vessel volume and tortuosity, provide meaningful, individualized biomarkers for predicting response to NACT in NSCLC. Their combination with tumor morphology enhances predictive accuracy and holds strong potential for guiding personalized treatment decisions.

CLINICAL RELEVANCE/APPLICATION

Integrating CT-derived macrovascular biomarkers with tumor features offers a non-invasive approach to predict chemotherapy response in NSCLC, helping clinicians tailor treatment plans and avoid unnecessary toxicity in non-responders.

M2-SPCH-3 3D REGION-GROWING NNU-NET OUTPERFORMS 2D MODELS IN AUTOMATED DETECTION AND CLOT-VOLUME QUANTIFICATION OF ACUTE PE

Angela Ammirabile, MD (*Presenter*)
Ezio Lanza, MD (*Abstract Co-Author*)
Andrea Vanzulli, MD (*Abstract Co-Author*)
Arosh S. Perera Molligoda Arachchige (*Abstract Co-Author*)
Riccardo Levi (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)

PURPOSE

To identify the optimal nnU-Net model configuration for automated detection and volumetric quantification of acute pulmonary embolism (PE) on CTPA, by comparing 2D, 2D + region-growing, and 3D + region-growing architectures.

METHODS AND MATERIALS

We retrospectively curated 9,715 CTPA studies from 2015-2024 at our center, isolating 1,151 exams with clot volume > 800 µL. Two radiologists confirmed 874 PE-positive and 339 PE-negative cases. From these, 437 studies (195 central PE, 158 peripheral PE, 84 negative) formed the training set. Three nnU-Net models were trained: Model A 2D segmentation Model B 2D + 5-pixel region-growing Model C 3D + 5-pixel region-growing All models were tested on the external RSPECT-RSNA dataset. Performance metrics (accuracy, sensitivity, specificity, AUROC) were computed at two thresholds: (1) ROC-derived optimal cutoff; (2) any detectable thrombus. Secondary analyses assessed correlations between predicted blood clot volume (BCV), survival, and major adverse cardiovascular/cerebrovascular events (MACE)

RESULTS

At ROC-optimal cutoffs, Model C outperformed Model A/B: internal accuracy 87.2% (sensitivity 94.4%, specificity 75.3%, AUROC 0.909) versus A 70.9%/0.784 and B 70.8%/0.816; external accuracy 82.3% (sensitivity 41.9%, specificity 98.5%, AUROC 0.868) versus A 79.0%/0.843 and B 78.0%/0.846. With zero-threshold, sensitivity rose (A 91.8%, B 92.0%, C 83.6%) but specificity fell (A 44.3%, B 46.1%, C 77.9%). No significant correlation was found between BCV (continuous or > 800 µL) and survival, MACE, or stroke ($p > 0.05$). An inverse correlation emerged between tumor presence and survival ($r = -0.258$; $p < 0.0001$).

CONCLUSION

A 3D nnU-Net augmented with region-growing (Model C) delivers superior accuracy and AUROC for acute PE detection and volumetry compared to 2D configurations. Threshold selection mediates a trade-off between sensitivity and specificity, with zero-threshold favoring high sensitivity. BCV alone did not predict clinical outcomes in this cohort.

CLINICAL RELEVANCE/APPLICATION

In the quest to achieve—or even surpass—expert radiologist accuracy in PE detection and quantification, developers should prioritize a 3D nnU-Net architecture with region-growing, as it demonstrated the highest diagnostic performance and is thus the most accurate configuration for clinical-grade AI tools.

M2-SPCH-4 DEVELOPMENT AND VALIDATION OF AUTOMATIC DETECTION MODEL OF ESOPHAGEAL FOREIGN BODIES BASED ON CT IMAGES: A MULTICENTER STUDY

Ouyang Zhiqiang, MD (*Presenter*)

PURPOSE

An automatic detection model of esophageal foreign bodies in CT images based on deep learning is developed to solve the problems of low detection rate of tiny foreign bodies and transparent foreign bodies and insufficient prediction ability of complications by traditional methods.

METHODS AND MATERIALS

A total of 1495 patients with suspected esophageal foreign bodies were enrolled in 4 medical centers in China (2020-2025). Based on their plain CT images of neck and chest, the improved 3D U-Net architecture is adopted, and the multi-scale feature fusion module and attention mechanism are integrated to realize the automatic segmentation of esophagus and the dual-path analysis of foreign body density, spatial location and complications. The labeling of training set includes the location, shape, volume and complications (perforation and mediastinal inflammation) of foreign bodies. The internal verification is cross-contrast (model vs. traditional threshold method vs. primary doctors reading films), and the external verification is carried out in two independent medical institutions. At the same time, the prediction efficiency of the model for complications such as esophageal perforation and mediastinal abscess is evaluated.

RESULTS

Detection efficiency: The sensitivity of the model to sharp foreign bodies is 94.2%(95%CI:91.5-96.3%), and the specificity is 92.7% (89.8-94.9%), which is significantly better than the traditional threshold method (76.4%) and the primary physician (82.3%). The accuracy rate was 91.4% when the foreign body volume was more than 2 cm, and decreased to 83.6% when it was less than <0.5cm³, but it was still higher than that of the artificial group (71.2%). Prediction of complications: AUC of esophageal perforation was 0.891 (detection rate was 87.9%) and AUC of mediastinal inflammation was 0.832 (79.3%), which was better than the simple imaging evaluation reported in the literature.

CONCLUSION

Generally speaking, CT image analysis based on deep learning can significantly improve the diagnostic efficiency of esophageal foreign bodies, reduce the missed diagnosis rate (especially for tiny foreign bodies and transparent foreign bodies), and have the ability to dynamically predict the risk of complications.

CLINICAL RELEVANCE/APPLICATION

Primary medical application: the model can replace inexperienced doctors to read films in resource-limited scenes, reducing the utilization rate of invasive examinations such as endoscopy.Optimization of emergency intervention: by predicting the risk of complications (such as perforation and aortic fistula), we can assist in formulating graded treatment plans and reduce the incidence of operation-related esophageal fistula.

M2-SPCH-7 OPPORTUNISTIC SCREENING OF FRAILTY FROM CHEST RADIOGRAPHS AND PREDICTING SURVIVALS IN ELDERLY

Namkug Kim, PhD (*Presenter*)
Seungjoo Park (*Abstract Co-Author*)
Ki Duk Kim, MD (*Abstract Co-Author*)
Sangah Park (*Abstract Co-Author*)
Sunghwan Ji (*Abstract Co-Author*)

PURPOSE

To develop and validate an Inception-v3 deep learning model for age regression and frailty classification using chest X-rays from a tertiary hospital cohort and evaluate the model’s clinical utility by applying it to survival analysis in an independent health screening population.

METHODS AND MATERIALS

We retrospectively collected 99,485 posterior-anterior chest X-rays (PA CXR) from 68,341 patients aged =50 years with Clinical Frailty Scale (CFS) records at a tertiary hospital. The dataset was randomly split 8:2 for training and test; the training set was further divided 7:3 for training and validation. An Inception-v3 model was first trained for age regression, then fine-tuned for binary frailty classification using 1,359 chest X-rays from patients who underwent comprehensive geriatric assessment. External validation used a separate health screening cohort of 5,932 individuals aged =65 screened between 2014 and 2018 at the same center but from a distinct population. All-cause mortality was ascertained using National Health Insurance eligibility status. Frailty status in the screening cohort was assigned by the fine-tuned model. Cox regression adjusted for age and sex was used to estimate hazard ratios (HRs) with 95% confidence intervals (CIs).

RESULTS

The age regression model achieved a mean absolute error (MAE) of 4.23 ± 5.32 and a root mean square error (RMSE) of 5.38 on the test set, which was obtained from the 8:2 split of the original dataset. The frailty classification model showed an accuracy of 0.763 and an area under the curve (AUC) of 0.763.A total of 173 patients were grouped as frail and 417 participants died during a median follow-up of 8.7 years. CXR predicted frailty was associated with higher mortality according to the Kaplan-Meier curves. Frail group showed higher all-cause mortality (HR: 1.84, 95% CI: 1.29-2.61, P -value<0.001) even after the adjustment for age and sex. Age per year (HR: 1.15, 95% CI: 1.13-1.17, P -value<0.001) and male sex (HR: 1.66, 95% CI: 1.35-2.05, P -value<0.001) were also associated with higher mortality.

CONCLUSION

A deep learning model using PA CXR demonstrated robust performance in both age and frailty prediction. When applied to an external health screening cohort, the model effectively stratified patients into frail and non-frail groups, revealing significant differences in survival probability between the groups.

CLINICAL RELEVANCE/APPLICATION

Deep learning predicted frailty from CXR was associated with higher mortality in the elderly. These findings suggest that opportunistic screening of frailty from routine CXR may provide valuable prognostic information for mortality and patients who needs close observation.

M2-SPCH-9 AN AI-BASED SYSTEM FOR AUTOMATIC EVALUATION OF THE TECHNICAL QUALITY OF CHEST X-RAY IMAGES

Ali Akhavi Milani (*Presenter*)

PURPOSE

To develop an AI-based system capable of automatically evaluating the technical quality of chest X-ray (CXR) images upon acquisition and provide feedback to radiographers to enable corrective measures.

METHODS AND MATERIALS

We developed a deep learning model using a convolutional neural network (CNN) architecture trained on a curated dataset of labeled CXR images. The quality control criteria included positioning, exposure, inspiration level, and presence of artifacts. This project involved the evaluation of 4,000 CXR images acquired in the [blinded] imaging center in Tabriz, Iran. The images were assessed by two experienced radiologists, each with more than 10 years of experience in reading chest X-rays. The radiologists labeled the images with categorical and numerical labels for quality control attributes. A convolutional neural network (CNN) was then trained on these labeled images to detect and classify the mentioned quality attributes. The model's performance was evaluated using accuracy, precision, and area under the curve (AUC) metrics.

RESULTS

The AI system demonstrated moderate to high performance across multiple quality metrics, achieving an AUC of 0.86 for detecting improper positioning, 0.94 for improper exposure, 0.88 for poor inspiratory effort, and 0.86 for identifying motion artifacts.

CONCLUSION

Our AI-driven CXR quality assessment tool offers an accurate, and scalable solution for quality control in radiography.

CLINICAL RELEVANCE/APPLICATION

By automatically assisting the quality of CXR images, it is possible to improve diagnostic reliability, reduce repeat imaging, and enhance workflow efficiency.

M2-SPCH-10 THYMIC EPITHELIAL TUMORS: DISCRIMINATIVE AND PROGNOSTIC CT FEATURES

Akiko Sumi, MD, PhD (*Presenter*)
Ann N. Leung, MD (*Abstract Co-Author*)
Emily B. Tsai, MD (*Abstract Co-Author*)
Margaret Lin, MD (*Abstract Co-Author*)
Tomonori Chikasue (*Abstract Co-Author*)
Masahiro Mitsuoka (*Abstract Co-Author*)
Jun Akiba (*Abstract Co-Author*)
Gerald Berry, MD (*Abstract Co-Author*)
Kiminori Fujimoto, MD, PhD (*Abstract Co-Author*)

PURPOSE

To identify features of thymic epithelial tumors (TET) on computed tomography (CT) that can differentiate between histologic subtypes and predict outcome.

METHODS AND MATERIALS

This retrospective study enrolled 240 consecutive patients with pathologically-proven TET and pretreatment CT scans at two institutions located in Japan and the United States. CT scans were independently reviewed by two fellowship-trained chest radiologists blinded to clinical and pathologic data. Twelve CT features of tumors were assessed including margin, attenuation, contrast-enhancement ratio, mediastinal location, presence of vascular invasion, and metastatic disease. Interobserver agreement was calculated using kappa statistics. Logistic regression was used to identify CT discriminators of histologic subtypes and a weighting score model was constructed using partial regression coefficients (ß) of significant features. Recurrence-free survival (RFS) was evaluated using Kaplan-Meier and Cox regression analyses.

RESULTS

The study population consisted of 105 male and 135 female patients with a median age of 64 years (IQR: 52.8-70.0) and a median follow-up period of 46 months (IQR: 22-74). TET cases consisted of 122 low-risk thymomas (type A, AB, B1, and micronodular), 79 high-risk thymomas (B2 and B3), and 39 thymic carcinomas, including neuroendocrine neoplasms. Interobserver agreement in evaluation of CT features was substantial with a mean kappa of 0.61 (range, 0.38-0.93). On multivariate analysis, non-smooth margins (ß = 2.1, p = 0.04), heterogeneous attenuation (ß = 1.1, p = 0.04), and visceral compartment involvement (ß = 2.3, p < 0.001) were found to be independent predictors of thymic carcinoma with an AUC of 0.79 (95% CI: 0.71-0.87). Kaplan-Meier analysis showed that tumors with an epicenter in midline and those located above the aortic arch were associated with significantly lower RFS (p = 0.006 and p < 0.001, respectively). Tumor location above the aortic arch was found to be an independent negative predictor of RFS (hazard ratio = 4.9, p = 0.002).

CONCLUSION

A simple and reproducible CT model incorporating three specific imaging features can be used to effectively discriminate between thymic carcinoma and thymoma. Determination of the mediastinal location of TET can also provide prognostic information.

CLINICAL RELEVANCE/APPLICATION

This CT-based model can be used as a practical tool to aid in TET histologic subtype classification and prediction of survival. Our study is the first to identify tumor location above the level of the aortic arch as a useful imaging biomarker in prediction of TET recurrence.

M2-SPCH-12 ENHANCING PREOPERATIVE PREDICTION OF LYMPH NODE METASTASIS IN CT1 SOLID NSCLC WITH CT-BASED RADIOMICS

Fan Liu (*Presenter*)
LU XIAO YAN (*Abstract Co-Author*)
Jiahui E (*Abstract Co-Author*)
Jingyi Yang (*Abstract Co-Author*)
Yicai Zhang (*Abstract Co-Author*)
Qiliang Wang (*Abstract Co-Author*)
Xiaoting Cai (*Abstract Co-Author*)
Huaxin Li (*Abstract Co-Author*)
Hua Wang (*Abstract Co-Author*)
Ying Liu (*Abstract Co-Author*)

PURPOSE

This study aimed to develop and validate a contrast-enhanced computed tomography (CECT)-derived standardized radiomics model for predicting lymph node metastasis (LNM) in cT1 solid NSCLC, while systematically comparing its diagnostic performance against alternative radiomics approaches, clinical model, and standalone radiological evaluation of lymph node status.

METHODS AND MATERIALS

A total of 686 NSCLC patients from two hospitals were retrospectively enrolled and allocated into training, internal validation, and external validation cohorts. Radiomics features were extracted from three distinct volumes of interest (VOIs), comprising two tumor-associated VOIs (one delineating the entire tumor on plain CT and another on CECT), along with a VOI capturing the descending aorta across five consecutive axial slices on CECT at the left pulmonary artery trunk level. Standardized radiomics features were obtained by calculating the ratio of radiomics features between tumor region and the descending aortic region. All radiomic features were normalized using the z-score method, followed by further feature selection utilizing the Recursive Feature Elimination (RFE) algorithm. Three radiomics models (Plain CT radiomics model, CECT radiomics model and standardized CECT radiomics model) along with a clinical model were developed through logistic regression analysis employing tenfold cross-validation. Model performance was evaluated by area under curve (AUC), accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).

RESULTS

The standardized CECT radiomics model demonstrated superior predictive performance for LNM when compared to both CECT and Plain CT radiomics models across all cohorts, and the clinical-radiomics model integrating CEA with standardized CECT radiomics signature outperformed clinical model and imaging-based lymph node assessments, with AUCs of 0.783 (95% CI, 0.735-0.832), 0.772 (95% CI, 0.691-0.854), and 0.802 (95% CI, 0.701-0.904), in the training, internal validation, and external validation cohorts, respectively.

CONCLUSION

The standardized CECT radiomics model effectively predicts preoperative LNM in cT1-stage solid NSCLC patients, offering potential to guide clinical decision-making and facilitate personalized therapeutic strategies.

CLINICAL RELEVANCE/APPLICATION

The clinical-radiomics model surpassed conventional radiological interpretation paradigms and traditional clinical model in diagnostic performance, establishing a robust quantitative methodology for non-invasive preoperative stratification of patients with high-risk LNM.

M2-SPCH-13 CT ANGIOGRAPHIC ASSESSMENT OF PULMONARY EMBOLISM: IS THE RELATIONSHIP BETWEEN PULMONARY OBSTRUCTION INDEX AND PULMONARY VEIN METRICS A PROGNOSTIC FACTOR

Ali Borhani, MD, MD (*Presenter*)
Morteza Saneitaheri (*Abstract Co-Author*)
Tayeb Hosseini (*Abstract Co-Author*)
Mojtaba Arabshahi (*Abstract Co-Author*)
Maede Mohammadian (*Abstract Co-Author*)
Omid Ebrahimi Bapirvand (*Abstract Co-Author*)
Hamid Nasiri Tousi (*Abstract Co-Author*)

PURPOSE

In this study, we aimed to evaluate the associations between the pulmonary artery obstruction index (PAOI) and pulmonary vein (PV) metrics on Computed Tomography Pulmonary Angiogram (CTPA) in patients with pulmonary thromboembolism (PE) and their potential role in predicting hemodynamic compromise and short-term outcomes in patient affected with acute pulmonary thromboembolism.

METHODS AND MATERIALS

This retrospective, single-center study included adults with CTPA-confirmed PE between January 2022 and 2024. Two blinded thoracic radiologists measured the PAOI, PV diameter, and cardiac metrics. Statistical analyses included nonparametric tests, Spearman correlation, and multivariable logistic regression, with significance at $p < 0.05$.

RESULTS

A total of 250 participants (median age 59.5 years (62 men, 68 women) in PE patients and 64.0 years (57 men, 63 women) in controls) were evaluated. The right and left PAOIs were significantly greater in the PE patients than in the controls ($P<0.0001$). The right superior and inferior PVs were narrower in patients ($P=0.005$ and $P=0.015$, respectively), whereas the left PV diameters did not differ significantly ($P>0.3$). The left pulmonary artery diameter was modestly greater in these patients ($P=0.011$). According to the subgroup analysis, the PAOI values and PV diameters varied significantly with the embolus distribution ($P<0.004$). In the unilateral PE group, the ipsilateral veins were significantly smaller than those in the contralateral and control groups ($P<0.0001$). The right superior PV diameter was reduced in nonsurvivors ($P=0.013$) but was not independently associated with short-term mortality after adjustment ($P=0.22$)

CONCLUSION

In acute PE, PAOI is significantly associated with a reduced ipsilateral PV diameter, particularly on the right side. Although PV metrics cannot predict short-term mortality independently, they may be valuable in composite risk model.

CLINICAL RELEVANCE/APPLICATION

This study offers strong evidence that embolic obstruction leads to a measurable reduction in the PV caliber on the affected side, but the contralateral veins remained comparable to controls. This suggests that PV narrowing was specific to the obstructed lung rather than reflecting a global or systemic process. The strength of negative correlation between PAOI and ipsilateral PV diameter suggests that clot burden and venous remodeling occur along a continuum, offering potential clinical value in semi quantitative imaging assessments. Smaller right SPV diameters may flag higher-risk patients initially. They are not independent predictors of death but has potential role in composite risk models.

M2-SPER-1 COST-EFFECTIVENESS OF CT PERFUSION, LOW-FIELD MRI, AND OBSERVATION OR TRANSPORT TO HIGH-FIELD MRI FOR EVALUATION OF PATIENTS PRESENTING TO THE EMERGENCY DEPARTMENT WITH DIZZINESS

Kyle Tegtmeyer, MD (*Presenter*)
Ramtin Hajibeygi (*Abstract Co-Author*)
Mobina Fathi (*Abstract Co-Author*)
Amirali Aali (*Abstract Co-Author*)
Long H. Tu, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the cost-effectiveness of alternative neuroimaging strategies, CT perfusion (CTP), low-field portable MRI, and observation or transport to high-field MRI, for assessing dizziness in emergency department (ED) patients when immediate access to high-field MRI is unavailable.

METHODS AND MATERIALS

A Markov decision-analytic model was developed using a healthcare system perspective to simulate lifetime costs and quality-adjusted life years (QALYs) for six imaging strategies: non-contrast head CT, head and neck CTA, CT perfusion added to CT and CTA, low-field portable MRI, observation for high-field MRI, and interfacility transport for high-field MRI. The model incorporated differential costs, diagnostic sensitivities, and long-term stroke outcomes. Deterministic and probabilistic sensitivity analyses assessed the robustness of findings, with results expressed as incremental cost-effectiveness ratios (ICERs).

RESULTS

Observation for high-field MRI was the most cost-effective strategy, yielding an incremental gain of 0.42 QALYs at an incremental cost of US$13,783 compared to non-contrast head CT. CT perfusion added minimal incremental QALYs (0.02) at an additional cost of US$1,052, thus dominated by extension. Portable MRI ranked third in cost-effectiveness, outperforming CTA and CT alone but less effective than observation or transport to high-field MRI. Sensitivity analyses consistently supported these results across various parameter adjustments, with the best-case analysis confirming observation for high-field MRI as consistently cost-effective even under the most favorable conditions for alternative strategies.

CONCLUSION

Admission for observation with subsequent high-field MRI provides superior cost-effectiveness by enhancing stroke detection and guiding secondary preventive measures in patients presenting with dizziness. CT perfusion and portable MRI are viable alternatives if high-field MRI is inaccessible.

CLINICAL RELEVANCE/APPLICATION

Optimizing neuroimaging strategies in the ED for dizziness improves long-term patient outcomes, reduces stroke-related morbidity, and efficiently utilizes healthcare resources, particularly in settings lacking immediate MRI access.

M2-SPER-2 EVALUATION OF SECOND-GENERATION RECONSTRUCTION ALGORITHMS TO IMPROVE GRAY-WHITE MATTER DIFFERENTIATION ON NON-CONTRAST HEAD CT STUDIES

Kyobin Hwang (*Presenter*)
Ian Anderson, BSc, MD (*Abstract Co-Author*)
Asutosh Sahu, MBBS, MD (*Abstract Co-Author*)
Akhil P. Nair (*Abstract Co-Author*)
Brian E. Nett, PhD (*Abstract Co-Author*)
Joel Kosowan, MD (*Abstract Co-Author*)
Shobhit Mathur, MD (*Abstract Co-Author*)

PURPOSE

Different reconstruction algorithms have been developed to render the gray-white matter interface more conspicuous to increase detection of subtle findings. We performed this study to compare the second-generation “Enhanced Boundary” (EB) algorithm and first-generation “Enhanced Contrast” (EC) in non-contrast head CTs performed for acute stroke.

METHODS AND MATERIALS

Sixty consecutive code stroke patients were included in this study, including 30 patients positive and 30 patients negative for acute ischemic stroke. All patients were imaged with a non-contrast head CT performed as part of an acute stroke protocol study. Images were retrospectively reconstructed using a vendor provided first-generation EC algorithm (EC3) as well as three strengths of the second-generation EB algorithm (EB1, EB2, EB3). Two blinded radiologists independently compared the images, subjectively grading the gray-white matter differentiation (in the posterior fossa, the deep gray matter, and the supra-tentorial cortical-subcortical interface) as well as noise, image texture, changes in beam-hardening artifact, and diagnostic confidence in detecting gray-white matter differentiation loss, hyperdense intracranial arteries and hemorrhage. All scoring was based on a 5-point Likert scale. Contrast to noise ratio (CNR) measurements were performed on a subset of the cohort. ASPECTS (Alberta Stroke Program Early CT Score) was also noted. Kappa test was used to test inter-observer agreement and image quality parameters were compared using Kruskal-Wallis, Friedman and Wilcoxon signed-rank tests.

RESULTS

EB3 algorithm was found to have subjectively improved gray-white matter differentiation compared to EC3, EB1 and EB2 ($p<0.05$). There was no statistically significant difference in subjective noise, beam hardening artifact, or image texture. Quantitative analysis of CNR showed no noise penalty. Diagnostic confidence in detecting stroke, hemorrhage and hyperdense intracranial arteries and ASPECTS were similar across all reconstruction methods and strengths.

CONCLUSION

Second-generation reconstruction algorithm provides subjectively improved gray-white matter differentiation without negative impact on noise, artifact, or image texture.

CLINICAL RELEVANCE/APPLICATION

Improvement in gray-white matter differentiation on head CTs using second-generation reconstruction algorithm (EB3) without noise penalty is a promising advancement for imaging in acute stroke.

M2-SPER-3 EXTRAVASCULAR BLOOD VOLUMES AS MEASURED ON ADMISSION WHOLE BODY CT FOR MULTI-SYSTEM TRAUMA CORRELATES WITH BLOOD TRANSFUSION REQUIREMENTS DURING RESUSCITATION

Rebeca Santos (*Presenter*)
Greg Gaski, MD (*Abstract Co-Author*)
Todd McKinley, MD (*Abstract Co-Author*)
Katherine Frey (*Abstract Co-Author*)
Scott D. Steenburg, MD (*Abstract Co-Author*)

PURPOSE

To determine the relationship between extravascular blood product volumes as measured on admission whole body CT and blood transfusion requirements.

METHODS AND MATERIALS

Data were extracted from the PRECISE study database, which was a large, prospective multi-center trial comprised of trauma centers participating in the Major Extremity Trauma and Rehabilitation Consortium (METRC). Extravascular blood products were measured on deidentified admission whole body CT (WBCT) scans using a semi-automated 3-dimensional annotation tool. The extravascular blood volumes on two patient populations, those who received blood transfusions and those who did not, were compared using unpaired t-tests. P-values were calculated to determine the correlation of each patient's transfusion status and CT-detected extravascular blood product volumes. In addition, patients who received packed red blood cells (pRBCs) as part of a massive transfusion protocol (MTP) were separated into two groups: those who met the Critical Administration Threshold (CAT), defined as patients who received three or more units of PRBCs within 60 minutes, and those who did not meet CAT threshold. Data were analyzed using unpaired T-tests, with a P value of < 0.05 considered to be statistically significant.

RESULTS

The study cohort consisted of 278 patients with a mean age of 36.0 years (range 18-56), including 195 males (70.1%) with an average Injury Severity Score (ISS) of 26 (range 5-75). The most common mechanism of injury was motor vehicle collision (N=239, 86.0%). All patients had extravascular blood products detected on CT. A total of 144 patients (51.8%) received blood transfusion products, most commonly packed red blood cells (PRBCs, N=138 or 95.8%) which also comprised the largest average volume of blood products (mean 1478.8 mL per patient). There was a statistically significant difference in the hematoma volume between patients who did and did not receive a blood transfusion (405.1 mL vs 173.2 mL, p=0.0001). There was a statistically significant difference in hematoma volumes for patients who met CATs criteria versus those who did not (614.3 mL vs 299.9 mL, p<0.0001). There was a strong, positive and linear relationship between pRBC volumes transfused and measured extravascular blood product volumes (R-value = 0.82).

CONCLUSION

Extravascular blood product volumes as measured on admission CT positively correlated with blood transfusion volumes received.

CLINICAL RELEVANCE/APPLICATION

The findings from our study suggest that admission CT-measured extravascular blood product volumes could potentially be used to predict blood transfusion needs in the initial resuscitation period.

Luke Funk (*Abstract Co-Author*)
Oliver Wieben, PhD (*Abstract Co-Author*)
Claude B. Sirlin, MD (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)

PURPOSE

Although 4D flow MRI can measure portal venous flow, prior studies required contrast agents due to challenges such as complex anatomy, small vessels, extensive coverage, and slow flow. Obesity adds complications such as high fat signal, reduced signal-to-noise ratio, and complex background phase corrections. Radial 4D flow MRI can acquire large volumes with improved resolution compared to traditional Cartesian k-space sampling, enabling non-contrast acquisitions. This study evaluates the feasibility of non-contrast 4D flow MRI in obese adults undergoing weight loss surgery (WLS).

METHODS AND MATERIALS

This prospective study enrolled adults (BMI > 35 kg/m²) undergoing WLS at two academic centers. Non-contrast radial 4D flow MRI (3.0T) was performed five times after 12-hr fasting: before a pre-surgical diet, 1-2 days pre-surgery, and 12, 26 and 52 wks post-surgery. Two readers independently measured flow in proximal, middle, and distal portal vein (PV), splenic vein (SV), and right (RPV) and left (LPV) portal vein cross-sections. Image quality was rated qualitatively as 'analyzable', 'marginally analyzable', or 'unanalyzable' using pre-defined criteria. Feasibility was assessed via conservation of mass, comparing flow in the PV to that at the confluence (SMV, SV) and bifurcation (LPV, RPV) by linear regression, and by computation of Bland-Altman bias and limits of agreement (LoA). Inter-reader variability to assess reproducibility was also analyzed (Bland-Altman bias, LoA). All analyses pooled data from all visits.

RESULTS

One hundred five participants (90 women; 44 ± 10 yrs) were enrolled. BMI decreased from 46 ± 7 kg/m 2 to 35 ± 7 kg/m 2 one yr post-surgery. Of 413 attempted 4D flow acquisitions, 3 failed to reconstruct, 375 were analyzed (311 'analyzable', 64 'marginally analyzable'), and 35 were excluded as being 'unanalyzable'. Conservation of mass showed strong correlation at bifurcations (R^2=0.94) and confluences (R^2=0.84), with small bias (-5% and -13%) and moderate LoA: [-22%, 13%] and [-43%, 17%]. Inter-reader variability showed minimal bias (-0.4%) with moderate LoA [-19%, 18%].

CONCLUSION

Non-contrast radial 4D flow MRI is feasible in obese adults, with low rates of reconstruction failure and of 'unanalyzable' data, good conservation of mass performance comparable to prior contrast-enhanced studies, and good inter-reader agreement. These findings support radial 4D flow MRI as a potential quantitative tool for assessing portal venous flow in obesity.

CLINICAL RELEVANCE/APPLICATION

Limited 4D flow MRI adoption for portal assessment is primarily due to technical challenges including the need for contrast. Demonstrating reliability of this non-invasive method with minimal preparation could significantly enhance its clinical use.

M2-SPGI-2 PHOTON-COUNTING CT WITH VIRTUAL MONOENERGETIC IMAGING FOR GASTRIC CANCER: ENHANCINGPREOPERATIVE T/N STAGING AND VASCULAR VISUALIZATION

Bin Lin (*Presenter*)
Jiaxing Wu (*Abstract Co-Author*)
Xue Geng (*Abstract Co-Author*)

PURPOSE

To evaluate the image quality of arterial-phase photon-counting computed tomography (PCCT), including three-dimensional (T3D) imaging and virtual monoenergetic images (VMIs) at different energy levels, in gastric cancer patients. The study aimed to assess the clinical value of PCCT in improving preoperative tumor (T) and nodal (N) staging accuracy and facilitating surgical planning.

METHODS AND MATERIALS

Patients with pathologically confirmed gastric cancer underwent arterial-phase PCCT (NAEOTOM Alpha, Siemens). T3D and VMI datasets (40-170 keV, 10-keV intervals) were reconstructed. Objective metrics included CT attenuation, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). Two radiologists

independently assessed subjective image quality using a 5-point Likert scale and evaluated T/N staging. Paired t-tests and Wilcoxon signed-rank tests were used for statistical comparisons.

RESULTS

A total of 33 patients (16 males, 17 females; mean age 67.1 ± 11.2 years) were included. CT attenuation and noise decreased progressively with increasing energy levels ($P < 0.05$). The 60-keV VMI achieved the highest tumor-to-wall CNR and received the highest subjective scores (mean score 4.92) for tumor conspicuity and overall image quality ($P < 0.05$). T3D reconstructions demonstrated superior vascular SNR (46.01 [6.67, 161]) and CNR (50.84 [19.10, 87.08]) ($P < 0.05$). In the surgical subgroup (n = 18), pathological-radiological correlation demonstrated a concordance rate of 94.4% (17/18) for T-staging and 77.8% (14/18) for N-staging, highlighting the diagnostic utility of PCCT.

CONCLUSION

60-keV VMIs offer optimal lesion delineation, while T3D reconstructions enhance vascular visualization. The combined application of these PCCT-based techniques provides a comprehensive and reliable approach for preoperative assessment in gastric cancer, improving T/N staging accuracy and supporting individualized surgical planning.

CLINICAL RELEVANCE/APPLICATION

Photon-counting CT with optimized 60-keV VMI and T3D imaging significantly improves gastric tumor characterization and vascular mapping compared to conventional CT approaches. Integrating these advanced imaging protocols into preoperative workflows enhances staging precision, informs surgical strategies, and potentially improve clinical outcomes for gastric cancer patients.

M2-SPGI-4 INTRAINDIVIDUAL COMPARISON OF PHOTON-COUNTING AND ENERGY-INTEGRATING DETECTOR CT IN PERIHILAR CHOLANGIOCARCINOMA

Moritz Halfmann, MD (*Presenter*)
Tilman S. Emrich, MD (*Abstract Co-Author*)
Tobias Baeuerle, MD (*Abstract Co-Author*)
Lukas Mueller, MD, PhD (*Abstract Co-Author*)

PURPOSE

Perihilar cholangiocarcinomas (pCCC) remain diagnostically and surgically challenging. While ERCP, conventional CT, and MRI/MRCP each offer advantages for preoperative planning, imaging of the individual hilar anatomy is often limited. Photon-counting detector CT (PCD-CT) has shown promising results in high-resolution vascular and oncologic imaging and may thus provide superior delineation of hilar structures and tumor extent in pCCC. Therefore, this study aimed to directly compare objective and subjective image quality between PCD-CT and energy-integrating detector CT (EID-CT) in patients with pCCC who received consecutive scans on both imaging modalities.

METHODS AND MATERIALS

From an institutional database of 302 patients with pCCC (2008-2025), eight patients who had undergone both contrast-enhanced abdominal PCD-CT and EID-CT were retrospectively included. An intraindividual comparison was conducted assessing objective image quality by measuring vessel attenuation, image noise, signal-to noise (SNR) and contrast-to-noise ratios (CNR). Additional subjective image analysis was performed using a 5-point Likert scale by three independent readers (2 radiologists, 1 visceral surgeon), evaluating overall image quality, noise, sharpness, and assesibility of the hilum. Paired t-tests and Wilcoxon signed-rank tests were used for statistical analysis.

RESULTS

Patients had a mean age of 64 ± 16 years with equal gender distribution. The median interval between scans was 21 (IQR 58) days. Dose-length product was comparable between PCD-CT and EID-CT (480 vs. 496 mGy*cm; P =.44). Nevertheless, PCD-CT showed significantly higher SNR (6.9 vs. 3.5 for arterial phase and 21.2 vs. 13.0 for venous phase; P =.02 and .04, respectively). In the subjective analysis, PCD-CT achieved significantly higher scores for overall image quality (4 [quartiles 4-5] vs. 3 [3-3]; P =.009), noise (4.5 [4-5] vs. 2.5 [2-3]; P =.008), and sharpness (4 [4-5] vs. 3 [3-3]; P =.009). Additionally, hilar assessibility was rated superior in PCD-CT (3 [3-3] vs. 4 [4-4.75], P =0.02).

CONCLUSION

Preliminary findings suggest improved subjective and objective image quality with PCD-CT at comparable radiation doses. Reduced image noise and enhanced contrast may facilitate superior assessment of the individual hilar anatomy. These findings support further investigation in larger prospective cohorts.

CLINICAL RELEVANCE/APPLICATION

PCD-CT may improve individualized imaging in patients with pCCC, enhancing preoperative planning and potentially impacting clinical management through better tumor visualization.

M2-SPGI-5 MANUAL VERSUS AUTOMATED 2D MR ELASTOGRAPHY FOR FIBROSIS STAGING IN MASLD: ACCURACY AND INTER-METHOD REPRODUCIBILITY

Mahnaz Hosseinibensenjan, MD (*Presenter*)
Jake Weeks, BS (*Abstract Co-Author*)
Tanya Wolfson, MS (*Abstract Co-Author*)
Walter Henderson (*Abstract Co-Author*)
Gavin Hamilton, PhD (*Abstract Co-Author*)
Gage Tanzman (*Abstract Co-Author*)
Sami Khoury (*Abstract Co-Author*)
Mina Balen (*Abstract Co-Author*)
Michael S. Middleton, MD, PhD (*Abstract Co-Author*)
Rohit Loomba, MD, MSc (*Abstract Co-Author*)
Claude B. Sirlin, MD (*Abstract Co-Author*)

PURPOSE

Fibrosis staging is important for metabolic dysfunction-associated steatotic liver disease (MASLD) management, especially to establish eligibility for metabolic dysfunction-associated steatohepatitis (MASH) clinical trials, and emerging therapies for which F = 2 fibrosis is considered to be an eligibility criterion. This study evaluates diagnostic performance of manual and automated 2D magnetic resonance elastography (MRE) analysis to detect F = 2 fibrosis using histology as reference standard, and reproducibility of manual and automated 2D MRE analysis.

METHODS AND MATERIALS

This is a secondary analysis of two completed prospective studies of adults with known or suspected MASLD who underwent 3T 2D MRE and liver biopsy within = 180 days. MRE liver stiffness was assessed manually by trained readers following Quantitative Imaging Biomarker Alliance (QIBA) guidelines, and automatically using a convolution network-based algorithm created by our research team. Readers were blinded to histology, and to each other's results. Fibrosis was staged (NASH CRN criteria). For each method, the area under the receiver operating characteristic curve (AUC) and its 95% confidence interval (CI) for classifying F = 2 fibrosis, and sensitivity and specificity at rule-in (specificity = 90%) and rule-out (sensitivity = 90%) thresholds, respectively, were calculated. Reproducibility between methods was assessed using QIBA-recommended precision metrics: Bland-Altman (BA) bias, limits of agreement (LoA), within-participant coefficient of variation (wCV), proportional

reproducibility coefficient (RDC%), and intraclass correlation coefficient (ICC). Bootstrapped 95% CIs were constructed. Bonferroni-adjusted comparisons were made with bootstrap-based tests.

RESULTS

Two hundred twenty-eight participants were enrolled (127 women; mean age 51.5 ± 13.8 yrs; mean BMI 31.4 ± 5 kg/m²), underwent 274 MRE exams. For F = 2 fibrosis, AUROCs [95% CIs] were 0.89 [0.82, 0.93] for manual and 0.90 [0.85, 0.94] for automated analyses (p=0.08). Rule-in threshold was 3.2 kPa (manual) and 3.0 kPa (automated); rule-out was 2.45 kPa for both. Sensitivity was 72% at rule-in for manual and 76% for automated analyses (p=0.22). Specificity was 59% at rule-out for manual and 60% for automated (p=0.79). BA bias, LoA, wCV, RDC%, and ICC [95% CIs] for manual vs. automated analyses were 0.09 kPa, [-0.4, 0.6], 6%, 16%, and 0.97 [0.94, 0.98], respectively.

CONCLUSION

Automated and manual MRE analyses shows comparable diagnostic performance for identifying F = 2 fibrosis in MASLD.

CLINICAL RELEVANCE/APPLICATION

Automated MRE may offer a reliable, efficient alternative to manual interpretation, reducing inter-reader variability and streamlining fibrosis staging in MASLD.

M2-SPGI-6 UTILITY OF ULTRA-HIGH B-VALUE (B=3000) DIFFUSION-WEIGHTED IMAGING IN DIFFERENTIATING LIVER METASTASES FROM HEMANGIOMAS

Kumi Ozaki, MD, PhD (*Presenter*)

PURPOSE

To evaluate the diagnostic performance of ultra-high b-value (b=3000 s/mm²) diffusion-weighted imaging (DWI) compared to conventional b-values in differentiating liver metastases from hemangiomas, with particular focus on small (<10 mm) lesions.

METHODS AND MATERIALS

This prospective study included 67 patients (mean age, 65.7±10.6 years) with 208 liver lesions (133 metastases, 75 hemangiomas) confirmed by histopathology or follow-up imaging. Of these, 83 metastases and 54 hemangiomas measured less than 10 mm in diameter. All patients underwent liver MRI on a 3T scanner with multiple b-value DWI (0, 800, and 3000 s/mm²). Three diagnostic protocols were compared: (1) conventional DWI (b=800) with ADC maps generated from b=0 and b=800; (2) conventional DWI plus computed DWI (cDWI) at b=1500, 2000, 2500, and 3000 s/mm²; and (3) conventional DWI plus cDWI plus acquired ultra-high b-value DWI (b=3000). Diagnostic performance was evaluated by two experienced radiologists blinded to clinical information and lesion type. Sensitivity, specificity, accuracy, and area under the receiver operating characteristic curve (AUC) were calculated for each protocol.

RESULTS

For lesions =10 mm, no significant differences in diagnostic performance were observed among the three protocols (AUC: 0.921 vs. 0.933 vs. 0.940, p>0.05). However, for lesions <10 mm, the addition of ultra-high b-value DWI (b=3000) significantly improved diagnostic accuracy compared to conventional DWI alone (AUC: 0.874 vs. 0.731, p<0.01). The protocol including computed DWI showed intermediate performance (AUC: 0.812), significantly better than conventional DWI alone (p<0.05) but inferior to the protocol including acquired b=3000 DWI (p<0.05). Sensitivity for detecting small metastases increased from 76.4% with conventional DWI to 83.2% with computed DWI and 91.5% with acquired b=3000 DWI. Specificity for small hemangiomas also improved progressively across the three protocols (70.5% vs. 79.8% vs. 87.3%).

CONCLUSION

Ultra-high b-value (b=3000) DWI significantly improves the diagnostic performance in differentiating small (<10 mm) liver metastases from hemangiomas compared to conventional b-value DWI. While computed DWI offers some improvement, acquired ultra-high b-value images provide superior diagnostic accuracy, particularly for challenging small lesions.

CLINICAL RELEVANCE/APPLICATION

Implementation of ultra-high b-value DWI (b=3000) in routine liver MRI protocols could enhance detection and characterization of small liver metastases, potentially impacting patient management by enabling earlier detection of metastatic disease.

M2-SPGI-7 MRI-BASED PREOPERATIVE RISK FACTORS ANALYSIS OF LAPAROSCOPIC VERSUS OPEN LIVER RESECTION FOR PATIENTS WITH BCLC STAGE 0-A HEPATOCELLULAR CARCINOMA

Chen Yidi, MD (*Presenter*)
Bin Song, MD (*Abstract Co-Author*)

PURPOSE

Surgical resection remains the most effective treatment for hepatocellular carcinoma (HCC). However, regardless of whether laparoscopic liver resection (LLR) or open liver resection (OLR) is utilized, the high postoperative recurrence rate remains the primary obstacle to achieving a cure. The aim of this study was to explore MRI-based preoperative risk factors of long-term outcomes of LLR versus OLR for patients with BCLC Stage 0-A HCC.

METHODS AND MATERIALS

This two-center retrospective study was approved by the Ethics Committees of our institution, consecutive patients who fulfilled the following criteria were identified from April 2011 to May 2023. Treatment plans for patients were determined during a comprehensive surgical board or mutil-disciplinary team. Recurrence-free survival (RFS) and overall survival (OS) rates following liver resection were computed using the Kaplan-Meier method. The inverse probability of treatment weighting approach was employed to address potential selection bias inherent between the LLR and OLR outcomes. The preoperative predictive models were developed and validated for RFS and OS after OLR and LLR, that based on the preoperative clinical and MR imaging predictors.

RESULTS

667 eligible patients were enrolled in this study, 235 patients underwent pure LLR and 441 patients underwent OLR for HCC, the 5-year RFS rate after LLR was 47.3%, the 5-year OS rate was 87.1%. The 5-year RFS rates after OLR was 38.0%, the 5-year OS rate was 73.8%. Cirrhosis, Esophageal Gastric Varices, Tumor Size, Markedly Low ADC, PVP Peritumoral Hypoenhancement were the independent risk factors of RFS after LLR, AFP (=400), Esophageal Gastric Varices, Tumor Size, RimAPHE, T2 Peritumoral Hyperintensity and PVP Peritumoral Hypoenhancement were the independent risk factors of OS after LLR. Cirrhosis, MVI, tumor Size, Infiltrative Subtype and Tumor blood products were the independent risk factors of RFS after OLR, Tumor grade, Ascites, Tumor Size, Infiltrative Subtype, Corona Enhancement, and Nodule-in-nodule Architecture were the independent risk factors of OS after OLR. In the training and validation set of LLR group, the AUC was 0.734 and 0.702 for the RFS, 0.919 and 0.643 for the OS, in the OLR group, AUC was 0.648 and 0.669 for the RFS, 0.709 and 0.760 for the OS.

CONCLUSION

The outcomes of LLR and OLR were associated to clinical and MRI characteristics, the predictive model based on preoperative MRI is utilized to implement the risk stratification after LLR and OLR surgeries.

CLINICAL RELEVANCE/APPLICATION

1) The outcomes of LLR and OLR were associated to individual clinical and MRI characteristics. 2) The predictive model based on preoperative MRI has significant clinical significance for risk stratification after LLR combined with OLR surgery.

M2-SPGI-8 MEDSEGGEN: SEMANTIC SYNTHESIS FOR MEDICAL IMAGING SEGMENTATION DATA GENERATION

Pascal N. Tyrrell, PhD (*Presenter*)
Xin Lei Lin (*Abstract Co-Author*)
Soroush Mehraban (*Abstract Co-Author*)
Daniel Saragih (*Abstract Co-Author*)
Varun Sahni (*Abstract Co-Author*)

PURPOSE

Robust medical image segmentation models are hindered by limited access to large, high-quality labeled datasets, especially in specialized domains like gastrointestinal (GI) imaging. Current generative augmentation techniques, including inpainting and stitching, lack anatomical diversity and often produce inconsistent outputs. This study introduces MedSegGen, a semantic synthesis framework using Latent Diffusion Models (LDMs), designed to generate diverse, anatomically realistic image-mask pairs to improve segmentation model training.

METHODS AND MATERIALS

We developed a two-stage training pipeline on the HyperKVasir dataset, which contains 88,000 unlabeled and 1,000 labeled GI endoscopy images. First, a Vector-Quantized Generative Adversarial Network (VQ-GAN) was fine-tuned on the unlabeled data to learn a structured latent space. Second, a conditional LDM was trained in this latent space using segmentation masks to guide image generation. To increase anatomical variation, we implemented a novel mask interpolation module that blends existing binary masks via radial per-pixel interpolation, smoothing, and spatial augmentations. A Sobel-based contour loss was selectively applied during diffusion training on labeled data, preserving anatomical boundary fidelity. Evaluation metrics included Fréchet Inception Distance (FID), Learned Perceptual Image Patch Similarity (LPIPS), and Multi-Scale Structural Similarity Index (MS-SSIM), computed across bootstrapped sets of synthetic images and masks.

RESULTS

Our VQ-GAN baseline achieved a FID of 66.85, while MedSegGen generated diverse conditional samples with an average FID of 142.0477 ± 1.6877, LPIPS of 0.6698 ± 0.0020, and MS-SSIM of 0.2313 ± 0.0013. Despite higher FID values, which reflect deviation from real distributions, generated samples exhibited clinically realistic variability and structural consistency in visual inspection. The mask interpolation pipeline introduced novel anatomical configurations absent in the original dataset. Contour-aware loss improved the alignment of synthetic images with the guiding masks.

CONCLUSION

MedSegGen successfully synthesizes diverse, high-fidelity GI image-mask pairs from limited labeled data. The model's two-stage structure, mask interpolation, and conditional regularization offer a scalable solution for medical image augmentation through novel image backgrounds and foregrounds.

CLINICAL RELEVANCE/APPLICATION

By augmenting limited medical imaging datasets with anatomically realistic synthetic pairs, MedSegGen improves the training and generalization of segmentation models, potentially enhancing diagnostic performance in GI endoscopy and other imaging domains.

M2-SPGI-9 POST-LYMPHANGIOGRAPHIC CT (PLCT) IN PROTEIN-LOSING ENTEROPATHY

Yuming Yang (*Presenter*)

PURPOSE

To investigate the imaging features and clinical value of post-lymphangiographic CT in diagnosis and differential diagnosis in protein-losing enteropathy (PLE).

METHODS AND MATERIALS

Forty-two patients diagnosed as PLE were retrospectively reviewed in this study from 2011 to 2017, including 42 primary intestinal lymphangiectasia (PIL), and 15 other kinds of PLE, confirmed by 99 Tc m -labelled human serum albumin scintigraphy and/or capsule endoscopy. All patients underwent direct lymphangiography and post-lymphangiographic CT. All the imaging were blinded reviewed by two radiologists respectively, and the assessments of imaging features included intestinal wall thickening, dilation of intestinal lumen, edematous lesions, abnormal distribution of contrast agents, reflux, lymph nodes and leakage. Statistical analyses were performed with $P < 0.05$.

RESULTS

Compared with other kinds of PLE, patients with PIL demonstrated lower onset age (14.7 ± 10.6 vs. 38.8 ± 10.7, $P < 0.01$). The proportion of abnormal distribution of contrast media in intestinal wall and mesentery are higher in PIL than other PLE as well as lymph reflux. While no statistical difference was found in intestinal wall dilatation, edematous lesions, abnormal distribution of contrast media in other abdominal cavity, leakage and lymph node (all $P > 0.05$).

CONCLUSION

Post-lymphangiographic CT demonstrates capability in detection of location, distribution and range of abnormal lymphatics, which is useful for differential diagnosis and therapeutic adoptions for PLE.

CLINICAL RELEVANCE/APPLICATION

It is necessary to evaluate the systematic lymphatic circulation abnormality in patients with PLE using post-lymphangiographic CT, as this assessment plays a crucial role in guiding personalized therapeutic strategies.

M2-SPGI-10 ASSESSMENT OF EXTRAPANCREATIC PERINEURAL INVASION IN PANCREATIC DUCTAL ADENOCARCINOMA: CORRELATION OF CT AND RADIOMIC FEATURES WITH HISTOPATHOLOGY AND PROGNOSTIC IMPLICATIONS

Duygu D. Ekizalioglu, MD (*Presenter*)
Ozgur I. Koska, PhD, MD (*Abstract Co-Author*)
Ali Caglar C. Turgut, MD (*Abstract Co-Author*)
Cagan Koska (*Abstract Co-Author*)
Deniz Nart (*Abstract Co-Author*)
Funda Yilmaz Barbet (*Abstract Co-Author*)
Alper Uguz (*Abstract Co-Author*)
Ezgi Guler, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the non-invasive predictability of extrapancreatic perineural invasion (EPNI) in pancreatic ductal adenocarcinoma (PDAC) using CT and radiomic analysis, assess concordance with histopathology and determine prognostic value.

METHODS AND MATERIALS

This retrospective, single-center study included patients with histopathologically confirmed PDAC who underwent pancreatoduodenectomy between 2016 and 2023. Preoperative contrast-enhanced CTs were independently reviewed by two blinded radiologists for evaluation of EPNI. CT findings including peripancreatic linear stranding/soft-tissue suggesting the presence of EPNI, pancreatic duct involvement, duodenal and vascular invasion, lymph node metastasis, and shortest tumor-celiac/(superior mesentersc artery)SMA distances were recorded. Manual 3D segmentations of the tumor and mesopancreas were performed using ITK-SNAP.Radiomic

features were extracted with PyRadiomics; feature selection employed correlation filtering, mRMR, RFE, and feature importance ranking. Predictive models(SVM, RF) were developed using stratified cross-validation for radiomic-only and combined radiologic-radiomic models.Model performance was assessed by F1 score, accuracy, and AUC.Comparative statistical, interobserver agreement and survival analyses were performed.

RESULTS

Among 90 patients, histopathological EPNI was present in 67.8%.Sensitivity and specificity for detection of EPNI were 93.4%, 58.6%, respectively for Reader 1; and 90.2%, 72.4%, respectively for Reader 2.Interobserver agreement was substantial(?=0.661).Concordant radiologic EPNI showed strong association with histopathological EPNI($p<0.05$).Significant correlations were found between EPNI and surgical margin positivity, peripancreatic fat invasion, lymph node metastasis, tumor-celiac distances ($p<0.05$).The radiomics-based model achieved an F1 score of 0.842 and an AUC of 0.707; whereas the combined radiologic-radiomic model demonstrated improved performance with an F1 score of 0.859 and an AUC of 0.832.EPNI-positive patients had shorter progression free survival (19.8 vs. 39.5 months, $p=0.069$) and overall survival (22.3 vs. 29.7 months, $p=0.235$), though not statistically significant.

CONCLUSION

Radiologic and radiomic assessments are effective non-invasive tools for preoperative EPNI prediction in PDAC.EPNI may impact prognosis, warranting further prospective validation.

CLINICAL RELEVANCE/APPLICATION

CT-based radiologic-radiomics combined model could noninvasively predict EPNI.

M2-SPGI-11 DEEP LEARNING-DERIVED THREE-DIMENSIONAL BODY COMPOSITION PREDICTS PANCREATIC FISTULA POST RADICAL DISTAL PANCREATECTOMY

Qi Miao, MD, PhD (*Presenter*)
Kexin Zhu (*Abstract Co-Author*)
Yuanxi Jiang, MD (*Abstract Co-Author*)
Dongli Feng (*Abstract Co-Author*)
Guoguang Fan, PhD (*Abstract Co-Author*)

PURPOSE

Accurate prediction of postoperative pancreatic fistula (POPF) after radical distal pancreatectomy (DP) is critical for optimizing surgical strategies. The objective of this study was to develop and validate a deep learning-based framework for three-dimensional (3D) body composition analysis to forecast POPF in patients with pancreatic cancer (PC).

METHODS AND MATERIALS

A retrospective analysis was conducted on patients who underwent radical DP at two institutions between 2015 and 2022. A deep learning-based 3D segmentation model was developed to assess abdominal muscles and fat using preoperative computed tomography (CT) images. Predictive models for POPF were constructed using Gradient Boosting Decision Trees (GBDT) and their performance was evaluated using the area under the receiver operating characteristic curve (AUC) and decision curve analysis (DCA) on validation and external test datasets.

RESULTS

The study comprised 230 patients with PC, with a mean age of 62 years. The incidence of POPF was observed to be 47.4%. In terms of muscle segmentation, the Dice similarity coefficients (DSCs) for the testing set varied between 91.84% and 98.41% across different regions of the abdominal musculature. For the segmentation of visceral and subcutaneous adipose tissue, the DSCs in the testing set were 97.10% and 98.57%, respectively. The integrated clinical and imaging-based POPF prediction model demonstrated superior performance, achieving an AUC of 0.82, with a sensitivity of 0.81 and a specificity of 0.76 in the external test set.

CONCLUSION

The implementation of a deep learning-based 3D body composition analysis pipeline exhibited high accuracy in predicting POPF following radical DP for PC.

CLINICAL RELEVANCE/APPLICATION

Deep learning-based 3D body composition analysis accurately predicts pancreatic fistula risk after radical distal pancreatectomy, facilitating individualized perioperative management for patients with pancreatic cancer.

M2-SPGI-13 DIRECT COMPARISON OF LIVER STIFFNESS AND FAT QUANTIFICATION BY VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY (VCTE), ULTRASOUND (US), AND MAGNETIC RESONANCE IMAGING (MRI)

Stephanie T. Chang, MD (*Presenter*)
Aditya Indla (*Abstract Co-Author*)
Brian M. Dale, PhD (*Abstract Co-Author*)
Om Patel (*Abstract Co-Author*)
Miki Kwan (*Abstract Co-Author*)
Molly Ma (*Abstract Co-Author*)

Gabriela Torres (*Abstract Co-Author*)
Jacqueline A. Bailey, ARRT (*Abstract Co-Author*)
Yassin Labyed (*Abstract Co-Author*)
Vibhas Deshpande, PhD (*Abstract Co-Author*)
Ramsey Cheung (*Abstract Co-Author*)
Daniel Ennis (*Abstract Co-Author*)

PURPOSE

Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of liver failure. Although multiple modalities quantify liver stiffness and fat, direct comparison of modalities is needed to determine the most effective screening approach for MASLD. We directly compared vibration-controlled transient elastography (VCTE) and ultrasound (US) using magnetic resonance imaging (MRI) as the reference standard with all modalities performed sequentially on the same day.

METHODS AND MATERIALS

Veterans (n=101) with obesity (body mass index (BMI) > 30) and/or type 2 diabetes (DM2) were enrolled in an IRB-approved study in 2022-2024. Liver stiffness was obtained by VCTE (FibroScan, M or XL probe), US auto point shear wave elastography (auto-pSWE, Siemens ACUSON Sequoia, DAX transducer), and MRI elastography (MRE, Siemens MAGNETOM Vida Fit). Liver fat quantification was obtained by controlled attenuation parameter (CAP) in VCTE, ultrasound derived fat fraction (UDFF), and MRI proton density fat fraction (PDFF). Blood-based tests including fibrosis-4 (FIB-4) index and enhanced liver fibrosis (ELF) test were included. Several linear models were developed to determine accuracy of liver stiffness and fat measurements based on available data to predict MRI values. After fitting a Bayesian linear model using US, VCTE, FIB-4, ELF, and patient data (age, gender, BMI, race, ethnicity, and DM2), we used projection predictive variable selection to analyze the best possible sub-models and plotted their root mean squared error (RMSE) in estimating MRI values for liver stiffness and fat. Models were compared using leave-one-out resampling for post-selection inference.

RESULTS

Of 101 veterans enrolled (median age 68 years, range 37-75 years), most were male (n=90) and had type 2 diabetes (n=84). Median BMI was 31.6 (range 19.3-49.1). Quantitative US is the strongest predictor of MRI for liver stiffness and fat. US auto-pSWE can predict liver stiffness by MRE with a RMSE of 0.62 kPa in conjunction with BMI, DM2, and FIB-4. US UDFF can predict liver fat fraction by MRI PDFF with a RMSE of 5.0% in conjunction with age, BMI, race, ethnicity, and DM2. Without US, VCTE is a weaker predictor of MRE with a RMSE of 0.77 kPa with 7 predictors (VCTE, age, BMI, race, DM2, FIB-4, and ELF). Similarly, VCTE CAP is a weaker predictor of MRI PDFF with a RMSE of 7.2% with 4 predictors (VCTE CAP, race, ethnicity, and DM2).

CONCLUSION

Quantitative US auto-pSWE and UDFF are strong predictors of MRI values for liver stiffness and fat. VCTE is less accurate than quantitative US. Quantitative US performance can be improved by incorporation of additional clinical variables.

CLINICAL RELEVANCE/APPLICATION

Quantitative US instead of VCTE should be considered for frontline MASLD screening.

M2-SPGI-15 MULTIMODEL MRI AND MULTIOMICS REVEAL HIGH-RISK NEUROPHENOTYPE IN BRAIN-GUT CIRCUITS AS THERAPEUTIC TARGET FOR CROHN'S DISEASE

Xiao Di Shen (*Presenter*)
Xuehua Li II (*Abstract Co-Author*)
Ruonan Zhang (*Abstract Co-Author*)
Zhoulei Li, PhD (*Abstract Co-Author*)
Yang Di Wang (*Abstract Co-Author*)
Lili Huang, MD (*Abstract Co-Author*)
Xinyue Wang (*Abstract Co-Author*)
Qingzhu Zheng (*Abstract Co-Author*)
Luyao Wu (*Abstract Co-Author*)
Yaoqi Ke (*Abstract Co-Author*)
Weikai Zheng (*Abstract Co-Author*)
Mengchen Zhang (*Abstract Co-Author*)
Li Huang (*Abstract Co-Author*)
Jinjiang Lin (*Abstract Co-Author*)
Zhuangnian Fang (*Abstract Co-Author*)
Weitao He (*Abstract Co-Author*)

PURPOSE

The brain-gut axis shapes Crohn’s disease (CD) pathogenesis, yet CD-associated neurophenotypes lack defined clinical and mechanistic significance. We aimed to define these neurophenotypes, assess their prognostic impact, elucidate neurophenotype-driven progression mechanisms using multiomics, and validate their therapeutic potential in vivo .

METHODS AND MATERIALS

This prospective double-center study enrolled 109 CD patients undergoing baseline multimodal neuro-MRI, MR enterography, ileocolonoscopy, and fecal/blood samples collection. The neurophenotypes were characterized using multimodal neuro-MRI model developed from 13 out of 13,870 features. 83 patients were followed up for disease progression, with repeated brain-gut assessments. Multi-omics (fecal microbiome/metabolomics, serum metabolomics/neurotransmitters) were used to decode the mechanisms underlying neurophenotype-driven progression. Dextran sulfate sodium (DSS)-induced colitis mice with different neurophenotypes were treated with repeated transcranial magnetic stimulation (rTMS) to explore its therapeutic potential.

RESULTS

Multimodal neuro-MRI accurately mapped CD-specific neural signatures (Fig.A), stratifying patients into high-risk (neurophenotype score=0.45) and low-risk neurophenotypes with robust cross-center validity (training cohort AUC=0.842, test cohort AUC=0.824) (Fig.B). High-risk neurophenotype was identified as an independent predictor of accelerated disease progression (Hazard ratio=15.46, P=0.030), independently of intestinal inflammation. Integrated multi-omics revealed that high-risk neurophenotype contributed to CD progression through microbial-metabolic-neurotransmitter networks wherein tryptophan emerged as the central regulatory hub (Fig.C). Serum tryptophan levels negatively correlated with neurophenotype severity and intestinal disease progression (Fig.D). rTMS targeting high-risk neurophenotype in DSS-induced colitis mice elevated tryptophan levels and ameliorated intestinal disease activity (Fig.E).

CONCLUSION

This study redefines high-risk neurophenotype as a sustained pathogenic driver rather than a mere phenomenon, proposing brain-gut axis modulation as a promising therapeutic strategy distinct from conventional anti-inflammatory approaches.

CLINICAL RELEVANCE/APPLICATION

Using repetitive transcranial magnetic stimulation to treat high-risk neurophenotype elevated serum tryptophan levels and alleviated colitis in DSS-colitis mice, confirming its therapeutic potential for translation into clinical practice.

M2-SPGI-16 A STUDY OF DEEP LEARNING RECONSTRUCTION ALGORITHM IN IMPROVING PORTAL VEIN CT IMAGE QUALITY

Le Cao (*Presenter*)
Xiang Liu (*Abstract Co-Author*)
Jianying Li, PhD (*Abstract Co-Author*)
Jianxin Guo (*Abstract Co-Author*)

PURPOSE

To explore the application value of deep learning reconstruction algorithm (DLIR) in improving portal vein CT image quality.

METHODS AND MATERIALS

32 cases of portal vein rawdata were retrospectively reconstructed into 1.25mm slice thickness images using 50% adaptive statistical iterative reconstruction (ASIR-V) and DLIR at medium (DLIR-M) and high strengths (DLIR-H). The CT value and image noise of main portal vein, right portal vein branch, left portal vein branch and paravertebral muscle were measured, and the contrast-noise-ratio (CNR) for vessels was calculated. Moreover, the edge-rising-slope (ERS) of main portal vein edge was measured to evaluate image spatial resolution. The overall image noise, image contrast, and portal vein branch display were evaluated using a 5-point grading scale and image artifacts using a 4-point grading scare by two experienced radiologists. In addition, the display rate of small portal vein branches (display score>2) in the three reconstruction algorithms were calculated.

RESULTS

DLIR-M and DLIR-H images had significantly lower image noise and higher CNR for the main portal vein, right branch and left branch than 50% ASIR-V images, with DLIR-H having the lowest noise and highest CNR. The ERS values of DLIR (M, H) images were also significantly higher than 50% ASIR-V images (all $P<0.01$). The subjective scores of DLIR-H images were higher than 50% ASIR-V images, ($P<0.01$). In addition, the display rates of small branches of portal vein in DLIR images were (DLIR-M: 93.75%; DLIR-H: 100%), significantly higher than ASIR-V 50% (68.75%).

CONCLUSION

Compared with conventional 50%ASIR-V algorithm, DLIR algorithm can significantly reduce the image noise of portal vein, improve the spatial resolution and the display rate of small branches of portal vein, and has the potential to be applied to the follow-up portal vein scanning with reduced radiation and contrast doses.

CLINICAL RELEVANCE/APPLICATION

To explore the application value of deep learning reconstruction algorithm (DLIR) in improving portal vein CT image quality.

M2-SPGI-17 CT-BASED FRACTAL DIMENSION ANALYSISPREDICTS INTRA-TUMORAL TERTIARY LYMPHOID STRUCTURES AND SURVIVAL IN PANCREATIC DUCTAL ADENOCARCINOMA: A RETROSPECTIVE MULTICENTER STUDY

Haopeng Yu (*Presenter*)
Xiaoying Li (*Abstract Co-Author*)
Yuqi Wang (*Abstract Co-Author*)
Yu Li (*Abstract Co-Author*)
Yan Deng (*Abstract Co-Author*)
Jing Zhu (*Abstract Co-Author*)
Bin Song (*Abstract Co-Author*)
Zixing Huang (*Abstract Co-Author*)
Dan Cao (*Abstract Co-Author*)

PURPOSE

To develop a CT-based fractal dimension model integrated with clinical variables for predicting intra-tumoral tertiary lymphoid structures (TLS) statues in pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

This retrospective multicenter study enrolled 164 pathologically confirmed PDAC patients (training/validation: 131/33) with pretreatment multiphase CT and TLS status determined by histopathology (2020-2023). Fractal dimension and lacunarity were quantified on arterial/portal venous phase (PVP) CT. Clinical variables (CA125, CA19-9, TNM stage, etc.) were analyzed. Predictive models were developed using logistic regression and validated for survival stratification.

RESULTS

TLS positivity (45.7%, 75/164) correlated with prolonged overall survival (OS) in both cohorts ($p<0.001$). In the training cohort, univariate analysis revealed significant differences in lacunarity in PVP ($p = 0.008$), CA125 ($p = 0.007$), CA19-9 ($p = 0.005$), and age ($p = 0.015$) when comparing across the TLS groups. Multivariable logistic regression analysis incorporating clinical features and lacunarity in PVP indicated that only lacunarity in PVP was independently associated with TLS ($p = 0.036$). The logistic model achieved an area under the curve (AUC) of 0.696 in the training cohort (positive predictive value [PPV] = 0.737, negative predictive value [NPV] = 0.656) and 0.67 in the external validation cohort (PPV = 0.778, NPV = 0.667). Using a cutoff value of 0.501 for the predictability of the logistic model, patients predicted as TLS-positive exhibited significantly better OS than those predicted as TLS-negative in both the training cohort ($p = 0.002$) and the external validation cohort ($p = 0.011$).

CONCLUSION

This study establishes CT-based fractal lacunarity in PVP as an independent predictor of intra-tumoral TLS in PDAC, with its integration into a clinical-radiographic model enabling noninvasive TLS stratification and prognostication. The validated model highlights TLS as a critical imaging biomarker for guiding immunotherapeutic strategies in pancreatic oncology.

CLINICAL RELEVANCE/APPLICATION

This model provides a preoperative imaging tool to assess TLS status in PDAC, which may inform immunotherapy eligibility evaluation (e.g., PD-1/IL-33-targeted therapies) and risk-adapted therapeutic approaches. The lacunarity-TLS correlation provides a quantifiable imaging surrogate for immune microenvironment remodeling, complementing traditional biomarkers like CA19-9 in personalized prognosis. Its multicenter validation supports clinical translation for dynamic monitoring of TLS evolution during neoadjuvant therapy.

PURPOSE

To evaluate multi-b-value diffusion models for Banff classification of renal allografts

METHODS AND MATERIALS

n a prospective, IRB-approved two-center study, 99 patients (50±13yo, 64M/35F) with surveillance or clinically indicated biopsy underwent 3T MRI (Skyra, Siemens Healthcare). MRI included multi-b-value DWI (9 b-values: 0-800 s/mm2) and diffusion models of ADC, intravoxel incoherent motion, and spectral diffusion. 2017 Banff classifications were scored by pathologists and serum GFR collected. Cortical regions-of-interest were delineated in all allografts by Observer 1 and in a subset of 20 by Observer 2 for interobserver analysis by intraclass correlation coefficient (ICC), and two subjects scanned twice for tests-retest coefficient of variation (CoV) assessment. Diagnostic performance was calculated via ROC analysis of univariate logistic regression models built with 5-fold cross-validation and bootstrapping.

RESULTS

CKD-EPI GFR was 47±21mL/min/1.73m2 and Banff 2017 interstitial fibrosis and tubular atrophy (IFTA) scores were as follows: 39 IFTA=0, 22 IFTA=2, 20 IFTA=4, 18 IFTA=6. Multi-b-value diffusion parameters demonstrated significant diagnostic ability for Banff classifications of severe tubulitis (AUC=0.86, p<0.001), interstitial inflammation (AUC=0.82, p=0.002), inflammation in areas of fibrosis (AUC=0.65, p=0.012) , glomerulitis (AUC=0.70, p<0.001), arteriolar hyalinosis (AUC=0.62, p=0.03), fibrosis (AUC=0.69, p<0.001), tubular atrophy (AUC=0.69, p=0.001), and tubular injury (AUC=0.63, p=0.025). Spectral diffusion was sensitive to mild-to-moderate fibrosis (IFTA=1-4; AUC=0.65, p=0.023), and detected fibrosis in allografts still presenting with normal function (AUC=0.72, p=0.007). Decreased tubular diffusion and increased tissue diffusion suggesting tubular injury and collagen deposition correlated with fibrosis score (Fig.1). Interobserver correlation ranged from poor to excellent with 14/40 features returning an ICC between 0.50 and 0.75, and 10/40 above 0.75. Tissue diffusion components showed the highest interobserver reliability, and IVIM and ADC demonstrated better ICC and CoV(%) than spectral diffusion.

CONCLUSION

Multi-b-value diffusion demonstrates promise for noninvasive Banff Classification of kidney transplant pathology and may provide clinically relevant information on transplant pathology. Parameter reliability needs further work; ROIs sampling cortical strips may improve ICC.

CLINICAL RELEVANCE/APPLICATION

Banff classification of transplant biopsy samples is a consensus grading system for renal allograft failure and rejection. Multi-b-value DWI MRI of renal allografts may improve non-invasive assessment of allograft histopathology.

M2-SPGU-2 PREDICTING PELVIC LYMPH NODE METASTASES IN PROSTATE CANCER: INTEGRATING PRIMARY TUMOR FEATURES FROM MRI AND PSMA PET/CT

Jonas Kluckert, MD (*Presenter*)
Volkan Beylergil, MD (*Abstract Co-Author*)
Jenna Schabdach (*Abstract Co-Author*)
Natalie Gangai (*Abstract Co-Author*)
Maida Wasim (*Abstract Co-Author*)
Yousef Mazaheri, PhD (*Abstract Co-Author*)
Lawrence H. Schwartz, MD (*Abstract Co-Author*)
Oguz Akin, MD (*Abstract Co-Author*)

PURPOSE

The presence of pelvic lymph node metastases in the initial staging of prostate cancer has a significant impact on treatment planning. PSMA PET/CT is superior to MRI for lymph node assessment, but has limitations, particularly for micrometastases. We aimed to identify features of the primary tumor on biparametric MRI and PSMA PET/CT that more accurately predict pelvic lymph node invasion than imaging features of the pelvic lymph nodes alone.

METHODS AND MATERIALS

We retrospectively identified consecutive patients with treatment-naïve prostate cancer who underwent prostate MRI and PSMA PET/CT within 90 days between January 2017 and August 2024 followed by radical prostatectomy and extended lymph node dissection within 180 days. We performed univariate correlation analysis of imaging and clinical features with histopathological N-stage as a reference standard. Numerical features were analyzed using Point-Biserial Correlation, ordinal features with Spearman's rank correlation and binary features using Chi-Square-Test. Features with significant univariate correlation were then used to train a logistic regression model to predict pelvic lymph node invasion. Model predictions were compared to predictions made using only the pelvic lymph node appearance on PET/CT through 10-fold cross-validation and performance was evaluated using the area under the receiver operating characteristic curve (AUROC), positive predictive value (PPV), and negative predictive value (NPV).

RESULTS

We analyzed 348 patients with an average age of 63.3 years (IQR 59.0-69.0). PI-RADS score, index lesion size, suspected presence of extracapsular extension, seminal vesicle invasion or adjacent organ invasion, ISUP grade group at biopsy, suspected pelvic lymph node metastasis on PET/CT and pre-treatment PSA level demonstrated a significant correlation ($p<0.05$) with pN1 in the extended pelvic lymph node dissection. A logistic regression model based on these features outperformed diagnosis based on pelvic lymph node appearance on PET/CT alone with an AUROC of 0.77 (CI: 0.72-0.82) compared to 0.58 (0.53-0.62), respectively. Our model's PPV and NPV for pelvic lymph node metastases were 0.75 (0.61-0.89) / 0.69 (0.45-0.88) and 0.82 (0.80-0.84) / 0.83 (0.81-0.84) in the full cohort and in the 331 PET/CT negative cases, respectively.

CONCLUSION

Combining primary tumor characteristics on MRI with findings on PSMA PET/CT markedly improves the accuracy of predicting pelvic lymph node metastases in prostate cancer.

CLINICAL RELEVANCE/APPLICATION

Our study supports the predictive value of combined clinical and imaging features for pelvic lymph node metastases in prostate cancer and highlights the diagnostic accuracy of combined PSMA PET/CT and MRI features.

M2-SPGU-3 EVALUATION OF A SIMPLIFIED PROSTATE MRI EXTRAPROSTATIC EXTENSION SCORE

Andrei S. Purysko, MD (*Presenter*)
Emily Knott (*Abstract Co-Author*)
Ryan Ward, MD, MBA (*Abstract Co-Author*)
Jennifer Bullen, MSc (*Abstract Co-Author*)

PURPOSE

The primary aim of this study was to evaluate the ability of a simplified prostate MRI score to predict extraprostatic extension (EPE) and to assess whether lesion location impacted accuracy. A secondary aim was to determine the incremental value of adding this MR score to known clinical predictors.

METHODS AND MATERIALS

661 consecutive patients underwent prostate MRI followed by radical prostatectomy (RP) at a single center between January 2019 and January 2025. Exclusion criteria included prior treatment, >6 months between MRI and RP, or incomplete data, yielding a final sample of 507 patients. MRIs were prospectively interpreted using PI-RADS, and EPE was assessed with a simplified 5-point score: Absent - no capsule/anterior fibromuscular stroma (AFS) contact;Probably absent - capsule/AFS contact <1.5 cm, no irregularity/bulge;Equivocal - capsule/AFS contact =1.5 cm OR irregularity/bulge;Probably present - contact =1.5 cm AND irregularity/bulge;Present - tumor extends beyond the capsule.ROC curves and AUCs were estimated for detecting any EPE, focal EPE, and non-focal EPE. Subgroup analyses evaluated differences by zone (PZ vs TZ/CZ) and lesion location (base-mid-apex; anterior-lateral-medial-posterior). A multivariable logistic regression model included PSA, pre-MRI biopsy grade group, PI-RADS, and lesion diameter. A second model added the MR score. AUCs were compared using DeLong's method.

RESULTS

The simplified MR EPE score achieved an AUC of 0.765 (95% CI: 0.725-0.805) for detecting any EPE. Accuracy was higher for non-focal vs focal EPE (AUC: 0.808 vs 0.640; $p < 0.001$). No significant differences in AUC were found across anatomic zones or lesion locations. Among 428 patients with complete data, the MR score was a significant independent predictor of EPE (OR: 1.5; 95% CI: 1.2-2.1; $p = 0.003$). Adding the MR score improved model AUC from 0.801 to 0.812, though not significantly ($p = 0.139$).

CONCLUSION

The simplified MRI score demonstrated good performance for predicting EPE, particularly non-focal disease. While lesion location did not affect accuracy, the score was an independent predictor and modestly improved multivariable model performance.

CLINICAL RELEVANCE/APPLICATION

This scoring system may assist with preoperative risk stratification by providing a simple, structured MRI-based method to evaluate EPE.

M2-SPGU-4 MOLECULAR-BASED PROSTATIC MRI WITH 3D CHEMICAL EXCHANGE SATURATION TRANSFER (CEST) IMAGING AND DIFFUSION-WEIGHTED IMAGING (DWI): CAPABILITY FOR DISTINGUISHING MALIGNANT FROM BENIGN PROSTATIC AREAS

Takahiro Ueda, MD, PhD (*Presenter*)
Kaori Yamamoto (*Abstract Co-Author*)
Maiko Shinohara (*Abstract Co-Author*)
Natsuka Yazawa (*Abstract Co-Author*)
Yuichiro Sano, RT (*Abstract Co-Author*)
Masato Ikedo (*Abstract Co-Author*)
Masao Yui (*Abstract Co-Author*)
Masanori Ozaki (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)
Yoshiharu Ohno, MD, PhD (*Abstract Co-Author*)

PURPOSE

3D Chemical exchange saturation transfer (CEST) imaging is recently reported as useful for providing regional CEST information within entire tumor. The purpose of this study was to compare the capability of molecular-based MRI consisting of 3D CEST imaging, diffusion weighted imaging (DWI) for distinguishing malignant from benign prostatic areas.

METHODS AND MATERIALS

Fifty-two suspected prostatic cancer patients underwent DWI at b value as 0 and 1500 s/mm 2 and 3D CEST imaging at a 3T MR system, surgical treatments and pathological examinations. According to the pathological results, 154 areas were determined as malignant prostatic areas, and 154 out of 470 areas were computationally selected as benign prostatic areas. On each 3D CEST imaging, magnetization transfer ratio asymmetry (MTR asym) at 3.5 ppm map was generated from z-spectra by pixel-by-pixel analyses. Then, 308 ROIs were placed over malignant or benign areas on each map, and MTR asym and ADC values were determined. Each index was compared between malignant and benign areas by Student's t-test. Then, logistic regression analysis was performed to investigate the discriminating factors. ROC analysis was performed to compare diagnostic performance among MTR asym , ADC and combined discriminators. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's test.

RESULTS

MTR asym and ADC of malignant area had significant differences with those of benign area (MTR asym : $p<0.0001$, ADC: $p<0.0001$). MTR asym (Odds ratio [OR]: 1.01, $p<0.0001$) and ADC (OR: 0.03, $p<0.0001$) were determined as significant discriminators. Area under the curves (AUC) of combined discriminators (AUC=0.86) was significantly better than that of MT Rasym (AUC=0.81, $p=0.001$) and ADC (AUC=0.76, $p<0.0001$). Specificity (SP) and accuracy (AC) of combined discriminators (SP:

72.1%, AC: 78.6%) were significantly higher than those of MTR asym (SP: 60.4%, p<0.0001; AC: 73.1%, p<0.0001) and ADC (SP: 64.2%, p<0.0001; AC: 74.0%, p<0.0001).

CONCLUSION

Molecular-based MRI would be better to combine 3D CEST imaging and DWI for improving diagnostic performance for differentiating malignant from benign prostatic area, when compared with each method.

CLINICAL RELEVANCE/APPLICATION

When combined 3D CEST imaging with DWI, molecular-based MRI shows superior diagnostic performance to each method for differentiating malignant from benign prostatic areas.

M2-SPGU-6 CLOSING THE EXPERTISE GAP: AI-ASSISTED PI-RADS SCORING VS. FULLY AUTOMATED AI

Guillaume Herpe, MD (*Presenter*)
Chloe Adam, PhD (*Abstract Co-Author*)
Luc Beuzit (*Abstract Co-Author*)
Camille Ruppli (*Abstract Co-Author*)
Gaspard d'Assignies, MD, PhD (*Abstract Co-Author*)

PURPOSE

Prostate MRI plays a crucial role in detecting clinically significant prostate cancer (csPCa), but its effectiveness is hindered by inter-reader variability and moderate specificity in spite the development of a standardized framework : The Prostate Imaging Reporting and Data System (PI-RADS). Advances in artificial intelligence (AI) have introduced automated tools capable of improving diagnostic accuracy, standardizing interpretation, and enhancing workflow efficiency. This study evaluates the performance of an AI-based PI-RADS scoring system (PAROS v1.0.0, Incepto Medical), comparing it to radiologists with varying expertise.

METHODS AND MATERIALS

A total of 201 prostate MRI cases from the ProstateX dataset were analyzed in a multi-reader, multi-case study. Five general radiologists (250-500 prior prostate MRI reads) evaluated cases in two sequential sessions: first without AI assistance and then with AI assistance after a four-week washout period with randomized case reshuffling. One expert (>1000 reads) read the cases without AI assistance. The AI tool performed lesion detection for csPca (PI-RADS =3). Ground truth was established using biopsy results, with csPCa defined as ISUP grade =2. Performance metrics included sensitivity, specificity, accuracy, and comparison between standalone AI, non-expert radiologists, and the expert reader.

RESULTS

The study included 201 patients with a mean age of 63.6 years and a median PSA level of 11.0 ng/ml, with 76 cases of csPCa primarily located in the peripheral (n=40) and transition zones (n=36). Five general radiologists and one expert completed a total of 2,211 reads.Standalone AI outperformed AI-assisted non-expert radiologists, with an accuracy of 73% (95% CI : 67%-79%) ($p < 0.001$) vs 65% (95% confidence intervals [CI]: 62%-68%)($p < 0.001$) respectively. AI-assisted non-expert radiologists improved in specificity (34% to 50%, $p = 0.04$) and accuracy (55% to 65%, $p = 0.04$), approaching expert-level performance. However,Expert radiologist w/o AI remained superior to both AI and AI-assisted non-experts with an accuracy of 79% (95% CI: 72-84%).

CONCLUSION

Standalone AI demonstrates superior diagnostic performance compared to non-expert radiologists, supporting its role in bridging the expertise gap and standardizing prostate MRI interpretation.These results align with the findings of Saha et al., who demonstrated that an AI system achieved a statistically superior AUROC (0.91) compared to a pool of 62 radiologists (AUROC 0.86) in detecting csPCa using PIRADS framework.

CLINICAL RELEVANCE/APPLICATION

These findings suggest that AI could enhance screening programs by reducing reliance on specialized expertise and improving overall diagnostic consistency.

M2-SPHN-1 SEGMENTAL VISUALIZATION OF 100 HYPOGLOSSAL NERVES IN CADAVERS USING HIGH RESOLUTION 3D ISOTROPIC CISS MR IMAGING: INITIAL EXPERIENCE FROM SPARC-REVA

Owen Emch (*Presenter*)
Shruti Kumari, MBBS (*Abstract Co-Author*)
Mridhula Muthukumar (*Abstract Co-Author*)
Chris A. Flask, PhD (*Abstract Co-Author*)
Daniel Herzka (*Abstract Co-Author*)
Ari M. Blitz, MD (*Abstract Co-Author*)

PURPOSE

High-resolution isotropic 3D MR imaging with and without contrast is routinely used for imaging evaluation of cranial nerve anatomy and pathologic conditions. Imaging is essential to make an accurate topographical and causal diagnosis of CN XII pathology and injury. Clinical examination cannot localize with accuracy the site of pathology or damage to the nerve. The purpose of this research is to study the extent to which the different segments of CN XII can be seen on 0.5mm 3T 3D CISS MRI in cadavers and compare the visibility of CN XII on CISS, T1 VIBE, and T2-weighted sequences.

METHODS AND MATERIALS

50 embalmed cadavers were scanned with a 3T MRI scanner using 3D isotropic 0.5-0.6 mm resolution 3D-CISS, T1-VIBE, and T2-weighted MRI sequences; a total of 100 CN XII were examined. Two readers independently evaluated visualization of the segments of CN XII (medullary, cisternal, skull base segment, carotid space and anterior extracranial segment) on CISS MRI according to a qualitative scale ranging from 1 to 5 with 5 being the best.

RESULTS

3D CISS allows for visualization of CN XII on MRI along its length up to the anterior segment. CN XII is best seen in the cisternal, skull base (hypoglossal canal), and carotid space segment on CISS MRI and can be traced up to the middle of the anterior extracranial segment. The nuclear segment could not be seen but the hypoglossal trigone can be easily delineated on CISS MRI. Compared to T1-VIBE, and T2 sequences, CN XII is much better seen on CISS MRI.

CONCLUSION

The superior visibility of the segments of CN XII on CISS sequences allows for assessment of involvement of nerve by pathologies and injury. The high signal-to-noise ratio, along with high spatial resolution with isotropic 3D CISS images that can be reconstructed in multiple planes, makes this sequence superior to conventional 2D MR imaging sequences, as well as the high-resolution T1-weighted postcontrast sequences in current use.

CLINICAL RELEVANCE/APPLICATION

Routine use of 3D isotropic CISS MRI for the pathological assessment of cranial nerve XII offers significant advantages over other MRI sequences, providing superior imaging quality. Its ability to produce high-resolution, isotropic images with excellent contrast allows for a more detailed visualization of the nerve's anatomy and its potential pathologies.

M2-SPHN-2 HIGH-RESOLUTION INTRAORAL ULTRASOUND FOR DEPTH OF INVASION ASSESSMENT IN EARLY TONGUE SQUAMOUS CELL CARCINOMA: TECHNICAL REFINEMENTS AND VALIDATION

Maria Paola Belfiore (*Presenter*)
Marialuisa Balzano (*Abstract Co-Author*)
Marco Montella (*Abstract Co-Author*)
PASQUALE PARRELLA (*Abstract Co-Author*)
Dario Di Stasio (*Abstract Co-Author*)
Salvatore Cappabianca, MD (*Abstract Co-Author*)

PURPOSE

To validate the accuracy and reproducibility of high-resolution intraoral ultrasound (ioUS) in measuring depth of invasion (DOI) in early-stage oral squamous cell carcinoma (OSCC) of the tongue and to address common methodological inconsistencies in current imaging practices.

METHODS AND MATERIALS

Thirty-five patients (21 males, 14 females; mean age 64.7 ± 10.3 years) with histologically confirmed OSCC of the tongue (dorsal, lateral, or ventral surfaces) and clinical tumor size =2 cm (T1-T2) were prospectively enrolled. ioUS imaging was performed using an 18 MHz linear probe in a non-contact technique. For each patient, three high-quality images were selected based on bilateral visualization of intact epithelial margins. A horizontal DOI reference line was defined at the epithelium-connective tissue interface, and DOI was measured perpendicularly to the deepest hypoechoic area. Images with acoustic shadowing were excluded. DOI values were normalized to correct for tissue shrinkage during histopathological processing. Measurements were performed using ImageJ software. Statistical analysis included Spearman's correlation, intraclass correlation coefficient (ICC), and Mann-Whitney U test.

RESULTS

ioUS demonstrated a strong correlation with pathological DOI (Spearman's ? = 0.93; $p < 0.001$), and all lesions were correctly staged as T1 or T2, with 100% concordance with pathological staging. Normalized DOI data showed excellent reproducibility (ICC >0.90). No significant differences were found between ioUS and pathological DOI measurements ($p > 0.05$).

CONCLUSION

High-resolution ioUS provides accurate and reproducible measurements of DOI in early tongue OSCC, with staging performance equivalent to histopathological analysis. Technical refinements, including standardized image acquisition and definition of reference lines, are critical for clinical reliability.

CLINICAL RELEVANCE/APPLICATION

ioUS represents a reliable, non-invasive imaging tool for precise preoperative assessment of DOI in early tongue OSCC, offering a cost-effective alternative to CT or MRI and aiding in accurate staging and surgical planning. Furthermore, ioUS represents a valid alternative for the study of patients who cannot undergo MRI due to the presence of dental prostheses that would create artefacts on the study volume, due to adverse reactions to the contrast medium or in general in all those conditions that represent contraindications to magnetic resonance imaging

M2-SPHN-3 CHARACTERISTICS OF VAGUS NERVE VARIATIONS IN THE NECK ON HIGH RESOLUTION 3T 3D CISS MRI IN CADAVERS: A SPARC-REVA STUDY

Mridhula Muthukumar (*Presenter*)
Shruti Kumari, MBBS (*Abstract Co-Author*)
Chris A. Flask, PhD (*Abstract Co-Author*)
Daniel Herzka (*Abstract Co-Author*)
Ari M. Blitz, MD (*Abstract Co-Author*)

PURPOSE

The cervical portion of vagus nerve (CN X) is located within the carotid sheath, usually posterolateral to the carotid artery (CA) and posteromedial to the internal jugular vein (IJV). However, several variations in the CN X position have been reported. CN X is commonly manipulated during neck dissection along with the CA and the IJV, and can be injured during these procedures. Therefore, knowledge of these anatomical variants is paramount to reduce the risk of CN X injury during both surgical and non-surgical management of various diseases of the cervical region. Our aim is to study the characteristics of CN X variations using the carotid artery (CA) and the internal jugular vein in cadavers on 3D CISS MRI.

METHODS AND MATERIALS

55 embalmed cadavers were scanned with a 3T MRI scanner using 3D isotropic 0.5-0.6 mm resolution 3D-CISS MRI sequence; a total of 110 CN X were examined by two readers. These findings were confirmed on anatomic dissection. Based on the method used by Dongbin et al for studying CN X position relative to CA and IJV using ultrasound, variations of the CN X position are based on a reference axis consisting of both the CA and IJV (C-I axis). On MRI, a CN X variation was defined as a CN X located anterior or medial to the C-I axis in the suprahyoid and infrahyoid regions of the neck, which makes CN X susceptible to injury. The subtypes of CN X variations were classified as anterolateral, anteromiddle, anteromedial, and medial based on the relative location of the CN X to the CA. The primary outcome parameters were the percentage of CN X variations and differences according to the side and level of the neck.

RESULTS

Out of 55 cadavers, right and left CN X variations were identified in 6 (10.91%) and 18 (32.73%), respectively. The anterolateral type was the commonest type observed on both sides. There are more variations in the infrahyoid neck compared to the suprahyoid region of the neck. 1 right (1.8%) and 5 left CN X (9.09%) were located <2 mm from the lateral border of the ipsilateral thyroid gland.

CONCLUSION

Variations in the CN X position were relatively common on MRI. The variations primarily involved CN X in the lower cervical region with a significant left sided predominance.

CLINICAL RELEVANCE/APPLICATION

In clinical practice, surgeons and interventional radiologists should consider the presence of variations in the CN X position, and take steps to avoid inadvertent CN X injuries, particularly in the left lower cervical region. Also given the extensive variability of CN X, our study highlights the importance of pre-operative imaging of CN X specially using CISS MRI to prevent procedural nerve injuries and complement therapeutic targeting.

M2-SPHN-4 APPLICATION ANALYSIS OF PLAIN MRI WITH DELAYED CONTRAST-ENHANCED TECHNIQUES IN PATIENTS WITH SUDDEN SENSORINEURAL HEARING LOSS

Qingyu Zhang (*Presenter*)
Xueming Zeng (*Abstract Co-Author*)

PURPOSE

By analyzing the clinical and magnetic resonance imaging (MRI) characteristics of sudden sensorineural hearing loss (SSNHL), this study aims to clarify the diagnostic value of MRI and delayed contrast-enhanced techniques in the disease, as well as explore the pathophysiological processes of the inner ear during its onset.

METHODS AND MATERIALS

A retrospective analysis was conducted on clinical data of SSNHL patients treated in the Otolaryngology Department of BenQ Hospital from September 2020 to June 2024. Patients were categorized into four groups based on hearing loss patterns: low-frequency descent, high-frequency descent, flat-type, and total deafness. Inner ear abnormalities, including endolymphatic hydrops and labyrinthine hyperenhancement, were identified using plain T1WI, T2WI, and delayed (8-hour post-contrast) 3D-FLAIR imaging. Statistical analysis was performed on the findings.

RESULTS

Among 215 patients (96 male, 116 female; age 46.69±15.06 years), 40 underwent plain MRI, 58 delayed contrast-enhanced MRI, and 146 combined plain+delayed MRI.Low-frequency group (n=62): 58 underwent contrast-enhanced MRI. Endolymphatic hydrops: 15.5% (9/58); labyrinthitis: 5.2% (3/58).High-frequency group (n=50): 38 underwent contrast-enhanced MRI. Endolymphatic hydrops: 5.3% (2/38); labyrinthitis: 13.2% (5/38).Flat-type group (n=77): 61 underwent contrast-enhanced MRI. Endolymphatic hydrops: 9.8% (6/61); labyrinthitis: 23.0% (14/61).Total deafness group (n=55): 47 underwent contrast-enhanced MRI. Endolymphatic hydrops: 2.1% (1/47); labyrinthitis: 50.1% (24/47). On T1WI plain scans, 19 cases showed higher signal intensity compared to the healthy side:Low-frequency group: 4.7% (2/43);High-frequency group: 4.9% (2/41);Flat-type group: 8.8% (5/57);Total deafness group: 22.2% (10/45)

CONCLUSION

In delayed contrast-enhanced 3D-FLAIR MRI sequences of the inner ear, we observed that the low-frequency hearing loss group predominantly exhibited endolymphatic hydrops as the primary imaging feature, whereas the flat-type hearing loss group and total deafness group more frequently demonstrated inflammatory labyrinthine enhancement characteristics.

CLINICAL RELEVANCE/APPLICATION

The delayed post-contrast 3D-FLAIR imaging technology not only enables precise localization of lesions in peripheral vestibular disorders but also supports preliminary inferential diagnosis of pathological mechanisms in conditions such as Ménière's disease (MD), sudden sensorineural hearing loss (SSNHL), and related pathologies, including endolymphatic hydrops (EH), vascular compromise, inflammation, or hemorrhage.

M2-SPHN-6 IMAGING-GUIDED AI MODEL FOR HIF-1α-DRIVEN RECURRENCE RISK STRATIFICATION IN PAPILLARY THYROID CANCER

Yan Zhou, MD, MD (*Presenter*)

PURPOSE

Accurately predicting recurrence risk in papillary thyroid cancer (PTC) is critical for guiding personalized treatment strategies and improving patient outcomes. This study aimed to establish HIF-1a as a key prognostic biomarker and develop an artificial intelligence (AI)-based model integrating imaging and clinical data for HIF-1a-driven recurrence risk stratification.

METHODS AND MATERIALS

A total of 491 PTC patients were divided into training (n=149), internal test (n=112), and two external test sets (n=110, n=120). Data from TCGA, lab experiments, and our center were used to validate HIF-1a's prognostic role. An AI-driven predictive model was developed using radiomics features from thyroid ultrasound and CT imaging combined with clinical data to predict HIF-1a expression. Ten machine learning algorithms were employed, and model performance was evaluated using the area under the receiver operating characteristic curves, calibration curves, and precision-recall analysis. A web-based risk calculator was developed based on SHapley Additive exPlanations (SHAP) analysis for model interpretation. Recurrence-free survival analysis (RFS) was performed to assess the model's prognostic value across all datasets.

RESULTS

High HIF-1a expression was significantly associated with advanced tumor stage, lymph node metastasis, extrathyroidal extension, and recurrence in PTC. The random forest model exhibited excellent performance, with strong calibration and high precision-recall results. SHAP analysis identified the radscore, Hashimoto's thyroiditis, and tumor size as key predictors of HIF-1a expression. Multi-center validation confirmed the model's ability to predict RFS, with high HIF-1a expression associated with worse outcomes ($p < 0.01$).

CONCLUSION

This study established HIF-1a as a key biomarker for recurrence risk and developed an AI-enhanced model integrating imaging and clinical features for HIF-1a-driven recurrence risk stratification, thus supporting clinical decision-making in PTC patients.

CLINICAL RELEVANCE/APPLICATION

This AI-based model offers a practical tool for preoperative HIF-1a-driven recurrence risk stratification in PTC. Through using HIF-1a as an intermediary biomarker, it links imaging features with tumor biology and recurrence risk, providing a non-invasive way to predict recurrence and guide personalized treatment strategies.

M2-SPHN-8 HIGH RESOLUTION 3D ISOTROPICCISS MR IMAGING OF RECURRENT LARYNGEAL NERVE IN CADAVERS WITH ANATOMIC-RADIOLOGIC CORRELATION: INITIAL EXPERIENCE FROM SPARC-REVA

Shruti Kumari, MBBS (*Presenter*)
Mridhula Muthukumar (*Abstract Co-Author*)
Chris A. Flask, PhD (*Abstract Co-Author*)
Daniel Herzka (*Abstract Co-Author*)
Ari M. Blitz, MD (*Abstract Co-Author*)

PURPOSE

Recurrent laryngeal nerve (RLN) preservation is an essential component of thyroid and parathyroid surgeries. Permanent RLN injury can result in dysphonia, aspiration, and dyspnea with a signi&#7;cant impact on patient quality of life. Pre-operative imaging can determine both the location and trajectory relative to key cervical structures and guide surgical planning or be used with a navigation system during surgery to localize and preserve the RLN in real-time. Imaging RLN is fraught with several technical challenges, including small size and physiological motion in the neck. Routine clinical use of CISS MRI to visualize the vagus nerve and its branches in patients is limited and we hope to address this problem. In our research our aim is to study the extent to which we can visualize the right and left RLNs on CISS MRI in cadavers and lay the foundation for translation of this work to living subjects.

METHODS AND MATERIALS

55 embalmed cadavers were scanned with a 3T MRI scanner using 3D isotropic 0.5-0.6 mm resolution 3D-CISS (Constructive Interference in Steady state), VIBE (Volumetric Interpolated Brain Examination), T1 and T2 TSE, PSIF techniques; a total of 110 CN X were examined. Two readers independently evaluated visualization of the left and right RLN on CISS MRI. Following this the findings were confirmed on anatomic dissection, micro-CT evaluation and histological analysis.

RESULTS

Based on our results we found that 3D CISS MRI is superior in visualizing CN X and RLN compared with other sequences. Out of the 55 cadavers we could confidently identify, and trace left RLN in 27 (49%) and right RLN in 13 (24%) cadavers, with some newly reported anatomic variants.

CONCLUSION

In cadavers the use of 3T CISS MRI allows visualization of left and right RLN in the neck and thorax. There are differences in visualization of left and right RLN, with the left being better visualized. SPARC-REVA is the most comprehensive mapping of CN X and its branches to date, from the perspectives of sample size, range of imaging modalities, lengths of nerve, and imaging resolutions. These data may aid in the translation of this work into clinical imaging for pre-operative identification and pathological detection.

CLINICAL RELEVANCE/APPLICATION

The identi&#7;cation and preservation of the RLN is an essential goal of thyroid and parathyroid surgeries. MRI represents a promising adjunctive technique to assist surgeons in this respect with the potential to decrease RLN injury rates. The future integration of CISS MRI for visualizing the RLN in living subjects, with reasonable imaging acquisition times and motion compensation, holds great promise for routine pre-operative, diagnostic and therapeutic imaging.

M2-SPIN-1 APPLICATION OF DEEP LEARNING-BASED CT QUANTIFICATION OF MUSCLE, VISCERAL FAT, AND INTRAMUSCULAR FAT TO IDENTIFY LABORATORY AND CLINICAL RISK FACTORS FOR SARCOPENIA

Richard Zhuang (*Presenter*)
Arijitt Borthakur, PhD, MBA (*Abstract Co-Author*)
Charles E. Kahn JR, MD, MS (*Abstract Co-Author*)
Jeffrey Duda (*Abstract Co-Author*)
Daniel Rader (*Abstract Co-Author*)
James C. Gee, PhD (*Abstract Co-Author*)
Walter R. Witschey, PhD (*Abstract Co-Author*)
Hersh Sagreiya, MD (*Abstract Co-Author*)

PURPOSE

Sarcopenia, the age-related loss of muscle mass and function, affects 5-10% of the population and causes impaired mobility and increased mortality. However, it is not clinically well-recognized, and muscle estimation methods like DXA lack accuracy. Deep learning CT segmentation can accurately quantify body composition, but prior studies analyzed small sample sizes or lacked comprehensive disease associations. The goal was to apply deep-learning segmentation to CT scans in the Penn Medicine BioBank to quantify body composition trends and identify risk factors associated with sarcopenia.

METHODS AND MATERIALS

Segmentations of abdominal CT scans were performed between the inferior aspect of the lung and inferior aspect of the L5 vertebrae to quantify muscle, visceral fat, and intramuscular fat (IMF). Associations of HDL-C, A1C, and triglyceride levels with body composition were evaluated. Phenome-wide association studies (PheWAS) assessed statistical interactions between clinical phenotypes and the three imaging-derived metrics, adjusting for age, sex, race, and BMI, with statistical significance set at p<2.82E-5 (Bonferroni correction).

RESULTS

Among 6,747 patients, higher HDL-C levels were linked to lower visceral fat and IMF: patients above the 90th percentile exhibited 49.6% less visceral fat and 30.9% less IMF than those below the 10th percentile. In contrast, visceral fat increased by 62.0% with higher A1C and 104% with higher triglycerides, while IMF rose by 43.7% and 39.7%, respectively (<10th to >90th percentile). PheWAS identified multiple disease associations for each imaging phenotype: lower muscle was associated with obesity (p=3.74E-11) and diaphragmatic hernia (p=1.68E-07); higher visceral fat was associated with diabetes (p=6.62E-28) and hypertension (p=3.24E-20); and higher IMF was linked to fluid overload (p=8E-67) and pulmonary heart disease (p=8.79E-48).

CONCLUSION

This study identified quantitative trends of metabolic markers in a large cohort, measuring how muscle volume changes in relation to laboratory values. Furthermore, PheWAS provided insight into comorbidities that may accelerate sarcopenia progression, such as diabetes, obesity, and hypertension. These findings help refine the clinical risk profile for sarcopenia, linking body composition metrics to laboratory results and comorbidities. Future research can explore genetic risk factors via genome-wide association studies.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the potential of integrating AI tools into clinical practice, providing age- and sex-based criteria for body composition and relating them to laboratory values and comorbidities — improving sarcopenia diagnosis, risk stratification, and treatment monitoring.

M2-SPIN-2 CAN AI BE TRUSTED TO SUMMARIZE RADIOLOGY REPORTS FOR PATIENTS? A ROBUSTNESS EVALUATION USING ADVERSARIAL EDITS

Magdalini Paschali, PhD (*Presenter*)
Asad Aali (*Abstract Co-Author*)
Arogya Koirala, BS, MS (*Abstract Co-Author*)
David B. Larson, MD, MBA (*Abstract Co-Author*)
Akshay Chaudhari, PhD (*Abstract Co-Author*)

PURPOSE

Large Language Models (LLMs) show promise in creating patient-friendly summaries of radiology report impressions. However, there is a need to assess their reliability, ideally without manual evaluation. Thus, we propose evaluating LLM-generated summaries by comparing those generated before and after controlled modifications ("adversarial edits") to assess whether they reliably capture the introduced edits.

METHODS AND MATERIALS

We analyzed 5,125 abdominal CT report impressions, systematically creating pairs of original and modified impressions with adversarial edits. These known edits served as ground truth, enabling evaluation of a summarizer LLM (Llama 3.3 70B) without manual annotation. We used two editing approaches: (1) substitution of terms (e.g., anatomy, pathology, confidence terms) to test whether summaries accurately maintained the unaltered facts and correctly reflected the modified terms, and (2) removal of specific imaging findings to test whether the summaries included the expected number of findings before and after the edits. Each approach included difficulty levels of easy, medium, and hard. We used a second LLM (Llama 3.1 8B) to quantify the factual faithfulness, sensitivity to substitutions, certainty fidelity, and absence of hallucinations between the two summaries. We hypothesize that if the evaluator LLM considers the summaries from both original and edited impressions identical, the summarizer LLM failed to adapt its summary to capture the adversarial edits.

RESULTS

After the original impressions were edited with hard term substitutions, LLM-generated patient summaries were fully factually accurate in 51% of cases. Certainty fidelity was correctly maintained in 66% of summaries, while 86% of summaries were sensitive to the substitutions. Hallucinations were introduced in 15% of cases. A negative Spearman correlation (?=-0.22, p<0.01) between factual faithfulness and hallucinations indicated factual inaccuracies coinciding with invented details.

CONCLUSION

Our automated framework for evaluating LLM summaries via adversarial testing revealed that summaries can include factual errors, fail to capture subtle term substitutions, and introduce hallucinations. Thus, systematic evaluation methods that detect such errors are crucial to ensure the reliability of LLMs before deployment.

CLINICAL RELEVANCE/APPLICATION

LLM translation of radiological impressions into layperson language holds promise for improving patient understanding but remains vulnerable to errors. This study introduced a framework to evaluate the accuracy of LLMs for summarization without placing the burden solely on radiologists. The identified potential risks can guide the development of safer patient-facing AI applications.

M2-SPIN-3 RESNETFFT: SEEING BEYOND PIXELS FOR RADIOLOGICAL IMAGE CLASSIFICATION

Stephanie Marie Aguilera, BSc (*Presenter*)
Arie Nakhmani (*Abstract Co-Author*)
Titipat Achakulvisut, PhD, BEng (*Abstract Co-Author*)
Nagasrikanth Kallakuri Kallakuri (*Abstract Co-Author*)
Muhammad Faizyab Ali Chaudhary (*Abstract Co-Author*)
Carlos E. Cardenas, PhD (*Abstract Co-Author*)
Manoj Tanwar, MD (*Abstract Co-Author*)
Surya P. Bhatt (*Abstract Co-Author*)
Sandeep Bodduluri, MS, PhD (*Abstract Co-Author*)

PURPOSE

Conventional deep learning approaches for medical image analysis primarily focus on spatial features, potentially overlooking critical frequency-domain information inherent in radiological images. This study introduces ResNetFFT, a novel architecture augmenting standard ResNet model with Fast Fourier Transform (FFT) features to capture both spatial and frequency characteristics.

METHODS AND MATERIALS

Our ResNetFFT model enhances the conventional ResNet-18 architecture by incorporating FFT features with spatial information. For each input image (2D|3D), we apply FFT to convert spatial data into frequency domain representations. The resulting FFT magnitude coefficients are then concatenated with the original spatial data along the channel dimension, providing the network complementary information from both domains. This enriched input was processed through a modified ResNet-18 architecture with squeeze-and-excitation attention mechanisms to weight feature channel importance dynamically. The model was evaluated on multiple datasets from MedMNIST v2, including chest X-rays, breast mammograms, retinal OCT scans (2D), and lung nodule, fracture, intracranial vessels, and multi-organ CT scans (3D). Performance was assessed using accuracy and area under the ROC curve (AUC) with direct comparisons to ResNet-18 and 2.5D approaches.

RESULTS

ResNetFFT demonstrated superior performance across diagnostic tasks. For 2D datasets, the model achieved 84.9% accuracy and AUC of 0.95 for pneumonia detection (vs. ResNet-18: 81.7%, AUC 0.93), 88.5% accuracy and AUC of 0.90 for breast cancer classification (vs. ResNet-18: 83.2%, AUC 0.88), and 70.8% accuracy with AUC of 0.92 for OCT classification (vs. ResNet-18: 68.3%, AUC 0.89). In 3D volumetric data, ResNetFFT reached 78.1% accuracy and AUC of 0.720 for lung nodule detection (vs. 3D ResNet-18: 75.3%, AUC 0.698), 46.7% accuracy and AUC of 0.624 for fracture classification (vs. 3D ResNet-18: 43.1%, AUC 0.601), 94.0% accuracy and AUC of 0.944 for vessel classification (vs. 3D ResNet-18: 90.2%, AUC 0.921), and 89.0% accuracy with AUC of 0.992 for organ classification (vs. 3D ResNet-18: 85.6%, AUC 0.975). Compared to 2.5D approaches, ResNetFFT showed 3-7% improvement in AUC while maintaining comparable computational efficiency.

CONCLUSION

ResNetFFT enhances medical image analysis by integrating frequency-domain features with spatial information providing a complimentary perspective in diagnostic tasks.

CLINICAL RELEVANCE/APPLICATION

ResNetFFT's improved performance in detecting radiological patterns offers value in scenarios requiring high diagnostic sensitivity, such as early-stage lung nodule detection and vascular abnormality identification.

M2-SPIN-4 ESTABLISHING A SEMANTIC ALIGNMENT FRAMEWORK FOR PRE/POST-CONTRAST CT: TOWARD MULTIMODAL IMAGE CORRESPONDENCE WITH ATTENTION-BASED MATCHING

Kyungwon Yun (*Presenter*)
Jungwon Kwak, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop a semantic alignment framework for pre-/post-contrast CT registration using transformer-based matching, with an emphasis on phase-robust and anatomically adaptive components. The goal is to enable automated subtraction imaging and MPR generation and lay the groundwork for multimodal alignment.

METHODS AND MATERIALS

A transformer-based semantic matcher was implemented with three key components: (1) Token Similarity Masking , which suppresses attention between tokens with large inter-phase intensity differences; (2) ROI-Adaptive Keypoint Filtering , which stratifies keypoints by segmentation-defined anatomical classes and selects top-k salient points per class; (3) Multiplane Keypoint Projection , which aggregates features across axial, sagittal, and coronal planes to improve 3D alignment. Phantom CT data were used to compare performance with ORB. Keypoint feature alignment error (in pixels) was used for quantitative evaluation.

RESULTS

Compared to ORB (mean 35.05 px, s = 61.73 px), the proposed method achieved a substantially lower mean feature distance error of 3.32 pixels with a standard deviation of only 2.77 pixels. Median error also improved from 6.61 px (ORB) to 2.56 px. This indicates not only improved alignment accuracy, but also remarkable consistency and robustness across samples. Subtraction images generated using the proposed alignment showed improved structural coherence.

CONCLUSION

The proposed framework significantly improves CT alignment across contrast phases, offering more accurate and stable correspondence than traditional methods. Its modular design supports integration into clinical post-processing and scalable extension to multimodal imaging.

CLINICAL RELEVANCE/APPLICATION

By enhancing subtraction imaging and anatomical alignment consistency, this method reduces manual effort in vascular imaging workflows and provides a generalizable foundation for future multimodal AI-assisted diagnostic tools.

M2-SPIN-5 AUTOMATED 3D CT REPORT GENERATION USING LLM WITH EXPERT-INFORMED ASSESSMENT

Vanshali Sharma, PhD (*Presenter*)
Andrea Bejar, BA, MD (*Abstract Co-Author*)
Wanying Dou (*Abstract Co-Author*)
Gorkem Durak, MD (*Abstract Co-Author*)
Ulas Bagci, MSc, PhD (*Abstract Co-Author*)

PURPOSE

While large language models (LLMs) have shown promise in generating reports for X-rays and 2D CT slices, comprehensive 3D image-based reporting solutions remain largely unexplored despite their importance in capturing spatial and pathological nuance in clinical practice. Our study aims to: 1) develop an automated system to generate standardized reports for 3D CT scans through LLM integration with 3D imaging; and 2) develop an expert-based validation framework to evaluate clinical acceptability of AI-generated reports.

METHODS AND MATERIALS

We developed 3DRadReport, a novel automated system that analyzes 3D CT scans to generate clinically relevant reports. This system involves a specialized 3D image processing module inspired by recent foundation models, which efficiently extracts relevant image embeddings for interpretation by an LLM (GPT2-Medium). This study involved a public dataset of 50,188 3D chest CT scans with reports. To comprehensively assess report quality, we used both automated metrics and expert validation. For expert evaluation, we developed a web-based scoring system and sampled 200 borderline cases using clinical metric (0.4<GREEN score<0.6). The scoring template included fields for 1-10 rating, missing findings across 17 diagnostic categories, and a qualitative feedback section. This enabled a statistical comparison between the clinical metric and expert ratings to estimate how well the metric reflects clinical efficacy.

RESULTS

For 3,039 test cases, our model achieved strong performance on text-based metrics: Average BLEU: 0.28, METEOR: 0.44, and Average ROUGE: 0.46. The GREEN Score was 0.58±0.26, indicating moderate report quality. Among 200 borderline cases, only 15.6% were expert-accepted, with a modest positive correlation between expert and the GREEN score (Spearman's ? = 0.17, p = 0.019). In a multivariate regression analysis, expert-identified missed findings were the strongest independent predictor of expert ratings, each lowering the rating by 7.2% (p < 0.001). GREEN score-based missed findings (ß = 0.0234, p = 0.028) were positively associated with the ratings but had a substantially weaker impact than expert-marked ones.

CONCLUSION

Our 3D report generation system demonstrated strong text-based performance across a large test set. Our study is the first comprehensive evaluation combining the GREEN score with detailed expert analysis, revealing significant limitations of current clinical metrics and highlighting the need for more robust evaluation tools.

CLINICAL RELEVANCE/APPLICATION

As the first study to systematically evaluate GREEN score performance against expert assessments, it highlights critical gaps in current automated clinical metrics for reliable deployment of 3D reporting solutions.

M2-SPIN-6 DUAL-TASK LEARNING WITH SEMANTICALLY-ENRICHED FEATURES ENHANCES ANALYSIS PERFORMANCE OF AP AND PA CHEST X-RAYS

Hyewon Kang (*Presenter*)
Heeguen Kang (*Abstract Co-Author*)
Hongjun Yoon (*Abstract Co-Author*)
Seongeun Lee (*Abstract Co-Author*)
Sohyun Jeong (*Abstract Co-Author*)

PURPOSE

To address performance degradation in automated chest X-ray (CXR) interpretation for anteroposterior (AP) views compared to posteroanterior (PA) views, we developed and evaluated deep learning (DL) models to enhance semantic understanding, robustness, and general performance. Existing approaches often suffer from label noises, ambiguous findings, and domain mismatches from pretraining non-clinical data. We hypothesized that learning deeper semantic structures could improve classification of predefined abnormalities and generalize better across views.

METHODS AND MATERIALS

Model 1 was a standard classification network with an ImageNet-pretrained encoder to classify five chest abnormalities: consolidation (CSN), pneumothorax (PTX), nodule or mass (NDL), fibrosis (FIB), and pleural effusion (PEF). Model 2 added an image reconstruction decoder, in comparison to model 1, to promote semantic feature learning while sharing the same classification task. Both models were fully fine-tuned with basic augmentations using 1,600,905 CXR images from three public datasets and four private hospitals (82.09% normal). External evaluation was performed using a separate private dataset (272 images; 40.44% normal) and the public ChestX-Det dataset (2,216 images; 24.55% normal).

RESULTS

Model 2 showed overall performance gains when evaluating with AP, PA, and collective view images improving mAUROC of 0.019 (AP: +0.0179, PA: +0.0223) in public and 0.0286 (AP: +0.0358, PA: +0.0359) in private dataset when compared to model 1. In the public dataset, the AP-PA AUROC gap was modestly reduced (Model 1: -0.0198; Model 2: -0.0158). In the private dataset, the gap remained stable (Model 1: +0.0496; Model 2: +0.0497). For individual findings, Model 2 improved view consistency for PTX (?AUROC: -0.1023 to -0.0211, p=0.0089) and FIB (?AUROC: +0.1309 to +0.0995, p=0.0002) in the public dataset. In the private dataset, CSN, FIB, and NDL showed favorable but non-significant trends. No notable differences were observed for PEF.

CONCLUSION

Adding a reconstruction task to abnormality classification improved model performance under full fine-tuning, regardless of view. Model 2 selectively improved robustness for PTX and FIB in the AP-PA performance gaps. Learning deeper semantic features may enhance view-invariant diagnostic consistency.

CLINICAL RELEVANCE/APPLICATION

Semantic-aware learning strategies can improve CXR classification performance and reduce view-related gaps, enhancing reliability and fairness of AI-assisted interpretation in clinical practice.

M2-SPIN-7 A GENERALIZABLE AI-BASED BONE MINERAL DENSITY CLASSIFICATION FROM CONTRAST AND NON-CONTRAST SPINE CT SCANS

Christian Wiedemeyer (*Presenter*)
Niklas Eisl (*Abstract Co-Author*)
Karine Louis (*Abstract Co-Author*)
Marko Zlatic (*Abstract Co-Author*)
Patrick Schmidt (*Abstract Co-Author*)
Lea-Elena Braunschneider (*Abstract Co-Author*)
Pia Zimmermann (*Abstract Co-Author*)
Valentin Koch (*Abstract Co-Author*)

PURPOSE

We aimed to develop and validate a generalizable, contrast-aware algorithm for the automatic classification of osteoporosis and osteopenia from sagittal spinal CT scans, to support routine clinical diagnosis with high specificity and adequate sensitivity in order to minimize unnecessary follow-up procedures.

METHODS AND MATERIALS

We collected data from a diverse, multi-center cohort that included CT scans from seven scanner manufacturers and 32 different scanner models. We compiled two independent datasets: one for training a contrast phase correction model (n = 633 studies) and another for bone mineral density (BMD) classification (n = 779 studies). To assign ground truth BMD categories (normal, osteopenia, or osteoporosis) we used T-scores from matched DEXA scans obtained from the same patients. We included only cases where the DEXA scan occurred between 30 days before and 90 days after the CT scan to minimize treatment-induced label shifts. Radiologists manually reviewed all data after strict anonymization.For BMD analysis, we selected CT scans that covered at least three vertebrae and segmented the vertebral bodies using TotalSegmentator, a U-Net based model. We trained a separate model on the contrast phase dataset to correct for intravenous contrast, ensuring consistency in HU measurements. After segmenting the vertebrae, we isolated the spongiosa region and calculated the median Hounsfield Unit (HU) values for each vertebra. Using cross-validated grid search, we determined sex-specific HU thresholds to classify BMD. We then evaluated the model on a fully independent holdout set (n = 184) to validate classification performance.

RESULTS

The contrast correction model significantly reduces the measured HU value difference between contrast-enhanced and uncontrasted scans (R^2 from 0.86 to 0.96) from the same study. The BMD prediction model achieves 60.0% sensitivity and 88.0% specificity on the holdout set. Subgroup analyses revealed consistent performance across sex and age groups as well as contrast presence, with no evidence of systematic bias. Qualitative evaluations confirmed robust segmentation and prediction behavior.

CONCLUSION

To the best of our knowledge, this is the first CT-based algorithm capable of classifying bone mineral density across the entire spine in both contrast-enhanced and non-contrast scans. It demonstrates strong performance under real-world conditions and represents a substantial step forward in opportunistic osteoporosis screening.

CLINICAL RELEVANCE/APPLICATION

This algorithm enables accurate, automated BMD assessment from routine CT scans, supporting opportunistic osteoporosis screening and aiding early detection to help prevent fractures.

M2-SPIN-8 SEQUENCE-AWARE MTANN FOR SEGMENTATION OF RARE SOFT-TISSUE SARCOMAS IN MULTI-SEQUENCE MRI WITH MISSING SEQUENCES

Wahyu Rahmaniar (*Presenter*)
Haitian Zhang (*Abstract Co-Author*)
Yuqiao Yang, MS (*Abstract Co-Author*)
Fumihiko Nakatani (*Abstract Co-Author*)
Mototaka Miyake, MD, PhD (*Abstract Co-Author*)
Kenji Suzuki, PhD (*Abstract Co-Author*)

PURPOSE

Rare soft-tissue sarcomas (STS), accounting for less than 1% of adult cancers, pose diagnostic and therapeutic challenges due to heterogeneity and limited data. As conventional deep learning models require large datasets, their effectiveness is limited for rare cancers. We developed a clinically applicable model that accurately segments STS in MRI, even with small datasets and incomplete sequences, capturing fine anatomical details and dynamically adapting to available imaging to improve diagnosis and treatment planning.

METHODS AND MATERIALS

A dataset of 155 patients with benign and malignant tumors (STS) was collected, including 155 T2-weighted (T2w) and 76 gadolinium-enhanced (GD) MRI scans. Tumors were manually segmented by a radiologist and verified by an orthopedic surgeon. We propose a sequence-aware massive-training artificial neural network (SA-MTANN) comprising: (1) a multi-kernel MTANN backbone, (2) a multi-resolution mechanism, and (3) a sequence-aware (SA) module. The multi-kernel MTANN processes 3D patches using different receptive fields to capture global and local tumor features. The multi-resolution mechanism integrates high-, mid-, and low-resolution representations for enhanced context. Outputs are up-sampled and combined through a weighted sum to create the segmentation map. The SA module adapts to missing sequences by pooling and dynamically weighting T2w and GD features; when GD is absent, the model relies on T2w alone, maintaining robust performance. The model is trained with binary cross-entropy loss at the patch level with post-processing refinement.

RESULTS

The dataset was divided into large (109 cases), medium (54 cases), and small (26 cases) subsets, with 20 cases for testing (9 T2w+GD, 11 T2w only). The main metric was the Dice similarity coefficient (DSC). SA-MTANN achieved DSCs of 83.0%, 80.6%, and 78.7% for large, medium, and small sets, respectively, outperforming nnU-Net and U-Net, particularly in small datasets. The SA module was crucial for handling missing GD sequences, maintaining accuracy with T2w-only inputs. SA-MTANN also provided superior boundary delineation compared to nnU-Net and MAML.

CONCLUSION

We developed a sequence-aware deep learning model for rare cancer segmentation, excelling with limited datasets and incomplete imaging. SA-MTANN dynamically adapts to available inputs, outperforming conventional models. It maintains high accuracy without GD and requires fewer computational resources, making it ideal for clinical use in rare cancers with limited infrastructure.

CLINICAL RELEVANCE/APPLICATION

Our method enables accurate STS segmentation from limited T2 MRI data, using low resources and improving clinical decision-making despite rare cancer imaging challenges.

M2-SPIN-9 DIFFICULTY-BASED ACTIVE BOOSTING FOR ROBUST LUNG NODULE CLASSIFICATION WITH MULTI-EXPERT MTANN ENSEMBLE

Shogo Kodera (*Presenter*)
Seyed Mohammad Chavoshian (*Abstract Co-Author*)
Hiroko Oshibe (*Abstract Co-Author*)
Ze Jin, PhD (*Abstract Co-Author*)
Kenji Suzuki, PhD (*Abstract Co-Author*)

PURPOSE

Deep learning (DL) AI for diagnostic aid has shown promise but requires extensive training data and expensive GPU resources, limiting clinical adoption. While massive-training artificial neural network (MTANN) operates efficiently with limited data, recent research indicates that combining multiple specialized MTANNs as expert models yields higher classification performance than using a single comprehensive MTANN. We developed a Difficulty-Based Active Boosting (DBAB) framework using histogram-based resampling to create and ensemble specialized MTANN submodels.

METHODS AND MATERIALS

LIDC-IDRI database with 381 malignant and 303 benign nodules was utilized. Nodules were processed into 51×51×51 voxel volumes of interest. Using 3-fold cross-validation, one-third of the data served as training/validation with two-thirds as testing. Our framework involves: 1) Training an initial MTANN on a small subset; 2) Analyzing malignancy-score histograms to identify difficult nodules: malignant nodules with low scores (false negative (FN) risk) and benign nodules with high scores (false positive (FP) risk); 3) Strategically resampling these challenging cases to train expert submodels for FN and FP reduction; 4) Integrating outputs through a neural network. This approach systematically targets specific nodule types that cause overlapping distributions.

RESULTS

We developed a histogram-guided DBAB framework that strategically creates expert MTANN submodels to robustly handle challenging nodule types. This systematic approach significantly improved classification accuracy and robustness by reducing overlap in malignancy score distributions, leading to fewer FNs and FPs. In addition, with exceptional parameter efficiency (0.034M parameters) enables CPU operation, making it practical for clinical deployment where high-performance computing resources are unavailable.

CONCLUSION

We developed a histogram-guided DBAB framework that strategically creates expert MTANN submodels to robustly handle challenging nodule types. This systematic approach significantly improved classification accuracy and robustness by reducing overlap in malignancy score distributions, leading to fewer FNs and FPs. In addition, with exceptional parameter efficiency (0.034M parameters) enables CPU operation, making it practical for clinical deployment where high-performance computing resources are unavailable.

CLINICAL RELEVANCE/APPLICATION

By enhancing robustness against difficult-to-classify lung nodules, our DBAB MTANN ensemble supports radiologists in achieving more accurate diagnoses. Its CPU compatibility further enables AI in practical use without high-end hardware.

M2-SPIN-10 BEYOND PIXELS: RADIOLOGIST ASSESSMENT OF AI-GENERATED MAMMOGRAM REALISM, DISTINGUISHABILITY, AND THE INFLUENCE OF CLINICAL EXPERIENCE

Stephanie Nadine Benz, MD (*Presenter*)
Marc Molina (*Abstract Co-Author*)
Maria Luiza Teixeira (*Abstract Co-Author*)
Julia Stefanne Santos Simao (*Abstract Co-Author*)
Daniela Sarahi Ramirez Figueroa, MD (*Abstract Co-Author*)
Felice A. Burn, MD (*Abstract Co-Author*)

PURPOSE

Generative AI offers potential for synthetic medical imaging data, yet clinical realism is critical. Standard metrics may miss nuances discernible by experts. This Turing test with radiologists assessed synthetic mammogram verisimilitude, aiming to understand expert perception complexities and identify assessment factors, informing robust evaluation and guiding AI development towards clinical utility.

METHODS AND MATERIALS

Six radiologists of varying experience evaluated 420 mammograms (140 real; 140 Diffusion; 140 StyleGAN). Real 2048x2048 images were from an in-house dataset used for model training. Participants assessed realism (0-100), classified images as real/synthetic, and noted micro-calcifications. Responses and decision times were recorded.

RESULTS

Overall, radiologists distinguished synthetic from real mammograms with sensitivity 0.66 and specificity 0.74. Performance varied by experience; more experienced radiologists showed lower error rates, less experienced approached chance-level decisions for synthetic images. Inter-radiologist agreement for image classification was slight overall (average Cohen's Kappa: 0.217), yet this varied markedly with experience: ranging from slight to moderate. Higher synthetic image realism correlated positively with increased radiologist detection error. Additionally, incorrect real image classifications incurred significantly longer assessment times. Diffusion model images were rated more realistic than GANs and incurred longer assessment times.

CONCLUSION

This Turing test revealed Diffusion models generated mammograms perceived as more realistic than GAN, though neither fully replicated real image characteristics. Radiologist experience critically impacted synthetic image identification and substantially modulated inter-rater agreement. The correlation between higher realism and detection difficulty, alongside variations in inter-radiologist consistency linked to experience, highlights complexities in expert visual assessment. These findings, including varied decision times, underscore that robust generative AI validation in medical imaging must account for observer experience and multiple perceptual factors to ascertain synthetic data reliability, guiding development towards genuine clinical value.

CLINICAL RELEVANCE/APPLICATION

Robustly evaluating synthetic medical images using expert radiologists, considering experience, is crucial for the safe integration of generative AI into clinical training, research, and potential diagnostic support.

M2-SPIN-11 IMPROVED PENETRATING BRAIN INJURY CASE MANAGEMENT THROUGH ATTENTION-BASED MULTIPLE INSTANCE LEARNING

Jordan Fuhrman, PhD (*Presenter*)
Ali Mansour (*Abstract Co-Author*)
Olga Pasternak Wise, MD, MS (*Abstract Co-Author*)
Joel Toledo-Urena (*Abstract Co-Author*)
Farima Fakhri (*Abstract Co-Author*)
Fernando Goldenberg (*Abstract Co-Author*)
Maryellen L. Giger, PHD (*Abstract Co-Author*)

PURPOSE

To develop improved understanding of the imaging manifestation of penetrating brain injury (PBI) and utilize predictive models to better stratify patients based on outcomes and treatment response.

METHODS AND MATERIALS

This IRB-approved retrospective study analyzed head CT (HCT) images obtained from PBI patients from our local Level 1 Trauma Center. Inclusion criteria were if the patient 1) was older than 16 years old, 2) suffered a PBI caused by gunshot wound to the head, 3) showed dural injury on initial HCT, and 4) was not pronounced dead on arrival to the hospital. Ultimately, we obtained a dataset of 230 cases, with 110 survivors and 120 deceased. The MIDRC Generalized Stratified Sampling algorithm was used to split cases into training and testing sets with matched distributions of survival% and GCS, giving 174 training cases and 56 test cases, which were utilized for machine learning model development and evaluation, respectively. We implemented a deep attention-based multiple instance learning (AMIL) algorithm to predict patient mortality from initial HCT. Briefly, this approach extracts deep learning embeddings from individual HCT slices via a pre-trained ResNet50 model, then aggregates slice information into an HCT representation to predict likelihood of survival. Performance was evaluated via ROC analysis in the binary mortality prediction task with 95% confidence intervals estimated via 1000 bootstrap iterations. We compared predictions with GCS and provided model interpretability via attention weight curve,

conveying which regions were, on average, most important to the classification decision. Finally, we obtained an external dataset of 102 military PBI cases on which to evaluate model generalizability.

RESULTS

The AMIL approach achieved an AUC of 0.90 [80, 0.96], comparing favorably to standard risk scores (Rotterdam AUC=0.80, Marshall AUC=0.66) and other published models. A case-by-case comparison of the AMIL predictions with GCS shows moderate agreement, with deviations explicable given broader context. Similarly, the attention weight curve reveals that the model found higher relative importance in lower brain regions (e.g., below the 3 rd ventricle), agreeing with clinical expectation. The model generalized to the external validation set with an AUC of 0.85 [0.75, 0.93].

CONCLUSION

The AMIL approach has demonstrated significant potential in evaluating PBI cases, achieving strong performance on both internal and external data while matching clinical expectations for GCS comparison and explainable output.

CLINICAL RELEVANCE/APPLICATION

Current clinical standards do not properly evaluate PBI. This AI study is a strong first step toward improving PBI case stratification and management.

M2-SPIN-12 DEBLURRING ULTRASOUND IMAGES TO IMPROVE CLASSIFICATION OF THICKENED SYNOVIUM

Pascal N. Tyrrell, PhD (*Presenter*)
Youyang Guo (*Abstract Co-Author*)
Noushin Jafarpisheh (*Abstract Co-Author*)

PURPOSE

To determine if a deblurring masked auto-encoder (DeblurMIM (Kang et al, 2023)) improves automated detection of thickened synovium with the presence of knee recess distension on knee musculoskeletal ultrasound compared with a published convolutional neural-network (CNN) baseline (Balla et al, 2024) trained for detecting thickened synovium.

METHODS AND MATERIALS

The study is the first application of DeblurMIM to musculoskeletal ultrasound to my knowledge. In this retrospective study, 4,389 suprapatellar ultrasound images (1,651 positive; 2,738 negative) were balanced by patient and splitted 70/10/20 % by patient for training, validation, and testing. A DeblurMIM encoder was first pretrained to reconstruct sharp images from synthetically blurred inputs (Gaussian s = 1.1; mask ratio 75 %). The pretrained encoder was then fine-tuned with a MLP. The comparator was an EfficientNet-B4 CNN retrained under identical data partitions. Five-fold patient-level cross-validation was performed. Accuracy was the primary metric to evaluate the model; AUROC, sensitivity, and specificity were secondary metrics. Differences were assessed with paired bootstrap resampling (5,000 replicates); $p < 0.05$ denoted significance.

RESULTS

DeblurMIM achieved an accuracy of 79.4 %, outperforming the CNN baseline (71.5 %) by 7.9 percentage points (95 % CI 3.5 - 11.6; $p < 0.001$). AUROC improved from 0.81 to 0.87 (+0.06), and sensitivity increased from 0.58 to 0.80 (+0.22). Specificity decreased non-significantly from 0.84 to 0.78 (CI includes 0). Under additional synthetic blur (s = 2.5), DeblurMIM preserved 93 % of its original accuracy, whereas the baseline retained 96 %, but the absolute performance gap remained = 5 percentage points across all blur levels.

CONCLUSION

Learned deblurring with a masked auto-encoder significantly enhances classification of thickened synovium on knee ultrasound and remains robust under increased image blur. The higher sensitivity comes at a modest loss of specificity; threshold optimization may be required in settings where rate of false positives needs to be reduced. DeblurMIM represents a practical preprocessing strategy to improve musculoskeletal ultrasound interpretation without enlarging training datasets. Limitation: The network was exposed only to synthetic Gaussian blur during pretraining, which may lead to overfitting and reduced generalizability to real-world degradations such as speckle noise. Diverse image noises and imperfections are needed for multicentre validation.

CLINICAL RELEVANCE/APPLICATION

By recovering diagnostically useful detail from blurred MSK-US frames, DeblurMIM could support earlier, more reliable detection of thickened synovium in routine clinical settings.

M2-SPIN-13 INCORPORATING RADIOLOGISTS' EYE-GAZE IN MACHINE LEARNING MODELS IMPROVES IDENTIFICATION OF UNCOMMON FINDINGS: A PROOF-OF-CONCEPT STUDY

Prateek Prasanna, PhD (*Presenter*)
Moinak Bhattacharya (*Abstract Co-Author*)

PURPOSE

Long-tailed disease classification from chest X-rays remains a critical challenge due to the imbalance between frequent and rare pathologies. While radiologists can accurately interpret incidental findings through dynamic visual attention, deep learning models often fail to detect such underrepresented "tail-class" diseases due to training data imbalance. We introduce GazeLT, a novel radiologist-in-the-loop framework that incorporates temporal eye gaze patterns of radiologists to improve long-tailed classification performance.

METHODS AND MATERIALS

GazeLT models the temporal visual search process of radiologists using an integration-disintegration mechanism that captures both fine-grained and coarse-level features. The framework is trained and evaluated on two large-scale public datasets: NIH-CXR-LT (n = 89,237) and MIMIC-CXR-LT (n = 111,898). The model uses gaze-conditioned attention modules to prioritize clinically relevant regions across time windows during image interpretation. Baselines include state-of-the-art long-tailed loss functions and visual attention-based models without temporal gaze integration.

RESULTS

GazeLT outperforms the best-performing long-tailed loss function by 4.1% and a visual attention-based baseline by 21.7% in average accuracy across both datasets. The greatest improvements are observed in the classification of rare pathologies, validating the effectiveness of modeling temporal gaze dynamics.

CONCLUSION

Integrating radiologist eye gaze into deep learning architectures significantly enhances performance in long-tailed classification tasks. GazeLT provides a novel strategy for incorporating expert-level attention patterns into medical image interpretation.

CLINICAL RELEVANCE/APPLICATION

GazeLT demonstrates the potential of human-in-the-loop AI systems to improve diagnostic performance, especially for rare diseases often missed by traditional AI models. This approach could help bridge the gap between expert radiology practice and automated interpretation in real-world clinical settings.

M2-SPIR-1 FACTORS CONTRIBUTING TO LOCAL RECURRENCE OF HEPATOCELLULAR CARCINOMA AFTER TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION: INCORPORATING TEXTURE ANALYSIS OF CONE-BEAM CT DURING HEPATIC ARTERIOGRAPHY

Hideki Ishimaru, MD, PhD (*Presenter*)
Tomoki Nakano, MD (*Abstract Co-Author*)
Satomi Yoshimi (*Abstract Co-Author*)
Shuto Miyamura (*Abstract Co-Author*)
Oka Taiga (*Abstract Co-Author*)
Takamasa Nishimura (*Abstract Co-Author*)
Chika Somagawa, MD (*Abstract Co-Author*)
Ryo Toya, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to investigate the factors contributing to local recurrence after transcatheter arterial chemoembolization (TACE) by incorporating texture analysis data from CT during hepatic arteriography using cone-beam CT (CBCTHA).

METHODS AND MATERIALS

Of 257 HCC nodules (101 patients) treated with TACE between October 2019 and February 2024, 96 nodules (62 patients) were enrolled and retrospectively analyzed after excluding nodules smaller than 2 cm in diameter that were difficult to analyze using 3D volumetric analysis. At the beginning of the TACE treatment session, CBCTHA was obtained by injecting one-half diluted iodine contrast medium through the proper or common hepatic artery (the imaging delay was 4sec). 3-D angiography generated from CBCTHA data was used to identify each target lesion and feeding arteries. Chemoembolization was performed as selectively as possible with 1.7-F microcatheters and involved the injection of a mixture of anticancer drug (up to 50 mg of epirubicin) and emulsified lipiodol. Embolization was performed using gelatin sponge particles. The CBCTHA data were loaded onto a 3D workstation. Two radiologists in consensus manually segmented the tumor volumetric region of interest on the CBCTHA, and texture parameters (kurtosis, skewness, and entropy) were calculated. In addition to texture parameters, several other factors were correlated with the local recurrence rate through a univariate analysis using the Cox proportional hazards model. These factors included age, sex, tumor size and number, AFP, PIVKA-II, BCLC stage, and systemic drug therapy prior to TACE. Factors with a significance level of $p < 0.20$ were included in the multivariate model.

RESULTS

In the univariate analysis, tumor size, AFP, PIVKA-II, and entropy emerged as risk factors for local recurrence, with $P < 0.05$. The P values for kurtosis and skewness were 0.36 and 0.07, respectively, in the same analysis. In the multivariate analysis, systemic drug therapy before TACE (Lenvatinib prior to TACE, hazard ratio 3.14, $P<0.01$), tumor size (hazard ratio 7.78, $P=0.03$), and entropy on CBCTHA (hazard ratio 0.11, $P=0.01$) were identified as independent risk factors for local recurrence.

CONCLUSION

CBCTHA-derived tumor entropy, tumor size, and lenvatinib administration prior to TACE were predictors of local recurrence after TACE.

CLINICAL RELEVANCE/APPLICATION

Entropy of tumors observed on cone-beam CT during hepatic arteriography serves as an indicator for forecasting local recurrence following TACE.

M2-SPIR-2 BLOCKING IL-6/STAT3 SIGNALING PATHWAY TO INHIBITS HEPATIC METASTATIC GROWTH FOLLOWING RADIOFREQUENCY ABLATION

Haixing Liao, PhD (*Presenter*)
Yu Yi Cai (*Abstract Co-Author*)
Zheng-Nan Lai (*Abstract Co-Author*)
Peirong Fang (*Abstract Co-Author*)
Qing Tang (*Abstract Co-Author*)
Lian-Tu He (*Abstract Co-Author*)
Yuanzhen Liu (*Abstract Co-Author*)

PURPOSE

To evaluate targeted blockade of IL-6/STAT3 inflammatory signaling pathway can effectively suppress tumor burden after radiofrequency ablation (RFA), while elucidating its underlying molecular mechanisms.

METHODS AND MATERIALS

Eighty mice(40 normal mice,20 IL-6KO mice,and 20 STAT-3KO mice) were used in this institutional animal care and committee-approved study. First, a mouse hepatic metastasis model was established by implanting 2*10 5 tumor cells via splenic injection followed by immediate splenectomy.The mouse colorectal cancer tumor cell lines, MC38, was injected into C57B/6 mice. Next, animals were randomized to receive either standardized RFA or a sham procedure 24hr post-transplantation. Procedures were performed by means of laparotomy that exposed the liver surface for placement of a 21-gauge needle with a 1-cm exposed tip. Energy was titrated to a mean temperature of 70°C±1 for 300sec. Sham procedures consisted of electrode placement without energy application. The whole liver was harvested at 21 days for MC38 to permit quantification of tumors. Data were compared with analysis of variance and two-tailed Student t test.

RESULTS

For C57BL/6 mice with MC38 tumor implantation,RFA of 3.5%±0.02 of the mouse liver volume induced an increased tumor load distributed throughout the entire liver in comparison to that of sham procedure (RFA vs Sham:100.6±60.7 vs 43.0±22.4,$P<0.05$). For IL-6 KO and STAT-3 KO C57BL/6 mice with MC38 tumor implantation, tumor counts were measured at two diameter thresholds (>3 mm and <3 mm). Post-RFA versus sham treatment showed no statistically significant difference in tumor

count and the proportion of liver surface area occupied by tumors (IL-6 KO experiment:34.17 vs. 19.43; P = 0.0569)(STAT-3 KO experiment:41.1 ± 30.4 vs. 40.0 ± 23.1; P = 0.941). (The proportion of liver surface area occupied by tumors: 42.0% ± 14.5 vs.30.2% ± 7.0; P = 0.092).In MC38 cells genetically modified via CRISPR-Cas9 to knock out STAT3,it also revealed no significant difference in tumor count between RFA and sham groups (43.5 vs. 40.0; P = 0.788).

CONCLUSION

RFA significantly increase tumor load in normal mice by activating the inflammatory microenvironment.However,after systemic knockout of IL-6 or STAT3,RFA fails to induce significant tumor growth, indicating that IL-6/STAT3 inflammatory signaling pathway plays a critical role in RFA-induced tumor progression.

CLINICAL RELEVANCE/APPLICATION

Targeting IL-6/STAT3 signaling pathway effectively suppresses pro-tumorigenic inflammation triggered by RFA, offering a robust experimental foundation to refine adjuvant therapeutic strategies post-RFA.

M2-SPIR-4 PREOPERATIVE EMBOLIZATION CAN REDUCE INTRAOPERATIVE BLOOD LOSS AND PERIOPERATIVE BLOOD TRANSFUSION FOR SPINAL TUMOR RESECTIONS

Yanqing Zhao, MD (*Presenter*)

PURPOSE

Spinal tumor surgeries are associated with challenges such as massive intraoperative blood loss (IBL), perioperative blood transfusion (PBT), and prolonged surgery time (ST). However, the efficacy of preoperative embolization (PE) across different surgical approaches remains controversial. This study aimed to evaluate the impact of PE on IBL, PBT, and ST in spinal tumor en-bloc resections and debulking surgeries, while identifying associated risk factors and assessing the safety of PE.

METHODS AND MATERIALS

A single-center ambispective cohort study of 706 patients (374 males; mean age, 51.0 ± 16.2 years) with primary and metastatic spinal tumors treated between January 2015 to December 2023 was analyzed. Among them, 208 underwent PE (en-bloc resection = 122, debulking surgery = 86), and 498 did not (en-bloc resection = 83, debulking surgery = 415).Statistical analyses included Wilcoxon rank-sum tests, Fisher's exact tests, and Poisson regression to identify associations and calculate incidence rate ratios (IRR).

RESULTS

PE significantly reduced IBL and PBT in en-bloc resections compared to non-PE cases(both $p < 0.001$). In debulking surgeries, PE significantly decreased PBT ($p = 0.002$).Multivariate analyses identified non-PE cases (both $p < 0.001$) and tumors involving =2vertebrae (both $p < 0.001$) as independent risk factors for increased IBL and PBT, whilehypovascular tumors were associated with significantly lower IBL (IRR = 0.840, $p = 0.001$).Coil + particle embolization (n = 103) significantly outperformed coil-alone embolization (n =105), reducing IBL ($p = 0.002$), PBT ($p < 0.001$), and ST ($p = 0.001$). Adverse events occurred in34 patients (16.35%), with 32 mild and 2 moderate cases.

CONCLUSION

PE can reduce IBL and PBT in spinal tumor surgeries, particularly in en-blocresections and hypervascular tumors. Coil + particle embolization offers superior efficacy overcoil-alone embolization in minimizing IBL, PBT, and ST.

CLINICAL RELEVANCE/APPLICATION

Preoperative embolization (PE) proved highly effective in optimizing outcomes forspinal tumor en-bloc surgeries, significantly reducing intraoperative blood loss (IBL) andperioperative blood transfusions (PBT) compared to non-PE cases. Furthermore, non-PE casesand tumors involving =2 vertebrae were identified as significant risk factors for increased IBLand PBT. Notably, coil + particle embolization enhanced the benefits of PE, markedly reducingIBL, PBT, and surgery time compared to coil-alone embolization.

M2-SPIR-5 PROTECT THE RECURRENT LARYNGEAL NERVICES IN US-GUIDED MICROWAVE ABLATION OF THYROID NODULES AT ZUCKERANDL TUBERCLE: A PILOT STUDY

Ziyue Hu (*Presenter*)
Man Lu, PhD (*Abstract Co-Author*)

PURPOSE

MWA is a new and important minimally invasive treatment option that can be used to treat benign and malignant tumors of the thyroid, breast, liver, and lung. Numerous studies have demonstrated that MWA is a safe and effective technique to reduce the volume of thyroid nodules. However, recurrent laryngeal nerve (RLN) injury is still a prevalent complication, with neurological abnormalities described in 1.0-9.1% of patients. Moreover, if the patient has thyroid nodules at the Zuckerkandl tubercle (ZTTN), the RLN is at a higher risk of damage as the ZTTN is located in close proximity to the RLN. In this context, we employed high-frequency ultrasound (US) to preoperatively visualize the RLN and to lower the risk of the RLN injury during MWA for ZTTN. The purpose of our study was to evaluate the safety and efficacy of US-guided MWA in patients with ZTTN.

METHODS AND MATERIALS

103 consecutive patients with thyroid nodules at Zuckerkandl tubercle (ZTTN) were enrolled in this study from November 2017 to August 2021. Prior to the surgery or US-guided microwave ablation (MWA), preoperative ultrasound visualization of the recurrent laryngeal nerve (RLN) and ZTTN was performed, the size and the position relationship between them were observed. Patients were followed up at 1, 3, 6, and 12 months after MWA and the volume reduction rates (VRR) of the thyroid nodules were analyzed.

RESULTS

All patients successfully had the RLN and ZTTN detected using ultrasound before surgery or ablation with a detection rate of 100%. For the 103 patients, the majority of ZTTN grades were categorized as grade 2, with the distance from the farthest outside of ZTTN to the outer edge of thyroid ranging between 6.0 and 10.0 mm. The position relationship between ZTTN and RLN was predominantly type A in 98 cases, with type D observed in 5 cases. After MWA, the median nodule volume had significantly decreased from 4.61 (2.34, 8.70) ml to 0.42 (0.15, 1.41) ml and the VRR achieved 84.36±13.87% at 12 months. No nodules regrew throughout the 12-month follow-up period. Of the 11 patients experienced hoarseness due to RLN entrapment before ablation, 7 recovered immediately after separation of the RLN and ZTTN during MWA, 2 recovered after one week, and the other 2 recovered after two months.

CONCLUSION

In conclusion, the RLN is closely related to ZTTN and mainly located at the back of it. Hydrodissection during MWA can separate the RLN from ZTTN. US-guided MWA is a safe and efficient treatment for ZTTN. Accurate identification of the RLN during MWA is crucial to protect the nerve and prevent nerve damage.

CLINICAL RELEVANCE/APPLICATION

The RLN is closely related to ZTTN and mainly located at the back of ZTTN. The RLN can be separated from ZTTN by hydrodissection during MWA. US-guided MWA is a safe and effective treatment for ZTTN.

M2-SPIR-6 PREDICTING CRYOABLATION OUTCOMES IN RENAL CELL CARCINOMA USING 3D VOLUMETRIC IMAGING FEATURES

Chih-Ying Huang, MD (*Presenter*)
Jia-An Hong, MD (*Abstract Co-Author*)

Nai-Wen Chang, MD (*Abstract Co-Author*)
Chih Chien Li, MD (*Abstract Co-Author*)
Chien An Liu, MD (*Abstract Co-Author*)
Shu Huei Shen, MD (*Abstract Co-Author*)

PURPOSE

Cryoablation has been established as an effective treatment for renal cell carcinoma (RCC). This study aimed to implement automated segmentation of renal structures on pre-treatment CT images, extract relevant imaging features, and identify potential predictors of treatment outcomes following cryoablation in RCC.

METHODS AND MATERIALS

Patients with RCC who underwent cryoablation were included. Pre-treatment CT images were processed to generate segmentation masks for the kidney, tumor, cysts, and renal sinus. Relevant imaging features were extracted and analyzed to assess their associations with treatment response.

RESULTS

A total of 142 patients were included. Univariable logistic regression revealed significant associations between local tumor control and both tumor volume (P=.001) and the contact area between the tumor and the renal sinus (P<.001). Multivariable logistic regression further demonstrated that larger tumor volume (P=.019, OR=1.043) and a greater tumor-renal sinus contact area (P=.002, OR=1.340) were independently associated with failure of local tumor control. Additionally, the Cox proportional hazards model showed that a greater tumor-renal sinus contact area (P=.019, HR=1.261) was significantly associated with local tumor progression following complete cryoablation.

CONCLUSION

Tumor volume and the contact area between the tumor and the renal sinus were associated with failure of local tumor control following cryoablation in RCC. A greater tumor-renal sinus contact area was also predictive of local tumor progression despite complete cryoablation.

CLINICAL RELEVANCE/APPLICATION

Pre-treatment imaging features may serve as predictive markers for treatment outcomes following cryoablation in RCC, potentially guiding clinical decision-making.

M2-SPMK-2 DIAGNOSTIC PERFORMANCE AND RELIABILITY OF QUALITATIVE ASSESSMENT AND QUANTITATIVE PARAMETERS DERIVED FROM THIRD-GENERATION DUAL-ENERGY CT FORDIAGNOSING ANTERIORCRUCIATE LIGAMENT INJURY

Xiao-Ling Ma (*Presenter*)

PURPOSE

This study aims to investigate the diagnostic value of visual assessment and quantitative parameters derived from third-generation low-dose dual-energy CT (DECT) in detecting the integrity of anterior cruciate ligament (ACL) in patients with acute trauma.

METHODS AND MATERIALS

Patients with unilateral knee joint injury who were scheduled to undergo ACL reconstruction or suture were prospectively enrolled. The bilateral knees of all participants were examined by third-generation dual-source DECT and 3.0 T MRI, followed by arthroscopy of the knee joint within two weeks. Two radiologists independently observed ACL staining in Bone Marrow 2 color-coded map of Mono+ mode, blinded to patients' clinical information, where the normal ACL was stained to be dark red while the injured ACL was stained lightly or almost unstained. Then the mixed-energy CT value, 50 Kev CT value, electron cloud density (Rho), effective atomic number (Z) and Rho/Z were measured and compared between intact ACLs and torn ACLs in mixed-energy mode, Mono+ mode and Rho/Z mode, respectively. MRI examination and knee arthroscopy were used as the reference standards.

RESULTS

A total of 66 patients diagnosed with unilateral ACL injury were enrolled. The sensitivity, specificity, PPV and NPV of dual-energy staining reduction for diagnosing ACL injury were 93.9%, 90.9%, 91.2% and 93.8%. The intraclass correlation coefficients for quantitative parameters ranged from 0.848 to 0.930, indicative of excellent agreement. The mixed-energy CT value, 50 Kev CT value, Rho and Rho/Z of the injured ACLs were significantly lower than those of the intact ACLs (all P <0.001), and Z value of the injured ACLs was slightly higher than that of the intact ACLs (P =0.006). The optimal cutoff values of mixed-energy CT, 50 Kev CT, Rho, Z and Rho/Z for diagnosing ACL injury were 69.5, 68.1, 65.6, 7.55 and 8.9, with AUCs of 0.997, 0.987, 0.958, 0.652 and 0.952. The mixed-energy CT value had highest diagnostic efficacy in diagnosing ACL injury [sensitivity, 1.000 (95% CI: 0.894, 1.000); specificity, 0.970 (95% CI: 0.842, 0.999); PPV, 0.971 (95% CI: 0.844, 0.999); NPV, 1.000 (95% CI: 0.891, 1.000)]. No statistically significant difference was found in diagnostic efficacy of MRI and dual-energy CT in detecting ACL injury (P =0.731).

CONCLUSION

The visual assessment and quantitative parameters derived from the third-generation dual-source DECT harbor a satisfactory performance in detecting ACL injury.

CLINICAL RELEVANCE/APPLICATION

The visual assessment and quantitative parameters derived from third-generation dual-source DECT are expected to replace MRI as a promising imaging approach for evaluating the integrity of ACLs and the maturity of autologous ACL transplantation after surgery.

M2-SPMK-3 FROM INCIDENTAL TO INTENTIONAL: UNLOCKING BONE HEALTH INSIGHTS FROM ROUTINE CT DATA

Bryn Matheson (*Presenter*)
Matthias Walle (*Abstract Co-Author*)
Steven K. Boyd, PhD (*Abstract Co-Author*)

PURPOSE

Computed tomography (CT) scans represent a vast, underutilized resource for the opportunistic assessment of bone health. However, the lack of standardized, publicly available automated analysis tools and large-scale normative reference cohorts has limited their application in clinical settings. This study demonstrates the feasibility of an automated, open-source workflow that combines deep learning segmentation and density calibration to extract volumetric bone mineral density (vBMD) from real-world clinical CT scans to generate normative centile curves.

METHODS AND MATERIALS

A retrospective cohort of 4602 clinical CT scans was obtained from 35 health centres across Alberta, Canada. Scans were excluded if patients were taking bone-altering medications at the time of the scan or had a documented history of hip fracture. Automated segmentation of the first lumbar vertebra (L1) and calibration tissues was performed using a custom-trained nnU-Net model. A previously established internal calibration approach was used to convert Hounsfield Units (HU) to bone-equivalent densities. The integral vBMD (mg/cc) of the L1 was calculated. Age- and sex-based comparisons were performed using Mann-Whitney U tests. Centile curves were generated using Generalized Additive Models for Location, Scale and Shape (GAMLSS).

RESULTS

The cohort included 2461 males and 2143 females. Sex differences were observed in vBMD ($p<0.05$), and age-stratified analysis (<50 vs >50 years) revealed significant declines in both groups with increasing age ($p<0.01$). Females exhibited a substantially greater reduction in vBMD than males (-31% vs -12%), particularly during the 40 to 60-year range, likely reflecting accelerated bone loss perimenopause.

CONCLUSION

This study showcases the feasibility of fully automated vBMD extraction from clinical CT by integrating image processing, deep learning, and density calibration with large-scale real-world data. While this analysis was performed at the vertebral level, this approach can be applied to any musculoskeletal site. The resulting site- and sex-specific centile curves provide a foundation for osteoporosis screening and diagnosis.

CLINICAL RELEVANCE/APPLICATION

Most existing tools for vBMD measurement from large-scale clinical CT data are expensive and operate as black-box systems with limited transparency, which makes integration into clinical settings challenging. In contrast, our open-source approach (https://github.com/Bonelab/Ogo) offers a free, transparent, and reproducible alternative. Generating population-based normative data using fully automated tools marks significant steps toward integrating bone health assessment into routine imaging and broadening access to bone health assessment.

M2-SPMK-4 CLINICAL ASSESSMENT OF TECHNIQUES FOR MINIMIZING METAL ARTIFACTS IN PHOTON COUNTING CT SCANS FOR LUMBAR FIXATION EVALUATION

Liu Xing (*Presenter*)

PURPOSE

To compare the image quality of Monoenergetic Plus 190keV and iterative Metal Artifact Reduction (iMAR) technique in patients with lumbar fixation.

METHODS AND MATERIALS

Sixty patients were prospectively enrolled and randomly assigned to two groups, with examination performed using Siemens photon counting CT (NAEOTOM Alpha). Group A patients underwent examination using Twin-Beam (TB) scanning mode, with 190keV images reconstructed using Monoenergetic Plus technique, while group B patients underwent examination using single-energy scanning mode, with images reconstructed using iterative Metal Artifact Reduction (iMAR) technique. The standard deviation (SD) values of the high-density artifacts area, low-density artifacts area, and surrounding soft tissue regions at the most severe metal artifacts in the two groups of images were measured. Independent sample T-test was utilized to compare the differences between the two groups. Two senior radiologists utilized the 5-component table (1~5 points, non-assessable ~ excellent) method to score the metal artifacts removal ability and overall image quality of the two groups of images. Mann-Whitney U test was used to compare the subjective scores of the two groups of images, and the consistency of the scores was analyzed by Kappa test.

RESULTS

In terms of objective measurements, the SD values for group A were significantly lower than those of group B (Group A=63.5±49.3, Group B=134.7±73.8; t=-3.492, P<0.05). When it comes to the subjective assessment of metal artifact removal, the images from group A were rated higher than group B (Group A: 4.33±0.61, Group B: 3.12±0.90; P<0.05), and the consistency of the two groups' image evaluations was good (Kappa=0.603, P<0.05). However, for the subjective assessment of overall image quality, the images from group A were rated lower than group B (Group A: 3.01±0.66, Group B: 4.12±0.52; P<0.05) with excellent consistency (Kappa=0.901, P=0.000).

CONCLUSION

When examining patients with lumbar fixation, Monoenergetic Plus 190keV images have demonstrated superior ability in reducing metal artifacts compared to iMAR algorithms. However, the iMAR technique was found to be more effective in improving the overall subjective quality of the images.

CLINICAL RELEVANCE/APPLICATION

Different clinical situations may require different imaging techniques and reconstruction methods to ensure accurate diagnosis and treatment. Therefore, selecting the appropriate scanning and reconstruction methods based on specific clinical needs can be crucial for achieving optimal results.

M2-SPMK-5 ASSOCIATION OF CT-DERIVED BIOLOGICAL AGE WITH ALL-CAUSE MORTALITY IN THE NATIONAL LUNG SCREENING TRIAL

Leon Lenchik, MD (*Presenter*)
Fang-Chi Hsu (*Abstract Co-Author*)

PURPOSE

There is increasing interest in using CT scans as biomarkers of aging. Our purpose was to use a novel large vision-language model based on three-dimensional (3D) CT scans to determine the biological age of older adults and examine its association with all-cause mortality in the National Lung Screening Trial (NLST).

METHODS AND MATERIALS

13,311 baseline CT scans from older adults (mean age: 64.8 years, age range: 60-74 years;) in the NLST were partitioned into an 80% training set (10,648 CT exams) and a 20% testing set (2,663 CT exams). We developed a biological age prediction model using a publicly available large vision-language model (Merlin). First, we encoded each 3D CT dataset into a 512-dimensional vector. We then used a prediction head consisting of a two-layer perceptron to output the biological age. During the training phase, the parameters within Merlin model were fixed but the weights of the prediction head were optimized. In the test set, the biological age was predicted using the trained model. The associations between biological and chronological age with all-cause mortality were determined using logistic regression models, adjusted for sex, race, pack-years of smoking, and body mass index.

RESULTS

In the 2,663 individuals (1064 women, 1599 men) in the test set, the CT-derived biological age had a mean absolute error (MAE) of 2.74 years. At a mean 6 years of follow-up, 240 (9.01%) of individuals were deceased. Both the CT-derived biological age and patients chronological age were associated with all-cause mortality. The odds ratio (OR) for CT-derived biological age was 1.22 (95%CI: 1.15, 1.29); p<0.0001). For patient chronological age, the OR was 1.12 (95% CI: 1.08, 1.16; p<0.0001).

CONCLUSION

CT-derived biological age was associated with all-cause mortality in a large heterogeneous population of older adults.

CLINICAL RELEVANCE/APPLICATION

Large vision language models allow for measurement of surrogates of biological age on CT exams. CT-derived biological age can improve clinical practice by helping develop novel prediction models for adverse health outcomes in older adults.

M2-SPMK-6 IMPACT OF CALCIUM SUPPRESSION IMAGING ON HAND AND WRIST FRACTURE DETECTION IN SPECTRAL CT: A COMPARISON WITH X-RAY AND CT

Thomas Marth, MD (*Presenter*)
Franziska Adomat (*Abstract Co-Author*)
Fides Schwartz, MD (*Abstract Co-Author*)
Reto Sutter, MD (*Abstract Co-Author*)
Anna L. Falkowski, MD (*Abstract Co-Author*)

PURPOSE

Calcium suppression (CaSupp) bone imaging from spectral computed tomography (SpCT) can detect bone marrow edema, such as in the setting of acute fractures. However, its impact on fracture detection in clinical routine is not yet fully understood.

METHODS AND MATERIALS

Retrospective evaluation of both 127 X-ray and 127 SpCT examinations of the hand and wrist of 125 patients (male/female, 60/67; mean age, 55 ± 19.5 years). Three successive readouts were conducted with a minimum time interval of four weeks. The first reading was performed using X-ray images only, the second with conventional

CT images only, and the third with conventional CT images plus CaSupp images reconstructed from SpCT data. Two readers evaluated images independently for the presence of fractures. Fracture counts were evaluated and compared for each readout. Inter-reader agreement was assessed using kappa statistics.

RESULTS

Reader 1 rated a total of 162 bones as fractured on X-ray images, 180 on CT images, and 193 on conventional CT plus CaSupp images. Reader 2 rated 184 bones as fractured on X-ray, 191 on conventional CT and 203 on conventional CT plus CaSupp images. When using CaSupp images alongside conventional CT, compared to conventional CT images alone, reader 1 identified a total of 13 additional fractures (four scaphoid, two capitate, two metacarpale I, two ulna, one lunate, one triquetrum, and one metacarpale V fracture), while reader 2 found 12 additional fractures (three lunate, two triquetrum, one scaphoid, one ulna, one metacarpale I, one radius, one trapezium, one capitate, and one hamate fracture). Inter-reader agreement for fractures was moderate for X-ray (& 81;;=0.44), moderate to substantial for conventional CT (& 81;;=0.52), and almost perfect for CaSupp images combined with conventional CT (& 81;;=0.92).

CONCLUSION

CaSupp images of the hand and wrist, when combined with conventional CT images, can reveal additional fractures missed on X-ray and conventional CT images alone. In particular, fractures of the carpal bones could be revealed due to the presence of bone marrow edema in CaSupp images.

CLINICAL RELEVANCE/APPLICATION

As missed fractures lead to poor patient outcomes and high costs for the health care system, reconstruction and evaluation of CaSupp images of the inherently available spectral raw data in spectral dual-layer CT systems are recommended for fracture diagnosis.

M2-SPMK-7 AI-DRIVEN ASSESSMENT OF VERTEBRAL ROTATION IN ADOLESCENT IDIOPATHIC SCOLIOSIS USING WEIGHT-BEARING CONE-BEAM CT

Jianrong He (*Presenter*)
Zejun Liang (*Abstract Co-Author*)
Yiteng Zhang (*Abstract Co-Author*)
Yu Zhang (*Abstract Co-Author*)
Zhenlin Li (*Abstract Co-Author*)
Jing Tang (*Abstract Co-Author*)

PURPOSE

To assess the accuracy of an AI algorithm for quantifying vertebral rotation angles on weight-bearing cone-beam CT images in AIS patients, and to investigate how well the two-dimensional Nash & Moe grading system represents three-dimensional vertebral rotation under weight-bearing conditions.

METHODS AND MATERIALS

This prospective study included 72 adolescents diagnosed with AIS. Six vertebrae per patient were selected and measured manually by two experienced radiologists. All vertebrae were also analyzed using a U-Net-based deep learning algorithm to obtain automated vertebral rotation angles. Nash & Moe grades were independently assessed from standing radiographs. Agreement between automated and manual 3D measurements was evaluated using intraclass correlation coefficients and correlation analyses. The explanatory power of Nash & Moe grades for 3D vertebral rotation was analyzed by linear regression.

RESULTS

The automated measurement of vertebral rotation angles showed good agreement and strong correlation with manual measurements (Intra-class correlation coefficient=0.882, Spearman R=0.900, both $p < 0.001$). The linear relationship between automated and manual measurements was strong for thoracic ($R\ 2 = 0.777$) and lumbar vertebrae ($R\ 2 = 0.792$). Nash & Moe grades showed moderate explanatory power for 3D vertebral rotation angles measured by the algorithm, with R^2 values of 0.549 (thoracic) and 0.629 (lumbar) in linear regression model. Similar R 2 values were obtained between Nash & Moe grades and manual rotation measurements ($R\ 2 = 0.526$ for thoracic and $R\ 2 = 0.621$ for lumbar vertebrae).

CONCLUSION

Our AI-driven measurement algorithm enables accurate quantification of vertebral rotation under weight-bearing conditions. In comparison, the 2D Nash & Moe classifications only offers an approximate estimation of vertebral rotation and lack the precision required for detailed assessment.

CLINICAL RELEVANCE/APPLICATION

This AI-based 3D measurement approach may enhance the diagnostic precision of scoliosis assessment, offering clinicians a more objective and reproducible tool for evaluating vertebral rotation in standing AIS patients. It could inform better treatment planning and improve monitoring of disease progression.

M2-SPMS-1 CODE-FREE DEEP LEARNING (CFDL) IN CLASSIFYING RADIOGRAPHIC IMAGES FOR KNEE OSTEOARTHRITIS (KOA) AND PEDIATRIC PNEUMONIA

Matthew Bilson, BA (*Presenter*)
Andrew Farah (*Abstract Co-Author*)
Peter Joseph Mounsef (*Abstract Co-Author*)
Wassim Elmasry, MD (*Abstract Co-Author*)
James Man Git Tsui (*Abstract Co-Author*)
Natalia Gorelik, MD, MPH (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility of using code-free deep learning (CFDL) to classify radiographic images, by (1) comparing its performance against state-of-the-art (SOTA) models for grading knee osteoarthritis and (2) assessing its accuracy in distinguishing between types of pediatric pneumonia.

METHODS AND MATERIALS

Medical students with no prior programming experience utilized CFDL to develop models for classifying knee osteoarthritis (KOA) severity and pediatric pneumonia subtypes. The public KOA dataset, obtained from the NIH, includes 9,786 radiographic images annotated with Kellgren-Lawrence (K-L) severity scores (2,578 minimal, 1,286 moderate, 295 severe). The public pneumonia dataset, sourced from Guangzhou Women and Children's Medical Center, consists of pediatric 5,856 chest radiographs labeled as normal (1,582), viral (1,494), or bacterial (2,780). Google Cloud AutoML Vertex AI, a plug-and-play platform that automates model building and hyperparameter tuning, was used to develop classification models. The datasets were split into training, validation, and testing sets (70:10:20 for KOA as per SOTA, and 80:10:10 for pneumonia). Performance was evaluated using accuracy from the test set. For KOA, results were compared to SOTA models, while for pediatric pneumonia, only the accuracy was reported, as no direct comparisons were available.

RESULTS

Vertex AI achieved an accuracy of 86.3%, compared to the reported SOTA performance of 89.0% in classifying KOA images. For pediatric pneumonia, the model reached an accuracy of 83.2%.

CONCLUSION

Vertex AI performed comparably to SOTA for the classification of KOA severity and better than chance regarding pediatric pneumonia. CFDL democratizes AI, enabling clinicians without programming experience to achieve near-expert performance.

CLINICAL RELEVANCE/APPLICATION

Code-free AI tools like Vertex AI allow for accurate KOA grading and paediatric pneumonia triage. Thus, these models can be used expertly by those with little coding experience and is scalable in low-resource settings.

M2-SPNMMI-1 POTENTIAL OF LARGE LANGUAGE MODELS FOR PROOFREADING PET REPORTS

Wolfgang Roll (*Presenter*)
Max Masthoff, MD (*Abstract Co-Author*)
David Ventura (*Abstract Co-Author*)
Clemens Backhaus (*Abstract Co-Author*)
Michael Schaefers, MD (*Abstract Co-Author*)
Kambiz Rahbar (*Abstract Co-Author*)
Lucas Plagwitz (*Abstract Co-Author*)
Philipp Schindler, MD (*Abstract Co-Author*)

PURPOSE

The aim of this study was to investigate the ability of three large language models (LLMs), GPT-o1 DeepSeek R1-70b and Llama 3.3-70b, to detect common errors in anonymized German PET/CT and PET/MRI reports.

METHODS AND MATERIALS

A retrospective dataset of 200 consecutive PET reports (100 correct, 100 with up to three artificially introduced errors each) was used. A total of 183 deliberately introduced errors were categorised as spelling & grammar, content or technical. Each report was presented to the three LLM with the same single prompt without subsequent modifications. The number of correctly identified errors and the time taken to complete each log were recorded.

RESULTS

Overall, GPT-o1 detected 84.2% (154/183) of the errors, significantly outperforming DeepSeek R1-70b (47.0%, 86/183) and Llama 3.3-70b (57.4%, 105/183; $p < 0.001$). GPT-o1 also showed superior detection rates for spelling & grammar (76.8% vs. 25.3% vs. 38.9%) and technical (97.1% vs. 57.1% vs. 65.7%) errors. The detection of content errors did not differ significantly between the three models ($p = 0.406$). Reading time per report was significantly faster for GPT-o1 (28 ± 4 seconds), followed by Llama (48 ± 8 seconds) and DeepSeek (108 ± 29 seconds) ($p < 0.0001$).

CONCLUSION

In PET/CT and PET/MRI reports based on German texts, GPT-o1 demonstrated the highest error detection rate of the LLMs evaluated. Future efforts to optimize and potentially fine-tune privacy-compliant open-source models might further improve their accuracy.

CLINICAL RELEVANCE/APPLICATION

Imaging reports are the key component of information transfer between the imaging specialist and the referring physician. Final review and approval of these report is done by board-certified imaging specialists. Increasing workload in PET-CT, due to novel tracers and technical developments, e.g. large axial field of view scanners, underlines the need for technical improvements also in error detection, potentially by the help of LLM.

M2-SPNMMI-2 PROSPECTIVE EVALUATION OF COMFORTABLE OPEN-COIL MRI FOR WHOLE-BODY PET/MRI

Fatemeh Rashidi, MD (*Presenter*)
James Wang (*Abstract Co-Author*)
Alan B. McMillan, PhD (*Abstract Co-Author*)
Ali Pirasteh, MD (*Abstract Co-Author*)

PURPOSE

Evaluate the potential of whole-body PET/MRI using the scanner’s embedded posterior array (PA) and transmit/receive (TR) in combination. This novel approach (c omfortable o pen coil M RI f or whole-body i maging, COMFI) enables a PET/MRI setup/experience that is similar to PET/CT (more streamlined and comfortable than traditional full coil PET/MRI).

METHODS AND MATERIALS

This was a prospective single-center study using a single scanner (Signa PET/MR, GE Healthcare). To assess image quality, Dixon-fat-suppressed T2- and T1-weighted images were obtained on healthy volunteers using COMFI and full coil setups (consecutively) with identical parameters. To assess lesion detectability, patients referred for clinical PET/MRI underwent COMFI PET/MRI shortly after the full coil clinical exam with identical parameters. A dual-board-certified radiologist/nuclear medicine physician reviewed anonymized full coil and COMFI exams independently, blinded, separated by a washout period and in randomized order. To assess image quality (in healthy volunteers), 4 anatomical regions (head/neck, thorax, abdomen/pelvis, and musculoskeletal) were evaluated on each T1- and T2-weighted images using a 5-point Likert scale; scores =3 were considered diagnostic. An exam was rated diagnostic if all anatomic regions rated =3 on one image series. To assess lesion detectability (in patients), lesions suspicious for malignancy were recorded in the following regions (up to 20 per region): liver, pancreas, bowel, lung, bones, lymph nodes, and other less common regions. Average scores and number of lesions were compared between COMFI and full coil exams using the paired t test; $P < 0.05$ was considered significant.

RESULTS

Full coil and COMFI setups yielded diagnostic quality exams among all 22 healthy volunteers. Full coil setup yielded higher image quality than COMFI on a per-sequence basis, respective average scores 3.8 and 4.8, $P<0.01$). Among the 11 patients enrolled, full coil and COMFI PET/MRI respectively detected 113 and 120 lesions ($P=0.07$). There was no lesion detected on full coil PET/MRI that was missed on COMFI PET/MRI.

CONCLUSION

Patient setup without anterior surface coils and with hybrid utilization of the embedded PA and T/R coils can provide diagnostic quality PET/MRI exams with potentially no compromise in lesion detectability. COMFI setup may not be sufficient for exams that need dedicated high-quality MRI of an anatomic region; further investigation is needed to demonstrate its diagnostic accuracy and potential improvement in patient comfort and access.

CLINICAL RELEVANCE/APPLICATION

PET/MRI without anterior surface coils can improve workflow and patient comfort/access without compromising lesion detectability, thus improving PET/MRI utilization.

M2-SPNPM-1 ENVIRONMENTAL SUSTAINABILITY IN RADIOLOGY: SWITCH FROM PAPER-BASED TO DIGITAL OUTPATIENT APPOINTMENT COMMUNICATION

Aly Muhammad Ladak (*Presenter*)
Hayley Panet (*Abstract Co-Author*)
Daphne Antonopoulos (*Abstract Co-Author*)
Ania Z. Kielar, MD, FRCPC (*Abstract Co-Author*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)

PURPOSE

There is growing interest in digital communication systems in healthcare. However, there is limited data on the associated environmental benefits in radiology. The purpose of this study was to determine greenhouse gas emissions and paper waste avoided by switching from paper-based to digital communications for outpatient medical imaging appointment scheduling.

METHODS AND MATERIALS

This retrospective study employs a natural experimental design, leveraging an unplanned national postal strike to evaluate the impact of disrupted mail-based appointment communication at an academic medical imaging department covering 5 hospital sites. The Canada Post strike disrupted the ability to send outpatient MRI appointment letters from November 15 to December 17, 2024, necessitating a temporary switch to digital-only communication (telephone and electronic patient portal). The control period was defined as the rest of 2024, with baseline paper-based mail communication of all outpatient MRI appointments scheduled more than 30 days in advance. Environmental impact was evaluated as paper waste and greenhouse gas emissions in carbon dioxide equivalents (CO 2 e) avoided.

RESULTS

A total of 54,158 outpatient MRIs were scheduled in 2024, of which 41,333 (76.3%) were booked more than 30 days in advance (3970 with digital-only communication during the strike period and 37,360 with paper-based communication during the control period). GHG emissions were significantly lower with digital compared to paper-based mail communication (median 1.2 kg/day CO 2 e, IQR 0.5-1.3 kg/day vs. 24.0 kg/day CO 2 e, IQR 17.2-30.8 kg/day, p<0.001). Compared to baseline paper-based mail communication, digital appointment communication avoided 155.2 g CO 2 e GHG emissions (95.6% reduction) and 11.3 g paper waste (100% reduction) per MRI, with no difference in the proportion of missed (no-show) appointments (43 [1.1%] vs. 521 [1.4%], p=0.11). A permanent switch to digital appointment communication for outpatient MRI would avoid 465 kg of paper waste and 6414 kg CO 2 e per year in one department, equivalent to 16,335 miles driven by an average passenger vehicle. Extrapolating across Canada, this change could avoid 786 metric tons of paper waste and 10,837 metric tons CO 2 e per year, equivalent to 2258 homes' electricity use for one year.

CONCLUSION

The adoption of digital-only appointment communication for outpatient MRI led to a significant reduction in GHG emissions and paper waste without increasing the proportion of missed appointments.

CLINICAL RELEVANCE/APPLICATION

Unexpected events, such as a national postal strike, can be leveraged to build environmentally sustainable and climate-resilient radiology departments by bouncing forward rather than back to baseline after a disruption.

M2-SPNPM-2 CLINICAL PRODUCTIVITY AND COMPENSATION FOR RADIOLOGISTS ACCORDING TO PRACTICE TYPE

Dheeman Futela, MBBS (*Presenter*)
Ajay Malhotra, MD, MMM (*Abstract Co-Author*)

PURPOSE

To assess recent trends in clinical productivity and compensation of radiologists according to practice and provider characteristics.

METHODS AND MATERIALS

We studied deidentified data from the American Medical Group Association for providers in "Radiology: Non-interventional" (DR) and "Radiology: Interventional" (IR) specialties from survey years 2019 and 2023. Primary outcomes were total clinical compensation (CC), work RVUs performed (wRVUs), and clinical compensation per unit work RVU (CC/wRVU). Outcomes were adjusted to 1.0 clinical full-time equivalent (FTE) and compared using non-parametric statistical tests. Trends over time were analyzed as percentage growth in median values and compared to overall market inflation using the consumer price index (CPI).

RESULTS

The 2023 AMGA survey included compensation and productivity responses from 1791 diagnostic radiologists and 386 interventional radiologists. DRs had a lower median CC ($561K vs $708K) with greater wRVUs (10673 vs 8087) compared to IRs (P<.001). Therefore, median CC/wRVU for DRs ($56) was significantly lower than IRs ($81, P<0.001). Non-academic practice was associated with a greater median CC ($592K) and wRVUs (11239) compared to medical schools ($569K and 10566) and teaching hospitals ($557K and 10124) (P<.001). However, CC/wRVU was lowest for non-academic DRs ($53), followed by medical school ($56), and highest for teaching hospitals ($58) (P<.001). Practices of group size fewer than 50 had the highest CC ($656) and wRVU (12932), and the lowest median CC/wRVU ($49) among all practice types. Since 2019, median CC for DRs increased by 8.9% and median CC/wRVU increased by 3.6%, both lagging behind the consumer price index (18.8%). According to physician characteristics, age less than 40 years, female gender, and less than 10 years in practice were associated with lower median CC; however, CC/wRVU did not differ significantly by age, gender, or years in practice (P>.05).

CONCLUSION

Non-academic practices and practices with smaller group sizes are associated with the highest CC but lowest CC/wRVU. CC/wRVU did not vary by physician age, gender or years in practice. Between 2019-2023, CC increased but trailed behind market inflation. Further, increased productivity during this interval resulted in stagnant CC/wRVU.

CLINICAL RELEVANCE/APPLICATION

This study shows clinical compensation and productivity trends according to practice types to inform both practice managers and newly graduating or early career radiologists. Using this data could help in address staffing, ensuring access to care for patients, and negotiations for subsidies, or additional sources of funding, especially in the face of decreasing reimbursements and academic consolidation.

M2-SPNPM-3 UNDERUTILIZATION OF FOLLOW-UP IMAGING AMONG INCARCERATED PATIENTS: A RETROSPECTIVE ANALYSIS OF ADHERENCE TO RADIOLOGIC RECOMMENDATIONS

Yu Sakai, MD (*Presenter*)
Daniel Lee (*Abstract Co-Author*)
Regina O. Redfern, BS (*Abstract Co-Author*)
Tessa S. Cook, MD, PhD (*Abstract Co-Author*)
Rose Onyeali (*Abstract Co-Author*)
Colbey W. Freeman, MD (*Abstract Co-Author*)

PURPOSE

The United States has a significant incarcerated population, with approximately 1.5 million persons in state and federal prisons and over 10 million admitted to local jails annually. Incarcerated patients face significant obstacles in obtaining medical care. No study has systematically examined adherence to follow-up imaging recommendations in currently incarcerated individuals. We hypothesize that incarcerated patients have a lower rate of successful imaging follow-up compared to broader populations.

METHODS AND MATERIALS

This retrospective, single-center study utilized the electronic medical record (EMR) to identify radiology reports for incarcerated individuals admitted to the emergency department or inpatient. Identification of incarceration status was based on correctional facility addresses, phone numbers, or incarceration-related discharge flags from Pennsylvania, New Jersey, and Delaware. Reports were screened using a structured text-query to identify potential recommendations (“recommend” and/or “follow-up”). Two radiologists manually reviewed each report to determine inclusion. Inclusion criteria included use of definitive language (e.g., “recommends” rather than “optional”) and time-specific suggestions for follow-up imaging, endoscopy, and/or biopsy. EMRs were then searched to assess follow-up adherence, defined per the American College of Radiology as 30 days before and 60 days after the recommended follow-up interval.

RESULTS

Between January 2017 and November 2024, 15,680 imaging records (accessions) were identified for incarcerated patients. Screening by text-query yielded 1,891 records. Manual review yielded 243 individual radiology reports that met inclusion criteria. Among these, 83 (34.2%) showed evidence of any follow-up, of which only 37 (15.2%) were true outpatient follow-up. 24 (9.9%) were completed incidentally during subsequent emergency department visits or readmissions, and 22 (9.1%) during the initial ED or inpatient encounter. The 15.2% follow-up rate is markedly lower than the above 50% adherence rate reported in broader populations (Mabotuwana et al., AJR 2019) and lower than reported rates of 46% and 36% in ED and inpatients, respectively (Hansra et al., JACR 2021).

CONCLUSION

Timely outpatient follow-up occurred in fewer than one in six cases among incarcerated individuals, a rate notably lower than in the general population.

CLINICAL RELEVANCE/APPLICATION

There is potentially a critical gap in continuity of care for incarcerated patients. Future efforts could focus on improving care coordination, facilitating access to outpatient imaging, and exploring follow-up strategies tailored to the needs of incarcerated and recently released individuals.

M2-SPNR-1 HIGH PERFORMANCE HEAD GRADIENT SYSTEM AND MULTI-ECHO RESTING STATE FMRI ENHANCES SENSITIVITY FOR FUNCTIONAL NETWORKS AND CONNECTIVITY IN NEUROLOGICAL STUDIES FOR BRAIN TRAUMA

Jiayu Shao (*Presenter*)
Herman Morris, PhD (*Abstract Co-Author*)

PURPOSE

The use of fMRI in neuroradiology is limited by the challenge of distinguishing neurological function related signals from physiological noise. This often results in longer scan durations, increasing both patient burden and costs. High-performance head gradient (HPHG) MRI systems may help address these limitations. Their faster slew rates enable the acquisition of multiple gradient echoes (ME) within the time typically required for a single echo (SE) on conventional whole body clinical systems. Here, we discuss how HPHG scanners improve fMRI performance, offering enhanced imaging speed, signal sensitivity, and resting state network detection.

METHODS AND MATERIALS

Eight healthy volunteers (mean [SD] age: 34.3 years [11.2]; 4 females) were scanned on a General Electric MAGNUS 3.0 T scanner. Resting-state T2*-weighted BOLD images were acquired using a Nova 3T 32-channel head coil and a 3-echo ME imaging sequence (TR = 1900 ms; TEs = 11, 21, 32 ms). A high-resolution T1-weighted anatomical image (MPRAGE) was also obtained. The third gradient echo was used to simulate a conventional SE acquisition. Data were preprocessed using the AFNI software package (Cox 1999), denoised with the ANATICOR method, and combined across ME acquisitions using the Tedana method (Kundu 2011). The resulting residual time series were registered to standard Talairach space. Temporal signal-to-noise ratio (tSNR) was calculated by dividing the voxel-wise time series mean by its standard deviation. Resting-state functional connectivity (rsFC) was assessed by computing the Pearson correlation between a Default Mode Network (DMN) seed, extracted from a functional atlas (Yeo 2011), and the rest of the brain in each participant.

RESULTS

We evaluated HPHG fMRI performance using tSNR as a measure of signal sensitivity. In all four brain lobes, the ME method showed a significant tSNR advantage over SE, with the most notable improvements in the frontal and occipital lobes. To assess the practical impact of this increased sensitivity, we conducted an rsFC analysis. We derived DMN-to-whole-brain rsFC maps from both SE and ME datasets. The ME data revealed more specific and sensitive functional connectivity, identifying more connections at a higher statistical threshold compared to the SE data.

CONCLUSION

HPHG scanners enable faster image acquisition and shorter gradient echo-times compared to conventional scanners. The ME fMRI method on an HPHG scanner produced more sensitive measures of resting-state fMRI, and better detection of functional networks compared to SE methods available on conventional systems.

CLINICAL RELEVANCE/APPLICATION

HPHG ME fMRI reduces scan times and produces superior functional brain mapping results in neuroradiology examinations for better diagnosis.

M2-SPNR-5 INTRA-ARTERIAL THROMBOLYTIC VS. MECHANICAL THROMBECTOMY IN DISTAL MEDIUM MIDDLE CEREBRAL ARTERY ACUTE ISCHEMIC STROKE: A PRELIMINARY MULTINATIONAL MULTICENTER PROPENSITY SCORE-MATCHED STUDY

Hamza A. Salim, MD (*Presenter*)
Benjamin Pulli, MD (*Abstract Co-Author*)
Vivek Yedavalli, MD, MS (*Abstract Co-Author*)
Dhairya Lakhani, MD (*Abstract Co-Author*)
Adrien Guenego, MD (*Abstract Co-Author*)
Adam A. Dmytriw, MD,FRCPC (*Abstract Co-Author*)
Max Wintermark, MD (*Abstract Co-Author*)

PURPOSE

Optimal treatment for acute ischemic stroke due to distal medium-vessel occlusion (DMVO) in the middle cerebral artery (MCA) is uncertain. Mechanical thrombectomy (MT) may carry higher risks in DMVO. Intra-arterial thrombolysis (IAT) might be a safer alternative. We compared outcomes of IAT and MT in MCA DMVO patients.

METHODS AND MATERIALS

We conducted a retrospective, multicenter, propensity score-matched study within the MAD-MT registry, including patients with acute ischemic stroke due to MCA DMVO (M2, M3, M4 segments) who underwent IAT or MT, with or without intravenous thrombolysis. Propensity score matching controlled for confounders. The primary outcome was an excellent functional outcome, defined as a modified Rankin Scale score of 0 to 1 at 90 days.

RESULTS

After matching, 184 patients were analyzed (19 IAT, 165 MT). Baseline characteristics were balanced. At 90 days, an excellent functional outcome was achieved in 37% of IAT patients and 29% of MT patients (P = 0.47). Functional independence (modified Rankin Scale score of 0 to 2) rates were 50% versus 40% (P = 0.42). Mortality rates were similar (13% vs. 17%). Successful reperfusion (modified Thrombolysis in Cerebral Infarction score of 2b to 3) was higher with MT (90% vs. 68%; P = 0.018), but symptomatic intracranial hemorrhage occurred only in the MT group (7.1% vs. 0%).

CONCLUSION

In patients with MCA DMVO, IAT was associated with similar functional outcomes and fewer safety events compared to MT, despite lower recanalization rates.

CLINICAL RELEVANCE/APPLICATION

IAT may be a safer alternative to MT in selected patients.

M2-SPNR-6 LEVERAGING DEEP LEARNING TO SYNTHESIZE AMYLOID PATHOLOGY IMAGES FROM MULTI-MODAL MRI

Manmohi Dake, PhD (*Presenter*)
Abhilasha Jain, MS (*Abstract Co-Author*)
Jeremiah Fadugba (*Abstract Co-Author*)

PURPOSE

To assess the clinical utility of a synthetic image created using multi-modal Magnetic Resonance Imaging (MRI) in detecting amyloid pathology, a hallmark pathology seen in Alzheimer's disease (AD). Given the limited accessibility, high cost, and invasiveness of conventional amyloid detection methods such as PET imaging, this technology may help facilitate affordable and accessible amyloid detection, particularly in resource-constrained settings.

METHODS AND MATERIALS

A deep learning model was developed using a U-Net framework in order to synthesize amyloid pathology images from multi-modal MRI scans (T1 and T2-weighted MRI). The model was trained using 1,327 paired MRI and 18F-AV-45 Positron Emission Tomography (PET) data from the Alzheimer's Disease Neuroimaging Initiative (ADNI), with patients across the Alzheimer's disease spectrum. A subset of 188 pairs of images was used as the validation set. Similarity between the actual PET images and the synthetic images was assessed using Structural Similarity Index Measure (SSIM), Peak signal-to-noise ratio (PSNR), Mean Squared Error (MSE) and Pearson Correlation for image quality assessment. The percentage difference in Standard Uptake Value ratio (SUVR) was calculated using FreeSurfer with the whole cerebellum as the reference region to assess the clinical utility of the synthetic images.

RESULTS

On comparing the synthetic images and the original PET images from the validation set, an SSIM of 0.9895 ± 0.01, PSNR of 33.5213 ± 3.56, MSE of 0.0007 ± 0.0007 and high correlation ($r = 0.99$, $p < 0.01$), was observed. Composite SUVR values derived from the synthetic and the actual PET images showed an absolute percentage difference of 12.38% ± 8.29 ($W = 8388$, $p = 0.68$).

CONCLUSION

Synthesis of amyloid pathology images from multi-modal MRI using a deep learning model may provide a clinically relevant surrogate for traditional amyloid detection methods. The minimal, non-significant differences in SUVR between synthetic and actual PET images, and the high structural fidelity of the synthetic images, suggest a compelling alternative to conventional approaches, particularly in regions devoid of traditional amyloid detection methods.

CLINICAL RELEVANCE/APPLICATION

The ability to synthesize amyloid pathology images from MRI offers an accessible, non-invasive, and cost-effective screening tool needed in clinical practice. In settings with limited access to PET imaging, this approach could significantly enhance early detection of amyloid pathology, improving diagnosis and facilitating earlier, more effective interventions. Further validation across diverse populations is essential to fully establish its clinical utility and bring this solution to healthcare systems worldwide.

M2-SPNR-7 FUNCTIONAL HAND MOTOR CORTEX IS NOT ALWAYS ON ANATOMICAL"HANDKNOB"

Ziang Wang (*Presenter*)
Jialan Zheng (*Abstract Co-Author*)
Zihan Li (*Abstract Co-Author*)
Hongjia Yang (*Abstract Co-Author*)
Jennifer McNab, PhD (*Abstract Co-Author*)
Zuo-Xiang He (*Abstract Co-Author*)
Qiyuan Tian (*Abstract Co-Author*)

PURPOSE

Tracking fibers from the thalamus to the hand motor cortex (HMC) using diffusion MRI accurately identifies the thalamic Vim nucleus for effectively planning MRI-guided focused ultrasound (MRgFUS) thalamotomy for essential tremor. The anatomically defined "handknob" region (AHMC) known for its "knob" shape is often used to approximate the functional HMC (FHMC) area. This study aimed to verify the validation of this approximation.

METHODS AND MATERIALS

Data. Preprocessed T1w data, activation z-maps from finger tapping task fMRI (tfMRI) and myelination maps (T1w/T2w) of 34 subjects from Human Connectome Project were used. ROI delineation. AHMC regions were manually delineated by an expert neuroradiologist on T1w images. FHMC regions were defined as the largest cluster of tfMRI activation ($z>2.3$) within the pre-central gyrus segmented by FreeSurfer on T1w data. Overlap measurement. Overlap between AHMC and FHMC was quantified using: (1) Centroid Distance (i.e., Euclidean distance between centroids) and 2) Peak Deviation Index (PDI) (i.e., relative difference between peak z-values within AHMC and FHMC regions). A hemisphere was defined as "anatomy-function mismatched" (AFM) if both of its metrics were outliers. Mye lination analysis. Given HMC receives myelinated axons, myelination level in AHMC, FHMC, and their overlap region was examined and compared using Wilcoxon signed-rank test.

RESULTS

2 hemispheres from 2 subjects were identified as AFM. This percentage (2/34) is comparable to the previously reported percentage of MRgFUS non-responders (1/8) (Tian et al. 2018. NeuroImage: Clinical). AHMC regions exhibit clear "knob" shapes, indicating that the AFM phenomenon is biologically plausible. Moreover, AHMC regions exhibited significantly lower myelination compared to both FHMC and their overlapping, which exhibited highest myelination, indicating that AHMC regions might not represent HMC in while typically encompasses the most highly myelinated portion of FHMC.

CONCLUSION

AHMC and FHMC regions may exhibit spatial inconsistence in cases, which might be a biomarker for the abnormality of thalamocortical structural connectivity that might lead to change of Vim location in the thalamus and non-respondence to MRgFUS treatment.

CLINICAL RELEVANCE/APPLICATION

AFM of AHMC and FHMC regions can be potentially used for screening patients for MRgFUS treatment. FHMC regions can be potentially used for improving diffusion MRI fiber tracking to more accurately localize the Vim nucleus.

M2-SPNR-8 ROLE OF THE POSTERIOR CIRCULATION INVOLVEMENT IN MOYAMOYA DISEASE BASED ON 7T MRI

Qi Duan (*Presenter*)
Jinhao Lyu (*Abstract Co-Author*)
Xiangbing Bian (*Abstract Co-Author*)
Caohui Duan (*Abstract Co-Author*)
Song Wang (*Abstract Co-Author*)
Xin Lou, MD, PhD (*Abstract Co-Author*)

PURPOSE

Moyamoya disease (MMD) is a chronic cerebrovascular disease characterized by progressive steno-occlusion of the internal carotid arteries and compensatory development of a "puff of smoke" collateral network. As the internal carotid artery (ICA) progressively narrows, the posterior cerebral artery (PCA) may develop as a collateral pathway to compensate for anterior circulation insufficiency, therefore, steno-occlusive changes in the PCAs can lead to poorer clinical outcomes in patients with MMD. Despite its potential significance, posterior circulation MMD (PCMMD) remains understudied, likely due to the limited visualization of the posterior circulation using conventional non-invasive imaging techniques. 7.0T MRI has a advantage in imaging small vessels, therefore, We aim to investigate the relationship between the progression of PCMMD and the MMD progression based on 7T MRI.

METHODS AND MATERIALS

We retrospectively analyzed 241 hemispheres from 123 patients with MMD (mean age: 41.67 ± 11.21 years; 54 male) who underwent 7T MRI scans. Hemispheres were stratified into symptomatic (with stroke events) and asymptomatic (without stroke events) subgroups based on clinical presentation and standard MRI findings. PCA involvement was graded on a 4-point scale (0: no disease; 1: mild; 2: moderate; 3: severe) using 7T time-of-flight magnetic resonance angiography (TOF-MRA). Additionally, distal PCA compensation and Suzuki staging were assessed.

RESULTS

PCA involvement identified in 205 (85.0%) hemispheres. Of those 205 patients with PCMMD, disease severity ranged from 99 (41.3%) with mild, 80 (33.3%) with moderate, and 25 (10.4%) with severe. The distribution of cases was as follows: 49 symptomatic (20.3%), and 192 asymptomatic (79.7%).The MMD stroke event was significantly associated with PCMMD severity ($P<0.001$). Patients with higher Suzuki stage have more severe PCMMD ($P<0.001$). A total of 139 (58.1%) hemispheres had distal PCA compensation. Patients with a high Suzuki stage are more likely to have distal PCA compensation ($P<0.001$).

CONCLUSION

PCMMD severity based on 7T showed a significant related to the MMD progression, which may serve as a valuable factors to selecting MMD patients with high risk of progression.

CLINICAL RELEVANCE/APPLICATION

Posterior circulation moyamoya disease (PCMMD) is understudied due to poor conventional imaging. 7T MRI excels in small vessel visualization. PCMMD severity correlates with MMD stroke risk, higher Suzuki stages, and distal PCA compensation. 7T-based PCMMD grading significantly predicts MMD progression, serving as a key marker for identifying high-risk patients.

M2-SPNR-9 QUANTITATIVE MRI FOR ASSESSING THE RESPONSE TO DISEASE-MODIFYING TREATMENT IN ALZHEIMER'S DISEASE: 5.0 T T1RHO MAPPING IN MEDIAL TEMPORAL LOBE

Lijun Dong (*Presenter*)

PURPOSE

To investigate the potential of the longitudinal relaxation time in the rotating frame (T1rho) mapping, a new quantitative imaging sequence for Alzheimer's disease, in visualizing the treatment response before and during disease-modifying treatment (DMT) at 5.0 T ultra-high field.

METHODS AND MATERIALS

Thirty prospectively recruited patients with Alzheimer's disease diagnosed based on cerebrospinal fluid biomarkers went through 5.0 T MRI examinations, including three-dimensional T1-weighted imaging (3D-T1WI) and T1rho mapping. All patients received DMT (Lecanemab). MRI examinations were performed before, 3-month and 6-month after the treatment. T1rho mapping was registered to 3D-T1WI, and brain region segmentation was applied to 3D-T1WI. T1rho values of the medial temporal lobe were calculated. The T1rho values were compared between the time points using analysis of variance. Spearman correlations were assess between T1rho values with mini-mental state examination (MMSE), Alzheimer's disease assessment scale-cognitive subscale (ADAS-Cog), Alzheimer's disease cooperative study scale for activities of daily living (ADCS-ADL), and neuropsychiatric inventory (NPI).

RESULTS

Significant differences in T1rho values at the three time points ($P<0.05$) were detected. Twenty (67%) patients showed a decrease of T1rho values in medial temporal lobe after received DMT. The T1rho values showed a weak negative correlation with ADCS-ADL ($r= -0.216$, $P=0.043$; $r= -0.198$, $P=0.049$; $r= -0.294$, $P=0.031$) and weak positive correlation with ADAS-Cog ($r= 0.230$, $P=0.032$; $r= 0.199$, $P=0.044$; $r= 0.026$, $P=0.029$). However, no correlation was observed between the T1rho values and MMSE or NPI ($P>0.05$).

CONCLUSION

The treatment response before and during DMT could be detected on T1rho mapping in medial temporal lobe. Moreover, T1rho values showed correlations with clinical scales such as ADCS-ADL and ADAS-Cog.

CLINICAL RELEVANCE/APPLICATION

It is possible to apply T1rho mapping in assessing the treatment response of DMT in Alzheimer's disease. T1rho value in medial temporal lobe has the potential to complement clinical scales in the clinical practice.

M2-SPNR-10 EVALUATION OF VENDOR-AGNOSTIC DEEP LEARNING DENOISING IN PEDIATRIC NON-CONTRASTED LOW DOSE CRANIAL CT

Sebastian Steinmetz, MD (*Presenter*)
Mario Abello Mercado (*Abstract Co-Author*)
Antoine Sanner (*Abstract Co-Author*)
Andrea Kronfeld (*Abstract Co-Author*)
Marc A. Brockmann, MD (*Abstract Co-Author*)
Ahmed Othman, MD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the effect of a vendor-agnostic deep learning denoising (DLD) algorithm on the diagnostic image quality of pediatric non-contrast low dose cranial computed tomography (cCT).

METHODS AND MATERIALS

This retrospective single-center study included cCT data from 59 consecutive patients under 18 years of age who underwent routine imaging for neurological emergencies and trauma, followed by MRI within 7 days after cCT. The images were reconstructed using filtered back projection (FBP) and a vendor-agnostic deep learning-based denoising method (DLD-cCT). Quantitative analysis was performed using specialized MatLab tool and included the signal-to-noise ratio (SNR). Qualitative analysis was conducted by two independent readers using a 4-point Likert scale to evaluate the following cCT quality criteria: overall image quality, image noise, artifacts, gray matter-white matter differentiation (GM-WM), sharpness, and diagnostic confidence.

RESULTS

DLD-cCT outperformed conventional cCT. Quantitative analysis demonstrated significant improvements in SNR (DLD-cCT = 14.33 ± 8.5 vs. cCT = 6.63 ± 3.28; $p < 0.001$). Qualitative analysis revealed significantly better results across all assessed criteria for both readers ($p < 0.001$). Interrater agreement ranged from moderate to almost perfect.

CONCLUSION

The vendor-agnostic deep learning denoising algorithm significantly improved quantitative and qualitative imaging parameters.

CLINICAL RELEVANCE/APPLICATION

Vendor-agnostic deep learning denoising contributes to improved image quality, thereby facilitating greater diagnostic confidence.

M2-SPNR-11 UNREMARKABLE BRAIN CT SCREENING VIA MODALITY-SPECIFIC ADAPTATION OF A MULTIMODAL FOUNDATION MODEL: A RETROSPECTIVE CLINICAL SIMULATION STUDY

Namkug Kim, PhD (*Presenter*)
Seungjun Lee (*Abstract Co-Author*)
Sujeong Kwon, BA (*Abstract Co-Author*)
Gil-Sun Hong, MD, PhD (*Abstract Co-Author*)

PURPOSE

Emergency departments (EDs) generate large volumes of imaging, with most non-contrast brain CTs (NCCTs) being unremarkable but still requiring full radiologist review—contributing to workload and burnout. Existing AI tools often target specific findings or rely on general foundation models lacking CT-specific optimization, limiting their effectiveness. We developed and externally validated BrainCT-CLIP, a multimodal foundation model tailored for NCCT, to automatically identify unremarkable scans and evaluated its potential to reduce workload through a clinical simulation with supplementary AI tools.

METHODS AND MATERIALS

In this retrospective study, we trained BrainCT-CLIP on 135,635 NCCTs paired with radiology reports from Hospital A (2000-2018). Two independent, consecutive ED cohorts—544 from Hospital A (February 2019) and 1,795 from Hospital B (January-May 2019)—were labeled "unremarkable" or "remarkable" by an experienced radiologist. BrainCT-CLIP extends BioMedCLIP's vision-text framework with a learnable Hounsfield-Unit (HU) windowing layer and additional transformer encoder blocks to capture CT-specific features. Benchmarks included MedicalNet, PubMedCLIP, and BioMedCLIP (with and without CT preprocessing). Metrics were area under the receiver operating characteristic curve (AUC), sensitivity, specificity, negative predictive value (NPV), and workload reduction—and the proportion of scans auto-flagged as unremarkable. The threshold was set on internal data to ensure = 95% sensitivity and NPV. In simulated clinical workflow, we combined BrainCT-CLIP with a commercial AI screening tool to estimate practical workload reduction.

RESULTS

BrainCT-CLIP achieved an AUC of 0.87, surpassing MedicalNet (0.53), PubMedCLIP (0.68 with CT preprocessing; 0.67 without), BioMedCLIP (0.77 with; 0.67 without). At its threshold, BrainCT-CLIP reduced radiologist workload by 23% while preserving sensitivity of 0.97 and NPV of 0.98. Other models failed to meet sensitivity/NPV targets or yield meaningful workload reduction. In the simulated workflow, the combined AI system yielded a 24% workload reduction with sensitivity of 0.99 and NPV of 0.99.

CONCLUSION

By integrating CT-specific preprocessing and architectural enhancements, BrainCT-CLIP outperforms existing foundation models on NCCT. It automatically flags 23% of scans as unremarkable, offering a practical triage tool that streamlines emergency workflows and ensures prompt detection of critical findings.

CLINICAL RELEVANCE/APPLICATION

By safely identifying unremarkable scans and prioritizing urgent cases, BrainCT-CLIP can reduce radiologist review time by 23%, accelerate patient management, and optimize resource allocation in emergency settings.

M2-SPNR-12 STRUCTURAL AND FUNCTIONAL ALTERNATIONS OF MEDIAL AND LATERAL ENTORHINAL CORTEX WITH SUBJECTIVE COGNITIVE DECLINE: ASSOCIATIONS WITH SPATIAL NAVIGATION AND OLFACTORY FUNCTION

Danni Ge (*Presenter*)
Jiaming Lu (*Abstract Co-Author*)
Qian Chen, PhD (*Abstract Co-Author*)
Futao Chen (*Abstract Co-Author*)
Yajing Zhu (*Abstract Co-Author*)
Xin Zhang, MD (*Abstract Co-Author*)
Bing Zhang, PhD (*Abstract Co-Author*)

PURPOSE

Subjective cognitive decline (SCD) is a preclinical stage of Alzheimer's disease (AD) and considered its best diagnostic window. Entorhinal cortex, one of the most vulnerable regions for AD, is divided into medial entorhinal cortex (MEC) and lateral entorhinal cortex (LEC), which is associated with spatial navigation and olfactory function, respectively. In the present study, we aimed to explore the structural and functional alterations of the medial and lateral entorhinal cortex in SCD individuals, and to investigate their associations with cognitive performance, spatial navigation, and olfactory function.

METHODS AND MATERIALS

Seventy-seven control subjects and 106 SCD individuals were enrolled, and neuropsychological evaluations, 2D computerized spatial navigation test, olfactory assessment, structural and resting-state functional MRI were collected. Bilateral MEC and LEC were selected as seeds to investigate alternations of the volumes, ALFF value, ALFF/VBM ratio, static (sFC) and dynamic functional connectivity (dFC).

RESULTS

In SCD individuals, the medial/lateral EC exhibited decreased sFC with the whole brain, primarily within the visual, sensory motor, and default mode network. The dFC between right LEC and right triangular part of inferior frontal gyrus decreased, while dFC between left MEC and right putamen, and between right MEC and right middle temporal gyrus increased. Additionally, the increase of ALFF/VBM ratio was found in right LEC. The olfactory function was associated with both LEC and MEC, while spatial navigation function was more related to MEC. Finally, the model integrating neuroimaging metrics, cognitive performance, spatial navigation and olfactory function achieved an AUC of 0.955.

CONCLUSION

Early pathological changes occur in the medial/lateral EC despite the absence of cognitive impairment at the SCD stage, and, they are strongly associated with spatial navigation and olfactory function. The structural and functional metrics of medial/lateral EC may serve as early AD diagnostic biomarkers.

CLINICAL RELEVANCE/APPLICATION

This study is expected to identify biomarkers for early diagnosis of AD. By investigating the mechanisms underlying AD-related impairments in spatial navigation and olfactory function, it aims to provide insights for precision therapeutics.

M2-SPNR-13 MA-NET-BASED AUTOMATED MEASUREMENT OF PITUITARY GLAND VOLUME ACROSS DIFFERENT AGE GROUPS AND GENDERS USING MRI

Hayoun Kim, MD, PhD (*Presenter*)
Boda Nam, MD (*Abstract Co-Author*)

PURPOSE

Accurate evaluation of pituitary gland anatomy, including physiological variations in volume across age groups and sex, is important for clinical assessment. Manual measurement of pituitary volume (PV) is time-consuming and operator-dependent. This study aims to apply an automated method using MRI and MA-net to evaluate PV across a broad age range and both sexes.

METHODS AND MATERIALS

This retrospective study included 1,823 patients (911 males and 912 females) aged between 1 and 89 years who underwent brain MRI scans. Patients with pituitary or endocrine abnormalities were excluded. The participants were categorized into the following age groups in 10-year intervals from 1 to 90 years. PV was measured using T1 sagittal MRI images with a thickness of 1-3 mm from non-enhanced brain MRIs. The measurements were analyzed using the MA-net artificial intelligence learning method. The relationship between mean PV and age, as well as between mean PV and sex, was evaluated using the Chi-square test, Mann-Whitney U test, and ANCOVA, with a p-value < 0.05 considered statistically significant.

RESULTS

The mean PV was 672.78 ± 261.93 mm^3 in male and 752.66 ± 281.53 mm^3 in female, with female showing an average volume 79.88 mm^3 larger than male. This difference was statistically significant ($p < 0.001$). PV also demonstrated significant differences based on both gender and age, with F-values of 192.568 and 75.404, respectively ($p < 0.001$). As age increased, there was an interaction effect on the differences in pituitary volume between genders ($F = 5.783$, $p < 0.001$). Pituitary volume increased rapidly in younger individuals (up to their 20s), with female showing a significantly greater increase compared to male. After the 20s, the volume decreased rapidly in male during their 30s and then showed a gradual decline thereafter. In female, the volume gradually decreased after their 30s ($p < 0.001$).

CONCLUSION

Pituitary volume was significantly larger in females than in males across all age groups, with peak values in the teens and twenties. Age- and sex-related patterns were clearly demonstrated using MA-net-based automated MRI analysis. These values may serve as a reference for distinguishing physiological variation from pathology. The automated method enables rapid, objective assessment of pituitary size. This approach may improve diagnostic accuracy and efficiency in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Automated AI-based measurement of pituitary volume across age and gender variations enhances diagnostic efficiency and accuracy, providing valuable insights for clinical assessments and research.

M2-SPNR-14 AI-BASED AUTOMATED MEASUREMENT OF PITUITARY GLAND VOLUME IN IDIOPATHIC CENTRAL PRECOCIOUS PUBERTY: DIAGNOSTIC UTILITY AND HORMONAL CORRELATION

Hayoun Kim, MD, PhD (*Presenter*)
Boda Nam, MD (*Abstract Co-Author*)

PURPOSE

Idiopathic central precocious puberty (IPP) is associated with a significant increase in pituitary gland volume (PV) compared to age-matched controls. However, PV measurements most commonly used are time-consuming and labor-intensive, relying on manual methods. This study evaluates the feasibility of using artificial intelligence (AI) to automate PV measurement and assesses its potential for diagnosing IPP. Additionally, the study explores the correlation between PV, hormone levels, and physical parameters in IPP patients.

METHODS AND MATERIALS

A total of 163 patients were analyzed, including 77 patients diagnosed (25 males and 52 females, median age, 8 years; interquartile range, 7-9 years) with IPP and who underwent brain MRI from July 2016 to December 2024. A control group of 86 patients who underwent brain MR imaging without symptoms of precocious puberty was also included (50 males and 36 females, median age, 7 years; interquartile range, 8-9 years). Out of a total of 168 collectd patients, 5 were excluded due to in accurate pituitary gland volume date. The pituitary gland volume was measured using 1-3 mm thickness T1 sagittal images from non-enhanced brain MR imaging, analyzed with the MA-net artificial intelligence learning method.

RESULTS

There were significant differences in height, weight, and Luteinizing Hormone levels between the IPP group and the control group. However, there were no significant differences in age, BMI, thyroid hormone, vitamin D, testosterone, and estradiol levels between the two groups. The median values of PV were 420 mm^3 in the IPP group and 367 mm^3 in the control group, showing a significant difference of 53 mm^3 ($P < .05$).

CONCLUSION

Pituitary volume (PV) was significantly higher in the IPP group compared to controls. Automated PV measurement, along with hormone levels and physical parameters, could enable more efficient and accurate diagnosis of IPP.

CLINICAL RELEVANCE/APPLICATION

AI-based automated pituitary volume measurement may provide a rapid and objective method for diagnosing idiopathic central precocious puberty

M2-SPNR-16 SYSTEMATIC ERRORS IN MEDIAL SUPERIOR FRONTAL AND CINGULATE PARCELLATIONS BY FREESURFER: IMPLICATIONS FOR CLINICAL NEUROIMAGING

Shun-Chin Wu, MD, MSc (*Presenter*)
Saadi Karim (*Abstract Co-Author*)
Heloise De Vareilles (*Abstract Co-Author*)
Stener Nerland (*Abstract Co-Author*)
Lynn Morch-Johnsen (*Abstract Co-Author*)
Ingrid Agartz, MD,PhD (*Abstract Co-Author*)
Kang-Lung Lee, MD (*Abstract Co-Author*)
Tomasz Matys, PhD, FRCR (*Abstract Co-Author*)
John Suckling (*Abstract Co-Author*)
Graham Murray (*Abstract Co-Author*)

PURPOSE

Region of interest (ROI) analysis is widely used in neuroimaging for pathology detection, treatment, and prognosis. Although the medial superior frontal and anterior-middle cingulate regions are implicated in neuropsychiatric disorders, variability in the paracingulate sulcus (PCS), present in 50-75% of hemispheres, may cause parcellation errors (e.g., FreeSurfer) by misidentifying it as the cingulate sulcus, causing misalignment. This shifts ROI boundaries, misassigning the PCS from the superior frontal to cingulate regions. Although recognized, this misalignment has not been quantified. This study quantifies FreeSurfer's misalignment and its association with PCS prominence, hypothesizing that greater PCS prominence correlates with larger errors.

METHODS AND MATERIALS

T1-weighted MRIs from 278 healthy individuals (mean age = 34.7 ± 9.7 years; 146 males [52.9%]; 223 right-handed [80.2%]) were analyzed. Data were preprocessed and parcellated using FreeSurfer v6.0.0 and v7.4.1, focusing on four regions from the default Destrieux Atlas: superior frontal, anterior cingulate, middle-anterior cingulate, and middle-posterior cingulate. PCS was manually labeled across 556 hemispheres. Correct alignment was quantified as %PCS vertices within the superior frontal region; misalignment was %PCS vertices in the cingulate regions. Associations between PCS prominence (vertex count) and correct alignment/misalignment were assessed using Pearson correlations, with differences evaluated via bootstrap resampling (5,000 iterations).

RESULTS

Among 278 participants, 136 (48.9%) had < 80% correct alignment in the left hemisphere and 138 (49.6%) in the right; 130 (46.8%) and 124 (44.6%) showed > 20% misalignments in the left and right, respectively. PCS prominence correlated more strongly with misalignment than correct alignment (left hemisphere: r = 0.83 vs. 0.68, 95% CI of the difference = [0.07, 0.25]; right hemisphere: r = 0.84 vs. 0.51, 95% CI = [0.22, 0.44]). Findings were consistent across both FreeSurfer versions.

CONCLUSION

FreeSurfer's default parcellation (v6.0.0 and v7.4.1) showed that about 50% of participants had < 80% correct alignment or > 20% misalignment in superior frontal and cingulate regions. Misalignment showed a stronger association with PCS prominence, supporting our hypothesis.

CLINICAL RELEVANCE/APPLICATION

This study highlights the high prevalence of mislocalized boundaries between medial superior frontal and cingulate ROIs in FreeSurfer, the most widely used structural neuroimaging tool. Manual editing should be considered for these regions, as accurate localization is critical for precision medicine. Misassignment may compromise treatments like transcranial magnetic stimulation for depression.

M2-SPNR-17 PRELIMINARY STUDY ON SPATIAL HETEROGENEITY OF GLIOMAS THROUGH MULTIPARAMETRIC MRI: INSIGHTS INTO TUMOR MICROENVIRONMENT

Xingwei Dai (*Presenter*)
Mingmei Li, MMed (*Abstract Co-Author*)
Zhiping Lin (*Abstract Co-Author*)
Liping Qing (*Abstract Co-Author*)
Qin Zhao (*Abstract Co-Author*)
Hao Li (*Abstract Co-Author*)
Meiying Chen (*Abstract Co-Author*)
Demin Xu (*Abstract Co-Author*)
Yulong Qi (*Abstract Co-Author*)
Guanxun Cheng, PhD (*Abstract Co-Author*)

PURPOSE

To explore the potential of multiparametric MRI-derived habitat imaging for preoperative prediction of IDH-1 mutation status, recurrence, WHO grade, and Ki-67 expression in gliomas.

METHODS AND MATERIALS

Volumes of interest (VOIs) including tumor and peritumoral infiltrative edema regions were delineated on T2-weighted fluid-attenuated inversion recovery (T2 FLAIR) and contrast-enhanced T1-weighted (T1CE) images. Eight spatial habitats were generated from apparent diffusion coefficient (ADC), T1CE, and FLAIR sequences using the Otsu algorithm. The volumetric fraction of each habitat (H_i, representing the proportion of the i-th habitat to the entire VOI) was analyzed using the Mann-Whitney U test and univariate logistic regression. The performance of significant predictors was further evaluated using the area under the receiver operating characteristic curve (AUC).

RESULTS

A total of 39 patients (mean age, 47.8 ± 14.9 years [SD]; 29 male) were included. For IDH-1 mutation status, H 3 showed increased odds (OR = 2.609, 95% CI: 1.179-5.771; P = 0.018; AUC = 0.754), while H 8 showed decreased odds (OR = 0.301, 95% CI: 0.108-0.836; P = 0.021; AUC = 0.735). Regarding recurrence, H 5 (OR = 3.453, 95% CI: 1.202-9.923; P = 0.021; AUC = 0.783) and H 6 (OR = 5.589, 95% CI: 1.375-22.721; P = 0.016; AUC = 0.919) were identified as significant predictors. Furthermore, H 3 was associated with lower odds of high tumor grade (OR = 0.283, 95% CI: 0.117-0.686; P = 0.005; AUC = 0.814) and high Ki-67 expression (OR = 0.358, 95% CI: 0.158-0.811; P = 0.014; AUC = 0.751). Conversely, H 8 was associated with higher odds of high tumor grade (OR = 47.113, 95% CI: 1.117-1986.923; P = 0.044; AUC = 0.845) and high Ki-67 expression (OR = 3.179, 95% CI: 1.173-8.614; P = 0.023; AUC = 0.743).

CONCLUSION

Multiparametric MRI-derived spatial habitats effectively characterize glioma spatial heterogeneity and show potential as a non-invasive preoperative tool for inferring key tumor biology aspects.

CLINICAL RELEVANCE/APPLICATION

This non-invasive predictive capability of spatial heterogeneity features holds potential to improve preoperative patient stratification and facilitate personalized treatment planning for glioma.

M2-SPNR-19 HIGHER TEA CONSUMPTION IS ASSOCIATED WITH LOWER BASAL GANGLIA SUSCEPTIBILITY IN AGING: EVIDENCE FROM THE UK BIOBANK

Pengcheng Liang (*Presenter*)
Changhu Liang, MD, PhD (*Abstract Co-Author*)
Lingfei Guo, MD (*Abstract Co-Author*)
Yilin Guo (*Abstract Co-Author*)
Yiwen Chen (*Abstract Co-Author*)
Zhenyu Cheng (*Abstract Co-Author*)
Na Wang (*Abstract Co-Author*)

PURPOSE

Iron deposition in the basal ganglia is a key biomarker of brain aging and neurodegeneration. This study investigated the relationship between tea consumption, demographic and lifestyle factors, and quantitative susceptibility mapping (QSM) values in basal ganglia nuclei among healthy middle-aged and elderly adults in the UK Biobank.

METHODS AND MATERIALS

We included 25,980 participants (aged 50-79) from the UK Biobank who underwent 3T MRI. Susceptibility values of the caudate nucleus, putamen, globus pallidus, and substantia nigra were derived from QSM. Daily tea intake, coffee consumption, smoking, alcohol use, sleep, waist circumference, and C-reactive protein were recorded. Linear and polynomial regression models assessed associations between tea intake and susceptibility values, with gender-stratified analysis and adjustment for confounders.

RESULTS

Daily consumption of =4 cups of tea was associated with significantly reduced susceptibility values in all basal ganglia nuclei (e.g., -0.063 in caudate, -0.093 in substantia nigra; all $P < .001$). In men, increasing tea intake from 0 to 3 cups/day corresponded to a 0.044 SD reduction in susceptibility, equating to a "rejuvenation" effect of 1.50 brain years; in women, the reduction was 0.162 SDs, equivalent to 5.59 brain years. Additional factors positively associated with basal ganglia susceptibility included age, waist circumference, smoking status, and C-reactive protein. Coffee intake was not significantly associated with susceptibility values.

CONCLUSION

Tea consumption is independently associated with lower iron-related susceptibility in basal ganglia, with a dose-dependent and gender-specific "neuroprotective" effect. These findings support tea as a modifiable lifestyle factor linked to healthier brain aging.

CLINICAL RELEVANCE/APPLICATION

Quantitative susceptibility values of basal ganglia offer sensitive imaging markers of iron burden and brain aging. Tea intake may represent a modifiable factor with potential neuroprotective implications.

M2-SPOB-1 AMIDE PROTON TRANSFER - WEIGHTED HABITAT RADIOMICS: AN SUPERIOR APPROACH FOR PREOPERATIVE PREDICTION OF LYMPHOVASCULAR SPACE INVASION IN CERVICAL CANCER

Jie Li (*Presenter*)
Qinghe Han (*Abstract Co-Author*)

PURPOSE

To explore the predictive ability of habitat radiomic features extracted from amide proton transfer-weighted (APTw) MRI for lymphovascular space invasion (LVSI) in patients with cervical cancer (CC).

METHODS AND MATERIALS

This prospective study included consecutive adult patients with suspected CC who underwent APTw MRI from December 2022 to December 2024. The regions of interest delineated on T2-weighted images were replicated on APTw images, and radiomic scores for the APTw habitats (APTw_h3) were calculated. The pathological assessment of LVSI from hysterectomy samples served as the reference standard. Multivariable logistic regression was employed to identify variables associated with LVSI and to develop a diagnostic model for predicting LVSI. The areas under the receiver operating characteristic curve (AUCs) were used to evaluate the performance of the imaging parameters and the overall model and were compared with the DeLong test.

RESULTS

A total of 124 patients were included, among whom 74 were LVSI-negative (median age, 47 years [IQR, 41-55 years]) and 50 were LVSI-positive (median age, 51 years [IQR, 42-58 years]). Compared with the APTw value (AUC, 0.704) and the apparent diffusion coefficient (AUC, 0.609), APTw_h3 (AUC, 0.796) demonstrated better predictive performance for LVSI. Tumour size, cancer antigen-125 level, and APTw_h3 were associated with LVSI positivity (odds ratio range, 1.01-9.06; $P < 0.001$). The combined model (AUC, 0.903; $P < 0.001$) showed better predictive performance for LVSI than the clinicoradiological model (AUC, 0.733; $P < 0.001$) and the APTw_h3 model (AUC, 0.796; $P < 0.001$).

CONCLUSION

The habitat radiomic features of APTw images can be used to predict LVSI in CC.

CLINICAL RELEVANCE/APPLICATION

By utilizing habitat radiomic features derived from APTw MRI, clinicians can obtain a non-invasive and more accurate prediction of lymphovascular space invasion (LVSI), a critical factor influencing treatment strategies and patient outcomes. The superior predictive performance of the APTw_h3 feature, as demonstrated by its AUC of 0.796 compared to traditional APTw and ADC values, offers a more reliable imaging biomarker for LVSI. Furthermore, the combined model incorporating APTw_h3 with clinical and radiological factors achieved an impressive AUC of 0.903, providing a robust tool for preoperative risk stratification. This advancement enables clinicians to identify patients at higher risk of LVSI early, facilitating personalized treatment planning. For instance, patients predicted to be LVSI-positive can undergo more aggressive surgical approaches and adjuvant therapies, while those predicted to be LVSI-negative can avoid potential overtreatment.

M2-SPOB-2 COMPARISON OF RADIOMICS MODEL WITH O-RADS AND RADIOLOGISTS FOR RISK STRATIFICATION OF OVARIAN MASSES: A RETROSPECTIVE MULTI-CENTER STUDY

Long Ling (*Presenter*)
Jin Junjie (*Abstract Co-Author*)

PURPOSE

To develop an MRI-based radiomics model to categorize ovarian masses and to compare the model performance to Ovarian-Adnexal Reporting and Data System (O-RADS) and radiologists' assessments.

METHODS AND MATERIALS

This retrospective multicenter study included 497 patients (249 benign, 248 malignant) allocated to training, internal, and external validation sets(293/124/80 masses, respectively). Radiomics features were extracted from preoperative MRI. The minimum redundancy maximum relevance and least absolute shrinkage and selection operator algorithm were used for feature selection. The diagnostic performance of the radiomics model, O-RADS, and independent assessments by junior and senior radiologists was evaluated using the area under the receiver operating characteristic curve (AUC) and compared using DeLong's test.

RESULTS

In external validation, the radiomics model (AUC = 0.939) outperformed O-RADS (AUC = 0.862; $P = 0.047$) and the junior radiologist (AUC = 0.802; $P = 0.003$) and was similar to the senior radiologist (AUC = 0.886; $P = 0.231$). Subgroup analysis of O-RADS score 4 showed the model (AUC = 0.879) outperformed both radiologists (junior: $P = 0.001$; senior: $P = 0.005$).

CONCLUSION

The performance of radiomics model to categorize ovarian masses was superior to O-RADS and junior radiologist and similar to senior radiologist. As a complementary tool to O-RADS, it allows for refined risk stratification for ovarian masses with an O-RADS score 4, providing clinicians with quantitative decision support to improve preoperative diagnosis and guide treatment planning.

CLINICAL RELEVANCE/APPLICATION

Radiomics model improved risk stratification and supports precise clinical decision-making for ovarian masses with an O-RADS score of 4, thereby improving the management of patients with ovarian masses.

M2-SPOB-3 LONG-GRADIENT ECHO IMAGES FOR FETAL MR IMAGING OF THE FETAL SPINE, RIBS AND EXTREMITIES - INTERGROUP COMPARISON BETWEEN T2WI, UNPROCESSED AND PROCESSED LONG-GRADIENT ECHO IMAGES AT DIFFERENT GESTATIONAL AGES

Nitin P. Ghonge, MD, MBBS (*Presenter*)
Nidhi Goyal, MD, FRCR (*Abstract Co-Author*)

PURPOSE

To evaluate feasibility of long-gradient echo images for fetal MR imaging at different gestational ages. To compare the quantitative and qualitative assessment of T2-HASTE, unprocessed and processed long-gradient echo images for fetal spine, ribs and long bones. To describe the potential role of long-gradient echo for fetal MRI.

METHODS AND MATERIALS

22 consecutive patients referred for fetal MRI were included. MRI was performed on Philips 3T scanner [Ingenia]. Apart from T2 HASTE, long gradient echo sequence was performed. Magnetic susceptibility of fetal vertebrae varies linearly over gestation. TE of 7-8 msec was used. The raw phase images were processed using a homodyne high pass filter of size 32*32. This provided clean filtered phase images to create the susceptibility weighting mask, which was multiplied with the magnitude images. Mean SNR values were calculated from each set using circular ROI on a mid-dorsal vertebral body and compared. Qualitative assessment was performed by two radiologists in consensus. The evaluation parameters are mentioned in the pdf file. '3-point Likert scale' was used to decide the level of confidence in interpretation as NORMAL [2: HIGH level of confidence / 1: LOW level of confidence / 0: NOT sure]. The scale values were compared between three image groups for each of the anatomical parameters.

RESULTS

Long gradient echo MR sequence could be acquired in all the patients and allowed evaluation of fetal spine, ribs and long bones. T2W images showed mean SNR value of 2.6 as compared to 3.9 in the unprocessed and 3.6 in the processed long gradient echo images. Processed echo images seem to further increase the mean SNR values, in the gestational age category of < 24 weeks. Qualitative assessment showed higher degree of confidence with long gradient echo sequence images for the vertebral counting, cranio-vertebral junction, vertebral bodies, intervertebral disc, spinal alignment, closure of posterior elements and the long bones. Spinal canal, spinal cord and conus were better visualized on the T2WI.

CONCLUSION

Long gradient echo MR sequence could be optimally performed for the evaluation of fetal spine, ribs and long bones from 20-37 weeks gestation. This showed increased mean SNR values as compared to T2WI for the fetal spine. Processed images seem to further increase the mean SNR values at gestational age < 24 weeks. Qualitative assessment showed higher degree of confidence with long gradient echo sequence images for the assessment of the osseous structures.

CLINICAL RELEVANCE/APPLICATION

Long gradient echo MR sequence may be included in the routine Fetal MRI protocol. This may serve as a robust alternative to low-dose CT imaging for prenatal evaluation of the fetal spine, ribs and long bones in appropriate clinical settings.

M2-SPPD-1 MRI FEATURES AND PREVALENCE OF SUBCUTANEOUS AXILLARY RIDGE TISSUE IN HEALTHY ADOLESCENT PATIENTS; ARE THESE VESTIGIAL BREAST MOUNDS ALONG THE EMBRYOLOGICAL MILK LINE?

Pedro Henrique Caldeira Brant Faria, MD (*Presenter*)
Philip N. Asamoah, MD (*Abstract Co-Author*)
Ani Maroyan (*Abstract Co-Author*)
Sarah D. Bixby, MD, MBA (*Abstract Co-Author*)

PURPOSE

A thin band of soft tissue in the axillary ridge mimicking breast tissue has been noted on adolescent patients undergoing MR shoulder arthrography for suspected intra-articular pathology. According to surgical literature, most adults have chains of vestigial breast mounds along the embryological milk line starting at the axilla, which would correlate with MRI findings. This study aimed to determine the prevalence and imaging features of a band of subcutaneous soft tissue in the anterior axillary ridge in healthy adolescent patients undergoing shoulder MRI, which likely represents normal fibroglandular tissue based on comparison with imaging findings in patients with biopsy-proven axillary breast tissue.

METHODS AND MATERIALS

We retrospectively searched PACS for shoulder MR arthrogram studies performed in patients aged 10-18 years from April 2023 to July 2024. Exams were reviewed to ensure inclusion of T1-weighted and T2-weighted sequences through the axilla. Two radiologists independently assessed each study for the presence of a well-demarcated band of tissue—T2 intermediate and T1 hypointense—following the contour of the axillary fold. Maximal thickness of the tissue was measured when present. Associated soft tissue findings were recorded. Differences in mean thickness between males and females were assessed using a t-test. Electronic medical records were reviewed for current medications and associated medical conditions.

RESULTS

A total of 200 studies were reviewed; 107 included adequate imaging of the axillary fold. Of these, 93% (n = 99; 41 male, 60 female) demonstrated the axillary band of tissue. No patients were taking relevant medications or had associated medical comorbidities. The mean tissue thickness was 2.29 mm in males and 2.72 mm in females, with no statistically significant difference (p = 0.516). Thickness ranged from 1.0-6.0 mm in females and 0.7-5.2 mm in males. The tissue was consistently confined to the anterior aspect of the axillary ridge with a characteristic inverted-U shape. No associated cysts or masses were identified.

CONCLUSION

A subcutaneous ridge of axillary soft tissue with surrounding fat is a common incidental finding on shoulder arthrograms in adolescents, present in 93% of cases regardless of gender. This feature has not been previously described and may be mistaken for a pathological process if not recognized.

CLINICAL RELEVANCE/APPLICATION

Recognition of this common, likely normal variant in the axillary fold is important to prevent misinterpretation as a soft tissue abnormality, particularly in the adolescent population undergoing shoulder MRI.

M2-SPPD-2 REDEFINING PEDIATRIC KIDNEY TRANSPLANT SURVEILLANCE? PRELIMINARY FINDINGS OF CEUS AS A NONINVASIVE PREDICTOR OF HISTOLOGIC DAMAGE

Tatiana Morales, MD (*Presenter*)
Hansel J. Otero, MD (*Abstract Co-Author*)
Susan J. Back, MD (*Abstract Co-Author*)
Laith R. Sultan, MD, MPH (*Abstract Co-Author*)
Bernarda Viteri, MD (*Abstract Co-Author*)

PURPOSE

Contrast-enhanced ultrasound (CEUS) offers an alternative to biopsy for assessing microvascular damage of kidney transplants. We compared CEUS parameters with histopathological measures of transplant dysfunction.

METHODS AND MATERIALS

This prospective, single-center study enrolled pediatric kidney transplant recipients undergoing clinically indicated biopsies from Nov 2020 to Dec 2024. CEUS imaging was performed within 48 hours prior to biopsy. After intravenous administration of ultrasound contrast agent (0.03 mL/kg) a 2-minute cine loop of the transplanted kidney was obtained. Four cortical regions of interest (ROI) were identified in post-processing using Interactive Data Language (IDL) software, depicting: mean transit time (MTT), time to peak (TTP), peak enhancement (PE) and perfusion index (PI). The values were compared to Banff 2017 histopathologic criteria of rejection, total inflammation (ti : categorized as 0 vs. 1-3), and the chronic allograft damage index (CADI) composite score. A generalized estimating equations model was used to account for repeated measures.

RESULTS

Forty CEUS examinations were performed; one had an incomplete clip, leaving 39 exams from 28 subjects (75% male) for analysis. The median age at the time of CEUS was 16 years (IQR: 6). The mean estimated glomerular filtration rate was 68.9 mL/min/1.73m² (IQR: 20.3), and the median time from transplant to biopsy was 14 months (IQR: 23). Median CEUS parameters were: TTP 12.7 seconds (IQR: 17.6), MTT 57.1 seconds (IQR: 41.2), PE 136.3 a.u. (IQR: 29.3), and PI 27.6 a.u. (IQR: 1.52). The median CADI score was 2 (IQR: 2), 26/39 biopsies (66.7%) showed a ti score of 0, and 15 showed rejection (38.5%). TTP and PE were significantly associated with CADI score (ß = 0.05, p = 0.013 and ß = 0.02, p = 0.048, respectively). MTT was significantly associated with both CADI (ß = 0.37 per 10 seconds, p = 0.002) and ti score (OR = 1.51, p = 0.013).

CONCLUSION

As CEUS perfusion parameters increased, CADI also did. Mean transit time was also strongly associated with total inflammation suggesting delayed or reduced perfusion in affected allografts.

CLINICAL RELEVANCE/APPLICATION

CEUS may serve as a non-invasive tool for surveillance of kidney allograft health and detecting early dysfunction.

M2-SPPD-3 ASSOCIATION OF CONTRAST-ENHANCED ULTRASOUND PARAMETERS WITH MICROVESSEL DENSITY IN HEPATOBLASTOMA

Yazi YOU (*Presenter*)
Yi Tang (*Abstract Co-Author*)

PURPOSE

This study aimed to explore the association between qualitative and quantitative features of contrast-enhanced ultrasound (CEUS) and microvessel density (MVD) in hepatoblastoma (HB), while assessing the potential of CEUS as a noninvasive, preoperative method for predicting tumor progression.

METHODS AND MATERIALS

This retrospective analysis was carried out in one medical center and included 40 children with histopathologically confirmed HB (22 males, 18 females; average age, 3.8 ± 1.2 years). Both gray-scale ultrasound and CEUS results were reviewed. Lesions were evaluated using time-intensity curve (TIC) analysis software to extract quantitative parameters. Postoperative tissue specimens were stained with CD34 immunohistochemistry, and MVD was quantified as the reference standard. Statistical analyses were conducted to assess the correlation between CEUS findings and MVD.

RESULTS

Lesions were separated into high (n = 22, 55%; MVD > 38) and low (n = 18, 45%; MVD = 38) MVD groups, based on a cutoff value of 38 vessels per high-power field (hpf). High MVD lesions exhibited significantly more uneven distribution, non-diffuse enhancement, and a higher incidence of perforating vessels than low MVD lesions ($p < 0.05$). Additionally, a significant association was observed between high MVD levels and higher Adler-grade vascular flow ($p < 0.05$). Receiver Operating Characteristic (ROC) curve analysis revealed that the relative wash-out rate (rWoR) value of = 1.36 could serve as a predictor for low MVD, with a sensitivity of 61.1% and specificity of 81.8% (AUC = 0.717; 95% CI: 0.549-0.885; p = 0.019).

CONCLUSION

The qualitative and quantitative aspects of CEUS show a notable correlation with MVD, endorsing its application as a noninvasive tool before surgery for forecasting HB malignancy and assisting in clinical decision processes.

CLINICAL RELEVANCE/APPLICATION

This study highlights the potential clinical utility of CEUS as a noninvasive imaging modality for evaluating HB in pediatric patients. By demonstrating a significant correlation between CEUS features—particularly perfusion patterns and time-intensity curve parameters—and tumor MVD, the findings support CEUS as a preoperative surrogate marker of tumor angiogenesis and aggressiveness. Integrating CEUS into routine clinical assessment may aid in risk stratification, surgical planning, and individualized treatment decisions, reducing the reliance on invasive procedures for histopathological evaluation.

M2-SPPD-4 PICC-ING THE RIGHT SPOT: A COMPARISON OF UPPER VS. LOWER EXTREMITY PLACEMENTS IN PEDIATRIC PATIENTS

Aarti Luhar, MD (*Presenter*)
Luo Xu (*Abstract Co-Author*)
James W. Sayre, PhD,MS (*Abstract Co-Author*)

PURPOSE

Durable venous access in pediatric patients poses a significant challenge due to the small size of the patient and their vasculature. Peripherally inserted central catheters (PICCs) are frequently utilized for blood draws, medication administration, intensive care unit (ICU) drips, nutrition support, and long-term antibiotic administration. At our institution, PICCs have typically been placed through upper extremity veins, but recent anecdotal evidence suggests greater success with lower extremity PICC placements in these patients. This study aims to compare the success rates and complication rates of PICCs placed in the upper versus lower extremities in the youngest pediatric patients.

METHODS AND MATERIALS

A retrospective chart review was conducted for pediatric patients aged 0-6 months who underwent PICC placement at our institution from 2013 to 2022. Data were extracted from our institutional electronic medical record system (EPIC Systems). Complications of PICC placement were defined as local swelling, suspected infection, failed attempt, stenosis, malposition, and malfunction (ie difficulty aspirating or flushing). The data was analyzed using IBM SPSS software to evaluate for differences in successful placement and complications between lower and upper extremities.

RESULTS

A total of 480 pediatric patients were identified for inclusion in the study. Statistical analysis using Pearson Chi-square test revealed a significantly higher success rate for single PICCs placed in the lower versus upper extremity 95.2% vs 86.2%, with a p-value=0.001. No significant difference was observed in overall complication rates, between lower versus upper 5.6% versus 5.2%, with a p-value=0.849.

CONCLUSION

For the youngest pediatric patients requiring durable venous access, lower extremity PICC placement demonstrated a significantly higher success rate compared to upper extremity placement without significant difference in complication rates. This suggests that lower extremity placement may be the preferred option in this patient population.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that PICC placement in the lower extremity offers a higher success rate without increase in complication, thereby improving PICC placement success and preserving upper extremity vessels for future venous access in our youngest patients.

M2-SPPH-2 EVALUATION OF INTELLIGENT NOISE REDUCTION IN NEONATAL PORTABLE CHEST RADIOGRAPHS. A VISUAL GRADING STUDY OF RESPIRATORY FINDINGS

Atsuko Fujikawa, MD, PhD (*Presenter*)
Shin Matsuoka, MD (*Abstract Co-Author*)
TAKAO TANUMA (*Abstract Co-Author*)
Yuki Saito, MD,BS (*Abstract Co-Author*)
Hidefumi Mimura, MD (*Abstract Co-Author*)

PURPOSE

To determine how Canon's Intelligent Noise Reduction (INR) and subsequent sharpness enhancement affect visual detection of transient tachypnea of the newborn (TTN) and respiratory distress syndrome (RDS) signs on first-day portable chest radiographs in neonates.

METHODS AND MATERIALS

For each of 61 neonates, the initial bedside chest radiograph was post-processed four ways: Raw, Raw + Sharpness, INR, and INR + Sharpness. Images were randomized and scored independently by pediatric radiologists using a 3-point Likert scale (1 = Not, 2 = Uncertain, 3 = Yes) for seven findings: perihilar streaks, fluid in fissures, reticulogranular pattern, air bronchograms, diffuse opacity, hyperinflation, and low lung volume. Paired Wilcoxon tests compared each processed image with its Raw counterpart; subgroup analysis explored birth-weight effects.

RESULTS

INR significantly increased scores for reticulogranular pattern ($p = 0.003$), diffuse opacity ($p = 0.013$) and hyperinflation ($p = 0.003$) versus Raw. INR + Sharpness retained these gains and provided an additional rise for diffuse opacity ($p = 0.016$). Sharpness applied without prior noise reduction produced no significant change in any finding. Mean score improvements were greatest in infants < 1.5 kg, where quantum mottle is most limiting. Air-bronchogram visibility improved numerically with INR but did not reach significance on the 3-point scale.

CONCLUSION

Noise reduction is the primary driver of image-quality enhancement in neonatal portable radiography, while sharpness adds value only after noise is suppressed. The INR ± Sharpness workflow improves depiction of key RDS/TTN findings without increasing radiation dose.

CLINICAL RELEVANCE/APPLICATION

Integrating INR into routine NICU chest-radiograph protocols can sharpen early diagnosis of neonatal respiratory disorders while preserving current low-dose exposure.

M2-SPPH-4 GADOLINIUM CONCENTRATION DEPENDENT SIGNAL ENHANCEMENT PROFILES USING ROUTINE CLINICAL SEQUENCES WITH GADOPICLENOL, GADOTERATE, GADOBUTROL, AND GADOXETATE AT 1.5, 3 AND 7 TESLA

Thomas Marth, MD (*Presenter*)
Johannes M. Froehlich, PhD (*Abstract Co-Author*)
Daniel Nanz (*Abstract Co-Author*)
Reto Sutter, MD (*Abstract Co-Author*)

PURPOSE

Gadopiclenol, a new macrocyclic gadolinium- (Gd) based contrast agent (GBCA), exhibits a higher longitudinal relaxivity (r_1) than current standard GBCAs, and, thus, has the potential to be used at lower dose or to generate a brighter T1-weighted (T1w) signal at equivalent dose. As the relationship between enhancement and contrast agent concentration (c) is non-linear and can strongly vary between sequences, the corresponding signal profiles were experimentally explored in a phantom study and compared to those of established GBCAs.

METHODS AND MATERIALS

Standardized aqueous dilution series (0.0, 0.1, 0.25, 0.5, 1, 2.5, 5, 10, and 25 mmol/L in normal saline (0.9% sodium chloride)) of gadopiclenol, and the current standard GBCAs gadoterate, gadobutrol, and gadoxetate were imaged at a field strength of 1.5, 3, and 7 Tesla (T) in a standardized setting at room temperature. The imaging protocol included 9 clinical fast spin-echo (FSE) and gradient-echo sequences. Signal intensities (SIs) were measured for each c, set in relation to the SI of water (rSI), and compared across the 4 GBCAs. Additionally, T1 relaxation times were measured at 3 T and r_1 was calculated and compared across the 4 GBCAs.

RESULTS

The maximum rSI in T1w FSE was observed at a lower Gd c (1.0 mmol/L at all 3 field strengths, 1.5, 3, and 7 T) in the gadopiclenol series than in the series with the current standard GBCAs (gadoterate and gadobutrol, 2.5 mmol/L for all 3 field strengths, gadoxetate, 2.5 mmol/L at 1.5 and 3 T, and 1.0 and 2.5 mmol/L at 7 T). The maximum rSI measured at 1.0 mmol/L gadopiclenol was comparable (± 12% rSI) to the maximum rSI measured at 2.5 mmol/L of gadoterate, gadobutrol, and gadoxetate (at 1.5 T, 552 to 629, 607, and 590; at 3 T, 520 to 532, 534, and 512; at 7 T, 330 to 347, 318, 336; respectively). Molar gadopiclenol relaxivity, r_1, in aqueous solution at 20°C at 3 T (12.0 $s^{-1} \cdot mM^{-1}$) was 3 to 4 times higher than r_1 of gadoterate and gadobutrol (2.8 and 3.4 $s^{-1} \cdot mM^{-1}$, respectively), and 2.7 times higher than that of gadoxetate (4.5 $s^{-1} \cdot mM^{-1}$).

CONCLUSION

The experiments confirmed the maximum SI in clinical T1w images to be shifted to lower Gd c of gadopiclenol compared to standard GBCAs at all field strengths. In the low-c range, approximately half the Gd c was sufficient to produce a comparable T1w signal enhancement compared to current standard GBCAs at all field strengths.

CLINICAL RELEVANCE/APPLICATION

Our study is the first to confirm the expected maximum SI shift to a lower Gd c of the new contrast agent gadopiclenol in clinical T1w FSE acquisitions compared to standard GBCAs. The results confirm the potential to reduce the Gd c or dose when using gadopiclenol compared to the current standard GBCAs in clinical T1w sequences and can help guide the choice of Gd c for clinical examinations with gadopiclenol.

M2-SPPH-5 SEGMENTATION-GUIDED SEQUENTIAL REGISTRATION FOR CT PERFUSION IN LIVER

Jinzhong Yang, PhD (*Presenter*)
Zhan Xu, PhD (*Abstract Co-Author*)
Yao Zhao (*Abstract Co-Author*)
Xinru Chen (*Abstract Co-Author*)
Jinyong Lin (*Abstract Co-Author*)
Roya Barati (*Abstract Co-Author*)
Chaan Ng, MD (*Abstract Co-Author*)

PURPOSE

Sequential image registration in dynamic CT perfusion (CTp) is essential for accurate liver cancer diagnosis and treatment assessment. CTp scans typically comprise multiple cine scans with a narrow craniocaudal extent (~ 4 cm), and may include sequential helical scans also with limited craniocaudal coverage (~ 20 cm). Reliable registration of these scans into a common space is important but challenging due to breath-hold variations during scan and post-perfusion intensity changes. We developed a deep learning-based registration framework to achieve fully automated registration of CTp cine and helical scans.

METHODS AND MATERIALS

A total of 39 CTp scans from 20 patients, each with 1 to 3 scan sessions, were included in this study. Each CTp scan has 59-89 cine scans and 8-10 helical scans. Liver was manually segmented on 20 randomly selected helical scans, which were used to train a 2D nnU-Net model for liver auto-segmentation of and on another 5 cine scan and 5 helical scans for testing. In each CTp scan, the first helical scan in the middle of the entire CTp acquisition was used as the reference and all other cine and helical scans were registered to it. The registration framework first applied rigid registration focusing on liver to correct the craniocaudal displacement due the breath-hold variations. Next, a deformable registration based on TransMorph and Swin transformer with liver guidance were applied to achieve a finer-scale registration of in-plane details. 30 CTp scans were used to train the model and the remaining 9 CTp scans were used for testing. Registration performance was evaluated using Dice Similarity Coefficient (DSC, =1 in perfect result) between the contoured reference and deformed images. and Hausdorff Distance (HD, =0 in perfect result) by comparing the contour directly of deformed liver with the reference liver contours/masks.

RESULTS

Liver segmentation was validated the testing set with an average DSC of 0.91±0.07. Of the 9 testing CTp scans, a total of 658 registration were performed. After registration, the DSC of liver contours was improved from 0.834 ± 0.025 to 0.959 ± 0.019, and the HD was improved from 4.6 ± 2.1 mm to 0.959 ± 0.019, respectively. A Student's t-test showed significant difference before and after registration in terms of both DSC and HD ($p<0.001$).

CONCLUSION

The proposed segmentation-guided registration framework has demonstrated effectiveness for automatic sequential registration for liver CTp scans.

CLINICAL RELEVANCE/APPLICATION

The sequential image registration framework can automatically register cine scans and helical scans from a CTp acquisition with high accuracy; this will greatly facilitate the workflow and accuracy of CT perfusion analyses.

M2-SPPH-7 DOES THE USE OF ULTRASOUND INCREASE THE ANTIBIOTIC SENSITIVITY OF BACTERIA ADHERENT TO PENILE IMPLANT SURFACES? AN IN VITRO STUDY

Priscilla Machado, MD (*Presenter*)
Saatvik Kambhampati (*Abstract Co-Author*)
Analyse Giordano (*Abstract Co-Author*)
Francisco Aguirre (*Abstract Co-Author*)
Brian Im (*Abstract Co-Author*)
Lauren J. Delaney, PhD (*Abstract Co-Author*)
Noreen J. Hickok, PhD (*Abstract Co-Author*)
Flemming Forsberg, PhD (*Abstract Co-Author*)
Paul H. Chung, MD (*Abstract Co-Author*)

PURPOSE

Erectile dysfunction (ED) occurs due to cardiovascular disease, diabetes, among others. Approximately 25,000 men with ED opt for placement of a penile implant (ED implant) each year with the rate increasing on average 8% annually. Approximately 1-3% of patients undergoing primary and 7-18% undergoing revision ED implant surgery will experience the devastating complication of device infection. Ultrasound may be an optimal, external method to reduce implant infection in the post-operative period. Ultrasound is known to increase tissue permeability and antibiotic susceptibility and may be able to disrupt biofilms. This study investigated whether the application of ultrasound could increase antibiotic susceptibility and reduce adherent bacteria on ED implant surfaces.

METHODS AND MATERIALS

Sterile 12 mm discs were obtained from Coloplast Titan implants and incubated with 10 5 colony-forming units per milliliter (CFU/mL) of methicillin-sensitive Staphylococcus aureus (ATCC25923) in trypticase soy broth (TSB) for 24 hours. Samples were then rinsed with phosphate-buffered saline (PBS) and placed into 10% human serum solutions containing normal saline or 0.5 mg/mL vancomycin and 0.04 mg/mL of gentamicin. Samples were then incubated for 6 hours in 15 mL of the respective solution and removed for ultrasound treatment. Ultrasound treatment using a Logiq E10 scanner with a C1-6 probe (GE HealthCare) was applied for 30 min using color Doppler imaging with an MI of 1.6. Next samples were rinsed with PBS and adherent bacteria released by shaking in 0.3% Tween-20. Suspended bacteria were serially diluted, plated onto 3M PetriFilms, and counted. Experiments were conducted as 3 repetitions. Mann-Whitney U tests were performed to compare outcomes with $p<0.05$ being considered significant.

RESULTS

Vancomycin/gentamicin alone reduced adherent S. aureus bacterial counts by ~0.5 log compared to normal saline ($p=0.054$). Ultrasound further increased vancomycin/gentamicin antibiotic sensitivity by an additional ~2 log, reducing bacterial load by a total of ~2.5 log compared to normal saline control ($p=0.019$). Samples in the normal saline with ultrasound group showed no decrease in bacterial counts when compared to normal saline alone ($p=0.82$). Ultrasound application increased antibiotic susceptibility and reduced adherent bacteria by an additional ~2 log compared to antibiotic alone (~0.5 log) for a total reduction of ~2.5 log.

CONCLUSION

Ultrasound post-operatively may be used as a method to reduce implant infection.

CLINICAL RELEVANCE/APPLICATION

Infection remains a serious surgical concern and current antibiotic regiments are not completely effective. Ultrasound combined with the existing antibiotics regimen can reduce implant infection.

Ron N. Alkalay, PhD (*Abstract Co-Author*)
David B. Hackney, BA, MD (*Abstract Co-Author*)
Tracy A. Balboni, MD, MPH (*Abstract Co-Author*)

PURPOSE

The Spinal Instability Neoplastic Score (SINS) is the most common method of assessing spine stability in the setting of spinal metastases. We sought to assess (1) the SINS score as a predictor of vertebral compression fracture (VCF), (2) the risk contributions of the 6 SINS individual factors, and (3) other contributors to fracture risk.

METHODS AND MATERIALS

In total, 194 patients with 391 spinal lesions that had not previously been treated with vertebroplasty/kyphoplasty, radiation therapy (RT), or surgery were enrolled prior to RT and followed for new or worsened fracture.

RESULTS

187 patients who were treated to 361 vertebral levels underwent post-RT follow-up. Average follow-up time for patients on study was 9.4 months (range: 0.2-38.8 months). A total of 33 new or worsened fractures (9.1% of lesions followed) were observed, with an average time to fracture of 4.4 months (range 0.1-27.8 months). Of all 6 SINS factors, three were found to be individually significantly associated with increased risk of fracture, these were: lesion location in L2-L4 (HR=2.78, p=0.04), mixed or lytic appearance on CT (mixed HR=3.87, p=0.01, lytic HR=2.68, p=0.02), and <50% vertebral collapse (HR=3.52, p<0.01). SINS as a summated score was significantly associated with increased risk of fracture on multivariable analysis (MVA, p<0.01). Use of bone-strengthening medications such as bisphosphonates was also significantly associated with decreased risk of fracture in MVA in stable (SINS =6) (HR=0.10, p=0.03) and potentially unstable (SINS 7-12) lesions (HR 0.18, p=0.03).

CONCLUSION

These findings support that SINS is a useful tool for estimating VCF risk, with lesion location, metastasis bone morphology, and presence of <50% collapse being the strongest predictors. Additionally, findings suggest that bone-strengthening medications such as bisphosphonates may mitigate the risk of developing VCF after RT.

CLINICAL RELEVANCE/APPLICATION

Better understanding of the risk factors involved in post-RT VCF may help to inform multidisciplinary clinical decision making around the treatment of metastases in the bony spine.

M2-SPVA-1 CORRELATION BETWEEN BRACHIOCEPHALIC ARTERY FAT ATTENUATION INDEX AND CLINICAL ACTIVITY IN PATIENTS WITH TAKAYASU ARTERITIS

Yang Lu, BMedSc, MMEd (*Presenter*)

PURPOSE

This study aimed to evaluate the imaging characteristics of the perivascular fat attenuation index (FAI) in patients with Takayasu's arteritis (TA) and assess the correlation between FAI and disease activity.

METHODS AND MATERIALS

This retrospective study included 70 consecutive TA patients [40 patients with brachiocephalic artery involvement (TA-BCA) and 30 patients without BCA involvement (TA-nonBCA)], along with 55 normal individuals. Computed tomography angiography (CTA) was performed utilizing a standardized protocol, encompassing the region from the common carotid artery (CCA) bifurcation to 3cm below the aortic arch. Image processing was conducted using the Skviewer software to delineate perivascular fat as adipose tissue radially displaced from the outer wall of the blood vessel to an extent equivalent to its diameter. Divide the BCA into the innominate artery (IA), proximal segment of the left common carotid artery (p-LCCA), middle segment of the left common carotid artery (m-LCCA), proximal segment of the right common carotid artery (p-RCCA), and middle segment of the right common carotid artery (m-LRCA). Intergroup analysis of vascular segment data with SPSS 25.0. MedCalc software was utilized to generate ROC curves and relevant indicators. Disease activity was assessed using ITAS (2010) and ITAS-A.

RESULTS

FAI values were significantly higher (P<0.05) in the TA-BCA and TA-nonBCA groups than in the normal control cohort. Notably, the p-LCCA demonstrated the most consistent measurable and easily affected segment. In the TA-nonBCA group, the optimal cutoff was -89.715 Hu, with 73.3% sensitivity and 98.2% specificity (AUC: 0.927, 95% CI: 0.872-0.982, P<0.001). In the TA-BCA group, with the active stage (n=23) and inactive stage (n=17), the optimum cutoff with 100% sensitivity and 82.4% specificity (AUC: 0.951, 95% CI: 0.890-1, P<0.001) was -73.445 HU. In the TA-BCA group, univariate and multivariate analyses showed that the FAI is an independent risk factor for determining active inflammation (OR: 1.267, 95% CI: 1.035-1.551, P=0.022).

CONCLUSION

A reliable biomarker to distinguish TA patients from normal individuals was their significantly higher FAI from CTA of the brachiocephalic artery. Quantitative parameters from FAI enable the assessment of Takayasu arteritis inflammatory activity.

CLINICAL RELEVANCE/APPLICATION

The perivascular FAI is a reliable biomarker for separating TA patients from normal individuals. Monitoring inflammation activity and anti-inflammatory efficacy may benefit from this study.

M2-SPVA-2 HIGH-FREQUENCY ULTRASONIC COMBINED WITH SUPERB MICROVASCULAR IMAGINGTECHNOLOGY IN THE EVALUATION OF HYPERTROPHIC SCARS:A PRELIMINARY STUDY

Xiaoyi Chen, BS (*Presenter*)
Yi Zhang (*Abstract Co-Author*)
Yixuan Zhang (*Abstract Co-Author*)
Xinping Bai (*Abstract Co-Author*)
Jianxin Liu (*Abstract Co-Author*)

PURPOSE

In this study, high-frequency ultrasonic and Superb Microvascular Imaging (SMI) technology were used to evaluate the thickness and microvascular changes in skin layer of hypertrophic scar lesions, and to discuss the evaluation value of high-frequency ultrasonic combined with SMI technology in hypertrophic scar lesions.

METHODS AND MATERIALS

This study prospectively included 9 patients (2 males and 7 females) with hypertrophic scar lesions diagnosed by senior physicians in the Department of Plastic and Aesthetic Surgery of XX Hospital from December 2024 to March 2025, and analyzed a total of 20 lesions. First, high-frequency ultrasonic was used to measure the thickness of the skin at the lesion of hypertrophic scar and the skin on the healthy side. The Vascular Index (VI) was measured by SMI technology to compare the differences of VI in skin layer between the lesion and the healthy side.Seven of the lesions were treated with triamcinolone olone injection. One month later, high-frequency ultrasound combined with SMI technology was re-employed to evaluate the scars. The differences in scar thickness and VI before and after treatment were compared.

RESULTS

The skin thickness of 20 hypertrophic scar lesions was 2.97±1.21mm and that of the healthy site was 1.36±0.33mm (P < 0.05). The VI of lesions of 20 hypertrophic scar lesions and healthy sides were 6.80 (4.73, 18.50) % and 1.15 (0.25, 2.83) %, respectively (P < 0.05). The skin thickness of 7 hypertrophic scar lesion sites before triamcinolone injection was 2.93±1.20mm (P < 0.05), and after triamcinolone injection was 2.11±1.09mm (P < 0.05). The VI of the lesion site before and after triamcinolone injection were 6.20 (4.50, 9.50) % and 3.70 (0.30, 5.70) % , respectively (P < 0.05).

CONCLUSION

High-frequency ultrasonic combined with SMI technology can accurately detect thickness and microvessels changes in skin layer. It’s more objective to evaluate the activity of hypertrophic scar lesions than the current clinical scar scoring scale and physicians' subjective evaluation. Ultrasound technology is convenient and non-invasive, suitable for scar follow-up and guides the selection of follow-up treatment.

CLINICAL RELEVANCE/APPLICATION

Hypertrophic scar lesions were thicker than normal skin layer, and microvessels in skin layer increased. After triamcinolone injection, the lesions' skin became thinner and the microvessels decreased. It's more objective to evaluate the activity of hypertrophic scar lesions than the current clinical scar scoring scale and physicians' subjective evaluation. Ultrasound technology is convenient and non-invasive, suitable for scar follow-up and guides the selection of follow-up treatment.

M2-SPVA-3 A PRELIMINARY STUDY ON PREDICTING THE STABILITY OF DEEP VEIN THROMBOSIS USING CT TEXTURE ANALYSIS

Fei Yang, MS (*Presenter*)
DAWEI WANG (*Abstract Co-Author*)

PURPOSE

To evaluate the predictive value of CT-based thrombus texture analysis for assessing deep vein thrombosis (DVT) stability.

METHODS AND MATERIALS

A total of 108 patients with DVT diagnosed through clinical examination and ultrasound at our hospital between May 2020 and October 2024 were enrolled. Patients were divided into DVT with acute pulmonary embolism (APE) (n=40) and DVT without APE (n=23) groups. Texture features were extracted from CT thrombi images using the Least Absolute Shrinkage and Selection Operator algorithm. Imaging, clinical, and combined models were developed through logistic regression analyses and evaluated using receiver operating characteristic (ROC) curves, calibration curves, and clinical decision curves, with the areas under the curves (AUCs) compared using the DeLong test.

RESULTS

DVT textural features (gray-level run-length matrix run entropy, gray-level co-occurrence matrix (GLCM) cluster shade, GLCM-maximum cross-correlation), and clinical parameters (smoking, sex, D-dimer), were identified as independent predictors of DVT stability. The AUCs for the imaging, clinical, and combined models were 0.792 (0.705-0.880), 0.832 (0.753-0.910), and 0.890 (0.825-0.954), respectively. The combined model outperformed the clinical and imaging models ($P < 0.05$). Clinical decision curve analysis revealed superior predictive accuracy (0.03-0.75) compared to the clinical (0.13-0.87) and imaging (0.12-0.83) models. It achieved the highest net benefit at a risk probability > 0.03, offering optimal efficacy and the greatest clinical value in predicting DVT stability.

CONCLUSION

Integrating CT texture features with clinical parameters enhances the prediction of DVT stability, underscoring its potential clinical applications.

CLINICAL RELEVANCE/APPLICATION

1. This study innovatively applies CT texture analysis to predict the stability of deep vein thrombosis (DVT), offering a novel imaging-based approach for clinical assessment. 2. Texture features, including gray-level run-length matrix run entropy, gray-level co-occurrence matrix cluster shade, and GLCM-maximum cross-correlation, are identified as independent predictors of DVT stability, providing new insights into thrombus characterization. 3. We establish and compare three predictive models (imaging, clinical, and combined models), demonstrating that the combined model incorporating both CT texture features and clinical parameters could enhance the precision of DVT management and improve patient outcomes, highlighting its potential for early identification of unstable DVT and prevention of acute pulmonary embolism.

M5A-SPBR-1 TOPOGRAPHICAL DISTRIBUTION OF BREAST CANCER BRAIN METASTASIS SUBTYPES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Sami Almasri (*Presenter*)
Gordon R. Daly (*Abstract Co-Author*)

PURPOSE

This systematic review aims to analyze spatial distribution of breast cancer brain metastasis (BCBM) among different subtypes, to improve clinical decision-making, refine treatment approaches, and improve prognostic predictions for BCBM.

METHODS AND MATERIALS

A systematic review was conducted in accordance with PRISMA guidelines and registered on PROSPERO. Eligible studies included those including specific information on BCBM subtype and anatomical location. Meta-analyses were performed for each molecular subtype and their distribution in each brain region using random effects models

RESULTS

Eleven studies were included, with six eligible for quantitative meta-analysis. The highest proportion of frontal lobe metastases originated from triple-negative breast cancer (TNBC) at 32% (95% CI: 18-50%), followed by HR+/HER2- at 29% (95% CI: 21-38%). Cerebellar metastases were most common in HR+/HER2- cases at 37% (95% CI: 27-47%), followed by HR-/HER2+ at 29% (95% CI: 19-41%). Occipital lobe involvement was highest in HR+/HER2- at 33% (95% CI: 25-41%). The temporal lobe showed high involvement from HR+/HER2- (30%, 95% CI: 20-41%) and TNBC (28%, 95% CI: 19-41%). HR+/HER2- predominated in the parietal lobe (32%, 95% CI: 24-40%). HR+/HER2- significantly favored posterior circulation regions ($p < 0.05$), whereas TNBC significantly favored anterior circulation territories ($p<.05$).

CONCLUSION

BCBM demonstrates non-random topographic patterns in accordance with molecular subtype, suggesting that metastatic spread may be influenced by tumor biology.

CLINICAL RELEVANCE/APPLICATION

These findings support the development of targeted imaging protocols and subtype-specific treatment strategies. Understanding metastatic pathways of each subtype has important implications for personalized oncology, aiding in surveillance, therapeutic planning, and risk stratification of high-risk brain regions.

M5A-SPBR-2 OVERVIEW OF DIFFERENT REIMBURSEMENT STRATEGIES AMONG CONTRAST-ENHANCED MAMMOGRAPHY (CEM) EXPERTS - A SURVEY STUDY

Thiemo van Nijnatten, MD, PhD (*Presenter*)
Javier Azcona Saenz, MD (*Abstract Co-Author*)
Rodrigo Alcantara, MD, MSc (*Abstract Co-Author*)
Pascal A. Baltzer, MD (*Abstract Co-Author*)

PURPOSE

To perform an international survey among global expert breast radiologists regarding contrast-enhanced mammography (CEM) on the topic of reimbursement strategies.

METHODS AND MATERIALS

An online questionnaire on CEM reimbursement strategies was distributed to 29 selected global expert breast radiologists regarding CEM. Hospital information, CEM implementation, estimated costs, reimbursement availability, registration and declaration codes, as well as personal opinions on CEM reimbursement were collected. Replies were exploratively analyzed with descriptive and non-parametric statistics.

RESULTS

Twenty out of 29 global expert breast radiologists regarding CEM responded this survey. Initiation of local CEM implementation ranged from 2011 to 2024. All hospitals offered CEM for clinical/diagnostic indications, with price ranges for breast MRI higher than for CEM in all, but two cases. Sixty percent of hospitals (12/20) reported receiving reimbursement for CEM. The remaining 40% declared not receiving reimbursement, citing reasons such as coverage by department budget, lack of dedicated billing code, or absence of reimbursement by the national healthcare system and/or insurance providers. Among the 12 hospitals receiving reimbursement, 67% (8/12) obtained full reimbursement for all components of CEM, and 75% (9/12) for all indications. Reimbursement sources varied by hospital type, with public and university hospitals mainly publicly funded, and private hospitals relying on insurance or patient payments.Most respondents (75%, 15/20) reported no dedicated national reimbursement code for CEM currently exists. Of these respondents, 53% (8/15) used FFDM code. Most hospitals lacked separate codes for the contrast medium (60%, 9/15) or its intravenous injection (93.3%, 14/15). Among hospitals without a national code, 73% (11/15) were aware of efforts to establish one. Although nearly half of participants (45%, 9/20) faced reimbursement challenges, 65% (13/20) stated that reimbursement strategies did not affect CEM adoption.

CONCLUSION

Substantial heterogeneity in CEM reimbursement strategies do exist, with most hospitals securing full coverage through alternative strategies until dedicated national reimbursement codes are established.

CLINICAL RELEVANCE/APPLICATION

Different CEM reimbursement strategies do exist on a global level. This information might affect the convenience for CEM implementation in different institutes.

M5A-SPBR-3 PREOPERATIVE BREAST EDEMA ON T2-WEIGHTED MRI AS A PREDICTOR OF SENTINEL LYMPH NODE METASTASIS IN CLINICALLY NODE-NEGATIVE BREAST CANCER: A RETROSPECTIVE BICENTRIC STUDY

Tianwen Xie (*Presenter*)
Yan Huang (*Abstract Co-Author*)
Qiufeng Zhao (*Abstract Co-Author*)
Yajia Gu (*Abstract Co-Author*)

PURPOSE

To investigate the predictive value of breast edema identified on preoperative T2-weighted MRI for sentinel lymph node (SLN) metastasis in patients with clinically node-negative (cN0) invasive breast cancer.

METHODS AND MATERIALS

In this retrospective bicentric study, women with cN0 invasive breast cancer who underwent preoperative breast MRI between January 2016 and December 2019 at two independent institutions were included. Breast edema on T2-weighted images was assessed. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of SLN metastasis. The area under the receiver operating characteristic curve (AUC) and negative predictive value (NPV) were calculated.

RESULTS

Of the 381 patients, SLN metastasis was observed in 67 of 267 patients (25.1%) in the primary cohort and in 24 of 114 patients (21.1%) in the validation cohort. Breast edema was independently associated with SLN metastasis in both cohorts. A model based solely on breast edema achieved an AUC of 0.738 (95% CI: 0.667-0.809) and an NPV of 89% in the primary cohort, with consistent performance in the validation cohort. Compared with a model using only clinicopathological features (age and molecular subtype), the combined model incorporating breast edema significantly improved predictive performance (AUC: 0.822 vs. 0.654, $p < 0.001$; NPV: 92% vs. 83%), which was confirmed in the validation cohort (AUC: 0.793 vs. 0.616, $p = 0.021$; NPV: 92% vs. 88%).

CONCLUSION

Breast edema is independently associated with SLN metastasis. Breast edema combing with clinical-pathological features may help identify patients at lower risk of SLN metastasis, potentially aiding in SLNB omission decisions.

CLINICAL RELEVANCE/APPLICATION

The preoperative breast MRI assessment of edema may serve as a valuable risk-stratification tool for predicting SLN metastasis in cN0 breast cancer patients. The combination of breast edema with clinical-pathological factors enhances predictive performance and may help identify patients who could be suitable candidates for SLNB omission.

M5A-SPBR-4 A BIOPHYSICS-BASED COMPUTATIONAL APPROACH BOTH OUTPERFORMS AND SYNERGIZES WITH A COMMERCIAL MAMMOGRAPHIC DENSITY ASSESSMENT SOFTWARE FOR BREAST CANCER PREDICTION

Andre Khalil, PhD, MS (*Presenter*)
Joshua Hamilton, MS, BS (*Abstract Co-Author*)
Jeremy Juybari (*Abstract Co-Author*)

PURPOSE

The accelerated growth of AI approaches found a niche with image-based risk prediction from mammography. These methods' uninterpretability limits their clinical acceptance. Mammographic breast density is the most widely recognized image-based risk factor for breast cancer. We developed an interpretable biophysics-based computational approach that categorizes mammographic tissue into fatty tissue, active dense tissue, which is structurally reorganizing, and passive dense tissue. This categorization relies on robust measurements of scale-invariant tissue organization features and, as a result, is agnostic to mammogram gantry processing. We hypothesize that these active vs. passive dense tissue regions are more predictive of breast cancer than overall mammographic dense tissue.

METHODS AND MATERIALS

Using the OPTIMAM database, bilateral mammographic screenings were acquired on Hologic's Selenia units ~3 years prior to diagnosis for n=197 cases (mean age = 59.4), or the last screening on record for n=3712 controls (mean age = 59.8). The areas of fatty, active dense, and passive dense tissue were calculated, and the volumetric breast density (VBD) and fibro-glandular volume (FGV) were obtained from software developed by Lunit Inc. Three pairs of "main effects" and "interaction" generalized linear models (GLM) were developed to predict cancer vs. control status with the predictive variables being, for model 1 (Commercial-derived Model): VBD, FGV, and patient age; for model 2 (Our Model): amounts of fatty, passive dense, active dense tissue, our own measurement of mammographic percent density, and patient age; and for model 3 (Combined Model): a synergistic combination of the variables from models 1 and 2. For each model, the mean and 95% confidence intervals were calculated for the area under the curve (AUC) from bootstrapped receiver operating characteristic curves. The images and data used in this publication are derived from the OPTIMAM imaging database (https://medphys.royalsurrey.nhs.uk/omidb/about-omi-db/). We acknowledge the OPTIMAM project team and staff at the Royal Surrey NHS Foundation Trust who developed the OPTIMAM database, and Cancer Research UK who funded the creation and maintenance of the database.

RESULTS

Our model (AUCs = 0.64, 0.71) outperforms and synergizes (AUCs = 0.66, 0.82) with the commercial-derived model (AUCs = 0.6, 0.61).

CONCLUSION

Our biophysics-based approach produces interpretable measurements that could provide improved breast cancer risk prediction.

CLINICAL RELEVANCE/APPLICATION

Our model outperforms deep learning models from the literature, but it does not suffer from these models' limitations, such as generalizability, calibration, and interpretability.

M5A-SPBR-5 POTENTIAL OF ARTIFICIAL INTELLIGENCE TO DETECT INTERVAL BREAST CANCERS

Babita Panigrahi, MD (*Presenter*)
Lisa A. Mullen, MD (*Abstract Co-Author*)
Emily Ambinder, MD, MS (*Abstract Co-Author*)

PURPOSE

Interval breast cancers (IBCs), diagnosed within one year of a negative or benign screening mammogram, tend to be more aggressive than screen-detected cancers. Causes include radiologist oversight or subtle/absent findings. These false-negative (FN) cases offer an opportunity to assess whether artificial intelligence (AI) could have detected IBCs earlier.

METHODS AND MATERIALS

We retrospectively reviewed all patients at a multisite academic center with BI-RADS 1 or 2 screening mammograms between July 1, 2013, and June 30, 2020, who were diagnosed with an IBC within a year. An FDA-approved AI tool (Transpara v1.7.4, ScreenPoint Medical) retrospectively scored the FNs, assigning lesion-level risk as low (=42), intermediate (43-74), or elevated (=75), which was not available when the exam was performed. Radiologists categorized IBCs as missed, minimal

actionable, minimal nonactionable, true interval, mammographically occult, or technical exclusion. Lesions were considered AI-detected if scored intermediate or elevated. Chi-square analysis tested associations of AI detection with patient and cancer characteristics, with p-values <0.05 considered significant.

RESULTS

Of 211,517 eligible screening mammograms, 96 IBCs were diagnosed (FN rate: 0.45/1000). 66 FN mammograms (69%) utilized digital breast tomosynthesis (DBT). Mean patient age was 62 ± 12 years. Radiologists classified 12 (13%) as missed, 16 (17%) minimal actionable, 16 (17%) minimal nonactionable, 13 (14%) true interval, 38 (40%) mammographically occult, and 1 (1%) technical exclusion. AI assessed 82 cases (14 excluded), yielding lesion-specific risk scores of low in 51 (62%), intermediate in 19 (23%), and elevated in 12 (15%). 31 IBCs (38%) with intermediate/elevated scores were considered detectable by AI. Among these, 23 (74%) were soft tissue findings, 1 (3%) calcifications, and 7 (23%) both. AI detection was significantly associated with retrospective mammographic visibility (p<0.001), symptomatic presentation (e.g., pain, lump, nipple discharge) vs. asymptomatic screening MRI detection (p=0.005), and scattered/heterogeneously dense breasts (p=0.01). DBT use and tumor features were not significantly associated.

CONCLUSION

AI may have facilitated earlier detection of 38% of IBCs, particularly those retrospectively visible and presenting symptomatically.

CLINICAL RELEVANCE/APPLICATION

AI has the potential to enhance early detection of interval breast cancers, especially those missed or underestimated by radiologists, supporting its role as an adjunct in screening.

M5A-SPBR-6 PROGNOSTIC MODEL BASED ON MRI FEATURES FOR PREDICTING DISEASE-FREE SURVIVAL IN BREAST CANCER PATIENTS AFTER NEOADJUVANT CHEMOTHERAPY

Shuluan Chen (*Presenter*)
Shunan Che, MD (*Abstract Co-Author*)
Mengying Yang (*Abstract Co-Author*)
Yuan Tian (*Abstract Co-Author*)
Dehong Luo, MD (*Abstract Co-Author*)
Jing Li, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop a prognostic model based on clinicopathological variables and magnetic resonance imaging (MRI) findings to predict disease-free survival (DFS) in breast cancer patients after neoadjuvant chemotherapy (NAC).

METHODS AND MATERIALS

A retrospective analysis was conducted on 286 patients with invasive breast cancer who underwent MRI before and after NAC (hereafter, referred to as pre- and post-NAC, respectively), received NAC and surgical treatment from January 2014 to December 2021. Univariate Cox regression analysis was used for preliminary screening and variables with P<0.05 were included in the Lasso-Cox analysis to construct models. The predictive performance of the models was evaluated using the area under the curve (AUC) of receiver operating characteristic (ROC) curves, concordance index (C-index), and calibration curves. Risk scores derived from the combined model stratified patients into high- and low-risk groups. Survival differences were analyzed using the log-rank test.

RESULTS

After univariate Cox regression and Lasso-Cox analysis, the clinicopathological model included clinical T stage, clinical N stage, pathological complete response (pCR) in primary tumor, pCR in axillary lymph nodes, pathological T stage and microvessel invasion. The pre-NAC MRI model included multifocal or multicentric lesions, lesion enhancement types, peritumoral edema and ipsilateral suspicious internal mammary lymph nodes. The post-NAC MRI model included regression patterns, max diameter, TIC types, recist response and radiological complete response (rCR). The combined model incorporating clinicopathological variables, pre-NAC, and post-NAC MRI features demonstrated superior predictive performance (C-index=0.765) compared to individual models or pairwise combined models. A risk score cut-off of 1.014 from the combined model effectively stratified patients into high- and low-risk groups.

CONCLUSION

The prognostic model based on clinicopathological variables, pre-NAC and post-NAC MRI features offers improved predictive accuracy for DFS in breast cancer patients after NAC, enabling enhanced risk stratification and individualized follow-up strategies.

CLINICAL RELEVANCE/APPLICATION

The prognostic model facilitates early identification of high-risk recurrence factors, enabling personalized treatment and potentially improving survival outcomes for breast cancer patients after NAC.

M5A-SPBR-7 THE RADIOACTIVE SEED LOCALIZATION FOR IMPALPABLE BREAST CANCER CONSERVATIVE SURGERY: META-ANALYSIS

Hortencia Ferreira, MSc, PhD (*Presenter*)

PURPOSE

Breast cancer is the most common among women with malignant neoplasm in Brazil and the early diagnosis is essential to provide less mutilating treatment for patients. The lesions are impalpable and can be submitted to conservative surgery, which requires an intraoperative localization method to guide the surgeon during tumor excision. This study aimed to develop a meta-analysis comparing the surgical efficiency of two intraoperative breast localization techniques, wire-guided localization (WGL) and radioactive seed localization (RSL).

METHODS AND MATERIALS

The systematic research was performed in databases such as Embase, LILACS, PubMed, SciELO, and Web of Science. The selected studies in the screening process went through a standard form of data extraction. The ROBINS-1 and ROB-2 tool was applied to analyze the bias risk and methodological quality. The Review Manager 5.4 software was used to perform the meta-analysis by the random effects analysis model to calculate the relative risk, considering a 95% confidence interval.

RESULTS

Six randomized controlled trials and 32 cohort studies were identified, meeting the inclusion criteria. The overall quality was high for randomized trials and moderate for cohort studies. The population consisted of women with impalpable breast cancer, aged 22-92 years old, with single or multiple markers, and neoadjuvant chemotherapy patients were included. The results demonstrated an RSL superiority over WGL for the rates of positive surgical margin (RR 0.78, 95% CI [0.70-0.88], 15085 patients), reoperation (RR 0.71, 95% CI [0.61-0.84], 13884 patients) and recurrence (RR 0.41, 95% CI [0.19-0.86], 1525 patients, followed up for 13-109 months).

CONCLUSION

The results demonstrated that RSL is superior to WGL in surgical efficiency in the intraoperative localization of impalpable breast lesions. RSL is a valid localization method for surgical efficiency for patients with non-palpable breast cancer and can be applied in various indications for breast-conserving surgery with intraoperative localization, including neoadjuvant treatment.

CLINICAL RELEVANCE/APPLICATION

The success of breast-conserving surgery depends on the complete removal of the tumor. So, completing surgery with negative surgical margins reduces reoperation rates and the risk of disease recurrence. Furthermore, a longer time between lesion localization and surgery allows greater flexibility in scheduling radiology and surgery

sectors, in addition to the possibility of the seed placement procedure taking place before neoadjuvant chemotherapy.

M5A-SPBR-8 ARTIFICIAL INTELLIGENCE-DERIVED MAMMOGRAPHY SCORES CAN PREDICT ONCOTYPE DX RISK SCORES IN ESTROGEN RECEPTOR POSITIVE BREAST CANCERS

Jung-Oh Lee, MD, MSc (*Presenter*)
Su Min Ha, MD (*Abstract Co-Author*)
Jung Hyun Yoon, MD, PhD (*Abstract Co-Author*)
Hye Sun Lee (*Abstract Co-Author*)

PURPOSE

The Oncotype Dx Recurrence Score (RS) is a multigene assay that predicts the risk of recurrence and potential benefit from chemotherapy in estrogen receptor (ER)-positive early-stage breast cancers. In this study, we evaluated whether artificial intelligence (AI) scores derived from preoperative mammography could serve as imaging biomarker to predict Oncotype Dx RS and patient outcomes in ER-positive invasive breast cancers.

METHODS AND MATERIALS

From December 2012 to August 2022, 1852 women who were treated for ER-positive, HER2-negative invasive breast cancers who had Oncotype Dx assays from two tertiary institutions were included. Preoperative mammograms were retrospectively analyzed for imaging data (density, abnormality type, BI-RADS assessment). A commercially-available AI system for mammography interpretation was used for AI scores. Patients were stratified into low (RS<18), intermediate (RS 19-31), and high (RS >31) risk groups. Logistic regression identified factors associated with RS groups. Cox proportional hazards and competing risk analysis assessed predictors for recurrence.

RESULTS

Among 1852 patients, 1047 (56.5%), 649 (35.0%) and 156 (8.4%) had low, intermediate, and high RS, respectively. Median AI score was significantly higher in high RS group (96.7%, IQR: 79.7-99.0) compared to intermediate (92.0%, IQR: 30.4-98.8) or low RS groups (86.0%, IQR: 22.0-98.0, P<.001). Higher rates of patients with age >50 years, dense breast tissue, presence of calcifications on mammography, and higher AI scores were seen in high RS group (all P<.05). In multivariable analysis, breast density (OR=0.61, P=.03), presence of calcifications (OR: 3.971, P=.006), and AI score (cutoff at 73.8%, OR=2.387, P<.001) independently predicted high RS. Regarding recurrence, age (>50 years, HR=0.36, P=.004), and invasive cancer size (HR=1.68, P=.027) and Oncotype Dx score (HR=1.02, P=.004) were independent predictors. Although significant on univariable analysis (HR=2.216, P=.038), AI score at 73.8% did not show association to recurrence on multivariable analysis (P=.236).

CONCLUSION

AI scores from preoperative mammography demonstrate significant correlation with Oncotype Dx RS, particularly in identifying high RS. These findings suggest that AI-based imaging factor may complement genomic assays and contribute to noninvasive personalized risk stratification.

CLINICAL RELEVANCE/APPLICATION

AI-based imaging biomarker show promise for preoperative risk stratification and may be integrated into clinical decision making for adjuvant therapy.
