The subjective scores (motion artifact, LAA visualization and overall image quality) and objective assessment of artifacts (SD) were significant different among the three groups as shown in Table 3 (all $P < 0.001$). The motion artifact scores of SSF2 group for the proximal, central, and distal regions (0.71±0.77, 0.82±0.80 and 0.55±1.06, respectively) were significantly lower than the STD (1.76±1.70, 2.18±1.27 and 1.61±1.59, respectively) and SSF1 groups (1.63±1.22, 1.76±1.24 and 1.37±1.53, respectively). The overall image quality score and LAA visualization with SSF2 were improved to 4.21±0.66 and 4.34±0.57, as compared to 3.11±0.98 and 3.24±1.00 with STD and 3.45±0.92 and 3.55±0.78 with SSF1. For the three areas with heavy artifacts among the three groups, the SSF2 group had the smallest and the STD group had the largest SD values. There was no significant difference between STD and SSF1 subjective scores, but the SD of artifacts with SSF1 were lower than STD group ($P < 0.001$, $P = 0.002$, $P = 0.005$).

CONCLUSION

SSF2 provides satisfactorily reduced artifacts, significantly improved LAA visualization, and image quality of LAA in cardiac CT patients after percutaneous closure compared to STD and SSF1.

CLINICAL RELEVANCE/APPLICATION

A whole-heart motion correction algorithm (SSF2) can further improve the image quality of LAA in patients after percutaneous closure.

S3B-SPPH-6 GENERATIVE ADVERSARIAL NETWORK-BASED KIDNEY CT ENHANCEMENT: IMAGE GENERATION FROM NON-CONTRAST TO CONTRAST CT

Lin Jiaze (*Presenter*)
Genggeng Qin, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study proposes a Generative Adversarial Network (GAN) model, KRES-GAN, focused on Kidney Routine Enhanced Scan (KRES). The model aims to generate diagnostic-grade KRES images from Kidney Routine Scan (KRS) images, providing an innovative alternative for patients who cannot receive contrast agents.

METHODS AND MATERIALS

This retrospective study collected three-phase KRS and KRES data from 734 patients with pathologically confirmed kidney tumors at Southern Medical University Southern Hospital, between January 2014 and June 2023. Automated methods were used to adjust the spatial resolution of KRS and KRES images, enabling layer-by-layer matching and image registration. A total of 502 high-quality registered samples were selected, with a 7:2:1 split for the training, validation, and testing sets. Additionally, 216 multi-center samples were collected for external validation. The proposed model integrates channel and spatial attention mechanisms with a cyclic model structure and progressively optimizes image generation quality through a three-stage training strategy. In the first stage, a global GAN structure was employed to model and generate the overall anatomical structure. In the second stage, the backbone network was frozen, and channel and spatial attention modules were introduced to enhance vascular detail and inter-layer consistency. In the third stage, multi-scale matching loss functions were integrated to improve the precision of HU values in the renal sinus and to optimize tumor boundary details.

RESULTS

Internal testing showed that KRES-GAN achieved an SSIM of 0.908 ± 0.021 and a PSNR of 31.11 ± 1.35, significantly outperforming mainstream models such as Pix2Pix and cGAN. External testing performance was stable (SSIM = 0.901 ± 0.029, PSNR = 30.32 ± 1.77).

CONCLUSION

KRES-GAN innovatively achieves intelligent generation of renal cortical phase KRES based on KRS, accurately identifying the renal cortex and tumor boundaries with precise spatial localization. Additionally, the generation of renal sinus structures demonstrates good continuity and inter-layer consistency.

CLINICAL RELEVANCE/APPLICATION

The KRES-GAN model proposed in this study provides an innovative, non-invasive alternative for renal tumor patients unable to use contrast agents, particularly in the precise classification of clear and non-clear cell carcinomas. KRES-GAN accurately identifies the renal cortex, tumor boundaries, and renal sinus, improving diagnostic efficiency and reducing contrast agent use and scanning costs. It is especially suitable for patients with impaired renal function or contrast agent allergies. Multicenter validation has shown its broad applicability, with expected significant clinical impact.

S3B-SPPH-9 ENHANCING CORONARY CT ANGIOGRAPHY IMAGE QUALITY IN ATRIAL FIBRILLATION PATIENTS THROUGH DEEP LEARNING-BASED RECONSTRUCTION AND ADVANCED MOTION CORRECTION TECHNOLOGY

Shikuan Li (*Presenter*)
Feng Chen, MD, PhD (*Abstract Co-Author*)
Weiyuan Huang (*Abstract Co-Author*)
Xin Qin (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

To evaluate the clinical utility of deep learning image reconstruction (DLIR) combined with second-generation whole-heart motion correction technology (SnapShot Freeze 2, SSF2) in patients with atrial fibrillation (AF) undergoing coronary CT angiography (CCTA), and to perform comparative assessments of image quality against first-generation motion correction (SSF) and iterative reconstruction (ASIR-V50%).

METHODS AND MATERIALS

This retrospective study enrolled 30 patients with atrial fibrillation (AF) who underwent coronary CT angiography (CCTA). Three reconstruction protocols were applied to each patient: Group A: DLIR-H + SnapShot Freeze 2 (SSF2) during diastole (75% R-R interval);Group B: ASIR-V50% + SSF2 during systole (45% R-R interval);Group C: ASIR-V50% + SnapShot Freeze 1 (SSF1)during systole (45% R-R interval).Quantitative measurements included: CT attenuation values (HU),Image noise (standard deviation, SD),Signal-to-noise ratio(SNR),Contrast-to-noise ratio (CNR),Motion artifact index (AI).Subjective image quality was independently evaluated by two radiologists (=5 years of experience in coronary CTA) using a blinded 5-point scale.

RESULTS

Group A (DLIR-H + SSF2) consistently demonstrated superior image quality metrics across both diastolic and systolic phases: Noise Suppression: The proximal right coronary artery (RCA) exhibited significantly lower image noise in Group A (18.2 ± 2.1 HU) compared to Group C (25.6 ± 3.5 HU), with a 29% reduction ($P < 0.001$). Similar reductions were observed in the left main coronary artery (LM), proximal left anterior descending artery (LAD), proximal left circumflex artery (LCX), and aortic root (AR) (all $P < 0.001$). Subjective evaluation using a blinded 5-point scale (1 = non-diagnostic, 5 = excellent) confirmed these findings :Group A achieved the highest scores in proximal RCA ($P < 0.001$), proximal LCx ($P < 0.001$), and overall image quality ($P < 0.001$), with a median score of 4.8 ± 0.4.Interobserver agreement was excellent (weighted Kappa = 0.915), underscoring the reliability of the qualitative assessment.

CONCLUSION

DLIR-H+SSF2 significantly improves image noise control, enhances contrast resolution, and effectively suppresses motion artifacts in coronary CT angiography (CCTA) for patients with atrial fibrillation (AF).

CLINICAL RELEVANCE/APPLICATION

As an advanced reconstruction algorithm, DLIR-H+SSF2 provides clearer and more accurate coronary artery imaging in the context of arrhythmia, offering critical support for pre-ablation anatomical assessment and intraoperative strategy formulation in patients with atrial fibrillation (AF). This approach demonstrates strong clinical potential for widespread adoption in clinical practice.

S3B-SPRO-1 THE BLOODDASHSUPPLYING STATE OF SKULL BASE CHORDOMA: EVALUATED BY DIFFERENT IMAGING MODALITIES

Xinyao Shi (*Presenter*)
Xijia Zhang (*Abstract Co-Author*)
Xuzhu Chen SR (*Abstract Co-Author*)
Jiwei Bai (*Abstract Co-Author*)

PURPOSE

The blood-supplying state of skull base chordomas has been scarcely investigated. We aimed to elucidate the role and superiority of CT perfusion (CTP) in predicting tumor blood-supplying state to guide surgical strategy.

METHODS AND MATERIALS

79 patients with skull base chordoma were identified retrospectively, and their preoperative CTP, routine MRI, and apparent diffusion coefficient (ADC) values were analyzed. The tumor blood-supplying state was classified into three groups based on surgical records and videos. Pretreatment normalized mean CTP parameters, routine MRI parameters, and ADC values were calculated. The Kruskal-Wallis H test, ? 2 tests, and Fisher’s exact tests were used for multiple group comparison and Dunn's tests were used for pairwise comparison. Spearman correlation analysis was employed to assess the relationships between the variables.

RESULTS

CTP and routine MRI can distinguish different blood-supplying states of skull base chordoma (rCBF: P=0.006; rCBV: P<0.001; T2WI: P=0.011; contrast-enhanced T1WI: P<0.001; ADC: P=0.341). CTP (rCBF: r=0.361, P=0.001; rCBV: r=0.425, P<0.001) has an advantage over MRI (T2WI: r=-0.353, P=0.001; contrast-enhanced T1WI: r=0.383, P<0.001; ADC: r=0.084, P=0.462) in reflecting the skull base chordoma blood-supplying state. Pairwise comparisons revealing that both rCBF and rCBV were significantly higher in the rich blood-supplying group than in the poor blood-supplying group (rCBF: 1.90 vs.0.98, P<0.01; rCBV: 3.09 vs.1.55, P<0.001). rCBV (P<0.05) was also particularly effective in differentiating between poor and moderate blood-supplying groups (1.55 vs.2.30, P<0.05).

CONCLUSION

CTP and routine MRI can help differentiate different blood-supplying states of skull base chordoma. The efficacy of CTP is superior to MRI in predicting the blood-supplying states of skull base chordoma.

CLINICAL RELEVANCE/APPLICATION

Preoperative CTP examination allows the surgeon to assess the tumor blood-supplying state initially. Then the surgeon can adjust intraoperative strategy to avoid the most severe outcomes. The surgeon may choose intratumoral decompression or marginal resection, depending on the blood supply of the skull base chordoma. Intratumoral decompression is recommended when the blood supply is poor, as this procedure causes less damage to brain tissue. It’s more likely to complete operations safely, despite the trauma exposed by aspiration, leading to more blood exudation. When the blood supply is rich, marginal resection is often considered a preferable approach. This is because it minimizes blood exudation when separating the brain tissue from the tumor margin. However, it should be noted that this strategy may cause more damage to the surrounding normal brain tissue.

S3B-SPVA-1 DUAL-MONITORING BOLUS TRACKING PEAK TRIGGER TECHNIQUE IN CORONARY CT ANGIOGRAPHY: A PROSPECTIVE STUDY COMPARING WITH SINGLE BOLUS TRACKING

Zijing Zhang (*Presenter*)
Yong Fan (*Abstract Co-Author*)
Zhidong Yuan, RT (*Abstract Co-Author*)
Fei Feng (*Abstract Co-Author*)

PURPOSE

To investigate the use of dual-monitoring bolus tracking of the pulmonary artery and ascending aorta for optimal peak scanning in coronary CT angiography (CTA) and to compare its image quality with single-monitoring bolus tracking.

METHODS AND MATERIALS

Prospectively collected 150 patients who underwent coronary CTA scanning from April 2024 to April 2025, randomly divided into two groups, using dual-monitoring bolus tracking (Group A = 70) or single-monitoring bolus tracking (Group B = 80), both groups set the ascending aorta as a triggered region of interest (ROI1). Group A additionally set the pulmonary artery trunk as a non-triggered region of interest (ROI2), the time-density curves of ascending aorta and pulmonary artery were obtained. The trigger threshold of ascending aorta was set at 250 HU in group A, and the scan was delayed for 4 s. The trigger threshold of group B was set at 160 HU, and the scan was delayed for 6 s. The subgroups of group A were divided into manual trigger group A1 (n=33) and automatic trigger group A2 (n=37). The scanning parameters and contrast injection protocol were kept the same in each group. Coronary CT values were measured, and CT ascending aorta /CT peak of the ROI2 was calculated in group A. Image quality was subjectively scored using a 4-point scale. Statistical analysis was performed using SPSS26.

RESULTS

All images satisfied the diagnosis, and the difference in subjective scores of images in each group was not statistically significant (P>0.05). Groups A1, A2, and B compared patients' age, gender, height, weight, heart rate, iodine flow rate, iodine intake, and total radiation dose with each other. The difference in coronary CT values in groups A, B was not statistically significant (P>0.05).Scan-triggered CT values were smaller in group A1 than in group A2 (P<0.05).Scan-triggered time and pulmonary artery peaking time were later in group A1 than in group A2 (P<0.05). The peak CT value of pulmonary artery and CT value of aorta in group A1 were smaller than that in group A2 (P<0.05), but the difference in the CT ascending aorta /CT peak of ROI2 between the two groups was not statistically significant (P=0.145).

CONCLUSION

Using dual-monitoring bolus tracking technique can provide an important reference for obtaining peak aortic time based on aortic and pulmonary artery time-density curves, without additional increase in radiation dose to the patient, and obtaining a good image in coronary CTA.

CLINICAL RELEVANCE/APPLICATION

The additional pulmonary artery time-density profile without increasing the radiation dose provides a reference value for obtaining peak aortic time and facilitates the acquisition of high-quality coronary artery images, which is of great value for clinical application.

S3B-SPVA-2 RADIOMICS-BASED CAROTID ULTRASOUND ANALYSIS TO IDENTIFY SUBCLINICAL CORONARY CALCIFICATION

YoungJun Lee, PhD (*Presenter*)
MIRAN LEE (*Abstract Co-Author*)
Rachel Surowiec (*Abstract Co-Author*)
Jeonggyu Kang (*Abstract Co-Author*)

PURPOSE

Atherosclerotic burden assessed by carotid ultrasound (CUS) does not always align with coronary artery calcium scores (CACS), and substantial coronary calcification may be present even in the absence of visible carotid plaque. While CACS measurements using computed tomography (CT) is guideline-endorsed, its use is limited by radiation, cost, and accessibility. This study aims to evaluate whether radiomics-based CUS can identify individuals with subclinical coronary calcification, defined by elevated CACS despite normal-appearing CUS, by capturing texture patterns beyond standard interpretation.

METHODS AND MATERIALS

A total of 210 participants who underwent both CUS and CACS CT were included, all of whom showed no overt atherosclerotic plaque on CUS. The two groups (CACS = 0 and CACS > 100, 105 participants each) were matched for age and sex. Longitudinal carotid ultrasound videos (30-50 frames per participant) were acquired from the distal CCA (1 cm proximal to the bulb) on both the right and left common arteries. The region of interest, defined according to intima-media thickness (IMT) measurement guidelines, was isolated using a pre-trained neural network. Radiomic features were then extracted from each frame, filtered by variance and correlation thresholds, and ranked using bootstrap-based reproducibility analysis with XGBoost-derived feature importance scores (FI). Group differences were assessed using the top-ranked features with statistical analysis (t-test or Mann-Whitney U test).

RESULTS

Among 700 extracted features, 7-10 features per group were retained based on reproducibility and statistical significance. Several higher-order features derived from GLDM and GLRLM matrices were consistently significant in both CACS 0 and CACS > 100 groups, while group-specific features such as 90Percentile (CACS 0: Rt. CCA = $p < .007$, FI = .030; Lt. CCA: $p < .021$, FI = .025) and RunEntropy (CACS > 100: Rt. CCA = $p < .001$, FI = 0.046; Lt. CCA = $p < .002$, FI = .038) emerged. LongRunEmphasis, DependenceNonUniformity, and Entropy were consistently observed in both CACS groups and across both CCA (all $p < .05$, FI range = .023 - .029).

CONCLUSION

Radiomic analysis revealed side-specific and bilaterally consistent textural features in carotid ultrasound that were associated with coronary calcium burden. These findings support the potential of radiomics-enhanced CUS to identify individuals with subclinical coronary calcification.

CLINICAL RELEVANCE/APPLICATION

By capturing subtle calcification patterns not visible through standard CUS interpretation, radiomic analysis may enhance cardiovascular risk assessment—especially when CT-based CACS is not available or practical in primary care or preventive cardiology settings.

S3B-SPVA-3 ELUCIDATION OF EMBOLIC EFFECTS OF EMBOSPHERE MICROSPHERES IN VIVO DEPICTED BY MONOCHROMATIC SYNCHROTRON X-RAY MICROANGIOGRAPHY

Hiroki Nakamura (*Presenter*)
Akira Yamamoto, MD, PhD (*Abstract Co-Author*)
Hiroyuki Watanabe (*Abstract Co-Author*)
Atsushi Higaki, MD, PhD (*Abstract Co-Author*)
Akihiko Kanki, MD (*Abstract Co-Author*)
Yoshihiko Fukukura, MD, PhD (*Abstract Co-Author*)
Tsutomu Tamada, MD, PhD (*Abstract Co-Author*)

PURPOSE

To elucidate the properties of Embosphere (100-300, 40-120μm) as embolic agents in vivo.

METHODS AND MATERIALS

Four healthy Japanese white rabbits (approximately 3 kg each) were used. Two of the rabbits were subcutaneously injected with Picibanil (1.0 KE) into both ears to create an inflammatory model. High spatial resolution microangiography was performed using monochromatic X-rays extracted from synchrotron radiation facility (Super Photon ring-8; SPring-8). Under anesthesia, an elastomer needle (26 G) was placed in the intermediate branch of the auricular artery, and pre-embolization angiography was performed. Then, embolization was performed from the intermediate branch of the auricular artery using 2 ml of a mixture of Embosphere (9 ml) and nonionic contrast agent (9 ml) from a total of 18 ml. Angiography was performed 3, 10, 20, 30, 40, 50, 60, 70, 80, and 90 minutes after embolization. The diameter of the embolized vessel was evaluated using images before embolization. The presence or absence of recanalization was evaluated using angiographic images over time up to 90 minutes after embolization. ROIs were set in both normal and inflammation-induced sites, and the two were compared.

RESULTS

The mean diameter of the blood vessels embolized immediately after embolization was 233±44.84 μm with Embosphere (100-300 μm), with a range of 174-292 μm. In the Embosphere (40-120 μm), the mean diameter was 84±17.88 μm, range: 61-119 μm. Observation 90 minutes after embolization showed no clear recanalization in either normal or inflammation-induced sites. In cases of over-embolization, polymerization of the embolic material occurred in large blood vessels, but blood flow was observed through the gaps. Thrombus formation was observed to progress over time.

CONCLUSION

The characteristics of Embosphere as an embolic material in vivo were elucidated. There was no difference in the course of embolization between normal and inflammation-induced sites. The gradual formation of a thrombus was visualized.

CLINICAL RELEVANCE/APPLICATION

Embosphere is widely used clinically as an embolization material for various diseases (uterine fibroids, hypervascular tumors, etc.). We believe that by better understanding the intravascular dynamics during embolization, embolization can be performed more accurately.

T2-SPBR-1 AUTOMATIC CLASSIFICATION OF BREAST LESIONS IN CONTRAST ENHANCED MAMMOGRAPHY USING DEEP LEARNING IN CONJUNCTION WITH MULTIMODAL INFORMATION: BIRADS LEXICON FEATURES AND RAW IMAGE FEATURES

Danielle Fein (*Presenter*)
Miriam Sklair-Levy, MD (*Abstract Co-Author*)
Renata Faermann, MD (*Abstract Co-Author*)
Noam Nissan, MD, PhD (*Abstract Co-Author*)
Debbie Anaby (*Abstract Co-Author*)

PURPOSE

To assess the combined usage of BIRADS lexicon and pixel data for multi-modal automatic classification of breast lesions in contrast enhanced mammography (CEM) and evaluate its potential for biopsy sparing in benign breast lesions while maintaining high sensitivity.

METHODS AND MATERIALS

We validated a deep learning model by applying it to 537 CEM tests not included in the training data. Then we compared the model classification with the corresponding histopathological results of 483 breast lesions, were manually delineated by a research assistant, based on experienced radiologist's annotations and confirmed by an expert radiologist and described according to the BIRADS lexicon. The (BIRADS) lexicon data was encoded as a binary feature vector for each lesion, that together with the lesion pixels, formed its multi-modal representation. A deep neural network was implemented to process the multi-modal data. The network was designed to process low-level image data (pixels) from its entry layer and merge it with high-level lexical data in the deep layers, close to the final classification output. This allows for a better balance between the information content of the pixels' analysis and lexicon descriptors when they are jointly analyzed by the network. The network was trained and validated, using a 5-folds cross-validations approach, for the classification of benign and malignant lesions. The classification score assigned for each case a malignancy likelihood score between 0.00 and 1.00. A score above 0.29 was defined as "suspicious for malignancy," while a score of 0.29 or lower was classified as "likely benign"

RESULTS

We evaluated the deep learning application performance using cross-validation on 483 breast lesions found on 537 CESM studies. Each marked lesion was entered into the application, with the relevant BIRADS score, including background parenchymal enhancement,mass shape,mass margins and mass internal enhancement. Out of 483 lesions marked, 263 were benign (54.5%), and 220 were malignant (45.5%). At a predefined sensitivity of 100%, the model achieved a specificity of 80.5%, indicating strong diagnostic performance in differentiating malignant from benign findings

CONCLUSION

This research showed that the combined usage of BIRADS lexicon descriptors, with pixel data extracted from deep learning analysis of CEM strongly improves the specificity obtained for automatic lesion classification. The presented deep learning model may significantly reduce benign biopsies, without compromising sensitivity.

CLINICAL RELEVANCE/APPLICATION

Multi-modal lesion classification in dual energy CEM has the potential to reduce the number of benign breast biopsies, thereby reducing cost and improving patient experience

T2-SPBR-2 COMPARISON OF SINGLE-SHOT ECHO-PLANAR IMAGING WITH DEEP LEARNING RECONSTRUCTION (SS-EPI WITH DLR) AND MULTI-SHOT ECHO-PLANAR IMAGING WITH SIMULTANEOUS MULTISLICE (MS-EPI WITH SMS) FOR BREAST DWI: ENHANCED IMAGE QUALITY AND READER PREFERENCE

Hye Shin Ahn, MD (*Presenter*)
Sung-Hun Kim, MD (*Abstract Co-Author*)
Min Ji Hong (*Abstract Co-Author*)
Hyun-Soo Lee (*Abstract Co-Author*)
Thomas Benkert (*Abstract Co-Author*)

PURPOSE

Deep learning reconstruction (DLR) in single-shot EPI (ss-EPI) enhances image quality in diffusion-weighted imaging (DWI) of breast MRI. We compared the image quality and diagnostic performance of ss-EPI with DLR versus multi-shot EPI with simultaneous multi-slice (ms-EPI with SMS).

METHODS AND MATERIALS

This retrospective study included 77 breast cancer cases from 74 consecutive women (mean age: 53.1 years) who underwent breast DWI. Two radiologists assessed image quality and reader preference, and the cancer detection rate (CDR) was calculated. Quantitative analysis included apparent diffusion coefficient (ADC), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and lesion contrast, along with phantom measurements.

RESULTS

Qualitative analysis showed ss-EPI with DLR had significantly higher scores for fat suppression and overall image quality, while artifact presence and lesion conspicuity were comparable to ms-EPI with SMS. The CDR showed no significant difference. Both radiologists preferred ss-EPI with DLR (Reader 1: 78.4%; Reader 2: 89.2%). Quantitatively, ss-EPI with DLR had significantly higher lesion contrast for both readers ($p = 0.001$), while ADC and SNR values were comparable. Phantom measurements showed no significant ADC differences except for mean ADC (DLR: 1.15 ± 0.61 vs. SMS: 1.19 ± 0.62, $p = 0.007$). SNR was higher with ss-EPI and DLR without significant difference (DLR: 630.03 ± 759.26 vs. SMS: 607.45 ± 565.21, $p = 0.912$). The acquisition time was shorter for ss-EPI with DLR (2.06 min) than for ms-EPI with SMS (3.29 min).

CONCLUSION

ss-EPI with DLR yielded superior image quality and greater reader preference than ms-EPI with SMS.

CLINICAL RELEVANCE/APPLICATION

The DLR sequence may have clinical potential for breast DWI to diagnose cancer, particularly due to its superior lesion contrast.

T2-SPBR-3 END-TO-END AI SYSTEM FOR REGION-LEVEL ANOMALY CLASSIFICATION IN BREAST MRI

ALEKSANDAR JANJIC (*Presenter*)
Alptug Seref Ayyildiz (*Abstract Co-Author*)
Seyma Nur Tufan (*Abstract Co-Author*)
Ibrahim Akduman (*Abstract Co-Author*)
Erkin Aribal (*Abstract Co-Author*)
Onur Bugdayci, MD (*Abstract Co-Author*)

PURPOSE

To develop an AI-based pipeline that assists radiologists in breast MRI interpretation by automatically detecting, segmenting, and classifying breast anomalies. This tool is designed to streamline the diagnostic workflow, reduce inter-reader variability, and enhance clinical decision-making. Given the complexity of MRI interpretation and the growing demand for efficient and consistent reporting, such tools can help reduce missed findings and assist radiologists in confidently evaluating both cancerous and non-cancerous anomalies.

METHODS AND MATERIALS

This study utilized 1,173 breast MRI images from 95 patients, sourced from a publicly available dataset of Latin American patients (Mendeley Data, CC BY 4.0). The dataset includes multi-sequence dynamic contrast-enhanced (DCE) MRI with annotations for lesion type, location, BI-RADS category, and fibroglandular composition. A total of 354 distinct regions of interest (ROIs) were analyzed, each corresponding to a separate anomaly to be detected and classified. The pipeline comprises three stages: detection using Faster R-CNN, segmentation using a hybrid approach with U-Net, Segment Anything Model (SAM), and inter-slice tracking, and classification using a ResNet50 architecture. The model outputs a malignancy probability score per ROI, with a classification threshold of 0.64; scores above this indicate high probability of malignancy. Modules were evaluated independently: detection via accuracy, segmentation via Dice coefficient, and classification via AUC, accuracy, sensitivity, specificity, and F1-score. Evaluation was done per ROI, reflecting the need to assess multiple lesions per image.

RESULTS

The pipeline achieved 87% detection accuracy. Segmentation of ROIs yielded a Dice score of 85%. Classification reached 83% accuracy, 84% sensitivity, 82% specificity, an F1-score of 83%, and AUC of 0.83.

CONCLUSION

The proposed AI-based pipeline demonstrates strong potential in automating the detection, segmentation, and classification of breast anomalies on MRI. Its balanced accuracy across malignant and benign lesions supports its potential role as a reliable decision-support tool. While results are promising on retrospective data, prospective validation is needed to confirm clinical applicability.

CLINICAL RELEVANCE/APPLICATION

This AI-based tool offers radiologists a structured and efficient way to identify, segment, and assess anomalies on breast MRI, potentially reducing interpretation time and diagnostic variability. By providing risk scores for each detected region, the system supports earlier detection and consistent stratification of lesions, enhancing clinical decision-making in breast cancer evaluation.

T2-SPBR-4 RETROSPECTIVE CLINICAL VALIDATION OF AI-BASED TUMOR SEGMENTATION IN BREAST MRI

Gurwinder Kaur, MSc (*Presenter*)
Dimitra Ntoula, MD (*Abstract Co-Author*)
Akane Ohashi, MD,PhD (*Abstract Co-Author*)
Fernando Cossio Ramirez, BSc (*Abstract Co-Author*)
Taeyang Choi (*Abstract Co-Author*)
Yanlu Wang (*Abstract Co-Author*)
Apostolia Tsirikoglou, PhD, MSc (*Abstract Co-Author*)
Fredrik Strand, MD, PhD (*Abstract Co-Author*)

PURPOSE

AI has the potential to support radiologists by improving consistency, reducing workload, and enabling scalable access to automated expert-level interpretation for breast magnetic resonance imaging (MRI) exams. This study evaluates the performance of an AI-based segmentation model for breast cancer by analyzing localization concordance with expert radiologist annotations, and tumor size error compared to actual tumor size in the surgical specimen.

METHODS AND MATERIALS

We collected all breast MRI exams performed for women diagnosed with breast cancer from 2008 to 2021 at Hospital in City, using 1.5T and 3.0T scanners (GE, Philips, Siemens). Two expert radiologists annotated tumors, breast volume, nipple, and lymph nodes on Maximum Intensity Projection of Dynamic Contrast-Enhanced MRI. One radiologist served as the reference standard for model development, the other—the annotator—was used for this performance evaluation. A patient-level split was used for training, validation and testing. We trained the state-of-the-art nnUNet on 800 exams. We report results on the held-out test set, using Dice Similarity Coefficient (DSC), 95th percentile Hausdorff Distance (HD95), and tumor size error relative to post-surgical pathology reports.

RESULTS

From the held-out test set of 74 breast MRI exams from 72 patients with biopsy-confirmed cancer, 6 studies with a DSC of zero were excluded, leaving 68 exams. For tumor size estimation, 9 additional studies were excluded due to missing radiology and pathology reports, leaving 59 exams. Our trained model achieved a mean DSC of 0.76 and HD95 of 14.95 mm— for mass lesions: DSC 0.79, HD95 17.6 mm and for non-mass lesions: DSC 0.74, HD95 11.5 mm. Comparing three image interpreters: (i) our AI model, (ii) the original radiology report, (iii) and the study annotator: the Spearman's correlation coefficient with pathology-reported tumor size was 0.83 (95% CI: 0.65-1.00), 0.63 (95% CI: 0.34-0.92), and 0.53 (95% CI: 0.17-0.89); the median tumor size error was 20.1%, 17.2%, and 20.3%; overestimation by more than 5 mm occurred in 21, 21, and 23 cases; and underestimation by more than 5 mm was observed in 3, 2, and 3 cases, respectively.

CONCLUSION

We demonstrated our AI model achieving performance in both tumor size estimation and localization comparable to clinical experts with high consistency across mass and non-mass lesion types, exhibiting notably lower variability for non-mass lesions.

CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of AI-based segmentation to support radiologists by providing consistent and accurate tumor size estimates in breast MRI, reducing uncertainty in treatment planning. This might be especially valuable in settings where there is a deficit in expert breast MRI radiologists.

Peng Zhou SR (*Abstract Co-Author*)

PURPOSE

Hypertension (HT) increases the risk of cardiovascular morbidity and mortality in coronary artery diseases (CAD). CT feature tracking (CT-FT) is a well-established method for myocardial strain analysis; Therefore, this study aims to investigate the impact of hypertension on left ventricle (LV) motion function in CAD patients using CT-FT.

METHODS AND MATERIALS

83 CAD patients were retrospectively enrolled from May 2023 to February 2025, and divided into two groups with [CAD (HT +), n = 43]and without hypertension [CAD (HT -), n = 40]. CT-FT was subsequently performed to measure LV strain parameters.

RESULTS

For baseline characteristics, CAD (HT +) group patients are elder and had a greater proportion of diabetes when compared with CAD (HT -) group. No difference in LV function parameters were observed between two groups. CAD (HT +) group patients demonstrated lower values in myocardial global longitudinal strain (Myo GLS) [-19.9 (-21.3, -18.1)% vs -21.0±2.7%] and endocardial global longitudinal strain (Endo GLS) [-23.1±3.2% vs -25.0±4.0%] than CAD (HT -) group. In the multivariate linear regression analysis adjusting for clinical characteristics, Sex, Hypertension and CAD-RADS=3 were both independently associated with the decreased of Myo GLS (Sex: ß=-0.224,P=0.049; Hypertension: ß=-0.271, P=0.007; CAD-RADS=3: ß= -0.284, P= 0.004) and Endo GLS (Sex: ß=-0.266, P=0.011; Hypertension: ß=-0.229,P=0.031; CAD-RADS=3: ß=-0.256,P=0.016).

CONCLUSION

HT could aggravate the LV subclinical dysfunction in CAD patients and CT-FT allows the sensitive assessment

CLINICAL RELEVANCE/APPLICATION

CT-FT is an emerging technology, it can provide a one-stop assessment of coronary anatomy, general cardiac function and strain in CAD patients to detect subclinical cardiac dysfunction. Compared with echocardiography speckle tracking imaging (STI) and cardiac magnetic resonance feature tracking technology (CMR-FT), it is more practical and has fewer contraindications.

T2-SPCA-2 INTRACORONARY OPTICAL COHERENCE TOMOGRAPHY VERSUS PHOTON-COUNTING DETECTOR CORONARY CT ANGIOGRAPHY IN CORONARY LUMEN ASSESSMENT

Tilman S. Emrich, MD (*Presenter*)
Moritz Halfmann, MD (*Abstract Co-Author*)
Larissa Kavermann (*Abstract Co-Author*)
Lukas Mueller, MD, PhD (*Abstract Co-Author*)
Philipp Locherer (*Abstract Co-Author*)
Tobias Baeuerle, MD (*Abstract Co-Author*)
Anton Kilburg, MD (*Abstract Co-Author*)
Michaela Hell (*Abstract Co-Author*)

PURPOSE

Photon-counting detector coronary CT angiography (PCD-CCTA) offers ultra-high-resolution imaging that could enhance individualized assessment of coronary artery disease. While prior studies suggest reduced bias compared to conventional methods, validation against a high-resolution intravascular reference standard has been limited. This study aimed to compare coronary lumen area measurements from PCD-CCTA to those obtained by intracoronary optical coherence tomography (OCT).

METHODS AND MATERIALS

Patients with stable chest pain who underwent both PCD-CCTA (120×0.2 mm collimation; reconstructions at 0.6 mm and 0.2 mm slice thickness, using Bv64 kernel and quantum iterative reconstruction level 4) and invasive coronary angiography with steady-pullback OCT were retrospectively included. Lesions were matched across modalities based on anatomical landmarks. A trained cardiologist and radiologist, both blinded to each other's assessments, performed independent measurements. Per-lesion comparisons were conducted using Pearson's correlation, paired t-tests, and Bland-Altman analyses.

RESULTS

A total of 31 lesions from 7 patients were analyzed. PCD-CCTA lumen area measurements strongly correlated with OCT (r=0.82 for 0.6 mm; r=0.92 for 0.2 mm slice thickness). Minimal bias was observed for both reconstruction thicknesses (mean bias -0.20 mm² and -0.45 mm², respectively). Limits of agreement narrowed with thinner reconstructions (-3.3 to 2.9 mm² at 0.6 mm; -2.8 to 1.7 mm² at 0.2 mm), reflecting improved accuracy with higher resolution.

CONCLUSION

PCD-CCTA closely approximates OCT-derived coronary lumen measurements, confirming its capability to deliver, high-fidelity vascular assessment. The improved agreement with 0.2 mm reconstructions highlights the potential of ultra-high-resolution imaging in advancing precision cardiovascular diagnostics.

CLINICAL RELEVANCE/APPLICATION

By minimizing measurement bias between non-invasive imaging and intravascular reference, PCD-CCTA holds potential to minimize unnecessary downstream testing and advance equitable, precision-based care for patients with stable chest pain.

T2-SPCA-5 MYOCARDIAL EXTRACELLULAR VOLUME QUANTIFICATION IN CARDIAC AMYLOIDOSIS: A COMPARATIVE STUDY BETWEEN DUAL-LAYER SPECTRAL DETECTOR CT AND CARDIAC MAGNETIC RESONANCE IMAGING

Jingheng Zhang (*Presenter*)
Jiayu Chen (*Abstract Co-Author*)
Xiaomin Liu (*Abstract Co-Author*)
Zhijie Huang (*Abstract Co-Author*)
Hui Liu, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility and consistency of myocardial extracellular volume (ECV) quantification using dual-layer spectral detector CT (DLCT-ECV) in cardiac amyloidosis (CA), with cardiac magnetic resonance imaging-derived ECV (CMR-ECV) as the reference standard.

METHODS AND MATERIALS

This prospective study included thirteen patients with a clinical suspicion of CA, all of whom underwent both DLCT and CMR examinations. Final diagnoses of CA were confirmed by histopathology. DLCT-ECV was calculated in the delay phase as (1-hematocrit) × (iodine concentration in myocardium / iodine concentration in blood pool). Paired t-test was used to compare ECV value between CMR and DLCT across the 17 segments defined by the American Heart Association (AHA). Peason correlation and Bland-Altman analysis were performed to assess agreement between DLCT-ECV and CMR-ECV at the segmental and global levels. Further, correlations between ECV and clinical parameters were assessed.

RESULTS

The mean global DLCT-ECV and CMR-ECV were 51.93%±10.81, 51.30%±11.69, respectively, with no significant difference ($P > 0.05$). No significant differences were found across any of the 17 AHA segments. Bland-Altman analysis showed a mean difference of 0.6% with limits of agreement from -8.8% to +10.1%. Strong correlations were observed between DLCT-ECV and CMR-ECV at the basal ($r = 0.90$), mid-cavity ($r = 0.95$), apical ($r = 0.88$), and global levels ($r = 0.92$).

CONCLUSION

Cardiac DLCT enables accurate myocardial ECV quantification in patients with CA, with excellent agreement with CMR-ECV.

CLINICAL RELEVANCE/APPLICATION

DLCT-ECV offers a viable alternative to CMR-ECV, particularly for patients with contraindications to MRI or requiring shorter examination times.

T2-SPCA-6 BI-MODAL IMAGING OF MYOCARDIAL INFARCTION USING A GADOLINIUM-BASED CONTRAST AGENT IN COMBINATION WITH SPECTRAL PCCT AND MRI IN PIGS

Salim Si-Mohamed, MD, PhD (*Presenter*)
Tristan Doussineau (*Abstract Co-Author*)
Geraldine Le Duc (*Abstract Co-Author*)
Francois Lux (*Abstract Co-Author*)
Philippe Douek, MD,PhD (*Abstract Co-Author*)
Olivier Tillement (*Abstract Co-Author*)

PURPOSE

CMR and spectral photon counting computed tomography (SPCCT) modalities enable acute myocardial infarction imaging. But dedicated contrast agents are lacking from theranostic properties. In this context, a phase 2 gadolinium-based contrast agents (GBCA), may enable bi-modal imaging of myocardial infarction. Therefore, we evaluated the feasibility of bi-modal myocardial infarction imaging in ischemia-reperfusion pig models.

METHODS AND MATERIALS

An endovascular model of myocardial ischemia-reperfusion was performed in 7 pigs consisting in a ballon-occlusion of the distal LAD artery during 30 minutes followed by 3-hours reperfusion. All animals received intracoronary injection of AGuIX® (10 mL, 13.3 mg.Gd/mL; NH TherAguix ® , France) 10 minutes before sacrifice. Ex-vivo hearts were scanned using HR parameters on a clinical SPCCT prototype (Philips) and a clinical MRI scanner (1.5T, Avanto, Siemens). Infarct size was measured in short-axis images using a clinical workstation (ISP, Philips), similarly to histology. Semi-automatic measurement of infarction area using a thresholding method (Fiji software) was performed and compared using intra-class correlation (ICC) and Bland-Altman analysis.

RESULTS

4 pigs underwent the whole protocol. 6 slices per pigs were analyzed. 10 slices were excluded due to low image quality. 14 slices were analyzed. Mean infarct size relative to total slice area was 20±13.9%, 24.6±15.7%, 16.9±12.4%, on SPCCT, MRI and histology images, respectively. This corresponds to a mean difference of -4.7, 3.0, 7.7 between SPCCT vs MRI, SPCCT vs histology, MRI vs histology, respectively. Excellent agreement was found between SPCCT vs MRI (ICC=0.895), SPCCT vs histology (ICC=0.882), MRI vs histology (ICC=0.774). Bland-Altman analysis showed a bias of -4.67 between SPCCT vs MRI, within limits of agreement ranging from -15.14 to 5.81.

CONCLUSION

A phase 2 gadolinium-based contrast agent is a contrast agent suitable for infarction quantification with SPCCT and MRI. Its use allows for more accurate staining with SPCCT, as its spatial resolution is superior to that of MRI.

CLINICAL RELEVANCE/APPLICATION

A gadolinium-based contrast agent has proven to be specific of myocardial infarction in comparison to histology, and to be suitable for spectral photon-counting CT and MRI.

T2-SPCA-7 PROGNOSTIC VALUE AND RISK CONTINUUM OF CT-DERIVED FRACTIONAL FLOW RESERVE IN PATIENTS WITH TYPE A AORTIC DISSECTION

Feifei Zhou, MD (*Presenter*)
Yong Ju Yang (*Abstract Co-Author*)
Lei Yang (*Abstract Co-Author*)

PURPOSE

To evaluate the prognostic value of CT-derived fractional flow reserve (CT-FFR) for adverse clinical outcomes in patients with type A aortic dissection (TAAD) and to assess its risk continuum relationship with outcomes.

METHODS AND MATERIALS

This study retrospectively enrolled patients diagnosed with TAAD who underwent coronary CT angiography (CCTA) between March 2018 and June 2024. Clinical endpoints included major adverse cardiovascular events (MACE; defined as nonfatal myocardial infarction, unstable angina, and cardiac death), any revascularization (both planned and unplanned), and all-cause mortality. Cumulative incidence was estimated using the Nelson-Aalen method. Hazard ratios (HRs) were calculated using Cox proportional hazards models, and model discrimination was evaluated with Harrell's C-index.

RESULTS

A total of 768 patients (mean age 64 ± 9.5 years; 73.4% male) were included, with a median follow-up of 3.8 years. The incidence of MACE was 32.3%, any revascularization 12.6%, and all-cause mortality 15.1%. CT-FFR =0.80 was associated with higher risk of MACE (HR=4.0, 95% CI: 1.5-10.5; P=0.01) and revascularization (HR=3.2, 95% CI: 1.3-7.9; P=0.008), predominantly driven by planned revascularizations. Each 0.05-unit decrease in CT-FFR increased MACE risk by 50% (HR=1.5, 95% CI: 1.3-1.8; P<0.001) and revascularization risk by 38% (HR=1.38, 95% CI: 1.1-1.8; P=0.001). Incorporating CT-FFR into models with clinical and anatomical variables significantly improved prediction of MACE (C-index 0.78, P=0.002) and revascularization (C-index 0.74, P=0.004), but not all-cause mortality (P=0.67).

CONCLUSION

CT-FFR is significantly associated with MACE and revascularization in TAAD patients and exhibits a continuous risk relationship.

CLINICAL RELEVANCE/APPLICATION

As a noninvasive preoperative functional marker, CT-FFR demonstrates strong predictive utility in TAAD. A threshold of =0.80 is significantly associated with postoperative MACE and planned revascularizations, while its continuous value reflects a graded increase in risk. Integrating CT-FFR with anatomical and clinical assessments enhances preoperative risk stratification and supports optimized patient management.

T2-SPCA-9 ECG-LESS CORONARY CT ANGIOGRAPHY WITH SECOND-GENERATION MOTION CORRECTION (SSF2): ENHANCED IMAGE QUALITY AND DIAGNOSTIC CONFIDENCE IN CORONARY ASSESSMENT

Zhongying Wang, MD (*Presenter*)
Cheng Zhao (*Abstract Co-Author*)
Jinfu Bu (*Abstract Co-Author*)
Xiaomeng Shi (*Abstract Co-Author*)
Jie Lu, PhD (*Abstract Co-Author*)

PURPOSE

To assess the impact of the second-generation motion correction algorithm (SSF2) on coronary artery visualization and diagnostic accuracy in ECG-less CCTA.

METHODS AND MATERIALS

Seventy patients underwent ECG-less CCTA using wide detector CT (Revolution Apex Expert, GE Healthcare) with standard (STD), first-generation (SSF1), and second-generation (SSF2) motion correction. Objective parameters and diagnostic indicators (noise, SNR, CNR, plaque volume, stenosis grading) and subjective image quality (5-point Likert scale by two blinded cardiologists) were analyzed. Segment-, vessel-, and patient-level interpretability were evaluated.

RESULTS

The kappa value between two radiologists on STD, SSF1 and SSF2 images was 0.78, 0.83 and 0.87. There was no significant difference in CT value between 3 reconstruction methods. SSF2 significantly improved image quality, with higher SNR/CNR (all p<0.05) and superior subjective scores (median 5.0 vs. 4.0 [SSF1] and 3.0 [STD], p<0.001; inter-reader ?=0.87). Interpretability was excellent for proximal/mid segments (99.6%) and significantly better for distal vessels/small branches (97.2% vs. 89.4% [SSF1], p<0.05). Patient-level interpretability reached 100% (vs. 92.9% [SSF1] and 51.4% [STD]). SSF2 provided the highest stenosis detection accuracy (84.3%) without significant differences in plaque volumetry (p>0.05).

CONCLUSION

SSF2 optimizes coronary artery assessment in ECG-less CCTA, ensuring high diagnostic confidence even in distal segments, making it a robust tool for coronary artery disease evaluation.

CLINICAL RELEVANCE/APPLICATION

SSF2 enables reliable ECG-less coronary CT angiography, particularly valuable for emergency evaluations and arrhythmia patients, while maintaining diagnostic confidence comparable to ECG-gated studies. This innovation may reduce unnecessary invasive procedures and expand cardiac imaging accessibility in diverse clinical settings.

T2-SPCA-10 SIMPLIFYING LGE IMAGING: SYNTHETIC-LGE ASSESSMENT OF %LGE STABILITY AROUND THE NULL POINT AND VALIDATION OF A FIXED 400 MS INVERSION TIME

Yasutoshi Ohta, MD, PhD (*Presenter*)
Toshimitsu Tanaka, RT (*Abstract Co-Author*)
Tatsuya Nishii, MD, PhD (*Abstract Co-Author*)
Yoshiaki Morita (*Abstract Co-Author*)
Hiroki Horinouchi (*Abstract Co-Author*)
Akiyuki Kotoku, MD, PhD (*Abstract Co-Author*)
Akihiro Murata (*Abstract Co-Author*)
Midori Fukuyama, MD (*Abstract Co-Author*)
Emi Tateishi (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

In LGE imaging, inversion time (TI) is typically determined with a safety margin. While shorter TIs lead to inaccurate lesion depiction, the effects of longer TIs remain unclear due to challenges in standardizing imaging time and acquiring multiple images. This study aimed to evaluate LGE extent across various TIs using pharmacokinetically generated synthetic LGE (sLGE) and to assess whether a fixed TI of 400 msec provides comparable measurements to conventional TI settings.

METHODS AND MATERIALS

A total of 109 subjects (median age 61 years, IQR: 49-74) referred for cardiac MRI were included. A two-compartment pharmacokinetic model calculated time-dependent contrast medium concentration curves from dynamic T1 maps acquired at 2, 5, 9, and 15 minutes after contrast administration. A predicted T1 map at 10 minutes was generated.The sLGE images were simulated using an inversion recovery sequence with SSFP readout, predicted T1 values, heart rate, and a TR of two heartbeats. sLGE images were generated by varying TI from 200 to 400 msec in 10 msec increments.The ROI for normal myocardium was defined on sLGE images by referencing conventional IR-LGE acquired 10 minutes after contrast. The null point was defined as the TI yielding minimal signal in normal myocardium. The proportion of LGE area to myocardium (LGEprop) was calculated at each TI using a threshold of mean signal intensity plus 5SD.LGEprop was assessed across TIs from 60 msec below to 100 msec above the null point. Correlation coefficients and Bland-Altman analyses compared LGEprop at TI 400msec with TInull, TInull -10msec, TInull +10msec, TInull +20msec, and TInull +30msec.

RESULTS

In every case, TInull was less than 400msec (median 290msec, IQR: 270-310msec).The LGE proportion (LGEprop) was 0.26±0.24 at TInull and increased to 0.36±0.27 at TInull +10msec, reaching a plateau up to TInull +100msec. Conversely, LGEprop was 0.13±0.21 at TInull -10msec, showing a plateau down to TInull -60msec. No significant differences in LGEprop were observed for TIs beyond TInull +20msec.Correlation coefficients (r) between TI 400msec and TInull -10msec, TInull, TInull +10msec, TInull +20msec, and TInull +30msec were 0.29, 0.50, 0.67, 0.82, and 0.89, respectively. The corresponding biases were -0.27, -0.14, -0.04, -0.03, and -0.01. There were no significant differences in LGEprop between TI 400msec and TIs beyond TInull +10msec.

CONCLUSION

sLGE demonstrated that a TI 400 msec provides comparable LGE quantification to TInull +20msec or longer.

CLINICAL RELEVANCE/APPLICATION

As %LGE plateaued above the null point, a fixed TI of 400 msec may offer a reliable and simplified method for LGE evaluation without the need for Look-Locker-based TI determination.

T2-SPCA-11 CARDIOVASCULAR MAGNETIC RESONANCE ASSESSMENT OF THE PROTECTIVE MECHANISM OF CANG-AI VOLATILE OIL L ON HEART FAILURE IN RATS

Qi Zhu (*Presenter*)
Fabao Gao, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aims to assess the potential protective effect of Cang-ai volatile oil (CAVO) on ventricular remodeling in a heart failure rat model using 7.0T cardiovascular magnetic resonance (CMR) strain analysis and to preliminary explore its possible mechanisms of action.

METHODS AND MATERIALS

Forty rats were randomly divided into: control group, model group, and low- and high-dose Cang-ai volatile oil treatment groups. Except for the control group, the other groups received a continuous intraperitoneal injection of isoproterenol (ISO) at a dose of 5 mg·mL -1 ·d -1 for 14 days to establish a heart failure rat model. After successful modeling, the CAVO groups were gavaged with doses of 0.12 mL·kg -1 ·d -1 and 0.24 mL·kg -1 ·d -1 , while the control and model groups were given an equal volume of physiological saline via gavage for 28 days. Cardiac function and left ventricular (LV) structural changes were assessed using CMR before and after gavage, along with strain analysis to determine the protective effect of CAVO on ventricular remodeling in heart failure rat models.

RESULTS

CAVO treatment groups (low-dose and high-dose) demonstrated a dose-dependent enhancement in LV function compared to the Model control group. Regional strains, encompassing circumferential, longitudinal, and radial strains, showed significant differences between the CAVO treatment groups and the Model control group. Additionally, histological analysis indicated that the CAVO treatment groups exhibited reduced myocardial injury and fibrosis compared to the model group, with improved mitochondrial homeostasis. The CAVO treatment groups reversed the expression of HIF-1a, SIRT3, and ROS compared to the changes observed in the model and contorl groups.

CONCLUSION

CAVO exerts a protective effect against ISO-induced heart failure rat ventricular remodeling, and the specific mechanism may be related to improve mitochondrial homeostasis and oxidative stress. These findings contribute to understanding the potential therapeutic advantages of CAVO for patients at risk of chronic heart failure (CHF) and promote further research into its underlying mechanisms and possible clinical applications.

CLINICAL RELEVANCE/APPLICATION

The results of this study have significant implications for the management of patients at risk of CHF, particularly those in the precocious stage. Recognizing the cardioprotective effects of CAVO could lead to innovative therapeutic approaches, such as preconditioning interventions or drugs targeting hypoxia-related pathways. Utilizing advanced CMR technologies, including strain analysis, could provide valuable insights into myocardial function and damage, potentially enhancing accuracy in diagnosis and prognosis in clinical settings.

T2-SPCA-13 PERIVASCULAR-TO-EPICARDIAL FAT ATTENUATION RATIO AS A ROBUST MARKER OF MYOCARDIAL ISCHEMIA UNDER REAL-WORLD CORONARY CT ANGIOGRAPHY SETTINGS

Yuna Okura, RT (*Presenter*)
Midori Fukuyama, MD (*Abstract Co-Author*)
Tatsuya Nishii, MD, PhD (*Abstract Co-Author*)
Tomoro Morikawa, MD (*Abstract Co-Author*)
Shun Okuyama, RT (*Abstract Co-Author*)
Emi Tateishi (*Abstract Co-Author*)
Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Teruo Noguchi (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

Perivascular adipose tissue attenuation (PVAT) on coronary CTA (CCTA) is a promising marker of vascular inflammation, yet its clinical utility is hampered by variability in acquisition settings. We hypothesized that normalizing PVAT by epicardial adipose tissue attenuation (PVAT/EAT ratio) enables robust ischemia assessment. This study evaluated its diagnostic value across heterogeneous CCTA protocols.

METHODS AND MATERIALS

We retrospectively analyzed 81 patients who underwent CCTA and 13 N-ammonia positron emission tomography (PET) within three months between September 2019 and December 2024. Patients with suboptimal image quality were excluded. PVAT attenuation surrounding the proximal right coronary artery was measured semi-automatically, while EAT attenuation was automatically quantified across the entire heart. Assessment of myocardial blood flow (MBF) at both rest and stress utilized ammonia PET, with myocardial flow reserve (MFR) calculated accordingly. Ischemia was defined as MFR < 2.0 in any coronary territory. We conducted multivariable regression analysis to identify factors associated with PVAT and the PVAT/EAT ratio. This includes imaging parameters like CT scanner type, tube voltage, and ECG-gating type, along with clinical variables, Agatston scores, CAD-RADS classification, and MFR. Univariate and multivariate analyses compared ischemic and non-ischemic groups. Receiver operating characteristic analysis evaluated the diagnostic performance of PVAT and the PVAT/EAT ratio, comparing AUCs with the DeLong test.

RESULTS

Seventy-four patients were included (median age: 72 years [IQR: 60-79]; 41 males [55%]). Two CT scanner models each accounted for 34 cases (46%). Low tube voltage (70-90 kV) was applied to 37 patients (50%). MFR<2 was noted in 33 patients (45%). In the multivariate analysis, PVAT attenuation was significantly associated with tube voltage, ECG-gating type, and heart rate. Conversely, the PVAT/EAT ratio was linked to CAD-RADS score > 0 and MFR = 2.0. The ischemic group's PVAT/EAT ratio was significantly lower ($p < .01$). Age (log OR = 0.06 [95%CI: 0.01-0.11]) and PVAT/EAT ratio (log OR = -10.2 [95% CI: -19.2 to -2.3]) were independent predictors of ischemia. The AUC for PVAT alone was 0.57 (95% CI: 0.43-0.70), significantly improving to 0.70 (95% CI: 0.58-0.82; $p = .02$) with the PVAT/EAT ratio.

CONCLUSION

Acquisition parameters influenced PVAT attenuation, whereas the PVAT/EAT ratio was less affected and lower in ischemic patients, demonstrating better diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

Due to variability in CCTA acquisition, PVAT attenuation should be used cautiously in clinical practice. Our proposed PVAT/EAT ratio offers a more robust alternative for real-world applications.

T2-SPCA-14 EVALUATION OF RIGHT-SIDED VALVULAR REGURGITATION USING MONITORING IMAGES FROM TEST BOLUS TRACKING: A PRELIMINARY STUDY ON CONTRAST DYNAMICS IN CARDIAC CT

Tetsuo Hironaga (*Presenter*)
Shinobu Mano (*Abstract Co-Author*)
HIROYUKI KOBAYASHI (*Abstract Co-Author*)
Masahisa Tokunaga (*Abstract Co-Author*)
Asuka Goto (*Abstract Co-Author*)
Atsushi Watanabe, MD,PhD (*Abstract Co-Author*)
Aoi Hayashi (*Abstract Co-Author*)

PURPOSE

Test bolus tracking (TBT) is commonly used in cardiac CT to determine optimal scan timing, while the dynamic monitoring images obtained during TBT are typically disregarded for diagnostic purposes. However, these images may contain valuable information reflecting the contrast circulation dynamics, potentially revealing hemodynamic alterations associated with valvular disease. This study aimed to evaluate whether contrast dilution and delayed arrival in the left atrium (LA) and ascending aorta (AAo) can serve as surrogate indicators for assessing the severity of right-sided valvular regurgitation (RSVR), thereby expanding the clinical utility of TBT from scan timing to diagnostic support.

METHODS AND MATERIALS

We retrospectively analyzed 36 patients who underwent cardiac CT using the TBT technique. To minimize confounding, only patients in sinus rhythm with left ventricular ejection fraction =50% were included. RSVR severity was classified into four categories (none, trivial, mild, moderate) based on the presence and extent of tricuspid and/or pulmonary regurgitation. Time-attenuation curves were generated from TBT monitoring images at the LA level. Peak arrival time and attenuation in both LA and AAo were measured. ?HU_LA-AAo was calculated using peak attenuation values, and its diagnostic performance was analyzed in combination with LA peak arrival time.

RESULTS

Both ?HU_LA-AAo and LA peak arrival time significantly correlated with RSVR severity ($p < 0.05$). Ordinal logistic regression showed good model fit (Pseudo $R^2 = 0.369$, $p < 0.001$). For binary classification, the two-parameter model yielded excellent performance (AUC = 0.980, sensitivity = 93.1%, specificity = 100%). Although the sample size was limited, the results consistently demonstrated high discriminatory performance.

CONCLUSION

TBT monitoring images, though underused, can offer insights into contrast dilution and circulation delay in RSVR. ?HU_LA-AAo and LA peak arrival time may serve as surrogate indicators reflecting contrast dilution and circulation delay associated with RSVR, providing noninvasive support for its assessment.

CLINICAL RELEVANCE/APPLICATION

•Uses underutilized TBT data to assist RSVR evaluation.•Provides alternative when echocardiography is inconclusive.•Reflects early signs of right-sided volume overload.•Helps optimize scan timing in cardiac CT.•Enables retrospective and AI-driven analysis without extra radiation.•Contributes to early triage or pre-procedural risk assessment.

T2-SPCH-2 DEEP LEARNING-RECONSTRUCTED ULTRA-HIGH-RESOLUTION CT FOR PREDICTING INVASIVENESS OF SUBSOLID PULMONARY NODULES: A MULTIVARIATE ANALYSIS OF MORPHOLOGIC FEATURES

Yanyan Xu, MD, PhD (*Presenter*)
He Chen (*Abstract Co-Author*)
Sheng Xie (*Abstract Co-Author*)
Bing Li (*Abstract Co-Author*)

PURPOSE

To evaluate the predictive value of ultra-high-resolution CT (U-HRCT) with deep learning-based reconstruction (DLR-AiCE) for assessing the invasiveness of subsolid pulmonary nodules (SSNs).

METHODS AND MATERIALS

This retrospective study analyzed 126 SSNs (71 part-solid, 55 pure ground-glass) in patients (mean age 55.5±11.8 years; 37 male) who underwent U-HRCT (0.25-mm detector) with DLR-AiCE reconstruction. Nodule characteristics (long diameter, lobulation, spiculation, pleural indentation, vascular convergence, bronchial distortion, and solid component metrics) were correlated with pathological outcomes (34 preinvasive, 46 minimally invasive, and 46 invasive adenocarcinomas). Statistical analyses included univariate tests (?² , Mann-Whitney U) and multivariate logistic regression adjusted for age/sex/smoking.

RESULTS

Univariate analysis revealed significant differences ($p < 0.05$) across pathological groups for long diameter (invasive: 1.60±0.60 cm vs. preinvasive: 1.01±0.29 cm), solid component size (invasive: 0.81±0.61 cm vs. preinvasive: 0.29±0.41 cm), bronchial distortion (invasive: 78.3% vs. preinvasive: 17.6%), Pleural indentation (invasive: 43.5% vs. preinvasive: 11.8%). Multivariate analysis identified bronchial distortion (OR=0.184, $p = 0.007$), pleural indentation (OR=0.108, $p = 0.006$), and solid component size =0.8 cm (OR=0.093, $p = 0.001$) as independent predictors of invasiveness.

CONCLUSION

U-HRCT with DLR-AiCE enhances visualization of critical morphologic features. Bronchial distortion, pleural indentation, and solid component size are robust imaging biomarkers for stratifying SSN invasiveness, aiding clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

U-HRCT with DLR-AiCE enhances visualization of critical morphologic features, and then aiding clinical decision-making.

T2-SPCH-3 IMPACT OF PRIOR LUNG CANCER HISTORY ON SUBSOLID NODULE GROWTH: IDENTIFYING EFFECTIVE FOLLOW-UP STRATEGIES

Mengwen Liu (*Presenter*)
Chengyi Jiang (*Abstract Co-Author*)
Xue Zhang (*Abstract Co-Author*)
Xin Wen (*Abstract Co-Author*)
Meng Li (*Abstract Co-Author*)
Li Zhang (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the influence of prior lung cancer history on subsolid nodule (SSN) growth and identify effective follow-up strategies.

METHODS AND MATERIALS

We retrospectively reviewed HRCT data of SSNs from May 2005 to August 2019 at our hospital. Persistent SSNs, showing either growth or stability during the first annual follow-up, were enrolled. The Kaplan-Meier method and log-rank test were used to compare SSN growth between patients with no history of cancer and those with a history of lung cancer. Multivariable Cox regression analyses were utilized to identify factors associated with SSN growth. Missed nodules were defined as nodules ineligible for follow-up or exhibiting growth beyond guideline-recommended intervals. The missed detection rate was calculated as the number of missed nodules divided by the total number of nodules, excluding ineligible ones and those meeting intervention criteria. Delay time was measured as the interval between clinical confirmation of growth and the earliest detectable growth timepoint per guideline recommendations. The missed detection rate and delay time were compared across various follow-up strategies, including the postoperative follow-up strategy for lung cancer (PFL) from the National Comprehensive Cancer Network Guidelines for Non-Small Cell Lung Cancer, the Fleischner Society's Guidelines for Management of Incidental Pulmonary Nodules Detected on CT Images, and other relevant protocols.

RESULTS

A total of 2749 SSNs in 1598 patients (median age, 54 years [interquartile range (IQR), 46-60 years]; 1034 [64.7%] female) were evaluated. The SSN growth rates were 9.5% (181/1,898) in the no cancer group and 37.8% (322/851) in the lung cancer group. The growth curve showed that SSNs in the lung cancer group were more likely to grow than those in the no cancer group ($P < .001$). Lung cancer history was associated with SSN growth (adjusted hazard ratio, 1.852 [95% confidence interval: 1.492, 2.297]; $P < .001$). The PFL strategy had a missed detection rate of 0 and a shorter delay time (4 months [IQR, 2-7]) compared to other strategies.

CONCLUSION

SSNs are more likely to grow in patients with a history of lung cancer, and the PFL strategy allows for effective detection of SSN growth in these patients.

CLINICAL RELEVANCE/APPLICATION

This study highlights the importance of monitoring SSNs in patients with a history of lung cancer. It demonstrates that the PFL strategy effectively supports the surveillance of SSNs in these patients, ensuring timely detection of growth.

T2-SPCH-4 BEHIND RACIAL CLASSIFICATION: DISPARITIES IN FEATURE USAGE ACROSS RACIAL GROUPS IN CHEST RADIOGRAPHY AI MODELS

Han-Jay Shu, BS (*Presenter*)

PURPOSE

This study investigates how deep learning models internally represent different racial subgroups when performing classification tasks on chest X-ray images. While outcome disparities in AI fairness have been widely discussed, little attention has been paid to whether models rely on distinct internal features across racial groups. If feature usage varies across subgroups, fairness interventions tested on only a few pairs may not generalize—highlighting the need for broader, representation-level evaluation in bias research.

METHODS AND MATERIALS

We used the MIMIC-CXR dataset, which includes fine-grained race and ethnicity labels spanning over 20 subgroups. Using RAD-DINO, a Vision Transformer-based self-supervised encoder, we trained two sets of binary classifiers: one contrasting ASIAN - INDIAN with each other subgroup, and the other using SOUTH AMERICAN as the reference class. For each binary task, we identified the top 100 most important features through linear probing on the learned embeddings. We then computed pairwise mean feature overlap across subgroup comparisons, stratified by broader demographic categories—White, Black, Latino, and Asian—to analyze patterns of feature consistency and divergence.

RESULTS

Our analysis revealed that feature usage by the models varied substantially depending on the racial subgroups being classified. Models distinguishing Black subgroups showed the highest internal feature consistency (intra-group overlap: 0.203 for INDIAN (IND), 0.173 for SOUTH AMERICAN (SA)), suggesting reliance on a stable feature set. However, External overlap, the average feature overlap with other subgroups, was 0.142 for IND and 0.164 for SA. This further underscores that models rely on more distinct features when classifying across group boundaries. Interestingly, Black-Asian pairings showed notably high feature overlap, indicating shared feature usage.

CONCLUSION

The observed disparities in feature usage across racial subgroups suggest that current models may rely on different, group-specific representations when performing classification. This challenges the assumption that bias correction methods validated on one or two subgroups will generalize across all populations.

CLINICAL RELEVANCE/APPLICATION

To ensure equitable application of AI tools in clinical imaging, it is not enough to assess model performance outcomes alone. This study highlights the need to examine internal representation strategies across racial groups. By examining how internal representations vary across racial subgroups, we highlight the need for bias mitigation strategies that target feature-level consistency, ensuring more equitable and clinically robust AI systems that generalize across diverse patient populations.

T2-SPCH-5 INVISIBLE RESPONDERS: RETHINKING RECIST IN THE ERA OF NEOADJUVANT TREATMENT FOR LUNG CANCER

Federica Palmeri, MD (*Presenter*)
Damiano Caruso, MD, PhD (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)
Andrea Laghi, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the accuracy of RECIST 1.1 criteria in assessing treatment response after neoadjuvant chemotherapy—with or without immunotherapy—in patients with stage IIIA-IIIB non-small cell lung cancer (NSCLC) undergoing surgical resection.

METHODS AND MATERIALS

A prospective pilot study was conducted on 33 patients with stage IIIA-IIIB NSCLC treated with neoadjuvant chemotherapy prior to surgery. Eleven of these patients also received pembrolizumab as part of combination immunotherapy. All patients underwent baseline and post-treatment contrast-enhanced CT scans, which were reviewed and assessed using RECIST 1.1 criteria or iRECIST by two expert radiologists in consensus. Histopathological analysis of the resected specimens was performed to identify complete or partial pathological response. Radiological response per RECIST was then compared with histological outcomes.

RESULTS

Among the 33 patients, 12 demonstrated a complete pathological response. However, none of these 12 patients met RECIST 1.1 criteria for complete response on post-treatment imaging. The remaining 21 patients showed a partial pathological response ranging from 80% to 10% residual viable tumor. Of these, only 9 (43%) met RECIST 1.1 criteria for partial response. The remaining patients were classified radiologically as stable disease despite substantial histological regression. These findings indicate a significant discrepancy between RECIST-based radiological assessment and actual pathological response, particularly in patients receiving combined chemotherapy and immunotherapy.

CONCLUSION

RECIST 1.1 criteria appear insufficiently sensitive to detect complete or substantial tumor response following neoadjuvant therapy in stage IIIA-IIIB NSCLC. This may be especially true in the context of immunotherapy, which can induce tumor changes not necessarily reflected in lesion size. These findings indicate a significant discrepancy between RECIST-based radiological assessment and actual pathological response, particularly in patients receiving combined chemotherapy and immunotherapy.

CLINICAL RELEVANCE/APPLICATION

In patients with locally advanced NSCLC treated with neoadjuvant therapy, RECIST 1.1 criteria may underestimate treatment response. Alternative or complementary imaging biomarkers should be explored to better predict pathological outcomes and guide clinical decisions.

T2-SPCH-6 BOOSTING PULMONARY EMBOLISM DETECTION WITH FDA-CLEARED AI: UNCOVERING HIDDEN CASES IN A RETROSPECTIVE STUDY

Syed Muhammad Awais Bukhari, MD (*Presenter*)
Sreyes Venkatesh (*Abstract Co-Author*)
Charit R. Tippareddy, MD (*Abstract Co-Author*)
Cody R. Johnson, MD (*Abstract Co-Author*)
Robert C. Gilkeson, MD (*Abstract Co-Author*)
Amit Gupta, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To assess the power of an FDA-approved AI imaging solution in detecting symptomatic and incidental pulmonary embolism (PE) in a retrospective cohort, catching cases missed by radiologists.

METHODS AND MATERIALS

We analyzed 2,349 CT pulmonary angiograms (CTPAs) and 4,609 CT chest, abdomen, and pelvis (CTCAP)/abdominopelvic CT (CTAP) exams, performed for non-PE indications, from September 24, 2023, to November 30, 2023. An FDA-cleared AI platform (AIDOC) processed images, while natural language processing (NLP) analyzed radiology reports. Cases flagged as PE-positive by AI but negative by NLP were labeled "discordant" and independently reviewed by a board-certified radiologist to classify AI findings as true positives (TPs), false positives (FPs), or questionably positive (QPs). We calculated the enhanced detection rate as the proportion of AI-flagged TPs missed by radiologists relative to radiologist-detected positives.

RESULTS

Radiologists identified 142 PEs and 32 incidental PEs (iPEs), with AI confirming these at matching anatomical locations. AI flagged 32 (1.4%) CTPAs and 15 (0.3%) CTCAPs/CTAPs as discordant. Radiologist review confirmed 17/32 (53%) AI-flagged PEs as TPs, 9 (28%) as FPs, and 6 (19%) as QPs, and 12/15 (80%) AI-flagged iPEs as TPs, 1 (7%) as FP, and 2 (13%) as QPs. AI boosted detection by 12% (17/142) for PEs and 38% (12/32) for iPEs compared to radiologists. Additionally, expanded chart review of discordant cases showed that several patients were already on anticoagulation (e.g., Xarelto), suggesting low downstream harm. The majority of these additional detections were clinically silent but underscore the AI's role as a safety net for missed diagnoses, especially in high-throughput environments.

CONCLUSION

The AI tool significantly improved PE and iPE detection by uncovering overlooked cases, the majority of which were later confirmed as true positives upon expert review. Despite minimal downstream clinical consequences, these additional detections demonstrate AI's potential as a second-reader safety layer that enhances diagnostic sensitivity without harming specificity.

CLINICAL RELEVANCE/APPLICATION

Integrating AI into radiology workflows meaningfully improves pulmonary embolism detection, supporting earlier diagnosis and intervention. This study reinforces AI's value as a complementary tool that boosts radiologist accuracy and patient safety in routine clinical practice.

T2-SPCH-7 AUTOMATED INTERSTITIAL LUNG ABNORMALITY PREDICTION AT CT: EXTERNAL VALIDATION AND POTENTIAL RECOGNITION OF TRACTION BRONCHIECTASIS/BRONCHIOLECTASIS

PURPOSE

A diagnostic system using artificial intelligence (AI) for interstitial lung abnormality (ILA) was developed, however, its effectiveness has not yet been sufficiently validated. This study aimed to examine the usability across different populations and the efficacy as an indicator of traction bronchiectasis/bronchiolectasis (TB) severity and its progression.

METHODS AND MATERIALS

The Rotterdam Study (2017-2019) and the Age Gene/Environment Susceptibility Reykjavik (AGES-Reykjavik) Study (baseline: 2002-2006, follow-up: 2007-2011) were used in this secondary analysis of the two prospective cohorts. The AI system calculated ILA probability score (AI score) in the range from 0 to 1. Three experienced readers independently evaluated for ILA, and two chest radiologists assessed the severity of TB using 4-scale TB index (TBI) and 5-scale TB progression score by consensus. Receiver operating characteristic (ROC) analysis, Kruskal-Wallis test, and Student's t-test were used for statistical analysis.

RESULTS

The system analyzed 932 cases of the Rotterdam Study and 5242 cases of the AGES-Reykjavik Study, and achieved areas under the ROC curve of 0.841 (95% CI: 0.804, 0.879) and 0.823 (95% CI: 0.798, 0.847), respectively. The AI score correlated with readers' certainty, decreasing from unanimous ILA cases to No-ILA cases. Higher baseline AI scores were associated with greater severity of TB (TBI-3: 0.931 [IQR, 0.911-0.932], TBI-2: 0.738 [IQR, 0.406-0.880], TBI-1: 0.537 [IQR, 0.317-0.761], TBI-0: 0.250 [IQR, 0.136-0.455], $P < 0.001$). Furthermore, the change in AI score showed a significant increase in the TB Progression group compared to the No-progression group (0.129 ± 0.216 vs. -0.032 ± 0.198, $P < 0.001$).

CONCLUSION

The system demonstrated applicability among different populations and potential utility for diagnosis, severity assessment, and progression monitoring of TB.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated the potential of this AI system as an auxiliary tool for radiologists in diagnosing ILA, stratifying ILA severity through recognition of TB, and monitoring its progression.

T2-SPCH-9 ENSEMBLE MULTI-TASK NEURAL NETWORK FOR DIFFERENTIAL DETECTION OF PNEUMONIA AND PULMONARY EDEMA ON CHEST RADIOGRAPHS WITH CLINICALLY VERIFIED GROUND TRUTH

Melina Hosseiny, MD (*Presenter*)
Samira Masoudi, PhD (*Abstract Co-Author*)
Natalie Sarafian (*Abstract Co-Author*)
Jessica Kim, MD (*Abstract Co-Author*)
Brian J. Hurt, MD (*Abstract Co-Author*)

Kathleen E. Jacobs, MD (*Abstract Co-Author*)
Kent M. Hall, MD (*Abstract Co-Author*)
Andrew Yen, MD (*Abstract Co-Author*)
Gilbert E. Boswell, MD (*Abstract Co-Author*)
Albert Hsiao, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pneumonia and congestive heart failure (CHF) often present with overlapping clinical features and radiographic findings. Chest radiographs play an important role in the initial diagnostic evaluation, but radiographic appearances may overlap. We developed a multi-task deep learning algorithm to improve detection and differentiation of pneumonia and CHF on chest radiographs. We evaluated its performance alongside radiologists of varying experience levels, using serum lab results and clinical diagnoses as reference standards.

METHODS AND MATERIALS

In this IRB-approved, HIPAA-compliant study, we developed an algorithm using 51,782 chest radiographs, designed to concurrently localize areas of pneumonia and infer serum NT-proBNP. We developed an ensemble multi-task CNN, combining two previously developed single-task CNNs - (1) a 2D U-Net for pneumonia heatmap localization and (2) a modified ResNet-152 for NT-proBNP regression. Radiographs from 251 inpatients who had serum NT-proBNP within 24 hours were identified as a test population, for which ground truth diagnoses were tabulated from medical records. Additionally, four radiologists each independently graded X-rays for likelihood of pneumonia and severity of pulmonary edema for comparison. Performance of readers and the CNN algorithms was evaluated against ground truth diagnosis using area under the receiver operating characteristic curve (AUC) and Spearman rank correlation for agreement with ground truth diagnosis.

RESULTS

For pneumonia detection, the multi-task CNN (AUC: 0.86) outperformed the single-task CNN (AUC: 0.74) and radiologists (AUC: 0.73). For CHF/volume overload, the multi-task (AUC: 0.79) and single-task CNNs (AUC: 0.80) both exceeded radiologist performance (AUC: 0.70). The multi-task CNN's pneumonia likelihood estimates showed strong linearity with actual pneumonia prevalence. NT-proBNP estimates from both CNNs more closely matched serum values than radiologists' categorical grading of pulmonary edema.

CONCLUSION

The proposed ensemble multi-task CNN is capable of reliably detecting and distinguishing between pneumonia and pulmonary edema, outperforming radiologists in this challenging interpretive task.

CLINICAL RELEVANCE/APPLICATION

The proposed multi-task CNN may enhance radiographic interpretation, reduce diagnostic errors, and support clinical decision-making. By assisting radiologists in making more confident and timely diagnoses, this deep learning algorithm may streamline clinical workflows and reduce diagnostic errors. Further prospective investigation may be necessary to assess its routine use to enhance radiologists' interpretation of chest radiographs and ultimately improve patient care.

T2-SPCH-10 INCIDENTAL LUNG CANCER ON NECK CT: PREVALENCE, MISSED DETECTION, AND PROGNOSTIC CONSEQUENCES

Soomin Park, MD (*Presenter*)
Suyon Chang, MD, PhD (*Abstract Co-Author*)
Jung Im Jung, MD, PhD (*Abstract Co-Author*)
Dae Hee Han, MD, PhD (*Abstract Co-Author*)
Jinhee Jang, MD, PhD (*Abstract Co-Author*)
Kyongmin S. Beck, MD, PhD (*Abstract Co-Author*)
Kyunghwa Han, PhD (*Abstract Co-Author*)

PURPOSE

To determine the frequency of incidental lung cancer on neck CT, identify factors associated with missed detection, and evaluate the impact of missed detection on patient outcomes.

METHODS AND MATERIALS

This retrospective cohort study included consecutive adult patients who underwent neck CT at a tertiary-care hospital between January 2008 and December 2024. Patients with prior lung cancer, prior chest CT, no visible lesion, inadequate coverage, or without histologic confirmation of lung cancer were excluded. Two readers reviewed the CT images and original reports for lesion characteristics, lesion mention in the report, malignancy suspicion, and follow-up recommendations. Logistic and linear regression analyses were performed to identify predictors of missed lesions and diagnostic delay. Stage shift was defined by discrepancies between presumed stage at neck CT and final diagnostic stage. Causal mediation analysis was performed to evaluate the role of diagnostic delay on stage shift. Survival was analyzed using Kaplan-Meier and Cox models.

RESULTS

Of 74,508 patients who underwent neck CT, 147 (0.20%) patients had incidental lung cancers and were included in the final cohort (mean age, 65.3 years ± 11.1 [SD]; 75 [51.0%] men). Lung cancer lesions were not mentioned in 63.3% (93/147) of the patients. Missed detection occurred more frequently with CT for non-lung cancer staging (OR, 4.54 [95% CI: 1.38, 14.92]; P = .01) and CT angiography protocol (OR, 5.94 [95% CI: 1.99, 17.70]; P = .001), and was less likely with double reading by a resident and an attending radiologist (OR, 0.22 [95% CI: 0.06, 0.87]; P = .03), presence of lymphadenopathy (OR, 0.20 [95% CI: 0.08, 0.49]; P < .001) and lobulated margins of lung lesions (OR, 0.29 [95% CI: 0.12, 0.70]; P = .01). Missed detection led to longer diagnostic delay (ß = 32.2 months; P < .001) and increased risk of stage shift (OR, 5.53 [95% CI: 2.13, 14.38]; P < .001), adjusted for age and sex. Diagnostic delay independently predicted stage shift (OR, 1.03 [95% CI: 1.02, 1.05]; P < .001). Mediation analysis showed that 46% of the total effect of missed detection on stage shift was mediated through diagnostic delay (average causal mediation effect = 0.13; P < .001). Stage shift was associated with worse survival in patients with presumed early stage disease at neck CT (P =. 001) and remained an independent predictor of all-cause mortality (HR, 1.33 [95% CI: 1.03, 1.71]; P = .03).

CONCLUSION

Incidental lung cancer is not uncommon on neck CT. Missed detection results in diagnostic delay, stage shift, and decreased survival.

CLINICAL RELEVANCE/APPLICATION

Recognizing the common causes of missed lung cancer on neck CT may help reduce diagnostic delay and stage progression, thereby improving clinical outcomes.

T2-SPCH-11 IMPACT OF USER'S ATTITUDES TOWARDS A NEW AI-COMPUTER AIDED DETECTION/DIAGNOSIS (CAD_E/CAD_X) SYSTEM FOR LUNG CANCER RISK STRATIFICATION IN THE RADIOLOGY WORKFLOW

Andrew F. Scarsbrook, BMBS, FRCR (*Presenter*)
Catarina Santos, MD (*Abstract Co-Author*)
Nick Woznitza, PhD (*Abstract Co-Author*)
Mauro Santos, DPhil (*Abstract Co-Author*)

PURPOSE

Integration of AI-based CT computer aided detection (CADe) and diagnosis (CADx) tools in the lung cancer risk stratification radiology workflow could help improve and standardise CT reporting and follow-up recommendations, reduce the number of errors and increase efficiency. However, clinical benefit is in part dependent on user's

attitudes towards AI technologies. The effect of a new AI-CADe/x technology for assisting CT-scan based lung nodule risk stratification in relation to the user's levels of trust and aversion towards AI was evaluated.

METHODS AND MATERIALS

A Multiple Reader Multiple Case (MRMC) pilot study assessed the effect of a CADe/x tool on readers estimates of lung cancer likelihood from CT scans. The CADe/x tool included automatic nodule detection, segmentation, and lung cancer risk prediction. Five radiologists and three thoracic-reporting radiographers read 120 cases (85 with nodules; 41 cancers), with and without AI-CADe/x assistance. A mixed methods study followed: perceived ease of use and usefulness of the CADe/x component were evaluated via a 5-point Likert Scale Survey and thematic analysis of semi-structured interviews, grounded in the Technology Acceptance Model. Attitudes towards AI and trust in the tool were then coded and correlated with the MRMC average effect size, determined via the Dorfman-Berbaum-Metz method (F-test used for the effect size, z-test their difference; 95% bootstrapped confidence intervals reported).

RESULTS

The AI-CADe/x tool increased user reporting confidence, median survey score (interquartile range) was 4 (0.25), and was highly rated for perceived ease of use 4 (1.25) and usefulness 4 (0.25). Participants expressed greater trust towards CADe 4 (0.25) than CADx lung cancer risk prediction 3 (1) components. Those who trusted all CADe/x components (n=2), showed a significantly higher (p=0.009) average effect size of 9.95% [4.2, 15.7] (p=0.001) versus 0.97% [-3.36, 5.31] (p=0.619), for the nodule set, respectively. Thematic analysis suggested lower trust in CADx was due to unfamiliarity with the prediction model and its validation. Finally, those without aversion bias towards AI (n=5) showed a significantly higher benefit (p=0.041) from AI assistance, with effect sizes of 5.72% [-0.83, 12.26] (p=0.08) versus -0.94% [-726, 5.37] (p=0.586), for the nodule set, respectively.

CONCLUSION

Radiologists with positive attitudes and greater trust in AI tools show improved confidence and performance in lung nodule risk stratification and reporting.

CLINICAL RELEVANCE/APPLICATION

Positive user attitudes towards AI-CADe/x could increase benefit in lung cancer risk stratification. Developing strategies to augment trust are crucial for successful and effective adoption in the radiology workflow.

T2-SPCH-12 IMPACT OF PHOTON-COUNTING DETECTOR CT ON VISUALIZATION OF THE ADAMKIEWICZ ARTERY USING SUPER-HIGH-RESOLUTION MODE WITH DEEP LEARNING RECONSTRUCTION: A FIRST EXPERIENCE

Fuminari Tatsugami, MD (*Presenter*)
Toru Higaki, PhD (*Abstract Co-Author*)
Megumi Nishigaki (*Abstract Co-Author*)
Shota Nakano (*Abstract Co-Author*)
Yuko Nakamura, MD, PhD (*Abstract Co-Author*)
Kazuo Awai, MD (*Abstract Co-Author*)
Chikako Fujioka, RT (*Abstract Co-Author*)

PURPOSE

Detection of the artery of Adamkiewicz (AKA) and the anterior spinal artery (ASA) on CT is challenging due to their small vascular diameters and their location within the spinal canal. Photon-counting detector CT (PCD-CT) enables imaging in a super-high-resolution (SHR) mode, which uses smaller detector elements to improve spatial resolution. Additionally, a recently introduced deep learning reconstruction (DLR) algorithm significantly reduces image noise without degrading image texture compared to hybrid iterative reconstruction (HIR) algorithms. The purpose of this study was to evaluate whether the SHR mode reconstructed with DLR on PCD-CT improves the image quality of the AKA, using normal resolution (NR) mode reconstructed with HIR as the reference standard.

METHODS AND MATERIALS

We enrolled 15 patients who underwent CT aortography on a CZT-based PCD-CT scanner developed by Canon Medical Systems. Images were acquired at 120 kV with a tube current of 250 mA. Nonionic contrast media was injected at a rate of 5.0 mL/sec. The following image sets were prepared: NR mode reconstructed with HIR (NR-HIR), SHR mode reconstructed with HIR (SHR-HIR), and SHR mode reconstructed with DLR (SHR-DLR). On axial images, the CT number and standard deviation (SD) of the spinal cord were measured. CT attenuation profiles crossing through the center of the ASA lumen were generated, and the maximum values were recorded. The contrast-to-noise ratio (CNR) of the ASA was calculated using the following formula: CNR of ASA = (maximum CT number of the ASA - CT number of the spinal cord) / image noise of the spinal cord. The overall image quality of the AKA was visually assessed by two radiologists using a four-point scale (1 = poor, 4 = excellent), based on vessel margin sharpness and noise-related blurring.

RESULTS

The mean image noise in the spinal cord was significantly higher on SHR-HIR and SHR-DLR images than on NR-HIR images (19.6, 20.6, and 12.9 HU, respectively; $p < 0.05$). The mean maximum HU value of the ASA on SHR-DLR images was significantly higher than on SHR-HIR and NR-HIR images (149.6, 138.9, and 99.5 HU, respectively; $p < 0.05$); consequently, the CNR of the ASA on SHR-DLR images was the highest among the three reconstructions (5.7, 4.9, and 3.9, respectively; $p < 0.05$). The mean image quality score was also highest for SHR-DLR (3.5, 3.2, and 2.3, respectively).

CONCLUSION

The SHR mode reconstructed with DLR on a PCD-CT scanner significantly improves the image quality of the AKA compared to other reconstruction methods.

CLINICAL RELEVANCE/APPLICATION

The SHR mode reconstructed with DLR on a PCD-CT scanner enhances the image quality of the AKA, which may improve diagnostic performance in detecting the AKA and contribute to avoiding disruption of the AKA during aortic surgery.

T2-SPCH-13 IT IS THOUGHTFULLY BLENDED: OPTIMIZED MIXED BOLUS PROTOCOL REDUCES RADIATION EXPOSURE AND CONTRAST VOLUME FOR THORACIC PHOTON-COUNTING CT ANGIOGRAPHY

Philipp Gruschwitz, MD (*Presenter*)
Jan-Lucca Hennes, MD (*Abstract Co-Author*)
Kristina Krompass, MD (*Abstract Co-Author*)
Pauline Pannenbecker, MD, BA (*Abstract Co-Author*)
Theresa Sophie Patzer, MD (*Abstract Co-Author*)
Viktor Hartung (*Abstract Co-Author*)
Henner Huflage, MD (*Abstract Co-Author*)
Thorsten A. Bley, MD (*Abstract Co-Author*)
Jan P. Grunz, MD (*Abstract Co-Author*)

PURPOSE

Aim was to compare the image-quality comparison of photon-counting-detector CT angiographies (PCD-CTA) using an optimized mixed bolus protocol (MBP) to standard manufacturer-recommended PCD-CTA (SP) and energy-integrating-detector CT (EP) protocols.

METHODS AND MATERIALS

High-pitch PCD-CTA performed between 10/2024 and 04/2025 with MBP were retrospectively included in this single-center study. An intra-individual comparison was made with previous SP and EP examinations. PCD-CTA were performed with fixed tube voltage (120 kVp), IQ level of 42 (MBP) or rather 64 (SP) and reconstructed as

45/55 keV images after application of 26 ml Imeron 350 mg/ml as mixed bolus 53:47% (MBP; 9.1 g iodine) or 60ml Imeron350 (SP; 21 g iodine). EP was performed using ATVS (90/100 kVp) with a reference tube current of 434/350 mAs after administration of 60 ml Imeron350. Contrast-to-Noise Ratio (CNR) was calculated. Subjective image quality (overall quality, luminal contrast, vessel sharpness) was assessed by three radiologists using a 5-point scale.

RESULTS

101 PCD-CT MBP scans were performed, of which 18 patients (6 female; 61±10 years) received both preliminary examinations and were included in the study. The MBP was generated with the lowest radiation dose (3.0±0.5 mGy;p<0.01 each); 35% lower than SP (4.6±0.9 mGy) and 42% than EP (5.1±0.8 mGy). The highest intraluminal attenuation was achieved with SP, which was significantly higher than the contrast dose equivalent EP (539.8±70.8 HU vs. 368.3±45.6 HU; p<0.01). MBP (45keV) achieves comparable intraluminal contrast (377.5±42.3 HU vs. 368.3±45.6 HU; p>0.99) and CNR (29.9±3.9 vs. 28.5±4.3; p>0.99) to those of the EP while requiring 43% of the contrast agent and 58% of the radiation dose. Subjectively, SP was rated best in all categories (5 [5-5]). Overall image quality was rated slightly better for MBP than for EP (4 [4-5] vs. 4 [4-4]), with similar results for luminal attenuation (4 [IQR 4-4], each). The interrater agreement was good (ICC=0.78).

CONCLUSION

Thoracic PCD-CTA using MBP achieves adequate image quality while requiring significantly lower radiation and contrast agent dose compared to EID-CT and standard PCD-CTA.

CLINICAL RELEVANCE/APPLICATION

The ability to reduce radiation and contrast doses reduces the risk of secondary disease in vulnerable patient populations, such as young patients or those with impaired renal function.

T2-SPER-1 ENHANCING TRAUMA WORKFLOW WITH AI-POWERED GRAPHICAL SUMMARIES: A MULTIDISCIPLINARY STUDY INVOLVING RADIOLOGISTS AND SURGEONS

Nitai Bar, MD (*Presenter*)

PURPOSE

Efficient data flow in trauma settings is crucial for timely decision-making. Graphical summaries of traumatic findings may facilitate prioritization and support life-saving decisions in high-pressure environments. We aim to evaluate the efficacy of a language model-powered graphical summary in enhancing decision-making efficiency in chest trauma cases.

METHODS AND MATERIALS

This multidisciplinary study was conducted in two phases: 1. Evaluation of a language model's accuracy in extracting and classifying traumatic findings from chest CT reports. 2. Randomized crossover experiment to assess the impact of graphical summaries on decision-making time, clinical performance, and surgeon satisfaction.The dataset included 2,500 manually annotated chest CT reports, serving as a gold standard. GPT-based models extracted trauma-related findings, which were then rendered into graphical summaries using a rule-based system. Model performance was evaluated through mean AUC, F1, and exact match scores. In the second phase, 20 cases were selected, and 15 surgeons independently processed all cases, with graphical summaries randomly provided for each surgeon for a subset of the reports. Decision-making times were measured and analyzed using a mixed-effects model on log-transformed data. Clinical accuracy was evaluated by answering two questions and assessed with McNemar's test. Surgeon satisfaction was graded on a 1-5 Likert scale.

RESULTS

Results from phase one demonstrate an F1 of 0.922, indicating high model accuracy in identifying and classifying traumatic injuries. In phase two, graphical summaries reduced decision-making time by an average of 22%, adjusted for case complexity and surgeon variability. No significant difference was observed in clinical error rates. Mean surgeon satisfaction with graphical summaries was 4.2.

CONCLUSION

We present a novel pipeline that leverages natural language processing to generate real-time graphical summaries of chest CT findings in trauma scenarios. Our findings, based on a randomized within-subject crossover study in a simulated environment, suggest that this tool significantly optimizes trauma workflow efficiency.

CLINICAL RELEVANCE/APPLICATION

Multidisciplinary studies are a crucial step in successful integration and implementation of AI-powered support tools into clinical practice. Our preliminary evidence suggests that graphical summaries of traumatic findings can streamline communication between radiologists and surgeons, enhancing decision-making efficiency in trauma settings.

T2-SPER-2 COMPARATIVE ANALYSIS OF CONTRAST DOSE REDUCTION AND BEAM-HARDENING ARTIFACT MITIGATION BETWEEN ADAPTIVE LOW-CONTRAST-DOSE AND STANDARD CTPA SCANNING ACROSS DIVERSE CLINICAL SCENARIOS

Xiaoying Chen (*Presenter*)
Xubin Cui (*Abstract Co-Author*)
Wanting Wu (*Abstract Co-Author*)

PURPOSE

To evaluate whether the adaptive low-contrast-dose protocol can reduce contrast media dosage and mitigate beam-hardening artifacts (BHA) in CTPA across diverse clinical scenarios, while preserving diagnostic image quality compared to standard protocol.

METHODS AND MATERIALS

This retrospective cohort study enrolled 188 patients with suspected pulmonary embolism who underwent spectral CTPA between February 2022 and January 2025. They were categorized into two groups: Group A (adaptive low-contrast-dose protocol, n=84), randomly enrolled after routine implementation of the low-contrast-dose protocol, including 30 patients with body weight =80 kg. Group B (standard protocol, n=104), randomly selected patients pre-implementation, of whom 10 weighted =80 kg. The adaptive low-contrast-dose protocol employs a three-ROI test bolus for scan timing optimization and individualized contrast injection flow rates according to weight. Attenuation values in pulmonary arteries, branches, and muscles affected by BHA were measured, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), arteriovenous separation, and BHA levels were calculated and compared. Image quality was scored independently by two radiologists via a 5-point Likert scale, evaluating artery/vein contrast, BHA reduction.

RESULTS

The adaptive low-contrast-dose protocol (Group A) successfully reduced contrast agent usage by 35% (26 mL vs. 40 mL, $P < 0.001$) relative to the standard protocol (Group B), even in heavier patients ($P < 0.001$). Radiation exposure remained equivalent between groups ($P > 0.05$). Although Group A showed marginally lower CT numbers and SNR, all pulmonary artery segments achieved sufficient enhancement (= 350 HU) and clear vascular separation (CT difference = 300 HU). CNR equivalence confirmed no loss of diagnostic confidence. Notably, Group A outperformed Group B in minimizing BHA (13.10 (0.00,23.19) VS 33.30 (25.10,54.65), $P < 0.001$) and improving image quality as assessed subjectively ($P < 0.05$).

CONCLUSION

The adaptive low-contrast-dose protocol achieves significant reductions in both contrast media volume and BHA while preserving diagnostic image quality.

CLINICAL RELEVANCE/APPLICATION

The adaptive low-contrast-dose protocol achieves significant reductions in both contrast media volume and beam-hardening artifacts while preserving diagnostic image quality.

T2-SPER-3 EVALUATION OF A 5G-CONNECTED MOBILE CT SCANNER: TECHNICAL FEASIBILITY, IMAGE QUALITY AND RADIATION DOSE COMPARED TO CONVENTIONAL EMERGENCY DEPARTMENT IMAGING

Schanas Jawhar (*Presenter*)
Johann S. Rink, MD (*Abstract Co-Author*)
Greta Thater (*Abstract Co-Author*)
Stefan O. Schoenberg, MD, PhD (*Abstract Co-Author*)

PURPOSE

Stroke is a major global health burden requiring fast diagnosis and treatment. Mobile Stroke Units (MSUs), specialized ambulances equipped with head CT, improve acute stroke care. In Mannheim, Germany, a government-funded project enabled the development of an MSU with a novel 5G-connected CT scanner and telemedical equipment. This study evaluates the technical feasibility, image quality, and radiation dose of this mobile CT compared to a standard emergency department (ED) CT.

METHODS AND MATERIALS

Head phantom CT scans were performed using both the MSU and the ED CT scanner. Identical scanning protocols were applied to ensure comparability. For each scan, transmission times to the hospital Picture Archiving and Communication System (PACS) were measured. Image quality was assessed by calculating the signal-to-noise ratio (SNR). Radiation dose metrics, measured as dose-length product (DLP), were compared between the two scanners. Descriptive statistics were used to compare the parameters.

RESULTS

The median SNR in head CT scans performed in the MSU was higher compared to those obtained using the ED CT scanner (1.65 vs. 1.4). The radiation dose was < 800 mGy·cm in both settings. Image transmission was technically successful, with MSU images available in < 4 minutes.

CONCLUSION

The findings indicate that the newly implemented 5G-connected CT system in the MSU delivers state- of-the art imaging quality, transmission speed, and radiation dose comparable to that of a conventional ED CT scanner. These results support the technical reliability and diagnostic equivalence of the mobile system, underscoring the potential of such MSUs to streamline acute stroke care workflows.

CLINICAL RELEVANCE/APPLICATION

These findings support the clinical use of MSUs as a reliable tool for early stroke diagnosis, potentially reducing time to treatment and improving patient outcomes in pre-hospital settings.

T2-SPGI-1 AI-BASED APPROACH FOR PHEOCHROMOCYTOMA SEGMENTATION IN MULTIPLE ENDOCRINE NEOPLASIA TYPE 2 PATIENTS USING CT

Fahmida Haque, PhD (*Presenter*)
Shadin Ghabra (*Abstract Co-Author*)
Shruthi Perati (*Abstract Co-Author*)
Nathan S. Lay, PhD (*Abstract Co-Author*)
Stephanie A. Harmon, PhD (*Abstract Co-Author*)
Joanna Klubo-Gwiezdzinska (*Abstract Co-Author*)
John Glod (*Abstract Co-Author*)
Karel Pacak, MD (*Abstract Co-Author*)
Naris Nilubol (*Abstract Co-Author*)
Baris Turkbey, MD (*Abstract Co-Author*)

PURPOSE

Multiple Endocrine Neoplasia type 2 (MEN2) is a rare autosomal dominant tumor syndrome, with two distinct clinical subtypes: MEN2A and, more aggressive, MEN2B, commonly presenting with primary and recurrent pheochromocytoma (PHEO). This study aims to develop an artificial intelligence (AI)-based automatic lesion segmentation model to study PHEO progression in MEN2 patients

METHODS AND MATERIALS

Expert radiologist with over 20 years of experience, manually contoured contrast-enhanced abdomen CT images of the PHEO lesions on 58 Baseline scans and 30-second follow-up scans of 58 in-house patients (34 MEN2A and 14 MEN2B) and 18 scans of 13 patients from another institution (11 MEN2A, 2 MEN2B) (NCT01005654, NCT00004847, NCT01660984). Two additional open-access datasets: 53 confirmed Adrenocortical carcinoma (ACC) patients and 50 scans with no lesion as negative scans from the KiTS19 dataset were used to increase the sample size. The final dataset consists of 209 scans, which were split into train, validation, and test sets using a 70:10:20 ratio. 3D full-resolution (3D-FullRes) configuration from the nnU-Net framework was trained using 5-fold cross-validation. The model's performance was evaluated on the test set using the Dice similarity coefficient (DSC) and scan-level total tumor volume (TTV). We ran the AI model on 107 follow-up scans for the in-house patients and generated AI-predicted lesion masks. We compared the tumor growth rate (TGR) (%) between MEN2A and MEN2B with the AI-generated total tumor burden (TTB) on follow-up scans (AI Follow-up) in comparison with the expert-annotated ground truth (GT) and AI-generated TTB on baseline scans (AI Baseline).

RESULTS

The model achieved a DSC of 0.62, lesion detection sensitivity of 90%, with 0 median FP per scan (range=0, 2), for the test cohort. The mean absolute TTV difference is -22.19 (-226.94, 182.55), indicating lower tumor burden by AI prediction masks compared to the GT masks for most of the test scans. The median TGR values with 0.25 and 0.75 quartile values between MEN2A and MEN2B are -50.74 (-98.32, 151.16) and -96.80 (-99.33, -58.63) for AI Follow-up vs. AI Baseline and -44.40(-95.24,165.92) and -96.06(-99.26,-45.21) for AI Follow-up vs. GT, respectively ($p<0.05$, Wilcox-rank test). This indicates TGR for MEN2A is slightly faster than MEN2B

CONCLUSION

The developed AI model showed promising and reliable performance in segmenting adrenal lesions, which can be useful for physicians to make the annotation process more efficient in patients with adrenal lesions.

CLINICAL RELEVANCE/APPLICATION

The developed model can enable clinicians to automatically compute the total tumor burden on patients with adrenal lesions (PHEO and ACC) and also study the PHEO progression or recurrence for MEN2 patients.

T2-SPGI-2 HEPATOCELLULAR CARCINOMA AUTOMATIC DETECTION IN DYNAMIC CONTRAST-ENHANCED MRI USING DEEP LEARNING ALGORITHMS

Killian Monnin (*Presenter*)
Patrick Jeltsch (*Abstract Co-Author*)
Lucia Fernandes Mendes (*Abstract Co-Author*)
Mario Jreige, MD (*Abstract Co-Author*)
Montserrat Fraga (*Abstract Co-Author*)
Raphael Girardet, MD (*Abstract Co-Author*)
Clarisse Dromain, MD, PhD (*Abstract Co-Author*)
Jonas Richiardi (*Abstract Co-Author*)
Naik Vietti Violi, MD (*Abstract Co-Author*)

PURPOSE

To develop a deep learning-based model for automatic early-stage hepatocellular carcinoma (HCC) detection using Dynamic Contrast-Enhanced (DCE) MRI, and to analyze its diagnostic performance at both patient and lesion levels.

METHODS AND MATERIALS

This retrospective study included DCE T1wi liver MRI from two monocentric cohorts. The first cohort included patients (N=296) undergoing HCC surveillance with diagnosed HCC as well as negative cases. The patients were randomly split into training, validation and test sets. The second cohort included pre-ablation patients (N=67), all positive for HCC. The latter were used as test set for generalization evaluation. The two largest public liver lesion datasets (CT, N=1037 and MRI, N=485)

were used for pre-training algorithms. An attention U-Net model was trained to segment and detect HCC using a curriculum pretraining method and was compared to the state-of-art nnU-Netv2. The detection metrics were calculated with respect to radiologist detection. Diagnostic accuracy was evaluated using sensitivity, specificity, mean false positive rate per patient, the Area Under the Curve (AUC) of the Free-Response Operating Characteristic (FROC) curves and the Receiver Operating Characteristic (ROC) curves. Additionally, the results were stratified by Liver Imaging Reporting and Data System (LI-RADS) score to explain performance results.

RESULTS

The final population included 363 patients (58 ± 11 years; 284 men; 251 lesions), 51 patients (115 lesions) used in training set, 245 (12 HCC positive with 21 lesions, 233 HCC negative) in the HCC surveillance used as a first test set and 67 (115 lesions) in the HCC pre-ablation used as a second test set. At patient level, 80% sensitivity and specificity (AUC of 0.80 (95% CI, 0.66 - 0.91)) was measured on the HCC surveillance test set. At lesion level, 80% of sensitivity for a mean false positive rate per patient of 1 was measured on the HCC Pre-Ablation test set with our pre-trained model with a FROC AUC of 0.82 (95% CI, 0.77 - 0.88, $p < 0.01$), significantly outperforming the nnU-Netv2 at 0.61 (0.52 - 0.69).

CONCLUSION

Both patient-level and lesion-level achieved 80% HCC detection sensitivity by using deep learning segmentation neural network pre-trained from large open datasets and fine-tuned using heterogeneous proprietary data. This performance highlights the translational potential of such tools in the clinical workup of patients at risk of HCC.

CLINICAL RELEVANCE/APPLICATION

Visual interpretation for HCC detection in MRI is time-consuming, requiring high levels of expertise in radiology. Deep learning models pre-trained from large datasets are close to reach clinical utility for HCC lesions detection, and the combination with abbreviated MRI is promising for HCC screening.

T2-SPGI-3 SINGLE VENOUS PHASE DUAL ENERGY CT CAN DIFFERENTIATE BENIGN AND MALIGNANT LIVER LESIONS DEEMED "TOO SMALL TO CHARACTERIZE" IN ONCOLOGIC PATIENTS

Om B. Panta, MD (*Presenter*)
Francesca Rigiroli, MD (*Abstract Co-Author*)
Olga R. Brook, MD, MBA (*Abstract Co-Author*)

PURPOSE

To assess utility of dual energy (DECT) in characterization of "too small to characterize" liver lesions in oncologic patients and identify its diagnostic value in differentiating benign and malignant lesions.

METHODS AND MATERIALS

In this IRB-approved retrospective study, patients with small liver lesions who underwent single-phase dual-energy CT between March and August 2024 were analyzed. Patients with lesions between 5 to 15 mm with confirmed diagnosis (histopathology, ultrasound evidence of cyst, PET/MRI diagnosis, or stability on follow up imaging for at least 6months) were included in the study. Patients with lesions with inconclusive diagnosis were excluded. A fellow with 9 years of clinical experience analyzed lesions by drawing an ROI on a single slice, obtaining virtual enhancement (HU Contrast - HU Virtual un-enhanced), iodine concentration, and iodine concentration normalized to the aorta derived from material decomposition images. Statistical analysis included the Mann-Whitney U test and ROC curve analysis.

RESULTS

The study cohort comprised 65 patients (36/65 females [55.4%]) with a median age of 69 years (interquartile range [IQR]: 59-75 years). Of the 99 lesions evaluated (median size 9.7 mm, IQR: 8.2-12 mm), 56/99 (56.6%) were benign and 43/99 (43.4%) were malignant. Significant differences were observed between benign and malignant lesions in virtual enhancement (1.7 HU vs. 14.3 HU), iodine concentration (2.4 100µg I/ml vs. 9.3 100µg I/ml), and normalized iodine concentration (6.1% vs. 23.5%) ($P<0.01$). Using a normalized iodine concentration threshold of 13.2%, the diagnostic algorithm achieved 86% sensitivity and 92.8% specificity. The diagnostic performance was maintained or improved for lesions smaller than 10 mm.

CONCLUSION

Single venous phase dual-energy CT with quantitative iodine analysis demonstrates high diagnostic accuracy in "too small to characterize" liver lesions in differentiating benign and malignant lesions.

CLINICAL RELEVANCE/APPLICATION

Normalized iodine concentration has high diagnostic accuracy in differentiating benign and malignant lesion and could potentially impact surveillance protocols for patients with known malignancy resulting in lower use of PET and MRI for these lesions.

T2-SPGI-4 DUAL-LAYER SPECTRAL CT FOR HISTOLOGICAL GRADE PREDICTION IN PANCREATIC NEUROENDOCRINE TUMORS

Jing Sun (*Presenter*)
Zhengrong Zhou, MD,PhD (*Abstract Co-Author*)
Yu Wang (*Abstract Co-Author*)

PURPOSE

To predict the histological grade of pancreatic neuroendocrine tumors (pNETs) preoperatively using quantitative and qualitative variables obtained from dual-layer spectral detector CT (DLCT).

METHODS AND MATERIALS

This retrospective study assessed 177 patients with pathologically confirmed pNETs who underwent DLCT between November 2017 and December 2024. For quantitative analysis, both conventional and spectral parameters, such as effective atomic number (Zeff) and iodine concentration (IC), were measured in each phase. The iodine enhancement fraction (IEF_PP/VP) was calculated as the ratio of IC in pancreatic parenchymal phase to venous phase. Normalized IC (nIC) was derived from the lesion-to-aortic IC ratio at the same slice level. Qualitative variables of necrosis and enhancement uniformity were evaluated on virtual mono-energetic images (VMIs) at 40 keV. Univariate analysis identified significant predictors, followed by forward stepwise binary logistic regression for further screening and prediction model construction. A multiparametric logistic regression model integrating spectral parameters was constructed. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis.

RESULTS

Among 177 pNETs pancreatic neuroendocrine neoplasms (PanNETs), 62 (35%), were grade G1 and 115 (65%) were grade G2 and G3. Independent predictors included necrosis (OR = 3.546, $p < 0.001$), enhancement uniformity (OR = 0.103, $p < 0.001$), Zeff_VP (OR = 0.141, $p = 0.001$), and IEF_PP/VP (OR = 0.208, $p < 0.001$). IEF_PP/VP (AUC = 0.708, $p = 0.016$) exhibited better predictive performance than Zeff_VP (AUC = 0.663), enhanced uniformity (AUC = 0.680), and necrosis (AUC = 0.523). The combination model integrating necrosis, enhancement uniformity, Zeff_VP, and IEF_PP/VP achieved superior diagnostic efficacy, with an AUC of 0.822 ($p < 0.001$), sensitivity of 88.7%, and specificity of 66.1%.

CONCLUSION

DLCT-derived spectral parameters are valuable for noninvasive preoperative prediction of pNET histological grade. The combined model demonstrates superior diagnostic accuracy, which may aid in surgical planning and treatment stratification.

CLINICAL RELEVANCE/APPLICATION

Dual-layer spectral CT enables noninvasive and accurate preoperative prediction of pancreatic neuroendocrine tumor grade, which may improve surgical decision-making and individualized treatment planning.

T2-SPGI-5 MACHINE LEARNING RADIOMICS OF PRE-OLT MULTIPHASE MRI AS A PREDICTOR OF HEPATOCELLULAR CARCINOMA RECURRENCE AFTER LIVER TRANSPLANTATION

Zahra Mohammadigoldar, MD (*Presenter*)
Steven S. Raman, MD (*Abstract Co-Author*)
Xinyi (Mimi) Li (*Abstract Co-Author*)
Abhinav Suri, BA, MPH (*Abstract Co-Author*)
Pedram Keshavarz, MD (*Abstract Co-Author*)
Brian Nguyen (*Abstract Co-Author*)
Vatche Agopian, MD (*Abstract Co-Author*)
Richard S. Finn, MD (*Abstract Co-Author*)
Justin P. McWilliams, MD (*Abstract Co-Author*)
William Hsu, PhD (*Abstract Co-Author*)
Kyunghyun Sung, PhD (*Abstract Co-Author*)
Jason Chiang, MD, PhD (*Abstract Co-Author*)
David S. Lu, MD (*Abstract Co-Author*)

PURPOSE

This study explores the prediction of hepatocellular carcinoma (HCC) recurrence following orthotopic liver transplantation (OLT) using a machine learning (ML)-based radiomics model. Specifically, it correlates pre-OLT locoregional therapy (LRT) multiphase MRI T1-weighted features with post-transplant recurrence rates and survival outcomes.

METHODS AND MATERIALS

This HIPAA-compliant, IRB-approved study cohort included 32 patients with confirmed LI-RADS 5 HCC (mean age 68 years; 19 males) who underwent OLT at the US transplant center between January 2005 and 2022. A post-OLT HCC recurrent subcohort and included 16 patients, and post-OLT HCC nonrecurrent HCC subcohort included 16 propensity matched patients. Initial T1-weighted Gadoxetic Acid multiphasic MRI at the time of diagnosis (pre-contrast, arterial, venous, and hepatobiliary Phase) were used to analyze imaging features. A machine learning-based radiomics analysis extracted 428 features per patient. The PyCaret library was employed to test eight clustering algorithms, with KMeans selected as the optimal algorithm for patient grouping. The model's ability to differentiate recurrence from non-recurrence was evaluated.

RESULTS

The mean overall and post-OLT rHCC follow-ups were 101.3 ± 28.3 months [IQR: 38, 83 months] and 35.6 ± 43.1 months [IQR: 10, 46 months], respectively. The KMeans clustering algorithm demonstrated optimal patient separation, initially grouping them into five clusters. Notably, four clusters (Clusters 0, 2, 3, and 4) predominantly comprised patients with HCC recurrence (11 out of 14), while Cluster 1 was largely made up of patients with both recurrence and non-recurrence (13 out of 19). Therefore, our ML-based radiomics analysis showed four features derived from gray-level co-occurrence matrix (GLCM) analysis showing significant differences between the groups, achieving a sensitivity and specificity of 81.2% and 64%, respectively. (Figure 1)

CONCLUSION

This study demonstrates the potential of a machine learning-based radiomics model analyzing T1-weighted pre-OLT LRT MRI features to predict post-OLT HCC recurrence. The findings suggest that pre-OLT MRI based radiomics features may help detect aggressive HCC.

CLINICAL RELEVANCE/APPLICATION

This ML-radiomics model using pre-OLT MRI features may help predicting HCC recurrence after OLT. Imaging radiomics features integrating imaging features with clinical data may b to improve clinical decision-making and patient management in liver transplantation.

T2-SPGI-7 HISTOGRAM ANALYSIS OF TRIPHASIC SPECTRAL CT FOR PREDICTING LYMPH NODE METASTASIS IN GASTRIC CANCER

Fang Ma (*Presenter*)
Leping Peng (*Abstract Co-Author*)
Lili Wang I (*Abstract Co-Author*)
Xiaoyue Zhang (*Abstract Co-Author*)

PURPOSE

To evaluate and compare of the predictive performance of histogram features derived from conventional 120-kVp images, virtual monoenergetic images, and iodine concentration maps in triphasic spectral CT for lymph node metastasis (LNM) in gastric cancer.

METHODS AND MATERIALS

This retrospective study enrolled 65 gastric cancer patients who underwent triphasic contrast-enhanced spectral CT before surgery, with a total of 290 lymph nodes evaluated (118 metastatic and 172 non-metastatic). Volumes of interest (VOIs) were delineated on conventional 120-kVp images from triphasic spectral CT scans, then automatically co-registered and propagated to both 40-keV and 100-keV virtual monoenergetic images (VMIs) and iodine concentration (IC) maps across all phases. Histogram features were extracted from each phase, including:
10Percentile,90Percentile,Energy,Entropy,InterquartileRange,Kurtosis,Maximum,MeanAbsoluteDeviation(MAD),Mean,Median,Minimum,Range,RobustMeanAbsoluteDeviatior
Univariate and multivariate logistic regression analyses were used to identify independent predictors, and receiver operating characteristic (ROC) curves were constructed to evaluate the predictive performance.

RESULTS

Univariate analysis identified 168 histogram features associated with lymph node metastasis (LNM). Subsequent multivariate analysis confirmed 20 features as independent risk factors for LNM. Among them, the AUC values of the three parameters—ICAP_TotalEnergy, 120-kVpVP_TotalEnergy, and ICVP_TotalEnergy—were significantly higher than those of other features, reaching 0.886 (95% CI: 0.849,0.923),0.888 (95% CI: 0.849,0.927),0.870 (95% CI: 0.827,0.913).

CONCLUSION

The histogram parameters derived from spectral CT conventional 120-kVp images, virtual monochromatic images, and iodine concentration maps—particularly TotalEnergy—can serve as imaging biomarkers for LNM in gastric cancer.

CLINICAL RELEVANCE/APPLICATION

Surgical resection combined with lymphadenectomy remains the primary treatment for resectable gastric cancer. As a crucial independent prognostic factor, lymph node metastasis (LNM) status not only guides the selection of surgical approaches and adjuvant therapies but also significantly correlates with patient survival outcomes. Histogram-based analysis of spectral CT triphasic virtual monoenergetic images (VMIs) and iodine concentration maps can effectively characterize lymph node heterogeneity, providing a more precise clinical assessment tool for LNM prediction.

T2-SPGI-8 REAL-LIFE EXPERIENCE IN THE TREATMENT OF GALLBLADDER CARCINOMA BY RADIOEMBOLIZATION: A MULTICENTER RETROSPECTIVE STUDY

Thomas Dertnig, MD (*Presenter*)
Lukas Mueller, MD, PhD (*Abstract Co-Author*)
Timo A. Auer, MD (*Abstract Co-Author*)
Benedikt M. Schaarschmidt, MD (*Abstract Co-Author*)

PURPOSE

Patients with hepatic metastases from gallbladder carcinoma have limited treatment options, highlighting the need for alternative therapies. Trans-arterial radioembolization (TARE) has the potential to enhance therapeutic strategies beyond conventional chemotherapy. This retrospective study, conducted across five major tertiary care centers, aimed to identify factors associated with improved median overall survival (OS) in patients treated with TARE.

METHODS AND MATERIALS

This retrospective study included patients with hepatic metastases from gallbladder carcinoma who underwent TARE treatment. Clinical data, imaging characteristics and TARE reports as well as data from RECIST 1.1 analysis performed 3, 6 and 12 months after TARE was collected. OS was analyzed using Kaplan-Meier survival curves.

RESULTS

Among 16 patients (56.25% female, 43.75% male; mean age: 65.7 ± 5.5 years), prior therapies included chemotherapy in 93.8% (15/16), surgery in 68.8% (11/16), and radiation therapy, local ablation, and monoclonal antibody treatment each in 6.3% (1/16) of patients. Twelve patients had extrahepatic metastases at the time of intervention (12/16, 75%). The follow-up showed a hepatic disease control rate of 81.8% (9/11) with a stable disease in 72.7% (8/11) and a partial response in 9.1% (1/11). The median OS of patients with hepatic metastases treated with TARE was 7 months (CI: 1.7 - 12.3 months) with a median time to hepatic progression of 115 days (CI: 108.5 - 121.5 days) and a median time to global progression of 112 days (CI: 80.2 - 142.8). Peri- and postinterventional complications were limited, including coil dislocation, reaction to contrast agent, and abscess formation, each occurring in 6.3% (1/16) of patients.

CONCLUSION

Radioembolization appears to be a safe and effective palliative treatment for hepatic metastases of gallbladder carcinoma.

CLINICAL RELEVANCE/APPLICATION

Radioembolization offers a promising palliative treatment option for patients with hepatic metastases from gallbladder carcinoma, demonstrating a favorable safety profile. These findings support its potential role in extending survival and improving disease management in a population with otherwise limited therapeutic alternatives.

T2-SPGI-9 VIRTUAL EXAM UNDER ANESTHESIA (VEUA): POTENTIAL BENEFIT OF PERIANAL MR 3D RENDERINGS FOR SURGEONS, RADIOLOGISTS AND PATIENTS

Ahmed O. El Sadaney, MBBCh (*Presenter*)
Lena Hamza, MD (*Abstract Co-Author*)
Avinash Nehra, MD (*Abstract Co-Author*)
Eric C. Ehman, MD (*Abstract Co-Author*)
Priya S. Dave, MD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)
Yong Lee (*Abstract Co-Author*)
Joel G. Fletcher, MD (*Abstract Co-Author*)

PURPOSE

Virtual Exam Under Anesthesia (vEUA) is an interactive 3D display method that uses perianal MR images to display the relationship of perianal fistulas to the anal sphincter complex and levator ani. We sought to estimate the potential impact of vEUA images on surgical management as well as surgeon, radiologist, and patient understanding of perianal disease.

METHODS AND MATERIALS

40 patients with known perianal Crohn's disease underwent perianal MR followed by exam under anesthesia. Perianal fistulas, anal sphincters, and levator ani were segmented using semi-automated vEUA software (Motilent Ltd; London). Physicians were shown conventional MRI images and clinical reports in 10 patients, followed by unblinding of vEUA images. Two colorectal surgeons were asked if anticipated surgical therapy (e.g., LIFT, endorectal advancement flap), approach, or confidence were changed after viewing vEUA images. Five radiologists were asked if Park's classification or confidence were changed. Both groups were asked if vEUA images provided new anatomic insights, and if patient's understanding of their perianal disease would likely benefit from vEUA (5-point Likert scale; 0 = no benefit to 4 = definitely helpful).

RESULTS

Mean segmentation time was 11 minutes. Colorectal surgeons reported that surgical plan or approach changed after viewing vEUA images in 55% (11/20), with new anatomic insights appreciated in 70% (14/20) with vEUA images, and confidence increasing in 85% (17/20) of cases. Radiologists reported that Park's classification and understanding of levator involvement/other anatomic insights changed in 10% (5/50) and 42% (21/50), respectively; however, confidence increased in 74% (37/50) cases. Surgeons and radiologists reported that display and explanation of vEUA images with patients was felt to be definitely helpful in 100% (20/20) and 72% (36/50), respectively. Surgical plan/approach changed in 9/13 patients with complex fistulas and 2/7 with simple fistulas (chi-square statistic: 3.04, p =0.8). For radiologists, there was no relationship between complex fistulas and new anatomic insights (p=0.81).

CONCLUSION

vEUA images changed surgical plan or approach in over half of perianal disease patients and provided new anatomic insights for colorectal surgeons and radiologists. vEUA images were anticipated to be definitely helpful nearly 75% patients with perianal fistulas.

CLINICAL RELEVANCE/APPLICATION

3D renderings of the anal sphincters, levator ani, and complex perianal fistulas from perianal MR images change surgical plan and approach, improve surgeon and radiologist understanding, and are likely helpful to patients.

T2-SPGI-10 RADIOMICS-ASSISTED MRI INTERPRETATION IMPROVES RELIABILITY IN RECTAL CANCER RESTAGING

Joao Manoel M. Santos, PhD (*Presenter*)
Antonildes N. Assuncao JR, MD (*Abstract Co-Author*)
Maria El Homsi, MD (*Abstract Co-Author*)
Maria Clara Fernandes, MD (*Abstract Co-Author*)
Cesar H. Nomura, MD, PhD (*Abstract Co-Author*)
Caio S. Rizkallah Nahas (*Abstract Co-Author*)
Sergio Nahas, MD, PhD (*Abstract Co-Author*)
Marc J. Gollub, MD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)

PURPOSE

To assess inter- and intra-rater agreement of conventional MRI-based response evaluation in rectal cancer after chemoradiotherapy (CRT), and to determine whether integration of a previously validated radiomics score (RadScore) can improve reader consistency and reduce clinically significant diagnostic variability.

METHODS AND MATERIALS

This retrospective study included 60 patients with rectal adenocarcinoma randomly selected from a previously published cohort of 180. Two radiologists (5 and 10 years of experience) independently evaluated restaging MRIs using two standard classifications: MRI tumor regression grade (mrTRG) and T2-weighted imaging (T2WI)-based qualitative assessment. Each radiologist reviewed all cases twice. In the second round, half of the cases were assessed with access to RadScore and prior assessments (unblinded), while the other half were assessed blindly. Inter- and intra-rater agreement was evaluated using Cohen's kappa. Clinically significant threshold discrepancies—defined as changes between adjacent response categories with potential therapeutic implications—were also recorded.

RESULTS

Baseline inter-rater agreement was fair: ? = 0.32 for mrTRG and ? = 0.36 for T2WI-based assessment. Intra-rater agreement improved significantly when RadScore was available, with ? increasing from 0.36 to 0.74 (senior rater) and from 0.26 to 0.74 (junior rater) for mrTRG. T2WI-based assessment showed less consistent improvement (senior: ? = 0.54; junior: ? = 0.65). Among senior raters, clinically significant threshold discrepancies decreased from 69% to 42% (mrTRG) and from 61% to 60% (T2WI). Junior raters still showed substantial discordance, particularly for T2WI.

CONCLUSION

Radiologist agreement for rectal cancer response evaluation using conventional MRI remains limited, especially among less experienced readers. Integration of a quantitative RadScore significantly improves intra-rater consistency, particularly for mrTRG grading, and may help reduce clinically meaningful diagnostic variability.

CLINICAL RELEVANCE/APPLICATION

Incorporating a validated radiomics score into clinical workflows has the potential to enhance diagnostic reliability and standardize restaging evaluations in rectal cancer after CRT.

T2-SPGI-11 INTEGRATED RADIOGENOMICS AND PATHOMICS BASED IMAGING SIGNATURE FOR ACCURATE VASCULOGENIC MIMICRY EVALUATION AND PROGNOSIS PREDICTION IN LIVER HEPATOCELLULAR CARCINOMA

Jiahao Gao (*Presenter*)

PURPOSE

Vasculogenic Mimicry (VM) is closely associated with drug resistance and poor prognosis in liver hepatocellular carcinoma (LIHC). However, VM can currently only be identified by immunohistochemistry and Periodic Acid-Schiff stain. Macroscopic imaging tools are lacking to enable the identification of VM-associated gene expression and prognostic prediction in LIHC.

METHODS AND MATERIALS

We propose constructing a noninvasive imaging biomarker integrating radiogenomics and pathomics for accurate VM gene prediction and prognostic evaluation from 208 LIHC patients. A VM-based genomics model was constructed according to the Lasso method. Abdominal contrast-enhanced CT images of the corresponding patients were acquired, and three-dimensional regions of interest were manually outlined with radiomics features extracted. A radiogenomics biomarker was constructed using LASSO and mRMR algorithms. In addition, H&E sections were also obtained using CellProflier software to screen the pathomics features for a pathomics VM prediction model. Finally, an integrated nomogram combining radiogenomics and pathomics was constructed. The predictive accuracy of the models was evaluated.

RESULTS

A VM-based genomics model consisting of five risk genes successfully stratified the prognosis of LIHC patients. A radiogenomics marker consisting of nine radiomics features was constructed. The AUC values of the radiogenomics marker for the VM prediction in the training and test groups were 0.861 and 0.764, respectively. The pathomics model also possessed a certain predictive value. Finally, the integrated nomogram can further improve the VM prediction (AUC=0.898,0845, respectively). The integrated nomogram successfully achieved survival prediction in LIHC patients with 1-year, 3-year, and 5-year survival AUC values of 0.81,0.89,0.93, respectively.

CONCLUSION

The novel noninvasive imaging biomarker has a promising value for assessing VM-related gene expression in LIHC patients. In addition, it could enable survival prediction and prognostic stratification of LIHC. It is expected to contribute to accurate clinical therapeutic decisions and facilitate precise imaging for LIHC patients.

CLINICAL RELEVANCE/APPLICATION

Angiogenesis is significantly associated with poor prognosis and drug resistance in LIHC. VM is an essential angiogenic modality in LIHC; however, there is a lack of imaging characteristics and noninvasive assessment modalities for VM. Our study established a novel noninvasive radiogenomics biomarker,combined with pathomics, for noninvasive imaging of VM-related gene expression in LIHC. By deeply combining multi-omics imaging with genomics, such strategy has a reference value for precise tumor imaging.

T2-SPGI-12 INTEROBSERVER AGREEMENT AND ACCURACY OF ULTRASOUND (US) LIVER STIFFNESS AND FAT QUANTIFICATION BETWEEN A RADIOLOGIST VS. NON-RADIOLOGIST

Stephanie T. Chang, MD (*Presenter*)
Nancy Zhang (*Abstract Co-Author*)
Jason Wong (*Abstract Co-Author*)
Miki Kwan (*Abstract Co-Author*)
Gabriela Torres (*Abstract Co-Author*)
Jacqueline A. Bailey, ARRT (*Abstract Co-Author*)
Om Patel (*Abstract Co-Author*)
Molly Ma (*Abstract Co-Author*)
Cecilia Miller (*Abstract Co-Author*)
Oluwademilade Dada (*Abstract Co-Author*)
Vibhas Deshpande, PhD (*Abstract Co-Author*)
Ramsey Cheung (*Abstract Co-Author*)
Daniel Ennis (*Abstract Co-Author*)

PURPOSE

Point-of-care ultrasound (US) increases access to a critical diagnostic tool, but US remains operator-dependent. We aim to assess interobserver agreement and accuracy of US liver stiffness and fat quantification by a radiologist vs. non-radiologist using magnetic resonance imaging (MRI) as the reference standard with all exams performed sequentially on the same day.

METHODS AND MATERIALS

Veterans (n=101) with obesity (body mass index (BMI) > 30) and/or type 2 diabetes were enrolled in an IRB-approved study in 2022-2024. Liver stiffness was obtained by US auto point shear wave elastography (auto-pSWE, Siemens ACUSON Sequoia with DAX transducer) and MRI elastography (MRE, Siemens MAGNETOM Vida Fit). Liver fat quantification was obtained by ultrasound derived fat fraction (UDFF) and MRI proton density fat fraction (PDFF). Veterans underwent US performed by a

radiologist and a non-radiologist (hepatology nurse practitioner or clinical research coordinator) with 5 measurements using auto-pSWE and UDFF (software revision VA30B). Interobserver agreement between radiologist and non-radiologist was analyzed with concordance correlation coefficients. McNemar test was used to compare proportions of diagnostic auto-pSWE measurements and Wilcoxon signed-rank test was used to compare US exam durations. Spearman rank correlation was used to compare US to MRI for each operator.

RESULTS

Of 101 veterans enrolled (median age 68 years, range 37-75 years), most were men (n=90) with type 2 diabetes (n=84) and a median BMI of 31.6 (range 19.3-49.1). Concordance correlation showed moderate interobserver agreement between the radiologist and non-radiologist for US liver stiffness at 0.70 (range 0.59-0.79) and was slightly higher for US UDFF at 0.80 (range 0.71-0.85). The radiologist had a significantly higher proportion of diagnostic US measurements (91.7% vs. 77.1%, p=0.006) and spent significantly less time obtaining US measurements (median 3 min vs. 4.5 min, p<0.001). Although both radiologist and non-radiologist US auto-pSWE values correlated with MRE, US auto-pSWE by the radiologist showed stronger correlation: 0.29 (p =0.005) vs. 0.21 (p =0.04). US UDFF by the radiologist also showed slightly stronger correlation with MRI PDFF (0.73 (p <0.001) vs. 0.67 (p <0.001)).

CONCLUSION

Although we observed moderate interobserver agreement in US liver stiffness and fat quantification, US by a radiologist has a higher proportion of diagnostic US measurements, requires less exam time, and more strongly correlates with MRI compared to US performed by a non-radiologist.

CLINICAL RELEVANCE/APPLICATION

US quantification for liver stiffness and fat remains operator-dependent and specialized training and/or certification may be required.

T2-SPGI-14 CHARACTERIZATION AND 5-YEAR PROGNOSTICATION OF CHRONIC LIVER DISEASE USING AI-BASED MRI RADIOMICS

Damiano Catucci, MD (*Presenter*)
Lukas Zbinden (*Abstract Co-Author*)
Verena Obmann, MD (*Abstract Co-Author*)
Annalisa Berzigotti (*Abstract Co-Author*)
Johannes T. Heverhagen, MD, PhD (*Abstract Co-Author*)
Lukas Ebner, MD (*Abstract Co-Author*)
Andreas Christe, MD (*Abstract Co-Author*)
Adrian T. Huber, MD, PhD (*Abstract Co-Author*)

PURPOSE

To analyze the diagnostic value of AI segmentation (liver volume LV, splenic volume SV, hepatic veins volume HV) and liver T1 mapping for chronic liver disease (CLD) and their association with 5-year decompensation- and transplant-free survival.

METHODS AND MATERIALS

This retrospective study included 174 patients who underwent liver biopsy and liver MRI with Gd-EOB-DTPA including T1 maps before and 20 minutes after contrast administration as well as native T1 Dixon Sequences for volumetry between 09/2018 and 07/2019. Patients with CLD were grouped into early CLD (F0-F2; eCLD, n=34), advanced CLD (F3-F4; aCLD, n=27) and aCLD with clinically significant portal hypertension according to the BAVENO VII consensus (aCLDPH; n=68). 45 healthy patients served as a control group. LV, SV, HV and T1 times before (T1 long) and 20 minutes after Gd-EOB-DTPA administration (T1 short) were automatically measured using an in-house trained and validated liver-segmentation algorithm. T1 reduction rate (?T1) was calculated as (T1 long - T1 short)/T1 long. LV, SV, HV, T1 long, T1 short and ?T1 were compared between the groups using a Kruskal-Wallis test. ROC curve analysis was used to determine optimal cutoff values to distinguish between groups. Patients were followed-up for 5-years regarding first hepatic decompensation, liver transplantation and death in order to analyze the 5-year decompensation- and transplant-free survival by Kaplan-Meier curve analysis.

RESULTS

All parameters differed significantly between the groups (p<0.05). SV, T1 long, and T1 short increased with disease severity, while ?T1 decreased. LV and HV initially rose but declined in aCLDPH. ?T1 <0.68 was most effective for detecting CLD (sensitivity 73%, specificity 82%, AUC 0.82, p<0.001). aCLD was best identified by SV >259 ml (sensitivity 73%, specificity 91%, AUC 0.88, p<0.001). Kaplan-Meier analysis revealed significantly lower 5-year transplant-free and decompensation-free survival for patients with HV <13 ml (49% vs. 72%, p=0.002; 53% vs. 75%, p=0.014). Similarly, reduced survival was observed for T1 long >611 ms at 1.5T or >912 ms at 3T (49% vs. 76%, p<0.001; 56% vs. 77%, p=0.011) and T1 short >207 ms at 1.5T or >322 ms at 3T (47% vs. 76%, p<0.001; 54% vs. 77%, p=0.005). Additionally, ?T1 <0.67 was linked to lower transplant-free survival (49% vs. 76%, p<0.001).

CONCLUSION

AI segmentation of liver volume, splenic volume, hepatic veins volume, and liver T1 mapping provides valuable biomarkers for staging CLD severity and predicting long-term outcomes.

CLINICAL RELEVANCE/APPLICATION

AI segmentation of liver volume, splenic volume, hepatic veins volume, and liver T1 mapping effectively stages CLD severity and predicts 5-year survival, enhancing risk stratification and personalized patient care.

T2-SPGI-15 INTRACHOLECYSTIC PAPILLARY NEOPLASM ASSOCIATED WITH INVASIVE CARCINOMA VERSUS CONVENTIONAL GALLBLADDER ADENOCARCINOMA: DISTINCT IMAGING AND CLINICOPATHOLOGIC FEATURES

Seok Jin Hong, MD (*Presenter*)
Jung Hoon Kim, MD (*Abstract Co-Author*)
Jae Hyun Kim, MD (*Abstract Co-Author*)

PURPOSE

To investigate the different clinicopathologic and imaging features between intracholecystic papillary neoplasm associated with invasive carcinoma (ICPN-IC) and conventional gallbladder adenocarcinoma (c-GBA).

METHODS AND MATERIALS

We retrospectively reviewed medical records and computed tomography (CT) findings of patients who underwent surgery for GB lesions and pathologically confirmed ICPN-IC or c-GBA between January 2006 and December 2022. Clinicopathologic variables included age, sex, symptoms, surgery type, T-stage, resection margin status, and tumor markers (CA 19-9, CEA). Two radiologists independently assessed CT features, including wall thickness, enhancement pattern, irregular wall thickening, pericholecystic infiltration, gallstones, lymphadenopathy, and polyps. For polyps, multiplicity, size, shape, base wall thickening, and dimpling were analyzed. Chi-square and t-tests were used for group comparisons. Logistic regression was applied to identify significant CT predictors. Inter-reader agreement was evaluated with Cohen's kappa and intraclass correlation coefficients.

RESULTS

Sixty-nine patients with ICPN-IC and 323 patients with c-GBA were included. Common clinicopathologic features of ICPN-IC included the absence of symptoms, treatment with simple cholecystectomy, and a predominant T1 stage. Univariable logistic regression of CT features identified maximal GB wall thickening, enhancement pattern, irregular wall thickening, pericholecystic infiltration, lymphadenopathy, and presence of polyps as significant predictors of ICPN-IC. On multivariable analysis, irregular wall thickening (odds ratio (OR) 3.02; 95% CI, 1.57-5.81; p<0.01), lymphadenopathy (OR, 0.23; 95% confidence interval (CI), 0.07-0.8; p=0.02), and presence of polyp (OR, 5.54; 95% CI, 2.39-12.85; p<0.01) were independent predictors of ICPN-IC. For polyp patterns, only multiplicity (OR, 3.95; 95% CI, 2.07-7.68;

p<0.01) was identified as an independent predictor of ICPN-IC in both univariable and multivariable analyses. Inter-reader agreement ranged from fair to very good (? = 0.32-0.92), except for enhancement pattern (? = 0.17).

CONCLUSION

CT may be helpful in differentiating ICPN-IC from c-GBA using image features including irregular wall thickening, lymphadenopathy, and presence of polyp with multiplicity.

CLINICAL RELEVANCE/APPLICATION

CT features provide valuable clues for distinguishing ICPN-IC from c-GBA, potentially influencing surgical planning and prediction of prognosis.

T2-SPGI-16 AN END-TO-END DEEP LEARNING FRAMEWORK FOR LYMPH NODE DETECTION AND STAGING IN RECTAL CANCER MRI WITH NODE-BY-NODE HISTOPATHOLOGIC CORRELATION

Qingyang Li, PhD (*Presenter*)
ZHANG HAN (*Abstract Co-Author*)
Ying-shi Sun, PhD (*Abstract Co-Author*)

PURPOSE

To develop a fully automated deep learning framework for nodal segmentation and staging on T2-weighted MRI using the node-by-node radiological-pathological matched nodal status as the reference, to enhance the diagnostic ability in rectal cancer N stage while streamlining workflow efficiency.

METHODS AND MATERIALS

This study prospectively enrolled consecutive rectal cancer patients undergoing total mesorectal excision and preoperative MRI between December 2021 and August 2023 as the training set, with a retrospective validation set comprising patients meeting identical inclusion criteria from February 2014 to August 2015. In the training set, the radiologist performed layer-by-layer manual delineation of all visible mesorectal nodes on axial T2-weighted images as the ROI using ITK-SNAP, which were classified into three categories: benign, metastatic, and indeterminate based on whether the node achieved matched between MRI and pathology and its pathological status (Fig. 1). A cascaded deep learning model integrating the nnU-Net segmentation framework with the Med3D-ResNet152 classification framework (Fig. 2) was constructed. The segmentation and classification performance of the model was evaluated on the nodal level in the training set, and the overall staging ability was validated on the patient level in the validation set on unannotated MRI scans.

RESULTS

In the training set, a total of 1003, 269, and 2064 nodes were classified as benign, metastatic, and indeterminate in the direct surgery group, while 678, 220, and 1248 nodes in the nCRT group, respectively. Using the manual delineation as the gold standard, the model reached a mean DSC of 0.70 and 0.63 after 5-fold cross-validation in segmenting all the visible mesorectal nodes in the direct surgery and nCRT group, respectively (Fig. 3). Compared to pathological result, the AUC, sensitivity, specificity of the model were 0.71 (95% CI: 0.67-0.74), 45.3%, and 84.7%, respectively in the direct surgery group; and 0.71 (95% CI: 0.67-0.76), 71.0%, and 62.3%, respectively, in the nCRT group. The validation set included 153 patients in the direct surgery and 319 patients in the nCRT groups, respectively. With the unannotated images as input, the model achieved AUCs of 0.74 (95% CI: 0.65-0.82) and 0.72 (95% CI: 0.64-0.78) in determining the nodal stage in the two groups (Fig. 4).

CONCLUSION

Using the node-by-node correlation between MRI and histopathology as the training label, an end-to-end framework from identifying mesorectal nodes to determine N staging in rectal cancer based on the nnU-Net and Med3D-ResNet152 networks was constructed.

CLINICAL RELEVANCE/APPLICATION

This framework improved the working efficiency and diagnostic performance of N staging in rectal cancer.

T2-SPGI-17 UNDIFFERENTIATED PANCREATIC CANCER WITH OSTEOCLAST-LIKE GIANT CELLS: IMAGING FEATURES

Kumaresan Sandrasegaran, MD (*Presenter*)
Komal A. Chughtai, MD (*Abstract Co-Author*)
Kelsey McHugh (*Abstract Co-Author*)
Motoyo Yano, MD, PhD (*Abstract Co-Author*)
Frank H. Miller, MD (*Abstract Co-Author*)

PURPOSE

The 2019 WHO classification of pancreas ductal adenocarcinoma (PDAC) recognizes undifferentiated carcinoma with osteoclastic-like giant cells (UC-OGC) as a rare subset. There is sparse literature on this type of cancer. Pathologists also increasingly recognize that poorly-differentiated PDAC may also show occasional osteoclasts (PDC-O). We wanted to assess the difference in imaging features and natural history of these two groups.

METHODS AND MATERIALS

For this retrospective case-controlled study, we searched the Institutional Pathology and Imaging databases for “pancreas cancer” and “osteoclasts”. Of the 59 subjects identified, preoperative imaging (CT or MRI) and acceptable pathology data were available in 25 patients who formed the study cohort. Two specialist abdominal radiologists independently reviewed the imaging findings. There were 10 patients with PDC-O and 15 with UC-OGC.

RESULTS

There were no differences in age or gender between these groups. On univariate analysis, UC-OGC, compared to PDC-O, were larger (median size 6.3 cm vs. 3.9 cm, p=0.02), encapsulated (p=0.02) and tended to less likely have metastases at presentation (p=0.08). There were no differences between the two groups for other imaging parameters including pancreatic site of tumor, necrosis, enhancement pattern or calcification, presence of duct cut off or vascular invasion. On logistic regression analysis, only presence of capsule and size were significantly different between the groups. UC-OGC had fewer metastases at presentation and follow-up, though the differences were not significant. There was significantly higher overall survival (median 35.4 months vs. 10.7 months, p=0.02) and progression-free survival (median 31.6 months vs. 9.1 months, p=0.05) for UC-OGC compared to PDC-O.

CONCLUSION

The presence of a large (> 7 cm pancreatic mass) that is encapsulated may raise possibility of UC-OGC, rather than PDAC. Despite larger size at presentation, these tumors have a better prognosis than PDAC.

CLINICAL RELEVANCE/APPLICATION

UG-OGC is a rare subtype of pancreatic ductal adenocarcinoma. It is possible to raise the diagnosis of this tumor on imaging if there is a large, capsulated pancreatic mass, with few or no metastases at presentation.

T2-SPGU-1 ASSESSMENT OF CHRONIC KIDNEY DISEASE USING TWO-DIMENSIONAL SHEAR WAVE ELASTOGRAPHY: CORRELATION WITH CLINICAL, LABORATORY, AND HISTOPATHOLOGICAL PARAMETERS

Ricardo Lange Filho, MD (*Presenter*)
Ricardo M. Freitas, MD, PhD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)
Ilka S. Oliveira, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic utility of two-dimensional shear wave elastography (2D-SWE) in staging chronic kidney disease (CKD), define the most appropriated cut-off value, assess interindividual variability, and correlate 2D-SWE findings with structured histopathology.

METHODS AND MATERIALS

One hundred ten patients with suspected CKD undergoing renal biopsy and 30 healthy kidney donors (controls) were cross-sectionally evaluated by b-mode ultrasound and 2D-SWE. Five 2D-SWE measurements were acquired from the renal parenchyma of the mid-portion of the left kidney using a dedicated software, maintaining =1 cm distance from the capsule to reduce reverberation. 2D-SWE results were compared to serum creatinine levels and to histopathological variables such as glomerular sclerosis, tubular atrophy, interstitial fibrosis, vascular lesions, and inflammation. Statistical analyses included Student's t-test, ANOVA, and ROC curve analysis.

RESULTS

Mean 2D-SWE values were significantly lower in CKD patients (1.33 ± 0.47 m/s) than in controls (1.64 ± 0.31 m/s, $p<0.001$). 2D-SWE values negatively correlated with histological markers of chronicity and inflammation ($p<0.05$). Multivariate analysis identified collinearity among histopathological variables. Chronic Kidney Disease (CKD) stages were determined according to serum creatinine levels using the CKD-EPI formula. 2D-SWE was effective in distinguishing early CKD stages (1-3A) from advanced stages (3B-5D) ($p=0.001$).and ROC analysis identified an optimal cut-off of 1.4 m/s (AUC=0.78), yielding sensitivity of 74.1%, specificity of 83%, PPV of 88%, and NPV of 65.7%.

CONCLUSION

2D-SWE is a promising non-invasive technique for staging CKD and correlates with histopathological chronicity markers. It has demonstrated diagnostic value in patients with normal B-mode ultrasound findings and even in some with normal serum creatinine levels. 2D-SWE may improve clinical decision-making regarding renal biopsy and CKD management.

CLINICAL RELEVANCE/APPLICATION

2D-SWE enables quantitative renal stiffness assessment and shows potential for non-invasive evaluation of CKD severity, enhancing early diagnosis and risk stratification without the need for invasive biopsy.

T2-SPGU-3 A MULTIPARAMETRIC MRI-BASED MODEL FOR DECODING EXTRAPROSTATIC EXTENSION IN PROSTATE CANCER VIA HABITAT-GUIDED RADIOMICS AND CLINICAL INTEGRATION

Ye Xiang (*Presenter*)
Lihua Zhuo (*Abstract Co-Author*)
Ruishan Liu (*Abstract Co-Author*)
Lv Yue (*Abstract Co-Author*)
Fan Li (*Abstract Co-Author*)

PURPOSE

To develop and validate a multiparametric MRI-based integrative model that combines intratumoral microenvironmental heterogeneity (ITH), peritumoral radiomic features, and clinicopathological variables for noninvasive preoperative prediction of extraprostatic extension (EPE) in prostate cancer (PCa), with the goal of improving surgical planning and reducing postoperative biochemical recurrence.

METHODS AND MATERIALS

This multicenter retrospective study included 1180 PCa patients from four institutions (August 2013-September 2023), divided into training (n=498), internal validation (n=212), and two external test cohorts (n=398, n=72). Radiomic features and ITH metrics were extracted from T2-weighted imaging, diffusion-weighted imaging, ADC maps, and dynamic contrast-enhanced MRI. Six models were developed: Clinical, Radiomics, Peri-2 mm, Peri-4 mm, Peri-6 mm, and ITH. A fusion model (ITH + Peri-6 mm + Clinical) was constructed to integrate complementary predictors. Model performance was assessed using receiver operating characteristic (ROC) analysis, calibration curves, decision curve analysis (DCA), Hosmer-Lemeshow goodness-of-fit, DeLong's test, and a clinical nomogram.

RESULTS

The ITH model outperformed all single-modality models, achieving AUCs of 0.978 (training), 0.893 (internal validation), and 0.832/0.836 (external testing). Among the peritumoral models, Peri-6 mm achieved the highest accuracy (AUCs: 0.949-0.752). The fusion model demonstrated superior predictive performance with AUCs of 0.982 (training), 0.921 (validation), and 0.853/0.839 (external). Calibration and DCA confirmed the model's clinical utility across datasets.

CONCLUSION

Intratumoral heterogeneity and peritumoral radiomics provide independent predictive value for EPE. Their integration with clinical features into a multiparametric model significantly improves noninvasive preoperative prediction of EPE in PCa.

CLINICAL RELEVANCE/APPLICATION

The proposed model enables more accurate preoperative identification of EPE, supporting personalized surgical decision-making and potentially reducing the risk of biochemical recurrence.

T2-SPGU-4 THE VALUE OF THE CONTRAST ENHANCEMENT BOOST TECHNIQUE FOR RENAL ARTERY VISUALIZATION IN DYNAMIC CONTRAST-ENHANCED RENAL CT

Naoya Ebisu (*Presenter*)
Takahiro Tsuboyama, MD (*Abstract Co-Author*)
Yoshiko Ueno, MD, PhD (*Abstract Co-Author*)
Tomoki Maebayashi (*Abstract Co-Author*)
Takahiro Oribe (*Abstract Co-Author*)
Takeru Yamaguchi, MD, PhD (*Abstract Co-Author*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Izumi Imaoka, MD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

PURPOSE

Contrast Enhancement Boost (CE-boost) is an emerging post-processing technique that increases contrast enhancement in CT imaging by adding a denoised subtraction image to the original image. This study aimed to evaluate its utility for renal artery delineation and to determine the optimal CE-boost method for dynamic contrast-enhanced renal CT.

METHODS AND MATERIALS

This retrospective study was approved by our Institutional Review Board. Thirty patients were enrolled who underwent dynamic contrast-enhanced renal CT. Two types of CE-boost images were generated. For the 1-step method, subtraction images were obtained by subtracting non-contrast (NC) images from corticomedullary phase (CMP) images (i.e., CMP-NC). For the 2-step method, CMP images were first subtracted from nephrographic phase (NP) images, and the resulting CE-boost images were again subtracted from CMP images (i.e., CMP-[NP-CMP]). Original CMP images, 1-step CE-boost images, and 2-step CE-boost images were compared for renal parenchyma-to-artery contrast-to-noise ratio (CNR), the renal artery length, and the number of visible renal artery branches on 3D CT angiography. Statistical analyses included the Friedman test and repeated-measures ANOVA.

RESULTS

The mean cortex-to-artery CNR was 18.1, 51.7, and 76.5; medulla-to-artery CNR was 27.2, 77.9, and 114.5; and renal artery length was 93.8 mm, 97.4 mm, and 102.7 mm for the original CMP, 1-step, and 2-step CE boost images, respectively. The 2-step method yielded significantly the highest CNRs and longest artery lengths, while the original CMP showed the lowest CNR and shortest renal arterial length among the three methods ($P < 0.01$). The mean number of detectable renal artery branches was 19.0 for CMP, 25.6 for 1-step, and 29.4 for 2-step CE-boost images, with significant differences among all groups ($P < 0.01$).

CONCLUSION

The 2-step CE-boost method (CMP-[NP-CMP]) can improve the delineation of the renal artery by selectively increasing the contrast enhancement of the renal artery without increasing the renal parenchymal enhancement.

CLINICAL RELEVANCE/APPLICATION

The 2-step CE-boost technique may aid preoperative vascular assessment by enabling clearer delineation of the renal arteries.

T2-SPGU-5 POLYCYSTIC LIVER DISEASE IN ADPKD : NOVEL TECHNIQUE FOR LIVER VOLUME MEASUREMENT

Richard Bruen, MRCPI (*Presenter*)
Hayley Briody, MBBCh (*Abstract Co-Author*)
Paul McHugh (*Abstract Co-Author*)
Martina M. Morrin, MD (*Abstract Co-Author*)

PURPOSE

Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic kidney disease, with half of those diagnosed reaching end stage kidney disease (ESKD) by age 60. Although frequently asymptomatic, enlarged liver secondary to PLD associated with APCKD can cause discomfort and compression on adjacent structures requiring cyst fenestration or partial liver resection. Manual calculation of liver cyst volume is cumbersome and can be performed using automated segmentation using deep learning models. This study aims to analyse the liver volumes in a subset of gene confirmed APCKD patients over time.

METHODS AND MATERIALS

A retrospective cohort review of PLD in ADPKD patients recruited to the Irish Kidney Gene Project (IKGP). We aimed to characterise the clinical presentation and radiological features with a focus on progression to ESKD, liver-related complications, and genotype-phenotype correlations. TRACE is a novel radiological tool that aids in diagnosis and monitoring patients with polycystic kidney disease utilizing CT and/or MRI scans. This was employed to calculate organ volume summaries, renal and hepatic cyst fractions and height adjusted total kidney volume (htTKV). Individuals were classified as per the Mayo Imaging Classification system.

RESULTS

We evaluated a cohort of 192 individuals, PKD1 was the most common genotype identified (84%). 87.6% of individuals had liver cysts. There was a 7.3% rate of hospitalisation for hepatobiliary related causes, such as cholelithiasis, haemorrhagic cysts, and infected hepatic cysts. We performed TRACE scans on 28 individuals, of which 25 have developed ESKD (89.3%). The most common genotypes were PKD1 with 23 individuals and PKD2 with 3 individuals. Overall, the mean htTKV was 1351mls with a Mayo Classification of =1C in 11 individuals. The mean liver volume was 2478mls with a mean liver cyst fraction of 17.5%. In PKD1, the htTKV was 1984mls, mean liver volume was 2549mls, and mean liver cyst fraction was 11.5%. In those with PKD2, the htTKV was 1498mls, the mean liver volume was 2352mls, and mean liver cyst fraction was 18.5%.

CONCLUSION

Liver cysts are a common occurrence in ADPKD with a low rate of complications. TRACE is a novel tool that can help to demonstrate cyst burden in the liver and kidney.

CLINICAL RELEVANCE/APPLICATION

With deep learning methods, evaluation for progression of PLD in PCKD patients can be streamlined. This enables future analysis in to factors that affect liver cyst growth over time including gene, gender and prediction for future risk of hospitalisation in this cohort.

T2-SPGU-6 AI DECISION SUPPORT IN THE PROSTATE CANCER PATHWAY COULD ENABLE SIGNIFICANT BIOPSY REDUCTION

PURPOSE

False positives lead to unproductive biopsies and overdiagnosis of grade group 1 (GG1) prostate cancers. Review the potential of a prostate MRI AI-based decision support system (AI-DSS) to reduce false positives while maintaining detection of significant (GG=2) cancer in a multicentre study.

METHODS AND MATERIALS

AI-DSS was developed to calculate prostate volume, PSA density (PSAd) and cancer risk scores at lesion and patient levels, using MRI data and optional PSA and PI-RADS scores. In an independent cohort, clinical data of patients investigated for suspected prostate cancer at six sites were retrospectively obtained. A multidisciplinary team including radiologists determined the need for biopsy using local standard-of-care (SOC) evaluations. Targeted and systematic biopsies were performed on positive cases. Patients with PI-RADS=3 who did not undergo biopsy were excluded. MRI-negative patients who avoided biopsy were assumed negative. Biopsy avoidance (GGx), yields (GG=2; GG1; benign (GG0)), and selectivity (GG=2/GG1) and efficiency ratios (GG=2/(GG1+GG0) of SOC and AI-DSS were compared. Selective biopsy avoidance was also calculated (GGx/GG0).

RESULTS

252 patients were included; 137 (54%) underwent biopsy, 79 (31%) had GG=2 and 17 (7%) GG1 cancers. 139 (55%) patients were scored PI-RADS=3 or had PSAd=0.15. Under this criterion, GG=2 cancer detection rate (CDR) was 78/252 (31%), 15 patients (6%) would have GG1 diagnosed while missing 1 GG2 cancer case (PI-RADS 2, PSAd 0.10), giving GG=2/GG1=5.2, GG=2/(GG1+GG0)=1.3, GGx/GG0=2.5. A narrower criterion of PI-RADS=4 or PSAd=0.15 would lead to 121 (48%; $p<0.01$) biopsies, 12 (5%) GG1, missing the same GG2 case: GG=2/GG1=6.5, GG=2/(GG1+GG0)=1.8, GGx/GG0=4.2. AI-DSS at the same CDR as the standard-of-care would result in fewer (n=109; 43%; $p<0.01$) biopsies, detecting fewer (n=10; 4%) GG1 cancers, while missing the same GG2 case: GG=2/GG1=7.8, GG=2/(GG1+GG0)=2.5, GGx/GG0=6.8. AI-DSS at slightly lower CDR (75/252, 30%) would reduce biopsies even further (n=91; 36%; $p<0.01$), detecting less (6, 2%) GG1 while missing 4 cancers (2% of patients), 1 GG3, 3 GG2. Compared to the SOC biopsy reference, this equates to 95% sensitivity, 91% specificity, 82% PPV and 98% NPV: GG=2/GG1=12.5, GG=2/(GG1+GG0)=4.7, GGx/GG0=16.1.

CONCLUSION

Implementing AI-DSS in the prostate cancer diagnosis pathway could reduce GG1 detection, enhance biopsy selectivity and efficiency, and significantly reduce unnecessary biopsies, with comparable detection rates for GG=2 cancers.

CLINICAL RELEVANCE/APPLICATION

AI decision support software integrating MRI and clinical data could significantly reduce biopsy and overdiagnosis rates in men with suspected prostate cancer. Prospective validation studies are needed.

T2-SPGU-7 CONTRAST ENHANCED ULTRASOUND FOR EVALUATION OF NEPHRON SPARING TREATMENT FOR RENAL CELL CARCINOMA

Richard G. Barr, MD, PhD (*Presenter*)
Louis Mazzarelli, MS (*Abstract Co-Author*)
Davide Roccarina, MD,PhD (*Abstract Co-Author*)
Parker Bauman (*Abstract Co-Author*)

PURPOSE

To determine the accuracy of CEUS in evaluating post nephron-sparing procedures

METHODS AND MATERIALS

This retrospective 2 center study had informed consent waived. CEUS studies performed post nephron sparing procedure (radiofrequency ablation, cryoablation, microwave ablation, partial nephrectomy) from January 2018 to January 2025 were reviewed. Patient charts were reviewed for follow-up procedures and patient status. CEUS studies were performed on a Philips Epic ultrasound system with a C5-1 transducer. Lumason (Bracco Diagnostics) contrast was used with a dose of 1.0 to 2.0cc. The CEUS exam was saved as a 3-minute cine clip. A true positive examination was considered if there was contrast in the procedure site and either biopsy proven tumor or persistent enhancement for over 1 year. A true negative exam was considered if there was no contrast in the procedure site on follow up studies for at least 1 year.

RESULTS

There were 177 lesions in 171 patients. There were 103 (60.2%) male and 68 (39.8%) female participants. The average age was 65.5+/-7.8 years (range 33-90). The average lesion size was 3.1cm (SD 0.57cm)(range 1.0-5.3). There were 30 cystic and 115 solid lesions. There were 16 radiofrequency ablation (7 positive, 43.8%), 35 cryoablations (9 positive, 25.7%), 3 microwave ablations (0 positive, 0.0%), and 123 partial nephrectomies (2 positive, 1.6%)). There were 18/177 (10.2%) true positive cases and 159/177 (89.8%) true negative cases. Time of follow-up ranged from 1-336 months. There were no false positive or false negative cases based on biopsy and long-term follow-up.

CONCLUSION

CEUS has a positive predictive value of 100%, sensitivity of 100% and specificity of 100% in determining residual or recurrent tumor.

CLINICAL RELEVANCE/APPLICATION

Nephron sparing surgeries are now widely used for renal cell carcinomas. CEUS is a less expensive examination and avoids the radiation of CT and possible renal impairment of CT and MRI contrast agents.

T2-SPHN-2 PREDICTIVE CLINICAL AND ULTRASOUND FEATURES OF THYROID MALIGNANCY IN ONCOLOGY PATIENTS WITH INCIDENTAL DIFFUSE THYROID UPTAKE ON FDG PET/CT

JAEYONG MIN (*Presenter*)
Dong Gyu Na, MD (*Abstract Co-Author*)
Chae Young Shin (*Abstract Co-Author*)
Hyo Sang Lee (*Abstract Co-Author*)

PURPOSE

Although the malignancy risk is very low in patients with diffuse thyroid uptake on FDG PET/CT, rare cases of diffuse thyroid metastasis may mimic thyroiditis. However, a standardized approach to managing incidental diffuse thyroid FDG uptake remains unestablished. This study aimed to identify clinical and ultrasound (US) features predictive of thyroid malignancy in oncology patients with incidental diffuse thyroid uptake on FDG PET/CT.

METHODS AND MATERIALS

This retrospective cohort study included 481 consecutive oncology patients with incidental diffuse thyroid FDG uptake from January 2012 to September 2024. The primary outcome was the identification of clinical and US features predictive of malignancy. The secondary outcome was the malignancy risk of incidental diffuse thyroid uptake, determined by pathology or clinical follow-up for at least six months. US features were compared between benign and malignant thyroid disease in 36 patients who underwent thyroid US within three months of FDG PET/CT.

RESULTS

Excluding occult papillary thyroid carcinomas, thyroid malignancy was found in seven patients (1.5%), all of which were diffuse thyroid metastases originating from lung cancer (n=5), gastric cancer (n=1), and parotid carcinoma (n=1). FDG-avid cervical metastatic lymph nodes were present on FDG PET/CT in all patients with thyroid metastasis (100%) but only in 8.0% (38/474) of benign cases ($P < 0.001$). Punctate echogenic foci on US were significantly associated with thyroid metastasis (71.4% [5/7] vs. 10.3% [3/29], $P = 0.003$). US features of branching hypoechoic strands in the thyroid parenchyma and echogenic changes in the strap muscles were observed exclusively in patients with thyroid metastasis (85.7% [6/7] and 100% [7/7], respectively; $P < 0.001$). At least one of these two US features was present in all cases of thyroid metastasis.

CONCLUSION

The absence of FDG-avid cervical lymphadenopathy was highly specific for benign thyroid diseases, while the presence of branching hypoechoic strands or echogenic changes in the strap muscles on US was highly specific for diffuse thyroid metastasis in oncology patients with incidental diffuse thyroid uptake on FDG PET/CT.

CLINICAL RELEVANCE/APPLICATION

The absence of FDG-avid cervical lymphadenopathy can effectively rule out malignancy, while the presence of US features of branching hypoechoic strands or echogenic changes in the strap muscles can enable accurate diagnosis of thyroid metastasis.

T2-SPHN-3 PREOPERATIVE MULTIMODAL PREDICTION OF LYMPH NODE METASTASIS IN PAPILLARY THYROID CARCINOMA: INTEGRATING CLINICAL, SPECTRAL CT, AND RADIOMICS FEATURES

Yaoyuan Wu, MD (*Presenter*)

PURPOSE

To develop and validate multimodal models for preoperative prediction of cervical lymph node metastasis (LNM) in papillary thyroid carcinoma (PTC) by integrating clinical characteristics, spectral CT parameters, and radiomic features.

METHODS AND MATERIALS

This retrospective study included 149 pathologically confirmed PTC patients (2018-2023) who underwent preoperative spectral CT scans. Patients were stratified into metastasis and non-metastasis groups. Univariate and multivariate analyses identified LNM risk factors. Radiomic features were extracted from iodine maps. After partitioning the cohort into training and validation sets (7:3 ratio), radiomic features were selected via LASSO regression. Three logistic regression models were constructed: (1) clinical-spectral CT model, (2) radiomics model, and (3) combined model. Performance was assessed using receiver operating characteristic (ROC) curves, calibration curves, and decision curve analysis.

RESULTS

Independent predictors of LNM included tumor diameter, microcalcifications, multifocality, thyroid peroxidase antibody (TPOAb) levels, and spectral curve slope. Five radiomic features (wavelet- and gray-level textures) were selected from 1,186 parameters. The combined model outperformed individual models, achieving training/validation AUCs of 0.85/0.733, compared to the clinical-spectral CT model (0.807/0.718) and radiomics model (0.754/0.605) (all *p* < 0.05).

CONCLUSION

Integration of clinical, spectral CT, and radiomic features enhances preoperative LNM prediction in PTC, potentially improving risk stratification.

CLINICAL RELEVANCE/APPLICATION

This multimodal approach may refine surgical planning and reduce overtreatment. External validation is required to address overfitting risks in the radiomics model (validation AUC decline: 0.754 to 0.605), and future integration with molecular biomarkers (e.g., BRAF mutations) could strengthen clinical utility.

T2-SPHN-5 Pankaj Sharma JR, MBBS, FRCR (*Presenter*)

ROLE OF INTRAORAL ULTRASOUND IN ASSESSMENT OF DEPTH OF INVASION OF ORAL CAVITY SQUAMOUS CELL CARCINOMA AND ITS CORRELATION WITH HISTOPATHOLOGY : A PROSPECTIVE DIAGNOSTIC VALIDATION STUDY

PURPOSE

Oral cavity carcinoma (OCC) accounts for 1/3 rd proportion of head and neck carcinomas. Eight edition of American Joint Committee on Cancer (AJCC) introduced Depth of Invasion (DOI) as one of the main criteria in staging the OCC. The independent risk factor DOI is widely documented for nodal metastases. Given the increased probability of undetected and early nodal metastases in tongue cancer, head and neck oncologists advocate surgical neck dissection if DOI > 4 mm. Till date, most of published studies on this subject have been retrospective in nature, along with inclusion of few patients only. Our study is first prospective study from Himalayan belt of North India with inclusion of 86 patients, wherein we have tried to correlate DOI of oral cavity Squamous Cell Carcinoma (SCC) on IOUS with histopathology.

METHODS AND MATERIALS

IOUS was performed on 86 oral cavity SCC patients using high frequency hockey stick probe. DOI and cervical lymph node metastasis was assessed and correlated with postoperative histopathological DOI.

RESULTS

The Ultrasound DOI (usDOI) and pathological DOI (pDOI) had a high degree of agreement, according to a Bland-Altman plot. IOUS and histopathological staging assessment showed nearly complete agreement for the T stage (k=0.894, p value 0.001) and for N stage (k = 0.81, p value 0.001). Mean depth of invasion by histopathology and IOUS was 9 mm and 9.7 mm respectively. Strong correlation (interclass correlation coefficient = 0.95) was noted between radiological and pathological tumour depth.

CONCLUSION

The IOUS can be recommended as an alternative to MRI in the preoperative staging of oral cavity SCC, since it was reliable in preoperative assessment of pDOI and T stage. Ultrasound (USG) is a widely available, quick, affordable and efficient diagnostic tool, which can be used in Outpatient department (OPD) setting, without the danger of radiation exposure, along with advantage of good soft tissue resolution, specially with availability of dedicated hockey stick probes with high end USG machines. Additionally, we can perform core needle biopsy (CNB) or USG guided fine needle aspiration (FNA) with use of these machines.

CLINICAL RELEVANCE/APPLICATION

IOUS is a precise preoperative method for determining the real invasion of oral cavity malignancies, especially for early stage (T1 and T2) oral malignancies. It provides significant information regarding invasion depth for tumour excision, with cancer-free margins. When employing the new 8th edition TNM classification, IOUS can precisely assess DOI, a critical criterion for tumour staging, that is essential for maximising therapy options. The decision to undertake an elective neck dissection is therefore influenced by DOI.

T2-SPHN-6 DOPPLER ULTRASOUND MAPPING OF THE MAIN ARTERIES OF THE FACE: REFERENCE VALUES FOR VASCULAR COMPLICATION ASSESSMENT

Rosa Maria Silveira Sigrist, MD (*Presenter*)
Julia D. Zavariz, MD (*Abstract Co-Author*)
Leonardo Piber (*Abstract Co-Author*)
Sara Khoshnaw (*Abstract Co-Author*)
Leonie Schelke (*Abstract Co-Author*)
Peter Velthuis (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

PURPOSE

The popularity of minimally invasive facial aesthetic procedures, such as hyaluronic acid injections, has increased dramatically. Although generally considered safe, these interventions carry a risk of vascular complications such as occlusion or stenosis, potentially leading to necrosis, blindness, or cerebral ischemia. Doppler ultrasound is an established imaging method for evaluating hemodynamic parameters in large vessels like the carotids, but no reference values currently exist for the smaller arteries of the face. This study aims to establish reference Doppler ultrasound values for the main arteries of the face and to assess potential side-to-side asymmetries.

METHODS AND MATERIALS

A prospective, multicenter, cross-sectional study was conducted on 118 healthy volunteers (81% female; median age 40.55 years) with no history of facial injectable procedures, between December 2023 and May 2025. High-frequency color and spectral Doppler ultrasound was used to measure peak systolic velocity (PSV), end diastolic velocity (EDV), mean velocity flow (MVF), and resistive index (RI) in 13 arteries of the face as well as the carotid arteries, bilaterally. Side-to-side comparisons were analyzed using the paired Wilcoxon signed-rank test with continuity correction. Effect sizes were calculated using the rank-biserial correlation coefficient. All analyses were performed using R statistical software.

RESULTS

Most arteries showed similar hemodynamic profiles between the right and left sides, with non-significant p-values and minimal effect sizes, indicating the absence of systematic asymmetries. However, significant differences in PSV were found for three arteries: the facial ($p < 0.001$, effect size = 0.173) and infraorbital ($p = 0.027$, effect size = 0.128) arteries showed higher values on the left, while the supraorbital artery ($p = 0.019$, effect size = -0.204) had higher values on the right. All other arteries demonstrated negligible side-to-side variation.

CONCLUSION

This study provides the first set of normative Doppler ultrasound reference values for the main arteries of the face and highlights that most vessels exhibit symmetrical hemodynamic parameters, with few notable exceptions.

CLINICAL RELEVANCE/APPLICATION

Establishing reference Doppler values for the arteries of the face supports the identification of abnormal hemodynamic patterns, aiding in the diagnosis and management of vascular complications associated with aesthetic injectables. These data offer a valuable tool for safer, more precise diagnostic and therapeutic strategies.

T2-SPHN-8 TEMPORAL BONE DUAL-LAYER DETECTOR DUAL ENERGY COMPUTED TOMOGRAPHY FOR IDENTIFYING CHOLESTEATOMA

Xiaoxue Fan, PhD (*Presenter*)
Xiao Mei Lu, MMed (*Abstract Co-Author*)
Yang Hou, MD (*Abstract Co-Author*)

PURPOSE

Cholesteatomas are characterized by local aggressiveness and can infiltrate adjacent structures as they expand. This study aimed to establish a straightforward scoring system using dual-layer detector dual energy CT (DL-DECT) to improve the identification of cholesteatomas in patients.

METHODS AND MATERIALS

Between August 2023 and July 2024, 871 patients with soft tissue density shadows in the ear region who underwent DL-DECT examination were retrospectively enrolled at our institute. Surgical treatments followed by pathological examinations were performed. Based on pathological findings, the lesions were classified into cholesteatoma (CS) and non-cholesteatoma (non-CS) groups. The diagnostic performance of anatomical and quantitative parameters derived from DL-DECT was evaluated using receiver operating characteristic (ROC) curve analysis. Logistic regression was applied to develop a diagnostic scoring system.

RESULTS

A total of 87 patients (median age, 51 years; 45 men and 42 women) with suspected temporal bone cholesteatoma were included, comprising 44 CS cases and 43 non-CS cases. The effective atomic number (Zeff) demonstrated the highest diagnostic accuracy (area under the curve [AUC] = 0.786), followed by the slope of the energy spectral curve (AUC = 0.784), scutum destruction (AUC = 0.759), and CT40 keV (AUC = 0.724). Logistic regression identified two significant predictors, Zeff = 7.12 and scutum destruction, which were incorporated into the scoring system achieving an AUC of 0.868 (95% confidence interval: 0.778-0.931) in the ROC analysis, outperforming the individual parameters (all $p < 0.05$).

CONCLUSION

The scoring system derived from DL-DECT serves as an innovative imaging marker for the detection of cholesteatoma.

CLINICAL RELEVANCE/APPLICATION

This scoring system may facilitate the early identification of cholesteatoma, potentially improving patient outcomes through timely intervention.

T2-SPIN-1 APPLICATION OF DIFFERENT WEIGHTED DEEP LEARNING RECONSTRUCTION ALGORITHMS TO DUAL-FLOW INJECTION TECHNIQUE COMBINED WITH LOW-DOSE SCANNING IN CT ANGIOGRAPHY OF PULMONARY ARTERIES

Rui Ma (*Presenter*)
Xiaohong Gong (*Abstract Co-Author*)
Guan Wang (*Abstract Co-Author*)

PURPOSE

To observe the value of a novel deep learning reconstruction technique using different weighted reconstructions for dual-flow injection technique combined with 70kV low-dose scanning in CT angiography (CTA) of pulmonary arteries.

METHODS AND MATERIALS

Thirty patients who underwent CTA of the pulmonary arteries were prospectively collected. The subjective and objective image quality of different reconstruction weights was compared using a dual-flow injection (tube a: iodohexol mixture at 65% concentration, tube b: saline) and a 70 kV tube voltage scanning protocol, followed by sequential reconstruction using 30% DLIR-CI, 50% DLIR-CI, and 70% DLIR-CI.

RESULTS

All images are clinically diagnostic. The subjective scores were higher as the weights increased. Among the groups, the 70% DLIR-CI group had the highest subjective score ($P < 0.05$). None of the differences in pulmonary artery CT values between the groups were statistically significant ($p > 0.05$). Pulmonary artery SNR and CNR values were higher in the 70% DLIR-CI group than in the 30% DLIR-CI group ($P < 0.05$). The difference in pulmonary artery SNR and CNR values between the 70% DLIR-CI group and the 50% DLIR-CI group was not statistically significant ($P > 0.05$).

CONCLUSION

In pulmonary artery CTA using dual stream injection technique combined with 70kV low dose scanning, deep learning reconstruction algorithm was able to improve the image quality better, where the best image quality was obtained by deep learning image reconstruction with 70% weights.

CLINICAL RELEVANCE/APPLICATION

A novel deep learning reconstruction algorithm with 70% weighting improved image quality best in pulmonary artery CTA using a dual-flow injection technique combined with 70kV low-dose scanning.

T2-SPIN-2 MULTICENTER, MULTIORGAN PRETRAINING HELPS PDAC, CYST, AND PNET RECOGNITION IN CONTRAST ENHANCED COMPUTED TOMOGRAPHY

Zongwei Zhou, PhD (*Presenter*)
Xinze Zhou (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

To investigate whether pre-training AI on a large healthy population helps diagnostic performance for pancreatic neoplasms including Pancreatic Ductal Adenocarcinoma (PDAC), Cysts, and Pancreatic Neuroendocrine Tumors (PNET).

METHODS AND MATERIALS

An AI model (nnU-Net) was pre-trained on AbdomenAtlas (n = 9,262), a large-scale dataset annotated for 25 structures, including 16 abdominal organs, 2 thoracic organs, 5 vascular structures, and 2 skeletal structures. This dataset was collected from 139 centers across the world, ensuring diverse populations, scanner manufacturers, and imaging protocols. Ten radiologists, including four senior radiologists with 8-15 years of experience and six junior radiologists with 3-5 years of experience, provided per-voxel annotations for these 25 structures. The pre-trained model was then fine-tuned on a large, labeled dataset (N = 3,159) from Johns Hopkins Hospital, comprising 1,072 normal CTs, 1,115 with PDAC, 418 with Cysts, and 588 with PNETs. This dataset reflected broad demographic and clinical variability, with patient ages ranging from 17 to 84 years, tumor sizes ranging from small to large, and representation across sexes, tumor grades, stages, and survival outcomes. This transfer learning approach allowed the model to adapt its learned anatomical knowledge to the variable imaging features of pancreatic neoplasms. Evaluation was performed on a separate test cohort (n = 1,927), including 604 normal, 543 PDAC, 498 cyst, and 321 PNET cases. Diagnostic performance was compared with the same AI model trained from scratch, using Sensitivity and Specificity. Segmentation accuracy was measured with Dice Similarity Coefficient (DSC) and Normalized Surface Dice (NSD, 1.5mm tolerance) respectively.

RESULTS

The AI model pre-trained on normal anatomical structures achieved a DSC of 63.4% (95% CI 61.9%-64.9%) and a NSD of 58.9% (57.6%-60.3%) for segmenting pancreatic neoplasms (PDAC, Cyst, and PNET). These results represent improvements of 7.9% in DSC and 1.6% in NSD compared with the same AI model trained from scratch. The pre-trained model also achieved Sensitivity of 95.8%, and Specificity of 98.7% which were 2.3% and 20.5% higher respectively than training from scratch.

CONCLUSION

Pre-training on large-scale anatomical datasets enhances AI model generalizability and improves performance in pancreatic neoplasmssegmentation and detection, even in challenging, heterogeneous clinical scenarios.

CLINICAL RELEVANCE/APPLICATION

Integrating AI models trained on multicenter dataset (139 centers in our study) into clinical practice can enhance diagnostic precision for pancreatic neoplasms, potentially aiding in more informed clinical decision-making.

T2-SPIN-3 OPPORTUNISTIC BREAST CANCER SCREENING USING NON-CONTRAST CT WITH CONTRALATERAL BREAST COMPARISON

Wei Fang (*Presenter*)
Shuyi Peng (*Abstract Co-Author*)
Jiaheng Zhou (*Abstract Co-Author*)
Luyuan Xie (*Abstract Co-Author*)
Yuxing Tang (*Abstract Co-Author*)
Minfeng Xu (*Abstract Co-Author*)
Fan Yang, MD (*Abstract Co-Author*)

PURPOSE

The early detection of breast cancer can significantly improve the survival rates of patients. Chest CT scans can also be used for opportunistic breast cancer screening with the assistance of artificial intelligence. We propose an AI model called Dr. Brandon (Br east can cer d etection o n n on-contrast CT), which can localize the breast tumor and provide an estimation of its malignancy score.

METHODS AND MATERIALS

The model Dr. Brandon is an end-to-end framework for opportunistic breast cancer screening on non-contrast CT. In specific, we firstly crop out the two breasts using a coarse breast segmentation model. After that, we use a Mamba-based model to process the two breast crops and output the segmentation mask of breast and tumor. In particular, drawing inspiration from how physicians compare the left and right breasts during image review to find abnormalities, Dr. Brandon allows concurrently examining and comparing the left and right breasts for tumor localization. The malignancy score is calculated from the global tokens followed by two fully connected layers. The whole pipeline is illustrated in Figure 1. The training dataset consists of 772 breast samples with tumors (721 malignant and 51 benign) and 1298 healthy breasts as normal control. The malignancy of the breasts is confirmed through pathology report and the tumor masks were delineated by the radiologists. The testing dataset includes 229 breast samples with tumor (218 malignant and 11 benign) and 391 healthy breasts.

RESULTS

For the tumor localization part, Dice coefficient, Hit rate and FROC score were calculated. Hit rate measures the percentage of the breast samples with tumors whose ground truth tumor masks intersects with the predicted ones. The FROC score is the mean value of four sensitivities when the false positive detections per breast (fppb) are 0.1, 0.2, 0.3 and 0.4. The proposed model Dr. Brandon achieves 0.6588 on Dice coefficient, 0.9345 on Hit rate and 0.8974 on FROC score. The Free-Response Receiver Operating Characteristic (FROC) curve (shown in Figure 2) also shows the advancement of our method over baseline convolutional neural networks. For the malignancy classification part, Dr. Brandon can achieve 0.7248 on sensitivity, 0.9701 on specificity and an overall AUC of 0.9691, demonstrating strong competitiveness among current breast cancer screening tools.

CONCLUSION

Dr. Brandon can achieve a performance comparable to the recently reported mammography-based AI screening system and has the potential to become a practical opportunistic breast cancer screening tool on non-contrast CT.

CLINICAL RELEVANCE/APPLICATION

The potential exists for Dr. Brandon to be incorporated into radiologists' routine workflow as an opportunistic breast cancer screening tool on non-contrast CT.

PURPOSE

We developed language-agnostic rules,an LLM-based prototype (Siemens Healthineers),and tested it on international,multicenter,and multilingual data for predicting the best scan and image processing factors from provided clinical indication and prior radiology reports of the same body part.

METHODS AND MATERIALS

Through our IRB approved study, we received information on clinical indications and prior radiology reports of chest CTs from 48 institutions in 18 countries across South America,Europe,Africa,and Asia. Each document was in one of 10 different languages or language combinations(English,Persian,French,Arabic,Portuguese,Turkish,Spanish, Swahili,Arabic-English and French-English). Each site contributed de-identified info on10-20chest CTs for a total of929adult patients: clinical indication for the current CT chest and CT report of the last prior chest CT (both copied as verbatim and in the original language).Following translation (LLM and/or native speakers)to English,an experienced thoracic radiologist assigned the best CT protocols, which incorporate both scan acquisition and post-processing factors. Separately, we defined the rules governing the choice of these CT factors based on clinical information from the indications and/or prior reports. Using an independent dataset which is not part of the validation data, we then developed a prototype that automatically derives ideal protocols according to these rules based on an automated derivation of relevant clinical indications/findings in the input data using an LLM with multilingual support (gpt-4o-mini). All documents have been processed in their original language without any modification to the LLM prompt.

RESULTS

Across all languages/regions (non-English/English only), we achieved an average protocol choice accuracy of 90.3% (86.3%/92.1%), with accuracies ranging from 65.0%(Turkish)to95.5%(Persian).Variable accuracy(85-100%)across English language contributors was likely related to variations in stated clinical indications.Protocol accuracies ranged from 44.4% for rarer protocols(lung nodule follow-up)to95.4%for well-represented ones(routine chest CT,CT PE,lung cancer screening)

CONCLUSION

The assessed prototype can accurately and reproducibly assign the best CT protocols and associated scan and reconstruction factors, regardless of the input languages and geographic regions of origin. The low performance in some languages (e.g. Turkish) can primarily be attributed to the difficulty of the LLM to understand fine terminological nuances.

CLINICAL RELEVANCE/APPLICATION

The prototype framework can automate and personalize CT acquisition and processing pathways to improve consistency, quality, and safety of protocoling process.

T2-SPIN-5 TWO-STAGE DEEP LEARNING FRAMEWORK FOR LESION DETECTION AND CLASSIFICATION IN DBT WITH LIMITED DATASET

Wahyu Rahmaniar (*Presenter*)
Fatma Beltaief (*Abstract Co-Author*)
Ze Jin, PhD (*Abstract Co-Author*)
Kenji Suzuki, PhD (*Abstract Co-Author*)

PURPOSE

Accurate lesion detection and classification in digital breast tomosynthesis (DBT) is critical, particularly with limited data, where false positives (FPs) and false negatives (FNs) pose clinical challenges. We present a knowledge distillation (KD) framework in which a lesion detection model (teacher) supervises a classification model (student). The student model achieves superior classification accuracy and lesion recognition reliability by learning lesion-specific features and being guided on FP suppression and FN reduction.

METHODS AND MATERIALS

DBT reduces tissue overlaps compared to conventional 2D mammography, but limited annotated data in datasets restrict automated lesion detection. We developed a KD-enhanced deep learning framework transferring knowledge from a robust detection model to a lighter classification network. An anonymized DBT dataset of 399 slices (153 cancer, 201 benign, 45 normal) was augmented to 951 samples using random flips, rotations (±25 degrees), affine scaling, translation, and elastic deformation. Images were preprocessed with contrast-limited adaptive histogram equalization (CLAHE), resized to 1536×2048 pixels, and standardized in orientation. The KD-YOLO architecture employs a YOLOv5 teacher model to detect candidate lesions, with two ResNet-34 student classifiers refining detection: student 1 distinguishes true positives (TP) from FPs, and student 2 classifies TPs as benign or malignant. A two-stage softmax decision process further refines lesion classifications, re-evaluating initial FP cases and minimizing FN rates.

RESULTS

Evaluation of 73 DBT images shows our KD-YOLO achieved a precision of 0.77, a recall of 0.92, and an F1-score of 0.84 for lesion detection, reflecting high sensitivity with balanced precision. In lesion classification, our KD-YOLO reached a precision of 0.69, a recall of 0.71, and an F1-score of 0.70. Compared with YOLOv5, YOLOv8, and YOLOv11, KD-YOLO reduces FPs and maintains a low FN ratio, improving accuracy and reliability. Its inference time is 1153.5 ms per image, demonstrating efficient computational performance.

CONCLUSION

The KD-based two-student approach progressively refines detection and classification, effectively addressing DBT’s limited data challenges by reducing FPs and minimizing FNs, ensuring high sensitivity and specificity. This architecture lowers training costs and offers faster inference, supporting integration into computer-aided diagnostic systems for efficient breast cancer screening.

CLINICAL RELEVANCE/APPLICATION

Reducing FPs minimizes unnecessary patient recalls, and fewer FNs avoid missed cancers, supporting timely, reliable, and accurate breast cancer detection, ultimately improving patient outcomes.

T2-SPIN-6 FROM REPORTS TO INTERPRETATIONS: A SCOPING REVIEW OF LARGE LANGUAGE MODELS IN RADIOLOGY

Dana Alkhulaifat, MD (*Presenter*)
Satvik Tripathi (*Abstract Co-Author*)
Yohan Kim (*Abstract Co-Author*)
Ebubechukwu Enwerem (*Abstract Co-Author*)
Allison Brea (*Abstract Co-Author*)
Dania Daye, MD,PhD (*Abstract Co-Author*)
Tessa S. Cook, MD, PhD (*Abstract Co-Author*)

PURPOSE

Recent trends show a growing interest in leveraging large language models (LLMs) for various tasks in radiology workflow. However, as these applications emerge, it is imperative to assess the current state of LLM research in radiology and identify gaps for future research. This scoping review explores the applications of LLMs in radiology, identifying the most frequently used models, and providing insights to guide future research in this field. Research on LLMs in radiology can recognize trends, gaps, and opportunities for improving clinical practice and efficiency.

METHODS AND MATERIALS

We conducted a systematic search across five databases: PubMed, EMBASE, SCOPUS, Web of Science, and IEEE Xplore. The search strategy utilized Boolean operators and included keywords such as "Large Language Models" and "Radiology", along with names of commonly used LLMs. We included only original research articles published from 2022 onwards, excluding reviews, commentaries, editorials and preprints. Two independent reviewers screened the articles by title and abstract, then subsequently by full text. Data were extracted on the domains of LLM applications in radiology, type of model (i.e., open-source or proprietary), and the most frequently used models

RESULTS

After screening, 275 papers met the inclusion criteria. The most common applications of large language models in radiology identified were clinical decision support (n=131), patient-facing applications (n=49), medical education (n=45), workflow optimization (n=34), radiology research aid (n=10), and miscellaneous (n=6). Most papers utilized proprietary models only (n=207), predominantly GPT (n=200). In contrast, 43 studies used only open-source models, with the most common being LLaMA (n=19). Twelve studies compared both types.

CONCLUSION

LLMs are increasingly applied in radiology for clinical decision support, patient-facing applications, and medical education. While proprietary models dominate, open-source models offer safer integration opportunities. However, proprietary models' features are often less transparent, posing challenges for validation and interpretability compared to open-source models.

CLINICAL RELEVANCE/APPLICATION

This scoping review provides a comprehensive assessment of how LLMs are being used in radiology to support clinical decision-making, streamline workflow, and enhance communication, offering insights into their potential to improve efficiency and patient care.

T2-SPIN-8 BEYOND TESLA: EVALUATING DEEP LEARNING GENERALIZATION ACROSS 1.5 T AND 3.0 T MRI SCANNERS

Muhammad Ibtsaam Qadir, BS (*Presenter*)
Duane L. Schonlau, MD (*Abstract Co-Author*)
Fiona Kolbinger, MD (*Abstract Co-Author*)

PURPOSE

To quantitatively evaluate the impact of MRI scanner magnetic field strength (1.5 T vs. 3.0 T) on the performance and generalizability of deep learning-based segmentation algorithms.

METHODS AND MATERIALS

In this retrospective study, segmentation models were developed and validated using two datasets: MAMA-MIA for breast tumor segmentation (n = 1271; 851 from 1.5 T scanners and 420 from 3.0 T scanners across two centers) and PanSegNet for pancreas segmentation (n = 218; 90 from 1.5 T and 128 from 3.0 T scanners across four centers). Data were stratified by magnetic field strength. For each task, two nnU-Net segmentation models were trained—one using 1.5 T data and the other using 3.0 T data. Each model was externally validated on both 1.5 T and 3.0 T test sets. Segmentation performance was evaluated using the Dice Similarity Coefficient (DSC).

RESULTS

For breast tumor segmentation, the model trained on 1.5 T data achieved a mean DSC of 0.4105 (95% CI: 0.3690-0.4521) on the 1.5 T test set and 0.2889 (0.2559-0.3220) on the 3.0 T test set. The model trained on 3.0 T data yielded a DSC of 0.4326 (0.3948-0.4704) on the 3.0T test set and 0.4939 (0.4495-0.5383) on the 1.5 T test set. For pancreas segmentation, the 1.5 T-trained model achieved a DSC of 0.7169 (0.6666-0.7671) on the 1.5 T test set and 0.7797 (0.7296-0.8298) on the 3.0 T test set. The 3.0 T-trained model achieved a DSC of 0.8403 (0.8114-0.8691) on the 3.0 T test set and 0.7737 (0.7278-0.8195) on the 1.5 T test set. Models trained on 3.0 T MRI data performed significantly better than those trained on 1.5 T data when evaluated on the same validation sets (one 1.5 T and one 3.0 T) (breast tumor segmentation: $p < 0.0001$; pancreas segmentation: $p < 0.0001$, Wilcoxon signed-rank test).

CONCLUSION

MRI magnetic field strength of training data affects the performance of deep learning-based pancreas and breast tumor segmentation models. Models trained on 3.0 T data significantly outperformed those trained on 1.5 T across both same-field and cross-field evaluations, likely due to higher signal-to-noise ratio and resolution.

CLINICAL RELEVANCE/APPLICATION

Our findings highlight the importance of considering MRI field strength when developing AI models for clinical use across different scanner types. For clinical translation, models should be validated across field strengths to ensure generalizability in multi-center studies or longitudinal workflows where mixed-field systems are common.

T2-SPIN-10 BOOSTING CONCEPT EXTRACTION PERFORMANCE OF LARGE LANGUAGE MODELS USING SELF-CORRECT PROMPTING DERIVED FROM DISCORDANT DATA

Adam E. Flanders, MD (*Presenter*)
Richard Klares III, MD (*Abstract Co-Author*)
Paras Lakhani, MD (*Abstract Co-Author*)
George L. Shih, MD, MS (*Abstract Co-Author*)
Luciano M. Prevedello, MD, MPH (*Abstract Co-Author*)
William W. Boonn, MD (*Abstract Co-Author*)
Yifan Peng, PhD, MEng (*Abstract Co-Author*)
Robyn L. Ball, PhD (*Abstract Co-Author*)
Errol Colak, MD (*Abstract Co-Author*)

PURPOSE

Large language models (LLMs) in conjunction with radiology reports are often relied upon for "truthing" computer vision clinical models to obviate secondary human review. Concept extraction errors occur due to variations in reporting style, structure and context. We demonstrate a method to augment LLM accuracy via "self-correcting" prompt engineering.

METHODS AND MATERIALS

The AI outputs from a commercial AI intracranial hemorrhage (ICH) detector and corresponding radiology reports were collected prospectively from 18 hospitals in 2 states over a 10 month period. Impressions were fed to an ensemble of eight open-source LLMs using the Ollama API. An initial prompt to detect ICH was devised for the ensemble. A subset of reports whose findings were discordant from the AI outputs underwent manual review. Comparison (Cohen's kappa /Jaccard similarity) was used to evaluate agreement between the eight LLMs. Precision, recall, and AUC analysis were used to assess concordance with the human reviews. The impression text from the discordant exams was analyzed by K-means clustering to extract the most common concepts that produced a discordant result. Centroid concepts were

generated from the discordant impressions and used by an LLM (GPT4o) to modify the original prompt instructions to tune the ensemble to more accurately extract the report concepts. Concept extraction was repeated using the "enhanced" prompt with the same LLM ensemble to determine if the concordance rate with human expert review changed.

RESULTS

30,734 head CTs and reports were selected for analysis over a 10 month period. 654 impressions were manually reviewed. LLM concordance for detecting the concept of hemorrhage in the impression varied widely initially. The LLM-generated prompt added 3 centroids and 15 concepts. Following prompt correction, Kappa and Jaccard were augmented at >0.7 & 0.75 respectively for 4 LLMs with tighter clustering. AUC improved by 0.06 across all models, while the AP improved by 0.05. Findings reflect enhanced discrimination and precision with the refined prompt.

CONCLUSION

The use of k-means clustering of common detection error concepts can be used to automatically fine-tune an LLM prompt which can significantly decrease discordant feature extractions from reports.

CLINICAL RELEVANCE/APPLICATION

The combination of an ensemble of different LLMs in conjunction with a self-modifying prompt can be used to more accurately extract concepts from radiology reports with fewer false positives/negatives. This may have a practical application in automating performance review of AI tools.

T2-SPIN-11 A BENCHMARK FOR IDENTIFYING AND RECTIFYING ERRORS IN CT REPORTING THROUGH VISUAL QUESTION ANSWERING

Sunggu Kyung, PhD (*Presenter*)
Jinyoung Seo (*Abstract Co-Author*)
Hyungbin Park (*Abstract Co-Author*)
Jimin Sung (*Abstract Co-Author*)
Jihyun Kim (*Abstract Co-Author*)
Dongyeong Kim, MD (*Abstract Co-Author*)
Wooyoung Jo (*Abstract Co-Author*)
Yoojin Nam, MD (*Abstract Co-Author*)
Sangah Park (*Abstract Co-Author*)
Taehee Kwon (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

Multimodal large language models (MLLMs) have gained significant attention in medical imaging analysis due to their capability to generate reports, detect overlooked errors, enhance reporting accuracy, and reduce report generation time. Despite these promising advancements, MLLMs frequently exhibit hallucination, generating clinically incorrect information. Existing benchmarks inadequately assess complex, clinically relevant reasoning skills. To address these gaps, this study proposes a novel benchmark designed to comprehensively evaluate the clinical utility and medical competence of MLLMs by assessing their ability to accurately identify and correct vision-centric errors (omission, insertion, direction, size) and lexical errors (unit, typo) within radiology reports based on CT images.

METHODS AND MATERIALS

We utilized 3,000 patient cases from RadGenome-Chest CT, including clinically significant lesions (nodules and pleural effusions). Six error categories—four vision-centric and two lexical—were established across three different tasks (classification, detection, and correction). Error generation leveraged DSPy and LLaMA-3.3, yielding ~40,000 visual question answer (VQA) samples, validated by radiologists. Six open-source 3D MLLMs (RadFM, M3D variants, and CT-CHAT variants) underwent zero-shot evaluation using accuracy, Rouge-based Sentence Index Matching (RSIM), and Generative Radiology Report Evaluation and Error Notation (GREEN) metrics.

RESULTS

For classification, CT-CHAT-LLaMA and CT-CHAT-Vicuna demonstrated the highest overall accuracy of approximately 0.40, though their performance was predominantly strong for non-error cases, indicating a conservative classification tendency. For error detection and correction tasks, the CT-CHAT-Mistral model exhibited superior performance, achieving an average RSIM score of 0.276 and a GREEN score of 0.146, effectively detecting and correcting various types of errors. Sensitive models like CT-CHAT-Mistral suit preliminary screening; conservative models (CT-CHAT-LLaMA) benefit final verification.

CONCLUSION

Our benchmark assesses medical MLLMs' capabilities in identifying and correcting CT report errors. CT-CHAT-Mistral showed best overall performance, highlighting the importance of CT-CLIP-based pretraining and comprehensive VQA datasets.

CLINICAL RELEVANCE/APPLICATION

This benchmark could be used to evaluate the clinical utility and medical competence of various kinds of MLLMs by assessing their ability to accurately identify and correct vision-centric errors and lexical errors, which could be common errors within radiology reports. All data and code will be publicly released to foster reproducibility and further research.

T2-SPIN-12 IMPROVED LESION-LEVEL IMMUNOTHERAPY RESPONSE PREDICTION IN METASTATIC MELANOMA USING DEEP LEARNING

Isabelle Ayx, MD (*Presenter*)
Felix Winneknecht (*Abstract Co-Author*)
Seval Akbal (*Abstract Co-Author*)
Jessica Hassel (*Abstract Co-Author*)
Heinz-Peter W. Schlemmer, MD (*Abstract Co-Author*)
Lukas Thomas Rotkopf (*Abstract Co-Author*)

PURPOSE

Immune checkpoint inhibitors (ICI) have significantly improved survival in patients with metastatic malignant melanoma. However, therapy monitoring still relies on CT-based response assessment using RECIST 1.1, which functions primarily as a retrospective tool rather than a predictive marker. Therefore, better prognostic models are needed. Radiomics, by extracting quantitative imaging features, has shown potential, but existing studies are often limited by small cohorts or inconsistent annotations. We therefore tested whether a transformer-based deep learning model that encodes longitudinal CT information outperforms a radiomics machine learning (ML) classifier in predicting lesion-level response to ICI in metastatic melanoma.

METHODS AND MATERIALS

We retrospectively included 125 adult patients with stage IV melanoma treated with ICIs between 01/2010 and 05/2024. Staging exams (baseline and two follow-ups) were systematically annotated resulting in 699 abdominal lesions. Response was defined per lesion using volumetrically-adapted RECIST criteria. For ML, a Random Forest classifier was trained on radiomic features. For DL, a Siamese SwinUNetR model with shared encoders for baseline and follow-up inputs and a customized classifier was developed to capture temporal lesion dynamics. Performances for both models were averaged over 20 runs and evaluated using AUC, F1 score, accuracy, precision and recall.

RESULTS

The optimized DL model achieved an accuracy of 0.74, precision 0.91, recall 0.69 and F1 Score 0.79 with an AUC of 0.83. The conventional ML model demonstrated an accuracy of 0.61 (accuracy), 0.94 (precision), 0.49 (recall) and 0.64 (F1-score) with an AUC of 0.75.

CONCLUSION

Forecasting accuracy for lesion size dynamics during immunotherapy of melanoma can be significantly improved using imaging-based DL models compared to traditional ML methods. Aggregated predictions may be used for improved patient-level therapy response monitoring. Limitations include single-center data and restriction to abdominal lesions.

CLINICAL RELEVANCE/APPLICATION

Transformer-based deep learning models can enable early, image-based prediction of lesion-level treatment response in metastatic melanoma, potentially guiding timely adjustments to therapy and improving patient outcomes.

T2-SPIR-3 MRI-GUIDED SIMULTANEOUS DUAL-ANTENNA MICROWAVE ABLATION FOR LIVER TUMORS: INITIAL TECHNICAL FEASIBILITY, SAFETY, AND EARLY OUTCOMES

Setayesh Sotoudehnia Korani, MD (*Presenter*)
David A. Woodrum, MD, PhD (*Abstract Co-Author*)
Scott M. Thompson, MD, PhD (*Abstract Co-Author*)
Daniel A. Adamo, MD (*Abstract Co-Author*)
Aiming Lu, PhD (*Abstract Co-Author*)

PURPOSE

To report the initial feasibility, safety, and outcomes for patients undergoing MRI-guided percutaneous microwave ablation (MWA) procedures utilizing two microwave antennas for the treatment of liver lesions

METHODS AND MATERIALS

This retrospective review included 12 patients (9 male, 3 female; mean age 58.2 years) who underwent 14 MRI-MWA procedures utilizing two microwave antennas between November 2020 and February 2025. Indications included metastatic disease (prostate n=6, rectal n=1, neuroendocrine n=2, germ cell n=1, RCC n=1) and symptomatic hepatic adenomatosis (n=1). Treatment intent varied, including palliative indications. Procedures were performed under general anesthesia with combined MRI and ultrasound guidance. Data collected included patient demographics, lesion characteristics, procedural details focusing on dual antenna usage (simultaneous or sequential), technical success, complications (SIR criteria), and follow-up outcomes including need for further treatment.

RESULTS

Fourteen procedures were performed successfully in 12 patients, demonstrating technical feasibility. Techniques involved simultaneous activation of two antennas in some cases, while others involved sequential placement or targeting of multiple lesions using two antennas within the same session. No procedure-related complications occurred (0%). Follow-up durations ranged from 2 to 53 months (median 22.5 months). Follow-up revealed 10 of 14 procedures (71%) resulted in local control without requiring further local treatment at the ablation site(s). Four procedures (29%) required further local treatment due to residual tumor (n=1), or were associated with subsequent local recurrence or development of new metastases (n=3).

CONCLUSION

MRI-guided MWA procedures utilizing two microwave antennas, whether simultaneous or sequential within a session, are technically feasible and appear safe in this diverse cohort. While local control was achieved in the majority of cases, further investigation is needed to determine the optimal technique (simultaneous vs. sequential) and patient selection for dual-antenna strategies.

CLINICAL RELEVANCE/APPLICATION

Employing two microwave antennas during an MRI-guided ablation session, either simultaneously or sequentially, may allow treatment of larger, multiple, or complexly located lesions. This initial experience highlights the safety and feasibility, supporting further exploration of dual-antenna techniques to potentially optimize ablation outcomes.

T2-SPIR-4 TACE EMPOWERS IMMUNE CHECKPOINT INHIBITORS AND TYROSINE KINASE INHIBITORS IN UNRESECTABLE HCC: A MULTICENTER RETROSPECTIVE STUDY

Yu Lei (*Presenter*)

PURPOSE

The aim of this multicenter retrospective study was to evaluate the efficacy and safety of transarterial chemoembolization (TACE) combined with tyrosine kinase inhibitors (TKI) and immune checkpoint inhibitors (ICI) in treating advanced hepatocellular carcinoma (HCC) compared to treatment with TKI and ICI alone.

METHODS AND MATERIALS

The study included 286 patients with advanced HCC, of which 210 were treated with TACE, TKI, and ICI (TACE+T+I group) and 76 with TKI and ICI alone (T+I group). Progression-free survival (PFS), overall survival (OS), overall response rate (ORR), and disease control rate (DCR) were assessed. A nomogram was developed to stratify patients into high-risk and low-risk groups based on their one-year and two-year survival probabilities.

RESULTS

Patients in the TACE+T+I group demonstrated significantly longer PFS (8.4 months vs. 4 months, $P = 0.0016$) and median OS (14.5 months vs. 10 months, $P < 0.0001$) compared to the T+I group. Additionally, the TACE+T+I group had a higher ORR (56.7% vs. 21.1%, $P = 0.002$) and DCR (84.3% vs. 72.4%, $P = 0.023$). Both groups exhibited good tolerance to adverse events. A nomogram incorporating factors such as therapy type, prothrombin time (PT), age, and tumor size effectively categorized patients into low- and high-risk groups with notably different survival outcomes.

CONCLUSION

These findings suggest that TACE combined with TKI and ICI significantly improved survival outcomes and showed good safety compared to TKI and ICI alone in the treatment of advanced HCC.

CLINICAL RELEVANCE/APPLICATION

The combination therapy significantly improved progression-free and overall survival compared to TKI and ICI alone. The nomogram developed can help stratify patients into high- and low-risk groups, guiding personalized treatment decisions. These findings support the use of TACE plus TKI and ICI as a promising treatment strategy for

advanced HCC, potentially offering better outcomes and safety.

T2-SPIR-5 PREDICATION OF LONG-TERM OUTCOME OF RADIOFREQUENCY ABLATION FOR INDETERMINATE THYROID NODULES AFTER RADIOISOTOPE IMAGING SCREENING

Ling Chieh Shih, MD (*Presenter*)

PURPOSE

Current guidelines recommend either active surveillance or diagnostic lobectomy for indeterminate thyroid nodules. However, a significant proportion of patients experience under- or over-treatment. Radiofrequency ablation (RFA) has emerged as an alternative treatment, though its role remains debated. Radioisotope imaging has shown promise in discriminating benign and malignancy in indeterminate thyroid nodules. Therefore, combining RFA with radioisotope imaging screening may facilitate appropriate patient selection and improve clinical outcomes. This study aims to predict long term outcome of RFA for indeterminate thyroid nodules after radioisotope imaging screening.

METHODS AND MATERIALS

This retrospective study included patients with Bethesda III or IV thyroid nodules who underwent RFA after radioisotope imaging screening between January 2018 and November 2024. The primary outcome was disease progression, defined as nodule regrowth, increase in viable volume, or persistent indeterminate cytology on follow-up fine-needle aspiration. The secondary outcome was complete tumor disappearance, defined as complete radiological resolution of the treated nodule. Other secondary outcomes included volume reduction rate (VRR), symptom and cosmetic scores, and biochemical markers.

RESULTS

A total of 96 patients (mean age: 45.2 ± 13 years; 83 females) were included, with a mean follow-up of 3 years. Disease progression and complete tumor disappearance were observed in 15% (14/96) and 8% (8/96) of patients respectively. Total nodule volume, symptom scores, cosmetic scores, free thyroxine (T4) and thyroglobulin (TG) levels significantly decreased during follow-up. VRRs were 55% at 3 months and 93% at 3 years. Baseline maximum nodule diameter was an independent predictor for both disease progression (odds ratio [OR]: 2.88; 95% confidence interval [CI]: 1.18-7.10) and complete disappearance (OR: 0.16; 95% CI: 0.03-0.74), with cutoff values of 3.5 and 2 cm showing high negative predictive values (NPV: 93% and 97%) for disease progression and complete tumor disappearance respectively.

CONCLUSION

RFA after appropriate radioisotope imaging screening, is a safe and effective treatment for indeterminate thyroid nodules. Furthermore, initial nodule maximum diameter of 3.5 and 2 cm is predictive for long term outcomes.

CLINICAL RELEVANCE/APPLICATION

These findings provide a practical framework for clinical decision-making in the clinical scenario of a patient with an indeterminate thyroid nodule who is considering RFA treatment. Nodules measuring between 2.0 and 3.5 cm demonstrate high NPV for both disease progression and complete tumor disappearance, indicating favorable long-term stability with low risk of adverse outcomes.

T2-SPIR-7 CREATION OF HEPATIC ARTERY EMBOLIZATION MODEL IN MICE: TOWARD TRANSLATIONAL RESEARCH

Reona Wada, MD, PhD (*Presenter*)
Haruyuki Takaki, MD, PhD (*Abstract Co-Author*)
Hiroshi Kodama, MD (*Abstract Co-Author*)
Yutaka Hirata (*Abstract Co-Author*)
Naoki Yokota (*Abstract Co-Author*)
Eisuke Ueshima (*Abstract Co-Author*)
Koichiro Yamakado, MD, PhD (*Abstract Co-Author*)

PURPOSE

Although hepatic artery embolization (HAE) is an effective treatment for hypervascular liver tumors, its biological mechanisms of action and recurrence in tumors are not fully understood. However, there is no animal model suitable to HAE in conducting basic research. Mice have access to extensive biological databases and tools. Furthermore, they have the advantage of low cost and require only a small amount of drugs to be used. This study aims to create HAE animal model in mice.

METHODS AND MATERIALS

Colon cancer cells expressing luciferase were injected into the spleens of 11 BALB/c mice to create liver metastases. After confirmation of tumor engraftment in the liver by bioluminescence imaging, mini-laparotomy was performed in all mice. HAE was performed in 6 mice (HAE group). The lienogastric artery was retrogradely punctured with a 34G needle under microscopy and the periphery of the lienogastric artery was ligated. 15-μm fluorescence-labeled microbeads were injected via a 34G needle into the hepatic artery until hepatic arterial blood flow stagnated. HAE was not performed in the other 5 mice (control group). The technical success rate of HAE, and changes in relative bioluminescence activity of liver tumors the day after mini-laparotomy were evaluated. Histopathological analysis of the liver metastases was also performed 2 days later.

RESULTS

HAE was technically successful in all 6 mice in the HAE group (technical success rate: 100%, 6/6). Although relative bioluminescence activity of liver tumors significantly decreased in the HAE group (1.00 +/- 0 to 0.23 +/- 0.13, $p < 0.001$), it didn't change in the control group (1.00 +/- 0 to 1.44 +/- 0.97, $p = 0.37$). Percentage of tumor necrosis was significantly higher in the HAE group than the control group (19.7% +/- 15.1% vs. 0.19% +/- 0.42%, $p < 0.05$).

CONCLUSION

The mouse HAE model was successfully created, which can serve as a useful platform to conduct basic research toward translational research.

CLINICAL RELEVANCE/APPLICATION

This novel mouse HAE model has a potential to become a valuable platform in investigating mechanisms of tumor response and recurrence after embolization and in evaluating new interventional oncology strategies in a preclinical setting.

T2-SPMK-1 DIAGNOSTIC DECISION IN HYBRID HUMAN-AI MULTIRATER DISAGREEMENT SITUATIONS

Wolfram Bosbach, MD, PhD (*Presenter*)
Jan Felix Senge (*Abstract Co-Author*)
Nasir Gozlugol (*Abstract Co-Author*)
Robert Seifert (*Abstract Co-Author*)
Marc-Andre Weber, MD (*Abstract Co-Author*)
Keivan Daneshvar Ghorbani, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of incorporating AI-generated diagnoses on decision accuracy and certainty in human-AI hybrid settings, particularly in scenarios with multirater disagreement within clinical routine and tumor board contexts.

METHODS AND MATERIALS

We analyzed combined human and AI vote data from two MSK studies: an imaging-based study where human raters outperformed AI (human accuracy 0.868 vs. AI accuracy 0.444), and a text-based study where AI outperformed human raters (human accuracy 0.865 vs. AI accuracy 0.957). Two clinical scenarios were analyzed: clinical routine (1 human rater with 10 AI votes) and tumor board (10 human raters with 10 AI votes). Democratic majority voting and certainty-weighted decisions were evaluated.

RESULTS

In the tumor board setting, well-performing AI improved certainty of combined human-AI decisions, while underperforming AI moderately lowered combined decision accuracy (from 0.868 human-only to 0.656 human+AI). In the clinical routine setting with text data, accuracy of combined human-AI decisions reached 1.0 for several human raters, exceeding both individual human (ranging 0.652-0.957) and AI accuracy (0.957). However, with image data where AI underperformed, the combined human-AI decisions showed substantially lower accuracy (0.4) compared to human-only decisions (0.52-1.0). Notably, certainty levels of underperforming AI were not reliable indicators of AI accuracy.

CONCLUSION

Well-performing AI can effectively support human diagnosticians in both clinical routine and tumor board settings, potentially increasing decision certainty and accuracy. However, incorporating underperforming AI, even under AI-rater majority conditions, can significantly diminish diagnostic performance, highlighting the importance of careful AI validation before clinical integration.

CLINICAL RELEVANCE/APPLICATION

Understanding when and how to incorporate AI into diagnostic decision-making processes is crucial as healthcare systems face increasing imaging service demands. This study provides evidence-based guidance on human-AI collaborative diagnostic frameworks that can potentially enhance diagnostic capacity without compromising accuracy.

T2-SPMK-2 DIAGNOSTIC ACCURACY OF CT-BASED RADIOMIC MODELS FOR OPPORTUNISTIC OSTEOPOROSIS SCREENING: A SYSTEMATIC REVIEW AND META-ANALYSIS

Guilherme Augusto Silva (*Presenter*)
Jessica Carvalho (*Abstract Co-Author*)

PURPOSE

Assess the overall diagnostic performance of CT-based radiomic models for opportunistic identification of low bone mineral density.

METHODS AND MATERIALS

In accordance with PRISMA-DTA, we searched PubMed, Embase and Cochrane CENTRAL through April 2025 for CT + radiomics + osteoporosis/osteopenia. After dual screening of 82 records and full-text review of 20 articles, 17 studies (n = 2 720; 63 % female; mean age 62 ± 9 years) met inclusion, reporting sensitivity, specificity and/or AUC against DXA/QCT. We performed random-effects bivariate meta-analysis of sensitivity/specificity (GLMM) and random-effects meta-analysis of logit-AUC (REML+Hartung-Knapp; meta v8.0-2), back-transforming AUC via logistic. Heterogeneity was quantified by I^2 (significant if $p < 0.10$ or $I^2>25$ %).

RESULTS

Seventeen studies comprising 14 645 participants (mean age 64 ± 8 years; 59 % female) were included in the quantitative synthesis. In random-effects meta-analysis, the pooled sensitivity of CT-based radiomic models for opportunistic osteoporosis detection was 0.87 (95 % CI 0.85-0.90; I^2 = 94.1 %), and the pooled specificity was also 0.87 (95 % CI 0.82-0.90; I^2 = 97.2 %). The summary area under the ROC curve (AUC), back-transformed from the logit scale, was 0.89 (95 % CI 0.85-0.90; I^2 = 79.5 %). Despite high between-study heterogeneity, no evidence of small-study effects was found (Deeks' test p = 0.18). These results demonstrate that CT radiomics provides robust diagnostic accuracy for opportunistic osteoporosis screening.

CONCLUSION

CT-radiomic models demonstrate high accuracy (AUC ˜ 0.9; sensitivity/specificity ˜ 0.87) for opportunistic screening of low BMD. Although heterogeneity was substantial, the consistency of results supports their robustness. Future prospective multicenter validation is warranted.

CLINICAL RELEVANCE/APPLICATION

Incorporation of validated radiomic algorithms into routine CT workflows enables noninvasive, cost-effective opportunistic screening for osteoporosis without additional radiation or cost.

T2-SPMK-3 SIMPLIFIED RISK SCORE FOR PREDICTION OF POST-SURGICAL MARGIN INVOLVEMENT IN SOFT-TISSUE SARCOMA

Atefe Pooyan, MD, MPH (*Presenter*)
Ehsan Alipour, MD, PhD (*Abstract Co-Author*)
Chankue Park, MD, PhD (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

PURPOSE

Soft tissue sarcomas (STS) typically require precise surgical resection to achieve local disease control. The status of the post-surgical tissue margin is a critical determinant of surgical success and a key predictor of local recurrence. In this study, we propose a risk stratification system with high sensitivity based on six clinical variables and imaging features derived from pre- and post-neoadjuvant MRI scans.

METHODS AND MATERIALS

We identified a cohort of patients with soft tissue sarcoma (STS) who underwent neoadjuvant radiotherapy. Inclusion criteria required the availability of both baseline and post-neoadjuvant therapy MRI scans, surgical resection following neoadjuvant treatment, and pathology reports detailing post-surgical margin status. Two musculoskeletal radiologists independently reviewed the MRI scans and extracted 18 key imaging features, including markers of marginal infiltration. Clinical variables—including tumor histopathology, grade, patient age, and sex—were incorporated. LASSO logistic regression with 3-fold cross-validation was applied to identify the most predictive features. The final model coefficients were scaled and rounded to integer values to generate a practical risk scoring system.

RESULTS

Our cohort included 119 patients, with a mean age at diagnosis of 55 years (±16). The female-to-male ratio was approximately 2:3. The most common histological subtype was undifferentiated pleomorphic sarcoma, and 67% of tumors were located in the lower extremities. Six variables were retained for inclusion in the risk model. These included post-treatment imaging features such as intratumoral enhancement (odds ratio [OR]: 0.17) and tail sign (OR: 1.4), as well as pre-treatment features such as necrosis (OR: 0.76) and tumoral extension (OR: 1.8). This risk score AUROC of 0.79 (95% CI: 0.68-0.90). Using the Youden index to determine the optimal threshold, the model demonstrated a sensitivity of 80% and a specificity of 63%. The complete risk score is presented in Table 1.

CONCLUSION

We present a risk scoring system designed to identify patients at increased risk of post-surgical margin involvement in STS. Our findings indicate that low-risk patients are characterized by the presence of intratumoral enhancement on post-treatment imaging and the absence of adverse radiologic features such as tumor extension and the tail sign. Future directions include external validation in independent cohorts and prospective studies to assess the utility of this scoring system in guiding surgical planning.

CLINICAL RELEVANCE/APPLICATION

This risk score can aid in preoperative planning by identifying high-risk patients for positive post-surgical tissue margin, who may benefit from tailored surgical strategies.

T2-SPMK-6 PERSONALIZED RISK PREDICTION OF VERTEBRAL FRAGILITY FRACTURES USING GENDER- AND AGE-SPECIFIC BONE MINERAL DENSITY ANALYSIS BASED ON QCT

Wei Duan (*Presenter*)

PURPOSE

To develop and validate a predictive model for vertebral fragility fractures by analyzing the interaction between gender, age group, and bone mineral density (BMD) measured by quantitative CT (QCT), and to visualize its performance using ROC, calibration, and decision curve analysis (DCA).

METHODS AND MATERIALS

A total of 1,825 patients who underwent QCT between 2020 and 2024 were retrospectively enrolled and divided into a training set (n = 1,672) and a test set (n = 153). Vertebral fractures were diagnosed based on imaging criteria. Logistic regression incorporating interaction terms (gender × BMD, age group × BMD) was used to construct the model. Discriminative ability was assessed via ROC curves , calibration via calibration plots, and risk scores were stratified into low-, intermediate-, and high-risk groups. Baseline characteristics were summarized.

RESULTS

Significant interactions were found between BMD and gender (OR = 1.009, P = 0.047) and between BMD and age group (OR = 0.989, P < 0.001). The model achieved an AUC of 0.921. Calibration curves showed good agreement between predicted and observed probabilities. Risk stratification showed fracture rates increased significantly across risk categories (P < 0.001).

CONCLUSION

Gender and age significantly modulate the effect of BMD on fracture risk. Incorporating interaction terms significantly improves model accuracy for vertebral fracture prediction.

CLINICAL RELEVANCE/APPLICATION

This interaction-based QCT model enables accurate risk stratification and supports personalized preventive strategies in high-risk populations.

T2-SPMK-7 A VISUAL GRADING SYSTEM FOR DIFFUSION TENSOR IMAGING OF THE PEDIATRIC KNEE: CORRELATION WITH QUANTITATIVE TRACTOGRAPHY

Jenny Vo-Phamhi, MS (*Presenter*)
Camilo Perdomo, MD (*Abstract Co-Author*)
Ola F. Kvist, MD, PhD (*Abstract Co-Author*)
Ingrid Galvis, MD, MS (*Abstract Co-Author*)
Sogol Mostoufi-Moab (*Abstract Co-Author*)
Diego Jaramillo, MD, MPH (*Abstract Co-Author*)

PURPOSE

To evaluate a structured grading system for tractographic images of the femur and tibia scoring tract direction and density. We have correlated the grading with quantitative DTI parameters in pediatric patients.

METHODS AND MATERIALS

3 independent observers reviewed images from a prospective multicentric study of 49 healthy patients aged 12-16 undergoing knee DTI at 0 and 12 months. For 40 patients, the reviewers—a pediatric musculoskeletal radiologist, a postdoctoral MD researcher, and a medical student—assigned scores (1, 2) to the distal femur and proximal tibia for tract direction and density, using a guide created by another pediatric musculoskeletal radiologist who graded 9 patients. Composite density-direction scores were correlated with tract volume and fractional anisotropy (FA) using Pearson correlation. Interrater agreement was calculated for tract density, direction, length, and distribution.

RESULTS

The correlation of mean composite density-direction scores with tract volume was strong in the femur (Pearson ? = 0.99, $p < 0.01$) and statistically insignificant but notable in the tibia (? = 0.99, $p = 0.14$). Correlation with FA did not achieve significance (femur: Pearson ? = -0.99, $p = 0.11$; tibia: ? = 0.6187, $p = 0.58$). In both femur and tibia, interrater agreement and reliability were substantial or moderate for direction (? = 0.63, 0.55; ICC2 = 0.63, 0.56) and density (? = 0.63, 0.54; ICC2 = 0.63, 0.55). We also evaluated correlation of DTI parameters with length (? = 0.36-0.45; ICC2 = 0.39-0.48) and distribution (? = 0.28, 0.14; ICC2 = 0.32, 0.21) of tracts, and found lower correlations.

CONCLUSION

A simple, visual grading system for pediatric knee DTI correlated well with tract volume and demonstrated strong interrater agreement for tract direction and density. These findings suggest that the direction-density grading system could serve as a simple, reproducible framework for longitudinal assessment of musculoskeletal tract development.

CLINICAL RELEVANCE/APPLICATION

This novel, two-point grading system offers a practical, interpretable approach for radiologists to assess tract maturation in growing children and may complement quantitative measures in both clinical and research settings.

T2-SPMS-1 SCREENING OF CHILDREN WITH FAMILY HISTORY OF HHT (HEREDITARY HEMORRHAGIC TELANGIECTASIA) FOR DISEASE EXPRESSION IN BRAIN, LIVER AND LUNG BY MAGNETIC RESONANCE IMAGING

Guenther K. Schneider, MD, PhD (*Presenter*)
Diane Wagner-Jochem (*Abstract Co-Author*)
Arno Buecker, MD (*Abstract Co-Author*)

PURPOSE

To evaluate magnetic resonance imaging for screening of pediatric patients who are children of clinically and/or genetically proven HHT patients for AVMs (arterio-venous malformations) in the brain, liver or lungs.

METHODS AND MATERIALS

59 Pts. (age range 3-17 years; mean 12 years; male/female 38/21) underwent unenhanced and contrast-enhanced MRI examinations of the brain, liver and pulmonary vasculature for the detection of AV malformations in a single examination. The imaging protocol included unenhanced MRI of the brain (T2w, FLAIR, SWI, DWI and T1w imaging) followed by unenhanced T1w and T2w liver imaging and flow-sensitive GRE-sequences of the liver to detect increased vessel density. This was followed by a time-resolved and high-resolution CE MR-angiography of the thorax. Finally a CE T1w scan of the liver and of the brain was performed, so with one CM dose a complete work-up could be performed.

RESULTS

In 34 of 59 Pts. (58 %) at least one disease expression in either brain, liver or lung was found. Cerebral AVMs were found in 6 (10 %), pulmonary AVMs 31 (53%) and liver AVMs 3 (5%) Pts. Of these, 25 only showed pulmonary AVMs and 3 only liver AVMs respectively. 6 Pts. had simultaneous AVMs in both brain and lung. No patient demonstrated AVMs in all evaluated organs. The male/female ratio of Pts. with at least one disease expression was 19/15.Additional findings related to the disease included microgyria and schizencephaly in 4 Pts. Two Pts. initially presented with stroke, one patient with cerebral abscess formation. Peripheral O2-saturation in the group of Pts. with PAVM was < 95% in 11 Pts. and < 80% in 2 Pts. In all other Pts., including those with PAVM and stroke, O2 saturation was normal. 20 Pts. with PAVM underwent interventional therapy of PAVMs, with the result of a normal O2 saturation in 18 / 20 pts., 2 patients had diffuse PAVMs and saturation was significantly increased post occlusion of the larger PAVMs. Nose bleeding as a major symptom of the disease was found in 12 of 34 Pts. (35%) with visceral disease expression.

CONCLUSION

MRI is a feasible one stop screening method for evaluation of disease expression in brain, liver and lung in children of Pts. diagnosed with HHT. Together with genetic testing, MRI can give important information of visceral manifestation of this autosomal dominant disease with variable expression.

CLINICAL RELEVANCE/APPLICATION

Since in our study population even pts. without any clinical signs of the disease suffered from PAVMs and related complications like stroke or brain abscess, screening for possibly live-threatening AV-Malformations is necessary and MRI can provide an overview of disease expression of HHT with the goal of normal quality of life and life expectancy.

T2-SPNMMI-1 ROLE OF PET-CT METABOLIC METRICS IN PREDICTING SURVIVAL IN RECTAL CANCER PATIENTS

Marta Vaillant, MD (*Presenter*)
Gonzalo Cuesta Domingo, MD (*Abstract Co-Author*)
Eliseo Vano Galvan, PHD (*Abstract Co-Author*)
Cristina Rodriguez Rey (*Abstract Co-Author*)
Paloma Dauden (*Abstract Co-Author*)
Cristina G. Wakfie Corieh, MD (*Abstract Co-Author*)
Luisa F. Leon, MD (*Abstract Co-Author*)
Patricia Romero Fernandez, MBBS (*Abstract Co-Author*)
Pedro Nespral Torres, MD (*Abstract Co-Author*)

PURPOSE

Rectal cancer is one of the most common malignanciesof the digestive tract. Its management poses challenges due to its anatomical location and silent progression. We aim to analyze the independent prognostic value of metabolic parameters from [18F-FDG]PET-CT in patients with rectal cancer

METHODS AND MATERIALS

We conducted a retrospective cohort study (2020-2023) including 59 patients with rectal cancer referred for staging with [18F-FDG]PET-CT. Clinical, imaging, and metabolic variables were collected, including MTV, SUVmax, and SUVmean of the primary lesion. Tumor-related death was defined as the primary endpoint during follow-up. A multivariate Cox regression analysis was performed to identify independent prognostic predictors. Model discrimination capacity was assessed using Harrell's C-index.

RESULTS

The mean age was 65.62 ± 12.06 years, with 49.15% of the cohort being male. Adenocarcinoma was the predominant histological subtype (98.31%). Nine patients (15.25%) presented with metastatic disease at diagnosis. The mean values for the metabolic parameters were: MTV 16.55 ± 20.44, SUVmax 21.36±8.07, and SUVmean 12.29 ± 4.62. The average follow-up time was 35.15 months. In the univariate analysis, MTV (HR 1.039; 95% CI 1.010-1.069; p=0.007) was the only metabolic parameter significantly associated with the event, along with surgery, radiotherapy, nodal involvement on PET/CT, and the presence of metastases. In the multivariate Cox regression analysis, surgery (HR 0.142; 95% CI 0.024-0.850 ; p=0.033), radiotherapy (HR 0.085; 95% CI 0.013-0.580; p=0.012), and MTV (HR 1.037; 95% CI 1.008-1.068; p=0.014) remained as independent prognostic factors. Harrell's C-index demonstrated excellent discriminative ability of the final model (0.931; 95% CI 0.873-0.989)

CONCLUSION

In our cohort, MTV emerged as an independent prognostic factor for mortality in patients with rectal cancer, indicating that higher MTV values are associated with decreased survival.

CLINICAL RELEVANCE/APPLICATION

This study underscores the prognostic utility of metabolic tumor volume (MTV) derived from [18F-FDG]PET-CT in patients with rectal cancer. MTV was identified as an independent predictor of tumor-related mortality, with higher values correlating with poorer survival outcomes. These findings suggest that MTV could enhance current risk stratification strategies and support more personalized treatment planning in rectal cancer management.

T2-SPNMMI-2 A DEEP-LEARNING APPROACH TRAINED ON SIMULATED DATASET FOR PET IMAGE QUALITY ENHANCEMENT: VALIDATION ON A MULTI-CENTER, MULTI-VENDOR STUDY

Thomas C. Arnold, PhD (*Presenter*)
Muzi Guo (*Abstract Co-Author*)
Lei Xiang (*Abstract Co-Author*)

PURPOSE

Positron emission tomography (PET) has demonstrated significant diagnostic value in various oncological applications. However, its clinical utility is often limited by long acquisition time. While reducing scan duration can improve efficiency, it inevitably compromises image quality. Recent advances in deep learning have led to the development of PET image denoising techniques. However, many of these methods suffer from undesirable image blurring. In this study, as it is challenging to acquire real paired low-resolution (LR) and high-resolution (HR) PET dataset, we propose a deep-learning based method trained on simulated datasets for super-resolution of PET images. Our objective is to evaluate the performance and generalizability of this algorithm in a realistic multicenter, multivendor environment clinically.

METHODS AND MATERIALS

The training dataset comprised 150 subjects scanned with the ^{18}F-FDG tracer on a Biograph Vision Quadra system. High-resolution (HR) ground-truth images were reconstructed with a matrix size of 440×440×644. To generate LR counterparts, the HR images were retrospectively processed through the following steps: (1) convolved with Gaussian functions of 2 mm, 3 mm, and 4 mm full-width at half-maximum (FWHM) to mimic the point spread function (PSF) of a PET imaging system, and (2) downsampled to isotropic voxel sizes of 2 mm, 3 mm, and 4 mm, respectively. The test dataset comprised 30 cases collected from three hospitals using different PET/CT scanners: a Biograph64 TruePoint, a Vereos PET/CT, and a Discovery 710. For quantitative assessment, the SNR and CNR were calculated for low-dose scans w/ and w/o enhancement.

RESULTS

The enhanced images demonstrated superior visual quality with improved delineation of both physiological and pathological structures when compared to low-count scans, achieving even better performance than standard-count scans. Furthermore, quantitative measurements of ROIs in enhanced low-count images showed

agreement with standard scan. From a quantitative perspective, the SNR and CNR were improved by an average of 31.2% and 22.6%, respectively.

CONCLUSION

The deep-learning approach trained on simulated dataset could significantly improving the contrast and sharpness of low-count PET after denoise without sacrificing image quality.

CLINICAL RELEVANCE/APPLICATION

The high-quality publicly available dataset acquired using advanced imaging systems can be leveraged to develop deep learning algorithms for enhancing low-quality PET images obtained from outdated PET/CT scanners. Our proposed method significantly improves tumor and tissue delineation, which is particularly valuable for clinical applications such as myocardial blood flow quantification and whole-body assessment.

T2-SPNPM-1 ENVIRONMENTAL IMPACT OF PATIENT TRAVEL FOR OUTPATIENT MEDICAL IMAGING

Jimin Lee (*Presenter*)
Hayley Panet (*Abstract Co-Author*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)

PURPOSE

Patient travel for medical appointments generates substantial greenhouse gas (GHG) emissions. However, there is limited data on specific estimates for medical imaging. The purpose of this study was to determine GHG emissions due to patient travel for outpatient medical imaging.

METHODS AND MATERIALS

In this retrospective cross-sectional study, outpatient medical imaging performed at an academic medical imaging department covering 5 hospital sites was evaluated between April 2022 and March 2025. Patient travel for each imaging procedure was calculated as double the distance between the centroid of each patient's residential postal code and the location of the hospital site where the imaging was performed. Travel-related GHG emissions were calculated as 400 grams carbon dioxide equivalents (CO_2e) per mile driven in an average passenger vehicle. Patient-travel related GHG emissions that could be avoided by scheduling multiple imaging procedures in the same patient on the same day were estimated.

RESULTS

A total of 672,442 outpatient medical imaging procedures were performed during the study period (224,147 per year) in 112,197 unique patients (54% female, mean age 54.7±17.7 years). Median total travel distance was 16.0 miles (IQR 5.9, 37.2) per imaging procedure. Annual total patient travel-related GHG emissions were 4979 metric tons CO_2e/year, equivalent to 1038 homes' electricity use. Overall, median patient travel-related GHG emissions were 6.4 kg CO_2e (IQR 2.4, 14.9) per imaging test. Patient travel-related emissions differed by imaging modality, highest for interventional procedures (9.6 kg [IQR 3.7, 23.5]), followed by CT (7.2 kg [IQR 2.7, 16.4]), MRI (6.2 kg [IQR 2.3, 15.4]), and ultrasound (4.9 kg [IQR 1.9, 11.6]), $P<0.001$ for all comparisons. For diagnostic imaging, total GHG emissions from patient travel were 2.3 times higher than total modality-specific use-phase GHG emissions. Among patients with multiple outpatient imaging procedures, bundling imaging appointments that had been performed in the same patient within 30 days but not on the same day would reduce annual patient travel-related GHG emissions by 733 metric tons CO_2e/year (14.7% reduction compared to baseline), equivalent to 153 homes' electricity use.

CONCLUSION

Patient travel for outpatient medical imaging generates substantial GHG emissions, equivalent to 1038 homes' electricity use at a single medical imaging department in one year.

CLINICAL RELEVANCE/APPLICATION

This data can be used to inform strategies to reduce travel-related GHG emissions in radiology such as scheduling multiple imaging appointments on the same day. Future studies can explore the incremental impact of coordinating outpatient imaging with other procedures and clinic visits on the same day.

T2-SPNPM-2 CAN AI KEEP UP WITH LUNG CANCER RESEARCH? A COMPARATIVE EVALUATION OF LLMS FOR RADIOLOGY LITERATURE SUMMARIZATION

Sarah Meribout, MD (*Presenter*)
Seyedehelaheh Hosseini, MD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate and compare the performance of various large language models (LLMs) in retrieving and summarizing original radiology research articles on lung cancer. Specific goals included assessing LLM retrieval accuracy, summarization relevance and completeness, tabulation reliability, and overall usability.

METHODS AND MATERIALS

We conducted a comparative analysis of six commercially available LLMs, both general and medical (ChatGPT 4.o DeepSearch, OpenEvidence, Consensus.ai, Qwen 2.5Max, DeepSeek, and Gemini DeepSearch), across three tasks. (1) Medical Article Retrieval: From PubMed, AI tools were instructed to identify original radiology research articles published in December 2024 on lung cancer using standardized prompts. Results were compared with MeSH-based Medline searches. (2) Summarization: Quality was assessed using two metrics on relevant retrieved articles: Relevance Fraction (proportion of relevant information) and Completion Fraction (proportion of predefined required facts correctly identified). Manually extracted gold-standard summaries and checklists were created for verifying LLM outputs. (3) Tabulation: Each model's ability to extract and structure key information in tabular form was tested for accuracy and completeness. A Usability Index (1-5 scale) was also assigned based on research efficiency and interface performance.

RESULTS

Out of 102 retrieved articles in December 2024 with MeSH Advanced Search, 62 were deemed eligible. ChatGPT extracted 8 articles (9.7%); other models retrieved =1. ChatGPT had a relevance fraction of 92% and 95% completion rate. Gemini DeepSearch achieved 74% relevance but 98% completion. Qwen and DeepSeek produced concise summaries with high relevance (97-100%) but lower completion rate (81-91%). Consensus.ai repeatedly failed to generate usable outputs. In tabulating relevant information, all functional models achieved a 100% accuracy and 91-100% completeness. Usability scores were highest for ChatGPT (3), with others scoring =1.5 due to limitations in handling longer text, slow or failed responses, or lack of retrieval functionality.

CONCLUSION

Most LLMs have a limited role in searching relevant research publications within the years of their specified search updates. However, ChatGPT DeepSearch showed the best overall performance across retrieval, summarization, and usability tasks, though it still missed relevant articles compared to manual PubMed searches.

CLINICAL RELEVANCE/APPLICATION

Both generic and medicine-targeted LLMs provide incomplete retrieval of the latest research literature, traditional MeSH-based Medline search provides best retrieval rates; most LLMs excel in tabulating details of retrieved research article.

T2-SPNPM-3 ERGONOMICS AND MUSCULOSKELETAL HEALTH IN SONOGRAPHER

Sabrina Bintalib, BSc, MPH (*Presenter*)
Pauline Soh (*Abstract Co-Author*)
Li Ern Tang (*Abstract Co-Author*)
Le Yi Ruth Wong (*Abstract Co-Author*)

PURPOSE

Sonographers worldwide face a high risk of work-related musculoskeletal disorders (WMSDs) due to prolonged static postures, repetitive movements, and physically demanding tasks, with reported prevalence rates between 63% and 98.7%. However, limited research has examined these risks within Southeast Asian contexts. This study investigated the prevalence of WMSDs among sonographers in Singapore and explored associations with demographic factors and ergonomic awareness.

METHODS AND MATERIALS

A cross-sectional online survey was conducted among 68 sonographers across 24 public and private healthcare institutions in Singapore (ethics approval: SIT IRB RECAS-0414). Eligible participants were aged 20-69 years with at least one year of professional experience. The Cornell Musculoskeletal Discomfort Questionnaire (CMDQ) was used to assess the prevalence, severity, and impact of WMSDs. Ergonomic awareness was categorized as Good (scores 6-7), Moderate (4-5), or Poor (1-3). Logistic regression analyses evaluated associations between demographic factors and WMSD risk, while nonparametric tests examined relationships between ergonomic awareness and WMSD prevalence.

RESULTS

WMSDs were reported by 98.5% of respondents, with 25% indicating that discomfort interfered with work. The most affected areas were the shoulders (85.3%), back (83.8%), and neck (67.7%), while lower limb discomfort was minimal. Sonographers aged over 40 years had 7.25 times greater odds of experiencing back-related WMSDs ($p<0.04$). Although 76.5% demonstrated good ergonomic awareness (mean score 6.23±0.16), prolonged scanning sessions exceeding three hours without breaks significantly increased WMSD risk ($p<0.05$), while post-scan stretching reduced risk ($p=0.01$).

CONCLUSION

Despite high ergonomic awareness, WMSDs remain highly prevalent among sonographers, highlighting a persistent knowledge-practice gap. Age and scanning duration are key risk factors.

CLINICAL RELEVANCE/APPLICATION

These findings emphasize the urgent need for practical ergonomic interventions, including mandated break protocols and stretching programs, to reduce WMSD risk globally and to support a sustainable sonography workforce.

T2-SPNR-1 CEREBRAL MICROBLEEDS IMAGED BOTH IN-VIVO AND EX-VIVO: AN MRI AND NEUROPATHOLOGY STUDY IN A COHORT OF COMMUNITY-BASED OLDER ADULTS

Md Tahmid Yasar, PhD (*Presenter*)
Grant Nikseresht, MS (*Abstract Co-Author*)
Abdur Raquib Ridwan, PhD (*Abstract Co-Author*)
Shengwei Zhang, PhD (*Abstract Co-Author*)
David A. Bennett, MD (*Abstract Co-Author*)
Julie A. Schneider, MD (*Abstract Co-Author*)
Konstantinos Arfanakis, PhD (*Abstract Co-Author*)

PURPOSE

Cerebral microbleeds (CMBs), seen as small hypointense spots on T 2 * -weighted gradient echo MRI, are primarily small brain hemorrhages. CMBs are common in community-based older adults and are linked to increased risk of intracerebral hemorrhage and stroke.To date, the link between CMBs in in-vivo and ex-vivo MRI has not been systematically investigated in older adults. In this study, CMBs that appear in both in-vivo and ex-vivo MRI were investigated and the association of these findings with neuropathologies were assessed.

METHODS AND MATERIALS

The longitudinal study included 37 community-based older adults who participated in aging studies. All participants underwent cognitive function testing and brain MRI annually. Whole brain 3D-T 1 w MPRAGE (1×1×1mm 3), and multi-echo gradient-echo (ME-GRE) (0.7×0.7×1.3mm 3) MRI were acquired in-vivo using 3T scanners. After death and autopsy, one cerebral hemisphere 3D multi-echo spin-echo (ME-SE) (0.6×0.6×1.5mm 3) and ME-GRE (1×1×1mm 3) of each participant was imaged ex-vivo with 3T scanners. Following ex-vivo MRI, all hemispheres underwent pathologic assessment including vascular pathologies like cerebral amyloid angiopathy (CAA), arteriolosclerosis, atherosclerosis, gross and microscopic infarcts. CMBs were annotated on the last acquired in-vivo before death and ex-vivo ME-GRE blinded to all pathologic, clinical and other imaging data. The ex-vivo CMB mask was first transformed to ME-SE space, then registered to the MIITRA atlas. The in-vivo CMB mask for the corresponding ex-vivo hemisphere was registered to MPRAGE and subsequently registered to the MIITRA template. The two CMB masks for each participant were then superimposed in MIITRA atlas to assess chronological changes in CMB characteristics. In-vivo and ex-vivo CMBs that overlapped exactly were considered to be the same CMBs and denoted as matched CMBs.

RESULTS

Of the 37 participants, 13 (35%) had at least one CMB in in-vivo, 22 (59%) had at least one CMB in ex-viv, 21 (57%) showed exact match between in-vivo and ex-vivo CMBs. In most of the mismatched cases, ex-vivo CMB counts were higher than in-vivo. The ex-vivo CMB counts were higher than in-vivo in participants with higher antemortem intervals, higher CAA burden (odd ratio: 3.6, $p < 0.1$).

CONCLUSION

This study combined in-vivo and ex-vivo MRI with pathological data from 37 older adults within a community cohort. This investigation showed that CMBs observed during life persist in the brain and can be detected on ex-vivo MRI. More CMBs develop over time in individuals CAA.

CLINICAL RELEVANCE/APPLICATION

We demonstrated that cerebral microbleeds (CMBs) detected in-vivo were also detected ex-vivo. Ex-vivo CMBs can be reliably utilized to develop biomarkers for age-related neuropathologies.

T2-SPNR-3 IDENTIFICATION OF THE OUTER SUBARACHNOID SPACE IN PATIENTS AFTER ANEURYSM CLIPPING SURGERY

Toshiteru Miyasaka, MD, PhD (*Presenter*)
Ryota Nakano, MD,PhD (*Abstract Co-Author*)
Yumi Tai (*Abstract Co-Author*)
Tomoko Ochi (*Abstract Co-Author*)
Toshihiro Tanaka, MD, PhD (*Abstract Co-Author*)

PURPOSE

Subarachnoid lymphatic-like membranes (SLYMs) have recently been identified. SLYMs are the fourth meningeal layer in the arachnoid space and are considered impermeable membrane structures, as they do not allow the passage of hemoglobin or even dextran with a molecular weight as small as 3 kDa. Consequently, the subarachnoid space (SAS) is subdivided into outer and inner compartments. Physical rupture of the SLYMs can occur during craniotomy clipping. This study aimed to identify normally invisible SLYMs on MRI and investigate the appearance of abnormal outer SAS in patients who underwent aneurysm clipping surgery.

METHODS AND MATERIALS

We retrospectively analyzed 19 out of 29 patients who underwent craniotomy clipping surgery at our institution in 2023, excluding four patients who did not undergo postoperative T2-weighted image and six patients whose MRI was not performed within 30 days after surgery. The mean age was 65.8 years, with 13 females and 6 males. Fifteen patients had ruptured aneurysms and four had unruptured aneurysms. Head MRI was performed at an average of 7.6 days postoperatively. Based on the anatomical fact that the superficial cerebral veins run along the SLYM, membrane-like structures accompanying these veins were interpreted as SLYMs on MRI. A fluid area located lateral to these membranes was considered to be an enlarged outer SAS. The thickness of this space was measured on both the craniotomy and contralateral sides. For patients with available follow-up imaging, changes in the size of the outer SAS were also evaluated over time.

RESULTS

An enlarged outer SAS was observed in 16 patients, with a mean thickness of 5.4 mm (standard deviation 2.42). In seven patients, an enlarged outer SAS was also found on the contralateral side, with a mean thickness of 3.9 mm (standard deviation, 1.64). Among the 16 patients with an enlarged outer SAS, 11 underwent follow-up imaging: the outer SAS disappeared in 8 patients, persisted in 2 patients, and evolved into hemorrhage in 1 patient.

CONCLUSION

An enlarged outer SAS was identified in a relatively large number of patients after aneurysm clipping surgery. Follow-up observations showed that the outer SAS disappeared in the majority of patients.

CLINICAL RELEVANCE/APPLICATION

Visualization of the outer subarachnoid space on postoperative MRI may serve as indirect evidence for the presence of SLYMs, supporting the anatomical concept of compartmentalization within the subarachnoid space. This enhanced understanding of membrane-based neuroanatomy may contribute to more accurate interpretations of cerebrospinal fluid dynamics as well as the pathophysiology of conditions such as subpial fluid collections and subarachnoid hemorrhage.

T2-SPNR-4 ALTERED SUPERFICIAL WHITE MATTER IN ADOLESCENTS WITH CONDUCT DISORDER: A DIFFUSION MRI STUDY OF REPRODUCIBLE U-FIBER BUNDLES

Panshi Liu (*Presenter*)

PURPOSE

To investigate superficial white matter microstructural alterations in adolescents with conduct disorder (CD) by analyzing the fractional anisotropy (FA) of reproducible U-fiber bundles, and to compare these findings with typically developing controls (TC) using diffusion MRI.

METHODS AND MATERIALS

A total of 331 adolescents with CD were included, and 331 age-, sex-, and socioeconomic status-matched TC adolescents were selected using a propensity score matching approach from a publicly available dataset. Diffusion-weighted MRI data were processed using a tractography pipeline in MRtrix to generate two million anatomically constrained streamlines, with lengths ranging from 10 to 50 mm. Streamlines were filtered for U-shaped morphology using the Scilpy toolbox and further refined by excluding outliers. Reproducible U-fiber bundles were identified by retaining streamlines present in at least 75% of participants, an empirically determined threshold, resulting in 78 consistent bundles. DTI microstructural measures of FA values were computed for each of the 78 U-fiber bundles. Because the U-fiber data were highly correlated, we used principal component analysis (PCA) to extract the most relevant components that accounted for the primary variance. Linear mixed-effects (LME) models were used to assess group differences, with group (CD vs. TC) treated as a fixed effect.

RESULTS

Four principal components (PCs) were retained based on visual inspection of the scree plot: PC1, PC2, PC3, and PC4, encompassing 39, 19, 8, and 12 U-fiber bundles, respectively. LME model results showed significant group differences in PC1 (ß = 0.6949, P FDR = 0.0386) and PC4 (ß = 0.5527, P FDR = 0.0106). These findings suggest that FA values in the corresponding U-fiber bundles were lower in the TC group, indicating relatively higher FA in adolescents with CD in these superficial white matter pathways.

CONCLUSION

Our findings suggest that atypical superficial white matter microstructure, reflected in increased FA of reproducible U-fiber bundles, may be a characteristic neurodevelopmental feature of CD in adolescence.

CLINICAL RELEVANCE/APPLICATION

These structural differences, identifiable through diffusion MRI, underscore the potential of U-fiber-based biomarkers in differentiating developmental psychopathologies and advancing precision psychiatry in adolescent populations

T2-SPNR-5 TEXT-PROMPTED AI WITH VESSEL-VOLUME GUIDANCE FOR ACCURATE ANTERIOR LVO CLASSIFICATION ON CT ANGIOGRAPHY

Gyeongyeon Hwang, MSc (*Presenter*)
Jiwoo Song, MSc (*Abstract Co-Author*)
Dohyun Kim, PhD (*Abstract Co-Author*)
Soohwa Song, PhD (*Abstract Co-Author*)
Aleum Lee, PhD, MD (*Abstract Co-Author*)
Dong Hoon Shin, MD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate and compare the performance of AI-based CT angiography analysis for classifying anterior large vessel occlusion (LVO), depending on the application of automated text-prompting guided by vascular volume information.

METHODS AND MATERIALS

We used 1,862 CTA cases of acute ischemic stroke to train the classification model. To extract vascular volumes, the input images were resampled to 1-mm isotropic voxels and intensity-normalized. Cerebral vessels were manually segmented by two neuro-experts, covering the distal cavernous segment of the internal carotid artery (ICA) to the distal middle cerebral artery (MCA). Right and left vessel volumes were quantified and converted into an English sentence (e.g., "Right ICA is larger: R 1,119 mm^3, L 878 mm^3; ratio 1.27"). The CTA source images and the generated sentence were then tokenized using a frozen text encoder (CLIP (ViT-B/32)). An independent test set (total = 284; LVO-positive = 142, LVO-negative = 142) was collected, with the ground truth determined by an experienced neuro-interventionist. The performance of the text-prompted network was compared to that of an identically configured image-only network. Ensemble-based inference was performed using combined 5-fold cross-validated models for both networks.

RESULTS

The text-prompted network demonstrated higher performance than the image-only network (AUC = 0.982 vs. 0.968; accuracy = 0.949 vs. 0.912). It identified five additional true positives while reducing the number of false positives and negatives. As a result, sensitivity and specificity improved from 90% to 94%, and from 92% to 96%, respectively.

CONCLUSION

Embedding vessel-volume text prompts in a CTA-based LVO classifier significantly enhances the automated detection of ICA and MCA occlusions, while reducing false alerts compared to an image-only approach.

CLINICAL RELEVANCE/APPLICATION

Integrating quantitative vessel-volume descriptions as text prompts can strengthen automated LVO triage and support faster, more reliable endovascular treatment decisions.

T2-SPNR-6 ENHANCED NEUROVASCULAR IMAGING WITH ULTRA-HIGH-RESOLUTION CT AND DEEP LEARNING-BASED IMAGE RECONSTRUCTION: FOCUS ON INTRACRANIAL VEINS AND SINUSES

Steinmetz, MD (*Presenter*)
Mariya Kondova (*Abstract Co-Author*)
Mario Abello Mercado (*Abstract Co-Author*)
Antoine Sanner (*Abstract Co-Author*)
Marc A. Brockmann, MD (*Abstract Co-Author*)
Ahmed Othman, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic benefits of deep learning-based image reconstruction for venous neurovascular imaging using Ultra-High-Resolution CT (UHR-CT) in comparison to standard hybrid iterative reconstruction (HIR) applied to UHR-CT datasets.

METHODS AND MATERIALS

This retrospective, single-center study included 33 consecutive patients who underwent cranial computed tomography (CCT) and venous computed tomography angiography (CTA) to exclude sinus or venous thrombosis, post-interventionally after stent implantation for hydrocephalus, or to assess the anatomical relationship of sinus/venous structures in cases of intra-axial tumors. Imaging was performed using a UHR-CT system. Hybrid iterative image reconstruction (HIR) was applied to UHR-CTA datasets, which were reconstructed with a 0.25 mm slice thickness and a 1024 x 1024 reconstruction matrix. Additionally, a vendor-specific deep learning algorithm, trained for neurovascular analysis, was applied to the UHR-CTA datasets (DL-UHR-CTA), also reconstructed with a 0.25 mm slice thickness and a 1024 x 1024 reconstruction matrix. Quantitative analyses included the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) using software tools. Qualitative assessments of image quality, contrast, noise, artifacts, diagnostic confidence, and assessability of various sinuses and intracranial veins were conducted by three radiologists using a 4-point Likert scale.

RESULTS

SNR and CNR values in DL-UHR-CTA significantly outperformed UHR-CTA ($p < 0.05$). Qualitative analysis showed that DL-UHR-CTA provided significantly better overall image quality, contrast, diagnostic confidence, and assessability across all vessel segments, with fewer artifacts and less noise compared to UHR-CTA and NR-CTA ($p < 0.05$).

CONCLUSION

Deep learning-based reconstruction of UHR-CT images in neurovascular imaging significantly improves overall image quality, vascular delineation, SNR, and CNR compared to hybrid iterative reconstruction alone.

CLINICAL RELEVANCE/APPLICATION

These enhancements may improve the anatomical understanding of the sinus and intracranial veins and be helpful in assessing pathologies such as thrombosis.

T2-SPNR-7 HYBRID DIFFUSION (HYDI): NEURITE ORIENTATION DISPERSION AND DENSITY IMAGING (NODDI) AND DIFFUSION KURTOSIS MRI OF THE SPINAL CORD AS BIOMARKERS OF ALS DISEASE PROGRESSION IN INDIVIDUALS CARRYING C9ORF72

Spandana Tammiraju, MBBS (*Presenter*)
Sara Naghizadehkashani, MD (*Abstract Co-Author*)
Zahra Sadeghi Adl, MSc (*Abstract Co-Author*)
Devon M. Middleton (*Abstract Co-Author*)
Laura Krisa (*Abstract Co-Author*)
Feroze B. Mohamed, PhD (*Abstract Co-Author*)

PURPOSE

Familial ALS is most often associated with pathogenic expansion of C9orf72 . Timely diagnosis can be limited by the absence of early markers of disease progression, between the onsets of cellular change and clinically observable muscle weakness. While cervical motor function offers survival prognosis, the predictive role of neuroimaging in those at genetic risk remains of interest. The standalone clinical utility of diffusion tensor imaging (DTI) is limited by low specificity. Kurtosis imaging (DKI) characterizes non-gaussian diffusion of water molecules in the presence of microstructural hindrances. Neurite orientation dispersion and density imaging (NODDI) allows voxel-wise compartmentalization of diffusion signal as intracellular, extracellular, or isotropic/CSF. The derived orientation dispersion index (ODI) corresponds to wider variations in directionality, providing a more inclusive view of neuronal microstructure. This study examines DTI and higher-order microstructural (NODDI/DKI) metrics in the cervical spinal cord as potential early biomarkers of latent ALS progression in asymptomatic C9orf72 carriers (C9+).

METHODS AND MATERIALS

Clinical and MRI data were obtained from four C9orf72 carriers and six age- and sex-matched, neurologically intact controls (mean age 41 years). The C9+ group was also scanned after six months. Images of the cervical spinal cord (C1-C7) were acquired using a 3.0T Siemens Prisma MRI scanner system with 64-channel and 24-channel coils, with T1 and T2 anatomical sequences and a custom inner field-of-view hybrid diffusion (iFOV-HYDI) MR sequence. Diffusion metrics were extracted after motion correction, coregistration, and model fitting. Results were examined by group and spinal level using t-tests and Pearson correlation coefficients.

RESULTS

Group-wise comparisons showed significant differences in ODI and axial kurtosis (AK) at both time points between control and C9+ groups, mostly at C3-C6. Paired t-tests of the C9+ group at baseline and follow-up showed a statistically significant increase in average MK and RK of the cervical cord, and increased FA at C5 and C6. Sporadic but significant changes of AD, MD, KFA, and ICVF were noted.

CONCLUSION

Higher-order microstructural models in diffusion MRI produce distinct observable differences between study groups as compared to standard diffusion tensor data. With a small sample size, the consistency and clinical relevance of these changes warrant ongoing recruitment and analysis.

CLINICAL RELEVANCE/APPLICATION

Continued follow-up of asymptomatic C9+ subjects may clarify temporal change and correlation of diffusion MRI and NODDI with clinical progression of disease, offering insight into improved sensitivity of radiologic biomarkers for ALS.

T2-SPNR-8 CLINICAL VALIDATION OF A COMMERCIALLY AVAILABLE AI TOOL FOR EMERGENCY INTRACRANIAL HAEMORRHAGE DETECTION ON NCCT

Igor R. Oliveira, MD (*Presenter*)
Easwar Lakshmi Narayanan, MD (*Abstract Co-Author*)
Sarang Ingole, MBBS (*Abstract Co-Author*)
Amit Kumar (*Abstract Co-Author*)
Vidur Mahajan, MBA, MBBS (*Abstract Co-Author*)
Bruno A. Rocha, MD, PhD (*Abstract Co-Author*)
Carlos Jorge da Silva, PhD, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic performance of a commercially available AI tool for detecting ICH on non-contrast head CT, using expert radiologist consensus as the reference standard.

METHODS AND MATERIALS

This retrospective study included 973 anonymized non-contrast head CT scans from routine clinical practice, representing a mix of hemorrhagic and non-hemorrhagic cases. The AI tool was tested for its ability to detect brain hemorrhages, with ground truth labels determined by consensus review from two board-certified neuroradiologists. Diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUC).

RESULTS

The AI tool demonstrated strong diagnostic performance across various hemorrhage subtypes, with high AUC values: 0.885 for intracranial hemorrhage, 0.905 for pericerebral hematoma, 0.898 for subdural hematoma, 0.827 for subarachnoid hemorrhage, 0.918 for intraparenchymal hemorrhage, and 0.948 for intraventricular hemorrhage. The tool showed high specificity (>0.94), making it effective for ruling out hemorrhages. Sensitivity varied from 0.43 (subdural hematoma) to 0.79 (intracranial hemorrhage), with potential for improvement through post-deployment threshold adjustments. Negative predictive value (NPV) was high (0.71-0.98), supporting triage use, while positive predictive value (PPV) ranged from 0.46 to 0.90, highlighting the need for radiologist confirmation.

CONCLUSION

The AI tool demonstrated strong performance, with high specificity and NPV across multiple hemorrhage subtypes. Its ability to detect both common and critical hemorrhages supports its role in emergency and high-volume settings. Adjusting thresholds could improve sensitivity, optimizing its clinical utility.

CLINICAL RELEVANCE/APPLICATION

AI-assisted CT interpretation can expedite diagnosis, reduce missed findings, and assist radiologists in delivering timely care, particularly in high-demand environments. It can also reduce clinician workload and improve patient outcomes by aiding early intervention in cases of brain haemorrhage.

T2-SPNR-9 DEVELOPMENT OF INTRACRANIAL ATHEROSCLEROTIC DISEASE AND ISCHEMIC STROKE RISK IN BRAIN TUMOR PATIENTS: A LONGITUDINAL STUDY;PRELIMINARY FINDINGS

Mohamed Hassan, MD (*Presenter*)

PURPOSE

As brain tumor patient survival improves, acute ischemic stroke (AIS) is a growing concern in this population [1,2]. . Since intracranial atherosclerotic disease (ICAD) is a leading cause of stroke globally [3], we developed a unique intracranial vessel wall MRI (IVW) database to longitudinally assess ICAD and AIS incidence in brain tumor patients.

METHODS AND MATERIALS

we retrospectively reviewed imaging for brain tumor patients (diagnosed from 1984 to 2024) at our oncology center from 2018 to 2025. Demographic and clinical data, including the brain tumor (primary or metastasis, WHO grade and IDH mutation) and therapy details (surgery, radiation, and chemotherapy) and cardiovascular risk factors , were recorded. All patients underwent brain MRI with IVW surveillance during follow-up. we reviewed each IVW for the presence of vasculopathy and associated features. For ICAD, plaque prevalence, pattern of involvement, circumferential location, total plaque number, arterial segment of involvement and the degree of ICAD lumen stenosis were assessed. Additionally, AIS occurrence was assessed as an endpoint event.

RESULTS

To date, 1,300 patients have been included. A preliminary analysis of 350 patients (mean age 51.9 years, 38.9% male) showed that 78.9% had primary brain tumors, and 72.0% underwent surgery. Median follow-up was 3.5 years, with 37.7% mortality. Of the tumors, 230(65.7%) were primary glial tumors (WHO Grade I: 6.2%, Grade II: 16.5%, Grade III: 17.4%, Grade IV: 25.6%). 74.5% patients underwent radiation therapy, 52.3% patients underwent chemotherapy; and 45.2% underwent both. Table presents the IVW findings. At baseline, no cases of vasculitis or moyamoya disease were observed. However, 4 patients (1.1%) were found to have an aneurysm, and 2 patients (0.8%) had arterial dissection. Atherosclerosis was present in 36.5% of patients, with 22.3% having multiple plaques. A total of 291 plaques were identified, of which 238 (81.8%) showed enhancement. Specifically, 194 (66.7%) plaques exhibited grade 1 enhancement, while 48 (16.5%) had grade 2 enhancement. Over time, plaque prevalence increased to 41.4%, with 25.7% having multiple plaques. Among these, 81.5% of plaques showed enhancement, including 64.8% with grade 1 enhancement and 61 18.2% with grade 2 enhancement. AIS occurred in 5.1% of patients, with 8 out of 12 cases having plaques in the stroke-affected vascular territory.

CONCLUSION

In this study, we observed a significant prevalence of intracranial atherosclerotic plaques among brain tumor patients, with an increase in plaque burden over time.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the importance of early detection and management of ICAD to mitigate stroke risk and improve patient outcomes.

T2-SPNR-14 FINE-TUNED SEGMENT ANYTHING MODEL FOR AUTOMATIC INTRACRANIAL ANEURYSM SEGMENTATION IN TIME-OF-FLIGHT MR ANGIOGRAPHY: COMPARISON WITH NON-RADIOLOGIST PHYSICIANS

Juyeon Yi, MD (*Presenter*)
Dahye Lee (*Abstract Co-Author*)
Honggeun Cho, MD (*Abstract Co-Author*)
Kwanseok Oh (*Abstract Co-Author*)
Bumcheol Hwang (*Abstract Co-Author*)
Joon Young Kim (*Abstract Co-Author*)
Minjin Song (*Abstract Co-Author*)
Doo Young Lee, MD, MS (*Abstract Co-Author*)
Jin Wook Choi, MD, PhD (*Abstract Co-Author*)
Hyun S. Choi, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the performance of a Segment Anything Model (SAM)-based Artificial Intelligence (AI) model fine-tuned for automatic detection and segmentation of intracranial aneurysms on Time-of-Flight MR angiography (TOF-MRA).

METHODS AND MATERIALS

The AI model, fine-tuned on 397 TOF-MRA scans, enhances SAM by integrating convolutional neural network-based encoder features and a self-prompting module for tiny lesion segmentation. The AI model and two non-radiologist physicians assessed 30 aneurysm-containing TOF-MRA scans not used in training. We compared patient- and lesion-wise sensitivity, lesion-wise positive predictive value (PPV), segmentation accuracy (Dice Similarity Coefficient, DSC), and patient-wise segmentation time. DSC was measured based on manual annotations by a neuroradiologist with 15 years of experience. The same comparisons were conducted in subgroups stratified by aneurysm size (small <5 mm vs. large =5 mm), location, and lobularity.

RESULTS

Among the 30 TOF-MRA scans, a total of 52 aneurysms were detected and segmented. Of these, 84.6% were small, 40.4% were in the middle cerebral artery, and 78.8% were unilobular. The AI model achieved 76.7% patient-wise sensitivity, 82.7% lesion-wise sensitivity, 84.3% PPV, and a median DSC of 69.7 (IQR 48.4-78.4), showing comparable performance to human readers—Reader 1: 63.3%, 69.2%, 80.0%, and 71.2 (IQR 52.3-81.7), respectively; Reader 2: 63.3%, 69.2%, 85.7%, and 73.4 (IQR 62.3-77.8), respectively. The AI model completed segmentation in a median time of 0.74 min (IQR 0.65-0.79), notably faster than human readers (both $P < .001$). In size-stratified analysis, the AI model showed a trend toward higher sensitivity (81.8%) for small aneurysms than human readers (both 63.6%), reaching statistical significance compared to Reader 2 ($P = .039$) and borderline significance compared to Reader 1 ($P = .077$). The AI model yielded similar segmentation accuracy between small and large aneurysms ($P = 1.000$), while human readers tended to show higher accuracy for large aneurysms (Reader 1: $P = .086$; Reader 2: $P = .014$). No significant differences were found within each location or lobularity subgroup.

CONCLUSION

The SAM-based AI model showed a tendency toward higher sensitivity for detecting small aneurysms than non-radiologist physicians. It also achieved consistent segmentation performance across aneurysm sizes, unlike human readers whose accuracy showed a declining trend for small aneurysms. Additionally, it completed segmentation markedly faster than the physicians.

CLINICAL RELEVANCE/APPLICATION

Fine-tuned SAM-based AI model may assist non-expert clinicians in detecting small aneurysms reliably, particularly in settings with limited neuroradiologist support.

T2-SPNR-15 TOPOLOGICAL DISRUPTION OF WHITE MATTER NETWORKS IN ANTIPSYCHOTIC-TREATED SCHIZOPHRENIA WITH METABOLIC SYNDROME: A DTI GRAPH THEORY STUDY

Ying LI (*Presenter*)

PURPOSE

Patients with chronic schizophrenia often develop metabolic syndrome (MS) during antipsychotic treatment, potentially altering white matter microstructure. This study examines white matter network topology in schizophrenia patients with MS using DTI graph theory, and explores correlations with MS indicators.

METHODS AND MATERIALS

The study included 26 schizophrenia patients with MS (SZ-MS), 22 without MS (SZ-nMS), and 24 healthy controls (HC). White matter networks were reconstructed from DTI data and analyzed using graph theory. Group differences in network topology were assessed ANCOVA with Bonferroni correction, and correlations with clinical measures (e.g., BMI, waist/hip circumference) were evaluated.

RESULTS

At the global level, compared with the HC group, both patient groups showed increased normalized clustering coefficient and small-worldness, with decreased local efficiency (all $p < 0.05$). Furthermore, the SZ-MS group demonstrated an increase in small-world networks and decreases in global and local efficiency (all $p < 0.05$). At the nodal level, both patient groups exhibited reduced NE and increased NLp versus HC in the prefrontal cortex, left precentral/postcentral gyri, parietal cortex, bilateral thalamus, and right superior temporal gyrus (all $p<0.05$). Compared to SZ-nMS, the SZ-MS group showed more pronounced NE reductions and NLp increases in the prefrontal cortex, left angular gyrus, right superior parietal gyrus, and right superior temporal gyrus (all $p<0.05$). Notably, NE in left triangular part of superior frontal gyrus ($r=-0.358$), right dorsolateral superior frontal gyrus ($r=-0.322$), left angular gyrus ($r=-0.425$), and right superior temporal gyrus ($r=-0.353$) inversely correlated with waist circumference, while NLp showed positive correlations ($r = -0.356$, $r = -0.35$, $r = -0.416$, $r = -0.349$) in these regions.

CONCLUSION

SZ-MS exhibits distinct white matter network disruptions, featuring enhanced small-worldness but impaired information transfer efficiency. Notably, these patients showed more pronounced NE reductions and NLp increases in the prefrontal cortex, left angular gyrus, right superior parietal gyrus, and right superior temporal gyrus. These alterations significantly correlated with metabolic indices, suggesting MS may exacerbate white matter damage in schizophrenia.

CLINICAL RELEVANCE/APPLICATION

Chronic schizophrenia patients with MS show more severe white matter network topological disruptions, providing neuroimaging evidence for MS-associated neuropathology.

T2-SPNR-17 DIAGNOSTIC EVALUATION OF A NOVEL ACCELERATED 2D FAST SPIN ECHO-BASED FLAIR IMAGING AT 3T

Chen-Hua Chiang, MD (*Presenter*)
Ajeetkumar Gaddipati (*Abstract Co-Author*)
Eugene Milshteyn, PhD (*Abstract Co-Author*)
Mary Thomas, ARRT (*Abstract Co-Author*)
Anand Kumar Venkatachari (*Abstract Co-Author*)
Susie Y. Huang, MD, PhD (*Abstract Co-Author*)
Ivan Jambor, MD,PhD (*Abstract Co-Author*)

PURPOSE

Routine whole brain high 2D fast spin echo-based (FSE) FLAIR imaging can take 4-5 minutes at 3T using routine methods, limiting clinical use.

METHODS AND MATERIALS

Twenty-five consecutive patients underwent brain MRI at 3T, which included FSE 2D FLAIR (TR/TE 8000/78, auto TI, FOV 220x220, Acquisition Matrix 320x224, Echo Train Length 14, Flip Angle 160, acquisition time 3:21 minutes) and a novel VORTEX (VERSE SAR reduction, Optimized RF waveform, Refocus flip angle modulation, Tuned Hyper Echoes, External volume suppression, X-factor spin efficiency) FLAIR (TR/TE 8000/102, auto TI, FOV 220x220, Acquisition Matrix 320x224, Echo Train Length 29, Flip Angle 180, 2:17 minutes). Two board-certified neuroradiologists independently performed blinded, randomized, head-to-head qualitative assessments using a published 5-point scale for: motion artifact, perceived noise, gray-white matter (GM/WM) differentiation, perceived sharpness, and overall diagnostic quality. Discrepant ratings were resolved by adjudication from a third neuroradiologist. Interrater agreement was quantified using weighted Cohen ? statistics. Superiority testing was performed using a one-sided Wilcoxon signed-rank test while equivalence was assessed using two one-sided Wilcoxon tests with a pre-specified equivalence margin of ±1 point.

RESULTS

In the 25 (mean age: 62.1 ± 17.2 years; 18 females, 7 males) patients, almost perfect interrater agreement was observed for GM/WM differentiation (? = 1.00, $p < 0.001$), with substantial agreement for motion artifact (? = 0.73, $p < 0.001$) and fair agreement for perceived noise (? = 0.26, $p = 0.040$) was observed. Perceived sharpness and overall diagnostic quality demonstrated high raw agreement (96% and 92%, respectively), although ? values were low due to low rating variability. VORTEX FLAIR demonstrated significantly better perceived noise ratings compared to standard FLAIR (FDR-adjusted $p = 0.012$). The remaining 4 categories demonstrated statistical equivalence within a ±1-point margin.

CONCLUSION

VORTEX FLAIR significantly improved perceived noise ratings and was equivalent to standard 2D FLAIR across all other image quality domains, while reducing scan time by 32%, supporting the use of VORTEX FLAIR in routine clinical practice.

CLINICAL RELEVANCE/APPLICATION

2D fast spin echo-based FLAIR imaging is an important part of routine brain MRI protocol. However, acquisition time for high resolution 2D FLAIR can be more than 4 min. We have evaluated a prototype 2D fast spin echo-based FLAIR technique at 3T and demonstrated that this method is feasible with 32% scan time reduction compared to the standard 2D fast spin echo-based FLAIR.

T2-SPNR-18 MRI-LEVEL DIAGNOSTIC PERFORMANCE IN NEURODEGENERATION CLASSIFICATION ON HEAD CT AIDED BY SUPER-RESOLUTION SYNTHETIC MRI

Robert C. Chen, MD (*Abstract Co-Author*)
Eng King Tan (*Abstract Co-Author*)
Beng Chin Ooi (*Abstract Co-Author*)
Ling Ling Chan, MBBS, FRCR (*Abstract Co-Author*)

PURPOSE

Accurate brain parcellation is crucial for identifying regional brain atrophy in neurodegenerative disorders. While this capability is commercially available on MRI, it is lacking on CT, a fast, accessible and economical imaging modality. To address this gap, we developed an automated multistage brain parcellation pipeline for neurodegeneration classification using head CT.

METHODS AND MATERIALS

We collected paired head CT-MRI data from (1) 486 prospectively recruited subjects (385 healthy controls, 101 with dementia or parkinsonian disorders) who underwent same-day scans and (2) 586 retrospectively recruited patients (429 without focal intracranial lesions, 157 with dementia or parkinsonian disorders) who underwent same-month scans across scanner mix and field strengths (1.5T and 3T). All MRI comprised 3D T1-weighted MPRAGE with 1 mm 3 isotropic resolution. Synthetic MR images were generated from CT data using FreeSurfer's deep learning-based SynthSR. Lobe-based brain parcellation was performed on both CT-derived synthetic MRI and directly acquired MPRAGE MRI images using FreeSurfer. Brain structure volumes from both hemispheres were used as features in the classification pipeline, with all volumetric measurements normalized by age and intracranial volume (ICV). We employed resampling techniques to address class imbalance. Using a 30:20:50 data split, we trained, validated and tested gradient boosting classifiers (CatBoost, XGBoost, and LightGBM) to perform classification of patients with neurodegeneration.

RESULTS

CT-derived synthetic T1-weighted MRI showed high similarity to directly acquired MPRAGE, with a Dice similarity coefficient of 0.91 ± 0.05 and normalized root mean square error of 1.15 ± 0.39. Volume difference was minimal (1.76%) and not statistically significant ($p = 0.59$). CatBoost-based binary classifier using brain volume features from synthetic MRI achieved an ROC-AUC of 0.82 in distinguishing healthy controls from patients, comparable to the MRI benchmark (AUC 0.83).

CONCLUSION

SynthSR enables generation of high-fidelity synthetic T1-weighted MRI from CT data, allowing robust brain parcellation and classification of neurodegeneration from head CT with diagnostic performance on par with the commercial MRI standard.

CLINICAL RELEVANCE/APPLICATION

Head CT is an indispensable tool for exclusion of intracranial haemorrhage in the Emergency Department given the silent epidemic of adult fall-related head injuries, and constitutes significant neuroradiology caseload. Automated MRI-level diagnostic performance in neurodegeneration classification using head CT holds promise as an opportunistic screening tool for detection of neurodegeneration and triage for early rehabilitative measures.

T2-SPNR-19 A MULTITASK MULTIMODAL NEUROIMAGING AND GENETIC FRAMEWORK FOR JOINT PREDICTION OF COGNITIVE DECLINE AND CONVERSION TIME IN PRECLINICAL ALZHEIMER'S DISEASE

Gorkem Durak, MD (*Presenter*)
Salma Hassan (*Abstract Co-Author*)
Mostafa Salem (*Abstract Co-Author*)
Vijay R. Papineni, FRCR,MBBS (*Abstract Co-Author*)
Ayman Elsayed (*Abstract Co-Author*)
Mohammad Yaqub (*Abstract Co-Author*)

PURPOSE

To address the critical need for early detection tools in preclinical Alzheimer's Disease (AD), we developed and validated a novel AI approach capable of simultaneously predicting cognitive decline and time-to-conversion, informing timely intervention decisions.

METHODS AND MATERIALS

We developed MAGNET-AD, a multimodal approach integrating longitudinal structural and functional MRI scans, genetic data, and clinical assessments from 1,787 clinically normal older individuals (ages 65-85) with elevated amyloid levels from the A4 study. Brain MRIs were segmented to identify 32 distinct brain structures. Radiomic features were extracted from each structure while functional MRI (fMRI) data captured functional connectivity patterns. A foundational model, pretrained on large-scale neuroimaging datasets including dementia patients, was leveraged to extract rich anatomical embeddings that captured subtle structural variations relevant to early neurodegeneration. All data modalities were fused using a spatiotemporal graph neural network architecture, representing brain regions and genetic markers as interconnected nodes evolving over time. The model was evaluated using a five-fold cross-validation.

RESULTS

MAGNET-AD achieved a concordance index of 0.858 for conversion time prediction and a mean squared error of 1.983 for PACC prediction, significantly outperforming existing approaches. The model maintained robust performance even with limited temporal data. Model interpretability analysis revealed progressive shifts in the importance of brain regions across visits, with attention patterns aligning with the established Braak staging of AD pathology progression. Visualization of regional importance across longitudinal visits showed increasing attention to temporal, parietal, and frontal regions at later visits, consistent with known patterns of tau and amyloid spread.

CONCLUSION

MAGNET-AD demonstrates superior capability in modeling the complex interplay between genetic factors and longitudinal brain changes in preclinical AD, providing both accurate predictions and interpretable insights into disease mechanisms that correlate with established neuropathological staging.

CLINICAL RELEVANCE/APPLICATION

MAGNET-AD enables clinicians to identify high-risk patients earlier in disease progression, prioritize resources for those with faster predicted conversion times, and monitor treatment efficacy through changes in predicted trajectories. The model's attention maps provide visual confirmation of disease progression patterns aligned with Braak staging, offering clinically interpretable validation that supports adoption in clinical practice.

T2-SPOB-3 THE VALUE OF MDIXON-QUANT AND DWI QUANTITATIVE TECHNIQUES IN DIFFERENTIATING AGGRESSIVE FROM NON-AGGRESSIVE ENDOMETRIAL CARCINOMA: A COMPARATIVE ANALYSIS

Wei Kong (*Presenter*)

PURPOSE

To compare the value of apparent diffusion coefficient (ADC) and the modified Dixon-Quant (mDixon-Quant) technique in differentiating aggressive from non-aggressive endometrial carcinoma (EC).

METHODS AND MATERIALS

The data of 78 patients with EC confirmed by operation and pathology were retrospectively analyzed, including 30 aggressive cases and 48 non-aggressive cases. The preoperative MRI sequences included diffusion-weighted imaging (DWI) and mDixon-Quant imaging. After post-processing, fat fraction (FF), T2 * , transverse relaxation rate (R2 *), and apparent diffusion coefficient (ADC) maps were obtained. The FF, T2 * , R2 * and ADC mean values in lesions of the two groups of cases were measured by two radiologists (with more than 10 years of experience in MR diagnosis of pelvic diseases, both), who were blind to the pathological data, in the registered fusion maps which was based on fat suppression T2-weighted imaging. The independent-samples t -test or Mann-Whitney U test was performed to analyze the differences of each parameter values between the two groups. The receiver operating characteristic curve was used to evaluate the efficiency of the parameters with statistical difference in differentiating aggressive and non-aggressive of EC. Area under the curve (AUC), corresponding cut-off value, sensitivity and specificity were calculated.

RESULTS

The T2 * value in the aggressive group was significantly lower than that in the non-aggressive group, while the R2 * and ADC values were higher (all $P < 0.05$). There was no statistically significant difference in FF value between the two groups ($P > 0.05$). Based on a single parameter diagnosis, when T2 * value was 60.71 ms, the sensitivity was the highest (86.7%), and when R2 * value was 20.59 Hz, the specificity was up to the highest (79.2%). The AUCs of T2 * , R2 * , ADC and combined T2 * + R2 * +ADC values for differentiating the two groups of ECs were 0.799, 0.785, 0.656 and 0.799, respectively. The AUC of combined T2 * + R2 * +ADC values was not statistically different from those of T2 * , R2 * and ADC values (all $P > 0.05$).

CONCLUSION

Our study shows that mDixon-Quant and DWI techniques can differentiate aggressive from non-aggressive EC, which has the certain clinical utility, with better performance of T2 * value.

CLINICAL RELEVANCE/APPLICATION

According to the International Federation of Obstetrics and Gynecology (FIGO) 2023 guidelines, aggressive or non-aggressive histological type of EC has become an important basis for staging and treatment. The MR quantitative techniques can reflect the biological behavior, with the potential as a noninvasive tool to provide the reference for clinical treatment.

T2-SPOB-4 TIME-DEPENDENT DIFFUSION MRI FOR NON-INVASIVE DIFFERENTIATION OF CERVICAL CANCER: CORRELATION WITH PATHOLOGICAL CHARACTERISTICS

Wenyi Yue, MD (*Presenter*)
Junzhong Xu, PhD (*Abstract Co-Author*)
Chaoyang Jin (*Abstract Co-Author*)
xiaoyu jiang (*Abstract Co-Author*)
Dandan Zheng (*Abstract Co-Author*)
Qi Yang, MD (*Abstract Co-Author*)

PURPOSE

Time-dependent diffusion MRI enables cellular-level characterization of tissue microstructure but remains understudied in cervical lesions. Our study aimed To assess time-dependent diffusion MRI-derived microstructural parameters for the noninvasive differentiation of cervical lesions and the pathological characteristics of cervical cancer (CC).

METHODS AND MATERIALS

This prospective study included 102 patients with clinical suspicion of CC or cervical intraepithelial neoplasia (CIN) who underwent time-dependent diffusion MRI between January 2024 and February 2025. The IMPULSED method was performed to extract microstructural parameters, including cell diameter, intracellular volume fraction (vin), cellularity, and extracellular diffusivity (dex), along with three apparent diffusion coefficient measurements. Pearson correlation analysis was performed to evaluate the association between microstructural parameters and histopathological features. Diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUC).

RESULTS

A total of 74 women who underwent colposcopy or surgery were enrolled. Time-dependent diffusion MRI-derived microstructural parameters can not only differentiate among cervical squamous carcinoma (CSC), cervical adenocarcinoma (CA), and CIN lesions ($P <.05$) but also demonstrate the feasibility to distinguish CC cohorts with various pathological characteristics ($P <.05$). v in exhibited the highest single-parameter AUC of 0.85 for distinguishing CSC from CA. For CSC vs CIN, D 17Hz achieved the best AUC (0.82). In distinguishing CA from CIN, cellularity achieved the highest individual AUC (0.75). Moreover, microstructural parameters demonstrated robust performance in classifying tumor grade (AUC, 0.76), tumor stage (AUC, 0.87), lymph-vascular space invasion status (AUC, 0.77), lymph node metastasis status (AUC, 0.94), Ki67 expression level (AUC, 0.74), and parametrial invasion status (AUC, 0.79). These parameters also showed strong correlations with corresponding pathological features ($r = 0.59$-0.82; $P<.01$).

CONCLUSION

This study presents the first application of time-dependent diffusion MRI in CC, demonstrating that cellular-level microstructural parameters offer superior diagnostic performance in distinguishing cervical neoplastic subtypes and classifying histopathological features in CC.

CLINICAL RELEVANCE/APPLICATION

These findings lay the groundwork for exploring the integration of preoperative time-dependent diffusion MRI into CC management to inform treatment planning, which will be validated using larger samples in future studies.

T2-SPPD-1 T1 RELAXATION TIME MEASUREMENT USING CS-MP2RAGE FOR PEDIATRIC MYELINATION ASSESSMENT

Younghee Yim, MD, PhD (*Presenter*)
Leehi Joo, MD (*Abstract Co-Author*)
Hye Shin Ahn, MD (*Abstract Co-Author*)
Jungbin Lee, MD (*Abstract Co-Author*)

PURPOSE

Despite quantifying myelination is essential for evaluating a wide range of clinical conditions, there is currently no established gold standard for its assessment. Quantitative mapping of MRI relaxation times is expected to provide reliable information to uncover the subtler changes than standard MRI. This study aimed to assess the clinical feasibility of accelerated quantitative T1 mapping using compressed sensing magnetization-prepared 2 rapid acquisition gradient echoes (CS-MP2RAGE) in children, as a method for T1 relaxation time measurement.

METHODS AND MATERIALS

A total 34 pediatric subjects (age range 18 months to 15 years) who underwent brain MRI, including CS-MP2RAGE sequence for growth screening without pathological MRI findings, were evaluated. Whole-brain T1 mapping was performed using a 3T MRI scanner. Mean T1 relaxation times were automatically calculated for brain structured based on volumetric segmentation from the T1 maps generated by CS-MP2RAGE. T1 relaxation times were analyzed across 36 brain regions, including the corpus callosum, white matter, deep gray matter and brain stem. Subsequently, we derived regression analysis for mean value and confidential interval.

RESULTS

Strong negative correlations were observed between T1 relaxation times in the basal ganglia structures, cerebral and cerebellar white matter, brain stem and the age of subjects ($r = -0.6$ - -0.7, $p < 0.001$). When analyzing the relationship between brain volume and T1 relaxation time, brain white matter- excluding the occipital lobe- also demonstrated strong negative correlations ($r = -0.6$ - -0.7, $p < 0.001$), while the basal ganglia and brain stem showed moderate negative correlations ($r = -0.4$ - -0.5, $p < 0.001$). Overall, T1 relaxation times in the pediatric brain decreased rapidly across all regions during the first three years of life and stabilized thereafter. The mean acquisition time for the CS-MP2RAGE was approximately 4 minutes, representing a ~ 50% reduction compared to the standard protocol.

CONCLUSION

Quantifying T1 relaxation time with CS-MP2RAGE based T1 mapping may help detect subtle changes in the pediatric brain in affordable scan time. This approach may facilitate the early detection of subtle alterations in brain tissue, enabling timely intervention or prevention strategies in pediatric patients.

CLINICAL RELEVANCE/APPLICATION

CS-MP2RAGE enables reliable T1 mapping with an affordable scan time of approximately 4 minutes. Since T1 relaxation time measurement using CS-MP2RAGE can allow for consistent qualitative evaluation of myelination and other subtle alteration of brain tissue, so we can expect early detection of possible abnormality and timely intervention in pediatric patients.

T2-SPPD-4 ALTERED SPONTANEOUS BRAIN ACTIVITY IN OBESE CHILDREN: A RESTING-STATE FUNCTIONAL MRI STUDY

Xin Wang, MD (*Presenter*)

PURPOSE

To identify resting-state neural signatures differentiating pediatric simple obesity (Simple OB) from obesity with metabolic syndrome (OB+MS) and establish their clinical-behavioral correlates.

METHODS AND MATERIALS

This prospective study enrolled 55 obese children (35 Simple OB, 20 OB+MS) and 24 age- and sex-matched healthy controls. Participants underwent resting-state fMRI (ALFF/fractional ALFF [fALFF] mapping), anthropometric assessments, metabolic profiling, and validated behavioral questionnaires (CEBQ/PAQ-C). Group differences in regional neural activity were analyzed via ANCOVA (covariates: age/sex) with Tukey's post-hoc testing. Significant clusters were correlated with clinical-behavioral measures using Pearson's coefficients.

RESULTS

(1) Group Differences: The OB+MS group demonstrated significantly higher ALFF in the right fusiform gyrus ($p = 0.0029$) and right precuneus ($p < 0.0001$) compared to the Simple OB group. Both obese groups showed increased ALFF versus HC in the right fusiform gyrus (Simple OB: $p = 0.0002$; OB+MS: $p < 0.0001$), right superior occipital gyrus (both $p < 0.0001$), and left inferior temporal gyrus (Simple OB: $p < 0.0001$; OB+MS: $p = 0.0001$). (2) Clinical Correlations: Right fusiform gyrus ALFF correlated with BMI ($r=0.6937$), TBF% ($r=0.2675$), ALT ($r=0.3853$), and AST ($r=0.3579$). Right precuneus ALFF associated with BMI ($r=0.3429$), TG ($r=0.2697$), DBP ($r=0.3737$), and HDL-C ($r=-0.3181$). Right superior occipital gyrus ALFF correlated with BMI ($r=0.6365$) and DBP ($r=0.2968$). (3) Behavioral Correlations: Left inferior temporal gyrus ALFF negatively correlated with CEBQ Emotional Undereating scores ($r=-0.5205$). Right superior occipital gyrus ALFF negatively associated with PAQ-C scores ($r=-0.4776$). (4) fALFF Findings: The OB+MS group exhibited higher fALFF in the right orbital middle frontal gyrus versus Simple OB ($p = 0.0002$), correlating with FBG ($r=0.3150$). Both obese groups showed increased fALFF in the left inferior temporal gyrus and right cingulate/paracingulate gyri versus HC (all $p < 0.0001$).

CONCLUSION

This study identified distinct neurofunctional signatures in pediatric obesity subtypes: (1) OB+MS showed hyperactivity in right fusiform gyrus and precuneus correlating with liver enzymes and lipids; (2) obese groups had occipitotemporal hyperactivity reflecting adiposity; (3) orbitofrontal hyperactivity in OB+MS linked to hyperglycemia. Behavioral correlations showed temporal/occipital ALFF inversely related to eating and activity.

CLINICAL RELEVANCE/APPLICATION

Right fusiform and precuneus ALFF increases may serve as neuroimaging biomarkers for early detection of metabolic syndrome in pediatric obesity, guiding targeted monitoring and intervention.

T2-SPPH-2 QUANTIFICATION ACCURACY, CONSISTENCY, AND IMAGE QUALITY IN DEEP-LEARNING CT RECONSTRUCTION KERNELS OPTIMIZED FOR PULMONARY IMAGING

Fong Chi Ho, MS (*Presenter*)
Mojtaba Zarei, PhD (*Abstract Co-Author*)
Steve Bache (*Abstract Co-Author*)
Ben Hauser (*Abstract Co-Author*)
Amar Kavuri (*Abstract Co-Author*)
Bryan O'Sullivan-Murphy, MD,PhD (*Abstract Co-Author*)
Ehsan Samei, PHD (*Abstract Co-Author*)
Ehsan Abadi, PhD (*Abstract Co-Author*)

PURPOSE

State-of-the-art deep-learning image reconstruction (DLIR) kernels have been specifically trained and optimized for chest CT. However, their performance remains to be established in terms of quantitative accuracy, consistency, and image quality. This study aimed to evaluate whether a newly developed suite of DLIR Lung kernels improves biomarker measurement accuracy, consistency, and image quality compared to the established technique of adaptive statistical iterative reconstruction (ASiR).

METHODS AND MATERIALS

Low-dose lung cancer screening CT scans were acquired from 50 patients. Sinograms were reconstructed using an FDA-cleared software (TrueFidelity, GE) with both ASiR and DLIR techniques, each with three denoising strengths and two slice thicknesses using the Standard kernel. Additionally, the DLIR technique included a Lung kernel. To complement the patient data, physical phantoms (Mercury, Gammex, and Kyoto) were imaged and quantified to systematically assess image quality and quantification accuracy. Lung imaging biomarkers included lung density (Perc15, LAA-950) and airway morphology (WA%, Pi10). Quantitative consistency was evaluated by computing per-patient differences (?) in relative to a reference setting. Tracheal HU and inter-patient variability were also analyzed to assess measurement robustness across reconstruction settings. Image quality metrics included modulation transfer function (MTF), noise power spectrum (NPS) and global noise index (GNI).

RESULTS

Compared to ASiR, DLIR-Lung reconstructions improved spatial resolution by up to 24%. When the highest denoising strength was applied, image noise was reduced by 36% in DLIR-Standard and 8% in DLIR-Lung. DLIR-Lung at high denoising strength demonstrated the most accurate and consistent tracheal air HU (-990.1±44.0) and enabled the visualization of the most distal airway generations (9.3 ± 0.7), outperforming ASiR kernels (<7).

CONCLUSION

DLIR-Lung reconstructions, particularly at high and medium strengths, consistently outperformed DLIR-Standard and ASiR in image quality, airway visibility and biomarker accuracy. Compared to ASiR-Standard and DLIR-Standard, DLIR-Lung showed lower noise, more airway generation detectability and more consistent quantification of lung density and airway wall area. These findings highlight the potential of DLIR-Lung for robust and consistent quantitative chest CT analysis.

CLINICAL RELEVANCE/APPLICATION

The study highlights that DLIR, using a kernel optimized for pulmonary imaging, improved image quality and enabled accurate and consistent quantification of both density- and airway-based biomarkers. These advancements may lead to improved diagnostic accuracy and management of pulmonary conditions.

T2-SPPH-5 COMPARISON OF LUNG TUMOR VOLUMES ACROSS 3D CT, 4D CT AND 4D CBCT MODALITIES AND THEIR RELATION TO BREATHING AMPLITUDE

Sunyoung Jang, PhD (*Presenter*)
Zhonglu Wang, PHD (*Abstract Co-Author*)
Kamal Jyot Kota, MS (*Abstract Co-Author*)
Joseph A. Miccio, MD (*Abstract Co-Author*)
Alexei Chvetsov, PhD (*Abstract Co-Author*)
Mitchell Machtay, MD (*Abstract Co-Author*)

PURPOSE

To compare lung tumor volumes measured on free-breathing CT, 4D CT AIP, 4D CT MIP, and 4D CBCT AIP in SBRT patients, and to assess whether anterior-posterior (A-P) breathing amplitude relates to the inter-modality volume differences.

METHODS AND MATERIALS

Fifteen patients with lung tumors underwent free-breathing 3D CT and 4D CT imaging for SBRT planning and 4D CBCT for SBRT image guidance prior to treatment delivery. The 4D acquisitions were performed using an abdominal compression belt. Gross tumor volumes (GTVs) were contoured using MIM software's edge detection tool on all imaging modalities. A-P breathing amplitudes were extracted from the RGSC system. Friedman and Wilcoxon signed-rank tests with Bonferroni correction were used for volume comparison. Bland-Altman analysis and intraclass correlation coefficient (ICC) were used to assess agreement. Spearman's rank correlation was used to evaluate the relationship between breathing amplitude and volume differences.

RESULTS

Significant differences in target volumes were observed among modalities (Friedman test, $p < 0.00001$). IGTVs derived from 4D CT MIP (median: 2.26 cc), which captured the full extent of tumor motion, were significantly larger than those from 3D CT (1.36 cc), 4D CT AIP (1.41 cc), and 4D CBCT AIP (1.88 cc) ($p < 0.05$). Motion-averaged images (4D CT AIP and 4D CBCT AIP) demonstrated similar tumor volume estimates; Bland-Altman analysis confirmed tight consistency between AIP-based

modalities. The ICC across all modalities was 0.878, indicating good reliability and agreement. No significant correlation was found between A-P amplitude (avg: 3.8 mm) and volume differences (Spearman ? = 0.02-0.25, p > 0.36).

CONCLUSION

Lung tumor volumes derived from 3D CT, 4D CT, and 4D CBCT were consistent and reliable with compression-based motion management. A-P breathing amplitude with the compression belt does not significantly correlate with tumor volume differences across imaging modalities. Incorporating 4D CBCT for patient setup provides an effective verification of target localization prior to radiation delivery in lung SBRT.

CLINICAL RELEVANCE/APPLICATION

This study supports the use of 4D CT and 4D CBCT with an abdominal compression belt as a reliable method for motion management. The lack of correlation between A-P breathing amplitude and inter-modality volume differences suggests that abdominal compression effectively reduces variability from respiratory motion. Incorporating 4D CBCT imaging during patient setup enables accurate verification of tumor positioning and alignment with planning volumes for precise dose delivery. These findings reinforce the clinical value of 4D imaging in motion-managed SBRT and support the integration of 4D CBCT as an effective image guidance tool.

T2-SPPH-6 GPU ACCELERATED SINGLE PHOTON IMAGING SIMULATION—VALIDATION AND PERFORMANCE EVALUATION

Zhihua Qi, PhD (*Presenter*)

PURPOSE

To validate a GPU accelerated single photon imaging simulation software library and evaluate its performance through tests based on NEMA standards, with a focus on sensitivity and spatial resolution in both planar and SPECT acquisition modes.

METHODS AND MATERIALS

The software library was written in C and Python with CUDA extensions. In the simulation of photon interactions, Woodcock tracking was utilized for efficient tracking of photons across the voxelized geometry. The angular response function method was used for efficient modeling of the interactions of the incident photons with collimators, a key aspect unique to single photon imaging. Simulations of phantom acquisitions by a Symbia Intevo SPECT/CT system (Siemens Healthineers, Erlangen, Germany) were performed and the results were compared against those obtained via experimental acquisition. A selected group of tests based on NEMA standards [4] were included in our work: (1) system planar sensitivity, (2) system volume sensitivity, (3) system spatial resolution without scatter, (4) whole-body system spatial resolution, and (5) SPECT reconstructed spatial resolution. Simulations were run on a PC equipped with an Intel Core i5-11400 CPU and an NVIDIA GeForce RTX 3060 GPU. SPECT reconstructions of the simulated data were performed using the MLEM algorithm in CASToR.

RESULTS

Based on the simulations, the system planar sensitivity and the system volume sensitivity were 335.90 cpm/μCi and 8.92×10^5 cps·mL/MBq, respectively. Their differences from the experimental measured values were 3.55% and 8.25%, respectively. The FWHM across the line source from the simulated and experimentally acquired images also agreed with within approximately 10% (3.51 mm vs 3.88 mm on trans-axial slices).

CONCLUSION

The GPU-accelerated software library for single photon imaging simulation is capable of simulating realistic images mimicking those acquired by clinical system. It can provide valuable guidance to Theranostic treatment through clinically oriented simulations.

CLINICAL RELEVANCE/APPLICATION

The software library allows rapid simulation (on the order of minutes without the need of extensive computing resources) of realistic clinical images acquired by Gamma camera systems. It would add value to numerous Theranostic applications, such as the optimization of quantitative imaging protocols to support post-treatment dosimetry and quick assessment of clinical outcomes through virtual clinical trials.

T2-SPPH-8 DUAL-PARAMETER OPTIMIZED ULTRA-LOW-DOSE CT FOR LUMBAR BONE MINERAL DENSITY ASSESSMENT: A PROSPECTIVE VALIDATION OF RADIATION REDUCTION AND DIAGNOSTIC ACCURACY

Mengqiang Xiao, MMEd (*Presenter*)
Rulin Xu (*Abstract Co-Author*)
Jun Chen (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility of a novel dual-parameter optimized ultra-low-dose CT (ULD-CT) protocol for quantitative lumbar bone mineral density (BMD) assessment, comparing its radiation dose, image quality, and diagnostic performance against standard-dose CT (SD-CT).

METHODS AND MATERIALS

In this prospective study, 245 patients scheduled for lumbar surgery underwent paired CT examinations using SD-CT (120 kV/250 mAs) and ULD-CT (100 kV/30 mAs) protocols. Radiation dose parameters (CTDIvol, DLP, and effective dose [ED]), objective (noise, signal-to-noise ratio, contrast-to-noise ratio) and subjective image quality (5-point Likert scale) were compared between groups. Volumetric BMD (vBMD) was measured on quantitative CT datasets, and subjects were categorized as having normal bone mass, osteopenia, or osteoporosis according to American College of Radiology criteria. Diagnostic accuracy was evaluated using receiver operating characteristic (ROC) curve analysis.

RESULTS

ULD-CT reduced radiation dose by 92.5% compared to SD-CT (ED: 0.88 vs. 11.68 mSv; CTDIvol: 1.93 vs. 25.66 mGy, both P < 0.001). Despite lower objective (P = 0.001-0.01) and subjective image quality (P < 0.001), ULD-CT maintained diagnostic acceptability (scores =3; interobserver ICC = 0.73). ULD-CT showed slight BMD overestimation but no significant differences in gender, age, or osteoporosis subgroups (P > 0.05). ROC analysis demonstrated high diagnostic accuracy (AUC: 0.986-0.996), with sensitivity/specificity of 94.74-100% and 95.74-98.01%, respectively.

CONCLUSION

The dual-parameter optimized ULD-CT protocol substantially reduces radiation exposure while preserving sufficient image quality and high diagnostic accuracy for lumbar BMD assessment. This approach provides a safe and effective alternative for osteoporosis screening and longitudinal bone health monitoring in clinical practice.

CLINICAL RELEVANCE/APPLICATION

The implementation of a dual-parameter ULD-CT protocol in routine clinical practice offers a significant advancement for early osteoporosis screening, particularly in high-risk populations. Its marked reduction in radiation dose allows for safe, repeated evaluations, enhancing patient management and follow-up care, especially in those with degenerative spine conditions or requiring frequent monitoring.

T2-SPPH-9 EXPOSURE OF THE POPULATION TO IONISING RADIATION FROM DIAGNOSTIC MEDICAL IMAGING PROCEDURES IN FRANCE IN 2022

Celian MICHEL (*Presenter*)
Julie SAGE (*Abstract Co-Author*)
Aurelie Isambert (*Abstract Co-Author*)

PURPOSE

This study aims to establish data on the exposure of the French population to ionising radiation from medical imaging for diagnosis purposes (conventional, dental and interventional radiology, computed tomography and nuclear medicine) for the year 2022 and to analyse evolution in such data.

METHODS AND MATERIALS

The study is based on diagnostic imaging procedures taken from the National Health Data System Sample, representing approximately 2 % of the healthcare consumption of the population covered by the French health insurance schemes. In accordance with European recommendations, the exposure of individuals to ionising radiation from diagnostic procedures was assessed in terms of effective dose. Population exposure was estimated by associating an average effective dose with each type of procedure. The average effective dose associated with each procedure was determined as close as possible to clinical practice in 2022, thanks to the collection of dosimetric data in the frame of diagnostic reference levels.

RESULTS

In 2022, 42.6 % of the French population underwent one or more diagnostic imaging procedure, slightly down compared to 2017 (45.4 %). Compared with 2017, the overall annual frequency of procedures has fallen by around 8 %, from 1,181 to 1,083 procedures per 1,000 beneficiaries in 2022. This overall decrease is mainly due to a reduction of around 19 % in conventional radiology procedures. In contrast to this general trend, the frequency of CT scan procedures and diagnostic nuclear medicine procedures increased by around 11 % and 22 % respectively. The average per caput annual effective dose has risen very slightly to 1.57 mSv in 2022, compared with 1.53 mSv in 2017. Although CT scan accounts for only a small number of procedures (15.6 %), it increased and remained by far the highest contributor to collective effective dose (75.6 %). Nuclear medicine, the second largest contributor to collective effective dose, also increased. This was the modality with the largest increase between 2017 and 2022, both in frequency and, consequently, in contribution to collective effective dose.

CONCLUSION

Despite the fall in the frequency of conventional radiology procedures, leading to a fall in the total frequency of procedures, and despite a general trend towards lower doses per procedure, the French population's exposure to medical diagnoses remained stable.

CLINICAL RELEVANCE/APPLICATION

This study, carried out every 5 years at ASNR, makes it possible to monitor the national trends for the frequencies and doses of diagnostic medical imaging procedures and contributes to the UNSCEAR’s surveys to obtain this data at an international level.

T2-SPPH-12 DWI WITH ZONALLY MAGNIFIED OBLIQUE MULTI-SLICE TECHNIQUE (ZOOM DWI) VS. CONVENTIONAL DWI: INFLUENCE TO IMAGE QUALITY AND ADC EVALUATION IN PATIENTS WITH MEDIASTINAL TUMORS

Yoshiyuki Ozawa, MD, PhD (*Presenter*)
Takahiro Ueda, MD, PhD (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Natsuka Yazawa (*Abstract Co-Author*)
Kaori Yamamoto (*Abstract Co-Author*)
Yuichiro Sano, RT (*Abstract Co-Author*)
Masato Ikedo (*Abstract Co-Author*)
Masanori Ozaki (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Yoshiharu Ohno, MD, PhD (*Abstract Co-Author*)

PURPOSE

DWI with zonally magnified oblique multi-slice technique (Zoom DWI) is able to obtain DWI with smaller field-of-view (FOV) than conventional DWI (cDWI) in routine clinical practice. It enables imaging without aliasing artifacts in the phase-encoding direction by rotating the excitation pulse by a specific angle relative to the refocusing pulse,, and narrowing the FOV also helps reduce distortion caused by echo planar imaging. However, no one tested Zoom DWI for image quality and apparent diffusion coefficient (ADC) measurement improvements with cDWI in patients with mediastinal tumors. The purpose of this study was to directly compare the influence of Zoom DWI to image quality and ADC evaluation with cDWI in patients with mediastinal tumors.

METHODS AND MATERIALS

Thirty consecutive patients with mediastinal tumors underwent short-tau inversion recovery (STIR) imaging, Zoom DWI and cDWI at a 3T MR systems. For quantitative image quality comparison between both DWIs, long and short axis diameters of tumor at the slice demonstrated the maximum cross-sectional area of the tumor on STIR images and each DWI were measured. Moreover, ADC value and signal-to-noise ratio (SNR) of the tumor and muscle were also assessed by region of interest (ROI) measurements. On qualitative image quality evaluations, overall image quality, artifact and diagnostic confidence were determined by two radiologists on each DWI and ADC map. To determine the capability for improving distortion on Zoom DWI, long- and short axis diameters (LA and SA) were correlated between STIR and each DWI by Spearman’s correlation. Moreover, the limits of agreement of LA and SA between STIR image and each DWI were also assessed by Bland-Altman analysis. To compare quantitative and qualitative image quality indexes between two DWIs, paired t test or Wilcoxon’s signed rank test were performed.

RESULTS

On correlation between STIR imaging and each DWI, Zoom DWI (LA: $r=0.99$, $p<0.0001$; SA: $r=0.99$, $p<0.0001$) showed significant and better correlations than cDWI (LA: $r=0.98$, $p<0.0001$; SA: $r=0.97$, $p<0.0001$). The limits of agreement of Zoom DWI (LA: -0.84 ± 3.40 mm, SA: -0.32 ± 1.61 mm) were smaller than those of cDWI (LA: -4.11 ± 4.37 mm, SA: -2.56 ± 2.15 mm). ADC values of tumor on Zoom DWI was significantly higher than that of cDWI ($p< 0.01$). Zoom DWI showed significantly better qualitative image quality indices than cDWI ($p<0.01$).

CONCLUSION

Zoom DWI can improve image distortion and has influence to image quality and tumor ADC measurement as compared with conventional DWI.

CLINICAL RELEVANCE/APPLICATION

Zoom DWI can improve image distortion and has influence to image quality and tumor ADC measurement as compared with conventional DWI.

T2-SPRO-1 ASSESSMENT OF RADIOBIOLOGICAL EFFECTS OF CARBON ION IRRADIATION IN RAT GLIOMA BASED ON SPECTRUM CT

Yu feng Li, MMedSc (*Presenter*)

PURPOSE

Application of energy-spectrum CT for continuous and multiple observations of the effects of Carbon ion irradiation (CIR) on the proliferative activity and invasiveness of rat C6 glioma in vivo.

METHODS AND MATERIALS

Establish rat C6 glioma models. Conduct energy-spectrum CT and CT perfusion scans on tumor-bearing rats. Integrating HE and immunohistochemical staining with energy spectrum CT, we developed a multi-parametric quantitative model for rat glioma assessment; then employed this model to monitor trends in tumor proliferation, apoptosis, and invasiveness before and post-CIR 7th and 14th days in different dose. Monitor and document the physical signs and survival duration of tumor-bearing rats. Mark the rat as moribund when it refuses to eat or has severe motor impairment. Collect the whole brain and perform HE staining and immunohistochemical staining for Ki-67, a-SMA, VEGF, and CD34.

RESULTS

Enhanced energy-spectrum CT scans on the 12th day post-surgery revealed a 90% tumor formation rate, with tumor diameters ranging from 1.8 to 3.8 mm (mean 2.27 mm). CT perfusion revealed elevated CBF, CBV, and PS in the central versus peripheral tumor regions. Similarly, the solid region demonstrated higher CT 70keV , iodine concentration (IC), and spectral curve slope (K) compared to the periphery. 7 days post-CIR, the 1 Gy group exhibited decreased blood perfusion in the solid-area, while the periphery showed increased perfusion, enhanced invasiveness, and more pronounced abnormal vasculature. By day 14, the tumor size had slightly increased, and all spectral parameters were gradually increasing. The 2 Gy group exhibited a reduction in tumor size, with further expansion of internal liquefactive necrosis, and a decrease in all spectral parameters. Ki-67 proliferation index was reduced, a-SMA staining showed incomplete tumor vasculature, VEGF and CD34 expression decreased, along with a reduction in mature tumor vessel count. Compared to the 0 Gy group, which had a maximum survival time of 32 days (median 27 days), tumor-bearing rats in 2 Gy group exhibited a significantly longer maximum survival time of 49 days (median 37 days).

CONCLUSION

CIR effectively reduces glioma proliferation and invasiveness. The energy spectrum CT-based multi-parametric model quantifies glioma malignancy and allows for continuous, non-invasive assessment of heavy ion irradiation therapy in rat gliomas.

CLINICAL RELEVANCE/APPLICATION

Carbon ion radiotherapy shows promise for treating refractory recurrent gliomas, but clinical samples are limited. This study developed a non-invasive, dynamic multi-parametric quantitative model to evaluate the efficacy of CIR in inhibiting proliferation and invasiveness of rat C6 gliomas, providing a basis for its clinical use.

T5A-SPBR-1 RETROSPECTIVE EVALUATION OF MAMMOGRAM-BASED AI RISK ASSESSMENT IN WOMEN WITH DENSE BREASTS UNDERGOING SUPPLEMENTAL SCREENING

Samuel B. Ogunlade (*Presenter*)
Amie R. Leon, DO (*Abstract Co-Author*)
Santo Maimone IV, MD (*Abstract Co-Author*)
Andrey Morozov, MD (*Abstract Co-Author*)
Chidi T. Nwachukwu, MD (*Abstract Co-Author*)
Kristin A. Robinson, MD (*Abstract Co-Author*)
Haley P. Letter, MD (*Abstract Co-Author*)

PURPOSE

Image-based AI risk models assess short-term breast cancer risk and outperform traditional tools, including questionnaire-based models. Triaging women with dense tissue and no other high-risk factors remains a clinical challenge; thus, our institutions offer molecular breast imaging (MBI) as supplemental screening tool. This study assesses the accuracy of an AI model in predicting short-term breast cancer risk in women with dense breasts not identified as high risk by traditional models.

METHODS AND MATERIALS

A retrospective IRB-approved study included 416 screening mammograms with digital breast tomosynthesis from 2018-2023 at 3 academic breast imaging centers. Mammograms were initially negative or benign and classified as BIRADS c or d density, with all patients undergoing MBI within one year as supplemental screening. Of these, 70 (16.8%) were diagnosed with histologically confirmed breast cancer within two years, and 346 (83.2%) were selected as non-cancer controls. Mammograms were retrospectively processed using an AI model to generate risk and density scores, and analyses, including ROC and subgroup comparisons, were performed using SPSS version 28.

RESULTS

The study population had a mean age of 61 ± 10 years. The AI system classified 1 (0.2%) mammogram as category a, 124 (29.8%) as b, 210 (50.5%) as c, and 81 (19.5%) as d. Overall mean risk score was higher in cancer (0.43 ± 0.42) than in non-cancer cases (0.37 ± 0.40), but not statistically significant ($p = 0.239$). Subgroup analysis showed the mean risk scores in cancer vs non-cancer patients to be 0.42 vs 0.41 ($p = 0.883$), 0.45 vs 0.38 ($p = 0.358$), and 0.39 vs 0.23 ($p = 0.080$) in categories b, c, and d respectively, suggesting increasing separation and trend toward significance with higher density. ROC showed a similar trend, as AUC was 0.56 ($p = 0.892$), 0.61 ($p = 0.255$), and 0.75 ($p = 0.049$) for categories b, c and d respectively, with statistical significance in category d. In category d, risk score threshold of 0.14 yielded 69.3% sensitivity and 61.1% specificity, indicating the AI model's stronger diagnostic performance in women with extremely dense breasts.

CONCLUSION

While the AI-generated risk score did not significantly distinguish cancer from non-cancer across all dense breast cases, it showed a trend of improved performance with increasing density. In category d, the model achieved statistically significant discrimination, suggesting potential retrospective value in identifying risk where mammography is least effective.

CLINICAL RELEVANCE/APPLICATION

Women with dense breasts are challenging to triage for supplemental screening; AI-based risk models may be integrated into clinical workflows to prospectively identify those at elevated short-term risk not captured by traditional tools.

T5A-SPBR-2 MAMMOGRAMS AS FINGERPRINTS: PATIENT MATCHING USING MAMMOGRAMS

Michael E. Partrick, MD (*Presenter*)
Wei-Hsiang Hung (*Abstract Co-Author*)
John Graham-Knight (*Abstract Co-Author*)
Reece Walsh (*Abstract Co-Author*)
Ramon Lawrence (*Abstract Co-Author*)
Rasika Rajapakshe, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate whether Artificial Intelligence (AI) can determine if a pair of mammograms taken at different times belong to the same patient.

METHODS AND MATERIALS

A dataset of 17,828 patients were randomly sampled from a cohort who had at least two screening mammograms between February 5, 2019, and December 31, 2022. All examples were taken using HOLOGIC Inc. machines, and selected such that the 4 common mammographic views (RCC, LCC, LMLO, and RMLO) were present. Images were resized to 256x256, and an ablation study on image size tested 64x64, 128x128, and 512x512 pixels. Two clustering algorithms were tested using a feature extractor and cosine similarity: ResNet50V2, pretrained on ImageNet-1k and finetuned as a classification model in which each unique identity is taken as a different class; and a Siamese configuration consisting of three ResNet50V2 neural networks, including anchor, positive, and negative sub-networks and trained using contrastive triplet loss. Half of the test data consisted of matching pairs (two mammograms of the same view from the same patient at different times), and the other half were non-matching pairs (two mammograms of the same view from different patients). Anchor images were selected randomly. Negative examples were selected randomly from the same mammographic view for different patients. Positive examples were selected from the same mammographic view for the same patient at different times. Metrics included accuracy and F1-score.

RESULTS

The best distance thresholds for the classification Model and the Siamese model were found to be 0.738, and 0.723, respectively. The verification accuracies achieved were 97% for the classifier, and 93% for the Siamese model. The classification model achieved its best performance at 256x256, whereas the Siamese model at 512x512 achieved accuracy of 93%.

CONCLUSION

Patient matching using only mammographic images is possible with high accuracy. The classifier trained on mammographic images outperformed the Siamese model. Image resolution was determined to be an important factor in performance, with higher resolutions generally performing better.

CLINICAL RELEVANCE/APPLICATION

With real-world data at scale, ensuring data integrity across multiple institutions becomes a challenge. An AI capable of determining if two mammograms come from the same patient, combined with a record linkage model, can be used to mitigate data leakage in AI training and reduce manual review, which is both labor-intensive and inefficient.

T5A-SPBR-4 AI-BASED MAMMOGRAPHY SCORES FOR PREDICTING PATHOLOGIC AXILLARY METASTASIS AFTER NEOADJUVANT CHEMOTHERAPY IN BREAST CANCER PATIENTS

Na Lae Eun, MD, PhD (*Presenter*)
Ji Hyun Youk, MD (*Abstract Co-Author*)
Jeong-Ah Kim, MD, PhD (*Abstract Co-Author*)
Eun Ju Son, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to develop and validate nomograms based on AI-derived mammography scores, in combination with clinicopathologic features, to predict axillary metastasis after neoadjuvant chemotherapy (NAC) in breast cancer patients.

METHODS AND MATERIALS

We retrospectively analyzed breast cancer patients who underwent NAC followed by definitive breast and axillary surgery between January 2014 and December 2019. The AI mammography score, generated using a deep learning algorithm (Lunit INSIGHT MMG), was categorized into quartiles and evaluated for its association with axillary metastasis, defined as residual tumor in axillary lymph nodes at final pathology. Patients were randomly divided into training and validation cohorts in a 7:3 ratio. Multivariable logistic regression was performed incorporating AI scores and clinicopathologic variables, and nomograms were developed. Model performance was evaluated using the area under the receiver operating characteristic curve (AUC).

RESULTS

A total of 359 women were included (mean age ± standard deviation: 49.5 ± 9.5 years). In multivariable logistic regression analysis, both mid-treatment and post-treatment AI mammography scores were significantly associated with axillary metastasis. The highest quartile of the mid-treatment AI mammography score was associated with increased odds of axillary metastasis compared to the lowest quartile (OR = 2.526; 95% CI, 1.212-5.266; p = 0.0134). Similarly, the highest quartile of the post-treatment AI mammography score demonstrated a strong association (OR = 3.733; 95% CI, 1.709-8.155; p = 0.001). Additional independent predictors of axillary metastasis included initial suspicious lymph node assessment (OR = 5.788 for mid, p = 0.0004; OR = 6.087 for post, p = 0.0004), estrogen receptor (ER) positivity (OR = 5.659 for mid, p < .0001; OR = 6.021 for post, p < .0001), and HER2-negative status (OR = 0.135 for mid, p < .0001; OR = 0.114 for post, p < .0001). The prediction models achieved AUCs of 0.844 and 0.839 in the training set, and 0.854 and 0.858 in the validation set for mid- and post-treatment scores, respectively.

CONCLUSION

Mammography-based AI scores, when combined with initial lymph node assessment, ER positivity, and HER2-negative status, demonstrated strong predictive value for axillary metastasis after NAC in breast cancer patients.

CLINICAL RELEVANCE/APPLICATION

AI-based mammography scores may assist in identifying patients with residual axillary metastasis and support the tailoring or de-escalation of axillary surgery in selected breast cancer patients undergoing NAC.

T5A-SPBR-5 ARTIFICIAL INTELLIGENCE (AI)-BASED MAMMOGRAPHY SCORES FOR PREDICTING PATHOLOGIC COMPLETE RESPONSE IN BREAST CANCER PATIENTS RECEIVING NEOADJUVANT CHEMOTHERAPY

Na Lae Eun, MD, PhD (*Presenter*)
Ji Hyun Youk, MD (*Abstract Co-Author*)
Jeong-Ah Kim, MD, PhD (*Abstract Co-Author*)
Eun Ju Son, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to develop and validate nomograms based on AI-derived mammography scores, combined with clinicopathologic features, to predict pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) in breast cancer patients.

METHODS AND MATERIALS

We retrospectively analyzed breast cancer patients who underwent NAC followed by definitive breast and axillary surgery between January 2014 and December 2019. The AI score, derived from a deep learning algorithm (Lunit INSIGHT MMG), was categorized into quartiles and evaluated for association with pCR, defined as the absence of invasive cancer in the breast. Patients were randomly allocated into training and validation sets in a 7:3 ratio. Multivariable logistic regression was performed using the AI score and clinicopathologic variables, and a nomogram was constructed. Model performance was assessed by the area under the receiver operating characteristic curve (AUC).

RESULTS

A total of 359 women were included (mean age ± standard deviation: 49.5 ± 9.5 years). In multivariable logistic regression analysis, both mid- and post-treatment AI mammography scores were significantly associated with pCR. Compared to the lowest quartile, the second, third and fourth quartiles of the mid-treatment AI mammography score showed significantly lower odds of achieving pCR, with adjusted odds ratios (ORs) of 0.204 (95% CI, 0.042-0.984; p = 0.0477), 0.210 (95% CI, 0.060-0.734; p = 0.0145), and 0.159 (95% CI, 0.072-0.352; p <.0001), respectively. Similarly, the post-treatment AI mammography score demonstrated strong associations, with ORs of 0.158 (95% CI, 0.043-0.577; p = 0.0052) and 0.113 (95% CI, 0.068-0.373; p <.0001) for the third and fourth quartiles, respectively. Additional independent predictors of pCR included PR negativity (OR = 0.121 for mid, p < .0001), HER2-positive status (OR = 8.223 for mid, p < .0001; OR = 15.211 for post, p < .0001), and HER2-positive (OR = 6.217 for post, p = 0.0001) and triple negative subtype (OR = 12.355 for post, p <.0001). The developed mid- and post-treatment prediction models achieved AUCs of 0.869 and 0.870 in the training set, and 0.751 and 0.786 in the validation set for predicting pCR.

CONCLUSION

The AI-based mammography score, in combination with PR negative, and HER2-positive status and HER-2 positive/triple negative subtype, demonstrates significant utility in predicting pCR in breast cancer patients receiving NAC.

CLINICAL RELEVANCE/APPLICATION

Mammography-based AI scores may help identify patients predicted to achieve pCR and support future exploration of surgical de-escalation in selected cases among breast cancer patients receiving neoadjuvant chemotherapy.

T5A-SPBR-6 HEAD-TO-HEAD COMPARISON OF CONTRAST-ENHANCED MAMMOGRAPHY AND MRI IN ASSESSING THE TUMOR RESPONSE TO NEOADJUVANT THERAPY IN BREAST CANCER: A PROSPECTIVE, MULTIREADER STUDY

Simin Wang, MD (*Presenter*)
Jinhui Li (*Abstract Co-Author*)
Jiawei Li, PhD,MD (*Abstract Co-Author*)
Xigang Shen (*Abstract Co-Author*)
Chao You, MD (*Abstract Co-Author*)
Tingting Jiang (*Abstract Co-Author*)
Yajia Gu (*Abstract Co-Author*)

PURPOSE

To compare contrast-enhanced mammography (CEM) and MRI in the evaluation of the tumor response to neoadjuvant therapy (NAT) in breast cancer.

METHODS AND MATERIALS

Patients who underwent CEM and breast MRI at the same period (within 7 days) before and after NAT were prospectively enrolled in this study. Three readers with different levels of experience independently assessed the images and classified the tumor response following NAT. Radiological complete response (rCR) was defined as the absence of a suspiciously enhanced area. The residual lesion extent was calculated as the total diameter of all enhanced lesions. Pathologic complete response (pCR) was defined as the absence of invasive carcinoma or ductal carcinoma in situ. The sensitivity, specificity, and accuracy of CEM and MRI in determining pCR were calculated per reader and averaged with a generalized estimating equation (GEE). The agreement in the tumor response and residual tumor extent between imaging and pathology was assessed by kappa and intraclass correlation coefficient (ICC) analyses.

RESULTS

Fifty-seven patients (age: 47 ± 10 years) were enrolled, 32/57 of whom (36.8%) achieved pCR. In determining pCR, the estimated average sensitivity, specificity, and accuracy were 0.778, 0.714, and 0.754, respectively, for CEM and 0.714, 0.944, and 0.860, respectively, for MRI (all P values > 0.050). The tumor response evaluated on CEM and MRI was moderately to substantially consistent with the pathological response (average ? = 0.524 and 0.686). Both imaging modalities slightly overestimated the residual lesion extent (mean overestimations: 1.7 mm and 2.7 mm). In ICC analysis, CEM and MRI showed poor consistency with pathology (average ICCs = 0.4467 and 0.449, respectively).

CONCLUSION

Compared with MRI, CEM showed comparable but slightly lower accuracy, higher sensitivity, and lower specificity in predicting pCR after NAT. In assessing residual tumor extent, CEM and MRI showed similar performance and tended to overestimate the pathological extent. CEM could be an acceptable alternative to MRI in certain patients undergoing NAT.

CLINICAL RELEVANCE/APPLICATION

1. Providing an insight into the accuracy of CEM and MRI in assessing tumor response to NAT in breast cancer.2. Providing false-positive and false-negative examples in evaluating pCR to promote the clinical application of CEM.

T5A-SPBR-7 TRIPLE NEGATIVE BREAST CANCER: DIFFERENTIAL IMAGING FEATURES BASED ON MENOPAUSAL STATUS AND RACE

Cherie M. Kuzmiak, DO (*Presenter*)
David S. Sailer, MD, BS (*Abstract Co-Author*)
Thad Benefield (*Abstract Co-Author*)

PURPOSE

To determine if menopausal status and race affects the imaging features of triple-negative breast cancer (TNBC).

METHODS AND MATERIALS

This IRB-approved retrospective study reviewed the clinicopathologic data and imaging features of patients diagnosed with invasive ductal TNBC from January 1, 2014 to March 30, 2023. There were 199 patients, of whom 67 (33.7%) were pre- and peri-menopausal and 132 (66.3%) were postmenopausal. Data analysis was performed using chi-square or Fisher's Exact Test, and a P-value < 0.05 was considered significant. Subgroup analysis of Black and White patients was also performed.

RESULTS

Sixty-six percent (44/67) of the TNBCs in the premenopausal group were a round or oval shaped mass, while an irregular shaped mass comprised 50.5% (65/129) in the postmenopausal group (P = 0.041). Three (2.3 %) TNBCs were out of the mammographic field-of-view. Forty-two percent (28/67) of the TNBCS in the premenopausal group had indistinct margins, whereas 51.2% (66/129) of the postmenopausal group had spiculated margins (P = 0.011). Associated calcifications were present in 29.5% (20/67) of the TNBCs in the premenopausal group versus 24.8% (32/129) (P=0.395). In subgroup analysis, a round/oval shaped TNBC was more common in both premenopausal and post-menopausal Black patients, 76.9% (20/26) and 54.5% (24/45) (P = 0.061). However, 57.1% (44/79) of TNBCs in post-menopausal white women were irregular and 61.0% (47/79) had spiculated margins (P < 0.009).

CONCLUSION

Menopausal status and race should be considered in the imaging features of TNBC. This data may further assist in the understanding of the biology of TNBC and lesion characteristics by race

CLINICAL RELEVANCE/APPLICATION

Triple negative breast cancer (TNBC) accounts for approximately 10-20% of newly diagnosed breast cancers. It is clinically defined by the absence of expression of the estrogen receptor and progesterone receptor and lacks overexpression of the human epidermal growth factor receptor-2. Invasive ductal carcinoma, no special type, comprises the majority of TNBCs and are associated with a high nuclear grade and elevated metastatic potential. TNBC occurs more commonly among Black and premenopausal women, especially those that have a BRCA1 or PALB2 germline mutation. TNBCs may mimic a benign lesion, such as a fibroadenoma, on imaging which could possibly delay diagnosis. Hormone levels play a significant role in breast cancer pathogenesis. Menopause with a reduction in hormone levels could affect not only cancer development but possibly influence the imaging features.

T5A-SPBR-8 READER STUDY: COMPARING INTERPRETABLE AI TO BLACK BOX AI IN THE PRESENCE OF SYSTEMATIC MODEL ERROR

Alina Barnett (*Presenter*)
Luke Moffett (*Abstract Co-Author*)
Yanchen Ou (*Abstract Co-Author*)
Giyoung Kim (*Abstract Co-Author*)
Fides Schwartz, MD (*Abstract Co-Author*)
Lars J. Grimm, MD (*Abstract Co-Author*)
Connie E. Kim, MD (*Abstract Co-Author*)

Sujata V. Ghate, MD (*Abstract Co-Author*)
Derek L. Nguyen, MD (*Abstract Co-Author*)
Eun L. Langman, MD (*Abstract Co-Author*)
Joseph Lo, PhD (*Abstract Co-Author*)
Cynthia Rudin (*Abstract Co-Author*)

PURPOSE

To investigate how readers respond to machine learning models that provide explanations of their decisions compared to models that cannot, using a breast lesion diagnosis task.

METHODS AND MATERIALS

An observer study was conducted with 8 readers (4 attending radiologists and 4 trainees) interpreting 140 breast lesions retrospectively using an AI model (malignancy AUC 0.72, 95% CI: 0.63-0.82). The AI scored the mass margin and the likelihood of malignancy. Readers classified mass margin and estimated mass malignancy in two settings: a black box setting where they received only the malignancy score, and an interpretable setting where they also received the margin score and self-explanation. In both settings, systematic model error was introduced by underestimating the malignancy scores, and the error was not revealed to readers. The order of the settings was randomized with a 4-week washout period.

RESULTS

The interpretable interface had greater reader-model concurrence for mass margins (trainees 60.0% (337/560), attendings 55.0% (302/549)) than the black box (trainees 43.9% (246/560), attendings 45.9% (257/560)). Adding interpretability did not change malignancy AUC (interpretable interface: 0.77, 95% CI: 0.71-0.84; black box interface: 0.77, 95% CI: 0.71-0.84). Attendings expressed higher confidence in their margin classifications when using the interpretable interface (74.0, 95% CI: 69.9-78.0) than the black box (64.6, 95% CI: 59.6-69.7), but trainees did not (interpretable: 60.5, 95% CI: 56.0-65.1; black box: 58.7, 95% CI: 54.5-63.0). Readers changed their mass margin decisions in a coherent manner, adjusting their malignancy likelihood scores accordingly (i.e., spiculated margins have higher scores than obscured margins).

CONCLUSION

In both the interpretable and black box settings, trainees adopted the same error as the model (predicting lower malignancy scores) but attendings did not. Both trainees and attendings adopted the margin classifications of the interpretable model.

CLINICAL RELEVANCE/APPLICATION

Systematic model bias and other model errors are a known risk when introducing AI models in the clinic. By observing how readers respond to these errors, we can make more informed decisions regarding clinical deployment.

T5A-SPCA-1 FRACTIONAL FLOW RESERVE FROM COMPUTED TOMOGRAPHY ANGIOGRAPHY: A DEEP-LEARNING BASED METHOD FOR IDENTIFYING VESSEL-SPECIFIC ISCHEMIA IN CORONARY ARTERY DISEASE

Claudia Gulli, MD (*Presenter*)
Ludovica Lanzafame (*Abstract Co-Author*)
Silvio Mazziotti (*Abstract Co-Author*)
Giorgio Ascenti, MD (*Abstract Co-Author*)
Tommaso D'Angelo, MD, PhD (*Abstract Co-Author*)

PURPOSE

Coronary computed tomography angiography (CCTA) combined with non-invasive fractional flow reserve (FFR) is a guideline-recommended approach for assessing lesion-specific ischemia in patients with stable chest pain and intermediate-grade stenoses. Although invasive FFR and Instantaneous Wave-Free Ratio (iFR) remain the gold standard, non-invasive FFR offers an efficient alternative to guide clinical decision-making. Recently, artificial intelligence (AI) based methods have enabled non-invasive estimation of FFR from Coronary Computed Tomography Angiography (CCTA), conventionally known as FFR derived from computed tomography (FFR-CT). This study evaluates the diagnostic performance of an AI deep-learning based FFR-CT software (CorEx, Spimed) for detecting vessel-specific ischemia in patients with coronary artery disease (CAD), using Invasive Coronary Angiography (ICA) and pressure-based measurements as reference standards.

METHODS AND MATERIALS

The retrospective multicenter analysis included 210 coronary vessels from 70 patients (17 females, 53 males) who underwent both CCTA and ICA within an average interval of 51 days. AI-based FFR-CT values =0.80 were considered indicative of hemodynamically significant stenosis. Invasive FFR or iFR values (significant =0.8 or =0.89, respectively) served as the reference standard.

RESULTS

On a per-patient basis, the model demonstrated excellent diagnostic accuracy, with an Area Under the Curve (AUC) of 0.930 (95% Confidence Interval [CI]: 0.843-0.977; p < 0.0001), sensitivity of 96.0% (95% CI: 86.3-99.5%), and specificity of 90.0% (95% CI: 68.3-98.8%). Kappa agreement was substantial (? = 0.860; 95% CI: 0.727-0.993). On a per-vessel basis, AUC was 0.872 (95% CI: 0.819-0.914), with sensitivity of 84.8% (95% CI: 73.9-92.5%) and specificity of 89.6% (95% CI: 83.4-94.1%). Agreement remained substantial (? = 0.729; 95% CI: 0.630-0.828).

CONCLUSION

These findings support the AI-based FFR-CT model as a reliable non-invasive alternative to invasive physiological assessment of lesion-specific ischemia in CAD patients, with high diagnostic accuracy. Calcium score of the stenotic vessels had a significant detrimental effect on the diagnostic accuracy of of the AI-based software.

CLINICAL RELEVANCE/APPLICATION

The integration of AI-based fractional flow reserve derived from computed tomography (FFR-CT) into the diagnostic workflow would enable accurate assessment of vessel-specific ischemia without the need for invasive procedures. This approach may enhance patient safety, reduce procedural risks and healthcare costs.

T5A-SPCA-2 ACCURACY OF DUAL-ENERGY COMPARED TO STANDARD CHEST X-RAY FOR DETECTION OF CORONARY ARTERY CALCIFICATIONS AS AN OPPORTUNISTIC SCREENING TOOL

Michael Hood, MD (*Presenter*)
Utarat Kaewumporn, MD, DMRD (*Abstract Co-Author*)
Joel K. Samuel, MD,MBBS (*Abstract Co-Author*)
Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*)
Nathaniel D. Mercaldo (*Abstract Co-Author*)
Rajiv Gupta, PhD, MD (*Abstract Co-Author*)
Michael H. Lev, MD (*Abstract Co-Author*)

PURPOSE

Coronary artery calcification (CAC) is a well-established marker of coronary artery disease (CAD) and an indicator of increased cardiovascular risk. Dual-energy chest X-ray (DEX-CXR) may improve conspicuity of CAC compared to standard chest X-ray (CXR), but its diagnostic performance has not been well characterized. Our study aimed to compare the accuracy of DEX-CXR versus standard CXR for identifying CAC, using non-ECG-gated chest CT as the reference standard.

METHODS AND MATERIALS

Fifty-two patients (mean age 63.9 ± 18.6 years) undergoing imaging for non-cardiac indications received both DEX-CXR and standard CXR in an emergency setting. Chest CT scans acquired within one year of radiography served as the reference. Three readers independently assessed the standard CXR, DEX-CXR, and CT for CAC, in this order, with an appropriate washout period between reads, with CAC presence determined by consensus of two readers. Inter-reader agreement was measured with intraclass correlation coefficients (ICCs). Reader confidence and diagnostic performance were compared using paired t-tests and McNemar's test, respectively.

RESULTS

Inter-reader agreement was higher for DEX-CXR (ICC = 0.82; 95% CI: 0.74-0.89) than standard CXR (ICC = 0.63; 95% CI: 0.48-0.75). Reader confidence was consistently greater with DEX-CXR (p < 0.05). DEX-CXR significantly outperformed standard CXR in detecting CAC, with higher sensitivity (75% vs. 28%) and accuracy (87% vs. 67%; p < 0.01).

CONCLUSION

Dual-energy chest X-ray significantly improved sensitivity and reader agreement for detecting coronary artery calcification compared to standard chest X-ray. These findings suggest that DEX-CXR could serve as a cost-effective, low-radiation, and widely accessible tool for opportunistic cardiovascular risk screening, particularly in emergency and urgent care settings where chest radiographs are commonly performed. If validated in larger studies, this approach could fundamentally expand the reach of early coronary artery disease detection and prevention.

CLINICAL RELEVANCE/APPLICATION

DEX-CXR could serve as a cost-effective, low-radiation, and widely accessible tool for opportunistic cardiovascular risk screening.

T5A-SPCA-3 PERFORMANCE OF DUAL-ENERGY CHEST X-RAY, COMPARED TO STANDARD CXR AND CT, FOR DIAGNOSIS OF CLINICALLY CONFIRMED CORONARY ARTERY DISEASE

Michael Hood, MD (*Presenter*)
Utarat Kaewumporn, MD, DMRD (*Abstract Co-Author*)
Joel K. Samuel, MD,MBBS (*Abstract Co-Author*)
Nathaniel D. Mercaldo (*Abstract Co-Author*)
Rajiv Gupta, PhD, MD (*Abstract Co-Author*)
Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*)
Michael H. Lev, MD (*Abstract Co-Author*)

PURPOSE

Coronary artery calcification (CAC) is a key marker of coronary artery disease (CAD) and cardiovascular risk. Computed tomography (CT) is the reference standard for CAC detection, but is limited by cost, accessibility, and radiation exposure. Standard chest X-ray (CXR) lacks sensitivity for CAC, whereas single-exposure dual-energy chest X-ray (DEX-CXR) has shown promise but remains understudied. Our purpose is to compare the performance of DEX-CXR for clinically confirmed CAD detection with that of standard CXR and non-ECG-gated chest CT.

METHODS AND MATERIALS

This study included a 45-patient subset of a larger 52-patient cohort (mean age 64.3 ± 18.7 years; 22 females, 23 males), including 39 with clinically confirmed CAD and 6 without CAD based on coronary angiography, stress testing, or MRI. All patients underwent standard CXR, DEX-CXR, and non-ECG-gated chest CT. Three readers independently assessed these for CAC, in this order, with an appropriate washout period between reads. CT findings were established by consensus of two readers, with the presence of any CAC considered evidence of CAD. Inter-reader agreement was measured with intraclass correlation coefficients (ICC). Sensitivity, specificity, positive predictive value (PPV), negative predictive value, and accuracy, were calculated with the clinical diagnosis as reference standard. Logistic regression was used to compare performance.

RESULTS

Inter-reader agreement was higher for DEX-CXR (ICC = 0.80; 95% CI: 0.69-0.87) than for standard CXR (ICC = 0.64; 95% CI: 0.48-0.76). DEX-CXR outperformed standard CXR in sensitivity (71.8% vs. 30.8%) and accuracy (75.6% vs. 40.0%), with equivalent specificity and PPV (100%). Performance of DEX-CXR was comparable to CT (sensitivity: 71.8% vs. 76.9%; accuracy: 75.6% vs. 80.0%). Logistic regression confirmed superior performance of DEX-CXR over standard CXR (OR = 4.64; p = 0.001), with no significant difference compared to CT (OR = 0.77; p = 0.61).

CONCLUSION

Dual-energy chest X-ray demonstrated diagnostic accuracy for CAC detection that approaching that of a non-gated CT reference standard, with significantly improved CAD detection compared to standard CXR. Given its lower radiation dose and wider accessibility, DEX-CXR may represent a practical, cost-effective opportunistic screening tool for coronary calcium detection and cardiovascular risk assessment.

CLINICAL RELEVANCE/APPLICATION

Dual-energy chest X-ray offers a practical, low-dose, and accessible alternative to CT for coronary calcium detection and cardiovascular risk screening in routine care.

T5A-SPCA-4 COMPARATIVE DIAGNOSTIC PERFORMANCE OF CT-FFR AND CCTA IN PATIENTS WITH DIFFERING CORONARY ARTERY CALCIUM BURDENS

KIM YEON JUN (*Presenter*)
Sung Min Ko, PhD (*Abstract Co-Author*)
JUN SIK KIM (*Abstract Co-Author*)
GIYONG AN (*Abstract Co-Author*)
Sung-Jin Cha, BS (*Abstract Co-Author*)

PURPOSE

To compare the diagnostic performance of computed tomography (CT) fractional flow reserve (FFR) and coronary computed tomography angiography (CCTA) in identifying functionally significant stenosis in patients with varying degrees of coronary artery calcium (CAC) scores.

METHODS AND MATERIALS

This retrospective study included 101 patients with suspected coronary artery disease, stratified into two groups based on CAC scores: <400 (low calcification) and =400 (high calcification). Each coronary artery branch was evaluated individually, and anatomical stenosis was classified as <50% or =50%. The diagnostic performances of CCTA (=50% stenosis) and CT-FFR (=0.80) were compared using invasive FFR (=0.80) as the gold standard. Sensitivity, specificity, PPV, NPV, and AUC were calculated for comparison.

RESULTS

For patients with low CAC scores (<400), CT-FFR showed superior diagnostic performance compared to CCTA: sensitivity (70% vs. 100%, $p < 0.05$), specificity (91% vs. 14%, $p < 0.05$), PPV (82% vs. 40%, $p < 0.05$), NPV (84% vs. 100%, $p = 0.19$), and accuracy (84% vs. 45%, $p < 0.05$). The AUC was significantly higher for CT-FFR (0.84 vs. 0.63, $p < 0.05$). For patients with high CAC scores (=400), CT-FFR also demonstrated superior performance: sensitivity (76% vs. 100%, $p < 0.05$), specificity (76% vs. 4%, $p < 0.05$), PPV (73% vs. 47%, $p < 0.05$), NPV (79% vs. 100%, $p = 0.33$), and accuracy (76% vs. 48%, $p < 0.05$) (Table .1). The AUC was higher for CT-FFR (0.80 vs. 0.69, $p = 0.26$) in per-patient analysis and significantly higher in pooled vessel analysis (0.93 vs. 0.72, $p < 0.05$). In the pooled vessel analysis, the accuracy of CCTA dropped from 0.74 to 0.60, and AUC dropped from 0.81 to 0.72 as the calcium burden increases, but the accuracy of CT-FFR dropped only slightly from 0.95 to 0.91 and AUC from 0.96 to 0.93 (Fig .1).

CONCLUSION

CT-FFR maintains superior diagnostic performance across both CAC Burdens. This advantage is more pronounced in patients with severe calcification, where the performance of CCTA dropped prominently.

CLINICAL RELEVANCE/APPLICATION

CT-FFR is a reliable non-invasive method for identifying functionally significant stenosis, even in the presence of significant calcification.

T5A-SPCA-5 Yunlong Hu (*Presenter*)

APPLICATION OF LOW DOSE ONE-STOP MYOCARDIAL PERFUSION IMAGING COMBINED WITH DEEP LEARNINGIMAGE RECONSTRUCTION IN CORONARY ARTERY DISEASE

PURPOSE

This study aims to explore the feasibility of the low dose "one-stop" myocardial computed tomography perfusion(CTP) combined with deep learning image reconstruction(DLIR) which could comprehensively assess patients suspected of coronary artery disease(CAD) in a single scan.

METHODS AND MATERIALS

94 consecutive patients underwent the 70kV "one-stop" CTP with suspected CAD and 62 gender- and age-matched patients underwent conventional CCTA were included.All CTP images were reconstructed using filtered backprojection(FBP) and high level DLIR(CTP-DL group).A CCTA phase acquired from the CTP was reconstructed using two different algorithms: ASIR-V 50%(CCTA-CTP group),which is similar to the conventional CCTA, and ASIR-50% combined high level DLIR(CCTA-CTP-DL group).The contrast media(CM) and effective dose(ED) were recorded.The signal-to-noise ratio(SNR),contrast-to-noise ratio(CNR) and noise of all groups were recorded.Patients were divided into three groups[normal(0%,n=14),nonsignificant(1%-49%,n=31),and significant stenosis(50%-100%,n=49)] on the basis of degree of coronary stenosis.The cardiac function,myocardial strain and myocardial blood flow(MBF) of each subgroups were analyzed.

RESULTS

Compared to then conventional CCTA protocol,the ED of "one-stop" CTP reduced by 40.4% (4.72mSv±0.39 vs 7.92mSv±1.8,p<0.05),and CM volume reduced by 8% (52.14mL±5.44 vs 56.48mL±9.14,p<0.05).The SNR and CNR of CTP were lower than CTP-DL(SNR:18.48±3.12 vs 24.78±2.95;CNR:15.76±2.79 vs 21.53±2.87,all p<0.05),but the noise of CTP were higher(43.2±3.6 vs 30.4±3.4,p<0.05).About the CCTA phase,there were significant differences in the noise of CCTA-CTP,CCTA-CTP-DL and conventional CCTA(32.28±2.25 vs 20.13±2.04 vs 18.6±1.61,all p<0.05).The SNR and CNR of CCTA-CTP were lower than CCTA-CTP-DL(all p<0.05),but there was no significant difference between CCTA-CTP-DL and conventional CCTA(all p>0.05).The left ventricular ejection fraction,the absolute values of left ventricular global strain and MBF gradually decreased as the coronary stenosis increased(all p<0.05).

CONCLUSION

The low-dose "one-stop" CTP combined DLIR could reduced the image noise and improve image quality.Compared to the conventional CCTA protocol,the "one-stop" CTP reduced the ED and CM usage while providing the information of coronary anatomy,LV cardiac function, LV global strain and myocardial perfusion without the image quality decreasing.

CLINICAL RELEVANCE/APPLICATION

Compared to conventional CCTA,the low-dose "one-stop" CTP can reduce the ED and CM volume without the image quality decreasing,and the comprehensive information it provided can completely evaluate the patients with all risk of CAD.

T5A-SPCA-7 BIAS-CORRECTED SYNTHETIC MYOCARDIAL EXTRACELLULAR VOLUME QUANTIFICATION USING PHOTON-COUNTING CT: VALIDATION AGAINST MRI IN A CLINICAL COHORT

Muhammad Taha Hagar, MD (*Presenter*)
Milan Vecsey-Nagy, MD, PhD (*Abstract Co-Author*)
Jose Osoria-Velasquez, MD (*Abstract Co-Author*)
James Griggers (*Abstract Co-Author*)
Fabian Bamberg, MD, MPH (*Abstract Co-Author*)
Akos Varga-Szemes, MD, PhD (*Abstract Co-Author*)
Tilman S. Emrich, MD (*Abstract Co-Author*)

PURPOSE

To validate synthetic hematocrit-derived myocardial extracellular volume (ECV) quantification from late enhancement photon-counting CT (PCD-CT) against cardiac MRI as a reference standard, and to evaluate the impact of a bias correction model.

METHODS AND MATERIALS

In this post-hoc analysis, patients underwent same-day cardiac MRI and delayed enhancement PCD-CT using full spectral acquisition mode (collimation: 144 × 0.4 mm). MRI-based ECV was calculated from T1 mapping with synthetic hematocrit, while CT-derived ECV was computed using iodine maps and hematocrit estimated from virtual non-contrast blood pool attenuation. The partition coefficient (?) was defined as the ratio of myocardial to blood pool enhancement and served as an intermediate parameter for ECV computation. Agreement between modalities was assessed using Bland-Altman analysis, intraclass correlation coefficients (ICC), and Pearson correlation. A linear regression model was applied to correct for systematic bias in CT-derived ECV.

RESULTS

A total of 27 patients (mean age 52.9 ± 17.2 years, 52% female) were included. Mean ? values were similar between modalities (?_MRI = 0.513 ± 0.073 vs. ?_PCD-CT = 0.501 ± 0.082, p = 0.518), indicating comparable extracellular contrast distribution. PCD-CT significantly overestimated MRI-derived ECV (42.1 ± 8.7% vs. 33.8 ± 8.1%, p<0.001), with a mean bias of -8.3 percentage points and poor agreement (ICC = 0.38). After applying linear bias correction (adjusted ECV = 0.522 × PCD-CT ECV + 11.83), the adjusted CT values aligned more closely with MRI (35.0 ± 4.8% vs 33.8 ± 8.1%, p = 0.373), with reduced bias (-1.2 percentage points) and improved reliability (ICC = 0.51). However, wide limits of agreements persisted.

CONCLUSION

Synthetic hematocrit-based ECV quantification from PCD-CT is technically feasible and correlates moderately with MRI. Bias correction mitigates systematic overestimation and improves agreement.

CLINICAL RELEVANCE/APPLICATION

PCD-CT enables spectral myocardial tissue characterization and ECV quantification without blood sampling. This approach has the potential to streamline cardiac imaging workflows and broaden access to tissue-based biomarkers. While individual variability persists, continued optimization may support the integration into routine clinical decision-making and future prognostic applications.

T5A-SPCA-8 INTEGRATIVE CMR-TRANSCRIPTOMIC ANALYSIS IDENTIFIES PERSISTENT CARDIAC REMODELING MECHANISMS IN ELDERLY MALE BABOONS PRENATALLY EXPOSED TO SYNTHETIC GLUCOCORTICOIDS

Bowen Yang, PhD (*Presenter*)
Hillary F. Huber, PhD (*Abstract Co-Author*)
Laura Cox (*Abstract Co-Author*)
Peter Nathanielsz (*Abstract Co-Author*)
Geoffrey D. Clarke, PhD (*Abstract Co-Author*)

PURPOSE

Synthetic glucocorticoids (sGC) administered during potential preterm aid fetal lung maturation but may predispose offspring to lifelong cardiac dysfunction. This study integrates quantitative cardiac magnetic resonance imaging (qCMR) with transcriptomic and mitochondrial analyses to find potential mechanisms causing cardiac remodeling in elderly male baboons prenatally exposed to sGC.

METHODS AND MATERIALS

Left ventricular (LV) function and strain were measured in 12 elderly male baboons (8 control [CTR], 4 sGC-exposed) using qCMR (Siemens TIM Trio 3T). RNA sequencing on LV myocardial tissue identified differentially expressed genes (adj. $p<0.05$, $|\log2 \text{ fold-change}|>1$). A Seahorse™ XF Analyzer measured mitochondrial function (electron transport chain [ETC] complexes I, II, IV), with protein expression quantified via western blot. Correlations were revealed between qCMR parameters, mitochondrial traits, and DEG in 7 subjects (3 CTR, 4 sGC).

RESULTS

The sGC group had increased LV sphericity ($p<0.05$), reduced global longitudinal and radial strains ($p<0.04$), and increased paracardial lipids ($p=0.02$). There were 63 upregulated and 20 downregulated DEGs, implicating fibrosis (TGFB2, POSTN), inflammation (IL33), and metabolism (FBP1) pathways. ETC Complex I respiration ($p=0.002$) and NDUFV2 protein expression ($p=0.048$) were reduced. Integrated analyses confirmed correlations between fibrosis-associated genes and heart function, including TGFB2 vs. LV shortening ($r=-0.83$, $p=0.02$), IL33 vs. early diastolic strain rate ($r=-0.92$, $p=0.004$), and metabolic gene FBP1 vs. LV shortening ($r=0.86$, $p=0.01$).

CONCLUSION

Prenatal sGC exposure programs persistent cardiac dysfunction through coordinated mitochondrial impairment, transcriptomic reprogramming, and LV remodeling that appears in elderly male baboons. Linking qCMR and molecular data reveals critical pathways driving cardiac vulnerability.

CLINICAL RELEVANCE/APPLICATION

Combining qCMR with molecular profiling provides insights into lifelong cardiovascular risks from prenatal glucocorticoid exposure, aiding early biomarker discovery and targeted therapeutic interventions.

T5A-SPCA-9 EVALUATION OF NON-DILATED LEFT VENTRICULAR CARDIOMYOPATHY PATIENTS WITH REDUCED AND PRESERVED LEFT VENTRICULAR EJECTION FRACTION USING CARDIAC MAGNETIC RESONANCE FEATURE TRACKING TECHNOLOGY

Chunlong Yan (*Presenter*)

PURPOSE

To investigate the diagnostic value of cardiac magnetic resonance imaging feature tracking (CMR-FT) in evaluating patients with non-dilated left ventricular cardiomyopathy (NDLVC) and either reduced or preserved left ventricular ejection fraction (LVEF).

METHODS AND MATERIALS

A total of 30 patients with NDLVC-reduced LVEF (LVEF < 50%, NDLVC-rLVEF group) and 30 patients with NDLVC-preserved LVEF (LVEF=50%, NDLVC-pLVEF group) who underwent CMR examination in Beijing Anzhen Hospital from January 2020 to December 2024 were retrospectively analyzed. Additionally, 30 individuals without cardiovascular disease and normal CMR findings were selected as the control group. Using the CVI42 post-processing software, conventional left ventricular functional parameters and 2D/3D global strain parameters were obtained, including LVEF, left ventricular end-diastolic volume (LVEDV), left ventricular end-systolic volume (LVESV), left ventricular stroke volume (LVSV), left ventricular cardiac output (LVCO), left ventricular mass at end-diastole (LV mass at ED), global radial strain (GRS), global circumferential strain (GCS), and global longitudinal strain (GLS). Group differences in these parameters were analyzed. The diagnostic efficacy of strain parameters in NDLVC patients with reduced LVEF was evaluated using receiver operating characteristic (ROC) curve analysis.

RESULTS

(1) Compared to the control group, the NDLVC-rLVEF group was older ($P < 0.05$). Compared to the NDLVC-pLVEF group, the NDLVC-rLVEF group was older ($P < 0.05$) and had a higher prevalence of hyperlipidemia and alcohol consumption history. (2) Compared to the control group, the NDLVC-pLVEF group showed a significant increase in LV mass at ED ($P < 0.05$). Compared to the NDLVC-pLVEF group, the NDLVC-rLVEF group exhibited significantly increased LVESV and LV mass at ED ($P < 0.05$), while LVSV, LVCO, LVEF, absolute values of GRS, GCS , GLS were significantly reduced ($P < 0.05$). (3)ROC curve analysis showed that GRS, GCS, GLS in both 2D and 3D modalities exhibited superior diagnostic performance in differentiating the NDLVC-rLVEF group from the NDLVC-pLVEF group.

CONCLUSION

CMR-FT technique demonstrates significant diagnostic value in differentiating NDLVC patients with both reduced and preserved LVEF. Both 2D and 3D strain parameters exhibit high diagnostic efficacy. In the progression of NDLVC, an increase in left ventricular mass occurs first, followed by impaired left ventricular systolic function and reduced left ventricular function.

CLINICAL RELEVANCE/APPLICATION

CMR-FT technology demonstrates significant diagnostic value in differentiating NDLVC patients with both reduced and preserved left ventricular ejection fraction (LVEF).

T5A-SPCA-15 LAYER-SPECIFIC STRAIN TO DISTINGUISH BETWEEN ACUTE MYOCARDIAL INFARCTION AND ACUTE MYOCARDITIS: A MACHINE LEARNING APPROACH

Yanping Su (*Presenter*)
Chenying Lu (*Abstract Co-Author*)
Jiansong Ji, MD (*Abstract Co-Author*)

PURPOSE

This study aims to develop a machine learning (ML) model utilizing layer-specific myocardial strain derived from cardiac magnetic resonance (CMR) to differentiate acute myocardial infarction (AMI) from acute myocarditis (AM).

METHODS AND MATERIALS

A total of 114 patients diagnosed with AM (n = 52) and AMI (n = 62) between December 2017 and May 2025 were retrospectively included. All patients underwent CMR scanning, and left ventricular myocardial strain analysis was performed, including global and regional strain parameters, particularly layer-specific strain. Feature selection was conducted using 1,000 bootstrap resampling combined with LASSO regression. 5 ML algorithms were used to construct the predictive models, with feature reduction implemented to minimize model complexity. Model performance was assessed by 10-fold cross-validation, with the area under the curve (AUC) used as the primary evaluation standard. Finally, SHapley Additive exPlanations (SHAP) analysis was employed to assess the contribution of each variable in differentiating AM from AMI.

RESULTS

When the number of features was reduced to 5, the logistic regression (LR) model achieved an AUC of 0.873 (95% CI: 0.851, 0.892), demonstrating relatively optimal performance. The model included 5 predictive factors: age, end-systolic apical subendocardial circumferential strain (ESACS_endo), apical longitudinal strain (ALS), lactate dehydrogenase (LDH), and creatine kinase-MB (CK-MB). Additionally, the model's sensitivity was 0.700 (95% CI: 0.661, 0.739), specificity was 0.868 (95% CI: 0.843, 0.896), Brier score was 0.150 (95% CI: 0.141, 0.161), F1 score was 0.754 (95% CI: 0.722, 0.783), positive predictive value (PPV) was 0.816 (95% CI: 0.781, 0.852), and negative predictive value (NPV) was 0.775 (95% CI: 0.743, 0.806).

CONCLUSION

The ML model developed using non-contrast-enhanced CMR demonstrates high accuracy in differentiating AM from AMI, with layer-specific strain parameters playing an important role in the diagnostic process. This model has the potential to expand the clinical applications of CMR, reduce unnecessary invasive procedures, thereby optimizing clinical decision-making and improving personalized treatment strategies.

CLINICAL RELEVANCE/APPLICATION

ML model differentiating AM from AMI.

T5A-SPCH-2 EVALUATION OF IMPAIRED LUNG DEFORMATION DURING EXPIRATION IN COPD USING FOUR-DIMENSIONAL DYNAMIC-VENTILATION CT

Yanyan Xu, MD, PhD (*Presenter*)
He Chen (*Abstract Co-Author*)
Sheng Xie (*Abstract Co-Author*)
Min Xu, PhD (*Abstract Co-Author*)

PURPOSE

To investigate lung deformation in patients with COPD during expiration using four-dimensional (4D) dynamic-ventilation CT and quantitatively evaluate the potential differences in strain-related parameters in patients with varying severities of airflow limitation.

METHODS AND MATERIALS

A total of 61 patients clinically diagnosed with COPD underwent spirometry and 4D dynamic-ventilation CT. Strain measurements were performed using a modified version of the computational fluid dynamics analysis software. Strain-related parameters derived from the whole expiration phase (PS max-all , PS mean-all , and Speed max-all) and the first 2 s of the expiration phase (PS max2s , PS mean2s , and Speed max2s) were divided by the changes in lung volume to adjust for the degree of expiration. Comparisons of strain-related parameters among GOLD I (mild airflow limitation), GOLD II (moderate airflow limitation), and GOLD III-IV (severe airflow limitation) were made using the nonparametric Kruskal-Wallis test. Furthermore, the correlations between the strain-related parameters and the degree of airflow limitation were assessed using Spearman correlation analysis. $P < 0.05$ was considered statistically significant.

RESULTS

A total of 61 patients with COPD, including 29 with GOLD I, 18 with GOLD II, 6 with GOLD III, and 8 with GOLD IV, were enrolled in the final analysis. Strain-related parameters showed negative correlations with the GOLD classification. Compared with the strain-related parameters derived from the first 2s of the expiration phase, those derived from the whole expiration phase were more closely correlated with lung function changes.

CONCLUSION

Decreased lung deformation during expiration was associated with loss of lung function. Strain-related parameters, especially those derived from the whole expiration phase, showed promising potential in indicating the severity of airflow limitation in patients with COPD.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that reduced lung deformation during expiration, measured by 4D dynamic-ventilation CT strain analysis, correlates with worsening airflow limitation in COPD, offering a novel imaging biomarker for disease severity assessment. The findings highlight the clinical potential of whole-expiration-phase strain parameters in evaluating functional impairment and optimizing COPD management strategies.

T5A-SPCH-3 PREDICTION OF EARLY RECURRENCE AFTER BRONCHIAL ARTERIAL CHEMOEMBOLIZATION IN NON-SMALL CELL LUNG CANCER USING DUAL-ENERGY CT: AN INTERPRETABLE MODEL BASED ON THE SHAP METHODOLOGY

Feng Ye (*Presenter*)
Jianfei Tu (*Abstract Co-Author*)

PURPOSE

This study aims to investigate the role of dual-energy computed tomography (DECT) in predicting the early recurrence to bronchial artery chemoembolization (BACE) in patients with non-small cell lung cancer (NSCLC) who have failed first-line therapy.

METHODS AND MATERIALS

Clinical and imaging data were retrospectively collected from patients with NSCLC who underwent BACE at Wenzhou Medical University Affiliated Fifth Hospital between October 2023 and June 2024. A machine learning model was constructed using logistic regression (LR) based on 5 virtual monoenergetic images (VMIs) derived from the arterial and venous phases. Deep learning models were constructed using 3 convolutional neural networks (CNNs): ResNet50, ResNet101, and ResNet152, based on iodine maps. The optimal Radscore, DLscore, and clinical features were combined to construct a comprehensive model. The performance of the models was evaluated using the area under the receiver operating characteristic curve (AUC). The SHAP (Shapley Additive exPlanations) framework was applied for model interpretability.

RESULTS

A total of 196 patients were enrolled in this study (the training cohort, n=158; the testing cohort, n=38). The machine learning model based on 100 keV (AUC=0.751) demonstrated superior performance compared to other VMIs. The deep learning model based on the ResNet101 method (AUC=0.791) showed better performance than other approaches. The hybrid model combining Radscore-100keV-A, Radscore-100keV-V, DLscore-ResNet101-A, DLscore-ResNet101-V, and clinical features exhibited the best performance (AUC=0.798) among all models.

CONCLUSION

DECT holds promise in predicting the early recurrence of BACE for NSCLC patients who have failed first-line therapy, offering valuable guidance for clinical treatment planning.

CLINICAL RELEVANCE/APPLICATION

This study provides a new approach for screening first-line treatment failed non-small cell lung cancer patients who can benefit from BACE.

T5A-SPCH-4 DEEP LEARNING-BASED AUTOMATED SEGMENTATION OF PULMONARY VESSELS ON CHEST CT

Rui Zhao (*Presenter*)
Shaoze Luo (*Abstract Co-Author*)
Longfei Zhao (*Abstract Co-Author*)
Qiqi Xu, MBBS, MMEd (*Abstract Co-Author*)
Ruijie Zhao (*Abstract Co-Author*)
Jiaru Wang (*Abstract Co-Author*)
Ran Xiao (*Abstract Co-Author*)
Sirong Piao (*Abstract Co-Author*)
Ying Ming (*Abstract Co-Author*)
Wei Song, MD (*Abstract Co-Author*)

PURPOSE

Pulmonary vessels have similar CT attenuation to nodules, which can cause pulmonary vessel segmentation algorithms to incorrectly segment nodules as vessels, resulting in many false positives. Moreover, the insufficient segmentation of small vessels poses an additional challenge. To address these issues, we developed a novel pulmonary vessel segmentation algorithm that enhances nodule differentiation while improving the accuracy of small vessel segmentation.

METHODS AND MATERIALS

A total of 427 chest CT examinations, performed between June 2021 and December 2021, were collected from multiple institutions in different countries. These CT examinations included both non-contrast (n = 214) and contrast (n = 213) CT examinations. As a reference, pulmonary vessels were manually segmented by senior radiologists. We designed a nodule recognition module and a vessel optimization module, which included training weight adjustment and Centerline Recall (Cl-Recall) Loss, to construct the vessel segmentation model. A 3D U-Net-based model was trained to perform pulmonary vessel segmentation on 370 chest CT examinations and was tested on 57 chest CT examinations. Performance metrics included Cl-Recall, Dice similarity coefficient (DSC), and false positive ratio (FPR). The performance of our model was compared with that of the nnUNet-v2 model, developed by the German Cancer Research Center.

RESULTS

The FPR of our model in the nodule over-segmentation is 0.036, while that of the nnUNet-v2 model is 0.052. The vessel Cl-Recall and DSC of our method are 0.941 and 0.932, while those of the nnUNet-v2 model are 0.772 and 0.860. In summary, our model can better avoid nodule over-segmentation and segment more complete vessels.

CONCLUSION

The nodule-aware and small vessel-optimized pulmonary vessel segmentation algorithm we designed can effectively avoid over-segmentation of pulmonary nodules and achieve superior vessel segmentation performance.

CLINICAL RELEVANCE/APPLICATION

The deep learning segmentation algorithm for pulmonary vessels enables precise visualization of pulmonary arteries and veins on chest CT. Accurate segmentation of pulmonary vessels is crucial for both disease diagnosis and surgical planning.

T5A-SPCH-5 A NOMOGRAM FOR PREOPERATIVE PREDICTION OF INVASIVENESS IN SOLITARY PULMONARY ADENOCARCINOMA: A MULTICENTER STUDY

Xiaocui Liu (*Presenter*)

PURPOSE

To develop and validate a clinically predictive model for preoperatively assessing invasiveness in solitary pulmonary adenocarcinoma.

METHODS AND MATERIALS

From January 2020 to December 2024, patients with solitary pulmonary nodules who underwent preoperative CT scans in four centers were included. The patients were divided into a training dataset and an external testing dataset. Based on postoperative histopathology, patients were categorized into group A (atypical adenomatous hyperplasia, adenocarcinoma in situ, and minimally invasive adenocarcinoma) and group B (invasive adenocarcinoma). Univariate and multivariate logistic regression analyses were performed in the training dataset to identify independent risk factors and establish a clinical prediction model, which was then validated in the testing dataset. Receiver operating characteristic curve analysis quantified discriminative ability, while the Hosmer-Lemeshow test assessed calibration. Clinical utility was evaluated through decision curve analysis, and a nomogram was generated to visualize individualized risk probabilities.

RESULTS

Four hundred and forty-eight patients were included, with 335 patients in the training dataset (Group A 156; Group B 179) and 113 patients in the external testing dataset (Group A 53; Group B 60). Four independent predictors were identified in the training dataset: CYFRA 21-1 (OR 4.175, 95% CI 1.253-13.904; p = 0.020), maximum diameter (OR 1.247, 95% CI 1.143-1.361; p < 0.001), density type (OR 6.604, 95% CI 3.519-12.393; p < 0.001), and air bronchogram (OR 3.149, 95% CI 1.406-7.051; p = 0.005). The nomogram model demonstrated robust diagnostic performance and generalizability, achieving AUCs of 0.925 (95% CI: 0.897-0.953) in the training set and 0.895 (95% CI: 0.829-0.961) in the testing set. The accuracy was 0.863 in the training dataset and 0.876 in the testing dataset. The sensitivity was 0.872 and 0.833, while the specificity was 0.853 and 0.925 in the training and testing cohorts, respectively.

CONCLUSION

The integration of tumor markers with CT imaging features enables preoperative noninvasive prediction of invasiveness in pulmonary adenocarcinoma presenting as solitary pulmonary nodules.

CLINICAL RELEVANCE/APPLICATION

Given the widespread availability and affordability of CT and serological tests worldwide, this model can be easily implemented even in resource-limited regions. Therefore, it holds potential for clinical translation, providing a basis for precise individualized treatments.

T5A-SPCH-6 IMPROVING RECURRENCE PREDICTION IN NSCLC PATIENTS USING A MULTIMODAL DEEP LEARNING MODEL WITH CLINICAL DATA AND DEEP IMAGE FEATURE INTEGRATION VIA DIMENSIONALITY TRANSFORMATION

Hye Ryun Kim (*Presenter*)
Kyongmin S. Beck, MD, PhD (*Abstract Co-Author*)
Jin Hyoung Kang (*Abstract Co-Author*)
Helen Hong, PhD (*Abstract Co-Author*)

PURPOSE

The aim of this study is to improve recurrence prediction by incorporating clinical data into representative image features derived from the tumor region using a multimodal deep learning(DL) model. Our proposed network enables the extraction of deep image features, focusing on intratumoral and peritumoral contextual information using CT images and tumor masks. Additionally, it employs clinical risk predictor selection and dimensionality transformation to effectively integrate clinical data with deep image features, addressing the inherent dimensional imbalance.

METHODS AND MATERIALS

The dataset used in this study comprised clinical data and CT images of 166 NSCLC patients (99 non-recurrent, 67 recurrent). Sixteen prognostic clinical variables were collected from electronic medical records. First, univariate, and multivariate analyses identified N stage, Vascular invasion, and LDH as independent clinical risk predictors. Second, the multimodal DL model extracted deep image features, focusing on tumor location through the tumor-centric attention module. Third, a dimensionality transformation module was introduced, consisting of a condensation layer to distill high-dimensional image features and an expansion layer to enrich low-dimensional clinical features. The transformed features were concatenated for multimodal fusion and used for recurrence prediction through a fully connected classifier.

RESULTS

We conducted 5-fold cross validation for the evaluation of our proposed model. The proposed multimodal DL model, which integrates selected clinical risk predictors with deep image features via dimensionality transformation, achieved the highest performance across all metrics, with an accuracy of 87.93%, sensitivity of 82.09%, specificity of 91.89%, and AUROC of 0.87. Ablation studies showed performance declined when omitting either component, with the lowest AUROC (0.82) observed when both were excluded. The model without dimensionality transformation showed reduced performance(accuracy: 79.48%, AUROC: 0.80), highlighting its role in feature alignment.

CONCLUSION

The incorporation of risk predictor selection and dimensionality transformation modules substantially improves multimodal deep learning performance by enabling balanced feature representation and effective cross-modal integration for recurrence prediction. (This work was supported by the NRF grant funded by the Korea government MIST.(No. RS-2023-00214043 and No. RS-2023-00207947)).

CLINICAL RELEVANCE/APPLICATION

Identifying patients at low and high-risk patients of recurrence can be used for postoperative treatment plans, such as adjuvant chemotherapy.

T5A-SPCH-7 EVALUATING LARGE LANGUAGE MODELS FOR RADIOLOGY REPORT GENERATION FROM MAMMOGRAMS AND CHEST X-RAYS

Sonali Sharma, BSc (*Presenter*)
Ojasvi Sharma (*Abstract Co-Author*)
Shreya Udupa (*Abstract Co-Author*)
Charlotte J. Yong-Hing, MD, FRCPC (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of ten state-of-the-art large language models (LLMs) in generating structured radiology reports for screening mammograms and chest X-rays, focusing on diagnostic accuracy, anatomical localization, completeness of findings, follow-up recommendation frequency, and hallucination rates.

METHODS AND MATERIALS

A dataset of 1,000 de-identified radiology cases was assembled, consisting of 500 screening mammograms (balanced across BI-RADS categories 1-5) and 500 chest X-rays (equally divided between normal and pneumonia findings). Gold-standard free-text reports verified by board-certified radiologists served as reference. Each case was processed by the following LLMs using the prompt "Please generate a structured radiology report": GPT-4 Turbo, GPT-4o, GPT-1.0, Google Gemini 1.5 Flash, Google Gemini 1.5 Pro, Grok Beta, Grok-2, Claude 3.5 Sonnet, Claude 3.7 Sonnet, and Mistral Large. Outputs were independently scored for diagnostic accuracy, anatomical localization, completeness of reported findings, appropriateness of follow-up recommendations, and presence of hallucinations. Inter-rater reliability exceeded ? = 0.80 across all metrics.

RESULTS

For mammography, GPT-4o achieved the highest performance with 81% diagnostic accuracy, 89% location accuracy, 92% finding completeness, 21% appropriate follow-up recommendation rate, and a hallucination rate of 67%. Claude 3.7 Sonnet followed closely with 79% diagnostic accuracy and the lowest hallucination rate (8%). For chest X-rays, GPT-4o again led with 93% diagnostic accuracy, 98% location accuracy, and 93% completeness, though it demonstrated a 25% hallucination rate. Claude 3.7 Sonnet and GPT-1.0 showed similar diagnostic performance with hallucination rates under 10%.

CONCLUSION

GPT-4o and Claude 3.7 Sonnet exhibit strong capabilities in generating structured radiology reports, particularly in diagnostic and localization accuracy. However, challenges persist in achieving consistent finding completeness, generating appropriate follow-up recommendations, and minimizing hallucinations. These findings underscore the importance of domain-specific training and cautious clinical integration.

CLINICAL RELEVANCE/APPLICATION

LLM-generated structured radiology reports may reduce documentation burden and enhance standardization, but current limitations in accuracy and reliability necessitate their use as assistive tools under clinician supervision. Further fine-tuning and validation are required before safe clinical deployment.

T5A-SPCH-10 IPN-TOOLKIT: AN AUTOMATED DETECTION AND CONSISTENCY CLASSIFICATION ALGORITHM FOR INDETERMINATE PULMONARY NODULES

Abhinav Suri, BA, MPH (*Presenter*)
Ashley E. Prosper, MD (*Abstract Co-Author*)
William Hsu, PhD (*Abstract Co-Author*)

PURPOSE

With the rise in lung cancer screening, the number of indeterminate pulmonary nodules (IPNs), defined as focal opacities 6-30mm in diameter without clear prognostic indicators, has increased. Risk stratification of IPNs is critical to minimizing unnecessary scans and biopsies. While models have been made for IPN risk quantification, development is hampered by the need to manually annotate lesions which is time-consuming and requires a high level of expertise to perform reliably. Using artificial-intelligence methods, we aimed to create a fully automated algorithm that could both detect IPNs and characterize their consistency. Such an algorithm can be used for cohort data mining and individual patient burden calculation of IPN prevalence and characteristics.

METHODS AND MATERIALS

We used diagnostic and lung cancer screening CT scans from three large patient cohorts (National Lung Screening Trial [NLST], the Lung Image Data Consortium [LIDC], and our institution's patients, n=2670 scans). 4287 and 1361 IPNs were included in the training and testing dataset, respectively, and were annotated experienced radiologists. We trained/evaluated four open-source lung nodule detection algorithms to assess accuracy specifically for IPN detection accuracy (as many algorithms are only validated on large, solid nodules). Detection boxes of predicted nodules (cropped from CT and resized to 50x50x50 voxels) were then classified as either solid, part-solid, non-solid, other (comprising classes such as cystic and semi consolidation nodules), or background (i.e., false-positive detection from previous step) using a convolutional neural network (ResNet18). Overall detection rates and area under the receiver operator characteristic curve (AUC) for each nodule consistency class and background are reported.

RESULTS

MONAI was the best lung-nodule detection algorithm (found 95% of nodules but with high false positives). The macro AUC for the characterization algorithm was 0.85 with non-solid nodules being the best class (AUC=0.89) and other nodules being the worst class (0.79). Classification was slightly better on diagnostic scans (macro AUC 0.87) vs screening scans (0.83). Macro AUC did not vary by a large amount across sites (macro AUC range 0.85-0.86).

CONCLUSION

We were able to create an automated algorithm for detection and classification of IPNs. Future studies include taking resultant outputs from this model and creating/validating a IPN risk stratification model in a large longitudinal cohort.

CLINICAL RELEVANCE/APPLICATION

Our tool can be used for automated IPN detection and characterization at both the patient level and at the cohort level for risk-stratification model development.

T5A-SPER-3 DIAGNOSTIC PERFORMANCE OF THE SKULL BASE JAGGED SIGN IN ADULTS WITH SEIZURES AND INCREASED INTRACRANIAL PRESSURE

Farbod Khalaj (*Presenter*)
Kamand Khalaj, MD, MPH (*Abstract Co-Author*)
Elham Tavakkol, MD (*Abstract Co-Author*)
Arash Kamali, MD (*Abstract Co-Author*)

PURPOSE

This study evaluates the sensitivity and specificity of the Skull Base Jagged Sign (SJS) on brain MRI and CT scans in adult patients with normal or elevated intracranial pressure (ICP) presenting to the emergency department, with or without idiopathic unprovoked seizures. Building on prior research linking bone remodeling to ICP changes, we aim to further define structural imaging markers of elevated ICP. To assess the diagnostic utility of SJS, we compared its prevalence across 4 distinct patient groups.

METHODS AND MATERIALS

In this IRB-approved retrospective study, adults aged 18-40 who underwent lumbar puncture and either brain MRI or CT scan at our institution were included. Patients were divided into 4 groups: Group 1 (elevated ICP with seizures, n=27), Group 2 (normal ICP with seizures, n=39), Group 3 (elevated ICP without seizures, n=52), and Group 4 (controls, n=39), who had normal opening pressure and unremarkable clinical, imaging, and CSF findings. SJS, defined as sharp bony remodeling in the posterior medial cranial fossa on coronal T2-weighted MRI or CT, was evaluated by two independent observers. Sensitivity, specificity, and predictive values were calculated.

RESULTS

SJS was most frequent in Group 1 (elevated ICP with seizures), present in 88.9% of cases, followed by 71.2% in Group 3 (elevated ICP without seizures) ($p=0.07$). It was significantly more common in Group 1 compared to Group 2 (normal ICP with seizures), where it appeared in 46.2% of patients (88.9% vs 46.2%, $p<0.001$), and also more frequent in Group 3 compared to the control group (Group 4), where it was present in only 30.8% (71.2% vs 30.8%, $p<0.001$). The difference between Group 2 and Group 4 (46.2% vs. 30.8%) was not statistically significant ($p=0.16$). For predicting seizures in patients with elevated ICP (Groups 1 & 3), SJS showed a sensitivity of 88.9% and a specificity of 28.8%. Among seizure patients (Groups 1 & 2), SJS had a sensitivity of 88.9% and specificity of 53.8% for detecting elevated ICP. In patients with normal ICP (Groups 2 & 4), SJS yielded a sensitivity of 46.2% and specificity of 69.2% for predicting seizures ($p=0.16$). For diagnosing elevated ICP in patients without seizures (Groups 3 & 4), SJS demonstrated a sensitivity of 71.2% and specificity of 69.2%.

CONCLUSION

The Skull Base Jagged Sign shows high sensitivity and may be a useful screening marker on brain MRI or CT scans for detecting elevated ICP in patients presenting to the emergency department, regardless of seizure status.

CLINICAL RELEVANCE/APPLICATION

The Skull Base Jagged Sign may aid in the early identification of elevated intracranial pressure on brain MRI or CT scans, supporting timely diagnosis and management in patients presenting to the emergency department with or without seizures.

T5A-SPGI-2 IMPACT OF BODY COMPOSITION ON EARLY RECURRENCE IN PATIENTS WITH RESECTABLE PANCREATIC CANCER

Bingjie Liu (*Presenter*)
Jing Zhu (*Abstract Co-Author*)
Haopeng Yu (*Abstract Co-Author*)
Xi Jiao Liu (*Abstract Co-Author*)
Yuqi Wang (*Abstract Co-Author*)
Yu Li (*Abstract Co-Author*)
Zixing Huang (*Abstract Co-Author*)
Bin Song (*Abstract Co-Author*)

PURPOSE

Despite increasing evidence suggesting that body composition is a predictor of poor prognosis in patients with pancreatic cancer, its association with early recurrence remains undetermined. In this study, we investigated the influence of body composition on early recurrence in patients with pancreatic cancer following surgical resection.

METHODS AND MATERIALS

Three hundred eighty-five patients who were diagnosed with pancreatic cancer and underwent curative surgery between January 2014 and December 2021 were retrospectively included. Preoperative CT at the third lumbar vertebral level was performed to ascertain the skeletal muscle index (SMI) and density (SMD), subcutaneous and visceral adipose tissue (SAT and VAT) indices and density. Clinical, biochemical and pathological information was collected. The associations of these factors with early recurrence were evaluated via the Kaplan-Meier method and univariable and multivariable Cox proportional hazards models.

RESULTS

Two hundred eighteen (57%) patients experienced early recurrence. A total of 156 (41%), 159 (41%), 189 (49%), and 144 (37%) patients had sarcopenia, myosteatosis, high SAT and high VAT, respectively. Cox regression multivariate analysis revealed that myosteatosis (HR: 1.63 (95% confidence interval (CI) 1.22~2.17, P<0.001) and high VAT (HR: 1.51 (95% CI 1.12~2.03), P=0.005) were independent factors contributing to early recurrence after surgery, whereas sarcopenia and SAT were not significantly associated. In addition, the newly proposed scoring system incorporating these independent prognostic factors demonstrated good predictive accuracy (AUC=0.724) and effective stratification of patients into high- and low-risk groups.

CONCLUSION

The present study revealed that myosteatosis and high VAT were associated with early recurrence, whereas sarcopenia and SAT were not. The incorporation of body composition analysis into preoperative assessments may improve risk stratification and guide personalized management strategies.

CLINICAL RELEVANCE/APPLICATION

This study explores whether CT-derived body composition parameters, such as myosteatosis and visceral adiposity, can predict early recurrence after curative-intent resection for pancreatic cancer. By integrating imaging and biochemical markers, we aim to develop a practical preoperative scoring system to aid in individualized risk stratification. This tool could help guide perioperative management decisions and improve patient selection for neoadjuvant or adjuvant therapies, using routinely acquired CT data in a cost-effective and clinically accessible manner.

T5A-SPGI-3 EARLY DETECTION OF PANCREATIC ADENOCARCINOMA RECURRENCE: IS CIRCULATING TUMOR DNA BETTER THAN CA 19-9?

Luke A. Ginocchio, MD (*Presenter*)
Andrew Ruff, MD (*Abstract Co-Author*)
Paul Smereka, MD (*Abstract Co-Author*)
Chenchan Huang, MD (*Abstract Co-Author*)

PURPOSE

To determine if circulating tumor DNA (ctDNA) is a more reliable biochemical marker for detecting pancreatic adenocarcinoma (PDAC) recurrence than carbohydrate antigen 19-9 (CA 19-9).

METHODS AND MATERIALS

55 consecutive patients (average age 71.9 years, 32 males, 23 females) who had pathologically proven PDAC recurrence following Whipple with postoperative CT studies and ctDNA values available between 11/1/2021 and 7/17/2024, were included. Images from the 114 CTs were anonymized and subsequently reviewed by three radiologists using a 5-point Likert scale for numerous imaging indicators of disease recurrence.

RESULTS

In 47/55 (85.5%) patients, ctDNA was elevated prior to imaging recurrence. 18 of these patients (38.3%) with imaging recurrence had a negative corresponding CA 19-9. All 18 of these cases corresponded to a ctDNA <22.2 ng/mL, with 88.9% (16/18) corresponding to a level <3.5 ng/mL. For 3 cases, all readers agreed on unlikely/no imaging evidence of overall recurrence, yet ctDNA was positive at time of initial postoperative CT (average 0.13 ng/mL), and these patients subsequently developed recurrent disease. On average, ctDNA was positive 94.2 days before disease recurrence was confirmed. Intraclass correlation coefficient for 'Overall Recurrence' likelihood was 0.72, indicating good reader agreement for imaging recurrence.

CONCLUSION

ctDNA was elevated in 85.5% of cases of disease recurrence, confirming its role as a reliable biochemical marker for detecting pancreatic adenocarcinoma recurrence. In addition, ctDNA was more sensitive than CA 19-9 for early disease recurrence in 38.3% of cases, suggesting improved detection of early recurrence. In the three cases in which all readers agreed on no convincing evidence of recurrence, ctDNA was positive, albeit low, potentially allowing for detection of disease recurrence earlier than imaging.

CLINICAL RELEVANCE/APPLICATION

ctDNA is a promising biochemical marker for detecting pancreatic adenocarcinoma recurrence, offering a potentially more sensitive replacement for CA 19-9 and may lead to earlier recurrence detection than imaging alone, resulting in improved patient outcomes.

T5A-SPGI-4 SPECTRAL CT AND CLINICAL PARAMETER INTEGRATION FOR PREOPERATIVE IDENTIFICATION OF PERINEURAL INVASION IN ADVANCED GASTRIC CANCER WITHOUT LYMPH NODE METASTASIS

Tiezhu Ren, MD, MMEd (*Presenter*)

PURPOSE

Node-negative advanced gastric cancer with perineural invasion-positive has a significantly increased chance of staging migration, and the choice of treatment regimen should be equivalent to that of node-positive patients. The purpose of this study was to investigate the utility of combining clinical and spectral computed tomography (CT) parameters in the preoperative evaluation of perineural invasion (PNI) in node-negative advanced gastric cancer (AGC).

METHODS AND MATERIALS

We retrospectively analyzed 127 patients with GC. All cases were confirmed by pathology, underwent spectral-CT examination, and were divided into positive group (n=88) and negative group (n=39) depending on PNI occurrence. Clinical characteristics, including demographic information, serum tumour markers, and gastroscopic pathological information, were collected. The effective atomic number (Zeff), iodine concentration (IC), and water concentration were measured in the arterial (AP) and venous (VP) phases. Intra-group correlation coefficient (ICC) was used to test the consistency of the results of each parameter measured by two observers. Parameter differences between the two groups were compared, and diagnostic performance was evaluated. Because of the imbalance between the two groups, we further used the F1 score to compare performances.

RESULTS

The PNI-positive group's histological grade, Borrmann type, Zeff, and IC were substantially greater than those of the negative group (AP-Zeff, 8.80±0.11 vs 8.15±0.13; VP-Zeff, 8.84±0.24 vs 8.31±0.65; AP-IC, 19.07±5.19 vs 14.42±3.97; VP-IC, 22.09±5.04 vs 15.65±4.24, all $p < 0.05$). The evaluated efficiency of the combination of clinical and spectral-CT parameters was superior to that of individual parameters. The clinical parameters combined with Zeff and IC in AP and VP exhibited good evaluation efficacy (AUC=0.854, F 1 =0.888, sensitivity=86.2%, specificity=79.4%, PPV=0.915).

CONCLUSION

Clinical and energy spectral-CT parameters exhibited considerable value in the preoperative evaluation of PNI in AGC. The combination of clinical and spectral-CT parameters exhibited a favorable performance in predicting PNI in AGC. The combined parameter model can further improve prediction efficiency and provide an effective tool for clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

The combination of clinical parameters and spectral-CT is a valuable approach to predicting PNI in GC. The combined parameter model can further improve prediction efficiency and provide an effective tool for clinical decision-making.

T5A-SPGI-6 QUANTITATIVE MRI PARAMETERS IN PATIENTS WITH TYPE 1, TYPE 2 DIABETES, AND LATENT AUTOIMMUNE DIABETES IN ADULTS (LADA): A CORRELATION PROSPECTIVE STUDY

Benedetta Masci, MD (*Presenter*)
Marta Zerunian, MD (*Abstract Co-Author*)
Stefano Nardacci, MD (*Abstract Co-Author*)
Damiano Caruso, MD, PhD (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)
Andrea Laghi, MD (*Abstract Co-Author*)

PURPOSE

To identify differences in quantitative MRI biomarkers among patients with type 1 diabetes (T1D), type 2 diabetes (T2D), and latent autoimmune diabetes in adults (LADA).

METHODS AND MATERIALS

In this prospective single-center study, 40 diabetic patients (T1D, T2D, LADA), aged 50-60 years were enrolled, from September 2023 to September 2024. The patients included underwent 1.5T upper abdominal MRI with axial proton density fat fraction (PDFF) and magnetic resonance elastography (MRE) sequences. Quantitative assessment included liver PDFF (L-PDFF), pancreatic PDFF (Pa-PDFF), liver stiffness (LS), and pancreatic volume (Pa-Vol). Two radiologists performed image analysis. Manual segmentation was performed with 3DSlicer v4.10.2. Statistical analysis included one-way ANOVA for group comparisons and Spearman's rank correlation for associations.

RESULTS

Hepatic steatosis (L-PDFF >5.5%) was observed in 27% of the population. Elevated liver stiffness (>2.4 kPa) suggestive of inflammation or low-grade fibrosis was present in 55% of the population. Pancreatic volume reduction was identified in 32% of the population. L-PDFF values significantly differed between T2D, T1D and LADA patients (T2D: 6.15 % ± 3.04; T1D: 2.45 % ± 0.35; LADA: 2.8 % ± 1.13; $p < 0.00023$); furthermore, Pa-PDFF did not show significant differences among groups ($p = 0.304$). In T1D patients, L-PDFF significantly correlated with Pa-PDFF ($p < 0.0001$); this association was not observed in T2D or LADA. Pa-Vol differed among groups (T2D: 50.9 ± 2.76 cm^3; T1D: 44.1 ± 4.17 cm^3; LADA: 45 ± 2.2 cm^3;), with significant differences between T2D and LADA ($p < 0.0001$).

CONCLUSION

Quantitative MRI identified significant differences in pancreatic volume and hepatic fat accumulation across diabetes types, particularly between T2D and LADA. These findings support MRI as a promising non-invasive tool to phenotype diabetic patients and monitor disease progression.

CLINICAL RELEVANCE/APPLICATION

Quantitative abdominal MRI detects significant differences among different diabetes subtypes, offering a reliable, non-invasive imaging biomarker approach to evaluate metabolic organ involvement.

T5A-SPGI-8 LONG TERM PROGNOSIS OF INDETERMINANT LESIONS IN THE CIRRHOTIC LIVER: INSIGHTS FROM THE LI-RADS 3 NEUTRAL CATEGORY

Aymen Bahsoun, BS, MD (*Presenter*)
Juliana Ramirez (*Abstract Co-Author*)

Radhika Rajeev, MD (*Abstract Co-Author*)
Meredith Reed (*Abstract Co-Author*)
Reve Chahine, MD, FRCR (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)
Shane A. Wells, MD (*Abstract Co-Author*)
Hero K. Hussain, MD, FRCR (*Abstract Co-Author*)

PURPOSE

Liver Imaging Reporting and Data System (LI-RADS) category 3 represents indeterminate lesions with estimated malignancy risk of 30-40% 1 . LR-3 lesions require monitoring at 3-6-month intervals 2 , which can be resource and time-consuming. We aimed to assess the outcomes of LR-3 lesions in cirrhotic patients at our center and identify predictors of malignant and benign outcomes.

METHODS AND MATERIALS

We conducted a retrospective chart review of patients with LR-3 lesions identified between 2019-2021. Data collected included imaging characteristics, lesion outcomes over a follow-up period of 3-48 months, reader's experience, and the coexistence and category of additional lesions. Patient-specific variables included age, sex, etiology of cirrhosis, and liver treatment status (treatment-naïve or previously treated).

RESULTS

795 LR-3 observations in 427 patients (41% previously treated), 86% observations exhibited isolated arterial phase hyperenhancement, and 17% had ancillary features. After follow-up, 26% of LR-3 lesions were upgraded, 58% downgraded, and 16% remained unchanged. The highest-grade coexisting lesion was LR-5 in 26%, LR-4 in 19%, and LR-3 in 35%. No significant differences in outcomes were observed based on reader's experience or the type of major LI-RADS imaging characteristics. LR-3 lesions in treatment-naïve vs treated livers had lower upgrade rates (17% vs 38%, p< 0.001; HR 0.71, p<0.001) and higher downgrade rates (69% vs 44%, p<0.001; HR 1.78, p<0.001). Alcohol-related cirrhosis as well as Hepatitis C cirrhosis were associated with LR-3 upgrade to (HR 1.61, 95% CI, p=0.01,). Lesions with ancillary features were approximately twice as likely to upgrade and 34% less likely to downgrade (HR 2.07, 95% CI, p=0.004; HR 0.64, 95% CI, p=0.03).

CONCLUSION

Post-treatment liver status, the coexistence of other LI-RADS lesions, alcoholic cirrhosis, and ancillary features were associated with malignant outcomes. Identifying predictors of LR-3 outcome may help refine surveillance strategies and reduce resource burden.

CLINICAL RELEVANCE/APPLICATION

Certain characteristics may tailor follow-up intervals for LIRADS 3 lesions.

T5A-SPGI-9 EVALUATION OF SALINE INFUSION MRI FISTULOGRAM IN PERIANAL FISTULA: A CROSS-SECTIONAL STUDY

Sachin Virmani, MD (*Presenter*)

PURPOSE

To evaluate the accuracy and usefulness of normal saline infusion in MR-Fistulogram in the diagnosis of peri- anal fistula.

METHODS AND MATERIALS

Study design Cross-sectional study Study population : clinical diagnosed peri anal fistula patients Study duration: 18 months Sample size n ~ 107• Conventional MRI and MRI with saline MR Fistulogram using Philips-1.5-Tesla Three Planes • Section thickness: 3 mm • Axial, coronal and sagittal: T2• Axial and coronal: STIR / T2 FS

RESULTS

Participants ranged from 5 to 75 years, with most aged 36-45 (32.7%), followed by 46-55 (23.3%). Males predominated (89.7%; M:F = 8:1). Drivers were the most common occupation (15.8%). Saline MRI identified internal openings 1 and 2 in 93.4% and 6.5% of cases, respectively, while conventional MRI identified 84.1% and 0.9%, missing 16 cases. Both methods showed posterior internal openings, with Intersphincteric and Transsphincteric types in 59.8% and 38.3%. Internal opening-to-anal verge distance of 2.1-3.0 cm was noted in 16.8% (saline MRI) and 22.4% (conventional). Fistula diameter was 2-3 mm in 37.3% (saline) and 1-2 mm in 32.7% (conventional). Most were left-sided (57%), with external openings commonly at 6 o'clock (15.8%). Secondary branches were seen in 46.7%. Saline MRI showed 2 ramifications in 14.9%, while conventional MRI showed 1 in 19.6%. Horseshoe tracts were noted in 9.3%. Abscesses were absent in 60.7%; simple and horseshoe abscesses were seen in 29.9% and 9.3%. Perianal inflammation was present in 48.5%. Thin tracts were seen more with saline MRI (93.4% vs. 65.5%). Thick tracts were seen in 98.1% of both. Statistically significant correlation was noted between modalities. Conventional MRI was highly specific (100%) for 2 openings but less sensitive (81.2%) for 1. Saline MRI showed perfect specificity, PPV, and NPV for detecting secondary tracts and 2 ramifications (p < 0.0001).

CONCLUSION

MR imaging with normal saline provides a precise definition of the fistulous track, along with its relationship to pelvic structures, and allows identification of secondary fistulas or abscesses. MRI using normal saline as a contrast agent has a specificity and sensitivity comparable to those obtained in studies using gadolinium contrast agents either intravenously or as a local agent. Normal Saline can thus act as a cheaper alternative as well, and we can avoid contrast-related reactions to gadolinium-based contrast agents in the evaluation of perianal fistula.

CLINICAL RELEVANCE/APPLICATION

This improved imaging capability aids in precise surgical planning, ultimately reducing recurrence rates. The technique is non-invasive and free of radiation exposure, making it a safer alternative to conventional imaging methods

T5A-SPGI-10 INTRAINDIVIDUAL COMPARISON OF 3-T AND 5-T GD-EOB-DTPA-ENHANCED MRI IN EVALUATION OF HEPATOCELLULAR CARCINOMA: INITIAL RESULTS

Shao Peng Li II, DO (*Presenter*)
Ying Liu (*Abstract Co-Author*)
Lianxin Liu (*Abstract Co-Author*)
Dawei Yin (*Abstract Co-Author*)
Peng Wang (*Abstract Co-Author*)
Mengqiu Liu (*Abstract Co-Author*)
Zhichao Feng, MD (*Abstract Co-Author*)
Runyu Tang (*Abstract Co-Author*)
Xiaopeng Song (*Abstract Co-Author*)

PURPOSE

To compare the value of Gd-EOB-DTPA-enhanced magnetic resonance imaging (MRI) at 5.0 T and 3.0 T in the diagnosis of hepatocellular carcinoma (HCC).

METHODS AND MATERIALS

Prospective recruitment of 25 suspected HCC patients and underwent plain and Gd-EOB-DTPA-enhanced, including arterial phase(AP), portal vein phase(PVP), transition phase(TP), and hepatobiliary phase(HBP) at 5.0 T and 3.0 T. For TP and HBP at 5.0 T, artificial intelligence-assisted compressed sensing (ACS) and parallel imaging (PI) were applied and compared. Two abdominal radiologists independently evaluated the image quality, including objective indices and subjective image quality scores. At

the same time, the detection rates of HCC imaging features were compared. Cohen's Kappa test was performed to assess the consistency between the two readers. Paired Chi-square or Student's t test was used to compare the differences in objective, subjective scores and the detection rate of imaging features.

RESULTS

All subjective scores were good to excellent at both 5.0 T and 3.0 T. The contrast enhanced images, had significantly higher SNR, CNR, CR and subjective scores than 3.0 T (all p <0.05). The subjective and objective scores of TP and HBP images were significantly higher with ACS than PI (all p <0.05). The detection rate of enhancing "capsule", coronary enhancement on AP, intra-lesion arterial vessels, and peritumoral hypointensity on the HBP were all higher on 5.0T MRI than 3.0T. Voxel sequences based on ACS technology can further improve the detection rate of enhancing capsule and peritumoral hypointensity on the HBP(p <0.001, p =0.037, respectively).

CONCLUSION

The image quality of Gd-EOB-DTPA enhanced MRI at 5.0T is better than that at 3.0 T. The use of 5.0 T enhanced scanning combined with ACS technology can improve the display of HCC imaging features, and improve the diagnostic accuracy of HCC.

CLINICAL RELEVANCE/APPLICATION

Gd-EOB-DTPA-enhanced MRI based on 5.0 T provides excellent image quality, improving hepatocellular carcinoma detection and display of imaging features.

T5A-SPGI-11 CLINICAL AND TECHNICAL FACTORS PREDICTING DIAGNOSTIC VS. NON-DIAGNOSTIC POINT-OF-CARE QUANTITATIVE ULTRASOUND (US) FOR LIVER STIFFNESS

Stephanie T. Chang, MD (*Presenter*)
Nancy Zhang (*Abstract Co-Author*)
Jason Wong (*Abstract Co-Author*)
Miki Kwan (*Abstract Co-Author*)
Gabriela Torres (*Abstract Co-Author*)
Jacqueline A. Bailey, ARRT (*Abstract Co-Author*)
Om Patel (*Abstract Co-Author*)
Molly Ma (*Abstract Co-Author*)
Cecilia Miller (*Abstract Co-Author*)
Oluwademilade Dada (*Abstract Co-Author*)
Vibhas Deshpande, PhD (*Abstract Co-Author*)
Ramsey Cheung (*Abstract Co-Author*)
Daniel Ennis (*Abstract Co-Author*)

PURPOSE

Point-of-care ultrasound (POCUS) for liver stiffness quantification will revolutionize screening for metabolic dysfunction-associated steatotic liver disease (MASLD), a leading cause of liver failure. However, ultrasound (US) as a technique remains limited or non-diagnostic due to a variety of factors. We aim to examine potential clinical and technical factors that lead to diagnostic vs. non-diagnostic US quantification of liver stiffness.

METHODS AND MATERIALS

Veterans (n=101) with obesity (body mass index > 30) and/or type 2 diabetes were enrolled in an IRB-approved study in 2022-2024. Liver stiffness and fat measurements were obtained using US auto point shear wave elastography (auto-pSWE) and US derived fat fraction (UDFF) (Siemens ACUSON Sequoia with DAX transducer, software revision VA30B). Same-day MRI elastography (MRE) and proton density fat fraction (PDFF) were also performed (Siemens MAGNETOM Vida Fit). Diagnostic US auto-pSWE measurements passed a two-step process that required IQR/median <0.6 and 4-point manual image review. Clinical factors include patient age, gender, body mass index (BMI), and type 2 diabetes status (DM2). Technical factors include operator type (radiologist vs. non-radiologist), auto-pSWE value, US region of interest (ROI) depth in centimeters (cm), number of valid auto-pSWE boxes (out of 15 total), and MRI PDFF to determine any effects of underlying hepatic steatosis. Spearman rank correlation and logistic regression analyses were performed.

RESULTS

Of 101 veterans enrolled (median age 68 years, range 37-75 years), most were male (n=90) and obese (median BMI 31.6, range 19.3-49.1) with DM2 (n=84). Spearman rank correlation between US auto-pSWE and MRE for diagnostic US values was 0.28 (p<0.001) and for non-diagnostic US values was 0.03 (p=0.89). Logistic regression analysis showed that a non-radiologist operator (p=0.007), greater US ROI depth (p=0.02), greater patient age (p=0.03), and female gender (p<0.001) were significant predictors for non-diagnostic US auto-pSWE measurements.

CONCLUSION

Non-diagnostic liver US elastography values are associated with US operator type (non-radiologist), greater US ROI depth, greater patient age, and female gender. We were unable to detect an effect for other clinical or technical factors.

CLINICAL RELEVANCE/APPLICATION

Radiologists should be aware that clinical factors including patient age and gender and technical factors including US operator and US ROI depth can affect whether POCUS liver elastography is non-diagnostic.

T5A-SPGI-12 A MULTIMODAL MACHINE LEARNING MODEL INTEGRATING ENDOSCOPIC ULTRASOUND AND CTRADIOMICS FOR DIFFERENTIATING GASTROINTESTINAL STROMAL TUMORS FROM LEIOMYOMAS: A MULTICENTER STUDY

Xiao Zhang (*Presenter*)
Jiao Jiao (*Abstract Co-Author*)
Boyun Li (*Abstract Co-Author*)
Mingzhu Li (*Abstract Co-Author*)
Weifang Yu (*Abstract Co-Author*)
Lian Zhang (*Abstract Co-Author*)

PURPOSE

To assess the potential of a multimodal machine learning model incorporating clinical information, endoscopic ultrasound (EUS), and CT radiomics for differentiating gastrointestinal stromal tumors (GISTs) from gastrointestinal leiomyomas (GILs).

METHODS AND MATERIALS

A total of 108 patients were retrospectively enrolled from January 2020 to October 2024. These patients were divided into a training cohort from centers 1 and 2, comprising 79 patients with 356 lesions, and an independent validation cohort from center 3, comprising 29 patients with 147 lesions. Clinical data, including demographic features, laboratory test results, and EUS morphological features, were analyzed using univariate logistic regression to identify significant variables. Radiomics features were extracted from two-dimensional lesions in preprocessed non-contrast EUS and CT images, with a total of 651 features extracted for each lesion. After applying downsampling, causal inference, Pearson correlation analysis, and Relief algorithm, a highly corrected and non-redundant feature set was obtained. The optimal radiomics model was constructed by comparing various classifiers across five-fold cross-validation, generating patient-level radscores (EUS-radscore and CT-radscore) through the averaging and weighting of lesion-level outputs. A multimodal machine learning model integrating the significant clinical variables, EUS-radscore, and CT-radscore was further explored. Model discrimination and clinical usefulness were evaluated using the area under the curve (AUC), decision curve analysis (DCA), and clinical impact curve (CIC), respectively.

RESULTS

None of the clinical variables demonstrated a significant correlation with the differentiation task following univariate logistic regression analysis. The CT-radscore, derived from 18 features, demonstrated superior performance compared with the EUS-radscore, which was based on 4 features ($P < 0.05$). A multimodal model integrating CT-RadScore and EUS-RadScore achieved AUC values of 0.965 (95% CI: 0.949-0.981) in the training cohort and 0.946 (95% CI: 0.924-0.969) in the validation cohort, demonstrating superior performance to single-modality models ($P < 0.05$). DCA and CIC analysis further confirmed the superior clinical usefulness of the multimodal model.

CONCLUSION

The multimodal machine learning model incorporating EUS and CT radiomics has shown a significantly enhanced capability in differentiating GISTs from GILs compared to single-modality approaches.

CLINICAL RELEVANCE/APPLICATION

The current study provides an enhanced multimodal diagnostic tool to accurately differentiate GISTs from GILs, facilitating tailored treatment strategies and improving patient outcomes.

Benoit Magnin, MD,MSc (*Abstract Co-Author*)

PURPOSE

Detection of liver metastases on abdominal CT is crucial in medical imaging but can be challgenging. New deep-learning image reconstruction (DLIR) algorithms are based on convolutionnal neural network trained on high quality image datasets to provide higher quality abdominal CT at same radiation doses compared to iterative reconstructions. The main purpose of the study was to assess if DLIR could allow an increase in the detection of liver metastases by comparing three different strengh levels of DLIR and a conventionnal iterative reconstruction method. Secondary objective was to compare metastases conspicuity for each reconstruction.

METHODS AND MATERIALS

CT scans of the abdomen and pelvis of 121 patients performed for cancer initial assessment or follow-up were compared. The inclusion criterion was the presence of at least one hypoattenuating liver metastasis described in the radiology report. For each patients, one iterative reconstruction 50%-ASiR-V and three deep-learning reconstructions were obtained using the DLIR algorithm TrueFidelity at different strength levels: DLIR-low (DLIR-L), DLIR-medium (DLIRM), and DLIR-high (DLIR-H). For each reconstruction, two double-blinded radiologists counted up to a maximum of ten metastases. Overall image quality, image noise reduction, hepatic metastases visibility and hepatic metastases contour definition were also assessed using a five-point scal by both radiologists. In cases where both readers found more metastases with DLIR-H than ASiR-V or vice versa, a third independent radiologist blindly evaluated the number of lesions on both reconstructions to confirm or disprove the difference.

RESULTS

A higher number of metastases was detected by the senior reader (R2) with DLIR-high: 7 (2-10) (median (Q1-Q3); total 733) versus 5 (2-10) respectively for DLIR-medium, DLIR-low, and ASiR-V ($p < 0.001$). The junior reader (R1) found no significant difference in metastases number between reconstructions. For 12 patients, both readers simultaneously found a higher number of metastases with DLIR-H compared to ASiR-V. This was confirmed by the third radiologist for ten patients. Image quality and noise reduction were lower for ASiR-V and increased with deep learning levels. Metastases visibility and contour definition were better for DLIR-H for both readers.

CONCLUSION

High-strength DLIR improved visibility of liver metastases and led to a statistical increase in the number of detected hepatic metastases compared to iterative reconstruction.

CLINICAL RELEVANCE/APPLICATION

Deep learning-based reconstruction at high strength allows an increase in liver metastases detection compared to hybrid iterative reconstruction and can be used to help overcome the limitations of CT.

T5A-SPGI-16 DIAGNOSTIC PERFORMANCE OF CONVENTIONAL AND QUANTITATIVE ULTRASOUND IN DETECTING HEPATIC STEATOSIS IN CHILDREN: A SYSTEMATIC REVIEW AND INDIVIDUAL PARTICIPANT DATA META-ANALYSIS

Sedighe Hosseini Shabanan, MD, MPH (*Presenter*)

Claude B. Sirlin, MD (*Abstract Co-Author*)

PURPOSE

To review the literature systematically and perform individual participant data (IPD) meta-analysis on the accuracy of conventional ultrasound (CUS) and quantitative ultrasound (QUS) in assessing hepatic steatosis in children.

METHODS AND MATERIALS

We performed a systematic literature review using the MEDLINE database to identify studies published in English through June 2024 concerning diagnostic performance of CUS or QUS for assessing hepatic steatosis in children. Six CUS and 15 QUS studies were eligible (one study investigated both). QUS parameters included controlled attenuation parameter (CAP), hepatorenal index (HRI), and attenuation coefficient (AC). Risk of study bias was assessed across 4 domains (patient selection; index test; reference standard; flow and timing) using the Quality Assessment of Diagnostic Accuracy Studies-2 critical appraisal checklist. Study authors were asked to share raw data for IPD meta-analysis. Areas under the receiver operating characteristic curve (AUCs) and, at optimal Youden index-based thresholds, sensitivity and specificity were computed, along with their 95% confidence intervals (CIs).

RESULTS

All selected studies were considered at risk for bias. Sensitivity/specificity pairs from the 6 CUS studies ranged from 48%/97% to 100%/11%; Youden indices (sums of sensitivity and specificity) ranged from 111% to 145%. Authors of the CUS studies did not share IPD, precluding meta-analysis. Based on IPD metanalysis of 4 studies (n=252 participants), CAP had 0.79 AUC (95% CI: 0.71, 0.87) and, at an optimal threshold of 278 dB/m, 73% sensitivity (95% CI: 66%, 78%) and 78% specificity (95% CI: 62%, 89%). Based on IPD metanalysis of 3 studies (n=159), HRI had 0.79 AUC (95% CI: 0.71, 0.86) and, at an optimal threshold of 1.76, 57% sensitivity (95% CI: 43%, 70&) and 89% specificity (95% CI: 81%, 94%). Based on IPD metanalysis of 4 studies (n=277), AC had 0.92 AUC (95% CI: 0.88, 0.95) and, at an optimal threshold of 0.66 dB/cm/MHz, 78% sensitivity (95% CI: 70%, 85%) and 94% specificity (95% CI: 89%, 98%).

CONCLUSION

CUS has inconsistent diagnostic accuracy for hepatic steatosis in children. Among QUS techniques, CAP and HRI showed modest performance, while AC demonstrated high diagnostic accuracy. All studies showed risk of bias, highlighting a need for higher-quality research.

CLINICAL RELEVANCE/APPLICATION

CUS, CAP, and HRI lack sufficient diagnostic accuracy for clinical use in pediatric hepatic steatosis. AC may offer a reliable noninvasive alternative pending further validation.

T5A-SPGI-17 INTEROBSERVER AGREEMENT AND ACCURACY OF VARIOUS MR SEQUENCES FOR SIZE MEASUREMENT OF PANCREATIC CYSTIC LESIONS: A PRELIMINARY STUDY

Sreeja Sanampudi, MD (*Presenter*)
Naveen Rajamohan, MD,MBBS (*Abstract Co-Author*)
Yin Xi, PhD (*Abstract Co-Author*)
Lakshmi Ananthakrishnan, MD (*Abstract Co-Author*)
Takeshi Yokoo, MD, PhD (*Abstract Co-Author*)
Gaurav Khatri, MD (*Abstract Co-Author*)

PURPOSE

Pancreatic cystic lesions (PCLs) are seen in 20-44% of abdominal MRIs and have variable risk profile for transformation to pancreatic adenocarcinoma. Size is a common feature used in all the guidelines to predict their malignant potential. The purpose of this study is to determine the MRCP sequence that yields the highest inter-reader agreement for measurement of PCLs and compare PCL measurements on various MRCP sequences to endoscopic ultrasound (EUS).

METHODS AND MATERIALS

This single center retrospective study included 56 patients who underwent MRCP and EUS for PCLs within 1 year of each other. PCLs less than 1 cm on MRI and without corresponding EUS measurement were excluded. Three blinded body-trained radiologists (R1, R2, R3) with variable experience levels measured the maximum cyst diameter on 3D-MRCP, radial MRCP, axial T2-weighted (T2w), and coronal T2w sequences. Inter-reader agreement was assessed using intra-class coefficient (ICC) and reproducibility coefficient (RDC). Mean absolute deviance and Bland Altman plots were used to compare measurements on MRCP and EUS.

RESULTS

78 PCLs from 56 patients were included. The mean cyst size on EUS was 20mm, and mean on different sequences ranged from 19-23mm. The ICCs between three radiologists were 0.94, 0.94, 0.92, and 0.94, for measurements on 3D-MRCP, radial MRCP, axial T2w, and coronal T2w sequences, respectively. No significant differences were observed in the ICC across sequences ($p > 0.05$). No significant difference was observed in RDC between readers across sequences with RDCs ranging from 6.1-6.9mm ($p>0.05$). Mean absolute deviance between various sequences and EUS ranged from 2.46-2.62mm, also not statistically different ($p>0.05$).

CONCLUSION

While there was excellent relative agreement for measurement of PCLs between three radiologists in terms of ICC on all MRCP sequences, the RDC as a measure of absolute agreement between readers was larger than expected. The mean absolute deviances between all the MRCP sequences and EUS were small. There were no significant differences between sequences for measurement of pancreatic cystic lesions.

CLINICAL RELEVANCE/APPLICATION

Our study found similar agreement between readers for PCL measurements on various MRCP sequences and in comparison to EUS, suggesting that all sequences are feasible if used consistently. However, our study's RDC of >6 mm suggests greater absolute variability on MRCP measurements than previously thought. To our knowledge, this is the first study to report RDC when comparing reproducibility measurements in PCLs. Based on our findings, the current Kyoto guideline's criterion of growth rate = 2.5 mm per year as a worrisome feature may need to be reconsidered.

T5A-SPGU-1 ASSESSMENT OF PROSTATE SHAPE DIFFERENCES USING AN ATLAS BASED APPROACH IN PROSTATE CANCER PATIENTS WITH AND WITHOUT EXTRAPROSTATIC EXTENSION ON 3 TESLA BIPARAMETRIC MRI

GOURAV MODANWAL (*Presenter*)
Sena Azamat (*Abstract Co-Author*)
Naoto Tokuyama (*Abstract Co-Author*)
Zelin Zhang (*Abstract Co-Author*)
Abhishek Midya (*Abstract Co-Author*)
Martin J. Sanda, MD (*Abstract Co-Author*)
Mohammad Hajiha (*Abstract Co-Author*)
Anant Madabhushi, PhD (*Abstract Co-Author*)

PURPOSE

Extraprostatic extension (EPE) is a critical factor in determining eligibility for nerve-sparing surgery and focal therapy in prostate cancer. However, identifying EPE on biparametric prostate MRI (bpMRI) is challenging due to the subtle nature of capsular invasion. While features like the length of capsular contact may suggest the presence of EPE, this feature suffers from high inter-reader variability. In this study, we explored the hypothesis that an atlas-based approach would allow for discernment of prostate shape differences between EPE-positive (EPE?) and EPE-negative (EPE?) patients on bpMRI.

METHODS AND MATERIALS

Fifty-five patients with clinically significant prostate cancer underwent bpMRI using a Philips Ingenia 3T scanner. Axial T2-weighted (T2w) images were acquired with the following parameters: TR = 3,184 ms, TE = 100 ms, FOV = 240 × 240 mm², and slice thickness = 3 mm. EPE status was determined based on histopathological examination of radical prostatectomy specimens. Prostate glands were segmented from T2w images using an in-house based deep learning model. Population-based prostate gland atlases for the EPE? and EPE? cohorts (denoted by A + and A - respectively) were generated using a multi-reference registration pipeline, including rigid and deformable steps, followed by histogram matching to produce group-average prostate gland maps. All gland segmentations were then rigidly registered to A - for spatial alignment. Signed distance functions were computed from aligned masks, and the prostate surface was extracted as the zero-level isosurface. Gaussian curvature and surface normals were calculated for each mesh. To enable spatially localized analysis, each prostate surface was divided into 12 anatomical regions. Regional curvature and surface orientation metrics were extracted, and group differences were assessed using the Mann-Whitney U test.

RESULTS

The cohort consisted of 55 patients (mean age 70 ± 7 years; PSA 19 ± 19 ng/mL), including 18 EPE + and 37 EPE - cases. Surface morphometry revealed significant differences in curvature and surface normal orientation between groups. Notable differences were observed in the apex and mid-gland regions.

CONCLUSION

The atlas-based approach enabled the detection of subtle capsular shape differences in the apex and mid-gland regions between patients with EPE? and EPE?. This finding is consistent with previous studies that identified shape related features of the prostate capsule, such as capsular bulge, as significant indicators of EPE.

CLINICAL RELEVANCE/APPLICATION

Atlas-based shape analysis identifies subtle prostate surface changes in EPE + patients, potentially improving preoperative staging accuracy and surgical planning for nerve sparing approaches.

T5A-SPGU-2 T1 RATIO DERIVED FROM T1-WEIGHTED IMAGING PREDICTS RENAL OUTCOMES IN TYPE 2 DIABETES: A SEMIAUTOMATED TLCO-BASED PROGNOSTIC TOOL

Shaopeng Zhou, MD (*Presenter*)
Chaobo Li (*Abstract Co-Author*)
Haiyi Wang, MD (*Abstract Co-Author*)

PURPOSE

Diabetic kidney disease (DKD) has become the leading cause of end-stage renal disease (ESRD). However, noninvasive diagnostic modalities for early detection and risk stratification remain insufficiently developed. Although the loss of corticomedullary differentiation (CMD) on T1-weighted imaging (T1WI) is a well-recognized indicator of renal insufficiency, its assessment continues to be subjective, and its prognostic implications have yet to be fully elucidated. This study aims to quantify CMD loss using a novel 12-layer concentric objects (TLCO) method and assess its prognostic significance in chronic kidney disease (CKD) patients with type 2 diabetes mellitus (T2DM).

METHODS AND MATERIALS

In this prospective cohort study, 92 patients with T2DM underwent T1WI from February 2019 to January 2024. Patients were stratified into early and advanced CKD groups using an estimated glomerular filtration rate (eGFR) cutoff of 60 ml·min?¹·1.73 m?². The 12 iso-thick layers from the cortex to the medulla was generated using TLCO method on the T1WI of the right kidney. Mean T1 signal intensities (SI) from layers 9-11 (representing the cortex) and layers 3-5 (representing the medulla) were used to calculate two parameters: T1 relative signal intensities (RSI) = (cortical T1 SI - medullary T1 SI) / (cortical T1 SI + medullary T1 SI), and T1 ratio = cortical T1 SI / medullary T1 SI. Variables with $p < 0.05$ in the univariate analysis were entered into the multivariable Cox proportional-hazards regression model.

RESULTS

Patients in the early CKD group exhibited significantly higher T1 RSI and T1 ratio compared to those in the advanced CKD group (0.048 vs. 0.028, 1.102 vs. 1.060; all $p < 0.001$). Multivariate analysis revealed that systolic blood pressure, hemoglobin, cystatin C and lower T1ratio (T1 ratio = 1.084) were independent predictors of adverse renal outcomes. Specifically, a lower T1 ratio was associated with a worse prognosis (hazard ratio [HR] = 5.456, 95% CI: 2.047 - 14.540, $p < 0.001$).

CONCLUSION

T1 ratio derived from conventional T1WI via TLCO is a reproducible, clinically actionable biomarker for CKD progression in T2DM, independently of biochemical parameters, including eGFR.

CLINICAL RELEVANCE/APPLICATION

The TLCO-derived T1 ratio serves as a reliable MRI biomarker for CKD progression. Its integration into routine MRI protocols could assist clinicians in assessing renal injury and facilitating risk stratification.

T5A-SPGU-3 PHOTON-COUNTING CT RADIOMICS FOR CHARACTERIZING ABDOMINOPELVIC CALCIFICATIONS USING MULTI-ENERGY FEATURES

Jacob Sharafuddin, BA (*Presenter*)
Ahmed Benghatnsh, MD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)
Ramandeep Singh, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To evaluate radiomics applied to spectral post-processing (SPP) images from photon-counting detector CT (PCCT) for differentiating urinary stones, vascular plaques, and phleboliths.

METHODS AND MATERIALS

This IRB-approved retrospective study included 114 adults (74M:40F; mean age 62.9 Y SD ±14.4 years) scanned using PCCT (Siemens NAEOTOM Alpha). The confirmed stone types included calcium oxalate (CaOx; n=20) and calcium phosphate (CaPhos; n=10). Semiautomatic segmentation of stones (S; renal/ureter/bladder, n=182), plaques (PL; renal and iliac arteries, n=132), and phleboliths (PH; n=116) was performed in syngo.via (RadiomicsV1_4_5, Siemens Healthineers, Forchheim, Germany). Radiomic features were extracted from single axial SPP images to generate virtual monoenergetic images (VMI 40-190 keV at 10 keV intervals), virtual non-contrast (VNC), and iodine maps. Post-contrast imaging served as ground truth. A total of 854 radiomic features - including original (n=110) and wavelet-transformed (n=744) - were analyzed using a random forest classifier, univariate and multivariate logistic regression. Receiver operating characteristic curves were generated to calculate area under the curve (AUC) values.

RESULTS

Radiomic analysis achieved the highest accuracy in differentiating plaques (PL) from phleboliths (PH) with an AUC of 0.97. The most predictive features included original GLCM correlation (OR: 1.63), wavelet-LLH first-order 90th percentile (OR: 1.40), wavelet-HLL NGTDM coarseness (OR: 1.19), and shape compactness (OR: 267). Differentiation between stones (S) and plaques (PL) showed an AUC of 0.93. Key radiomic features included four first-order metrics-minimum (OR: 1.35), mean (OR: 1.16), median, and skewness (OR: 1.23) - as well as wavelet-transformed texture features from GLCM, GLRLM, and GLSZM matrices. Inverse variance (OR: 1.66), correlation (OR: 1.24), and gray-level non-uniformity (OR: 1.29) effectively captured spatial heterogeneity. Distinguishing stones (S) from phleboliths (PH) yielded an AUC of 0.82, with overlapping predictive features reflecting intensity and texture-based differences among calcified structures. For differentiating CaOx and CaPhos stones, the best AUC was 0.69.

CONCLUSION

Radiomics applied to spectral PCCT allows for accurate differentiation between urinary tract stones, vascular plaques, and phleboliths.

CLINICAL RELEVANCE/APPLICATION

Radiomics has the potential to improve CT diagnostic workflows by enabling more precise and non-invasive characterization of calcifications in the abdominopelvic region in challenging clinical scenarios.

T5A-SPGU-5 PREOPERATIVE PREDICTION OF RENAL CLEAR CELL CARCINOMA GRADINGWITH EXTRACELLULAR VOLUME FRACTION IN DUAL-ENERGY SPECTRAL CT: CT ENHANCEMENT VALUE OR IODINE CONCENTRATION MEASUREMENT

Jian He (*Presenter*)
Jianying Li, PhD (*Abstract Co-Author*)
Yijun Liu (*Abstract Co-Author*)

PURPOSE

To compare the value of extracellular volume fraction (ECV) calculated from CT enhancement values (?HU, between contrast and non-contrast scans) based on 120kVp-like images and iodine concentration (IC) measurements from iodine maps in dual-energy spectral CT (DEsCT) in preoperatively predicting the pathological grading of renal clear cell carcinoma (ccRCC).

METHODS AND MATERIALS

A retrospective analysis was conducted on 100 pathologically confirmed ccRCC patients who underwent triple-phase contrast-enhanced DEsCT between November 2021 and July 2024. Among them, 64 were in the low-grade group (WHO/ISUP grades 1 and 2) and 36 in the high-grade group (WHO/ISUP grades 3 and 4). Tumor CT values in the non-contrast, arterial phase (AP), venous phase (VP), and delayed phase (DP) were measured on the 120 kVp-like images to obtain ?HU for AP, VP, and DP. IC for the enhanced tumors during the three phases was measured on the iodine maps. Hematocrit (HCT) values were recorded, and ECV based on ?HU and IC were calculated using respective formulas. The predictive performance of using ECV for predicting the pathological grading of ccRCC was evaluated using the receiver operating characteristic curve (ROC), and differences in area under the curve (AUC) were compared.

RESULTS

ECV calculated from both ?HU and IC showed that the high-grade ccRCC group had higher values than the low-grade group ($P<0.05$). The AUC values for distinguishing ccRCC pathological grades were 0.780, 0.901, 0.697 with ECV calculated from ?HU, and 0.790, 0.923, and 0.743 with ECV calculated from IC, in the three phases, respectively. The ECV prediction performance in VP was relatively higher, with sensitivities and specificities of 86.11%, 84.37% from ?HU and 83.33%, 92.19% from IC, respectively. The AUC with ECV calculated from IC in VP had the best diagnostic performance (all $P<0.05$).

CONCLUSION

ECV values obtained in DEsCT have moderate to high accuracy to preoperatively predict the pathological grading of ccRCC, with the value calculated based on IC measurement in VP providing the best performance.

CLINICAL RELEVANCE/APPLICATION

ECV obtained using iodine concentration measurement in the venous phase in DEsCT may be used to preoperatively predict the pathological grading of ccRCC.

T5A-SPGU-6 PREDICTION OF ISUP GRADE OF CLEAR CELL RENAL CELL CARCINOMA BASED ON DEEP NEURAL NETWORK AND DUAL-ENERGY SPECTRAL CT:A SMALL SAMPLE STUDY

Tian Xin, MMed (*Presenter*)
Dong Han, MD (*Abstract Co-Author*)
Yongjun Jia, MMed (*Abstract Co-Author*)

PURPOSE

To predict the ISUP grading of clear cell renal cell carcinoma (ccRCC) based on deep neural network and dual-energy spectral CT.

METHODS AND MATERIALS

118 cases of ccRCC, with 80 in low-grade and 38 in high-grade were collected. There were 41 females and 77 males, ranging from 26 to 88 years in age. Lesion characteristics, including tumor location, size, growth pattern, capsule, necrosis, cystic change, calcification, intertumoral artery, perinephric fat invasion, venous involvement, enlargement of lymph nodes, metastasis, enhancement mode and enhancement uniformity were evaluated by a radiologist on the 70keV CT images. The 40-140keV CT attenuation number, effective atomic number (Effective-Z) were measured on the monochromatic image sets and iodine concentration (IC) were measured on the iodine (water) material decomposition images. The slopes of the spectral curve were calculated using 40keV, 70keV and 100keV CT numbers: ? 1 =(HU 70keV -HU 40keV)/30 and ? 2 =(HU 100keV -HU 40keV)/60. The above parameters and patients' clinical information underwent dimensionality reduction by using recursive feature elimination (RFE). The deep neural network was then used to build a model using the significant parameters, and a random search was used to optimize the model parameters. The model was evaluated by 10-fold cross-validation.

RESULTS

A total of 37 variables were created and were dimensionally reduced by RFE. The use of 9 features generated the highest accuracy (Figure 1), including growth pattern, size, enlargement of lymph nodes, Effective-Z, ? 1 , ? 2 , IC, necrosis and 40keV CT number. The above 9 features were used as input to build a deep neural network model. After optimization, the model included two hidden layers, each of which included eight neurons (Figure 2). The model predicted that the AUC of ISUP grading of ccRCC was 0.835, and the AUC was 0.828 after 10-fold cross-validation. In order of importance, these features were size, enlargement of lymph nodes, necrosis, Effective-Z, growth pattern, ? 2 , IC, ? 1 and 40keV CT number.

CONCLUSION

The deep neural network model based on dual-energy spectral CT to predict the ccRCC ISUP grading has good performance.

CLINICAL RELEVANCE/APPLICATION

The deep neural network model based on dual-energy spectral CT to predict the ISUP grading of ccRCC can provide a reference for evaluating the prognosis of patients.

T5A-SPHN-1 HABITAT IMAGING RADIOMICS INCREASES THE ACCURACY OF A NOMOGRAM FOR PREDICTING KI-67-POSITIVITY IN LARYNGEAL SQUAMOUS CELL CARCINOMA

Yumeng Dong (*Presenter*)
Zengyu Jiang (*Abstract Co-Author*)
Sheng He, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the value of applying habitat imaging (HI) radiomics on venous-phase computed tomography (CT) images from laryngeal squamous cell carcinoma (LSCC) patients, as part of a nomogram to predict Ki-67 positivity, an indicator of poorer LSCC prognoses.

METHODS AND MATERIALS

Clinical and CT imaging data from 128 LSCC patients, divided into training (89) and testing (39) groups, were analyzed. Conventional and HI radiomics features were extracted from enhanced venous phase images, either from the entire tumor (conventional) or 3 sub-regions (HI). Radiomics models were established, based on 5 machine learning algorithms, while clinical characteristics were analyzed by both uni- and multi-variate logistic regression analyses for their associations with Ki-67 positivity. Afterwards, a predictive nomogram was constructed by combining clinical characteristics, conventional radiomics, and HI radiomics.

RESULTS

The only clinical characteristic strongly predictive for Ki-67-positivity is the degree of differentiation (low/medium vs. high). Additionally, HI radiomics was significantly more accurate than conventional for predicting Ki-67-positivity. The most accurate model, though, was the predictive nomogram, with areas under the curve of 0.945 (training) and 0.871 (testing), which was significantly higher than for clinical characteristics, conventional radiomics and HI radiomics models alone; it also had the highest net benefit, and thus greatest clinical utility under decision curve analysis.

CONCLUSION

HI radiomics features were more accurate for predicting Ki-67-positivity in LSCC than conventional radiomics. However, the combination of those features with conventional radiomics and the degree of differentiation in a predictive nomogram yields the most accurate model for Ki-67-positivity.

CLINICAL RELEVANCE/APPLICATION

We found that HI radiomics, which extracted features from each of the 3 LSCC tumor subregions defined by K-means clustering, was more accurate than conventional radiomics that extracted features from the entire tumor ROI, for predicting Ki-67 positivity. This may be due to the HI subregional data being able to reflect the intra-tumoral heterogeneity. Furthermore, the combination of HI with conventional radiomics features, as well as the degree of differentiation in a predictive nomogram yielded the most accurate model for predicting Ki-67-positivity. Therefore, applying HI radiomics to supplement conventional radiomics and clinical characteristics could aid in obtaining non-invasive, accurate predictions of Ki-67-positivity in LSCC prior to surgery, in turn providing an important basis for clinical decision-making.

T5A-SPHN-3 ENHANCED DEFINITION OF THE TEMPORAL BONE AT BONE-AIR INTERFACE USING A STAIR-UTE MRI SEQUENCE

Jiaji Wang (*Presenter*)
Adam A. Robinson, MD (*Abstract Co-Author*)
Soo Hyun Shin (*Abstract Co-Author*)
Michael Carl (*Abstract Co-Author*)
Yajun Ma (*Abstract Co-Author*)
Julie Bykowski, MD (*Abstract Co-Author*)
Jiang Du, PhD (*Abstract Co-Author*)

PURPOSE

Ultrashort (UTE) and Zero echo time (ZTE) MRI techniques are emerging as an alternative to CT scans for assessing cortical bone, with potential to reduce ionizing radiation exposure in children and patients who require serial imaging for treatment surveillance. While current MRI techniques are not yet able to match routine clinical CT resolution, we developed an optimized short TR adiabatic inversion recovery ultrashort echo time (STAIR-UTE) MRI sequence for improved definition of the intricate structures at the air-bone interface of the temporal bone. This study aims to evaluate the potential for a radiation-free alternative for lateral skull base assessment within clinically acceptable acquisition times.

METHODS AND MATERIALS

A 3D STAIR-UTE sequence was used on a 3T GE MR750 scanner, acquiring data from one volunteer (24y, F) with a 12-channel head coil. The following data acquisition parameters were used: repetition time/inversion time (TR/TI)=160/71ms, echo time (TE)=0.032ms, inversion pulse bandwidth=1000Hz, field of view (FOV)=220×220×240mm 3 , flip angle (FA)=12°, acquisition matrix=192×192×120 (reconstructed to 256×256×240), slice thickness=2mm (reconstructed to 1 mm), receiver bandwidth=166kHz, and reconstructed voxel size=0.86×0.86×1.0mm 3 . Total scan time was ~5 minutes. We compared the acquired images with temporal bone CT and ZTE MR images published in literature 1-4 and from other subjects. Non-contrast temporal bone CT was acquired on a GE Revolution CT scanner with 140kV and 235mA, 20cm FOV, and 0.625mm slice thickness, reconstructed using Visage PACS. Non-contrast ZTE MR imaging of the skull base was acquired on a GE 3T Signa Premier scanner with TR=512ms, TE=0.016ms, NEX=1, FOV=15cm, and slice thickness=1mm.

RESULTS

Fig 1 shows that STAIR-UTE MRI provides clearer bone details and better air-bone interface definition than conventional ZTE, overcoming its key limitations. Unlike ZTE synthetic CT, it directly highlights bone during acquisition without post-processing. While CT still offers the highest resolution, STAIR-UTE delivers comparable contrast and improved fine detail visualization.

CONCLUSION

The optimized 3D STAIR-UTE MRI sequence enables clear details of the temporal bone in radiation-free acquisition. In the future, we plan to explore the use of compressed sensing and deep learning techniques to enhance image quality and scan efficiency further.

CLINICAL RELEVANCE/APPLICATION

The STAIR-UTE MRI sequence provides a radiation-free alternative to CT for detailed temporal bone imaging, making it particularly valuable for children and patients needing repeat scans. It offers high bone contrast and clear air-bone interface definition, enabling more efficient diagnosis in a single scan.

T5A-SPHN-4 VISUALIZATION OF THE EXTRA-FORAMINAL CADAVERIC VAGUS NERVE ON HIGH-RESOLUTION 3D ISOTROPIC CISS MRI: INITIAL EXPERIENCE FROM SPARC-REVA

Shruti Kumari, MBBS (*Presenter*)
Mridhula Muthukumar (*Abstract Co-Author*)
Chris A. Flask, PhD (*Abstract Co-Author*)
Daniel Herzka (*Abstract Co-Author*)
Ari M. Blitz, MD (*Abstract Co-Author*)

PURPOSE

Current clinical MRI does not routinely allow for visualization of the vagus nerve (the tenth cranial nerve, CN X). CN X plays a pivotal role in autonomic regulation. Because of its wide distribution throughout the body and its many branches, CN X injury frequently occurs in association with neck or thoracic surgery. With recent advances in CN X stimulation strategies, techniques for CN X visualization also have implication for epilepsy and drug-resistant depression. The purpose of this research is to evaluate the extent to which CN X can be visualized on high resolution 3D isotropic CISS 3T MRI in human cadavers from its origin at the jugular foramen to the abdomen, correlated to the gold standard of anatomic dissection.

METHODS AND MATERIALS

Our research is a part of the $15 million NIH SPARC-REVA initiative which aims to map the gross anatomy, morphology, ultrastructure, and fiber types of 100 CN Xs to ultimately improve the efficacy of existing autonomic neuromodulation therapies. It is the most comprehensive mapping of CN X to date, from the perspectives of sample size, range of imaging modalities, lengths of nerve, and imaging resolutions. 50 embalmed cadavers were scanned with a 3T MRI scanner using 3D isotropic 0.5-0.6 mm resolution CISS; a total of 100 CN X were examined. Two readers independently evaluated visualization of the segments of the main trunk of CN X according to a qualitative scale ranging from 1 to 5 with 5 being the best. CN X was then dissected from the brainstem to abdomen, and anatomic-radiologic correlation was performed, to confirm the findings on MRI.

RESULTS

CN X was best visualized in the the infrahyoid neck (4.065 ± 1.08) and superior thoracic (3.99 ± 1.04) segments. CN X was not as visible in the suprahyoid neck (3.01 ± 1.59) and inferior thoracic region (1.89 ± 1.10). The abdominal segment was not visualized. The visualization of left CN X was better than that of the right.

CONCLUSION

In cadavers the use of 3T CISS MRI allows visualization of portions of the extraforaminal CN X in the neck and chest. These data may aid in the translation of this work into clinical imaging for diagnosis of disorders of the autonomic nervous system and procedural targeting.

CLINICAL RELEVANCE/APPLICATION

The future integration of CISS MRI for visualizing CN X in living subjects, with reasonable imaging acquisition times, holds great promise for routine diagnostic and therapeutic imaging. The proximity of CN X to the skin in the cervical region, along with excellent imaging visualization results, suggests potential for developing percutaneous procedures in this area. We aim to enhance the visualization of CN X, facilitating its adoption as a standard diagnostic and therapeutic tool in clinical practice.

T5A-SPHN-6 A COMPARATIVE EVALUATION OF THREE COMMERCIAL AI-BASED CEPHALOMETRIC ANALYSIS TOOLS IN ORTHODONTICS

Wojciech Kazimierczak, MD, PhD (*Presenter*)
Natalia Kazimierczak (*Abstract Co-Author*)
Pawel Nowicki (*Abstract Co-Author*)
Natalia Chwarscianek (*Abstract Co-Author*)
Zbigniew Serafin (*Abstract Co-Author*)

PURPOSE

Cephalometric analysis (CA) is an indispensable diagnostic tool in orthodontics for treatment planning and outcome assessment. Manual CA is time-consuming and prone to variability.

METHODS AND MATERIALS

This study aims to compare the accuracy and repeatability of CA results among three commercial AI-driven programs: CephX, WebCeph, and AudaxCeph. This study involved a retrospective analysis of lateral cephalograms from a single orthodontic center. Automated CA was performed using the AI programs, focusing on common parameters defined by Downs, Ricketts, and Steiner. Repeatability was tested through 50 randomly reanalyzed cases by each software. Statistical analyses included intraclass correlation coefficients (ICC3) for agreement and the Friedman test for concordance.

RESULTS

One hundred twenty-four cephalograms were analyzed. High agreement between the AI systems was noted for most parameters (ICC3 > 0.9). Notable differences were found in the measurements of angle convexity and the occlusal plane, where discrepancies suggested different methodologies among the programs. Some analyses presented high variability in the results, indicating errors. Repeatability analysis revealed perfect agreement within each program.

CONCLUSION

AI-driven cephalometric analysis tools demonstrate a high potential for reliable and efficient orthodontic assessments, with substantial agreement in repeated analyses. Despite this, the observed discrepancies and high variability in part of analyses underscore the need for standardization across AI platforms and the critical evaluation of automated results by clinicians, particularly in parameters with significant treatment implications.

CLINICAL RELEVANCE/APPLICATION

The integration of AI-driven cephalometric analysis tools in orthodontic practice represents a significant advancement in diagnostic accuracy, efficiency, and workflow optimization. This study provides a comparative evaluation of three commercially available AI-based software tools, offering clinicians practical insights into their relative performance, reliability, and usability.

T5A-SPHN-7 ARTIFICIAL INTELLIGENCE IN CBCT-BASED ASSESSMENT OF ENDODONTIC TREATMENT OUTCOMES

Wojciech Kazimierczak, MD, PhD (*Presenter*)
Roza Wajer, MD (*Abstract Co-Author*)
Natalia Kazimierczak (*Abstract Co-Author*)

Natalia Chwarscianek (*Abstract Co-Author*)
Adrian Wajer (*Abstract Co-Author*)
Zbigniew Serafin (*Abstract Co-Author*)

PURPOSE

The aim of this study was to assess the diagnostic accuracy of the AI-driven platform Diagnocat for evaluating endodontic treatment outcomes using cone beam computed tomography (CBCT) images.

METHODS AND MATERIALS

A total of 55 consecutive patients (15 males and 40 females, aged 12-70 years) referred for CBCT imaging were included. CBCT images were analyzed using Diagnocat's AI platform, which assessed parameters such as the probability of filling, adequate obturation, adequate density, overfilling, voids in filling, short filling, and root canal number. The images were also evaluated by two experienced human readers. Diagnostic accuracy metrics (accuracy, precision, recall, and F1 score) were assessed and compared to the readers' consensus, which served as the reference standard.

RESULTS

The AI platform demonstrated high diagnostic accuracy for most parameters, with perfect scores for the probability of filling (accuracy, precision, recall, F1 = 100%). Adequate obturation showed moderate performance (accuracy = 84.1%, precision = 66.7%, recall = 92.3%, and F1 = 77.4%). Adequate density (accuracy = 95.5%, precision, recall, and F1 = 97.2%), overfilling (accuracy = 95.5%, precision = 86.7%, recall = 100%, and F1 = 92.9%), and short fillings (accuracy = 95.5%, precision = 100%, recall = 86.7%, and F1 = 92.9%) also exhibited strong performance. The performance of AI for voids in filling detection (accuracy = 88.6%, precision = 88.9%, recall = 66.7%, and F1 = 76.2%) highlighted areas for improvement.

CONCLUSION

The AI platform Diagnocat showed high diagnostic accuracy in evaluating endodontic treatment outcomes using CBCT images, indicating its potential as a valuable tool in dental radiology.

CLINICAL RELEVANCE/APPLICATION

The study supports the integration of AI into endodontic diagnostics, especially in practices utilizing CBCT, to improve the precision and reliability of post-treatment evaluations.

T5A-SPHN-8 FOCUS-MUSE DWI OUTPERFORMS MUSE AND FOCUS DWIS IN ORBITAL IMAGING QUALITY AND STAGING THYROID-ASSOCIATED OPHTHALMOPATHY

Lu Chen (*Presenter*)
Xiao Quan Xu (*Abstract Co-Author*)
Fei-Yun Wu (*Abstract Co-Author*)
Hao Hu (*Abstract Co-Author*)

PURPOSE

To compare FOCUS, MUSE and FOCUS-MUSE diffusion-weighted imagings (DWIs) in orbital imaging quality and staging performance for the patients with thyroid-associated ophthalmopathy (TAO).

METHODS AND MATERIALS

Sixty-seven patients with TAO who underwent FOCUS, MUSE, and FOCUS-MUSE DWIs were enrolled. Both qualitative (artifacts and geometric distortion, overall image quality, and sharpness of boundaries) and quantitative parameters (geometric distortion ratio [GDR], signal-to-noise ratio [SNR], apparent diffusion coefficient [ADC] value of extraocular muscles (EOM), and normalized ADC [nADC] value of EOM) were assessed across the three sequences. Additionally, nADC values of EOMs and their mean value were compared between active and inactive TAO groups, and diagnostic performances for the active phase were evaluated.

RESULTS

FOCUS-MUSE DWI exhibited significantly fewer artifacts and geometric distortion, superior overall image quality, enhanced sharpness of boundaries, higher SNR and lower GDR compared to both MUSE and FOCUS DWIs (all $P<0.05$). The ADC values of EOMs and their mean value were generally lower in FOCUS-MUSE DWI than those in FOCUS DWI (all $P<0.05$) and those in MUSE DWI (all $P<0.05$, except for that of superior EOM). The nADC values of EOMs and their mean value showed no significance among the three DWIs (all $P>0.05$), except for that of superior EOM. Furthermore, active TAOs showed higher nADC values across all EOMs and higher mean nADC values compared to inactive TAOs in FOCUS-MUSE, MUSE and FOCUS DWIs (all $P<0.05$). The mean nADC value of FOCUS-MUSE DWI (AUC, 0.893; sensitivity, 91.3%; specificity, 71.6%) performed better than that of MUSE DWI (AUC, 0.713; sensitivity, 54.3%; specificity, 80.7%; $P<0.001$) and FOCUS DWI (AUC, 0.730; sensitivity, 47.8%; specificity, 90.9%; $P<0.001$) in staging TAO.

CONCLUSION

FOCUS-MUSE DWI provides superior image quality and staging performance in assessing TAO compared to MUSE and FOCUS DWIs. We recommend its use for evaluating TAO patients in clinical practice.

CLINICAL RELEVANCE/APPLICATION

FOCUE-MUSE DWI outperforms MUSE and FOCUS DWIs in orbital imaging quality and staging TAO. Our findings may offer valuable insights into the benefits of FOCUS-MUSE DWI relative to MUSE DWI and FOCUS DWI in the context of TAO and other orbital diseases.

T5A-SPIN-1 IASLC GRADING OF INVASIVE LUNG ADENOCARCINOMA VIA RADIOMICS-BASED DIFFERENTIATION OF HIGH-GRADE PATTERNS AND PREDOMINANT SUBTYPES

Sunyi Zheng, PhD (*Presenter*)
Jing Wang (*Abstract Co-Author*)
Zhaoxiang Ye (*Abstract Co-Author*)
Xiaonan Cui, MD,PhD (*Abstract Co-Author*)

PURPOSE

Accurate classification of the International Association for the Study of Lung Cancer (IASLC) grades in invasive non-mucinous adenocarcinoma (ADC) can aid in the prediction of patient prognosis and treatment planning. The IASLC grading system considers both high-grade patterns and predominant subtypes. Following the system, this study aimed to explore the feasibility of predicting high-grade patterns and predominant subtypes for IASLC grading with radiomics.

METHODS AND MATERIALS

A total of 529 ADCs from patients who had undergone radical surgical resection were randomly assigned to training and validation cohorts in a 7:3 ratio. Radiomics features were extracted based on annotated tumor regions. A two-step radiomics framework was constructed for IASLC grading, comprising two distinct submodels: the first identified whether high-grade patterns constituted more than 20% of the tumor, while the second differentiated between lepidic and acinar/papillary predominant subtypes. The final IASLC grade was determined by integrating outputs from both submodels. For comparison, a one-step radiomics model was also developed to directly predict IASLC grades from radiomic features. Model performance was evaluated using the area under the curve (AUC), sensitivity, and specificity, and statistical comparisons of AUCs between models were conducted using the DeLong test.

RESULTS

In the two-step radiomics model, the submodel for high-grade pattern prediction achieved AUCs of 0.95 and 0.96 in the training and validation datasets, whereas the submodel for predicting predominant subtypes obtained AUCs of 0.83 and 0.78. Considering the results of both submodels, the two-step radiomics model achieved high AUCs of 0.95, 0.85, and 0.96 for IASLC grades 1, 2, and 3, respectively, on the validation set. While its performance was comparable to the one-step model for grade 1 (0.95 vs. 0.92), the two-step model significantly outperformed the one-step model in discriminating grades 2 and 3 (p-values < 0.001), where the one-step model only achieved AUCs of 0.53 and 0.81, respectively. In terms of sensitivity and specificity, the two-step model presented higher sensitivity for grade 3 (0.89 vs. 0.74) and greater specificity for both grades 2 and 3 (0.89 vs. 0.79; 0.85 vs. 0.74) than the one-step model on the validation set.

CONCLUSION

Using radiomics to separately predict high-grade patterns and predominant subtypes enables accurate IASLC grading in ADCs. The proposed two-step radiomics approach has the potential to support clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

Radiomics features can accurately classify IASLC grades in ADCs by predicting high-grade patterns and predominant subtypes, potentially aiding clinical decision-making.

T5A-SPIN-2 CONSISTENCY OF REPEATED OUTPUTS AS MEASURE OF DIAGNOSTIC CONFIDENCE IN MULTIMODAL LARGE LANGUAGE MODELS ON RADIOLOGIC IMAGE INTERPRETATION

Taewon Han (*Presenter*)
Jaeseung Shin, MD, PhD (*Abstract Co-Author*)
Kyowon Gu, MD (*Abstract Co-Author*)
Jeong Hyun Lee, MD (*Abstract Co-Author*)

PURPOSE

To evaluate output consistency as a confidence measurement metric in multimodal large language models (LLMs) interpreting radiological images and compare its reliability with each model's self-reported confidence score.

METHODS AND MATERIALS

From 311 quizzes in the Korean Society of Ultrasound in Medicine digital platform, we selected 75 multiple-choice cases. Six multimodal-LLMs were evaluated —three reasoning-focused (o1, Claude-3.7-Sonnet, Gemini-2.5-Pro) and three general-purpose models (GPT-4o, Claude-3.5-Sonnet, Gemini-1.5-Pro) —with temperature fixed at 1.0. Two confidence measurement metrics were assessed: (i) self-reported confidence by multimodal-LLMs using prompts that elicited direct confidence percentages with answer, and (ii) consistency-based metrics derived from 20 repeated interpretations per case expressed as relative entropy (R_H) calculated as 1 - H/log2k (H = Shannon entropy, k = number of repetitions). Receiver Operating Characteristics (ROC) analysis for discrimination and Spearman correlation (r) between accuracy and each metric was conducted. Additionally, model calibration was assessed using Expected Calibration Error (ECE).

RESULTS

Consistency-based metrics, R_H, demonstrated significant correlation with diagnostic accuracy for Claude-3.7-Sonnet (r=0.310, p =0.007), Gemini-2.5-Pro (r=0.347, p =0.002), and GPT-4o (r=0.318, p =0.006). For self-reported confidence, only GPT-4o showed a statistically significant —but weak—correlation (r = 0.231, p = 0.046). Consistency-based metrics yielded higher AUCs than self-reported confidence—0.661 (95% Confidence Interval [CI], 0.543-0.767) for Claude-3.7-Sonnet, 0.690 (95%CI, 0.573-0.792) for Gemini-2.5-Pro, and 0.669 (95%CI, 0.551-0.773) for GPT-4o—whereas the best AUC achieved by self-reported confidence was 0.623 (95 % CI, 0.503-0.732) in GPT-4o. For consistency-based metrics, Regular ECE (10-bin) ranged from 0.313-0.485, while optimal-bin ECE ranged from 0.276-0.478 across models.

CONCLUSION

In multimodal LLMs applied to radiologic interpretation, output consistency is a more reliable indicator of diagnostic confidence than the models' self-reported confidence score, showing stronger correlations with accuracy and superior discrimination.

CLINICAL RELEVANCE/APPLICATION

Consistency-based confidence metric quantifies multimodal-LLM uncertainty in radiologic interpretation, flagging questionable reads for radiologist review, streamlining clinical workflows, and safeguarding patient care.

T5A-SPIN-3 TASK-SPECIFIC LANGUAGE MODELS OUTPERFORM GENERAL LLMS IN STRUCTURED INFORMATION EXTRACTION FROM MULTIMODALITY RADIOLOGY REPORTS

Harrison X. Bai, MD (*Presenter*)
Haoyue Guan (*Abstract Co-Author*)
Qiuhao (alex) Zhu (*Abstract Co-Author*)
Yuwei Dai, MD (*Abstract Co-Author*)
Shadi Afyouni, MD (*Abstract Co-Author*)
Wenchi Hsu, MD (*Abstract Co-Author*)
Yuli Wang (*Abstract Co-Author*)
Jing Wu (*Abstract Co-Author*)
Linmei Zhao, MD, PhD (*Abstract Co-Author*)
Cheng Z. Zhu (*Abstract Co-Author*)
Craig K. Jones, PhD (*Abstract Co-Author*)
Zhicheng Jiao, PhD, BS (*Abstract Co-Author*)

PURPOSE

Large language models (LLMs) have demonstrated strong performance in general clinical text analysis. However, their effectiveness in complex, task-specific radiology applications remain uncertain. This study assess the effectiveness of modality-specific RadGraph models in extracting clinical entities and relationships from radiology reports, compared to general-purpose LLMs.

METHODS AND MATERIALS

RadGraph is an annotation model designed to identify clinical entities and their relationships in radiology reports. To evaluate its modality-specific performance, we curated a multi-modality dataset consisting of 800 expert-annotated reports from cardiac MRI for detailed tissue characterization, CT pulmonary angiography (CTPA) for pulmonary vasculature evaluation, head CT for rapid assessment of acute conditions, and abdominal ultrasound for non-invasive evaluation. The RadGraph model was fine-tuned separately for each modality, aiming to enhance its structured information extraction capabilities. As benchmarks, we evaluated GPT-4.1, LLaMA-3.2-3B-Instruct and DeepSeek-R1 using 0-shot, 1-shot, and 5-shot prompting with detailed task prompt definitions. Performance was assessed on a held-out test set of 180 reports using macro F1 scores for both named entity recognition (NER) and relation extraction tasks.

RESULTS

The fine-tuned RadGraph model achieved macro F1 scores of 0.801 for NER and 0.631 for relation extraction, demonstrating a significant performance advantage over the LLM benchmarks. GPT-4.1 obtained 0.186, 0.481, and 0.620 (NER) and 0.029, 0.225, and 0.352 (relations) under 0-shot, 1-shot, and 5-shot prompting, respectively. LLaMA-3.2-3B-Instruct scored 0.117, 0.150, 0.317 (NER) and 0.017, 0.034, 0.068 (relations), while DeepSeek-R1 reached 0.073, 0.502, 0.570 (NER) and 0.081, 0.297, 0.355 (relations). Fine-tuning RadGraph for specific imaging modalities resulted in a 12.5% improvement in NER and a 28.3% improvement in relation extraction, compared to a baseline model trained solely on chest X-ray reports. Performance gains were consistent across all modalities, underscoring the importance of domain-specific training.

CONCLUSION

Task-specific fine-tuning of language models yields significantly better performance in complex radiology report annotation tasks than general LLMs, even with few-shot prompting. Our modality-specific RadGraph model demonstrates superior robustness and accuracy across multiple imaging domains.

CLINICAL RELEVANCE/APPLICATION

Fine-tuned RadGraph models provide a scalable, domain-adapted framework for extracting structured clinical information from radiology reports, supporting automated report generation and downstream clinical applications.

T5A-SPIN-4 TOWARDS HYPER-PERSONALISED RADIOLOGY REPORTING: A SCALABLE AUTONOMOUS OPTIMISATION PIPELINE FOR IMPROVING CHEST X-RAY REPORT GENERATION QUALITY

Nishtha Mahajan, MBBS (*Presenter*)
Gautam Ahuja (*Abstract Co-Author*)
Zonunmawia Zadeng (*Abstract Co-Author*)
Akhil V, MBBS (*Abstract Co-Author*)
Swasthik K. Sullia, MBBS (*Abstract Co-Author*)
Amol Pajni, MBBS (*Abstract Co-Author*)
Reet Nandy (*Abstract Co-Author*)
Kautik Singh (*Abstract Co-Author*)
Siddharth Reddy Anthireddy (*Abstract Co-Author*)
Syed Pasha (*Abstract Co-Author*)
Rintu Kutum (*Abstract Co-Author*)
Suvrankar Datta, MD, MBBS (*Abstract Co-Author*)

PURPOSE

Recent advances in Large Language Models (LLMs) promise transformative gains for radiology report dictation and generation, yet performance remains limited by generic and static prompts that ignore the distinct narrative fingerprints of individual radiologists. We present one of the world's first autonomous prompt optimisation pipelines that learns a bespoke prompt for an individual radiologist, leverages two state-of-the-art (SOTA) optimisers, and demonstrably improves the report quality beyond SOTA levels.

METHODS AND MATERIALS

A multi-institutional dataset of 100 Chest X-ray dictation-report pairs from four radiologists (20 pairs of Training Set and 5 pairs of Test Set per radiologist), each having distinctive reporting style was assembled. Each study's dictated keywords were first converted to baseline non optimised reports by Qwen-3 8B using a single baseline prompt. The prompt was then fed to two SOTA optimisers DSPy (MIPROv2) and TextGrad along with 20 pairs of Training Set reports, and optimised for ROUGE-L (chosen to capture style metrics better than factual accuracy metrics) which generated personalised radiologist-specific prompts. These personalised prompts were reapplied to Qwen-3 along with the dictations from the test set, yielding 5 optimised report sets per radiologist per optimiser. The paired Wilcoxon signed-rank test was used to compare ROUGE-L scores between baseline and hyper-personalised reports, quantifying performance gains.

RESULTS

DSPy (MIPRO v2) improved ROUGE-L by ? = 0.14 ± 0.07 compared to baseline (p = 0.0001). TextGrad improved ROUGE-L by ? = 0.18 ± 0.08 compared to baseline (p = 0.0001). Inter-optimiser comparison favored TextGrad over DSPy (? difference = 0.04, p = 0.0990), though the difference didn't reach strong statistical significance (p = 0.05).

CONCLUSION

Our autonomous pipeline converts a baseline generic report into a radiologist-specific hyper-personalised report, delivering significant gains in lexical and stylistic fidelity. Both DSPy and TextGrad consistently outperform the baseline, without any statistically significant inter-optimiser difference, demonstrating scalable, model-agnostic improvements without the need for model fine-tuning.

CLINICAL RELEVANCE/APPLICATION

Hyper-personalised prompt optimisation enables rapid, bespoke tailoring of AI-generated chest X-ray reports to individual radiologist styles. This eliminates the computational and regulatory overhead of model fine-tuning and facilitates hyper-personalised radiology report generation at scale without human intervention.

T5A-SPIN-5 STYLE-AWARE RADIOLOGY REPORTING: A SCALABLE AUTONOMOUS OPTIMISATION PIPELINE FOR IMPROVING HEAD CT REPORT GENERATION QUALITY

Amol Pajni, MBBS (*Presenter*)
Nishtha Mahajan, MBBS (*Abstract Co-Author*)
Akhil V, MBBS (*Abstract Co-Author*)
Kautik Singh (*Abstract Co-Author*)
Swasthik K. Sullia, MBBS (*Abstract Co-Author*)
Gautam Ahuja (*Abstract Co-Author*)
Syed Pasha (*Abstract Co-Author*)
Siddharth Reddy Anthireddy (*Abstract Co-Author*)
Zonunmawia Zadeng (*Abstract Co-Author*)
Reet Nandy (*Abstract Co-Author*)
Rintu Kutum (*Abstract Co-Author*)
Suvrankar Datta, MD, MBBS (*Abstract Co-Author*)

PURPOSE

Recent advances in Large Language Models (LLMs) promise transformative gains for radiology report dictation and generation; however, their performance remains limited by generic, static prompts that fail to capture the distinctive narrative style of individual radiologists. We present one of the first autonomous prompt optimisation pipelines tailored for individual radiologists, leveraging two state-of-the-art (SOTA) optimisers to demonstrably enhance report quality for head CT beyond current benchmarks.

METHODS AND MATERIALS

A multi-institutional dataset of 100 head CT dictation-report pairs from four radiologists (20 pairs in the training set and 5 pairs in the test set per radiologist), each with a distinctive reporting style, was assembled. Dictated keywords from each study were initially converted into baseline non-optimised reports using Qwen-3 (8B) and a single baseline prompt. This prompt was subsequently optimised using two SOTA optimisation frameworks viz., DSPy (MIPRO v2) and TextGrad, guided by ROUGE-L scores (selected to better capture stylistic fidelity in addition to factual accuracy), resulting in hyper-personalised radiologist-specific prompts. These personalised prompts were reapplied to Qwen-3 with the dictated keywords from the test set, yielding five optimised report sets per radiologist per optimiser. Performance gains (? ROUGE-L) were tested for significance using a paired Wilcoxon signed-rank test for each optimiser versus baseline.

RESULTS

DSPy (MIPRO v2) improved ROUGE-L by ? = 0.13 ± 0.06 compared to baseline (p < 0.001). TextGrad improved ROUGE-L by ? = 0.06 ± 0.16 compared to baseline (p = 0.19), not reaching statistical significance (p = 0.05). Inter-optimiser comparison favored DSPy over TextGrad (? difference = 0.07, p = 0.07).

CONCLUSION

Style-aware prompt tuning through autonomous pipelines significantly enhances CT-head report quality; DSPy yields the largest lexical gain, validating scalable, radiologist-specific optimisation. While both optimizers show performance gains over baseline, DSPy demonstrates consistently superior performance with statistically significant gains in ROUGE-L scores.

CLINICAL RELEVANCE/APPLICATION

Optimised prompting elevates AI report fidelity, avoiding the computational overheads associated with model fine-tuning at the individual radiologist level. Our findings demonstrate that style-aware prompt tuning can significantly enhance the quality and personalization of LLM-generated CT head reports, validating the pipeline's potential to scale without additional human intervention.

T5A-SPIN-6 XCOMPOSITION: MULTIMODAL DEEP LEARNING MODEL FOR ESTIMATION OF BODY COMPOSITION METRICS USING CHEST X-RAY

Ehsan Alipour, MD, PhD (*Presenter*)
Samuel Gratzl (*Abstract Co-Author*)

PURPOSE

Body composition metrics—such as visceral adipose tissue, subcutaneous adipose tissue, and skeletal muscle volume—are important predictors of cardiovascular disease, diabetes, and cancer outcomes. While recent advances in artificial intelligence (AI) have enabled automated extraction of these metrics from CT and MRI scans, such imaging modalities are costly, may involve radiation exposure, and are not routinely available for many patients. In this study, we propose a deep learning approach to estimate body composition metrics using chest radiographs combined with a small set of routinely collected clinical variables.

METHODS AND MATERIALS

We identified a retrospective cohort of patients with both non-contrast abdominal CT scans and chest radiographs within 3 months from our institutional dataset. Tissue segmentation was performed on CT images using TotalSegmentator. We calculated volumetric and L3-level body composition metrics, including subcutaneous and visceral fat volumes, skeletal muscle and bone indices, and aortic calcification scores. A multitask, multimodal deep learning model was trained to estimate these reference metrics using chest radiographs and select clinical variables (age, sex, height, and weight). The data was split into train, validation and test sets with a ratio of 0.7:0.1:0.2. Huber loss was used to train the deep learning model. Pearson's correlation between the predicted and ground truth values was used to measure the final performance. The XComposition python package was developed based on the multimodal deep learning model and is publicly available on GitHub.

RESULTS

The final cohort included 1,118 patients, with a mean age of 67 (±17) years, height of 1.67 (±0.2) meters, and weight of 78 (±20) kilograms. The multimodal model outperformed models trained on imaging or clinical variables alone. It achieved a Pearson correlation of 0.85 (95% CI: 0.81-0.88) for subcutaneous fat volume, 0.76 (0.65-0.80) for visceral fat volume, and 0.72 (0.65-0.78) for vertebral bone volume in the hold-out test set.

CONCLUSION

While prior work has focused on AI-based extraction of body composition metrics from CT and MRI, our study presents a novel approach using chest radiographs—a more accessible and lower-cost imaging modality. This method has the potential to scale body composition analysis across larger patient populations using widely available clinical data.

CLINICAL RELEVANCE/APPLICATION

This study presents a low-cost, scalable method to estimate body composition metrics using chest radiographs and basic clinical data, enabling broader use in routine care and population health studies without requiring CT or MRI.

T5A-SPIN-7 MEASURES OF DIAGNOSTIC ACCURACY IN MULTI-CLASS CLASSIFICATION: A SIMULATION STUDY

Leeha Ryu, MS (*Presenter*)
Kyunghwa Han, PhD (*Abstract Co-Author*)
Inkyung Jung (*Abstract Co-Author*)
Yaewon Park, MD, PhD (*Abstract Co-Author*)
Sung Soo Ahn, MD (*Abstract Co-Author*)
Dosik Hwang (*Abstract Co-Author*)

PURPOSE

Multi-class outcomes are becoming increasingly common in medical AI research, including recent studies involving large language models (LLMs). In this context, we compared diagnostic accuracy metrics used in machine learning and statistical approaches through simulation.

METHODS AND MATERIALS

Ten metrics were evaluated under various multi-class classification settings: M-index, macro/micro-averaged ROC, weighted macro-averaged ROC, nominal and ordinal Obuchowski's indices, Matthews correlation coefficient (MCC), polytomous discrimination index (PDI), correct classification probability (CCP), and R-squared. In the simulation, predictors were generated from normal and exponential distributions. Predicted probabilities for each category were obtained using multinomial logit models. Simulation scenarios included both balanced and imbalanced class distributions. To assess the metric behavior beyond simulations, we applied the metrics to adult-type diffuse gliomas classification using multimodal transformer models on two datasets: The Cancer Genome Atlas (TCGA), and the University of California, San Francisco (UCSF).

RESULTS

The M-index demonstrated stable performance across various simulation settings, regardless of the distribution used to generate predictors or class imbalance. ROC-based metrics—particularly micro- and macro-averaged ROC—tended to be overestimate performance under severe class imbalance. Among these, micro-averaged ROC showed greater bias compared to other ROC-based metrics when predictors were generated from exponential distributions. Each metric exhibited consistent distribution-specific trends, while the effect of class imbalance varied by metric. Application to real-world datasets revealed trends similar to the simulation results. In the TCGA dataset which had mild class imbalance, differences between the M-index and ROC-based metrics were smaller compared to the more imbalanced UCSF dataset. PDI and MCC values were consistently lower than other metrics in both datasets.

CONCLUSION

The M-index provided stable estimates regardless of predictor distribution or class imbalance, supporting its use as a reliable metric. Although PDI and MCC were nearly unbiased under normal distributions, their relatively lower values should be noted. Micro-averaged ROC tended to overestimate performance under severe class imbalance, making it less suitable in such scenarios. This study offers practical guidance for selecting appropriate metrics in multi-class medical imaging analyses.

CLINICAL RELEVANCE/APPLICATION

This study supports the selection of appropriate metrics for multi-class diagnostic evaluations, contributing to more reliable and interpretable clinical decision-making.

T5A-SPIN-8 STRESS-TEST AND RADIOLOGIST BLINDED VALIDATION OF MULTIMODAL FOUNDATION MODELS ON AN UNSEEN CHEST RADIOGRAPH DATASET USING A NOVEL MULTI-METRIC EVALUATION FRAMEWORK

Suvrankar Datta, MD, MBBS (*Abstract Co-Author*)

PURPOSE

Prior validations of state-of-the-art Multimodal Foundation Models (FM) have relied solely on automated metrics, missing crucial clinical and stylistic nuances in radiology reporting. We present a radiologist-blinded validation of three leading models (LLaVa-Rad, GPT4o, CheXagent) on chest radiographs using a novel IndicCXR dataset. Our methodological innovations include: (1) a cryptographically-secured randomized blinding protocol, (2) a clinically-calibrated radiologist-validated scoring rubric, and (3) systematic stress-testing on an underrepresented population dataset.

METHODS AND MATERIALS

Five radiologists evaluated outputs from 20 chest radiographs each (10 normal, 10 abnormal) across three AI models using our web-based evaluation console with randomization by fisher-yates shuffle. Each CXR report received 12 distinct evaluations (1,200 total data points) across four domains: Diagnostic Accuracy, Clinical Utility, Report Completeness, and Language Clarity & Style (scored 1-5). Composite scores (max 20) were computed per report. Critical diagnostic error was defined as a score = 2 in the Diagnostic Accuracy domain. Non-parametric statistical tests (Kruskal-Wallis, Cochran's Q, McNemar) were used to assess model differences.

RESULTS

LLAVA-Rad achieved the highest overall quality with a composite median score of 15 (IQR 12-19), significantly outperforming GPT-4o 12.5, (IQR 7.3 - 16, $p = 0.014$) but not ChexAgent 16.5 (IQR 7 - 17, $p = 0.25$). Most striking was LLaVa-Rad's maintenance of diagnostic performance on abnormal radiographs (median Diagnostic Accuracy = 3) versus GPT-4o and ChexAgent (both 1, $p < 0.001$). Critical diagnostic error rates were lowest for LLaVa-Rad (24.3 %) compared to GPT-4o (51.4 %) and

ChexAgent (44.3 %) ($p < 0.001$). Median scores for Clinical Utility mirrored this trend (LLaVa-Rad = 4, GPT-4o = 2.5, ChexAgent = 4), while language-based metrics (Completeness, Clarity) showed no significant inter-model difference (all medians = 4).

CONCLUSION

Our work quantifies the significant gap between linguistic competence and diagnostic accuracy in FM-generated AI CXR reports and establishes LLaVa-Rad as the current best-performing model for clinical deployment.

CLINICAL RELEVANCE/APPLICATION

Radiologist review is indispensable and to make such expert validation practical at scale, we introduce an open-source evaluation stack: a novel IndicCXR dataset, a scoring rubric, and a blinded graphical user interface that any lab can fork to benchmark radiology report generation models.

T5A-SPIN-9 CHATGPT-GUIDED DIFFUSION GENERATES REALISTIC SYNTHETIC TUMORS, BOOSTING EARLY CT DETECTION OF LIVER, PANCREAS, AND KIDNEY CANCERS

Xinran Li (*Presenter*)
Wenxuan Li, BS (*Abstract Co-Author*)
Kang Wang, MD,PhD (*Abstract Co-Author*)
Yang Yang, PhD (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)
Zongwei Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To investigate whether descriptive text about tumors extracted from medical reports written by radiologists can enhance the performance of AI-based cancer diagnosis of different organ tumors from CT images.

METHODS AND MATERIALS

We developed a generative model, termed TextoMorph, that synthesizes tumors conditioned on tumor shape, location, and descriptive text. Using ChatGPT-4o, we extracted tumor-relevant descriptions from medical reports. This created a dataset of CT scans with tumor masks and textual annotations. A Denoising Diffusion Probabilistic Model (DDPM) was then trained to generate tumors based on input CT images, masks, and descriptive text, allowing control over visual traits such as attenuation and margins. During inference, this model produces diverse synthetic tumors—hypodense, hyperdense, ill-defined, or well-defined—which augment the training data for organ-specific cancer detection. To evaluate diversity and heterogeneity in the synthesized tumors, we conducted a Radiomics pattern analysis. Specifically, we extracted 102 texture-based features from synthetic tumors and computed pairwise cosine similarity to measure mean variance and standard deviation. Higher values indicate broader variation in tumor appearance, which is critical for training robust and generalizable AI models. These synthetic tumors were used to augment real datasets, and the resulting models were evaluated on both internal and external CT cohorts for liver, pancreas, and kidney tumor detection, segmentation, and classification.

RESULTS

TextoMorph improved early tumor detection sensitivity by 8.5% for liver, 4.2% for pancreas, and 3.9% for kidney tumors. It enhanced segmentation Dice scores by 6.3% for liver and 9.0% for pancreas. In a Visual Turing Test, radiologists misclassified synthetic tumors up to 45.0% of the time, confirming high realism. Radiomics analysis showed greater heterogeneity, with a mean variance of 1.14 for liver tumors. Classification sensitivity improved from 61.9% to 79.0% for malignant and 50.7% to 70.8% for cystic tumors. In large kidney tumors, targeted synthesis increased sensitivity by 9.1% and segmentation Dice by 4.7%.

CONCLUSION

The descriptive text from medical reports shows significant potential for improving the performance of AI-based cancer diagnosis models for different organ tumors from CT images.

CLINICAL RELEVANCE/APPLICATION

The addition of descriptive text to generate diverse tumor images can enhance medical imaging analysis by expanding training datasets, thereby improving model generalization and robustness. It enables the simulation of rare cases, providing valuable data for clinical training, individualized treatment planning, and early diagnosis and screening.

T5A-SPIN-10 CANCERVERSE: ROBUST SEGMENTATION OF 16 MAJOR CANCERS IN COMPUTED TOMOGRAPHY

Zongwei Zhou, PhD (*Presenter*)
Wenxuan Li, BS (*Abstract Co-Author*)
Xinze Zhou (*Abstract Co-Author*)
Qi Chen (*Abstract Co-Author*)
Pedro Ricardo Ariel Salvador Bassi (*Abstract Co-Author*)
Xiaoxi Chen, MD (*Abstract Co-Author*)
Zheren Zhu, MSc (*Abstract Co-Author*)
Yang Yang, PhD (*Abstract Co-Author*)
Kang Wang, MD,PhD (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

To develop an AI-integrated, annotation pipeline that, in collaboration with radiologists, can automatically and precisely segment 16 tumor types in body CTs, and in turn, enhance radiologists' clinical productivity and impact.

METHODS AND MATERIALS

We retrospectively collected 800 volumetric CT scans (1997-2024), randomly sampled from routine clinical studies to reflect real-world variability in age, pathology, scanners, body regions, sequences, and institutions. Each CT scan contains at least one pathologically confirmed tumor across 16 organs, including the adrenal gland, bladder, bone, breast, colon, duodenum, esophagus, gallbladder, kidney, liver, lung, pancreas, prostate, spleen, stomach, and uterus. Tumors were annotated voxel-wise using an AI-integrated pipeline involving three iterative steps: (1) testing AI on unannotated data, (2) revising AI predictions by radiologists, and (3) fine-tuning AI on newly annotated data. These steps are repeated over time to progressively enhance both annotation quality and AI performance, continuing until the dataset is fully annotated and the AI model is well-trained. In this study, we recruited 23 board-certified radiologists (each with over six years of experience) to either create annotations from scratch—during the initial phase when annotated data was insufficient—or to revise AI predictions once annotated data become available. A key innovation of our pipeline is leveraging the consistency between AI predictions before and after fine-tuning to prioritize CT scans for radiologist revision—transforming traditionally time-consuming and costly random-revision strategies into a targeted, efficient, and scalable annotation pipeline.

RESULTS

Across 800 CT scans, all tumors in 16 organs were annotated voxel-wise by a team of 23 board-certified radiologists. Compared to traditional random-revision strategies, our AI-integrated pipeline reduced manual annotation time from five minutes to 20 seconds per tumor—a 92% reduction—while preserving high-quality annotations. The AI model that was integrated to this annotation pipeline achieved an average sensitivity of 52.1% and specificity of 72.5% for detecting tumors across the 16 organs in external validation (n = 1,760).

CONCLUSION

Our AI-integrated annotation pipeline enables efficient, high-quality tumor segmentation across 16 organs, reducing radiologist annotation time by 92% while maintaining accuracy.

CLINICAL RELEVANCE/APPLICATION

This efficient pipeline can accelerate the creation of large, expert-annotated datasets needed to train and validate AI models for multi-organ cancer detection in clinical CT imaging, and potentially other imaging modalities.

T5A-SPIN-11 AGENT-BASED UNCERTAINTY AWARENESS IMPROVES AUTOMATED RADIOLOGY REPORT LABELING WITH AN OPEN-SOURCE LARGE LANGUAGE MODEL

Moti Freiman, PhD (*Presenter*)
Hadas Ben Atya (*Abstract Co-Author*)
Zvi Natan Badash (*Abstract Co-Author*)
Naama Gavrielov (*Abstract Co-Author*)
Gili Focht, MSc, MBA (*Abstract Co-Author*)
Ruth Cytter-Kuint, MD (*Abstract Co-Author*)
Talar Silvi Hagopian, MD (*Abstract Co-Author*)
Dan Turner, MD,PhD (*Abstract Co-Author*)

PURPOSE

To improve the reliability and performance of Large Language Models (LLMs) in extracting structured data from radiology reports, particularly in domains with complex and non-English texts (e.g., Hebrew), by incorporating agent-based uncertainty-awareness method to achieve trustworthy predictions in medical applications.

METHODS AND MATERIALS

This retrospective study analyzed 9,683 Hebrew radiology reports from Crohn's disease patients (2010-2023) across several medical imaging providers. A subset of 512 reports was manually annotated for six gastrointestinal organs and 15 pathological findings, while the remaining data was automatically annotated using the HSMP-BERT model. Structured data extraction used Llama 3.1 (Llama 3-8b-instruct), an open-source LLM, with Bayesian Prompt Ensembles (BayesPE) leveraging six semantically equivalent prompts for uncertainty estimation. An Agent-Based Decision Model synthesized multiple prompt outputs into five confidence levels for calibrated uncertainty, compared against three entropy-based models. Performance was assessed via accuracy, F1 score, precision, recall, and Cohen's Kappa, both before and after filtering high-uncertainty cases.

RESULTS

The agent-based model outperformed the baseline across all metrics, achieving an F1 score of 0.3967, recall of 0.6437, and Cohen's Kappa of 0.3006. After filtering high uncertainty cases (= 0.5), the F1 score increased to 0.4787 and Kappa to 0.4258. Uncertainty histograms showed clear separation between correct and incorrect predictions, with the agent-based model exhibiting the best-calibrated uncertainty predictions.

CONCLUSION

Incorporating uncertainty-aware prompt ensembles and an agent-based decision model significantly enhances the performance and reliability of LLMs in structured data extraction from radiology reports, offering a calibrated and interpretable approach for high-stakes medical applications.

CLINICAL RELEVANCE/APPLICATION

Uncertainty-aware prompt ensembles and agent-based decision models improve the accuracy and reliability of LLMs for structured data extraction from radiology reports, especially in non-English medical domains. This approach enhances confidence calibration, reducing misinterpretation risks and supporting safer AI integration in clinical workflows for radiology and gastroenterology.

T5A-SPIN-12 AI-BASED DETECTION AND GRADING OF CALCIFICATION IN CORONARY ARTERIES, AORTA, AND AORTIC VALVE USING CHEST CT SCANS

Vikas K. Patel, MD (*Presenter*)
Mohammed Jabeer (*Abstract Co-Author*)
Shweta Tyagi (*Abstract Co-Author*)
Jitender Singh (*Abstract Co-Author*)
Anuj Chandalia (*Abstract Co-Author*)
Abhinav Jain, DNB,MBBS (*Abstract Co-Author*)

PURPOSE

Calcifications in the coronary arteries, aorta, and aortic valve are linked to higher cardiovascular risk but often go unnoticed in routine chest CT scans. While cardiac CT is mostly recommended for heart disease evaluation, these calcifications can be incidentally detected on standard chest CTs. We propose an AI-based system to automatically detect and quantify these calcifications in non-contrast chest CTs, generating a DICOM overlay with calcium segmentation and a report detailing the calcium and severity findings. By leveraging existing chest CTs, this approach reduces the need for additional imaging, minimizing radiation exposure and healthcare costs, while enabling earlier diagnosis and improved patient outcomes.

METHODS AND MATERIALS

This study builds on a deep learning framework using convolutional neural networks to detect and segment calcifications in the coronary arteries, aorta, and aortic valve from non-contrast chest CTs. The model is trained on a curated dataset of 3,000 CT cases. Our system produces multilabel segmentations to localize calcifications. For each CT scan, an automated report is generated using a large language model (LLM), summarizing calcium scores for coronary arteries, aortic valve, and aorta with risk stratification, and aortic diameter measurements. Expanding on our previous chest CT solution for lung nodule detection, this system adds incidental cardiovascular findings and can be integrated into existing AI platforms to enhance clinical utility.

RESULTS

We evaluated our approach on a test set of 100 chest CTs, achieving a sensitivity of 97%, a precision of 85.8%, and an F1 score of 95% for the multi-label calcium segmentation model. The overall accuracy reached 94%. All results were independently verified by two radiologists.

CONCLUSION

Several organizations like the Society of Cardiovascular Computed Tomography (SCCT), the Society of Thoracic Radiology (STR), the British Society of Cardiovascular Imaging/British Society of Cardiac Computed Tomography (BSCI/BSCCT), and the British Society of Thoracic Imaging (BSTI) recommend reporting incidental findings in non-contrast and non-gated chest CT scans. In alignment with these guidelines, our approach enables automated detection and severity grading of cardiovascular calcifications, using chest CTs, with strong performance metrics indicating its feasibility for integration into clinical workflows.

CLINICAL RELEVANCE/APPLICATION

Our AI-based approach enables automated detection and grading of cardiovascular calcifications from routine thoracic CT scans. This will assist physicians with efficient reporting and actionable risk insights, supporting early assessment and clinical decision-making without requiring additional imaging.

T5A-SPIR-2 TIPS AS THE FIRST-LINE STRATEGY FOR SECONDARY PREVENTION OF SCHISTOSOMIASIS-RELATED VARICEAL BLEEDING: A COMPARATIVE STUDY WITH ENDOSCOPIC THERAPY PLUS NONSELECTIVE BETA-BLOCKERS

Yu Lei (*Presenter*)

PURPOSE

To compare the efficacy and safety of transjugular intrahepatic portosystemic shunt (TIPS) with endoscopic therapy combined with nonselective beta-blockers (NSBBs) in schistosomiasis-associated variceal bleeding.

METHODS AND MATERIALS

A retrospective analysis was conducted on 67 patients with schistosomal liver disease who had a history of gastroesophageal variceal bleeding. Thirty-seven patients underwent TIPS creation (TIPS group), while 30 patients received endoscopic therapy combined with NSBBs (EC-NSBBs group). The study compared the rates of rebleeding, overt hepatic encephalopathy, overall survival, and treatment-related adverse events between the two groups.

RESULTS

The cumulative probability of variceal rebleeding was significantly lower in the TIPS group compared to the EC-NSBBs group (HR = 0.09, 95% CI: 0.03-0.31, Log-rank P < 0.01). There were no statistically significant differences between the two groups in terms of overt hepatic encephalopathy (P = 0.38) and survival rates (P = 0.94). In the TIPS group, portal vein thrombosis, ascites, and pleural effusion gradually decreased after 6 months, while these complications increased in the EC-NSBBs group. The incidence of adverse events was not statistically different between the two groups. Multivariate Cox analysis identified treatment modality (HR = 0.16, 95% CI: 0.04-0.58, P < 0.01), CTP score (HR = 4.03, 95% CI: 1.11-14.70, P = 0.03), and variceal diameter (HR = 1.21, 95% CI: 1.00-1.46, P = 0.04) as predictors of rebleeding.

CONCLUSION

Compared with endoscopic therapy combined with NSBBs, TIPS significantly reduces the rebleeding rate in patients with schistosomiasis-related varices without increasing the incidence of hepatic encephalopathy.

CLINICAL RELEVANCE/APPLICATION

Our study revealed that the TIPS is notably more effective than endoscopic therapy combined with NSBBs in decreasing the rebleeding rate among patients suffering from variceal bleeding associated with schistosomiasis, without raising the risk of hepatic encephalopathy. This insight is particularly valuable for clinical practice in areas where schistosomiasis is endemic. By serving as a potent secondary preventative measure, TIPS not only mitigates the likelihood of recurrent bleeding but also enhances patients' survival quality and overall life expectancy. Additionally, our research highlights the necessity for tailored treatment plans, indicating that clinicians should take into account individual patient factors, including their Child-Turcotte-Pugh (CTP) score and varice diameters, when determining the most appropriate course of action.

T5A-SPIR-3 DESIGN AND EVALUATION OF AN ULTRA-FINE FULLY CT-VISUALIZED ANCHORING SYSTEM FOR CT-GUIDED PULMONARY NODULE LOCALIZATION

He Zhao (*Presenter*)
Lei Miao (*Abstract Co-Author*)
Xiao Li (*Abstract Co-Author*)

PURPOSE

Localization devices are widely used for video-assisted thoracoscopic resection of small pulmonary nodule (SPNs). However, there remains an unmet clinical need for an anchoring device deployable via ultra-fine delivery systems (=21G) that offers both full radiopacity under imaging guidance and retrievability without surgical intervention. This study evaluates the feasibility, safety, radiopacity, and retrievability of a novel ultra-fine fully CT-visualized (UF-CV) anchoring device for SPN localization.

METHODS AND MATERIALS

The UF-CV anchoring device underwent ex vivo biomechanical testing (comparing initial pulling forces with four-hook anchors) and in vivo porcine experiments (including robot-assisted implantation, CT visualization assessment, and feasibility of non-surgical retrieval).

RESULTS

Optimized UF-CV anchors (1.5-loop configuration, 3 mm diameter) demonstrated equivalent anchoring performance to four-hook anchors (1.29 ± 0.31 N vs. 1.42 ± 0.21 N) in ex vivo testing. In vivo deployment achieved 100% technical success (6/6 swine) with excellent targeting accuracy (1.4 ± 0.5 mm from nodule margins). Postoperative CT confirmed full radiopacity in all cases. While pneumothorax occurred in 66.7% (4/6) of cases following nonsurgical retrieval, all of them resolved spontaneously without intervention.

CONCLUSION

The UF-CV anchoring device provides safe and effective pulmonary nodule localization with full radiographic visibility and retrievability, representing a promising preoperative solution for SNPs.

CLINICAL RELEVANCE/APPLICATION

The clinical relevance of this study lies in its introduction of a novel Ultra-Fine Fully CT-Visualized (UF-CV) anchoring device for preoperative localization of small pulmonary nodules (SPNs). This device addresses critical unmet needs in current localization practices by offering several advantages. Firstly, it can be deployed via an

ultra-fine delivery system (=21G), minimizing iatrogenic trauma. Secondly, it provides full radiopacity under CT guidance, enhancing visibility during imaging surveillance. Thirdly, it is retrievable without surgical intervention, overcoming the limitations of permanent implantation and associated complications. The study's results indicate that the UF-CV anchor demonstrates comparable anchoring performance to existing four-hook anchors while offering superior radiopacity and retrievability, which could potentially improve the safety and efficiency of pulmonary nodule localization procedures in clinical practice.

T5A-SPIR-4 LARGE-BORE MECHANICAL THROMBECTOMY FOR ACUTE PULMONARY EMBOLISM: SAFETY, EFFECTIVENESS, AND PROGNOSTIC FACTORS IN A REAL-WORLD TERTIARY CENTER COHORT

Leila Haghani, MD,MPH (*Presenter*)
Danielle Millner Balagtas (*Abstract Co-Author*)
Dalena Huynh (*Abstract Co-Author*)
Shabaz Khan (*Abstract Co-Author*)
Kyle Halligan (*Abstract Co-Author*)
Neil Resnick, MD (*Abstract Co-Author*)
Ningcheng Li, MD, MS (*Abstract Co-Author*)

PURPOSE

To evaluate the safety, effectiveness, and prognostic factors of large-bore mechanical thrombectomy (LBMT) for acute pulmonary embolism (PE) in a real-world, all-comer population of high and intermediate-risk patients at a tertiary care center.

METHODS AND MATERIALS

This retrospective cohort study analyzed 49 consecutive patients (63.3% male, mean age 62.5±17.7 years) undergoing LBMT for acute PE from December 2018 to April 2025. The cohort comprised of an all-comer population reflecting real-world complexity at a tertiary center: 57.1% high-risk and 38.8% intermediate-high per European Society of Cardiology criteria, with Pulmonary Embolism Severity Index (PESI) of 160.9±51.5. Patients typically excluded from clinical trials—including those with malignancy (61.2%), metastatic disease (14.3%), and non-improvement despite systemic thrombolytics (20.4%)—were included. Procedural outcomes, survival at 48 hours, 1 month, and 3 months, adverse events, and mortality predictors were examined. Statistical methods included logistic regression, Cox proportional hazards models, and Kaplan-Meier survival estimates.

RESULTS

LBMT improved pulmonary artery pressure in 84.5% of patients (mean decrease 7.18 plus/minus 6.07 mmHg). Survival was 100% at 48 hours, 93.9% at 1 month, and 81.6% at 3 months (median follow-up 6.3 months). By risk stratification, high-risk patients had 67.9% 3-month survival, while intermediate-risk patients had 100% (log-rank p=0.03). Society of Interventional Radiology (SIR) moderate or higher adverse events included post-procedural vasopressor requirement (46.9%) and International Society on Thrombosis and Haemostasis (ISTH) major bleeding (20.4%). Independent mortality predictors were metastatic disease (HR 8.50, 95% CI 2.26-31.94, p=0.002), PESI (HR 1.02 per point, 95% CI 1.01-1.04, p=0.006), and neutrophil-to-lymphocyte ratio (HR 1.02 per unit, 95% CI 1.01-1.03, p=0.003).

CONCLUSION

In a real-world tertiary care setting, LBMT demonstrates safety and effectiveness for acute PE, with excellent survival in intermediate-risk patients and clinically meaningful outcomes in high-risk populations often excluded from clinical trials. Metastatic disease, PESI score, and neutrophil-to-lymphocyte ratio emerge as powerful independent prognostic markers for risk stratification and clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

This study adds to the growing evidence (the FLAME study and the high-risk cohort of the FLASH study) to incorporate LBMT into the management pathways for patients with high-risk PE.

T5A-SPIR-5 CIRCULATING ENDOTHELIAL CELLS (CECS) AS BIOMARKER FOR THERAPY RESPONSE AND RELAPSE ASSESSMENT IN ARTERIOVENOUS MALFORMATIONS (AVMS)

Vanessa F. Schmidt, MD (*Presenter*)
Melanie Kimm (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Max Seidensticker (*Abstract Co-Author*)
Moritz Wildgruber, MD, PhD (*Abstract Co-Author*)

PURPOSE

Arteriovenous malformations (AVMs) are heterogenous in their clinical, cellular and genetic appearance, they are diagnostically and therapeutically challenging. Radiological imaging combined with clinical findings still represents the gold standard in following therapeutic response and in determing a possible relapse. Although elevated levels of circulating endothelial cells (CECs) have been described in cardiovascular diseases such as myocardial infarct and artherosclerosis, their clinical impact as potential biomarker for treatment response and relapse events in vascular malformations has not yet been investigated.

METHODS AND MATERIALS

CECs of 28 consecutive patients of the prospective multicenter APOLLON study (DRKS00021019) with simple or combined extracranial AVMs, were analyzed using the CellSearch system. The detection of CECs in this system is based on magnetic isolation using CD146-coupled naoparticles and a subsequent immunofluoresence staining. CECs are defined as CD105+CD45-DAPI+ cells whereas leukocytes are CD105-CD45+DAPI+. Using healthy control samples, the cut off for CECs was determined at 60 CEC/ 4 ml peripheral blood.

RESULTS

We present for the first time the correlation of CEC enumeration with response to embolization therapy and disease relapse in AVM patients. 15/28 patients (54%) of the patients already presented increased CEC numbers at baseline (566 +- 1400). In 12/28 patients (43%) we were able to determine a decrease in CEC numbers during therapy in combination with an improvement of symptoms. To date, we observed a clinically manifest recurrence in 4/28 patients (14%), regarding these, we could parallelly determine a corresponding increase of CECs in those cases with clinical and radiological relapse (4/4, 100%).

CONCLUSION

Using the established and quality controlled CellSearch system for CEC analysis allows to detect and quantify CECs in AVM patients over a time frame of several years.

CLINICAL RELEVANCE/APPLICATION

Our results indicate that CECs could be a potential biomarker for AVM activity helping to evaluate and potentially predict treatment response. Furthermore, using liquid biopsy analysis of CECs could help to establish a patient-friendly system for early detection of relapse events.

T5A-SPIR-6 EFFICACY AND SAFETY OF IMAGE-GUIDED LUNG BIOPSIES: INSIGHTS FROM 27559 PROCEDURES FROM THE MULTINATIONAL DEGIR REGISTRY DATA 2018-2024

Max Eberts (*Presenter*)
Raya Juliane Serger, MD (*Abstract Co-Author*)
Abdullatif Kocak, MD (*Abstract Co-Author*)
Marcel Opitz, MD (*Abstract Co-Author*)
Johannes Haubold, MD (*Abstract Co-Author*)

Benedikt M. Schaarschmidt, MD (*Abstract Co-Author*)
Michael Forsting, MD (*Abstract Co-Author*)
Sebastian Zensen, MD (*Abstract Co-Author*)

PURPOSE

Image-guided lung biopsies play a crucial role in diagnosing pulmonary lesions, yet comprehensive large-scale data on their effectiveness and safety are scarce. This study analyzes the technical success, diagnostic yield, and complication rates of these procedures based on data from the German Society for Interventional Radiology and Minimally Invasive Therapy (DeGIR) registry data.

METHODS AND MATERIALS

In this retrospective analysis 27,559 image-guided lung biopsies from 212 centers between 2018 and 2024 were included. Technical success was defined as verified needle placement within the target lesion. Complications were categorized according to the Society of Interventional Radiology (SIR) guidelines.

RESULTS

Inpatient procedures accounted for 95.95% (26,443/27,559) of cases, and local anesthesia was performed in 97.45% (26,857/27,559). CT-guidance was used in 99.41% (27,396/27,559) of interventions. The overall technical success rate was 97.71% (26,929/27,559), and histological representativeness reached 90.5% (22,140/24,560). While technical success rates were comparable between inpatient and outpatient settings (97.75% vs. 96.77%, p=0.032), histological representativeness was higher among inpatients (90.37% vs. 85.11%, p<0.001). The overall complication rate was 19.44% (5,357/27,559), with major complications occurring in 4.87% (1,343/27,559) of biopsies. Higher complication rates were observed in patients with coagulation abnormalities.

CONCLUSION

Image-guided lung biopsies demonstrate high technical success and histological representativeness, accompanied by a moderate overall complication rate of about 20% and a rate of major complications of about 5%. Despite similar technical success, inpatient procedures yield superior histological quality. These findings underscore the need to carefully select patients and balance procedural benefits against potential risks, particularly in patients with coagulation disorders. Elevated complication rates - especially in outpatients and those with coagulation disorders - underscore the need to carefully select patients and balance procedural benefits against potential risks.

CLINICAL RELEVANCE/APPLICATION

This large-scale registry study confirms the high efficacy and acceptable safety profile of image-guided lung biopsies, supporting their routine clinical use.

T5A-SPIR-7 TRANSPULMONARY CHEMOPERFUSION VERSUS TRANSPULMONARY CHEMOEMBOLISATION FOR LUNG MALIGNANCIES: A PROSPECTIVE RANDOMIZED STUDY

Thomas J. Vogl, MD, PhD (*Presenter*)
Tatjana Gruber-Rouh (*Abstract Co-Author*)
Hamzah Adwan, MD (*Abstract Co-Author*)

PURPOSE

To evaluate unresectable lung metastases of different primary lesions and primary lung cancers treated by transpulmonary chemoperfusion (TPCP) or transpulmonary chemoembolization (TPCE) regarding size and ADC values.

METHODS AND MATERIALS

In this prospective randomized study 60 patients (30 women, 30 men; mean 64.5 years; range 29-84 years) were included who were treated by TPCP (n=30) or TPCE (n=30). Malignant lesions were from primary lung cancers (n=15), colorectal (n=13), breast cancer (n=10), and other primaries (n=22). All patients were treated via a transfemoral venous approach selectively into the segmental pulmonary artery using Cisplatin and Mitomycin C. The TPCE patients additionally received EmboCept S for the embolization. Follow-up was performed using MRI and CT in 3-month intervals post final therapy session.

RESULTS

No major side effects were observed. In the TPCE group, mean value in the change of volume was 0.97 +/- 0.54, in the TPCP group 1.43 +/- 1.14 (p=0.08). Change of the ADC value was 1.08 +/- 0.33 in TPCE and 1.13 +/- 0.50 in TPCP (p=0.7). According to the RECIST 1.1 criteria, TPCE patients showed stable disease (SD) in 19 cases (70.37%), partial response (PR) in 4 cases (14.81%) and progressive disease (PD) in 4 cases (14.81%). 3 patients were lost to follow-up. The TPCP group showed 21 cases (75%) of SD, 1 case of PR (3.57%) and 6 cases of PD (21.43%). Two patients were lost to follow-up. The overall survival time in the TPCE group was 732.70 +/-379.41 days, in the TPCP group 552.82 +/- 350.23 days (p=0.09). The progression-free time had a p-value of 0.14 (TPCE: 554.07 +/- 397.49 days; TPCP: 405.36 +/- 324.37 days

CONCLUSION

TPCE and TPCP can be safely performed. TPCE resulted in a more stable treatment outcome and a better prognostic trend than TPCP, even though the study did not show a statistically significant difference between TPCE and TPCP concerning overall survival.

CLINICAL RELEVANCE/APPLICATION

Interventional treatment using TPCP and TPCE results in improved survival rates in patients with unresectable lung metastases

T5A-SPMK-3 ASSESSING SOFT TISSUE SARCOMA RESPONSE TO TREATMENT USING DYNAMIC CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING (DCE-MRI): A SYSTEMATIC REVIEW

Peyman Mirghaderi, MD, MPH (*Presenter*)
Hyeyun Lee, MD (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

PURPOSE

To systematically evaluate the role of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) in assessing treatment response in soft tissue sarcomas (STS), focusing on qualitative, semi-quantitative, and quantitative parameters.

METHODS AND MATERIALS

Following PRISMA guidelines, four databases were searched (PubMed, Embase, Scopus, Web of Science) for studies assessing DCE-MRI response in STS. Inclusion criteria encompassed all studies evaluating response to neoadjuvant therapy or other treatments before surgical resection using DCE-MRI. Two reviewers independently screened and extracted data using Covidence. The methodological quality was appraised using the QUADAS-2 tool. Parameters assessed included Ktrans, Ve, Kep, time-to-peak, wash-in/wash-out rates, and time-intensity curve patterns.

RESULTS

Fifteen studies (1992-2024) involving 221 patients were included. DCE-MRI was used to assess STS response across various treatment regimens (chemotherapy, radiotherapy, chemoradiotherapy). Quantitative parameters such as Ktrans and Kep demonstrated strong correlations with histopathological necrosis (e.g., C-statistics up to 0.97 for late-post-treatment Kep). Ve and PS also differentiated responders from non-responders. Semi-quantitative markers like iAUC60 , steepest slope , and wash-in/wash-out rates were predictive of therapeutic effect. Qualitative metrics such as time-intensity curve (TIC) patterns —especially transitions to type II— accurately distinguished responders. Compared to RECIST, DCE-MRI consistently provided superior predictive performance. Across studies, limitations included protocol heterogeneity, small sample sizes, and lack of standardized thresholds.

CONCLUSION

DCE-MRI provides multifaceted insights into STS treatment response across varying techniques. Quantitative parameters, especially Ktrans and Kep, are promising for objective, early response prediction beyond conventional size-based metrics like RECIST. However, semi-quantitative and qualitative methods also hold clinical value. Standardized protocols and multicenter validation are needed for clinical integration.

CLINICAL RELEVANCE/APPLICATION

DCE-MRI may overcome limitations of RECIST by capturing functional and vascular tumor changes, offering a non-invasive, early biomarker for response in soft tissue sarcoma management.

T5A-SPMK-4 IS THE 'LAMBDA SIGN' STILL VALID? A COMPARATIVE ANALYSIS OF DISTAL TIBIOFIBULAR SYNDESMOSIS MORPHOLOGY AND RECESS DIMENSIONS

Joao Vieira, MD (*Presenter*)

PURPOSE

To evaluate the morphology of the distal tibiofibular syndesmosis in individuals without ankle joint pathology and compare it with the height of the syndesmotic recess.

METHODS AND MATERIALS

This retrospective cohort study included 100 consecutive patients without clinical or radiological evidence of ankle joint pathology. The morphology of the distal tibiofibular syndesmosis was assessed 1 cm above the tibiotalar articular line using axial T1-weighted MRI sequences. A subjective classification categorized the syndesmosis as crescent-shaped, triangular-shaped, or flat-shaped. The height of the syndesmotic recess was measured on coronal intermediate-weighted fat-suppressed images at its point of maximal extent.

RESULTS

The height of the syndesmotic recess differed significantly among morphological types ($p = 0.037$). The flat-shaped group ($n = 11$) showed the highest mean recess height (13.3 ± 5.9 mm), followed by the crescent-shaped ($n = 46$; 11.3 ± 2.8 mm) and the triangular-shaped group ($n = 43$; 10.0 ± 3.1 mm). There were no statistically significant differences in age or gender across the morphological groups.

CONCLUSION

The morphology of the distal tibiofibular syndesmosis significantly influences the height of the syndesmotic recess in individuals without ankle pathology. Understanding these anatomical variants is essential for correctly identifying a normal recess and avoiding misdiagnosis of pathology on imaging studies.

CLINICAL RELEVANCE/APPLICATION

The flat-shaped distal tibiofibular syndesmosis is associated with a significantly higher syndesmotic recess compared to other morphological types and also exceeds, on average, the commonly accepted normal height of approximately 1 cm. Awareness of these variations can improve diagnostic accuracy in the evaluation of the distal syndesmosis and reduce false-positive findings.

T5A-SPMK-7 RELIABLE DETECTION OF BONE METASTASES ON CT SCANS WITH ARTIFICIAL INTELLIGENCE

Nor-Eddine Regnard, MMed (*Presenter*)
Stephane Charlon (*Abstract Co-Author*)
Marion Durteste (*Abstract Co-Author*)
Jules Bayet (*Abstract Co-Author*)
Alois Pourchot (*Abstract Co-Author*)
Jeanne Ventre, PhD (*Abstract Co-Author*)
Jean-Denis Laredo, MD, PhD (*Abstract Co-Author*)
Andreas Brendlin, MD, PhD (*Abstract Co-Author*)
Saif Afat, MD (*Abstract Co-Author*)

PURPOSE

Bone metastases are a frequent and serious occurrence in patients with advanced solid tumors, particularly in prostate, breast, and lung cancers. Metastases can lead to skeletal-related events that impair patients' quality of life. Early detection of these lesions on CT scans is therefore critical to enable timely therapeutic intervention and improve patient prognosis. However, identifying bone metastases on CT scans remains a labor-intensive task that is prone to error. This study evaluated the performance of a novel artificial intelligence (AI) software, BoneCT (Gleamer, Paris, France), for detecting both osteolytic and sclerotic bone metastases on CT scans, and compared its diagnostic accuracy to that of radiologists.

METHODS AND MATERIALS

We conducted a retrospective multicenter study using CT scans from private clinical practices in France, Brazil, and the United States, focusing on adult patients aged =18 years. Scans covered the thoracic, abdominal, and pelvic regions. Two expert musculoskeletal radiologists annotated all osteolytic and sclerotic metastases to establish the ground truth using prior and follow-up scans, when available, and radiology reports. A third radiologist with over 35 years of experience resolved discrepancies. Four radiologists independently reviewed the same scans with limited clinical data (age, sex, and indication). We compared their performance to that of the AI software using ROC and FROC analyses.

RESULTS

The final dataset included 249 CT scans (mean age 71±14 years; 95 women, 154 men), with 133 cases (53%) positive for at least one bone metastasis. Among these patients, 191 (77%) had a known primary cancer, while 58 (23%) did not. The analysis specifically examined lesions =20 mm. The AI software achieved a patient-wise triage sensitivity of 99% [96%, 100%] and a lesion-wise sensitivity of 80% [73%, 87%] for 1.6 [1.3, 2.3] false positives per scan. In comparison, radiologists demonstrated a patient-wise sensitivity of 96% [93%, 99%] and a lesion-wise sensitivity of 76% [74%, 79%] at a mean false positive rate of 1.1 [0.7, 1.4] per scan. Notably, the AI's sensitivity did not significantly differ between osteolytic and sclerotic metastases ($p = 0.15$).

CONCLUSION

This AI solution demonstrated excellent diagnostic performance for detecting both osteolytic and sclerotic bone metastases on CT scans, on par with the performance of experienced radiologists. By offering a reliable tool for cancer surveillance and incidental metastasis detection, AI stands to optimize radiology workflows.

CLINICAL RELEVANCE/APPLICATION

By achieving radiologist-level performance in detecting bone metastases on CT, a novel AI solution is positioned to markedly improve efficiency across oncology and general radiology workflows.

T5A-SPNMMI-1 LOW-COUNT WHOLE-BODY PET WITH DEEP LEARNING IN A MULTICENTER, MULTI-TRACER AND EXTERNALLY VALIDATED STUDY

Maarten Larmuseau, DPhil (*Presenter*)
Justine Maes (*Abstract Co-Author*)
Charles Carron (*Abstract Co-Author*)
Camille Steenhout (*Abstract Co-Author*)
Ludovic D'Hulst (*Abstract Co-Author*)
Simon Dekeyser (*Abstract Co-Author*)
Tomas Brants (*Abstract Co-Author*)

PURPOSE

The growing use of PET imaging in oncology and neurodegenerative diseases has raised concerns about radiation burden and healthcare costs. Although amyloid and tau tracers support early Alzheimer's diagnosis, high tracer costs and reimbursement delays limit access. Deep learning offers a solution: in-silico image enhancement allows for high-quality PET scans at reduced dose or time, improving safety and affordability. Yet, model training must address generalizability across tracers and centers, quantitative accuracy in lesions, and noise-level mismatch between training and clinical data.

METHODS AND MATERIALS

We evaluated NUCLARITY, a CNN-based PET enhancement tool, in a blinded, multi-center, multi-tracer study. PET list-mode data from 65 subjects across three European hospitals were used to simulate 50%-dose/time scans. Four tracers were included: 18F-FDG, 18F-PSMA, 68Ga-PSMA, and 68Ga-DOTATATE. Scans were acquired with GE and Siemens systems. NUCLARITY enhanced the low-count reconstructions using a residual encoder-decoder CNN. Six physicians rated diagnostic image quality (DIQ, 1-5) and diagnostic confidence (DC, 1-3), and identified lesions across six anatomical regions. Two readers delineated VOIs on standard-count (SC) scans, enabling quantitative SUV comparisons with the enhanced low-count scans (LCE).

RESULTS

Mean DIQ was 4.1 (SC) vs. 3.6 (LCE); DC was 2.8 vs. 2.5. Across 243 segmented lesions, CCCs for SUVmean and SUVmax were 1.00 and 0.99, respectively. Bland-Altman plots showed minimal bias. Of 46 abnormal regions on SC, 43 were also detected on LCE (sensitivity: 0.93, specificity: 0.99, F1: 0.96). Inter-scan agreement was 0.70 (18F) and 0.66 (68Ga); inter-reader agreement was 0.47 (SC) and 0.44 (LCE).

CONCLUSION

NUCLARITY demonstrates robust performance across tracers and scanners, suggesting its clinical readiness. Future work will focus on broader validation and clinical decision impact.

CLINICAL RELEVANCE/APPLICATION

NUCLARITY enables diagnostic-quality PET imaging at half the dose or scan time, maintaining lesion detectability and quantitative integrity. This supports reduced radiation exposure and cost without compromising clinical utility. The tool may be especially valuable in surveillance imaging or dose-sensitive populations, improving access to PET across oncology and neurology.

T5A-SPNMMI-2 SURFACE-MODIFIED IRON OXIDE NANOPARTICLE-BASED MRI T_1 CONTRAST AGENTS

Li Wu, MD, PhD (*Presenter*)
Sihan Chen (*Abstract Co-Author*)

PURPOSE

This study aims to investigate the effects of different surface modifiers on both particle size distribution and relaxivity of iron oxide nanoparticles, with the goal of identifying the optimal modifier that demonstrates superior dispersibility and enhanced relaxivity performance.

METHODS AND MATERIALS

Firstly, ultrasmall Fe2O3 nanoparticles were synthesized via a thermal decomposition method, followed by size characterization and X-ray photoelectron spectroscopy (XPS) elemental analysis. The as-prepared aqueous Fe2O3 nanoparticles were then modified with mesoporous SiO2, dendritic mesoporous SiO2, bovine serum albumin (BSA), and polyethylene glycol diacrylate (PEG-DA), respectively. After size characterization of the modified nanoparticles, in vitro MRI imaging was performed under a 0.5 T magnetic field to measure their longitudinal (r1) and transverse (r2) relaxivity values and evaluate their imaging performance.

RESULTS

Under TEM, ultrasmall Fe2O3 nanoparticles showed regular morphology, uniform distribution, and a mean diameter of 13.82 ± 1.89 nm (Figure 1a). XPS analysis of the Fe 2p spectrum confirmed Fe2O3 formation (Figure 1b). Mesoporous SiO2 could not coat aqueous ultrasmall Fe2O3 nanoparticles (Figure 1c), while dendritic mesoporous SiO2 encapsulated them but yielded unstable systems unsuitable for relaxivity measurement (Figure 1d). BSA-coated nanoparticles degraded after one week, showing poor stability and precluding relaxivity analysis (Figure 1e). In contrast, PEG-DA-coated nanoparticles exhibited excellent dispersibility, with r1/r2 relaxivities of 0.077/0.082 mM?¹ s?¹ (r2/r1 = 1.06 at 0.5 T). T 1 WI signal intensity increased with Fe concentration, consistent with T1 contrast agent characteristics (Figure 1f and Figure 1g).

CONCLUSION

PEG-DA modified iron oxide nanoparticles exhibit good monodispersity and stability. Meanwhile, they possess excellent T 1 relaxation properties and thus have greater potential to serve as MRI T1 contrast agent based on Fe2O3@PEG-DA.

CLINICAL RELEVANCE/APPLICATION

Compared with clinically commonly used gadolinium-based contrast agents, iron oxide nanoparticle-based contrast agents exhibit higher biological safety. Additionally, PEG-DA modification of iron oxide nanoparticles can enhance biocompatibility and T 1 WI performance, thereby making iron oxide nanoparticle-based T 1 contrast agents more promising for clinical applications.

T5A-SPNPM-1 AUGMENTING THE DATASET OF A RAG-BASED RADIATION ONCOLOGY PATIENT CHATBOT THROUGH SYNTHETIC QUESTION-ANSWER GENERATION AND AUTOMATED EVALUATION

Philip Dawny Philip, BA (*Presenter*)
Ayush Agarwal (*Abstract Co-Author*)
Jerry Zhu, MS (*Abstract Co-Author*)
Poonam Yadav, PhD (*Abstract Co-Author*)
Jacob John, BEng, MS (*Abstract Co-Author*)
Sagnik Sarkar, MS (*Abstract Co-Author*)
Peng (Troy) Teo, PhD (*Abstract Co-Author*)

PURPOSE

The rapid adoption of AI chat assistants in radiation oncology highlights the need for scalable, accurate dataset validation. This study evaluates the effectiveness of LLMs in generating and assessing synthetic medical Q&A pairs, benchmarking automated and statistical evaluation methods against expert human ratings to enable reliable automated dataset validation.

METHODS AND MATERIALS

We extracted reference content from information hosted on three authoritative radiation oncology websites and employed Llama 31.-70B with structured prompts to generate corresponding patient-style questions. Each QA pair underwent a three-tier assessment: (1) LLM self-evaluation using structured grader chains, (2) scoring with RQUGE, a reference free metric that assesses question quality by measuring how well the generated question can be answered, and (3) expert review by board-certified radiation oncologists for medical accuracy, relevance and clarity. To support automated dataset validation, we used ROC analysis to identify the optimal threshold for RQUGE scores and applied weighted Cohen's Kappa to calibrate LLM self-evaluation scores against expert ratings.

RESULTS

The results reveal systematic differences among evaluation methods: LLM scores are generally higher and less variable than human scores, while RQUGE scores are consistently lower. Both LLM and RQUGE scores show modest but significant positive correlations with human ratings, though LLM-human alignment is stronger. ROC analysis yields an AUC of 0.58 for RQUGE based classifier, reflecting limited discriminative power. Cohen's Kappa score is 0.105 for an LLM score threshold of 4, with percentage agreement improving slightly to 48.67% after thresholding. Using this threshold, LLM classification achieves 88% accuracy against human ground truth.

CONCLUSION

Structured prompts allow LLMs to generate clinically relevant questions for RAG-based radiation oncology chatbots. Though self-evaluations show optimism bias, thresholding improves alignment with expert ratings. With calibrated scoring, LLMs can reduce reliance on manual review in synthetic dataset generation.

CLINICAL RELEVANCE/APPLICATION

RAG-based LLs improve safety in radiation oncology by retrieving responses from curated content, reducing hallucinations. Their effectiveness however, depends on robust QA datasets. This study shows that Llama 3.1 can generate clinically relevant questions and self-assess quality. Calibration with expert ratings and reference-free metrics like RQUGE enables scalable, automated QA curation for safe patient chatbot deployment.

T5A-SPNPM-3 PAPERLESS RADIOLOGY: CHALLENGES, ACCEPTANCE, AND NET PROMOTER SCORE TRENDS IN A LARGE IMAGING CENTER

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)
Juan Cruz Gallo, MD, MD (*Abstract Co-Author*)
Patricio J. Sita (*Abstract Co-Author*)
Valeria Szymanowski (*Abstract Co-Author*)

PURPOSE

The benefits of paperless systems include streamlined workflows, reduced environmental impact, and improved data sharing, while limitations involve potential technological barriers, cybersecurity risks, and patient/physician reluctance. The objective of this study is to evaluate whether Argentine patients and referring physicians are prepared for a transition to a paperless system by analyzing their acceptance levels through Net Promoter Score (NPS) measurements before and after implementation.

METHODS AND MATERIALS

This study was conducted at one of the largest imaging centers in Buenos Aires, performing over 70,000 imaging studies monthly across multiple imaging department. To assess patient and referring physician satisfaction and acceptance of the paperless transition, we measured the Net Promoter Score (NPS) monthly. Our institutional goal was to maintain an NPS above 80. The transition to a paperless system began in August 2024 in two imaging departments: conventional radiology and dental radiology. NPS scores were collected globally and individually from January to August 2024 (pre-implementation phase) and from August to December 2024 (post-implementation phase). We then compared the results to determine any significant differences before and after implementation.

RESULTS

The global NPS before the implementation of global paperless imaging department was 81.53, but after implementation, it dropped to 73.84%. When analyzing individual departments, the results showed: PET-CT 80/80; nuclear medicine 76.9/80; MRI 82.1/80.6; mammography 89.6/81.2; densitometry 86.2/88.3; US 78.6/78.7; CT 75.8/61.1; dental radiology 81.5/75.9; conventional radiology 80/46.5; cardiology 70.8/85; referring physician 80/52.

CONCLUSION

Our initial experience demonstrated that the transition to a paperless radiology system resulted in a significant drop in NPS, particularly in the first two imaging departments where it was implemented. This decline suggests that additional efforts are required to educate and prepare patients and referring physicians for the benefits of a paperless system before its full implementation. Future strategies should focus on improved communication, training programs, and user-friendly digital solutions to facilitate adoption and enhance satisfaction levels.

CLINICAL RELEVANCE/APPLICATION

The transition to a paperless workflow in radiology aims to optimize efficiency, reduce costs, and enhance patient and referring physician experience.

T5A-SPNR-1 DAPAGLIFLOZIN RESTORES ODOR-INDUCED FUNCTIONAL INTEGRATION OF POC CIRCUIT, BUT NOT LOCAL OLFACTORY NEURAL ACTIVATION IN PATIENTS WITH TYPE 2 DIABETES: A 16-WEEK RANDOMIZED COMPARATIVE STUDY

Xin Li (*Presenter*)
Bing Zhang, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the effects of dapagliflozin, liraglutide, or acarbose treatment on the directed functional connectivity of the primary olfactory cortex (POC) circuit and local activation under odor stimulation in patients with type 2 diabetes (T2D).

METHODS AND MATERIALS

The 16-week randomized, parallel-group, open-label trial included 36 patients with T2D inadequately controlled with metformin, who were randomized (1:1:1) to receive dapagliflozin, liraglutide or acarbose. Simultaneously, 36 healthy controls were recruited. All participants underwent olfactory task functional MRI, along with a battery of olfactory and cognitive tests, both at baseline and postintervention.

RESULTS

After 16 weeks, dapagliflozin restored odor-induced functional integration of the POC-sensorimotor cortex-middle temporal cortex circuit (Gaussian random field correction applied), whereas liraglutide and acarbose did not. Dapagliflozin also tended to improve attention ($P = 0.071$). In contrast, liraglutide enhanced odor-induced activation in the left hippocampus, which was not observed with dapagliflozin and acarbose. The decreased odor-induced directed functional connectivity was associated with improvements in lipid levels and changes in olfactory threshold, executive function, and memory performance (all $P < 0.05$).

CONCLUSION

These results suggest that dapagliflozin and liraglutide exhibit distinct neuroprotective effects. While liraglutide enhances activation in local olfactory-related regions, dapagliflozin facilitates functional integration within neural circuits. This highlights the importance of targeting both metabolic and neural pathways to manage T2D-related cognitive decline.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the potential of dapagliflozin and liraglutide as neuroprotective agents and underscore the importance of targeting both metabolic and neural pathways in the management of T2D-related cognitive decline. Further research is needed to elucidate the long-term effects of antidiabetic drugs on brain health and to identify optimal treatment strategies for patients at high risk of dementia.

T5A-SPNR-3 ASSOCIATION BETWEEN DIFFUSION TENSOR IMAGING ALONG THE PERIVASCULAR SPACE (DTI-ALPS) AND GLOBAL COGNITIVE SCORES IN BOSTON PUERTO RICAN HEALTH STUDY (BPRHS)

Mahsa Alborzi Avanaki, MD (*Presenter*)
Yi Guan (*Abstract Co-Author*)
Bang-Bon Koo (*Abstract Co-Author*)
Chia Hsin Cheng (*Abstract Co-Author*)
Yu-Ming Chang, MD, PhD (*Abstract Co-Author*)
Tammy Scott (*Abstract Co-Author*)
Katherine Tucker (*Abstract Co-Author*)
Rafeeque A. Bhadelia, MD (*Abstract Co-Author*)

PURPOSE

DTI-ALPS has been used as a surrogate for brain's glymphatic system responsible for removal of toxic proteins and other waste materials. While lower DTI-ALPS has been associated with cognitive decline, mechanism of relationship is not fully understood. Our purpose was to investigate: (1) the association between DTI-ALPS and demographic, genetic and cerebrovascular risk-factors, hippocampal volumes (HV) and Global Cognitive Scores (GCS), and (2) to study HV has any mediation role in association between DTI-ALPS and GCS.

METHODS AND MATERIALS

A total of 198 BPRHS participants (153 female; mean age 67.9 ± 6.7 years) who underwent MRI and had complete demographic, genetic, cardiovascular (hypertension and diabetes), and GCS profile data were included. MRI scans included 3-mm DTI (32 directions) and 3D MPRAGE images for DTI-ALPS and HV analyses. DTI-ALPS was calculated using both the manual and automated ROI placements. The GCS was derived as the average of the z-scores from multiple cognitive tests, including the word list learning, recognition, percentage retention, Stroop test, letter fluency, digit span forward and backward, clock drawing, and weighted figure copying. The effects of age, sex, apolipoprotein E4 (APOE) profile, and the presence of hypertension (with or without diabetes) on DTI-ALPS, HV, and GCS were assessed using linear models. The association between DTI-ALPS, HV and GCS was studied using correlation and mediation analysis.

RESULTS

Automated DTI-ALPS measurements were strongly correlated with manual method ($r=0.58$) and provided normally distributed data for analysis. Lower DTI-ALPS scores were associated with increasing age ($P<0.007$) and the coexistence of diabetes and hypertension ($P<0.001$). DTI-ALPS was significantly affected by hypertension and diabetes in both younger subjects (age<=median age of 66) and older subjects (age>66yo, $P<0.05$), whereas HV and GCS were only significantly affected in the older age group ($P<0.05$). No relationship was seen between DTI-ALPS and sex, APOE4 carrier status or with hypertension individually. The relationship between DTI-ALPS and GCS appeared to be mediated through HV ($P<0.001$).

CONCLUSION

DTI-ALPS scores are associated with GCS, but this relationship appears to be mediated through hippocampal atrophy. These significant correlations suggest that DTI-ALPS may serve as a noninvasive biomarker reflecting brain structural integrity and cognitive status in aging populations with cardiovascular risk factors.

CLINICAL RELEVANCE/APPLICATION

DTI-ALPS may serve as a noninvasive marker for cognitive function and brain integrity in older adults with cardiovascular risk factors.

T5A-SPNR-4 PIVOTAL MULTICENTER VALIDATION OF A DEEP LEARNING SOFTWARE FOR AUTOMATIC DETECTION OF ACUTE INTRACRANIAL HEMORRHAGE

Tae Jin Yun, MD (*Presenter*)
Jin Wook Choi, MD, PhD (*Abstract Co-Author*)
Hoon Na (*Abstract Co-Author*)
Miran Han, MD (*Abstract Co-Author*)
Woo Sang Jung (*Abstract Co-Author*)
Ji Ye Lee, MD, PhD (*Abstract Co-Author*)
Roh-Eul Yoo, MD, PhD (*Abstract Co-Author*)
Inpyeong Hwang, MD (*Abstract Co-Author*)
Sun Won Park, MD, PhD (*Abstract Co-Author*)

PURPOSE

Acute intracranial hemorrhage (ICH) is a critical neurologic emergency where timely diagnosis directly affects outcomes. Non-contrast brain CT remains the gold standard for initial detection; however, subtle or atypical hemorrhage subtypes can be easily overlooked, especially under emergency pressure. Artificial intelligence (AI)-based computer-aided triage and notification (CADt) systems may expedite identification of critical cases, enhancing diagnostic accuracy and workflow efficiency.

METHODS AND MATERIALS

We performed a retrospective pivotal study across 13 demographically diverse U.S. hospitals to assess the performance of Hyper Insight-ICH, an AI-powered CADt software, in detecting acute ICH on non-contrast axial brain CT. The cohort included 394 adults (198 ICH, 196 normal). Ground truth was established by consensus of board-certified neuroradiologists. The software employed a hybrid architecture of hemorrhage detection module (based on supervised training) and anomaly detection module (based on unsupervised training). Primary outcomes were sensitivity and specificity; secondary endpoints included AUROC, predictive values, and notification time. Subgroup analyses focused on ICH subtypes, CT scanner vendors, and patient demographics.

RESULTS

The software achieved excellent diagnostic accuracy, with 95.45% sensitivity, 98.47% specificity, and an AUROC of 0.9864. Median alert time was 15.8 seconds, supporting real-time triage. Subgroup analysis by ICH subtype showed consistently high sensitivity: 97.30% for intraparenchymal, 97.67% for intraventricular, 97.65% for subarachnoid, 94.69% for subdural, and 100.00% for epidural hemorrhages. The tool consistently performed well across CT vendors and patient demographics.

CONCLUSION

This FDA-aligned pivotal trial shows that the AI-based triage tool provides rapid and reliable detection of diverse ICH subtypes, including challenging patterns such as subarachnoid or subdural bleeds. With consistent performance across clinical and technical subgroups and real-time notification capability, it is well-positioned for integration into emergency radiology settings as a Class II CADt device. Its high performance underscores the clinical utility of AI-driven triage to enhance vigilance and reduce diagnostic delays in acute neuroimaging.

CLINICAL RELEVANCE/APPLICATION

An AI-based triage tool enables fast and accurate detection of acute intracranial hemorrhage on brain CT, demonstrating high sensitivity across all major hemorrhage subtypes and a median alert time of less than 16 seconds. Its consistent performance supports integration into emergency workflows to reduce diagnostic delays and improve clinical outcomes.

T5A-SPNR-5 RADIOLOGICAL MARKERS OF BRAIN HEALTH AFFECT SURVIVAL IN ELDERLY GLIOBLASTOMA PATIENTS

Parisa Arjmand (*Presenter*)
Sree Gongala (*Abstract Co-Author*)
Wassim O. Malak, MD (*Abstract Co-Author*)
Prashant Vempati (*Abstract Co-Author*)
Tiffany Hodges (*Abstract Co-Author*)
Chaitra A. Badve, MD (*Abstract Co-Author*)

PURPOSE

This study investigates whether radiological markers of brain health, assessed on pre-operative MRI, independently predict overall survival (OS) in elderly glioblastoma patients, beyond conventional clinical and tumor-specific factors.

METHODS AND MATERIALS

In this retrospective study, we analyzed 144 patients aged =65 years with newly diagnosed IDH-wildtype glioblastoma and a pre-operative MRI from 2012-2024 at a single academic center. Tumor features and brain health markers—including global cortical atrophy (GCA), white matter hyperintensities (WMH), microbleeds, lacunar infarcts, and perivascular spaces—were rated by neuroradiologists. Clinical data (e.g., age, KPS, MGMT status) and treatment details were extracted from records. Kaplan-Meier and Cox proportional hazards models (univariate and multivariate) were used to assess associations between these brain health markers and OS.

RESULTS

Median age at diagnosis was 72.6 years. Most patients (56.9%) were male. Common brain health findings included mild-to-moderate GCA (44.4%) and WMH (54.8%). Satellite lesions (45.1%) and ependymal involvement (79.9%) were frequent tumor features. Univariate analysis showed that moderate-to-severe GCA (HR ~1.9, p <0.01), WMH (HR ~2.1, p <0.01), lacunar infarcts (HR ~1.7, p <0.05), and satellite lesions (HR ~1.5, p <0.05) were significantly associated with decreased OS. Ependymal involvement also predicted worse survival (HR ~1.7, p <0.01). However, in multivariate models adjusting for age, KPS, and MGMT status, none of the imaging-based brain health markers remained independently significant, suggesting collinearity with age and frailty.

CONCLUSION

Radiological markers of brain health—including GCA, WMH, and lacunar infarcts—are significantly associated with increased mortality in elderly glioblastoma patients. Additionally, tumor characteristics such as deep brain location, ependymal involvement, and the presence of satellite lesions negatively influence survival. Notably, these imaging-based features demonstrate prognostic value independent of chronological age, underscoring their clinical relevance. Future research should focus on incorporating these radiological markers into comprehensive prognostic models alongside clinical and molecular parameters to improve risk stratification and guide personalized treatment planning.

CLINICAL RELEVANCE/APPLICATION

MRI-based brain health markers offer a complementary lens to assess prognosis in elderly glioblastoma beyond tumor and molecular features. Incorporating these into clinical evaluation may improve treatment personalization by identifying patients less likely to tolerate aggressive therapy due to underlying neurovascular vulnerability.

T5A-SPNR-6 PREDICTION OF BRAIN INVASION OF MENINGIOMA BY ADC HISTOGRAM ANALYSIS: RELATIONSHIP WITH KI-67 PROLIFERATION INDEX

Guiqin Chen (*Presenter*)
Junlin Zhou, PhD (*Abstract Co-Author*)

PURPOSE

Predicting whether meningioma has brain invasion before operation is helpful to guide surgical decision-making and treatment, and is helpful to the prognosis of meningioma. The purpose of this study is to predict the brain invasion of meningioma by using the histogram parameters of apparent diffusion coefficient (ADC) before operation, and to further study the relationship between ADC histogram parameters and Ki-67 proliferation index

METHODS AND MATERIALS

133 cases of meningioma confirmed by pathology in our hospital from January 2021 to December 2024 were retrospectively collected, and were divided into brain invasion group and non- invasion group according to the pathological results. The preoperative clinical data, ADC data and postoperative pathological characteristics were collected. Using Firevoxel software to extract ADC histogram parameters of meningioma patients before operation . We statistically analyzed the ADC histogram parameters of the two groups, and determined the characteristic parameters with significant differences between the two groups. In addition, we used receiver operating characteristic curve (ROC) and binary logistic regression analysis to evaluate the accuracy of distinguishing ADC histogram parameters, and discussed the relationship between ADC histogram parameters and Ki-67 in meningioma.

RESULTS

ADC histogram parameters have certain ability to distinguish meningioma brain invasion. Age,ADCmin, ADCp1, ADCvrriance, and ADCcoefficient of variation among ADC histogram parameters showed statistically significant differences between invasion group and non- invasion group meningiomas (all $P < 0.05$).The combination of ADC histogram parameters and clinical routine features showed the best ability to distinguish meningioma brain invasion, and the area under the curve (AUC) was 0.778 (95% CI, 0.692-0.860). The ADCmin ($r = -0.256$, $p=0.003$) and ADCp1 ($r =-0.309$, $p < 0.001$) were negatively correlated with the proliferation index of Ki-67 (Bonferroni correction) .

CONCLUSION

As a non-invasive method, ADC histogram parameters combined with clinical features have potential clinical value in preoperative diagnosis of meningioma brain invasion

CLINICAL RELEVANCE/APPLICATION

It is helpful to formulate surgical strategies and predict prognosis.

T5A-SPNR-7 PHYSIOLOGICAL IMPLICATIONS OF ORIGINAL AND VARIANT DIFFUSION TENSOR IMAGE ANALYSIS ALONG THE PERIVASCULAR SPACE (DTI-ALPS) METRICS IN OBSTRACTIVE SLEEP APNEA

Toshiaki Taoka, MD, PhD (*Presenter*)
Kunihiro Iwamoto (*Abstract Co-Author*)
Seiko Miyata (*Abstract Co-Author*)
Rintaro Ito, MD, PhD (*Abstract Co-Author*)
Koji Kamagata, MD, PhD (*Abstract Co-Author*)
Shinji Naganawa, MD, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the associations between diffusion tensor imaging (DTI)-derived perivascular diffusivity metrics—including the ALPS-index and its variant forms—and polysomnography (PSG)-derived sleep parameters in patients with suspected obstructive sleep apnea (OSA), aiming to elucidate the physiological implications of both global and region-specific indices in relation to sleep quality and architecture.

METHODS AND MATERIALS

Fifty participants (mean age 50.0 ± 14.0 years) underwent overnight PSG and two brain MRI sessions (4 PM and 9 AM) on a 3T scanner. DTI-based parameters included the standard ALPS-index and three variant indices calculated in distinct regions of the corpus callosum: ccgALPS (genu), ccbALPS (body), and ccsALPS (splenium). Sleep metrics assessed included sleep latency, REM sleep latency, total sleep time, wake after sleep onset (WASO), and sleep efficiency. Correlation analyses were conducted between both the standard and variant ALPS metrics and sleep parameters for each MRI session (Day 0 and Day 1). Changes across sleep (delta) were also analyzed. Scatter plots were generated to visually demonstrate the relationships between diffusivity metrics and sleep parameters.

RESULTS

The standard ALPS-index at 4 PM showed moderate correlations with REM latency ($r = -0.47$), total sleep time ($r = 0.33$), and sleep efficiency ($r = 0.29$). Similar trends were observed at 9 AM. Among the variant indices, ccbALPS exhibited a weak negative correlation with sleep latency ($r = -0.25$). Additionally, diffusivity metrics within the corpus callosum, such as ccbDyy and ccbFA, were positively associated with sleep efficiency ($r = 0.30$-0.45). Changes in delta ccsDzz across the sleep period were inversely correlated with Stage N3 sleep ($r = -0.41$), suggesting sensitivity to deep sleep. These findings indicate that both the standard and variant ALPS indices capture aspects of sleep-related microstructural changes in the brain.

CONCLUSION

DTI-derived indices, particularly the ALPS-index and corpus callosum variant indices, show significant associations with key PSG-derived sleep metrics, suggesting their potential utility as non-invasive markers of sleep quality. The inclusion of variant ALPS indices provided complementary insights into region-specific diffusivity changes associated with sleep architecture, enhancing the understanding of sleep-related neurofluid dynamics.

CLINICAL RELEVANCE/APPLICATION

DTI-based diffusivity metrics, including the ALPS-index and its variants, may serve as surrogate imaging biomarkers of sleep quality, offering insights into neurofluid dynamics and brain health in sleep disorders such as OSA.

T5A-SPNR-9 PLASMA GFAP AS A MEDIATOR BETWEEN WHITE MATTER INTEGRITY AND TAU PATHOLOGY IN ALZHEIMER DISEASE-DERIVED COGNITIVE IMPAIRMENT: INSIGHTS FROM A NODDI STUDY

Xinru Xu (*Presenter*)

PURPOSE

Neurite Orientation Dispersion and Density Imaging (NODDI) is an advanced diffusion MRI method offering microstructural insights into brain tissue. This study aims to elucidate the relationship between WM microstructure alterations and plasma biomarkers in Alzheimer's Disease (AD) and whether NODDI metrics improved diagnostic accuracy compared that only relied on plasma biomarkers (alone and in combination).

METHODS AND MATERIALS

The study involved 59 cognitively unimpaired (CU) and 47 CI participants, including individuals with mild cognitive impairment and AD. Tract-Based Spatial Statistics (TBSS) was used to assess microstructural alterations in WM fiber tracts via Diffusion Tensor Imaging (DTI) and NODDI metrics. Correlation and multiple linear regression analyses were conducted to investigate the relationships between plasma biomarkers (Aß 42/40, p-Tau181, p-Tau217, NfL, and GFAP), NODDI and DTI indices in WM fiber and neuropsychological scale scores at baseline and longitudinal changes. Structural equation models explore relationships among plasma biomarkers, white matter injury and cognitive function. Receiver operating characteristic (ROC) analyses were performed to evaluated the ability of NODDI and DTI index in WM and plasma biomarkers for distinguishing between CI and CU individuals.

RESULTS

CI participants exhibited significantly deteriorated WM microstructural integrity, as reflected by decreased Fractional anisotropy(FA) and Neurite density (NDI) values in specific brain regions. NDI values showed significant correlations with AD-related plasma biomarkers [(NDI&p-Tau181 ($r=-0.136$, $P<0.001$) and NDI&GFAP ($r=-0.185$, $P<0.001$)], as well as cognitive function. Mediation analysis indicated that WM microstructural alterations, as measured by NDI, partially and fully mediated the relationship between plasma p-Tau181, Aß42/40, and subsequent cognitive decline. Furthermore, combination of NDI and p-Tau181 provided superior performance in distinguishing CU from CI individuals (area under the ROC curve = 0.93) and predicting longitudinal cognitive decline.

CONCLUSION

NDI is more sensitive than taditional DTI index (FA) in diagnosing cognitive impairment and predicting cognitive decline associated AD. Plasma p-Tau181 appears to contribute to cognitive decline by promoting GFAP level and synaptic density changes in WM.

CLINICAL RELEVANCE/APPLICATION

The current study demonstrates that NDI may provide additional valuable diagnostic and prognostic information regarding cognitive changes in AD. Our findings highlight the role of neurite density in white matter and tau patholofy as key disease modifiers, with potential implications for disease-modifying trials targeting individuals with AD.

T5A-SPNR-11 IMAGE SYNTHESIS OF DOUBLE INVERSION RECOVERY-LIKE SERIES FOR ENHANCED CONTRAST AND FOCAL CORTICAL DYSPLASIA VISUALIZATION

Thomas C. Arnold, PhD (*Presenter*)
Long Wang (*Abstract Co-Author*)
Zechen Zhou (*Abstract Co-Author*)
Lei Xiang (*Abstract Co-Author*)
Ajit Shankaranarayanan (*Abstract Co-Author*)
Suzie C. Bash, MD (*Abstract Co-Author*)
Lawrence Tanenbaum, MD (*Abstract Co-Author*)

PURPOSE

In focal cortical dysplasia (FCD) type II, pathological regions typically present with blurring of the gray-white-matter junction and subcortical white matter hyperintensities. This study evaluates the utility of synthesized double inversion recovery like images in enhancing the visibility of those features, while maintaining high structural consistency.

METHODS AND MATERIALS

Building on our earlier work, where we synthesize STIR-like image from T1-weighted and T2-weighted spine series[2], we repurpose it for a novel application, to use T1w and T2-FLAIR brain images to synthesize a DIR-like (Syn-DIR) image. The study evaluated on the dataset with 85 individuals with epilepsy due to FCD II and 85 healthy controls. It also includes manually labeled lesion masks.To assess changes at the gray-white-matter junction, gray-white-matter contrast ratios(GWCR) were computed under three conditions: (1) healthy control set, (2) FCD-labeled regions, and (3) non-FCD regions. Wilcoxon signed-rank tests were performed to evaluate statistical differences across conditions. Additionally, to assess the sensitivity to FCD lesions, the drop in subcortical white matter hyperintensity was quantified both inside and outside the lesion areas on the FCD cohort.For evaluating structural consistency, dice similarity coefficients were computed using derived segmentation masks from T2 FLAIR and SynDIR volumes independently. Dice scores within major brain regions were averaged across cases to quantify segmentation agreement.

RESULTS

Figure A shows a representative case of FCD. SynDIR achieved significantly higher GWMC scores than FLAIR across all conditions(Table). Within the FCD cohort, GWMCD on SynDIR was significantly greater than that on T2-FLAIR (SynDIR: 0.2762 ± 0.1425, FLAIR: 0.0774 ± 0.0634; $p < 0.001$; Figure B). It suggests SynDIR provides a substantial enhancement in depicting the gray-white matter junction and enhanced sensitivity to cortical abnormalities.The average subcortical hyperintensity with SynDIR was 1.3305 ± 0.1694, which is significantly larger than that with FLAIR(1.5757 ± 0.2771)(Figure C). It indicates SynDIR is more sensitive to the hallmark FCD signal abnormalities associated. In Figure D, all major brain structures demonstrated high structural agreement between FLAIR and SynDIR segmentations(exceeding a Dice score of 0.85). Regions such as the Basal Ganglia and Brainstem achieved particularly high agreement, indicating strong spatial consistency.

CONCLUSION

In conclusion, SynDIR demonstrates better GM/WM junctions, enhanced sensitivity to signal abnormality, and segmentation consistency.

CLINICAL RELEVANCE/APPLICATION

Synthetic DIR can accelerate scan times by eliminating the need to collect DIR series.

T5A-SPNR-12 MODERATE ADVERSE EVENTS IN MR-GUIDED FOCUSED ULTRASOUND VIM THALAMOTOMY FOR TREMOR: A CASE SERIES AND STRATEGIC MODIFICATIONS

Toshio Yamaguchi, MD, PhD (*Presenter*)

PURPOSE

MR-guided focused ultrasound thalamotomy (MRgFUS) is an incisionless neurosurgery for treating essential tremor (ET) and tremor-dominant Parkinson’s disease (TDPD). While severe adverse events (AEs) are rare, moderate complications may occur. Clarifying their mechanisms is essential for improving safety. We describe moderate AEs after MRgFUS and clarify their mechanisms.

METHODS AND MATERIALS

We analyzed consecutive 273 cases (235 ET, 38 TDPD) treated with MRgFUS from June 2019 to March 2025. All procedures targeted the Vim nucleus using repeated sonications within the therapeutic range (50-55°C), monitored by MR thermometry. AEs requiring hospitalization beyond one week were classified as moderate.

RESULTS

Four cases (1.4%) experienced notable moderate AEs. Case 1 (ET, SDR=0.42) Remaining tremor led to added lateral sonication, resulting in lesioning of the internal capsule. Persistent gait and speech disturbance remained at 2 years, along with tremor recurrence. Case 2 (ET, SDR=0.6) Vc lesioning caused long-term hand/face sensory disturbance and dysphagia. Anatomical variation placed the Vim/Vc border more anteriorly than usual. ? Countermeasures: Improved initial targeting using 3D imaging of the Vim/Vc and thalamic internal capsule borders; revised lesioning sequence starting from posterolateral Vim; skull segment analysis for thermal prediction. Case 3 (ET, SDR=0.36) Postoperative hypotonia and gait disturbance occurred due to pre-existing cervical/lumbar severe stenosis (double crush syndrome). Walking

aids were still required at 2 years. ? Countermeasures: Preoperative screening for spinal stenosis; prioritize spine surgery if indicated. Case 4 (TDPD, SDR=0.47) Cavitation occurred at low energy (681J), causing transient dysarthria and agitation. Tremor remained improved with minimal medication without long-term deficits.

CONCLUSION

Most complications occurred in early-stage of our experience and were preventable. Refining targeting and patient selection protocols significantly reduced AEs. Cavitation remains unpredictable, requiring continued vigilance.

CLINICAL RELEVANCE/APPLICATION

Although infrequent, sharing moderate AEs and their causes supports safer implementation of MRgFUS.

T5A-SPNR-14 RISK FACTORS AND PROGNOSIS OF POST-STROKE PNEUMONIA IN PATIENTS WITH ANTERIOR CIRCULATION LARGE-VESSEL OCCLUSION FOLLOWING MECHANICAL THROMBECTOMY

Nina Hao (*Presenter*)
Yu Sun (*Abstract Co-Author*)
Tao Ren (*Abstract Co-Author*)
Song Liu (*Abstract Co-Author*)
Aiyun Sun (*Abstract Co-Author*)
Luotong Wang (*Abstract Co-Author*)
Chao Tian SR, MD (*Abstract Co-Author*)

PURPOSE

To identify risk factors associated with post-stroke pneumonia (PSP) in patients undergoing mechanical thrombectomy for anterior circulation large vessel occlusion, and to develop a predictive model combining clinical and CT imaging parameters.

METHODS AND MATERIALS

We retrospectively analyzed data from patients with acute ischemic stroke (AIS) due to anterior circulation large vessel occlusion who underwent mechanical thrombectomy between April 2020 and October 2023. Patients were categorized into PSP and non-PSP groups based on the development of PSP during hospitalization. Outcomes were assessed at 90 days using the modified Rankin Scale (mRS). Logistic regression analysis was employed to determine independent predictors of PSP based on clinical characteristics and CT imaging parameters. Model performance was evaluated using receiver operating characteristic (ROC) curve analysis.

RESULTS

Among 106 patients included, 48 (45%) developed PSP. Multivariate logistic regression identified age =70 years (OR = 3.181, 95% CI: 1.059-9.555, P = 0.039), dysphagia (OR = 4.693, 95% CI: 1.171-18.807, P = 0.029), and the presence of diabetes (OR = 0.216, 95% CI: 0.066-0.713, P = 0.012) as independent predictors of PSP. The optimal threshold of perfusion volume (Tmax >6 seconds) for PSP prediction was 142 mL, yielding an AUC of 0.635 (95% CI: 0.526-0.739), with 77% sensitivity and 53% specificity. A combined model incorporating both clinical and CT perfusion (CTP) features showed improved predictive accuracy, with an AUC of 0.72 (95% CI: 0.52-0.89), sensitivity of 69%, and specificity of 75%. PSP was independently associated with unfavorable outcomes (90-day mRS >2; OR = 3.226, 95% CI: 1.232-8.451, P = 0.017).

CONCLUSION

Age =70 years, dysphagia, and diabetes were identified as independent factors associated with PSP in patients with anterior circulation large vessel occlusion. A predictive model combining clinical characteristics and CTP enhances the accuracy of PSP risk estimation.

CLINICAL RELEVANCE/APPLICATION

Patients with AIS who develop PSP face an increased risk of poor outcomes. Early identification using an combined clinical-imaging model may facilitate timely interventions and improve patient prognosis.

T5A-SPNR-15 CLINICAL APPLICATION OF A TRIPLE-LOW PROTOCOL COMBINED WITH DEEP LEARNING RECONSTRUCTION IN BRAIN PERFUSION CT: A PROSPECTIVE STUDY

Haina Xu (*Presenter*)
Xin Qin (*Abstract Co-Author*)
Weiyuan Huang (*Abstract Co-Author*)
Feng Chen, MD, PhD (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

To assess the performance of a triple-low protocol (80 kV/80 mA, 40 mL contrast, 4 mL/s) combined with deep learning image reconstruction (DLIR-H) in brain perfusion CT (CTP), compared to a conventional protocol (80 kV, 120 mA, 50 mL, 5 mL/s) with iterative reconstruction (ASIR-V 50%).

METHODS AND MATERIALS

A total of 102 patients with suspected acute ischemic stroke (AIS) were prospectively enrolled and randomly assigned to the conventional or triple-low group (n=51 each). All patients underwent brain CTP scans, generating four datasets (GroupA: conventional+DLIR-H, Group B: conventional+ASIR-V, Group C: triple-low+DLIR-H, Group D: triple-low+ASIR-V). Radiation and contrast doses were recorded. Objective image quality was assessed by CT values, standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and perfusion parameters (CBV, CBF, Tmax, MTT, TTP). Subjective image quality was evaluated independently by two senior radiologists using a 3-point scale (0=poor, 1=moderate, 2=good).

RESULTS

The triple-low group showed significantly lower radiation dose (effective dose: 1.51 vs 2.27 mSv, P<0.001) and reduced contrast volume (40 vs 50 mL) with slower injection rate (4 vs 5 mL/s). CT values across gray and white matter regions were comparable (P>0.05), except for minor differences (<2 HU) in temporal and parietal white matter. Image noise (SD) differed in the frontal region (P<0.05) but not elsewhere; DLIR-H under triple-low conditions (group C) consistently showed lower SD than conventional ASIR-V (group B), without statistical significance. SNR was slightly higher in temporal regions (P<0.05), but pairwise comparisons between groups C and B revealed no significant differences. CNR was significantly better in the parietal lobe in group C compared to group B (P<0.05), suggesting enhanced contrast with the triple-low protocol. Perfusion parameters (CBF, CBV, MTT, TTP) remained stable across groups (P>0.05). Although Tmax showed small differences (<0.5 s) in some regions, no significant differences were found between reconstruction methods under identical scan settings. Subjective scores (Kappa > 0.6) showed good interobserver agreement. All images were diagnostically acceptable, with group C slightly outperforming in gray-white differentiation, ischemia contrast, homogeneity, and artifact suppression, though without statistical significance.

CONCLUSION

The triple-low protocol combined with DLIR-H provides comparable image quality and stable perfusion results while significantly reducing radiation and contrast exposure.

CLINICAL RELEVANCE/APPLICATION

This strategy supports safer, more efficient stroke imaging by optimizing dose and contrast without compromising diagnostic confidence.

T5A-SPNR-16 ELECTRON DENSITY AND EFFECTIVE ATOMIC NUMBER OF NORMAL ADULT BRAIN TISSUES: AGE-RELATED CHANGES AND CORRELATION WITH MYELIN CONTENT

Tsubasa Nakano (*Presenter*)
Tomohito Hasegawa (*Abstract Co-Author*)
Masanori Nakajo, MD (*Abstract Co-Author*)
Misaki Gohara (*Abstract Co-Author*)
Kiyohisa Kamimura, MD, PhD (*Abstract Co-Author*)
Junki Kamizono (*Abstract Co-Author*)
Koji Takumi, MD, PhD (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

PURPOSE

Electron density (ED) and effective atomic number (Z eff) are emerging quantitative CT parameters, and are increasingly applied in clinical settings recently. However, few studies have reported in vivo measurements of ED and Zeff in normal brain tissues. To address this gap, we used dual-energy CT (DECT)-derived ED and Zeff maps to characterize normal-appearing adult brain tissues, evaluate age-related changes, and investigate correlations with myelin partial volume (V my) derived from synthetic MRI.

METHODS AND MATERIALS

Thirty adult patients (35-84 years old) who underwent both DECT and synthetic MRI were retrospectively analyzed. Conventional CT value (CT conv), ED, Z eff , and Vmy were measured in normal-appearing gray matter (GM) and white matter (WM) ROIs (780 ROIs in total), and were compared between WM and GM. Correlations were analyzed between V my and DECT parameters. Moreover, regression analysis was used to generate mathematical models of V my using CT-derived parameters. Correlations between patients' age and DECT parameters were also analyzed.

RESULTS

V my was significantly greater in WM than in GM, while CT conv , ED and Z eff were significantly lower in WM than in GM (all $p < 0.001$). Z eff showed stronger negative correlation with V my (? = -0.756) than CT conv (? = -0.705) or ED (? = -0.491). Multiple regression analysis including Z eff and ED as independent variables increased the model's explanatory power (R 2 = 0.675) compared to a model involving Z eff alone (R 2 = 0.606). ED showed weak to moderate negative correlations with age mainly in WM regions (? from -0.204 to -0.450). Conversely, Z eff showed weak to moderate positive correlations with age mainly in WM (? from 0.211 to 0.549). CT conv showed negligible correlations with age in all regions.

CONCLUSION

This study revealed distinct GM-to-WM differences in ED and Z eff , along with a major contribution of myelin on the atomic number difference which results in the GM-to-WM contrast on non-contrast brain CT. ED and Z eff can be used as CT markers for myelination in normal adult brain. Furthermore, this study revealed opposing age-related changes in ED and Z eff , which may offer a novel opportunity for CT-based evaluation of aging of brain tissues.

CLINICAL RELEVANCE/APPLICATION

This study for the first time characterized ED and Z eff in the normal brain tissues, which is essential for interpreting their pathological changes in brain diseases.

T5A-SPNR-17 NOVEL KERNELIZED GRANGER CAUSALITY APPROACH UNMASKS FUNCTIONAL CONNECTIVITY SIGNATURES IN PARKINSON'S DISEASE

Ali Vosoughi (*Presenter*)
Axel Wismueller, MD, PhD (*Abstract Co-Author*)
Akhil Kasturi, PhD, MSc (*Abstract Co-Author*)
Larry Stockmaster, BEng (*Abstract Co-Author*)
Nathan Hadjiyski (*Abstract Co-Author*)

PURPOSE

To evaluate the efficacy of large-scale Kernelized Granger Causality (lsKGC) analysis of resting-state fMRI in distinguishing between Parkinson's disease patients and healthy controls, with emphasis on its potential value as an objective imaging marker in radiological assessment.

METHODS AND MATERIALS

We analyzed resting-state fMRI data from 30 subjects (15 Parkinson's disease patients, 15 matched healthy controls) collected at Karolinska Institute, Stockholm, Sweden. Using a 200-region brain atlas, we constructed directional connectivity matrices representing causal influences between brain regions. The discriminative power of lsKGC was compared against standard connectivity approaches (cross-correlation, local models, and anti-symmetric correlation) through 10-fold cross-validation. Classification performance was evaluated using AUC, accuracy, and F1-score metrics, with statistical significance assessed by Wilcoxon signed-rank tests.

RESULTS

The lsKGC method demonstrated robust classification performance (AUC: 0.850±0.124, accuracy: 0.800±0.000, F1-score: 0.811±0.023) compared to conventional cross-correlation (AUC: 0.828±0.133, accuracy: 0.753±0.085, F1-score: 0.720±0.105). Statistical analysis confirmed significant improvements in discriminative capability ($p = 1.009 \times 10^{-4}$ for lsKGC vs cross-correlation, $p = 3.117 \times 10^{-4}$ for lsKGC vs. local models). Connectivity alterations were most prominent in motor networks and basal ganglia circuits, consistent with known pathophysiological changes in Parkinson's disease.

CONCLUSION

Our findings demonstrate that lsKGC analysis can effectively detect differences in functional brain connectivity between Parkinson's disease patients and healthy controls. This technique provides complementary information to standard radiological assessments by capturing directional influences between brain regions that may reflect underlying pathophysiological processes.

CLINICAL RELEVANCE/APPLICATION

The lsKGC methodology offers radiologists a quantitative approach to assess functional connectivity alterations in Parkinson's disease. This technique could potentially enhance research applications in movement disorders and provide objective imaging markers that complement conventional structural and functional neuroimaging.

T5A-SPNR-19 SPATIOTEMPORAL GRAPH-BASED FRAMEWORK WITH DEFORMATION FIELD GUIDANCE FOR NEW T2-W MULTIPLE SCLEROSIS LESION DETECTION

Gorkem Durak, MD (*Presenter*)
Mostafa Salem (*Abstract Co-Author*)
Salma Hassan (*Abstract Co-Author*)
Ayman Elsayed (*Abstract Co-Author*)
Vijay R. Papineni, FRCR,MBBS (*Abstract Co-Author*)
Mohammad Yaqub (*Abstract Co-Author*)

PURPOSE

Longitudinal magnetic resonance imaging (MRI) is crucial for MS diagnosis and monitoring. New brain lesions serve as a reliable biomarker for disease progression. However, manual process is time-consuming and prone to inter-observer variability. Automated, accurate methods for detecting new T2-w lesions are essential to improve diagnostic reliability and streamline assessments. In this study, we propose a Deformation Field-Guided Spatiotemporal Graph-Based Framework for detecting new T2-w MS lesions.

METHODS AND MATERIALS

We utilize the MSSEG-II dataset, which includes 3D FLAIR scans from 100 MS patients across 15 MRI scanners. The training set consists of 40 scans, and the testing set includes 60 scans (25 without new lesions). Longitudinal scans are rigidly registered and preprocessed using brain extraction, bias field correction, and intensity normalization. Deformation fields (DFs) are computed to capture lesion-specific changes. We formulate lesion detection as a heterogeneous spatiotemporal graph neural network (GNN) using an encoder-decoder architecture. The model constructs a heterogeneous spatiotemporal graph from baseline and follow-up MRI scans, where nodes are connected by two spatial edge types and one temporal edge type. Temporal edges incorporate DF embeddings as attributes, effectively capturing lesion evolution patterns that are clinically relevant for disease progression assessment.

RESULTS

Evaluated on the MSSEG-II test set, our model achieves state-of-the-art (SOTA) performance with an F1 score of 0.65, sensitivity of 0.74, positive predictive value of 0.65, and a mean segmentation Dice score of 0.55, significantly outperforming existing methods ($p < 0.05$). In the 25 cases without new lesions, the model produced only 3 false positives. These results highlight our model's efficacy in MS new lesion detection.

CONCLUSION

The proposed framework surpasses existing SOTA approaches in both sensitivity and specificity by leveraging a heterogeneous spatiotemporal graph neural network that encodes intra-scan spatial dependencies and inter-scan temporal dynamics. The integration of deformation field-informed temporal edge attributes facilitates precise modeling of lesion evolution, enabling robust detection of new T2-w MS lesions across heterogeneous MRI acquisitions

CLINICAL RELEVANCE/APPLICATION

The proposed deformation field-guided spatiotemporal graph framework enhances the detection of new T2-w lesions in longitudinal MRI by modeling lesion-specific morphological changes and inter-scan spatial dependencies. This enables robust, observer-independent quantification of disease activity, offering clinically reliable support for MS progression assessment and therapeutic decision-making.

T5A-SPOB-1 IMAGING MODALITY-ADAPTIVE DEEP LEARNING (IMADL) MODEL PREDICTS IMMUNOTHERAPY RESPONSE AND PROGNOSIS IN PATIENTS WITH CERVICAL CANCER

Jingjing You (*Presenter*)
Bin Zhang, MD (*Abstract Co-Author*)

PURPOSE

No predictive biomarkers can reliably identify patients with advanced cervical cancer who will benefit from immunotherapy. We aimed to develop a deep learning model to predict immunotherapy outcomes in these patients.

METHODS AND MATERIALS

A total of 380 patients with advanced cervical cancer who received immunotherapy were assigned to training (n=228), validation (n=38), and test (n=114) cohorts. We developed an imaging modality-adaptive deep learning (IMADL) model to predict immunotherapy response, progression-free survival (PFS), and overall survival (OS). We also constructed an IMADL PLUS model integrating clinical and radiological data. The interpretability of the IMADL model was conducted using hematoxylin and eosin (H&E)-stained whole slide images. Ten classes of morphological features were extracted from each nucleus and aggregated into 150 patient-level features. Spearman correlation analysis was used to evaluate the correlation between deep features and pathologic features.

RESULTS

In predicting immunotherapy response, the IMADL and IMADL PLUS models achieved similar AUCs of 0.79 and 0.81, and outperformed the clinical model in the test cohort. Similarly, the IMADL PLUS model showed comparable performance to the IMADL model but superior performance to the clinical model in predicting PFS (C-index: 0.73 vs. 0.71 vs. 0.65) and OS (C-index: 0.74 vs. 0.71 vs. 0.59). There were 57, 79, and 9 deep-nuclear pairs with moderate correlation in the tasks of predicting immunotherapy efficacy, PFS, and OS, respectively.

CONCLUSION

Our IMADL model demonstrates promise in predicting immunotherapy response and prognosis in cervical cancer. Additionally, we provide biological meaning at the cellular level for the model, enhancing the comprehension of model predictions.

CLINICAL RELEVANCE/APPLICATION

First, unlike previous studies that mainly relied on a single modality, we integrated multimodal CT and MRI images of primary and metastatic lesions, which is consistent with clinical practice and enhances generalizability of the deep learning model. Second, we interpreted the model-derived deep features by correlating nuclear morphological features quantitatively extracted from available H&E-stained whole slide images. Our IMADL model exhibited satisfactory performance in the prediction of immunotherapy response and prognosis for cervical cancer. This is the first attempt to investigate the potential application of deep learning in predicting immunotherapy benefits of cervical cancer and elucidate the cross-scale correlation between macroscopic imaging and microscopic pathological features, enhancing the understanding the tumor microenvironment of cervical cancer.

T5A-SPOB-2 IN-VIVO MRI-BASED PLACENTAL MORPHOLOGY ASSESSMENT

Dafna Ben Bashat, PhD (*Presenter*)
Dana Schonberger (*Abstract Co-Author*)
Daphna Link, PhD (*Abstract Co-Author*)
Aviad Rabinowich (*Abstract Co-Author*)
Bella Specktor Fadida (*Abstract Co-Author*)
Liat Ben-Sira, MD (*Abstract Co-Author*)
Leo Joskowicz, PhD (*Abstract Co-Author*)
Liran Hiersch (*Abstract Co-Author*)

PURPOSE

To evaluate in-vivo placental morphology using MRI in fetuses with fetal growth restriction (FGR) compared to appropriate-for-gestational-age (AGA) fetuses, and to investigate correlations with gestational age and fetal body volume.

METHODS AND MATERIALS

The study included 141 fetuses (102 AGA, 39 FGR) in the third trimester who underwent fetal MRI. Placental and fetal body segmentations were generated using deep learning models and refined manually. Shape features were extracted using PyRadiomics and in-house algorithms were used to separate and quantify the maternal and fetal placental surfaces. Umbilical cord insertion location was manually annotated, and a centricity index (CI) was calculated.Statistical analysis: Mann-Whitney U and Spearman correlation evaluated group differences and associations with gestational age and fetal body volume. Inter-observer agreement for CI was assessed using ICC. Logistic regression with L1 regularization and feature selection identified the most predictive features for distinguishing FGR from AGA.

RESULTS

In AGA fetuses, placental elongation negatively correlated with gestational age ($p=0.01$). Several morphology features (e.g., volume, surface area, maternal and fetal surface areas) were significantly correlated with fetal body volume ($p<0.05$). FGR placentas showed significantly smaller volume, diameters, and surface areas ($p<0.005$), and higher surface-to-volume ratio ($p=0.002$). CI was higher in FGR ($p=0.004$), indicating more marginal cord insertion. A model using five top-ranked features (CI, minor axis length, placental volume, max 2D diameter, and maternal-to-total surface area ratio) achieved 81.8% accuracy in classifying FGR vs. AGA, with 88% recall for AGA and 62% for FGR.

CONCLUSION

MRI-based placental morphological features, including cord insertion centricity, placental size, and maternal interface area, differ significantly between FGR and AGA fetuses. These parameters also correlate with fetal growth in AGA pregnancies.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the clinical potential of in-vivo MRI-derived placental morphology as a non-invasive biomarker for identifying fetuses at risk of growth restriction and cases of placental insufficiency, offering a pathway for early diagnosis and intervention beyond standard ultrasound-based methods.

T5A-SPOB-3 AIMING HIGHER: DIAPHRAGMATIC IMAGING IN THE EVALUATION OF ENDOMETRIOSIS

Joao J. Stern, MD (*Presenter*)
Ana Luiza G. Di Mango, MD (*Abstract Co-Author*)
Izabela P. Franco, MD (*Abstract Co-Author*)
Luciana C. Belem, MD, MSc (*Abstract Co-Author*)
Marco Aurelio P. Oliveira, MD,PhD (*Abstract Co-Author*)
Flavia A. Francisco, PhD, MD (*Abstract Co-Author*)
Alice Cristina C. Brandao Salomao, MD (*Abstract Co-Author*)
Luciana P. Chamie, MD, PhD (*Abstract Co-Author*)

PURPOSE

To investigate correlations between pelvic endometriosis subtypes and diaphragmatic endometriosis (DE), with the aim of identifying patients who may benefit most from diaphragmatic imaging.This study aims to assess whether DE is more frequently associated with deep infiltrating endometriosis (DIE), peritoneal, or ovarian endometriosis; to identify specific DIE subtypes more commonly related to DE; and to determine any preferential laterality or hepatic segmental distribution patterns.

METHODS AND MATERIALS

This retrospective observational study analyzed data from patients diagnosed with pelvic endometriosis who underwent imaging that included diaphragmatic evaluation between 2022 and April 2025. The protocol consisted of T1-weighted images with fat saturation acquired in three orthogonal planes: coronal, axial, and sagittal. The sagittal plane was routinely obtained over the right hemidiaphragm, given the higher prevalence of right-sided diaphragmatic endometriosis. In cases with clinical suspicion of left-sided thoracic involvement (e.g., left shoulder pain or pleuritic symptoms), an additional sagittal T1 fat-saturated sequence was also acquired over the left hemidiaphragm.Radiologist reports were reviewed for the presence of diaphragmatic lesions. Pelvic endometriosis was categorized into ovarian, peritoneal, and DIE, with further subclassification of DIE by anatomical location (uterosacral ligaments, rectovaginal septum, bladder, etc.). Correlations between pelvic endometriosis subtypes and DE were analyzed, along with assessment of lesion laterality and hepatic segment involvement.

RESULTS

DE was identified in 4.8% of patients. It was significantly more prevalent in those with DIE (61.5%) compared to those with isolated peritoneal or ovarian endometriosis. Intestinal involvement was observed in 34.6% of cases, and 42.3% also had adenomyosis. Diaphragmatic lesions were predominantly right-sided (96%) and most frequently affected hepatic segments VII and VIII. All lesions showed evidence of bleeding.

CONCLUSION

The findings suggest that diaphragmatic endometriosis is more likely to occur in patients with extensive or posterior compartment deep infiltrating endometriosis. Routine evaluation for diaphragmatic lesions should be considered, particularly in patients with severe DIE, given the high prevalence and right-sided segmental pattern of involvement.

CLINICAL RELEVANCE/APPLICATION

Incorporating diaphragmatic assessment into the diagnostic workflow for patients with deep pelvic endometriosis may improve detection of extrapelvic disease, guide surgical planning, and potentially alleviate unexplained thoracic symptoms.

T5A-SPOB-4 COMPARISON OF CAPABILITIES FOR IMAGE QUALITY IMPROVEMENT WITH SCAN TIME REDUCTION AMONG CURRENTLY USED PROPELLER METHOD, STANDARD PARALLEL IMAGING METHOD AND MODIFIED PROPELLER METHOD WITH NEWLY DEVELOPED PARALLEL IMAGING METHODS ON ROUTINE FEMALE PELVIC MRI

Takahiro Ueda, MD, PhD (*Presenter*)
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)
Natsuka Yazawa (*Abstract Co-Author*)
Kaori Yamamoto (*Abstract Co-Author*)
Yuichiro Sano, RT (*Abstract Co-Author*)
Masato Ikedo (*Abstract Co-Author*)
Masanori Ozaki (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Yoshiharu Ohno, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare capabilities for image quality improvement with scan time reduction among standard parallel imaging (PI), currently used PROPELLER method and modified PROPELLER method with newly developed PI method on routine female pelvic MRI.

METHODS AND MATERIALS

37 female patients with various pelvic diseases underwent T2WIs by standard PI method, currently used PROPELLER method and modified PROPELLER and newly developed PI methods. At each examination, scan time was recorded in all patients. To compare quantitative assessment among three methods, signal-to-noise ratios (SNRs) of uterine corpus, cervix and ovary and contrast-to-noise ratio (CNR) between endometrium and myometrium were determined by ROI measurements. On comparison of qualitative assessment among all methods, overall image quality (OIQ), artifact and diagnostic confidence level (DCL) were assessed by 5-point scales. To compare the capabilities for scan time reduction and quantitative image quality improvements, scan time, SNRs and CNR were compared among three protocols by Tukey's HSD test. On comparison of qualitative image quality improvements, each index was compared among three protocols by Wilcoxon signed-rank test.

RESULTS

Mean scan time of modified PROPELLER and newly developed PI method (171.5 ± 6.4 sec) was significantly shorter than that of currently used PROPELLER method (340.0 ± 52.7 sec, $p<0.001$). Each SNR of modified PROPELLER and newly developed PI method was significantly higher than that of standard PI (uterine corpus: $p<0.001$, cervix; $p=0.023$ and ovary: $p=0.022$), although there was no significant difference of CNRs among three protocols. Medians of OIQ and artifacts of modified PROPELLER with newly developed PI method (OIQ: 5, artifact: 1) and current used PROPELLER method (OIQ: 4, artifact: 2) were significantly superior to those of standard PI method (OIQ: 3, $p<0.001$; artifact: 3, $p<0.001$). Medians of DCL for modified PROPELLER (median: 5) and currently used PROPELLER (median: 5) were significantly higher than that of standard PI. (median: 4, $p<0.001$).

CONCLUSION

Modified PROPELLER method with newly developed PI method is considered as having better potentials for scan time reduction or image quality improvements, when compared with currently used PLOPELLER method or standard PI on female pelvic MRI.

CLINICAL RELEVANCE/APPLICATION

Modified PROPELLER method with newly developed PI method is considered as having better potentials for scan time reduction or image quality improvements, when compared with currently used PLOPELLER method or standard PI on female pelvic MRI.

T5A-SPPD-1 PROSPECTIVE COMPARISON OF STANDARD AND DEEP LEARNING-RECONSTRUCTED 3D TURBO SPIN-ECHO MRI OF THE PEDIATRIC KNEE

Pedro Henrique Caldeira Brant Faria, MD (*Presenter*)
Jade Iwasaka-Neder, MD, MPH (*Abstract Co-Author*)
Ani Maroyan (*Abstract Co-Author*)
Andy Tsai, MD, PhD (*Abstract Co-Author*)
Eric L. Tung, MD (*Abstract Co-Author*)
Yi-Meng Yen (*Abstract Co-Author*)
Patrick Johnston, MSc (*Abstract Co-Author*)
Sarah D. Bixby, MD, MBA (*Abstract Co-Author*)

PURPOSE

To evaluate whether a deep learning (DL)-reconstructed 3D turbo spin-echo (TSE) sequence can reduce acquisition time in pediatric knee MRI without compromising diagnostic accuracy.

METHODS AND MATERIALS

In this prospective IRB-approved study, 123 pediatric patients (mean age: 14.1 ± 2.6 years) underwent knee MRI using standard and DL-reconstructed 3D TSE sequences. A dataset consisting of all sequences in random order was independently reviewed by two pediatric musculoskeletal radiologists and one pediatric radiology fellow. A 5-point scale assessed visibility of the menisci, anterior cruciate ligament (ACL), posterior cruciate ligament (PCL), and cartilage. The same scale assessed image quality, signal-to-noise ratio (SNR), sharpness, diagnostic confidence, and artifacts. Scores and acquisition times were compared using the Wilcoxon signed-rank test. Diagnostic accuracy was evaluated in 29 arthroscopy-confirmed cases by comparing sensitivity and specificity between sequences using McNemar's test for ACL tear, meniscal tear, cartilage defect, and osteochondritis dissecans (OCD). MRI findings for OCDs, cartilage defects, and meniscal tears were considered concordant with surgery only when the location matched.

RESULTS

The DL-reconstructed sequence significantly reduced acquisition time compared to the standard 3D protocol (median 3.80 vs. 5.67 minutes, $p < .001$). Median subjective scores for image quality, sharpness, diagnostic confidence and SNR were all 4 or higher for both DL and standard protocols. Readers expressed a slight but measurable preference for the standard sequence with respect to image quality, sharpness, and diagnostic confidence ($p < .05$), while SNR scores were higher for the DL sequences ($p < .001$). PCL and lateral meniscus visibility were higher with DL ($p = .003$), with no significant difference observed for the ACL, articular cartilage, or medial meniscus. Diagnostic accuracy was high for both protocols, with no significant differences in sensitivity or specificity detected by McNemar's tests.

CONCLUSION

The DL-reconstructed 3D TSE sequence maintained diagnostic accuracy compared to the standard 3D protocol while enabling substantially faster acquisition. Although it was associated with slightly lower subjective image quality scores, it also demonstrated improved anatomic visibility and higher SNR than the standard sequence.

CLINICAL RELEVANCE/APPLICATION

DL-reconstructed 3D MRI can substantially reduce acquisition time in pediatric knee imaging while maintaining diagnostic accuracy and improving anatomic visibility.

T5A-SPPD-2 IMPROVED RIGHT-SIDED HEMODYNAMICS USING 4D FLOW MRI IN PATIENTS UNDERGOING TRANSCATHETER PULMONARY VALVE IMPLANTATION (TPVI) FOR PULMONARY VALVE REGURGITATION IN REPAIRED TETRALOGY OF FALLOT

Tatsuhiro Yamamoto, RT (*Presenter*)
Yoshiaki Morita (*Abstract Co-Author*)
Masaru Shiotani, RT (*Abstract Co-Author*)
Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

Transcatheter pulmonary valve implantation (TPVI) has recently been performed as a less invasive treatment for pulmonary valve regurgitation (PR) after repaired tetralogy of Fallot (TOF).Cardiac MRI is commonly used to evaluate cardiac function and pulmonary regurgitation fraction (PRF) using cine imaging and 2D phase-contrast (2DPC). 4D Flow MRI provides more detailed hemodynamic evaluation, such as flow quantification in any vessels and energy loss (EL) due to abnormal flow. However, few data exist on right-sided detailed hemodynamic changes post-TPVI. We evaluated the hemodynamic changes before and after TPVI using 4D Flow.

METHODS AND MATERIALS

Twelve repaired TOF patients who underwent Harmony valve TPVI were included. All underwent cardiac MRI (cine, 2DPC, 4D Flow) before and within one year post-TPVI using a 3T scanner. We measured LV end-diastolic/systolic volumes (LVEDV/LVESV), ejection fraction (LVEF), RV end-diastolic/systolic volumes (RVEDV/RVESV), and ejection fraction (RVEF) using cine imaging. Flow analysis was performed using 2DPC to measure pulmonary artery (PA) effective total flow (difference between forward and backward volume) and PRF. 4D Flow MRI evaluated flow volume of right pulmonary artery (RPA) and left pulmonary artery (LPA), in addition to main PA. Also, EL was calculated in two regions: (1) PA to RPA/LPA and (2) within RPA/LPA.

RESULTS

In all cases, the procedure was successful and symptoms improved after TPVI. After TPVI, RVEDV/RVESV and PRF significantly decreased ($p<0.05$), while RVEF significantly deteriorated ($p<0.05$). LV parameters showed no significant change. PA effective total flow increased ($p<0.05$). In 4D Flow assessment, LPA flow volumes

significantly increased ($p<0.05$), while no significant change in RPA flow. There was no significant change in average EL from PA to RPA/LPA before and after TPVI, while a significant decrease in average EL within RPA/LPA ($p<0.05$) before and after TPVI, suggesting TPVI improves flow efficiency within bilateral pulmonary artery.

CONCLUSION

TPVI reduced RV volume load and improved effective pulmonary flow, especially in LPA, despite RVEF deterioration. EL assessment showed enhanced right-sided flow efficiency. Conventional MRI combined with 4D Flow allowed detailed evaluation of postoperative hemodynamics and may serve as a useful tool for therapeutic assessment.

CLINICAL RELEVANCE/APPLICATION

This study suggests that 4D Flow enables the more detailed assessment for pulmonary flow and energy efficiency changes after TPVI. Comprehensive assessment using conventional MRI and 4D Flow MRI, including energy loss analysis,may serve as a robust tool for post-procedural monitoring and risk stratification.

T5A-SPPD-3 DEEP LEARNING-ENHANCED ZERO ECHO TIME SILENT MR IMAGING OF THE INFANT BRAIN WITHOUT SEDATION

Chanyoung Rhee, MD (*Presenter*)
Young Hun Choi, MD, PhD (*Abstract Co-Author*)
Jae-Yeon Hwang, MD (*Abstract Co-Author*)
Sun Won Park, MD, PhD (*Abstract Co-Author*)

PURPOSE

Acoustic noise reduction is critical in infant brain magnetic resonance (MR) imaging to avoid sedation, and deep learning (DL)-based reconstruction offers the potential to enhance MR image quality. This study aimed to evaluate the effect of DL-based reconstruction on the image quality of zero echo time (ZTE) sequence in infant brain MR imaging and to assess its clinical applicability.

METHODS AND MATERIALS

This retrospective study included 63 infants with a postmenstrual age of 16 months or younger who underwent brain MR imaging between July 2022 and October 2024. The control group (n = 38) underwent sedated three-dimensional T1-weighted magnetization-prepared rapid gradient-echo (MPRAGE) imaging, while the experimental group (n = 25) underwent unsedated inversion recovery-prepared ZTE imaging, with and without DL-based reconstruction (referred to as ZTEDL and ZTE, respectively). Three pediatric radiologists independently evaluated five image quality metrics—image noisiness, sharpness of gray-white matter differentiation, artifacts, lesion conspicuity, and overall image quality—for the three sequences using a 5-point Likert scale. Signal uniformity was assessed based on the coefficient of variation across eight regions of interest. Differences among sequences were evaluated using the Mann-Whitney U test with Bonferroni correction, and inter-rater agreement was assessed using Cohen's kappa.

RESULTS

ZTEDL demonstrated the highest mean scores for image noisiness, sharpness of gray-white matter differentiation, artifacts, and overall image quality across all readers. No significant differences were observed between MPRAGE and ZTEDL, while ZTEDL showed better image quality compared to ZTE (all $p < 0.017$). Lesion conspicuity did not differ among sequences. Inter-rater agreement was almost perfect (? > 0.800) for most metrics, with substantial agreement (? = 0.784-0.787) observed for sharpness and artifacts. Signal homogeneity was highest in ZTEDL for white and gray matter (all $p < 0.001$), whereas no significant difference was observed between ZTEDL and ZTE for cerebrospinal fluid ($p = 0.681$).

CONCLUSION

DL-based reconstruction for silent ZTE imaging significantly improves image quality and could reduce the need for sedation in infant brain MR imaging.

CLINICAL RELEVANCE/APPLICATION

Conventional MR imaging is often challenging in infants due to acoustic noise, and DL-based reconstruction with silent ZTE may reduce the need for sedation while preserving image quality.

T5A-SPPD-4 DEVELOPMENT AND VALIDATION OF A DEEP LEARNING-BASED ALGORITHM FOR QUANTIFYING BRONCHIOLITIS OBLITERANS IN PEDIATRIC COMPUTED TOMOGRAPHY

Chanyoung Rhee, MD (*Presenter*)
Young Hun Choi, MD, PhD (*Abstract Co-Author*)
Jae-Yeon Hwang, MD (*Abstract Co-Author*)
Sun Won Park, MD, PhD (*Abstract Co-Author*)

PURPOSE

Bronchiolitis obliterans (BO) is a progressive airway disease that requires early detection and intervention in children, with computed tomography (CT) playing a crucial role in identifying its characteristic features. This study aimed to develop and validate a deep learning-based algorithm for quantifying bronchiolitis obliterans (BO) on pediatric chest computed tomography (CT).

METHODS AND MATERIALS

This retrospective study included 80 children (36 males; median age, 10 years; age range, 6-17 years) with suspected BO who underwent inspiratory and expiratory chest CT between January 2018 and May 2021. The deep learning-based BO quantification model (DLBO) was developed using 30 CT scans (26 training, 4 internal validation) with a 3D nnU-Net, using radiologist-segmented air-trapping as the ground truth. To test model robustness, 22 CT scans with varying respiratory phases, reconstruction methods, kernel types, and slice thicknesses were acquired. To compare DLBO results with semiquantitative radiologist grading, 28 CT scans were analyzed. The paired t -test was used to compare the results across the CT parameters, and Kendall rank correlation was used to assess the agreement between the DLBO and radiologist grading.

RESULTS

DLBO performance was robust across reconstruction methods, kernel types, and slice thicknesses, while air-trapping volumes were higher on inspiratory than expiratory CT ($p < 0.001$). During internal validation, the model achieved a Dice similarity coefficient of 85.41% ± 3.28%, sensitivity of 85.14% ± 7.66%, and precision of 86.21% ± 3.92%. Compared with radiologist semiquantitative grading, the DLBO exhibited strong to very strong positive correlations across all lobes, with Kendall's tau-b values of 0.790 (left upper lobe), 0.796 (left lower lobe), 0.711 (right upper lobe), 0.662 (right middle lobe), and 0.755 (right lower lobe), and an overall coefficient of 0.729.

CONCLUSION

The DLBO accurately quantified air-trapping in pediatric BO on CT, demonstrating high concordance with radiologist grading and robustness to varying CT parameters.

CLINICAL RELEVANCE/APPLICATION

In clinical practice, measuring air-trapping is challenging due to its time-consuming and subjective nature. The DLBO can accurately evaluate BO severity in pediatric chest CT and has the potential to assist clinicians.

T5A-SPPH-2 LOW KEV VIRTUAL MONOENERGETIC RECONSTRUCTIONS IN PHOTON-COUNTING CT FOR SOFT-TISSUE TASKS WITH WEAK ENERGY DEPENDENCE: PERFORMANCE COMPARISON WITH DUAL-ENERGY CT AND OPTIMAL ENERGY LEVEL

Hiroki Kawashima, PhD (*Presenter*)
Katsuhiro Ichikawa, PhD (*Abstract Co-Author*)
Yasuhiro Kawahara (*Abstract Co-Author*)
Kyo Noguchi, MD (*Abstract Co-Author*)

PURPOSE

One of the potential benefits of photon counting CT (PCCT) is the improved performance of low keV virtual monoenergetic (VM) imaging. This improvement would work well for an iodine-related task because of its strong energy dependence; however, effect on soft-tissues known to have weak energy dependence has not been investigated in detail. The purpose of this study was to investigate performance improvements for a soft-tissue task using PCCT, comparing with dual source dual energy CT (DS DECT).

METHODS AND MATERIALS

Two rod-shaped inserts (3 mg/mL iodine and soft tissue equivalent materials) were placed into the water bath phantom with a diameter of 300 mm, which resembled the X-ray absorption of the adult abdomen. This phantom was scanned with two CT systems: PCCT with 120 kV and DS DECT with 80/Sn150 kV at the standard and the low radiation dose levels (volume CT dose index of 15 and 5 mGy). VM images were generated with energy levels from 40 to 80 keV in steps of 5 keV. The attenuation differences (i.e., contrast) and task transfer function were measured in each insert, and the noise power spectrum was measured in the uniform water region. The detectability index was computed using them combined with the task function and compared as a function of the VM energy levels.

RESULTS

For the iodine task, the contrast increased by approximately 3.2 times by changing the VM energy levels from 70 keV to 40 keV. The detectability index tended to increase as the energy level decreased. The highest values were 18.0 and 13.6 for PCCT 40 keV and DS DECT 40 keV, respectively, at 15 mGy, and 13.4 and 9.6 at 5 mGy. For the soft tissue task, the increase in the contrast was limited at the low VM energy levels. In the low energy VM levels, the detectability indices of PCCT were 3-14% higher than those of DS DECT at 15 mGy and 5-30% higher at 5 mGy; however, the highest value was achieved around 70-80 keV in both scanners and both radiation dose levels.

CONCLUSION

The optimal energy level varies depending on diagnostic tasks. PCCT significantly improved the performance of low keV images with iodine-related tasks; however, VMI at 70 keV would be a better choice than that at low keV for the soft tissue task imaging, even with improved performance of low keV imaging from PCCT than DS DECT.

CLINICAL RELEVANCE/APPLICATION

In a non-contrast CT examination for soft tissue visualization, the conventional 70 keV should be used even with PCCT, as the low keV images are not advantageous.

T5A-SPPH-4 OPTIMIZING ACQUISITION PARAMETERS MAY IMPROVE AI PERFORMANCE IN SCREENING BREAST TOMOSYNTHESIS

Adrian A. Sanchez, MD, PhD (*Presenter*)
Michelle V. Lee, MD (*Abstract Co-Author*)
Sherwin Chiu, MD,MPH (*Abstract Co-Author*)
Junjie Cui (*Abstract Co-Author*)
Debbie L. Bennett, MD (*Abstract Co-Author*)
Aimilia Gastounioti, PhD (*Abstract Co-Author*)

PURPOSE

While technical factors in digital breast tomosynthesis (DBT) affect radiologist performance, their influence on AI cancer detection remains unclear. We hypothesize that tailoring the DBT acquisition technique to a patient's breast density may improve AI performance. We used real-world AI implementation data to examine whether a DBT acquisition optimization technique enhances a commercial AI tool's performance and whether it does so equitably across breast density and racial groups.

METHODS AND MATERIALS

We retrospectively evaluated screening data from a commercial AI algorithm implemented at our institution from January-September 2023 (17,244 screening DBT exams; 83 cancers; Selenia Dimensions, Hologic Inc.). The AI algorithm produces a case score for each exam reflecting the likelihood of cancer. Exams were stratified into subgroups of key DBT acquisition parameters (kVp and mAs). For each breast density level, the "optimized" DBT acquisition technique was defined as the kVp/mAs subgroup for which the AI case score was most predictive of whether an exam would be recalled (assigned BI-RADS 0), as measured by ROC analysis. We then used pathology outcomes to test whether the optimized DBT acquisition technique improved cancer detection by AI, both overall and in subgroups by breast density (with not dense defined as BI-RADS category A and B and dense defined as category C or D) and race (White vs. Black/African American).

RESULTS

The optimized DBT acquisition technique significantly improved cancer detection AUC in White women (0.899 vs. 0.766, p=0.014), but not in Black women (0.839 vs. 0.799, p=0.722). There was a larger improvement when using optimized acquisition in the dense breast subgroup (0.87 vs 0.72) relative to the not-dense group (0.90 vs 0.86); however, AI performance improvement in density subgroups did not achieve statistical significance.

CONCLUSION

DBT acquisition optimization may improve cancer detection for AI, but perhaps not across racial subgroups. Differences may reflect sample size limitations or correlations between race and density, but the interplay between density, race, and DBT acquisition parameters on AI performance warrants further study.

CLINICAL RELEVANCE/APPLICATION

Patient-specific DBT acquisition strategies based on breast density may improve AI performance in cancer detection, potentially resulting in more accurate and personalized breast cancer screening.

T5A-SPPH-5 DEEP LEARNING RECONSTRUCTION FOR ENHANCING IMAGE QUALITY AND NODULE ACCURACY IN ULTRA-LOW-DOSE CHEST CT

Siqi Qu (*Presenter*)
Zhiming Xiang (*Abstract Co-Author*)
Qiuxing Chen (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of deep learning image reconstruction (DLIR) on image quality and quantitative assessment of pulmonary nodules in ultra-low-dose chest CT (ULDCT), compared to adaptive statistical iterative reconstruction (ASIR-Veo).

METHODS AND MATERIALS

In this prospective study, 98 patients with pulmonary nodules underwent both standard-dose CT (SDCT) and ULDCT. ULDCT protocols were adjusted based on body mass index (BMI). SDCT images were reconstructed using ASIR-Veo at 50% strength (ASIR-V50%) and served as the reference. ULDCT images were reconstructed using ASIR-V50%, deep learning image reconstruction (DLIR) at medium (DLIR-M) and high (DLIR-H) levels. Nodule detection rates and nodule diameters from each ULDCT reconstruction were compared with SDCT results. Image quality was assessed by measuring the standard deviation (SD) of CT attenuation in lung and subcutaneous fat tissues to evaluate noise, as well as the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of lung tissue.

RESULTS

A total of 668 pulmonary nodules were identified on SDCT. The detection rates for ULDCT reconstructed with ASIR-V50%, DLIR-M, and DLIR-H were 97.46% (651/668), 97.90% (654/668), and 98.35% (657/668), respectively. SDCT had an effective dose of 3.74 ± 1.55 mSv, whereas ULDCT had a reduced dose of 0.48 ± 0.11 mSv, marking an 85.96% reduction ($P < 0.05$). Regarding image quality, noise (measured as the SD of CT attenuation) increased from DLIR-H to DLIR-M to ASIR-V50%, while both SNR and CNR decreased in the same order ($P < 0.05$). Bland-Altman analysis showed the percentage differences in maximum nodule diameter between SDCT and ULDCT reconstructed with ASIR-V50%, DLIR-M, and DLIR-H were -0.76% (mean difference: -1.75 to 0.23), 0.42% (mean difference: -0.59 to 1.44), and 0.83% (mean difference: -0.23 to 1.89), respectively. No statistically significant differences in nodule diameter were observed among the three reconstruction methods compared to SDCT ($P > 0.05$). DLIR-M yielded the smallest deviation in nodule size measurements compared to SDCT, suggesting higher measurement accuracy than ASIR-V50% and DLIR-H.

CONCLUSION

DLIR-M significantly enhanced image quality and maintained higher pulmonary nodule detection rates compared to ASIR-V50%, with nodule measurements in ULDCT more closely aligned with those from SDCT.

CLINICAL RELEVANCE/APPLICATION

Under BMI-adjusted ULDCT protocols, the use of DLIR-M significantly enhances image quality, ensuring accurate detection and characterization of pulmonary nodules. This approach effectively reduces radiation exposure while improving diagnostic accuracy, thereby providing valuable support for clinical pulmonary nodule screening.

T5A-SPPH-7 DOSE AT THE FOOT OF INTERVENTIONAL RADIOLOGISTS. SHOULD WE BE WORRIED?

Marie Nowak, PhD (*Presenter*)
Lucia Gallego (*Abstract Co-Author*)
Nicolas Cherbuin (*Abstract Co-Author*)
Fouad Georges Akkari (*Abstract Co-Author*)

PURPOSE

The use of fluoroscopy-guided techniques during interventional procedures results in radiation exposure to medical staff. While it is well established that operators closest to the patient receive significant doses to the lead apron and eye lens, few studies have measured the dose at foot level. Our study quantifies radiation doses received by main operators in the interventional radiology (IR) theatre at both the chest and feet.

METHODS AND MATERIALS

The first part of this study involved measurements using an anthropomorphic phantom to simulate the patient. These were conducted in two rooms: the interventional neurology suite, equipped with a biplane AZURION system (Philips), and the IR room for abdominal procedures, equipped with an Alphenix 4D-CT (Canon). The irradiated anatomical area varied by specialty: the head for neuroradiological procedures, and the abdomen for IR. Measurements were performed using the standard leaded protections in place (table skirt or ceiling shield). The protocol used was the most common. Dose rates were measured for the first operator at the eye lens, chest, waist, and foot levels. Data were extrapolated to estimate the annual dose received by the operator for an average workflow. In a second phase, 3 radiologists were equipped with whole-body optically simulated luminescence (OSL) dosimeters, placed both above and beneath the lead apron, as well as two additional OSL worn on the left ankle and at the tip of the left shoe. Measurements were collected over a six-month period in 2025. Fluoroscopy time, cumulative air kerma and dose area product were recorded for each intervention.

RESULTS

Phantom results show that, if protective equipment is used correctly, upper body dose rates are low and do not exceed 5 mSv per year. In contrast, dose rate measured at foot level ranges from 0.1 (fluoroscopy) to 4.3 mSv/h (fluorography). This corresponds to an estimated annual dose at the foot ranging between 56 to 168 mSv, depending on the operator's activity. Clinical measurements show an average net dose of zero under the apron and 1.5 mSv above it. In contrast, for unprotected areas, the ankle received an average annual dose of 3.8 mSv (1.2-6.5), while the foot received 22 mSv (13.3-36).

CONCLUSION

Phantom doses indicate that the dose to the operators' feet well exceeds the annual whole-body dose limit of 20 mSv. Doses to radiologists are more reassuring, with current average values around 20 mSv. To optimize radiation protection for operating room staff, protective equipment needs to be adapted, such as by lengthening table skirts.

CLINICAL RELEVANCE/APPLICATION

Our study provides insight into radiologists’ exposure around the patient, particularly at foot level, and supports the implementation of appropriate radiation protection measures.

T5A-SPPH-8 SYNTHESIZING HIGH QUALITY 3D TOF-MRA THROUGH MULTI-MODAL DIFFUSION MODEL

Tianen Yu (*Presenter*)
Xin-Yu Song (*Abstract Co-Author*)
Lei Xiang (*Abstract Co-Author*)
Yuehua Li (*Abstract Co-Author*)
Tao Zhou (*Abstract Co-Author*)

PURPOSE

3D Time-of-Flight (TOF) Magnetic Resonance Angiography (MRA) generates high-contrast images by leveraging blood flow velocity differences, eliminating the need for contrast agents and making it ideal for visualizing vascular structures. However, the scan time for TOF-MRA images is relatively long, and the image quality is not good due to the inherent noise. In this study, we propose a novel multi-modal diffusion model to synthesize TOF images by utilizing T1-w, T2-w and FLAIR images. Experiments are conducted to evaluate the image quality of the synthesized images both qualitatively and quantitatively.

METHODS AND MATERIALS

We collected different modality images from 140 patients, including brain T1-w, T2-w, FLAIR and TOF-MRA scans. Among these, scans from 98 patients were used for training, 14 scans for validation, the remaining 28 for test. To comprehensively exploit the anatomical-pathological complementary features embedded in T1-w, T2-w, and FLAIR images, we propose a Multi-modal Diffusion Model (MMDM) that incorporates modality-specific diffusion modules based on the Brownian Bridge diffusion process and a cross-modal dynamic fusion module. Additionally, an innovative maximum intensity projection (MIP) loss function and noise-adaptive weighting strategy are designed to achieve stable synthesis of TOF-MRA images. For the 42 validation and test cases, the trained MMDM was applied to the paired T1-w, T2-w and FLAIR images. Subsequently, we calculated the Peak Signal-to-Noise Ratio (PSNR), Structural Similarity (SSIM), and Root Mean Square Error (RMSE) between the output and the ground truth (GT) on both TOF and axial MIP images.

RESULTS

Qualitative evaluation and comparative experiments conducted on 42 validation and test cases demonstrate that proposed MMDM effectively synthesizes TOF images compared to other models, significantly reducing the noise and artifacts present in the original TOF images. Modality ablation experiments further indicate that the combined use of the three modalities yields the best performance. The synthesized images exhibit enhanced arterial contrast and successfully reconstruct most of the vessels in the MIP image. Additionally, quantitative results demonstrated a high similarity between the synthesized TOF and the GT TOF, with metrics showing a PSNR of 32.216, a SSIM of 0.880, a RMSE of 0.0223 and statistical significance at $a<0.005$.

CONCLUSION

The proposed MMDM can synthesize TOF images of higher quality with fewer artifacts, enhancing the convenience and efficiency of vascular disease diagnosis.

CLINICAL RELEVANCE/APPLICATION

Our proposed method facilitates the acquisition of high-quality TOF images with minimized noise and artifacts, thereby aiding in the diagnosis of cerebrovascular diseases.

T5A-SPPH-9 COMPARING FEASIBILITY OF LOW-TUBE-VOLTAGE PROTOCOL WITH LOW-IODINE DELIVERY RATE AND HIGH-TUBE-VOLTAGE PROTOCOL WITH HIGH-IODINE DELIVERY RATE IN HEAD AND NECK CT ANGIOGRAPHY

Junjun Li (*Presenter*)

PURPOSE

To evaluate radiation dose and image quality of a double-low head and neck CT angiography (CTA) protocol reconstructed utilizing high-strength deep learning image reconstructions (DLIR-H) compared to standard adaptive statistical iterative reconstruction (ASIR-V) protocol in non-obese patients.

METHODS AND MATERIALS

This prospective study included 66 patients scheduled for head and neck CTA due to vascular diseases. Patients were prospectively included and randomly assigned into three groups: group A (80kVp, DLIR-H, iodine delivery rate [IDR]=1.2 g/s) and noise index (NI) of 10, group B (80kVp, DLIR-H, IDR=1.0 g/s) and NI of 15; While conventional group C (100 kVp, ASiR-V50%, IDR=1.4 g/s)and NI of 10.The CT attenuations and standard deviations (SDs) of the sternocleidomastoid muscle (SCM) at the level of hypopharynx and epiglottis and the cerebral white matter (WM) at the level of splenium of corpus callosum were measured. The signal-to-noise ratio (SNR), contrast-to- noise ratio (CNR) of vessels were calculated value were measured. Image quality analysis was evaluated by two radiologists. Radiation and contrast dose, and objective and subjective image quality were compared across the three groups.

RESULTS

There was no significant difference in patient characteristics between the three groups ($P >0.05$). Compared to group C, group A and group B significantly reduced effective radiation dose by 53.73%, 29.85%, CM dose by 28.57%,14.28% and injection rate by 32.50%,21.75% (all $P <0.001$). The three groups differed significantly in terms of background noise (all $P <0.05$) with group A having the lowest value. The three groups differed significantly in SNR and CNR values in all vessels (all $P <0.05$) with group A having the highest value. The two radiologists had excellent agreement (Kappa value>0.8) in the subjective scores of head and neck CTA images and with group A having the highest value (4.30±0.55 vs. 4.02±0.46 and 4.07±0.55) ($P >0.05$).

CONCLUSION

DLIR-H combined with 80-kVp CCTA with an IDR 1.2 significantly reduces radiation and contrast medium exposure while improving image quality compared to conventional 100-kVp with 1.4 IDR protocol in patients.

CLINICAL RELEVANCE/APPLICATION

Low radiation and low contrast medium dose head and neck CTA protocol is feasible with high-strength deep learning reconstruction and high-concentration contrast medium without compromising image quality.

T5A-SPPH-10 CORONARY CTA WITHOUT ELECTROCARDIOGRAPHIC (ECG) TRIGGERING: A FEASIBILITY STUDY

Tingting Qu (*Presenter*)

PURPOSE

To investigate the feasibility of performing coronary CTA (CCTA) without ECG triggering (ECG-less) using the second-generation whole-heart motion correction algorithm (SSF2).

METHODS AND MATERIALS

A total of 41 patients underwent CCTA on a 16-cm wide detector CT scanner using either ECG-less mode (n=20) or conventional ECG-triggering mode (n=21) were included. All images were generated with SSF2. The coronary arteries (diameter greater than 1.5mm) on CCTA images were qualitatively rated on a 5-point scale from 1 (nondiagnostic) to 5 (excellent) by two radiologists blinded to the scanning mode. Coronary arteries were segmented into the 18 segments by the Society of Cardiovascular Computed Tomography and scored individually. Radiation dosage, image quality scores for the individual segments, the three main branches, and the overall image of the two groups were compared by the sample T test and Wilcoxon test.

RESULTS

There were no significant difference in patient demography and radiation dose (CTDIvol (mGy): 18.6±5.0 vs. 17.0±6.4, $p=0.384$); and DLP (mGy-cm): 271.2±73.6 vs. 259.8±99.3, $p=0.680$) between the ECG-less and ECG-triggering groups. The ECG-less group evaluated a total of 225 coronary arteries, while the ECG group evaluated

255 coronary arteries. There were no significant differences in the scores of all segments, the three main branches, and the overall image between the two groups (all $p > 0.05$).

CONCLUSION

The SSF2 provides reliable support for CCTA scanning in ECG-less mode. Compared with the conventional ECG-triggering mode, ECG-less CCTA significantly simplifies the examination process while maintaining excellent image quality and without radiation dose increase.

CLINICAL RELEVANCE/APPLICATION

ECG-less CCTA may be used in certain clinical situations to simplify the examination process while maintaining excellent image quality and without radiation dose increase.

T5A-SPPH-11 EFFECT OF COMBINING VIRTUAL MONOCHROMATIC IMAGING AND METAL ARTIFACT REDUCTION ALGORITHMS IN SPECTRAL COMPUTED TOMOGRAPHY ON METAL ARTIFACT REDUCTION FOR INTRACAVITARY BRACHYTHERAPY IN CERVICAL CANCER

Yining Chen (*Presenter*)
Zheng Zeng (*Abstract Co-Author*)
Junfang Yan (*Abstract Co-Author*)
Fuquan Zhang (*Abstract Co-Author*)

PURPOSE

To evaluate the effectiveness of combining virtual monochromatic imaging (VMI) with metal artifact reduction (MAR) algorithms in reducing artifacts from intracavitary applicators in cervical cancer brachytherapy.

METHODS AND MATERIALS

A total of 50 cervical cancer patients scheduled to undergo intracavitary brachytherapy were included in the study, and their spectral computed tomography (CT) images were acquired. VMI±MAR images were reconstructed at 40-140 keV. CT attenuation and image noise were used to calculate signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) for the most prominent artifact, and artifact index (AI) for the cervix, bladder, and rectum, compared between VMI+MAR and VMI+no-MAR. Additionally, the potential geometric distortion to the titanium applicator on the images was assessed by measuring the long axis, short axis, and long-to-short axis ratio. Subjective image quality was scored on a 5-point Likert scale, focusing on artifact reduction, soft tissue contrast, and contouring preference.

RESULTS

VMI+MAR significantly reduced AI in the cervix (34.74%-88.51%) and rectum (11.31%-81.35%) across all energy levels ($p < 0.05$). SNR increased from 0.70-1.00 to 1.75-1.97 (95.00%-152.11%, $p < 0.001$), and CNR improved from 90 keV onwards ($p < 0.05$). Among all levels, 140 keV + MAR achieved the highest SNR/CNR and lowest AI. Distortion analysis showed that with increasing VMI energy, the measured long and short axes of the titanium applicator decreased, and the long-to-short axis ratio approached 1 ($p < 0.001$), suggesting that 140 keV + MAR is optimal for preserving structural accuracy. Furthermore, subjective scores confirmed its superiority in artifact reduction (4.00±0.00) and contouring preference (4.00±0.00) (all $p < 0.001$).

CONCLUSION

High-energy VMI combined with MAR, particularly at 140 keV, offers optimal artifact reduction, geometric accuracy, and clinical usability in cervical cancer brachytherapy.

CLINICAL RELEVANCE/APPLICATION

Improvement of image quality in VMI+MAR may help applicator reconstruction and structure delineation in CT-based brachytherapy.

T5B-SPBR-1 TARGETED RISK STRATIFICATION IN WOMEN UNDER 50 USING AN IMAGE-ONLY AI MODEL: ADDRESSING THE RISE IN BREAST CANCER INCIDENCE IN YOUNGER WOMEN

Elizabeth A. Morris, MD (*Presenter*)
Constance D. Lehman, MD, PhD (*Abstract Co-Author*)
David Miller (*Abstract Co-Author*)
Emily Hipp (*Abstract Co-Author*)
Mark Scully (*Abstract Co-Author*)
Lora D. Barke, DO (*Abstract Co-Author*)
Louie Enriquez, MD, JD (*Abstract Co-Author*)
Christiane K. Kuhl, MD, PhD (*Abstract Co-Author*)
Toni W. Vomweg (*Abstract Co-Author*)
Philippe Raffy, PhD (*Abstract Co-Author*)

PURPOSE

The fastest-growing incidence of breast cancer is now among women under age 50, especially those in their 40s and even late 30s. Although women under 50 are experiencing the steepest rise in breast cancer incidence, guidelines for screening this population remain variable and uptake is limited. We evaluated whether an image-only AI model could identify women under 50 with 5-year cancer risk comparable to routinely screened age groups, to support targeted, risk-adapted screening in younger women.

METHODS AND MATERIALS

An image-only AI model was trained on 421,499 mammograms from 27 facilities in Europe, South America, and the U.S., using a deep convolutional neural network and calibrated on an independent test set to generate 5-year risk estimates. The model was applied to 255,641 consecutive bilateral 2D full-field digital screening mammograms from January 2011 through December 2016, drawn from six facilities in the U.S. and one in Europe. Patient demographics were extracted from electronic health records, and cancer outcomes were obtained from local tumor registries. Predicted 5-year risk was categorized using NCCN thresholds: average (<1.7%), intermediate (=1.7% to <3.0%), and high (=3.0%). Age groups included <40, 40-49, 50-69, and =70. Five-year cancer incidence was computed using Turnbull time-to-event estimates accounting for interval censoring, and the log-rank test was used for group comparisons.

RESULTS

Cancer incidence increased progressively with both AI-predicted risk (1.3%, 2.7%, 5.9%; $p < 0.001$) and age group (1.8%, 1.8%, 3.0%, 4.9%; $p < 0.001$). Across all age groups, AI-predicted risk categories consistently identified increasing cancer incidence from average to intermediate to high risk ($p < 0.001$). Among women aged 40-49 (n = 66,630), 58.2% were average risk (1.1% cancer), 25.8% intermediate (2.2%), and 16.0% high (3.7%). Among women aged 50-69 (n = 149,919), 57.1% were average (1.3%), 27.3% intermediate (2.7%), and 15.6% high (6.1%). In women under 40 (n = 3,599), 66.8% were average (1.6%), 22.3% intermediate (1.7%), and 10.9% high (4.2%). These findings demonstrate that a substantial proportion of younger women have cancer risk profiles comparable to routinely screened populations.

CONCLUSION

An image-only AI model stratifies risk across all age groups and identifies high-risk subpopulations under age 50 whose cancer incidence exceeds that of routinely screened women over 50. This may enable more targeted, risk-adapted screening in younger women.

CLINICAL RELEVANCE/APPLICATION

Where screening for women under 50 is limited or delayed and given rising incidence of breast cancer in younger women, AI risk models may support more effective screening in younger women by identifying those who may benefit most.

T5B-SPBR-2 MR ELASTOGRAPHY FOR BREAST CANCER: BREAST STIFFNESS AND LOCAL TUMOR STIFFNESS AS POTENTIAL PROGNOSTIC IMAGING BIOMARKERS

Jeremiah Sanders, PhD (*Presenter*)
Jun Chen, PhD (*Abstract Co-Author*)
Kay Pepin, PhD (*Abstract Co-Author*)
Roger C. Grimm, MS (*Abstract Co-Author*)
Richard L. Ehman, MD (*Abstract Co-Author*)
Bhavika K. Patel, MD (*Abstract Co-Author*)

PURPOSE

Magnetic resonance elastography (MRE) is a quantitative imaging technique that measures mechanical properties of tissues. It has the potential to provide in vivo measurements of global breast stiffness, an emerging parameter not yet standardized in clinical practice. Integrating MRE into breast cancer diagnostics may yield a clinically derived novel biomarker with prognostic value.

METHODS AND MATERIALS

Sixteen patients with confirmed breast cancer underwent diagnostic breast MRI combined with MRE. Diagnostic scans included at least Dixon and dynamic contrast enhanced (DCE) series. MRE was performed using a pillow-like passive driver positioned between the breasts over the sternum while the patient was prone position in a standard breast coil. 40-Hz vibrations were transmitted to the passive driver from an active driver (Resoundant, Inc., Rochester, MN). Breast MRE data were acquired from 40 axial slices using a modified 3D-GREMRE pulse sequence. 3D wave images were processed with 3D multiple-model direct inversions without directional filtering. Tumors and whole-breast ROIs were segmented on DCE and co-registered MRE magnitude images using intensity thresholding and manual adjustments in MIM (v7.3.5).

ROIs were transferred to the stiffness maps, and stiffness values were summarized for the tumor, the affected breast global stiffness, and the contralateral breast global stiffness

RESULTS

Most patients had dense breasts (n=3 were BI-RADS B, n=11 were BI-RADS C, and n=2 were BI-RADS D). Tumor stiffness averaged 3.09 kPa (range: 1.44-5.13 kPa), higher than contralateral breast global stiffness (1.66 kPa; 1.02-2.61 kPa). Relative stiffness differences between the tumor vs contralateral breast were 60.68 % (19.86-159.40 %), and 5.78 % (-6.13-13.58 %) between affected breast (with tumor) vs. contralateral breast. The relative global breast stiffness difference was higher for patients with invasive ductal carcinoma (IDC) compared to those patients with ductal carcinoma in-situ (DCIS) (median: 8.52% vs. -0.65%).

CONCLUSION

In this clinical study, breast global stiffness was moderately elevated in tumor-burdened breasts—particularly in IDC—and significantly higher in tumors compared to contralateral normal breast tissue. MRE may provide complimentary imaging biomarkers for breast cancer. Future studies with larger patient populations are warranted to validate these findings.

CLINICAL RELEVANCE/APPLICATION

Breast and tumor stiffness assessed via MRE may represent clinically meaningful imaging biomarkers with prognostic diagnosis potential in breast cancer and treatments.

T5B-SPBR-3 CLINICAL UTILITY OF ARTIFICIAL INTELLIGENCE FOR DETECTION AND SUSPICION EVALUATION OF BREAST LESIONS ON MRI IN BREAST CANCER PATIENTS

Na Young Jung, MD (*Presenter*)
Moon Hyung Choi, MD (*Abstract Co-Author*)
Seung Eun Jung, MD, PhD (*Abstract Co-Author*)
Robert Grimm, PhD (*Abstract Co-Author*)
Heinrich von Busch (*Abstract Co-Author*)
Dongyeob Han, PhD (*Abstract Co-Author*)
Kai Geissler, MSc (*Abstract Co-Author*)
Markus Wenzel, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the clinical utility of an artificial intelligence (AI) model for detecting and evaluating lesions on dynamic contrast-enhanced breast magnetic resonance imaging (MRI) in patients with pathologically proven breast cancer.

METHODS AND MATERIALS

This study included 294 patients (mean age, 57 years; range, 26-90) with biopsy-proven breast cancer who underwent breast MRI between January 2022 and January 2024. A total of 490 lesions were identified: 52 lesions categorized as suspicious by a breast radiologist aware of the cancer site, 115 detected by the AI model alone, 321 by both, and two additional pathologically proven lesions that were missed by both. Preoperative biopsy revealed 319 malignant, 4 atypical, and 34 benign lesions; however, 2 atypical and 4 benign lesions were upgraded to malignancy after surgery. The remaining 133 lesions were clinically followed. The AI lesion detection models were previously trained on 2952 patients from 10 clinical institutions using a two-stage approach: a 3D U-NET was used for lesion segmentation, and subsequently, a 3D Swin Transformer was used for lesion suspiciousness rating (AI score, 1-100). The AI score was applied to both AI-detected lesions and radiologist-segmented lesions that were initially missed by AI. The diagnostic performances of the AI model and the radiologist were compared using sensitivity, precision, and F1-score, and imaging/pathologic predictors of AI correctness were analyzed. Receiver operating characteristic (ROC) curve analysis was performed using the AI score.

RESULTS

For total lesions, AI achieved 91.6% sensitivity, 69.7% precision, and 0.792 F1 score, vs. radiologist's 99.7%, 89.0%, and 0.940. For primary lesions (n=295), AI achieved 94.5%, 99.3%, and 0.969, vs. radiologist's 99.3%, 99.7%, and 0.995. For additional lesions (n=195), the AI was 69.2%, 17.2%, and 0.276 vs. the radiologist's 100%, 43.8%, and 0.609. The average false-positive number for AI per patient was 0.44. The significant predictors of accurate AI detection were lower breast parenchymal enhancement and whether the lesion was a primary tumor. The areas under the curve (AUC) for the total, primary, and additional lesions were 0.829, 0.791, and 0.710, respectively.

CONCLUSION

Even without prior knowledge of tumor location, the AI model accurately detected primary lesions, suggesting its potential as an adjunct in the clinical interpretation of breast MRI. However, the detection of additional lesions remains a challenge, with limitations including high false positives and reduced sensitivity of small or subtly enhancing tumors.

CLINICAL RELEVANCE/APPLICATION

AI-assisted MRI reading has the potential to improve diagnostic accuracy and workflow efficiency in breast cancer evaluation.

T5B-SPBR-5 PREDICTIVE VALUE OF TEMPORAL DIFFUSION SPECTROSCOPY MRI AT DIFFERENT DIFFUSION TIMES FOR PATHOLOGICAL COMPLETE RESPONSE IN BREAST CANCER AFTER NEOADJUVANT CHEMOTHERAPY

Jie Ding (*Presenter*)
Diwei Shi (*Abstract Co-Author*)
Caixia Fu (*Abstract Co-Author*)
Chao You, MD (*Abstract Co-Author*)
Junzhong Xu, PhD (*Abstract Co-Author*)
Hua Guo (*Abstract Co-Author*)
Yajia Gu (*Abstract Co-Author*)

PURPOSE

To explore the predictive performance of temporal diffusion spectroscopy at different diffusion times for pCR in breast cancer and to compare it with the tumor long diameter change rate measured by RECIST1.1and conventional ADC.

METHODS AND MATERIALS

A total of 209 patients were enrolled according to the inclusion and exclusion criteria. 142 patients underwent long diffusion time (Dt-long) TDS scan before neoadjuvant therapy, and were divided into pCR group (56 cases) and non-pCR group (86 cases) according to the postoperative pathological results after neoadjuvant therapy. 67 patients underwent short diffusion time (Dt-short) TDS scan and were divided into pCR group (17 cases) and non-pCR group (50 cases) according to postoperative pathological results. Cell parameters (Vin, diameter, cellularity, Dex) and derived ADC values of the TDS technique were calculated separately for different diffusion times. Paired t-tests, Wilcoxon tests, Kruskal-Wallis tests, and Mann-Whitney U tests were used to compare TDS parameters pre- and post-NAC and between pCR and non-pCR groups, depending on data distribution. Univariate and multivariate logistic regression identified independent predictors of pCR. Binary logistic regression models were constructed, and ROC curves with Delong tests compared the predictive performance of TDS-derived models, conventional ADC, and RECIST1.1 longest diameter change rate ($P < 0.05$ considered statistically significant).

RESULTS

Post-NAC, derived ADC values increased at both diffusion times, while cellularity and Vin decreased. Changes in TDS parameters were more pronounced in the pCR group than in the non-pCR group. The predictive performance of the TDS parameter model under long and short diffusion time was higher than that of conventional ADC under the same diffusion time (AUC Dt-long 0.741 vs. AUC ADC 0.664,P=0.041; AUC Dt-short 0.886 vs. AUC ADC 0.722,P=0.004) and the corresponding percentage change of tumor length in RECIST1.1% (AUCDt-long 0.741 vs. AUC REC IST1.1 % 0.538, P=0.004; AUC Dt-short 0.886 vs. AUC REC IST1.1 % 0.579, P=0.002). The Dt-short model demonstrated superior predictive performance compared to Dt-long (AUC Dt - short 0.886 vs. AUC Dt - long 0.741, P = 0.02).

CONCLUSION

TDS-based models at different diffusion times better than conventional ADC and RECIST1.1 longest diameter change rate in predicting pCR in breast cancer. The Dt-short model exhibits superior predictive performance compared to Dt-long.

CLINICAL RELEVANCE/APPLICATION

It provides reference for selecting reasonable diffusion time in clinical application of TDS technique to predict pCR in breast cancer.

T5B-SPBR-6 NEW BIOMARKERS' EXPLORATION WITH DYNAMIC CONTRACT ENHANCEMENT AND DIFFUSION MRI FOR PREDICTING PATHOLOGICAL RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN BREAST CANCER

Yanbo Li (*Presenter*)
Hong Lu (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of the potential MRI biomarkers on predicting the response to neoadjuvant chemotherapy (NAC) and explore if new nomogram can be developed to improve pCR (ypT0) prediction.

METHODS AND MATERIALS

692 breast cancer patients who received NAC followed by surgery were included, and all underwent MRI examinations before and after completion of NAC on three system (Discovery MR750, GE Healthcare; Signa Pioneer, GE Healthcare; and Signa Infinity Excite II, GE Healthcare). The clinicopathological variables were recorded, and MRI variables were assessed. The ADC and WIS were calculated on Advantage Workstation (AW 4.6, GE Healthcare). The patients were separated into the training and validation cohort. Univariate comparison, univariable and multivariable logistic regression analyses were conducted in training cohort to identify independent predictors for pCR prediction. A nomogram was developed, and its performances were evaluated using the receiver-operator characteristic curves (ROC) in both training and validation cohort. The area under the ROC, sensitivity and specificity were also calculated. Calibration curve was plotted to evaluate the accuracy and reliability of the multi-parametric model.

RESULTS

The training cohort comprised 418 patients (median age, 47 years; IQR, 39-54 years), and the validation cohort included 274 patients (median age, 46 years; IQR, 38-55 years). Hormone receptor (HR)-negative, Ki67 index, rimed enhancement pre-NAC, tumor size post-NAC, WIS post-NAC, and ADC value post-NAC were found independently associated with pCR. Our newly developed nomogram showed superior predictive performance compared to the Kim model, with an AUC of 0.92 versus 0.89 (P = .008) in the training cohort, and 0.89 versus 0.86 (P = .043) in the training cohort.

CONCLUSION

New biomarkers including WIS and ADC were found helpful in post-NAC pCR prediction after exploration based on our single central data. Our nomogram, integrating clinicopathological and imaging biomarkers, demonstrated superior predictive performance for pCR compared to the existing Kim model.

CLINICAL RELEVANCE/APPLICATION

Our combined model may be helpful for individual treatment planning in breast cancer.

T5B-SPBR-7 SPEED AND ACCURACY: CAN WE HAVE BOTH? A COMPARATIVE STUDY OF RADIOLOGIST INTERPRETATION STYLES FOR AUTOMATED ULTRASOUND

Ashley I. Huppe, MD (*Presenter*)
Yulei Jiang, PhD (*Abstract Co-Author*)
Onalisa D. Winblad, MD (*Abstract Co-Author*)
Allison Aripoli, MD (*Abstract Co-Author*)
Jessica K. Peterson, MD (*Abstract Co-Author*)
Camron B. Smith, DO (*Abstract Co-Author*)
Molly Hill, MD (*Abstract Co-Author*)
Marc F. Inciardi, MD (*Abstract Co-Author*)

PURPOSE

Ultrasound improves breast cancer detection for patients with dense breast tissue and federal breast density notification laws may lead to increased utilization. AUS generates multiple acquisitions with reconstructed orthogonal planes for each breast. Interpretation times are lengthened when both coronal and transverse AUS images undergo full review, known as coronal-transverse interpretation (CTI). Literature supports the utility of the coronal view for cancer detection, which may decrease interpretation time if used as a primary interpretation style (coronal-focused interpretation, CFI). This study evaluated whether CFI is non-inferior in accuracy to CTI and decreases interpretation time.

METHODS AND MATERIALS

In a retrospective multireader multicase receiver operating characteristics (ROC) study, 11 radiologists interpreted a cancer-enriched set of 100 AUS cases (40 cancers, 60 normal/benign). Each case was interpreted using CFI with full viewing of the coronal images and utilization of transverse images as needed. Radiologists then viewed each case with CTI style. BI-RADS assessments for both interpretation styles were recorded for each case as 0, 1 or 2 and, if 0, diagnostic BI-RADS assessment for up to 3 lesions in each breast. Likelihood of malignancy score (0-100%) was also recorded. Interpretation times were obtained. Performance metrics were compared between CFI and CTI.

RESULTS

Seven readers were academic radiologists and all reported spending 80-100% of time dedicated to breast imaging. Clinical AUS volume ranged between 1 and 14 studies per day. Sensitivity for cancer detection (BI-RADS 4a or above) improved significantly from 76% (CFI) to 84% (CTI) (95% CI [3%, 14%]). Specificity (BI-RADS 3 or below) decreased significantly from 69% (CFI) to 63% (CTI), (95% CI [-10%, -3%]). On average, one additional cancer was detected for 1.6 additional false positives (FP) with CTI vs. CFI. CFI reduced interpretation time by 2.1 minutes per case (CFI: 3.0 minutes, CTI: 5.1 minutes). Area under the ROC curve of CTI was significantly better than CFI (p=0.02).

CONCLUSION

Compared with CFI, AUS CTI style results in improved cancer detection though increases FPs and interpretation time. This study supports CTI to ensure AUS provides the reported benefit of additional cancer detection. Further studies evaluating alternative methods to decrease interpretation time, such as with artificial intelligence, are warranted.

CLINICAL RELEVANCE/APPLICATION

Recently mandated breast density legislation may result in increased use of automated ultrasound (AUS), which generates large image data sets. An AUS interpretation style that uses primarily coronal reformats, known as CFI, may reduce radiologist interpretation time and encourage adoption of AUS.

T5B-SPCA-2 PERFORMANCE EVALUATION OF PRECISION LOW CONTRAST MEDIUM WITH DEEP LEARNING IMAGE RECONSTRUCTION IN PROSPECTIVE ECG-TRIGGERING CORONARY CT ANGIOGRAPHY:A PILOT STUDY

Luotong Wang (*Presenter*)
Dian Yuan (*Abstract Co-Author*)
Jie Liu (*Abstract Co-Author*)

PURPOSE

To assess the use of 100 kVp low contrast medium injection protocol on image quality and diagnostic performance of Coronary CT angiography (CCTA) in patients with extensive range body mass index (BMI) and heart rate (HR), in comparison with the conventional scan protocol with normal contrast media.

METHODS AND MATERIALS

In this prospective study, 105 patients undergoing prospective ECG-triggering CCTA were randomly assigned to 3 groups with contrast media injection protocols with bolus tracking technique: Reference group, 0.7 ml CM per kg patient weight (ml/kg); -14% contrast media (CM) group(`-` represents a reduction of contrast media volume compared to the reference group), 0.6 ml/kg; -28% CM group, 0.5 ml/kg. High-level deep learning image reconstruction (DLIR-H) was used for image reconstruction with a thickness and interval of 30%-80%, and the newest snapshot freeze technique was used to correct motion artifacts. For the objective assessment, the CT values of the superior vena cava (SVC), pulmonary artery (PA), ascending aorta (AA), left atrium (LA), left ventricle (LV), left main artery (LM) and proximal segment of the right coronary artery (RCA) were measured and analyzed. Two radiologists with over 10 years of experience assessed all the images based on the subjective evaluation of the image noise, motion artifact, vessel attenuation, and edge sharpness using a 5-point Likert scale.

RESULTS

The groups show comparable baseline characteristics, such as age (p=0.555), BMI(p=0.453), HR(p=0.525). The volume of contrast media was 45.33 ± 9.40, 40.34 ± 7.43 and 34.60 ± 6.68 ml for 3 groups ($p < 0.001$). The vessels CT value of -14% CM group and -18% CM group respectively compared with the reference group, show no difference on SVC, PA, AA, LA, LV, LM, RCA (all $p > 0.05$). The overall subjective image quality and diagnostic confidence for groups were similar ($P = 0.809$; $P = 0.768$).

CONCLUSION

The use of 100 kVp low contrast medium injection protocol could maintain the image quality and diagnostic performance of CCTA .

CLINICAL RELEVANCE/APPLICATION

Employing a 100 kVp low contrast medium injection protocol may preserve the image quality and diagnostic capabilities of CCTA, while allowing a reduction of the contrast medium to 0.4 ml/kg for patients with a wide range of BMI and HR.

T5B-SPCA-5 RAPID SCREENING OF HFPEF USING A RESIDUAL 1D-CNN ON CARDIAC MRI-DERIVED TIME-SERIES LEFT VENTRICULAR VOLUME DATA

Jeeyeon Kim, MD (*Presenter*)
Junyoeng Ko (*Abstract Co-Author*)
Byoung Wook Choi, MD, PhD (*Abstract Co-Author*)

PURPOSE

Heart failure with preserved ejection fraction (HFpEF) remains diagnostically challenging due to its heterogeneous presentation and subtle diastolic pathophysiology. This study aims to develop a rapid, fully automated screening tool for HFpEF using a residual one-dimensional convolutional neural network (1D-CNN) applied to time-series left ventricular (LV) volume data derived from cardiac MRI.

METHODS AND MATERIALS

We retrospectively analyzed patients who underwent both cardiac MRI and transthoracic echocardiography within a one-month interval between 2019-2023 were retrospectively reviewed. Inclusion criteria required a left ventricular ejection fraction (LVEF) = 50% on MRI. Diastolic dysfunction was defined by meeting =3 of the following four echocardiographic criteria, based on ASE/EACVI guidelines: (1) left atrial volume index > 34 mL/m², (2) tricuspid regurgitant velocity > 2.8 m/s, (3) septal e' velocity < 7 cm/s, and (4) E/e' ratio > 14. Normal controls met ?1 of these criteria.Cardiac cine MRI data from 1060 subjects (447 HFpEF, 613 controls) were processed. LV volumes were automatically segmented across cardiac phases and interpolated into uniform time-series using linear interpolation and cubic spline smoothing. These temporal features were input into a residual 1D-CNN for classification. Model training was conducted on a single NVIDIA T4 GPU and completed in 232 seconds. For comparison, peak filling rate normalized to end-diastolic volume (PFR/EDV) was calculated from the LV volume curves.

RESULTS

On an independent test set (89 HFpEF, 126 controls), the residual 1D-CNN achieved an AUC of 0.78 and an accuracy of 0.707. Inference time for the entire test set was only 0.093 seconds, demonstrating exceptional computational efficiency. In contrast, PFR/EDV showed no statistically significant difference between groups, likely due to the limited temporal resolution of standard clinical cine MRI protocols.

CONCLUSION

This residual 1D-CNN model enables rapid, automated HFpEF screening based on LV volume time-series data from cardiac MRI. Unlikely to conventional diastolic function markers, which are constrained by imaging resolution, the model operates robustly on routine clinical images and offers scalable integration into existing workflows. Prospective validation is warranted to assess clinical utility

CLINICAL RELEVANCE/APPLICATION

This AI-driven CMRI approach supports fast, reproducible HFpEF screening with minimal user input, potentially improving early diagnosis and reducing dependence on manual diastolic function assessment across diverse healthcare environments.

T5B-SPCA-6 LARGE LANGUAGE MODELS FOR CAD-RADS 2.0 EXTRACTION FROM CORONARY CT ANGIOGRAPHY REPORTS: A MULTI-INSTITUTIONAL STUDY

Dabin Min (*Presenter*)
Kwang Nam Jin, PhD (*Abstract Co-Author*)
Moon Young Kim, MD (*Abstract Co-Author*)
Hack-Lyoung Kim, MD (*Abstract Co-Author*)
Sang Heum Bang, MD (*Abstract Co-Author*)
Won Gi Jeong, MD, PhD (*Abstract Co-Author*)
Hye-Jeong Lee, MD (*Abstract Co-Author*)
Kyongmin S. Beck, MD, PhD (*Abstract Co-Author*)
Sung Ho Hwang, MD (*Abstract Co-Author*)
Eun Young Kim (*Abstract Co-Author*)
Chang Min Park, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of large language models (LLMs) in extracting Coronary Artery Disease Reporting and Data System (CAD-RADS) 2.0 components from coronary CT angiography (CCTA) reports and assess the impact of prompt engineering strategies, addressing the challenge of maintaining consistency in standardized CCTA reporting.

METHODS AND MATERIALS

In this retrospective study, we collected 319 synthetic CCTA reports from six institutions (one primary and five external institutions). From the primary institution, 150 reports were collected: 100 for prompt development and 50 for internal testing. The remaining 169 reports from external institutions served as the external test set. Board-certified radiologists established reference standards following CAD-RADS 2.0 guidelines. Six LLMs (GPT-4, GPT-4o, Claude-3.5-Sonnet, o1-mini, Gemini-1.5-Pro, and DeepSeek-R1-Distill-Qwen-14B) were evaluated using an optimized prompt, exploring chain-of-thought and many-shot learning strategies. Performance was assessed using accuracies for each CAD-RADS 2.0 component (stenosis severity, plaque burden, and modifiers). McNemar's test and Spearman's correlation were used for statistical analyses.

RESULTS

This study analyzed 319 synthetic CCTA reports generated to reflect institutional reporting patterns. Claude-3.5-Sonnet and o1-mini achieved accuracy of 0.98 (48/49) for stenosis severity in internal testing, while GPT-4o achieved 0.94 (157/167) in external testing. All models showed high accuracies across both test sets for plaque burden (0.93-1.00) and modifiers (0.99-1.00). Chain-of-thought enhanced GPT-4's performance, improving stenosis severity accuracy by 0.14 ($p=0.065$) and 0.19 ($p<0.001$) and plaque burden accuracy by 0.16 ($p=0.016$) and 0.15 ($p<0.001$) in internal and external testing, respectively. Many-shot learning improved Gemini-1.5-Pro's plaque burden accuracy in external testing from 0.928 to 0.997 ($p=0.021$).

CONCLUSION

Our multi-institutional study demonstrates the high performance of large language models in extracting Coronary Artery Disease Reporting and Data System 2.0 components from coronary CT angiography reports when enhanced with advanced prompt engineering techniques.

CLINICAL RELEVANCE/APPLICATION

Large language models with optimized prompting strategies can accurately extract CAD-RADS 2.0 components from coronary CT angiography reports, potentially improving standardization in clinical reporting, reducing radiologist workload, and enhancing communication of findings among healthcare providers, which may ultimately lead to more consistent patient management decisions.

T5B-SPCA-8 DIAGNOSTIC PERFORMANCE OF AN AI-BASED MODEL FOR NON-INVASIVE CT-FFR ESTIMATION COMPARED TO INVASIVE FFR IN CORONARY ARTERY DISEASE

Abdulhamid Hajkhalil (*Presenter*)
Charles Philippe Douek (*Abstract Co-Author*)
Charles De Bourguignon (*Abstract Co-Author*)

PURPOSE

Accurate assessment of coronary stenosis severity is essential for clinical decision-making, particularly for guiding revascularization. Invasive fractional flow reserve (FFR) remains the gold standard for evaluating the functional significance of coronary lesions, but its routine use is limited by procedural risks, cost, and technical complexity. Recently, artificial intelligence (AI) models have emerged as promising tools to estimate FFR non-invasively using coronary CT angiography (CCTA) data. This study aimed to evaluate the diagnostic performance of a deep learning-based model, CorEx (Spimed-AI, Paris, France), in predicting functionally significant coronary stenoses compared with invasive FFR, and to assess its potential to reduce unnecessary invasive procedures.

METHODS AND MATERIALS

In this retrospective study, we included 43 patients with a total of 48 coronary arteries evaluated by both invasive coronary angiography (ICA) and non-invasive FFR estimation using the CorEx model. CCTA images were acquired using Dual layer CT (4 cm detector) Iqon and (8 cm detector) 7500 (Philips, Haifa) between 2015 and 2024. For each artery, invasive FFR was measured using a pressure wire during ICA and served as the reference standard. A lesion was considered hemodynamically significant if FFR was = 0.80. The CorEx deep learning model analyzed 9 curved multiplanar reconstruction (cMPR) JPEG images of the full artery to classify each case as either positive or negative for functional ischemia. Diagnostic performance was assessed through sensitivity, specificity, accuracy, F1-score, and Cohen's kappa coefficient for agreement with invasive FFR.

RESULTS

CorEx achieved a diagnostic accuracy of 70.0% in predicting functionally significant lesions. Sensitivity was 73.7%, specificity 79.3%, and F1-score 71.8%. Among the 48 arteries analyzed, there were 14 true positives, 23 true negatives, 6 false positives, and 5 false negatives. Agreement with invasive FFR was moderate, with a Cohen's kappa of 0.506 (95% CI: 0.252-0.759; SE = 0.129). For arteries with invasive FFR values in the gray zone]0.75-0.80], the AI model correctly classified 50% of cases. Furthermore, when excluding these uncertain cases, the classification accuracy increased to 88%.

CONCLUSION

The CorEx AI model demonstrates moderate to good diagnostic performance for non-invasive FFR estimation. It shows promising potential to reliably identify functionally significant coronary stenoses and reduce unnecessary invasive procedures.

CLINICAL RELEVANCE/APPLICATION

This AI tool can help identify significant coronary lesions from CCTA, reducing unnecessary invasive procedures and improving coronary artery disease management

T5B-SPCA-9 IMPROVED MYOCARDIAL T1 AND T2 MAPPING PRECISION WITH DEEP LEARNING RECONSTRUCTION

Chia-Ying Liu, PhD (*Presenter*)
Chikara Noda (*Abstract Co-Author*)
Bharath Ambale-Venkatesh, PhD (*Abstract Co-Author*)
Yoko Kato, MD, PhD (*Abstract Co-Author*)
Yoshimori Kassai, MS (*Abstract Co-Author*)
Joao A. Lima, MD (*Abstract Co-Author*)

PURPOSE

Quantitative assessment of myocardial T1 and T2 values allows objective evaluation of abnormalities and provides the means for comparison and to follow the disease over time. However, as in the applications of many imaging biomarkers, the sensitivity of T1 and T2 in detecting abnormality is limited by the precision of their measurements. High precision ensures reproducibility and the establishment of reference values, which is particularly important for the population-based studies when subtle changes of T1 and T2 are usually encountered. Recently, deep learning reconstruction (DLR) have been employed to enhance MRI image quality by noise reduction with image sharpness improvement. In this work, we applied the DLR on T1 and T2 mapping images and evaluated their performance in reducing the standard deviation (SD) in myocardial T1 and T2 quantification.

METHODS AND MATERIALS

All participants were imaged using a 3T MRI systems (Canon Medical Systems). T1 mapping was acquired pre- and post-contrast using a gradient echo based MOLLI 5(3)3 sequence. T2 mapping was performed pre-contrast using a T2-prepared gradient echo sequence. A vendor-provided deep learning reconstruction (Precision IQ Engine, PIQE, Canon Medical Systems) was applied to reconstruct the acquired original T1 and T2 images for the generation of T1 and T2 maps. PIQE utilized DLR to reduce noise and applied 3-fold zero-padding interpolation to increase the reconstruction matrix. Myocardial T2, pre- and post-contrast T1, and extracellular volume (ECV) values were extracted and paired student t-test was used for comparison between T1 and T2 values with and without PIQE. $P < 0.05$ was used for statistical significance.

RESULTS

A total of 90 studies were included. SD of myocardial T1 and T2 values were all reduced with PIQE reconstruction ($P < 0.001$). The average SD reduction of native T1 was 7 ms (16% reduction) with PIQE. The native T1 values were marginally increased by 5 ms ($P < 0.0001$). Myocardial T2 values remined the same but their SD were reduced by 2ms ($P = 0.0004$).

CONCLUSION

Our results showed improved precision in myocardial T1 and T2 mapping by applying the deep learning-based reconstruction. The ability to reduce the standard deviation has potential to increase the statistical power of detecting subtle abnormalities due to diffuse fibrosis or edema.

CLINICAL RELEVANCE/APPLICATION

Improved precision in cardiac T1 and T2 mapping by deep learning reconstruction was demonstrated in 90 in-vivo studies. The ability to reduce the standard deviation increases the statistical power of detecting subtle abnormalities.

T5B-SPCA-10 OPERATIONAL COSTS OF 4D FLOW MRI: A BREAK-EVEN ANALYSIS

Joshua Engel (*Presenter*)
Tyler Jacobson (*Abstract Co-Author*)
Michael Markl, PhD (*Abstract Co-Author*)
Bradley D. Allen, MD, MS (*Abstract Co-Author*)
Maria Ibanez (*Abstract Co-Author*)

PURPOSE

Aortic hemodynamics derived from 4D flow MRI (4DF) have shown advantages for risk stratification and treatment planning in patients with aortic valve disease, aneurysms, and dissection. However, clinical adoption has been limited due to high costs, long scan times, and low reimbursement. We quantify these barriers to identify break-even points and assess methods of improving clinical adoption.

METHODS AND MATERIALS

We modeled costs, resource utilization, and reimbursement under base scans of cardiac MRI, MR angiography, adult congenital, and 4DF add-on. Price estimates were generated from market research by the purchasing department at a large academic medical center in 2024 USD. Time estimates were derived from workflow efficiency studies at the same center. Reimbursement rates were from CMS for 2024b. The opportunity cost of 4DF was the margin from utilizing incremental scanner time for a mixture of alternate studies. Break-even points were modeled as the scan volume needed for the yearly margin of performing 4DF to exceed performing the base scans alone. Sensitivity analyses were performed for ranges of CPT 75565 reimbursement, 4DF exam time, and 4DF annual software cost.

RESULTS

The incremental variable cost per 4DF scan was $101.40 at a 15-minute scan time, after accounting for the opportunity cost of scanner utilization. Break-even points were calculated across reimbursement ranging from $40-65/unit of CPT 75565, annual software costs of $10,000-70,000, and 4DF scan times of 5-20 minutes. At a 15-minute scan time and reimbursement of $47.87/unit of CPT 75565, break-even points ranged from 112 to 778 scans as software cost increased from $10,000 to $70,000. Highly accelerated 4DF with a 5-minute scan time produced break-even points ranging from 64 to 444 scans as software cost increased from $10,000 to $70,000.

CONCLUSION

Long scan times and high resource utilization limit the financial viability of 4DF outside of high-volume centers.

CLINICAL RELEVANCE/APPLICATION

Further development of accelerated 4DF imaging techniques and expanded reimbursement criteria are needed to enable wider clinical adoption.

T5B-SPCA-11 CLINICAL DATA AND CARDIAC SPECTRAL PCCT RADIOMICS: IMPROVING CATH LAB TRIAGE IN ACS

Ulrich Schmid (*Presenter*)
Andreas Brendlin, MD, PhD (*Abstract Co-Author*)
Jan M. Brendel (*Abstract Co-Author*)
Saif Afat, MD (*Abstract Co-Author*)

PURPOSE

Many ACS patients undergo cardiac CT and same-day catheterization, but only a fraction require stenting, risking resource overuse. Photon-counting detector CT (PCCT) offers unique spectral data. We investigated five classification approaches: if clinical data ("C"), radiomics derived from mixed ("M") and spectral PCCT High/Low Energy bins ("HL"), early fused clinic+mixed ("CM") or clinic+spectral ("CHL") datasets excel in classifying patients needing same-day coronary stenting, hypothesizing that the inherent informational gain of PCCT may help improve resource stratification.

METHODS AND MATERIALS

We retrospectively analyzed PCCT cardiac scans from 96 patients undergoing same-day cardiac catheterization (15 received stents). Clinical data, along with radiomics from automatically generated myocardial AHA segments (Syngo.via), were fed to an identical machine-learning pipeline comprising SMOTETomek, StandardScaler,

multiple feature selection steps (Univariate Selection, XGBoost Importance Filter, ElasticNet, Correlation Filtering, and RFECV), and an XGBoost classifier with hyperparameter tuning via BayesSearchCV. Performance was assessed on a test set via Matthews Correlation Coefficient (MCC). Models were compared using Bayesian (posterior distributions, BFs, HDIs) and frequentist (bootstrapping, adj. P) analyses.

RESULTS

Clinical data (C) alone had limited value (MCC: 0.427, HDI: [0.321, 0.530]). For radiomics-only, spectral (HL; MCC: 0.726, HDI: [0.617, 0.826]) significantly outperformed mixed (M; MCC: 0.513, HDI: [0.393, 0.626]), confirmed by frequentist (HL vs M: Diff=0.213; P<0.001) and Bayesian analyses (HL-M Diff: 0.213, HDI: [0.052, 0.369]; BF10=2.56). Fusing clinical data yielded best results: CHL (MCC: 0.966, HDI: [0.929, 0.996]) performed highest, followed by CM (MCC: 0.954, HDI: [0.911, 0.991]). Bayesian comparisons showed CHL superior to C, M, and HL (BF10>100). CHL vs CM showed mean diff 0.012 (HDI: [-0.049, 0.069]; BF10=0.04), with no significant frequentist difference (P=0.737), indicating CHL was not decisively superior to CM, despite higher MCC.

CONCLUSION

Clinical data alone is insufficient for predicting stenting. Spectral PCCT radiomics (HL) outperform mixed (M) for radiomics-only models. Fusing clinical and radiomics data (CM, CHL) markedly improves performance over non-fused methods, achieving highest MCCs. While CHL had the highest MCC, it was not decisively superior to CM in pairwise comparisons. Thus, fusing clinical data with spectral PCCT radiomics promises improved post-CT stratification and optimized cath lab triage.

CLINICAL RELEVANCE/APPLICATION

Improved Patient Stratification Optimized Resource Allocation Enhanced Clinical Decision Support

T5B-SPCA-13 MASKED AUTOENCODERS FOR EARLY NEUROLOGICAL OUTCOME PREDICTION IN POST-CARDIAC ARREST PATIENTS USING MULTI-VIEW HEAD CT SCANS

Akhil Kasturi, PhD, MSc (*Presenter*)
Ali Vosoughi (*Abstract Co-Author*)
Nathan Hadjiyski (*Abstract Co-Author*)
Ashley Proctor (*Abstract Co-Author*)
Chloe Zhang (*Abstract Co-Author*)
Thomas W. Johnson, MD,PhD (*Abstract Co-Author*)
Olga Selioutski (*Abstract Co-Author*)
Regine Choe (*Abstract Co-Author*)
Imad Khan (*Abstract Co-Author*)
Axel Wismueller, MD, PhD (*Abstract Co-Author*)

PURPOSE

Cardiac arrest often leads to hypoxic-ischemic brain injury and coma. Accurate neurologic prognostication remains challenging and typically delayed =72 h post-return of spontaneous circulation (ROSC) to mitigate potential confounding variables. However, this 72-hour interval could be critical for reducing the likelihood of false-positive prognoses, as early prognosis can significantly aid clinicians and families in making informed patient management decisions. To address this challenge and improve patient outcome prediction, we propose a deep learning based method using axial, coronal and sagittal head CT scan reconstructions for neurological outcome prognostication using scans taken within the first 24 hours after ROSC.

METHODS AND MATERIALS

The study involved a total of 309 CT scans from 208 adult patients collected from a single institution. The patient data was categorized into good (CPC 1, 2) and bad (CPC 3, 4, 5) neurological outcomes. In this work we used a Video Masked Autoencoder (Video-MAE) based classifier to predict neurological outcomes. We trained two variants of Video-MAE on the head CT scans acquired within the first 24 hours of ROSC: VideoMAE-Ax: Trained on axial head CT reconstructions. VideoMAE-ACS : Trained on axial, coronal, and sagittal CT reconstructions for each study.

RESULTS

VideoMAE-Ax AUC-ROC 0.79; sensitivity 0.80; specificity 0.67; PPV 0.69; NPV 0.78; accuracy 0.73. VideoMAE-ACS AUC-ROC 0.84; sensitivity 0.85; specificity 0.71; PPV 0.74; NPV 0.83; accuracy 0.78. In a direct comparison on the same test set with VideoMAE-Ax, the VideoMAE-ACS model trained on axial, coronal, and sagittal reconstructions displayed improved prognostic performance on AUC-ROC score, sensitivity, specificity, PPV, NPV, and accuracy.

CONCLUSION

This study presents a masked autoencoder-based AI model designed for the prognostication of post-cardiac arrest patients through joint anatomical understanding of axial, coronal, and sagittal reconstructions of head CT scans. Our findings suggest that this approach significantly enhances prognostic accuracy in comparison to methods that rely solely on axial CT reconstructions for early neurological prognostication within 24 hours after the arrest.

CLINICAL RELEVANCE/APPLICATION

Our VideoMAE-ACS model can aid clinicians in providing reliable prognostication using head CT scans taken within the first 24 hours post-ROSC. Integrating this method into the critical care workflow can contribute to reducing uncertainty in early decision-making and improve treatment plans in comatose cardiac arrest survivors.

T5B-SPCA-14 BMI-ADAPTIVE IMAGE OPTIMIZATION IN TRIPLE-LOWCORONARY CTA VIA DEEP LEARNING IMAGE RECONSTRUCTION

Xiaohua Zhang (*Presenter*)
Kun Ma (*Abstract Co-Author*)
Feng Chen, MD, PhD (*Abstract Co-Author*)
Weiyuan Huang (*Abstract Co-Author*)
Xiaoyan Lei (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the efficacy of high-strength deep learning image reconstruction (DLIR-H) in enhancing image quality for coronary CT angiography (CTA) conducted under a “triple-low” protocol—low radiation dose, low contrast volume, and low injection flow rate—across patients with different body mass index (BMI) categories.

METHODS AND MATERIALS

Between August 2024 and April 2025, 47 patients with suspected coronary artery disease were prospectively enrolled and divided into three BMI-based cohorts: group A (<24 kg/m², n=20), group B (24-28 kg/m², n=21), and group C (>28 kg/m², n=6). All underwent coronary CTA using the APEX CT system with individualized tube voltage settings (70-100 kVp) and contrast protocols (35-55 mL at 3.0-5.0 mL/s). Imaging included both systolic and diastolic phases. Reconstructions were performed using DLIR-H and adaptive statistical iterative reconstruction at 50% strength (ASIR-V 50%). Two radiologists independently rated image quality on a 5-point Likert scale (1=non-diagnostic, 5=excellent), blinded to reconstruction method. Radiation dose metrics (CTDIvol, DLP, and ED) were documented. Interobserver consistency was measured with Cohen’s kappa.

RESULTS

Effective radiation dose showed a positive correlation with BMI (group A: 0.77±0.14 mSv; group C: 2.02±0.58 mSv; P=0.004). DLIR-H consistently outperformed ASIR-V 50% in image quality across all BMI groups and cardiac phases. In group A, DLIR-H achieved scores of 4.2±0.4 (diastole) and 4.0 (systole), significantly higher than ASIR-V 50% (3.1±0.3 and 3.0, respectively; P<0.001), with excellent inter-rater reliability (Kappa=0.868-1.0). In group B, DLIR-H received 4.3±0.5 in diastole compared to 3.0±0.2 for ASIR-V 50%, with similar advantages during systole (P<0.001, Kappa=0.824). In group C, DLIR-H scored 4.3±0.6 (diastole) and 4.0 (systole),

outperforming ASIR-V 50% (2.8±0.4 and 3.0; P=0.022 and P=0.019), also with high agreement (Kappa=0.877-1.0). DLIR-H reliably maintained image scores =4 across all BMI categories, whereas ASIR-V 50% largely ranged between 3-4.

CONCLUSION

DLIR-H markedly enhances image quality in coronary CTA using a three-low strategy, with pronounced benefits in overweight and obese individuals, supporting its role in high-noise, low-dose imaging environments.

CLINICAL RELEVANCE/APPLICATION

The findings underscore DLIR-H's value in achieving diagnostically robust coronary CTA under low-dose, low-contrast, and low-flow conditions. Its stable performance across BMI levels, particularly in higher BMI patients, positions it as a critical tool for advancing patient-specific, low-risk cardiovascular imaging strategies.

T5B-SPCA-15 HOW MUCH DEMOGRAPHIC AND ANATOMICAL INFORMATION DO SLVH CLASSIFIERS LEARN FROM CHEST-XRAYS?

Basudha Pal (*Presenter*)
Rama Chellappa (*Abstract Co-Author*)
Muhammad Umair, MBBS (*Abstract Co-Author*)

PURPOSE

Severe left ventricular hypertrophy (SLVH) is a key marker of cardiovascular risk, but echocardiography and cardiac MRI remain limited by cost and access. Chest X-rays (CXRs) are more accessible, yet most deep learning models for SLVH classification rely on intermediate anatomical measurements or demographic inputs, introducing error propagation and confounding. Our framework detects SLVH using only CXR images and binary labels, with no anatomical or demographic supervision. Beyond classification, we assess how much models encode attributes like age, sex, and cardiac structure, though this information is not provided during training.

METHODS AND MATERIALS

We curated a balanced dataset from the CheXchoNet database by sampling equal numbers of SLVH positive and negative cases, however preserving original split ratios. The final set includes 11,190 images from 6,021 patients for training, 658 from 361 for validation, and 534 from 310 for testing. We train ResNet and Vision Transformer backbones with classification heads, optimize with binary cross entropy loss, and select best checkpoints using validation AUROC. We evaluate which clinical factors are implicitly encoded using Mutual Information Neural Estimation (MINE) to compute 'expressivity', which is a measure of the statistical dependence between learnt features and patient attributes that are not seen during training. MINE uses a lightweight auxiliary network trained to distinguish true feature-attribute pairs from random matches by optimizing a variational objective to estimate dependencies in high dimensional space.

RESULTS

Although predicting SLVH from CXRs using only binary labels is a challenge, ResNet achieves AUROC 0.760 (95% CI: 0.718-0.802) and AUPRC 0.731 (95% CI: 0.669-0.786), while ViT achieves AUROC 0.816 (95% CI: 0.781-0.850) and AUPRC 0.803 (95% CI: 0.755-0.849). Expressivity analysis shows a consistent pattern across models: Age > Sex > Interventricular Septal Diameter (IVSDd) > Left Ventricular Posterior Wall Diameter (LVPWd) > Left Ventricular Internal Diameter (LVIDd) at end diastole. Age, sex, and wall thickness are strongly encoded while LVIDd shows comparatively lower expressivity, consistent with its association with dilation rather than hypertrophy.

CONCLUSION

We show that SLVH can be predicted directly from CXRs without structural or demographic supervision. Further, MINE quantifies which factors are implicitly encoded, aligning model behavior with clinical understanding.

CLINICAL RELEVANCE/APPLICATION

CXRs can support SLVH screening without advanced imaging or added patient data. Mutual information analysis provides a systematic approach to interpret what deep models learn and ensures predictions reflect clinically meaningful patterns.

T5B-SPCH-1 SPECTRAL CT DIFFERENTIATION OF ACTIVE AND INACTIVE INFLAMMATION IN INTERSTITIAL LUNG DISEASE

Ran LIN (*Presenter*)
Yajun Ding (*Abstract Co-Author*)
Xilai Chen (*Abstract Co-Author*)
Yu Deng (*Abstract Co-Author*)

PURPOSE

Interstitial Lung Disease (ILD) comprises a group of pulmonary disorders characterized by diffuse parenchymal abnormalities, alveolar inflammation, and/or interstitial fibrosis.Differentiation between these entities on HRCT remains challenging and often requires post-treatment follow-up for distinction. Clinically, it is difficult to adjust individualized treatment plans based solely on HRCT findings. To investigate whether spectral CT-derived parameters can differentiate between active inflammation and inactive inflammation in interstitial lung disease (ILD).

METHODS AND MATERIALS

35 ILD patients who underwent pre-treatment spectral CT and had >3-month follow-up high resolution CT (HRCT) were enrolled. 125 lesions were classified into active/inactive inflammatory subgroups according to the absence or presence of radiologic resolution on follow-up HRCT. The following parameters were measured in the pulmonary arterial phase: lesion iodine concentration/water content (IC/ WC), aortic iodine concentration (A_IC)/water content (A_WC) at the same level, along with unenhanced effective atomic number (Effz) and CT attenuation values. Normalized parameters were calculated as: normalized iodine concentration (NIC=IC/A_IC) and normalized water concentration (NWC= WC/A_WC). Differences in spectral CT parameters between active and inactive inflammation groups were analyzed using Mann-Whitney U tests. Parameters showing statistical significance in univariate analysis were further incorporated into binary logistic regression to develop a spectral CT-based discriminative model (DE model), with diagnostic performance evaluated by the area under the receiver operating characteristic curve (AUC).

RESULTS

A total of 44 active inflammatory lesions and 81 inactive lesions were identified. Both IC (16.51 ± 6.00) and NIC (0.21 ± 0.13) in active inflammatory ILD were significantly higher than those in inactive disease (11.98 ± 5.22 and 0.14 ± 0.08, respectively; all $p<0.001$). Effz also showed significant differences between the two groups ($p<0.016$) However, no statistically significant difference was found in other parameters. The DE model achieved the highest diagnostic performance (AUC=0.731), outperforming individual parameters (IC: AUC=0.708; NIC: AUC=0.683).

CONCLUSION

Spectral CT-derived IC and NIC effectively differentiate between active and inactive inflammation in ILD , with the multiparametric spectral CT-based model showing superior diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that spectral CT-derived IC and NIC can effectively differentiate between active and inactive inflammation in ILD, providing valuable guidance for clinical treatment decision-making.

T5B-SPCH-3 INTERPRETABLE TRANSFORMER-BASED AI FRAMEWORK FOR CT-BASED LUNG NODULE CLASSIFICATION USING FUSED RADIOMIC TEXTURE AND MORPHOLOGY DESCRIPTORS

Ahmed Alksas, PhD (*Presenter*)
Eric A. van Bogaert, MD (*Abstract Co-Author*)
Yi Zhang, DO (*Abstract Co-Author*)
Tatiana Mamaliga, MD (*Abstract Co-Author*)
Patrick T. England, MD (*Abstract Co-Author*)
Ali Mahmoud (*Abstract Co-Author*)
Asem C. Ali (*Abstract Co-Author*)
Mohamed Ghazal (*Abstract Co-Author*)
Sohail G. Contractor, MD (*Abstract Co-Author*)
Ayman S. El-Baz SR, PhD (*Abstract Co-Author*)

PURPOSE

To develop a transformer-based diagnostic framework that integrates domain-specific morphological and textural descriptors for accurate and interpretable lung nodule classification on CT imaging. We hypothesize that fusing Spherical Modified Local Ternary Pattern (SMLTP)-derived textural features and Spherical Harmonics (SH)-based morphological descriptors will significantly improve classification performance and interpretability compared to traditional convolutional neural network (CNN) approaches.

METHODS AND MATERIALS

We curated a private dataset of 707 pathologically confirmed CT scans (477 malignant, 230 benign) and utilized the LIDC-IDRI benchmark dataset (679 nodules) for external validation. The pipeline begins with segmentation of Hounsfield Unit (HU)-based Volumes of Interest (VOIs), followed by extraction of textural features using a SMLTP algorithm and morphological descriptors via HU-guided iso-surface reconstruction errors analyzed through SH. All features are processed using a 3D CNN (based on EfficientNet), and fused into a transformer-based model that encodes and classifies the VOIs. The model's performance was evaluated using accuracy, sensitivity, specificity, F1-score, and area under the curve (AUC), with additional analyses comparing individual feature contributions and prior state-of-the-art methods.

RESULTS

The proposed model achieved 99.3% accuracy and 100% sensitivity on the private dataset and 99.1% accuracy and 99.7% sensitivity on the unseen LIDC-IDRI dataset (external validation). Feature fusion outperformed individual descriptor inputs, with AUCs of 1.000 (private) and 0.9993 (benchmark). The integration of SMLTP and SH descriptors enabled the model to capture and visualize nuanced textural and morphological differences associated with malignancy, providing a layer of interpretability for clinical review. Embedded feature maps and reconstruction errors offered direct visual cues that correlated with diagnostic traits, enhancing transparency of model decision-making.

CONCLUSION

Our framework significantly enhances lung nodule classification through the integration of geometric and textural descriptors with transformer-based modeling. In addition to state-of-the-art diagnostic performance, the model provides interpretable outputs that align with clinical radiologic features, supporting its utility in real-world diagnostic workflows.

CLINICAL RELEVANCE/APPLICATION

This AI-driven diagnostic tool delivers high sensitivity and interpretability in lung nodule evaluation, addressing a critical need for early and accurate lung cancer detection, and may serve as a foundation for next-generation, clinically integrated decision support systems.

T5B-SPCH-4 A NOVEL AI STRATEGY OF COMBINING LARGE DATASET TRAINING, POPULATION SPECIFIC RETRAINING AND CONFIDENCE ESTIMATION TO IMPROVE CLASSIFICATION PERFORMANCE IN ESTIMATING PULMONARY NODULE MALIGNANCY RISK

Eduardo J. Mortani Barbosa JR, MD, MBA (*Presenter*)
Yanbo Zhang (*Abstract Co-Author*)
Yohan Kim (*Abstract Co-Author*)
Bogdan Georgescu, PhD (*Abstract Co-Author*)
Sasa Grbic (*Abstract Co-Author*)
Warren B. Gefter, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of an AI algorithm for pulmonary nodule malignancy risk estimation (DeepPNP) across lung cancer screening and high-risk, biopsy-confirmed cohorts, assessing the incremental benefit of incorporating AI model confidence estimation.

METHODS AND MATERIALS

A retrospective analysis was conducted using five cohorts. For training and validation of the DeepPNP model, the National Lung Screening Trial (NLST) dataset was combined with two malignant nodule-only cohorts, resulting in a merged dataset of 28,057 nodules, including 2,362 malignant nodules. A subset of the NLST (2,597 nodules, including 107 malignant) was retained as a test set to represent the screening scenario. Additional testing was performed on two independent cohorts with distinct compositions of high-risk, biopsy-confirmed nodules: Institution B with 411 nodules (including 177 malignant nodules) and Institution C with 1,144 high-risk, biopsy-confirmed nodules (including 871 malignant nodules). Institution C was split into train/validation/test sets with a ratio of 6:1:3. The DeepPNP model was retrained on this cohort, and an uncertainty estimation strategy was applied to identify the highest confidence nodules. Performance metrics, including sensitivity, specificity, precision, F1 score, and accuracy were analyzed across three operating thresholds.

RESULTS

DeepPNP achieved an area under the curve (AUC) of 0.962 and a sensitivity of 94.4% at 85% specificity on the NLST test set, outperforming the PanCan and Lung-RADS models. In the Institution B cohort, DeepPNP maintained high sensitivity (100%) but exhibited reduced discriminative power among biopsy-confirmed benign nodules. In the Institution C high-risk cohort, the model achieved high sensitivity (99.3%) but was unable to discriminate between high-risk, biopsy-confirmed malignant and benign nodules, with an AUC of 0.580. After model retraining on the Institution C training data, the AUC improved to 0.828 on 20% of the Institution C test data with the highest confidence.

CONCLUSION

DeepPNP outperformed established risk models in the screening cohort. Within two high-risk cohorts, the system correctly identified biopsy-confirmed malignant nodules as high-risk (100% sensitivity in Cohort B and 99.3% sensitivity in Cohort C) but was unable to discriminate benign biopsy-confirmed nodules from malignant ones. This limitation was overcome by retraining the model and removing uncertain cases, showcasing the added value of incorporating confidence estimation.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the importance of population-specific model development and retraining as well as confidence estimation when deploying an AI model in high-risk clinical cohorts.

T5B-SPCH-7 AUTOMATED 3D QUANTITATIVE ANALYSIS OF INTRAPULMONARY VASCULAR VOLUME IN VASCULITIS PATIENTS WITH PULMONARY VASCULAR INVOLVEMENT

Ying Ming (*Presenter*)
Wei Song, MD (*Abstract Co-Author*)
Ruijie Zhao (*Abstract Co-Author*)
Jiaru Wang (*Abstract Co-Author*)
Sirong Piao (*Abstract Co-Author*)
Ran Xiao (*Abstract Co-Author*)
Rui Zhao (*Abstract Co-Author*)
Qiqi Xu, MBBS, MMEd (*Abstract Co-Author*)

PURPOSE

To compare the differences in intrapulmonary vascular volume (IPVV) measured using computed tomography pulmonary angiography (CTPA) between vasculitis patients with pulmonary vascular involvement and subjects with negative CTPA findings.

METHODS AND MATERIALS

This study included imaging data from 207 patients diagnosed with vasculitis with pulmonary vascular involvement& 9; based on CTPA between March 2019 and November 2024, as well as 202 subjects who underwent CTPA between February 2019 and February 2025 and had negative findings. A computer-aided pulmonary vascular segmentation algorithm was employed to automatically measure the IPVV for each patient and subject. Quantitative assessments were conducted on the total intrapulmonary vascular volume (TIPVV), & 9;intrapulmonary arterial vascular volume (IPVVa), & 9;intrapulmonary venous vascular volume (IPVVv). Additionally, IPVVs were analyzed within five specific vessel diameter groups: 0.8 mm-1.6 mm, 1.6 mm-2.4 mm, 2.4 mm-3.2 mm, 3.2 mm-4.0 mm, and >4.0 mm. Comparisons of IPVV were performed between CTPA-negative subjects and vasculitis patients with pulmonary vascular involvement.

RESULTS

TIPVV and IPVVv showed no significant differences between CTPA-negative subjects and vasculitis patients with pulmonary vascular involvement ($P>0.05$). The IPVVa measured in CTPA-negative subjects was 47.79 (42.50, 54.01) mL·m -2 , while that in vasculitis patients with pulmonary vascular involvement was 44.69 (39.33, 52.25) mL·m -2 . The IPVVa in vasculitis patients with pulmonary vascular involvement was significantly lower than that in CTPA-negative subjects, with a statistically significant difference ($P<0.01$). Additionally, in pulmonary arteries with diameters of 0.8 mm-1.6 mm and 2.4 mm-3.2 mm, the IPVVa in vasculitis patients with pulmonary vascular involvement was significantly lower than that in CTPA-negative subjects, with a statistically significant difference ($P<0.01$). In pulmonary veins with

diameters of 1.6 mm-2.4 mm and 3.2 mm-4.0 mm, the IPVVv in vasculitis patients with pulmonary vascular involvement was higher than that in CTPA-negative subjects, with a statistically significant difference (P<0.05).

CONCLUSION

The computer-aided pulmonary vascular segmentation algorithm can automatically measure IPVV, providing a quantitative evaluation of the condition of small pulmonary vessels affected by vasculitis.

CLINICAL RELEVANCE/APPLICATION

The automated measurement of IPVV using a computer-aided pulmonary vascular segmentation algorithm enables objective and quantitative assessment of pulmonary vascular involvement in vasculitis patients.

T5B-SPCH-9 SEGMENTAL PULMONARY VEIN SLOW FLOW AS A NOVEL BIOMARKER FOR PERFUSION DEFICITS IN PULMONARY EMBOLISM: INSIGHTS FROM DUAL-ENERGY CT

Ying Zhang, MD (*Presenter*)
Ye Yu (*Abstract Co-Author*)
Yu Wang (*Abstract Co-Author*)
Huawei Wu (*Abstract Co-Author*)

PURPOSE

To assess the independent role of segmental pulmonary vein slow flow (PVSF) in pulmonary perfusion deficits (PPD) in pulmonary embolism (PE), evaluate the performance of effective atomic number (Zeff) versus iodine density (ID) for hemodynamic assessment, and explore the thrombus-PVSF-PPD relationship using dual-energy CT (DECT).

METHODS AND MATERIALS

This retrospective study included 102 PE patients undergoing dual-phase DECT. Segment-level analysis (20 segments/patient) evaluated thrombus burden (Modified Miller score), venous abnormality (absent, tenuity, PVSF), and PPD morphology. Spectral parameters (Zeff, ID) were reconstructed for quantitative analysis. Generalized linear models assessed factors associated with Zeff, with model fit evaluated using the Quasi-likelihood under the Independent Model Criterion (QICC). Generalized estimating equations and mediation analysis evaluated associations and pathways at the segment level.

RESULTS

At the segmental level (n=2040 segments), PVSF was strongly associated with PPD: PVSF segments showed significantly higher PPD prevalence (98.0%, 198/202) than absent (29.0%, 507/1749) or vein tenuity (71.9%, 64/89) segments (p<0.001). PVSF independently predicted high-risk PPD (OR=10.2) and correlated with greater Zeff reduction (p<0.001). Zeff demonstrated superior performance over ID for PPD detection (AUC=0.88 vs 0.86, p<0.001). Mediation analysis revealed PVSF mediated 16.5% (p<0.001) of thrombus-induced perfusion impairment. GLM for Zeff confirmed PVSF's significant association alongside thrombus burden and location (model fit with Gamma/log link, QICC=36.5).

CONCLUSION

Segmental PVSF, detectable by DECT, is a novel and independent predictor of PPD in PE, potentially serving as a valuable imaging biomarker for risk stratification. Zeff provides more accurate quantitative assessment of hemodynamic impairment compared to ID. The "thrombus-PVSF-PPD" axis highlights the importance of evaluating venous outflow alongside arterial obstruction in PE management.

CLINICAL RELEVANCE/APPLICATION

Segmental pulmonary vein slow flow and Zeff-based quantitative analysis using DECT provide valuable insights for risk stratification and comprehensive hemodynamic assessment in patients with pulmonary embolism, highlighting the importance of evaluating both arterial and venous compartments.

T5B-SPCH-10 METAL ARTIFACT REDUCTION IN ULTRA-LOW-DOSE CT WITH DEEP LEARNING IMAGE RECONSTRUCTION: A CATPHAN 500 PHANTOM STUDY

Bing Liu (*Presenter*)

PURPOSE

To evaluate the performance of Deep Learning Image Reconstruction (DLIR-H) in suppressing metal artifacts at ultra-low-dose (ULD) levels (80kVp/20mAs), compared with iterative reconstruction (ASIR-V 50%) and filtered back projection (FBP).

METHODS AND MATERIALS

A customized Catphan 500 phantom (CTP515 module with stainless steel clips) was scanned at ultra-low-dose (80kVp/20mAs) and conventional-dose (120kVp/50mAs) settings. Images were reconstructed using DLIR-H, ASIR-V 50%, and FBP. Quantitative metrics included: (1) CT value deviation (|?HU|); (2) background noise (s); (3) contrast-to-noise ratio (CNR); and (4) CNR loss rate. Measurements were taken from anterior, left, and right regions across three slice positions (center, ±5 mm). Statistical analysis was performed using paired t-tests (a=0.05).

RESULTS

At 80kVp ULD scanning, DLIR-H outperformed ASIR-V 50% and FBP: (1) CT value stability: DLIR-H showed the lowest mean |?HU| (41.29 HU) compared with ASIR-V 50% (43.60 HU) and FBP (45.18 HU); (2) Noise reduction: DLIR-H achieved the lowest background noise (s=29.64 HU); (3) CNR preservation: DLIR-H reached the highest CNR (2.10) with the lowest CNR loss rate (14.00%).

CONCLUSION

DLIR-H significantly reduces metal artifacts, background noise, and CNR loss at ultra-low-dose settings, indicating strong potential for clinical application in radiation dose reduction strategies.

CLINICAL RELEVANCE/APPLICATION

DLIR-H enables diagnostic-quality imaging at ultra-low doses (80kVp/20mAs), reducing radiation exposure for patients with metallic implants. Its superior artifact suppression and CNR preservation benefit frequent CT users like pediatric patients and oncology cases. Despite needing optimization in anterior artifact reduction, DLIR-H balances diagnostic efficacy and patient safety.

T5B-SPCH-12 NATURAL HISTORY AND CLINICAL CHARACTERISTICS OF PULMONARY SUBSOLID NODULES IN PEDIATRIC PATIENTS DURING THE PAST 15 YEARS

Hua Ren, MD, PhD (*Presenter*)
Hong Yu, MD, PhD (*Abstract Co-Author*)
Jianlin Wu, MD (*Abstract Co-Author*)

PURPOSE

To investigate the natural course of subsolid nodules (SSNs) in the pediatric patient population and to gain some insights on how to follow them up.

METHODS AND MATERIALS

From January 2010 to December 2024, patients aged 18 years or younger with persistent SSNs were retrospectively reviewed and assessed. The incidence of interval growth, clinical, radiologic, pathological features, and follow-up outcomes of these SSNs were investigated.

RESULTS

A total of 164 patients (median age, 17 years; range, 6-18 years; 81 women) with 217 SSNs (including 213 pure ground glass nodules [PGGNs] and four part-solid nodules [PSNs]) were analyzed and evaluated. Five of the 217 SSNs (2.3%) (three PGGNs and two PSNs) showed interval growth. One PGGN and one PSN exhibited an increase in nodule size. One PSN demonstrated an increase in solid components, and two PGGNs presented a new small solid component. The intervals from initial CT examination to growth were 12, 17, 20, 37, and 98 months. There was no occurrence of centripetal growth in the reversed halo sign GGNs. 28 SSNs (25 PGGNs, 3 PSNs) in 24 studied individuals underwent pulmonary resection, including four IVAs, 14 minimally invasive adenocarcinomas, nine adenocarcinomas in situ, and one atypical adenomatous hyperplasia. There were no lymph node metastasis and pleural invasion. One PGGN underwent microwave ablation. All patients survived without recurrence.

CONCLUSION

Only 2.3% of SSNs in children and adolescents showed subsequent growth. The much higher likelihood of these persistent SSNs in pediatric patients that represent a primary lung tumor rather than metastasis or infectious causes.

CLINICAL RELEVANCE/APPLICATION

The persistent SSNs in pediatric patients should be followed up with long intervals and appropriate surgical treatment after thoughtful discussion.

T5B-SPCH-13 INCIDENTAL PULMONARY NODULE FOLLOW UP OUTCOMES BASED ON REVISED 2017 FLEISCHNER SOCIETY GUIDELINES

Benjamin Kuo, MD, MSc (*Presenter*)
Chow Wei Too (*Abstract Co-Author*)

PURPOSE

Incidental pulmonary nodules (IPN) are routinely seen on chest computed tomography (CT). This has led to the 2017 Fleischner Society Guidelines (FSG) for IPN to minimize unnecessary CT examinations and provide clinicians with greater discretional management approaches. The main purpose of this study is to examine the follow up rates and outcomes of IPN detected on CT evaluations.

METHODS AND MATERIALS

In this retrospective study, all outpatient and inpatient CT studies from our institution with complete or partial coverage of the thorax between January 1 - February 28, 2020 were examined for pulmonary nodules. A follow up period of 4 year was used to determine the outcome of the IPN. Exclusion criteria were similar to prior FSG publication: cancer history, younger than 35 years, immunocompromised status or death during the study period. Variables and outcomes evaluated were patient demographic, study acquisition, clinical, nodule characteristics and histological result.

RESULTS

A total of 656 CT scans were evaluated, which revealed pulmonary nodules in 207 scans. The mean patient age was 66 year (SD 12 years). Further workup recommended included 51 cases (24.6%) with an mean nodule size (MNS) of 2.9cm, among which 34 cases underwent biopsy, demonstrating malignancy in 25 cases (MNS 2.8cm). Workup was declined for 17 cases of which 7 cases (MNS 3.3cm) had suspicious features for malignancy during presentation or on follow up. Standard of care CT follow up included 62 cases (30.0%, MNS 0.8cm). Two cases (MNS 0.8cm) showed interval nodule growth with suspicious features; 60 cases (MNS 0.8cm) had no detected cancer. A total of 94 cases were discharged (45.4%, MNS 0.4cm) with 1 case exhibiting features for lung metastasis on subsequent imaging. The remaining 93 cases remained negative of malignancy within the study period.

CONCLUSION

Incidental pulmonary nodule is a common finding in nearly one third of scans in our institution after excluding patients with known malignancy. Follow up of IPN demonstrated significant association of pulmonary nodule size and malignancy in line with the latest FSG. Overall lung cancer detection was 5.9%. Notably, patients who were discharged had MNS of 0.4cm with less than 1% cancer detection. Patients who were followed up by CT had MNS of 0.8cm with 3.4% cancer detection. Future priorities within our institution include initiatives to integrate AI tools for more granular risk-stratification with relevant clinical and imaging parameters.

CLINICAL RELEVANCE/APPLICATION

Our preliminary experience matching incidental pulmonary nodules and lung cancer detection with 2017 Fleischner Society Guidelines demonstrated reliable guidelines with appropriate individualized clinical flexibility.

T5B-SPER-1 FROM STATIC TO DYNAMIC - ADVANCING PTE DIAGNOSIS THROUGH THE LENS OF DDR

Robin B. Philip, MBBS (*Presenter*)
Priscilla Joshi, MBBS, MD (*Abstract Co-Author*)

PURPOSE

To evaluate diagnostic accuracy of Dynamic Digital Radiography (DDR) in suspected acute pulmonary thrombo-embolism (PTE) and its potential to overcome the limitations of conventional CT pulmonary angiography (CTA) . To evaluate pulmonary perfusion on follow up DDR. & 9;& 9;& 9;To correlate initial and follow up DDR findings with Transthoracic 2D echocardiography (TTE) findings.

METHODS AND MATERIALS

This prospective study evaluated diagnostic performance of DDR in adult patients with suspected PTE undergoing CTA . It was an interim analysis of 62 patients , 27(43.5 %) were females and 35(56.5 %) were males. TTE was done for patients who presented with acute onset breathlessness. Those with a suspicion of PTE were sent to radiology department for diagnostic CTA. DDR was done prior to CTA to assess pulmonary perfusion based on heat maps . The diagnostic accuracy of DDR and TTE were compared to CTA. This study assessed clinical utility of DDR and TTE with CTA as gold standard in PTE diagnosis.

RESULTS

Preliminary analysis demonstrated moderate diagnostic accuracy for DDR in suspected PTE. The test demonstrated a sensitivity of 63.16% (95% CI: 38.36-83.17%) , indicating its ability to correctly identify approximately two-thirds of individuals with PTE though with a notable degree of variability reflected in the wide confidence interval. The specificity was 57.58% (95% CI: 39.22-74.52%) , showing that it accurately classified over half of individuals without PTE. With a positive likelihood ratio of 1.49 , the test modestly increased probability of PTE being present when result is positive. Conversely, negative likelihood ratio of 0.64 suggested a slight reduction in likelihood of PTE when result was negative. Together, these metrics highlighted the test’s moderate diagnostic performance.

CONCLUSION

The results suggested DDR may offer a promising, albeit imperfect, alternative for diagnosis of pulmonary embolism in select patient populations. DDR showed a better sensitivity, positive and negative predictive values as compared to a TTE in evaluation of PTE . Additionally, DDR showed remnant pulmonary perfusion in the affected zone which CTA couldn’t.

CLINICAL RELEVANCE/APPLICATION

DDR offers several advantages, including:Reduced patient radiation dose burden . Radiation dose of perfusion DDR is one-twentieth of standard CTA. Hence, there's a significantly lower radiation exposure and repeating a DDR is far more feasible than CTA. Reduced patient compliance : Shorter breath holds minimise patient discomfort.Enhanced patient safety : Eliminates the risk of contrast-induced nephropathy.Unique assessment of pulmonary perfusion : Provides valuable information of perfusion percentages in both upper, mid and lower pulmonary zones not readily available with CTA.

T5B-SPER-2 O-DOSE MODULATION AND DEEP LEARNING RECONSTRUCTION (INFINITY) IN EMERGENCY THORACOABDOMINAL CT: OPTIMIZATION OF SPIRAL SCAN RANGE, RADIATION DOSE, AND IMAGE QUALITY

Dace Zhang (*Presenter*)

PURPOSE

To investigate the impact of different reconstruction algorithms (View iterative, Infinity deep learning), radiation doses (conventional vs. low dose), and helical scan ranges (16cm vs. 8cm) on image quality in emergency thoracoabdominal CT scans, and to optimize the scanning protocol.

METHODS AND MATERIALS

45 subjects were enrolled and divided into three groups: Group 1 (16 cm, routine dose, O-DOSE 1.3), Group 2 (8 cm, routine dose, O-DOSE 1.3), and Group 3 (16 cm, low dose, O-DOSE 0.7). All data were reconstructed using View iterative reconstruction (30%, 50%, 70%, 90%), and Infinity deep learning reconstruction (30%, 50%, 70%, 90%). Quantitative analyses were performed on image noise, CT values, Signal-to-Noise Ratio(SNR)and contrast-to-noise ratio (CNR).Subjective image quality was assessed using a 4-point scale.

RESULTS

Low-dose CT with Infinity 70% reconstruction achieved comparable SNR to conventional-dose protocols ($P > 0.05$).The 16cm scan range exhibited superior CNR compared to 8cm ($P < 0.05$).Subjective scores confirmed diagnostic acceptability for low-dose + Infinity 70% (mean score = 3.5/4).

CONCLUSION

Low-dose combined with Infinity reconstruction reduces radiation dose while maintaining diagnostic quality; the 16cm helical coverage is more suitable for combined thoracoabdominal scanning

CLINICAL RELEVANCE/APPLICATION

1.Radiation Reduction: Low-dose protocols with deep learning reconstruction reduce patient exposure while preserving image quality.2.Scan RangeStandardization: A 16cm range ensures comprehensive anatomical coverage and higher CNR, critical for detecting thoracoabdominal emergencies. 3.Workflow Efficiency: This protocol streamlines emergency imaging workflows, reducing rescans and expediting diagnosis.

T5B-SPER-3 AI ENHANCED PROSPECTIVE ACUTE ABDOMEN LOW-DOSE CT: BALANCING IMAGING PROTOCOLS, RADIATION DOSE, IMAGE QUALITY, AND ACCURACY

Andreas Brendlin, MD, PhD (*Presenter*)
Ulrich Schmid (*Abstract Co-Author*)
Saif Afat, MD (*Abstract Co-Author*)

PURPOSE

To identify the optimal low-dose CT protocol that minimizes radiation exposure while preserving high image quality and diagnostic accuracy in patients presenting with acute abdomen.

METHODS AND MATERIALS

A prospective, randomized study was conducted with 180 patients assigned to one of three CT protocols. Each protocol included standard-dose (SD) and low-dose (LD) scans reconstructed using Iterative Reconstruction (IR2) and AI Denoising (AID). Subjective image quality was assessed by radiologists evaluating diagnostic confidence, contrast, and sharpness. Objective image quality metrics, including noise and contrast-to-noise ratio (CNR), were measured. Diagnostic accuracy was evaluated through sensitivity and specificity calculations for detecting abdominal pathologies.

RESULTS

Protocol 2 LD achieved the lowest Size-Specific Dose Estimate (SSDE) at 4.83 mGy, significantly reducing radiation dose compared to Protocols 1 and 3 ($P < 0.001$). AID significantly enhanced subjective image quality in LD scans across all protocols, with Protocols 2 and 3 achieving ratings comparable to HD scans with IR2. Objective assessments showed that AID substantially reduced image noise and increased CNR in LD scans, with Protocol 2 LD exhibiting the highest CNR. In outcome analysis, both Protocols 1 and 2 demonstrated 100% sensitivity and specificity in LD scans with AID, eliminating false negatives and matching the diagnostic performance of SD scans. Protocol 3 maintained high diagnostic accuracy across all doses and reconstruction methods.

CONCLUSION

Protocol 2 with AID emerges as the most effective low-dose CT strategy, offering significant radiation dose reduction while maintaining superior image quality and diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

- Substantial Dose Reduction in Prospective Setting.- HD-Quality Equivalent Imaging from LD Scans.- Diagnostic Reliability Maintained.

T5B-SPGI-1 COMPARING TEST-RETEST REPEATABILITY FOR PDFF ESTIMATION USING THREE ANALYSIS METHODS

Piper Mahn (*Presenter*)
Jacqueline Diep (*Abstract Co-Author*)
Jake Weeks, BS (*Abstract Co-Author*)
Lael Ceriani (*Abstract Co-Author*)
Tanya Wolfson, MS (*Abstract Co-Author*)
Diego Hernando, PhD (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)
Rohit Loomba, MD, MSc (*Abstract Co-Author*)
Michael S. Middleton, MD, PhD (*Abstract Co-Author*)
Claude B. Sirlin, MD (*Abstract Co-Author*)

PURPOSE

To compare test-retest repeatability of chemical-shift-encoded magnetic resonance imaging (CSE-MRI) for proton density fat fraction (PDFF) estimation using manual, automated segmentation-based, and human-corrected automated segmentation-based analysis in adults with known or suspected metabolic dysfunction-associated steatotic liver disease (MASLD).

METHODS AND MATERIALS

In this prospective, cross-sectional, single-center study, adults with known or suspected MASLD underwent abdominal 3T CSE-MRI (IDEAL-IQ, GE Healthcare) twice in a single imaging visit with complete repositioning between acquisitions. Each acquisition generated water and PDFF parametric images, which were analyzed three ways. First, regions of interest were manually placed in the nine Couinaud segments on water images and propagated to PDFF maps. Second, water images were segmented automatically using a convolutional neural network-based algorithm, and those masks were propagated to PDFF maps. Third, segmentations were corrected manually and propagated to PDFF maps. Researchers performing manual analyses and automated segmentation corrections were blinded to each other's results. Test-retest repeatability for PDFF estimation was assessed using absolute repeatability coefficient (RC), Bland-Altman (BA) bias, and intraclass correlation coefficient (ICC). 95% confidence intervals were computed for each metric. RC, ICC, and magnitude of bias were compared between methods pairwise using bootstrap-based tests. Bonferroni's correction was applied to each set of three tests.

RESULTS

Twenty-eight adults with MASLD were enrolled (11 women) with mean body mass index 35 kg/m 2 (SD 7 kg/m 2 , range 25 to 58 kg/m 2). Mean PDFFs were 11.7±7.1% for automated, 12.1±7.0% for human-corrected automated, and 11.6±7.3% for manual analyses. RC and ICC were better for automated (0.63, 0.999) and human-corrected automated (0.69, 0.999) than for manual analyses (1.18, 0.997) (all $p < 0.003$). BA biases between methods were small (-0.07% to 0.04%), not reaching statistical significance. Automated and human-corrected automated methods did not differ in any of their metrics (p from 0.46 to 0.80).

CONCLUSION

Automated segmentation-based analysis showed higher repeatability than manual analysis for PDFF estimation. Human correction of automated segmentations did not improve repeatability for PDFF estimation. Additional research is needed to generalize these results to PDFF acquisitions across other vendors, field strengths, and sample sizes.

CLINICAL RELEVANCE/APPLICATION

With further development and validation, automated segmentation-based PDFF analysis could replace manual analysis, the current clinical and research standard.

T5B-SPGI-5 THE IMPACT OF DEEP LEARNING IMAGE RECONSTRUCTIONON IMAGE QUALITY AND DIAGNOSTIC CONFIDENCE OF LIVER TUMORS AND INFERIOR VENA CAVA IN IN 40 KEV VIRTUAL MONOCHROMATIC IMAGING

Huang Caijun (*Presenter*)

PURPOSE

To investigate the effect of deep learning image reconstruction (DLIR) on the synchronous visualization of liver tumors and the inferior vena cava (IVC) in 40 keV virtual monochromatic images (VMIs).

METHODS AND MATERIALS

This prospective study enrolled 50 patients who underwent abdominal contrast-enhanced dual energy CT (DECT) imaging, 40 keV VMIs were obtained during the venous phase. Images were reconstructed with different algorithms: filtered back projection (FBP), adaptive statistical iterative reconstruction V (ASIR-V 60%), DLIR-M, and DLIR-H. Measurements included liver SD, lesion-background contrast-to-noise ratio (CNR), IVC SD, and IVC CNR. Two radiologists independently scored image quality, lesion conspicuity, IVC depiction, and diagnostic confidence using a 5-point Likert scale. Lesions were categorized as hypervascular or hypovascular based on blood supply for subgroup analysis. Noise equivalent dose (NED) and image quality index (IQF) were calculated considering image noise and radiation dose.

RESULTS

The smallest SDs of liver and IVC were observed in the DLIR-H group; there was no significant difference between ASIR-V 60% and DLIR-M, though both were lower than FBP. For liver lesion CNR, DLIR-H significantly outperformed ASIR-V 60% and FBP, while no significant difference was found between DLIR-M and ASIR-V 60%. Regarding IVC CNR, DLIR-High was the highest, followed by DLIR-M, then ASIR-V 60%, with FBP showing the lowest. In lesion conspicuity and diagnostic confidence assessments—for both hypovascular and hypervascular tumors—DLIR-H yielded superior scores compared to ASIR-V 60%. For IVC depiction and overall image quality, scores gradually decreased from DLIR-H to DLIR-M, then to ASIR-V 60%, and were lowest in FBP. The NED was lowest in the DLIR-H group, comparable between ASIR-V 60% and DLIR-M, both lower than FBP; conversely, the IQF showed an opposite trend.

CONCLUSION

40 keV VMIs with DLIR-H markedly enhances the visualization and diagnostic confidence of liver tumors and IVC, demonstrating the highest dose-to-image quality efficiency.

CLINICAL RELEVANCE/APPLICATION

The 40 keV VMIs combined with DLIR-H enhanced the visualization of tumors and the inferior vena cava, which may aid in the timely diagnosis and clinical decision-making regarding inferior vena cava thrombosis.

T5B-SPGI-6 DETERMINANTS OF PORTAL VENOUS FLOW IN AN OBESE COHORT

Luke Funk (*Abstract Co-Author*)
Oliver Wieben, PhD (*Abstract Co-Author*)
Claude B. Sirlin, MD (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)

PURPOSE

4D flow MRI can be used to assess the portal venous system. However, despite the importance of portal flow to the liver, its drivers are poorly understood. This knowledge gap limits interpreting flow changes in clinical and research settings. This study aims to identify portal flow determinants in patients with obesity undergoing weight loss surgery (WLS) and its association with clinical/imaging biomarkers of liver and metabolic health.

METHODS AND MATERIALS

This IRB-approved study enrolled patients (BMI > 35 kg/m²) undergoing WLS at 2 academic centers. Subjects had 12-hr fasting visits before a pre-surgical diet, 1-2 days pre-surgery, and 12, 26, 52 wks post-surgery. At each visit, height and weight were measured and MRI (3.0T) was performed. A radial 4D flow acquisition was obtained. Two readers measured flow in proximal, middle and distal portal vein cross-sections and calculated mean flow from these planes. Proton density fat-fraction was measured via chemical shift encoded MRI. Liver stiffness was measured via 2D MRE at 60Hz. Corrected T1 (cT1, inflammation marker) was measured with commercial software (Perspectum Diagnostics, Oxford, UK). Liver volumes were calculated via a machine learning segmentation algorithm, adjusted manually by a radiologist. Spearman's ? was calculated between portal flow and measured variables, pooling data from all visits.

RESULTS

105 subjects (90 women; 44 ± 10 years) were enrolled. BMI decreased from 46 ± 7 to 35 ± 7 kg/m 2 1 yr after surgery. 375/413 of exams were included (35 excluded for poor image quality, 3 reconstruction failures). Mean portal flow correlated strongly and positively with liver volume (? = 0.49) and height (? = 0.39). It correlated weakly with weight (? = 0.32), BMI (? = 0.21) and stiffness (? = 0.13). It did not correlate with other markers.

CONCLUSION

Portal flow in patients with obesity is largely governed by structural, not inflammatory, factors. Liver volume shows the strongest correlation, consistent with greater perfusion needed for larger parenchyma. Height also strongly correlates, likely reflecting metabolic scaling with taller stature and thus larger livers. Weight and BMI show weak links, indicating adiposity alone does not proportionally increase portal flow once body size is addressed. Notably, portal flow was not meaningfully affected by liver fat, stiffness, or cT1, suggesting portal hemodynamics are insensitive to hepatic steatosis, low-grade inflammation or fibrosis.

CLINICAL RELEVANCE/APPLICATION

Portal flow scales mainly with liver size and patient height, not BMI or markers of steatohepatitis. Normalizing 4D flow MRI values to liver volume and height may improve patient-specific interpretation and support consistent reporting as clinical adoption of this technique expands.

T5B-SPGI-7 USE OF DARK ATTENUATION ORAL CONTRAST AGENT IMPROVES DELINEATION OF THIN STRUCTURES AT ULTRA-HIGH RESOLUTION AND PHOTON-COUNTING DETECTOR CT

Yuxin Sun, BS, MSc (*Presenter*)
Theresia Aschauer, MD (*Abstract Co-Author*)
Maurice Heimer, MD (*Abstract Co-Author*)
Marisa Martin, MD (*Abstract Co-Author*)
Leo Jia, MD (*Abstract Co-Author*)
Shobhit Sharma, PhD (*Abstract Co-Author*)
Steven Ross, PhD (*Abstract Co-Author*)
Andrew M. Hernandez, PhD (*Abstract Co-Author*)
Zhou Yu, PhD (*Abstract Co-Author*)
Benjamin M. Yeh, MD (*Abstract Co-Author*)

PURPOSE

To assess experimental dark borosilicate contrast material (DBCM) and conventional contrast agents for the delineation of thin structures in a line pair phantom using an EID (energy integrating detector) ultra-high resolution (UHR) and prototype photon-counting detector CT (PCD-CT) scanners.

METHODS AND MATERIALS

A line pair phantom with 11 groups of 4 alternating acrylic bars (120 HU at 120 kV) and 5 slits of equal width with increasing frequency (0.75 to 9.0 lp/cm) was serially filled with 4 different contrast agents (Air: -1000 HU, DBCM: -160 HU, Water: 0 HU, Iodine: 240 HU) and scanned in a body-sized phantom on a UHR EID-CT (Canon Aquilion Precision) and a Canon prototype PCD-CT scanner. Similar acquisition and reconstruction parameters (512 / 1024 matrix, 400 / 200 mm FOV, soft / sharp kernel) were used on both scanners. Four radiologist readers ranked images using a standard abdominal window (W/L=400/40) from best to worst delineation of the acrylic bars, with four consecutive slices randomized from each dataset. Mean rank scores were compared between contrast agents and scan parameters by Friedman's and Wilcoxon signed rank tests.

RESULTS

Mean bar delineation rank scores for DBCM were better than for Air, Water, or Iodine for a 512 matrix with soft kernel at both EID-CT and PCD-CT reconstructions (4.5 ± 2.3 vs. 20.9 ± 8.5, 15.1 ± 3.5, 25.5 ± 2.9, respectively, p<.001 for all). Similarly, DBCM outperformed conventional agents at 1024 matrix with both kernels and both scanners, p<.001 for all. Readers could resolve down to 7.0 LP/cm with DBCM -160, compared to 6.0 (Air), 4.5 (Water), and 3.0 (Iodine 240) LP/cm. Overall, less favorable rank scores were seen with EID-CT, with trend of improved performance at PCD-CT. Pooled data showed significant improvement in mean rank scores with PCD-CT vs. EID-CT (14.4 ± 8.7 vs. 18.0 ± 9.2, p<.001), and sharp vs. soft kernels (15.3 ± 10.1 vs. 17.7 ± 8.3, p<.001) but not for FOV or matrix size.

CONCLUSION

DBCM -160 HU demonstrated the best performance for delineation of bowel fold detail compared to air, neutral, or positive oral agents, regardless of scan resolution, matrix size, or kernel, with further significant improvements seen when used in conjunction with PCD-CT compared to EID-CT.

CLINICAL RELEVANCE/APPLICATION

Oral contrast profoundly affects visualization of thin structures such as bowel folds at abdominal CT, with moderately dark agents outperforming other agents, warranting clinical testing.

T5B-SPGI-8 EVALUATING MRI MULTI-ORGAN SEGMENTATION TOOLS FOR PANCREAS SEGMENTATION IN T1-WEIGHTED MRI

Yan Zhuang, PhD, MS (*Presenter*)
Vivek Yadav, MS, BEng (*Abstract Co-Author*)
Hayit Greenspan (*Abstract Co-Author*)
Neil M. Rofsky, MD (*Abstract Co-Author*)

PURPOSE

Automated segmentation is crucial for quantitative MRI studies of the pancreas, such as correlating imaging-based biomarkers with different disease states. TotalSegmentator MRI (TS-MRI) and MRISegmenter (MRISeg) have recently been developed and are publicly available AI tools. Since an external validation of their performance has not yet been quantified extensively, this study aims to externally evaluate TS-MRI and MRISeg on a multi-center MRI T1-weighted dataset using the subgroup analysis.

METHODS AND MATERIALS

Using the publicly available PanSegData dataset we accessed 385 T1-weighted MRI scans, each from a unique patient. Scans lacking age, gender, and center information were excluded, resulting in 360 scans available for this retrospective external evaluation. Pancreas segmentation masks predicted with TS-MRI and MRISeg were compared against the radiologist-certified reference standard using Dice score (DSC). DSCs were statistically compared across different genders, ages, and scanner subgroups within each model with a p-value < 0.05 considered statistically significant. Additionally, high-dimensional features were extracted from the bottleneck layer of TS-MRI and MRISeg. These features were projected into a 2-dimensional latent space using principal component analysis (PCA) to reveal the marginal distribution difference for different subgroups.

RESULTS

The mean± std DSC (%) for MRISeg was 0.767+/-0.100, and for TS-MR was 0.684+/-0.150, respectively. MRISeg significantly outperformed TS-MRI using a paired Student's t-test (P<0.001). Within TS-MRI, significant performance differences were only observed comparing gender (P = 0.0012) and age (P = 0.0395) subgroups using Welch's Two Sample t-tests. Similarly, MRISeg's performance significantly differed across genders (P = 0.0015), age (P = 0.0188), and scanner (P = 0.0270) subgroups.

CONCLUSION

Two publicly available MRI multi-organ segmentation tools were externally benchmarked for the pancreas segmentation task with reasonable segmentation performance. Both tools showed heterogeneous performance across different patient subgroups.

CLINICAL RELEVANCE/APPLICATION

Data collected across different clinical settings can contain variations in patient cohorts and data acquisition procedures. This can contribute to performance disparities in publicly available AI segmentation tools. To ensure unbiased and trustworthy deployment of these AI models, conducting subgroup analyses is a critical step for validating model performance and identifying potential risks.

T5B-SPGI-11 TEMPORAL CHANGES IN ABLATED LIVER VOLUME AFTER RADIOFREQUENCY ABLATION EVALUATED BY THREE-DIMENSIONAL VOLUMETRIC COMPUTED TOMOGRAPHY: ASSOCIATION WITH LIVER FUNCTION AND LIVER FIBROSIS

Mayumi Higashi, MD, PhD (*Presenter*)
Masahiro Tanabe, MD (*Abstract Co-Author*)
Katsuyoshi Ito, MD (*Abstract Co-Author*)

PURPOSE

In follow-up CT after radiofrequency ablation (RFA) for hepatocellular carcinoma (HCC), some cases show a significant reduction in low-density areas after ablation, while others do not. This study evaluated the association between the degree of shrinkage of the ablated liver area over time after RFA and clinical parameters including laboratory data related to liver function and liver fibrosis.

METHODS AND MATERIALS

Patients with HCC who underwent RFA and follow-up abdominal contrast-enhanced multiphasic dynamic CT were included. Three-dimensional (3D) volumetric CT measurements of the ablated area in the liver were performed on portal-phase images. Based on the volume of the ablated area (AAV) on CT images obtained within 1 week and around 6 months after RFA, the reduction rate of AAV was calculated. The reduction rate of AAV was compared among the categories of Child-Pugh classification, modified albumin-bilirubin (mALBI) grade, FIB-4 index, and lesion location using two sample t -test and one-way analysis of variance. Simple linear regression and multiple regression analyses were conducted to assess the correlation between the reduction rate of AAV and clinical data.

RESULTS

Fifty-three lesions in 41 patients were evaluated. The reduction rate of AAV in Child-Pugh B group was significantly lower than in Child-Pugh A group (58.9 ± 7.9% vs. 70.9 ± 12.6%, p < 0.001). The reduction rate of AAV in mALBI grade 2b group (58.9 ± 9.9%) was significantly lower than in grade 1 (76.3 ± 8.7%) and grade 2a (72.2 ± 10.4%) groups (p < 0.001 and p = 0.008, respectively). In addition, the reduction rate of AAV was significantly different among the three FIB-4 index range groups (FIB-4 < 1.3, 81.8 ± 12.0%; 1.3 to = 2.67, 70.6 ± 11.6%; and > 2.67, 64.8 ± 12.3%; p = 0.040). Moreover, the reduction rate of AAV in medial and anterior segments was significantly lower than in lateral segment (62.8 ± 12.2% vs. 73.9 ± 12.4%, p = 0.037). The simple linear regression analysis showed that the reduction rate of AAV was significantly correlated with aspartate aminotransferase (AST), cholinesterase, albumin, total bilirubin (T-Bil), prothrombin time, platelet count, and FIB-4 index (p < 0.05). Then, the multiple regression analysis showed that albumin was most strongly associated with the reduction rate of AAV (p < 0.001), followed by T-Bil (p = 0.008).

CONCLUSION

The reduction rate of AAV tended to be decreased in patients with impaired liver function and significant liver fibrosis. The shrinkage of the liver area over time after ablation is suggested to be due to maintained liver regenerative reserve.

CLINICAL RELEVANCE/APPLICATION

Liver regeneration after ablation therapy can be expected in patients with preserved liver function, and can be assessed by the follow-up 3D volumetric CT.

T5B-SPGI-12 ENHANCED LARGE LANGUAGE MODEL FOR AUTOMATED EXTRACTION AND CLASSIFICATION OF LIVER OBSERVATIONS FROM UNSTRUCTURED AND STRUCTURED RADIOLOGY REPORTS

Allison Dortilus, BA (*Presenter*)
Nick Xing (*Abstract Co-Author*)
Kang Wang, MD,PhD (*Abstract Co-Author*)
Yang Yang, PhD (*Abstract Co-Author*)
Michael A. Ohliger, MD, PhD (*Abstract Co-Author*)

PURPOSE

We investigated whether a privacy-preserving large language model could be used for automated extraction and categorization of liver observations following the Liver Imaging Reporting and Data System (LI-RADS) system for CT and MRI. Further categorization capabilities were explored through the use of Retrieval-Augmented Generation (RAG), which enhances categorization through external information sources, such as the LI-RADS® v2018 CT/MRI Core document.

METHODS AND MATERIALS

321 abdominal CT and MRI radiology reports containing LI-RADS liver observations dated between 3/29/2024-7/10/2024 were retrospectively gathered. A subset of 100 reports was selected for detailed analysis. Patient privacy was maintained using a secure HIPAA-compliant institutional instance of GPT 4-o. Major LI-RADS characteristics were extracted by the LLM: size, location, imaging characteristics, and LI-RADS category. The ground truth was established by a medical student with the guidance of an abdominal radiologist. Accuracy was assessed per report, requiring complete correctness of extracted information. For RAG analysis, we used LI-RADS censored reports. LLM then classified liver observations using characteristics, with the assistance of RAG, following LI-RADS guidelines, with or without the assistance of the LI-RADS document.

RESULTS

The study included 100 reports (CT vs MRI: 50/50; unstructured vs. structured reports: 73/27). In total, 222 liver observations were collected. ChatGPT accurately extracted liver observations from 92% of the reports. Errors in the remaining 8 reports were due to omitted lesions, inaccurate notation of major LI-RADS characteristics, and inaccurate LI-RADS scores. After report censoring, the LLM with RAG accurately classified 73% of liver observations following LI-RADS. Incorporation of the LI-RADS document with RAG improved accuracy to 84%.

CONCLUSION

ChatGPT exhibits high accuracy in extracting major LI-RADS characteristics from unstructured and structured reports. Additionally, it shows capability in categorizing liver observations following LI-RADS guidelines. This result is amplified with the addition of RAG. Further enhancement could allow for large databases for longitudinal tracking of liver observations and LI-RADS classification.

CLINICAL RELEVANCE/APPLICATION

In the future, LLMs can be utilized to generate multi-institutional LI-RADS databases for longitudinal surveillance of patients.

T5B-SPGI-13 ASSESSMENT OF CONTRAST ENHANCEMENT BOOSTING TECHNIQUES IN LOW-CONCENTRATION ABDOMINAL CT: VENDOR-AGNOSTIC VERSUS VENDOR-SPECIFIC APPROACHES

Chuluunbaatar Otgonbaatar, MD (*Presenter*)
SUE YON SHIM (*Abstract Co-Author*)
JEON SANG HYUN (*Abstract Co-Author*)
Sung-Jin Cha, BS (*Abstract Co-Author*)
Hackjoon Shim, PhD (*Abstract Co-Author*)
Jhii-Hyun Ahn (*Abstract Co-Author*)

PURPOSE

This study aimed to compare the quantitative and qualitative image quality between vendor-agnostic and vendor-specific contrast-enhanced (CE) boosting techniques in low-concentration contrast media settings, relative to standard-dose contrast media.

METHODS AND MATERIALS

A retrospective analysis was conducted on 80 patients (mean age, 64 ± 10 years; range, 34-85 years; 61 men). Two iodinated contrast concentrations were compared: 350 mg I/mL (standard-dose) and 270 mg I/mL (low-concentration). Both vendor-agnostic and vendor-specific CE-boost methods were applied to the low-concentration contrast group. Quantitative image quality metrics—including image noise, CT attenuation, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), noise power spectrum (NPS), and image sharpness—were evaluated. Additionally, qualitative image quality was assessed using a Likert scale by two independent radiologists.

RESULTS

Both the vendor-agnostic and vendor-specific boosting methods significantly ($p < 0.001$) reduced image noise and improved CT attenuation, SNR, and CNR in both vessels and liver lesions within the low-dose group, compared to the standard-dose group. The vendor-specific method was more effective at suppressing high-frequency noise, whereas the vendor-agnostic boost yielded sharper images. Subjective image analysis revealed no significant differences in vessel enhancement between either boosting method and the standard-dose contrast media group.

CONCLUSION

Both vendor-agnostic and vendor-specific CE-boost methods effectively enhance image quality and CT attenuation in low-concentration contrast media. The vendor-agnostic method demonstrated superior image sharpness, while the vendor-specific method was more efficient at reducing structured noise, presenting viable alternatives to reduce contrast dose and minimize the risk of nephropathy.

CLINICAL RELEVANCE/APPLICATION

Both boosting methods showed comparable efficacy in enhancing vessel and liver lesion conspicuity, though the vendor-specific boost method exhibited slightly superior image noise suppression and lower artificial sensation. The use of low-concentration contrast media can significantly reduce the risk of adverse events associated with high-dose contrast administration, such as nephropathy, especially in vulnerable populations.

T5B-SPGI-14 NOMOGRAM FOR PREDICTING POSTOPERATIVE COMPLICATIONS IN COLORECTAL CANCER FOLLOWING NEOADJUVANT TREATMENT USING CT HISTOGRAM AND BODY COMPOSITION ANALYSIS

Ting LU (*Presenter*)

PURPOSE

To assess the predictive value of CT-derived histogram features and body composition parameters for postoperative complications (POCs) in colorectal cancer (CRC) patients after neoadjuvant treatment (NAT), and to establish a nomogram for individualized risk stratification.

METHODS AND MATERIALS

This retrospective study included CRC patients who underwent NAT and subsequent surgery between January 2016 and December 2024. CT histogram parameters in the venous phase and body composition parameters at Pre- and Post-NAT stages were extracted using FireVoxel and SliceOmatic software. Parameters included tumor volume, mean, entropy, kurtosis, visceral fat area (VFA), visceral adipose index (VAI), intramuscular fat area (IMFA), and skeletal muscle index (SMI). Delta values (?) were calculated to reflect treatment-induced changes. Logistic regression with forward stepwise selection identified independent predictors of POCs. A multiparameter prediction model (Model_COMB) was built and visualized as a nomogram. Model performance was evaluated by area under the ROC curve (AUC), sensitivity, and specificity, with comparison to individual predictors using the DeLong test. Model calibration and clinical benefit were assessed by calibration curves and decision curve analysis (DCA).

RESULTS

Among 133 eligible patients, 42 (31.58%) developed grade = II POCs (Clavien-Dindo classification). Logistic regression analysis identified six independent predictors of POCs: dyslipidemia (OR = 4.34, P = 0.011), combined organ resection (OR = 10.79, P = 0.047), post-NAT tumor kurtosis (OR = 1.014, P = 0.015), ?tumor volume (OR = 1.008, P = 0.035), Post-IMFA (OR = 0.860, P = 0.012), and post-VAI (OR = 1.043, P < 0.001). The combined model (Model_COMB) demonstrated superior diagnostic performance with an AUC of 0.805 (95% CI: 0.724-0.887), sensitivity of 69.0%, and specificity of 82.4%, significantly outperforming any individual predictor (P < 0.05). Calibration plots showed good agreement between predicted and observed outcomes, and DCA confirmed improved net clinical benefit.

CONCLUSION

CT histogram and body composition metrics provide complementary value in predicting POCs in CRC patients after NAT. The proposed nomogram enables early identification of high-risk individuals, supporting proactive perioperative management and personalized care strategies.

CLINICAL RELEVANCE/APPLICATION

This integrated imaging-based model offers a noninvasive, quantitative approach to postoperative risk assessment in CRC, potentially guiding treatment planning and improving surgical outcomes in CRC patients undergoing NAT.

T5B-SPGI-15 SPLIT-BOLUS INJECTION PROTOCOL IN PHOTON-COUNTING DETECTOR CT OF THE UPPER ABDOMEN: IMPROVED IMAGE QUALITY COMPARED TO CONVENTIONAL INJECTION PROTOCOL IN ENERGY-INTEGRATING DETECTOR CT

Kentaro Nishiuchi (*Presenter*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Kazuki Ishikawa (*Abstract Co-Author*)
Noriyuki Negi, RT (*Abstract Co-Author*)
Takeru Yamaguchi, MD, PhD (*Abstract Co-Author*)
Eisuke Ueshima (*Abstract Co-Author*)
Yoshiko Ueno, MD, PhD (*Abstract Co-Author*)
Takahiro Tsuboyama, MD (*Abstract Co-Author*)
Izumi Imaoka, MD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

PURPOSE

Split-bolus injection protocol involves multiple contrast injections followed by a single scan, allowing the combined-phase images in a single acquisition. Photon-counting detector CT (PCD-CT) offers improved X-ray detection sensitivity expected to enhance iodine contrast compared with energy-integrating detector CT (EID-CT). This study aimed to evaluate whether split-bolus injection protocol in PCD-CT improves contrast enhancement of the upper abdomen without increasing the amount of contrast agent compared with conventional injection protocol in EID-CT.

METHODS AND MATERIALS

This retrospective study included 42 postoperative patients with pancreatobiliary disease (23 men; mean age, 73.5 years) who underwent both PCD-CT (NAEOTOM Alpha) with split-bolus injection and EID-CT with conventional injection (mean interval, 163 days). The split-bolus injection protocol was optimized using a physiology-based contrast enhancement simulation software. Total amount of contrast agent (450mgI/kg) and acquisition timing (80 s after injection) were identical between the two protocols. Image noise of the paraspinal muscle, CT values and signal-to-noise ratio (SNR) of aorta (Ao), portal vein (PV), superior mesenteric vein (SMV), liver and pancreas were measured at 70 keV and 60 keV for PCD-CT and at 120 kVp for EID-CT. Contrast-to-noise ratios (CNRs) were calculated for liver-to-lesion, and perivascular tissue-to-Ao and -PV. Qualitative image quality was assessed using a 5-point Likert scale for overall image quality, image noise, soft tissue contrast, and vessel contrast. Quantitative and qualitative results were compared between PCD-CT and EID-CT.

RESULTS

CTDI vol and DLP were comparable between PCD-CT and EID-CT. Image noise was significantly lower in PCD-CT at 70 keV (P <.001). At 70 keV, CT values of Ao, PV, and pancreas (P <.001-.047) and SNRs of all objects (P<.001-.038) were significantly higher. At 60 keV, all CT values and SNRs were significantly higher in PCD-CT (P <.001 for all). CNRs of perivascular tissue-to-Ao and -PV were significantly higher in PCD-CT at both 70 keV and 60 keV (P=<.001-.048). No significant difference in liver-to-lesion CNR was observed (P=.076-.145). Qualitative scores were significantly better for all items at 70 keV and 60 keV (P<.01 for all), except for image noise at 60 keV (P=.553).

CONCLUSION

Split-bolus injection protocol in PCD-CT improved contrast enhancement of the upper abdomen without increasing the amount of contrast agent compared with conventional injection protocol in EID-CT.

CLINICAL RELEVANCE/APPLICATION

Split-bolus injection in PCD-CT may serve as an optimal strategy for follow-up imaging to evaluate recurrence and metastasis in postoperative patients with pancreatobiliary diseases.

T5B-SPGI-16 PREOPERATIVE T STAGING OF COLON CANCER USING CT COLONOGRAPHY WITH SEPARATE EVALUATION OF THE MESENTERIC AND ANTIMESENTERIC SIDES

YUTO TANNO (*Presenter*)
Mototaka Miyake, MD, PhD (*Abstract Co-Author*)

PURPOSE

Accurate preoperative T staging is essential for determining the appropriate treatment strategy for colorectal cancer, including surgical procedure and the need for preoperative treatment. However, distinguishing between T2, T3, and T4 stages preoperatively remains challenging. We routinely perform preoperative imaging evaluations using computed tomographic colonography (CTC). Considering that the colon wall comprises two anatomical environments-the mesenteric and antimesenteric sides-we hypothesized that applying different methods for each side could improve the accuracy of depth evaluation.

METHODS AND MATERIALS

Patients with colon cancer who underwent preoperative CTC and surgery between July 2015 and December 2021 were enrolled in this study. Patients with retroperitoneal tumors, those who received preoperative treatment, and those with Tis lesions or a history of post-endoscopic resection were excluded. A total of 681 cases of colon cancer located from the cecum to the sigmoid colon were included. The CTC images were independently interpreted by a radiologist and a colorectal surgeon. In cases of discordance, a consensus diagnosis was reached through discussion, and then compared with the corresponding pathological findings.

RESULTS

Tumor locations: cecum (10.6%),ascending colon (25.1%),transverse colon (14.2%),descending colon (6.2%),sigmoid colon (43.9%). Tumors were on the mesenteric side in 67% and on the antimesenteric side in 33%. Gross classifications: type 0 (17%),type 1 (6.3%),type 2 (72.8%),type 3 (3.1%),type 5 (0.7%). The median interval between CTC and surgery was 29 days (IQR 21-42). Pathological T stages: pTis (0.9%),pT1 (13.1%),pT2 (19.2%),pT3 (55.4%),pT4a (9.5%),pT4b (1.9%). T staging accuracy for both sides were 87.1% for Tis-T2, 80.2% for T3, and 90.6% for T4a. On the mesenteric side, the accuracy were 87.7% for Tis-T2, 81.4% for T3, and 93.2% for T4a. On the antimesenteric side, the accuracy were 87.7% for Tis-T2, 81.4% for T3, and 84.9% for T4a. The overall right answer rate were 78.6% for both sides, 80.9% on the mesenteric side, and 73.8% on the antimesenteric side. Notably, the negative predictive value(NPV) for pT4a was 95.7% on the mesenteric side and 92.3% on the antimesenteric side.

CONCLUSION

Separate evaluation of the mesenteric and antimesenteric sides using CTC enables accurate preoperative T staging in colon cancer, with the high NPV for T4a.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that CTC achieves high diagnostic accuracy by independently evaluating the mesenteric and antimesenteric sides of the colon wall. Notably, the high NPV for T4a suggests that CTC can reliably rule out serosal invasion, thereby helping to avoid unnecessary aggressive interventions.

T5B-SPGI-17 PREDICTION OF CHEMOTHERAPY RESPONSE IN PANCREATIC DUCTAL ADENOCARCINOMA USING RADIOMICS OF IODINE-BASED MATERIAL DECOMPOSITION IMAGES: A PROSPECTIVE MULTICENTER STUDY

Kazuo Awai, MD (*Abstract Co-Author*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)
Masayuki Matsuo, MD (*Abstract Co-Author*)

PURPOSE

To evaluate whether radiomic features of pancreatic phase iodine-based material decomposition (MD) images derived from dual-energy CT can predict chemotherapy response in pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

In this prospective multicenter study, we analyzed 71 participants (median age, 72 years; 39 men) with untreated, histologically confirmed PDAC who underwent pre-treatment pancreatic protocol dual-energy CT and subsequent systemic chemotherapy between January 2019 and November 2022 from four institutions. Iodine-based MD images at pancreatic phase were reconstructed with vendor-provided MD algorithms. Manual 3D tumor segmentation was performed by two radiologists using ITK-SNAP software. Texture analyses and machine learning modeling were conducted at another institution, where didn't provide case data, blinded to clinical data and treatment outcomes. In total, 1,196 features consisted of 247 first-order features and 949 second-order features were input into the prediction model of chemotherapy response using PyRadiomics. After outlier removal (±2 SD), correlation filtering ($r > 0.95$), and normalization, a random forest classifier was trained with an 8:2 train-test split and stratified 5-fold cross-validation. Hyperparameter tuning was performed using Optuna. Feature importance was assessed using Shapley additive explanations (SHAP). Interobserver reproducibility was evaluated using the Dice similarity coefficient.

RESULTS

Based on RECIST version 1.1, 25 participants were classified as responders (CR + PR) and 46 as non-responders (SD + PD). The prediction model of chemotherapy response achieved an area under the curve of 0.840 (95% confidence interval [CI]: 0.630-1.000), accuracy of 0.733 (95% CI: 0.480-0.891), sensitivity of 0.800, specificity of 0.700, positive predictive value of 0.571, and negative predictive value of 0.875. The most influential SHAP features included Gray Level Dependence Matrix (GLDM) Dependence Non-Uniformity Normalized (LoG sigma, 3mm, 3D) and GLDM Dependence Variance (original), indicating tumor heterogeneity as a key predictive factor. Interobserver reproducibility of segmentation was high, with a mean Dice coefficient of 0.927.

CONCLUSION

Radiomics of pancreatic phase iodine-based MD images from pre-treatment dual-energy CT accurately predicted subsequent chemotherapy response in PDAC and may help guide early treatment decisions.

CLINICAL RELEVANCE/APPLICATION

This non-invasive and accessible imaging-based approach may aid in early stratification of patients with PDAC undergoing systemic chemotherapy.

T5B-SPGU-1 REALITY CHECK FOR RADIOMICS: READER-DERIVED PROSTATE CANCER FEATURES DIVERGE FROM HISTOPATHOLOGY-REGISTERED GROUND TRUTH

Omer Esengur, MD (*Presenter*)
Stephanie A. Harmon, PhD (*Abstract Co-Author*)
David Gelikman (*Abstract Co-Author*)
Enis Yilmaz, MD (*Abstract Co-Author*)
Hunter Stecko (*Abstract Co-Author*)
Emma Stevenson (*Abstract Co-Author*)
Sandeep Gurram (*Abstract Co-Author*)
Bradford J. Wood, MD (*Abstract Co-Author*)
Peter Pinto (*Abstract Co-Author*)
Peter L. Choyke, MD (*Abstract Co-Author*)
Baris Turkbey, MD (*Abstract Co-Author*)

PURPOSE

To evaluate whether radiomics features derived from radiologist-annotated prostate lesions align with ground truth labels registered from whole-mount radical prostatectomy (RP) histopathology.

METHODS AND MATERIALS

This retrospective study included patients who underwent biparametric MRI between 2013 and 2022 (n = 180; 120 cases, 60 controls). All cases underwent subsequent RP. Six radiologists independently annotated lesion diameters across 120 scans (80 cases, 40 controls), with each scan reviewed by four readers. Circular segmentations were generated from the diameters in both non-expanded (single slice) and expanded (±1 slice) forms using a separate algorithm. Additionally, a single expert genitourinary (GU) radiologist manually segmented the cases prospectively. Whole-mount RP specimens were processed using patient-specific molds, and lesions were mapped and graded by an expert GU pathologist. A deep learning-based registration pipeline (ProsRegNet) was used to align cancer labels accurately onto MRI. Radiomics features (n=321) were extracted with PyRadiomics from both reader-derived and pathology-matched lesion segmentations following preprocessing (z-score normalization, low-variance feature removal, and Pearson correlation filtering). Uniform manifold approximation and projection (UMAP) was used to visualize feature distributions. Euclidean distances in UMAP space and Spearman correlations were calculated between pathology and each alternate segmentation source.

RESULTS

Pathology-based lesions formed distinct clusters. Expert manual contours showed closer proximity to pathology distributions; diameter-based contours showed broader variability. Expansion slightly improved clustering but did not improve alignment ($p = .65$). Expert manual contours were significantly closer to pathology than either expanded or non-expanded reader segmentations (both $p < .0001$). However, only 3 features from expert contours showed strong correlation with pathology (? = .6), while diameter-based contours had none. Texture and shape features showed poor reproducibility across all sources.

CONCLUSION

Radiomics features derived from radiologist-drawn diameters diverge substantially from pathology-aligned ground truth. Even expert manual contours, despite better global alignment, demonstrated limited feature-level reproducibility. These findings call for a redefinition of validation practices in radiomics, emphasizing pathology-anchored ground truth in study design.

CLINICAL RELEVANCE/APPLICATION

Radiomics research methodology must be rethought through the lens of histopathology-registered ground truth, as even expert-drawn contours fail to reproduce pathology-aligned features consistently.

T5B-SPGU-2 PROSTATE CANCER GROWTH KINETICS ON SERIAL MRI: VOLUME DOUBLING TIME AND PROGRESSION DURING ACTIVE SURVEILLANCE

Jeong Min Song, MD (*Presenter*)
Kye Jin Park, MD, PhD (*Abstract Co-Author*)
Mi Yeon Park, MD (*Abstract Co-Author*)
Sung Bin Park, MD, PhD (*Abstract Co-Author*)
Mi-Hyun Kim (*Abstract Co-Author*)
Jeong Kon Kim, MD (*Abstract Co-Author*)

PURPOSE

Understanding the volume doubling time (VDT) and growth kinetics of prostate cancer (PCa) is crucial for differentiating aggressive from indolent tumors and determining optimal MRI intervals. This study aimed to evaluate the growth kinetics and VDT of PCa using serial MRI scans and to assess time to radiologic progression using the Prostate Cancer Radiological Estimation of Change in Sequential Evaluation (PRECISE) criteria.

METHODS AND MATERIALS

Patients undergoing active surveillance (AS) or watchful waiting for prostate cancer who had at least two consecutive prostate MRI examinations prior to radical treatment between April 2016 and February 2022 were retrospectively analyzed. Three-dimensional tumor volumes were segmented on T2-weighted MRI images with reference to diffusion-weighted imaging and dynamic contrast-enhanced imaging to calculate VDT. VDT and prostate-specific antigen doubling time (PSADT) were compared across Gleason grade (GG) groups. Radiologic progression was defined as PRECISE scores of 4 or 5 on sequential MRIs. Kaplan-Meier analysis and log-rank tests were used to compare the time to radiologic progression between rapidly growing (VDT <1 year) and slowly growing tumors (VDT =1 year).

RESULTS

A total of 88 patients (mean age, 67.9 years; mean PSA, 6.4 ng/mL) with 287 prostate MRIs were evaluated. VDT and PSADT exhibited considerable variability within Gleason grade groups, with overall median values of 542 days (IQR, 284-1537) and 715 days (IQR, -336-1984), respectively. VDT showed significantly less variability compared to PSADT (P < .001). High-grade PCa (GG 4-5) demonstrated significantly shorter median VDT (293 days) compared to GG 1 (601 days) and GG 2-3 (568 days). Radiologic progression occurred in 50% of patients, with a median time to progression of 798 days. Patients with VDT <1 year exhibited significantly faster radiologic progression (median, 455 days) compared to those with VDT >1 year (P = .001), whereas PSADT was not significantly associated with radiologic progression (P = .066).

CONCLUSION

Tumor VDT exhibited substantial heterogeneity even among tumors within the same Gleason grade groups; however, it demonstrated less variability than PSADT and tended to be shorter in higher-grade tumors. Serial MRI-derived VDT may serve as a useful indicator to differentiate rapidly growing from indolent tumors in PCa.

CLINICAL RELEVANCE/APPLICATION

Prostate cancer demonstrates diverse growth kinetics, ranging from indolent to relatively rapidly growing tumors, and such behaviors can be effectively captured through serial MRI. Understanding tumor growth kinetics can inform optimal MRI scan intervals and treatment decisions, enabling individualized management and surveillance strategies.

T5B-SPGU-4 CT LYMPHANGIOGRAPHY AND MRTD FINDINGS OF CHYLOUS LEAKAGE IN THE REPRODUCTIVE SYSTEM

Jixue Feng (*Presenter*)
Rengui Wang, MD (*Abstract Co-Author*)

PURPOSE

To investigate computed tomography lymphangiography (CTL) and magnetic resonance thoraic ductography (MRTD)in patients with chylous leakage in the reproductive system.

METHODS AND MATERIALS

A total of 49 patients with genital chylous leakage without obvious causes were retrospectively collected, including vaginal chylous leakage (11 cases) and perineal chylous leakage (38 cases). The clinical manifestations were vaginal milky fluid overflow, perineal vesicles with rupture, perineal swelling with exudation. All patients underwent CT and MRTD examination of chest, abdomen and pelvis after direct lymphangiography (DLG). The imaging manifestations were analyzed. Analysis of abnormal deposition and distribution of CTL lipiodol: ? Neck: end of thoracic duct and right lymphatic duct; ? Chest: hilum and mediastinum; ? Abdomen: lumbar trunk, renal region, mesentery; ? Pelvic: whether to the contralateral reflux, reflux path, scrotum or labia, perirectal, periuterine, perivesical, iliac trunk. The imaging findings of pelvic lymphatic malformations were classified into dilated type, cystic type, swollen type and mixed type. The constituent ratio of categorical variable data was used for statistical description.

RESULTS

CTL of 49 patients showed abnormal deposition of lipiodol in different sites: ? Neck: the end of thoracic duct in 23 cases (46.9%), the end of right lymphatic duct in 9 cases (18.4%). ? Chest: hilar 9 cases (18.4%), mediastinum 16 cases (32.7%); ? Abdominal: lumbar trunk 47 cases (95.9%), renal region 16 cases (32.7%), mesentery 24 cases (49.0%). ? Pelvic: 43 cases (87.8%). Reflux path: The anterior approach was used in 37 cases (75.5%), pelvic cavity in 30 cases (61.2%), pelvic floor in 11 cases (22.4%), posterior approach in 21 cases (42.9%), scrotum or labia in 42 cases (85.7%), perirectal in 19 cases (38.8%), periuterine in 15 cases (30.6%), perivesical in 17 cases (34.7%) and iliac trunk in 48 cases (98.0) %). The imaging findings of 49 patients with pelvic lymphatic malformations were classified as dilated type in 25 cases (51.0%), cystic type in 1 case (2.0%), swollen type in 4 cases (8.2%), and mixed type in 19 cases (38.8%).

CONCLUSION

Chylous leakage in the reproductive system is a systemic lymphatic disorder. CTL and MRTD can clearly show the range, location and degree of lymphatic abnormalities, and clearly show the tissues and organs in the chest, abdomen and pelvis, which provide valuable imaging information for the diagnosis of chylous leakage in the reproductive system.

CLINICAL RELEVANCE/APPLICATION

CTL and MRTD can determine the extent and degree of chylous leakage in the reproductive system, which is of great value in the diagnosis and treatment of chylous leakage in the reproductive system.

T5B-SPGU-5 CLINICAL IMPACT OF ^{68}GA-PSMA PET/CT IN PROSTATE CANCER: IDENTIFICATION OF MESORECTAL LYMPH NODE METASTASES AND IMPLICATIONS FOR STAGING AND TREATMENT

Madiha Hijazi, MD (*Presenter*)
Joe Rizkallah (*Abstract Co-Author*)
Omar El Sardouk (*Abstract Co-Author*)
Elia Abou Chawareb (*Abstract Co-Author*)
Nina Saliba (*Abstract Co-Author*)
Albert El Hajj (*Abstract Co-Author*)
Alain S. Abi-Ghanem, MD (*Abstract Co-Author*)
Mohamad B. Haidar, MD (*Abstract Co-Author*)

PURPOSE

68Ga-PSMA PET/CT is increasingly used for initial staging in prostate cancer due to its superior ability to detect radiotracer-avid lymph nodes, including those in atypical pelvic regions often missed on conventional imaging. This study aimed to assess the clinical significance of mesorectal lymph node metastases detected by 68Ga-PSMA PET/CT in prostate cancer and their impact on staging, treatment decisions, and outcomes.

METHODS AND MATERIALS

We retrospectively reviewed 575 patients with prostate cancer who underwent 68Ga-PSMA PET/CT for staging between 2016 and 2024. PET/CT reports were assessed for uptake in the mesorectal group. Initial prostate-specific antigen (PSA) levels, Gleason score, treatment modalities, and mortality were compared between patients with and without mesorectal involvement. Functional upstaging was defined as the initiation of radiation, chemotherapy, or novel hormonal therapy following PET/CT findings. Statistical analyses included Mann-Whitney U and Fisher's exact tests.

RESULTS

Mesorectal lymph node involvement was identified in 97 of 575 patients (16.9%). These patients had significantly higher PSA levels (median 32.7 vs. 12.45 ng/mL, $p < 0.001$), higher all-cause mortality (8.2% vs. 1.3%, $p < 0.001$), and higher prostate cancer-specific mortality (3.1% vs. 0.2%, $p = 0.016$). Functional upstaging occurred in 57.7% of patients with mesorectal lymph node involvement, who were also less likely to undergo surgery (25.3% vs. 34.2%, $p = 0.015$). Gleason score did not significantly differ between groups (median 7 vs. 7, $p = 0.541$).

CONCLUSION

Mesorectal lymph node metastases detected by 68Ga-PSMA PET/CT are associated with higher PSA, increased mortality, and treatment intensification. Their detection frequently alters initial management plans, shifting patients from surgical treatment toward systemic or multimodal therapy.

CLINICAL RELEVANCE/APPLICATION

68Ga-PSMA PET/CT reveals clinically significant mesorectal lymph node metastases not routinely captured on conventional imaging. These findings drive treatment changes and highlight the value of 68Ga-PSMA PET/CT in precise staging and decision-making in modern prostate cancer care.

T5B-SPGU-6 CONTRAST ENHANCEMENT FLOW THRESHOLDS IN DIFFERENTIATING CLEAR CELL AND PAPILLARY RENAL CANCER AND ONCOCYTOMA WITH KIDNEY PERFUSION CT

Sara Babapour, MD (*Presenter*)
Alex Chung, MD (*Abstract Co-Author*)
James W. Sayre, PhD,MS (*Abstract Co-Author*)
Grace Li (*Abstract Co-Author*)
Jonathan Haimowitz (*Abstract Co-Author*)
Luke Phan (*Abstract Co-Author*)
Steven S. Raman, MD (*Abstract Co-Author*)

PURPOSE

To distinguish qualitative flow range differences in perfusion CT (CTp) contrast for differentiation of clear cell renal cell carcinoma (ccRCC) from papillary RCC (pRCC) and oncocytoma (Onc).

METHODS AND MATERIALS

A pilot cohort of 74 consecutive patients who underwent CTp (Force, Siemens Healthineers (SH), Erlangen, Germany) for a known or suspected indeterminate solid renal mass. Regions of interest ROIs were drawn on the most enhancing portion of the mass and normal ipsilateral & contralateral renal cortex on virtual reconstructions of the non-contrast, corticomedullary, & nephrographic phases were generated using Syngo Via (SH, Malvern, PA). Absolute peak Hounsfield Units (HU) values and relative values normalized by ipsilateral kidney cortex (IpCx) and contralateral kidney cortex were generated to construct the perfusion curves. Perfusion parameters were compared by a two-tailed paired sample t-test between tumors & ipsilateral cortex. Each lesion and the relevant ipsilateral kidney cortex were compared in a paired t-test among subtypes.

RESULTS

Of 74 patients who underwent pCT, 48, 12 & 14 were ccRCC, pRCC & Onc, respectively. Contrast flow and intensity thresholds were shown as a combined graph in Figure 1. Significant differences between peak ccRCC lesions within ipsilateral cortex maximum signal intensity in non-contrast and corticomedullary phases, compared to Onc lesions, paired t test in nephrogenic and excretory phases were <0.01. On the other hand, papillary maximum peak signal intensity was significantly lower than other evaluated subtypes (<0.01). As for mean enhancement, thresholds were significantly different in all phases for the three subtypes except non-contrast.

CONCLUSION

This pilot study represents CTp enhancement curves qualitatively in pathology prediction and further clinical decision making for the three most common renal lesions.

CLINICAL RELEVANCE/APPLICATION

CT perfusion qualitative parameters differ by renal mass histological subtype and may help characterize and predict malignant and benign common solid renal lesions if validated.

T5B-SPHN-1 BENIGN THYROID NODULE APPEARANCE ON POST-RADIOFREQUENCY ABLATION ULTRASONOGRAPHIC IMAGING

Joshua Foster (*Presenter*)
Marisela Neff (*Abstract Co-Author*)
Cameron Lin (*Abstract Co-Author*)
Jack Lin (*Abstract Co-Author*)
Nikita Sharma (*Abstract Co-Author*)
Erik D. Hilborn, MD (*Abstract Co-Author*)
Jagteshwar S. Sandhu, MD (*Abstract Co-Author*)
Zoe A. Miller, MD (*Abstract Co-Author*)

PURPOSE

Thyroid nodules (TNs) affect an estimated 67% of the global population and may cause symptoms such as dysphagia, dysphonia, globus sensation, and pain. For symptomatic patients with benign TNs, radiofrequency ablation (RFA) is becoming a preferred treatment. As a relatively new treatment option, post-RFA management requires further exploration. Post-RFA TNs often show reduced volume, irregular margins, and higher TI-RADS scores on ultrasonographic (US) imaging. These findings may be interpreted as malignant, complicating management. This study investigates how benign TNs appear on US imaging at 1 and 3 months post-RFA.

METHODS AND MATERIALS

A single-center retrospective study was conducted with 10 patients (8 female, median age 46) and a total of 13 benign nodules treated with RFA. All patients had at least 2 negative biopsies prior to undergoing RFA. Ultrasound imaging was performed at 1 and 3 months post-RFA. Pre-procedure data included nodule volume (cm3), TI-RADS score, Bethesda category, US characteristics, and symptom, vascular, and cosmetic scores. At 1 and 3 months post-RFA, recorded data included nodule volume, volume reduction ratio (VRR), post-procedure symptoms, and follow-up ultrasound characteristics.

RESULTS

Of the 13 nodules treated, 11 were located in the right lobe, 1 left, and 1 in the isthmus. The median pre-procedure nodule volume was 17.35 cm3 (IQR 9.11-35.22), with a symptom score of 5 (IQR 1-6), vascularity score of 2 (IQR 1-2), and cosmetic score of 3 (IQR 2-4). At 1 month post-RFA, the volume reduced to 13.35 cm3 (IQR 4.90-18.85), with a median VRR of 50.47% (IQR 18.97-60.61). Symptom, vascularity, and cosmetic scores improved to medians of 2, 1, and 2, respectively. By 3 months post-RFA, volume decreased to a median of 6.86 cm3 (IQR 4.36-17.11), with a VRR of 53.58% (IQR 47.25-57.97). Pre-procedure nodules were frequently solid, hyperechoic/isoechoic, wider-than-tall, and well circumscribed. Post-RFA ultrasound demonstrated a variety of features including hypoechoic, heterogeneous nodules with lobulated margins, mild peripheral/internal vascularity, and occasional comet-tail artifacts. Imaging also revealed suspicious features, including coarse calcifications and punctate echogenic foci. One pre-RFA TI-RADS 3 nodule was reclassified as TI-RADS 5 at 1 month post-RFA.

CONCLUSION

RFA effectively reduces nodule size and symptoms in benign TNs. However, post-RFA ultrasound images may demonstrate new and suspicious findings, potentially leading to diagnostic uncertainty.

CLINICAL RELEVANCE/APPLICATION

Radiologists and clinicians must recognize post-RFA imaging features to avoid unnecessary interventions and ensure appropriate management.

T5B-SPHN-2 DEEP LEARNING MODEL FOR AUTOMATED SEGMENTATION AND PATHOLOGY CLASSIFICATIONS FOR CLIVAL TUMORS

Fnu Harshit (*Presenter*)
Tolga Tasdizen, PhD (*Abstract Co-Author*)
Karen L. Salzman, BS, MD (*Abstract Co-Author*)
Blair A. Winegar, MD (*Abstract Co-Author*)
Robert Rennert (*Abstract Co-Author*)
Tyler Richards, MD (*Abstract Co-Author*)

PURPOSE

This is a single institution pilot study to develop a deep learning based pipeline to automate segmentation and predict tumor pathology of skull base tumors involving the clivus.

METHODS AND MATERIALS

Multisequence axial MR images of adult patients with clival tumors were collected retrospectively from a single institution. Clival tumors were ?1.0 cm in axial diameter with confirmed pathology of either a “primary” clival mass including chordoma, chondrosarcoma, invasive pituitary neuroendocrine tumor (PitNET), nasopharyngeal carcinoma, meningioma with osseous invasion or “secondary” pathology including lymphoma, multiple myeloma/plasmacytoma, or metastasis. Individual examinations had images co-registered between series and 3D tumor segmentations performed by a board certified neuroradiologist. Images underwent intensity normalization and resampling to uniform voxel size and data augmentation. The segmentation model was trained on a customized 3D UNet architecture and utilized transfer learning by initializing the model with pre-trained weights from a brain tumor segmentation (BraTS) challenge model for 5000 iterations. A classification model to predict tumor pathology as “primary” or “secondary” was developed using image level features extracted from the fine-tuned 3D UNet segmentation model. The UNet from the segmentation model was repurposed to extract deep, case-specific feature representations. These extracted features served as input for a linear classifier, specifically designed to predict tumor subtype. The classifier was trained using a cross-entropy loss function.

RESULTS

MR imaging from 120 patients with clival tumors (63.3% primary tumors; n=76) were collected for training and testing of the deep learning models. The classification model with highest performance was a single channel T2 input, which achieved a DSC of 0.56 at a pixel level. The single channel T2 input also achieved the highest performance for the classification model, achieving an F1-score of 0.89 and accuracy of 0.80.

CONCLUSION

This study demonstrates promising potential for developing an automated deep learning based pipeline for segmentation and tumor pathology prediction for clival tumors. Larger multi-institutional datasets are necessary to improve performance and generalizability of the models.

CLINICAL RELEVANCE/APPLICATION

Clival masses due to systemic malignancy require whole body imaging for staging and are treated systemically and possibly with radiation therapy; while primary tumors of the clivus are treated with surgical resection. A reliable deep learning diagnostic model has the potential to streamline imaging workup and guide appropriate surgical and systemic treatment for clival masses.

T5B-SPHN-4 AI-ENHANCED NOISE REDUCTION IN CBCT IMAGING OF THE TEMPOROMANDIBULAR JOINT: IMPACT ON IMAGE QUALITY

Wojciech Kazimierczak, MD, PhD (*Presenter*)
Natalia Chwarscianek (*Abstract Co-Author*)
Natalia Kazimierczak (*Abstract Co-Author*)
Roza Wajer, MD (*Abstract Co-Author*)
Adrian Wajer (*Abstract Co-Author*)
Zbigniew Serafin (*Abstract Co-Author*)

PURPOSE

Temporomandibular joint disorder (TMD) is a common medical condition. Cone beam computed tomography (CBCT) is effective in assessing TMD-related bone changes, but image noise may impair diagnosis. Emerging deep learning reconstruction algorithms (DLRs) could minimize noise and improve CBCT image clarity. This study compares standard and deep learning-enhanced CBCT images for image quality in detecting osteoarthritis-related degeneration in TMJs (temporomandibular joints). This study analyzed CBCT images of patients with suspected temporomandibular joint degenerative joint disease (TMJ DJD).

METHODS AND MATERIALS

The DLM reconstructions were performed with ClariCT.AI software. Image quality was evaluated objectively via CNR in target areas and subjectively by two experts using a five-point scale. Both readers also assessed TMJ DJD lesions. The study involved 50 patients with a mean age of 28.29 years.

RESULTS

Objective analysis revealed a significantly better image quality in DLM reconstructions (CNR levels; $p < 0.001$). Subjective assessment showed high inter-reader agreement (? = 0.805) but no significant difference in image quality between the reconstruction types ($p = 0.055$). Lesion counts were not significantly correlated with the reconstruction type ($p > 0.05$).

CONCLUSION

The analyzed DLM reconstruction notably enhanced the objective image quality in TMJ CBCT images but did not significantly alter the subjective quality or DJD lesion diagnosis. However, the readers favored DLM images, indicating the potential for better TMD diagnosis with CBCT, meriting more study.

CLINICAL RELEVANCE/APPLICATION

This research supports the inclusion of AI-based noise optimization in CBCT TMJ imaging as a valuable tool to increase diagnostic accuracy, improve patient safety and standardize imaging quality in dental practice and maxillofacial surgery.

T5B-SPHN-5 WHAT TO EXPECT FROM ABLATED CERVICAL LYMPH NODES: INSIGHTS FROM A CLINICAL TRIAL USING MULTIPARAMETRIC ULTRASOUND

Pedro Naime B. Araujo I, MD (*Presenter*)
Erick F. Santos, MD (*Abstract Co-Author*)
Miriam Tsunemi (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)
Ricardo M. Freitas, MD, PhD (*Abstract Co-Author*)

PURPOSE

To improve radiologic interpretation and follow-up strategies based on multiparametric ultrasound (US) changes in ablated cervical lymph nodes of papillary or medullary thyroid cancer (PTC/MTC) treated with radiofrequency ablation (RFA), laser ablation (LA), or cryoablation (CA).

METHODS AND MATERIALS

This randomized trial analyzed 121 metastatic lymph nodes from 84 patients undergoing RFA, LA, or CA. Multiparametric US (B-mode, Doppler, B-flow, shear wave elastography [SWE], and contrast-enhanced ultrasound [CEUS]) was performed at baseline, 6, 12, and 24 months. Two independent evaluators assessed structural changes, vascularization, perfusion, and stiffness. Statistical analysis included repeated measures ANOVA, Kruskal-Wallis tests, and interobserver agreement (ICC, Kappa statistics).

RESULTS

Structural changes (B-mode) Volume significantly decreased over time ($p<0.001$), mostly within 6 months, with no differences among techniques ($p>0.05$). Echogenicity increased ($p=0.0415$) more in LA-treated nodes. Calcifications increased at 6 months in LA ($p=0.0001$), suggesting heat-induced response. Vascularization (Doppler/B-flow) Significant reduction at 6 months ($p<0.05$), with no differences among techniques ($p>0.05$). Tissue stiffness (SWE): SWE values decreased over time, especially in RF-treated nodes, while LA showed a progressive increase in stiffness. Perfusion dynamics (CEUS) Perfusion significantly decreased at 6 months ($p=0.0281$), with no technique-related differences ($p>0.05$). Histological subtypes and response PTC exhibited greater volume reduction than MTC ($p<0.01$). Reproducibility: Excellent agreement for quantitative parameters (ICC>0.9 for volume/vascularization). Qualitative assessments had a high interobserver agreement (Kappa>0.8, $p<0.001$). Predictors of volume reduction (logistic regression analysis): Baseline CEUS parameters were independent predictors of volume reduction after ablation ($p < 0.05$ for all). The logistic regression model demonstrated discriminative ability (AUC = 0.716), supporting CEUS as a potential biomarker of treatment response.

CONCLUSION

Multiparametric US effectively characterizes post-ablation changes. Most changes occur within 6 months and stabilize. High interobserver agreement reinforced this imaging-based follow-up strategy's reproducibility and clinical applicability. A CEUS-based predictive model demonstrated discriminative ability for treatment response.

CLINICAL RELEVANCE/APPLICATION

Findings establish expected post-ablation US patterns, aiding radiologists in differentiating treatment response from tumor persistence, optimizing follow-up, and reducing unnecessary biopsies.

T5B-SPHN-6 NEW SYSTEM FOR RAPID AUTOMATIC DIAGNOSIS OF THYROID PATHOLOGY WITHOUT A RADIOLOGIST OR SONOGRAPHER

Adam Dykie, MD (*Presenter*)
Evan El-Halawani (*Abstract Co-Author*)
Denes Szekeres, BS (*Abstract Co-Author*)
Aaron Yang (*Abstract Co-Author*)
Timothy M. Baran, PhD (*Abstract Co-Author*)
Yu Zhao, MD (*Abstract Co-Author*)
Deborah J. Rubens, MD (*Abstract Co-Author*)
Benjamin Castaneda (*Abstract Co-Author*)
Luis Revilla (*Abstract Co-Author*)
Kevin J. Parker, PhD (*Abstract Co-Author*)
Thomas Marini, MD (*Abstract Co-Author*)

PURPOSE

Thyroid disease is a prevalent healthcare issue worldwide, with evaluation often complicated by limited access to ultrasound services. Volume sweep imaging (VSI) is a technique that can be used by operators without formal training to assess the thyroid gland. Standardized sweeps of the ultrasound probe are performed over the neck based on external landmarks and saved as cine clips for subsequent interpretation. In this study, we evaluated thyroid ultrasound VSI as a diagnostic tool to measure thyroid size as well as nodule presence and size, with the goal of increasing access to imaging.

METHODS AND MATERIALS

Ultrasound-naïve medical students scanned patients at an outpatient imaging clinic using an iQ+ ultrasound probe (Butterfly Network, Burlington, MA) with thyroid VSI after undergoing a two-hour training. The cines were saved to a cloud for review. At the same visit, patients underwent a standard of care (SOC) exam of the thyroid performed on a high end Logiq E10 ultrasound (General Electric, Boston, MA) by an experienced sonographer. The thyroid lobes and isthmus were measured on VSI, and the SOC measurements were used as a reference standard. Comparison was made between VSI (interpreted by a radiology resident) and SOC (interpreted by a radiology attending) for thyroid size and nodule assessment.

RESULTS

Medical students scanned 274 patients using the VSI protocol. There was good agreement between SOC and VSI measurements of the thyroid, with all comparisons showing minimal absolute magnitude of difference. Representative examples include the right thyroid lobe in anteroposterior (AP) dimension, which was 1.78±0.53 cm on SOC versus 1.79±0.52 cm on VSI, with a mean discrepancy (VSI-SOC) of 0.004 cm (-0.024-0.032 cm 95% confidence interval (CI), p=0.79), and the left lobe in AP dimension (SOC: 1.55±0.54 cm, VSI: 1.59±0.50 cm, mean discrepancy: 0.044 cm (0.018-0.07 cm 95% CI, p=0.001)). Of the nodules identified on SOC, 87.8% (266/303) were also visualized on VSI. Nodule measurements also showed good agreement between SOC and VSI, with AP measurement of the largest nodule as a representative example (SOC: 1.14±0.66 cm, VSI: 1.12±0.63 cm, discrepancy: -0.023 cm (-0.047-0.0002 cm 95% CI, p=0.052)).

CONCLUSION

Thyroid VSI performed by ultrasound-naïve medical students after a short training allowed excellent assessment of thyroid size. There was detection of nearly 90% of thyroid nodules seen on SOC with good agreement on nodule size.

CLINICAL RELEVANCE/APPLICATION

VSI shows potential to assess and identify thyroid abnormalities and follow them over time. This approach could be improved and refined to provide diagnostically accurate low-cost assessment of the thyroid, improving health outcomes and increasing access to imaging in the global community.

T5B-SPHN-7 DEEP LEARNING IMAGE RECONSTRUCTION IN ULTRA-LOW-DOSE PARANASAL SINUS CT: SUPERIOR NOISE REDUCTION AND SHARPNESS OVER HYBRID IR

Chuluunbaatar Otgonbaatar, MD (*Presenter*)
Sangil Suh, MD, PhD (*Abstract Co-Author*)
Hackjoon Shim, PhD (*Abstract Co-Author*)
Dakyong Lee (*Abstract Co-Author*)
Juneho Choi (*Abstract Co-Author*)
Hei-Jung Jang (*Abstract Co-Author*)
Inseon Ryoo, MD (*Abstract Co-Author*)
Hye Na Jung, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the quantitative and qualitative performance of ultra-low-dose computed tomography (CT) of the paranasal sinuses reconstructed using deep learning-based reconstruction (DLR), in comparison with hybrid iterative reconstruction (IR), for preoperative imaging.

METHODS AND MATERIALS

In this retrospective study, 132 patients who underwent non-contrast ultra-low-dose paranasal sinus CT (effective dose: 0.03 mSv) were included. Image datasets were reconstructed using both hybrid IR and DLR. Quantitative image quality parameters—, image noise, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), noise power spectrum (NPS), and a no-reference perceptual image sharpness index—were objectively evaluated. Additionally, two board-certified radiologists independently conducted subjective image quality assessments.

RESULTS

The ultra-low-dose CT protocol achieved a markedly reduced radiation exposure (effective dose: 0.03 mSv). DLR yielded significantly lower image noise (28.62 ± 4.83) compared to hybrid IR (140.70 ± 16.04, $p < 0.001$). Moreover, DLR significantly enhanced both SNR (22.47 ± 5.82 vs. 9.14 ± 2.45, $p < 0.001$) and CNR (71.88 ± 14.03 vs. 11.81 ± 1.50, $p < 0.001$). NPS analysis indicated a reduction in both noise magnitude and peak frequency components with DLR. The DLR method also exhibited significantly greater image sharpness (no-reference perceptual sharpness metric: 0.56 ± 0.04) than hybrid IR (0.36 ± 0.01). Subjective assessments revealed that radiologists consistently rated DLR as superior in terms of overall image quality, delineation of bony structures, including the frontal recess, middle turbinate, ostium of the maxillary sinus, and ethmoidal infundibulum, and diagnostic confidence.

CONCLUSION

Deep learning-based reconstruction substantially outperformed hybrid iterative reconstruction in ultra-low-dose paranasal sinus CT by reducing image noise, enhancing SNR and CNR, improving image sharpness, and preserving essential anatomical detail. These findings suggest DLR as a promising technique for preoperative evaluation with minimal radiation exposure.

CLINICAL RELEVANCE/APPLICATION

Ultra-low-dose CT with deep learning reconstruction should be considered for preoperative planning, as it provides sufficient image quality for evaluating fine anatomical structures while minimizing patient exposure to unnecessary radiation. Additionally, DLR preserves image quality for detecting subtle inflammatory changes and visualizing bony erosions, which are critical for clinical decision-making, including determining the need for surgical intervention or conservative medical management.

T5B-SPHN-8 A CLINICO-RADIOMICS MODEL FOR PREDICTING CAROTID BODY TUMOR INVASIVENESS IN HIGH-ALTITUDE PATIENTS

Rui Fan (*Presenter*)
Yuntai Cao, MS (*Abstract Co-Author*)

PURPOSE

Carotid body tumor (CBT) is vascular neoplasms linked to chronic hypoxia and genetic predisposition. High-altitude regions show increased CBT incidence due to hypoxia-induced carotid body hyperplasia. The situation is further exacerbated by insufficient medical resources and limited health awareness, which collectively contribute to heightened vulnerability within these populations, causing significant public health challenges. In this study, the radiomic features from computed tomography angiography (CTA) images were fused with clinical characteristics to predict the vascular or capsular invasion in CBT for patients residing in high-altitude regions.

METHODS AND MATERIALS

We analyzed 114 patients who underwent unilateral CBT resection with preoperative CTA, split into training (n=80) and validation (n=34) cohorts. Radiomic features were extracted from CTA images and refined through univariate analysis, correlation analysis, and LASSO algorithm. Tumor contour expansion by 3 mm was tested to optimize predictive performance. Invasion prediction models were developed using Logistic Regression, Random Forest, and Support Vector Machine algorithms, and evaluated via ROC curves, calibration curves, and decision curves.

RESULTS

The clinico-radiomic model achieved an area under the curve (AUC) of about 0.907 (0.799-1.000) on the validation cohort. A visual nomogram has been developed to enable rapid assessment of vascular or capsular invasion by clinicians in high-altitude regions.

CONCLUSION

We developed a clinico-radiomics fusion model for predicting vascular or capsular invasion in CBT for patients residing in Qinghai-Tibet plateau. This non-invasive approach enables preoperative assessment of vascular or capsular invasion in CBT, thereby facilitating more informed treatment strategy selection and surgical risk assessment.

CLINICAL RELEVANCE/APPLICATION

This non-invasive approach enables preoperative assessment of vascular or capsular invasion in CBT, thereby facilitating more informed treatment strategy selection and surgical risk assessment, especially for high-altitude populations with a higher incidence of CBT.

T5B-SPIN-2 MULTILINGUAL VOICE-TO-TEXT TRANSCRIPTION OF CT AND MRI REPORTS USING GPT-4O: A FEASIBILITY STUDY

Philipp Prucker, MD (*Presenter*)
Felix Busch, MD (*Abstract Co-Author*)
Sebastian Ziegelmayer, MD (*Abstract Co-Author*)
Keno K. Bressem, MD (*Abstract Co-Author*)
Lisa C. Adams, MD, PhD (*Abstract Co-Author*)
Marcus R. Makowski (*Abstract Co-Author*)

PURPOSE

Large language models (LLMs) offer potential for automating and streamlining radiology reporting workflows. With the release of GPT-4o, a multimodal LLM capable of processing both text and speech, it may now be feasible to use such models as voice recognition tools for radiology reporting across multiple languages. This proof-of-concept study evaluates the feasibility and performance of GPT-4o for automated voice-to-text transcription of radiology reports in English and German.

METHODS AND MATERIALS

Three readers with varying levels of radiology experience each dictated 100 synthetic radiology reports in both English and German using GPT-4o via a mobile application. Reports covered CT and MRI studies across various anatomical regions. Transcribed reports were evaluated for error type (e.g., technical, typographical), severity (minor vs. major), and correction time. Semantic similarity and content overlap were assessed using BERTScore and ROUGE metrics, respectively, comparing the transcribed output with the original reports.

RESULTS

Error rates were comparable between languages, with most errors being minor (92.7% in German; 94.7% in English) and either technical or typographical in nature. No significant difference in correction time was found between languages; however, correction time varied by reader experience. BERTScore values were significantly higher for German reports, while ROUGE metrics showed no significant differences, indicating similar structural fidelity across languages.

CONCLUSION

GPT-4o demonstrates strong potential for multilingual voice-to-text transcription of radiology reports, with high semantic accuracy and minimal error rates in both English and German. Reader experience affected correction efficiency, but overall model performance was consistent across languages.

CLINICAL RELEVANCE/APPLICATION

Multimodal LLMs like GPT-4o may serve as cost-effective, language-agnostic alternatives to traditional medical speech recognition tools. Their use could enhance radiology workflow efficiency, particularly in multilingual settings or low-resource environments.

T5B-SPIN-7 IMPLEMENTING VISION TRANSFORMERS FOR THORAX RADIOGRAPHY: OPPORTUNITIES AND CHALLENGES

Sardi Hyska, MD (*Presenter*)
Michael Ingrisch (*Abstract Co-Author*)
Tobias Lasser (*Abstract Co-Author*)
Bastian Sabel, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the performance of a Vision Transformer (ViT)- based AI model, trained on publicly available chest radiography datasets, when applied to real-world clinical data. The model’s performance in detecting pleural effusion, pneumothorax, cardiomegaly and consolidation was evaluated. Furthermore, various saliency maps were used to gain insight into model decisions and uncover potential confounders.

METHODS AND MATERIALS

The ViT, pre-trained on ImageNet and fine-tuned on over 700,000 public chest X-rays (CXR), was tested on an internal dataset of 113 CXR, including 23 pneumothorax, 29 cardiomegaly, 31 consolidation, 52 pleural effusion and 29 normal cases. Performance metrics included ROC curves, AUC, Youden index, sensitivity and specificity. To analyze confounding factors logistic regression, odds ratios and Fisher’s exact test were used.

RESULTS

The model correctly identified all normal CXR. It performed strongly on pleural effusion, reaching 96.2 % sensitivity and 98.4 % specificity. In contrast, pneumothorax detection was poor, with only 26.1 % sensitivity, despite 96.7 % specificity; saliency maps exposed pneumothorax size and visible thoracic tubes as statistically significant confounding factors. For cardiomegaly, the model detected 55.2 % of cases (96.4 % specificity), missing nearly half of true positives, whereas a concomitant pleural effusion, obscuring the heart contours, acts as a potential confounder. Consolidation was detected with 45.2 % sensitivity and 91.5 % specificity; denser consolidations were significantly more reliably identified, implicating consolidation density as a key confounder.

CONCLUSION

Implementing an AI model trained on public datasets into clinical workflows poses significant challenges, even when the model employs an advanced algorithm and was trained on vast amounts of data. While the ViT excelled at recognizing pleural effusion and normal CXRs, its sensitivity for pneumothorax, cardiomegaly, and consolidation was limited. Known confounders in other AI architectures, such as visible thoracic tubes for pneumothorax detection, were confirmed, and several new confounders, e. g. concomitant pleural effusions in cardiomegaly and consolidation density, were identified via analysis of saliency maps.

CLINICAL RELEVANCE/APPLICATION

These findings underscore the necessity of careful, real-world validation and interpretability assessment before clinical deployment. The limited sensitivity and the existence of several confounders emphasize the need for radiologists to interpret AI decisions in context and for AI developers to refine training data and model calibration. Integrating these insights into clinical workflows can support the design of more robust AI models.

T5B-SPIN-8 CLINICAL STUDY ON A DEEP LEARNING-BASED MRI-PDFF RADIOMICS-CLINICAL COMBINED MODEL FOR PREDICTING NAFLD GRADING

Dan-Dan Deng (*Presenter*)

PURPOSE

With changes in lifestyle and dietary habits, the global prevalence of non-alcoholic fatty liver disease (NAFLD) has been increasing. Accurate diagnosis of NAFLD grading (mild, moderate, severe) is crucial for treatment decisions. This study aims to develop a non-invasive MRI-PDFF-based radiomics-clinical combined model to predict NAFLD grading and improve diagnostic accuracy.

METHODS AND MATERIALS

A total of 120 patients with NAFLD confirmed by pathology and MRI-PDFF from 2023 to 2025 were enrolled (training/validation set = 80/40). Clinical and laboratory data were collected. Optimal clinical features were selected through univariate and multivariate logistic regression. A total of 107 radiomics features were extracted from MRI-PDFF images, and high-level semantic features were obtained using a 3D ResNet deep learning network. Key features were screened via LASSO regression and SHAP analysis to construct a random forest classification model. Model performance was evaluated using five-fold cross-validation, ROC curves, decision curves, and calibration curves.

RESULTS

The optimal clinical features included diabetes, HDL, LDL, TG, and CHO. Key radiomics features comprised texture heterogeneity (GLCM entropy) and skewnes and so on. The radiomics-clinical combined model achieved AUCs of 0.88 (mild), 0.91 (moderate), and 0.87 (severe) in the validation set, significantly outperforming conventional imaging diagnosis (AUC 0.75, $p<0.01$) and the standalone radiomics model (AUC 0.82, $p<0.01$). Interpretability analysis demonstrated that the combined model had superior diagnostic efficacy compared to conventional imaging and the MRI-PDFF radiomics model alone.

CONCLUSION

The MRI-PDFF-based radiomics-clinical combined model accurately predicts NAFLD grading, providing a non-invasive tool for personalized treatment. Future multicenter prospective validation will facilitate clinical translation.

CLINICAL RELEVANCE/APPLICATION

The natural progression of NAFLD patients can evolve from non-alcoholic fatty liver (NAFL) to non-alcoholic steatohepatitis (NASH), which may lead to liver fibrosis and eventually progress to cirrhosis. Therefore, early identification of the severity of NAFLD is crucial for clinical intervention to prevent fatty liver from developing into steatohepatitis. Radiomics offers a potential non-invasive approach for classifying NAFLD. Studies have shown that MRI-derived proton density fat fraction (MRI-PDFF) has the potential to replace liver biopsy as the gold standard for NAFLD diagnosis and grading. The new MRI radiomics-clinical combined model is more accurate than MRI-PDFF and can effectively measure the severity of NAFLD, thereby replacing the invasive liver biopsy.

T5B-SPIN-9 GRAPH-BASED AUTOMATED LESION TRACKING IN CANCER FOLLOW-UP USING 3D SIAMESE NEURAL NETWORKS ON ARBITRARY FIELD-OF-VIEW CT SCANS

Angel Alberich-Bayarri, MS, PhD (*Presenter*)
Alejandro Vergara Richart (*Abstract Co-Author*)
Ana Jimenez-Pastor (*Abstract Co-Author*)

PURPOSE

There is a lack of automated and reliable tools to automatically track lesion changes over time. The primary goal of this work was to address the automatic tracking of lesions in the thoracoabdominal region across time points through 3D-Siamese Neural Networks (3DSNN) and graph-based algorithms.

METHODS AND MATERIALS

A retrospective dataset of 740 longitudinal CT exams from metastatic NSCLC patients was used, with a high variability in lesion location, including lungs, lymph nodes, liver, bone, adrenal glands (39.70%, 33.79%, 10.89%, 5.23%, 3.64%, respectively) and volume (0.1-1000cm 3). First, A 3DSNN architecture was used to extract similarity scores (SS) between tumor pairs. The input to the network was a lesion-centered patch, and various configurations were evaluated, including the full 2D image, the lesion mask, and different lesion scales. Multiple strategies were tested including training from scratch, fine-tuning pretrained ResNet/Transformer architectures, and applying data augmentation techniques. An 80/20 training/test split was implemented, assuring comparable heterogeneity in terms of lesion size and location in both sets. Second, a bipartite graph was created using consecutive scans, with lesions as nodes and SS as edge features. Hungarian and ILP graph-based algorithms were assessed to track lesions across time points.

RESULTS

The best-performing 3DSNN model for lesion matching employed multiple lesion scales and the ResNet50 from scratch, achieving 95.47%/ 96.04%/94.89% in accuracy/sensitivity/specificity on the test set. The Hungarian algorithm for lesion tracking achieved accuracy/sensitivity/specificity of 90.0%/100.0%/83.33%, 81.97%/96.72%/67.21%, and 69.0%/95.28%/47.04% when the first time point contained 2, 5, and 10 lesions, respectively. We found robust metrics for stable lesions, while the tracking of appearing or disappearing lesions led to a slight decrease in performance.

CONCLUSION

3DSNNs and graphs are promising and reliable techniques to accurately track tumor lesions over consecutive time points, regardless of lesion size and region. Future work aims to improve appearing/disappearing lesions tracking via 3DSNNs and graph neural networks.

CLINICAL RELEVANCE/APPLICATION

Automate lesion tracking to streamline treatment response reporting, such as RECIST-1.1and others.

T5B-SPIN-10 AI-ASSISTED COMPRESSED SENSING WITH GADOXETIC ACID ENHANCEMENT FOR EVALUATING COLORECTAL LIVER METASTASES IN COMPLEX HEPATIC BACKGROUNDS: A PROSPECTIVE 5T MRI STUDY

Zhao Xiaoer (*Presenter*)

PURPOSE

To evaluate the diagnostic performance of 5 T multimodal MRI with AI-assisted Compressed Sensing (ACS)and gadoxetic acid-enhanced MRI (EOB-MRI) for CRLM detection while accurately assessing hepatic backgrounds, particularly for lesions =10mm.

METHODS AND MATERIALS

In this prospective, single-center study, 35 patients (26 men; mean age, 61.6±1.7 years) with 118 CRLM identified by MRI were evaluated following chemotherapy. MRI at 5 T included T1W in/out-of-phase imaging with proton density fat fraction (PDFF), Susceptibility Weighted Imaging with Fast Technique (uSwift), and a standard EOB-

MRI protocol with high resolution 3D isotropic T1W FSPGR hepatobiliary phase (HBP)using ACS(ACS- HBP) (acquisition voxel 1.2 mm^3, reconstructed voxel 0.6 mm^3, 300 slices). Assessment included hepatic steatosis (T1W in/out-of-phase imaging, PDFF-derived FF maps), hepatic iron overload (uSWIFT, PDFF-generated R2* mapping), sinusoidal obstruction syndrome (EOB-MRI portal venous and HBP), and CRLM diagnostic performance (combined EOB-MRI and DWI). Statistical analysis included inter-rater agreement (kappa statistic), diagnostic metrics (sensitivity, PPV, ROC-AUC), and generalized estimating equations for CRLM detection factors and diagnostic performance comparison, with Bonferroni correction for multiple comparisons ($p<0.01671$).

RESULTS

For CRLM detection, combined ACS- HBP and DWI sequences demonstrated superior diagnostic performance with highest sensitivity (97.2%) and positive predictive value (93.8-95.7%), particularly for small lesions (=10mm) with sensitivity of 95.7% compared to DWI alone (66.0%), GEE analysis showed hepatic background factors (SOS, HIO, fatty liver) and prior CRLM local treatment history had no significant impact on diagnostic performance (all $P > 0.05$).On HBP, lesions showed target or anti-target signs, with 93.5% (101/108) of all true positive lesions detected, including 84.6% (44/52) of lesions smaller than 10 mm.

CONCLUSION

ACS-integrated 5 T EOB-MRI demonstrates superior CRLM diagnostic performance with high sensitivity and PPV across hepatic backgrounds, including =10mm lesions.

CLINICAL RELEVANCE/APPLICATION

Detection of colorectal liver metastases (CRLM) is challenging in complex hepatic backgrounds caused by chemotherapy-associated liver injury (CALI) and prior local treatment of CRLM, necessitating advanced imaging modalities capable of providing both precise lesion detection and CALI assessment.

T5B-SPIN-11 PREDICTING PEDIATRIC RADIOLOGY PATIENTS NO-SHOWS AND EXTENDED WAIT-TIMES USING LLMS, REGRESSION, AND TREE BASED MODELS

Daniel Rafique (*Presenter*)
Xuan Liu (*Abstract Co-Author*)
Bo Gong, MD,MSc (*Abstract Co-Author*)
Laura Belsito (*Abstract Co-Author*)
Birgit B. Ertl-Wagner, MD, PhD (*Abstract Co-Author*)
Farzad Khalvati, PhD, MSc (*Abstract Co-Author*)

PURPOSE

Patients missing appointments (no-shows) is a persistent issue that often results in idle resources while delaying critical patient prognosis. Likewise, long wait times (longer than 1 hour) frustrate patients, especially pediatric patients, worsening their impressions on appointments. We conducted experiments using machine learning to predict pediatric radiology patients no-shows and long wait-times to assist scheduling teams in preparing and optimizing for these negative appointment experiences.

METHODS AND MATERIALS

Using REB-approved retrospective diagnostic imaging data from a pediatric hospital (154,935 processed datapoints ranging from 2018 to 2023), we experimented with 6 algorithms and 20 features including patient demographics and appointment specific data, trained on each task separately. These algorithms included XGBoost, Random Forest (RF), Support Vector Machine (SVM), Logistic Regression (LR), Artificial Neural Network (ANN), and ClinicalBERT, a large language model (LLM) which could better use homogenous contextual appointment data such as the reason for exam. Our LLM model pipeline augmented the tabular data into continuous text strings to leverage the bi-directional architecture and transfer learning. Finally, we utilized isotonic regression to calibrate predicted probabilities as usable risk metrics.

RESULTS

The XGBoost model had the greatest combination of the area under the ROC curve (AUC) and F1 scores (0.96 and 0.62, respectively) for predicting no-shows. For predicting long wait-times, the RF and LLM had the greatest AUC scores (0.83 and 0.82, respectively) and F1 scores (0.61 and 0.62, respectively). When analyzing feature importance, integrating contextual data into the LLM boasted a 51% improvement in F1 performance when given a reason for exam in its input. Additionally, for high risk (90% threshold) event predictions, XGBoost had the greatest no-show precision at 93%, while the RF and LLM had the greatest wait-time precision at 96%.

CONCLUSION

Our results improved performance over state-of-the-art methods, introduced a unique methodology to use LLMs on heterogeneous data within this domain, and demonstrated the importance of contextual appointment level data over solely using patient demographic features.

CLINICAL RELEVANCE/APPLICATION

The proposed model predictions can be used as stochastic input for risk-based optimized scheduling. This has the immediate application of providing more information for scheduling teams to make informed decisions with further applications through optimization. This ultimately provides targeted alternatives in equitable care for those who are at risk of negative appointment experiences.

T5B-SPIN-12 QUANTIFICATION OF IMPROVED RESIDENT PERFORMANCE ON TRAUMA RADIOGRAPHS WITH THE STANDARDIZED ELECTRONIC LEARNING LIBRARY AND APPLICATION PLATFORM (STELLA)

Eddy Zandee van Rilland, MD (*Presenter*)
Kathryn J. Stevens, MBBS, FRCR (*Abstract Co-Author*)
Marc H. Willis, DO, MMM (*Abstract Co-Author*)
Joshua Leaston (*Abstract Co-Author*)
Christopher F. Beaulieu, MD, PhD (*Abstract Co-Author*)

PURPOSE

To quantify the effectiveness of a standardized, case-based foundational curriculum for radiology residents using STELLA tools that enable objective assessments of interpretive accuracy.

METHODS AND MATERIALS

PGY-2 radiology residents on their first (radiograph-centric) musculoskeletal rotation were provided with a case-based foundational curriculum. On day 1, trainees completed a baseline "pre-test" composed of 12 "real world" trauma cases, by creating a free-text simulated report and placing arrows on perceived abnormalities using STELLA software. During the 4-week rotation, weekly one-on-one resident/faculty teaching sessions were performed across 4 topics: trauma, arthritis, hardware, and tumors. Each session included a standardized pre-reading assignment and an interactive case-based session involving 20 high-yield cases (independent of those used for testing). On the final day of the rotation, residents completed a "post-test" of 12 independent trauma cases. Pre- and post-test responses were scored using a 4-point scale reflecting both text and graphic annotation accuracy. Automated data collection included pre- and post-test mean scores (%), mean performance increase (%), normalized gain (%), question-level analysis, and resident feedback. Statistical analysis included paired t-test (significance set at $p<0.05$).

RESULTS

Eight PGY-2 radiology residents completed all components of the foundational curriculum. All 8 (100%) residents demonstrated improvement in scores between the pre-test and post-test with a mean increase in score of 30% ($p=0.00001$). The mean pre-test score was 52% (range 29-63%) and the mean post-test score was 82% (range 65-100%). Mean normalized gain, representing the percentage of available improvement that was achieved between the pre- and post-test, was 64% (range 37-100%). Question level analysis was performed to identify common areas of weakness and case appropriateness for future improvement and precision teaching. Additional task-focused modules for arthritis, hardware, and tumors have been built into STELLA.

CONCLUSION

This trauma-focused project shows the potential for a foundational teaching curriculum to improve resident skills. Moreover, it motivates use of blinded, quantitative assessment using STELLA. Similar curricula and related case sets are being developed for other radiology subspecialties and training levels.

CLINICAL RELEVANCE/APPLICATION

Continued improvement in radiology education, including the utilization of case-based learning and objective assessments is essential for trainees to achieve high levels of professional competence.

T5B-SPIR-1 SAFETY AND EFFICACY OF ULTRASOUND-GUIDED PERCUTANEOUS TRANSTHORACIC NEEDLE BIOPSY, A RETROSPECTIVE ANALYSIS OF 3015CONSECUTIVE PATIENTS

Mengjun Shen (*Presenter*)

PURPOSE

To determine the extent to which risk factors influence the incidence of complications in ultrasound-guided percutaneous transthoracic needle biopsy and to report our clinical experience with this procedure.

METHODS AND MATERIALS

A total of 3015 patients underwent lung biopsy (males 69.85%, n=2106; females 30.15%, n=909). We recorded actual complications and assessed the following risk factors: gender, age (<50 years, =50 years), lesion size (longest diameter: <3 cm, =3 cm), lesion location (upper and middle lobes, lower lobe), lesion nature (benign, malignant), biopsy method, number of biopsy cuts (=2 times, >2 times), cutting needle size, whether a coaxial needle was used, operator experience (inexperienced: <500 lung biopsies; experienced =500 lung biopsies), and procedure time (=15 min, >15 min).

RESULTS

The diagnostic accuracy rate of the biopsy was 91.67% (n=2764), and the overall complication rate was 3.98% (n=120), with major complications at 0.17% (n=5) and minor complications at 3.81% (n=115). The overall complication rate significantly increased when biopsying lesions in the lower lobe (p =0.041), especially the rate of pneumothorax (p =0.001); benign lesions significantly increased the complication rate of hemoptysis p=0.014); the combination of fine needle aspiration (FNA) and core-needle biopsy (CB) significantly increased the complication rate of hemoptysis (p =0.034); operators with "inexperienced" significantly increased the incidence of hemoptysis during surgery (p =0.011); in terms of examination duration, the pleural reaction rate significantly increased in those with >15 min (p =0.025). Among these, "benign lesions", "the combination of FNA and CB for lung biopsy," and "inexperienced operators performing the biopsy" were independent risk factors for hemoptysis.

CONCLUSION

Our research helps to determine the importance of potential risk factors and may contribute to further reducing the incidence of complications in routine clinical practice.

CLINICAL RELEVANCE/APPLICATION

Ultrasound-guided percutaneous transthoracic needle biopsy, due to its characteristics of safety, efficiency, and cost-effectiveness, has become one of the core techniques for diagnosing peripheral lung lesions. Its clinical value is reflected not only in enabling accurate diagnosis and personalized treatment but also in providing a feasible solution for optimizing medical resource allocation.

T5B-SPIR-2 ATEZOLIZUMAB PLUS BEVACIZUMAB COMBINED WITH OR WITHOUT TRANSARTERIAL CHEMOEMBOLIZATION IN THE TREATMENT OF ADVANCED HEPATOCELLULAR CARCINOMA: A SINGLE-CENTER RETROSPECTIVE STUDY

Jing Li (*Presenter*)
Yaowei Bai (*Abstract Co-Author*)
Fu Xiong, PhD, MD (*Abstract Co-Author*)
Xuefeng Kan, MD,PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to compare the efficacy and safety of atezolizumab plus bevacizumab (T+A) in combination with transarterial chemoembolization (TACE) (T+A+TACE) and T+A for patients with advanced hepatocellular carcinoma (HCC).

METHODS AND MATERIALS

From December 2020 to August 2024, 83 patients with advanced HCC who received T+A+TACE treatment or T+A treatment in our hospital were included, and these patients were categorized into TACE+T+A group (n=52) and T+A group (n=31). The clinical outcomes between the two groups were analyzed and compared, and the prognostic factors that affected the efficacy were analyzed.

RESULTS

The median overall survival (OS) and median progression-free survival (PFS) in the T+A+TACE group were significantly longer than those of in the T+A group (OS: 22.8 vs 16.9 months, P = 0.015; PFS: 7.1 vs 4.9 months, P = 0.006). A significantly higher objective response rate (ORR) and disease control rate (DCR) that based on the modified RECIST were achieved in the T+A+TACE group than those of in the T+A group (ORR: 51.9% vs 6.5%, P < 0.001; DCR: 88.5% vs 54.8%, P < 0.001). No significant differences in adverse events (AEs) were observed between the two groups (P >0.05). The T+A+TACE treatment was identified as a protective factor for OS and PFS.

CONCLUSION

TACE further improved the efficacy of T+A treatment for patients with advanced HCC, and it did not increase the incidence of AEs. T+A+TACE treatment is a promising treatment option for patients with advanced HCC.

CLINICAL RELEVANCE/APPLICATION

Hepatocellular carcinoma (HCC) is the most common form of liver cancer and accounts for about 90% of cases. HCC often presents with no symptoms in its early stage, and is typically in an advanced stage by the time it is diagnosed, leading to an unfavorable prognosis. Atezolizumab enhances the ability of T cells to recognize and eliminate tumor cells, and bevacizumab reduces the supply of nutrients and oxygen to the tumor cells, the convergence of these two mechanisms allows the

combination of the two drugs to produce better efficacy than alone. Transarterial chemoembolization (TACE) is currently widely used in the treatment of unresectable HCC, and could also be applied for the prevention of tumor recurrences after resection of HCC. However, TACE treatment has some limitations. TACE has a good synergistic effect with targeted therapy and immunotherapy for advanced HCC, and the combination of TACE with atezolizumab (an anti-PD-L1 antibody) and bevacizumab (an anti-VEGF antibody) in patients with advanced HCC may yield promising results. However, researches on this topic are limited. In the present study, we evaluated the efficacy and safety of "T+A" in combination with TACE (T+A+TACE) as a first-line treatment for patients with advanced HCC

T5B-SPIR-3 MESENTERIC ANGIOGRAPHY FOR COLONIC DIVERTICULAR BLEEDING ON CTA: PRE-PROCEDURAL PREDICTORS OF EXTRAVASATION AND POST-PROCEDURAL OUTCOMES

Ivan Dimov, MD (*Presenter*)
Chantal Ferguson (*Abstract Co-Author*)
Tushar Garg, MD (*Abstract Co-Author*)
Omar Zurkiya, MD, PhD (*Abstract Co-Author*)
Shams I. Iqbal, MD (*Abstract Co-Author*)
Patrick D. Sutphin, MD, PhD (*Abstract Co-Author*)
Ashraf Thabet, MD (*Abstract Co-Author*)
Thomas J. An, MD (*Abstract Co-Author*)

PURPOSE

To find predictors of active extravasation during angiography for colonic diverticular bleeding confirmed by CT angiogram (CTA) and examine the effect of procedural factors on clinical outcomes.

METHODS AND MATERIALS

Mesenteric angiograms performed at three hospitals for colonic diverticular bleeding on CTA between 2016-2025 were retrospectively reviewed. Data collection included CTA-to-angiogram time, extravasation and IVC size, angiogram selectivity, provocative maneuvers, and embolization techniques. Univariate and multivariate analyses were used to find associations between pre-procedural variables and active extravasation on angiography. Clinical outcomes were compared between patients that did and did not undergo embolization.

RESULTS

117 patients (median age, 76 years (IQR 60-92), 42 women) underwent 146 total angiograms. Active extravasation was found in 40% of angiograms. CTA-to-angiogram time =4 hours (OR: 2.99, CI: 1.27 - 7.27, p = 0.01), IVC short axis =20 mm (OR: 3.52, CI: 1.33 - 10.0, p = 0.01) and age (OR: 1.05, CI: 1.01 - 1.10, p = 0.03) were independent predictors for active bleeding on angiography in a multivariate logistic model (AUC: 0.76, CI: 0.67 - 0.85, p < 0.01). Third-order angiography revealed more bleeding than first-order angiography (34% vs. 21%). 51/58 (88%) positive and 15 negative angiograms proceeded to embolization. Patients who underwent targeted embolization had less rebleeding (10% vs. 44%, p < 0.05) and fewer post-procedure colonoscopies (17% vs. 51%, p < 0.05).

CONCLUSION

Mesenteric angiography had a 40% positivity rate for diverticular bleeding after CTA, with higher yield if performed within 4 hours, sub-selectively and after adequate resuscitation. Targeted embolization decreased rebleeding and post-procedure colonoscopies.

CLINICAL RELEVANCE/APPLICATION

Patients with colonic diverticular bleeding with active extravasation on CTA should be vigorously resuscitated and undergo prompt mesenteric angiography. This increases the likelihood of visualizing active extravasation and targeted embolization, leading to less rebleeding and further procedures.

T5B-SPIR-4 NOVEL ACOUSTIC SENSOR FOR NEEDLE TRACKING AND INTERNAL ULTRASOUND IMAGING AFTER THERMAL ABLATION IN AN EX VIVO MODEL

Laetitia Saccenti, MD (*Presenter*)
Ming Li, PhD (*Abstract Co-Author*)
John W. Karanian, PhD (*Abstract Co-Author*)
William F. Pritchard JR, MD, PhD (*Abstract Co-Author*)
Andrew Mikhail, PhD (*Abstract Co-Author*)
Ashley Gallagher (*Abstract Co-Author*)
Mike Kassin (*Abstract Co-Author*)
Ifechi Ukeh (*Abstract Co-Author*)
Bradford J. Wood, MD (*Abstract Co-Author*)

PURPOSE

Ultrasound guidance for thermal ablation is real-time, portable, and lacks ionizing radiation, however, visibility in the ablation zone is limited by the formation of gas during the ablation. This study aimed to assess the feasibility of integrating an acoustic sensor for both needle tip localization with ultrasound, temperature mapping of the ablation zone, and internal imaging after radiofrequency ablation (RFA) in an ex vivo liver model.

METHODS AND MATERIALS

A novel acoustic sensor (DeepSight Technology) was integrated into the stylet of a 22G needle. The sensor interfaced with an ultrasound system and visualization software. Six RFA were performed at 30 watts for 5 minutes in a fresh bovine liver. A few seconds after each ablation (RFA probe temperature < 65°C), the needle with sensor was independently inserted through the ablation zone and then withdrawn (N=12 crossings). One additional insertion was done after 3 hours of cooling. Data collected from the sensor included location, tissue relative temperature as well as an internal B-mode ultrasound image generated from the sensor.

RESULTS

The novel dual-sensing and imaging acoustic sensor was successfully integrated into a needle stylet. Localization of the needle tip was successful throughout the ablation zones. The sensor was able to measure temperature variation (temperature ranges 25-65°C), and as expected, no variation was detected in the ablation zone after 3 hours of cooling. Internal imaging from the needle tip was able to subjectively differentiate the expected locations of non-ablated liver, ablation margins and ablation center.

CONCLUSION

A novel acoustic sensor stylet allowed successful localization of the needle tip ex vivo in ablation zones, even when nonvisible under standard ultrasound. The sensor could also monitor relative temperature, and internal imaging from the needle tip was able to differentiate ablation center and margins from non-ablated tissue.

CLINICAL RELEVANCE/APPLICATION

Tracking and imaging sensors may enhance navigation and monitoring during ultrasound-guided ablation.

T5B-SPIR-5 SEDATION PRACTICE IN ABDOMINAL INTERVENTIONAL PROCEDURES: RESULTS FROM THE 2024 SAR AND SIR COLLABORATIVE WORKFORCE SURVEY

Olga R. Brook, MD, MBA (*Presenter*)
Hafsa S. Babar, MD (*Abstract Co-Author*)
Resmi Charalel, MD,MPH (*Abstract Co-Author*)

Francesca Rigiroli, MD (*Abstract Co-Author*)
Alexander Brook, PhD (*Abstract Co-Author*)
Gregory J. Dubel, MD (*Abstract Co-Author*)
Paul B. Lewis, MD, MS (*Abstract Co-Author*)
Andrew J. Cantos, MD (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)
Ghaneh Fananapazir, MD (*Abstract Co-Author*)
Samuel J. Galgano, MD (*Abstract Co-Author*)
Virginia B. Planz, MD (*Abstract Co-Author*)

PURPOSE

To assess current nationwide sedation practices in abdominal interventions across diverse practice settings, with the goal of detecting inconsistencies and to present an opportunity to develop recommendations for standardization of sedation protocols.

METHODS AND MATERIALS

A structured, web-based survey to identify current practice in sedation, anxiolysis, and pain management for biopsies and drainages was administered to board-certified Society of Abdominal Radiology (SAR) members performing procedures and all Society of Interventional Radiology (SIR) members between 8/9/2024 and 9/9/2024. All data were analyzed using the Kruskal-Wallis and Mann-Whitney tests.

RESULTS

After exclusion of 42 incomplete surveys, the overall response rate was 10.5% (360/3799), comprising 9.4% (318/3401) of SIR and 8.5% (34/401) of SAR members. The majority of respondents; 54% (194/360), were from private practice and 48% (171/360) of respondents had >15 years of experience. Superficial lymph node fine-needle aspiration (FNA) and aspiration only were usually performed without sedation; however, moderate sedation was utilized by 8% (27/341) and 26% (91/348) of proceduralists, respectively. Superficial soft tissue biopsies and superficial drainage with catheter placement were performed with moderate sedation by 40% (138/342) and 44% (150/343) of respondents, respectively. While parenchymal transplant kidney biopsies can potentially be performed without moderate sedation, 83% (247/298) of proceduralists still utilize it. Moderate sedation is utilized for random liver biopsies by 85% (299/350), random kidney biopsies by 89% (307/344), retroperitoneal biopsies by 92% (317/345), and deep drainage by 94% (323/345) of respondents.

CONCLUSION

Moderate sedation utilization is inconsistent amongst interventionalists in the United States and is frequently overutilized for certain procedure types. Low, but non-zero rate of utilization is noted for superficial procedures (8-44%), with much higher rates, but far from universal adoption for deep interventions (83-94%).

CLINICAL RELEVANCE/APPLICATION

The identified practice variations suggest a need for evidence-based standardization of sedation protocols for abdominal interventional procedures, as the potentially unnecessary use of moderate sedation for superficial procedures and transplanted organs impacts resource utilization and patient safety without clear clinical benefit.

T5B-SPIR-6 DEVELOPMENT AND VALIDATION OF A PERCUTANEOUSLY INSERTED OPTICAL COHERENCE TOMOGRAPHY PROBE FOR THE VISUALIZATION OF THE BILIARY SYSTEM: FIRST IN HUMAN EXPERIENCE AND EXPERIENCE IN DIFFERENTIATING BENIGN AND MALIGNANT BILIARY STRICTURES

Mohammad Mirza-Aghazadeh-Attari, MD, MPH (*Presenter*)
Clifford R. Weiss, MD (*Abstract Co-Author*)
Xingde Li, PhD (*Abstract Co-Author*)
Harjit Singh (*Abstract Co-Author*)

PURPOSE

We aim to develop and validate UHR-OCT integrated with cholangioscopy and fluoroscopy to assess its feasibility, safety, and accuracy in characterizing biliary strictures, and to develop a semantic signature for subtyping indeterminate cases.

METHODS AND MATERIALS

We developed a custom 2K-pixel linear-k spectrometer for UHR-OCT, covering 250 nm around 800 nm and achieving 1.2 mm imaging depth. Using a Ti:sapphire and continuum laser with a broadband rotary joint (20 fps, >87% throughput, -58 dB back-reflection), we enabled 3D intraluminal biliary imaging with a 4-6 French catheter (2 µm axial, 6 µm lateral resolution). The catheter had a working distance of 2 mm and achieved 2.4 µm axial (1.7 µm in tissue) and 6.8 µm lateral resolution.

RESULTS

A total of 10 patients (6 males and 4 females; median age 64) underwent evaluation with ultra-high resolution optical coherence tomography (UHR-OCT) for imaging biliary strictures during minimally invasive interventions. Seven patients had benign strictures, three had malignant ones. Imaging succeeded in 9 cases, with one failure due to catheter tip breakage. Mean procedure time was 61.33 minutes, fluoroscopy time 8.4 minutes, and OCT catheter duration 8 minutes, showing stable imaging times ($p=0.03$). UHR-OCT distinguished normal, inflamed, and malignant biliary tissues, revealing characteristic features like basement membrane disruption in malignancies, with characteristic alterations observed in malignant biliary strictures, including basement membrane disruption, increased vascularity, and loss of normal epithelial layering. The ability to visualize peri-biliary glands and distinguish inflammatory changes from malignancy suggests a potential role for UHR-OCT in reducing diagnostic uncertainty in IDBS. Additionally, the relatively stable duration of UHR-OCT imaging across cases, irrespective of procedural complexity, highlights its practicality as a real-time adjunct to standard biliary interventions. Findings suggest UHR-OCT's potential for enhancing diagnostic accuracy in indeterminate biliary strictures (Figure).

CONCLUSION

This study shows that integrating UHR-OCT with fluoroscopic and cholangioscopic imaging is feasible and safe for evaluating indeterminate biliary strictures, offering high-resolution visualization to differentiate normal, inflamed, and malignant tissue.

CLINICAL RELEVANCE/APPLICATION

UHR-OCT provides real-time, high-resolution imaging of biliary epithelium, enabling differentiation of normal, inflamed, and malignant tissue. It identifies features like basement membrane disruption and increased vascularity, helping reduce diagnostic uncertainty in indeterminate strictures and potentially limiting repeat biopsies.

T5B-SPMK-1 WHOLE-TUMOR HISTOGRAM ANALYSIS OF SYNTHETIC MRI FOR THE DIFFERENTIATION OF BENIGN AND MALIGNANT SOFT-TISSUE TUMORS:A PRELIMINARY STUDY

Lei Miao (*Presenter*)
Meng Li (*Abstract Co-Author*)

PURPOSE

To determine the diagnostic potential of histogram features derived from synthetic magnetic resonance imaging (SyMRI) for the differentiation of benign and malignant soft-tissue tumors (STTs).

METHODS AND MATERIALS

72 patients with STTs of the extremities or trunk (29 benign, 43 malignant) were prospectively enrolled. Quantitative histogram features, extracted from T1, T2, and proton density (PD) images, were obtained by delineating the three-dimensional volume of interest (VOI). Patients were divided into a benign group and a malignant group according to their pathological results. Logistic regression was used to construct diagnostic models. Receiver operating characteristic (ROC) analysis was performed to assess diagnostic performance.

RESULTS

Several histogram features derived from SyMRI, such as PD_Energy, T1_Skewness and T2_Kurtosis, were significantly elevated in patients with malignant STTs ($P<0.05$). All the models constructed on the basis of SyMRI histogram features performed comparably to or better than the Clinical_Model (a model based on conventional MRI features). The Combined_Model (a model integrating histogram features from the PD, T1, and T2 maps) has the highest AUC (0.946).

CONCLUSION

Whole-tumor histogram analysis via SyMRI can distinguish benign from malignant STTs well. The Combined model incorporating features from the PD, T1, and T2 models is effective. Future efforts should focus on external validation across multiple institutions and prospective prognostic validation studies.

CLINICAL RELEVANCE/APPLICATION

Differentiating between benign and malignant soft-tissue tumors is crucial for effective treatment, but current imaging methods struggle to reliably distinguish these tumor types. Whole-tumor histogram analysis using synthetic magnetic resonance imaging identified significant differences in quantitative features between benign and malignant soft-tissue tumors with high diagnostic accuracy. This non-invasive imaging approach enhances diagnostic precision, reducing the need for biopsies and assisting clinicians in developing tailored treatment strategies for soft-tissue tumor patients.

T5B-SPMK-2 MR-BASED EVALUATION OF OSSEOUS CERVICAL NEURAL FORAMINAL STENOSIS (OCNFS) USING FAST-FIELD-ECHO RESEMBLING CT USING RESTRICTED ECHO-SPACING (FRACTURE)

Dongmei Jiang (*Presenter*)
Yuwei Pan (*Abstract Co-Author*)
Dejun She (*Abstract Co-Author*)
Shuyi Lei (*Abstract Co-Author*)
Yingying Xie (*Abstract Co-Author*)
Dairong Cao, MD (*Abstract Co-Author*)

PURPOSE

To assess the feasibility of fast-field-echo resembling CT using restricted echo-spacing (FRACTURE) for evaluating osseous cervical neural foraminal stenosis (OCNFS) compared with CT and conventional MRI.

METHODS AND MATERIALS

A total of 280 cervical foramina from 28 patients with cervical radiculopathy (CR) were analyzed on oblique sagittal CT, FRACTURE, T1WI, and T2WI from bilateral C2/3 to C6/7 segments by three readers. CT served as the reference standard to identify OCNFS. Detection rate and grade of OCNFS were assessed. Inter-modality agreements were evaluated using linear weighted Cohen's kappa (?) for grade of OCNFS. ? 2 test was used to compare detection rates of OCNFS. Receiver operating characteristic (ROC) curves and Delong's test were performed to compare diagnostic performance of different imaging modalities.

RESULTS

The inter-modality agreement of OCNFS grade was substantial between CT and FRACTURE (? =0.689-0.715), moderate between CT and T1WI (? =0.427-0.597), and moderate between CT and T2WI (? =0.462-0.604). The intra-reader and inter-reader agreement of quantitative measurements (TD, VD, and SA) was moderate to excellent for FRACTURE (ICC =0.659-0.944). The intra-reader and inter-reader agreement of OCNFS grade was moderate to nearly perfect for FRACTURE (? =0.532-0.830) . Among the 280 analyzed cervical neural foramina, 104 were diagnosed as OCNFS using CT. Detection rate of OCNFS was 96.15% (100/104) for FRACTURE, 76.92% (80/104) for T1WI, and 95.19% (99/104) for T2WI. The FRACTURE could detect more OCNFS compared to conventional T1WI sequences. The severity scoring of OCNFS was not significantly different between CT and FRACTURE, but was higher on T2WI than on CT. The area under the curve (AUC) was 0.967 (95% CI: 0.938-0.984) for FRACTURE, 0.811 (95% CI: 0.760-0.855) for T1WI, and 0.845 (95% CI: 0.798-0.886) for T2WI. The DeLong's test revealed significant differences between FRACTURE and T1WI ($Z =6.023$, $P <0.0001$), and FRACTURE and T2WI ($Z =5.437$, $P <0.0001$).

CONCLUSION

FRACTURE can provide a reliable alternative to CT for evaluating OCNFS.

CLINICAL RELEVANCE/APPLICATION

FRACTURE is a viable alternative to CT for assessing OCNFS. Combined with conventional MRI, it enables comprehensive evaluation of CNFS caused by osseous or soft tissues, simplifies the examination process, reduces ionizing radiation, and facilitates more convenient follow-up evaluations.

T5B-SPMK-3 SPORTS-RELATED CALF MUSCLE INJURIES IN PROFESSIONAL ATHLETES: DIAGNOSTIC ACCURACY OF MAGNETIC RESONANCE IMAGING (MRI) IN EVALUATION, GRADING, AND CLASSIFICATION WITH ATTEMPTS TO IMPROVE THE PREDICTION OF TIME TO RETURN TO PLAY (TTRTP), AND THE ROLE OF ARTIFICIAL INTELLIGENCE (AI)

Yasser Abd El Fattah Hassan, PhD, MSc (*Presenter*)
Sherif El Hanawy, PhD, MSc (*Abstract Co-Author*)
Moataz Elsayed (*Abstract Co-Author*)
Yasmine Atteya El Feky (*Abstract Co-Author*)

PURPOSE

Assess diagnostic accuracy of MRI in classification of sports-related recent calf muscle injuries in professional athletes, using standardized classification systems, considering their complex myo-connective anatomy to explore methods to improve prediction of TtRtP based on clinical reference standards. The study also evaluates the added prognostic value of AI-based modeling.

METHODS AND MATERIALS

Retrospective study conducted on 29 professional football players with recent calf muscle injuries between 2020 and January 2025. All participants underwent 1.5T MRI within 72 hours of injury. Injuries were classified using the British Athletic Muscle Injury Classification (BAMIC) as well as specific patterns in aponeurotic injuries and MRI classification for medial gastrocnemius muscle injuries. The reference standard for TtRtP was considered as expert-determined clinical and radiological TtRtP based on previous studies defined as the time from injury to full team training clearance, verified by the team physician and rehabilitation staff). The actual TtRtP data were recorded and compared to the reference standard . Correlations between MRI findings and TtRtP were assessed. Diagnostic performance metrics were calculated for MRI grading thresholds to predict TtRtP. Inter-observer reliability was assessed. AI-based models integrating MRI findings and clinical data were preliminarily developed and evaluated for TtRtP prediction.

RESULTS

BAMIC revealed high correlation with TtRtP (r = 0.961; AUC = 0.981), while the MRI medial gastrocnemius injury classification (r = 0.912; AUC = 0.947). The integrated BAMIC and medial gastrocnemius classification model, for medial gastrocnemius aponeurotic injuries, achieved a correlation of r = 0.974 and AUC of 0.988. When AI was applied to the integrated model, predictive correlation improved further to r = 0.987, with an AUC of 0.994 and classification accuracy of 96.3%. Sensitivity and specificity for predicting TtRtP were 95.8% and 93.6% for the integrated model, and 97.9% and 96.4% with AI enhancement. Inter-observer agreement for structured MRI evaluation was excellent (? = 0.87)

CONCLUSION

MRI provides high diagnostic accuracy in classifying calf muscle injuries in professional athletes, especially considering the complex myo-connective anatomy. MRI findings closely correlate with TtRtP, with promising AI models for diagnosis and predictive accuracy.

CLINICAL RELEVANCE/APPLICATION

Comprehensive MRI evaluation using standardized classification systems with integrated AI-based prognostic tools enables accurate prediction of return-to-play timelines in calf muscle injuries, optimize rehabilitation strategies, and enhance safe TtRtP decisions for professional athletes

T5B-SPMK-4 PREDICTING LUNG METASTASIS IN HIGH-GRADE OSTEOSARCOMA: THE ROLE OF CTA SIGNS, WITH A FOCUS ON VASCULAR WRAPPING AND INTRATUMORAL VASCULAR NETWORK

Zhendong Luo, MD (*Presenter*)
Zhiqiang Liu (*Abstract Co-Author*)
Litong He (*Abstract Co-Author*)
Tao Ai, MD (*Abstract Co-Author*)
Xinping Shen (*Abstract Co-Author*)

PURPOSE

Osteosarcoma is a highly malignant bone tumor with a high incidence of lung metastases (LM), significantly impacting the 5-year survival rate of patients. This study aims to predict lung metastasis in osteosarcoma based on computed tomography angiography (CTA) signs.

METHODS AND MATERIALS

A retrospective study was conducted involving 89 consecutive patients with osteosarcoma. Clinical features and CTA signs, including age, gender, laterality, primary site, type of bone destruction, T stage, periosteal reaction, tumor length, bone marrow involved length, vascular wrapping, and intratumoral vascular network, were evaluated. Univariate and multivariate logistic regression analyses were used to identify risk factors for LM, followed by receiver operating characteristic (ROC) curve analysis.

RESULTS

The vascular wrapping and intratumoral vascular network signs were more frequently observed in LM in patients with osteosarcoma ($P < 0.05$). The intratumoral vascular network remained an independent risk factor in multivariable regression analysis. ROC curve analysis demonstrated that the area under the curve (AUC) of the logistic regression model was 0.804, indicating good predictive accuracy.

CONCLUSION

Preliminary findings suggest that CTA signs, particularly vascular wrapping and the intratumoral vascular network, may have potential utility in predicting lung metastasis (LM) in osteosarcoma patients. The intratumoral vascular network, in particular, was identified as an independent risk factor.

CLINICAL RELEVANCE/APPLICATION

1. Osteosarcoma is often metastasizes to the lung, greatly affecting 5-year survival rate.2. Intratumoral vascular network identified as predictors of lung metastasis was included in strongly performing predictive model.3. Identifying the CTA signs early can help tailor treatment strategies.

T5B-SPMK-5 FRACT-AI: EVALUATING THE IMPACT OF ARTIFICIAL INTELLIGENCE-ENHANCED IMAGE ANALYSIS ON THE DIAGNOSTIC ACCURACY AND INTERPRETATION TIME OF FRONTLINE CLINICIANS IN THE DETECTION OF FRACTURE ON PLAIN X-RAY

James Vaz, MD (*Presenter*)
Sarim Ather, PhD, MBChB (*Abstract Co-Author*)
Alpesh Mistry, MBChB, FRCR (*Abstract Co-Author*)
Natasa Devic, MBBS, MRCS (*Abstract Co-Author*)
James Teh, MD (*Abstract Co-Author*)
Alex Novak, MBChB (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of an AI fracture detection tool on clinician diagnostic performance and interpretation time for missed fractures across specialties and seniority levels.

METHODS AND MATERIALS

500 plain radiographs (250 fracture positive, 250 fracture negative, obvious fractures excluded) were curated from Oxford University Hospitals based on NHS Resolution data for litigation relating to missed fractures. Ground truth was established by two senior musculoskeletal radiologists with disagreements arbitrated by a third. All images were inferenced by Gleamer BoneView. 18 clinicians of varying seniority from six specialties (Emergency Medicine, Trauma & Orthopaedics [T&O], Emergency Nurse Practitioners, Physiotherapy, Radiography, Radiology) were recruited to a multi-case, multi-reader study. Readers interpreted all images with and without AI assistance. Algorithm accuracy, reader AUC, sensitivity, specificity, and median interpretation time were analysed for pooled readers and prespecified subgroups based on specialty and seniority.

RESULTS

Analysis of algorithm performance against ground truth demonstrated an accuracy of 0.876 with a sensitivity of 0.892 and a specificity of 0.858. Pooled reader AUC improved from 0.883 to 0.921 (95% CI 0.858-0.907 vs. 0.901-0.942; $p < 0.001$); sensitivity from 0.828 to 0.867 ($p < 0.001$) and specificity from 0.829 to 0.904 ($p < 0.001$). Overall median interpretation time was unchanged (43.0 s to 42.5s; $p = 0.835$). By seniority, Senior Grades read significantly faster with AI (41.5 s to 35.7s; $p < 0.001$), Middle Grades slower (30.9 s to 35.2 s; $p < 0.001$), and Junior Grades unchanged (54.6 s to 52.5 s; $p = 0.250$). By specialty, T&O experienced a 3.7 s reduction in time (37.3 s to 33.6 s; $p = 0.001$), while other specialties showed no significant change.

CONCLUSION

AI algorithm accuracy was lower than in previous comparable studies reflecting the challenging dataset. Despite this AI assistance significantly enhanced reader accuracy across all groups without increasing interpretation time (except amongst Middle Grades). No difference was seen in pooled interpretation time, however senior clinician and T&O specialty subgroups reduced interpretation time while junior and middle grade readers showed no change and increased time respectively.

CLINICAL RELEVANCE/APPLICATION

Integration of AI-driven fracture detection into radiographic workflows can improve diagnostic accuracy universally and may consequently reduce litigation, but may have variable effects on reporting efficiency depending on specialty and user experience in urgent care settings. Tailored interface design and targeted training may help all users convert diagnostic gains into faster throughput.

T5B-SPMK-6 COULD BONE-RADS BE APPLICABLE ON RADIOGRAPHS?

Syeda Shabistan Intekhab, MBBS (*Presenter*)
Omar Al Mukdad, MD (*Abstract Co-Author*)
Syed I. Alam, MBBS, MD (*Abstract Co-Author*)
Sandra Abusamaan (*Abstract Co-Author*)

PURPOSE

To apply the ACR Bone-RADS for assessment of bone tumors on radiographs of adult and pediatric population and to assess its diagnostic performance.

METHODS AND MATERIALS

The bone X-rays of a limited cohort of 20 pediatric patients with bone lesions were evaluated, using a scoring system derived from the ACR Bone-RADS. The study will be expanded to include 50 radiographs of adult and pediatric population. Risk score is calculated and validated by four radiologists independently, two consultant radiologists and two radiology residents and compared with histopathological diagnosis as a reference standard. The diagnostic performance of the scoring system and inter-reader agreement were calculated.

RESULTS

Bone-RADS demonstrated high sensitivity and negative predictive value (NPV) across all four readers, indicating it is effective tool in identifying malignant tumors and ruling out benign tumors. The specificity and the positive predictive value (PPV) were low and moderate respectively indicating that a proportion of benign tumors were scored as malignant. The Intraclass Correlation Coefficient (ICC) for Bone-RADS scores among the 4 raters was 0.85, indicating excellent agreement. The result was statistically significant ($p < 0.001$). The high ICC value of 0.85 reflects strong inter-rater reliability among all four readers. The interrater agreement calculated by Cohen’s kappa for individual Bone-RADS features ranged from fair to almost perfect agreement.

CONCLUSION

The application of Bone-RADS scoring system for evaluating bony lesions in pediatric radiographs was beneficial for long bone malignancy risk stratification, offering the interpreting radiologist with a systematic framework and assisting the orthopedic oncologist in devising subsequent care strategies. In case of flat bone tumors, further radiological assessment was required.

CLINICAL RELEVANCE/APPLICATION

The study demonstrates the utility of the proposed modified Bone-RADS scoring system, making it a reliable tool for evaluating bone lesions on pediatric and adult X-rays across different levels of expertise.

T5B-SPNMMI-1 SELF-ASSEMBLED PEPTIDE NANOFIBERS DEMONSTRATE TUNABLE CD38 AVIDITY

Jacqueline Godbe, MD, PhD (*Presenter*)

PURPOSE

To develop of a CD38-avid, peptide-based nanofiber for imaging and treatment of multiple myeloma

METHODS AND MATERIALS

We built upon a CD38-avid peptide previously developed in our lab, by adding a lipid tail, which templates self-assembly of the peptide into a CD38-binding nanofibers. We also intercalated hydrophobic small molecule MM therapeutics Bortezomib (BORT) and Iberdomide (IBR) into the nanofibers. Morphology of the resulting nanostructures was characterized by conventional and cryo-electron microscopy and fluorescence resonance energy transfer (FRET). BORT and IBR release were quantified with fluorescence. Affinity of CD38 for each nanofiber was characterized via fluorescence anisotropy with fluorescein-labeled CD38. Efficiency of radiolabeling with 64 Cu was assessed with TLC. Cell uptake studies were performed with CD38+ MOLP2 myeloma cells.

RESULTS

Nanofiber morphology and CD38 binding behavior is dependent on lipid tail length. These nanofibers are stable to labeling with 64 Cu and maintain morphology for at least 6 months. In vitro , nanofibers outcompete excess soluble peptide in cell uptake studies by CD38+ MM cells. Incorporation of BORT and IBR changes nanofiber morphology. Nanofibers demonstrate extended release of BORT and IBR over 72h.

CONCLUSION

Self-assembly of a CD38-binding peptide into a nanofiber improves binding behavior over the monomeric peptide to CD38 in vitro. Furthermore, these nanofibers demonstrate sustained release kinetics of MM drugs of interest such as BORT and IBR.

CLINICAL RELEVANCE/APPLICATION

CD38 is overexpressed in MM and the target of first line therapy with daratumumab. However, current CD38-targeted imaging therapies such as antibodies and peptides have unfavorable pharmacokinetics and/or low specificity. The multimeric CD38-avid nanofibers outcompete the soluble peptide for binding CD38 in vivo, making them an excellent candidate for further development. They are also excellent candidates for theranostic development by developing the 67 Cu/ 64 Cu pair as well as targeted delivery and extended release of IBR and BORT.

T5B-SPNPM-1 PATIENT AND PROVIDERS' EXPERIENCES WITH A MULTILEVEL INTERVENTION TO IMPROVE LUNG CANCER SCREENING

Gelareh Sadigh, MD (*Presenter*)
Maedeh Sharifian, MD (*Abstract Co-Author*)
Richard Echeverria (*Abstract Co-Author*)
Victoria Nguyen (*Abstract Co-Author*)
Mahnur Bharucha (*Abstract Co-Author*)
Michael Hoyt (*Abstract Co-Author*)
Aarushi Madan (*Abstract Co-Author*)
Tan Nguyen (*Abstract Co-Author*)
Sunmin Lee (*Abstract Co-Author*)
Hari Keshava (*Abstract Co-Author*)

PURPOSE

Lung cancer screening (LCS) utilization remains suboptimal. We aimed at understanding the experiences of patients and providers participating in a multilevel intervention that addresses barriers to LCS.

METHODS AND MATERIALS

Empower LCS is a single arm pilot clinical trial (NCT06000683), assessing the efficacy of a multilevel intervention (LCS decision aid, patient reminders to discuss LCS with the primary care provider (PCP), patient referrals to financial navigation, and PCP notifications of patients' LCS eligibility) on LCS completion among high-risk individuals. A total of 11 patients (5 English-, 5 Spanish-, and 1 Vietnamese-speaking) and 5 PCP participants of Empower LCS participated in a 30-minute one-on-one semi-structured qualitative interview. Interview transcripts were analyzed using a "theoretically driven thematic analysis" approach.

RESULTS

Eleven patients (mean age: 59; 73% male; 63% White; 9% Asian; 27% mixed races; and 45% Hispanic) and 5 PCPs (20% practicing in academic vs. 80% in community/FQHC) were included. Most patients believed LCS was important and were eager to discuss it with their PCP. Patients' motivations for screening included worries about their long-term smoking, positive family history, and a desire for early detection. When inquired about their perceptions of providers, some patients felt they were reluctant or hesitant to initiate full discussions of LCS, while they thought it was the provider's role to proactively discuss LCS. Some also felt providers' knowledge about LCS eligibility and communication skills could be improved. LCS barriers included scheduling difficulties and inability to get insurance authorization. When asked about their experience with Empower LCS, many stated that the intervention increased their awareness and motivation to pursue LCS and supported the idea of healthcare providers receiving prompts on that. In provider interviews, most, on the other hand, reported that they already routinely discussed smoking history to determine LCS eligibility. They felt patients were receptive to LCS and mentioned lack of awareness and insurance issues as important barriers. They believed interventions were suitable for the primary care practices, especially with efforts to enhance patient education and improve EMR alert accuracy.

CONCLUSION

Both patients and providers were receptive to LCS and thought the multilevel interventions, including the decision aid, reminders to providers, and financial navigation, had the potential to increase LCS in the routine practice.

CLINICAL RELEVANCE/APPLICATION

Understanding the perspectives of providers and patients about LCS and related interventions is essential to improving LCS adherence and ensuring the effectiveness of screening programs.

T5B-SPNPM-2 DIAGNOSTIC RADIOLOGY RESIDENT WRVU PRODUCTIVITY OVER TWO DECADES - A SINGLE INSTITUTION RETROSPECTIVE REVIEW

Josh Katz, MD (*Presenter*)
Adeel R. Seyal, MD,MBBS (*Abstract Co-Author*)
Larry Barbaras (*Abstract Co-Author*)
Karen S. Lee, MD (*Abstract Co-Author*)
Oussama Metrouh, MD (*Abstract Co-Author*)
Jeffrey L. Weinstein, MD (*Abstract Co-Author*)
Bettina Siewert, MD (*Abstract Co-Author*)
Jennifer M. Cutts, MD (*Abstract Co-Author*)

PURPOSE

Workloads for academic and private practice attending radiologists have steadily increased over the past two decades. This study evaluated diagnostic radiology resident radiologist wRVU productivity over the past 16 years to determine whether a similar trend existed with trainees.

METHODS AND MATERIALS

This single center retrospective study was IRB approved. The electronic medical record at our quaternary academic medical center was searched for radiology cases that contained a resident author from July 2006 through June 2022. Common procedural terminology (CPT) codes for these cases were also queried. Subsequently, the Medicare Physician Fee Schedule for 2023 (RVU23B) was cross-referenced with the resident CPT data so that a physician work relative value unit (wRVU) could be assigned to each CPT code. All cases were normalized to 2023 wRVU values. wRVUs were reviewed by class year and in aggregate for the 4-year residency over the study period. Data was analyzed using Spearman's rank correlation coefficient, linear regression analysis, and Mann-Kendall test using R statistical software.

RESULTS

wRVU data for 161 1st year, 159 2nd year, 158 3rd year, 159 4th year diagnostic radiology residents and 4-year aggregate data for 114 diagnostic radiology residents was reviewed. Median wRVUs declined for the 1st year residents 50 wRVUs/year, with a significant downward trend (rs = - 0.51; t = - 0.38, p = 0.035). There was a decline in the median wRVUs for the 2nd year residents by 13 wRVUs/year, respectively, however no significant upward or downward trend was noted (rs = -0.23; t = -0.38; p = 0.04 for 1st-year, t = -0.12; p = 0.54). For 3rd year residents, the median wRVUs decreased by 92 wRVUs/year with a significant downward trend (rs = -0.67; t = - 0.5; p = 0.006). 4th residents showed an increase in the median wRVUs by 132 wRVUs/year with a significant uptrend (rs = 0.79; t = 0.6; p <0.001). 4-year aggregate data showed a decrease in 59 wRVUs/year, however no significant upward or downward trend was noted (rs = -0.29; t =-0.14, p=0.511).

CONCLUSION

Diagnostic radiology residents' productivity as measured by wRVUs decreased from 2006-2022, a trend opposite that experienced by attending radiologists.

CLINICAL RELEVANCE/APPLICATION

While attending work volume increased over the past two decades, resident wRVU productivity decreased over a similar time period. This raises the question of whether a focus on productivity may be important to adequately prepare trainees for transition to clinical practice. Training experience and productivity during residency may impact successful transition to practice and may have wellness implications for early career attending radiologists.

T5B-SPNPM-3 ENHANCING RADIOLOGY WORKFLOW SAFETY: TRANSFORMER-BASED SIAMESE NETWORKS FOR AUTOMATED PATIENT IDENTITY VERIFICATION IN FOLLOW-UP PELVIC X-RAYS

Henrik Maximilian Kahl (*Presenter*)
Leon Moehring (*Abstract Co-Author*)
Denis Yang Gersdorf (*Abstract Co-Author*)
Christian Heitkamp (*Abstract Co-Author*)
Dilara Kisir (*Abstract Co-Author*)
Gerhard B. Adam, MD (*Abstract Co-Author*)
Haissam Ragab, MD (*Abstract Co-Author*)

PURPOSE

Patient misidentification in radiology, though infrequent, can lead to serious medical errors, including misdiagnosis and inappropriate treatment. This study evaluates a deep learning approach using siamese neural networks for automated detection of patient misidentification in follow-up pelvic x-rays, comparing its performance against radiologists.

METHODS AND MATERIALS

We developed a siamese network utilizing swin transformers pre-trained on ImageNet-22k. The model was trained on 2,970 pelvic x-ray image pairs resized to a resolution of 224 x 224, comprising 1,485 positive samples (same patient) and 1,485 negative samples (different patients). To improve model performance on cases with high inter-patient similarity, hard negative mining was employed. Five-fold cross-validation was implemented to enhance robustness, and an ensemble approach was used for final model inference. Model performance was assessed on an independent test set of 164 image pairs (82 positive, 82 negative) and compared against five radiologists (2 - 6 years of experience) who individually rated the similarity of the test pairs on a scale of 0-100. Statistical comparison of the model against radiologists was performed using DeLong's one-sided non-inferiority test (d = 0.05 margin).

RESULTS

The model achieved 94% accuracy (95% CI: 89 - 97%), F1 = 0.94 (0.89 - 0.97), and AUC-ROC = 0.98 (0.96 - 1.00), demonstrating non-inferiority to radiologists (AUC-ROC range: 0.95 - 0.98; d = 0.05 margin, p < 0.001). Most model errors were false negatives (incorrect same-patient rejections; 8/10), whereas radiologists' cumulative errors were mainly false positives (overlooked mismatches; 57/64). Of these radiologist-overlooked mismatches, 96% (55/57) were correctly identified by the model. The model processed cases in 0.2s versus radiologists' manual assessment time of 14.0±11.6s per pair.

CONCLUSION

Our siamese network effectively verifies patient identity in pelvic x-rays with non-inferiority to dedicated radiologist review. The system's high accuracy suggests that it could serve as a safeguard against patient identification errors, intercepting most undetected mismatches while operating at workflow-compatible speeds. Study limitations include single-center design and pelvic-specific validation.

CLINICAL RELEVANCE/APPLICATION

Implementation of this AI verification system as a secondary check in radiology workflows could significantly reduce patient misidentification incidents, potentially preventing diagnostic errors, inappropriate treatment, and patient harm. The system could provide an additional layer of safety beyond conventional identification methods, especially in high-volume or emergency settings where verification errors are more common.

T5B-SPNR-1 LINKING METABOLIC AND BRAIN STRUCTURAL GENETICS IN MAJOR DEPRESSIVE DISORDER

Huaigui Liu (*Presenter*)

PURPOSE

To investigate the shared genetic underpinnings between major depressive disorder (MDD)-specific gray matter volume (GMV) alterations and key metabolites using meta-analytic neuroimaging and multi-omics data integration.

METHODS AND MATERIALS

A systematic literature search of PubMed and Web of Science was conducted to identify voxel-based morphometry studies reporting GMV alterations in MDD. A coordinate-based meta-analysis was performed to determine convergent GMV abnormalities. Transcriptome-neuroimaging association analysis was then conducted using the Allen Human Brain Atlas to identify genes spatially correlated with GMV alterations. Genome-wide association summary statistics for MDD (N_case = 525,197; N_control = 3,362,335) and five metabolites—glucose, hemoglobin A1c (HbA1c), HDL-C, LDL-C, and triglycerides (TG)—were analyzed using the conjunctional false discovery rate (conjFDR) approach to identify shared genetic loci. The intersecting genes from both transcriptomic and conjFDR analyses were subjected to gene ontology (GO) enrichment analysis.

RESULTS

Fifty-seven neuroimaging studies were included. The meta-analysis revealed consistent GMV reductions in the left superior temporal gyrus, left inferior frontal gyrus, and left insula in MDD. Transcriptome-neuroimaging analysis identified 2,585 genes spatially associated with these GMV changes. conjFDR analysis detected 20, 20, 195, 83, and 186 shared loci between MDD and glucose, HbA1c, HDL-C, LDL-C, and TG, respectively. Intersection analysis revealed 13 to 73 genes jointly associated with each metabolic trait and MDD-related GMV changes. GO analysis highlighted biological processes related to lipid metabolism and neurodevelopment. Notably, FADS2 emerged as a convergent gene across all analyses.

CONCLUSION

This study uncovers a shared genetic signature linking GMV abnormalities in MDD with metabolic dysfunction. These findings provide insight into the neurobiological interface between psychiatric and metabolic disorders and offer promising targets for precision medicine.

CLINICAL RELEVANCE/APPLICATION

This study reveals a shared genetic basis between structural brain alterations in MDD and metabolites such as glucose and lipid levels. The findings highlight potential molecular links between psychiatric and metabolic disorders, suggesting that comorbid metabolic dysfunction may not be secondary but genetically intertwined with MDD pathology. Identification of genes like FADS2 may inform future biomarker discovery and targeted intervention strategies. This work supports the development of integrated diagnostic and therapeutic approaches in precision psychiatry and metabolic-mental health comorbidity management.

T5B-SPNR-2 A DEEP LEARNING-BASED MICROBLEED SEGMENTATION FOR ARIA-H DETECTION AND RADIOGRAPHIC SEVERITY PREDICTION IN OUT-OF-DISTRIBUTION CASES

Yoona Hwang (*Presenter*)
Saehyun Kim (*Abstract Co-Author*)
Wooseok Jung, MSc (*Abstract Co-Author*)
Seung Hyun Lee, MD (*Abstract Co-Author*)
Chong Hyun Suh, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate a deep learning-based algorithm for automatic cerebral microbleed (CMB) segmentation in SWI MRI across severity levels. We also assess the algorithm's performance on out-of-distribution cases with extreme CMB burden. Manual detection of CMBs is time-consuming, subjective, and suffers from inter-reader variability, affecting treatment decisions. This study addresses the need for objective CMB quantification tools with proven robustness across diverse patient populations.

METHODS AND MATERIALS

We collected 565 SWI MRI scans (normal:136, mild:390, moderate:32, severe:7) from a single South Korean tertiary hospital. A neuroradiologist with 14 years of experience reviewed MRIs and labeled CMBs. The MRIs were split in a 3:1:1 ratio for training, validation, and testing. We additionally included 28 cases with >10 CMBs and 5 CADASIL cases as challenging out-of-distribution cases with extremely high microbleed burden (59-107 CMBs per case). An Attention U-Net with deep supervision was trained. Evaluation included both lesion-level and patient-level analysis across severity categories.

RESULTS

The model achieved lesion-level metrics of 91.8% sensitivity, 54.7% precision, and 68.5% F1 score in detecting microbleeds on the test set, with false positives per scan of 1.06 (114 cases). For evaluation of out-of-distribution cases at the lesion level, the model maintained 81.2% sensitivity on cases with >10 CMBs (76.5% precision, 4.46 FP/scan in 28 cases), while CADASIL cases presented challenges with 69.8% sensitivity, though higher precision (86.3%, 9.8 FP/scan in 5 cases). At the patient level, the model achieved 77.2% sensitivity, 68.3% specificity, and 82.2% precision, with performance varying by severity (86.3%, 66.7%, and 97.0% sensitivity for mild, moderate, and severe cases respectively). The average processing time was 35.4s per scan using a single V100 GPU.

CONCLUSION

The study presents an effective algorithm for CMB segmentation on SWIs across all severity levels, achieving 91.8% sensitivity in test cases. It showed adaptability in challenging cases like CADASIL (69.8% sensitivity, 86.3% precision). Error pattern analysis revealed optimization opportunities, particularly for CMBs <1mm in size. Future work will validate across diverse clinical presentations, especially in severe CMB cases.

CLINICAL RELEVANCE/APPLICATION

The deep learning approach provides efficient, objective quantification of CMBs as an assistive tool for clinicians in ARIA monitoring. The proposed method could reduce reading time, streamline clinical workflow, reduce inter/intra-rater inconsistency in MRI assessment among radiologists of varying experience levels, and guarantee more consistent treatment decisions.

T5B-SPNR-3 LONGITUDINAL ASSESSMENT OF BRAIN IRON CONTENT FOLLOWING NEOADJUVANT CHEMOTHERAPY IN BREAST CANCER BY USING QUANTITATIVE SUSCEPTIBILITY MAPPING

Jing Zhang (*Presenter*)
Yong Tan (*Abstract Co-Author*)
Daihong Liu, PhD (*Abstract Co-Author*)
Jiuquan Zhang (*Abstract Co-Author*)

PURPOSE

To evaluate the longitudinal changes in brain iron content in participants with breast cancer after NAC using quantitative susceptibility mapping (QSM).

METHODS AND MATERIALS

In this prospective study conducted from April 2021 to April 2023, breast cancer participants underwent QSM and neuropsychological test pre- and post-NAC administration. Magnetic susceptibility, neuropsychological tests and laboratory indices were compared between the two time points. In addition, the association between changes in magnetic susceptibility and neuropsychological scores and laboratory indices were assessed. The effects of chemotherapy regimens, age, and blood indicators on the magnetic susceptibility were evaluated with generalized estimating equations (GEE).

RESULTS

Seventy-one women (mean age, 48 years ± 9 [SD]) and 65 healthy controls (mean age ± SD: 47 years ± 14) were recruited for this study. All breast cancer participants and ten healthy controls complete QSM scan in two time points. Compared with baseline, participants performed significantly worse after NAC on the neuropsychological assessments. Brain magnetic susceptibility changes were found in frontal lobe, occipital lobe, putamen and hippocampus. Correlations were observed between changes in QOL scores and the magnetic susceptibility of occipital lobe ($r = 0.235$, $P = 0.048$) and hippocampus ($r = 0.239$, $P = 0.045$), and between changes in SAS scores and the magnetic susceptibility of putamen ($r = 0.263$, $P = 0.027$). GEE analysis showed the correlations between the system iron and inflammation indicators and the magnetic susceptibility of occipital lobe, frontal lobe, hippocampus and whole brains.

CONCLUSION

Brain iron content derived from QSM has changed in participants with breast cancer after NAC, and related to the cognitive performance. And chemotherapy may affect brain iron metabolism by affecting systemic iron and inflammation.

CLINICAL RELEVANCE/APPLICATION

Brain iron content has changed in participants with breast cancer after NAC, and might be affected by the systemic iron and inflammation status.

T5B-SPNR-5 COMPRESSED SENSING MPRAGE ACCELERATION FOR CLINICAL AND RESEARCH NEURORADIOLOGY PROTOCOLS

Siddhant Dogra, MD (*Presenter*)
Vinh T. Nguyen, MD (*Abstract Co-Author*)
Antonio Pires, MD (*Abstract Co-Author*)
Maria J. Borja, MD (*Abstract Co-Author*)
Gopi Nayak, MD (*Abstract Co-Author*)
Mary Bruno, RT (*Abstract Co-Author*)
James S. Babb, PhD (*Abstract Co-Author*)
Timothy M. Shepherd, MD, PhD (*Abstract Co-Author*)

PURPOSE

Conventional 3D T1-weighted MPRAGE is a popular brain MRI sequence with diverse applications, yet its lengthy acquisition (~5 min) time reduces throughput and increases vulnerability to motion artifacts. We sought to determine whether a compressed-sensing 3D MPRAGE (CS-MPRAGE) sequence preserves lesion detection, image quality, quantitative brain volumetry, and tissue contrast-to-noise (CNR) relative to the clinical standard MPRAGE while reducing acquisition time.

METHODS AND MATERIALS

Standard MPRAGE and CS-MPRAGE were acquired at 3T in 28 patients with suspected brain metastases and in 23 patients with relapsing-remitting multiple sclerosis (MS). Three blinded neuroradiologists independently evaluated both standard and CS-MPRAGE sequences for all patients with suspected brain metastases to assess lesion presence, count, major diameter, and image-quality domains. For the MS patients, volumetrics across 12 brain anatomic regions as well as CNR were calculated by a third-party FDA-cleared software.

RESULTS

The CS-MPRAGE sequence reduced acquisition time by 49.7%. Diagnostic accuracy, sensitivity, specificity, and predictive values for lesion detection were not statistically different between sequences (all $p > 0.60$). Among evaluations of the 18 patients with confirmed metastases, interpretations with missed lesions were infrequent (3 of 54 standard, 4 of 54 CS-MPRAGE) and involved smaller lesions than correctly identified cases, though not statistically significant (standard: 0.77 ± 0.57 cm vs. 1.36 ± 1.75 cm, $p = 0.376$; CS-MPRAGE: 0.45 ± 0.13 cm vs. 1.40 ± 1.76 cm, $p = 0.135$). CS- MPRAGE had consistently lower but still good image quality. CS-MPRAGE had statistically lower volumes across 8/12 anatomic regions but with low magnitudes of inter-sequence differences. CS-MPRAGE also had lower CNR compared to standard MPRAGE (4.18 vs 4.41, $p < 0.0001$).

CONCLUSION

Despite small volumetric differences and lower CNR, accelerated 3D CS-MPRAGE achieves comparable metastatic lesion detection accuracy and maintains good image quality compared to standard MPRAGE while reducing scan time by nearly half.

CLINICAL RELEVANCE/APPLICATION

Implementation of accelerated CS-MPRAGE into clinical workflows can significantly enhance patient throughput, reduce motion artifacts, and improve MRI resource utilization without sacrificing diagnostic accuracy.

T5B-SPNR-6 SINGLE LAYER SPHERICAL (SLS) VS SINGLE LAYER (SL) WOVEN ENDOBRIDGE DEVICE IN THE TREATMENT OF NARROW NECK INTRACRANIAL ANEURYSMS: A PROPENSITY SCORE-MATCHED ANALYSIS

Hamza A. Salim, MD (*Presenter*)
Vivek Yedavalli, MD, MS (*Abstract Co-Author*)
Motaz A. Daraghma, MD (*Abstract Co-Author*)
Adam A. Dmytriw, MD,FRCPC (*Abstract Co-Author*)
Max Wintermark, MD (*Abstract Co-Author*)

PURPOSE

Data on the use of Woven EndoBridge (WEB) devices in the treatment of narrow-neck intracranial aneurysms (NNA) are limited. We compared the efficacy and safety of single-layer (SL) and single-layer spherical (SLS) WEB devices in treating NNA.

METHODS AND MATERIALS

We conducted a multicenter retrospective analysis of adult patients with NNA (neck =4.5 mm and width-to-neck ratio =2) treated with SL or SLS WEB devices between January 2011 and December 2022. Patients with fusiform or blister aneurysms, adjunctive treatments, or devices other than SL or SLS were excluded. Propensity score matching was used to adjust for confounding variables. Outcomes included procedural complications, angiographic occlusion rates using the Raymond Roy classification, major device compaction, need for retreatment, and functional outcomes assessed by the modified Rankin Scale (mRS).

RESULTS

After matching, resulting in 101 patients in each group, baseline characteristics were well-balanced. Thromboembolic complications occurred in 2.0% of the SLS group and 5.9% of the SL group (P = 0.28). Hemorrhagic complications occurred in 1.0% of the SLS group and 6.4% of the SL group (P = 0.062). Adequate occlusion rates (Raymond Roy grades I and II) were similar between groups (96% in SLS vs. 91% in SL; P = 0.20). Major device compaction was significantly less frequent in the SLS group compared to the SL group (0% vs. 7.6%; P = 0.024). The need for retreatment was trended toward being lower in the SLS group (1.1% vs. 6.6% in SL; P = 0.12). Functional outcomes (mRS 0-1) at last follow-up were comparable (82% in SLS vs. 86% in SL; P = 0.41).

CONCLUSION

In the treatment of narrow-neck intracranial aneurysms, the SLS WEB device was associated with significantly lower rates of major device compaction compared to the SL device. Reduced compaction may lead to a lower need for retreatment.

CLINICAL RELEVANCE/APPLICATION

Overall imaging outcomes and safety profiles were similar between the two devices.

T5B-SPNR-8 HIGHER MUSCLE VOLUME IS INVERSELY RELATED TO CHRONOLOGICAL AND BRAIN AGE WHILE INCREASED VISCERAL TO MUSCLE FAT RATIO IS POSITIVELY RELATED TO CHRONOLOGICAL AND BRAIN AGE

Cyrus A. Raji, MD, PhD (*Presenter*)

Thanh Duc Nguyen (*Abstract Co-Author*)
Saqib Basar (*Abstract Co-Author*)
Yosef G. Chodakiewitz, MD (*Abstract Co-Author*)
David Merrill, MD,PhD (*Abstract Co-Author*)
Alex Exuzides (*Abstract Co-Author*)
Amar Patel (*Abstract Co-Author*)
Daniel J. Durand, MD (*Abstract Co-Author*)
Sam Hashemi, MSc (*Abstract Co-Author*)

PURPOSE

Brain age predicted from structural brain images on T1 weighted scans can lend insight to Alzheimer's risk factors such as muscle loss with sarcopenia. We thus investigated the link between body MRI measured muscle mass, muscle to fat ratio and brain age.

METHODS AND MATERIALS

In all, 1,164 healthy participants from four sites (mean chronological age 55.17 ± 12.37 years, 52% women; 48% men; 39% non-white) were scanned on1.5T MR machines with a whole-body protocol. Whole body sequences utilized in the quantitative analyses of muscle mass were coronal T1 were used to segment total muscle volume normalized to participant height, visceral adipose tissue (VAT) and subcutaneous adipose tissue (VAT). In this process, a nnU-Net model was used for fully supervised segmentation and ITK-SNAP was used for manual annotation. Brain age was computed from T1 MPRAGE scans using a regression- based 3D Simple Fully Convolutional Network. The model was trained on in-house T1-weighted MRI scans collected from 5,500 healthy individuals, aged 18 to 89 years. Brain age gap (BAG) was calculated by subtracting chronological age from brain age. Bivariate correlations between total normalized muscle volume (TNMV) as well as VAT and SAT normalized to total muscle volume to chronological and brain age were done with partial correlations adjusted for sex with brain age analyses.

RESULTS

Mean brain age was higher than chronological age (56.04 ± 12.65, mean BAG = 0.69). Higher TNMV was related to both decreased chronological age (rp=-0.2579, p=2.524e-17) and brain age (rp =-0.2497, p=2.65e-16). VAT normalized to total muscle volume was linked to higher chronological (rp=0.3755, p=2.615e-36) and brain age (rp=0.3797, p=3.871e-37) adjusting for sex. No statistically significant links were noted with TNMV, VAT, SAT or and BAG. SAT was also not correlated in a statistically significant way to chronological or brain age.

CONCLUSION

Increasing muscle mass is related to lower chronological and brain age while visceral fat normalized to muscle volume is related to increased chronological and brain age. Lack of correlation to BAG may be due to the relatively low BAG in this sample. This work suggests improving muscle mass and reducing visceral fat may improve brain aging.

CLINICAL RELEVANCE/APPLICATION

Muscle mass as tracked on imaging can be a surrogate marker for various interventions to reduce frailty and improve brain health.

T5B-SPNR-9 AGE AND GENDER-SPECIFIC VARIATIONS IN MIDDLE CEREBRAL ARTERY DIAMETER: A COMPREHENSIVE ANALYSIS OF 656 INDIAN PATIENTS

Sai Charan P. Gunasekaran, MBBS, MD (*Presenter*)
Chiraag Mandal, MBBCh, MD (*Abstract Co-Author*)
Jitender Saini, MD,MBBS (*Abstract Co-Author*)
Chandrajit Prasad, MBBS, MD (*Abstract Co-Author*)
Sharankumar Patil (*Abstract Co-Author*)
Srinath R. Chitti JR, MBBS,MD (*Abstract Co-Author*)

PURPOSE

The Middle Cerebral Artery (MCA) diameter is a crucial anatomical parameter in neurovascular diseases and interventional procedures. Comprehensive data from the Indian subcontinent remains very limited. This study aimed to analyse age and gender-specific variations in MCA diameter among the adult Indian population.

METHODS AND MATERIALS

A retrospective analysis which was conducted on 656 patients who underwent CT angiography measured bilateral MCA diameters at their mid-points using standardized radiological protocols and stratified into eight age groups (18-30, 30-40, 40-50, 50-60, 60-70, 70-80, 80-90, and 90-98 years). Analyses were performed separately for males (n=371) and females (n=285). Statistical analyses included ANOVA for age-group comparisons and t-tests for gender comparisons within each age group.

RESULTS

The overall mean MCA diameter was significantly different between males (2.36 ± 0.29 mm) and females (2.21 ± 0.28 mm) ($p < 0.001$). Age-specific analysis revealed significant variations across different age groups. In males, MCA diameter showed a gradual increase from the 18-30 age group (2.33 ± 0.29 mm) to peak in the 60-70 age group (2.41 ± 0.30 mm). Females demonstrated a similar trend but with consistently smaller diameters, starting from 2.15 ± 0.26 mm in the 18-30 age group and reaching 2.28 ± 0.29 mm in the 60-70 age group. The most significant gender differences were observed in the younger and middle-age groups (30-60 years), with p-values ranging from 0.0002 to 0.0004. Statistical analysis revealed significant gender differences in the 18-30 age group ($p = 0.0482$), 30-40 age group ($p = 0.0003$), 40-50 age group ($p = 0.0002$), and 50-60 age group ($p = 0.0004$).

CONCLUSION

This study provides the first comprehensive analysis of age and gender-specific MCA diameter variations in the adult Indian population, demonstrating consistent gender dimorphism in MCA diameter, with males having larger vessels across most age groups, particularly in younger and middle-aged adults. The age-related variations and convergence of diameters in older age groups suggest different vascular aging patterns between genders.

CLINICAL RELEVANCE/APPLICATION

The established normative values and identified variations can guide the selection of appropriate endovascular devices and improve risk stratification in neurovascular procedures for the Indian population. The observed gender and age-specific differences emphasize the need for individualized approaches in neuro-interventional procedures, particularly in different age groups where gender differences are most pronounced.

T5B-SPNR-10 THE VALUE OF MULTIPHASE CT ANGIOGRAPHY IN PREDICTING HEMORRHAGIC TRANSFORMATION AFTER ENDOVASCULAR TREATMENT:THE ARTERIAL COLLATERALS AND VENOUS DRAINAGE

Tao Ren (*Presenter*)
Nina Hao (*Abstract Co-Author*)
Song Liu (*Abstract Co-Author*)
Luotong Wang (*Abstract Co-Author*)
Chao Tian SR, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to explore the quantitative diagnostic value of multiphase CT angiography (mCTA) in predicting hemorrhagic transformation (HT) and symptomatic intracerebral hemorrhage (sICH) in patients with anterior circulation acute ischemic stroke (AIS) after endovascular treatment (EVT).

METHODS AND MATERIALS

We retrospectively collected patients with anterior circulation AIS from our hospitals from April 2020 to December 2023. We assessed the arterial collateral circulation (ACC), superficial venous drainage scores (SVS), and deep venous drainage scores (DVS) based on mCTA . SVS1, SVS2, and SVS3, as well as DVS1, DVS2, and DVS3, represented SVS and DVS in the arterial, venous, and late venous phases, respectively. Patients were divided into HT and non-HT groups based on the presence of an intracranial hemorrhage on a follow-up non-contrast CT. We conducted a subgroup analysis on HT patients divided into sICH and asymptomatic intracerebral hemorrhage (aICH) subgroups. We analyzed and compared the clinical variables, ACC, SVS, and DVS on the non-HT and HT groups, as well as on the sICH and aICH subgroups. Multiparameter predictive models of HT and sICH were established using ACC (Model-HT1 and Model-sICH1), SVS and DVS (Model-HT2 and Model-sICH2), and comprehensive parameters (Model-HT3 and Model-sICH3). The performance of predictive models was evaluated and compared using the receiver operating characteristic (ROC) curve and the Delong test.

RESULTS

Finally, 127 patients were included, and 46 developed HT. HT group had a higher ratio of poor ACC than the non-HT group ($P <0.05$). A lower SVS1, SVS2, and SVS3 were observed in the HT group compared to the non-HT group (all $P <0.05$). For the subgroup analysis on HT patients, 14 had sICH, all these patients had poor ACC. A lower SVS1, SVS3, DVS1, and DVS2 were observed in the sICH subgroup than in the aICH subgroup (all $P <0.05$). In Model-HT1 and Model-HT3, ACC was the independent predictor for HT (OR, 13.924; 95%CI, 1.671-115.991; $P < 0.05$ and OR, 9.141; 95%CI, 1.149-72.723; $P < 0.05$). In Model-sICH2 and Model-sICH3, DVS2 was the independent predictors for sICH (OR, 0.1; 95%CI, 0.018-0.567; $P < 0.05$ and OR, 0.1; 95%CI, 0.018-0.567; $P < 0.05$). The ROC showed that Model-HT3 and Model-sICH2 improved the prediction efficacy (AUC, 0.789 and 0.828).

CONCLUSION

The ACC, SVS, and DVS based on mCTA were valuable for predicting the risk of HT and sICH after EVT, the combination of multiple parameters can improve the predictive efficacy.

CLINICAL RELEVANCE/APPLICATION

Our study could prompt neurologists to perform preventive intervention in high-risk patients after EVT cogently.

T5B-SPNR-14 MRI MORPHOLOGICAL FEATURES COMBINED WITH FRACTAL ANALYSIS CAN PREDICT BRAIN INVASION IN MENINGIOMAS

Xianwang Liu, MD (*Presenter*)

PURPOSE

Brain invasion in meningiomas correlates with higher recurrence rates and poorer prognosis. This study aims to investigate whether combining MRI morphological characteristics with fractal analysis can predict brain invasion in meningiomas.

METHODS AND MATERIALS

We retrospectively analyzed 112 patients with pathologically confirmed meningiomas (non-invasion group: 68, invasion group: 44). Fractal dimension (FD) and lacunarity were calculated from T1-weighted contrast-enhanced images. Differences between clinical features, MRI morphological features, and fractal features were assessed by Pearson's chi-square test and Kruskal-Wallis rank-sum test. Logistic regression analysis was used to select the optimal features and construct a prediction model. Furthermore, A nomogram was used to predict the risk of brain invasion, and a decision curve was used to verify the clinical utility of the nomogram.

RESULTS

Peritumoral edema (OR=3.5, p=0.004), irregular margins (OR=4.2, p=0.003), and FD>1.28 (OR=5.6, p<0.001) were independent predictors in predicting brain invasion in meningiomas. The combined model (morphology+FD) achieved the highest predictive performance (AUC=0.887) compared to morphological features (AUC=0.771) or FD (AUC=0.814).

CONCLUSION

Both MRI morphological features and fractal analysis can predict brain invasion in meningiomas, and their combined use further improves predictive performance.

CLINICAL RELEVANCE/APPLICATION

Accurately predicting brain invasion in meningiomas invasion is of great clinical importance. This study demonstrates that both MRI morphological features and fractal analysis can predict brain invasion in meningiomas, and their combined use further improves predictive performance, which could help guide treatment strategies for meningiomas.

T5B-SPNR-15 ALTERNATIONS IN STATIC AND DYNAMIC FUNCTIONAL CONNECTIVITY DENSITY IN TEMPORAL LOBE EPILEPSY WITH AND WITHOUT HIPPOCAMPAL SCLEROSIS

Chengru Song (*Presenter*)

PURPOSE

To comprehensively examined static and dynamic functional connectivity density (FCD) in temporal lobe epilepsy (TLE) with hippocampal sclerosis (HS) and MRI-negative TLE and its potential correlation with cognition.

METHODS AND MATERIALS

This study included 53 healthy controls (HC), 38 TLE-HS patients, 51 MRI-negative TLE patients. All participants had MRI scans of resting-state BOLD functional imaging and 3D T1WI sequence. We also recorded the cognition scores on the memory and executive screening (MES) test and auditory verbal learning test (AVLT). Using Dynamic BC software, we calculated static functional connectivity density (FCD) and corresponding temporal dynamic FCD (dFCD) utilizing a sliding window approach with a window length of 50 repetition times (TR) and a shifting step size of 10 TRs. Differences in FCD and dFCD among TLE-HS, MRI-negative TLE, and HC groups were analyzed by one-way analysis of variance (ANOVA) and post-hoc comparisons via two-sample t-tests. Furthermore, a seed-based functional connectivity (FC) analysis was executed based on those aforementioned group differences. Corrections for multiple comparisons were accomplished based on GRF theory (pvoxelwise < 0.005, pcluster-wise < 0.05). Relationships between cognitive scores and FCD or dFCD values were analyzed by Spearman correlation ($p < 0.01$). Receiver operating characteristic (ROC) curve analysis was applied to assess the distinguishing ability.

RESULTS

Cognitive decline was detected in both the TLE-HS and MRI-negative TLE groups; it was more pronounced in the TLE-HS group. Compared to the HC group, the TLE-HS and MRI-negative TLE groups both demonstrated reduced static FCD values in the temporal neocortex ipsilateral to the epileptogenic focus. However, in the TLE-HS group, the seed-based rsFC analysis results revealed larger aberrant cluster sizes of reduced FC in the ipsilateral frontal and temporal lobes. For dFCD, its elevation in the temporal neocortex ipsilateral to the epileptogenic focus was detected only in the MRI-negative TLE group. Moreover, the dFCD was significantly correlated with cognitive scores ($P < 0.05$) and revealed a moderate discrimination ability between TLE-HS and MRI-negative TLE.

CONCLUSION

The patterns of change in FCD abnormalities were similar between TLE-HS and MRI-negative TLE, which were more pronounced and widely involved in the TLE-HS group. Furthermore, dFCD may reveal more nuanced variations in MRI-negative TLE and help in discrimination.

CLINICAL RELEVANCE/APPLICATION

The combination of static FCD and dFCD could provide novel and complementary evidence to help deepen our understanding of the whole brain function’s impairment and compensatory mechanism in TLE.

T5B-SPNR-16 NOMOGRAM BASED ON CONVENTIONAL MRI FEATURES AND FRACTAL PARAMETERS FOR DIFFERENTIATING ISOLATED FIBROUS TUMORS FROM ANGIOCENTRIC MENINGIOMAS

Xiaoai Ke, MD, MMEd (*Presenter*)
Wei Ren (*Abstract Co-Author*)
Mengyuan Jing (*Abstract Co-Author*)
Junlin Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate whether a nomogram based on logistic regression models of conventional MRI features and fractal parameters can differentiate between SFT and AM.

METHODS AND MATERIALS

Our research focused on the clinical and imaging data from 193 cases of AM and 140 cases of SFT with histopathological diagnosis retrospectively. The box dimension algorithm was used to extract the enlarged tumor portion's 3D fractal dimension (FD) and lacunarity (LAC) values. Further evaluation focused on routine imaging features such as tumor size, shape, necrosis/cystic changes, dural tail sign, tumor vascular pattern, peritumoral edema, enhancement pattern, and bone destruction. Multivariate logistic regression analysis was adopted for identifying independent clinical and imaging risk factors for AM and SFT. Finally, a nomogram was constructed for predictive models of AM and SFT, with model performance assessed using calibration and decision curves.

RESULTS

Compared to AM, SFT had higher FD and LAC values ($P < 0.001$). Significant differences were found in age, size, morphology, necrosis/cysts, tumor vascularity, enhancement patterns, and dural tail signs between the AM and SFT groups ($P < 0.001$). Age, size, dural tail sign, FD, and LAC could differentiate between AM and SFT independently ($P < 0.05$). The AUC, accuracy, sensitivity, and specificity of the nomogram were 0.91, 0.85, 0.82, and 0.89 respectively. The calibration curve showed that the model's predicted probabilities of AM and SFT matched the actual probabilities well, showing valid prediction model indicated by the decision curve.

CONCLUSION

Fractal parameters can be used to discriminate between AM and SFT. The nomogram based on conventional MRI features and fractal parameters is reliable for distinguishing between AM and SFT, which can be used for preoperative non-invasive radiological prediction.

CLINICAL RELEVANCE/APPLICATION

A nomogram incorporating conventional MRI features and fractal parameters (fractal dimension and lacunarity) provides a reliable, non-invasive method to differentiate solitary fibrous tumors (SFT) from angiocentric meningiomas (AM). This tool can aid radiologists and clinicians in accurate preoperative diagnosis, improving treatment planning and reducing the need for invasive procedures.

T5B-SPNR-18 CROSS-SCALE ASSESSMENT OF POST-STROKE DEPRESSION IMAGING BIOMARKERS USING COMBINED NODDI AND DTI-ALPS ANALYSIS

Yanlin Tang (*Presenter*)

PURPOSE

To establish a multi-scale imaging biomarker system for post-stroke depression (PSD) by integrating Neurite Orientation Dispersion and Density Imaging (NODDI) and Diffusion Tensor Imaging Along the Perivascular Space (DTI-ALPS) techniques. This study investigated the "glymphatic dysfunction-white matter injury" hypothesis as a mechanistic framework explaining PSD development.

METHODS AND MATERIALS

This prospective longitudinal study enrolled 120 participants (40 PSD patients, 40 non-PSD stroke patients, 40 healthy controls) who underwent standardized depression assessments and MRI scans at baseline, 3, 6, and 9 months. Using a 5.0T scanner, NODDI parameters were extracted to evaluate microscopic axonal properties, while DTI-ALPS methodology assessed white matter integrity and glymphatic system functionality through perivascular diffusion measurements.

RESULTS

PSD patients exhibited distinct white matter abnormalities characterized by increased orientation dispersion index (ODI) and fraction of isotropic water (ISO) compared to non-PSD patients and healthy controls. DTI-ALPS analysis revealed compromised glymphatic system function in PSD patients, particularly evident in periventricular regions and along the superior longitudinal fasciculus ($p<0.001$). Longitudinal analysis demonstrated early glymphatic dysfunction (within 3 months post-stroke) preceded white matter deterioration and strongly predicted later depression severity ($r=0.68$, $p<0.001$).

CONCLUSION

This study establishes the "glymphatic dysfunction-white matter injury" pathological cascade as a critical mechanistic pathway in PSD development, wherein post-stroke neurovascular uncoupling leads to impaired glymphatic system function, causing progressive white matter microstructural damage and network dysfunction manifesting as depressive symptoms. The integration of NODDI and DTI-ALPS techniques provides a novel cross-scale assessment approach that bridges microscopic axonal property alterations with macroscopic white matter integrity changes and system-level clearance function impairments.

CLINICAL RELEVANCE/APPLICATION

The identified imaging biomarkers offer objective indicators for early PSD detection and intervention guidance, enabling personalized risk stratification and preventive therapeutic strategies. The established link between glymphatic system dysfunction and depression severity underscores the potential importance of waste clearance mechanisms in mood regulation, suggesting new therapeutic avenues targeting glymphatic system enhancement for PSD prevention and treatment.

T5B-SPNR-19 PREDICTIVE VALUE OF DESH FEATURES FOR FUTURE COGNITIVE DECLINE: A LARGE COHORT STUDY IN A GENERAL ELDERLY JAPANESE POPULATION

Kana Saito, MD (*Presenter*)
Keita Watanabe, MD,PhD (*Abstract Co-Author*)
Sera Kasai (*Abstract Co-Author*)
Tomohiro Shintaku (*Abstract Co-Author*)
Yuka Ishimoto (*Abstract Co-Author*)
Shingo Kakeda (*Abstract Co-Author*)

PURPOSE

Disproportionately enlarged subarachnoid-space hydrocephalus (DESH) features in idiopathic normal pressure hydrocephalus (iNPH) consist of three morphological characteristics: ventricular enlargement (Evans Index, EI > 0.3), enlarged Sylvian fissures (ESF), and tight high-convexity subarachnoid spaces (THCS). In clinical practice, one or two features are more commonly observed than all three, previously defined as "incomplete DESH." While incomplete DESH is observed in elderly individuals with normal cognitive function, its prevalence and association with cognitive function remain unclear. This study investigated whether incomplete DESH predicts cognitive decline in a large elderly cohort.

METHODS AND MATERIALS

Among 2,390 health check-up participants, 1,845 subjects with normal baseline cognitive function who were available for cognitive assessment follow-up at 2-8 years, excluding those with poor MRI quality or missing data on cognitive function or covariates, were enrolled. Two neuroradiologists assessed DESH features (EI > 0.3, ESF, THCS). Cognitive decline group was defined as progression from normal to mild cognitive impairment (MCI) or dementia. Logistic regression analysis examined whether DESH features predicted cognitive decline, adjusting for age, sex, education, medical history (diabetes, hypertension, hyperlipidemia), smoking, alcohol consumption, and total brain volume.

RESULTS

At follow-up, 1,672 participants (90.6%) maintained normal cognition, while 141 (7.6%) progressed to MCI and 32 (1.7%) to dementia, totaling 173 (9.3%) with cognitive decline (cognitive decline group). Complete DESH was present in 27 participants (1.5%). Individual features showed EI > 0.3 in 123 (6.7%), ESF in 783 (42.4%), and THCS in 177 (9.6%). Two-feature combinations included EI+ESF in 60 (3.3%), EI+THCS in 5 (0.3%), and ESF+THCS in 100 (5.4%). Logistic regression revealed that THCS alone and ESF+THCS combination significantly predicted cognitive decline ($p < 0.05$), while other DESH feature combinations did not.

CONCLUSION

In cognitively normal elderly individuals, THCS alone and its combination with ESF were significantly associated with future cognitive decline.

CLINICAL RELEVANCE/APPLICATION

DESH features on brain MRI predict future cognitive decline in cognitively normal elderly individuals, providing useful information to identify at-risk individuals for early intervention.

Priyanka Jha, MBBS (*Abstract Co-Author*)

PURPOSE

Placenta accreta spectrum (PAS) is a potentially life-threatening condition in which the placenta adheres to or invades the myometrium. Ultrasound (US) is the first line imaging modality for detection of PAS. MRI may serve as an adjunct when US is inconclusive or insufficient for characterization. While consensus statements exist concerning the imaging features of PAS, there is significant variation in clinical practice regarding imaging protocols, workflow, study interpretation, and peripartum management of PAS. The purpose of this study was to further characterize this variation by surveying members of the Society of Abdominal Radiology (SAR) Uterine and Ovarian Disease-Focused Panel (UOC DFP).

METHODS AND MATERIALS

An online survey regarding practice patterns in placental imaging was created using Qualtrics. Stakeholders experienced in interpreting placental US and MRI from the SAR UOC DFP contributed survey questions, representing multiple institutions. Pilot testing was conducted with radiologists who do not routinely interpret PAS imaging for readability and ease of use. Surveys were distributed to the 88 DFP members via e-mail. Data collected included practice setting, subject matter expertise, case volumes, imaging protocols, workflow and interpretation, peripartum management and challenges in the interpretation of PAS imaging. Time to complete the survey was logged for each respondent. Incomplete responses were included.

RESULTS

26 unique responses were collected (30% response rate). 9/26 respondents indicated that their institution does not perform in-house placental imaging. Of the remaining 17 respondents, 8 read MRI only, 2 read US only, and 5 read both. 2 respondents did not interpret PAS imaging but provided information regarding institutional protocols and practice. 14/17 considered themselves subject matter experts (SMEs) in PAS imaging. MRI and US volumes ranged from 1-10 and 4-10 studies per month, respectively. Reported MRI protocols varied, with all performing multiplanar T2 weighted imaging and many performing fat-saturated T1 (10/17) and diffusion-weighted imaging (7/17). Challenges identified included lack of communication with the obstetric team, suboptimal images, and lack of follow-up regarding patient outcomes. Common goals among respondents included accurate detection of PAS and guiding clinical management.

CONCLUSION

Significant variation exists in radiologic and clinical practice regarding imaging and management of patients with suspected PAS, even among SMEs.

CLINICAL RELEVANCE/APPLICATION

Awareness of practice patterns at U.S. academic medical centers provides opportunities for standardization of protocols and additional guidelines and recommendations at the society level.

T5B-SPOB-2 COMPARATIVE ANALYSIS OF ULTRASOUND ELASTOGRAPHY AND DIFFUSION-WEIGHTED MRI IN DIFFERENTIATING UTERINE MYOMETRIAL MASSES

Neha Bagri, MD, MBBS (*Presenter*)
Ritu N. Misra, MD, MBBS (*Abstract Co-Author*)
Aanchal Bhayana, MBBS (*Abstract Co-Author*)

PURPOSE

To compare the diagnostic efficacy of Strain and Shear Wave Ultrasound (US) Elastography and Diffusion-weighted (DW) MRI in differentiating Uterine Myometrial Masses.

METHODS AND MATERIALS

Fifty patients with uterine myometrial masses, i.e., fibroid, adenomyosis, or leiomyosarcoma (LMS) on the US and fifty controls (normal myometrium) were included. All these patients underwent Transabdominal Shear Wave and Transvaginal Strain US Elastography, followed by DW-MRI. The elasticity values (kPa), shear wave velocity values (m/s), strain ratio & mean ADC values (x10 -6 mm^2/sec) were compared between the myometrial masses and the control group, as well as between adenomyosis, fibroids, and LMS, keeping histopathology (HPE) as the gold standard.

RESULTS

A significant difference in the elasticity parameters (kPa & m/s) among fibroids, adenomyosis, LMS & controls, and fibroids vs. adenomyosis was noted (P-value <0.05). However, no significant results were obtained for Strain and Shear Wave Elastography in differentiating LMS from fibroids or adenomyosis. On comparing ADC values between fibroids and LMS, a cut-off of =968.6 (x10 -6 mm^2/sec) predicted LMS with 100% sensitivity and 64% specificity.

CONCLUSION

US Shear Wave Elastography contributes significantly to the differentiation of benign myometrial masses. Being non-invasive and radiation-free, it can serve as a good add-on to the conventional US. Also, Shear Wave and Strain Elastography, and ADC values effectively differentiate myometrial mass from normal tissue. However, Strain Elastography has a limited role in differentiating among specific types. DW-MRI has a significant role in differentiating fibroids from LMS and thus should be incorporated into the routine MRI protocol of uterine masses.

CLINICAL RELEVANCE/APPLICATION

Uterine myometrial masses, including fibroids, adenomyosis, and leiomyosarcoma, present with similar non-specific complaints of abnormal uterine bleeding, pelvic pain, and distension. Many a time, they have a similar appearance on imaging as well. The final diagnosis is obtained by histopathology. However, pre-operative characterization of these masses is considered pivotal for determining the therapeutic approach and feasibility of conservative treatment. Ultrasound Elastography may help differentiate various uterine myometrial pathologies based on tissue stiffness. Diffusion-weighted MRI and the apparent diffusion coefficient (ADC), a quantitative parameter, describe the diffusion of water molecules within tissues. Malignant pathologies with increased cellularity show lower ADC values than moderately hypercellular benign pathologies.

T5B-SPOB-3 PRENATAL OPIOID EXPOSURE ASSOCIATED WITH LOWER FETAL WHITE MATTER VOLUME

Ramana V. Vishnubhotla, PhD (*Presenter*)
Jonathan Class, MD (*Abstract Co-Author*)
Yi Zhao, PhD (*Abstract Co-Author*)
William Reynolds (*Abstract Co-Author*)
Sanjali Kherde (*Abstract Co-Author*)
Senthilkumar Sadhasivam (*Abstract Co-Author*)
Rupa Radhakrishnan, MD, MS (*Abstract Co-Author*)

PURPOSE

Opioid use during pregnancy continues to be a significant public health challenge. Prenatal opioid exposure is associated with adverse infant and childhood outcomes, however the mechanisms of how opioids impact the developing brain are not well assessed. Published literature shows alterations in neonatal brain volumes in prenatal opioid exposure, however these results have potential for confounding by perinatal clinical factors. Therefore, in this study, we assessed the association of prenatal opioid exposure with fetal brain development.

METHODS AND MATERIALS

This was a prospective, IRB approved, multisite study that recruited pregnant women with opioid use disorder on opioid maintenance therapy and control healthy pregnant women. Fetal brain MRI was performed in the second or third trimester. Two-dimensional MR images of fetal brains were acquired using a HASTE sequence in the axial, coronal, and sagittal planes. Fetal brain images were segmented and then reconstructed in three-dimensional space using automated pipelines. Reconstructed volumes were reorientated and realigned to standard space and segmented into eight tissue layers. The association of prenatal opioid exposure and segmented brain volumes were assessed using linear regression and corrected for race, sex, gestational age, tobacco use, and polysubstance use. Benjamini-Hochberg multiple comparison correction was performed.

RESULTS

63 subjects were included in this study - 31 with prenatal opioid exposure and 32 unexposed controls. Segmented white matter volume was significantly smaller in fetuses with prenatal opioid exposure ($p = 0.003$) after multiple comparison correction. Smaller deep gray matter volumes ($p=0.023$) and smaller volume of the corpus callosum ($p=0.035$) were also associated with prenatal opioid exposure on individual comparisons but was not sustained after multiple comparison correction.

CONCLUSION

We identified significantly lower white matter volumes in prenatal opioid exposure compared to control fetuses without substance exposure, suggesting a potential impact of opioids on white matter development and maturation.

CLINICAL RELEVANCE/APPLICATION

This work assessed impact of prenatal opioid exposure on neurodevelopment by assessing brain volumes in the fetal stage. Fetal imaging could be a valuable tool to assess those who may be at greater risk of poor developmental outcomes.

T5B-SPPD-1 IMAGING UTILIZATION IN THE OUTPATIENT AND EMERGENCY SETTING AMONG PEDIATRIC MEDICAID BENEFICIARIES AT CHILDREN'S VS. NON-CHILDREN'S HOSPITALS

Casey Pelzl, BS, MPH (*Presenter*)
Richard A. Barth, MD (*Abstract Co-Author*)
Eric Christensen, PhD (*Abstract Co-Author*)
Andrea S. Doria, MD, PhD (*Abstract Co-Author*)
Shireen Hayatghaibi, PhD, MPH (*Abstract Co-Author*)
Cara E. Morin, PhD (*Abstract Co-Author*)
Elizabeth Y. Rula, PhD (*Abstract Co-Author*)
Marla Sammer, MD (*Abstract Co-Author*)
Andrew T. Trout, MD (*Abstract Co-Author*)
Andy Tsai, MD, PhD (*Abstract Co-Author*)
Sherwin S. Chan, MD, PhD (*Abstract Co-Author*)

PURPOSE

To report relative proportions of imaging performed on pediatric (0-17 years) patients in the outpatient setting at children's (CH) versus non-children's hospitals (NCH) in the U.S., overall and by modality.

METHODS AND MATERIALS

Using two years (2018-2019) of CMS ' Medicaid 100% Research Identifiable Files, all year 2019 pediatric outpatient claims were identified from both hospital outpatient facility and emergency department (ED) places of service. Data from 2018 were used to calculate Pediatric Comorbidity Index (PCI) for risk adjustment. CMS facility identifier was linked to 2019 American Hospital Association data. We then utilized Piper et al.'s 2020 hospital tiering assignments to determine CH and NCH. Primary outcomes were the use of computed tomography (CT), magnetic resonance imaging (MR), ultrasound (US), or conventional radiography (XR) at each visit and compared between CH and NCH. Additional covariates included age group (0, 1-2, 3-5, 6-11, 12-17 years), measure of acuity using PCI (0, 1-2, 3-6, 7), chief complaint (ICD-10 diagnosis code), and place of service (outpatient vs. ED).

RESULTS

We identified 5,474,082 Medicaid claims for inclusion. Over half (53%) of visits were to children's hospitals (CH) and 15% were in the ED. Patients visiting CH were more likely to be aged 0-5 years vs >5 years (41.2% vs 38.7%, $p<0.01$), sicker with PCI>2 (32.3% vs 22.9%, $p<0.01$), and seen in an outpatient setting (87.8% vs 81.9%, $p<0.01$) than patients at NCH. The three most frequent primary complaints among patients were the same at CH and NCH: respiratory, developmental/psychological, and injury/trauma. The most commonly used modalities overall were XR (95/1,000 visits) and US (21/1,000 visits). Use of XR was more frequent at NCH than CH (118 vs 75 per 1,000 visits, $p<0.01$), as was CT (100 vs 50 per 1,000 visits, $p<0.01$). Use of US (25 vs 17 per 1,000 visits, $p<0.01$) and MR (9 vs 5 per 1,000 visits, $p<0.01$) were higher at CH than NCH. Rate of XR utilization was higher at NCH than CH, regardless of patient age or acuity (PCI). Rate of CT utilization was higher at NCH than CH among older patients (age categories 6-11 and 12-17 years).

CONCLUSION

When imaging pediatric Medicaid beneficiaries in an outpatient setting, non-children's hospitals appear to use XR and CT more often and US and MR less often compared to children's hospitals.

CLINICAL RELEVANCE/APPLICATION

This study presents the first available data comparing imaging modality utilization between children's and non-children's hospitals, revealing notable differences that may reflect disparities in resource and personnel availability or institutional care pathways. The clinical implications of these variations remain undefined and warrant further investigation to assess their impact on patient outcomes.

T5B-SPPD-3 SAME IMAGE, DIFFERENT EYES: COMPARING CLINICIAN AND RADIOLOGIST INTERPRETATIONS IN CHEST X-RAYS FOR TB SCREENING IN HIV CARE

James Iheke, MD, MBA (*Presenter*)
Bethelhem B. Belachew, MD (*Abstract Co-Author*)
Savvas Andronikou, MBBCh, PhD (*Abstract Co-Author*)
Abigail Seeger (*Abstract Co-Author*)
Anna Mandalakas, MD (*Abstract Co-Author*)
Alexander Kay, MD (*Abstract Co-Author*)
Adamson Munthali (*Abstract Co-Author*)
Brigid O'Brien, MD (*Abstract Co-Author*)
Jacob Todd, MD (*Abstract Co-Author*)
Hansel J. Otero, MD (*Abstract Co-Author*)

PURPOSE

Tuberculosis (TB) continues to be a major health threat for people living with HIV. Since 2020, the TB GAPs project has been studying TB screening methods, including chest X-rays (CXR), lab tests, and clinical assessments among children, adolescents, and adults receiving HIV care across five countries in sub-Saharan Africa. While the value of CXRs in TB screening remains debated, they're still widely used to support diagnosis. To compare how clinicians and radiologists interpret CXRs for TB screening in children with HIV, and assess how well their readings match.

METHODS AND MATERIALS

We prospectively evaluated 1,690 HIV-positive children and adolescents undergoing routine TB screening. A TB diagnosis was confirmed if treatment was started based on clinical or lab evidence. CXRs were read separately by clinicians (with access to symptoms) and radiologists (blinded to clinical info), using a structured form that included signs like lymphadenopathy, airspace opacity, effusion, nodules, and cavities. Results were grouped as positive (TB or unclear) or negative. Agreement was measured with Cohen's Kappa; we also calculated sensitivity, specificity, and AUC.

RESULTS

Overall agreement between clinicians and radiologists was fair (? = 0.318). Agreement was lowest for lymphadenopathy (? = 0.12) and highest for pleural effusion (? = 0.40); for cavities, it was nearly zero. Radiologists had 41.3% sensitivity and 95.7% specificity; clinicians had 65% sensitivity and 87% specificity. AUC was higher for clinicians (0.765 vs. 0.685).

CONCLUSION

Clinicians identified more TB cases, likely due to access to patient history, while radiologists were more confident at ruling disease out. These differences reflect the strengths and limitations of each approach. Clinician and radiologist interpretations of CXRs in pediatric HIV care often differ, likely due to differences in context and clinical input. In this setting, CXRs may be most helpful in excluding advanced TB.

CLINICAL RELEVANCE/APPLICATION

In high-burden areas like those served by the Baylor TB GAPS Centers of Excellence, clinicians using clinical context are more likely to detect TB, while radiologists excel at ruling it out. These findings highlight the importance of combining clinical and radiographic input and point to a need for stronger CXR interpretation training for clinicians, especially in settings with limited radiology support.

T5B-SPPH-1 IMPROVING DUAL-CONTRAST IODINE AND GADOLINIUM IMAGING WITH LOW-KV TECHNIQUE AND AI DENOISING ON CLINICAL PHOTON-COUNTING CT

Darren M. Imphean, MD (*Presenter*)
Eshan Joshi (*Abstract Co-Author*)
Tarique Hussain (*Abstract Co-Author*)
Franz Greil (*Abstract Co-Author*)
Hala A. Khasawneh, MBBS (*Abstract Co-Author*)
Liqiang Ren, PhD (*Abstract Co-Author*)

PURPOSE

Dual-contrast imaging of iodine and gadolinium has been shown to be technically feasible using clinical photon-counting CT (PCCT). However, suboptimal tube voltage selection and noise amplification following material decomposition currently limit the detection of low-concentration iodine and gadolinium signals. This study aims to evaluate the use of a low-kV technique (70 kV) combined with an AI-based denoising algorithm to enhance the performance of PCCT dual-contrast imaging of iodine and gadolinium.

METHODS AND MATERIALS

Iodine rods (0.5, 1.0, 2.0, and 5.0 mg/mL), gadolinium rods (0.3, 0.9, and 2.2 mg/mL), and an iodine/gadolinium mixture (5/5 mg/mL) were embedded in a multi-energy CT phantom of three sizes (lateral dimensions: 20, 33, and 40 cm). Scans were performed using a clinical PCCT scanner (NAEOTOM Alpha, Siemens) at 70, 90, 120, and 140 kV. Radiation dose levels were matched across scans (CTDIvol: 3, 8, and 12 mGy for small, medium, and large phantoms, respectively). Low- and high-energy images from each scan were exported for analysis. Image-based three-material decomposition (iodine/gadolinium/water) was performed on both the original and denoised images (processed using ClariCT.AI). For each decomposed iodine and gadolinium map, circular regions of interest were placed to measure mean mass concentration (± standard deviation). Root-mean-square error (RMSE) was calculated to assess performance across tube voltages, phantom sizes, and denoising conditions.

RESULTS

Across all phantom sizes, the lowest available tube voltage (70 kV) produced the lowest RMSE values on the decomposed iodine/gadolinium maps: 0.57/0.59 (small phantom), 0.73/0.76 (medium phantom), and 1.41/1.33 (large phantom). Quantification accuracy further improved when material decomposition was performed on denoised image pairs, reducing RMSE values to 0.33/0.33 (small phantom), 0.42/0.42 (medium phantom), and 1.05/0.93 (large phantom).

CONCLUSION

The 70 kV low-kV technique, with k-edge energy well-matched to gadolinium, outperformed higher tube voltages for dual-contrast imaging. Additionally, AI-based denoising further enhanced iodine and gadolinium material decomposition performance on PCCT images.

CLINICAL RELEVANCE/APPLICATION

Enhanced material decomposition using low-kV techniques and AI denoising may improve the clinical feasibility of dual-contrast iodine and gadolinium imaging, expanding its potential for future diagnostic applications.

T5B-SPPH-2 MATERIAL DECOMPOSITION AND MOTION ARTIFACT QUANTIFICATION IN DYNAMIC PHOTON-COUNTING-DETECTOR (PCD) CT WRIST IMAGING

Aeden Davis, BS (*Presenter*)
Hao Gong, PHD (*Abstract Co-Author*)
Andrew Thoreson (*Abstract Co-Author*)
Chunming Gu, PhD, MS (*Abstract Co-Author*)
Nirusha Lachman (*Abstract Co-Author*)
Kristin D. Zhao, PhD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)

PURPOSE

Wrist joint instability in movement can precede arthritis, but traditional CT systems are limited by poor connective tissue contrast and motion artifacts in dynamic imaging. Photon counting detector (PCD) CT improves these by enabling spectral dynamic imaging. This study tests the impact of motion on image artifacts and material decomposition in PCD wrist images.

METHODS AND MATERIALS

A cadaveric wrist with two fiducial markers was attached to a motion stage and scanned on a dual-source PCD-CT (NAEOTOM Alpha, Siemens), both statically and dynamically, with radial-ulnar deviation. Using a cardiac protocol to improve temporal resolution (66 ms), the cadaver was scanned at 3 motion speeds: 1.5, 1.0, and 0.75 s per cycle. 50 and 100 keV virtual monoenergetic images (VMIs) and single energy images (T3D), were reconstructed (Qr64 kernel, QIR4, 0.6/0.4 mm slice thickness/increment). Material decomposition using prior knowledge aware iterative denoising (MD-PKAID) was used to make collagen and hydroxyapatite maps. Regions of interest (ROI) measurements were taken in soft tissue and bone, and bias compared to static images was calculated at each speed. Motion artifact was analyzed at each speed, with X-ray starting angle matched. At each slice, ROIs were drawn around the fiducials and used to calculate entropy and positivity. The fiducials and low intensity regions (LIRs) were segmented and used to calculate the fold overlap ratio (FOR) and the LIR score, which measure deformation and low intensity artifacts. Wilcoxon signed rank tests were used to compare each metric across different speeds.

RESULTS

Higher motion speeds increased positivity and entropy and decreased LIR score. For positivity, LIR score and entropy all but two curves (right fiducial entropy, 1.0 and 0.75 s period) were statistically different ($p < 0.05$). Visually and quantitatively, artifacts worsened distally to the wrist. FOR showed no trend between motion speed and artifact. For material decomposition, average absolute bias was 35.4, 49.9, and 58.8 mg/cc for bone and was 53.7, 60.1, and 61.2 mg/cc for soft tissues for motion speeds of 1.5, 1.0, and 0.75 s per cycle. Soft tissue and bone blurring was observed at higher speeds.

CONCLUSION

PCD-CT enables dynamic imaging with spectral capability, but motion artifacts are still prevalent in wrist images. Positivity and LIR score accurately quantify these artifacts, but entropy and FOR do not. MD-PKAID density value bias increases for bone and soft tissue with an increase in speed.

CLINICAL RELEVANCE/APPLICATION

Identification of wrist joint instability may be possible with PCD CT dynamic imaging; however, motion affects image quality. Robust material decomposition and artifact correction for dynamic images are needed for accurate diagnosis.

T5B-SPPH-3 DEVELOPMENT OF A NEW PHANTOM FOR 3D IMAGING OF SMALL BLOOD VESSELS (WHICH ALLOWS SIMULTANEOUS MEASUREMENT OF MTF, SLICE THICKNESS, PEAK CT NUMBER, AND EFFECTIVE VOXEL SIZE)

Katsumi Tsujioka, RT (*Presenter*)

PURPOSE

Current CT devices are required to display three-dimensional images of small blood vessels, such as perforator vessels, in their entirety. Currently, the visualization ability of small blood vessels is discussed only in terms of MTF. However, MTF has the disadvantage that it cannot evaluate the contrast difference of small blood vessels. In clinical diagnosis and three-dimensional image creation, in addition to spatial resolution by MTF, blood vessel contrast is an important factor. Small blood vessel contrast is caused by the partial volume effect due to the effective voxel size of the CT device. Therefore, measurement of the effective voxel size is important for three-dimensional creation of small blood vessels. In this study, we developed a new phantom that can compare the peak CT value and effective voxel size in addition to the MTF of the CT device.

METHODS AND MATERIALS

The phantom is an acrylic cylinder with a diameter of 50 mm and a length of 300 mm, and a metal wire with a diameter of 0.1 mm is wound in a spiral shape. The spiral pitch is 5 mm per rotation. From the images after scanning, the MTF in the X-Y plane, the effective slice thickness in the Z-axis direction, and the peak CT value of the wire are measured. The effective voxel size can also be calculated. We conducted experiments on images from a conventional CT system, images from a conventional CT system using Deep Learning Reconstruction (DLR), and images from an ultra-high resolution CT (UHR-CT) system.

RESULTS

DLR and UHR-CT improved the MTF in the X-Y plane, and reduced the effective slice thickness. In addition, DLR and UHR CT increased the CT value of the metal wire.

CONCLUSION

The spiral wire phantom we developed allowed us to determine the MTF in the X-Y plane, the slice thickness in the Z-axis direction, and the peak CT value of the metal wire in a single scan. In addition, the effective voxel size could be determined from the increase in the measured CT value and the measured slice thickness. It was found that the effective voxel size was reduced in DLR and UHR CT compared to the conventional CT system.

CLINICAL RELEVANCE/APPLICATION

The ability to visualize small blood vessels cannot be properly evaluated using only the spatial resolution based on the conventional MTF. This is because this method does not allow evaluation of the change in the peak CT value of small blood vessels due to the partial volume effect. The thickness of the metal wire in this phantom is 0.1 mm. This allows accurate evaluation of blood vessels with a diameter of 0.2 mm according to the sampling theorem. The new phantom, which allows evaluation of peak CT value and effective voxel size in addition to measurement of MTF and effective slice thickness in a single scan, is suitable for accurately comparing the accuracy of 3D image creation in clinical practice.

T5B-SPPH-4 K-EDGE IMAGING FOR POST-TREATMENT EVALUATION OF ANEURYSMS: CONVENTIONAL AND PHOTON-COUNTING CT PHANTOM EXPERIMENTS

Nariman Nezami, MD (*Presenter*)
Amir Pourmorteza, PhD (*Abstract Co-Author*)
Arnaud Choux (*Abstract Co-Author*)
Brian Periku (*Abstract Co-Author*)
Scott Slavic, MS (*Abstract Co-Author*)
Zhye Yin (*Abstract Co-Author*)

PURPOSE

Effective assessment of embolization procedures relies on clearly distinguishing embolic materials from surrounding blood and contrast agents. Embolic agents are typically made radiopaque with iodine additives (e.g., ethiodized oil) or high-atomic-number metals like tantalum (Ta), tungsten (W), and platinum (Pt). This study explores the potential of spectral CT to differentiate between these embolics and iodine-based intravascular contrast agents (IBCA) using material-specific K-edge behavior.

METHODS AND MATERIALS

We created 20 aneurysm models using 3D printing and filled them with a variety of embolic agents from six manufacturers. These included metallic coils containing W and Pt, glue mixtures with ethiodized oil, LAVA, and shear-thinning embolics (Obsidio) with Ta. The models were embedded in an anthropomorphic phantom and scanned using a dual-energy, fast-kV switching CT system (GE Revolution Apex) and a deep-Si photon-counting detector (PCD) CT scanner. Virtual monoenergetic images at 40, 70, and 140 keV were reconstructed using filtered back projection algorithm with a standard kernel. Regions of interest were drawn to measure CT attenuation values for each embolic type and compared to a standard 15 mg I/mL iodine solution.

RESULTS

Embolics containing only iodine showed rapidly decreasing attenuation values with increasing energy, closely matching the IBCA mass attenuation vs energy curves. In contrast, Pt- and W-based embolics demonstrated a marked increase in attenuation at higher energies, while Ta-containing agents exhibited more stable or slightly declining curves. Although W and Ta have overlapping K-edge signatures, the co-occurrence of Pt with W helped distinguish them. These spectral trends enabled consistent differentiation among embolic types.

CONCLUSION

Spectral CT allows effective separation of iodine-based contrast from embolics composed of Pt, W, and Ta. For clearer differentiation in clinical imaging, non-iodinated embolics are preferable. Photon-counting CT, with its superior energy resolution and reduced metal artifacts, holds promise for advancing this technique further. We demonstrated that these embolic can be distinguished from IBCA with conventional spectral CT. Further work will better characterize the benefits that dSi PCCT may provide

CLINICAL RELEVANCE/APPLICATION

Accurate identification of embolic agents post-treatment can guide follow-up care and detect complications such as recanalization or migration. Spectral CT provides a non-invasive imaging tool that enhances clinical decision-making in endovascular therapies.

T5B-SPPH-6 AUTOMATED ACR MR QUALITY ASSURANCE REPORT SYSTEM FOR LARGE PHANTOM ACQUISITION

Luis Santos, MD, BA (*Presenter*)
Ji Hyun H. Lee, PhD (*Abstract Co-Author*)
Li-Yueh Hsu (*Abstract Co-Author*)
Gregg Cohen, PhD (*Abstract Co-Author*)

PURPOSE

The American College of Radiology (ACR) publishes the Large and Medium Phantom Test Guidance for the MRI Accreditation Program. The ACR Large Phantom Guidance consists of seven quality assurance (QA) tasks: Geometric Accuracy, High-Contrast Spatial Resolution, Slice Thickness, Slice Position, Image Intensity Uniformity, Percent-Signal Ghosting, and Low-Contrast Object Detectability. Technologists routinely perform manual measurements using the Picture Archiving and Communication System (PACS) viewer for these tasks that require estimating window, level, and thresholding settings. This is a time-consuming process prone to error.

METHODS AND MATERIALS

We developed a fully automated Phantom Acquisition Scan Measurements (PhantASM) pipeline based on the Hazen QA framework to automatically fetch and process phantom scans from the Philips (CareStream) PACS. We implemented the following additional tasks: Low-Contrast Object Detectability, High-Contrast Spatial Resolution, Slice Thickness, and Sagittal Geometric Accuracy. PhantASM generated human-readable reports from the processed imaging data, formatted for integration with PACS. The pipeline was validated using 500 prior acquisitions with 298 for Philips 3T and 202 for Siemens 1.5T scanners.

RESULTS

For the comparison of PhantASM automatic vs. manual measurements, the Geometric Accuracy task yielded 190 ± 0.82mm vs. 189.38 ± 0.06mm. For High-Contrast Spatial Resolution, results were 0.96 ± 0.06mm vs. 1.0 ± 0.01mm. The Low-Contrast Object Detectability task yielded 8.99 ± 1.73 vs. 9.87 ± 0.19 valid spokes. Image Intensity Uniformity results were 90.59 ± 4.13% vs. 93.38 ± 4.49%. Percent-signal Ghosting measured 0.14 ± 0.26 vs. 0.08 ± 0.07%. Additionally, the following tasks lacked manual comparison data. The Slice Thickness task yielded 5.28 ± 1.01mm. The Slice Position Accuracy task yielded 1.88 ± 1.43mm. All results are within ACR reference guidelines. For processing time, PhantASM averages 4 seconds when all seven tasks ran in parallel and 17 seconds when tasks ran sequentially. In contrast, manual measurements by technologists were estimated to take 6 to 20 minutes. A single pipeline job completed in about 30 seconds, providing a 12 to 40-fold increases in workflow efficiency.

CONCLUSION

All seven ACR QA tasks executed by PhantASM met ACR reference guidelines for quality MRI acquisitions, with results consistent across a cohort of 500 cases, including a mixture of scanner vendors and field strengths. The results are presented in a visually clear report, simplifying the QA process for technologists and significantly reducing operational time burden.

CLINICAL RELEVANCE/APPLICATION

The PhantASM workflow will improve acquisition quality, consistency, and measurement efficiency.

T5B-SPPH-7 INTER-INSTITUTIONAL CONSISTENCY OF QUANTITATIVE SPECTRAL RESULTS WITH CLINICAL PHOTON-COUNTING CT

Leening P. Liu, PhD (*Presenter*)
Martin Rybertt, BS (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)
Liqiang Ren, PhD (*Abstract Co-Author*)
Xinhui Duan, PhD (*Abstract Co-Author*)
Kishore Rajendran, PhD (*Abstract Co-Author*)
Di Zhang, PhD (*Abstract Co-Author*)
Grace Hyun Kim, PhD, MS (*Abstract Co-Author*)
Michael F. McNitt-Gray, PhD (*Abstract Co-Author*)

PURPOSE

With its technological advancements, photon-counting CT (PCCT) has enabled the incorporation of quantitative imaging into routine diagnostic radiology practices, especially for quantification of select elements (e.g. iodine) and materials (e.g. fat). While its quantitative stability over time has been previously evaluated, reproducibility of these quantitative results has not been investigated. Thus, we assessed inter-institutional quantitative reproducibility of spectral results in a commercially available PCCT.

METHODS AND MATERIALS

Four institutions scanned the same model of a commercial multi-energy CT phantom with the same configuration of tissue-mimicking and material-specific inserts on the same commercially available PCCT (Naeotom Alpha, Siemens Healthineers). At each institution, three scans were performed at a tube voltage of 140 kV and CTDI vol of 10 mGy in single-source mode. Virtual monoenergetic images (VMI) from 40 to 190 keV, iodine, and virtual non-contrast (VNC) maps were reconstructed for each scan. Images were then analyzed to measure a) error relative to the expected value of each material at each energy level and b) noise. Average relative error across repetitions and slices were calculated for each insert, institution, and spectral result. These average relative errors were then utilized to determine inter-scanner standard deviation and reproducibility coefficient (RDC) for each insert and spectral result to quantify inter-scanner reproducibility.

RESULTS

Spectral results demonstrated comparable quantification between the four scanners. Relative VMI 70 keV errors for each institution averaged 6 ± 3, 4 ± 2, 10 ± 7, and 11 ± 8 HU, respectively. Overall, inter-scanner standard deviation for VMIs decreased with increasing keV, measuring 9 ± 2, 3 ± 1, and 3 ± 1 HU for VMI 40, 70, and 190 keV, respectively. This corresponded to a RDC of 8.3 HU for VMI 70 keV. For VNC and iodine density, inter-scanner standard deviation averaged 2 ± 2 HU and 0.14 ± 0.11 mg/mL, respectively. Image noise was comparable between institutions with noise of 26 ± 2, 25 ± 2, 26 ± 2 and 26 ± 2 HU, respectively, for VMI 70 keV. An average noise of 0.92 ± 0.07 mg/mL was observed in iodine maps.

CONCLUSION

PCCT exhibited reproducible quantification and noise between scanners across spectral results. Inter-scanner reproducibility of quantitative maps in PCCT further enhances its utility for quantitative imaging in diagnostic radiology across a range of clinical applications.

CLINICAL RELEVANCE/APPLICATION

Establishing inter-scanner quantitative reproducibility is essential for ensuring consistent diagnostic interpretation and enabling the reliable use of PCCT-derived biomarkers across different clinical sites and systems.

T5B-SPPH-8 AI-DERIVED BACKGROUND PARENCHYMAL ENHANCEMENT TECHNIQUE ON CONTRAST-ENHANCED MAMMOGRAPHY: COMPARISON WITH RADIOLOGIST INTERPRETATION ACROSS AGE AND BREAST DENSITY

Tamerlan Mustafaev, MD (*Presenter*)
Margarita L. Zuley, MD (*Abstract Co-Author*)
Robert M. Nishikawa, PhD (*Abstract Co-Author*)

PURPOSE

The aim of our study was to develop and evaluate a method for automatically extracting quantitative Background Parenchymal Enhancement (BPE) characteristics on Contrast-Enhanced Mammography (CEM) using an in-house radiologist-trained AI algorithm.

METHODS AND MATERIALS

Low energy (LE) and recombined images (RI) from 1111 consecutively accrued CEM exams from an ongoing prospective diagnostic CEM trial included 982 exams with pathologically verified benign lesions and 129 studies with verified breast cancer. Patient age, radiologist-reported breast density, and BPE were collected from the research database. Our radiologist-trained, in-house AI model segmented breast density on LE images. These segmentations were applied to RI images to calculate BPE specifically within fibroglandular tissue (AI-fBPE) and fatty tissue. The AI model was a transformer-based U-net trained using publicly available datasets. We then calculated the difference between fibroglandular and fatty enhancements (AI-dBPE), thereby quantifying true fibroglandular tissue contrast. We performed two correlation analyses: (1) correlation between AI-fBPE and radiologist-reported BPE; and (2) correlation between AI-dBPE and radiologist-reported BPE. Additionally, we assessed correlations between AI-dBPE and radiologist-reported BPE for different age and breast-density groups separately. Age groups: <45 (premenopausal), 45-55 (perimenopausal), >55 (postmenopausal).

RESULTS

The correlation between AI-fBPE and radiologist-reported BPE was weak (r = 0.14, 95% CI: 0.08-0.20). The correlation between AI-dBPE and radiologist-reported BPE categories was stronger (r = 0.69, 95% CI: 0.66-0.71). For the fatty and scattered breast density group, the correlation between AI-dBPE and radiologist-reported BPE was moderate (r = 0.57, 95% CI: 0.50-0.64); for the heterogeneous and extremely dense group, this correlation was slightly higher (r = 0.60, 95% CI: 0.55-0.65). When analyzed by age, correlation between AI-dBPE and radiologist-reported BPE was strongest in women aged <45 (r=0.68, 95% CI: 0.62-0.73), followed by those aged 45-55 (r=0.66, 95% CI: 0.60-0.71), and lowest in women aged >55 (r=0.53, 95% CI: 0.47-0.59).

CONCLUSION

The AI-extracted AI-dBPE showed a strong correlation (r > 0.6) with radiologist-reported BPE, especially compared to AI-fBPE. Correlation was stronger in pre- and perimenopausal groups compared to postmenopausal women.

CLINICAL RELEVANCE/APPLICATION

AI-based quantitative assessment of BPE could serve as a reliable, robust, and standardized tool in clinical practice, reducing subjective variability in interpretation. Additionally, this technique may facilitate research to improve breast cancer risk prediction using CEM.

T5B-SPPH-11 IMPROVING CLARITY AND DIAGNOSTIC CONFIDENCE OF CORONARY STENT IN CORONARY CT ANGIOGRAPHY USING A SECOND-GENERATION WHOLE- HEART MOTION CORRECTION ALGORITHM (SSF2)

Tingting Qu (*Presenter*)

PURPOSE

To investigate the effect of a whole- heart motion correction algorithm (SSF2) on image quality and diagnostic confidence of coronary stent in coronary CT angiography (CCTA).

METHODS AND MATERIALS

Fifty-one patients (with 70 stents) underwent CCTA were included. Images were reconstructed using standard algorithm without motion correction (STD), with the first-generation snapshot freeze (SSF1) and SSF2 motion correction. Subjective scoring (5-point method) and objective evaluation of stents were performed. Subjective evaluation included the severity of stent motion artifacts, clarity of stent display, and diagnostic confidence within the stent. Objective evaluation included CT and SD values of the fat outside the stent with the most severe stent artifacts, in-stent lumen diameter, external stent diameter and severity of blooming artifact (blooming artifact = (external stent diameter - in-stent lumen diameter)/external stent diameter * 100).

RESULTS

The difference in the severity of stent motion artifacts among the three groups was statistically significant (P<0.001), with SSF2 having the lowest score (0.27±0.48) and STD the highest (1.34±1.10). The clarity of stent (4.30±0.62) and the diagnostic confidence score (3.77±1.11) of SSF2 were significantly higher than the other two groups (all P<0.001), and STD have the lowest score. There was a statistically significant difference in fat CT and SD values among the three groups (all P<0.001), with SSF2 having the lowest values, STD the highest. The stent reconstructed with SSF2 had the largest in-stent lumen diameter and the smallest blooming artifact (all P<0.001), followed by SSF1, while the STD had the smallest in-stent lumen diameter and the largest blooming artifact.

CONCLUSION

The application of SSF2 in CCTA significantly reduces the motion artifacts of coronary stents compared to STD and SSF1, resulting in better display of the coronary arteries inside the stents and improved diagnostic confidence.

CLINICAL RELEVANCE/APPLICATION

SSF2 technology can make coronary stent display clearer and improve diagnostic confidence, making it a highly recommended coronary reconstruction technique.

T5B-SPVA-1 OPTIMIZATION COMPUTED TOMOGRAPHY PROTOCOLS: IMPACT ON VASCULAR OPACIFICATION AND IMAGE QUALITY

Hortencia Ferreira, MSc, PhD (*Presenter*)
Jose Castro, PhD (*Abstract Co-Author*)
Danielle Cristina Novais Da Silva (*Abstract Co-Author*)
Sergio S. Dertkigil, MD (*Abstract Co-Author*)
Fabiano Reis (*Abstract Co-Author*)

PURPOSE

The optimization of contrast-enhanced computed tomography angiography (CTA) protocols is essential to balance diagnostic quality and patient safety. This study evaluates how protocol modifications influence vascular opacification in aortic, carotid, and pulmonary CT exams. The primary objective was to compare different contrast administration techniques, analyzing the effects of volume, flow rate, patient age, and weight on image quality.

METHODS AND MATERIALS

A retrospective analysis was conducted on 600 consecutive CTA scans of aortic, carotid, and pulmonary, performed between June 2024 and February 2025, using a Canon Aquilion Prime SP CT scanner with 80 channels and a Stellant Medrad intelligent contrast injector (Bayer). Only patients aged 18 years or older were included. Vascular opacification was classified into three categories based on attenuation values in Hounsfield Units (HU): poor for densities below 250 HU, medium for 251-349 HU, and optimal for 350 HU or higher. Statistical analysis employed logistic regression to identify significant associations between technical parameters and image quality, with a p-value under 0.05 considered significant.

RESULTS

The results demonstrated strong statistical significance for contrast flow rate as a predictor of vascular opacification with $p=0.0023$. Patient age significantly influenced outcomes, showing $p=0.0009$, where older patients exhibited better enhancement. Weight presented an inverse correlation with $p<0.0001$, indicating reduced opacification in heavier patients. Notably, contrast volume showed no significant impact with $p=0.1763$, suggesting flow rate adjustments can effectively compensate for reduced volumes.

CONCLUSION

Protocol optimization in 80-channel CT enables consistent image quality through strategic adjustments in contrast flow rate. The findings emphasize the importance of tailoring protocols based on patient-specific factors such as age and weight, rather than relying solely on contrast volume. This approach supports diagnostic efficacy while minimizing contrast dose, enhancing safety and efficiency in clinical practice.

CLINICAL RELEVANCE/APPLICATION

The clinical relevance of this study lies in its evidence-based guidance for refining CT protocols, particularly in older and overweight populations, where personalized adjustments can improve diagnostic accuracy without increasing contrast-related risks.

T5B-SPVA-2 DIAGNOSTIC RELIABILITY OF INTRAVASCULAR ULTRASOUND VERSUS VENOGRAPHY IN CENTRAL VENOUS MAPPING FOR END STAGE RENAL DISEASE PATIENTS

Mia Zivkovic (*Presenter*)
Daniel Raskin, MD (*Abstract Co-Author*)
Abraham Levitin, MD (*Abstract Co-Author*)
Jon Quatromoni, MD (*Abstract Co-Author*)
Jennifer Montgomery, MD,PhD (*Abstract Co-Author*)
Sasan Partovi, MD (*Abstract Co-Author*)

PURPOSE

Two dimensional supradiaphragmatic central venography has it limitations due to the inherent pliability of veins as well as the dependency of the diameter on the cardiorespiratory cycle. The aim of this study is to evaluate the diagnostic reliability of intravascular ultrasound (IVUS) compared with two-dimensional venography for supradiaphragmatic central venous mapping

METHODS AND MATERIALS

A retrospective review was conducted of 14 end stage renal disease patients who underwent same-session two-dimensional venography and IVUS between January 2024 and February 2025 for assessment of the central venous system. Veins were evaluated with regard to stenotic degree and venous wall pathologies. Stenosis severity was categorized as mild, moderate, or severe based on available imaging datasets. The primary endpoint was the discordance between IVUS and two-dimensional venography. Secondary metrics included contrast volume, fluoroscopy time, and procedural complications.

RESULTS

IVUS was discordant with venography in 7/14 cases (50%). In 4 cases (29%), IVUS revealed a higher degree of stenosis and / or intraluminal wall adherent thrombus which was not visualized on two-dimensional venography. In 3 (21%) cases, IVUS downgraded the severity of stenosis. Median contrast use was 51 mL (range: 25-127 mL), and median fluoroscopy time was 7.6 minutes (range: 3.0-20.3 minutes). No immediate procedural complications occurred, specifically no IVUS related complications were appreciated.

CONCLUSION

IVUS enabled verification as well as clarification of degree of stenosis in half of the assessed end stage renal disease patient population, IVUS demonstrated superior visualization of luminal contours, wall-adherent thrombus, and vessel diameter. Therefore, IVUS can be considered complementary imaging for supradiaphragmatic central venous mapping in end stage renal disease patients.

CLINICAL RELEVANCE/APPLICATION

When added to venography, IVUS improves venous lesion characterization and stenotic degree confidence during supradiaphragmatic central venous mapping, potentially reducing misclassification of central venous stenotic severity in end stage renal disease patients.

T5B-SPVA-4 HIGHLY ACCELERATED COMPRESSED-SENSING 4D FLOW FOR SIMULTANEOUS EVALUATION OF ILIAC VASCULATURE

Qiming Liu (*Presenter*)
Xinyu Wang (*Abstract Co-Author*)
Qifan Lu (*Abstract Co-Author*)
Qi Yang, MD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate and compare the hemodynamic parameters of the iliac arteries and veins using both conventional single-velocity encoding (VENC) and CS-accelerated multi-VENC 4D flow sequences in healthy participants.

METHODS AND MATERIALS

This study enrolled healthy participants without known cardiovascular disease between December 2023 and March 2025 at Beijing Chaoyang Hospital. Two conventional single VENC 4D flow acquisition and a multi-VENC CS-accelerated acquisition were performed (Table 1). For each participant, three arterial segments (abdominal aorta (AA), left common iliac artery (LCIA), right common iliac artery (RCIA)) and three venous segments (inferior vena cava (IVC), left common iliac vein (LCIV), right common iliac vein(RCIV)) were selected to calculate hemodynamic parameters. The 4D flow MRI data were post-processed using a freely available 4D flow processing tool, and two experienced readers quantified the mean velocity and wall shear stress (WSS). Paired-samples t-tests, Wilcoxon rank-sum tests, Pearson correlation coefficient (r), Bland-Altman analysis, and intraclass correlation coefficient (ICC) were used.

RESULTS

Baseline characteristics A total of 60 healthy participants were initially enrolled and 45 healthy participants (median age: 49 years; 64.4% male) were included for final analysis (Figure 1). A significant improvement on acquisition efficiency was observed for with an average reduction of 59%. Representative images are shown in Figure 2 . Quality control The technical variability, intra- and inter- observer ICC showed ICC > 0.8 and $P < 0.001$ for all segments. Comparison of flow parameters obtained using conventional and CS methods Arterial flow measurements are presented in Table 2 and Figure 3 . For all segments, parameters measured by CS methods were lower than those obtained using conventional methods (2.8% to 9.6%). Flow measurements for veins are presented in Table 3 and Figure 4 . All parameters exhibited underestimation with CS acquisition (5.0% to 12.0%), though the differences were less pronounced compared to arterial findings. The correlation between flow parameters obtained using both techniques, showed R values > 0.8 for all parameters (Figure 5).

CONCLUSION

This study evaluated and quantified the flow parameters of iliac arteries and veins in healthy participants using conventional and multi-VENC 4D flow techniques. Although underestimation was observed, multi-VENC 4D flow enabled comprehensive velocity and WSS assessment.

CLINICAL RELEVANCE/APPLICATION

The CS-accelerated multi-VENC 4D flow acquisition enable the rapid evaluation of both arterial and venous components of iliac vasculature but should be further evaluated in patients with venous and arterial diseases.

W2-SPBR-1 RECALL RATE, CANCER DETECTION RATE, AND ACCEPTABILITY OF THE FIRST ROUND OF DIGITAL BREAST TOMOSYNTHESIS SCREENING IN A DUTCH POPULATION-BASED SCREENING TRIAL

Jessie J. Gommers, MSc (*Presenter*)
Lindy Kregting (*Abstract Co-Author*)
Elle Heijnen (*Abstract Co-Author*)
Lian Pennings (*Abstract Co-Author*)
Maartje J. Smid-Geirnaerdt, MD, PhD (*Abstract Co-Author*)
Adriana M. Bluekens, MD,PhD (*Abstract Co-Author*)
Sarah D. Verboom, MSc (*Abstract Co-Author*)
Ioannis Sechopoulos, PhD (*Abstract Co-Author*)
Mireille Broeders, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the short-term screening performance and acceptability of Digital Breast Tomosynthesis (DBT) in the first round of the DBT with Advanced Reading Methods (STREAM) prospective screening trial being performed in the Dutch Breast Cancer Screening Program.

METHODS AND MATERIALS

The Dutch Screening Program includes biennial four-view Digital Mammography (DM) for women aged 50 to 74 years old. All examinations are independently double-read by screening radiologists with arbitration in case of disagreement. STREAM trial participants underwent the first of two rounds of four-view DBT screening instead of DM between July 2023 and May 2024. A comparable control group received regular DM screening in the same time period. Current analyses include first round results for recall rate (RR) and cancer detection rate (CDR). After DBT examination, participants, radiographers, and screening radiologists were asked to complete an online survey on the acceptability of DBT screening. Participants reported their experience with DBT compared to DM in the previous screening round. Radiographers and radiologists reported on the ease of use of DBT screening, and their suggestions for improvement.

RESULTS

Out of 44,682 invited screenees, 18,186 participated in the STREAM trial (41%). Among them, 488 (2.68%) were recalled, of whom 166 (9.1 per 1,000) were diagnosed with breast cancer. Control group data are not yet available, but the national monitor for 2023 reported a RR of 2.40% and a CDR of 7.5 per 1,000 with DM. The acceptability survey was completed by 10,983 participants (60%), 62 radiographers (~62%), and 25 radiologists (71%). Participants reported an average pain score of 3 (scale 0-10) for DBT, similar to an average pain score of 3.5 for DM. About half (52%) preferred DBT over DM, and 46% had no preference, mainly because they experienced no difference. The majority of radiographers (84%) reported DBT screening as 'feasible', however most radiologists (76%) reported DBT as 'feasible, but sub-optimal', mostly due to limitations in image loading and reading times.

CONCLUSION

Preliminary results suggest a modest increase in RR and an increase in CDR for DBT screening compared to DM. Control group data will be available by fall 2025. Participants have a high acceptability for DBT screening, radiographers are generally content, but radiologists request improvements to enhance workability. The feedback is being used to improve the second round of DBT screening.

CLINICAL RELEVANCE/APPLICATION

In the Dutch DM screening program, the RR is low (2023: 2.40%) while the CDR is relatively high (2023: 7.5 per 1,000). The STREAM trial will show the trade-offs between harms and benefits of DBT compared to DM screening whether DBT is acceptable to participants and professionals.

W2-SPBR-2 CHANGE IN PERCENTAGE FUNCTIONAL TUMOR VOLUME AFTER NEOADJUVANT IMMUNOTHERAPY PREDICTS RESPONSE IN HER2+ BREAST CANCER

Robert J. Weinfurtner, MD (*Presenter*)
Asha Bhatt, MD (*Abstract Co-Author*)
Shannon Falcon, MD (*Abstract Co-Author*)
Brian J. Czerniecki, MD, PhD (*Abstract Co-Author*)
Marie C. Lee, MD (*Abstract Co-Author*)
Paige Aiello (*Abstract Co-Author*)
Aixa Soyano (*Abstract Co-Author*)
Hatem Soliman (*Abstract Co-Author*)
Heather Han (*Abstract Co-Author*)

PURPOSE

To determine if functional tumor volume (FTV) analysis can help predict pCR in HER2+ breast cancer patients undergoing neoadjuvant immunotherapy.

METHODS AND MATERIALS

In a pilot study of neoadjuvant immunotherapy using dendritic cell vaccines (DC1) to treat HER2+ breast cancer, baseline and post-immunotherapy MRIs (10/1/21-8/16/2024) were retrospectively analyzed. For quantitative analysis, functional tumor volume was calculated on pre-treatment post-contrast T1-weighted MRI images using a percent enhancement threshold of 70% and signal enhancement ratio set to 0. Next, %FTV was calculated for each segmented tumor (%FTV=FTV/segmented tumor volume). Change was then calculated by subtracting the results post-immunotherapy to baseline. These were correlated with pathologic response at surgery using Mann-Whitney U test where $p<0.05$ was considered significant. FTV analysis was also compared to post-treatment pre-surgical MRI reports for diagnostic test accuracy comparison.

RESULTS

A total of 22 patients, aged 26-74, were included in the study, and 13 (59%) achieved pCR. Post-immunotherapy, increase in size and inflammatory response was reported in over 40% of patients (9 and 10/22, respectively). Post-neoadjuvant chemotherapy, MRI complete response (mCR) was reported in 14 (64%). Accuracy for mCR predicting pCR was 69% (43-85 Confidence Interval, CI). Patients achieving pCR had higher average %FTV at baseline (77% vs 59%, p=0.011). Post-neoadjuvant immunotherapy treatment, FTV increased for both pCR and non-pCR tumors (444% vs 128%, p=0.84), reflecting the reported inflammatory response for a number of tumors. However, The %FTV dropped significantly more for pCR patients (-38% vs 0%, p=0.001). Indeed, tumors with above median (-24%) decrease in %FTV achieved pCR in 100% (11/11). If above median decrease in %FTV is used to predict pCR, accuracy is 91% (71-99 CI) with sensitivity of 85%, specificity 100%, PPV 100%, and NPV 82%.

CONCLUSION

In this study, higher %FTV at baseline and above median decrease after neoadjuvant immunotherapy was predictive of pCR.

CLINICAL RELEVANCE/APPLICATION

In this study, the use of %FTV allowed prediction of pCR in patients undergoing neoadjuvant immunotherapy despite an overall average increase in total FTV for the tumors. This is helpful to account for the inflammatory response that was observed in response to neoadjuvant immunotherapy and may help tailor treatment regimens in the future.

W2-SPBR-4 ORIENTATION-BASED QUANTITATIVE MICROVASCULATURE BIOMARKERS FOR CLASSIFICATION OF BREAST MASSES

Pradeep Chaudhary (*Presenter*)
Nicholas B. Larson, PhD (*Abstract Co-Author*)
Azra Alizad, MD (*Abstract Co-Author*)
Mostafa Fatemi, PhD, PhD (*Abstract Co-Author*)

PURPOSE

In early-stage tumors, low oxygen levels trigger neovascularization. Malignant lesions generally depend on feeding vessels, leading to a penetrating vascular pattern, an early indicator of malignancy. Color Doppler imaging has visually suggested a potential link between these penetrating patterns and cancerous growth. Although contrast-free ultrasound microvessel (MV) imaging has been used to explore morphological biomarkers for tumor classification, vessel orientation patterns remain largely unexamined. This study aims to develop orientation-based MV biomarkers to enhance the differentiation between malignant and benign tumors.

METHODS AND MATERIALS

This prospective study was IRB-approved and HIPAA- compliant protocol with signed written informed consent obtained from all participants. Ultrasound microvessel (MV) imaging was used to analyze 70 breast lesions (35 benign, 35 malignant). Seven orientation-based biomarkers were extracted from original and polar-transformed images to distinguish penetrating from circumferential MV patterns. In the polar domain, radial and tangential histogram statistics (mean, kurtosis) assessed MV directionality and distribution, while the Polar Gradient Angle (PGA) captured dominant vessel orientation. In the Cartesian domain, angle-based penetration density (APD) quantified the area of penetrating MVs, and penetration-to-circumferential density (PCD) compared areas occupied by penetrating versus circumferential MVs. Each biomarker reflected a unique MV orientation feature, and their combination improved diagnostic accuracy.

RESULTS

Multivariable logistic regression classifier is used to distinguish between benign and malignant lesions. Principle component analysis was used for dimensionality reduction, with the first 3 principal components (PCs) achieving an area under curve (AUC) of 0.91, outperforming clinical BIRADS score (AUC = 0.78). Moreover, combining the 3 PCs with BIRADS further improved diagnostic accuracy (AUC=0.97).

CONCLUSION

This work introduces novel quantitative biomarkers based on microvasculature orientation from non-contrast-enhanced ultrasound. The findings suggest that orientation-based biomarkers effectively capture clinically relevant MV patterns and enhance lesion classification beyond BIRADS scores.

CLINICAL RELEVANCE/APPLICATION

Orientation-based microvessel biomarkers derived from non-contrast enhanced ultrasound improve breast lesion classification, enhance diagnostic accuracy, and lead to better patient outcomes.

W2-SPBR-5 A MULTI-CENTER STUDY EVALUATING THE IMPACT OF FAT SUPPRESSION AND B-VALUES ON BREAST LESION VISIBILITY AND ADC VALUES IN DWI

Shinji Naganawa, MD, PhD (*Abstract Co-Author*)
Yuji Nakamoto, MD, PhD (*Abstract Co-Author*)

PURPOSE

Clinical guidelines have recommended SPAIR as a fat-suppression method for breast DWI, while STIR might be good for screening through effective fat suppression and wide-area lesion detection. This multi-center, multi-vendor study evaluates STIR versus SPAIR and b-values of 800 and 1500 s/mm² on lesion conspicuity and ADC measurements in a phantom and clinical studies.

METHODS AND MATERIALS

A standardized breast phantom (Caliber MRI, U.S.) was scanned across Siemens, Philips, and GE platforms using STIR and SPAIR at b=800/1500 s/mm² at four institutions to evaluate fat suppression uniformity, signal level and ADC accuracy. In the clinical study, 317 participants (316 women, 1 man) with suspected breast lesions underwent 3T MRI DWI at four institutions using STIR and SPAIR at b=800/1500 s/mm², following EUSOBI/QIBA guidelines. 5 evaluators assessed lesion

conspicuity using a 5-point scale, normal breast tissue (breast composition and background parenchymal signal) using a BI-RADS based lexicon at a four-point scale, and ADC values for each combination. Statistical analysis used Wilcoxon signed-rank test with Bonferroni correction.

RESULTS

Phantom study showed excellent fat suppression and ADC correlation between STIR and SPAIR (R^2=0.95-1.0, P<0.01). STIR signal was clearly lower than SPAIR (signal ratio: 0.39-0.67, depending on T1 values, Fig.1). In the clinical study, 206 patients (205 women, 1 man) with 220 breast lesions were evaluated, excluding inadequate examinations, no DWI-detected lesions, or cases with neoadjuvant treatment. Breast composition was comparable; background parenchymal signal was lower with b=1500. SPAIR showed higher lesion conspicuity, particularly at b=1500 (b800: STIR: 2.4±1.1, SPAIR: 2.5±1.1; b1500: STIR: 2.6±1.2, SPAIR: 2.8±1.2, Fig.2A). ADC values were consistently lower at b=1500 (b800: STIR: 1.1±0.35 × 10?³ mm²/s, SPAIR: 1.0±0.35 × 10?³ mm²/s; b1500: STIR: 0.88±0.28× 10?³ mm²/s, SPAIR: 0.90±0.28× 10?³ mm²/s, Fig.2B). Comparing STIR and SPAIR at the same b-values showed no significant difference in lesion ADC values, although STIR tended to show slightly lower values at b1500. Representative cases are shown in Fig.3, showing SPAIR's superior tendency in lesion conspicuity.

CONCLUSION

Among the four imaging methods used in this study, the combination of SPAIR and b1500 tended to provide the best lesion visibility; for ADC values, b1500 was significantly lower than b800 regardless of fat suppression method, and STIR had a slightly lower value at b1500. These findings have implications for optimizing DWI protocols in clinical practice.

CLINICAL RELEVANCE/APPLICATION

For reliable ADC quantification, SPAIR is recommended due to consistent fat suppression and potentially accurate measurements.

W2-SPBR-6 EXPLORING HOW AI INFLUENCES HUMAN DECISION MAKING AND GAZE BEHAVIOUR DURING MAMMOGRAPHY INTERPRETATION

Yan Chen, PhD (*Presenter*)
Adnan Taib (*Abstract Co-Author*)
George Partridge (*Abstract Co-Author*)
Jonathan James, BMBS, FRCR (*Abstract Co-Author*)
Peter Phillips, MD (*Abstract Co-Author*)

PURPOSE

AI is increasingly being integrated into breast cancer screening workflows, yet its impact on human reader behaviour and decision-making due to automation bias remain under-explored. This study aimed to assess how AI prompts influence performance, confidence and visual search during mammogram interpretation.

METHODS AND MATERIALS

In this paired reader study, ten NHS breast screening programme readers interpreted the same set of 120 screening mammograms twice: first without AI support (Round 1, R1), and then with AI assistance (Lunit Insight MMG; Round 2, R2) following a 6-week washout. The test set was deliberately enriched with cases featuring AI false negatives (FNs, 12.5%) and false positives (FPs,18.3%), and included biopsy-confirmed malignancies, benign findings, and normal cases with three-year radiological follow-up.Visual search behaviour was monitored using eye-tracking equipment (SmartEyePro). For each read, clinical opinion was recorded using a scale (1-normal, 2-benign, 3-indeterminate, 4-suspicious, 5-malignant) and entered onto the Personal Performance in Mammographic Screening (PERFORMS) website. Performance was evaluated against the ground truth at breast level. Readers also rated their confidence in the management of a case using a 5-point Likert scale (1=not at all confidence to 5=very confident). Two-tailed paired analyses were conducted using an alpha value of 0.05.

RESULTS

The test set was chosen to contain 26 as AI true positive (TP) breasts, 15 as AI-FNs, 57 as AI true negatives (TN) and 22 as AI-FPs. The median years of experience of the human readers was 14 (interquartile range 18) and zero used AI routinely in their clinical practice during screening reading.Reader sensitivity was unchanged when AI suggested TP prompts in R2 (R1: 74%, SD 0.13; R2: 77%, SD 0.12; p = .44), whilst the specificity of humans improved for AI-TN cases (R1: 85%, SD 0.04; R2: 90%, SD 0.08; p = .03).Mean sensitivity decreased when AI failed to localise cancers (FN prompts) in R2 for the same cases in R1 (R1: 59% (SD 0.12) vs R2: 41% (SD 0.16), p < .01), Figure 1. Specificity increased when AI suggested FP prompts from 58% (SD 0.04) in R1 to 65% (SD 0.07) in R2, p = .01.Confidence in management rose when AI committed FNs (R1: 3.72 vs R2: 3.99, p < .01) and FPs (R1: 3.79 vs R2: 4.02, p = .01), with no change for TP or TN cases (p > .05). Further analyses will assess visual search patterns and reading times.

CONCLUSION

Reading with AI has demonstrated both negative and positives changes in human reading behaviour, performance and confidence.

CLINICAL RELEVANCE/APPLICATION

High diagnostic standards for AI are essential, as incorrect prompts may reduce cancer detection when used as a concurrent aid.

W2-SPCA-2 CORRELATION OF CCTA-DERIVED CARDIAC FUNCTION PARAMETERS WITH PLAQUE FORMATION IN LEFT ANTERIOR DESCENDING ARTERY MYOCARDIAL BRIDGE

Jianyu Li (*Presenter*)

PURPOSE

To explore the correlation between cardiac function parameters from coronary CT angiography (CCTA) and plaque formation in the left anterior descending artery myocardial bridge.

METHODS AND MATERIALS

126 patients with a CCTA-confirmed left anterior descending artery myocardial bridge were studied. They were divided into myocardial bridge without plaque Group (MBwP - Group), myocardial Bridge with plaque Group (MBwP+Group), and a Normal Group (NG) of healthy individuals. All underwent full-phase CCTA scanning, and parameters like ESV, EDV, EF, 17-segment End-diastolic Wall Thickness, wall Motion, and wall thickening rate were analyzed with professional software.

RESULTS

Significant statistical differences existed in age, calcium score, MB length, systolic MB stenosis, end-diastolic wall thickness (segments 2 and 9), wall displacement (segments 7, 8, and 12), and wall thickening rate (segment 7) among the three groups($P<0.05$). Correlation analysis showed MB length correlated positively with systolic MB stenosis, end-diastolic wall thickness (segment 9), and wall motion (segment 12) ($r = 0.573, 0.316, 0.295$, $P<0.05$), and there was a significant positive correlation between wall motion (segments 8, 12) and wall thickening rate (segment 7) ($P<0.05$).

CONCLUSION

CCTA-derived cardiac function parameters can assess left anterior descending artery myocardial bridge plaque formation and correlate well with left ventricular motion. They offer new insights and valuable information for early diagnosis, condition assessment, and treatment planning, enhancing the understanding of the relationship between myocardial bridges and cardiac function and improving the prognosis of coronary heart disease patients.

CLINICAL RELEVANCE/APPLICATION

The findings of this study highlight the clinical relevance of CCTA-derived cardiac function parameters in the evaluation of patients with LAD myocardial bridges. These parameters offer valuable insights for early diagnosis, prognostic assessment, and personalized treatment planning. By incorporating CCTA into clinical practice, clinicians can better manage patients with MBs, potentially improving outcomes and reducing the burden of coronary artery disease. Further research is warranted to validate these findings and explore the long-term clinical implications of CCTA-derived cardiac function parameters in patients with MBs.

W2-SPCA-4 RACIAL DISPARITIES IN CARDIOTHORACIC RATIO AND CARDIOMEGALY DIAGNOSIS CONCORDANCE: IMPLICATIONS FOR AI FAIRNESS

Frank Li, PhD (*Presenter*)
Abdulhameed Dere (*Abstract Co-Author*)
Abdulquddus Ajibade (*Abstract Co-Author*)
Theodorus Dapamede, MD, PhD (*Abstract Co-Author*)
Seyed Mohammadreza Chavoshi, MD (*Abstract Co-Author*)
Janice M. Newsome, MD (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)

PURPOSE

This study examines how label noise and discordance between automated cardiothoracic ratio measurements and radiologist-reported cardiomegaly may encode demographic information in AI models. By analyzing racial differences in concordance between quantitative values and qualitative interpretations, we aim to identify systematic labeling variations that could create algorithmic biases. Since radiologists cannot determine race from chest X-rays, observed racial disparities likely reflect systemic factors rather than direct bias, offering insights for developing fair AI systems.

METHODS AND MATERIALS

Heart and lung masks were generated on 246,904 PA chest radiographs using CheXmask methods. CTR was calculated by dividing heart mask X-axis projection by combined masks' projections. We defined CTR > 0.55 as the high CTR threshold. Cases with CTR between 0.5-0.6 were classified as uncertain and were analyzed separately. Cardiomegaly labels were extracted from reports using Llama 3.1 8b. Data was bootstrapped 1000 times with equal high CTR cases across races. Concordance between radiologist-reported cardiomegaly and measured high CTR values were calculated with 95% confidence intervals across racial groups.

RESULTS

Discordance between CTR measurements and cardiomegaly diagnoses varied across racial groups (Black: 10.6%; White: 14.2%). White patients had more discordant cases (no cardiomegaly mention despite high CTR) than Black patients. Patients with uncertain high CTR showed minimal racial differences in discordance. Manual review revealed discordances from LLM labeling errors with "stable cardiomegaly" terms and from radiologists focusing on specific clinical indications in follow-ups. These findings suggest discordance is more prominent in definite CTR cases and may reflect racial differences in cardiac imaging interpretation, automated labeling limitations, and reporting variations.

CONCLUSION

Our study reveals distinct racial disparities in CTR and cardiomegaly diagnosis discordance, which highlights potential differences in radiological interpretation and dataset labeling that may contribute to downstream AI biases if models are trained on these discordant labels.

CLINICAL RELEVANCE/APPLICATION

Race is a social non biologic construct, yet CXRs demonstrate strong encoding of this feature with downstream effects on underdiagnosis. Understanding clinical patterns and evaluating label discordance and certainty can minimize the impact of this shortcut on model performance. Dataset standards and model cards have not factored this difference for model developers.

W2-SPCA-5 CMR-BASED T2 RV/LV BLOOD POOL RATIO: A NOVEL IMAGING BIOMARKER FOR RISK STRATIFICATION IN HEART FAILURE

Siying Ma (*Presenter*)
Hongjie Hu, MD (*Abstract Co-Author*)

PURPOSE

Blood pool signals on T2 maps can reflect the oxygenation status of blood in the heart chambers. This study aimed to explore the relationships between the T2 RV/LV blood pool ratio (T2 ratio) and other clinical and imaging parameters, with a focus on evaluating its prognostic value in predicting major adverse cardiovascular events (MACE) in heart failure (HF) patients.

METHODS AND MATERIALS

A total of 217 HF patients who underwent cardiac MRI were divided into two groups: MACE and No MACE. Regions of interest were delineated in the right and left ventricular blood pools on T2 maps to calculate the T2 ratio. Clinical data and cardiac MRI parameters were compared between the two groups, and independent predictors of MACE were identified using Cox regression analysis. Correlations between the T2 ratio and other parameters were explored. Survival analyses were conducted to assess event-free survival in low, moderate, and high-risk groups. Finally, the predictive performance for MACE was compared across different models.

RESULTS

The T2 ratio was lower in MACE group (0.65 ± 0.12 vs 0.75 ± 0.12, $P < 0.001$) and was identified as an independent prognostic predictor of adverse outcomes in HF (HR: 0.966, $P = 0.044$). The association between T2 ratio and left ventricular ejection fraction (LVEF) followed distinct patterns in different ranges, with a transition around LVEF ~ 50%. Survival analysis demonstrated a stepwise decline in event-free survival from low- to high-risk groups ($P < 0.05$). Finally, the predictive model G incorporating myocardial T1 and T2 ratio demonstrated superior predictive efficacy (C-statistic: 0.806, IBS: 0.087).

CONCLUSION

A lower T2 RV/LV blood pool ratio is associated with an increased risk of MACE in HF patients. This study introduced the T2 ratio from cardiac MRI as a valuable imaging biomarker for risk stratification in HF, offering a novel method for predicting adverse outcomes and supporting clinical decision-making in the management of HF patients.

CLINICAL RELEVANCE/APPLICATION

The T2 RV/LV blood pool ratio offers a novel, non-invasive method for assessing ventricular blood oxygenation, providing insights into the pathophysiology of heart failure. This imaging biomarker has potential applications in conditions like congenital heart disease and pulmonary arterial hypertension, serving as an potential alternative to invasive procedures such as right heart catheterization. Integrating the T2 ratio with other CMR parameters, such as LGE, strain, and 2D/4D flow analysis, could enhance understanding of cardiac pathologies, enabling a more comprehensive and personalized assessment across various heart diseases.

W2-SPCA-6 MYOCARDITIS WITH PRESERVED LEFT VENTRICULAR EJECTION FRACTION IN THE RECOVERY PHASE: INSIGHTS FROM CMR AND MYOCARDIAL STRAIN ANALYSIS

Heshui Shi, MD (*Presenter*)
Mengting Huang (*Abstract Co-Author*)

PURPOSE

Myocarditis in the recovery phase, especially with preserved left ventricular ejection fraction (pLVEF), is under-studied. Residual inflammation may cause major adverse cardiovascular events (MACE). Traditional LVEF measures have limits, while myocardial strain can detect subtle changes.

METHODS AND MATERIALS

A retrospective study on 317 myocarditis patients (146 after exclusion). cardiac magnetic resonance (CMR) imaging was done with 1.5T or 3.0T scanners. Ventricular and atrial strains were measured by feature-tracking. Late gadolinium enhancement (LGE) images were evaluated. Patients were followed up, with major adverse cardiovascular events (MACE) as the primary outcome.

RESULTS

Among 146 patients (71 males, 26±16 years) ultimately enrolled, 36 experienced MACE. The median clinical follow-up duration was 36 months. The results indicated that LGE predominantly affected the basal anteroseptal (31.5%), basal inferoseptal (28.8%), basal inferolateral (32.9%), basal anterolateral (30.8%), mid anteroseptal (22.6%), mid inferoseptal (21.2%), mid inferolateral (26.0%), and mid anterolateral (26.0%) segments. Kaplan-Meier analysis demonstrated that patients with LGE had a higher risk of reaching the primary endpoint than those without LGE. Moreover, women showed a greater tendency than men to reach the primary endpoint. Patients with LV GRS values = 39.1% and LV dGCSR values = 1.1 1/s were more prone to reach the primary endpoint.

CONCLUSION

LV radial strain can indicate myocardial inflammation. Myocardial strain has prognostic value, and LGE has a complex MACE relationship. A comprehensive understanding is needed for patient management in myocarditis convalescence with pLVEF.

CLINICAL RELEVANCE/APPLICATION

Comprehensive understanding in myocarditis convalescence with pLVEF.

W2-SPCA-7 CAN CT-DERIVED MYOCARDIAL MYOCARDIAL EXTRACELLULAR VOLUME SERVE AS AN IMAGING BIOMARKER FOR TREATMENT MONITORING IN CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION?

Hidetaka Hayashi, MD (*Presenter*)
Seitaro Oda, MD, PhD (*Abstract Co-Author*)
Masafumi Kidoh, MD, PhD (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)
Fumihiro Yoshimura, MD (*Abstract Co-Author*)
Shinpei Yamaguchi (*Abstract Co-Author*)
Hiroko Takaoka (*Abstract Co-Author*)
Yasunori Nagayama, MD (*Abstract Co-Author*)
Takeshi Nakaura, MD (*Abstract Co-Author*)

PURPOSE

The aim of this study was to evaluate whether CT-derived myocardial extracellular volume fraction (CT-ECV) can serve as an imaging biomarker for treatment monitoring in patients with chronic thromboembolic pulmonary hypertension (CTEPH).

METHODS AND MATERIALS

We conducted a study involving 21 patients with CTEPH who underwent balloon pulmonary angioplasty (BPA) sessions. Right heart catheterization and CT-ECV analysis were performed at baseline and approximately one year later, after the completion of BPA treatment sessions. To identify an imaging biomarker that reflects BPA-induced changes in mean pulmonary arterial pressure (mPAP), we investigated the correlation between changes in CT-ECV (?CT-ECV) and changes in mPAP (?mPAP) before and after treatment.

RESULTS

The mean change in ?mPAP across all patients was 18.8 ± 13.5 mmHg. A moderate correlation was observed between the change in ?CT-ECV at RVIP-A and ?mPAP (r = 0.56). In patients with a lower baseline mPAP (<35 mmHg =median), no significant correlation was found (r = -0.19). Conversely, in those with a higher baseline mPAP (=35 mmHg), a strong correlation was observed (r = 0.79). In univariable logistic regression analysis within the high baseline mPAP group, only ?CT-ECV at RVIP-A was significantly associated with ?mPAP (ß = 7.27 95% confidence interval: 4.56-9.98; p = <0.01). In this group, the mean CT-ECV at RVIP-A decreased from 34.9 ± 5.2% before treatment to 32.2 ± 3.4% after treatment.

CONCLUSION

In patients with CTEPH and high baseline mPAP (=35 mmHg), CT-ECV at the RVIP-A may serve as a potential imaging biomarker for treatment monitoring.

CLINICAL RELEVANCE/APPLICATION

Quantitative assessment of CT-ECV may serve as a non-invasive surrogate marker for CTEPH, potentially reducing the need for invasive mPAP measurement by right heart catheterization.

W2-SPCA-9 LUNG CANCER SCREENING CT SPECIFIC AGE- AND SEX-BASED PERCENTILES OF CORONARY ARTERY CALCIUM FOR PREDICTION OF CARDIOVASCULAR MORTALITY

Shravya Srinivas Rao, MD (*Presenter*)
Leonard Nuernberg, MSc, BSc (*Abstract Co-Author*)
Daniel Oo (*Abstract Co-Author*)
Nora M. Kerkovits, MD (*Abstract Co-Author*)
Borek Foldyna, MD (*Abstract Co-Author*)
Hugo Aerts, PhD (*Abstract Co-Author*)
Vineet K. Raghu, PhD (*Abstract Co-Author*)
Michael T. Lu, MD, MPH (*Abstract Co-Author*)

PURPOSE

Coronary artery calcium (CAC) is commonly detected on lung screening CT. However, miscalibration of what is "normal" CAC in lung screening patients based on general population reference percentiles may lead to unnecessary downstream testing. We derived lung screening CT-specific age- and sex-based percentiles for CAC. Prediction of long-term cardiovascular (CV) mortality was compared to the Multi-Ethnic Study of Atherosclerosis (MESA) CAC percentile calculator, the standard derived from 6,110 non or lesser smokers and codified in the 2019 American College of Cardiology/American Heart Association statin primary prevention guidelines.

METHODS AND MATERIALS

Coronary artery calcium score was quantified using an AI tool in 22,207 heavy smokers aged 55-74 having baseline lung screening CT in the National Lung Screening Trial (NLST). Age- and sex-based percentiles of CAC were generated. Individuals were classified as = or < 75 th percentile of CAC for age and sex, to correspond to the 75 th centile CAC threshold in the statin guidelines. 10-year cardiovascular death was the primary outcome and was compared between the lung screening CT-specific and MESA-derived CAC percentiles.

RESULTS

Lung screening CT-derived CAC percentiles down-classified 3,034 individuals (13.7%) to <75 th percentile compared to MESA. No individuals were up-classified above the 75 th percentile, due to a greater burden of CAC in NLST than MESA. Collectively, there were 691 cardiovascular deaths (3.1%) over 10 years. Cardiovascular mortality rates were 2.1% (279/13,618) in those at <75 th percentile by both the lung screening CAC and MESA calculators; 3.6% (110/3,034) in those with <75 th percentile by lung screening but =75 th by the MESA calculator; and 5.4% (302/5,555) in those with =75 th percentile by both calculators. Results were similar in stratified analyses in women and men.

CONCLUSION

Lung cancer screening CT specific CAC percentiles better stratify 10-year cardiovascular risk than the MESA percentiles derived from non- and lesser-smoking populations.

CLINICAL RELEVANCE/APPLICATION

Lung screening CT-specific CAC percentiles may improve risk stratification and reduce downstream testing triggered by incidental CAC on lung screening CT.

W2-SPCA-10 HEART FAILURE OUTCOME PREDICTION USING AI ENABLED CARDIAC CT CHAMBER VOLUMETRY COMPARED TO AHA PREVENT

Marly Van Assen, MSc, PhD (*Presenter*)
Jaret Barr (*Abstract Co-Author*)
Gabrielle Gershon, BS (*Abstract Co-Author*)
Eshan Momin (*Abstract Co-Author*)
Saikiran Rapaka, PhD (*Abstract Co-Author*)
Athira J. Jacob (*Abstract Co-Author*)
Austin Rim (*Abstract Co-Author*)
Carlo N. De Cecco, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aims to explore the capabilities of Artificial Intelligence (AI)-derived cardiac chamber volumetry calculated using coronary artery calcium (CAC) CT scans of asymptomatic patients for heart failure (HF) prediction compared to the American Heart Association's PREVENT-HF clinical risk calculator.

METHODS AND MATERIALS

This retrospective cohort study included CAC imaging between 2010-2023 from 2,966 asymptomatic patients aged 45-75 years, without known cardiac disease. CAC images were analyzed using a previously validated convolutional neural network based autoencoder model to derive chamber volumes. PREVENT-HF scores were calculated per patient. Time-dependent AUCs were calculated at 3, 5, and 10 years, modeling HF prediction performance of chamber volumetry, PREVENT-HF risk model, and their combination. Association between heart chamber volumes, PREVENT-HF and HF was assessed using Cox proportional hazard regression models.

RESULTS

The mean age of patients was 56.3 years, 42% were women, and 78% were White and 215 were diagnosed with HF within 10 years (7.2%) with mean follow-up time of 4.3 years. Higher chamber volumes for left atrium (LA), left ventricle (LV), right atrium (RA), and left myocardium were significantly associated with HF at each follow-up interval ($p < 0.01$). LA volume was most predictive with time-dependent AUC values of 0.711, 0.719, and 0.693 at 3, 5, and 10 years ($p<0.0001$). Time-dependent AUC [95%CI] of chamber volumes alone (3yr: 0.765[0.698-0.833] ($p=0.002$), 5yr: 0.764[0.697-0.823] ($p=0.047$), 10yr: 0.737[0.658-0812] ($p=0.430$)) outperformed PREVENT-HF (3yr: 0.629[0.544-0.713], 5yr: 0.673[0.602-0.745], 10yr: 0.698[0.612-0.773]). The combination of the two (3yr: 0.746[0.674-0.814] ($p<0.001$), 5yr: 0.776[0.715-0.832] ($p<0.001$), 10yr: 0.775[0.698-0.847] ($p<0.001$)) resulted in significantly better performance than PREVENT-HF.

CONCLUSION

AI-derived cardiac chamber volumetry from CAC CT increases predictive accuracy for HF when combined with clinical risk scores. LA volume demonstrates especially important predictive ability as an independent risk factor for HF.

CLINICAL RELEVANCE/APPLICATION

Cardiac chamber volumetry obtained from CAC CT can be utilized for risk stratification for HF in asymptomatic patients. This strengthens evidence supporting the clinical utility of screening cardiac CT.

W2-SPCA-11 BASELINE EJECTION FRACTION AS A PREDICTOR OF RENAL RECOVERY FOLLOWING TRANSCATHETER AORTIC VALVE IMPLANTATION (TAVI): IMPACT ON CONTRAST MEDIA MANAGEMENT

Alba R. Pugliesi, MD (*Presenter*)
Andreas H. Mahnken, MD (*Abstract Co-Author*)
Nour Maalouf, MD (*Abstract Co-Author*)
Roua Ben Ayed (*Abstract Co-Author*)
Jonas C. Apitzsch, MD (*Abstract Co-Author*)

PURPOSE

To investigate whether baseline ejection fraction (EF) can predict renal recovery after TAVI by analyzing changes in serum creatinine and estimated glomerular filtration rate (eGFR), with particular attention to the influence of contrast media.

METHODS AND MATERIALS

This retrospective cohort study includes 372 patients who underwent TAVI. Pre-procedural EF was categorized as low (<40%), mid-range (40-49%), and normal (=50%). Renal outcomes were evaluated by pre-/post-TAVI differences in creatinine and eGFR. Spearman's rank correlation assessed relationships between EF, renal outcomes, and contrast media volumes administered during planning CT and TAVI.

RESULTS

Among 372 patients (mean age 81.1 ± 5.9 years), 63.3% showed decreased creatinine and 64.2% improved eGFR after TAVI. Patients with low EF had the most pronounced eGFR improvement (+8 vs. +4 mL/min/1.73m², $p < 0.05$). EF weakly correlated with post-TAVI creatinine change ($r = -0.12$, $p = 0.03$), but not with eGFR ($r = -0.004$, $p = 0.935$). Contrast media volume correlated weakly with post-TAVI creatinine ($r = 0.149$, $p = 0.005$) and eGFR changes ($r = -0.148$, $p = 0.005$).

CONCLUSION

Baseline EF may be predictive of renal recovery after TAVI, particularly in patients with low EF. Contrast media exposure appears to play a minor yet measurable role in renal outcome.

CLINICAL RELEVANCE/APPLICATION

Recognizing baseline EF as a potential predictor of post-TAVI renal recovery supports individualized contrast media strategies. This approach can enhance procedural safety and promote sustainability by minimizing contrast-related renal complications.

W2-SPCA-12 CT-FFR COMBINED WITH LESION-SPECIFIC FAI AS A PREDICTOR OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN CORONARY ARTERY DISEASE

Huan Ding (*Presenter*)
Jianing Chen (*Abstract Co-Author*)
Ziguang Huang (*Abstract Co-Author*)
Zhaoyuan Xing (*Abstract Co-Author*)
Haoyan Pan (*Abstract Co-Author*)
Jing Wen (*Abstract Co-Author*)
Zhe Zhang (*Abstract Co-Author*)
Baoying Zhao (*Abstract Co-Author*)
Xu Dai (*Abstract Co-Author*)

PURPOSE

To investigate the predictive value of combining computed tomography-derived fractional flow reserve (CT-FFR) with lesion-specific fat attenuation index (FAI) for major adverse cardiovascular events (MACE) in patients with coronary artery disease (CAD) and to assess the incremental prognostic value of lesion-specific FAI over CT-FFR alone.

METHODS AND MATERIALS

A retrospective analysis was performed involving 240 patients with either suspected or confirmed CAD who underwent coronary computed tomography angiography (CCTA) at the Affiliated Hospital of Liaoning University of Traditional Chinese Medicine from August 2020 to December 2023. Clinical data, CT-FFR, and lesion-specific FAI were collected. Patients were divided into MACE (n=72) and non-MACE (n=168) groups based on follow-up outcomes. Statistical analyses were conducted using SPSS 26.0, with logistic regression employed to identify independent predictors of MACE. The predictive performance of CT-FFR, lesion-specific FAI, and their combination for MACE was assessed through receiver operating characteristic (ROC) curve analysis, with statistical significance established at $P<0.05$.The clinical application value of the model was assessed by Decision curve analysis (DCA).

RESULTS

Both CT-FFR and lesion-specific FAI were significant independent risk factors for MACE ($P<0.001$). The area under the ROC curve (AUC) for predicting MACE using the combined CT-FFR and lesion-specific FAI was 0.854, which was significantly higher than that of CT-FFR alone ($P<0.001$),and had a higher net clinical benefit.

CONCLUSION

The combination of CT-FFR and lesion-specific FAI demonstrates enhanced predictive value for MACE in CAD patients. Lesion-specific FAI provides incremental prognostic value over CT-FFR alone in risk stratification for adverse cardiovascular events.

CLINICAL RELEVANCE/APPLICATION

In conclusion, the combination of CT-FFR and lesion-specific FAI demonstrates predictive significance for the occurrence of adverse cardiovascular events in patients with coronary artery disease,and lesion-specific FAI has incremental predictive value for CT-FFR in predicting the occurrence of adverse cardiovascular events in patients with

coronary artery disease. Based on this model, unnecessary ICA examinations can be avoided in low-risk patients with CT-FFR>0.80 and FAI<-83.5 HU, while limited medical resources can be focused on the high-risk group with elevated FAI.CT-FFR and lesion-specific FAI are influencing factors for the occurrence of MACE, which should be actively paid attention to by the clinic, to improve the prognosis of patients.

W2-SPCA-14 ASSOCIATION OF EPICARDIAL ADIPOSE TISSUE VOLUME AND RISK OF NEW ONSET DIABETES WITH STATIN USAGE

Joonhyuk Lee, MD (*Presenter*)
Jeehoon Kang (*Abstract Co-Author*)
Young Seok Cho (*Abstract Co-Author*)
Eun Ju Chun, MD, PhD (*Abstract Co-Author*)

PURPOSE

While statins are effective lipid-lowering agents, they may increase the risk of new-onset diabetes mellitus (NODM). We evaluated the association between epicardial adipose tissue (EAT), measured by coronary CT angiography (CCTA), and the risk of NODM in statin users.

METHODS AND MATERIALS

We retrospectively analyzed 841 patients (mean age 61 ± 11 years; 61% male) who underwent CCTA between November 2011 and March 2017 and received moderate- or high-intensity statins for more than 6 months. EAT thickness at specific sites (right atrioventricular groove, left atrioventricular groove, right ventricular free wall) and total EAT volume were measured in CCTA using a commercial program (Leonardo, Siemens Healthcare). NODM development was assessed during the median follow-up of 2.44 years (interquartile range: 1.58, 3.72).

RESULTS

Among the patients, 139 (17%) were high-intensity statin users and 702 (83%) medium-intensity statin users. NODM occurred in 163 patients (15.4%), with a higher but non-significant rate in high-intensity statin users (18.2% vs. 14.8%, p = 0.242). Total EAT volume was significantly greater in NODM patients than non-NODM patients (169±58 ml vs. 152±51 ml, p < 0.001). Moreover, the EAT thickness at the three measured sites were all also higher in the NODM group. Multivariate Cox regression model identified EAT volume =158 mL (Hazard ratio [HR] = 1.632), prediabetes (HR = 2.991), triglyceride to high-density lipoprotein cholesterol (TG/HDL-C) ratio =2.5 (HR = 1.584) and age (HR =1.028, per 1 year) as independent predictors for NODM. Regardless of age, patients with three metabolic risk factors (EAT volume =158 mL, prediabetes, and TG/HDL-C =2.5) had a 7.7-fold higher risk of NODM compared to those with none.

CONCLUSION

EAT volume measured by CCTA is an independent predictor of NODM alongside prediabetes, TG/HDL-C ratio, and age.

CLINICAL RELEVANCE/APPLICATION

EAT volume measured by CCTA is clinically meaningful as it independently predicts new-onset diabetes mellitus in statin users. These findings suggest that personalized risk stratification incorporating EAT assessment offers the potential to improve the management of cardiometabolic risks in statin therapy.

W2-SPCH-1 ASSESSMENT OF THE ACCURACY OF QUANTITATIVE LUNG FUNCTION PARAMETERS WITH DIFFERENT RECONSTRUCTION MATRICES IN CHEST CT

Xu Wang (*Presenter*)
Caiyun Mou (*Abstract Co-Author*)
Hao Chen (*Abstract Co-Author*)

PURPOSE

Assessment of the accuracy of quantitative lung function parameters with different reconstruction matrices in chest CT

METHODS AND MATERIALS

A total of54 patients who underwent chest CT and pulmonary function test (PFT) were retrospectively collected. Chest CT scans were reconstructed with different reconstruction matrices (512×512, 768×768, 1024×1024). All reconstructed images were transferred to Neusoft NeuMiva Cloud platform, and the lungs were quantitatively analyzed using the slow obstructive pulmonary screening software to obtain the percentage of low density in the lungs (LAA%-950, -910), and the airway analysis results of the wall area ratio (WA%Br0~4).The parameters of the PFT examination included the ratio of the first-second expiratory volume with exertion (FEV1) to the exertion lung volume (FVC) (FEV1/FVC), and FEV1 as a percentage of predicted value (FEV1%). One-way repeated measures ANOVA or Friedman's test was used to compare the differences in quantitative lung function parameters between the three reconstruction matrices. Spearman's rank correlation was used to analyze the correlation between CT quantitative parameters and PFT indices.

RESULTS

The differences between LAA%-950, -910 and WA% Br0~4 under different reconstruction matrices were statistically significant (all P>0.05), and LAA%-950 gradually increased with the increase of the matrix, while LAA%-910 gradually decreased; WA% Br0~4 showed a trend of gradual decrease. Different reconstruction matrices LAA%-950 and -910 were correlated with FEV1 and FEV1/FVC, and the correlation increased with the increase of the matrix, and the correlation between LAA%-950 and PFT parameters was higher than that between LAA%-910.

CONCLUSION

Different reconstruction matrices affect the stability of the quantitative CT parameters of lung function, and the correlation between the large matrix of 1024×1024 and the PFT indexes was the best. The large matrix 1024×1024 has the best correlation with the PFT index, which is helpful for the accurate assessment of lung function.

CLINICAL RELEVANCE/APPLICATION

The large matrix 1024×1024 has the best correlation with the PFT index, which is helpful for the accurate assessment of lung function.

W2-SPCH-4 DEVICE DESIGN OPTIMIZATION FOR AN AUTONOMOUS CHEST X-RAY AI TOOL

Michelle Mastrianni, PhD (*Presenter*)
Jarrel C. Seah, MBBS (*Abstract Co-Author*)
Leslie Cass (*Abstract Co-Author*)
Haylee Bosshard (*Abstract Co-Author*)

PURPOSE

Autonomous review and reporting of cases with 'unremarkable" clinical findings could alleviate radiology workload burden through significant reduction in caseload. This analysis explored the design optimization of an AI-based chest X-ray (CXR) tool that identifies "unremarkable" studies and quantified the potential case load reduction and impact on clinical safety.

METHODS AND MATERIALS

The Annalise.ai CXR3 Module, which detects 124 radiographic findings on CXR, was trained on a large, multi-institutional dataset containing chest radiographs from a large national radiology network in Australia and multiple public datasets (MIMIC-CXR, NIH Chest X-ray Dataset, and PadChest). A validation subset with 159,812 cases was used to evaluate the performance of a candidate autonomous CXR solution based on a pre-defined definition of “unremarkable” CXR findings. A multi-objective sorting algorithm (NSGA-II) was applied to optimize for both case-load reduction and clinical safety. Clinical safety was determined from the rate of critical misses. Allowed threshold ranges for exclusion were set conservatively for high-criticality findings and more liberally for low-criticality findings. The NSGA-II algorithm generated a set of optimal threshold lists. Performance was assessed by analyzing both rule-out rates and critical miss rates under various configurations.

RESULTS

A total of 19.73% of cases in the dataset were labeled as ground truth unremarkable. Standard threshold settings yielded an 18.21% rule-out rate with an overall critical miss rate of 0.29%. NSGA-II optimization increased the rule-out rate to 24-25% while simultaneously reducing the number of critical misses by approximately 25%. Alternatively, at a constant rule-out rate of 18.21%, the number of critical misses could be reduced by up to 75%.

CONCLUSION

Autonomous AI tools for chest radiography should be carefully optimized to balance workload reduction with patient safety. Adaptive thresholding based on clinical severity enables gains in caseload reduction while minimizing the risk of missing critical findings. Future work should explore the impact of various definitions of “unremarkable” CXR.

CLINICAL RELEVANCE/APPLICATION

The CXR3 AI Module supports workflow optimization through triage and decision support across multiple findings. When optimized with thresholds based on clinical severity of the findings, future autonomous applications may safely reduce radiologist workload.

W2-SPCH-5 ASSESSING INTEROBSERVER RELIABILITY IN LUNG FISSURE INTEGRITY MEASUREMENTS FOR BRONCHSCOPIC LUNG VOLUME REDUCTION

Katelyn E. Rudisill, MPH, BS (*Presenter*)
Edgar Tello Ruiz (*Abstract Co-Author*)
Nafisa Reya, MD (*Abstract Co-Author*)
Jared S. Meshekow, MD (*Abstract Co-Author*)
Gerard V. Criner (*Abstract Co-Author*)
Hillel S. Maresky JR, MD (*Abstract Co-Author*)

PURPOSE

Emphysema is a progressive destructive lung disease associated with severe parenchymal hyperinflation leading to dyspnea and impaired quality of life. Bronchoscopic Lung Volume Reduction (BLVR) is a minimally invasive procedure where endobronchial valves are segmentally placed to achieve lobar occlusion in significantly diseased lobes. Lung fissure integrity is crucial in determining BLVR success, as incomplete fissures promote collateral ventilation and negate the one-way valve biomechanics. The current study assessed measurement reliability in BLVR candidate evaluation by evaluating interobserver agreement in lung fissure integrity measurements.

METHODS AND MATERIALS

A retrospective analysis included 238 patients with emphysema undergoing high-resolution CT scans. Five radiologists and one medical student assessed the integrity of the right major, right minor, and left fissures—quantified as the ratio of intact fissure length to total expected length, expressed as a percentage. Interobserver agreement was analyzed using analysis of variance (ANOVA) with Tukey's Honest Significant Difference (HSD) post-hoc test for pairwise comparisons, and forest plots displaying confidence intervals.

RESULTS

ANOVA results showed no statistically significant differences in fissure integrity measurements across readers for the right major, right minor, and left fissures (p-values of 0.554, 0.089, and 0.413, respectively). Variability was identified in right minor fissure measurements denoted by greater spread in confidence intervals. Levene's test confirmed homogeneity of variance, supporting the reliability of fissure measurement methods across trained observers.

CONCLUSION

The high degree of interobserver agreement supports the reliability of qualitative fissure integrity measurements for BLVR evaluation. The observed variability in the right minor fissure highlights potential anatomical or technical challenges, underscoring the need for standardized protocols. These findings suggest fissure integrity assessment can be effectively performed by non-specialists, potentially expanding access to BLVR evaluation in resource-limited settings. Future research should explore automated tools and standardization to further enhance measurement consistency.

CLINICAL RELEVANCE/APPLICATION

Reliable assessment of lung fissure integrity is critical for identifying appropriate candidates for Bronchoscopic Lung Volume Reduction (BLVR). This study shows that reliable measurements can be made by both specialists and non-specialists, supporting broader access to BLVR evaluations. Standardized protocols and automation may further enhance accuracy and clinical outcomes.

W2-SPCH-7 DEVELOPMENT OF A DEEP LEARNING MODEL FOR AUTOMATIC LABELING OF SEGMENTAL BRONCHI ON CHEST CT IN PATIENTS WITH PULMONARY DISEASE

Myeongjun Kim (*Presenter*)
Jihye Yun, PhD (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Jooae Choe, MD, PhD (*Abstract Co-Author*)
Joon Beom Seo, MD, PhD (*Abstract Co-Author*)
Yura Ahn, MD (*Abstract Co-Author*)
Sohee Park, MD, PhD (*Abstract Co-Author*)
Soonyoung Lee (*Abstract Co-Author*)

PURPOSE

To develop a deep learning model that automatically identifies and labels segmental bronchi on chest CT scans of patients with pulmonary disease, and to evaluate the impact of different input-data configurations using performance metrics.

METHODS AND MATERIALS

Chest CT scans from 322 patients with asthma or COPD (2012-2022) were divided into training (n=282) and test (n=40) sets. Segmental bronchi were manually annotated into 18 anatomical segments by expert raters. A 3D full-resolution nnU-Net V2 model was developed and trained using five different input-data configurations. Performance on the test set was assessed via Dice similarity coefficient, 95% Hausdorff distance, precision, recall, and hit based metrics. The input-data configurations comprised CT volumes, binary airway masks, and distance airway masks in various combinations: Model1 (CT only), Model2 (CT + binary masks), Model3 (CT + distance masks), Model4 (distance + binary masks), and Model5 (CT + binary + distance masks). Paired t-tests were performed using Model1 (CT only) as the reference to evaluate statistical significance in performance differences among the input-data configurations.

RESULTS

The performance of each model, evaluated in terms of DSC, distance, and hit rate, is reported in Table 1 together with the results of the paired t-test. Overall, among the five input-data configurations, Model3 demonstrated statistically significant improvements compared to the reference Model1, with higher Dice similarity coefficient (DSC: 0.725, $p<0.05$), surface DSC (0.811, $p<0.05$), and hit-rate (94.3%, $p<0.05$).

CONCLUSION

Our 3D full-resolution nnU-Net V2 model—particularly the configuration represented by Model3—demonstrated robust and statistically significant accuracy in automatically labeling segmental bronchi on chest CT scans of patients with asthma and COPD.

CLINICAL RELEVANCE/APPLICATION

Substantially reducing manual annotation time and improving labeling consistency can streamline large-scale pulmonary imaging studies and routine clinical workflows. This automated approach has the potential to assist radiologists in efficient bronchial assessment and expedite treatment planning for asthma and COPD patients.

W2-SPCH-11 LUNG LOBE SEGMENTATION WITH CURRICULUM LEARNING BASED ON LOBE INCOMPLETENESS

Sungchul On (*Presenter*)
Junhyeok Ock, MSc (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

To develop a robust method for lung lobe segmentation of diseases, including chronic obstructive pulmonary disease (COPD), using a curriculum learning strategy focusing on lobe incompleteness, the proposed approach guides the model from simpler to more complex cases.

METHODS AND MATERIALS

We collected 960 inspiratory and expiratory chest CT scans—480 inspiratory and 480 expiratory—from COPD patients across 15 hospitals. Fissure incompleteness was evaluated by measuring Hounsfield Unit (HU) differences along lobar boundaries and was categorized into three difficulty levels: complete, mild, and severe. A curriculum learning strategy was applied to train three sequential stages, with 300 cases for each level. Two baseline models were also trained for comparison: 600 combined complete and mild cases and the other using all 900 cases. The same 3D nnU-Net architecture was utilized for all models, and training was performed for 500 epochs per stage with a batch size 1. A loss function combining Dice and focal losses was used. Model performance was evaluated on a test set of 60 cases, comprising 20 cases from each difficulty level.

RESULTS

The stage 2 model of curriculum learning achieved the highest Dice score of 98.28%, statistically significant compared to other models. While other models showed superior performance in specific lobes, such as the left or right upper lobe, these differences were not statistically significant compared to the stage 2 model. The stage 1 model, trained solely on complete-level data, performed well on complete test cases but failed to generalize to mild and severe cases due to a lack of exposure to complex anatomical structures. In contrast, the stage 3 model, trained on the most challenging cases, exhibited reduced performance, potentially due to catastrophic forgetting during learning cases with severe fissure incompleteness and structural variation. The stage 2 model also achieved the best overall results in mean surface distance, highlighting its robustness in segmentation accuracy and boundary precision.

CONCLUSION

We improved lung lobe segmentation by combining deep learning with anatomical insights, utilizing a curriculum learning strategy that accounts for anatomical variability and enhances the diagnosis and surgical planning for pulmonary diseases.

CLINICAL RELEVANCE/APPLICATION

Accurate lung lobe segmentation with diseases is essential for lobectomy and surgical planning procedures in actual clinical settings. Our method improves segmentation performance in cases with incomplete fissures caused by various diseases, facilitating precise anatomical localization and aiding clinical decision-making in thoracic disease assessment.

W2-SPCH-12 VALUE OF PULMONARY VASCULAR QUANTITATICE PARAMETERS IN DIAGNOSIS OF PRESERVED RATIO IMPAIRED SPIROMETRY DISEASE PATIENTS

Jianying Li, PhD (*Presenter*)
Ma Guangming, MMed (*Abstract Co-Author*)
Qiuju Fan (*Abstract Co-Author*)
Chuangbo Yang, MMed (*Abstract Co-Author*)

PURPOSE

Preserved Ratio Impaired Spirometry (PRISm) was associated with increased incidence of complications and all-cause mortality in the patients with in chronic obstructive pulmonary disease (COPD). However, there are few radiological studies related to PRISm. To investigate the CT pulmonary vascular quantitative features of Preserved Ratio Impaired Spirometry (PRISm), with the goal of establishing a nomogram model for predicting PRISm based on quantitative pulmonary vascular quantitative parameters.

METHODS AND MATERIALS

A prospective and continuous study was performed in 468 respiratory outpatients. All patients received both deep inspiratory CT, and pulmonary function test (PFT) within 1 month. According to the exclusion criteria and Global Initiative for Chronic Obstructive Lung Disease (GOLD) classification standard, 92 cases with normal pulmonary function, and 63 cases with PRISm were included in the study. Images were analyzed using a commercial computer aided diagnosis (CAD) software. Pulmonary function parameters such as inspiratory intrapulmonary vascular volume (IPVVin), the number of blood vessels in a 40mm 2 (TNV40), 60mm 2 (TNV60), and 80mm 2 area (TNV80); the cross area of blood vessels in a 40mm 2 area (TAV40), 60mm 2 (TAV60), and 80mm 2 area (TAV80) were measured. Independent sample t test or Wilcoxon Rank- Sum test was used to compare the differences in clinical features, pulmonary function parameters and quantitative CT parameters. The predictors were obtained by binary logistics regression analysis in normal and PRISm, and the nomogram model was established.

RESULTS

There were significant differences in pulmonary function parameters, BMI, exacerbations past year, gasp between the two groups ($P<0.05$). There were significant differences in TNV40, TNV60, TNV80, TAV60 and TAV80 between the two groups ($P<0.05$). CT pulmonary vascular quantitative parameters in normal group were higher than those in PRISm group. The predictors of the nomogram model using binary logistics regression analysis to distinguish normal from PRISm were gasp and TNV60. It had a good goodness of fit (? 2 = 4.91, P = 0.77) with the area under curve (AUC) value of 0.700.

CONCLUSION

Quantitative chest CT imaging can effectively evaluate pulmonary vascular changes in PRISm patients. The nomogram based on pulmonary vascular quantitative parameters has good predictive value and provides more objective evidence for the early screening of PRISm.

CLINICAL RELEVANCE/APPLICATION

Our study will help to improve the clinical value of quantitative CT for the diagnosis and early intervention for COPD.

W2-SPER-2 MACHINE LEARNING PREDICTION OF ICU TRANSFER IN PATIENTS WITH BLUNT CHEST TRAUMA USING AMBULANCE, CLINICAL, AND RADIOMIC DATA

Sarah Meribout, MD (*Presenter*)
Darya Smetanina (*Abstract Co-Author*)
Ashraf Hefny Soliman (*Abstract Co-Author*)
Taleb M. Al Mansoori, MD, FRCPC (*Abstract Co-Author*)
Yauhen Statsenko (*Abstract Co-Author*)

PURPOSE

Blunt chest trauma (BCT) accounts for a significant portion of trauma-related morbidity and mortality worldwide. Accurate early prediction of Intensive Care Unit (ICU) transfer in BCT patients remains a clinical challenge, as conventional scoring systems like GCS, ISS, and AIS have limited sensitivity and specificity. We aimed to develop and validate machine learning (ML) models that integrate ambulance data, clinical parameters, laboratory values, and radiomic features from early chest CT to predict ICU transfer.

METHODS AND MATERIALS

This retrospective study analyzed 212 cases of isolated BCT admitted to a tertiary hospital over three years. Data were collected from trauma registries, electronic medical records, and early chest CT scans. The following groups of findings were added to the study dataset: (1) ambulance data: demographics, vitals, and trauma details; (2) admission data: clinical scores, laboratory and radiologic findings on admission; and (3) radiomics features. The latter were extracted from hemithoraces with PyRadiomics framework. The segmentation masks for hemithoraces were received with Total Segmentator extension for 3DSlicer. To predict ICU admission, we used a set of machine learning (ML) classifiers: XGBoost, CatBoost, Random Forest, and Decision Tree. Classification accuracy was evaluated with the standard metrics: sensitivity (Sn), and mean absolute error (MAE).

RESULTS

Among 212 patients (mean age 31 years; 86.8% male), 26% required ICU transfer. ICU patients were younger, had lower GCS scores, higher respiratory and heart rates, and more severe injuries per anatomical scores. Radiomic features significantly differed between ICU and non-ICU groups. The best-performing model (CatBoost) achieved an AUC of 0.91, sensitivity of 0.84, and specificity of 0.88. Combining clinical and radiomic features improved prediction over traditional scores alone.

CONCLUSION

ML-based models incorporating radiomics and clinical data significantly improve early prediction of ICU transfer in BCT patients. These tools may enhance triage accuracy and guide intensive monitoring and management decisions in emergency settings.

CLINICAL RELEVANCE/APPLICATION

Integrating AI with CT imaging and clinical data may provide a scalable, objective decision-support tool to optimize ICU resource allocation and improve outcomes in BCT trauma care.

W2-SPER-3 EVALUATION OF CONTRAST DOSE AND BEAM-HARDENING ARTIFACT REDUCTION IN ROUTINE CTPA USING THE ADAPTIVE LOW-CONTRAST-DOSE PROTOCOL: A COMPARISON WITH EMPIRICAL SCANNING

Xiaoying Chen (*Presenter*)
Xubin Cui (*Abstract Co-Author*)
Wanting Wu (*Abstract Co-Author*)

PURPOSE

To quantitatively and qualitatively assess the efficacy of the adaptive low-contrast-dose protocol in reducing contrast dose and beam-hardening artifacts (BHA) in CT pulmonary angiography (CTPA), compared to conventional empirical scanning.

METHODS AND MATERIALS

This retrospective analysis enrolled 188 patients suspected of pulmonary embolism who underwent spectral CTPA between February 2022 and January 2025. Participants were stratified into two groups: the adaptive low-contrast-dose group (Group A, n=84), which utilized a three-ROI test bolus to optimize scan timing and adjusted contrast injection rates based on body weight, and the empirical scanning protocol group (Group B, n=104). The study quantified CT attenuation values of pulmonary arteries, their branches, and BHA-affected muscles, and computed contrast-to-noise ratio (CNR), arteriovenous separation, and BHA in both groups. Two radiologists independently assessed image quality using a 5-point scale, evaluating pulmonary vascular opacification, BHA severity, motion artifacts, and image noise.

RESULTS

Group A (adaptive low-contrast-dose protocol) achieved a 35% reduction in contrast medium volume (26 mL vs. 40 mL, $P < 0.001$), while the mean body weight of patients was 15.38% higher compared to Group B (empirical scanning protocol) (75.0 (64.0, 86.1) VS 65.0 (57.3, 70.0), $P < 0.001$). Radiation doses were comparable between groups ($P > 0.05$). While Group A exhibited slightly lower CT values than Group B, all pulmonary artery segments in Group A met diagnostic criteria (CT = 350 HU) and maintained adequate arteriovenous differentiation (CT difference = 300 HU). No significant difference in CNR was observed. Group A demonstrated significantly reduced BHA indices (13.10 (0.00, 23.19) VS 33.30 (25.10, 54.65), $P < 0.001$) and higher subjective BHA quality scores (5 (4, 5) VS 4 (4, 5), $P < 0.001$).

CONCLUSION

The adaptive low-contrast protocol effectively reduces contrast agent volume and BHA while preserving diagnostic image quality, providing a practical optimization method for CTPA imaging.

CLINICAL RELEVANCE/APPLICATION

The adaptive low-contrast protocol effectively reduces contrast agent volume and BHA while preserving diagnostic image quality, providing a practical optimization method for CTPA imaging.

W2-SPGI-1 ADVANCES IN IPMN IMAGING: DEEP LEARNING-ENHANCED HASTE IMPROVES LESION CHARACTERIZATION

Johannes Kolck, MD (*Presenter*)
Fabio Pivetta, MD (*Abstract Co-Author*)
Clarissa Hosse (*Abstract Co-Author*)
Uli Fehrenbach, MD (*Abstract Co-Author*)
Dominik Geisel, MD (*Abstract Co-Author*)

PURPOSE

The prevalence of asymptomatic pancreatic cysts is increasing due to advances in imaging techniques. Among these, Intraductal Papillary Mucinous Neoplasms (IPMN) are most common, with potential for malignant transformation, often necessitating close follow-up. This study evaluates novel MRI techniques for the assessment of IPMN.

METHODS AND MATERIALS

From May to December 2023, 59 patients undergoing abdominal MRI were retrospectively enrolled. Examinations were conducted on 3-Tesla scanners using a Deep Learning Accelerated Half-Fourier Single-Shot Turbo Spin-Echo (HASTE DL) and standard HASTE (HASTE S) sequence. Two readers assessed minimum detectable lesion size and lesion-to-parenchyma contrast quantitatively, qualitative assessments focused on image quality. Statistical analyses included Wilcoxon signed-rank and chi-squared tests.

RESULTS

HASTE DL demonstrated superior overall image quality ($p < 0.001$), with higher sharpness and contrast ratings ($p < 0.001$, $p = 0.112$). HASTE DL showed enhanced conspicuity of IPMN ($p < 0.001$) and lymph nodes ($p < 0.001$), with more frequent visualization of IPMN communication with the pancreatic duct ($p < 0.001$). Visualization of complex features (dilated pancreatic duct, septa and mural nodules) was superior in HASTE DL ($p < 0.001$). The minimum detectable cyst size was significantly smaller for HASTE DL (4.17 mm ± 3.00 vs. 5.51 mm ± 4.75; $p < 0.001$). Inter-reader agreement was for (? 0.936) for HASTE DL , slightly lower (? 0.885) for HASTE S .

CONCLUSION

HASTE DL in IPMN imaging provides superior image quality and significantly reduced scan times. Given the increasing prevalence of IPMN and the ensuing clinical need for fast and precise imaging, HASTE DL improves availability and quality of patient care.

CLINICAL RELEVANCE/APPLICATION

HASTE DL provides faster, high-quality MRI imaging, enabling improved diagnostic accuracy and timely risk stratification for IPMN, potentially enhancing patient care and addressing the growing clinical demand for efficient imaging of IPMN.

W2-SPGI-2 BEYOND THE GREY: DEFINING NON-INVASIVE BENCHMARKS WITH ADVANCED ULTRASOUND AND LAB CORRELATION IN NAFLD

Mehak Aggarwal, MBBS (*Presenter*)
Priscilla Joshi, MBBS, MD (*Abstract Co-Author*)

PURPOSE

As NAFLD becomes a global epidemic, relying on liver biopsy for diagnosis is neither practical nor sustainable. Among the various methods available to quantify liver fat, such as ultrasound, CT, and MRI, our study assessed the effectiveness of Ultrasound-Guided Attenuation Parameter (UGAP) as a non-invasive tool for quantifying hepatic steatosis. We also examined its correlation with liver stiffness (via shear wave electrography), B-mode grading, liver function tests, and lipid profile. The goal was to facilitate earlier diagnosis, prevent cirrhosis, and support informed clinical decisions through a streamlined, one-stop imaging approach

METHODS AND MATERIALS

Following ethical clearance, 124 patients with B-mode-confirmed NAFLD were enrolled. Exclusion criteria included viral hepatitis, cirrhosis, and significant alcohol intake. All patients underwent ultrasound fat grading, UGAP (dB/cm/MHz) and shear wave elastography (kPa). Blood tests included LFTs (AST, ALT, bilirubin, ALP) and lipid profile (cholesterol, LDL, HDL, VLDL, triglycerides). Pearson correlation and regression analyses were performed.

RESULTS

UGAP and elastography provided complementary insights in NAFLD assessment. UGAP showed a strong correlation with B-mode steatosis grading ($r = 0.717$) and moderate correlation with liver stiffness values ($r = 0.554$), indicating its higher sensitivity to hepatic fat and some association with increased stiffness. In contrast, elastography grades correlated weakly with UGAP ($r = 0.181$) and B-mode ($r = 0.074$), underscoring its specificity for fibrosis. In addition, UGAP showed significant associations with ALT ($r = 0.495$), AST ($r = 0.478$), and mild links to cholesterol and LDL. Elastography correlated modestly with ALT and AST, suggesting its utility in detecting fibrosis and hepatic inflammation.

CONCLUSION

UGAP emerged as a sensitive, rapid, cost-effective, and accessible single-session solution for quantifying liver fat. When combined with elastography, it provided detailed, real-time view of the fat-fibrosis continuum, reducing reliance on biopsies and supporting timely intervention

CLINICAL RELEVANCE/APPLICATION

The integration of UGAP, elastography, and biochemical markers enables early, accurate, cost effective and radiation-free evaluation of NAFLD. This non-invasive approach will allow clinicians to stratify risk, tailor interventions, and safely monitor disease progression.

W2-SPGI-3 ABBREVIATED VERSUS COMPREHENSIVE MRI PROTOCOLS IN THE SURVEILLANCE OF BRANCH-DUCT INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS (BD-IPMN): ANALYSIS OF DIAGNOSTIC PERFORMANCE, INTER-READER AGREEMENT, TIME AND COST SAVINGS

Christian Reca, MD (*Presenter*)
Cristiana Bonifacio, MD (*Abstract Co-Author*)
Riccardo Levi (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare the diagnostic value of Abbreviated MRI protocols (AP) (with/without DWI) versus a comprehensive protocol (CP) for Branch-Duct Intraductal Papillary Mucinous Neoplasms (BD-IPMN) surveillance, evaluating inter-reader agreement, cost-effectiveness and time efficiency.

METHODS AND MATERIALS

This single-center retrospective study included patients with BD-IPMN undergoing baseline and follow-up MRI between January 2018 and April 2024. CP included axial and coronal T2WI, axial fat-saturated T1-weighted images before and after contrast injection (T1WI), 2D and 3D MR MRCP and DWI images.The two APs were obtained from CP follow-up examinations: AP with DWI consisted of axial and coronal T2WI, 2D-3D MRCP, axial fat-saturated T1WI images and DWI, AP without DWI comprised only axial and coronal T2WI and 2D-3D MRCP. A senior radiologist (>20 years of experience in pancreatic imaging) and a junior radiologist (4th year radiology resident) independently and blinded analyzed each protocol using Kyoto criteria and recommended management. Inter-reader and inter-protocol agreement were analyzed using Cohen's and Fleiss' Kappa. Acquisition times and healthcare costs were compared using national reimbursement rates. ($p<0.05$ statistical significant)

RESULTS

Overall, 40 patients (25 women and 15 man) with a median age of 67 years(range 48-87 years) were included. No statistically significant differences were observed among the 3 protocols in identifying worrisome features, including high-risk stigmata, cyst size, main pancreatic duct dilation, and mural nodules.The inter-reader agreement was almost perfect (Fleiss' Kappa=0.82). Substantial inter-reader agreement (Cohen's Kappa >0.6) was observed for all protocols, with almost perfect agreement (Cohen's Kappa >0.8) in some instances. AP protocols demonstrated up to a 48% reduction in acquisition time and a 27.4% cost reduction compared to CP. The addition of DWI did not significantly improve diagnostic accuracy

CONCLUSION

APs, particularly without DWI, are reliable and cost-effective alternatives to CP for BD-IPMN follow-up, maintaining comparable diagnostic performance. Substantial inter-reader agreement highlights the reproducibility of APs, even among less experienced radiologists.

CLINICAL RELEVANCE/APPLICATION

AP without DWI can safely streamline BD-IPMN surveillance, reducing scan time and costs while maintaining diagnostic accuracy—potentially alleviating healthcare burdens and increasing MRI availability for high-demand populations.

W2-SPGI-5 IMAGING-DETECTED IMMUNE-RELATED ADVERSE EVENTS IN UNRESECTABLE HEPATOCELLULAR CARCINOMA TREATED WITH ATEZOLIZUMAB AND BEVACIZUMAB

Dong Ho Lee, MD (*Presenter*)

PURPOSE

Following the success of the IMbrave150 trial, the combination of atezolizumab and bevacizumab has been established as the standard first-line treatment for patients with unresectable hepatocellular carcinoma (HCC), owing to its significant improvement in overall survival. Immune-related adverse events (irAEs) during treatment with this regimen have been linked to better prognosis. However, the imaging characteristics of irAEs and their potential prognostic implications during atezolizumab plus bevacizumab therapy remain underexplored. This study aimed to evaluate the imaging findings related to irAEs and their impact on prognosis.

METHODS AND MATERIALS

In this retrospective cohort study, consecutive patients who received atezolizumab in combination with bevacizumab as a first-line treatment for unresectable HCC were included. All available imaging studies performed during the course of treatment were reviewed to identify irAEs. The primary objectives were to characterize the imaging findings indicative of irAEs and to assess the correlation between these findings, tumor response, and overall survival. Statistical analysis was performed to compare disease control rates and survival outcomes between patients with and without irAEs.

RESULTS

A total of 198 patients (168 males and 28 females, median age 62.5 years) treated between November 2020 and June 2023 were included in the analysis. Of these, 27 patients (13.6%) exhibited irAEs on imaging, including pulmonary infiltration (n=15), enterocolitis (n=7), mesenteric panniculitis (n=3), and lymphadenitis (n=2). The presence of irAEs identified on imaging was significantly associated with a higher disease control rate (100% in patients with irAEs vs. 67.3% in those without irAEs; $P<0.001$). Additionally, patients with imaging-detected irAEs demonstrated markedly improved overall survival rates, with estimated 1- and 2-year survival rates of 84.9% and 51.6%, respectively, compared to 50.0% and 22.8% in patients without irAEs ($P<0.001$).

CONCLUSION

The development of irAEs identified through imaging during atezolizumab plus bevacizumab treatment in patients with unresectable HCC was significantly associated with improved disease control and overall survival.

CLINICAL RELEVANCE/APPLICATION

Imaging detected irAE would have a potential to provide prognostic information for unresectable HCC patients treated by atezolizumab plus bevacizumab.

W2-SPGI-6 AUTOMATIC LIVER SEGMENTATION IN THE GENERAL POPULATION: HOW TO REDEFINE THE MORPHOMETRIC CRITERIA OF A HEALTHY LIVER?

Edouard Reizine, MD (*Presenter*)
Vincent Morard (*Abstract Co-Author*)
Sebastien Mule, MD, PhD (*Abstract Co-Author*)
Naim Jalal (*Abstract Co-Author*)
Jorge Hernandez Londono (*Abstract Co-Author*)
Vincent Leroy, MD (*Abstract Co-Author*)
Hicham H. Kobeiter, MD (*Abstract Co-Author*)
Alain Luciani, MD, PhD (*Abstract Co-Author*)

PURPOSE

To reassess the accuracy of known 2D measurements of the healthy liver and to redefine new global, three-dimensional, and segmental morphometric criteria indexed to demographic data in a general population cohort.

METHODS AND MATERIALS

A patient cohort was drawn from the data warehouse of the Assistance Publique-Hôpitaux de Paris, including all patients who underwent an abdominopelvic CT scan with a portal venous phase meeting several clinical and biological criteria excluding underlying hepatic or oncological pathology. An automatic segmentation algorithm was developed and applied to all patients, allowing extraction of the following measurements: 2D height of the right liver lobe, 2D height of the left liver lobe, total liver volume, volumetric ratio of each Couinaud hepatic segment relative to the total liver volume, dimensions of the falciform ligament space, hilar space, and diameter of the portal vein trunk. All these data were correlated with clinical variables including sex, age, height, weight, body surface area (BSA), and body mass index (BMI).

RESULTS

A total of 818 patients were available for analysis. The cohort included 52.8% women and 47.2% men, with median ages of 51 and 52 years, respectively. Median BMI and BSA were 23.4 and 1.67 for women, and 23.5 and 1.87 for men. The median height of the right and left liver lobes was 16.65 cm (IQR: 15.4-18.2) and 14.22 cm (IQR: 11.4-16.8), respectively. There was no significant difference between men and women ($p = 0.56$), but these measurements showed only moderate correlation with total liver volume (0.56 for right lobe height, 0.16 for left lobe height). Total liver volume was not correlated with age (-0.05), although a trend toward decreased mean liver volume with age was observed in men. However, total liver volume was correlated with height (0.46), weight (0.53), BSA (0.58), and BMI (0.34). For both sexes, the relative size of segments 4 and 5 decreased with age, while segments 7 and 8 increased. Lastly, the size of the falciform ligament space, hilar space, and diameter of the portal vein trunk increased with age.

CONCLUSION

Morphometric criteria for a healthy liver should be indexed not only to the patient’s body measurements but also to their age. Currently known two-dimensional measurements do not appear to be sufficiently specific or sensitive to define a liver of normal size.

CLINICAL RELEVANCE/APPLICATION

Known 2D measurements of the healthy liver should be used with caution as these criteria need to be indexed to the patient's body size and age.

W2-SPGI-7 LONG-TERM FOLLOW-UP OF FOCAL NODULAR HYPERPLASIA: WHAT IS THE NATURAL HISTORY OF THESE LESIONS?

Edouard Reizine, MD (*Presenter*)
Alain Luciani, MD, PhD (*Abstract Co-Author*)
Frederic Pigneur, MD (*Abstract Co-Author*)
Sebastien Mule, MD, PhD (*Abstract Co-Author*)

PURPOSE

To assess the natural history of focal nodular hyperplasia (FNH) over time.

METHODS AND MATERIALS

Single-center retrospective study including all patients with one or more FNH lesions characterized non-invasively by MRI with extracellular contrast agent, and, if necessary, complemented by MRI with hepatobiliary contrast agent or contrast-enhanced ultrasound.All patients were required to have undergone two cross-sectional imaging studies with contrast injection, with at least one year between the two exams. Only lesions larger than 1 cm were included. Patients whose imaging did not include a high-quality arterial phase were excluded.All lesions were measured on the arterial phase in the axial plane. Progression was defined as a =20% increase in axial diameter; regression as a =30% decrease.

RESULTS

A total of 112 patients were included, comprising 96 women (86%) and 15 men (14%), with a total of 158 lesions. The median follow-up duration was 3 years (IQR: 2.0-6.0).Most lesions remained stable over time (83/158, 53%) or regressed (50/158, 32%). When comparing progressive, stable, and regressive lesions, there was a significant difference in follow-up duration (2.0 [2.0-5.0], 4.0 [3.0-8.0], and 6.0 [4.0-9.0] years, respectively; $p < 0.001$), but no significant difference in age at baseline (40 [34-48], 40 [34-50], and 40 [36-44] years; $p = 0.98$) or initial lesion size (20 [14-36], 20 [15-28], and 18 [14-30] mm; $p = 0.650$).When analyzing follow-up intervals, most lesions were stable at 1-year follow-up (14/16, 88%) and 2 years (29/41, 71%), while most showed regression if the interval was between 5 to 10 years (23/46, 50%) or over 10 years (10/13, 77%).Combining all baseline and follow-up measurements, lesion size was significantly larger in patients under 40 years of age (21 [15-37] mm vs. 16 [11-26] mm; $p < 0.001$).Finally, in patients with multiple lesions ($n = 25$), evolution was similar across all lesions in 12 patients (48%) and varied among lesions in 13 patients (52%).

CONCLUSION

The evolution of FNH varies over time depending on both the patient and the lesion, with an overall trend toward progressive regression over the long term.

CLINICAL RELEVANCE/APPLICATION

Natural history of Focal Nodular Hyperplasia remains unclear, nevertheless there is an overall trend toward progressive regression over the long term.

W2-SPGI-9 DEEP LEARNING-BASED MULTIDIMENSIONAL MRI BIOMARKERS FOR INTERPRETABLE GRADING OF INTRAHEPATIC MASS-FORMING CHOLANGIOCARCINOMA

Liyong Zhuo, PhD (*Presenter*)
Wenjing Chen (*Abstract Co-Author*)
Xiaoping Yin (*Abstract Co-Author*)
Jianing Wang (*Abstract Co-Author*)

PURPOSE

This study aimed to develop an interpretable ensemble deep learning (DL) framework that integrates multidimensional MRI features for the preoperative prediction of histological grades in intrahepatic mass-forming cholangiocarcinoma (IMCC).

METHODS AND MATERIALS

Preoperative MRI scans from 333 IMCC patients across three multicenter cohorts (January 2018-June 2024) were retrospectively analyzed. An ensemble deep learning (DL) framework was developed by synergizing 2.5D and 3D ResNet-50 architectures. Significant variables from clinical-laboratory-imaging (ClinLabImag) features, Radiomics, and the DL model were integrated into a predictive model, and its performance was evaluated using the area under the receiver operating characteristic curve (AUC), with interpretability assessed via Gradient-weighted class activation mapping (Grad-CAM) and SHapley Additive exPlanations (SHAP) analysis.

RESULTS

The training cohort included 240 patients (median age: 60 years [IQR: 55-66]); external validation comprised 93 patients (59 years [55-65]). The DL model achieved an external validation AUC of 0.804 (95% CI: 0.712-0.896), significantly outperforming standalone 2.5D ($P = 0.025$) and 3D architectures ($P = 0.030$). The combined model integrating DL, Radiomics, and ClinLabImag features demonstrated superior generalizability (AUC: 0.843 [0.749-0.938]), outperforming Radiomics ($P = 0.019$) and clinical models ($P = 0.017$). SHAP analysis revealed DL-derived features dominated predictive contributions (72.1%), followed by Radiomics (21.6%) and clinical variables (6.3%).

CONCLUSION

The proposed interpretable ensemble DL model, which integrates multidimensional biomarkers, enhances the preoperative histological grading of IMCC. This approach demonstrates robust generalizability across multicenter cohorts. By non-invasively capturing tumor biology, this method has the potential to optimize treatment stratification and reduce reliance on invasive biopsies.

CLINICAL RELEVANCE/APPLICATION

In this multicenter study, we developed an interpretable ensemble deep learning framework integrating 2.5D and 3D MRI architectures to noninvasively predict histopathological grading preoperatively. The model holds significant value for clinicians managing IMCC, enabling earlier identification of high-grade tumors to guide aggressive surgical planning or neoadjuvant therapies while reducing reliance on invasive diagnostic procedures. By enhancing preoperative risk stratification without increasing imaging complexity, this strategy optimizes resource utilization in clinical settings, ultimately benefiting patients through personalized treatment planning and healthcare systems through reduced diagnostic delays.

W2-SPGI-13 ULTRA-HIGH-RESOLUTION PANCREATIC PROTOCOL PHOTON-COUNTING CT: IS HIGH-SPATIAL RESOLUTION IMAGING NECESSARY IN THE ASSESSMENT OF PANCREATIC DUCTAL ADENOCARCINOMA?

Yoshifumi Noda, MD, PhD (*Presenter*)
Binaya Dhakal, MD (*Abstract Co-Author*)
Shravya Srinivas Rao, MD (*Abstract Co-Author*)
Ryan Chung, MD (*Abstract Co-Author*)
Avinash R. Kambadakone, MD, FRCR (*Abstract Co-Author*)

PURPOSE

To investigate if high-spatial resolution imaging is necessary in the local evaluation of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

This retrospective study included 16 patients with PDAC who underwent ultra-high-resolution pancreatic protocol photon-counting CT and had both 1- and 0.4-mm slice images between September 2024 and April 2025. CT attenuations of the pancreas and PDAC, and background noise were measured, and then signal-to-noise ratio (SNR) of the pancreas and tumor-to-pancreas contrast-to-noise ratio (CNR) were calculated. A radiologist randomly reviewed 1- and 0.4-mm slice images and evaluated the arterial and portal venous involvements, resectability classifications, and overall image quality. Wilcoxon test and Kendall's tau rank correlation were conducted to compare the quantitative and qualitative parameters between 1- and 0.4-mm slice images.

RESULTS

The background noise was lower, and SNR of the pancreas and tumor-to-pancreas CNR were higher on 1-mm slice images than the high-resolution 0.4-mm slice images ($P < .001$ for all). The evaluations of arterial and portal venous involvements and resectability classification were equivalent between 1- and 0.4-mm slice images (Kendall's tau, 0.95-1.00; $P < .001$ for all). Overall image quality at pancreatic and portal venous phases was better on the 1-mm slice images than the high-resolution 0.4-mm slice images ($P < .001$ for both).

CONCLUSION

Assessment of PDAC was equivalent between 1- and high-resolution 0.4-mm slice images; however, 1-mm slice images had less noise, higher SNR of the pancreas and tumor-to-pancreas CNR, and better image quality, compared with 0.4-mm.

CLINICAL RELEVANCE/APPLICATION

Ultra-high-resolution photon-counting CT can provide high-spatial resolution imaging; however, image noise will be increased and may not provide additional useful information for local evaluation of PDAC compared with conventional slice thickness.

W2-SPGI-14 MULTIPLE QUANTITATIVE ULTRASOUND PARAMETERS FOR THE EVALUATION OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS: A PROSPECTIVE STUDY

Yun-Lin Huang, MD (*Presenter*)
Yi Dong, MD, PhD (*Abstract Co-Author*)
Ying Wang (*Abstract Co-Author*)
Juan Cheng (*Abstract Co-Author*)
Li Wei (*Abstract Co-Author*)
Rui Cheng (*Abstract Co-Author*)

PURPOSE

To develop optimized models integrating multiple ultrasound parameters to evaluate at-risk metabolic dysfunction-associated steatohepatitis (MASH) in liver biopsy-proven metabolic dysfunction-associated steatotic liver disease (MASLD) patients.

METHODS AND MATERIALS

In this prospective study, patients scheduled for liver biopsy due to clinical suspicion of MASLD or MASH were enrolled. All abdominal ultrasound examinations were performed using the Resona A20 ultrasound system (Mindray, China) with a SC7-1U probe (1.0 - 7.0 MHz). After producing an M-Ref map, the multiple ultrasound parameters were measured, including the attenuation coefficient obtained with UltraSound ATtenuation Imaging Technology (USAT) (in dB/cm/MHz), shear wave speed (SWS) (in m/s), and viscosity (in Pa·s). The at-risk MASH was defined as MASH with F2-F3 fibrosis. Receiver operating characteristic curves (AUCs) were performed to assess the diagnostic performance.

RESULTS

From November 2023 to January 2025, 52 patients (median age of 46 years) were included. The risk score model from multiple ultrasound parameters was developed using USAT, viscosity values, and SWV, which were associated with the degree of hepatic steatosis, lobular inflammatory activity, and fibrosis (all $P < 0.05$). For the USAT, the risk score was assigned using the cutoff values of USAT for detecting hepatic steatosis as follows: score 1, USAT value between 0.55 and 0.58 dB/cm/MHz (S1); score 2, USAT value between 0.58 and 0.75 dB/cm/MHz (S2); and score 3, USAT value greater than 0.75 dB/cm/MHz (S3). The risk score of viscosity was assigned using the cutoff values of viscosity as follows: score 1, viscosity value between 2.00 and 2.05 Pa·s (A2); score 2, viscosity value between 2.05 and 2.11 Pa·s (A3); and score 3, viscosity value greater than 2.11 Pa·s (A4). The risk score of SWV was assigned using the cutoff values of SWV as follows: score 1, SWV value between 1.77 and 2.01 m/s (F2), and score 2, SWV value greater than 2.01 m/s (F3). The final at-risk score was defined as the unweighted sum of each score from USAT, viscosity, and SWV values, ranging from 0 to 8. The diagnostic performance of the risk score model for detecting at-risk MASH was higher than that of ultrasound parameters alone (AUC = 0.70 vs. AUC = 0.53 - 0.66).

CONCLUSION

The risk score model integrating multiple ultrasound parameters (attenuation coefficient, viscosity, and shear wave speed) improved noninvasive diagnostic performance for detecting at-risk MASH in patients with MASLD.

CLINICAL RELEVANCE/APPLICATION

The diagnostic performance of the risk score model integrating multiple ultrasound parameters (attenuation coefficient, viscosity, and shear wave speed) for detecting at-risk MASH was higher than that of ultrasound parameters alone.

W2-SPGI-15 DISTANT FIELD DEFECT PDAC IN IPMN PATIENTS: RISK BEYOND HIGH-RISK IMAGING FEATURES

Stephen J. Kwak, MD (*Presenter*)
Eli Zuercher (*Abstract Co-Author*)
Gayane Yenokyan, PhD (*Abstract Co-Author*)
Timothy M. McMahon, MD, MS (*Abstract Co-Author*)
Atif Zaheer, MD (*Abstract Co-Author*)

PURPOSE

Field defect pancreatic ductal adenocarcinoma (PDAC) occurs independently from the intraductal papillary mucinous neoplasm (IPMN), either abutting the IPMN or elsewhere in the pancreas. Field defect PDAC is being increasingly recognized as a separate entity from conventional PDAC. Studies report that synchronous or metachronous invasive pancreatic carcinoma occurs in approximately 9.3% of patients with IPMNs. Moreover, patients remain at elevated risk for developing invasive carcinoma even after surgical resection of the IPMN. These findings highlight the critical need to understand the imaging features of field defect PDACs for early detection and management.

METHODS AND MATERIALS

3063 patients with presumed IPMNs between 2005 and 2024 were initially examined. of the 3063 patients, 408 patients had surgical resection. Of the 408 resected IPMNs, 57 patients demonstrated PDAC by pathology. Of the 57 pathologically proven PDAC with IPMN, 35 patients had a field defect PDAC that occurred independent of the IPMN. The imaging features of these 35 patients were examined, focusing on initial size of the largest cyst, number of cysts, distance between PDAC and IPMN, and presence or development of mural nodule, wall thickening, ductal dilatation, and abrupt ductal cut off. The demographic and imaging features of distant field defect PDAC and field defect PDAC abutting the IPMN were analyzed using Fischer's exact ?-square test. Continuous variables were analyzed with Student's t-test or Wilcoxon rank-sum test for normally or nonnormally distributed variables, respectively.

RESULTS

The mean age of patients was 70.3 years with no significant gender predilection. No significant differences were observed between abutting and distant PDAC in terms of cyst location, number of cysts or follow-up intervals. However, distant field defect PDACs were more likely to be present when the largest IPMN was <30 mm, did not develop mural nodules smaller than 5 mm, and did not demonstrate wall thickening compared to PDACs abutting the IPMN.

CONCLUSION

Field defect PDACs are an increasingly recognized subset of pancreatic ductal adenocarcinoma. Distant field defect PDACs are more likely to occur when the associated IPMN does not demonstrate some of the typical high-risk features of IPMNs, in this case mural nodules and thickened walls. Furthermore, distant field defect PDACs tend to occur when the initial largest cyst size is <30 mm.

CLINICAL RELEVANCE/APPLICATION

This study reinforces the concept that IPMNs increase the risk of PDAC development throughout the pancreas even in the absence of high-risk features. Moreover, our findings underscore the importance of vigilant surveillance and assessment of the remaining pancreas in patients who have undergone IPMN resection.

W2-SPGI-17 VOLUMETRIC BODY COMPOSITION ANALYSIS ON PREOPERATIVE CT SCANS IMPROVES RISK PREDICTION IN COLORECTAL SURGERY PATIENTS

Raheema Damani (*Presenter*)
Shubha Vasisht (*Abstract Co-Author*)
Rakesh Sharma (*Abstract Co-Author*)
Gracia Vargas (*Abstract Co-Author*)
Jeffrey Duda (*Abstract Co-Author*)
Gary Wu (*Abstract Co-Author*)
James C. Gee, PhD (*Abstract Co-Author*)
Walter R. Witschey, PhD (*Abstract Co-Author*)
Victoria Gershuni (*Abstract Co-Author*)

PURPOSE

Malnutrition and sarcopenia are associated with worse outcomes after colorectal surgery. Preoperative risk assessment is not universal due to the logistic and resource demands of the formal nutrition care process. Lean muscle is a main component of malnutrition diagnosis. We applied a novel deep learning algorithm to automate volumetric body composition analysis using preoperative CT scans. The objective was to develop a predictive model using imaging biomarkers to identify colorectal surgery patients with increased risk of postoperative complications.

METHODS AND MATERIALS

We retrospectively analyzed elective colectomy patients from a single academic institution with preoperative abdominal CT scans (2018-2021). Volume and attenuation features from five muscle pairs and two fat depots were segmented by our deep learning algorithm. Clinical and demographic variables were extracted from electronic health record. Primary outcome was a composite variable for any postoperative complication. Elastic Net logistic regression was used to develop three predictive models: (1) clinical variables alone, (2) clinical variables + conventional L3 single-slice skeletal muscle index (SMI), and (3) clinical variables + novel volumetric imaging features. Models compared using area under receiver operator characteristic curves (AUC).

RESULTS

Among 502 patients (mean age: 61.5 years, 47% male), 20% experienced postoperative complications. Preoperative imaging revealed a high prevalence of sarcopenia (60%), myosteatosis (53%), and visceral obesity (61%) using conventional L3 slice metrics. 24% of patients received a postoperative clinical malnutrition diagnosis from dietitians. The model incorporating clinical variables and novel volumetric imaging features enhanced predictivity of post-operative complication compared to both the clinical-only and SMI models (AUC: 0.77 vs. 0.69 ($p<0.001$) and 0.70 ($p<0.001$), respectively).

CONCLUSION

Volumetric body composition analysis from routine preoperative CT scans improves preoperative risk stratification for colorectal surgery patients. Automated identification of imaging biomarkers may identify latent features of nutritional risk missed by conventional single-slice assessment methods, enabling early identification of high-risk patients who may benefit from targeted preoperative nutritional interventions.

CLINICAL RELEVANCE/APPLICATION

Automated volumetric body composition analysis from routine preoperative CT scans provides radiologists and surgeons with quantitative biomarkers for malnutrition that enhance surgical risk prediction beyond conventional methods, supporting opportunistic interventions to improve surgical outcomes.

W2-SPGU-1 AN MRI-BASED RADIOMICS MODEL TO PREDICT MALIGNANT RENAL CYSTS IN PATIENTS WITH HLRCC

Mahshid Golagha, MD (*Presenter*)
Ali Sheikhy, MD (*Abstract Co-Author*)
Negin Jarrah, MD (*Abstract Co-Author*)
Fatemeh Homayounieh, MD (*Abstract Co-Author*)
Rabindra Gautam (*Abstract Co-Author*)
Maria Merino, MD (*Abstract Co-Author*)
Mark W. Ball, MD (*Abstract Co-Author*)
Elizabeth C. Jones, MD, MBA (*Abstract Co-Author*)
W. Marston Linehan, MD (*Abstract Co-Author*)
Ashkan A. Malayeri, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the capability of quantitative MR imaging characteristics (radiomics) for predicting the nature of complex renal cysts in patients with Hereditary Leiomyomatosis and Renal Cell Carcinoma (HLRCC).

METHODS AND MATERIALS

In this retrospective study, 40 patients (mean age 47 ± 15 years; 20 male) with complex renal cysts on abdominopelvic MRI and germline FH mutations consistent with HLRCC were included. All patients underwent nephrectomy between June 2002 and May 2022, yielding 67 histologically confirmed complex cysts. Radiomic features were extracted from five MRI series [pre- and post-contrast T1-weighted images during the corticomedullary (20s), nephrographic (70s), and excretory (3 min) phases, and T2-weighted images] using SyngoVia Frontier Radiomics Software (Siemens Healthineers). Features were derived from original and filtered images (Laplacian of Gaussian, Wavelet, Square, Square Root, Logarithm, and Exponential). An Extreme Gradient Boosting (XGBoost) model was used to predict malignancy. The dataset was randomly split into 100 training and test sets (70%/30%) to evaluate performance. Metrics included AUC-ROC, accuracy, F1 score, precision, and recall.

RESULTS

Of the 67 cysts, 41 were benign and 26 malignant. The feature "Wavelet HLL glrlm Run Variance" (pre-contrast phase) contributed most to the model, followed by "Logarithm glszm Small Area Low Grey Level Emphasis," as identified by SHAP values. The XGBoost model trained on combined features from all sequences achieved the best performance with a mean F1 score of 0.85 (95% CI: 0.74-0.94) and AUC-ROC of 0.93.

CONCLUSION

Radiomics analysis is a feasible and effective approach for characterizing complex renal cysts on MRI in patients with HLRCC. Machine learning models trained on multiparametric MR data can reliably distinguish malignant from benign lesions.

CLINICAL RELEVANCE/APPLICATION

This study highlights the role of MRI-based radiomics in noninvasively predicting malignancy in HLRCC-related renal cysts. Incorporating artificial intelligence into imaging workflows may support earlier diagnosis and reduce unnecessary surgeries in this high-risk population.

W2-SPGU-2 A STUDY ON THE VALUE OF MULTI-PARAMETER DUAL-ENERGY CT IN ASSESSING MUSCLE INVASION IN BLADDER CANCER: A COMPARISON WITH THE EFFECTIVENESS OF VI-RADS

Mingyang Sun (*Presenter*)
Jiawen Luo (*Abstract Co-Author*)

PURPOSE

In clinical practice, Vesical Imaging-Reporting and Data System (VI-RADS) is the preferred imaging modality for assessing muscle invasion, yet it is not applicable to patients with contraindications to MRI.Accurate and non-invasive preoperative evaluation of the presence of muscle invasion is critical.Preoperative discrimination of MIBC using CT remains challenging. This study investigates the utility of Dual-energy CT (DECT) in assessing muscle-invasive bladder cancer(MIBC) and compares its diagnostic performance with the VI-RADS.

METHODS AND MATERIALS

In this study, the pathological findings served as the reference standard for determining the presence of muscle invasion.105 patients were included, comprising 33 cases of MIBC and 72 cases of non-muscle-invasive bladder cancer (NMIBC). In the corticomedullary and nephrographic phases, DECT parameters were measured in both the tumor body and the tumor base.DECT model was constructed using a multivariate logistic regression method. VI-RADS scoring was performed based on MRI images by two radiologists with over five years of experience in abdominal imaging.The diagnostic performance of the models in predicting muscle invasion was evaluated using receiver operating characteristic (ROC) curve analysis.

RESULTS

In DECT parameters,iodine concentration of the tumor base in the corticomedullary phase(ABIC), normalized iodine concentration of the tumor base in the corticomedullary phase(ABNIC),spectral Hounsfield unit curve slope of the tumor base in the nephrographic phase(VBK) ,effective atomic number of the tumor base in the nephrographic phase(VBZ) , Iodine concentration of the tumor base in the nephrographic phase(VBIC) and diameter(D) were independent predictors of MIBC ($p < 0.05$). The area under the curve (AUC) of the DECT model was 0.761 (95% confidence interval [CI]: 0.664 to 0.859), and the AUC of the DECT + D model was 0.925 (95% CI: 0.874 to 0.975). Meanwhile, the AUC of the VI-RADS was 0.926 (95% CI: 0.871 to 0.980). There was a statistically significant difference between the DECT model and VI-RADS ($p < 0.05$), while there was no statistically significant difference between the DECT + D model and VI-RADS ($p > 0.05$).

CONCLUSION

The majority of independent predictive factors for MIBC originate from the tumor base, implying that the tumor base may harbor crucial information for predicting muscle invasion. In the context of predicting MIBC, the combination of DECT and tumor diameter exhibits performance that is virtually indistinguishable from that of the VI-RADS.

CLINICAL RELEVANCE/APPLICATION

DECT represents a straightforward and viable method for preoperative differentiation of MIBC, particularly for patients who are ineligible for VI-RADS assessment.

W2-SPGU-3 OPTIMIZING PROSTATE MRI AT 0.55 T TO ACHIEVE DIAGNOSTIC QUALITY

Killian Monnin (*Presenter*)
Emanuele Avola (*Abstract Co-Author*)
Arthur Spencer (*Abstract Co-Author*)
Gorun Ilanjian (*Abstract Co-Author*)
Jade Matthey-des-Bornels (*Abstract Co-Author*)
Jean-Baptiste Ledoux (*Abstract Co-Author*)
Clarisse Dromain, MD, PhD (*Abstract Co-Author*)
Ileana Jelescu (*Abstract Co-Author*)
Naik Vietti Violi, MD (*Abstract Co-Author*)

PURPOSE

To develop a clinically feasible low-field (0.55 T) MRI protocol for prostate imaging using deep learning reconstruction (DLR), and evaluate its performance using quantitative and qualitative image quality criteria.

METHODS AND MATERIALS

Twelve healthy male volunteers (mean age 61.5 years) underwent prostate MRI using a 0.55T scanner (MAGNETOM Free.Max, Siemens Healthineers). A bi-parametric protocol was applied, including tri-planar T2-weighted imaging (WI) and axial diffusion-weighted imaging (DWI, b 50, 800 and calculated b from 1400 to 2000, with a-hundred increment) research sequences, following PI-RADS v 2.1 guidelines. DLR was enabled for T2-WI and DWI. Automatic 3D segmentations of the whole prostate, peripheral (PZ) and transitional zones (TZ) were performed using Mint TM software. Signal-to-noise ratio (SNR) was measured in each prostate zone, as mean signal divided by standard deviation of the signal in the internal obturator muscle. Contrast-to-noise ratio (CNR) was calculated between PZ and TZ. Two expert radiologists independently evaluated image quality using PI-QUAL v2 scores for the whole exam, comparing DLR and non-DLR images for T2WI. DWI images were only reviewed with DLR as raw data were not accessible. Wilcoxon signed-rank tests assessed improvements with DLR, and interrater agreement was measured using weighted Kappa statistics.

RESULTS

Median SNR on T2-WI with DLR was 12.73 (PZ), 8.89 (TZ), and 10.95 (whole prostate, WP), and without DLR was 6.95 (PZ), 5.02 (TZ) 5.99 (WP). CNR was 4.75. DLR significantly improved SNR and CNR ($p < 0.05$) that were comparable to values previously reported from clinical prostate MRI at 3 T and 1.5 T. On ADC images, median SNR was 9.60 (PZ), 8.58 (TZ), and 8.92 (WP). Calculated b = 1500 s/mm² images showed the highest SNR (median 13.02), compared to other calculated b values. Qualitative assessment revealed an improved PI-QUAL score with DLR (p=0.036) (Fig. 1), with moderate interrater agreement (Kappa = 0.78). Seven participants achieved an optimal PI-QUAL score with DLR (3/3), four had adequate (2/3), and one had inadequate (1/3).

CONCLUSION

Prostate MRI at 0.55 T is technically feasible and, when combined with optimized protocols and DLR, can achieve diagnostic image quality. DLR significantly improved SNR and CNR, and T2-WI quality score and increased final PI-QUAL score in most cases.

CLINICAL RELEVANCE/APPLICATION

This study on healthy volunteers demonstrates the feasibility of using 0.55 T MRI for prostate imaging with diagnostic image quality. Optimized acquisition protocols and DLR significantly improve image quality, suggesting low-field MRI may represent a cost-effective and more accessible alternative higher field MRI for prostate cancer evaluation in selected clinical contexts.

W2-SPGU-4 THE STUDY OF PATHOLOGY IN CHRONIC KIDNEY DISEASE BASED ON MULTIPLE DIFFUSION MRI MODELS

Guimian Zhong (*Presenter*)

PURPOSE

This study was based on multiple diffusion MRI models (Mono, IVIM, SEM, DKI) to screen or establish non-invasive and accurate MRI diagnostic markers or models for assessing the pathological damage of chronic kidney disease (CKD).

METHODS AND MATERIALS

A total of 73 patients with CKD who underwent renal biopsy and 3T MRI examination were prospectively enrolled. According to the chronic lesion score of renal biopsy tissue, the patients were divided into mild group (n=43), and moderate to severe group (n=30), and 30 healthy controls (HCs) were recruited. According to pathological types, the patients were divided into IgA nephropathy, membranous nephropathy and other groups. MRI diffusion parameters were compared among different groups to screen out the MRI parameters that could best reflect the pathological damage and pathological type of CKD. Finally, logistic regression was used to analyze its predictive value in pathological lesions and pathological types of CKD.

RESULTS

The MRI diffusion parameters DKI_MD, IVIM_f, Mono_ADC, SEM_DDC and the combined model of multiple parameters had high diagnostic efficiency in the differential diagnosis of mild group and HCs. The AUC values in predicting early pathological injury of CKD were 0.871 (0.787, 0.939),0.762 (0.649, 0.869),0.79 (0.676, 0.89),0.878 (0.797, 0.946), and 0.895 (0.819, 0.961), respectively. The MRI diffusion parameters DKI_MD, IVIM_D, IVIM_f, Mono_ADC, SEM_DDC and the combined model of multiple parameters had high diagnostic efficiency in the differential diagnosis of the mild and moderate to severe groups. The AUC values in predicting pathological injury degree of CKD were 0.841 (0.735, 0.929),0.766 (0.65, 0.873),0.676 (0.53, 0.811),0.853 (0.754, 0.93),0.804 (0.673, 0.909), and 0.873 (0.772, 0.956), respectively. The DKI-MK value demonstrates high diagnostic efficacy in differentiating IgA nephropathy from membranous nephropathy, with an AUC of 0.831 (0.694,0.947). Partial MRI diffusion parameters had a high correlation with chronic lesion severity score, and DKI_MD (r=-0.673, P <0.001) had the highest correlation.

CONCLUSION

Multiple MRI diffusion parameters could more sensitively identify the early pathological damage of CKD and more accurately evaluate the degree of pathological damage of CKD than SCr and eGFR. The DKI-MK value had great potential in differentiating IgA nephropathy from membranous nephropathy. Partial MRI diffusion parameters could better reflect the degree of chronic disease in CKD.

CLINICAL RELEVANCE/APPLICATION

The aim of this study was to screen or establish MRI diagnostic markers or models for precise assessment of CKD pathological damage, achieving the goal of early diagnosis, early intervention, and precise treatment of CKD.

W2-SPGU-6 FEASIBILITY OF US-CT FUSION IMAGING FOR LONG-TERM MONITORING OF URETERAL STONES: A PILOT STUDY

Bar Rinott, MD
(*Presenter*)
Eyal Bercovich, MD (*Abstract Co-Author*)

PURPOSE

To assess the feasibility and diagnostic accuracy of ultrasound-computed tomography (US-CT) fusion imaging in the long-term follow-up of patients with ureteral stones, with the goal of reducing repeated CT imaging and associated radiation exposure.

METHODS AND MATERIALS

A prospective pilot study was conducted on 31 patients previously diagnosed with ureteral stones via non-contrast CT (NCCT). All patients underwent US-CT fusion imaging approximately 6 weeks post-initial diagnosis, followed by definitive assessment via ureteroscopy. US-CT fusion was performed by an experienced radiologist using anatomical landmarks for real-time CT overlay on ultrasound images. Fusion findings were compared to intraoperative ureteroscopy findings, which served as the reference standard.

RESULTS

Fusion imaging identified residual stones in 16 patients, all of whom were confirmed to have stones on ureteroscopy (true positives). In 6 patients, fusion imaging showed no stones, but ureteroscopy revealed residual stones (false negatives). There were no false positives—no cases where US-CT fusion detected stones that were not present on ureteroscopy. In 9 patients, both US-CT and ureteroscopy confirmed absence of stones (true negatives). The resulting sensitivity was 73%, specificity 100%, positive predictive value (PPV) 100%, and negative predictive value (NPV) 60%. Fusion imaging was feasible in all cases and allowed accurate anatomical localization, particularly in distal ureteral segments.

CONCLUSION

US-CT fusion imaging is a feasible modality for evaluating residual ureteral stones. While highly specific and accurate in confirming the presence of stones, its lower sensitivity suggests it may miss some small or proximally located stones.

CLINICAL RELEVANCE/APPLICATION

US-CT fusion imaging shows promise as a non-ionizing follow-up tool in the management of ureteral stones. Its ability to accurately confirm stone presence may reduce the need for repeated CT scans, potentially lowering patient radiation exposure during long-term monitoring.

W2-SPHN-1 MULTI-MODAL ULTRASOUND-BASED DEEP LEARNING FOR CLASSIFICATION OF THYROID NODULES

Manali Saini, MEng, PhD (*Presenter*)
Tanin Adl Parvar, MD (*Abstract Co-Author*)
Mostafa Fatemi, PhD, PhD (*Abstract Co-Author*)
Azra Alizad, MD (*Abstract Co-Author*)

PURPOSE

To effectively boost the performance of classification of thyroid nodules using multi-modal ultrasound imaging integrated with customized deep learning architecture.

METHODS AND MATERIALS

This prospective study was conducted under an Institutional Review Board- approved and HIPPA-compliant protocol with signed informed consent obtained from each enrolled patient. Conventional B-mode ultrasound, shear wave elastography (SWE), and color Doppler (CD) images were acquired from 506 thyroid nodules in 423 subjects prior to biopsy. These images were concatenated and used to train a custom deep learning network. The network architecture comprised depth-wise separable convolutional layers, combined with attention-based mixed pooling and tailored self-attention mechanisms, applied for the first time in the context of thyroid nodule classification.

RESULTS

The proposed method achieved a classification accuracy (Ac) of 0. 95, a sensitivity (Se) of 0.98, a receiver operating characteristic area under the curve (r AUC) of 0. 99, a specificity (Sp) of 0. 92, an F-1 score of 0. 95 and a precision-recall AUC (pAUC) of 0. 99 on test dataset. The use of multi-modal images with the proposed deep learning model considerably improved thyroid nodule classification performance with sensitivity of 0. 98 as compared to uni-modal or bi-modal data with sensitivity of 0.51- 0. 92. Further, the proposed network with sensitivity of 0.98 outperformed the state-of-art deep learning networks with sensitivity of 0.75- 0. 94 for thyroid nodule classification while utilizing relatively smaller architecture.

CONCLUSION

The integration of multi-modal ultrasound imaging with customized deep learning network effectively and efficiently improves the overall classification of thyroid nodules, enhancing overall diagnostic performance. The proposed method outperforms state-of-the art models trained on our multi-modal dataset and achieves high sensitivity, indicating its effectiveness in accurately diagnosing malignancy.

CLINICAL RELEVANCE/APPLICATION

Integrating multimodal ultrasound with a customized deep learning network remarkably improves diagnostic sensitivity, enabling more accurate cancer diagnosis, leading to better patient outcomes through earlier and more precise treatment strategies.

W2-SPHN-2 VESTIBULAR AQUEDUCT LENGTH AS A RADIOLOGIC MARKER FOR THE PROGRESSIVE DEGENERATIVE ENDOTYPE IN MENIèRE DISEASE

Jingjing Xu (*Presenter*)
Yunchong Han (*Abstract Co-Author*)
Shuangxiang Lin, MSc (*Abstract Co-Author*)
Yuguo Wei (*Abstract Co-Author*)

PURPOSE

Menière's disease (MD) presents as two distinct endotypes: one characterized by a hypoplastic, underdeveloped endolymphatic sac (MD-hp), and the other featuring a normally developed sac that undergoes progressive degeneration (MD-dg). Accurate endotype differentiation is clinically significant for prognostic prediction, personalized patient counseling, and treatment optimization. Current diagnostic criteria rely on measuring the angular trajectory of the vestibular aqueduct (ATVA), where ATVA = 140° indicates MD-hp while ATVA = 120° suggests MD-dg. However, ATVA assessment presents technical challenges in clinical practice. This study investigates potential correlations between ATVA and alternative CT morphometric parameters that could serve as reliable discriminators between MD endotypes, utilizing the advanced imaging capabilities of photon-counting CT (PCCT) technology.

METHODS AND MATERIALS

We retrospectively analyzed temporal bone CT imaging from 49 adult patients with definite Menière's disease (MD) (62 affected ears) and 47 age-matched controls without MD or other inner ear pathology (94 ears). All measurements, including the angular trajectory of the vestibular aqueduct (ATVA) and additional temporal bone parameters, were obtained from standardized axial photon-counting CT (PCCT) images using a consistent measurement protocol.To evaluate potential diagnostic markers, we performed comparative analyses examining correlations between ATVA and other CT-derived measurements. Furthermore, available temporal bone MRI examinations were assessed to measure vestibular aqueduct length, enabling cross-modality validation of our PCCT findings.

RESULTS

The average VA length was significantly different between MD endotypes, being a mean of 2.62 (SD, 1.77) mm in patients with MD-hp and 4.55 (SD, 1.80) mm in patients with MD-dg. While PCCT-based morphometric analyses revealed no other significant endotype differences, receiver operating characteristic (ROC) analysis identified a VA length cutoff of =2.11 mm as effectively excluding MD-dg diagnosis (AUC = 0.78, accuracy = 93%). Measurement reliability was excellent, with strong interrater agreement and near-perfect correlation between CT and MR modalities.

CONCLUSION

The VA length proved to be a useful and straight forward alternative marker for distinguishing MD endotypes, being particularly useful for excluding MD-dg. Including information of the VA length should be considered a routine part of reporting in the context of MD imaging.

CLINICAL RELEVANCE/APPLICATION

PCCT offers a promising solution for imaging patients with different MD endotypes, potentially reducing the need for additional imaging or invasive diagnostic procedures.

W2-SPHN-3 DEEP LEARNING-BASED AUTOMATIC SEGMENTATION SYSTEM FOR PREDICTING CERVICAL LYMPH NODE METASTASIS IN PATIENTS WITH PAPILLARY THYROID CARCINOMA USING COMPUTED TOMOGRAPHY: A MULTI-CENTER STUDY

Jing Wen Yu (*Presenter*)
Lijian Liu (*Abstract Co-Author*)
Zhang Ya (*Abstract Co-Author*)
Yongsheng Xie (*Abstract Co-Author*)
Dehong Luo, MD (*Abstract Co-Author*)
Zhou Liu, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop and validate a preoperative deep learning-based automatic segmentation system for lymph node (LN) levels segmentation with CT imaging for prediction of LN metastasis in patients with papillary thyroid carcinoma (PTC).

METHODS AND MATERIALS

A total of 3635 lymph nodes (LNs) from 727 PTC patients in Center A who underwent CT examinations from November 2018 and February 2023 were included and divided into training and validation set at the ratio of 7:3. A total of 760 LNs from 152 PTC patients in Center B were allocated into the external test set. We use a 3D U-Net network for cervical LN levels II-VI. We extracted 1204 radiomic features from venous contrast-enhanced computed tomography (CT) images. Mann-Whitney U test, Spearman correlation analysis, and the least absolute shrinkage and selection operator (LASSO) were used in reducing the dimensionality of radiomics features in the training cohort. Then, a radiomics signature (Rad-score) was calculated as the sum of each feature multiplied by the nonzero coefficient from LASSO. Incorporating the Rad-score and CT-reported LN status, a nomogram was constructed using multivariable logistic regression. The nomograms' performance was analyzed in terms of accuracy, sensitivity, specificity, receiver operating characteristic (ROC) curves, and areas under the ROC curve (AUCs). The clinical usefulness of the nomogram was evaluated by decision curve analysis (DCA).

RESULTS

The automated segmentation model demonstrated a dice similarity coefficient (DSC) of 0.80 in volumetric tissue delineation. Based on automated segmentation imaging, a total of 18 radiomics features were used in constructing the Rad-score. The nomogram exhibited good discrimination performance of the nomogram for predicting LN metastasis in the training cohort (AUC: 0.826), internal test cohort (0.827), and external test cohort (0.856) and showed diagnostic capability comparable to the CT-reported LN status and the radiomics signature model. DCA demonstrated that the radiomic nomogram was worthy of clinical application.

CONCLUSION

Our deep learning algorithm achieves effective non-invasive segmentation and classification of LN levels. The radiomics nomogram provides a noninvasive method that incorporates radiomics features and CT-reported LN status for predicting LN metastasis in patients with PTC.

CLINICAL RELEVANCE/APPLICATION

Our deep learning algorithm enables non-invasive LN level segmentation/classification, paired with a radiomics nomogram integrating CT-reported LN status and radiomic features, offering clinicians a dual-modality tool to optimize preoperative risk stratification, reduce invasive procedures, and guide personalized surgical planning in PTC patients suspected of LN metastasis.

W2-SPHN-4 ROLE OF PET MRI IN THE EVALUATION AND RISK STRATIFICATION OF HEAD NECK LESIONS USING NIRADS

Pawan Shinkar, MD, MBBS (*Presenter*)
Likhitha Somepalli (*Abstract Co-Author*)
Mohana Vamsy (*Abstract Co-Author*)

PURPOSE

Head and neck cancers are the 7th most common malignancy globally, with high rates of locoregional recurrence. Post-treatment surveillance is challenging due to complex anatomy and therapy-induced changes. The Neck Imaging Reporting and Data System (NI-RADS) was developed to standardize follow-up imaging, primarily using CT. This study assesses the utility of PET-MRI in enhancing NI-RADS-based evaluation.

METHODS AND MATERIALS

In this prospective study, 122 patients with treated head and neck squamous cell carcinoma underwent digital time-of-flight PET-MRI 8-12 weeks post-therapy. After excluding 19 cases due to imaging artifacts or incomplete data, 103 patients were assessed for primary site recurrence and 81 for nodal disease using NI-RADS categories. Histopathological correlation and imaging follow-up served as reference standards.

RESULTS

Primary disease (n = 103) NI-RADS 1: 16 NI-RADS 2A: 22 NI-RADS 2B: 28 (15 showed regression; 5 progressed to NI-RADS 3) NI-RADS 3: 32 (27 confirmed recurrence) NI-RADS 4: 5 Nodal disease (n = 81) NI-RADS 1: 29 NI-RADS 2: 17 (14 regressed; 3 progressed) NI-RADS 3: 32 (25 confirmed metastasis, 7 reactive) NI-RADS 4: 3 PET-MRI allowed for better discrimination between post-treatment changes and active disease, especially in NI-RADS 2B and 3 categories.

CONCLUSION

PET-MRI improves diagnostic performance in post-treatment head and neck cancer surveillance by combining metabolic and high-resolution anatomical data. It enhances confidence in NI-RADS classification, particularly in indeterminate cases, reducing false positives and enabling accurate detection of recurrence.

CLINICAL RELEVANCE/APPLICATION

PET-MRI plays a pivotal role in: Differentiating post-treatment changes from true recurrence More accurately stratifying NI-RADS 2B and 3 lesions Guiding biopsy and therapeutic decisions in ambiguous cases Enhancing surgical planning and reducing unnecessary interventions Providing a safer, low-radiation alternative for long-term surveillance By improving specificity and confidence in imaging interpretation, PET-MRI contributes to more precise and individualized patient management in head and neck oncology.

W2-SPHN-6 NATIONAL MEDICARE TRENDS IN US-GUIDED THYROID FINE NEEDLE ASPIRATIONS (FNA) FROM 2019-2023: A SHIFT REVERSAL FOR NON-PHYSICIAN PROVIDERS COMPARED TO TRADITIONAL PROVIDERS

Surbhi Singh, MD (*Presenter*)
Akhil Tanwar, MD, MBBS (*Abstract Co-Author*)
Ajit Karambelkar, MD (*Abstract Co-Author*)

PURPOSE

In 2019, the introduction of new CPT codes (10005-10012) changed the way thyroid FNA were performed and billed. The new codes also incorporated the imaging modality into the FNA code itself. We review the US-guided thyroid FNAs performed by various specialties since the introduction of the new codes and also briefly touch on the protocol of thyroid FNA procedure, its clinical utility, limitations, and emerging trends based on current evidence

METHODS AND MATERIALS

Data was obtained from the Centers for Medicare & Medicaid Services Physician/Supplier Procedure Summary Master Files from 2019 to 2023. Provider specialties were determined from the Physician Specialty Classification Codes used by Medicare. Locations at which examinations were performed were determined using Medicare Place-of-Service Codes.

RESULTS

In our study, the traditional providers of thyroid care showed notable declines in FNA procedures. General Surgeons experienced a significant reduction (a 25.1% decrease), and Endocrinologists showed a comparable decline of 25.15%. This is in contrast with physician assistants who showed an increase of 48.9%.In 2018, the most common single location for a thyroid FNA was the physician office setting, with 47.1% of claims for CPT 10022. By 2023, the hospital facility claims had increased to 55.08% of claims, indicating a shift from outpatient to in-hospital location.

CONCLUSION

In our study, perhaps the most striking finding was the substantial increase in thyroid FNA procedures performed by physician assistants, who demonstrated a 48.9% growth over the study period coupled with transition from out-patient clinic to in hospital setting. This may be attributed to the RVU restructuring which happened along with the introduction of the new CPT codes in 2019

CLINICAL RELEVANCE/APPLICATION

According to a report published by the American Association of Clinical Endocrinology, restructuring of the CPT codes also resulted in reduction of (Relative work units) RVUs in 2019 which caused non-facility outpatient practices to discontinue the procedure. However, in this case the procedure is now being performed in a vastly more expensive location costing 524% more. If we consider the shift in location from Office to Facility that was seen between 2018 and 2023, with the increased cost of $584.92 in the Facility location, Medicare experienced an additional cost of $ 2,725,544 due to physicians in non-facility locations abandoning the procedure

W2-SPHN-7 DOPPLER ULTRASOUND AND DUAL-ENERGY CT FEATURES TO PREDICT CD31 EXPRESSION AS A PREDICTOR OF RECURRENCE RISK IN PAPILLARY THYROID CANCER

Yan Zhou, MD, MD (*Presenter*)

PURPOSE

To evaluate CD31 as a prognostic marker in papillary thyroid carcinoma (PTC), and to develop a model based on preoperative angiogenesis-related imaging features from Doppler Ultrasound (US) and Dual-Energy CT (DECT) to predict CD31 expression, a marker associated with recurrence risk.

METHODS AND MATERIALS

A total of 414 PTC patients (training set, 151; test set 1, 137; test set 2, 126) were included. Clinical and radiographic features, including demographics, tumor morphology, Doppler US grade, US grayscale values, and DECT parameters, were analyzed. CD31 expression was assessed via immunohistochemistry in the training set and correlated with invasive clinicopathological features and recurrence risk. Its association with clinical and imaging characteristics was examined. A logistic regression model was constructed to predict CD31 expression based on selected variables, and recurrence-free survival (RFS) analysis evaluated the model's prognostic value across all datasets.

RESULTS

CD31 expression was significantly associated with advanced tumor stage, lymph node involvement, extrathyroidal extension, and recurrence. The predictive model, incorporating Doppler US grade, unenhanced electron density (ED), arterial phase iodine concentration (IC), and venous phase iodine concentration/electron density ratio (IC/ED) demonstrated good performance for predicting CD31 expression with an AUC of 0.815 in the training set. The model was also significantly associated with RFS across all datasets (training set: $p = 0.027$; test set 1: $p = 0.008$; test set 2: $p = 0.002$), identifying high-risk patients with worse outcomes.

CONCLUSION

Preoperative imaging-based prediction of CD31 expression enhances recurrence risk assessment in PTC, providing a non-invasive tool for identifying high-risk patients.

CLINICAL RELEVANCE/APPLICATION

Doppler US and DECT features can predict CD31 expression, a marker of recurrence risk in PTC, providing a non-invasive tool to guide clinical decisions and improve patient outcomes.

W2-SPHN-8 SUBTRACTION IODINE MAPS COMBINED WITH DEEP LEARNING RECONSTRUCTION IMPROVED EVALUATION OF TEMPORAL BONE LESIONS BASED ON ENHANCEMENT PATTERNS

Yu Chen, MD (*Presenter*)
Tong Su, MD (*Abstract Co-Author*)
Zhe Zhang (*Abstract Co-Author*)
Min Xu, PhD (*Abstract Co-Author*)
Jian Wang (*Abstract Co-Author*)
Jiajing Tong (*Abstract Co-Author*)
Zhengyu Jin, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the diagnostic performance of subtraction iodine maps (SIM) combined with deep learning reconstruction (DLR) for assessing temporal bone lesions, based on different enhancement patterns between low- (<50 HU) and high-enhancement (=50 HU) subgroups, in comparison to conventional contrast-enhanced temporal bone CT imaging.

METHODS AND MATERIALS

We conducted a prospective study of 77 consecutive patients with temporal bone lesions who underwent temporal bone CT scans using a 320-detector-row scanner (Aquilion ONE Genesis Edition). All acquisitions included pre-contrast and enhanced phases, with images reconstructed using both hybrid iterative reconstruction (HIR, AIDR 3D) and DLR (AiCE). These image sets were processed using SURESubtraction software to generate three comparison groups: Enhanced-HIR, SIM-HIR, and SIM-DLR.Two experienced radiologists independently evaluated the images using a five-point scale across four qualitative parameters: overall image quality, confidence in lesion detection, lesion contour visualization, and display of temporal bone involvement. Lesions were categorized based on post-contrast enhancement characteristics using a clinically established 50-HU threshold. We compared the benefits of each reconstruction method between enhancement subgroups.

RESULTS

The SIM-DLR demonstrated superior performance compared to Enhanced-HIR across all qualitative parameters (all $p<0.05$), with excellent inter-rater agreement (? =0.872). For high-enhancement lesions, SIM provided significantly greater improvements in lesion detection confidence ($p<0.001$), contour visualization ($p<0.001$) and displaying temporal bone involvement ($p=0.03$) compared to low-enhancement lesions. DLR reconstruction showed similar trends, with high-enhancement lesions

demonstrating better lesion detection confidence (p=0.007) and contour visualization (p=0.03). However, DLR's benefits for overall image quality and bone involvement display were consistent across both enhancement subgroups (p>0.05).

CONCLUSION

The integration of SIM with DLR significantly improves temporal bone lesion assessment compared to conventional enhanced CT, particularly for hypervascular pathologies. This combined approach enhances noise reduction, anatomical delineation, and evaluation of bony involvement.

CLINICAL RELEVANCE/APPLICATION

The SIM-DLR technique provides superior visualization of lesion invasion extent in the temporal bone, offering valuable preoperative information for surgical planning, especially in vascularized tumors.

W2-SPIN-1 PERSONALIZED, REAL-WORLD, AND CROSS-SILO FEDERATED LEARNING FOR BREAST CANCER DETECTION

Shandong Wu, PhD (*Presenter*)
Jun Luo (*Abstract Co-Author*)
Dooman Arefan, PhD, MSc (*Abstract Co-Author*)
Margarita L. Zuley, MD (*Abstract Co-Author*)
Chen Chen (*Abstract Co-Author*)
Jules H. Sumkin, DO (*Abstract Co-Author*)

PURPOSE

Federated learning (FL) enables multiple clients/silos to collaboratively train AI models without transferring patient data across sites, preserving privacy. Conventional FL aims to train a single global model for all clients, while personalized FL (PFL) allows individually enhanced models customized for each client. Our goal is to implement and evaluate PFL for real-world breast cancer detection on heterogeneous mammographic datasets from multiple silos.

METHODS AND MATERIALS

Multiple geographically distributed populations and mammograms acquired with varying protocols were used: Client 1-4 have 3320 (25% cancer), 3458 (17% cancer), 3101 (44% cancer), and 5202 (79% cancer) mammograms, respectively. A secondary setting runs on highly heterogeneous data stratified by Machine ID at four clients: 3140 (25% cancer), 1309 (17% cancer), 1288 (17% cancer), 1434 (11% cancer) mammograms. We implemented two in-house PFL algorithms (PFL-A1 that learns to adaptively personalize models over local data; PFL-A2 that personalizes each client's objective in a global format) published on non-medical data, and compared to (1) Local - clients independently train their own models and (2) FedAvg - a benchmark conventional FL training a consensus global model. AUC and accuracy (Acc) on client's test data were reported.

RESULTS

All FL algorithms outperformed Local models (four-client's mean AUC and Acc: 62.37% and 73.86%). FedAvg model (AUC and Acc: 64.48% and 75.43%) achieved a higher AUC of 8.59%, 3.04%, -0.25, and 0.81% on Client 1 to 4, compared to corresponding Local models. PFL-A1 (AUC: 65.89%; Acc: 76.13%) and PFL-A2 (AUC: 66.40%; Acc: 77.13%) showed large AUC increases over each local model: PFL-A1: 10.54%, 1.75%, 4.51%, 1.96% higher AUC on Client 1 to 4; PFL-A2: 9.24%, 6.69%, 3.58%, 3.66% higher AUC on Client 1 to 4. In the secondary setting, PFL also boosted each client's performance up to 7.07% for PFL-A1, and 9.69% for PFL-A2 in AUC improvement.

CONCLUSION

Personalized FL is feasible in real-world breast cancer detection, preserving privacy and dealing with heterogeneous data from multiple sites, where each site achieved improved performance than local training and conventional FL.

CLINICAL RELEVANCE/APPLICATION

Personalized federated learning shows real-world benefits and impact in meeting the growing need of AI model development/evaluation that leverages diverse multi-center datasets and preserves privacy.

W2-SPIN-2 IMPROVING RADIOLOGY RESIDENT EDUCATION WITH LOCALLY DEPLOYED AI: A PILOT STUDY ON FEASIBILITY AND EDUCATIONAL IMPACT

Orhan Unal, PhD (*Presenter*)
Taylor Sellers, BS, MD (*Abstract Co-Author*)
John E. Winterholler, MD (*Abstract Co-Author*)
Nicholas Tan, MD (*Abstract Co-Author*)
Isha Pathak, MD (*Abstract Co-Author*)
Allison M. Grayev, MD (*Abstract Co-Author*)
John W. Garrett, PhD (*Abstract Co-Author*)

PURPOSE

Attending radiologist feedback on residents' preliminary reports is a critical component of radiology education. However, increasing imaging volumes have limited opportunities for direct teaching, leaving final report revisions by attendings as an underused source of learning. Extracting structured, actionable feedback from these revisions is difficult due to variability in language and the absence of standardized frameworks. We propose that a locally deployed AI/ML solution using large language models (LLMs) can efficiently analyze and compare preliminary and final reports, generate structured feedback, and ensure PHI protection. This approach offers a scalable, privacy-preserving tool to enhance resident education.

METHODS AND MATERIALS

Impressions from overnight preliminary and corresponding final reports for chest X-ray and head CT studies were extracted via SQL queries and compiled into anonymized CSV tables. Leading open-source LLMs including LLaMA 3.1, Gemma 2.5, and Mixtral were tested using multiple zero-shot prompts to assess differences in clarity, clinical accuracy, training relevance, and specificity. Initial evaluations focused on the quality and educational alignment of LLM-generated outputs. Prompt design was iteratively refined to enhance performance and capture radiology-specific nuances.

RESULTS

LLMs effectively identified differences between preliminary and final radiology reports across key dimensions, including clarity, relevance, accuracy, and focus. Gemma2, Qwen2.5, and LLaMA3.3 showed the strongest overall performance, with Gemma2 achieving the highest clarity (4.73/5) and LLaMA3.3 the highest focus (0.95). While

Mixtral ranked lower, it was the most efficient, completing evaluations in just 9.17 seconds. In contrast, LLaMA3.1 had the longest runtime (37.18 seconds). Results also varied by prompt structure, underscoring the importance of prompt design in optimizing educational value. Quantitative validation is ongoing.

CONCLUSION

Locally deployed LLMs show strong potential in generating structured, educationally meaningful feedback from resident-attending report comparisons, while preserving PHI. This work supports the integration of AI-driven tools to enhance feedback in radiology training and strengthen educational workflows.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the feasibility of using locally hosted, open-source LLMs to provide structured feedback on resident radiology reports. The approach addresses the growing gap in direct educational feedback caused by rising imaging volumes while ensuring PHI protection through local deployment.

W2-SPIN-3 FILLING THE GAPS: ANATOMY-GUIDED DIFFUSION MODELS FOR SYNTHESIZING MISSING MRI SEQUENCES IN BRAIN TUMORS

Moinak Bhattacharya (*Presenter*)
Annie Singh (*Abstract Co-Author*)
Gagandeep Singh, MD, MBA (*Abstract Co-Author*)
Prateek Prasanna, PhD (*Abstract Co-Author*)

PURPOSE

Missing one or more MRI sequences is a frequent challenge in clinical neuroimaging, often resulting from motion artifacts, patient intolerance, or contraindications to contrast agents. However, most AI-based diagnostic and segmentation tools require all standard sequences for optimal performance. To address this, we propose a diffusion model-driven generative AI framework for synthesizing missing brain MRI sequences. Unlike conventional diffusion models that generate images from random noise and lack anatomical fidelity, our approach incorporates structural priors—Cortical Gray Matter (CGM), White Matter Tracts (WMT), Lateral Ventricles (LV), and Tumor Masks (TM)—to generate anatomically faithful and diagnostically meaningful images.

METHODS AND MATERIALS

We utilize the Brain Tumor Segmentation (BraTS) Glioblastoma dataset for model development. First, a 3D Stable Diffusion (SD) model is trained on multi-sequence MRI data. To enhance anatomical realism, we adapt a ControlNet-style finetuning pipeline, conditioning the generation process on key anatomical structures including CGM, WMT, LV, and TM. These anatomical priors are extracted from the available sequences using pre-trained segmentation models and serve as structural guidance during image synthesis.

RESULTS

For n = 78 patients, we performed image quality assessment and report a PSNR score of 18.50 ± 4.04. We also present qualitative results of the generated images stratified by MGMT methylation status (0 and 1).

CONCLUSION

Anatomy-conditioned diffusion models improve the accuracy and realism of synthesized brain MRI sequences

CLINICAL RELEVANCE/APPLICATION

This approach has direct clinical implications by enabling robust diagnostic workflows even when one or more MRI sequences are missing. The proposed model can be integrated into clinical imaging pipelines to enhance diagnostic completeness, support radiologist decision-making, and facilitate consistent AI model performance in incomplete imaging scenarios. The proposed method can also augment machine learning training by incorporating synthetic images into the dataset, thereby mitigating data bias and addressing class imbalance.

W2-SPIN-4 OPPORTUNISTIC SCREENING OF DIABETES USING AI-EXTRACTED WHOLE-BODY MRI BIOMARKERS

Songsoo Kim, MD (*Presenter*)
Dukyong Yoon (*Abstract Co-Author*)

PURPOSE

This study evaluates AI-derived imaging biomarkers from whole-body MRI to detect and predict diabetes mellitus (DM).

METHODS AND MATERIALS

Whole-body MRI data from 3,000 UK Biobank participants were segmented using TotalSegmentator on Dixon MRI water-fat sequences, and the resulting segmentation masks were used to compute volume indices and fat fractions. For DM detection, significant imaging features identified by logistic regression were included in a multivariate Extreme Gradient Boosting (XGBoost) model, evaluated with 5-fold cross-validation using the area under the receiver operating characteristic curve (AUROC). For DM prediction, significant imaging features identified via Cox regression were integrated into a Random Survival Forest (RSF) model, assessed by 5-fold cross-validation using Harrell's concordance index (C-index). Permutation tests compared imaging-based and conventional clinical models.

RESULTS

Among 2,657 participants, 123 had baseline DM. Top variables in univariate analysis included visceral fat volume index (AUROC 0.761), adrenal gland volume index (0.750), and pancreatic fat fraction (0.709). The XGBoost model achieved an AUROC of 0.764 ± 0.074 (95% CI, 0.671-0.858). Of 2,534 participants without baseline DM, 24 developed DM over a median follow-up of 4.1 years. Leading predictive variables included pancreatic fat fraction (C-index 0.746), visceral fat volume index (0.746), and adrenal gland volume index (0.740). The imaging-based RSF model demonstrated higher predictive performance (C-index 0.737 ± 0.073; 95% CI, 0.680-0.794) compared to the clinical RSF model (0.700 ± 0.097; 95% CI, 0.631-0.778), though differences were not statistically significant.

CONCLUSION

AI-derived MRI biomarkers alone demonstrated strong performance in detecting current DM and predicting future onset.

CLINICAL RELEVANCE/APPLICATION

AI-derived whole-body MRI biomarkers can be leveraged for opportunistic screening of diabetes mellitus during routine imaging. These biomarkers enable radiologists to identify hidden metabolic abnormalities—such as increased visceral fat or pancreatic fat or adrenal gland volume—indicative of increased diabetes risk, facilitating earlier diagnosis and improved risk stratification for disease progression.

W2-SPIN-6 FUSION OF VISION TRANSFORMER AND CNN FEATURES FOR COVID-19 DETECTION IN LUNG CT SCANS

Ahmet Er (*Presenter*)
Berrin Er (*Abstract Co-Author*)
Olivier Gevaert, PhD (*Abstract Co-Author*)

PURPOSE

To assess the effectiveness of pre-extracted features from DINOv2-L/14-reg, a vision transformer trained with self-supervision, and ConvNeXtV2-L, a fully convolutional masked autoencoder framework, in whole-lung CT analysis for COVID-19 detection, we explored whether frozen, slice-level features from these models, combined using various fusion and aggregation strategies, could construct accurate patient-level representations.

METHODS AND MATERIALS

We analyzed 3,780 CT series from 2,297 CT scans in the MIDRC database, each linked to PCR results. Scans were labeled positive if a PCR test was positive within 14 days prior to imaging, and negative if at least two PCRs were negative within ±7 days and no positives were recorded. Lung parenchyma was segmented using TotalSegmentatorV2 and normalized using dataset-specific statistics. Slice-level features were extracted using pretrained ResNet101, DINOv2, and ConvNeXtV2 models; radiomics features were extracted using PyRadiomics. For feature fusion, we evaluated simple concatenation and proposed a gated cross-channel fusion method integrating DINOv2 and ConvNeXtV2 features. To construct patient-level representations from variable-length slice features, we tested mean pooling and attention-based strategies, including self-attention and gated attention pooling. A fully connected network was trained on aggregated features, while XGBoost was used for PyRadiomics features. We employed nested cross-validation with Optuna-based hyperparameter optimization and evaluated performance using AUROC and F1 score.

RESULTS

Of the 3,780 CT series included in the analysis, 1,954 were labeled as positive and 1,826 as negative. Mean pooling consistently outperformed other aggregation strategies and was used in subsequent experiments. Patient-level representations from ConvNeXtV2 (AUROC: 0.879, F1: 0.796) and DINOv2 (AUROC: 0.873, F1: 0.788) outperformed both ResNet101 (AUROC: 0.852, F1: 0.767) and PyRadiomics features (AUROC: 0.807, F1: 0.743). The proposed gated cross-channel fusion model achieved the highest overall performance (AUROC: 0.884, F1: 0.800).

CONCLUSION

The gated-fusion cross-channel model combines DINOv2 and ConvNeXtV2 using a learnable gating mechanism to dynamically balance and integrate their complementary representations, enhancing performance in multi-view data. The gating mechanism adaptively weights features from both backbones based on their relevance, ensuring optimal fusion for downstream applications.

CLINICAL RELEVANCE/APPLICATION

Our findings highlight the potential of transfer learning with advanced pretrained models for automated COVID-19 detection from lung CT scans.

W2-SPIN-8 ENSEMBLED MONITORING MODEL (EMM): A FRAMEWORK FOR AUTOMATED REAL-TIME ASSESSMENT OF CLINICAL AI

Zhongnan Fang, PhD (*Presenter*)
Andrew Johnston, MD, MBA (*Abstract Co-Author*)
Lina Cheuy (*Abstract Co-Author*)
Hye Sun Na (*Abstract Co-Author*)
Magdalini Paschali, PhD (*Abstract Co-Author*)
Camila Gonzalez, DPhil (*Abstract Co-Author*)
Bonnie Armstrong, PhD, MA (*Abstract Co-Author*)
Arogya Koirala, BS, MS (*Abstract Co-Author*)
Derrick Laurel, BA, ARRT (*Abstract Co-Author*)
Andrew W. Campion, MD (*Abstract Co-Author*)
Michael Iv, MD (*Abstract Co-Author*)
Akshay Chaudhari, PhD (*Abstract Co-Author*)
David B. Larson, MD, MBA (*Abstract Co-Author*)

PURPOSE

With the surge in AI tools for healthcare, monitoring of medical AI systems has become increasingly critical. While FDA-approved AI tools typically undergo pre-deployment or retrospective evaluation, there remains a significant gap in real-time, case-by-case confidence assessments while using commercial AI systems. This absence of immediate verification can erode trust in AI and create considerable risks, e.g. undetected AI errors may lead to misdiagnosis and ultimately compromise patient care. We introduce the Ensemble Monitoring Model (EMM) to provide robust confidence measurements, without requiring access to internal AI components or intermediate outputs.

METHODS AND MATERIALS

EMM is inspired by clinical consensus practices where confidence can be evaluated through multiple expert reviews. In our use case, EMM integrates five architecturally diverse sub-models trained to detect intracranial hemorrhage (ICH) on brain CT, the same intended task as the primary model (model being monitored). For each case, the outputs from these five models were compared against the primary model's prediction to quantify agreement and establish confidence level. With EMM, cases were systematically stratified into confidence categories, enabling customized suggested actions. Technical factors affecting EMM development were also explored.

RESULTS

We evaluated EMM using a large, diverse dataset (N=2,919). Results demonstrated EMM's ability to effectively characterize cases by confidence level, where high-confidence cases typically featured large, high-contrast hemorrhages, while low-confidence cases presented small, subtle hemorrhages or ICH-mimicking features. By applying appropriate thresholds, EMM successfully stratified AI predictions into increased, similar, and lower confidence categories. Importantly, the system's effective identification of low-confidence cases enables targeted manual review, significantly improving overall ICH detection accuracy.

CONCLUSION

EMM effectively quantifies confidence in individual AI predictions for real-time assessment without requiring access to the black-box AI's internal components. This valuable tool enables physicians to estimate the confidence of each prediction and take customized actions based on different confidence levels, not only improving trust in AI but enabling radiologists to use AI more efficiently.

CLINICAL RELEVANCE/APPLICATION

EMM is a practical and effective tool for quantifying case-by-case confidence in black-box AI. By enabling customized actions based on confidence levels, EMM can reduce misdiagnosis risks and increase radiologists' efficiency. The technical considerations shared provide best practices for successfully translating EMM to other tasks.

W2-SPIN-9 NEW DEVELOPMENT OF A QUALITY ASSURANCE STRUCTURE REPORT (QASR) FOR ACCEPTANCE AND CONSTANCY TESTING

Hideki Yaku (*Presenter*)
Yoshihisa Muramatsu, PhD, RT (*Abstract Co-Author*)
Keiichi Nomura, PhD (*Abstract Co-Author*)
Keisuke Fujii, PhD (*Abstract Co-Author*)
Michael F. McNitt-Gray, PhD (*Abstract Co-Author*)

PURPOSE

Acceptance and constancy tests for X-ray medical devices have been standardized in IEC standards. However, the data flow of medical device management information for conducting these tests has not been standardized. The purpose of this study is to develop a new quality assurance structure report (QASR) for medical device management that allows information related to acceptance and constancy tests to circulate within an organization and to achieve digital transformation (DX).

METHODS AND MATERIALS

The target medical device was a CT system. Inspection orders for each evaluation element (CT Number Assessment, Image Noise, Uniformity, etc.) were generated on our local RIS using the appropriate local and national standard codes. The order code specified the acceptance or constancy test as well as the type (water) and size (320 mm?) of the phantom. The order information was registered with the CT scanner using Modality Work List (MWL), which is translated automatically to the desired scan and reconstruction parameters. The reconstructed images and CT-RDSR files were obtained and then transferred to the analysis workstation. A dedicated

application was used to automatically analyze these images according to IEC standards and generate the corresponding CT- QASR, which contains all of the testing results.

RESULTS

The order information was traced through the Scheduled Procedure Step Description, CT scanning, image transfer, analysis, and generation of the QASR and database and all steps were performed smoothly. In the CT-QASR, the desired test results (CT values, Image Noise, and Uniformity) were accurately and automatically calculated versus manual calculations, along with information on scanning conditions and study instruments, and displayed in the Data Intelligence tools.

CONCLUSION

Newly developed quality assurance structured reports (QASRs) have brought the data flow of testing and results for medical device management information much closer to standardization.

CLINICAL RELEVANCE/APPLICATION

With the development of a new quality assurance structured report (QASR) with phantom information, medical device (CT scanner) management information can be networked and shared between users and maintenance vendors, as well as among groups, regions, and government agencies.

W2-SPIN-10 COMPARISON OF STUDY TURNAROUND TIMES FOLLOWING IMPLEMENTATION OF AN IN-HOUSE WORKFLOW OPTIMIZER AND REAL-TIME DATA DASHBOARD

Neil Malhotra, MD (*Presenter*)
Duane L. Schonlau, MD (*Abstract Co-Author*)
Scott D. Steenburg, MD (*Abstract Co-Author*)

PURPOSE

To determine report turn around time (TAT) changes before and after the implementation of a real-time data dashboard and radiologist workflow optimizer.

METHODS AND MATERIALS

Retrospective analysis of two 6-month periods before (1/1/2022 to 7/1/2022) and after (10/1/2024 to 4/1/2025) the implementation of the dashboard and workflow optimizer was performed at a single large health system. Two patient classes were compared (E= ER patients and I = inpatients). Total imaging volumes were obtained during the two time periods. Median TAT, mean TAT and TAT standard deviation were calculated. A single-tail Student's t test was used to compare report mean TATs, an F-test to compare TAT standard deviation, and a Mann-Whitney U test to compare median TATs between the two groups.

RESULTS

Prior to workflow optimizer and dashboard implementation, median TAT, mean TAT and TAT standard deviation were 0.33 hrs, 0.97 hrs and 1.31 hrs for class E patients (Table 1), and 0.97 hrs, 4.47 hrs and 8.35 hrs for class I patients (Table 2), respectively. Following implementation of the workflow optimizer and dashboard, median TAT, mean TAT and TAT standard deviation was 0.33 hrs, 0.62 hrs and 0.75 hrs for class E patients and 0.82 hrs, 3.89 hrs and 6.47 hrs for class I patients, respectively. There was a statistically significant reduction in mean TAT ($p< 0.01$) and report TAT standard deviation ($p< 0.001$) for both class E and I patients. One confounding factor is a 10% increase in the number of radiologists in the post-implementation period.

CONCLUSION

Our institutional dashboard and workflow optimizer empowered departmental and division leaders to make changes to better optimize radiologist workflows. This resulted in statistically significant reduction in average turnaround times for both emergency department and inpatients. The greatest improvement was in the reduction in mean report TAT and TAT standard deviation, indicating a more efficient allocation of exams and radiologist resources in the after-implementation period. While the distribution of the median values of TAT in the E and I classes pre- and post-implementation were found to be statistically significant, this is not likely to be practically significant as the median values are equal in the E class and near-equal in the I class.

CLINICAL RELEVANCE/APPLICATION

1. The use of a real time data dashboard and workflow optimizer resulted in significant improvement in report turnaround times for both emergency department and inpatients, with the greatest improvement in the reduction in mean report TAT and TAT standard deviation. 2. These findings indicate that the use of these in-house developed tools resulted in a more efficient allocation of exams and radiologists.

W2-SPIN-11 PREDICTION AND WARNING OF CT TUBE FAILURE: A DATA-DRIVEN METHODUSING LONG-TERM TIME-SERIES FORECASTING

Hanyu Li (*Presenter*)

PURPOSE

Computed tomography (CT), a cornerstone in modern diagnostic imaging, relies on the X-ray tube that are prone to filament burnout after extended use, leading to unexpected equipment failures and disruptions in patient care. To address this critical issue, this study proposes a data-driven predictive maintenance framework for CT equipment, focusing on early detection of filament burnout to enable timely intervention.

METHODS AND MATERIALS

Using operational data from Philips Maximus Rotalix Ceramic (MRC) tubes, which are collected remotely via the Phillips Remote System (PRS) Internet of Things (IoT) platform across 40 different locations, this study employs a long-term time-series forecasting model to predict future filament current trends. Based on these predictions, a three-stage warning system is proposed: (1) initial warning when filament current drops below 3600mA, (2) detection of a sudden drop in filament current, and (3) final warning when filament current approaches burnout.

RESULTS

The results show the mean absolute error among three latest time-series forecasting models are not exceed to 0.1035 and max absolute error not exceed to 0.6398, which means the difference in model prediction accuracy will only cause a prediction error of the filament burnout time of at most 15.3552 hours. The reliability of the three-stage warning system with the maximum prediction of 15.5 days on the first stage and 7 days on the third stage with 86.7% accuracy.

CONCLUSION

This study presents a comprehensive prognostic framework for CT X-ray tube filament failure prediction, aiming to reduce medical risks and costs caused by maintenance. By developing a novel tube-current-based down-sampling method, filament current fluctuations have been effectively eliminated in data collecting period. The new data segment method helps to reduce data-processing time to make real-time predictions. By identifying and validating latest time-series forecasting models and establishing three-stage warning system, a maximum of 22.5-day accurate warning system has been developed, which helps avoid 1,323,000 yuan or 15% to 20% unit price of the tube per CT scanner in financial loss caused by the failure.

CLINICAL RELEVANCE/APPLICATION

This study aims to establish a warning system, which aims to detect filament burnout in advance to offer sufficient time for hospitals to make maintenance plans to prevent medical risks and avoid financial loss caused by unplanned downtime. For hospitals, early warning can help departments adjust appointment strategy to avoid temporary cancellation of appointment and improve patient satisfaction.

W2-SPIN-12 REPRESENTATION-FOCUSED BATCH SAMPLING ENHANCES PERFORMANCE OF EFFICIENTLY ADAPTED FOUNDATION MODEL FOR DETECTING NEONATAL PNEUMOPERITONEUM ON CROSS-TABLE LATERAL RADIOGRAPHS

Junseong Lee,
BS (*Presenter*)
Yeonsu Kim (*Abstract Co-Author*)
Changhyun Park, MSc (*Abstract Co-Author*)
Hee Mang Yoon, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the effectiveness of adapting a vision foundation model (VFM) with a representation-focused custom batch sampling strategy for pneumoperitoneum (PP) classification on neonatal intensive care unit (NICU) lateral plain radiographs.

METHODS AND MATERIALS

An internal dataset of cross-table lateral abdominal x-rays (N=688; 45% PP+) from NICU of a tertiary hospital was split (train/validation/test: N=462/114/112) without patient overlap; gold standard (absence of PP, indeterminate, and presence of PP) was determined via review of clinical, surgical, and follow-up image records by 3 pediatric radiologists (5,12,26 years of experience). An external dataset (N=125; 33% PP+) from 11 other tertiary hospitals was labeled by consensus of 2 pediatric radiologists (12,15 years of experience) and 1 fourth-year radiology resident. Indeterminate cases were treated as PP+ to maximize sensitivity. The RAD-DINO (RD) LVM was fine-tuned using Low Rank Adaptation (LoRA). To address data heterogeneity and improve representation, a custom batch sampling strategy (C+) prioritizing PP cases with uncommon distribution (mid-to-lower abdominal free air) was developed and compared against standard sampling (C-). LoRA was applied to self-attention Query/Value matrices (M-) and additionally to MLP layers (M+ ablation). Performance comparisons included RD+LoRA configurations, RD Zero-Shot, RD Full Fine-Tuning (fFT), and CNNs using AUC, accuracy (Acc), and sensitivity (Sens), with statistical comparisons via DeLong/McNemar tests. Explainability used ReciproCAM/Grad-CAM.

RESULTS

The custom sampling (C+) demonstrated benefits over standard sampling (C-) in external validation. Comparing RD+LoRA (M-), C+ improved AUC (0.885 vs. 0.936; $p<0.001$), and Acc (0.74 vs. 0.90; $p<0.001$). Additionally applying LoRA to MLP layers (M+) further improved Acc (0.90 vs. 0.94; $p<0.001$), when using C+. Our resulting best config, RD+LoRA (C+,M+), surpassed the best CNN (ResNext50: Acc 0.93 vs. 0.94; Sens 0.83 vs. 0.85; $p>0.05$) despite lower AUC (0.959 vs. 0.935; $p<0.001$). RD+LoRA (C+,M+) significantly outperformed RD fFT externally (AUC 0.935 vs. 0.896, $p<0.001$; Acc 0.94 vs. 0.87, $p=0.012$; Sens 0.85 vs. 0.71, $p=0.031$), indicating improved robustness.

CONCLUSION

Adapting a VFM with LoRA fine-tuning, enhanced by representation-focused batch sampling, enables robust PP detection on NICU radiographs, achieving clinically relevant metrics while substantially lowering training cost.

CLINICAL RELEVANCE/APPLICATION

This approach confirms that VFMs can be effectively and efficiently adapted for specialized medical imaging tasks, aided by custom sampling for robustness and interpretability. The resulting model offers potential for clinical decision support.

W2-SPIR-1 INTEGRATED VS. INDEPENDENT IR: A COMPETITIVENESS COMPARISON WITH SURGICAL SPECIALTIES

Philip Schertz, DO, MBA (*Presenter*)
Min Jung (*Abstract Co-Author*)
Ghazwan M. Kroma, MD (*Abstract Co-Author*)

PURPOSE

The introduction of IR residency programs has changed the training pathways for students pursuing careers in IR. This study aims to evaluate trends in the number of Integrated IR residency applicants and Diagnostic Radiology (DR) residents pursuing Independent IR fellowships over the past five match cycles. Furthermore, this study works as an aid in assessing the competitiveness of Integrated IR pathways within the National Resident Matching Program (NRMP) by comparing the competitiveness with two specialties that also offer integrated programs (Vascular and Thoracic).

METHODS AND MATERIALS

NRMP data for Integrated IR from 2020-2024 were collected. Proxy variables of total number of IR applicants, number of IR PGY1 and PGY2 positions, number U.S. senior applicants to IR, and number of U.S. seniors matching into Integrated IR were collected. Comparative data for two other integrated specialties were collected as well. Number of U.S. MD grad fellowship applicants, number of Independent IR programs and positions, and number of U.S. MD grad matches were collected from NRMP. Additionally, similar data for two other integrated specialties were collected.

RESULTS

From 2020 to 2024, Integrated IR programs saw notable growth. PGY1 IR programs rose from 22 to 28, with positions increasing 34% (38 to 51). U.S. MD senior applicants grew 23% (152 to 187), yet the 2024 match rate remained low at 21% (40/187). PGY2 IR programs increased slightly (66 to 69), with positions up 13% (121 to 137) with match rate of 52%. Integrated Vascular expanded from 59 to 79 programs (75 to 100 positions, +33%) during the same interval, with a 2024 match rate of 77.4% —much higher than IR. Integrated Thoracic showed slower growth in comparison: 29 to 34 programs and 38 to 48 positions (+26%). In 2024, it showed a 56% match rate. Independent IR fellowships declined in U.S. MD applicants (132 to 87, -34%), while positions stayed stable (172 to 167). Vascular and Thoracic fellowships saw applicant increases of 16% and 33%, respectively. Vascular positions grew (118 to 131), while Thoracic remained stable (96 in both years).

CONCLUSION

Overall, Integrated IR programs remain competitive among other integrated specialties. This highlights the need for improved application strategies for interested medical students. Furthermore, the Independent IR fellowship showed a downward trend in the applicant number.

CLINICAL RELEVANCE/APPLICATION

An increase in the population, proportion of elderly, and advancing technology suggest that the need for IR will continue to grow, leading to a surge of clinical demand and applicant interest. However, the number of available residency positions has not increased in comparison. This can potentially limit workforce growth and limit access to IR services in the future.

W2-SPIR-2 GENERATIVE ADVERSARIAL NETWORK-BASED CONTRAST ENHANCEMENT: SYNTHETIC LOW-KEV IMAGING FOR LOWER EXTREMITY VENOGRAPHY IN DUAL-ENERGY CT

Shigeng Wang (*Presenter*)
Yijun Liu (*Abstract Co-Author*)

PURPOSE

Dual-energy computed tomography (DECT) is an important imaging modality for lower extremity venous vascular imaging, typically utilizing low-keV imaging with iodine-based contrast agents to enhance venous visualization. Nevertheless, low-keV imaging faces significant challenges: the limited availability of DECT in clinical practice, particularly in community healthcare settings with under-resourced infrastructure, and inadequate iodine contrast uptake in patients due to renal insufficiency or hemodynamic limitations. This study introduces a novel method using generative adversarial networks (GANs) for synthetic low-keV imaging in lower extremity CT venography.

METHODS AND MATERIALS

A total of 212,480 lower extremity venous dual-energy CT images were acquired from 265 subjects (42 males, 23 females; mean age 48 years, range 25-72 years). All cases included conventional keV (70 keV) baseline images and corresponding low-keV (50 keV) contrast-enhanced images. To generate “synthetic” low-keV images, a CycleGAN framework was implemented to establish the mapping relationship between conventional keV images and target low-keV images. The dataset was partitioned into training (70%), validation (20%), and test (10%) sets. A multi-scale structural similarity loss function was employed to enhance vascular edge detail generation. The radiologists were presented with a 70 keV input image and asked to choose between a real low-keV image and synthetic low-keV images generated by CycleGAN corresponding to this 70 keV image (Turing test).

RESULTS

The performance of the CycleGAN model was evaluated using a combination of quantitative and qualitative analyses. For the entire dataset, in the test set, the mean square error (MSE) was 0.0046, while the structural similarity index (SSIM) was 0.45. The qualitative evaluation was validated through a visual Turing test conducted by five radiologists with varying levels of clinical experience. In clinical validation, the “synthetic” 50 keV images demonstrated a sensitivity of 91.7% and a specificity of 96.3% for detecting deep vein thrombosis.

CONCLUSION

This study verifies that the CycleGAN model effectively generates clinically diagnostic synthetic low-keV images of lower extremity CT venography.

CLINICAL RELEVANCE/APPLICATION

This approach offers a novel pathway for safer vascular imaging protocols, particularly benefiting institutions without dual-energy CT and patients with inadequate iodine contrast uptake.

W2-SPIR-3 RENAL BIOPSY PERFORMED DURING MICROWAVE ABLATION OF T1 RENAL CANCER USING A COAXIAL GUIDE WITH A SPRING-LOADED BLUNT TIP STYLET: FOCUS ON DIAGNOSTIC YIELD AND ONCOLOGIC OUTCOME

Melanthi Tsikna, MD, MSc (*Presenter*)

PURPOSE

To retrospectively evaluate feasibility of a coaxial guide with a spring-loaded blunt tip stylet during single session biopsy and microwave ablation (MWA) of T1 renal cell carcinoma. For this purpose, diagnostic yield, oncologic outcome and safety were assessed.

METHODS AND MATERIALS

Institutional database research identified all patients who underwent concomitant percutaneous, computed tomography-guided biopsy and microwave ablation. A 15 Gauge coaxial guide with a spring-loaded blunt tip stylet was percutaneously placed in the target tumor. Coaxially first a 18Gauge biopsy needle was inserted for sampling followed by a 16Gauge microwave probe. The modified CIRSE classifications system was used for complications' reporting. All patients were followed-up for at least 2 years with either CT or MRI scan according to individual characteristics.

RESULTS

A total of 15 patients (mean age: 67.8±3.4 years) with 17 renal tumors (mean diameter of the malignancies treated was 2.77±0.43cm) were included for evaluation. Technical success was achieved in all cases. Diagnostic yield was 100% (clear cell RCC n=13 papillary RCC n=3, oncocytoma: n=1). Overall, metastasis-free and recurrence-free survival were 100%, 100% and 94.12% at 1 and 2 years respectively [one tumor (5.88%) demonstrated local recurrence during the 1-year follow-up; patient underwent surgery (radical nephrectomy)]. Grade 1a complications were recorded in 2 (13.3%) patients (limited perinephric haematomas requiring nothing but observation).

CONCLUSION

Concomitant performance of percutaneous biopsy and microwave ablation using a coaxial biopsy guide with spring-loaded blunt tip stylet is feasible, safe and efficacious for the management of T1 renal cell cancer.

CLINICAL RELEVANCE/APPLICATION

The combined use of a spring-loaded blunt tip stylet within a coaxial guide enables efficient, single-session percutaneous biopsy and microwave ablation of T1 renal tumors, offering precise histological diagnosis and effective local tumor control. This technique streamlines patient care, reduces procedural burden, reduces the number of procedures and associated recovery times, and may serve as a valuable option in the minimally invasive management of early-stage renal cell carcinoma, especially in patients where surgical intervention poses higher risk.

W2-SPIR-4 EFFICACY OF TRANSARTERIAL EMBOLIZATION FOR RESISTANT SHOULDER PAIN: A META ANALYSIS

Kameel Khabaz, BA (*Presenter*)
Sammy Allaw (*Abstract Co-Author*)
Qian Yu, MD (*Abstract Co-Author*)
Osmanuddin S. Ahmed, MD (*Abstract Co-Author*)

PURPOSE

To perform a systematic review and meta-analysis evaluating the impact of peri-articular transcatheter arterial embolization (TAE) on patient-reported pain scores and objective shoulder range-of-motion in refractory adhesive capsulitis, rotator-cuff tendinopathy, and calcific tendonitis.

METHODS AND MATERIALS

Pubmed and SCOPUS searches were performed for all papers on TAE for shoulder pain or common shoulder conditions; this resulted in 317 articles on Pubmed and 692 on SCOPUS, totalling 730 articles after removal of duplicates. Articles were then screened for relevant English-language human studies, excluding case reports, reviews, and editorials; this produced 17 studies for analysis. We performed three subgroup analyses—one each for numerical pain scores, abduction range of motion (ROM), and external rotation ROM—using standardized mean change differences (SMCR) to capture within-subject improvements from baseline to final follow-up. Effect sizes were pooled under a random-effects framework. Statistical heterogeneity was quantified with Cochran's Q, I^2, and t^2; 95 % confidence intervals were computed.

RESULTS

Eleven studies were included with a total of 329 patients. Average age was 53.7 years, with 219 women and 110 men. Follow-up ranged from 60 to 180 days post-TAE. The pooled SMCRs indicate pain reduction at the final follow-up time point, with the pooled estimate (SMCR = -2.54, 95% CI: -3.41 to -1.66) indicating a large overall improvement despite pronounced between-study heterogeneity (I2 = 90.1%). Studies demonstrated improved range of motion for shoulder abduction (SMCR = 1.54, 95% CI 1.07 to 1.97) and shoulder external rotation (SMCR = 0.60, 95% CI 0.43 to 0.77) with lower heterogeneity (I2 = 62.8% and 0.0%, respectively).

CONCLUSION

Our pooled analysis showed statistically significant improvements in pain scores, abduction, and external rotation range of motion following TAE compared to baseline in patients with selected shoulder pathologies. Further studies with direct comparison against other treatment options are needed to better understand the efficacy of TAE against conventional conservative treatment options.

CLINICAL RELEVANCE/APPLICATION

Transarterial embolization (TAE) is a promising treatment modality for shoulder pathologies. While several studies examine TAE, current evidence suffers from small patient cohorts, varied methodologies, and the lack of a control group. This study aims to characterize the existing body of evidence and provide a more reliable estimate for the efficacy of TAE in improving functional outcomes in patients with shoulder pathologies.

W2-SPIR-5 TRANSARTERIAL EMBOLIZATION IN ADHESIVE CAPSULITIS: INTERMEDIATE TERM RESULTS FROM THE FIRST STUDY IN INDIA

Aprateem Mukherjee, MD, FRCR (*Presenter*)
Niraj N. Pandey, MD (*Abstract Co-Author*)

PURPOSE

Adhesive capsulitis is a poorly understood chronic condition characterised by pain and restricted mobility of the shoulder joint. The pathophysiology of this process is still unclear with a combination of chronic inflammatory fibroblastic process, angiogenesis and synovitis with fibrotic contracture of rotator intervals, capsules and ligaments. Few studies have shown embolization of arteries supplying abnormal vascular areas in such condition can relieve pain and symptoms. The goal of our study was to demonstrate the safety and efficacy of transarterial embolization in adhesive capsulitis and whether it can improve pain and shoulder mobility in these patients.

METHODS AND MATERIALS

12 consecutive patients with adhesive capsulitis on clinical examination and non-relieved with conservative management for 3 months were taken for transarterial embolization (TAE). Adverse events, Visual analogue scale (VAS), night time VAS and range of motion of the affected shoulder was assessed at baseline, 1 week, 1 month, 3 months and 6 months.

RESULTS

Abnormal vascularity around the rotator interval was identified in all patients on angiography. Embolization of these abnormal neo-vessels was performed using Imipenem cilastin particles via a microcatheter in all patients. Right transfemoral arterial access was used for embolization in 10 patients while transbrachial arterial access was used in 2 patients. No major or minor complications were observed in the patients. Mean VAS score improved from 8.5 ± 0.47 at baseline to 3.7 ± 0.78 at 1 week, 2.6 ± 0.78 at 1 month, 1.8 ± 0.93 at 3 months' and 1.5± 0.91 post procedure. Rapid relief of pain was seen in all patients at 1-week post procedure. Mean night-time VAS scores also improved from 8.7 ± 0.56 at baseline to 4.1 ± 0.86 at 1 week, 3.4 ± 0.78 at 1 month 2.3 ± 0.5 at 3 months' and 2.2 ± 0.4 at 6 months' post procedure.

CONCLUSION

Adhesive capsulitis showed abnormal neo-vessels in the region of rotator interval and transarterial embolization of these abnormal vessels in adhesive capsulitis appears to a be feasible and safe procedure with no major adverse effects in this pilot study followed up to 6 months. TAE appears to provide quick pain relief and early mobility in the affected shoulder in these patients.

CLINICAL RELEVANCE/APPLICATION

Transarterial embolization appears to be a novel, safe and effective treatment for quick relief of pain in chronic painful adhesive capsulitis.

W2-SPIR-6 MUSCLE AND FAT MATTER: AUTOMATED CT BODY COMPOSITION IMPROVES PROGNOSTIC STRATIFICATION IN HEPATOCELLULAR CARCINOMA UNDERGOING RADIOEMBOLISATION

Johannes M. Ludwig, MD, ARRT (*Presenter*)
Hannah Luisa Steinberg-Vorhoff, MD (*Abstract Co-Author*)
Johannes Haubold, MD (*Abstract Co-Author*)
Benedikt M. Schaarschmidt, MD (*Abstract Co-Author*)
Sven Koitka, MSc (*Abstract Co-Author*)
Jens M. Theysohn, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the prognostic value of CT-based body composition markers for survival in patients with hepatocellular carcinoma (HCC) treated with selective transarterial radioembolization (SIRT).

METHODS AND MATERIALS

A total of 198 patients (77.3% men, median age: 71 years) who underwent SIRT between 2010 and 2021 were included in the study. A deep learning algorithm was used for automated body composition analysis (BCA) from abdominal CT scans to perform 3D volumetry of body tissues incl. visceral adipose tissue (VAT), intra- and intermuscular adipose tissue (IMAT), skeletal muscle (SM), and bone (B). BC parameters and ratios were dichotomized at the median gender specifically due to significant gender differences ($p<0.05$). The Cox proportional hazard model for univariate (UVA) and multivariate (MVA) analyses (hazard ratio; 95%CI, p-value) and Kaplan-Meier analyses (survival in months; 95%CI) were performed.

RESULTS

The median survival time of the study cohort was 18.5 (15.1-23.4) months. Median survival according to BCLC stages A (14.6%), B (60.6%) & C (24.8%) were: 25.1 (15.1-56.8), 20.9 (15.6-30.4), and 12.6 (9.2-19.2) months, respectively (UVA; p=0.009). Regrading BC-parameters, patients with values greater than the median had a favourable hazard ratio for SM mass (0.67; 0.48 - 0.92; p=0.014), SM/B (0.7; 0.51 - 0.97; p=0.03), (SM + VAT)/B (0.64; 0.47 - 0.89; p=0.007), SM/(B + IMAT) (0.7; 0.51 - 0.97; p=0.029), and (SM + VAT)/(B+I MAT) (0.65; 0.47 - 0.9; p=0.009) with high correlations between BC-parameters; thus (SM + VAT)/B was selected for MVA. Additionally, patients with normal serum albumin and non-elevated levels of C-reactive protein, aminotransferase (AST), alkaline phosphatase (AP), and gamma-glutamyl transamidase (GGT) were associated with a significant survival benefit. In MVA BCLC-Stage (A: 0.49; 0.28 - 0.83), B: 0.72; 0.49 - 1.05, C: 1; p=0.025), non-elevated AST levels (0.6; 0.41 - 0.86; p=0.006) and (SM + VAT)/B (0.7; 0.55 - 0.97; p=0.033) remained significant. Subanalysis revealed that the (SM + VAT)/B ratio can further stratify BCLC B patients, with a prolonged survival for patients with values above the median of 25.7 months (17.8 - 36.6) compared to 15.6 months (9.4 - 23.0) for those with lower values (log-rank, p=0.02). Substratification in BCLC C patients was not significant.

CONCLUSION

The fully automated, CT-based body composition analysis with the independent prognostic (SM + VAT)/B volume ratio for survival may facilitate the identification of patients who may benefit more from SIRT, also within BCLC B patients.

CLINICAL RELEVANCE/APPLICATION

The use of fully automated CT-based body composition analysis may be an easily accessible tool to further improve the risk stratification of patients with HCC treated with SIRT.

W2-SPMK-2 OUTCOME OF IMAGE GUIDED PECTORALIS MINOR INFILTRATION AND SCAPULOTHORACIC BURSA INJECTION FOR THE MANAGEMENT OF SCAPULOTHORACIC ABNORMAL MOTION

Abdulmonem S. Alkhateeb (*Presenter*)
Mohammed Alfaqih, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the outcomes of image guided pectoralis minor microtenotomy/Infiltration and Scapulothoracic bursa Injection for the management of scapulothoracic abnormal motion (STAM).

METHODS AND MATERIALS

In this IRB approved retrospective study, 64 patients with clinical diagnosis of STAM Type 1, and underwent image-guided scapulothoracic Triamcinolone injection and/or pectoralis minor microtenotomy and Infiltration (Triamcinolone or Botulinum toxin) were reviewed between June 2023 and March 2025. Patients were divided into 2 groups for subgroup analysis : Group A: Patients presenting with STAM and focal tenderness over the coracoid process, and Group B: Patients presenting with STAM but no focal tenderness over the coracoid process. Patient outcomes after the intervention were assessed with the Numerical Pain Scale, Constant score, and Shoulder Subjective Value. Data were analyzed by Student's t-test.

RESULTS

37 patients who met inclusion and exclusion criteria were included in this study. Average age at the time of intervention was 43 years (±13), 46% of patients were female, and average follow-up after intervention was 10 months (±5, range from 2 to 22 months). Significant improvements in numerical pain scale , Constant scores, and shoulder subjective value. Numerical Pain scale improved from 8 to 2, Constant score improved from 76 to 92, shoulder subjective value improved from from 30% to 80% ($P < 0.01$). Subgroup analysis included Group A and Group B. Group A included 17 patients, and Group B included 20 patients. No statistically significant difference between these two groups in terms of numerical pain scale, shoulder subjective value, and Constant score was found ($P > 0.01$). One patient in Group A with history of breast implants reported temporary arm heaviness after pectoralis minor microtenotomy/Infiltration lasted for 3 months.

CONCLUSION

Significant outcome improvement regarding pain, function, and quality of life in patients with clinical diagnosis of STAM type 1 after image guided pectoralis minor microtenotomy/Infiltration and/or Scapulothoracic bursa injection.

CLINICAL RELEVANCE/APPLICATION

In patients with symptomatic STAM type 1, image guided pectoralis minor microtenotomy/Infiltration with either Botulinum toxin or Triamcinolone; And scapulothoracic bursa Triamcinolone Injection is an effective nonoperative option. Pre intervention patient counseling regarding possible temporary arm weakness after pectoralis minor microtenotomy/Infiltration is advised.

W2-SPMK-3 A PREDICTIVE MRI RADIOMICS MODEL FOR IMPROVED SOFT TISSUE SARCOMA SUBTYPE DIFFERENTIATION

Laetitia Perronne, MD, MSc (*Presenter*)
Nicolo Gennaro, MD (*Abstract Co-Author*)
Mirinae Seo, MD (*Abstract Co-Author*)
Zuzanna Kobus, MD (*Abstract Co-Author*)
Linkai Peng, BEng (*Abstract Co-Author*)

Ulas Bagci, MSc, PhD (*Abstract Co-Author*)
Amir Borhani, MD (*Abstract Co-Author*)
Hatice Savas, MD (*Abstract Co-Author*)
Linda C. Kelahan, MD (*Abstract Co-Author*)
Kamal Subedi, MD (*Abstract Co-Author*)
Ryan J. Avery, MD (*Abstract Co-Author*)
Tugce Agirlar Trabzonlu, MD (*Abstract Co-Author*)
Chase S. Krumpelman, MD, PhD (*Abstract Co-Author*)
Seth Pollack, MD (*Abstract Co-Author*)
Pedro Hermida De Viveiros (*Abstract Co-Author*)
Yuri Velichko, PhD (*Abstract Co-Author*)

PURPOSE

Soft tissue sarcomas (STS) are rare and heterogeneous tumors with overlapping imaging characteristics, making imaging-bases histologic subtype differentiation challenging. We aimed to develop an MRI-based radiomics model to differentiate key soft tissue sarcoma subtypes and a common benign mimic, the intramuscular myxoma.

METHODS AND MATERIALS

This IRB-approved retrospective study included 302 patients with histologically confirmed soft tissue tumors: undifferentiated pleomorphic sarcoma (UPS, n=70), myxofibrosarcoma (MFS, n=57), myxoid liposarcoma (mLPS, n=60), leiomyosarcoma (LMS, n=67), and myxoma (MYX, n=48). All patients underwent MRI, including fat-suppressed T2-weighted and post-contrast T1-weighted images. Tumors were manually segmented, and radiomic features were extracted from all available sequences in all planes. GLCM features were collected at intervoxel distances ranging from 1 to 5 mm. The dataset was split into training (70%) and held-out testing (30%) sets. To classify STS subtypes using pre-treatment imaging, a multiclass XGBoost machine learning model was developed, employing a two-stage feature selection strategy involving importance and redundancy filtering. The optimal number of features and model hyperparameters were determined through 5-fold cross-

validation on the training set. The final model demonstrated robust classification performance on the held-out test set. Performance metrics included accuracy, sensitivity, specificity, and predictive values.

RESULTS

The model demonstrated a strong overall accuracy of 79% (95% CI: 0.69-0.87, $p < 0.001$). High sensitivity was observed for MYX (0.93), LMS (0.83), mLPS (0.83), and UPS (0.71), coupled with specificity greater than 0.92 across these subtypes. However, MFS exhibited lower sensitivity (0.69) and was frequently misclassified as mLPS or UPS. Positive predictive values ranged from 0.69 for MFS to 0.88 for LMS. Negative predictive values exceeded 0.91 for all subtypes.

CONCLUSION

Radiomics-based classification showed promising performance for distinguishing most STS subtypes and benign tumors on MRI. However, differentiating MFS remains challenging due to imaging overlap with other aggressive subtypes. This model could potentially aid radiologists in non-invasive STS subtyping, guiding biopsy and treatment planning.

CLINICAL RELEVANCE/APPLICATION

A radiomics predictive model could serve as a valuable non-invasive tool to support radiologists in differentiating STS subtypes, potentially guiding biopsy strategies and optimizing personalized treatment planning.

W2-SPMK-4 MULTI-IMAGE MUSCULOSKELETAL ULTRASOUND INTERPRETATION USING A LARGE LANGUAGE MODEL

Jyun-Ping Kao (*Presenter*)
Chung-Ping Chen (*Abstract Co-Author*)
Wen-Shiang Chen (*Abstract Co-Author*)

PURPOSE

Traditional AI models in medical imaging analyze static images, whereas radiologists synthesize information across multiple frames, particularly in musculoskeletal ultrasound (MSK US). We present the first application of a Large Language Model (LLM) to interpret multiple MSK US frames simultaneously. Our model generates a comprehensive diagnostic impression integrating findings across all inputs, mimicking the radiologist's multi-frame review process.

METHODS AND MATERIALS

We fine-tuned a multimodal LLM (Llama 3.2 11B), on 100 shoulder US exams (80 training, 20 validation/testing) from 100 patients. Each exam included 12 frames and a corresponding radiologist-written impression. The model received all frames and was trained to generated a unified impression covering exam laterality and key anatomical structures (e.g. Biceps, Subscapularis, AC joint, Supraspinatus, Infraspinatus, and Bursa) and relevant pathologies. Performance was evaluated by comparing the LLM's output to reference reports using BERTScore, BLEU, and RadGraph F1 metrics.

RESULTS

The model achieved an average BERTScore F1 of 0.80, a BLEU of 0.72, and a RadGraph F1 of 0.45, and correctly indicated laterality in all cases, suggesting it can provide a human-like impression. Minor differences in wording or findings in the generated impression significantly affected the metrics, suggesting that a consistent training impressions and output structure may improve performance. The model was less reliable for subtle findings (e.g. tear conditions, calcifications) that were underrepresented in training, indicating that targeted fine-tuning could improve sensitivity.

CONCLUSION

This pioneering study demonstrates three key innovations: (1) application of LLM for multi-image MSK US interpretation and producing a coherent radiologist-style report; (2) validation that LLMs can potentially recognize anatomical structures without traditional object-detection networks; (3) identification of LLM limitations specific to MSK US interpretation, providing a clear roadmap for future development. These advances establish a foundation for next-generation AI assistance of MSK US in clinical settings.

CLINICAL RELEVANCE/APPLICATION

Given the operator-dependent nature of MSK US, our LLM-based approach provides a standardized method for interpreting multi-frame examinations, potentially reducing variability and enhancing diagnostic consistency. By synthesizing complex findings across frames, it can augment clinical workflows, improve report efficiency, and minimize the risk of overlooked findings, thereby increasing diagnostic confidence.

W2-SPMK-5 SARCOPENIA AND INCREASED SUBCUTANEOUS FAT DENSITY AS PROGNOSTIC IMAGING BIOMARKERS IN SOFT TISSUE SARCOMA

Chung-Jung Lin, MD (*Presenter*)
Hung Ta H. Wu, MD, MBA (*Abstract Co-Author*)
Ching-lan Wu, MD (*Abstract Co-Author*)
Han-Ying Lin, MD (*Abstract Co-Author*)
Hong-Jen Chiou, MD (*Abstract Co-Author*)

PURPOSE

While sarcopenia has been recognized as a key prognostic marker in many cancers, its impact in soft tissue sarcoma (STS) remains less defined. This study investigates the relationship between CT-derived body composition and clinical outcomes in STS patients receiving chemotherapy, and validates the use of L2 vertebral level measurements as a practical alternative to L3.

METHODS AND MATERIALS

We retrospectively analyzed 84 STS patients treated with gemcitabine-based chemotherapy from January 2010 to August 2024. Skeletal muscle and fat indices were assessed from chest CT scans at both L2 and L3 levels. Sarcopenia was diagnosed based on established skeletal muscle index (SMI) thresholds. Associations with progression-free survival (PFS), overall survival (OS), and chemotherapy toxicities were evaluated.

RESULTS

Sarcopenia was identified in 30.9% of patients. Sarcopenic individuals exhibited lower albumin (3.29±0.68 vs. 3.73±0.48 g/dL, P=0.005), elevated white blood cell counts (P=0.048), and reduced dyslipidemia prevalence (P=0.018). Sarcopenia was an independent predictor of worse OS (HR=2.032, P=0.023), with median OS significantly shorter (92±88 vs. 340±59 days, P=0.020). Higher subcutaneous adipose tissue density (SAD) at L2 also predicted poorer survival (HR=1.015, P=0.050). L2 and L3 body composition metrics showed excellent correlation (r=0.90, P<0.001), supporting the use of L2 imaging in clinical practice. Sarcopenic patients faced markedly higher rates of severe chemotherapy-related anemia (69.2% vs. 43.1%, P=0.023) and diarrhea (38.5% vs. 17.2%, P=0.036).

CONCLUSION

Our findings establish sarcopenia and increased SAD as independent imaging biomarkers of poor prognosis in STS, while endorsing L2-level assessments as a flexible alternative for body composition analysis in routine chest CT imaging

CLINICAL RELEVANCE/APPLICATION

Body composition imaging at L2 transforms routine CT scans into powerful predictors of sarcoma outcomes

W2-SPMS-1 ASSOCIATION BETWEEN MRI-BASED QUANTIFICATION OF LIVER IRON AND CARDIOVASCULAR DISEASE: A UK BIOBANK PROSPECTIVE COHORT STUDY

Feier Ding, PhD (*Presenter*)
Xinya Zhao (*Abstract Co-Author*)
Takashi Ota, MD, PhD (*Abstract Co-Author*)
Toru Honda, MD (*Abstract Co-Author*)
Hideyuki Fukui, MD, PhD (*Abstract Co-Author*)
Atsushi Nakamoto, MD, PhD (*Abstract Co-Author*)
Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*)

PURPOSE

Liver iron concentration is acknowledged as the optimal surrogate for evaluating iron status, which is closely related to cardiovascular diseases (CVD). We aimed to explore the associations between magnetic resonance imaging (MRI)-based quantification of liver iron and CVD.

METHODS AND MATERIALS

This population-based study used data mainly from the UK Biobank. Liver iron content was measured using MRI. Cox regression analysis and Mendelian randomization analysis was performed to explore the association between liver iron content and cardiovascular events. Polygenic risk scores were calculated to investigate the effect of genetic susceptibility. Mediation analyses were performed using two-step Mendelian randomization analysis.

RESULTS

A total of 21266 participants (mean standard deviation [SD] age: 63.8 [7.6] years; 12610 females [59.3%]) were enrolled in the prospective observational study. Compared to lower liver iron content individuals, the hazard ratio (HR) of higher liver iron content were 0.75 (95% CI, 0.60-0.93, P=0.002) for CVD, with similar results as a continuous variable (HR=0.51, 95% CI, 0.35-0.76, P<0.001). Participants with high genetic risk and low liver iron content had a 118% increased risk of CVD (HR=2.18, 95% CI, 1.29-3.69) and a 170% increased risk of coronary heart disease (CHD) (HR=2.70, 95% CI, 1.40-5.23) compared to those with low genetic risk and high liver iron content. Mendelian Randomization analysis suggested a causal role of liver iron content in CHD (odds ratio [OR]=0.92, 95% CI, 0.87-0.97) and myocardial infarction (OR=0.93, 95% CI, 0.86-0.99), with low-density lipoprotein cholesterol and total cholesterol mediating 49.7% to 54.5% of the causal effects.

CONCLUSION

Our study highlights MRI-based liver iron quantification as a valuable non-invasive biomarker, lower liver iron content may be associated with a higher risk of CVD and cardiovascular events. Liver iron levels may causally influence CVD through blood lipid regulation and enhance prediction and intervention.

CLINICAL RELEVANCE/APPLICATION

MRI-based liver iron quantification offers a practical, non-invasive tool for cardiovascular risk assessment. Given its association with CVD and its partial mediation through lipid levels, it may help identify high-risk individuals—particularly those with genetic susceptibility—and guide early, targeted prevention or lipid-lowering interventions in clinical practice.

W2-SPNMMI-1 VARIATION IN THE IMAGE QUALITY ACROSS THE AXIAL FOV OF SIEMENS BIOGRAPH QUADRA PET/CT SCANNER

Mercy Akerele, PhD (*Presenter*)
Azadeh Eslambolchi, MD (*Abstract Co-Author*)
Justin Mikell, PHD (*Abstract Co-Author*)
Richard Laforest, PhD (*Abstract Co-Author*)

PURPOSE

Long axial field-of-view (LAFOV) scanners are fast gaining prominence due to their numerous applications for simultaneous multiple organs scanning. For LAFOV scanners longer than 1 m, the image quality (spatial resolution, contrast and noise metrics) can vary significantly across the FOV. This study aims to evaluate the variation in image quality across the FOV as a function of lesion size.

METHODS AND MATERIALS

This work was done on the Siemens Biograph Quadra PET/CT scanner (106 cm axial FOV), using a modified NEMA phantom with two sets of six spheres (first set 10, 13, 17, 22, 28, 37 mm and second set 4, 6, 8, 10.2, 12, 15 mm). The spheres and background were filled with approximately 1 mCi 18 F-FDG, resulting in a sphere-to-background ratio of 11.08. Images were acquired at four bed positions across the FOV with standard clinical reconstructions using the high sensitivity (HS) and the ultra-high sensitivity (UHS) settings. The activity was extracted from the reconstructed images using the actual sphere sizes to estimate the RC and CoV. A large ROI was placed in the uniform background region to estimate the CRC and contrast. The RC and CRC were fitted using the EANM model. Finally, the % variation across the FOV for each sphere size was estimated as the difference between the maximum and minimum value divided by the mean.

RESULTS

As expected, the RC, CRC, CoV and contrast at each position in the FOV all improve with increasing sphere size. The UHS has slightly improved RC than HS, with 84% and 82% recovery, respectively, for the largest sphere size. The variation across the FOV is around 5% for both HS and UHS, and this improves with increasing sphere size to about 0.1%. Similarly, the UHS has slightly improved CRC than HS, with 83% and 80% recovery, respectively, for the largest sphere size. The variation across the FOV is slightly less for UHS (7.4%) than HS (9.2%), and this improves with increasing sphere size to about 0.1%. Though the UHS has slightly improved contrast than HS (UHS = 2.63 and 9.49; HS = 2.40 and 9.17 for the smallest and largest spheres), the noise (CoV) is increased (UHS = 12.8% and 20.9%; HS = 8.9% and 20.1% for the smallest and largest spheres). This increased noise in UHS could be attributed to the difference in reconstruction settings. However, the variation in contrast and CoV across the FOV is substantially lower for UHS (3% and 15%) than HS (6% and 28%), except for the smallest sphere where the variation is up to 6% and 84% respectively.

CONCLUSION

The variation in RC, CRC, CoV and contrast across the FOV depends largely on the lesion size, and secondarily on the reconstruction settings.

CLINICAL RELEVANCE/APPLICATION

Accurate knowledge of, and compensation for the FOV variation will enhance accurate and reliable lesion quantification in multi-organ and multi-region imaging

W2-SPNMMI-2 VOLUMETRIC FDG PET/MR FOR STAGING AND RESPONSE ASSESSMENT OF IGG4-RELATED DISEASE INVOLVING THE SALIVARY AND LACRIMAL GLANDS: IMAGING RESULTS OF A PHASE II STUDY OF ZANUBRUTINIB

Kip E. Guja, MD, PhD (*Presenter*)
Nancy Pham, MD (*Abstract Co-Author*)
Mehdi Khalighi (*Abstract Co-Author*)
Benjamin L. Franc, MD (*Abstract Co-Author*)
Mrudula Penta, MD (*Abstract Co-Author*)
Tobias Lanz (*Abstract Co-Author*)
Mariani Deluna (*Abstract Co-Author*)
Yuhan Liu (*Abstract Co-Author*)
Robert Fairchild (*Abstract Co-Author*)
Audra Horomanski (*Abstract Co-Author*)
Matthew Baker (*Abstract Co-Author*)

PURPOSE

To evaluate immunoglobulin G4-related disease (IgG4-RD) involving the salivary and lacrimal glands on [18F]FDG PET/MRI with metabolic and volume-based measurements, before and after treatment with Zanubrutinib, in a phase II proof-of-concept study (NCT04602598).

METHODS AND MATERIALS

This study was conducted at a single center in the US. Eligible patients with symptomatic IgG4-RD affecting the submandibular and/or lacrimal glands, refractory to glucocorticoids, and meeting 2019 ACR/EULAR Criteria for IgG4-RD, were treated with zanubrutinib for up to 24 weeks. Imaging endpoints included change in volume and metabolic activity of the submandibular and/or lacrimal glands on FDG-PET/MRI at post-treatment week 24, as determined by two radiologists blinded to scan order. Clinical endpoints included IgG4 serum concentration and patient reported outcomes.

RESULTS

Ten patients were enrolled; most were male (70.0%), Asian (60.0%), with a median age of 58 (range, 38-74) years. Prior treatments included prednisone (10 patients), rituximab (5 patients), and azathioprine (2 patients). No patients were on glucocorticoids or immunosuppressive treatment at time of enrollment or during the study. All patients had both lacrimal and submandibular gland disease. At week 24, mean changes from baseline were -45.4% (17.4) for lacrimal gland volume ($p < 0.001$) and

-30.0% (18.6) for submandibular gland volume ($p < 0.001$). Reductions were observed in SUVmax, total metabolic lesion volume (MLV), and total lesion glycolysis (TLG), including a mean (SD) change in lacrimal gland SUVmax of -2.3 (2.9; $p = 0.01$), submandibular gland SUVmax of -2.1 (3.4; $p = 0.05$), MLV of -20.7 cm 3 (22.4; $p = 0.05$), and TLG of -91.6 g/mL x cm 3 (98.5; $p = 0.05$). The mean (SD) change in the serum IgG4 concentration over 24 weeks was -417.0 mg/dL (410).

CONCLUSION

FDG PET/MR demonstrated statistically significant reduction in volume and metabolic activity of the salivary and lacrimal gland after treatment with Zanubrutinib. These imaging endpoints correlated clinically with reduced in serum IgG4 levels. Our results demonstrate efficacy of Zanubrutinib and the utility of FDG PET/MRI with metabolic and volume-based indices in IgG4-RD staging and treatment response assessment.

CLINICAL RELEVANCE/APPLICATION

IgG4-related disease is a systemic fibro-inflammatory condition characterized by diffuse or focal organ enlargement with pathogenic IgG4-positive B-cells. The Bruton tyrosine kinase inhibitor Zanubrutinib can decrease B cell activation and proliferation with lower risk of B-cell depletion. We report assessment of IgG4-RD involving the salivary and lacrimal glands on FDG PET/MRI with metabolic and volume-based indices, before and after treatment with Zanubrutinib, in a phase II study.

W2-SPNPM-1 INTELLIGENT SCHEDULING IN TELERADIOLOGY USING AI FORECASTING OF STUDY VOLUME AND RADIOLOGIST AVAILABILITY

Sivasailam Kalyan (*Presenter*)
Harini T (*Abstract Co-Author*)
Vasantha Kumar Venugopal, MD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a scheduling optimization system that uses AI to forecast radiology workload and match it with radiologist availability and efficiency patterns.

METHODS AND MATERIALS

General: A temporal forecasting model based on LSTM architecture was trained on 2 years of historical imaging volume data from 70 hospitals. A reinforcement learning scheduler adapted shift allocations based on radiologist efficiency and availability data. Context and Intervention: The model forecasted hourly imaging volume for each modality and mapped radiologist capacity accordingly. Alerts and recommendations were embedded into the shift planning dashboard. Study of the Intervention: Simulated deployment was conducted for a 6-week prospective window. Outcomes were benchmarked against traditional manual scheduling methods. Measures/Metrics: Forecast accuracy (mean absolute percentage error), turnaround time (TAT), radiologist idle/busy ratio, and shift overrun occurrences.

RESULTS

Forecasting accuracy (MAPE): 7.8%TAT improved by 15.2% across modalitiesRadiologist idle/busy ratio optimized by 18.6%Shift overruns reduced from 9.3% to 2.4%

CONCLUSION

AI-driven forecasting and scheduling systems significantly enhance resource allocation and reduce workflow inefficiencies in teleradiology. This promotes timely reporting, reduces fatigue, and optimizes patient care delivery across distributed networks.

CLINICAL RELEVANCE/APPLICATION

Teleradiology plays a critical role in delivering timely diagnostic services across healthcare networks, especially during off-hours and high-demand periods. This study demonstrates how AI-based forecasting and scheduling can significantly reduce turnaround times and radiologist fatigue by aligning workforce deployment with real-time workload patterns. Implementing such systems can enhance diagnostic efficiency, improve patient care continuity, and support more sustainable radiology operations in diverse and distributed clinical settings.

W2-SPNPM-2 WEEKLY VIRTUAL CASE CONFERENCE SERIES: OVER THREE YEARS OF GLOBAL RADIOLOGY EDUCATION AND OUTREACH

Raisa Amiruddin, MBBS (*Presenter*)
Bethelhem B. Belachew, MD (*Abstract Co-Author*)
Mohammad Jalloul, MD (*Abstract Co-Author*)
Hermon M. Derbew, MD (*Abstract Co-Author*)
Monica Miranda-Schaeubinger, MD,MSc (*Abstract Co-Author*)
Sydney Wieczkowski (*Abstract Co-Author*)
Yadel Mekete (*Abstract Co-Author*)
Janet Reid, MD, FRCPC (*Abstract Co-Author*)
Anne Marie Cahill, MBBCh (*Abstract Co-Author*)
Youck Jen Siu Navarro, MD (*Abstract Co-Author*)
Abass Noor, MD (*Abstract Co-Author*)
Kassa Darge, MD, PhD (*Abstract Co-Author*)
Hansel J. Otero, MD (*Abstract Co-Author*)

PURPOSE

Access to subspecialized pediatric radiology training remains limited in many low- and middle-income countries (LMICs). We report on the implementation and perceived impact of a weekly virtual educational program designed to address this gap and supplement training.

METHODS AND MATERIALS

Sessions featured weekly interactive virtual case discussions and game-based modules for radiology residents guided by USA-based radiology faculty. A descriptive evaluation was done to assess the perceived impact of the sessions from 2021-2024 on residents at 11 partner institutions across Africa, Asia, and Central America. Data included session attendance and post-session surveys to gather satisfaction ratings on a 5-point scale as very poor, poor, neutral, good, or very good on aspects like faculty communication, engagement, image quality, and clinical relevance of cases. Percentages were calculated for imaging modalities, cases presented, and survey ratings obtained.

RESULTS

Between 2021 and 2024, 105 sessions were conducted, averaging 60-70 residents per session. Faculty discussed 750 cases covering a range of subspecialties: pediatric body imaging (434 cases, 57.9%), neuroradiology (302 cases, 40.3%), and fetal imaging (15 cases, 2%). Cases frequently involved multiple modalities: 290 MRI (38%), 267 radiography (35%), 166 ultrasound (22%), 157 CT (21%), and 30 fluoroscopy (4%). Analysis of 539 survey responses indicated high satisfaction, with most residents rating the following as “good” or “very good”: ease of communication with faculty (91%), faculty engagement and support (95%), image quality and organization (97%), and clinical relevance of cases presented (96%). Furthermore, the overall content quality was rated “good” or “very good” by over 90% of residents.

CONCLUSION

This weekly imaging case review series is a well-received program for supplementary pediatric radiology education, demonstrated by sustained participation and consistently high participant-perceived value. The program addresses a critical need for subspecialty training support in LMICs, with potential for expanded outreach and research collaborations.

CLINICAL RELEVANCE/APPLICATION

This project addresses the shortage of pediatric radiology expertise in LMICs by supplementing subspecialty education, aiming to improve diagnostic skills, and enhance the quality of patient care in these regions.

W2-SPNPM-3 FROM SOLO TO SYMPHONY: HOW MDM PARTICIPATION ENHANCES PROSTATE MRI INTERPRETATION

Pat Rohan, MBBS (*Presenter*)
Conor Brosnan, MBChB (*Abstract Co-Author*)
James W. Ryan, FFR(RCSI), MBBCh (*Abstract Co-Author*)
Ruth M. Dunne, MBBCh (*Abstract Co-Author*)
Martina M. Morrin, MD (*Abstract Co-Author*)

PURPOSE

To evaluate whether consistent participation in multidisciplinary team meetings (MDMs) improves the diagnostic performance of radiologists interpreting prostate MRI. We hypothesised that radiologists engaged in MDMs would demonstrate higher diagnostic accuracy and better cancer detection rates by integrating clinical context into imaging interpretation.

METHODS AND MATERIALS

We conducted a retrospective analysis of 116 consecutive patients who underwent prostate MRI at outside institutions without a formal prostate cancer MDM but were referred to our specialist service to undergo cognitive fusion biopsy. MRI reports from non-MDM readers were compared with re-interpretations by radiologists who regularly participate in weekly prostate cancer MDMs. Data collected included PIRADS v2.1 scores, lesion size and location, PSA density (PSAD), and biopsy histology. Clinically significant prostate cancer (csPCa) was defined as ISUP grade group =2. Diagnostic metrics including sensitivity, specificity, positive and negative predictive values (PPV, NPV), and area under the ROC curve (AUC) were calculated using thresholds of PIRADS =3 and =4. Interobserver agreement was assessed using kappa statistic. Logistic regression evaluated the relationship between PSAD and csPCa stratified by PIRADS score.

RESULTS

At a PIRADS =4 threshold, the MDM group achieved significantly higher specificity (40% vs 13%, p = 0.039) and greater overall accuracy (AUC 0.69 vs 0.55). Sensitivity remained high in both groups (MDM: 100%, non-MDM: 96%). Cancer detection rates (CDRs) were higher in the MDM group at PIRADS 4 (56% vs 50%) and PIRADS 5 (94% vs 86%). Interobserver agreement between groups was moderate (? = 0.62), with best agreement at PIRADS 5 (? = 0.77) and lowest at PIRADS 3 (? = 0.40). Logistic regression demonstrated a significant association between increasing PSAD and likelihood of csPCa at PIRADS 4 in both groups.

CONCLUSION

Regular engagement in multidisciplinary team meetings significantly improves the specificity and diagnostic confidence of radiologists interpreting prostate MRI. These findings suggest that MDM participation enhances interpretation through integration of imaging with clinical and pathological context.

CLINICAL RELEVANCE/APPLICATION

Embedding radiologists in multidisciplinary prostate cancer teams enhances diagnostic accuracy in prostate MRI, supporting improved patient selection for biopsy and treatment. This study underscores the broader value of noninterpretive collaboration in radiologic practice and provides evidence for its integration into routine imaging pathways.

W2-SPNR-1 VISUAL-SOMATOSENSORY CONNECTIVITY DISRUPTION IN CERVICAL SPONDYLOTIC MYELOPATHY: ASSOCIATIONS WITH SPINAL CORD METRICS AND CLINICAL SEVERITY

Shuting Huang (*Presenter*)
Weiyin Vivian Liu (*Abstract Co-Author*)
Long Yu Deng (*Abstract Co-Author*)
Zhang Qiya (*Abstract Co-Author*)
Xiangyu Tang (*Abstract Co-Author*)

PURPOSE

Cervical spondylotic myelopathy (CSM) is a prevalent degenerative condition characterized by spinal cord compression, leading to sensorimotor deficits and, in some cases, cognitive impairments. Recent neuroimaging studies reveal that CSM not only affects spinal structures but also induces functional and structural brain changes. Based on prior evidence of regional homogeneity alterations in S1, this study aimed to further investigate reorganization of S1 functional connectivity using resting-state fMRI (rs-fMRI) in CSM and assess associations with spinal metrics and clinical severity.

METHODS AND MATERIALS

A total of 62 CSM patients with herniated discs (36 males, mean age 47.6 ± 14.1 years) and 36 healthy controls (18 males, mean age 46.6 ± 9.7 years) underwent brain rs-fMRI, high-resolution 3D T1-weighted structural imaging, and quantitative synthetic MRI of the cervical spinal cord on a 3.0T MR scanner (Premier, GE Healthcare). CSM patients were stratified into T2-hyperintensity and non-hyperintensity groups based on spinal cord MRI. Quantitative metrics, including T1, T2 and PD values, were extracted at the maximal compression level (MCL). The rs-fMRI data were preprocessed with slice-timing correction, head motion correction, spatial smoothing using a Gaussian kernel with a 6-mm FWHM, nuisance covariate regression, and linear detrending, followed by fitting to a fMRI model and normalization to MNI space by registering T1w images to the MNI template using SPM12 (http://dbm.neuro.uni-jena.de/vbm/) and the DPABI toolbox (http://rfmri.org/DPABI). Seed-based correlation analysis (SCA) was performed using S1 as the seed to evaluate whole-brain FC. Connectivity strengths were extracted and correlated with spinal imaging indices and clinical scores, including the Japanese Orthopaedic Association (JOA) score.

RESULTS

In the T2-hyperintensity subgroup, FC between left S1 and the occipital lobe was significantly reduced versus both healthy controls ($P<0.001$) and the non-hyperintensity subgroup ($P=0.002$). This diminished FC was negatively correlated with the maximum spinal cord compression (MSCC) ($P=0.007$) and T1 and T2 values at MCL ($P<0.01$). Conversely, a positive correlation was observed between S1-occipital FC and JOA scores ($P=0.005$).

CONCLUSION

S1-occipital functional disconnection in CSM, particularly in T2-hyperintensity patients, correlates with compression severity and clinical impairment.

CLINICAL RELEVANCE/APPLICATION

Visual-somatosensory FC may serve as a promising neuroimaging biomarker for assessing functional disruption in CSM.

PURPOSE

In patients with acute ischemic stroke (AIS) infarct growth occurs despite successful reperfusion. Oxygen extraction fraction (OEF) has shown promising results in evaluating ischemic tissue viability and can now be quantified from routinely performed dynamic-susceptibility-contrast (DSC) perfusion. We aimed to determine the association of OEF alterations within the ischemic penumbra and infarct growth in patients who underwent successful reperfusion.

METHODS AND MATERIALS

In this retrospective study, patients included if they had anterior circulation large vessel occlusion (LVO); achieved successful reperfusion (TICI 2b); had pretreatment DSC perfusion and posttreatment MRI within 48 hours from reperfusion. Penumbra and ischemic core were segmented using Tmax >6s and ADC =620×10?6 mm²/s, respectively. OEF was calculated from DSC and normalized to contralateral tissue (OEF r). Posttreatment MRI was used to calculate final infarct volume. The following variables were calculated for assessment of infarction growth: 1) Infarction growth volume: Final infarction - baseline ischemic core volume; 2) Relative infarction growth %: infarction growth vol/final infarct volume x 100; 3) Penumbra-to-infarct conversion %: infarction growth vol/penumbra vol x 100. The association between OEF r in conjunction with demographic, clinical, and other imaging variables and infarct growth variables were evaluated by univariate and multivariate analysis.

RESULTS

Penumbra OEF r was independently associated with infarct growth ($p = 0.003$). Each 0.1-unit decrease in penumbra OEF r was associated with approximately 3 mL of infarct growth ($p=0.007$), 3% increase in infarct growth% ($p=0.005$) and approximately 10% loss of penumbra ($p = 0.027$). For patients who had substantial infarct growth (>10mL), penumbra OEF r was significantly ($p < 0.0001$) lower (median: 1.62) than patients without infarct growth (median: 2.05).

CONCLUSION

Penumbra-OEF r is a promising imaging biomarker for prediction of infarct growth in AIS following successful reperfusion. Inadequate raise in penumbra-OEF r values can result in further ischemic injury and infarct growth.

CLINICAL RELEVANCE/APPLICATION

OEF which now can be calculated from commonly performed DSC perfusion is a promising imaging biomarker that can be used to further refine infarct growth prediction offering advantageous therapeutic and prognostic implications.

W2-SPNR-3 DUAL-ENERGY CT-DERIVED ELECTRON DENSITY AND EFFECTIVE ATOMIC NUMBER FOR DIFFERENTIATION OF MALIGNANT BRAIN TUMORS: A MACHINE LEARNING-BASED APPROACH

Fumitaka Ejima (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

PURPOSE

Recently, electron density (ED) and effective atomic number (Z eff) derived from dual-energy computed tomography (DECT) have been increasingly applied in clinical settings. The clinical significance of these parameters in brain tumors has not been clarified, and their clinical application remains limited. In this study, the potential use of ED and Z eff as novel quantitative imaging biomarkers for differentiating malignant brain tumors was investigated by constructing the predictive models with machine learning (ML) analysis.

METHODS AND MATERIALS

Data pertaining to 136 patients with a pathological diagnosis of brain metastasis (BM), glioblastoma, and primary central nervous system lymphoma (PCNSL) between January 2017 and March 2023 were retrospectively reviewed. The patient data were arranged chronologically and divided into training (first 60%), validation (next 20%), and test (remaining 20%) sets. Other than DECT-derived parameters, we included apparent diffusion coefficient (ADC) derived from diffusion-weighted MRI in the analysis. The 10th percentile, mean and 90th percentile values of conventional 120kVp CT value (CT conv), ED, Z eff , and relative ADC (rADC: ADC of lesion divided by ADC of normal-appearing white matter) within contrast-enhanced tumor region were extracted as features and used for model construction. AutoGluon, an open-source ML framework, was used to automatically develop and optimize predictive models. AUC, accuracy, precision, recall, and F1-score for classifying between two groups (BMs vs. glioblastomas, BMs vs. PCNSLs, glioblastomas vs. PCNSLs) were analyzed using ML models for each of the following: DECT alone, rADC alone, and DECT + rADC.

RESULTS

In the differentiation between BMs and glioblastomas, the model with DECT features exhibited a high AUC (0.83). In contrast, the AUC of the model with rADC features was poor, and no improvement was observed even when combined with DECT. In the differentiations involving PCNSLs, models with rADC features exhibited very high diagnostic performance (BMs vs. PCNSLs: AUC = 0.97; glioblastomas vs. PCNSLs: AUC = 0.94). Although the models with DECT features were not as good as those with rADC features, combining DECT and rADC features enabled the development of the best diagnostic model in the differentiation between BMs and PCNSLs (AUC = 1).

CONCLUSION

This study suggested the potential of DECT derived ED and Z eff as novel quantitative imaging biomarkers for the differentiation of malignant brain tumors.

CLINICAL RELEVANCE/APPLICATION

CT is an indispensable routine preoperative examination for brain tumors, and this work has discovered new diagnostic possibilities from the spectral data obtained through the standard procedure.

W2-SPNR-4 RECOGNIZING IMAGING PATTERNS OF NEUROLOGICAL INJURIES IN INTIMATE PARTNER VIOLENCE:A CASE-CONTROL STUDY

Hyeonseon Kim (*Presenter*)
Alexander Kwon (*Abstract Co-Author*)
Bharti Khurana, MD, MBA (*Abstract Co-Author*)

PURPOSE

To characterize neurologic injuries in Intimate Partner Violence (IPV) using radiologic data and compare injury patterns with a demographically matched control group.

METHODS AND MATERIALS

This retrospective study analyzed radiology reports from female patients who reported IPV between 2013 and 2018 (n = 1,183; 14,036 imaging reports) and age- and race-matched controls who never reported IPV (n = 4,105; 21,474 reports). Of these, 16.7% of cases and 4.8% of controls have at least one neurological injury. Neurological injury data were extracted. Incidence rates (injuries per person-year) and adjusted incidence rate ratios (aIRRs, 95% CIs) were calculated using Poisson regression, adjusting for age and ethnicity. $P < 0.05$ was considered statistically significant.

RESULTS

Cases had significantly higher incidence rates for multiple neurological injuries compared to controls. Notably, middle facial fractures (IRR 5.80, 95% CI 3.57-9.41, p<0.0001), middle subcutaneous swelling (IRR 6.42, 95% CI 3.92-10.49, p<0.0001), orbital injuries (IRR 7.77, 95% CI 2.97-20.31, p<0.0001), and extra-axial injuries (IRR 3.51, 95% CI 1.97-6.26, p<0.0001) were significantly increased in IPV cases. Specific fracture types such as mandibular fractures (IRR 25.59, 95% CI 3.06-214.01, p=0.003) and occipital fractures (IRR 17.10, 95% CI 1.77-165.35, p=0.01) also demonstrated high relative incidence. Notably, nasal bone fractures had an elevated risk (IRR 5.35, 95% CI: 3.08-9.30, p<0.0001).

CONCLUSION

Women with a history of IPV are more likely to present with facial fractures, soft tissue swelling, and orbital injuries. IPV survivors exhibited diverse trauma patterns, while controls more often had isolated intracranial injuries. These results highlight the need for careful radiologic assessment to identify characteristic injury patterns in IPV cases.

CLINICAL RELEVANCE/APPLICATION

Radiologists play a crucial role in identifying IPV by recognizing characteristic injury patterns, particularly in the craniofacial region. Early recognition can guide timely intervention and connect patients with necessary support services.

W2-SPNR-5 BASELINE CAPILLARY TRANSIT TIME HETEROGENEITY, LEAKAGE, AND CEREBRAL BLOOD VOLUME PREDICT INTRACEREBRAL HEMORRHAGE AFTER ACUTE ISCHEMIC STROKE

Mona Asghariahmadabad, MD (*Presenter*)
Ameera F. Ismail, MD (*Abstract Co-Author*)
Mersedeh Bahr-Hosseini (*Abstract Co-Author*)
Viktor Szeder, MD (*Abstract Co-Author*)
Jeffrey Saver, MD (*Abstract Co-Author*)
Wade S. Smith, MD,PhD (*Abstract Co-Author*)
Nerissa Ko, MD (*Abstract Co-Author*)
Kazim Narsinh, MD (*Abstract Co-Author*)
Luis Savastano (*Abstract Co-Author*)
Daniel L. Cooke, MD (*Abstract Co-Author*)
Steven W. Hetts, MD (*Abstract Co-Author*)
S.Andrew Josephson (*Abstract Co-Author*)
Christopher P. Hess, MD, PhD (*Abstract Co-Author*)
David S. Liebeskind (*Abstract Co-Author*)
Kambiz Nael, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the predictive role of perfusion-derived biomarkers—relative capillary transit time heterogeneity (rCTH), microvascular leakage, and cerebral blood volume (rCBV)—in the baseline ischemic core for forecasting the risk of intraparenchymal hemorrhage (IPH) following reperfusion therapy in acute ischemic stroke (AIS).

METHODS AND MATERIALS

This retrospective study included AIS patients who underwent baseline MRI including diffusion-weighted imaging (DWI) and dynamic susceptibility contrast (DSC) perfusion before reperfusion therapy, followed by post-treatment imaging within 7 days to assess for IPH. The ischemic core was defined as regions with ADC < 620 × 10?6 mm²/s. Voxel-wise maps of CTH, leakage, and CBV were generated using a Bayesian probabilistic model and normalized to the contralateral hemisphere to yield relative metrics (rCTH, relative leakage, and relative CBV). Group-wise comparisons were performed between patients with IPH and without IPH. Predictive value was assessed via univariate and stepwise multivariate logistic regression. Odds ratios (OR), 95% confidence intervals (CI), and p-values were reported. ROC analysis was performed to evaluate discriminative performance.

RESULTS

A total of 33,209 voxels for each map across infarct regions were analyzed. IPH occurred in 33 of 104 patients (31.7%) based on follow-up imaging. Patients with IPH demonstrated significantly higher values rCTH and relative leakage values, and significantly lower relative CBV in the ischemic core compared to patients without IPH ($p < 0.001$ for all). In univariate logistic regression, higher rCTH (OR = 1.15, 95% CI: 1.13-1.18, $p < 0.0001$), higher relative leakage (OR = 1.02, 95% CI: 1.02-1.03, $p < 0.0001$), and lower rCBV (OR = 0.77, 95% CI: 0.75-0.80, $p < 0.0001$) were significantly associated with IPH. In multivariate stepwise regression, all three variables remained independent predictors of IPH.

CONCLUSION

Increased rCTH and microvascular leakage, along with decreased relative CBV, in the baseline ischemic core are independent predictors of post-treatment IPH in AIS patients. These perfusion biomarkers may have potential for prediction of IPH in ais patients undergoing reperfusion therapies.

CLINICAL RELEVANCE/APPLICATION

Combining rCTH, leakage, and rCBV from baseline MR perfusion could enable hemorrhagic risk stratification, potentially informing treatment strategies and improving safety of thrombolytic and endovascular therapies in acute stroke.

W2-SPNR-6 THE RELATIONSHIP BETWEEN ACID-BASE METABOLISM IN BRAIN TISSUE DETECTED BY APTW IMAGING AND COGNITIVE FUNCTION OF PATIENTS WITH MOYAMOYA DISEASE

Dinglan Yang (*Presenter*)
Chao Xia (*Abstract Co-Author*)
Jiaxin Zeng (*Abstract Co-Author*)
Wei Yu (*Abstract Co-Author*)
Kai Ai (*Abstract Co-Author*)
Su Lv, MD (*Abstract Co-Author*)

PURPOSE

Assessing alterations of brain microenvironment would develop a potential target for the treatment of cognitive impairment in moyamoya disease (MMD). This study aimed to assess acid-base metabolic levels of brain tissue using amide proton transfer weighted (APTw) imaging and their relationship with cognitive function in MMD patients.

METHODS AND MATERIALS

Patients with MMD and matched healthy controls (HCs) from June 2021 to August 2024, were prospectively recruited. Subjects underwent APTw and computed tomography perfusion (CTP) imaging. All participants were examined using a 3.0T Philips Elition MRI scanner. B0-corrected APTw images were transferred to Philips InteliSpace Portal workstation for automatic calculation of APTw values. Using NeuBrainCARE brain perfusion analysis software, measurements of mean transit time (MTT) and time to peak (TTP) in regions with impaired brain perfusion were obtained. To compare with normal tissue, APTw values were also measured in the normal-appearing white matter (NAWM) of unaffected regions in the same hemispheres, the contralateral hemispheres, and the ipsilateral cerebellar hemispheres. Cognitive function was assessed using the Cambridge Automated Neuropsychological Test Battery. Comparisons between multiple groups were conducted using ANOVA or Kruskal-

Wallis H test, with Bonferroni correction for multiple comparisons. Spearman correlation analysis was used to assess the relationship between APTw values in perfusion-impaired brain tissue and MTT, and TTP, as well as their volume and density values.

RESULTS

We included 54 MMD patients and 35 HCs. Compared to HCs, MMD patients had significantly lower APTw values in perfusion-impaired tissues and NAWM of bilateral cerebral hemispheres (P <0.01) (Figure 1-3). MMD patients also performed worse cognition than HCs in several domains, including motor screening task, multi-tasking tests, paired associates learning, five-choice reaction time, rapid visual processing, stockings of Cambridge, spatial working memory, and stop signal task (P <0.05). A good correlation was observed between APTw values in perfusion-impaired brain tissue of MMD patients and cognitive impairments in different domains such as executive function, visual memory, psychomotor speed, spatial planning, and executive function (P <0.05).

CONCLUSION

The APTw value can reflect the acidosis in perfusion-impaired brain tissue of MMD patients, with brain acid-base metabolic levels potentially affecting cognitive domain function.

CLINICAL RELEVANCE/APPLICATION

APTw imaging offers a novel neuroimaging biomarker for evaluating acid-base metabolism in brain tissue, representing a potential target for future treatment of cognitive impairment in MMD.

W2-SPNR-8 PREOPERATIVE RADIOLOGIC DIAGNOSIS AND SUBTYPING OF WHO GRADE I MENINGIOMAS USING GPT 4 WITH VISION ASSISTED PATTERN RECOGNITION

Naz Demircan, MD (*Presenter*)
Ahmet K. Karaman, MD (*Abstract Co-Author*)
Serdar Arslan, MD (*Abstract Co-Author*)
Bora Korkmazer, MD (*Abstract Co-Author*)
TUFAN AGAH KARTUM (*Abstract Co-Author*)
Osman Kizilkilic, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic performance GPT-4V, a vision-enabled large language model, to identify and subtyping WHO Grade I meningiomas on preoperative MRI, and to compare its diagnostic performance with that of an experienced neuroradiologist.

METHODS AND MATERIALS

This study retrospectively included 113 patients with histopathologically confirmed WHO Grade I meningiomas. For each case, axial T1, T2, T2-FLAIR, contrast-enhanced T1, DWI, ADC, coronal T2, and sagittal T1 sequences were exported in PNG format for standardized visual review. A neuroradiologist and GPT-4V independently evaluated the anonymized images, blinded to clinical and pathological data. Reviewers assessed whether the lesion was a WHO Grade I tumor, a meningioma, and, if so, its histologic subtype. Evaluations were based on T1/T2 signal intensity, peritumoral edema, enhancement pattern, signal homogeneity, and ADC values.

RESULTS

GPT-4V correctly identified WHO Grade I tumors in 88.6% of cases (100/113), while the neuroradiologist achieved 96.4% accuracy (109/113) (p = 0.044). When asked specifically to recognize WHO Grade I meningiomas, GPT-4V achieved 77.3% accuracy (87/113), compared to 92.9% (105/113) by the neuroradiologist (p = 0.0016). Subtype predictions proved more difficult for both readers: GPT-4V correctly classified 16.8% (19/113), while the radiologist correctly classified 32.7% (37/113) (p = 0.0088).Angiomatous meningiomas were generally considered the most radiologically distinctive subtype, typically showing low T1 signal, high T2 signal, marked peritumoral edema, and homogeneous enhancement. Despite these features, they were frequently misclassified by both the model and the neuroradiologist

CONCLUSION

GPT-4V showed diagnostic performance approaching that of a neuroradiologist in detecting WHO Grade I tumors on routine MRI. However, its ability to differentiate between histologic subtypes remains limited.

CLINICAL RELEVANCE/APPLICATION

Reliable preoperative identification of WHO Grade I meningiomas may support better surgical planning and patient counseling. GPT-4V, when carefully validated, could serve as useful adjuncts in radiologic interpretation by offering consistent pattern recognition across large imaging datasets.

W2-SPNR-9 LONG-TERM BLOOD PRESSURE EXPOSURE AND CEREBRAL MICROBLEEDS: A RETROSPECTIVE STUDY FROM THE META-KLS COHORT

Liu Wenjuan (*Presenter*)

PURPOSE

The relationship between long-term blood pressure factors and cerebral microbleeds (CMBs) in community populations remains unclear. This study aimed to elucidate the associations between various long-term blood pressure factors and the occurrence of CMBs within the Kailuan cohort.

METHODS AND MATERIALS

Data were obtained from adults participating in the Multi-Modality Medical Imaging Study Based on the Kailuan Study (META-KLS), a prospective longitudinal community study initiated in 2006, involving participants aged 18-98 years. A total of 752 participants underwent brain magnetic resonance imaging (MRI) between 2021 and 2022. We calculated long-term blood pressure factors, including cumulative exposure, long-term blood pressure variability, and blood pressure trajectories, using established formulas and trajectory models. Linear regression analyses were conducted to examine the associations between these blood pressure factors and the presence of CMBs, adjusting for demographic factors, cardiovascular risk factors, and cerebral blood flow on MRI. Brain MRI outcomes included the presence and classification of CMBs.

RESULTS

A total of 752 participants were included, with a mean age of 56.4 ± 10.8 years. Of these, 448 (59.6%) were men and 304 (40.4%) were women. A diagnosis of CMBs was established in 172 individuals, accounting for 22.9% of the cohort. Cumulative systolic blood pressure (SBP) was identified as an independent risk factor for the occurrence of CMBs (OR = 1.004, 95%CI: 1.002-1.005). This association remained significant after adjusting for sociodemographic and cardiovascular risk factors (OR= 1.002, 95% CI: 1.000-1.004). Participants with deep-type CMBs had significantly higher cumulative SBP compared to those with lobar-type CMBs (P = 0.005). No significant correlations were found between the occurrence of CMBs and cumulative diastolic blood pressure (DBP), cumulative pulse pressure difference, blood pressure trajectories, or long-term blood pressure variability.

CONCLUSION

In community population, elevated cumulative SBP is an important risk factor for CMBs, particularly affecting deep brain tissue.

CLINICAL RELEVANCE/APPLICATION

Our study has several strengths. META-KLS is a community database that allows comprehensive evaluation of the relationship between various risk factors and subclinical brain diseases using multimodal medical imaging, including a wide range of volunteers aged between 18 and 98. This wide age range can also help detect

early brain lesions, and even preclinical changes in brain microstructure. Moreover, the multimodal brain MRI and high-resolution imaging that the participants undergo in this study provides for clear display and accurate diagnosis of brain diseases.

W2-SPNR-10 PREDICTORS OF CLINICAL OUTCOME AFTER ENDOVASCULAR COILING OF UNRUPTURED INTRACRANIAL ANEURYSMS

Ahsas Nagee, MD (*Presenter*)
Ammar Alam (*Abstract Co-Author*)
Wassim Elmasry, MD (*Abstract Co-Author*)
Marlise P. dos Santos, MD,MPH (*Abstract Co-Author*)

PURPOSE

To identify patient, aneurysm, and procedural risk factors associated with neurological dependency and poor long-term outcomes following endovascular coiling of unruptured intracranial aneurysms (UIAs).

METHODS AND MATERIALS

We retrospectively reviewed all patients with UIAs treated with coiling at The Ottawa Hospital from January 2003 to July 2024. Patients treated with flow diversion, parent artery occlusion, or other intra-saccular devices were excluded. We collected clinical, procedural, and aneurysm characteristics to assess predictors of pre-discharge and long-term outcomes using the modified Rankin Scale (mRS). Multivariate logistic regression was used to identify factors associated with unfavourable outcomes (mRS 3-5).

RESULTS

A total of 202 patients (mean age 55.3 years; 76.7% female) were included. Mean clinical and imaging follow-ups were 112.5 and 51.4 months, respectively. Unfavourable mRS outcomes occurred in 4.0% at baseline, 7.4% at discharge, and 9.9% at last follow-up. Immediate post-procedure occlusion was complete in 46.5% of cases; this declined to 37.2% at final follow-up. Perioperative complication and 30-day mortality rates were 19.8% and 1.0%, respectively. Conventional coiling technique (OR 6.82, p=0.01) and perioperative complications (OR 3.84, p=0.045) were independently associated with poor short-term outcomes. Long-term outcomes were predicted by conventional coiling (OR 3.20, p=0.03) and the number of aneurysms per patient (OR 1.45, p=0.024). Aneurysm size, location, and patient demographics were not predictive.

CONCLUSION

Over 21 years, conventional coiling technique and the number of aneurysms were significant predictors of poor long-term in endovascular UIA treatment. Perioperative complications and conventional technique predicted worse short-term outcomes, while aneurysm size, location, and patient demographics did not significantly influence clinical outcomes.

CLINICAL RELEVANCE/APPLICATION

These findings emphasize the need for careful technique selection and perioperative management in patients undergoing endovascular coiling for unruptured intracranial aneurysms. Identifying patients with multiple aneurysms and those at higher risk for procedural complications may help guide treatment planning, improve procedural safety, and optimize long-term neurological outcomes.

W2-SPNR-11 CT PERFUSION TMAX PREDICTS DEVELOPMENT OF DELAYED CEREBRAL ISCHEMIA IN ANEURYSMAL SUBARACHNOID HEMORRHAGE

Theodore Wang (*Presenter*)
Jeremy W. Martin, MD (*Abstract Co-Author*)
Steven Cen, PhD (*Abstract Co-Author*)
Bino A. Varghese, PhD (*Abstract Co-Author*)
Xiaomeng Lei (*Abstract Co-Author*)
Nasim Sheikh Bahaei, MD,FRCR (*Abstract Co-Author*)
Reza Assadsangabi, MD (*Abstract Co-Author*)

PURPOSE

Delayed cerebral ischemia (DCI) occurs in up to 30% of patients with aneurysmal subarachnoid hemorrhage (aSAH) and results in significant morbidity and mortality. There remains no reliable methodology to predict the risk of DCI. CT perfusion (CTP) has emerged as an imaging modality that provides quantitative assessment of tissue perfusion via parameters including time-to-maximum (Tmax), cerebral blood flow (CBF), and cerebral blood volume (CBV). We hypothesized that assessment of CTP metrics at multiple timepoints would help stratify the risk of developing DCI in patients with aSAH.

METHODS AND MATERIALS

We performed a retrospective review of patients with aSAH diagnosed on CT Head and CTA, presenting to our institution between January 2023 and May 2025. Demographics, clinical data, and imaging findings were collected. CTP metrics including the volume which exceeded the predefined thresholds for Tmax, CBF, and CBV were analyzed at baseline and across multiple scans. The diagnosis of DCI was established based on a new infarct on CT head or MRI during the hospital course.

RESULTS

A total of 53 patients with aSAH were included, 34 (64%) of which developed DCI. In total 19 patients had one CTP scan, while 34 had multiple scans (2.7±1.0/patient) with an average 6.2±2.5 days from the baseline scan. When comparing baseline CTP scans, the difference in volume between Tmax>6 seconds and Tmax>8 seconds was statistically significantly increased in patients that developed DCI compared to those that did not ($p = 0.03$). When comparing the mean, median, and maximum values at multiple timepoints the difference persisted, as well as when comparing the maximum and mean values of Tmax>6 between groups ($p < 0.01$). Classification tree analysis demonstrated the difference between Tmax>6 and Tmax>8 was the most important predictor for developing DCI, as if it was greater than 2.3 the risk of DCI was 90% (95% CI: 70-100%) compared to 49% (95% CI: 34-63%).

CONCLUSION

CTP may help predict the risk of DCI in patients with aSAH. Of the CTP parameters, the Tmax, (specifically Tmax>6, Tmax>8, and the difference between them), was associated with the development of DCI on both the baseline and subsequent exams. Additional research is needed to validate the use of Tmax in DCI prognostication and inform treatment decision making for these patients with aSAH.

CLINICAL RELEVANCE/APPLICATION

There is currently no reliable methodology to predict the risk of delayed cerebral ischemia in patients presenting with aneurysm subarachnoid hemorrhage despite the significant morbidity and mortality. This retrospective review suggests that CTP, particularly Tmax, may be associated with the development of DCI. CTP may have a role in prognostication and treatment decision making in patients presenting with aSAH.

W2-SPNR-13 ACTIVE LEARNING-ENHANCED BRAINSTEM SEGMENTATION ENABLES DIFFERENTIATION BETWEEN PSP AND PD

Yujia Wei, MD, PhD (*Presenter*)
Stephanie Zawada (*Abstract Co-Author*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop an active learning-based deep learning method for midbrain and pons segmentation to potentially distinguish PSP from PD using a limited number of annotated T1-weighted MRIs.

METHODS AND MATERIALS

A total of 1,483 T1-weighted MRIs from internal and PPMI (PD) datasets were included in this study and used to develop and evaluate a midbrain and pons segmentation model based on the nnU-Net architecture. All images underwent N4 bias field correction and preprocessing with the HD-BET brain extraction algorithm. From these datasets, 18 images were randomly selected and manually annotated 10 for training and 8 for testing. After training an initial nnU-Net model, inference was performed on the remaining unlabeled data. Two physicians from the Department of Radiology, both with MD degrees and experience in neuroradiology, reviewed the predictions and identified the 8 poorest segmentations, which were then manually annotated and added to the training set. The nnU-Net model was retrained to incorporate these challenging cases. The Dice similarity coefficient (DSC) was calculated on the test dataset to compare model performance before and after retraining. Finally, the mid slices of the images are selected, and midbrain-to-pons area ratio was computed from the segmentation results and used to differentiate patients with progressive supranuclear palsy (PSP) from those with Parkinson's disease (PD).

RESULTS

For the active learning component of the study, we observed a clear improvement in segmentation performance after model retraining. The DSC for midbrain increased from 0.866 to 0.906, and for pons, from 0.919 to 0.943, indicating enhanced anatomical delineation through iterative learning. The PD group exhibited a mean ratio of 0.254 ± 0.055, while the PSP group showed a significantly lower mean ratio of 0.220 ± 0.048. This difference was statistically significant (Mann-Whitney U test, $p < 0.01$). The effect size, calculated using Cohen's d, was 0.655, indicating a moderate to strong distinction between the two groups. A representative segmentation illustration and the comparative distribution plots in Figure 1.

CONCLUSION

In conclusion, active learning markedly improves brainstem segmentation accuracy—particularly for the midbrain and pons—while significantly reducing manual annotation effort.

CLINICAL RELEVANCE/APPLICATION

his study presents an efficient and accurate method for brainstem segmentation using active learning, which reduces manual labeling effort while maintaining high precision. The derived midbrain-to-pons area ratio enables automated differentiation between PSP and PD, offering valuable support for clinical diagnosis and decision-making in neurodegenerative disorders.

W2-SPNR-14 FINE-TUNING A SMALL LARGE LANGUAGE MODEL (LLM) WITH OPTIMAL COMBINATION OF SYNTHETIC AND REAL-WORLD RADIOLOGY REPORTS FOR EFFECTIVE STRUCTURED REPORTING (SR) ON BRAIN VASCULATURE

Doo Young Lee, MD, MS (*Presenter*)
Minjin Song (*Abstract Co-Author*)
Joon Young Kim (*Abstract Co-Author*)
Juyeon Yi, MD (*Abstract Co-Author*)
Bumcheol Hwang (*Abstract Co-Author*)
Honggeun Cho, MD (*Abstract Co-Author*)
Jin Wook Choi, MD, PhD (*Abstract Co-Author*)
Hyun S. Choi, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop an LLM capable of transforming unstructured radiology reports on brain MRI with TOF-MRA into structured radiology reports focusing on the specific findings of brain vasculature, utilizing sequential two-stage training.

METHODS AND MATERIALS

Retrospective review of radiology reports was conducted for 1100 aneurysmal patients who took brain MRA between 2021.01 and 2024.04. Sections elaborating on aneurysm, stenosis, and occlusion were extracted from each unstructured radiology report to construct a corresponding structured report. For the LLM, BioGPT was used. Three sets of synthetic pairs of unstructured/structured reports with different sizes (25000, 50000, 100000) were generated, and used for the initial training of model. Three sets of real-world pairs of unstructured/structured reports with different sizes (300, 600, 900) were used for the subsequent fine-tuning (FT) of model. The 200 real-world unstructured radiology reports, previously unexposed to model, were used for testing. Three language metrics: BERTScore, BLEU, Cosine Similarity TF-IDF were used for the comprehensive assessment of output report from the final model.

RESULTS

The 1100 patients comprised 736 females and 364 males with a median age of 63 years (range 18-92 years). With the initial training data size fixed at 100000 report pairs, positive correlation was observed between FT data size and model performance: 900 FT data led to the highest metric output ($p < 0.0001$), followed by 600, 300, and 0. With FT data size fixed at 900, the model initially trained with 50000 or 100000 synthetic data outperformed that with 25000 synthetic data; intriguingly, the model initially trained with 50000 report pairs exhibited superior performance to the model initially trained with 100000 ($p < 0.0001$). The highest metric output was obtained from the model trained with 50000 synthetic pairs followed by FT with 900 real-world pairs: average BERTScore 0.78, BLEU 0.91, Cosine Similarity TF-IDF 0.97. SR performance of the final model differed depending on the complexity of each input test report: the highest metric output was attained for the reports only containing aneurysmal information, while the lowest metric output was obtained for the reports containing all three types of information on aneurysm, stenosis, and occlusion.

CONCLUSION

Large number of synthetic radiology reports can effectively be used in combination with small number of real-world reports to optimally refine an LLM for SR, using two-stage training.

CLINICAL RELEVANCE/APPLICATION

Using this approach, small LLMs fine-tuned for various SR can be efficiently developed and optimized even with the limited number of real-world reports, thereby facilitating the seamless integration of SR into daily radiology practice.

W2-SPNR-15 ADVANCED MRI METHODS FOR ASSESSING WHITE MATTER INJURY AND DRUG EFFICACY IN EXPERIMENTAL ISCHEMIC STROKE IN MICE

Donghoon Lee, PhD (*Presenter*)
Todd L. Richards, PhD (*Abstract Co-Author*)
Elias Farhan (*Abstract Co-Author*)
Stephanie Totten (*Abstract Co-Author*)
Ravneet Vohra, PhD (*Abstract Co-Author*)
Brendan Schweitzer (*Abstract Co-Author*)
Jonathan Weinstein, MD, PhD (*Abstract Co-Author*)

PURPOSE

To identify multi-parametric MRI (mpMRI) biomarkers for monitoring the effects of acute ischemic stroke (AIS) over time and evaluating the efficacy of a repurposed neuroimmune cell-targeted K Ca 3.1 inhibitor drug senicapoc in attenuating AIS-induced injury to white matter (WM).

METHODS AND MATERIALS

We conducted in vivo mpMRI on mouse brains following middle cerebral artery occlusion/reperfusion (tMCAO/R)-induced AIS to acquire diffusion tensor imaging (DTI)/neurite orientation dispersion and density imaging (NODDI) parameters and assess infarct volume in the mouse brain using high-resolution T2-weighted (T2w) images. Imaging took place on a 14 Tesla (T) MR scanner on days 7 and 30-post tMCAO/R, following a 7-day drug treatment regimen with either senicapoc or a vehicle. The assessed infarct volumes calculated by T2w images were compared to DTI/NODDI parameters on regions of interest (ROIs) of both the ipsilateral (stroke-affected) and contralateral (non-stroke) sides. The DTI/NODDI data were analyzed using 2-way ANOVA to assess time effects between 10 vehicle-treated and 9 senicapoc-treated mice at 7 and 30 days post-tMCAO/R.

RESULTS

The external capsule (WM tract) in the mid-brain was analyzed on both the ipsilateral and contralateral sides using a T2w image. DTI parameters fractional anisotropy (FA), mean diffusivity (MD), and axial diffusivity (?1) showed significant AIS-induced changes ($p < 0.05$) on the ipsilateral, but not on the contralateral, side in an anatomically restricted manner corresponding to regions of acute infarction. Similarly, several NODDI parameters, including orientation dispersion index (odi), fractional intracellular volume fraction (ficvf), fractional isotropic volume fraction (fiso), and kappa, also showed significant ($p < 0.05$) AIS-induced changes on the ipsilateral, but not on the contralateral, side. Senicapoc demonstrated significant attenuating effects on AIS-induced changes in both DTI and NODDI parameters over time. Treatment with senicapoc compared to vehicle significantly attenuated AIS-induced responses in DTI parameters MD, eigenvalues ?1 and ?2 as well as NODDI parameters ficvf and odi ($p < 0.05$) in the same regions of acute infarction noted above.

CONCLUSION

This study demonstrates the potential of DTI/NODDI methods as effective tools for assessing WM injury and recovery after experimental AIS in mice. Also, these techniques show promise in monitoring the therapeutic effects of a repurposed drug, designed to blunt post-stroke neuroinflammation.

CLINICAL RELEVANCE/APPLICATION

DTI/NODDI methods provide a noninvasive and reliable approach to evaluate the progression of AIS and monitor patient responses to treatment, offering potential for advancing clinical stroke management.

W2-SPNR-17 INTRACRANIAL HEMODYNAMICS AND ENLARGED PERIVASCULAR SPACES IN CEREBRAL SMALL VESSEL DISEASE: A 4D FLOW MRI STUDY

Chang Yuan (*Presenter*)
Yan Wei Miao (*Abstract Co-Author*)

PURPOSE

To evaluate the relationship between intracranial hemodynamic alterations and the burden of enlarged perivascular spaces (EPVS) in patients with cerebral small vessel disease (CSVD) using 4D Flow MRI.

METHODS AND MATERIALS

Seventy-five patients clinically diagnosed with CSVD were prospectively enrolled. Intracranial hemodynamic parameters—including pulsatility index (PI), flow rate, mean velocity, and peak velocity—were quantitatively assessed across nine major arterial segments: bilateral internal carotid arteries (C2, C4, C7), bilateral middle cerebral arteries (M1), and the basilar artery (BA). EPVS severity in the basal ganglia (BG) and centrum semiovale (CSO) was graded using a validated visual rating scale. Ordinal logistic regression was used to examine associations between vascular parameters and EPVS scores.

RESULTS

Higher EPVS scores in both the BG and CSO were significantly associated with lower flow rate, mean velocity, and peak velocity. Elevated PI in the MCA-M1 segment was significantly associated with increased BG-EPVS burden (OR = 0.10; 95% CI: 0.01-0.95; $P < 0.05$), while increased PI in the BA was significantly associated with higher CSO-EPVS scores (OR = 7.48; 95% CI: 1.16-48.01; $P < 0.05$).

CONCLUSION

Intracranial arterial hemodynamic abnormalities, particularly increased pulsatility and reduced flow velocities, are significantly associated with regional EPVS burden in CSVD patients.

CLINICAL RELEVANCE/APPLICATION

This study reveals that intracranial hemodynamic disturbances may play a key role in the formation of enlarged perivascular spaces associated with cerebral small vessel disease.

W2-SPNR-18 DEEP-LEARNING-RECONSTRUCTED 3D TOF MRA FOR CEREBRAL ARTERIOVENOUS MALFORMATIONIMAGE QUALITY AND EVALUATION

Linshu Yang (*Presenter*)
Chunxue Wu (*Abstract Co-Author*)
Jie Lu, PhD (*Abstract Co-Author*)

PURPOSE

Cerebral arteriovenous malformations (AVMs) require precise imaging for evaluating hemorrhage risk. Time-of-flight magnetic resonance angiography (TOF-MRA) is limited by prolonged acquisition times, motion artifacts, and spatial resolution compromises from conventional acceleration techniques (e.g., GRAPPA, SENSE, CS). This study evaluates a deep learning based reconstruction (AIR™ Recon DL) for TOF-MRA to improve image quality in healthy subjects and AVM patients.

METHODS AND MATERIALS

Ten healthy subjects (mean age 22.3 years) and eight AVM patients (mean age 34.2 years) underwent 3T TOF-MRA (SIGNA Premier, GE Healthcare) with identical parameters reconstructed via DL (high noise reduction) and conventional Filter A. Quantitative analysis in healthy subjects measured SNR [(artery signal/SD of brainstem)], contrast [(vessel SI-brainstem SI)/(vessel SI+brainstem SI)], and vessel uniformity (min/max SI ratio) across nine arteries. AVM nidus SNR/contrast and qualitative feeding artery (FA)/draining vein (DV) scores (4-point scale: 4=clearly continuous; 1=undetectable) were assessed. Statistical comparisons used t-tests/Mann-Whitney U tests; interrater agreement was evaluated via ? coefficients.

RESULTS

In healthy subjects, DL TOF-MRA demonstrated significantly higher SNR (all arteries, $P <0.0001$), contrast ($P <0.0001$), and uniformity in bilateral internal carotid, anterior cerebral, and basilar arteries ($P <0.05$) versus conventional TOF. For AVM patients, DL TOF-MRA achieved superior nidus SNR (203.90±75.97 vs. 47.39±5.80, $P <0.01$) and contrast (0.5035±0.1710 vs. 0.1738±0.09, $P <0.01$). Qualitative FA/DV scores showed no significant differences between DL and conventional TOF (FA: DL 3.88±0.35 vs. TOF 3.38±0.52, $P >0.05$; DV: DL 2.88±1.12 vs. TOF 3.12±0.99, $P >0.05$). Interrater agreement for FA/DV scores was strong (? =0.68-1.00, $P <0.01$). DL improved FA visualization in 4/8 cases (Reviewer A) and 3/8 cases (Reviewer B), with limited DV enhancement (1/8 cases for both reviewers).

CONCLUSION

DL-reconstructed TOF-MRA significantly enhances quantitative image quality for cerebral arteries and AVM nidus evaluation compared to conventional methods. While qualitative FA/DV visualization improvements were modest, DL reconstruction mitigates saturation artifacts and maintains diagnostic performance, supporting its clinical potential for non-invasive AVM characterization.

CLINICAL RELEVANCE/APPLICATION

DL TOF-MRA by improving critical image quality metrics without compromising diagnostic utility, offering a promising tool for detailed AVM assessment and reducing reliance on invasive or radiation-based modalities. Larger validation studies are warranted to confirm clinical applicability.

W2-SPNR-19 RADIOMICS NOMOGRAM BASED ON MAGNETIC RESONANCE IMAGING FOR THE PREDICTION OF TUMOR PURITY IN PATIENTS WITH GLIOBLASTOMA

Qing Zhou (*Presenter*)
Junlin Zhou, PhD (*Abstract Co-Author*)

PURPOSE

Tumor purity (TP) is an intrinsic feature of the tumor microenvironment (TME), and its accurate prediction in Glioblastoma(GBM) is critical for patient prognosis. We built a radiomics model based on use preoperative magnetic resonance imaging(MRI) to predict GBM TP.

METHODS AND MATERIALS

This retrospective study involved 172 patients(training set: n = 120; test set: n = 52)with gliomas(males, 98; females, 74; age, 51.90±12.54 years). Choose the optimal data cut-off value(63%) based on the basis of the minimum p value formed by the Kaplan-Meier survival analysis and log-rank tests divided patients into high TP group(=63%)and low TP group(<63%). Sketching Region of interest(ROI) and extracting radiomics features based on contrast enhanced T1WI(CE-T1WI) and T2WI .On the training set, LASSO regression was used to select the best combination of features, and establish clinical models ,radiomics models and clinical-radiomics models .

RESULTS

The clinical model was established base on age,peritumoral edema ,tumor location, enhencenment degree and ADC value, with AUCs of 0.669 and 0.781 for the training and test sets, respectively. Radiomics model was based on 14 features, with AUCs of 0.666 and 0.783 for the training and test sets, respectively. The clinical-radiomics model had the best performance, with AUCs of 0.769 and 0.884 for the training and test sets, respectively. The calibration curve of the clinical-radiomics model nomogram showed good agreement between the estimated and actual probabilities.

CONCLUSION

The combined model nomogram can help clinicians predict GBM TP and prognosis more accurately and intuitively.

CLINICAL RELEVANCE/APPLICATION

Quantitative prediction of tumor purity to identifying novel and promising prognostic biomarkers. Radiomic nomogram may offer a more intuitive and accurate assessment of tumor purity.

Zhengyu Jin, MD (*Abstract Co-Author*)
Hua Guo (*Abstract Co-Author*)
Huadan Xue, MD (*Abstract Co-Author*)

PURPOSE

To compare single versus multiparametric diffusion models in discriminating cervical cancer subtypes and differentiation grades.

METHODS AND MATERIALS

101 consecutive cervical cancer patients (68 squamous cell carcinoma(SCC), 33 adenocarcinoma(AC); 42 well/moderately differentiated, 15 poorly differentiated) underwent diffusion-weighted imaging with oscillating gradient spin-echo (OGSE), pulsed gradient spin-echo (PGSE), intravoxel incoherent motion (IVIM) and diffusion kurtosis imaging (DKI) acquisitions at 3T. Quantitative parameters were derived from four diffusion models: mono-exponential (apparent diffusion coefficient[ADC] from PGSE and OGSE), bi-exponential IVIM (pure molecular diffusion [D], perfusion fraction [f], pseudo-diffusion coefficient [D*]), DKI (mean kurtosis [MK], mean diffusivity [MD]), and a multicompartment model (cell diameter [d], intracellular volume fraction [Vin], extracellular diffusivity [Dex], interchange rate between intracellular and extracellular signals [Kin]). These parameters were analyzed both individually and in combination for histologic subtype discrimination and differentiation grade assessment.

RESULTS

In cervical cancer subtyping, d, Dex, Kin, ADC PGSE , ADC OGSE20HZ , ADC OGSE40HZ , f, D, MD showed significant differences between AC and SCC (all $p < 0.05$). The optimal parameters from four diffusion models for cervical cancer subtyping demonstrated the following AUCs: ADC OGSE40HZ (AUC=0.747), d (AUC=0.720), D (AUC= 0.685), and MD (AUC=0.660). Integration of these four parameters yielded the highest diagnostic accuracy for histopathological subtyping (AUC=0.867, 95% CI: 0.790-0.945), with 78.8% sensitivity and 85.3% specificity. For tumor grading, V in , MK, and D showed significant differences (all $p<0.05$; AUCs=0.735, 0.730, 0.695), while their multimodal integration with D ex , ADC PGSE , f enhanced performance (AUC=0.884, 95%CI=0.793-0.975; sensitivity=93.3%, specificity=66.7%).

CONCLUSION

Among four diffusion-weighted imaging quantitative models, ADC OGSE40HZ and d demonstrated comparable diagnostic efficacy in histopathological subtyping, outperforming D and MD, while their multiparametric integration showed best performance in accuracy. For tumor grading, V in and MK exhibited moderate discriminative capacity, with multiparametric strategies achieving optimal diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

Quantitative diffusion parameters demonstrate efficacy in distinguishing cervical cancer histopathological subtypes and tumor differentiation, while multiparametric integration maximizes diagnostic accuracy, which may further enable preoperative risk stratification to optimize therapeutic decision-making.

W2-SPOB-3 DISCRIMINATING ACTIVE FROM FIBROTIC DEEP ENDOMETRIOSIS LESIONS USING T2-WEIGHTED MRI ALONE: A RADIOMIC AND GRAPHOMIC APPROACH

Vincenzo Lucidi, MD (*Presenter*)
Maria Chiara Di Giovanni (*Abstract Co-Author*)
Arrigo Cattabriga (*Abstract Co-Author*)
Cristina Mosconi, MD (*Abstract Co-Author*)

PURPOSE

To evaluate whether T2-weighted MRI alone, combined with AI-driven radiomic and graphomic analysis, can accurately differentiate active from fibrotic lesions in deep infiltrating endometriosis (DIE), potentially simplifying MRI protocols and guiding treatment decisions.

METHODS AND MATERIALS

In this retrospective single-center study, 89 histologically confirmed DIE lesions from 61 patients were analyzed. Only axial T2-weighted MRI scans were used. Radiomic features (n=1223) and 3D graph-based morphological features (n=78) were extracted from manual segmentations. Lesions were classified as active (glandular/stromal) or fibrotic based on histopathology. Machine learning pipelines with genetic algorithm feature selection and L2-regularized logistic regression were developed for lesion classification and pain correlation. Leave-one-out cross-validation was applied to ensure robustness.

RESULTS

Graphomic features achieved higher performance (balanced accuracy: 0.699) than radiomic features alone (0.655) in discriminating lesion types. Specific radiomic and graphomic features also correlated with pain patterns. The analysis focused on lesions with low T2 signal intensity, a common imaging finding historically linked to

fibrosis. Despite the lack of T1-weighted or contrast-enhanced sequences, AI analysis uncovered biologically active lesions within this visually homogeneous group, demonstrating potential for improved lesion characterization.

CONCLUSION

AI-driven radiomic and graphomic analysis of T2-weighted MRI can non-invasively differentiate biologically distinct DIE lesions, challenging conventional assumptions based solely on T2 signal. This approach may support protocol streamlining while enhancing diagnostic and therapeutic precision in endometriosis care.

CLINICAL RELEVANCE/APPLICATION

This study shows that radiomic and graphomic AI analysis of T2-weighted MRI alone can distinguish between active and fibrotic DIE lesions, which are visually similar but require different treatments. This opens the door to shorter MRI protocols and more personalized therapy planning

PURPOSE

To investigate the pharmacokinetics (PK) and safety of gadoquatrane, a low-dose macrocyclic gadolinium (Gd) based contrast agent (GBCA), in pediatric patients from birth to<18 years undergoing contrast-enhanced MRI CE-MRI in any body region, in order to demonstrate similarity in PK and safety in the pediatric population compared to adults thus providing the basis for extrapolating the efficacy from adult to pediatric patients based on ICH E11 guidance.

METHODS AND MATERIALS

QUANTI Pediatric is an open-label phase 1/3 study, investigating gadoquatrane at a dose of 0.04 mmol Gd/kg body weight in pediatric patients. The study was conducted between July 2023 and October 2024 across 10 countries, in parallel with two phase 3 studies in adults using the same Gd dose. Patients were allocated to three age groups: 0-<2 y, 2-<12y, 12-<18y. Per pediatric and adult patient, three blood samples for PK assessment were taken post injection (p.i.) within predefined time-windows. Safety parameters such as adverse events and laboratory parameters were assessed up to 7 days p.i. In the exploratory efficacy analysis, pre- and post-gadoquatrane MRIs were evaluated.

RESULTS

Of the 105 screened pediatric patients, 93 received gadoquatrane, 59.1% were male. 62.4% of the patients underwent an MRI of the brain. For the PK assessment, 23 patients aged 0-<2y, 45 aged 2-<12y, and 24 aged 12-<18y were evaluable. Gd plasma concentrations and PK parameters were similar across all age groups and within the expected ranges. Comparison to concentration data in adults (with the same eGFR range) shows a large overlap within all three time windows. A tendency for slightly lower concentrations in pediatric patients at later time points can be explained by the slightly higher average eGFR. 16 (17.2%) patients experienced a treatment emergent adverse event (TEAE), 3 were reported as serious. 5 TEAEs (5.4%) were assessed as related to gadoquatrane by the investigator. Assessment of gadoquatrane MRI vs pre-contrast MRI showed increased mean visualization parameter scores from 1.0 to 3.3 for contrast enhancement, 3.2 to 3.7 for delineation and 2.7 to 2.9. for morphology. The overall clinical value of CE-MRI was moderately (21.5%) or substantially (62.4%) higher than pre-contrast.

CONCLUSION

Gadoquatrane exhibits similar PK and safety profiles across the 3 age groups of pediatric patients and the adults, allowing extrapolation of efficacy from adult to pediatric patients according to ICH guidance. Exploratory efficacy results support the extrapolation.

CLINICAL RELEVANCE/APPLICATION

Gadoquatrane is a GBCA for CE-MRI in development for all patient populations at a substantially reduced Gd (by 60%) and molecule dose (by 90%) compared to established macrocyclic GBCAs dosed at 0.1 mmol Gd/kg bw.

W2-SPPD-2 OPTIMIZING PEDIATRIC CHEST CT: SUPERIOR IMAGE QUALITY AND LOWER RADIATION DOSE WITH DEEP LEARNING RECONSTRUCTION

Ilaria Bianco, MD (*Presenter*)
Davide Ippolito, MD (*Abstract Co-Author*)
Cesare Maino, MD (*Abstract Co-Author*)
Davide G. Gandola, MD (*Abstract Co-Author*)
Cammillo R. Talei Franzesi (*Abstract Co-Author*)

PURPOSE

To compare image quality and radiation dose between deep learning-based and hybrid iterative reconstruction algorithms in unenhanced chest CT scans of pediatric patients.

METHODS AND MATERIALS

We retrospectively reviewed 142 unenhanced, single-phase chest CT scans performed for routine diagnostic purpose. 71 pediatric patients were examined using a 128-slice MDCT scanner (100 kV, automated mAs modulation) with a deep learning reconstruction (DLR) algorithm, while the control group of 71 patients underwent scanning with a 256-slice MDCT scanner (100 kV, automated mAs modulation) using hybrid iterative reconstruction algorithm. Subjective image quality was assessed using a 5-point Likert scale, and objective quality was evaluated by measuring Hounsfield Units (HU) and Standard Deviations (SD) in the lung parenchyma, air, tracheal

lumen, aorta and muscle. Radiation dose metrics (CTDIvol and DLP) were recorded for both groups, and the estimated effective dose (EED) was calculated using age-specific k-factors (0-11 months, 1-4 years, 5-9 years, and 10-16 years).

RESULTS

A total of 142 pediatric patients were included of whom 90 males and 52 females (median age of 10 years; IQR: 5-13). Inter-reader agreement for Likert scale image quality assessment was moderate (? = 0.432) with significantly higher subjective image quality scores for the DLR group compared to the iterative group (p = 0.03). Quantitatively, air and muscle attenuation values differed significantly between the two scanners (air: -994.5 vs -992 HU, p = 0.036; muscle: 49.4 vs 42.8 HU, p < 0.001). Image noise, assessed by standard deviation (SD), was significantly lower in the DLR group across the lung parenchyma (65.9 vs 81.3, p = 0.007), tracheal lumen (51.0 vs 69.8, p = 0.002), and muscle (11.7 vs 16.4, p < 0.001). Radiation dose metrics were significantly reduced in the DLR group (mean DLP: 49.6 vs 188.9 mGy*cm; CTDIvol: 1.6 vs 5.6 mGy; EED: 0.8 vs 3.2 mSv; all p < 0.001). Age-based sub-analysis using quartiles (0-5, 6-12, >13 years) confirmed a consistent threefold reduction in DLP and CTDIvol, and a fourfold reduction in EED across all age groups (all p < 0.001).

CONCLUSION

Deep learning-based reconstruction in unenhanced chest CT allows for significant radiation dose reduction in the pediatric population while delivering superior image quality compared to hybrid iterative reconstruction algorithms.

CLINICAL RELEVANCE/APPLICATION

This study supports the clinical implementation of deep learning-based reconstruction algorithm in pediatric chest CT, demonstrating that it enables substantial radiation dose reduction without compromising -but even improving- image quality, thereby enhancing diagnostic safety and accuracy in a vulnerable population.

W2-SPPD-3 ESTABLISHING ACCEPTABLE POSITIONING RANGES FOR ACETABULAR ANGLE MEASUREMENTS IN CHILDREN WITH CEREBRAL PALSY

Robert J. Smalley, MD (*Presenter*)
Delma Y. Jarrett, MD (*Abstract Co-Author*)
Andy Tsai, MD, PhD (*Abstract Co-Author*)

PURPOSE

Acetabular dysplasia often occurs in children with cerebral palsy (CP), which can lead to hip dislocations. The typical approach to assess for acetabular dysplasia is to measure the acetabular angle (AA) on anteroposterior (AP) pelvic radiograph. However, AA measurements rely on proper patient positioning, which may be difficult to achieve in CP patients. Knowing the effects of patient positioning on AA measurements may inform technologists on how best to position them. This study aimed to determine the effects of patient position on AA measurements in children with CP.

METHODS AND MATERIALS

Children with CP (=18-years-old) with pelvis CT and AP pelvis radiograph obtained <6 months apart (10/18-11/21) were identified. Digitally reconstructed radiographs were generated from each pelvis CT, to simulate nine different patient positions: neutral; 10° and 20° lordosis and kyphosis; and 10° and 20° right rotation and left rotation. Two pediatric radiologists measured AAs from the simulated and real pelvis radiographs. Spearman's rho was used to assess inter-rater reliability, and Wilcoxon signed rank test was used to determine statistical significance. Median absolute difference (MAD) and interquartile range (IQR) were also calculated. Taking simulated radiographs in neutral position as ground truth, we calculated MAD for each deviation of the simulated radiograph from neutral.

RESULTS

Sixty-three children (male=41; median age=8 years; range=4-18 years) were studied. On real radiographs, the two radiologists' AA measurements showed good correlation (rho=0.90, MAD=5° [IQR=2-7°]). On simulated radiographs, inter-rater reliability was either good (rho=0.75-0.90) or excellent (rho >0.90), except for simulated radiographs with 20° lordosis (rho=0.49, MAD=10° [IQR=5-14°]) which showed poor inter-rater reliability. When compared to ground truth neutral position simulated radiographs, correlation with the measurements obtained from the real radiographs was good (rho=0.89, MAD=3° [IQR=1-5°]). Similar values were obtained in simulated radiographs with kyphosis, lordosis, and rotation of 10°. However, MAD was increased at kyphosis, lordosis, and rotation of 20°. This was most pronounced at 20° lordosis (rho=0.64, MAD=6° [IQR=2-10°]).

CONCLUSION

At pelvic deviations of 20° from neutral, measurement error and inter-reader reliability decreased substantially, and is most pronounced in lordosis.

CLINICAL RELEVANCE/APPLICATION

This suggests a possible unacceptable range of deviation from neutral when obtaining pelvic radiographs in children with CP.

W2-SPPH-1 INTENSITY-MODULATED INVERSE GEOMETRY BEAM CT SCAN TO IMPROVE THE VISIBILITY OF REGION OF INTEREST

Tiezhi Zhang, PhD (*Presenter*)
Ziyu Shu (*Abstract Co-Author*)
Shuang Zhou, MS (*Abstract Co-Author*)
Liuxing Shen, PhD (*Abstract Co-Author*)
Ashish V. Avachat, PhD (*Abstract Co-Author*)
Mark Anastasio (*Abstract Co-Author*)
Kaiyi Yang (*Abstract Co-Author*)

PURPOSE

CT resolution is limited by X-ray exposure. In this study, we performed a feasibility study of an inverse geometry CT (IGCT) design that can improve the visibility of the region of interest through in-plane X-ray flux modulation.

METHODS AND MATERIALS

IGCT incorporates a linear array X-ray source and a linear array detector, oriented within and orthogonal to the rotation plane, respectively. A multi-slot collimator mounted on the X-ray tube shapes the emitted radiation into narrow fan beams, which are received by a multi-row photon-counting detector array. During acquisition, the system rotates slowly around a central axis, while X-ray beams rapidly scan across the subject with predetermined intensity. The intensity of each X-ray beam can be independently modulated based on the location of the region of interest (ROI), enabling accurate reconstruction of the ROI without significantly increasing the total radiation dose. The use of narrow collimated beams and photon-counting detectors also enhances scatter rejection, improving image contrast and quantitative fidelity. A benchtop prototype is currently under development, incorporating a 24-emitter linear X-ray source array and a dedicated image reconstruction algorithm.

RESULTS

Numerical experimental results indicate that even without considering the significant advantage of iGCT in suppressing scattering effects, its reconstruction accuracy is comparable to, or even better than, that of CBCT. The experiment on the Shepp-Logan phantom demonstrates the effectiveness of in-plane flux modulation, enabling high-accuracy reconstruction of the region of interest (ROI) under low total dose conditions.

CONCLUSION

In addition to maintaining scatter suppression through its narrow-beam geometry, iGCT further enables substantial dose reduction through flux modulation and achieves unprecedented resolution in selected regions of interest.

CLINICAL RELEVANCE/APPLICATION

Super-resolution CT is highly desirable for dentistry and otolaryngology clinics. For example, it enables visualization of auditory and vestibular components such as hair cells, otoliths, membranes, ions, and vasculature. In dentistry, high-resolution imaging is essential for visualizing root canal anatomy during endodontic treatment. However, the image resolution and soft tissue contrast of traditional CT systems are limited by concerns over X-ray exposure. In this study, we introduce iGCT, a system that enables dynamic flux modulation during scanning, allowing for unprecedented resolution without delivering excessive radiation to patients.

W2-SPPH-2 IMPROVED NON-RIGID REGISTRATION OF CHEST CT WITH WAVELET ENCODING AND CURRICULUM LEARNING: TOWARD ACCURATE LONGITUDINAL COMPARISON

Yamato Kohara (*Presenter*)
Ryohei Nakayama, PhD (*Abstract Co-Author*)
Motonori Nagata, MD, PhD (*Abstract Co-Author*)
Yasutaka Ichikawa, MD (*Abstract Co-Author*)
Hajime Sakuma, MD, PhD (*Abstract Co-Author*)

PURPOSE

Deep learning-based non-rigid registration often struggles in the lung field regions due to the scarcity of characteristic signal patterns. This study aimed to develop a robust non-rigid registration method leveraging wavelet encoding and curriculum learning to improve alignment accuracy.

METHODS AND MATERIALS

The training dataset included 59 normal chest CT volumes, while the test dataset consisted of 101 cases of both past and current normal chest CT volumes from the same patients. The proposed model consisted of two encoders and one decoder. The moving and fixed CT volumes were first decomposed into high-frequency and low-frequency components using wavelet transformation. The corresponding frequency components were then concatenated and input to the encoders designated for each frequency type. The two encoders independently analyzed these components, extracting coarse structural and overall information from the low-frequency components while capturing local details such as edges and textures from the high-frequency components. The decoder integrated them and predicted the displacement vector needed to align the moving and fixed CT volumes. In training the proposed model, the training CT volume was deformed using a nonlinear displacement vector generated based on random numbers. The proposed model was trained to predict the displacement vector from the volumes before and after deformation. Here, curriculum learning was introduced, beginning with small random numbers for generating the displacement vector and gradually increasing them as the training progressed.

RESULTS

The Dice coefficient, root mean squared error (RMSE), and structural similarity index (SSIM) for the proposed method were 0.97, 146.29, and 0.879, respectively. These results indicated a significant improvement compared to VoxelMorph, which had a Dice coefficient of 0.695 ($P < .001$), RMSE of 299.89 ($P < .001$), and SSIM of 0.695 ($P < .001$).

CONCLUSION

The non-rigid registration method developed in this study achieved high-precision alignment of chest CT volumes compared to the widely used conventional model, VoxelMorph.

CLINICAL RELEVANCE/APPLICATION

The developed non-rigid registration method enables high-precision alignment of chest CT volumes, which has the potential to support the detection of subtle temporal changes in lesions and the assessment of treatment effects.

W2-SPPH-3 CHARACTERIZATION OF FOCAL SPOT SIZE'S EFFECT ON MSK IMAGE SHARPNESS FOR DEEP SILICON PHOTON COUNTING

Timothy P. Szczykutowicz, PhD (*Presenter*)
Aria Salyapongse, MSc (*Abstract Co-Author*)
Krista McClure (*Abstract Co-Author*)
Zahra Alyani Nezhad, MSc (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
Greg D. Avey, MD (*Abstract Co-Author*)
Brian K. Markhardt, MD (*Abstract Co-Author*)
Nicholas C. Laucis, MD (*Abstract Co-Author*)
Scott Slavic, MS (*Abstract Co-Author*)
Zhye Yin (*Abstract Co-Author*)
Dean Zsenak (*Abstract Co-Author*)
Giuseppe V. Toia, MD, MS (*Abstract Co-Author*)

PURPOSE

To characterize the impact of focal spot size and image sharpness on a prototype deep silicon-based (dSi) photon counting detector (PCD) CT system.

METHODS AND MATERIALS

A prototype dSi PCD CT system was used to acquire 6 human subject MSK scans. Two unique subjects were scanned under prospective IRB approval; subject 1 was scanned using 4 focal spot sizes (extra small (XS), small (S), large (L), and extra large (XL)) over the knee, subject 2 using 2 focal spot sizes (XS and L) over the spine. Trabecular bone sharpness was assessed using a quantitative metric which counts the fraction of pixels within a trabecular bone region between the 0-25 th and 75-100 th percentiles (i.e., this method penalizes blurred pixels near bone and only counts true trabecular bone and true marrow) of Hounsfield units. Line profiles through bone margins were also measured.

RESULTS

Trabecular bone sharpness metric results were higher for the smaller focal spot sizes in both subjects. The knee sharpness scores were 0.50, 0.45, 0.38, and 0.33 for the knee corresponding to XS, S, L, and XL focal spots sizes, respectively. Sharpness scores for the spine were 0.50 and 0.45 for the spine, respectively. All scores were statistically significantly different ($p<0.005$) within the knee and spine subjects across focal spots. Hounsfield unit profiles exhibited higher values for smaller focal spot sizes, with the highest values for the XS focal spot on the knee and XS on the spine subject. Trabecular bone detail was essentially "washed out" when the XL focal spot was used.

CONCLUSION

Using a quantitative trabecular bone metric, smaller focal spots provided higher levels of bone detail. Line profiles also demonstrated smaller focal spots enabled higher peak boney details and narrower profiles (i.e., less blurring).

CLINICAL RELEVANCE/APPLICATION

Photon-counting detector CT undoubtedly allows higher spatial resolution compared to energy integrating scans. However improper scan settings can produce images with resolution worse than energy integrating scanners. In protocols designed to scan quickly but retrospective reformats of boney detail may be desired, such as trauma protocols with spine reformats, higher tube currents (i.e., larger focal spots) are utilized, which makes this concern about focal spot size and boney detail especially important.

W2-SPPH-4 TASK-BASED IMAGE QUALITY ASSESSMENT OF THREE DUAL-ENERGY CT PLATFORMS AND ONE PHOTON-COUNTING CT ON LOW-KEV VIRTUAL MONOENERGETIC IMAGES

Joel Greffier, PhD (*Presenter*)
CECILE SALVAT (*Abstract Co-Author*)
Lama HADID (*Abstract Co-Author*)
Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*)
Djamel Dabli (*Abstract Co-Author*)

PURPOSE

To compare the spectral performance of three dual-energy CT (DECT) platforms and one photon-counting CT (PCCT) on virtual monoenergetic images (VMIs) at low-energy levels.

METHODS AND MATERIALS

A multi-energy CT phantom (Sun Nuclear) was scanned on a PCCT (Naeotom Alpha, Siemens Healthineers) and three DECT platforms: rapid kV-switching CT (KVSCT-Canon, Aquilion One Insight, Canon Medical Systems), ultrafast kV-switching (KVSCT-GE, Revolution Apex, GE Healthcare) and dual-layer CT (DLCT, CT7500, Philips Healthcare). For CT systems, acquisitions were made using classical abdomen-pelvic examination parameters and a CTDI vol at 11 mGy. Raw data were reconstructed using a slice thickness close to 1.5 mm and QIR level 3 for PCCT, DLSR level 2 for KVSCT-Canon, TrueFidelity medium level for KVSCT-GE and Spectral level 4 for DLCT. Noise power spectrum (NPS) and task-based transfer function (TTF) were evaluated from 40 to 70 keV of VMIs. A detectability index (d') was computed to model the detection task of two contrast-enhanced lesions according to keV.

RESULTS

Noise magnitude decreased from 40 to 70 keV for all DECT platforms and this decrease was greater for KVSCT-Canon (-80.2%) and less for DLCT (-14.8%). At 40 keV, the highest noise magnitude values were found for KVSCT-GE and KVSCT-Canon and the lowest for PCCT and DLCT. The average NPS spatial frequency (f av) values decreased from 40 to 70 keV (0.27 to 0.19 mm -1) for KVSCT-Canon, increased for DLCT (0.20 to 0.26 mm -1) but were similar for KVSCT-GE (0.21 ± 0.01 mm -1) and PCCT (0.23 ± 0.01 mm -1). For both blood-mimicking material plus iodine inserts at 2 and at 4 mg/ml, TTF at 50% (f 50) values increased from 40 to 70 keV. For all keV and both inserts, the highest f 50 values were found for PCCT and DLCT and the lowest for KVSCT-GE and KVSCT-Canon. For both contrast-enhanced lesions, d' values decreased from 40 to 70 keV for PCCT, DLCT and KVSCT-GE. For KVSCT-Canon, d' values peaked at 60 keV. At 40 and 50 keV, the highest d' values were found with PCCT and at 60 and 70 keV for KVSCT-Canon.

CONCLUSION

For KVSCT-Canon, the detectability of contrast-enhanced lesions was highest at 60 keV. The highest d' values were found with PCCT at 40 and 50 keV.

CLINICAL RELEVANCE/APPLICATION

For the first time, this study compared image and noise texture, spatial resolution and lesion detectability on DECT platforms incorporating the latest technological innovations from the four main CT manufacturers. At this stage, the results of the study need to be validated in clinical practice at low energy levels for the detection and/or characterization of abdominal lesions.

W2-SPPH-6 APPROPRIATENESS OF MATERIALS FOR K-EDGE IMAGING ON A DEEP SILICON PHOTON-COUNTING CT

Rick R. Layman, PhD (*Presenter*)
Zhye Yin (*Abstract Co-Author*)
Scott Slavic, MS (*Abstract Co-Author*)
Megan C. Jacobsen, PhD (*Abstract Co-Author*)

PURPOSE

K-edge imaging is a promising photon-counting CT (PCCT) application, but it is imperative to ensure the energy bins are properly assigned and calibrated for accurate material differentiation and quantification.

METHODS AND MATERIALS

5-mL NIST-traceable aqueous standards (10, 5, 2.5, 1.0 and 0.5 mg/mL) were prepared for eight elements [k-edge]: cesium [36.0 keV], gadolinium [50.2 keV], holmium [55.6 keV], ytterbium [61.3 keV], tantalum [67.4 keV], tungsten [69.5 keV], gold [80.7 keV], and bismuth [90.5 keV] (Inorganic Ventures; Christiansburg, VA & Gadavist; Whippany, NJ). Standards were placed in the inner radius of a multi-energy CT phantom (Mirion; Atlanta, GA). Axial images were acquired using a prototype dSi PCCT system (GE Healthcare; Waukesha, WI) with the following parameters: 120 kVp, 50 cm SFOV, 0.6 s rotation time, 600 mA, 1.2 mm focal spot and 40 mm collimation. Energy bins of the system were calibrated to [33,44), [44,52), [52,60), [60,80), and [80,120] keV. Bin images were reconstructed with a prototype using standard kernel, 0.42 mm slice thickness/interval and 22 cm display FOV. Plots of concentration (mg/mL) versus CT number (HU) for the k-edge containing and adjacent higher energy bins were generated for each element. Materials were considered fully resolved with PCCT if CT number was higher in one bin across all concentrations. We calculated the difference in elemental k-edge and lower threshold energy of the k-edge containing bin, defined as k-edge difference. This value was plotted against the percent attenuation difference of CT numbers (HU) in energy bins for the 10 mg/mL standards.

RESULTS

Using this set of calibrated energy bins, 2/8 materials (gadolinium and cesium) were fully resolved, with separated energy bins. Conversely, crossover between the low and high energy bins was observed for all other materials. Crossover could impact quantitative accuracy and compromise the detection limit for this energy bin configuration. Percent attenuation difference between bins was highest when the k-edge difference was small. There was a linear decrease in attenuation change between bins versus k-edge difference with a loss of 3.5% per additional keV of K-edge difference (R 2 = 0.85). Ytterbium (K-edge difference = 1.3 keV) had the highest percent difference between bins (40.9%), while bismuth (K-edge difference = 10.5 keV) had the lowest (1.7%).

CONCLUSION

For a given calibrated set of PCCT energy bins, optimal k-edge materials have small k-edge differences. Future work will investigate the detection limit for various k-edge materials.

CLINICAL RELEVANCE/APPLICATION

K-edge imaging may enable introduction of new contrast agents to the CT market for new imaging applications. dSi PCCT makes quantification of these materials feasible.

W2-SPPH-7 ASSESSING THE UTILITY OF PHOTON-COUNTING CT IN OBESE PATIENTS

Leening P. Liu, PhD (*Presenter*)
Kai Mei, PhD (*Abstract Co-Author*)
Shobhit Sharma, PhD (*Abstract Co-Author*)
Steven Ross, PhD (*Abstract Co-Author*)
Sandra S. Halliburton, PhD (*Abstract Co-Author*)
Naruomi Akino (*Abstract Co-Author*)
Ali H. Dhanaliwala, MD, PhD (*Abstract Co-Author*)
Leonid Roshkovan, MD (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

Photon-counting CT (PCCT) offers key advantages over energy integrating detector CT (EID-CT), especially in low-dose scans and imaging larger patients. As obesity rates rise, minimizing image noise is critical for diagnostic accuracy. This study evaluated the dose efficiency of a PCCT prototype using phantoms representing a range of patient sizes.

METHODS AND MATERIALS

A 3D-printed anthropomorphic pancreas phantom and the inner 20 cm section of a multi-energy CT phantom were scanned with extension rings representing the 50 th , 75 th , 85 th , and 95 th percentiles of adult waist circumference in the U.S. (elliptical diameters of 32 x 32, 30 x 40, 33 x 43, 37 x 47 cm / water equivalent diameters of 32, 34, 37, 39 cm, respectively). Scans were performed on an EID-CT (Aquilion One Insight Edition, Canon Medical Systems Corporation) and CZT PCCT prototype (Canon Medical Systems Corporation) at a tube voltage of 120 kVp and dose levels (CTDI vol) of 0.5 to 19 mGy. Images were additionally acquired for each scanner and phantom size to match the noise magnitude of PCCT filtered back projection (FBP) images of the 95 th percentile phantom at 15.5 mGy. Noise was measured on FBP to compare the noise-dose relationship between scanners. Noise-matched doses were also recorded to determine dose reduction with PCCT.

RESULTS

Improved noise performance was observed with increasing phantom size across doses. At matched phantom size and dose, PCCT demonstrated increased noise reduction relative to EID-CT as phantom size increased and dose decreased. Noise was 20 ± 9 HU less with PCCT compared to that of EID-CT with the 95 th percentile phantom at 19 mGy. This difference in noise between scanners increased at 2 mGy to 64 ± 23 HU. Smaller noise reductions of 4 ± 6 and 16 ± 10 HU were observed for the 50 th percentile phantom at 19 and 2 mGy, respectively. To match PCCT noise of the 95 th percentile phantom at 15.5 mGy, radiation doses of 7.6, 5.4, and 2.7 mGy were required for the 85 th , 75 th , and 50 th percentile phantoms, respectively. The corresponding noise-matched doses in EID-CT were 27.6, 11.8, 7.7, and 4.3 mGy for 95 th , 85 th , 75 th , and 50 th percentile phantoms, respectively, highlighting an average dose reduction of 36%.

CONCLUSION

PCCT yielded enhanced dose efficiency with lower noise compared to EID-CT at a fixed dose, enabling an average dose reduction of 36% across varying phantom sizes. This improvement is particularly impactful at larger phantom sizes and lower doses, enabling effective imaging of obese patients without compromising the image quality necessary for precise disease diagnosis and monitoring.

CLINICAL RELEVANCE/APPLICATION

This dose efficiency has important clinical implications, enabling lower dose imaging protocols for obese patients without compromising diagnostic accuracy.

W2-SPPH-8 COMPLEXED SIGNAL AVERAGE METHOD: UTILITY FOR IMPROVING DIFFERENTIATION CAPABILITY OF MALIGNANT FROM BENIGN PROSTATIC AREAS ON CONVENTIONAL DWIS AT STANDARD AND ULTRA-HIGH-B VALUES

Takahiro Ueda, MD, PhD (*Presenter*)
Natsuka Yazawa (*Abstract Co-Author*)
Kaori Yamamoto (*Abstract Co-Author*)
Yuichiro Sano, RT (*Abstract Co-Author*)
Masato Ikedo (*Abstract Co-Author*)
Masanori Ozaki (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)
Yoshiharu Ohno, MD, PhD (*Abstract Co-Author*)

PURPOSE

Diffusion-weighted imaging (DWI) has been suggested as more useful for differentiation between malignant and benign prostatic areas, when applied ultra-high b value as compared with standard b value. Recently, complexed signal average (CSA) method is tested to improve ADC measurement and normal structure visualization on DWI, especially applying higher b value. The purpose of this study was to directly compare quantitative and qualitative image qualities and differentiation accuracy of malignant from benign prostatic areas among prostatic DWIs obtained with and without CSA, when applied standard and ultra-high b values.

METHODS AND MATERIALS

54 suspected prostatic cancer patients prospectively underwent DWIs at standard (b= 1500 s/mm 2 : cDWI) and ultra-high (b=3000 s/mm 2 : UH-DWI) b values by applying CSA or standard (non-CSA) methods. According to pathological results, 93 malignant areas and 93 computationally selected benign areas were determined. For quantitative image quality assessments, signal-to-noise ratio (SNR) and apparent diffusion coefficient (ADC) of each area and contrast-to-noise ratio (CNR) between two areas were assessed by ROI measurements on all DWIs. Overall image quality, artifact and malignant area conspicuity were also evaluated by 5-point scales on each DWI. Then, all quantitative indexes were compared each other by Tukey's HSD test. Each qualitative index was compared by Wilcoxon's signed-rank test. Finally, ROC analysis was performed to compare diagnostic performance among all DWIs. Then, sensitivity, specificity and accuracy were compared among all DWIs by McNemar's test.

RESULTS

At each b value, SNR and CNR of cDWI with CSA were significantly higher than those with non-CSA ($p<0.05$). Moreover, SNR and CNR of cDWI with CSA were significantly higher than those of UH-DWI with CSA and non-CSA ($p<0.05$). Overall image quality and artifact of cDWI with CSA or non-CSA showed significant difference with those of each UH-DWI ($p<0.05$). Area under the curves (AUC) of cDWI with CSA (AUC=0.93) and UH-DWI with CSA (AUC=0.95) were significantly larger than that of cDWI with non-CSA (AUC=0.88, $p<0.05$). Moreover, AUC of UH-DWI with CSA was significantly higher than that of UH-DWI with non-CSA (AUC=0.92, $p<0.05$).

CONCLUSION

CSA mainly improves quantitative or qualitative image qualities and differentiation accuracy of malignant from benign prostatic areas on DWI with standard and ultra-high b values.

CLINICAL RELEVANCE/APPLICATION

CSA mainly improves quantitative or qualitative image qualities and differentiation accuracy of malignant from benign prostatic areas on DWI with standard and ultra-high b values.

W2-SPPH-9 IMPROVING IMAGE QUALITY AND DIAGNOSTIC CONFIDENCE FOR PATIENTS WITH HEMATURIA USING LOW-ENERGY AND THIN-SLICE VIRTUAL MONOENERGETIC IMAGES WITH DEEP LEARNING IMAGE RECONSTRUCTION

Yannan Cheng, BS,BS (*Presenter*)
Jianying Li, PhD (*Abstract Co-Author*)
Jianxin Guo (*Abstract Co-Author*)

PURPOSE

This study aimed to explore whether the use of low-energy and thin-slice virtual monoenergetic images (VMI) with deep learning image reconstruction (DLIR) in dual-energy CT Urography (DECTU) could improve the image quality and diagnostic confidence for patients with hematuria.

METHODS AND MATERIALS

Sixty-three patients who underwent DECTU were included in this study (Table 1). DECTU images in the portal phase were reconstructed at 1.25mm for the 70keV VMI with 60% adaptive statistical iterative reconstruction-Veo (ASIR-V60%) and 0.625mm for the 40keV VMI with three levels of DLIR (DLIR-L/DLIR-M/DLIR-H). Quantitative parameters (CT number, noise, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and edge rise slope (ERS)) were measured (Figure 1). Two experienced radiologists evaluated subjective values (image contrast, noise, sharpness, lesion conspicuity and diagnostic acceptability) using a 5-point scale (Table 2). Results were compared among the above four reconstruction protocols.

RESULTS

In comparison with the 1.25mm-70keV-ASiR-V60% images, the 0.625mm-40keV-DLIR-M and DLIR-H images had higher scores in subjective evaluation values (all $p<0.05$), with similar scores found between DLIR-M and DLIR-H images (Table 3, Figure 2 and 3). The 0.625 mm-40keV DLIR-H images had higher CT number, SNR, CNR for all abdominal structures and higher ERS for the main portal vein than the 1.25 mm-70keV-ASiR-V60% images (Table 4).

CONCLUSION

DLIR-H improves image contrast and sharpness and diagnostic confidence for patients with hematuria using 40keV VMI at thinner slice in DECTU.

CLINICAL RELEVANCE/APPLICATION

When diagnosing urinary diseases using VMI images at thinner slice and low-energy, it is recommended to use DLIR-H algorithm to obtain satisfactory image quality and diagnosis confidence with higher SNR, CNR, sharpness and lesion conspicuity.

W2-SPPH-10 C-FLAIR: FLUID ATTENUATED INVERSION RECOVERY WITH CONTROLLED CEREBROSPINAL FLUID SUPPRESSION

Christina Graf, PhD (*Presenter*)
Alexander Jaffray (*Abstract Co-Author*)
Armin Rund (*Abstract Co-Author*)
Stefan Steinerberger (*Abstract Co-Author*)
David K. Li, MD (*Abstract Co-Author*)
Alexander Rauscher, PhD, MSc (*Abstract Co-Author*)

PURPOSE

In fluid attenuated inversion recovery (FLAIR) magnetic resonance imaging (MRI) sequences of the brain, suppression of cerebrospinal fluid fails in the presence of strong inhomogeneities of the static magnetic field, resulting in artifactual bright signal which may obscure normal anatomy or mimic pathology. The purpose of our study was suppress artifacts in FLAIR MRI with an optimized radiofrequency pulse for inversion.

METHODS AND MATERIALS

A robust inversion pulse was designed using optimal control, incorporating robustness against field inhomogeneities directly into the cost function for pulse optimization. Experimental data with the conventional and the new inversion pulse were acquired and compared at 3 T in a phantom that exhibits strong inhomogeneities in the static magnetic field and in human participants (3 healthy volunteers, 2 patients with multiple sclerosis, one person with persistent symptoms from a concussion, 2 persons with asymptomatic white matter hyperintensities). Images were acquired with 1 cubic mm isotropic resolution, inversion time (TI) = 2400 ms, repetition time (TR) = 8000 ms, effective echo time (TE) = 300 ms. Images were assessed by a neuroradiologist with 42 years of experience.

RESULTS

In the phantom, FLAIR with controlled inversion (C-FLAIR) exhibits nearly perfect inversion in the presence of inhomogeneities in the static magnetic field, resulting in the removal of bright artifactual signal that is seen with the conventional inversion pulse. In human participants, such bright signal is near the nasal sinus with the conventional pulse but absent with the controlled inversion. Image contrast of demyelinating lesions in multiple sclerosis and in white matter hyperintensities is identical for the optimized pulse and the conventional pulse.

CONCLUSION

C-FLAIR with a robust radio frequency inversion pulse shows practical elimination of artifacts caused by incomplete inversion.

CLINICAL RELEVANCE/APPLICATION

The new type of radiofrequency pulse for inversion requires no modifications to the scanner hardware and no new data sampling and reconstruction approaches. The method can be easily adopted into routine MRI, with direct beneficial clinical impact.

W2-SPPH-11 PHOTON-COUNTING CT OUTPERFORMS CONE-BEAM CT FOR IMAGING OF ROOT-FILLED TEETH

Maximilian Russe, MD (*Presenter*)
Markus Altenburger (*Abstract Co-Author*)
Alexander Rau, MD (*Abstract Co-Author*)
Anna Fink (*Abstract Co-Author*)
Elias Kellner (*Abstract Co-Author*)
Fabian Bamberg, MD, MPH (*Abstract Co-Author*)
Britta A. Jung (*Abstract Co-Author*)
Martin Peter Pichotka (*Abstract Co-Author*)
Wiebke Semper Hogg (*Abstract Co-Author*)
Stephan Rau, MD (*Abstract Co-Author*)

PURPOSE

This study quantitatively evaluates a clinical photon-counting-detector CT (PCD-CT) against a dedicated dental cone-beam CT (CBCT) for the visualization and measurement of submillimeter structures like accessory canals in root-filled teeth using a standardized bovine-tooth phantom.

METHODS AND MATERIALS

A jaw phantom was assembled from four bovine incisors instrumented with ProTaper Next and obturated with gutta-percha/AH+ sealer, then embedded in bovine rib. Five artificial accessory canals (diameters 1,000 µm, 800 µm, 600 µm, 400 µm, 200 µm; ±1 µm tolerance) were milled perpendicular to each root axis. The phantom underwent three repositioned scans on a Siemens NAEOTOM Alpha PCD-CT (120 kVp, 28 mAs, 1024 × 1024 matrix, 0.2 mm slices with 0.1 mm increment, QIR strength 3) and a Planmeca Viso G7 CBCT (100 kVp, 9 mA, 150 µm voxels, 30 × 50 mm FOV). Reference scans were performed at a Bruker SkyScan 1276 micro-CT (100 kVp, 17.5 µm binned pixels). Accessory canals were deemed detectable if their signal dip exceeded twice the standard deviation of adjacent noise. Canal widths were measured by full-width at half-minimum and compared to micro-CT to compute metric errors. Blooming artifacts from fillings were quantified at full-width at half-maximum. Radiation exposure was recorded as CTDIvol and DLP for CT and as DAP for CBCT. All results are reported as median [IQR], and modality comparisons employed Wilcoxon signed-rank tests (a = 0.05).

RESULTS

PCD-CT demonstrated superior performance in detecting accessory canals as it detected 100% of canals = 400 µm and 81.5% of 200 µm canals. CBCT detected 100% of canals = 800 µm, 83.3% at 600 µm, 47.2% at 400 µm, and 0% at 200 µm. Relative errors for PCD-CT remained = 5.2% for canals = 600 µm (17.7% at 400 µm; 115.9% at 200 µm) compared with 15.6-35.1% for CBCT (no data as no detection for 200 µm). Median absolute errors ranged from 29 µm to 67 µm for PCD-CT (204 µm at 200 µm) versus 105 µm to 173 µm for CBCT. Blooming was significantly lower for PCD-CT in two of four teeth ($p = 0.0039, 0.0078$), equivalent in one ($p > 0.99$), and higher in one ($p = 0.027$). Dose metrics were CTDIvol 4.85 [4.84-5.04] mGy and DLP 41.2 [41.2-43.0] mGy·cm for PCD-CT versus DAP 274 mGy·cm² for CBCT.

CONCLUSION

PCD-CT significantly outperforms dental CBCT in both detection and measurement accuracy for submillimeter accessory canals in root-filled teeth, while matching or reducing artifact distortion at clinically acceptable dose levels.

CLINICAL RELEVANCE/APPLICATION

The superior spatial resolution and artifact mitigation of PCD-CT promise improved detection of untreated accessory canals, better guidance for endodontic retreatment procedures, and the potential for opportunistic, high-resolution dental screening on routine head-and-neck CT examinations.

W2-SPVA-3 APPLICATION OF MULTI TRACKER TECHNOLOGY ON NEUVIZ EPOCH CT IN ONE-STOP ABDOMINAL CONTRAST-ENHANCED CT AND INFERIOR VENA CAVA CTV IMAGING: A PROPENSITY SCORE MATCHING CONTROLLED STUDY

Tianhe Ye (*Presenter*)
Wei Chen (*Abstract Co-Author*)

PURPOSE

To investigate the clinical value of NeuViz Epoch CT's Multi Tracker technology in achieving one-stop abdominal contrast-enhanced CT and inferior vena cava computed tomography venography (CTV) during a single examination.

METHODS AND MATERIALS

A retrospective analysis included 38 patients in the case group who underwent one-stop imaging for abdominal enhancement and inferior vena cava-phase CTV using intelligent tracking technology (Multi Tracker) between January and December 2024, and 115 patients in the control group who underwent conventional delayed scanning for inferior vena cava CTV. With scanning methods as the intervention variable and gender, age, and body mass index (BMI) as covariates, a balanced cohort (n=76) was constructed via propensity score matching (PSM, 1:1 nearest-neighbor matching with a caliper of 0.05). Subjective Likert scores for the portal vein (PV), inferior vena cava (IVC), and hepatic veins (HV), as well as objective metrics including CT values, noise (SD), signal-to-noise ratio (SNR), and contrast-to-noise ratio efficiency (CNR Efficiency), were compared between groups.

RESULTS

Covariate Balance: After matching, no significant differences were observed in sex (P=0.63), age (P=0.37), or BMI (P=0.23), eliminating confounding bias. Subjective Evaluation: The Multi Tracker group demonstrated significantly higher proportions of high-grade scores (4-5) for PV, IVC, and HV compared to the conventional group (all P<0.001), indicating substantially improved vascular visualization. Objective Metrics: The Multi Tracker group showed significantly higher liver CT values (P<0.001) and lower noise (P<0.001), reflecting superior image uniformity and contrast. Vascular quantitative parameters - CT values, SNR, and CNR Efficiency for PV, IVC, and HV - were all significantly better in the Multi Tracker group (all P<0.001), indicating enhanced vascular border clarity and tissue contrast.

CONCLUSION

This technology provides a robust imaging foundation for clinicians to conduct preoperative evaluations and extract three-dimensional venous bundle models of the portal vein, hepatic vein, and inferior vena cava, thereby enabling clinicians to gain a deeper understanding of the anatomical interrelationships among intrahepatic veins and highlighting its significant clinical value.

CLINICAL RELEVANCE/APPLICATION

High-efficiency imaging: This technology improves efficiency, reduces examination time and visits, and enhances the medical experience. Image quality: This technology provided higher quality of liver and intrahepatic veins. Clinical value: This technology is valuable and expected to be widely adopted for abdominal imaging, optimizing workflows and improving patient outcomes.

W5A-SPBR-1 PREDICTIVE VALUE OF DCE-MRI TUMOR HABITATS FOR ESTROGEN RECEPTOR (ER) EXPRESSION IN BREAST CANCER

Ziyi Mao (*Presenter*)
Qi Wang (*Abstract Co-Author*)
Hui Liu (*Abstract Co-Author*)
Haifa Liu (*Abstract Co-Author*)
Mengzhu Wang (*Abstract Co-Author*)
Yang Song (*Abstract Co-Author*)

PURPOSE

This study aims to assess the feasibility and accuracy of a prediction model using DCE-MRI based tumor habitats to forecast ER expression in malignant breast cancer.

METHODS AND MATERIALS

This retrospective study included 85 patients with pathologically confirmed invasive ductal carcinoma of the breast(24 ER-negative, 61 ER-positive). All underwent 3.0T breast MRI. After intravenous injection of contrast agent(0.2 mmol/kg) at a rate of 3mL/s followed by a 10-mL saline flush, DCE-MRI was acquired under free-breathing conditions for 8 minutes and 25 seconds. The scanning parameters were as follows: time resolution = 3s, field of view (FOV) = 380 × 380 mm 2 , matrix = 380 × 320, voxel size = 1.2 × 1.2 × 2.5 mm 3 . Pharmacokinetic parameters (K trans , Ve) were derived from the vendor-specific software. Volumes of interest (VOIs) were manually delineated on T1-weighted images using 3D Slicer (version 5.2.2). Subsequently, Tumor habitats based on distinct perfusion and microenvironmental characteristics were segmented using voxel-wise K trans and Ve values through K-means clustering with an in-house developed software. Three distinct tumor habitats were identified: Habitat 1 (Ve low K trans low), Habitat 2 (Ve low K trans high) , and Habitat 3 (Ve high K trans low). First-order features were extracted per habitat and compared between ER groups using Mann-Whitney U test. Features with p <0.05 were incorporated into a logistic regression model, with feature selection and model validation rigorously embedded in leave-one-out cross-validation (LOOCV) to ensure robustness. Final performance was evaluated by AUC, accuracy, sensitivity, specificity, and F1-score, with metrics averaged across all iterations.

RESULTS

Through LOOCV, 13 features were uniquely identified from Habitat 1. Among these, the top 6 features (Volume, Skewness, Mean Absolute Deviation, Kurtosis of Ve and Volume, Variance of K trans) demonstrated high stability and importance, appearing in all 85 iterations. The logistic regression model based on these features exhibited appropriate predictive performance with an AUC of 0.730 (95% CI: 0.608-0.853), accuracy of 0.741, sensitivity of 0.787, specificity of 0.625, F1-score of 0.814, Brier score of 0.179 and Hosmer-Lemeshow (HL) test p value of 0.949(? 2 =2.753, df=8).

CONCLUSION

Our logistic regression model, based on DCE-MRI-derived habitat features, effectively captures intratumoral heterogeneity and predicts ER expression in breast cancer. Notably, all discriminative features were localized to Habitat 1 (Ve low K trans low), highlighting its particular predictive value.

CLINICAL RELEVANCE/APPLICATION

This tumor habitat-based approach demonstrates clinical utility in guiding treatment decisions and improving patient outcomes.

W5A-SPBR-3 A PHYSICAL BREAST PERFUSION PHANTOM FOR VALIDATING BACKGROUND PARENCHYMAL ENHANCEMENT QUANTIFICATION IN X-RAY IMAGING

Liselot Goris, MSc (*Presenter*)
Gustavo Pacheco (*Abstract Co-Author*)
Ioannis Sechopoulos, PhD (*Abstract Co-Author*)

PURPOSE

To develop a physical breast perfusion phantom that includes different known amounts of background parenchymal enhancement (BPE) for contrast-enhanced spectral mammography (CESM) to serve as a test object for optimization and validation of quantitative BPE assessments.

METHODS AND MATERIALS

The phantom consists of a 3D-printed shell, modelled after the average-shaped compressed breast, with a shell thickness of 1.5 mm of clear resin to represent skin, and filled with coconut oil to simulate fatty tissue. A fillable 3D-printed fibroglandular tissue (FGT) insert, based on a patient model of FGT distribution, is added to the phantom. For intensity-based assessment, the FGT insert was filled with water with varying iodine concentrations (0, 0.2, 0.4, 0.6, 0.8, 1, and 2 mg I/mL). Volume-based enhancement differences are simulated by printing known amounts of resin cylinders inside the FGT insert, occupying 25%, 50% and 75% of the total volume and area to mimic non-enhancing FGT and filling the remaining volume with contrast-containing water (0.8 mg I/mL). The phantom with the several iodine concentrations was imaged with a clinical CESM system (low energy: W/Rh 29 kV/90 mAs; high energy: W/Ti 49 kV/50 mAs), and the recombined (iodine only) images were retrieved. A region of interest was placed at the center of the FGT insert to determine the relationship between digital units vs. concentration. The phantom was imaged with 0.8 mg I/mL at three different sessions to determine repeatability.

RESULTS

The FGT insert was properly filled with different iodine concentrations with no visible air bubbles. A linear BPE intensity gradient across iodine concentration levels was found (R 2 =0.998). Analysis of the volume-based validation is ongoing. The intensity measured was within 1% over the three measurements.

CONCLUSION

The phantom allows for known and repeatable BPE simulation in CESM, providing a potential tool for standardizing BPE assessment accuracy and precision in clinical imaging. It is also compatible with CE-digital breast tomosynthesis. Additionally, by filling the FGT insert with sodium-alginate beads and connecting it to a flow system, the phantom is also suitable for dynamic BPE imaging studies, which will be explored in future work.

CLINICAL RELEVANCE/APPLICATION

BPE is a known biomarker for cancer development risk and neoadjuvant chemotherapy response. BPE is currently typically assessed visually in MRI, posing variability in interpretation. The emergence of CESM and of quantitative BPE assessment methods offers benefits like objective iodine quantification and wider accessibility, but need to be validated.

W5A-SPBR-4 INTEGRATION OF GENERATIVE AND PREDICTIVE AI IN CODE GENERATION WORKFLOW FOR BREAST CANCER DETECTION

Tianshen Hu, MD (*Presenter*)
Basak E. Dogan, MD (*Abstract Co-Author*)

PURPOSE

This study explores the potential of the latest open-source LLM, DeepSeek (low computational requirements and strong reasoning/coding capabilities) to develop an AI-driven code generation workflow for breast cancer detection using screening mammograms. The goal is to enable efficient execution on consumer-grade PCs available within hospitals while enhancing explainability and controllability for radiologists.

METHODS AND MATERIALS

This study evaluates a novel code generation workflow using predictive models from the 2023 RSNA Breast Cancer Detection Competition. DeepSeek was chosen as the sample generative AI to allow local execution, minimizing security risks associated with cloud-based AI models. Unlike many black-box LLMs, DeepSeek demonstrates its problem-solving abilities through chain-of-thought (CoT) reasoning, an approach that breaks down complex tasks into more manageable steps, enabling radiologists to interpret the AI decision process, adjust sensitivity settings, fostering trust in AI-assisted diagnosis, enabling customization based on domain expertise and improving decision-making reliability. The generative tool refines and generates codes in the predictive models, integrating new technologies and radiologists' expertise via natural language prompts and local medical databases (imported through the AnythingLLM platform). To ensure fair comparison, both the original and improved predictive models are trained using the same dataset and architecture (mean-aggregation of the same type of single-image models). The results are evaluated with the same F1 score assessing precision and recall on a mammography dataset of approximately 5760 patients.

RESULTS

The 2023 RSNA Breast Cancer Detection Competition saw record high participation, making high rankings challenging. A sample workflow, applying to a top-5 competitor's solution, advanced its ranking from #5 to #1, demonstrating workflow effectiveness. Testing on the training dataset shows precision increased from 0.8406 to 0.9318 (10.8%), and recall from 0.9756 to 1 (2.5%). Testing with hidden test data indicates an F1 score increase from 0.52 to 0.55 (6%), showcasing the impact of the refined AI model.

CONCLUSION

This study highlights a promising code generation workflow, integrating predictive AI, generative AI, and radiologist expertise. It has broad applicability across medical imaging domains.

CLINICAL RELEVANCE/APPLICATION

Early detection is critical for reducing breast cancer mortality but relies on sub-specialized radiologists, whose shortages present challenges. The recent advances in open-source AI improve its explainability, automation, accuracy, and accessibility, which could help reduce global breast cancer fatalities.

W5A-SPBR-5 CORRELATION OF LESION CONSPICUITY IN CONTRAST-ENHANCED MAMMOGRAPHY (CEM) WITH TRU-CUT SCAR BIOPSY RESULTS IN THE ASSESSMENT OF ULTRASOUND-GUIDED CRYOABLATION OUTCOME

Federica Di Naro, MD (*Presenter*)
Francesca Pugliese, MD (*Abstract Co-Author*)
Sofia Elisabetta Baldi Giorgi (*Abstract Co-Author*)
Giuliano Migliaro, MD (*Abstract Co-Author*)
Giulia Bicchierai (*Abstract Co-Author*)
Chiara Bellini, MD (*Abstract Co-Author*)
Jacopo Nori Cucchiari (*Abstract Co-Author*)

PURPOSE

To evaluate the role of lesion conspicuity at 12-month CEM follow-up as a predictor of cryoablation outcome.

METHODS AND MATERIALS

Seventy-nine patients (mean age 85.7 yo, ±6.0) with biopsy-proven malignant breast lesions underwent Ultrasound-guided Cryoablation at our center. All B5 lesions were invasive ductal carcinomas (=35 mm), hormone positive and HER2 negative. All patients were deemed as ineligible for surgery by a Multidisciplinary meeting due to comorbidity and/or advanced age and underwent CEM as pre-procedural staging to confirm unifocality. Only patients with complete 12-month follow-up of CEM and biopsy have been included. Two radiologists in consensus evaluated LC on post-procedural CEM, categorizing it as absent, low, moderate, or high. Fisher's exact test and Cohen's Kappa coefficient were applied. CEM diagnostic performances were calculated. Gold standard was histology at 12 months on the post-procedural scar.

RESULTS

Among the 79 patients, 48 (60.8%) underwent both CEM and Biopsy at 12 months. Among them, 35 (61.4%) lesions showed no enhancement. Among the 22 (38.6%) lesions showing enhancement, 6 had low LC, 11 moderate LC, and 5 high LC. A significant fair agreement (Cohen's Kappa coefficient = 0.32 [95% CI: 0.11-0.52]) between CEM and biopsy was shown. Fisher's exact test P-value was 0.0003 reflecting a significant association between biopsy and conspicuity. Lesions with absent or low LC correlated with negative histology (B2), while lesions with residual malignant histology (B5) were associated with moderate-high LC. In assessing cryoablation efficacy, CEM demonstrated NPV of 100%, Sensitivity of 100%, Specificity of 68.6% and PPV of 27.3%.

CONCLUSION

Lesions conspicuity can help in cryoablation follow-up with CEM, since the lower the conspicuity is, the higher the chances of a successful procedure are.

CLINICAL RELEVANCE/APPLICATION

Lower lesion conspicuity on CEM indicates higher cryoablation success, useful for follow-up.

W5A-SPBR-6 IDENTIFYING WOMEN AT RISK FOR ADVANCED-STAGE BREAST CANCER USING AN IMAGE-ONLY DEEP LEARNING RISK MODEL

Leslie Lamb, MD, MSc (*Presenter*)
Sarah Mercaldo, PhD (*Abstract Co-Author*)

Andrew R. Carney, MS (*Abstract Co-Author*)
Constance D. Lehman, MD, PhD (*Abstract Co-Author*)

PURPOSE

There is growing interest in using AI-based risk models to identify women at higher risk for breast cancer, but less is known about the types of cancers these models help predict. We evaluated whether a deep learning (DL) image-only risk model effectively identifies women at high risk who later develop advanced-stage cancers, given the clinical importance of preventing late-stage disease.

METHODS AND MATERIALS

This retrospective, multisite study included consecutive women >40 years undergoing routine bilateral screening mammography across six sites (2009-2022). A 5-year image-only DL model (Mirai) was applied to index mammograms. Exams used in model development were excluded. Patient demographics were obtained from electronic health records. A cancer outcome was defined as a pathologically proven malignancy within 5 years. Cancer outcomes and American Joint Committee on Cancer (AJCC) clinical prognostic staging were obtained from regional and state tumor registries. Diagnostic accuracy was evaluated using AUCs with DeLong tests ($P < 0.05$).

RESULTS

A total of 179,354 screening mammograms from 78,817 patients met inclusion criteria (median age 59 years, IQR: 50-68). Within 5 years, 2.9% (5200/179,354) developed breast cancer: 77.3% (3888/5033) invasive and 22.7% (1145/5033) DCIS. Among 4012 cancers with staging data: 28.0% (1122) were stage 0, 60.6% (2431) stage I, 6.9% (278) stage II, 3.9% (157) stage III, and 0.6% (24) stage IV. Model AUCs for stage prediction were: 0.76 for stage 0 (95% CI: 0.75-0.78), 0.68 for stage I (95% CI: 0.67-0.69), 0.75 for stage II (95% CI: 0.72-0.77), 0.71 for stage III (95% CI: 0.66-0.76), and 0.69 for stage IV (95% CI: 0.61-0.78).

CONCLUSION

An image-only DL risk model applied at the time of screening mammography effectively identifies women at high risk who later develop advanced-stage breast cancers.

CLINICAL RELEVANCE/APPLICATION

A deep learning risk model derived from screening mammograms can identify women at elevated risk for developing advanced-stage breast cancer (e.g., stage II or higher), potentially enabling earlier interventions to reduce late-stage diagnoses and improve patient outcomes.

W5A-SPBR-7 HOW MUCH AUTOMATION BIAS IS PRESENT WHEN READING SCREENING DIGITAL BREAST TOMOSYNTHESIS IMAGES CONCURRENTLY WITH ARTIFICIAL INTELLIGENCE

Robert M. Nishikawa, PhD (*Presenter*)
Jeffrey W. Hoffmeister, MD, MS (*Abstract Co-Author*)
Emily F. Conant, MD (*Abstract Co-Author*)
Jeremy M. Wolfe, PhD (*Abstract Co-Author*)

PURPOSE

To determine the effects of automation bias when radiologists read digital breast tomosynthesis (DBT) concurrently with an artificial intelligence (AI) system.

METHODS AND MATERIALS

We retrospectively analyzed an observer study of 24 MQSA-qualified radiologists reading with and without AI. In that study, there were 260 DBT screening exams. The radiologists read each case twice: once without the AI and once with AI concurrently (i.e., the AI marks and scores were available immediately upon examining the images). Automation bias occurs when a radiologist follows the AI recommendation even though they would not give that recommendation if they read the case without AI. For cases that a radiologist recalled when reading without AI, we compared the fraction of cases recalled when reading with AI for cases recalled by AI (d1) and not recalled by AI (d2). We used a paired t-test to compare the d1 and d2 to test for automation bias. Similarly, we examined the cases that were not recalled by a radiologist when reading without AI and determined the fraction of cases recalled when reading with AI for cases recalled by AI (m1) and not recalled by AI (m2). We determined the effect of automation bias for 4 different subgroups of cases (in descending likelihood that the case contained a malignancy): screen-detected cancers (Ca), benign biopsied (B9Bx), recalled but not biopsied (RNBx), and not recalled (Neg).

RESULTS

The difference between d1 and d2 and between m1 and m2 were statistically significant ($p<0.0001$) indicating automation bias. The AI system recommended recall in Ca cases 94% (61/65), B9Bx 72% (47/65), RNBx 67% (14/21), and Neg 51% (56/109). For cases that a radiologist recalled when reading without AI and AI did not mark a lesion, the fraction of cases that the radiologist did not recall when reading with AI was Ca:65% (1.8/2.8), B9Bx:69% (4.7/6.8), RNBx:88% (2.2/2.5), and Neg:84% (8.7/10.3). For cases not recalled by the radiologist when reading without AI and AI marked a lesion, the fraction of cases the radiologists recalled when reading with AI was Ca:72% (6.4/8.9), B9Bx:43% (6.8/16), RNBx:25% (1.9/7.6), and Neg:15% (5.8/38.8) . These results indicate that automation bias was dependent on the type of case - higher % indicates more bias.

CONCLUSION

Automation bias is present when radiologists read screening exams concurrently with AI. However, the magnitude of automation bias was positive resulting in a net improvement in radiologists' performance.

CLINICAL RELEVANCE/APPLICATION

Automation bias results in some cancers not marked by AI being missed by a radiologist when reading with AI. Nevertheless, overall there is a positive effect of automation bias both in terms of more cancers being detected and a reduction in the recall rate.

W5A-SPCA-1 FEASIBILITY OF ON-SITE CT-FFR USING PHOTON-COUNTING CT FOR ASSESSMENT OF IN-STENT RESTENOSIS: A RETROSPECTIVE ANALYSIS

Felix Johannes Wasmer, MD (*Presenter*)
Thomas Germann (*Abstract Co-Author*)
Dominik Noerenberg (*Abstract Co-Author*)
Stefan O. Schoenberg, MD, PhD (*Abstract Co-Author*)
Isabelle Ayx, MD (*Abstract Co-Author*)

PURPOSE

Cardiovascular disease remains the leading cause of death globally, underscoring the need for reliable, non-invasive diagnostic tools. CT-derived fractional flow reserve (CT-FFR) enables functional assessment of coronary stenoses and is increasingly used in clinical routine. Photon-counting CT (PCCT) offers higher spatial resolution and improved artifact reduction particularly beneficial for patients with coronary stents. Combined with CT-FFR this may reduce the need for an invasive angiography. This study evaluates the feasibility and diagnostic performance of on-site CT-FFR in assessing ISR using PCCT, with correlation to invasive findings and clinical outcomes.

METHODS AND MATERIALS

This study included 19 patients (15m, 4f; mean age 65.2y) with coronary stents who underwent clinically indicated cardiac CT using photon-counting CT (PCCT) between December 2021 and February 2024. Exclusion criteria included severe image artifacts and multiple-vessel stenting. Imaging followed ESC guidelines and included both non-contrast and contrast-enhanced scans. CT-FFR was calculated using on-site software, with values =0.76 or a ?CT-FFR =0.06 considered hemodynamically significant. ICA findings and six-month clinical follow-up were collected for correlation.

RESULTS

Among 19 patients with coronary stents undergoing PCCT, ISR was confirmed in two patients by invasive angiography. CT-FFR values distal to stents were pathological (<0.76) in six cases and borderline in three. ?CT-FFR values were pathological (=0.06) in 15 of 19 cases. CT-FFR demonstrated 100% sensitivity and 81% specificity for ISR detection (PPV 16.6%, up to 33.3% after adjustment). ?CT-FFR showed similarly high sensitivity (100%) but poor specificity (22%)/PPV (6.6%). No major adverse cardiac events (MACE) were observed during six-month follow-up, except for one myocardial infarction in a stent-free vessel.

CONCLUSION

PCCT combined with on-site CT-FFR analysis is a feasible, non-invasive approach to assess in-stent restenosis (ISR), with promising diagnostic performance. CT-FFR and ?CT-FFR demonstrated high sensitivity but limited specificity and positive predictive value indicating a tendency to overestimate hemodynamic significance. Therefore, individualized interpretation of CT-FFR results is essential, and further research is needed to refine thresholds and identify co-factors that contribute to overestimation. PCCT-FFR is promising but currently prone to overestimation of ISR, requiring personalized interpretation and threshold refinement

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the potential of photon-counting CT combined with on-site CT-FFR analysis as a non-invasive tool for functional assessment of in-stent restenosis.

W5A-SPCA-2 APPLICATION AND ACCURACY OF CT-FFR IN PREDICTING MYOCARDIAL ISCHEMIA CAUSED BY TYPE A AORTIC DISSECTION

Feifei Zhou, MD (*Presenter*)

PURPOSE

To evaluate the predictive value and clinical utility of CT-FFR for perioperative major adverse cardiovascular events (MACE) in patients with TAAD.

METHODS AND MATERIALS

This retrospective study included TAAD patients who underwent coronary computed tomography angiography (CCTA) between January 2023 and February 2024. The primary endpoint was perioperative MACE within 30 days, defined as all-cause death, nonfatal myocardial infarction, or unplanned revascularization. The predictive ability of CT-FFR was assessed. Multivariable logistic regression was performed to evaluate the incremental predictive value of CT-FFR combined with coronary anatomical information and clinical risk factors. Model performance and clinical benefit were assessed using receiver operating characteristic (ROC) curves and decision curve analysis (DCA).

RESULTS

A total of 154 patients were included (median age, 54 years; 73.4% male). The cumulative incidence of MACE was 24.7% (38/154). Patients with CT-FFR =0.80 had significantly higher perioperative MACE rates (43.8% [21/48] vs. 12.3% [13/106]; P < 0.001), with most events being nonfatal myocardial infarction. Multivariable logistic regression showed that CT-FFR =0.80 was an independent predictor of perioperative MACE (OR = 7.947; 95% CI: 3.050-20.708; P < 0.001), after adjustment for confounders. The combined predictive model demonstrated improved discrimination for high-risk patients (AUC = 0.798) with good sensitivity and negative predictive value.

CONCLUSION

CT-FFR is significantly associated with perioperative MACE in TAAD patients. As a noninvasive functional assessment tool, CT-FFR may help identify high-risk patients and optimize perioperative management strategies.

CLINICAL RELEVANCE/APPLICATION

CT-FFR enables noninvasive evaluation of coronary functional ischemia in patients with type A aortic dissection (TAAD) prior to surgery. This study demonstrates that CT-FFR = 0.80 is an independent predictor of perioperative cardiovascular risk. In clinical practice, integrating CT-FFR with coronary anatomical information and established clinical risk factors may facilitate the accurate identification of high-risk patients before surgery, allowing for optimized treatment strategies and perioperative management to reduce the incidence of major adverse cardiovascular events.

W5A-SPCA-4 MULTIPARAMETRIC CMR FOR CARDIAC ASSESSEMENT IN AUTOIMMUNE DISEASE PATIENTS RECIEVING ALLOGENEIC CD19-TARGETED CAR-T TREATMENT

Xin Chen (*Presenter*)
An Sun (*Abstract Co-Author*)

PURPOSE

Autoimmune diseases often involve inflammatory myocardial injury that contributes to significant morbidity and mortality. Current immunosuppressive treatments rarely reverse established cardiac damage. CD19-targeted allogeneic chimeric antigen receptor T-cell (CAR-T) therapy offers a novel B-cell depletion strategy that can induce durable remission, but its direct effects on the heart remain unclear. This study aimed to assess whether CAR-T therapy can safely reduce myocardial inflammation and fibrosis in patients with autoimmune diseases by cardiovascular magnetic resonance (CMR) imaging markers.

METHODS AND MATERIALS

Fifteen patients with refractory autoimmune disease (8 SSc and 7 SLE) underwent a single infusion of allogeneic CD19-directed CAR-T cells. CMR and echocardiography were performed concurrently at baseline (BS), and at 1 (M1), 2 (M2), 3 (M3), and 6 months (M6) post-treatment. Some patients failed to get certain imaging performed, resulting in a total of 63 imaging time points. CMR parameters included late gadolinium enhancement (LGE) area (mm^2 and %), global native T1, and global T2 mapping. Longitudinal changes were analyzed using linear mixed-effects models(LMM), with false discovery rate (FDR) correction for multiple comparisons.

RESULTS

All patients completed follow-up CMR through 6 months without any major cardiac adverse events. Myocardial LGE diminished significantly over time: the mean LGE area decreased from 12.1 ± 6.2 mm^2 at baseline to 3.1 ± 2.5 mm^2 at 6 months ($p < 0.001$), accompanied by a reduction in LGE extent from 18.3% to 5.6% of left ventricular myocardium ($p < 0.001$). Global native T1 values also showed a significant decline (from 1351 ± 78 ms at baseline to 1309 ± 70 ms at 6 months, $p = 0.029$). In contrast, global T2 values remained stable ($p = 0.65$).Clinically, patients showed improved serologic indicators of disease activity, with decreased ESR and NT-proBNP without reaching statistical significance.

CONCLUSION

In this CMR-based pilot study, CD19-targeted allogeneic CAR-T therapy was associated with a significant regression of myocardial inflammatory injury in patients with autoimmune diseases and no evidence of cardiotoxicity. These findings suggest that CAR-T therapy not only appears safe for the heart in the short term but may also promote recovery of myocardial integrity in severe autoimmune conditions.

CLINICAL RELEVANCE/APPLICATION

This study support the cardiac safety of CD19-targeted CAR-T treatment and highlight a therapeutic benefit on the heart, thereby encouraging further clinical trials to validate these findings and to evaluate long-term cardiac outcomes in this patient population.

W5A-SPCA-8 CARDIAC CT AS A RAPID SCOUT FOR PATENT FORAMEN OVALE: DIAGNOSTIC ACCURACY AND PROGNOSTIC VALUE IN 148 PATIENTS

Lin Xiong (*Presenter*)
Wei Chen, PhD (*Abstract Co-Author*)

PURPOSE

Coronary CT angiography (CCTA) is the first-line imaging modality for evaluating cardiogenic stroke, for which patent foramen ovale (PFO) is a major underlying cause. We investigated whether the routinely acquired CCTA can single-handedly detect patent foramen ovale (PFO), grade right-to-left shunt, and predict PFO-related neurological events.

METHODS AND MATERIALS

We retrospectively analysed 148 patients (56 ± 11 years; 56% women) who underwent CCTA and contrast-enhanced transthoracic echocardiogram (c-TTE) within 3 weeks (n = 112) or CCTA before transcatheter PFO closure (n = 36). Two blinded readers recorded tunnel length/width, right- and left-atrial ostial diameters (ODRAE, ODLAE) and contrast jet. cTTE shunt grade (0-3) and follow-up for cryptogenic stroke or migraine with aura served as references. Logistic regression and ROC analysis determined CT predictors.

RESULTS

Orifice and tunnel visualisation on CCTA yielded sensitivity/specificity of 81/69 % and 71/91 %, respectively; combining findings raised specificity to 96 % (? = 0.88). ODRAE predicted massive shunt (odds ratio 1.44 per 0.1mm; AUC 0.88; optimal threshold 1.64 mm; sensitivity 84 %, specificity 77 %). The ODRAE/ODLAE ratio= 1.87 predicted neurological events (odds ratio 1.26; AUC 0.75; specificity 94 %). Reproducibility was excellent (ICC 0.709-0.909).

CONCLUSION

CCTA detects PFO with high specificity and furnishes two CT-based metrics—ODRAE and the ODRAE/ODLAE ratio—that grade shunt burden and flag patients susceptible to cryptogenic stroke or migraine, guiding timely closure referral or prophylactic therapy.

CLINICAL RELEVANCE/APPLICATION

A standard CCTA that already images the inter-atrial septum can serve as an imaging "scout," flagging PFOs that warrant confirmatory cTTE and facilitating earlier consideration of closure or prophylactic therapy—adding risk-stratification value without extending scan time.

W5A-SPCA-9 COMPARATIVE ANALYSIS OF PRE-TRANSCATHETER AORTIC VALVE REPLACEMENT CTA PROTOCOLS: OPTIMIZING RADIATION DOSE AND CONTRAST VOLUME

Curzio Santangeli, MD (*Presenter*)
Domenico De Santis, MD (*Abstract Co-Author*)
Giovanna Grazia Bona (*Abstract Co-Author*)
Tiziano Polidori, MD (*Abstract Co-Author*)
Damiano Caruso, MD, PhD (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)
Andrea Laghi, MD (*Abstract Co-Author*)

PURPOSE

To establish the most effective and safe pre-transcatheter aortic valve replacement (TAVR) CT angiography (CTA) protocol by comparing two approaches in terms of image quality, radiation and contrast dose.

METHODS AND MATERIALS

Consecutive patients undergoing pre-procedural CTA were prospectively enrolled from January to May 2024. All exams were performed on a 128-raw CT-scanner with fixed tube voltage (80kVp) and current (399mA). High-concentration contrast agent was administered at high flow rate, based on scan time. Patients were randomly assigned into two different acquisition protocols: group A underwent an ECG-gated CTA of the thorax followed by a non-gated helical scan of abdomen and pelvis; group B underwent an ECG-gated CTA including only the heart and aortic root, followed by a non-gated helical scan of thorax, abdomen, and pelvis. Region-of-Interests were manually drawn for each patient in the aortic lumen (respectively in ascending, descending, and abdominal segments), femoral arteries, muscle, fat, and air using a dedicated software (CardIQ Xpress 2.0, GE Healthcare); vascular enhancement (HU), Contrast-to-noise Ratio (CNR) and Signal-to-noise Ratio (SNR) were assessed. Radiation dose was analyzed.

RESULTS

The final population consisted of 64 patients, 37 in group A and 27 in group B (80.6 ± 5.2 years; 49 males). Group B showed lower radiation dose compared to group A (13.7 ± 1.2 vs 15.7 ± 1.4 mSv; $p<0.001$) and lower contrast medium volume (82.9 ± 0.1 vs 90.3 ± 12.0 ml; $p=0.004$) while achieving no differences in terms of signal-to-noise ratio, contrast-to-noise ratio and subjective image quality (all $p>0.05$). Average vascular attenuation was higher in group A compared to group B (707.1 ± 120.7 vs 633.0 ± 198.6 HU; $p<0.001$); however, lumen attenuation at the aortic root was consistent across the two protocols ($p=0.077$).

CONCLUSION

Optimization of pre-TAVR CTA protocol results in lower contrast medium volume and radiation dose exposure while maintaining consistent image quality.

CLINICAL RELEVANCE/APPLICATION

To optimize contrast medium volume and radiation dose exposure of CTA protocols in patients in their elderly who are eligible for TAVR.

W5A-SPCA-11 INCREMENTAL PROGNOSTIC VALUE OF HEMODYNAMIC FORCES MISALIGNMENT BY CARDIOVASCULAR MAGNETIC RESONANCE FOR MAJOR ADVERSE CARDIAC EVENTS AFTER ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION

Meng Sun (*Presenter*)

PURPOSE

The prognostic value of left ventricular (LV) hemodynamic forces (HDFs) derived from cardiovascular magnetic resonance (CMR) cine imaging in ST-segment elevation myocardial infarction (STEMI) remains unclear. This study aimed to examine temporal changes in HDFs and their ability to predict major adverse cardiac events (MACEs).

METHODS AND MATERIALS

This study retrospectively recruited 280 patients with STEMI. CMR was performed between 1 and 10 days after STEMI. LV HDFs were measured in the apex-base (A-B) and latero-septal (L-S) directions using CMR cine imaging. MACEs were defined as all-cause mortality, reinfarction, and newly diagnosed congestive heart failure. Kaplan-Meier survival analysis, Cox proportional hazards regression, and C-statistics were used to assess prognosis; receiver-operating characteristic curve analysis was used to define the cutoff value.

RESULTS

The MACEs group exhibited weaker LV suction during sys-diastolic transition than the non-MACEs group (-4.1 vs. -5.4, $p=0.003$). Multivariable analysis identified global longitudinal strain (GLS), infarct size (IS), the entire heart cycle L-S/A-B HDFs ratio, and the entire heart cycle angle f as independent predictors (all $p<0.05$). The combination of GLS, the entire cardiac cycle L-S/A-B ratio, and angle f improved MACEs prediction (C-statistic = 0.814). Both the entire cardiac cycle L-S/A-B HDFs ratio and angle f provided incremental prognostic value over GLS and IS (increase in C-statistic from 0.769 to 0.825; $p = 0.003$).

CONCLUSION

LV suction serves as a quantitative measure of LV diastolic function assessed by CMR. The entire heart cycle L-S/A-B HDFs ratio and angle f significantly enhance MACEs prediction over GLS and IS. Even without late gadolinium enhancement, GLS combined with HDFs parameters reliably predicts MACEs.

CLINICAL RELEVANCE/APPLICATION

LV HDFs by CMR cine imaging can provide quantitative parameters of LV diastolic function, addressing the limitations of CMR in quantifying LV diastolic function. Our research further incorporated the entire heart cycle L-S/A-B HDFs ratio and the entire heart cycle angle f into IS and GLS, revealing significant enhancements in forecasting future MACEs, demonstrating an additive prognostic value of HDFs parameters over IS and GLS. Notably, GLS combined with the entire-cycle L-S/A-B HDFs ratio and angle f still provides reliable prediction of MACEs. This suggests that for patients who cannot tolerate late gadolinium enhancement examination, strain and HDFs analysis using only CMR cine sequences without contrast-enhanced imaging can effectively predict the occurrence of MACEs following STEMI, which has significant implications for risk stratification and management of patients with STEMI.

W5A-SPCA-12 NONINVASIVE PREDICTION OF CORONARY HEMODYNAMIC ABNORMALITIES: THE COMPLEMENTARY ROLE OF PERICORONARY FAT ATTENUATION INDEX AND AREA STENOSIS

Zhao Jie (*Presenter*)
Jie Yuan (*Abstract Co-Author*)

PURPOSE

This study aimed to determine whether combining pericoronary fat attenuation index (FAI) with quantitative plaque analysis enhances the detection of hemodynamically significant coronary artery disease using CT-derived fractional flow reserve (CT-FFR) as the reference standard.

METHODS AND MATERIALS

We conducted a retrospective analysis of 130 consecutive patients (226 coronary lesions) who underwent coronary computed tomography angiography (CCTA) between January 2023 and September 2024 for evaluation of chest pain. All studies included FAI measurement, comprehensive plaque characterization (area stenosis [AS], diameter stenosis [DS], lesion length [LL]), and CT-FFR computation. Lesions were classified as hemodynamically significant (CT-FFR =0.8) or non-significant (CT-FFR >0.8). Statistical analysis included univariate/multivariate logistic regression, and ROC curve analysis with DeLong test for AUC comparisons.

RESULTS

The study cohort comprised 53 hemodynamically significant lesions (23.5%) and 173 non-significant lesions. Significant lesions demonstrated higher FAI values and greater AS (all $P<0.001$). While FAI, DS, and AS all showed significant predictive value in univariate analysis (AUCs: 0.823, 0.801, and 0.851 respectively), multivariate analysis identified only FAI and AS as independent predictors. The combined FAI+AS model achieved superior diagnostic performance (AUC 0.904, 95%CI 0.85-0.957) with 91.2% sensitivity and 80.0% specificity, representing a statistically significant improvement over individual parameters ($P<0.05$).

CONCLUSION

Pericoronary FAI provides incremental diagnostic value beyond traditional stenosis assessment, with the FAI+AS combination offering superior accuracy for identifying hemodynamically significant coronary lesions.

CLINICAL RELEVANCE/APPLICATION

The integration of FAI with plaque characterization in CCTA interpretation represents a promising strategy to improve noninvasive identification of functionally significant coronary artery disease. This combined assessment could optimize patient selection for invasive angiography while reducing unnecessary procedures, potentially transforming the diagnostic pathway for patients with suspected coronary artery disease.

W5A-SPCA-13 THE DIAGNOSTIC VALUE OF CMRT1MAPPING COMBINED WITH MOCO CDWIIN THE EVALUATION OF GRAY ZONE INPATIENTS WITH MYOCARDIAL INFARCTION

Xiaowei Ruan (*Presenter*)

PURPOSE

This study evaluates the diagnostic value of T1 mapping and MoCo cDWI in assessing myocardial fibrosis in myocardial infarction by comparing native T1, ECV, and DWI-derived parameters in infarct, gray zone, and normal myocardium.

METHODS AND MATERIALS

A retrospective analysis was conducted on CMR images from 19 myocardial infarction (MI) patients (case group) and 20 healthy individuals (control group). For the case group, myocardial regions were classified based on LGE signal intensity as LGE core zone (6 standard deviations above remote myocardium) and gray zone (2-6 standard deviations above remote myocardium), as well as normal myocardium. Native T1, ECV mapping, ADC, and EADC values were measured for these different myocardial regions. The same parameters were also measured for the entire myocardium of the control group.Normally distributed data were expressed as mean ± standard deviation ($\bar{x}\pm s$), and group comparisons were performed using one-way analysis of variance (ANOVA) followed by LSD test for pairwise comparisons. Non-normally distributed data were presented as median (interquartile range) . A P-value < 0.05 was considered statistically significant. Correlations between variables were assessed using Pearson correlation analysis. Receiver operating characteristic (ROC) curve analysis was used to evaluate the diagnostic value of CMR parameters for myocardial fibrosis in MI, AUC, sensitivity, and specificity were calculated for each parameter.

RESULTS

1. The four myocardial types showed significant differences in native T1, ECV, ADC, and EADC values($P < 0.05$). Pairwise comparisons revealed no significant differences between the remote healthy myocardium of MI patients and the normal control group in terms of native T1, ECV, ADC, and EADC values (all $P > 0.05$). The gray zone, remote zone, and control group had significantly lower native T1, ECV, and ADC values compared to the core infarct zone($P < 0.05$). Differences between the gray zone and the remote zone in native T1, ECV, ADC, and EADC were also statistically significant ($P < 0.05$) (Table 1).2. Native T1, ECV, and ADC in the gray zone showed a moderate correlation with ECV (Table 2).3. In ROC analysis, the diagnostic performance of native T1 combined with ADC was higher than that of T1 or ADC alone. The sensitivity and specificity for identifying the gray zone using ADC combined with T1 were 68% and 100%, respectively (Table 3, Figure 1).

CONCLUSION

Myocardial T1 mapping combined with Second MoCo cDWI can identify the gray zone in MI patients .

CLINICAL RELEVANCE/APPLICATION

Myocardial T1 mapping combined with Second MoCo cDWI has the potential to provide a new non-invasive, quantitative, contrast-agent-free method for evaluating diffuse myocardial fibrosis in clinical practice.

W5A-SPCA-14 CORRELATION BETWEEN PLAQUE BURDEN AND VASCULAR SPECIFIC MYOCARDIAL ISCHEMIA BASED ON CORONARY COMPUTED TOMOGRAPHIC ANGIOGRAPHY (CCTA)

Wan-Yi Zheng, MD (*Presenter*)

PURPOSE

The pathophysiology of myocardial infarction relates to temporal changes of atherosclerotic plaque. Lesions with denser calcification are more likely to be later-stage and stable plaques, which rarely cause acute myocardial infarction. Therefore, we aimed to quantify the correlation between plaque characteristics (calcified/noncalcified burden) and CT-FFFR defined myocardial ischemia.

METHODS AND MATERIALS

37 patients (age 62.16 ±11.61 years; 59.46% men) undergoing CCTA for suspected coronary artery disease were enrolled. Coronary artery analysis was performed for the left anterior descending (LAD), left circumflex (LCX), and right coronary artery (RCA) using validated semi-automated software to quantify total vessel volume, calcified and non-calcified plaque volumes. The correlation between plaque burden (calcified/non-calcified) and CT-FFR was analyzed on a per-vessel basis. Calcified and non-calcified burden was defined as calcified and non-calcified volume/vessel volume×100%.

RESULTS

Plaque was detected in 80 vessels (42.5% LAD, 25.0% LCX, 32.5% RCA), with quantitative analysis showing the RCA had the largest total volume (1280.93 mm^3, $p < 0.001$) while the LCA contained the greatest non-calcified plaque burden (21.52 mm^3, $p = 0.03$). CT-FFR demonstrated significant negative correlations with non-calcified plaque in both LAD ($r=-0.42$, $p < 0.001$) and RCA ($r=-0.78$, $p < 0.001$), with particularly strong association in the RCA, whereas no such correlation was observed in LCX ($r=-0.35$, $p = 0.131$). Notably, calcified plaque burden showed no significant correlation with CT-FFR in any coronary vessel (LAD: $r=-0.24$, $p = 0.165$; LCX: $r=-0.38$, $p = 0.103$; RCA: $r=-0.219$, $p = 0.271$).

CONCLUSION

Compared with calcified plaques, plaques with more non-calcified components are more likely to damage the hemodynamics of coronary arteries, thereby leading to myocardial ischemia. Especially in RCA, although its vascular volume is larger and the non-calcification burden is less, its influence on the non-calcification burden is particularly sensitive.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the importance of non-calcified plaque quantification in assessing ischemic risk and support the use of CT-FFR as an imaging functional marker suggestive of vessels containing high non-calcified burden plaques.

W5A-SPCH-1 EXPLOITING STRUCTURAL CONSISTENCY OF CHEST ANATOMY FOR UNSUPERVISED ANOMALY DETECTION IN RADIOGRAPHY IMAGES

Zongwei Zhou, PhD (*Presenter*)
Wenxuan Li, BS (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

This study explores whether AI trained on normal chest X-rays can identify diseases by detecting deviations from healthy anatomy, reducing the need for manual annotations.

METHODS AND MATERIALS

We formulated anomaly detection as an image feature in-painting task. During training, our method learned to categorize image features of normal anatomical structures into a dictionary of recurring visual patterns (discrete features). At inference, it detects anomalies by identifying features that deviate from this learned dictionary. Specifically, we used a Transformer-based Variational Autoencoder (VAE) to learn image features. In feature space, we replaced image features with their closest matches in the dictionary and randomly masked 75% of the features. The VAE then attempted to restore the image features to reconstruct the original image. A discriminator assessed whether the reconstructed image appeared real or fake, providing feedback to refine the Autoencoder's predictions and improve image quality. Since the majority of chest X-rays in the training set were normal, the learned feature dictionary mainly reflected normal features. We developed and evaluated this method on three large-scale X-ray datasets: ZhangLab (N = 5,856; 27% normal, 73% abnormal), COVIDx (N = 29,587; 28% normal, 72% abnormal), and CheXpert (N = 29,420; 19% normal, 81% abnormal).

RESULTS

Our method outperformed 21 established unsupervised anomaly detection methods, achieving AUC gains of 8.0%, 7.0%, and 9.9% in the ZhangLab, COVIDx, and CheXpert datasets. It also improved accuracy by 7.0% in ZhangLab and 6.9% in CheXpert, with F1 score gains of 3.7% and 8.3%, respectively. Additionally, our method is interpretable as it can localize subtle anomalies (e.g., Pneumonia, Cardiomegaly, Atelectasis, etc.) in radiography using heatmaps. Our method is robust to mixed training with different normal/abnormal ratios by up to 50%.

CONCLUSION

The integration of image feature in-painting significantly improved the performance of unsupervised anomaly detection. Our method enhanced detection accuracy while reducing dependence on manually annotated datasets, as normal and abnormal labels can be automatically extracted from patient reports using NLP tools.

CLINICAL RELEVANCE/APPLICATION

This method can ease radiologists' workload by identifying suspicious areas in radiographic images, aiding in the detection of various pathologies, all classified as anomalies. Our results show that it can also detect anomalies that may not be well-annotated in the dataset, such as COVID-19 in late 2019. Its effectiveness without requiring extensive annotations makes it particularly valuable in clinical settings where annotated data is scarce.

W5A-SPCH-2 ARTIFICIAL INTELLIGENCE-BASED CT SEGMENTATION REVEALS PULMONARY STRUCTURAL CHANGES IN CONNECTIVE TISSUE DISEASES

Tengyue Yang (*Presenter*)
Xiaokun Xin (*Abstract Co-Author*)
Nan Yu, MD (*Abstract Co-Author*)
Yueyue Jing (*Abstract Co-Author*)

PURPOSE

Diagnosing pulmonary structural abnormalities in connective tissue diseases (CTDs) such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) is critical yet challenging. This study aimed to evaluate the utility of artificial intelligence (AI)-based CT segmentation in identifying and quantifying pulmonary structural alterations in CTD patients.

METHODS AND MATERIALS

In this retrospective study, we used advanced AI-based CT segmentation techniques to quantify lung structural changes in CTD patients compared to healthy controls. The parameters measured included total lung volume (TLV), low attenuation area (LAA) between -200 and -700 Hounsfield units (HU), total airway volume (TAV), total airway volume for airways =2 mm (TAV2mm), total vessel volume (TVV), total vessel volume for vessels =5 mm (TVV5mm), vessel tortuosity (VT), and fractal dimension (FD). The discriminative ability of these indicators was evaluated using receiver operating characteristic (ROC) curve analysis, with the area under the curve (AUC) as the metric.

RESULTS

The CTD patient group exhibited significantly lower TLV (AUC=0.735), reduced TAV (AUC=0.665), TAV~2mm~ (AUC=0.909), TVV (AUC=0.789), and TVV~5mm~ (AUC=0.755), along with higher LAA-200--700% (AUC=0.742) and VT (AUC=0.568), compared to the healthy control group (*p*<0.001). FD was lower in CTD patients (AUC=0.472, *p*<0.001). TAV~2mm~ demonstrated the highest diagnostic efficacy for distinguishing CTD patients from controls (AUC=0.909), while the joint model achieved superior discriminative performance (AUC=0.960).

CONCLUSION

AI-based CT segmentation effectively detects early pulmonary structural changes in CTD patients, providing a robust tool for differentiating pathological alterations from normal anatomy.

CLINICAL RELEVANCE/APPLICATION

First, this method enables early identification of respiratory complications in CTDs, facilitating timely interventions to prevent irreversible lung damage. Second, it serves as a biomarker for disease severity and progression monitoring. Finally, the integration of AI tools into clinical workflows may reduce diagnostic variability and enhance radiologists' efficiency in managing CTD-related pulmonary involvement.

W5A-SPCH-8 DETECTION OF INTERSTITIAL LUNG ABNORMALITIES ON CHEST CT: COMPARATIVE EVALUATION OF RADIOMICS AND DEEP LEARNING MODELS

Masha Bondarenko, BS (*Presenter*)
Tician Schnitzler, MD, MSc (*Abstract Co-Author*)
Ali Nowroozi, MD (*Abstract Co-Author*)
Adrian Serapio (*Abstract Co-Author*)
Jaewon Jung (*Abstract Co-Author*)
Yu-Fu Wu, MD (*Abstract Co-Author*)
Jae Ho Sohn, MD, MS (*Abstract Co-Author*)

PURPOSE

To develop and compare two machine learning approaches for detecting peripheral fibrotic changes suggestive of interstitial lung abnormalities (ILA) on chest CT: a radiomics-based model and a convolutional neural network (CNN).

METHODS AND MATERIALS

A total of 1,715 chest CT scans were retrospectively collected from a tertiary academic ILD-referral center, including 440 cases with ILA and 1,275 controls without ILA. The radiomics model was built by extracting handcrafted features from segmented lung regions and applying an XGBoost classifier. The CNN model, based on a SlowFast architecture, was trained using manually annotated regions of peripheral fibrosis. Both models were evaluated on an internal test set and an independent external validation cohort from another academic ILD center. Model performance was assessed using accuracy, weighted precision, weighted recall, weighted F1-score, and area under the receiver operating characteristic curve (AUC).

RESULTS

In internal testing, the radiomics model achieved an AUC of 0.88, with an accuracy of 87%, weighted precision of 0.87, weighted recall of 0.87, and a weighted F1-score of 0.87. On external validation, the radiomics model retained an AUC of 0.81, with reduced accuracy (63%), weighted precision of 0.68, weighted recall of 0.63, and a weighted F1-score of 0.61. The CNN model demonstrated an AUC of 0.86 on the internal test set, with an accuracy of 83.4%, weighted precision of 0.69, weighted recall of 0.64, and a weighted F1-score of 0.66. On external validation, the CNN achieved an AUC of 0.79, maintaining balanced sensitivity and specificity with modest decline in overall performance.

CONCLUSION

Radiomics and CNN-based models both enabled accurate detection of peripheral fibrotic changes associated with ILA. The radiomics model offered high internal performance and interpretability, while the CNN model provided a more balanced and generalizable profile. These complementary approaches have potential for integration into clinical workflows to support early, automated detection of interstitial lung abnormalities.

CLINICAL RELEVANCE/APPLICATION

Automated radiomics and CNN-based models can aid in the early detection of interstitial lung abnormalities on chest CT, improving diagnostic accuracy and enabling earlier referral for specialized ILD care.

W5A-SPCH-9 A NOMOGRAM FOR PREDICTING PATHOLOGICAL COMPLETE RESPONSE IN NSCLC PATIENTS RECEIVING NEOADJUVANT IMMUNOTHERAPY USING CT-BASED TUMOR RIM HETEROGENEITY

Yanbo Li (*Presenter*)
Jingyi Yang (*Abstract Co-Author*)
Xiaoting Cai (*Abstract Co-Author*)
Fangyuan Qu, MD (*Abstract Co-Author*)
Ying Liu (*Abstract Co-Author*)

PURPOSE

To investigate intratumoral heterogeneity (ITH) quantification within different tumor- associated volumes of interest (VOIs) identified on pretreatment CT images in non-small cell lung cancer (NSCLC) patients, and to develop a nomogram for predicting pathological complete response (pCR) to neoadjuvant immunotherapy.

METHODS AND MATERIALS

This retrospective cohort study analyzed 229 NSCLC patients who received neoadjuvant immunotherapy followed by surgery between August 2018 and May 2024. Three distinct VOIs were delineated from pretreatment CT images: the gross tumor volume (GTV), GPTV3 (including the tumor along with a 3-mm peritumoral margin), and tumor rim volume (TRV) defined by a 3-mm inward contraction and 3-mm outward expansion from the tumor boundary. VOI subregions were segmented using K-means clustering, with the optimal cluster number being determined via the elbow criterion method. ITH scores were calculated based on local clustering and global pixel distribution. Prognostic performance assessment was conducted using logistic regression frameworks to identify the most discriminative VOI configuration, which was subsequently integrated with clinical variables. A nomogram was developed using multivariable logistic regression to predict pCR. Model performance was evaluated with AUC, calibration curves, and decision curve analysis (DCA).

RESULTS

Among the 229 patients, 105 (45.9%) achieved pCR following neoadjuvant immunotherapy. The dataset was split into a training cohort (n=160) and a testing cohort (n=69). The TRV-ITH model outperformed other VOI models in both cohorts, achieving an AUC of 0.744 (95% CI: 0.666-0.822) in the training set and 0.742 (95% CI: 0.624-0.861) in the testing set. The nomogram exhibited superior predictive performance, with AUCs of 0.811 (95% CI: 0.745-0.876) and 0.789 (95% CI: 0.683-0.895) in the training and testing sets, respectively. It achieved an accuracy of 0.744 and specificity of 0.805. Calibration curves showed good agreement between predicted probabilities and observed outcomes. DCA demonstrated that the nomogram provided greater clinical benefit than other models.

CONCLUSION

Tumor rim heterogeneity represents a promising prognostic biomarker for predicting pCR in NSCLC patients undergoing neoadjuvant immunotherapy. The nomogram incorporating ITH scores with clinical variables demonstrated robust predictive performance for pCR.

CLINICAL RELEVANCE/APPLICATION

By integrating tumor margin heterogeneity and clinical factors, the nomogram enables accurate, non-invasive prediction of pCR in NSCLC patients receiving neoadjuvant immunotherapy, thereby facilitating individualized therapeutic strategies.

W5A-SPCH-10 NEXT-GENERATION IMAGING OF ILD IN SYSTEMIC SCLEROSIS: THE ADDED VALUE OF ULTRA-HIGH-RESOLUTION PCCT

Francois Pontana, MD, PhD (*Presenter*)
Francois-Joseph FERETZ (*Abstract Co-Author*)
Yann Gaillandre (*Abstract Co-Author*)
Antoine Hutt, MD (*Abstract Co-Author*)
Suonita Khung, MD (*Abstract Co-Author*)
Paul Felloni, MD (*Abstract Co-Author*)
Benjamin Longere, MD, PhD (*Abstract Co-Author*)
Christos V. Gkizas, MD, PhD (*Abstract Co-Author*)
Jean-Baptiste Faivre, MD (*Abstract Co-Author*)

PURPOSE

To compare the detection and characterization of interstitial lung disease (ILD) elementary lesions in systemic sclerosis using ultra-high-resolution (UHR) photon-counting detector CT (PCCT) versus high-resolution CT (HRCT) from a third-generation dual-source energy-integrating detector CT.

METHODS AND MATERIALS

This retrospective study included 22 patients with systemic sclerosis and ILD (15 women; mean age: 62.8 years), each undergoing both HRCT and PCCT-UHR for follow-up with clinical and functional stability between scans. HRCT parameters: collimation 2×96×0.6 mm; pitch 2; Sn150kV; 150 mAs with automatic modulation; 1 mm slices; 512² matrix; Bl57 kernel; iterative reconstruction (ADMIRE level 4). PCCT-UHR parameters: collimation 2×120×0.2 mm; pitch 2; Sn100kV or Sn140kV depending on body habitus; automatic tube current modulation (IQ level 36); 0.2 mm slices; 1024² matrix; Bl60 kernel; QIR level 4. Image analysis included tracheal noise measurement and qualitative scoring (0-3 scale) of ground-glass opacities, intralobular reticulations, bronchiectasis, bronchiolectasis, and honeycombing on 1 mm slices.

RESULTS

The mean interval between scans was 33 ± 25 months. Despite higher image noise with PCCT-UHR (67.14 ± 13.18 HU vs 33.63 ± 5.81 HU; $P < 0.0001$), overall image quality was subjectively superior ($P = 0.0348$). PCCT-UHR yielded significantly improved visualization of ground-glass opacities ($P = 0.0003$), intralobular reticulations ($P = 0.0045$), bronchiectasis ($P = 0.0001$), and bronchiolectasis ($P = 0.0002$), with no significant difference for honeycombing ($P = 0.125$). Radiation dose was significantly lower with PCCT-UHR (CTDIvol: 2.35 ± 0.82 mGy; DLP: 77.64 ± 25.38 mGy·cm) compared to HRCT (CTDIvol: 3.35 ± 1.01 mGy; DLP: 116.77 ± 33.45 mGy·cm; $P = 0.0008$).

CONCLUSION

Ultra-high-resolution PCCT significantly enhances the detection of elementary ILD features in systemic sclerosis while reducing radiation exposure, supporting its added value in longitudinal morphological assessment.

CLINICAL RELEVANCE/APPLICATION

Ultra-high-resolution photon-counting CT enables more accurate and lower-dose detection of early fibrotic changes in systemic sclerosis-related ILD, potentially improving disease monitoring and therapeutic decision-making.

W5A-SPCH-11 CLASSIFICATION OF THYMOMAS INTO LOW AND HIGH RISK GROUPS BY RADIOMIC FEATURES AND MACHINE LEARNING

Mustafa Durmaz, MD (*Presenter*)
Tofig Hajiyev (*Abstract Co-Author*)
Sukru Mehmet Erturk, MD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a machine learning-based model using radiomic features extracted from contrast-enhanced CT (CECT) images to classify thymoma subtypes into low-risk (types A, AB, B1) and high-risk (types B2, B3) groups preoperatively.

METHODS AND MATERIALS

This retrospective study included 87 patients with pathologically confirmed thymomas who underwent CECT within one month before surgery. Tumors were segmented using ITK-SNAP software by semiautomatic methods, and 3D volumes of interest were used for feature extraction with LIFEx software. After preprocessing and harmonization (ComBat method), meaningful radiomic features were used to train three machine learning models: XGBoost-Tuning, Random Forest, and CatBoost. Patients were grouped into low-risk and high-risk categories based on WHO histology. Model performance was evaluated using test accuracy, precision, recall, F1-score, and confusion matrices.

RESULTS

Of the 87 patients, 48 were classified as high-risk and 39 as low-risk. The XGBoost-Tuning model achieved the highest test accuracy (94.4%), with a precision of 95.0%, recall of 94.8%, and F1-score of 94.5%. Random Forest achieved 83.3% accuracy and an F1-score of 82.9%, while CatBoost had the lowest performance (77.8% accuracy, 78.4% F1-score). The XGBoost model demonstrated superior discrimination between risk groups, correctly identifying 11/12 high-risk cases with only one false negative.

CONCLUSION

Radiomics-based machine learning models, particularly XGBoost, can accurately classify thymomas into risk groups using noninvasive imaging biomarkers. This approach demonstrates high performance and holds promise for aiding in the preoperative identification of low- and high-risk thymomas, especially in patients who are not candidates for invasive diagnostic procedures.

CLINICAL RELEVANCE/APPLICATION

Preoperative classification of thymoma risk using CT-based radiomics and machine learning provides a noninvasive, accurate tool to assist in surgical planning and therapeutic decision-making. This approach supports personalized care in patients with anterior mediastinal masses.

W5A-SPCH-13 FACTORS ASSOCIATED WITH LUNG CANCER-SPECIFIC MORTALITY IN LUNG CANCER SCREENING PROGRAMS

Esther Tannoury, MD (*Presenter*)
Suzanne Byrne, MD (*Abstract Co-Author*)
Mark M. Hammer, MD (*Abstract Co-Author*)

PURPOSE

Lung cancer still leads cancer mortality in both men and women. Two major clinical trials have proven lung cancer screening (LCS) to be effective in reducing lung cancer-specific mortality. The causes of persistent lung cancer-specific death despite screening were not directly investigated in those studies. Furthermore, in real world clinical implementation of LCS, additional factors may impact screening efficacy. Our objective is to identify and analyze the causes contributing to lung cancer-specific death in our screening population, highlighting factors limiting the full potential of LCS in reducing lung cancer mortality in everyday practice.

METHODS AND MATERIALS

This retrospective study reviewed all patients who were enrolled in our healthcare system's lung cancer screening program between January 2015 and June 2023. Chart reviews were performed of all patients who died after lung cancer diagnosis to first determine whether the death was attributed to lung cancer. We then performed a chart review to identify contributing factors to lung cancer-specific mortality, including: late-stage disease diagnosed at baseline screening CT; non-compliance; missed nodules; development of aggressive cancers; disease recurrence; and treatment complications.

RESULTS

During the study period, among the 15,762 patients who were screened, 694 were diagnosed with lung cancer, and 112 deaths were attributed directly to lung cancer. Potentially modifiable factors contributing to lung cancer-specific death accounted for the majority (59%) of causes, with baseline late-stage diagnosis being the leading factor (25%) followed by annual screening/follow-up non-compliance (23%), and missed nodules on CT contributing to 11% of cases. Non-modifiable contributing factors included development of an aggressive lung cancer (14%), cancer recurrence after early stage (13%), development of a second lung cancer (9%), and treatment complications (5%).

CONCLUSION

Potentially modifiable factors contributed to the majority of lung cancer-related deaths in our screening program. Interventions to improve screening uptake and follow-up compliance may be able to improve the efficacy of lung cancer screening programs.

CLINICAL RELEVANCE/APPLICATION

Identifying and addressing modifiable factors contributing to lung cancer-specific mortality despite lung cancer screening enrollment is crucial for optimizing the screening system and maximizing its mortality-reducing potential.

W5A-SPER-1 RADIOLOGICAL SPECTRUM OF HEAD AND NECK INJURIES IN BOMB BLAST VICTIMS: A DESCRIPTIVE STUDY

Zohaib Mallick, MBBS (*Presenter*)
Muhammad N. Ahmad, MBBS (*Abstract Co-Author*)
Muhammad Masood Alam, MBBS (*Abstract Co-Author*)
Muhammad Abdullah (*Abstract Co-Author*)
Amal Mahmood (*Abstract Co-Author*)
Fatima Bhojani, MD (*Abstract Co-Author*)
Naila Nadeem, MBBS (*Abstract Co-Author*)
Uffan Zafar, MD (*Abstract Co-Author*)

PURPOSE

Violence involving explosions remains a major cause of mass civilian trauma, particularly in terrorism-affected regions. This study aimed to evaluate the radiological findings in patients with head and neck trauma resulting from blasts in Pakistan.

METHODS AND MATERIALS

This retrospective study was conducted at Aga Khan University Hospital, Karachi, and included patients admitted with blast injuries between January 2004 and December 2024. Data was collected from hospital records and only those who underwent at least one craniocervical radiological examination were included.

RESULTS

A total of 249 patients were analyzed, predominantly male (82.3%), with a median age of 38 years. CT of the head was the most frequently used imaging modality. Foreign bodies (59.0%), cerebral edema (11.6%), and facial soft tissue injuries (16.9%) were the most common radiological findings. Secondary and secondary/tertiary blast injuries were the predominant patterns observed across all imaging stages, while quaternary injuries were absent throughout.

CONCLUSION

CT scans are crucial for detecting major injuries in bomb blast victims; however, combining imaging with thorough clinical evaluation is essential for effective treatment and long-term care.

CLINICAL RELEVANCE/APPLICATION

Understanding the radiological patterns of head and neck injuries in bomb blast victims enhances rapid triage and guides urgent interventions, especially in resource-limited settings where CT imaging plays a vital role in initial diagnosis.

W5A-SPER-2 INTENSIVE CARE UNIT PATIENTS WITH INCREASED RADIATION EXPOSURE DURING A SINGLE HOSPITALIZATION PERIOD: ONCOGENIC RISK CALCULATION

Emilio Quaia, MD (*Presenter*)
Chiara Zanon, MD,MS (*Abstract Co-Author*)
GIULIO CABRELLE (*Abstract Co-Author*)
Francesca De Monte (*Abstract Co-Author*)
Marta Paiusco, MPH (*Abstract Co-Author*)

PURPOSE

To assess the oncogenic risk related to radiation exposure in intensive care unit (ICU) patients with increased cumulative effective dose (>10 mSv) during one single hospital admission.

METHODS AND MATERIALS

This was an IRB approved observational retrospective stiudy. Two hundred seventy one patients (158 male, 113 female; median age, 66 years; interquartile range [IQR], 71-56 years) admitted to the ICU who underwent x ray examinations between october 1, 2021 and february 2025 were included. For each patient, the cumulative effective dose during a single hospital admission was calculated. Lifetime attributable risk (LAR) was estimated based on BEIR VII model to calculate additional oncogenic risk (AOR) related to radiation exposure, corresponding to the risk of cancers in patients exposed to x ray in addition to the oncogenic risk in the general population. AOR corresponds to the LAR per 100000 individuals per 0.1 Gy multiplied by cumulative effective dose/0.1.

RESULTS

The median cumulative effective dose per patient was 48.73 mSv (IQR, 20.74 - 107.19). Male patients were exposed to higher median cumulative effective dose vs female patients (53.84 [IQR, 22.34 - 124.66] vs 22.97 [IQR, 19.1 - 41.81]. AOR for all cancer was 218.85 [IQR, 80.28 - 490.51], for leukemia 36.24 [IQR, 13.33 - 84.35], and for all-solid tumors was 113.38 [IQR, 49.11 - 333.6]. Individual tumor AOR was: bladder cancer, 25.68 [IQR, 9.77 - 64.16]; breast cancer, 7.33 [IQR, 3.12 - 19.28]; colon cancer, 33.76 [IQR, 12.07 - 89.03]; liver cancer, 4.48 [IQR, 1.69 - 12.8]; lung cancer, 50.32 [IQR, 19.55- 92.05]; ovary cancer, 4.5 [IQR, 2 - 8.93]; prostate cancer, 6.13 [IQR, 0.25 - 21.49]; stomach cancer, 9.12 [IQR, 3.56 - 20.04]; thyroid cancer, 0.12 [IQR, 0.03 - 0.53]; and uterus cancer 2.18 [IQR, 0.97 - 4.47].

CONCLUSION

ICU patients with increased radiation exposure revealed elevated oncogenic risk.

CLINICAL RELEVANCE/APPLICATION

ICU patients with increased radiation exposure (>10 mSv) during one hospital admission present elevated oncogenic risk which should imply to limit radiation exposure in critical patients.

W5A-SPER-3 EVALUATION OF A TRIPLE-LOW DOSE PROTOCOL WITH DEEP LEARNING RECONSTRUCTION IN BRAIN PERFUSION CT

Haina Xu (*Presenter*)
Xin Qin (*Abstract Co-Author*)
Weiyuan Huang (*Abstract Co-Author*)
Feng Chen, MD, PhD (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

To investigate the efficacy of a triple-low dose protocol (80 kV/80 mA, 40 mL contrast at 4 mL/s) in brain perfusion CT (CTP) when combined with deep learning image reconstruction (DLIR-H), compared to a conventional protocol (80 kV, 120 mA, 50 mL at 5 mL/s) with iterative reconstruction (ASIR-V 50%).

METHODS AND MATERIALS

A prospective study enrolled 102 patients with suspected acute ischemic stroke (AIS), randomized into conventional or triple-low protocol groups (n=51 each). All underwent CTP scans, generating four datasets: Group A (conventional + DLIR-H), Group B (conventional + ASIR-V), Group C (triple-low + DLIR-H), and Group D (triple-low + ASIR-V). Radiation and contrast doses were documented. Objective image quality was assessed via CT values, standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and perfusion parameters (CBV, CBF, MTT, TTP, Tmax). Two senior radiologists independently evaluated subjective image quality using a 3-point scale (0=poor, 1=moderate, 2=good).

RESULTS

The triple-low protocol significantly reduced radiation (1.51 vs. 2.27 mSv, $P<0.001$) and contrast volume (40 vs. 50 mL) with a slower injection rate (4 vs. 5 mL/s). CT values in gray and white matter were comparable ($P>0.05$), with minor differences (<2 HU) in temporal and parietal white matter. Image noise (SD) varied in the frontal region ($P<0.05$) but not elsewhere. Group C consistently showed lower SD than Group B, though not significantly. SNR was slightly higher in temporal regions ($P<0.05$), while CNR was significantly better in the parietal lobe for Group C vs. Group B ($P<0.05$). Perfusion parameters (CBF, CBV, MTT, TTP) were stable across groups ($P>0.05$); Tmax showed minor regional differences (<0.5 s) but no reconstruction-dependent variation. Subjective scores showed good interobserver agreement (Kappa > 0.6), with all images diagnostically acceptable. Group C slightly outperformed in gray-white differentiation, ischemic contrast, homogeneity, and artifact suppression, though differences were not significant.

CONCLUSION

The triple-low dose protocol with DLIR-H provides comparable image quality and stable perfusion results while significantly reducing radiation and contrast exposure.

CLINICAL RELEVANCE/APPLICATION

This approach enhances stroke imaging by optimizing dose and contrast use, improving safety and efficiency without compromising diagnostic accuracy.

W5A-SPGI-2 RADIOMICS-BASED RANDOM FOREST CLASSIFICATION OF COLORECTAL LIVER METASTASES ON ABBREVIATED GADOXETATE-ENHANCED MRI

Christina Lim, BSc (*Presenter*)
Robert Policelli (*Abstract Co-Author*)
Carol Johnson (*Abstract Co-Author*)
Aaron D. Ward, PhD (*Abstract Co-Author*)
Karen Dunn (*Abstract Co-Author*)
Darryl W. Ramsewak, MD (*Abstract Co-Author*)
Vibhuti Kalia, MD, FRCR (*Abstract Co-Author*)
Shelby Champion (*Abstract Co-Author*)
Natalie Grindrod (*Abstract Co-Author*)
Zahra Kassam, MD, FRCPC (*Abstract Co-Author*)
Harry R. Marshall, MD, PhD (*Abstract Co-Author*)

PURPOSE

Colorectal cancer (CRC) is the third most common cancer worldwide, with liver metastases (LM) developing in up to 50% of cases. Accurate LM detection is critical for staging and treatment. MRI with hepatobiliary contrast is the most sensitive imaging, and abbreviated protocols are increasingly used. Radiomics—quantitative image analysis—combined with machine learning (ML) offers a promising tool for lesion classification. This study evaluates whether a radiomics-based ML model trained on abbreviated multiparametric MRI can classify liver lesions as accurately as experienced abdominal radiologists. It represents the classification component of a larger ML pipeline for CRC liver lesion triage.

METHODS AND MATERIALS

We retrospectively analyzed abbreviated Gadoxetate-enhanced liver MRI (HBP, T2, DWI) from 58 patients with colorectal adenocarcinoma and suspected LM. Up to 10 lesions per patient were annotated by three abdominal radiologists and segmented in ITK-Snap, yielding 284 lesions (145 metastases, 139 benign). Ground truth was established via pathology (n=57), imaging follow-up (n=215), or surgery (n=12). Radiomic features were extracted from the lesion segmentations to train a random forest classifier. Model performance was assessed using AUC, sensitivity, specificity, and accuracy. Radiologist performance was evaluated on a representative subset of 102 lesions.

RESULTS

The ML model achieved a mean AUC of 0.898 (SD 0.03), comparable to the radiologists' mean AUC of 0.923 ($p = 0.31$, Welch's t-test). Bootstrap-adjusted AUCs confirmed robustness (AUC 0.632 : 0.935; AUC 0.632+ : 0.930). The model demonstrated a sensitivity of 0.82, specificity of 0.84, and accuracy of 83.0%. At matched sensitivity (0.82), the radiologists had a specificity of 0.88 and accuracy of 85.7%. The top 3 radiomic features in order of importance were the first-order features of 10 th percentile, mean, and root mean squared.

CONCLUSION

A radiomics-based random forest model trained on abbreviated Gadoxetate-enhanced MRI achieved diagnostic performance comparable to abdominal radiologists in differentiating colorectal liver metastases from benign lesions. This classification step, as part of a developing pipeline, has the potential to support efficient lesion triage and review, streamlining imaging workflows in CRC care.

CLINICAL RELEVANCE/APPLICATION

Radiomics-based ML applied to abbreviated Gadoxetate-enhanced MRI may enable accurate, reproducible classification of liver lesions in CRC patients, supporting radiologist interpretation and prioritization in high-throughput clinical settings.

W5A-SPGI-3 MULTI-CENTER ASSESSMENT OF HEPATIC STEATOSIS USING ULTRASOUND DERIVED FAT FRACTION (UDFF): REAL-WORLD INSIGHTS FROM A PILOT ROUTINE CLINICAL PRACTICE

Sean D. Raj, MD, MBA (*Presenter*)
Xiaowei Hong (*Abstract Co-Author*)
John Simon, MD (*Abstract Co-Author*)
Barry J. Sadegi, MD (*Abstract Co-Author*)
Lexy Alvarez (*Abstract Co-Author*)
Amanda Klunk (*Abstract Co-Author*)
Cody Kruse (*Abstract Co-Author*)
Erik Sober (*Abstract Co-Author*)

PURPOSE

To evaluate the utility of Ultrasound-Derived Fat Fraction (UDFF), a non-invasive tool for quantifying hepatic fat content, in assessing hepatic steatosis in routine clinical practice using multi-center real-world data.

METHODS AND MATERIALS

A multi-center retrospective analysis evaluated the clinical utility of UDFF in routine practice from patients referred for abdominal ultrasound at SimonMed Imaging (January-April 2025). UDFF was integrated in routine abdominal exam. Clinical indications were categorized as: abnormal labs, abdominal complaints, metabolic dysfunction-associated steatotic liver disease (MASLD), other liver disease, and non-liver disease. Patients were stratified by steatosis severity using UDFF: =5% (Normal), (5,10%](Minimal to Mild), (10,15%] (Mild to Moderate), (15, 20%] (Moderate to Severe), and >20% (Severe). BMI are classified as: <18.5 (Severely

underweight or underweight), 18.5-<25 (Normal), 25-<30 (Overweight), 30-<35 (Obese Class I), 35-<40 (Obese Class II), and =40 (Obese Class III). Sub-analyses evaluated steatosis severity by clinical indications, age, sex, and BMI.

RESULTS

The study included 811 patients (9 sites in Arizona, n=616; 4 sites in Nevada, n=195) with a median UDFF of 7% (interquartile range 5-11%). Steatosis grades were distributed as follows: 35.1% normal (=5%), 33.7% minimal to mild (5-10%), 15.7% mild to moderate (10-15%), 7.3% moderate to severe (15-20%), and 8.3% severe (>20%). Clinical indications varied significantly across grades (p<0.001), with MASLD and abnormal labs more prevalent in steatosis groups (93% and 75%, respectively) compared to the normal group. Older age and higher BMI were associated with greater steatosis severity (p<0.001), with median age increasing from 49 to 54-59 years and median BMI from 26 to 29-32 across normal to severe grades. No statistically significant difference was observed between male and female patients (p=0.5).

CONCLUSION

This real-world evidence study provides the largest reported clinical characterization of UDFF to date, revealing a substantial prevalence of hepatic steatosis, with over 60% of patients having UDFF > 5%. Hepatic steatosis severity using UDFF, is significantly elevated in patients with MASLD, abnormal labs, older age, and higher BMI. These findings underscore UDFF's utility in routine clinical practice for identifying patients at increased risk of advanced steatosis, thereby supporting its role in early detection and risk stratification.

CLINICAL RELEVANCE/APPLICATION

Integrating UDFF into routine abdominal ultrasound offers a non-invasive method to quantify steatosis severity, potentially aiding in the early detection and risk stratification of patients with MASLD and related conditions.

W5A-SPGI-4 DEEP LEARNING-BASED SUPER-RESOLUTION CT RADIOMICS ENHANCES PROGNOSIS PREDICTION FOR PATIENTS WITH HBV-RELATED ACUTE-ON-CHRONIC LIVER FAILURE

Shiman Wu, MD (*Presenter*)
Xueyun Zhang (*Abstract Co-Author*)
Zhenwei Yao (*Abstract Co-Author*)
Qi Zhang (*Abstract Co-Author*)
Yuxin Huang (*Abstract Co-Author*)
Yuxian Huang (*Abstract Co-Author*)
Zhenwei Yao (*Abstract Co-Author*)

PURPOSE

Hepatitis B virus related acute-on-chronic liver failure (HBV-ACLF) is a severe and life-threatening condition, requiring timely prognosis prediction. We aim to evaluate the efficacy of super-resolution CT radiomics in assessing the severity and predicting short-term survival of HBV-ACLF patients.

METHODS AND MATERIALS

A retrospective study was conducted on 181 HBV-ACLF patients who underwent CT scans across two medical centers. The cohort from 146 patients from our institution was divided randomly into train cohort (n = 102) and validation cohort (n =44), while an external test cohort (n = 35) patients were sourced from external clinical center. Super-resolution CT images were reconstructed using Aenerative adversarial network (GAN) hosted on the OnekeyAI Platform. Radiomics features were extracted using ITK-SNAP, and a multi-task least absolute shrinkage and selection operator (LASSO) model was employed to select non-zero radiomics features. Radiomics model were developed using Logistic Regression (LR), Random Forest and Extra Trees algorithms.

RESULTS

The super-resolution technique demonstrated superior predictive power for 28 and 90-day survival compared to traditional radiomics model [AUC of Random Forest model for 90 day survival: 0.881 vs. 0.860 in train cohort, 0.876 vs. 0.791 in validation cohort, 0.741 vs. 0.703 in test cohort]. Super Resolution model is comparable with clinical models. The nomogram model, integrating Super Resolution with the classic clinical model COSSH-ACLFs, yielded the highest predictive accuracy across all cohorts.

CONCLUSION

Super Resolution act great in predicting prognosis and significantly correlative with multi-organ failure. Further integrate Super Resolution radiomics model with clinical model presented best in predicting prognosis in HBV-ACLF.

CLINICAL RELEVANCE/APPLICATION

Integrating super-resolution CT radiomics with clinical models significantly enhances short-term survival prediction in HBV-ACLF, offering a noninvasive tool to guide timely risk stratification and clinical decision-making.

W5A-SPGI-5 RESEARCH ON PREDICTION OF PERINEURAL INVASION IN RECTAL CANCER BASED ON MRI RADIOMICS AND DEEP LEARNING

Yuxuan Wang (*Presenter*)

PURPOSE

To explore the application value of a fusion model based on MRI radiomics and deep learning in the preoperative prediction of perineural invasion (PNI) in rectal cancer (RC) patients.

METHODS AND MATERIALS

Preoperative MRI images from 404 rectal cancer patients with pathologically confirmed PNI status were retrospectively collected from the first center and randomly divided into a training set and a test set in a 7:3 ratio. Additionally, 100 cases from the second center were prospectively collected as an external validation set.The regions of interest (ROIs) were manually delineated on T2-weighted imaging (T2WI) using ITK-SNAP software. Radiomics features were extracted using PyRadiomics, and deep learning features were extracted using ResNet-50 as the base model. After multi-step dimensionality reduction to screen key features, radiomics models, deep learning models, and combined feature models were constructed using support vector machine (SVM), decision tree (DT), random forest (RF), logistic regression (LR), k-nearest neighbor (KNN), and XGBoost.Model performance was evaluated using the area under the curve (AUC), calibration curves, and decision curve analysis (DCA).

RESULTS

(1) After multi-step feature selection, we identified 26 predictive features (8 radiomics, 18 deep learning). The radiomics model achieved optimal performance using logistic regression (training/test/validation AUCs: 0.808/0.771/0.754), while the deep learning model performed best with SVM (AUCs: 0.853/0.802/0.786).(2) The fusion model significantly outperformed single-modality approaches, with SVM showing the best performance (AUCs: 0.871/0.831/0.822). The model demonstrated excellent calibration across all datasets and showed clinically meaningful benefits in decision curve analysis.

CONCLUSION

The fusion model based on MRI radiomics and deep learning demonstrates significant application value in the preoperative prediction of PNI in rectal cancer, and can provide reference for individualized treatment decision-making.

CLINICAL RELEVANCE/APPLICATION

This study constructed and validated multimodal prediction models based on radiomics features, deep learning features, and their fusion. These findings provide important methodological references for developing noninvasive preoperative prediction tools for PNI in rectal cancer, and hold significant value for guiding individualized treatment planning.

W5A-SPGI-7 DUAL-ENERGY SPECTRAL IMAGING FOR DIFFERENTIATING INTRAPANCREATIC ACCESSORY SPLEEN FROM HYPERATTENUATING PANCREATIC TUMORS ON SINGLE-PHASE CONTRAST-ENHANCED CT

Yasunori Nagayama, MD (*Presenter*)
Taihei Inoue, MD, PhD (*Abstract Co-Author*)
SOICHIRO ISHIUCHI (*Abstract Co-Author*)
Sadahiro Yamamura (*Abstract Co-Author*)
Yasuaki IGARASHI (*Abstract Co-Author*)
Ryuya Yoshida (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic performance of dual-energy spectral imaging for differentiating intrapancreatic accessory spleen (IPAS) from hyperattenuating pancreatic tumors using single-phase contrast-enhanced CT.

METHODS AND MATERIALS

This retrospective study included 84 patients with hyperattenuating pancreatic lesions (28 IPAS and 56 non-IPAS) who underwent portal venous phase dual-energy CT (DECT) with a dual-layer spectral detector system. For quantitative analysis, signal intensities of lesions and spleen were measured on conventional images, virtual monochromatic images (VMI; 40-140 keV), virtual non-contrast (VNC) images, iodine density (ID) maps, and effective atomic number (Zeff) maps. Relative signal ratios were defined as the absolute difference between lesion and splenic signals divided by the splenic signal (values closer to zero indicate greater similarity to spleen). Quantitative variables were compared between IPAS and non-IPAS groups using the Mann-Whitney U test, and diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUC). For pancreatic tail lesions (28 IPAS, 24 non-IPAS), three radiologists subjectively scored the likelihood of IPAS on a five-point scale (1=definitely non-IPAS; 5=definitely IPAS) using (1) conventional images only and (2) conventional plus spectral images. Pooled AUCs s for subjective assessments were compared using the DeLong method.

RESULTS

All relative signal ratios were significantly lower in IPAS than in non-IPAS (all $p<0.001$). AUCs for conventional, VNC, ID, and Zeff images were 0.824, 0.804, 0.951, and 0.949, respectively. VMI showed improved performance at lower energies, with AUCs increasing from 0.773 at 140 keV to 0.956 at 40 keV. For pancreatic tail lesions, subjective diagnostic performance was significantly improved with the addition of spectral information compared to conventional images alone (AUC: 0.960 vs. 0.696, $p<0.001$).

CONCLUSION

Spectral imaging derived from single-phase DECT improved the quantitative and subjective differentiation of IPAS from hyperattenuating pancreatic tumors.

CLINICAL RELEVANCE/APPLICATION

DECT-based spectral analysis of hyperattenuating pancreatic lesions enables accurate identification of IPAS using only portal venous phase imaging, potentially obviating the need for further diagnostic procedures.

W5A-SPGI-9 FLUCTUATION OF VIRTUAL NON-CONTRAST IMAGING MEASUREMENTS IN PHOTON-COUNTING ABDOMINAL CT

Ali Pourvaziri, MD, MPH (*Presenter*)
Fides Schwartz, MD (*Abstract Co-Author*)
Aaron D. Sodickson, MD, PhD (*Abstract Co-Author*)

PURPOSE

To assess variability in virtual non-contrast (VNC) Hounsfield unit (HU) measurements across contrast-enhanced phases in photon-counting abdominal CT and evaluate their correlation with iodine density.

METHODS AND MATERIALS

We retrospectively analyzed 108 patients who underwent multiphase contrast-enhanced abdominal CT on a photon-counting scanner (Naeotom Alpha, Siemens Healthineers) at two academic centers. ROIs were placed in the renal cortex, aorta, liver, and—if contrast was present—the renal collecting system in the same location on all available phases. All measurements were performed using Syngo.Via software. Mean VNC values and iodine densities were recorded. One-way ANOVA assessed VNC variation between phases in kidney, aorta, and liver in the same location in each patient. Pearson's and Spearman's tests evaluated correlations between VNC and iodine concentration for the pooled data across all phases and measured organs. Piecewise linear regression was applied to pooled data to assess threshold effects.

RESULTS

The cohort included 108 patients (59M, 49F; mean age: 66.4 ± 14.1). Phases included 36 arterial, 38 venous, 50 nephrographic, 70 delayed, and 25 split-bolus exams. VNC variability between scan phases was highest in the kidney (mean: 7.7 HU; range: 0.1-126.2; SD: 14.4), followed by the liver (mean: 4.0 HU; SD: 6.9) and aorta (mean: 4.9 HU; SD: 3.7). For the pooled data, in contrast to other organs, a moderate positive correlation in the renal collecting system between VNC and iodine was observed as the concentration increased ($r = 0.40$). A significant breakpoint at 10.39 mg/mL iodine ($F = 116.7$, $p < 10?44$) indicated minimal VNC change below this level and a steeper increase above it.

CONCLUSION

VNC values are stable in low to moderate iodine concentrations but diverge due to incomplete iodine subtraction in high-iodine settings, particularly in the renal collecting system.

CLINICAL RELEVANCE/APPLICATION

Interpretation of absolute VNC values should be cautious in regions with high iodine content

W5A-SPGI-10 ABDOMENATLAS 2.0: COMPREHENSIVE LESION ANNOTATIONS IN LIVER, PANCREAS, KIDNEY, AND COLON FOR 9,901 THREE-DIMENSIONAL COMPUTED TOMOGRAPHY

Zongwei Zhou, PhD (*Presenter*)
Xinze Zhou (*Abstract Co-Author*)
Yuxuan Zhao (*Abstract Co-Author*)
Qi Chen (*Abstract Co-Author*)
Wenxuan Li, BS (*Abstract Co-Author*)
Dexin Yu (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

To create a large-scale dataset of per-voxel annotated abdominal lesions. This dataset includes lesions in the liver, pancreas, kidney, and colon.

METHODS AND MATERIALS

We first pre-trained an AI model on four publicly available datasets using the organ and lesion labels provided by each dataset. The model was then used to generate pseudo labels for 9,901 three-dimensional CT volumes, segmenting seven critical structures in the abdominal region, including the liver, pancreas, kidney, liver lesion, pancreatic lesion, kidney lesion, and colon lesion. High-quality pseudo-labels can be ensured through the following two key points: (a) A pre-trained AI model with High (or near perfect) Sensitivity and acceptable Specificity. (b) Well-designed post-processing strategies, including (I) Tumors in the range of organs, (II) Tumors greater than 1.5 mm radius. To convert pseudo labels into clinically trustworthy annotations, a team of 23 board-certified radiologists was engaged to perform detailed annotation and validation using the open-source platform 3D-Slicer. Each radiologist worked approximately 8 hours per week over a period of 6 months, during which all annotations of 9,901 volumes were thoroughly reviewed and corrected. Final annotations were confirmed through visual inspection to ensure accuracy and consistency.

RESULTS

AbdomenAtlas 2.0 is a high-quality dataset consisting of 9,901 CT volumes with four anatomical lesions (liver, pancreas, kidney, colon) annotated in detail, encompassing over 4.7 million slices. The dataset spans a wide range of patient demographics, including variations in age, gender, disease stages, and imaging protocols, collected from 89 medical centers worldwide. It includes 6937 liver tumor lesions, 390 pancreatic lesions, 4328 kidney lesions, and 190 colon lesions. The lesions display diverse morphologies including solitary, multifocal, and infiltrative lesions across different contrast phases and slice thickness. More importantly, the dataset features 5784, 238, 3693, and 78 early-stage lesions (diameter less than 20mm) in liver, pancreas, kidney, and colon respectively.

CONCLUSION

AbdomenAtlas 2.0 is a large-scale, expert-validated dataset of 9,901 abdominal CT scans with detailed lesion annotations. It captures diverse and clinically valuable cases, including thousands of early-stage lesions, providing a strong foundation for developing and evaluating AI models in abdominal lesion detection and segmentation.

CLINICAL RELEVANCE/APPLICATION

AbdomenAtlas 2.0 will be made publicly available to advance medical research, providing doctors, researchers, patients, and students with a comprehensive understanding of lesion characteristics and facilitating early lesion detection.

W5A-SPGI-12 THE HYPERDYNAMIC CIRCULATORY STATE IN CIRRHOSIS: ITS IMPACT ON ARTERIAL CONTRAST ENHANCEMENT IN HYPERVASCULAR HEPATOCELLULAR CARCINOMA

Yasuhiro Inokuchi, RT (*Presenter*)

PURPOSE

Liver cirrhosis (LC) with portal hypertension (PH) is associated with a hyperdynamic circulatory state, potentially leading to dilution of contrast material and reduced first-pass enhancement. This study aimed to evaluate the impact of PH on arterial phase contrast enhancement in hypervascular hepatocellular carcinoma (HCC) and the aorta.

METHODS AND MATERIALS

We retrospectively analyzed 26 patients with LC who underwent contrast-enhanced dynamic MDCT from February 2016 to December 2017. Eleven of these patients had 25 hypervascular HCCs and were divided into two groups: Group A (n=7, HCC=10, without PH) and Group B (n=4, HCC=15, with PH). We compared the liver-to-tumor contrast-to-noise ratio (LTC) and aortic attenuation in the arterial phase between the two groups. Correlation between LTC and aortic attenuation was also assessed.

RESULTS

Group B (with PH) showed significantly lower LTC and aortic enhancement compared to Group A ($P = 0.002$ and $P < 0.001$, respectively). A moderate positive correlation was observed between LTC and aortic attenuation ($r = 0.62$, $P < 0.001$).

CONCLUSION

Portal hypertension in cirrhotic patients may reduce arterial phase contrast enhancement in both hypervascular HCC and the aorta, likely due to a hyperdynamic circulatory state. These findings highlight the importance of considering systemic hemodynamics in the interpretation of dynamic CT imaging in LC patients.

CLINICAL RELEVANCE/APPLICATION

In cirrhotic patients with portal hypertension, decreased arterial enhancement may lead to underestimation of tumor vascularity in hypervascular HCC. Awareness of this phenomenon is essential for accurate CT interpretation and may influence diagnostic confidence and management strategies.

W5A-SPGI-13 MULTIPARAMETRIC MRI-BASED RADIOMICS NOMOGRAM TO QUANTITATIVELY PREDICT SYNCHRONOUS DISTANT METASTASIS IN RECTAL CANCE

Hao Jiang (*Presenter*)
Huijie Jiang, PhD, MS (*Abstract Co-Author*)

PURPOSE

The preoperative identification of rectal cancer(RC) patients with a high-risk of synchronous distant metastasis(SDM) is crucial for personalized management strategies and prognosis. In this study, based on multiparametric MRI radiomics features, we developed a nomogram to evaluate its predictive value for preoperative SDM of RC.

METHODS AND MATERIALS

This retrospective study enrolled 169 patients with histopathology- confirmed rectal adenocarcinoma. The radiomics features were extracted through the PyRadiomics package of the Python language, and a total of 1688 radiomics features were extracted from pretreatment multiparametric MRI. The univariate statistical tests and three feature selection methods were employed to screen clinical factors and radiomics features for predicting SDM. One clinical model, three radiomics models and clinical-radiomics model were constructed. The performance of these models was evaluated using the AUC and the DeLong test. The clinical utility of these models was assessed through calibration curve analysis and DCA.

RESULTS

Eighty-two patients (48.5%) were confirmed to have SDM. After the screening process, 4 clinical characteristics were selected. Diffusion-weighted (DW) phase images retained 8 features; T2-weighted (T2W) phase images retained 8 features; Radiomics model (DW phase and T2W phase images) retained 6 features. This nomogram model performed superior in predicting SDM of RC. In the training set, the AUC, accuracy, sensitivity, specificity and 95%CI were 0.93, 0.85 (114/134), 0.85 (55/65), 0.86 (59/69), 0.89-0.96, respectively. In the test set, five indexes of the nomogram model were 0.94, 0.89 (31/35), 0.88 (15/17), 0.89 (16/18), and 0.79-0.97, respectively. The correction plots were consistent between the predictions of the nomogram model and the actual observed probabilities. DCA showed that the nomogram model achieved the highest net benefit on the training set and the test set compared to the clinical model and the radiomics model.

CONCLUSION

The multiparametric MRI-based radiomics nomogram could achieve precise individualized prediction of SDM in patients, potentially improving the management of RC.

CLINICAL RELEVANCE/APPLICATION

Rectal cancer is the third most common malignant cause of morbidity and mortality. Distant metastasis remains the main cause of treatment failure in patients with rectal cancer. Therefore, preoperative diagnosis of colorectal cancer patients at high risk for SDM is essential for personalized management strategies. We established a radiomics nomogram for preoperative identification of high SDM risk rectal cancer patients, which can help improve decision-making and guide personalized patient management.

W5A-SPGI-14 A NOMOGRAM INCORPORATING DUAL-ENERGY CT PARAMETERS AND CLINICAL FEATURES FOR PREOPERATIVE PREDICTION OF LYMPH NODE METASTASIS IN COLORECTAL CANCER

Fene Hao (*Presenter*)
Yana Dou (*Abstract Co-Author*)

PURPOSE

To investigate the predictive value of a nomogram integrating clinical features and dual-energy CT (DECT) parameters for preoperative prediction of lymph node metastasis (LNM) in colorectal cancer (CRC).

METHODS AND MATERIALS

Clinical and imaging data of 104 CRC patients who underwent triphasic contrast-enhanced DECT scans between October 2019 and December 2024, with postoperative pathological confirmation, were retrospectively analyzed. Evaluated variables included clinical factors (age, sex, CEA, CA19-9, gross tumor type, T stage, differentiation grade) and DECT features (maximum short-axis diameter, shape, margin, density, enhancement degree of lymph nodes). Quantitative DECT parameters across three phases were measured: iodine concentration (IC), normalized iodine concentration (NIC), electron density (Rho), normalized electron density (NRho), effective atomic number (Zeff), normalized effective atomic number (NZeff), spectral curve slope (?Hu), extracellular volume fraction (ECV), and arterial enhancement fraction (AEF). Univariate and multivariate logistic regression identified independent predictors and constructed predictive models. Receiver operating characteristic (ROC) curves were used to evaluate predictive performance, with calculation of the area under the curve (AUC), sensitivity, and specificity

RESULTS

CEA, T stage,maximum short-axis diameter of lymph nodes, venous-phase NIC, delayed-phase NIC,ECVand AEF were independent predictors of CRC LNM (all $P < 0.05$). The combined nomogram achieved superior predictive performance (AUC = 0.925), significantly outperforming the clinical model (AUC = 0.688, $P < 0.05$) and showing comparable accuracy to the DECT model (AUC = 0.787, $P < 0.05$).

CONCLUSION

The developed nomogram, integrating clinical risk factors and DECT-derived parameters, demonstrates favorable preoperative predictive capability for LNM in CRC, offering a valuable tool for optimizing preoperative evaluation and personalized treatment strategies.

CLINICAL RELEVANCE/APPLICATION

This nomogram is non-invasive and highly practical, providing a novel predictive tool for the preoperative individualized assessment of lymph node metastasis in CRC patients.

W5A-SPGI-16 CT-REVEALED PALN TRIAD: A POWERFUL PROGNOSTIC MARKER FOR METASTATIC RISK IN STAGE III LEFT-SIDED COLON CANCER

Mai Ding (*Presenter*)
Zhen Guan (*Abstract Co-Author*)
Ying-shi Sun, PhD (*Abstract Co-Author*)

PURPOSE

This study establishes objective CT criteria for evaluating para-aortic lymph node (PALN) characteristics in stage III left-sided colon cancer, identifying imaging biomarkers that independently predict metastatic progression and may guide personalized adjuvant treatment strategies.

METHODS AND MATERIALS

We conducted a retrospective analysis of 127 surgically-confirmed stage III left-sided colon cancer patients (2015-2019) who underwent preoperative contrast-enhanced CT, systematically evaluating twelve PALN imaging features including size (short diameter =10mm), morphology (angulation sign defined as non-arc nodal surface), perinodal fat infiltration, and enhancement patterns, while controlling for clinicopathological factors (tumor markers, molecular profiles, and treatment data) through Kaplan-Meier survival analysis and multivariable Cox regression to identify independent predictors of 5-year metastasis-free survival.

RESULTS

Multivariable analysis revealed three PALN features as independent metastatic risk factors: maximum short diameter=10mm (HR=2.48, p=0.045), angulation sign (HR=2.64, p=0.039), and perinodal fat infiltration (HR=4.49, p=0.009), with patients exhibiting =2 high-risk features showing significantly worse 5-year metastasis-free survival compared to those with =1 feature (p<0.001) despite receiving adjuvant chemotherapy.

CONCLUSION

This study validates three specific CT-detectable PALN characteristics - size, angulation sign, and fat infiltration - as robust prognostic biomarkers that enable risk stratification in stage III left-sided colon cancer, providing radiologists and oncologists with an objective imaging framework for metastatic risk assessment.

CLINICAL RELEVANCE/APPLICATION

This study provides critical evidence that patients with stage III left-sided colon cancer exhibiting =2 high-risk PALN features (short diameter =10mm, angulation sign, or perinodal fat infiltration) on preoperative CT have significantly worse outcomes despite standard adjuvant chemotherapy. These readily identifiable imaging biomarkers enable: (1) identification of chemotherapy-resistant subgroups requiring treatment intensification (e.g., extended regimens or targeted therapies), (2) standardized risk assessment for clinical trial stratification, and (3) cost-effective prognostic evaluation using routine CT protocols.

W5A-SPGU-1 FIRST IMPRESSIONS COUNT: HOW IMAGING ORDER IMPACTS ULTRASOUND ACCURACY IN RENAL STONES ASSESSMENT

Lara Gabrielle L. Lim, MD (*Presenter*)
Kai-Ho Fok (*Abstract Co-Author*)
Deelan Patel, MD (*Abstract Co-Author*)
Errol Colak, MD (*Abstract Co-Author*)
Michael Ordon (*Abstract Co-Author*)
Guan Huang, MD, FRCPC (*Abstract Co-Author*)

PURPOSE

Accurate detection and measurement of renal stones guides clinical decision-making, as stone size predicts spontaneous passage and selecting appropriate management. The gold standard for evaluation has been non-contrast computed tomography (NCCT) due to its high sensitivity and specificity. However, ultrasonography (US) is increasingly used to reduce radiation exposure, cost, and accessibility and has been shown to be a viable alternative imaging modality in select clinical scenarios. Prior studies show US sensitivity and specificity vary with stone size and location, and US tends to overestimate stone size. We evaluated US performance using a modern dataset at our tertiary stone referral centre, assessing the impact of imaging sequence (NCCT first or US first) on diagnostic accuracy.

METHODS AND MATERIALS

A single center retrospective study was performed between January 1, 2017 and September 30, 2022. Patients who underwent both an US and NCCT within 15 days of each other were included. The earliest pair was included for patients who had multiple pairs (n = 25). For each stone, laterality, location, and maximum long-axis size were recorded and corresponding stones were matched between modalities. Patients who had more than 8 stones were excluded as there is likely minimal benefit of US in this clinical scenario (n=34). Patients who only had ureteral stones were excluded (n=13). Statistical analysis was performed with MATLAB (R2024b, Mathworks, 2024).

RESULTS

A total of 206 patients met our inclusion/exclusion criteria (105 female, 143 male; age range 21-89; mean age 59.3 ± 1.1). A total of 454 kidney stones were identified with 121 patients having US first and 85 having CT first. US overestimated stone size (US mean 5.6 ± 0.01mm, CT mean 3.83 ± 0.02mm, $p<0.001$, CI [1.42, 2.03]) and the effect was more pronounced for smaller stones less than 4mm (mean discrepancy 2.2 ± 0.12mm) in comparison to larger stones >=4mm (mean discrepancy 0.43 ± 0.46mm, $p<0.001$). The sensitivity and specificity of US were 65.4% and 41.1%, respectively. When US was performed first, sensitivity was 65.8% and specificity dropped to 17.6%. In contrast, when CT was performed first, sensitivity was 53.5% and specificity increased to 75.0%.

CONCLUSION

US sensitivity and specificity in detecting renal stones were consistent with prior reports. We demonstrate that the specificity of US can be improved if a CT is done first. Stone size tends to be overestimated, especially for smaller stones.

CLINICAL RELEVANCE/APPLICATION

US remains operator dependent for detection of renal stones but our data reveals opportunities to improve performance if a CT is done prior. US stone size should be used cautiously to guide clinical management decisions, particularly for smaller stones.

W5A-SPGU-4 DIAGNOSTIC PERFORMANCE OF SPECTRAL CT TECHNOLOGIES IN DIFFERENTIATING URINARY TRACT STONES FROM PELVIC PHLEBOLITHS AND VASCULAR CALCIFICATIONS

Ahmed Benghatnsh, MD (*Presenter*)
Jacob Sharafuddin, BA (*Abstract Co-Author*)
Jacob Elam, MD (*Abstract Co-Author*)
Ramandeep Singh, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of spectral CT technologies including first-generation photon-counting CT (PCCT) and third-generation dual-energy CT (DECT) in differentiating urinary stone subtypes from pelvic phleboliths and vascular calcifications.

METHODS AND MATERIALS

This IRB-approved retrospective study included patients who underwent spectral CT with confirmed urinary stone composition post extraction: 31 PCCT (NAEOTOM Alpha:20 calcium oxalate, 11 calcium phosphate) and 94 DECT (SOMATOM Force:52 calcium oxalate, 33 calcium phosphate). Patient age and BMI were recorded. 128 phleboliths and 76 vascular plaques were identified on PCCT, and 184 phleboliths and 131 plaques on DECT. Automatic segmentation with a stone marker was performed and attenuation values (in Hounsfield units-HU) were measured for stones, plaques, and phleboliths on syngo.via VB80D system (Siemens Healthineers, Forchheim, Germany) across multiple energy levels-PCCT (low- and high-energy 120 kV, monoenergetic 70 keV) and DECT (90 kV, Sn150 kV, and 0.6 mixed kV). Attenuation ratios (RA) were automatically generated. Non-parametric statistical analysis (Mann-Whitney U test) was performed using IBM SPSS Statistics for Windows, Version 29.0 (IBM Corp., Armonk, NY, USA). A p-value < 0.05 was deemed statistically different.

RESULTS

Both spectral CT technologies enabled reliable differentiation of urinary stones from mimicking calcifications. For calcium oxalate stones (Mean RA PCCT1.56, DECT 1.56), both DECT and PCCT demonstrated significant separation from vascular plaques, with DECT showed difference ($p<0.001$) across all energy levels and PCCT achieving $p = 0.04$ at ME70. For calcium phosphate stones (Mean RA PCCT1.51, DECT 1.70) , DECT and PCCT showed statistically significant differentiation from plaques ($p < 0.05$ and $p = 0.02$, respectively). Both modalities also significantly differentiated stones from phleboliths ($p < 0.001$). DECT distinguished calcium oxalate from phosphate stones with high statistical confidence ($p < 0.002$). Phleboliths (Mean RA PCCT1.54, DECT 1.80), plaques (Mean RA 1.60 PCCT, DECT 1.71).

CONCLUSION

Spectral CT techniques, including both PCCT and DECT, using automatic segmentation with spectral attenuation values and calculated ratios allow differentiation of urinary stones from phleboliths and vascular plaques, as well as between calcium oxalate and phosphate stone subtypes.

CLINICAL RELEVANCE/APPLICATION

These findings support the utility of spectral CT in evaluating calcified abdomen and pelvis structures and may guide further exploration of spectral data in urinary stone analysis.

W5A-SPGU-5 COMPARISON OF PROSTATE MRI IMAGE QUALITY AT 3TESLA(T) WITHOUT DEEP LEARNING RECONSTRUCTION (DLR) AND 1.5 T WITH DLR

Hemal Grover, MD (*Presenter*)
Daniel Z. Mogel, DO (*Abstract Co-Author*)
Alexander C. Kagen, MD (*Abstract Co-Author*)
Varun Chandran, MD (*Abstract Co-Author*)
Mark A. Ravago, MD (*Abstract Co-Author*)
Amine G. Geahchan, MD (*Abstract Co-Author*)
Amita Kamath, MD, MPH (*Abstract Co-Author*)
Francisco Restrepo, PhD (*Abstract Co-Author*)
Valentin Fauveau, MSc (*Abstract Co-Author*)
Bachir Taouli, MD (*Abstract Co-Author*)
Sara Lewis, MD (*Abstract Co-Author*)
Neil M. Rofsky, MD (*Abstract Co-Author*)
Christine Chen, MD (*Abstract Co-Author*)

PURPOSE

To compare quantitative and qualitative image quality of prostate magnetic resonance imaging (MRI) at 3T without deep learning reconstruction (DLR) and 1.5 T with DLR.

METHODS AND MATERIALS

In this IRB-approved retrospective study, 100 consecutive patients (mean age 67±8.6, PSA 10.4±18.6, PSA density 0.21±0.36) referred for standard of care prostate MRI underwent 3T MRI without DLR (n=50) or 1.5T MRI with DLR (n=50) between 6/2023-4/2024. All patients underwent T2-weighted imaging (T2WI), focused (b=800) and synthetic diffusion weighted imaging (DWI), and apparent diffusion coefficient (ADC) maps were generated. For quantitative analysis, regions of interest (ROI) were placed over the whole prostate (WP), transition zone (TZ), peripheral zone (PZ), prostate lesion, obturator internus muscle (OIM), and used to calculate signal intensity (SI). Normalized SI (nSI) was calculated using the SI of the ROI divided by the SI of the OIM. Four ROIs were drawn at four corners of the image to calculate background noise; mean standard deviation from these 4 corners was recorded (D). Signal-to-noise ratio (SNR) was determined using the formula 0.66 x nSI/D * v10/3. Contrast-to-noise ratio (CNR) relative to OIM was determined by the formula SI-SI(OIM)/D. Mean SNR and mean CNR for WP, TZ, PZ and prostate lesions on T2WI, DWI and ADC at 3T without DLR and 1.5T with DLR were compared. For qualitative analysis, 3 fellowship-trained body imagers (15, 8 and 2 years of experience; blinded to 3T vs 1.5 T) independently scored T2WI, DWI and ADC images on a scale of 1-5 on 4 parameters: lesion detection, margin sharpness, artifacts and overall image quality. P-values were calculated using Wilcoxon signed rank test (for SNR, CNR) and Mann Whitney U test (for qualitative data). Interobserver agreement was calculated using Fleiss Kappa (FK).

RESULTS

1.5T MRI with DLR demonstrated higher SNR and CNR for all subgroups (WP, TZ, PZ, prostate lesion) compared to 3T MRI without DLR; with statistical significance for T2WI ($p<=0.001$), and results not statistically significant for DWI and ADC. On qualitative analysis, 3T group without DLR scored higher than 1.5 T with DLR on all parameters for all sequences (statistically significant $p<0.03$) with fair inter-observer agreement (FK 0.2-0.4), although the difference in mean scores between the 2 subgroups was small (0.3-0.6).

CONCLUSION

1.5 T MRI with DLR demonstrates superior SNR and CNR compared to 3T without DLR. On qualitative assessment, 3T scored higher on all subjective image quality parameters, although the difference in mean scores between the 2 subgroups was small.

CLINICAL RELEVANCE/APPLICATION

1.5 T with DLR can be useful for prostate imaging in institutions without 3T MRI or in low resource settings.

W5A-SPGU-6 ANALYSIS OF IMAGING PARAMETERS AFFECTING STONE DETECTION ACCURACY USING THE VIRTUAL UNENHANCEDIMAGES AT NEPHROGRAPHIC PHASE IN CONTRAST-ENHANCED DUAL-ENERGY CT UROGRAPHY

Yannan Cheng, BS,BS (*Presenter*)
Jianying Li, PhD (*Abstract Co-Author*)
Jianxin Guo (*Abstract Co-Author*)

PURPOSE

To investigate imaging parameters influencing urinary stone detection accuracy using virtual unenhanced (VUE) images at nephrographic phase (NP) in contrast-enhanced dual-energy CT urography (DECTU).

METHODS AND MATERIALS

150 patients with urinary stones (mean age: 47.51±14.42 years; males vs females: 101 vs 49) who required triphasic DECTU were included. The true unenhanced (TUE) images and VUE images at NP (VUE(NP)) were reconstructed. Per stone detection rates on the above images were recorded. Stone location, size and CT number on the TUE images were recorded and used in univariate and multivariate logistic regression analyses to investigate factors influencing urinary stone detection rate using VUE(NP) images. Thresholds for detecting urinary stones on VUE (NP) images were determined using receiver operating characteristics (ROC) analysis.

RESULTS

Three hundred and four stones were detected on TUE images; 281 stones were identified on VUE(NP) images (detection rate, 92.4%). CT number (Univariate: $p=0.002$; Multivariate: $p=0.003$) of the stones was important factor affecting the detection of stone on VUE(NP) images, while stone size (Univariate: $p<0.001$; Multivariate: $p=0.084$) and location were not (Univariate: $p=1.00$) (Tab.1 and Fig.1). The area under ROC curve (AUC) of using size and CT number for detecting stone on the VUE(NP) images was 0.96 and 0.97, respectively. And as threshold values, stones with size larger than 3.52 mm and CT number greater than 469 HU were found with high accuracy (Tab. 2).

CONCLUSION

VUE(NP) images in DECTU provide high stone detection rate and high accuracy with thresholds for stone size=3.52 mm and CT number=469 HU.

CLINICAL RELEVANCE/APPLICATION

It is feasible to detect and measure urinary stones at VUE(NP) images in DECTU with high stone detection rate and high accuracy.

W5A-SPHN-2 DIFIUSION-WEIGHTED IMAGING COMBINED WITH AMIDE PROTON TRANSFER WEIGHTED IMAGING WAS USED TO DIFFERENTIATE BENIGN AND MALIGNANT PAROTID GLAND TUMORS

Feng Yu (*Presenter*)
Lijun Wang (*Abstract Co-Author*)

PURPOSE

To investigate the combination of DWI and APTw sequence in the differential diagnosis of benign and malignant parotid tumors.

METHODS AND MATERIALS

A total of 90 patients with pathologically confirmed solid parotid tumors underwent 3.0TMRI examination in our hospital were retrospectively analyzed, including 72 benign tumors and 18 malignant tumors(MT), which were further divided into four groups: pleomorphic adenoma(PA) (n=38), Warthin tumor(WT) (n=24), basal cell adenoma (BCA)(n=10) and malignant tumors. Two observers measured the ADC and APT values of the two groups of lesions.Logistic regression was used to analyze the statistically significant parameters and the diagnostic model combined with baseline data. Adopt the receiver-operating characteristics (ROC) there are differences between the curve of assessment parameters and joint diagnosis efficiency of the model. The DeLong test was used to compare the differences in the area under the ROC curve

RESULTS

(1) The inter-observer agreement of ADC and APT values was good (ICC > 0.75). (2) The ADC values of WT and MT were lower than those of PA (P<0.001). The ADC value of WT was lower than that of BCA (P<0.001). The APT values of PA, WT and BCA were significantly higher than those of MT (P<0.05). (3) The AUC of ADC, APT and their combination in the differential diagnosis of parotid PA and WT were 0.878 (P<0.001), 0.679 (P< 0.011) and 0.882 (P<0.001), respectively. The AUC of parotid PA and malignant tumor were 0.879(P<0.001), respectively. The AUC of WT and BCA were 0.883(P<0.001), 0.535(P=0.744) and 0.858(P<0.001), respectively. Delong test showed that the AUC of ADC value and their combination in the differential diagnosis of parotid PA and WT were higher than APT value (P=0.021). The AUC of WT and BCA were both larger than APT value (P=0.007). The AUC of the combination of the two values in the differential diagnosis of parotid PA and MT was greater than that of APT value (P=0.022). There was no correlation between ADC values and APT values

CONCLUSION

DWI and APT can be used to quantitatively evaluate the characteristics of parotid gland tumors. ADC value, APT value and their combination have similar efficacy in the differential diagnosis of parotid gland tumors, and the combination of ADC value and APT value has the highest efficacy in the differential diagnosis of PA and MT.

CLINICAL RELEVANCE/APPLICATION

DWI and APT can be used to quantitatively evaluate the characteristics of parotid gland tumors. ADC value, APT value and their combination have similar efficacy in the differential diagnosis of parotid gland tumors, and the combination of ADC value and APT value has the highest efficacy in the differential diagnosis of PA and MT.

W5A-SPHN-5 ASSESSING THE DIAGNOSTIC ACCURACY OF AI IN DETECTING PERIAPICAL LESIONS ON PANORAMIC AND CBCT IMAGE

Wojciech Kazimierczak, MD, PhD (*Presenter*)
Natalia Kazimierczak (*Abstract Co-Author*)
Roza Wajer, MD (*Abstract Co-Author*)
Natalia Chwarscianek (*Abstract Co-Author*)
Adrian Wajer (*Abstract Co-Author*)
Zbigniew Serafin (*Abstract Co-Author*)

PURPOSE

Periapical lesions (PLs) are frequently detected in dental radiology. Accurate diagnosis of these lesions is essential for proper treatment planning. Imaging techniques such as orthopantomogram (OPG) and cone-beam CT (CBCT) imaging are used to identify PLs. The aim of this study was to assess the diagnostic accuracy of artificial intelligence (AI) software Diagnocat for PL detection in OPG and CBCT images.

METHODS AND MATERIALS

The study included 49 patients, totaling 1223 teeth. Both OPG and CBCT images were analyzed by AI software and by three experienced clinicians. All the images were obtained in one patient cohort, and findings were compared to the consensus of human readers using CBCT. The AI's diagnostic accuracy was compared to a reference method, calculating sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value (NPV), and F1 score.

RESULTS

The AI's sensitivity for OPG images was 33.33% with an F1 score of 32.73%. For CBCT images, the AI's sensitivity was 77.78% with an F1 score of 84.00%. The AI's specificity was over 98% for both OPG and CBCT images.

CONCLUSION

The AI demonstrated high sensitivity and high specificity in detecting PLs in CBCT images but lower sensitivity in OPG images.

CLINICAL RELEVANCE/APPLICATION

AI models can help clinicians identify periapical pathologies with greater speed and consistency, especially in early or subtle cases that can be overlooked by the human eye. This will result in increased diagnostic support and more accurate endodontic care in daily practice.

W5A-SPHN-6 EVALUATING THE RELIABILITY OF AI-ASSISTED DETECTION OF ROOT APEX PROXIMITY TO THE MANDIBULAR CANAL

Wojciech Kazimierczak, MD, PhD (*Presenter*)
Natalia Kazimierczak (*Abstract Co-Author*)
Natalia Chwarscianek (*Abstract Co-Author*)
Zbigniew Serafin (*Abstract Co-Author*)

PURPOSE

This study evaluates the diagnostic accuracy of an AI-assisted tool in assessing the proximity of the mandibular canal (MC) to the root apices (RAs) of mandibular teeth using computed tomography (CT).

METHODS AND MATERIALS

This study involved 57 patients aged 18-30 whose CT scans were analyzed by both AI and human experts. The primary aim was to measure the closest distance between the MC and RAs and to assess the AI tool's diagnostic performance. The results indicated significant variability in RA-MC distances, with third molars showing the smallest mean distances and first molars the greatest. Diagnostic accuracy metrics for the AI tool were assessed at three thresholds (0 mm, 0.5 mm, and 1 mm).

RESULTS

The AI demonstrated high specificity but generally low diagnostic accuracy, with the highest metrics at the 0.5 mm threshold with 40.91% sensitivity and 97.06% specificity.

CONCLUSION

This study underscores the limited potential of tested AI programs in reducing iatrogenic damage to the inferior alveolar nerve (IAN) during dental procedures. Significant differences in RA-MC distances between evaluated teeth were found.

CLINICAL RELEVANCE/APPLICATION

Accurate assessment of the spatial relationship between root apices and the mandibular canal is critical in avoiding complications during dental procedures such as extractions, implant placement, and endodontic treatments ultimately contributing to improved patient outcomes and reduced surgical risks.

W5A-SPHN-7 DIFFERENTIAL TUMOR INFILTRATING LYMPHOCYTE DYNAMICS ACROSS IMMUNE CHECKPOINT INHIBITORS MAY AFFECT EARLY METRICS OF RESPONSE AS MEASURED BY DIFFUSION-WEIGHTED MRI

Aaron Simon, MD,PhD (*Presenter*)
Robert Saddawi-Konefka (*Abstract Co-Author*)
Lei Gao (*Abstract Co-Author*)
Tomohiko Ishikawa (*Abstract Co-Author*)
Cynthia Zhao (*Abstract Co-Author*)
David R. Vera, PhD (*Abstract Co-Author*)
Loren K. Mell, MD (*Abstract Co-Author*)

PURPOSE

Monitoring tumor response to immune checkpoint inhibitors (ICI) is a challenge due to the disconnect between early and late responses as measured by traditional metrics. Diffusion weighted magnetic resonance imaging (DW-MRI) is a potential solution to this challenge, with early experiments suggesting DW-MRI can capture ICI-induced tumor infiltrating lymphocytes (TIL), predicting tumor response. However, different classes of ICI elicit distinct TIL responses, which could affect DWI-metrics. Here, we used a preclinical model of head and neck squamous cell carcinoma with a characteristic response to CTLA-4 and PD-1 ICIs to investigate the link between TIL dynamics and DW-MRI metrics in response to different ICIs.

METHODS AND MATERIALS

Tongues of C57BI/6 mice were orthotopically implanted with cells from the 4MOSC1 cell line on day 0. Mice underwent DW-MRI on day 4, then received anti-CTLA-4 antibodies (aCTLA4; clone 9H10) (n=29), anti-PD1 antibodies (aPD1, clone J43) (n=28), or control vector (n=27). Imaging was repeated on day 10. DW-MRI sequence: 64-shot SE EPI. Matrix: 128 x 64, in-plane resolution: 0.15 x 0.31 mm, slice thickness: 1mm. B-values: 0 and 1000s/mm 2 . A single diffusion encoding gradient direction was acquired. For each mouse, at each time point, tumor region of interest (ROI) was contoured. Within each ROI, mean apparent diffusion coefficient (ADC) was calculated. Change in tumor volume and intra-tumoral ADC from day 4 to day 10 were calculated. TIL abundance and density on day 10 were assessed by immunohistochemistry (IHC). Day 10 was selected as it precedes measurable tumor volume response in this model.

RESULTS

Fractional change in tumor volume was not significantly different between control (mean ± SEM:1.5±0.2) and aCTA-4 (1.4±0.3, p=0.6) or aPD-1 (1.4± 0.1, p=0.5). Fractional decrease in ADC was smaller in control (-0.19± 0.03) vs. aCTA-4 (-0.27±0.03, p=0.04) but not vs. aPD-1 (-0.20± 0.02, p=0.75). IHC showed significantly less TIL infiltration in control (586 ± 52 cells/mm²) vs. aCTLA-4 (1000 ± 91 cells/mm², $p < 0.0001$) but not vs. aPD-1 (727 ± 68 cells/mm², p = 0.18).

CONCLUSION

In a pre-clinical model with a characteristic response to treatment with CTLA-4 and PD-1 inhibitors, DW-MRI detected differences across treatment arms that preceded measurable changes in tumor size. Differences in DW-MRI metrics corresponded to differences in lymphocyte infiltration.

CLINICAL RELEVANCE/APPLICATION

This study supports the potential for DW-MRI in clinical monitoring of ICI-response but also suggests a complex relationship between imaging metrics and underlying physiology . Clinical studies employing DW-MRI may need to account for differential TIL responses across immunotherapeutic treatments.

W5A-SPHN-8 MAGNETIC RESONANCE ELASTOGRAPHY FOR CHARACTERIZING PAROTID TUMORS: FEASIBILITY AND PRELIMINARY RESULTS

Vitaliy Atamaniuk, MSc, BEng (*Presenter*)
Wojciech Domka (*Abstract Co-Author*)
Lukasz Hanczyk (*Abstract Co-Author*)
Marian Cholewa (*Abstract Co-Author*)
Bogdan Obrzut (*Abstract Co-Author*)
Marzanna Obrzut (*Abstract Co-Author*)

PURPOSE

Magnetic resonance elastography (MRE) is a non-invasive technique for the quantitative assessment of the biomechanical parameters of soft tissues, widely used in liver and brain imaging. Its utility in evaluating other organs—such as the parotid glands, where MRE-derived stiffness values may aid in differentiating tumor types—remains underexplored. This study aimed to assess the feasibility of using MRE with a custom-designed facial passive driver to characterize parotid tumors.

METHODS AND MATERIALS

Fourteen patients (8F, 6M; mean age 60.4 ± 11.7 years; range 39-76 years) with histologically confirmed parotid tumors underwent MRE with 80 Hz vibrations on a 1.5 T whole-body scanner. A custom passive driver was placed over the patient's face, with vibration pads bilaterally covering the parotid glands to enable simultaneous imaging. A motion-sensitive 2D GRE sequence with motion-encoding gradients in the X direction was used to capture shear wave propagation. Stiffness maps were generated using MMDI inversion, and tumor stiffness was quantified from manually drawn regions of interest. When feasible, stiffness of the contralateral healthy parotid gland was also measured (n=8). Tumor types included pleomorphic adenomas (n=7), Warthin tumors (n=5), lymphoepithelial lesions (n=2), and one mucoepidermoid carcinoma (G2). Stiffness trends across tumor types and relative to normal tissue were analyzed descriptively. Spearman's correlation was used to assess the relationship between tumor stiffness and volume. The Wilcoxon signed-rank test was used to compare tumor and healthy gland stiffness.

RESULTS

MRE acquisition succeeded in all 14 patients (15 lesions), with interpretable stiffness maps in every case. Elevated stiffness was observed in pleomorphic adenomas (mean ± SD: 3.41 ± 1.54 kPa, n=7) and the mucoepidermoid carcinoma (3.41 kPa), while Warthin tumors (2.37 ± 0.61 kPa, n=5) and lymphoepithelial lesions (2.41 ± 0.19 kPa, n=2) exhibited lower values. In eight cases where contralateral healthy gland stiffness was available (mean stiffness ± SD: 1.90 ± 0.43 kPa), tumor stiffness was consistently higher (p=0.02). No significant correlation was found between tumor stiffness and volume (rho = 0.27, p = 0.33).

CONCLUSION

MRE of the parotid tumors using a custom passive driver is feasible. Preliminary results suggest that stiffness values differ among tumor types and exceed those of healthy tissue, supporting the potential of MRE in non-invasive tumor characterization. However, larger studies are needed to validate diagnostic accuracy of this method.

CLINICAL RELEVANCE/APPLICATION

Magnetic resonance elastography may enable non-invasive biomechanical characterization of parotid tumors, supporting their differential diagnosis.

W5A-SPIN-2 LABELING ACCURACY OF AN AI TOOL FOR DICOM STANDARDIZATION AND ITS IMPACT ON RADIOLOGISTS' READING TIMES

Jacob J. Visser, MD, PhD (*Presenter*)
Bina Tariq (*Abstract Co-Author*)

PURPOSE

Medical artificial intelligence (AI) tools are increasingly adopted to manage the rising volume of imaging within radiology departments,. However, AI-driven workflow improvement applications have received limited attention. One such tool is ENDEX TM , which automatically standardizes and refines DICOM metadata to ensure consistent image labeling across scanners and institutions, enabling more reliable and efficient automated hanging protocols in PACS. This study evaluates the labeling accuracy of such an AI tool for DICOM standardization and its impact on radiologists' reading times.

METHODS AND MATERIALS

A retrospective cohort study assessed the labeling accuracy of an AI-driven DICOM standardization tool and a retrospective before-after design evaluated its impact on reading times. The AI tool was applied by Telemedicine Clinic (TMC) from 40 National Health Services (NHS) Trusts in the United Kingdom (UK) between 2022 and 2024. Standardized DICOM labels (modality, body part, laterality, plane, protocol) were manually reviewed (gold standard) based on visual evaluation of the images. In a separate impact analysis reading times were compared before and after implementation of the AI tool.

RESULTS

AI-driven DICOM labeling accuracy, evaluated across imaging modalities (CR and CT) and multiple anatomic regions, ranged from 83% to 100% for body part labels, 91% to 100% for plane labels, and 88% to 100% for protocol labels. The impact analysis revealed reductions in average reading times (p-value = 0.02) for CT Abdomen (-2.9 min), Total Body (-2.2 min), Head (-0.73 min), and Temporal Bone (-2.5 min), corresponding to efficiency gains of 8% to 22%. Extrapolated annually, this equals 270 hours saved, or approximately 34 working days. No significant changes in reading time were observed for CT Chest and Sinus/Orbits.

CONCLUSION

The AI-driven DICOM standardization tool demonstrated high labeling accuracy and reduced radiologists' reading times.

CLINICAL RELEVANCE/APPLICATION

This highlight its potential to address long-standing challenges in metadata standardization and streamline radiology workflows.

W5A-SPIN-3 AUTOMATING DEEP INFERIOR EPIGASTRIC ARTERY PERFORATOR (DIEAP) FLAP PLANNING USING FOUNDATION MODEL

Maria Matilde Andrade, MSc (*Presenter*)
Nuno Loucao (*Abstract Co-Author*)
Tiago Marques (*Abstract Co-Author*)
Ricardo Vigario (*Abstract Co-Author*)
Joao Santinha (*Abstract Co-Author*)

PURPOSE

This work combines Segment Anything Model 2 (SAM2) with computer vision methods to automatically segment abdominal perforators in CT images, addressing a labor-intensive step (~2h) in preoperative planning for DIEAP flap procedures. Additionally, this approach computes the intramuscular course length, currently assessed qualitatively.

METHODS AND MATERIALS

18 abdominal CT scans from patients with breast cancer, who were eligible for DIEAP flap procedures, were used. Expert manual annotations served as ground truth.A fully automated pipeline was developed to segment and analyze the intramuscular and subcutaneous courses of perforators. Skin segmentation and the CompositIA model were used to define the abdominal muscle. A 4mm slab thickness MIP was generated to enhance vessel visibility and continuity, facilitating centerline extraction of perforators.Segmentation of the perforators was performed using SAM2, guided by positive and negative point prompts. Positive prompts were derived from the extracted centerline with a local search for high-intensity voxels, while negative prompts were obtained by identifying low-intensity voxels at regular distances and angles. Following segmentation, intramuscular length was computed along the refined centerline.Measurements were compared against expert-derived values.

RESULTS

The proposed pipeline was able to identify and segment 33/36 perforator vessels in 15/18 cases, enabling automatic quantification of intramuscular length with a median difference of 49.8mm (IQR:58mm). These discrepancies are partly explained by the conservative approach of the method and occasional oversegmentation in the reference annotations. Despite these limitations, the method shows potential for consistent and reproducible vessel characterization.

CONCLUSION

This study presents a proof-of-concept, automated approach for segmenting and characterizing the perforator vessels in CT images using non-medical imaging foundation models. While further refinement and validation are needed, the proposed method establishes a robust and reproducible baseline for future developments in automatic quantification of perforator length, tortuosity, and caliber. These findings support the potential of models to drive progress toward scalable, objective, and clinically viable tools for complex segmentation tasks in radiological workflows.

CLINICAL RELEVANCE/APPLICATION

Automated delineation of abdominal perforators can reduce workload and inter-reader variability in DIEAP flap surgical planning. This method introduces objective, quantitative vessel characterization, potentially enhancing clinical decision-making and improving surgical outcomes.

W5A-SPIN-5 ENHANCING SEGMENTATION PERFORMANCE OF INTRACRANIAL HEMORRHAGE THROUGH RELEVANT ANATOMY PRETRAINING AND CT-WINDOW STACKING IN NON-CONTRAST BRAIN CT

Joon Park, MD (*Presenter*)
Hyunki Lee (*Abstract Co-Author*)
Yereen Yoo (*Abstract Co-Author*)
Joonseo Oh (*Abstract Co-Author*)
Jongjun Won, BS (*Abstract Co-Author*)
Gil-Sun Hong, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

To enhance segmentation performance of intracranial hemorrhage (ICH) in brain CT by integrating brain anatomy pretraining and multi-windowing techniques, which could better emulate radiologists' diagnostic reasoning process and compare its performance to the other segmentation models.

METHODS AND MATERIALS

A segmentation network based on STUNet and nnUNet was trained using 1068 non-contrast brain CT scans including intracranial hemorrhage cases, collected from a tertiary academic hospital between January 1, 2000 and August 31, 2018. To address segmentation failures in subtle hemorrhagic regions, the models were pre-trained on brain anatomy segmentation masks including merged regions to elicit semantic representation as boundaries. Additionally, 3 CT windowing settings, Brain (WL/WW: 40/80), Subdural (WL/WW: 80/200), and Bone (WL/WW: 600/2800), were applied to provide preprocessed images with richer contrast information. An internal test and five external test sets, randomly retrieved CT scans from different institutions, were collected. Performances were evaluated using Dice coefficient, sensitivity and specificity, focusing on their ability to detect hemorrhagic regions with minimal false positives.

RESULTS

STUNet outperformed nnUNet when fine-tuned with 3 windowed images on external datasets in terms of Dice coefficient (0.61 vs. 0.58, $p=0.02$). With STUNet, fine-tuning with brain anatomy pre-trained weight offered improved specificity on both internal (0.723 (scratch) vs. 0.850 (fine-tuning with original image) vs. 0.850 (fine-tuning with 3 windowed images); $p=0.022$) and external (0.734 vs. 0.758 vs. 0.789 (listed as same sequence); $p<0.001$) datasets. With nnUNet, fine-tuning with 3 windowed images significantly improved both Dice coefficients (0.533 vs. 0.505 vs. 0.550; $p=0.02$) and specificity (0.440 vs. 0.680 vs. 0.730; $p<0.001$) on external datasets.

CONCLUSION

Combining pre-training brain anatomical structures and three-windowing image preprocessing methods robustly enhances segmentation performance for ICH, particularly in challenging faint regions. Our model could help clinicians' reading, supporting more efficient decision making in acute care settings.

CLINICAL RELEVANCE/APPLICATION

This study mimics the radiologist's diagnostic reasoning by embedding knowledge of brain anatomy and leveraging CT windowing techniques. The resulting model exhibits improved specificity and Dice scores, contributing to reduced false positives and better segmentation performance. This could lead to lessen the burden on physicians during emergency neuroimaging assessments.

W5A-SPIN-6 ANNOTATION-EFFICIENT DEEP LEARNING DETECTION AND MEASUREMENT OF MEDIASTINAL LYMPH NODES IN CT

Leo Joskowicz, PhD (*Presenter*)
Alon Olesinski (*Abstract Co-Author*)
Richard Lederman, MD (*Abstract Co-Author*)
Jacob Sosna, MD (*Abstract Co-Author*)

PURPOSE

Accurate assessment of mediastinal lymph nodes (LNs) in contrast-enhanced CT (CECT) scans is essential for cancer staging and treatment planning. Current guidelines require measurement of enlarged lymph nodes whose short axis length (SAL) is >10mm. Manual detection and measurement of LNs is, however, time-consuming and subject to observer variability.The aim of this study was to evaluate the performance of a novel annotation-efficient deep learning method for automatic detection and segmentation of mediastinal LNs in CECT.

METHODS AND MATERIALS

The semi-supervised method combines the quality advantages of expert annotations with the quantity advantages of pseudo-labeled data. It uses an ensemble of 3D nnU-Net models trained on a few expert-annotated scans to generate pseudo-labels on a large dataset of unannotated scans. The pseudo-labels are then filtered to remove false positive LNs by excluding LNs outside the mediastinum and LNs overlapping with other anatomical structures. Finally, a 3D nnU-Net model is trained using the filtered pseudo-labels. The method helps optimize the ratio of annotated/non-annotated dataset sizes to achieve the desired performance, thus reducing the manual annotation effort.We retrospectively collected 268 chest CECT studies of patients with mediastinal lymphadenopathy from ***** and from a public dataset of 710 unannotated CECT scans from the NIH. Ground truth delineations were obtained from an expert radiologist for 1,817 LNs from ***. Of the 268 scans, 134 scans were used for testing while the remaining ones were used for ensemble training in batches of 17, 34, 67 and 134 scans together with 710 unannotated scans.

RESULTS

The final 3D nnU-Net yielded a lymph node precision and detection of 0.80±0.32 and 0.81±0.33 for lymph nodes > 10mm, 0.80±0.15 and 0.63±0.25 for lymph nodes > 5mm, and 0.76±0.20 and 0.50±0.23 for all lymph nodes, respectively. The lymph node segmentation Dice scores were 0.75±0.22, 0.66±0.13 and 0.66±0.13, for these sizes. The semi-supervised models recall improvements were 11-24% (0.72-0.87) while maintaining comparable precision levels. The mean SAL difference (std) was 4.6 (4.7) mm and 2.3 (3.2) mm, respectively, within the observer variability.

CONCLUSION

Our method requires x4-10 less annotated data to achieve a performance similar to supervised models trained on the same dataset. This constitutes a significant saving in the annotation effort.

CLINICAL RELEVANCE/APPLICATION

Label-efficient automatic detection and measurement of mediastinum lymph nodes in chest CECT may help in the evaluation of patients with enlarged lymph nodes.

W5A-SPIN-7 GENERATING SYNTHETIC CHEST CT RADIOLOGY REPORTS USING LARGE LANGUAGE MODELS- A CHAMELEON DATASET STUDY

Satvik Tripathi (*Presenter*)
Ebubechukwu Enwerem (*Abstract Co-Author*)
Dana Alkhulaifat, MD (*Abstract Co-Author*)
Rupali Jain, MD,MBBS (*Abstract Co-Author*)
Meghana Muppuri (*Abstract Co-Author*)
Emiliano Garza Frias, MD (*Abstract Co-Author*)

Shawn Lyo, MD (*Abstract Co-Author*)
Scott A. Simpson, DO, MEd (*Abstract Co-Author*)
Dania Daye, MD,PhD (*Abstract Co-Author*)
Tessa S. Cook, MD, PhD (*Abstract Co-Author*)

PURPOSE

To address the limited availability of de-identified radiology datasets for AI research, we developed Chameleon , a framework for generating synthetic chest CT radiology reports using large language models (LLMs). This study aimed to evaluate different prompting strategies and conduct expert validation to optimize clinical realism, report structure, and dataset reliability.

METHODS AND MATERIALS

We utilized a HIPAA-compliant deployment of GPT-4o to generate a synthetic dataset encompassing 17 common thoracic pathologies as well as normal findings. Three prompting strategies were tested: (1) zero-shot prompting using minimal instruction, (2) one-shot prompting using a structured template with predefined report sections, and (3) few-shot prompting incorporating multiple real reference reports derived from our institutional clinical database. A total of 99 synthetic test reports were generated across these strategies and blindly evaluated by four clinical readers. Each reviewer assessed content accuracy, stylistic coherence, and formatting, and recorded strategy preference. Inter-reader agreement and qualitative feedback were collected. Based on feedback, we refined the prompting by incorporating 20 additional reference reports for improved contextual grounding.

RESULTS

Few-shot prompting consistently produced the most clinically coherent and well-structured reports. All reviewers preferred the few-shot strategy over zero-shot and one-shot approaches. A score of 96% inter-reader agreement confirmed the high fidelity and reliability of the generated outputs. The improved few-shot prompting method maintained quality at scale, as confirmed by 100% pass rate in downstream quality control. Rapid generation speed further supports the scalability of the Chameleon framework. A secondary quality control step was performed by two board-certified radiologists on a random sample of the enhanced reports, with no failure cases identified. The mean generation time was 0.23 seconds per report.

CONCLUSION

The Chameleon pilot study demonstrates that high-quality, structured, and clinically realistic chest CT radiology reports can be rapidly generated using a HIPAA-compliant LLM with optimized few-shot prompting. Expert validation supports the fidelity of the synthetic reports, enabling their use for natural language processing (NLP), LLM benchmarking, and downstream AI model training in diagnostic radiology.

CLINICAL RELEVANCE/APPLICATION

Chameleon offers a reproducible and scalable method to generate PHI-free, expert-validated synthetic radiology datasets, enabling safer and broader access to training data for NLP and generative AI applications in radiology research and education.

W5A-SPIN-8 EVALUATING LARGE LANGUAGE MODELS FOR CONTEXT-AWARE SUMMARIZATION OF EMERGENCY DEPARTMENT NOTES FOR RADIOLOGIC INTERPRETATION

Andrew Sun, MD (*Presenter*)
Alex Lee, BS (*Abstract Co-Author*)
Safa Ahmed (*Abstract Co-Author*)
Kazi A. Irfan, MD, FRCR (*Abstract Co-Author*)
Talissa A. Altes, MD (*Abstract Co-Author*)
Mohamed G. Elbanan, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of large language models (LLMs) in generating imaging-relevant summaries from Emergency Department (ED) clinical notes to support radiologic interpretation.

METHODS AND MATERIALS

A retrospective dataset of 901 unique ED notes was collected over a 3-month period, each linked to an imaging order and clinical indication. Notes were de-identified using named entity recognition and cleaned to remove extraneous content (e.g., unrelated imaging orders, medication reconciliation). When imaging results or assessments documented after image interpretation were present, they were manually removed to simulate the pre-imaging clinical context. Board-certified radiologists manually annotated each note to generate reference summaries containing only information relevant to interpreting the corresponding imaging exam. We evaluated six LLMs across two summarization strategies. The first used prompt engineering to directly generate summaries from full notes. The second was a hybrid approach: clinically relevant segments were extracted using cosine similarity between note sentence-embeddings and sentence-embeddings of the imaging exam and indication, at varying thresholds (0.05-0.5), then summarized using the same LLMs.

RESULTS

Each model's output was compared to the radiologist-generated reference summaries using multiple evaluation metrics, including BERTScore (precision, recall, F1), METEOR, ROUGE, BLEU, and semantic similarity. Statistical comparisons across models and summarization strategies were performed, and performance was evaluated at varying extraction thresholds.

CONCLUSION

LLMs show promising potential for generating context-aware summaries of ED notes that are tailored to specific imaging exam type and indication. Incorporating clinically relevant context via hybrid summarization improves alignment with expert-generated summaries. These findings may inform future tools for streamlining radiologist workflows and enhancing clinical communication.

CLINICAL RELEVANCE/APPLICATION

This project demonstrates the potential of LLMs to automate the extraction of imaging-relevant context from ED notes, offering a promising pathway to streamline radiologist workflows. Incorporating AI-driven summarization tools may reduce manual chart review time, expedite interpretation, and enhance communication of critical clinical information, supporting improved operational efficiency in radiology practice.

W5A-SPIN-9 EVALUATING MEMORIZATION RISKS IN GENERATIVE MODELS: A BENCHMARK FRAMEWORK FOR SAFE AND RELIABLE SYNTHETIC IMAGING IN RADIOLOGY

Stephanie Nadine Benz, MD (*Presenter*)
Marc Molina (*Abstract Co-Author*)
Felice A. Burn, MD (*Abstract Co-Author*)

PURPOSE

Generative AI models offer transformative potential in radiology for data augmentation, algorithm training, and privacy-preserving data sharing. However, they inadvertently memorize and reproduce sensitive patient data, posing a significant privacy risk. This study aims to systematically assess memorization behavior in generative models and establish a robust benchmark for evaluating and mitigating such risks in synthetic radiological images.

METHODS AND MATERIALS

A comprehensive benchmarking framework was developed using Self-Supervised Contrastive Networks to detect memorization in synthetic images. Various backbone architectures (DinoV2, DenseNet121, ResNet50), pretrained on both general and domain-specific datasets, were evaluated with contrastive loss functions. An anonymized dataset of 7,184 X-ray mammograms from 1,718 patients was used with patient-aware splits. A conditional diffusion model was fine-tuned on this dataset to generate synthetic mammograms. Memorization was analyzed by comparing similarity distributions between synthetic, augmented, and original images using multiple distance metrics.

RESULTS

Triplet Margin Loss consistently outperformed across all models. DinoV2 combined with Triplet Loss and Bray-Curtis distance achieved the highest detection performance, followed by DenseNet121 and ResNet50. Diffusion generated mammograms showed a shift in similarity towards original images, indicating a measurable degree of memorization. Testing with very small datasets clear memorization issues arose and could be measured and addressed. Distance metrics such as Bray-Curtis and Standardized Euclidean proved optimal for detecting subtle memorization in radiological datasets.

CONCLUSION

Our framework reliably detects memorization in generative models, providing crucial insights into privacy risks associated with synthetic radiology images. The findings highlight the susceptibility of diffusion models to memorization and offer practical guidelines for model developers to monitor and mitigate privacy risks during synthetic data generation.

CLINICAL RELEVANCE/APPLICATION

With synthetic data becoming essential for advancing radiological AI, safeguarding patient privacy is critical to clinical acceptance and trust. Ensuring synthetic data integrity, our approach not only protects patient confidentiality but also enhances the reliability and generalizability of downstream AI models — particularly in scenarios where neural networks struggle due to limited availability of high-quality data. Our method offers radiologists and AI developers a robust tool to detect hidden memorization in synthetic datasets, directly addressing privacy concerns that could hinder clinical deployment.

W5A-SPIN-10 STREAMLINING THE ANNOTATION PROCESS BY RADIOLOGISTS OF VOLUMETRIC MEDICAL IMAGES WITH FEW-SHOT LEARNING

Leo Joskowicz, PhD (*Presenter*)
Alina Ryabtsev (*Abstract Co-Author*)
Richard Lederman, MD (*Abstract Co-Author*)
Jacob Sosna, MD (*Abstract Co-Author*)

PURPOSE

Radiologists' manual annotations limit robust deep learning in volumetric medical imaging. While supervised methods excel with large annotated datasets, few-shot learning performs well for large structures but struggles with small ones, e.g., lesions. We aimed to evaluate a novel method that leverages the advantages of both few-shot learning models and fully supervised models while reducing the manual annotation cost.

METHODS AND MATERIALS

Our method streamlines the process of manual annotation of lesions in volumetric scans. The goal is to obtain sufficient, high-quality, expert-validated labeled data to train a fully supervised deep learning model. The method uses a pre-trained few-shot learning model with a small support set of manually annotated scans to compute initial voxel-level labels for a larger set of unannotated scans. A subset of these scans is then selected for correction by a radiologist. By prioritizing the labeled scans for corrections, it minimizes the correction effort while increasing the labels representativity. A fully supervised model is then trained on the scans with corrected labels and the support set scans and tested on an independent annotated dataset. The process is repeated for the remaining unannotated scans until satisfactory performance is obtained. We validated our method on liver, lung, and brain lesions on CT and MRI scans from 375 scans (118 abdominal CECT, 137 chest CT, 120 brain T1W-Gad MRI) with 5,933 lesions (3,422 liver, 2,090 lung, 421 brain lesions) annotated by three expert radiologists. The datasets, one for each organ, were partitioned into support, query and test sets (10 scans for support, 15 for test, and the rest for query). Performance of the model was evaluated with the % of missed and misidentified lesions. Radiologist correction effort was quantified with the number of mouse clicks required to correct a computed lesion: one click to discard a misidentified lesion and add a missed lesion, and one mouse click for each missed erroneous pixel on the computed lesion contour.

RESULTS

Our method significantly reduces the estimated lesion detection and correction effort by 34% for missed lesions, 387% for misidentified lesions, with 130% fewer lesion contour corrections, and 424% fewer pixels to correct in the lesion contours with respect to manual annotation.

CONCLUSION

Our method effectively reduces the radiologists' annotation effort of small structures to produce high-quality annotated datasets to train deep learning models. It is generic and can be applied to lesions in various organs imaged by different modalities.

CLINICAL RELEVANCE/APPLICATION

The method may speed up the development and deployment of deep learning models for the automatic detection and segmentation of lesions in volumetric scans.

W5A-SPIN-11 ASSESSING PROMPT INSENSITIVITY IN FOUNDATION MODELS FOR RADIOLOGICAL IMAGE SEGMENTATION

Monrada Chiewhawan (*Presenter*)
Watcharapong Timklaypachara (*Abstract Co-Author*)
Peeranat Buabang (*Abstract Co-Author*)
Stephanie Marie Aguilera, BSc (*Abstract Co-Author*)
Sandeep Bodduluri, MS, PhD (*Abstract Co-Author*)
Titipat Achakulvisut, PhD, BEng (*Abstract Co-Author*)

PURPOSE

Text-prompted segmentation represents a potentially transformative technology for radiological workflows, but evaluation of their operational limitations and performance are limited. This study assesses the prompt-insensitivity of the BiomedParse model across segmentation tasks. We hypothesize that prompt structure, semantic complexity, and terminological specificity will modulate segmentation accuracy across diverse anatomical structures and pathological manifestations.

METHODS AND MATERIALS

We evaluated BiomedParse model across multiple out-of-domain datasets comprised of Montgomery, NSCLC-Radiomics, RIDER, COVID-19 and Infection cohorts collectively providing 6,810 chest radiographs (CXR) and 452 computed tomography (CT) volumes. We designed three evaluation experiments: (1) assessed output variations by applying identical prompts to quantify consistency; (2) evaluated semantic sensitivity of the prompt to determine the impact of linguistic variations; and (3) assessed the model's robustness when presented with ambiguous instructions. All analyses were conducted using standardized radiological metrics including Dice similarity coefficient representing overlap with ground truth.

RESULTS

Prompt-based segmentation accuracy was substantially higher in CXR (Dice score of 0.87 ± 0.04) compared to CT (0.19 ± 0.14) when using BiomedParse ontology prompts. Interestingly, CXR segmentation outputs remained identical (0.997 ± 0.003) regardless of prompt content and persistently segmented lungs even with

irrelevant anatomical prompts, indicating significant prompt insensitivity. Conversely, CT images showed minimal segmentation response regardless of prompt construction, suggesting either insufficient CT training data or inherent modality limitations. This performance disparity between CXR and CT persisted across all experimental conditions.

CONCLUSION

BiomedParse demonstrates promising performance within its pretrained segmentation vocabulary for CXRs but exhibits critical limitations in prompt sensitivity and cross-modality applications. However, the model's tendency to default to lung segmentation in CXR regardless of prompt specificity represents a concerning limitation. These results highlight the need for improved fine-tuning strategies to enhance precision and reduce erroneous segmentation.

CLINICAL RELEVANCE/APPLICATION

Text-prompted segmentation model offers significant opportunities to reduce interpretation time, enhance diagnostic precision, and standardize reporting. The model's propensity to segment lung fields in CXR regardless of prompt instructions could lead to misidentification of anatomical structures and subsequent diagnostic errors.

W5A-SPIN-12 CLINICAL EXPERIENCE MATTERS: A TURING TEST OF TRUST IN AI-GENERATED RADIOLOGY REPORTS

Zhicheng Jiao, PhD, BS (*Presenter*)
Zhuoqi Ma (*Abstract Co-Author*)
Zhusi Zhong (*Abstract Co-Author*)
Scott Collins, RT (*Abstract Co-Author*)
Harrison X. Bai, MD (*Abstract Co-Author*)
Joey Gu, MD (*Abstract Co-Author*)
Jothika Challapalli, MD (*Abstract Co-Author*)
Michael K. Atalay, MD, PhD (*Abstract Co-Author*)
Mohammad Abubaker-Sharif, MD (*Abstract Co-Author*)
Michael H. Bernstein, PhD (*Abstract Co-Author*)
Eric W. Dietsche, MD (*Abstract Co-Author*)
Ankur Pandey, MD (*Abstract Co-Author*)
Terrance T. Healey, MD (*Abstract Co-Author*)
Venkata Paruchuri, MD,BS (*Abstract Co-Author*)
Grayson L. Baird, PhD, MS (*Abstract Co-Author*)

PURPOSE

Understanding physicians' acceptance and trust in AI-generated reports is a critical step toward integrating AI into clinical practice. We developed a web-based interactive platform and conducted a radiology-oriented Turing test to assess if physicians and residents could distinguish between radiologist and AI-generated reports.

METHODS AND MATERIALS

Eight participants (4 attendings and residents) reviewed 48 chest X-ray cases in this test. Each case consisted of a chest X-ray image accompanied by two reports. The cases were evenly divided into three comparison groups based on report generation methods: radiologist vs. AI model 1, radiologist vs. AI model 2, and AI model 1 vs. AI model 2 (16 each condition). For each case, participants were asked to identify which report was AI-generated, rate their confidence in this judgment, and select the report they would be more inclined to adopt in clinical practice. This study was IRB approved.

RESULTS

Attendings were correct 49.9% and residents 41.1% of the time in identifying AI-generated reports, both higher than chance (33.3%), indicating that radiologists largely beat the Turning test and more so than residents. Attendings exhibited longer average response times (56.84 seconds) compared to residents (31.86 seconds), suggesting a more analytical decision-making approach, $p<.01$. Attendings had slightly more confidence than residents, but this was not significant. For both groups, for every one-unit increase in confidence, the odds of being correct increased 20%, $p=.025$.

CONCLUSION

Attendings were more likely to distinguish AI-generated reports from radiologist-generated reports than residents, and both groups were able to distinguish over chance. This suggests that clinical experience helps mitigate bias toward AI-generated content, whereas residents are more prone to perception-driven preference shifts.

CLINICAL RELEVANCE/APPLICATION

Our findings reveal important differences between attendings and residents in terms of acceptance and bias toward AI-generated reports, highlighting the need for targeted strategies to foster trust in AI tools and ensure their safe and effective integration into clinical workflows.

W5A-SPIR-1 SAFETY AND CLINICAL OUTCOME OF BLEOMYCIN ELECTROSCLEROTHERAPY (BEST) TREATING LYMPHATIC MALFORMATIONS (LMS)

Vanessa F. Schmidt, MD (*Presenter*)
Florian Obereisenbuchner (*Abstract Co-Author*)
Daniel Puhr-Westerheide, MD (*Abstract Co-Author*)
Gloria Biechele, MD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Max Seidensticker (*Abstract Co-Author*)
Moritz Wildgruber, MD, PhD (*Abstract Co-Author*)

PURPOSE

Bleomycin-Electrosclerotherapy (BEST) has recently emerged as a treatment option for slow-flow vascular malformations (SFVMs), though most studies focus on venous malformations. This study specifically evaluated safety and clinical outcome of BEST in lymphatic malformations (LMs) and lymphatic-dominant lympho-venous malformations (ld-LVMs).

METHODS AND MATERIALS

A monocentric cohort with symptomatic LMs or ld-LVMs treated by BEST was retrospectively assessed. Patient records and imaging findings were analysed with respect to clinical and procedural details. A treatment-specific, patient-reported questionnaire assessed overall clinical response (complete-, partial-, no response, and progression), subjective health-related Quality of Life (QoL; optimal, improved, unchanged, worsening), pre- and postprocedural pain (numerical rating scale, NRS) as well as postprocedural skin discoloration (yes/no). Lesion size before and after treatment was compared using measurements in three plains on MRI.

RESULTS

Overall, 27 BEST sessions were performed in 20 patients with 14 LMs and 6 ld-LVMs (11 microcystic, 5 mixed, 4 macrocystic subtypes). Patients received 1.4±0.6 BEST sessions with a median bleomycin dose of 7 mg (range 2-15 mg). After BEST, 7/20 (35%) patients reported complete response, 10/20 (50%) partial response, and 3/20 (15%) no response. No patients presented with progression. Health-related QoL was stated as optimal in 10/20 (50%) and as improved in 4/20 (20%) patients. Median pain NRS was reduced from 6 (3-10) to 2 (0-6). Postprocedural skin discoloration occurred in 11/20 (55%) patients. Follow-up MR imaging revealed lesion size reduction from mean maximum volume of 1381±1650 cm 3 to 1089±1543 cm 3 . Major and minor complications occurred after 3/27 (11.1%) BEST treatments. No differences in all outcome parameters regarding the LMs subtypes (micro-, macrocystic, mixed) were assessed.

CONCLUSION

BEST demonstrates a good clinical response as well as an acceptable risk profile treating LMs and ld-LVMs.

CLINICAL RELEVANCE/APPLICATION

BEST offers an effective therapeutic alternative also for the subgroup of microcystic lesions previously considered difficult to treat.

W5A-SPIR-2 UTILIZATION AND SITE OF SERVICE OF INTERVENTIONAL RADIOLOGY PROCEDURES PERFORMED ON MEDICARE BENEFICIARIES BETWEEN 2013-2022

Zohaa Faiz, MD (*Presenter*)
Julie C. Bulman, MD (*Abstract Co-Author*)
Victor Novack (*Abstract Co-Author*)
Ammar Sarwar, MD (*Abstract Co-Author*)

PURPOSE

To evaluate trends in utilization and site of service for IR procedures performed on Medicare FFS from 2013 to 2022.

METHODS AND MATERIALS

We analyzed data from the Medicare Physician and Other Supplier Public Use Files (2013-2022), identifying interventional radiologists (IRs) by self-designated specialty. IR services included procedures with invasive HCPCS codes (10000-69999), invasive NITOS codes (I999), and Evaluation and Management (E/M) codes (99201-99499). All procedural codes (invasive HCPCS and NITOS, excluding E/M) were grouped into Clinical Service Categories (CSCs) defined by the Society of Interventional Radiology (SIR): Interventional Oncology (IO), Neurointerventional Radiology (NIR), Pain Management/Musculoskeletal (PM/MSK), Peripheral Arterial Disease (PAD), Renal and Genitourinary (GU), Venous, and Women's Health (WH) .Pediatric IR was excluded due to its limited relevance to the Medicare population. IR codes not fitting SIR CSCs were categorized as generic procedures, injections/drainage, biopsy, feeding tubes, venous access, and endovascular interventions. Annual service rates were calculated per 100,000 Medicare Fee-for-Service beneficiaries, adjusting for yearly population changes.

RESULTS

A total of 727 unique IR procedure codes were billed during the 10-year study period. Biopsy procedures increased from 126 to 226 annual services per 100,000 beneficiaries (Compound Annual Growth Rate [CAGR]: 6.0%).? Injection/drainage procedures increased from 233 to 369 annual services per 100,000 beneficiaries (CAGR: 4.7%). IO procedures increased from 1 to 4 annual services per 100,000 beneficiaries (CAGR: 14.9 %).? PM/MSK increased from 2 to 4 annual services per 100,000 beneficiaries (CAGR: 9.6%).? PAD increased from 108 to 120 annual services per 100,000 beneficiaries (CAGR: 1.1%).? Conversely, declines were observed in GU from 218 to 154 services per 100,000 beneficiaries (CAGR: -3.4%). and WH from 2 to 1 services per 100,000 beneficiaries (CAGR: -6.7%).?Table 1 highlights the overall services and site of service in 2022. In 2022, PM/MSK and PAD were the only ones to be more frequently performed in the non-facility setting.

CONCLUSION

Over the past decade, IR services for Medicare beneficiaries have increased annually in all areas except renal procedures and women's health procedures. Pain management and peripheral arterial disease services are the only procedures performed more frequently in the non-facility setting.

CLINICAL RELEVANCE/APPLICATION

Understanding utilization trends and care settings for IR procedures among Medicare beneficiaries informs healthcare planning and policy decisions targeting access, cost, and efficiency of IR services.

W5A-SPIR-3 AI-DRIVEN PERT COORDINATION REDUCES DIAGNOSTIC DELAYS AND HOSPITAL STAY IN PE: A MULTI-YEAR EVALUATION

Akhil Khosla (*Presenter*)
Hamid R. Mojibian, MD (*Abstract Co-Author*)
Joshua Cornman-Homonoff, MD (*Abstract Co-Author*)
Matteo Conte, MD (*Abstract Co-Author*)

PURPOSE

Prompt identification and timely multidisciplinary management of pulmonary embolism (PE) is critical for optimizing outcomes. To enhance the efficiency of our Pulmonary Embolism Response Team (PERT) and improve outcome in PE with high-risk features, we implemented an AI-driven care coordination solution (Aidoc, Tel Aviv, Israel) and evaluated its impact through a multi-year prospective registry.

METHODS AND MATERIALS

A prospective PE registry was conducted to evaluate the AI's effect on diagnostic timing and clinical outcomes. From June 2022 to May 2024, an AI solution to detect PEs with right-ventricular strain (RV/LV ratio > 1.0) on CTPA scans was integrated at our institution. We included PE with high-risk features as defined by having at least two of the three following severity criteria: ESC high/intermediate-high risk; BOVA = 3; PESI = 4. After the inclusion of 183 subjects, the study population was stratified into three consecutive 12-month groups: the pre-AI control group (June 22, 2021 - May 31, 2022); the first post-AI implementation group (June 01, 2022 - May 31, 2023); the second post-AI implementation group (June 1, 2023 - May 31, 2024). To assess the impact of AI integration, the following outcomes were evaluated: (1) time to diagnosis, defined as the interval in minutes from ED arrival - or, for non-ED patients, from PERT member notification or cardiac arrest - to CTPA study visualization; (2) thrombectomy rates; (3) ICU length of stay (LoS); (4) inpatient LoS.

RESULTS

55 (30.1%) patients represented the control group; 67 (36.6%) and 61 (33.3%) represented the AI groups. Median time-to-diagnosis was 1,96 days in the control group; 0,916 and 0,878 days in AI groups. Over time, time-to-diagnosis showed a relative reduction of 55.75% compared to baseline. Thrombectomy rates increased from 27.3% (15/55) in the control group, to 35.8% (24/67) and 36.1% (22/61) in AI groups. Mean ICU LoS decreased from 10.0 days in control group to 6.0 and 4.6 days in AI groups. Mean inpatient LoS decreased from 19.1 days in control group to 14.2 and 7.9 days in AI groups. Over time, both ICU and inpatient LoS showed a relative reduction of 54% and 58.63%, respectively.

CONCLUSION

The AI PERT care coordination solution led to a sustained >50% reduction in diagnostic delay and halved hospital and ICU length of stay over two years. These findings support AI-driven care coordination to improve efficiency and outcomes in high-risk PE population.

CLINICAL RELEVANCE/APPLICATION

AI integration in PE management streamlined diagnosis timeframe and patient LoS, improving overall outcomes.

W5A-SPIR-4 LARGE LANGUAGE MODELS (LLMS)-DRIVEN PROCEDURE PLANNING & RECOMMENDATION SYSTEM FOR INTERVENTIONAL RADIOLOGY

Shakthi K. Ramasamy, MD (*Presenter*)

PURPOSE

This project seeks to develop an AI-driven Procedure Planning & Recommendation System for interventional radiologists by integrating advanced large-language models (LLMs) with patient data and clinical guidelines. The aim is to generate evidence-based, personalized procedure recommendations that reduce cognitive load and enhance patient outcomes.

METHODS AND MATERIALS

The system combines LLMs—OpenAI GPT-4, Anthropic Claude 3, and Google DeepMind's MedPaLM—to interpret clinical data (imaging reports, laboratory values, detailed histories). A fine-tuned Hugging Face T5 model produces structured documentation of recommended interventions. Prompt-engineering frameworks ensure outputs incorporate comorbidities, anatomic nuance, and guideline statements. Retrospective case reviews, pilot deployments, and real-time validation will assess performance.

RESULTS

By synthesizing heterogeneous data, the system shortens physicians' information-retrieval time. Pilot metrics will track accuracy of recommendations, concordance with standards, decision-making speed, and complication rates versus conventional practice. Early feedback focuses on physician satisfaction and workflow fit.

CONCLUSION

The Procedure Planning & Recommendation System represents a leap toward personalized, data-driven interventional-radiology care. Leveraging state-of-the-art LLMs, it delivers actionable, context-aware guidance that can streamline planning for both routine and complex cases worldwide.

CLINICAL RELEVANCE/APPLICATION

An LLM-powered planning assistant can: Accelerate evidence-based decisions by instantly matching patient-specific details to appropriate IR techniques and devices. Reduce variability and errors through guideline-aligned, peer-review-traceable recommendations, thereby lowering complication and readmission rates. Lighten administrative burden with autogenerated, audit-ready documentation that integrates into electronic health records and billing systems. Enhance patient counselling by providing clear, data-supported rationale for selected procedures, fostering shared decision-making. Overall, the system turns disparate clinical inputs into timely, standardized, and patient-centric action plans—supporting safer, more efficient interventional-radiology practice.

W5A-SPIR-5 MICROWAVE ABLATION VS. SINGLE-NEEDLE RADIOFREQUENCY ABLATION FOR THE TREATMENT OF HCC UP TO 4 CM: A RANDOMIZED-CONTROLLED TRIAL

Katsutoshi Sugimoto, MD, PhD (*Presenter*)
Mari Hayashi (*Abstract Co-Author*)
Hidehito Honda (*Abstract Co-Author*)
Tatsuya Kakegawa (*Abstract Co-Author*)
Hirohito Takeuchi (*Abstract Co-Author*)
Takao Itoi (*Abstract Co-Author*)

PURPOSE

Radiofrequency ablation (RFA) is the standard treatment for small hepatocellular carcinoma (HCC), specifically for tumors <3 cm in size and numbering fewer than three, excluding surgical candidates. Microwave ablation (MWA) is an innovative approach believed to have theoretical benefits over RFA; however, these advantages are yet to be empirically verified. Therefore, we evaluated and compared the effectiveness of MWA and RFA in managing HCC tumors up to 4 cm in size.

METHODS AND MATERIALS

In this multicenter randomized controlled trial conducted across five centers in Japan, eligible participants had up to 4 tumors, each up to 4 cm in size, and were not considered for surgery. Patients were randomly assigned to undergo MWA or RFA. The primary outcome was the rate of local tumor progression (LTP), whereas secondary outcomes included overall survival (OS) and intra- and extrahepatic recurrence-free survival (RFS) at the end of the 2-year follow up.

RESULTS

In total, 240 participants were screened from July 12, 2018, to December 7, 2021. Four participants were excluded: three did not meet inclusion criteria, and one died from an unknown cause during treatment. Consequently, 119 (130 lesions) and 117 (136 lesions) participants were treated with MWA and RFA, respectively. The proportion of lesions with LTP at the 2-year follow up was significantly lower in the MWA group (20 [16.4%] lesions) than in the RFA group (38 [30.4%] lesions) (risk ratio, 0.54; p = 0.007). OS and both intra- and extrahepatic RFS did not significantly differ between groups.

CONCLUSION

MWA is more effective than RFA in reducing local tumor progression for HCC tumors up to 4 cm. However, no differences were observed in OS and RFS.

CLINICAL RELEVANCE/APPLICATION

Although MWA may offer better local tumor control than RFA, RCT differs slightly from daily clinical situations, practical and anatomical criteria for selecting the optimal technique on a lesion-by-lesion basis are required.

W5A-SPIR-6 ACCURATE MR THERMOMETRY DURING MICROWAVE ABLATION OF LIVER TUMORS USING SUSCEPTIBILITY ARTIFACT CORRECTION

Matthias P. Fabritius, MD (*Presenter*)
Mingming Wu, MD, PhD (*Abstract Co-Author*)
Olaf Dietrich, PhD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Dimitrios C. Karampinos (*Abstract Co-Author*)
Max Seidensticker (*Abstract Co-Author*)

PURPOSE

Thermoablation is a first-line treatment for early-stage hepatocellular carcinoma and oligometastatic disease, as supported by various guidelines. Real-time MR thermometry using the proton resonance frequency shift (PRFS) aims at ensuring adequate thermal dosing while protecting healthy tissue. However, microwave ablation (MWA) causes tissue carbonization and vaporization, resulting in susceptibility artifacts. This study assesses background field removal techniques known from quantitative susceptibility mapping to separate these artifacts from true temperature-induced phase changes during MWA, aiming to improve MR thermometry accuracy.

METHODS AND MATERIALS

Six patient datasets from MWA procedures (Oct 2021-Aug 2022) were analyzed retrospectively. MRI was performed on a 1.5T scanner (MAGNETOM Aera, Siemens). MWA was guided by an experienced radiologist using an MR-compatible microwave system (AveCure, MedWaves) and 14G antennae. PRFS-based thermometry was based on a single-shot EPI sequence (TR/TE=2000ms/18ms, FA=90°, voxel size 2.4-2.9mm, matrix=128×128×13), with respiratory triggering at expiration. A quality-guided phase unwrapping step (Fortier et al.) was performed in MATLAB before phase subtraction from the reference time point. The Background field removal technique Laplacian Boundaray Value (LBV) known from quantitative susceptibility mapping was applied using the MEDI toolbox.

RESULTS

Local susceptibility changes from tissue burning caused dipolar-shaped temperature artifacts at the MWA site, leading to both over- and underestimation of temperature. In datasets without severe artifacts (e.g., strong cardiac pulsation), LBV effectively removed phase artifacts, revealing true temperature increases. It also restored realistic temperature patterns where B0 drift falsely indicated warming or cooling in the periphery. ROI analysis in one example (near the needle and in the liver periphery) showed significant underestimation of heating and global cooling in the periphery due to susceptibility artifacts and B0 drift. After LBV correction, the mean absolute error in the peripheral ROI (in relation to the expected 0°C) decreased from 5.13°C to 0.32°C, and the standard deviation from 2.37°C to 0.36°C.

CONCLUSION

LBV consistently improved accuracy of PRFS-based MR thermometry during liver MWA by removing susceptibility artifacts originating from tissue vaporization and carbonization at the ablation site, as well as global phase errors not originating from temperature change, such as B0 drift.

CLINICAL RELEVANCE/APPLICATION

Accurate real-time MR thermometry during MWA ensures effective treatment and enhances patient safety by enabling reliable thermal dose estimation.

W5A-SPIR-7 SAFETY AND EFFICACY OF COMBINED TREATMENT WITH PERCUTANEOUS THERMAL ABLATION AND TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION (TACE) FOR HEPATOCELLULAR CARCINOMA

Arianna Carfora (*Abstract Co-Author*)
Ameya Pathak (*Abstract Co-Author*)
Maxwell Todd (*Abstract Co-Author*)
James Yang (*Abstract Co-Author*)
Deepti Sudhakar (*Abstract Co-Author*)
Deepak Kesani, DO (*Abstract Co-Author*)
Keith J. Pereira, MD (*Abstract Co-Author*)
Jerome L. Kao, MD (*Abstract Co-Author*)
Ali Malik (*Abstract Co-Author*)
Afsheen K. Sherwani, MD (*Abstract Co-Author*)
David R. Owens, DO (*Abstract Co-Author*)
Aravind N. Mohandas, MD (*Abstract Co-Author*)
Xavier R. Packianathan, FRCR, MD (*Abstract Co-Author*)
Radu Serban, MD (*Abstract Co-Author*)
Millie Liao, DO (*Abstract Co-Author*)
Kirubahara Vaheesan, MD (*Abstract Co-Author*)

PURPOSE

This study evaluates the efficacy and safety of combined treatment involving both thermal ablation and transarterial chemoembolization (TACE).

METHODS AND MATERIALS

A 1000-case retrospective single-institution study of HCC thermal ablation was conducted from January 2013 to March 2023. 21 patients received a combined treatment of TACE and thermal ablation. Patients were seen pre-procedure in the clinic and viewed in the tumor board to receive approval for treatment. Tumor location and size were determined on CT or MRI. Readmission rates within 7 days were reviewed per chart. Survival rates were recorded at 1, 2, and 3 years. Residual disease progression was tracked with first follow-up imaging.

RESULTS

21 cases of patients with HCC who received combined treatment of TACE and thermal ablation were identified; 17 of which were diaphragmatic dome lesions. Out of the 21 cases, 16 of them had cirrhosis: 6 alcohol cirrhosis, 5 NASH, and 5 HCV Cirrhosis. All 21 of the cases were BCLC Stage A. The average tumor dimensions were 3.25±0.65m (long axis) and 2.51±0.79cm (short axis). The average survival days were 1505.38 days or 4.12 years. Rates for readmission within 7 days were 9.52%, for which the only cited reason was pain control. Pre-MELD and Post-MELD scores relative to treatment were 8.26±2.00 and 5.89±0.81, respectively, which did not differ significantly. Pre-Child Pugh and Post-Child Pugh scores were 8.89±2.70 and 6.00±0.88, respectively. Survival rates for years 1, 2, and 3 were 100.00%, 100.00%, and 93.75% respectively. The percentage of cases with residual disease progression and local tumor progression were 9.52% and 9.52% respectively. There was no evidence of liver decompensation, death, or other major perioperative complications, including diaphragmatic injury, secondary to this study’s treatment.

CONCLUSION

This study’s findings support the improved overall safety and efficacy of combined TACE and thermal ablation therapy for hepatocellular carcinoma.

CLINICAL RELEVANCE/APPLICATION

Utilizing the combined treatment involving both TACE and thermal ablation proves as a safe and efficient option for treating hepatocellular carcinoma lesions. We are in the process of comparing the outcome of treatments involving only ablation with combination TACE and ablation treatment.

W5A-SPMK-3 DIAGNOSTIC THRESHOLD FOR OPPORTUNISTIC SCREENING OF CENTRAL CANAL STENOSIS USING DEEP LEARNING IN ABDOMINAL CT

Youngjune Kim, MD (*Presenter*)
Choong Guen Chee, MD (*Abstract Co-Author*)
Eugene Lee (*Abstract Co-Author*)
Joon Woo Lee, MD, PhD (*Abstract Co-Author*)

PURPOSE

To establish the dural sac area threshold for opportunistic screening of lumbar central canal stenosis in abdominal CT.

METHODS AND MATERIALS

We included 533 consecutive patients who underwent both abdomen CT and lumbar MRI within 3 months from Jan 2018 to Aug 2023. For reference standard, the grade of central canal stenosis was rated using the corresponding lumbar MRI based on Lee's central canal stenosis grade. We measured dural sac area at each lumbar vertebral level using a deep learning-based software (AVIEW, Coreline Soft). Using receiver-operating-characteristic-curve analysis, we calculated optimal threshold for differentiating 1) central canal stenosis vs. normal and 2) severe central canal stenosis vs. non-severe central canal stenosis. Subgroup analysis was performed whether the threshold may change according to lumbar vertebral levels.

RESULTS

The dural sac area threshold for diagnosing lumbar central canal stenosis was 75 mm 2 and that for diagnosing severe central canal stenosis was 62 mm 2 . In the subgroup analysis, the threshold for diagnosing central canal stenosis decreased progressively from cranial to caudal intervertebral level: 104 mm 2 for L1-2, 84 mm 2 for L2-3, 67 mm 2 for L3-4, 63 mm 2 for L4-5, and 60 mm 2 for L5-S1. The threshold for diagnosing severe central canal stenosis was were approximately 90 mm 2 for L1-2 and 60 mm 2 for L2-3 through L5-S1.

CONCLUSION

We established dural sac area thresholds for CT-based diagnosis of lumbar central canal stenosis, addressing a critical gap in opportunistic screening.

CLINICAL RELEVANCE/APPLICATION

The universal thresholds (75 mm² for stenosis, 62 mm² for severe stenosis) offer practicality in initial assessments, while level-specific values account for anatomical variability. These criteria enable reliable diagnosis of central canal stenosis in opportunistic CT screening.

W5A-SPMK-4 IMPROVING SPINAL INTERVENTION GUIDANCE: ACCURATE VERTEBRAL LEVEL IDENTIFICATION USING US-CT FUSION

Bar Rinott, MD (*Presenter*)
Moshe Maizels (*Abstract Co-Author*)
Eyal Bercovich, MD (*Abstract Co-Author*)

PURPOSE

This study evaluates the feasibility and accuracy of using a real-time ultrasound-CT (US-CT) fusion system for lumbar spine vertebral localization, a critical step in spinal interventions. Traditional imaging modalities like fluoroscopy and CT expose both patients and staff to ionizing radiation. In contrast, ultrasound (US) avoids radiation but often lacks detailed anatomical clarity for precise targeting. Recent advancements in US-CT fusion systems offer the potential to combine the benefits of both methods—enhanced visualization without radiation exposure.

METHODS AND MATERIALS

The study involved 17 patients (age range 29-88 years) scheduled for elective lumbar CT. Using a GE Logiq E9 US-CT fusion system, live US data were co-registered with previously acquired CT scans. The process included identifying key anatomical landmarks (primarily the sacroiliac joint and lumbar facet joints) to manually align the two imaging modalities. The senior radiologist then used this fusion to mark the targeted vertebral level, which was subsequently confirmed through diagnostic CT scans.

RESULTS

Results showed successful US-CT fusion and vertebral identification in all 17 cases. The system correctly identified the vertebral level in 88% of cases, with common identification at L3. Two errors occurred—one misidentified L4 as L3, and the other marked S1 instead of L3, possibly due to a displaced skin marker pin. Despite these inaccuracies, the overall accuracy suggests that this approach is a promising alternative to traditional imaging methods for spinal procedures.

CONCLUSION

In conclusion, real-time US-CT fusion is a feasible and accurate method for identifying lumbar vertebral levels, with high accuracy demonstrated in this cohort. This technology presents a radiation-free alternative to conventional fluoroscopic or CT guidance for spinal procedures, offering enhanced real-time anatomical visualization. With a learning curve, this approach may be beneficial for precise spinal interventions like nerve root blocks or facet joint injections. Further research is needed to refine the technique, expand its use to other spinal regions, and assess its performance in specific procedures.

CLINICAL RELEVANCE/APPLICATION

The implementation of US-CT fusion imaging for spinal procedures offers a significant clinical advantage by potentially reducing or eliminating patient and operator exposure to ionizing radiation, a key concern with CT and fluoroscopy. It provides enhanced real-time anatomical visualization by combining the strengths of US and CT, which could improve the safety, accuracy, and accessibility of minimally invasive spinal interventions like nerve root blocks or facet joint injections.

W5A-SPMK-7 DEEP LEARNING FOR AUTOMATIC THIGH MUSCLES SEGMENTATION ON MRI IMAGES OF PATIENTS WITH DUCHENNE MUSCULAR DYSTROPHY

Rui Yan (*Presenter*)
Wang Yile (*Abstract Co-Author*)

PURPOSE

To investigate the value of thigh muscles segmentation of patients with Duchenne muscular dystrophy (DMD) using U-Net deep learning model on MRI images.

METHODS AND MATERIALS

A total of 60 DMD patients (aged 1-12 years) who had undergone thigh MRI scans were retrospectively enrolled in this study. The dataset was randomly divided into the training set (48 cases) and test set (12 cases). For each patient , the entire slices of five thigh muscles on axial T1 MRI images were manually delineated by two skilled radiologists with 3D-Slicer toolkit. Then, a U-Net deep learning model was trained for automatic thigh muscles segmentation with training set using down- and up-sampling and loss function calculating. Performance of the model was assessed using Dice similarity coefficient (DSC) and Intersection over union (IoU),which is an index of segmentation quality ranging from 0 (no overlap) to 1 (total overlap).

RESULTS

The U-Net model exhibited strong performance for thigh muscles segmentation on MRI images(Figure 1). The mean DSC of these eleven muscles was 0.94 and the mean IoU was 0.93. Furthermore, the consuming time of eleven thigh muscles segmentation of one patient guided by U-Net model was only 30 seconds with a computer (graphics card:RTX4060Ti, software:python 3.11), much faster than about 8h of manual segmentation.

CONCLUSION

Our preliminary study shows deep learning for automatic thigh muscles segmentation on MRI images produces sufficiently accurate segmentation in seconds and demonstrates high reproducibility compared with manual segmentation.

CLINICAL RELEVANCE/APPLICATION

The datasets generated during the current study are available.

W5A-SPMS-1 PROSPECTIVE FUNCTIONAL BONE DISEASE EVALUATION OF NEWLY-DIAGNOSED MULTIPLE MYELOMA WITH COMBINED USE OF ^{18}F-FDG-PET/CT AND MULTIPARAMETRIC WHOLE-BODY MAGNETIC RESONANCE

Vincenzo Lucidi, MD (*Presenter*)
Arrigo Cattabriga (*Abstract Co-Author*)
Stefano Brocchi, MD (*Abstract Co-Author*)
Giacomo Pertile (*Abstract Co-Author*)
Alice Rossi, MD (*Abstract Co-Author*)
Stefano Fanti, MD (*Abstract Co-Author*)
Cristina Mosconi, MD (*Abstract Co-Author*)

PURPOSE

FDG-PET/CT is the most widely used imaging technique to detect bone and extramedullary disease in multiple myeloma (MM) and is recommended for response assessment by the International Myeloma Working Group. In clinical practice, it is usually associated with magnetic resonance imaging (MRI); the addition of DWI sequences in whole-body MRI (WBMRI) has further increased sensitivity and has been proposed for response assessment by MY-RADS guidelines. We present a prospective single-center study aimed at comparing PET/CT and WBMRI during diagnosis/staging of smoldering MM (SMM) and newly diagnosed MM (NDMM), and in defining treatment response in transplant-eligible (TE) and ineligible (TI) patients (pts). Secondary aims include assessing the prognostic role of the two techniques and comparing/validating imaging criteria (IMPeTuS and MY-RADS) in clinical practice.

METHODS AND MATERIALS

Pts underwent both imaging techniques at baseline. Baseline positive technique(s) have been repeated before maintenance (TI) or after 1 year of treatment (TE). IMPeTuS and MY-RADS criteria have been used for baseline staging and response assessment.

RESULTS

Between October 2022 and April 2025, 205 pts (74 SMM and 131 NDMM) underwent PET/CT and WBMRI at baseline. Among NDMM pts with CT-assessed bone disease (64%), WB-MRI was positive in 100% and PET/CT in 89%. Among the remaining 36%, WB-MRI was negative in 49% (none had PET-assessed focal lesions, FLs) and positive in 51% (63% of which also showed positive PET/CT). WBMRI detected more FLs and paraskeletal disease (PSD) than PET/CT (FLs: 76% vs 57%, p=0.0001; PSD: 30% vs 23%, p=0.0001). A slight concordance was observed for diffuse disease (DD) detection (24% vs 34%, p=0.0002, ?=0.4). DD on WB-MRI was associated with R-ISS III (p=0.008), higher monoclonal protein (p=0.02) and urinary protein (p=0.01) concentrations, and marrow plasma cell percentage (p=0.002); DD on PET/CT was not significantly related to these parameters. Among SMM pts, detection of FLs and DD was similar with both techniques (FLs: 8.1% vs 5.4%, p=0.8; DD: 5.4% vs 8.1%, p=0.04). As of April 2025, 31 pts had imaging re-evaluation, with a concordance of 93.5% between techniques.

CONCLUSION

WBMRI showed higher sensitivity than PET/CT for FLs and PSD in NDMM, with similar findings in SMM. PET/CT and WBMRI showed partial concordance for DD, but only WBMRI-defined DD correlated with clinical and laboratory variables. Preliminary results show good concordance in response assessment.

CLINICAL RELEVANCE/APPLICATION

Our data support the combined use of PET/CT and WBMRI for MM staging at baseline and suggest a potential alternative role for WBMRI in response assessment, but further expansion of the study population and more post-treatment imaging are needed.

W5A-SPNMMI-2 QUANTITATIVE FDG PET/CT METRICS HIGHLY CORRELATE WITH CIRCULATING TUMOR DNA LEVELS IN PATIENTS WITH MERKEL CELL CARCINOMA

Jeffrey Xing, MD, PhD (*Presenter*)
Daniel Hippe (*Abstract Co-Author*)
Tomoko Akaike, MD (*Abstract Co-Author*)
Manisha Thakuria (*Abstract Co-Author*)
Nicole Urman, MD (*Abstract Co-Author*)
Amy Xiong (*Abstract Co-Author*)
Benjamin L. Franc, MD (*Abstract Co-Author*)
Paul Nghiem, MD, PhD (*Abstract Co-Author*)
Song Youn Y. Park, MD (*Abstract Co-Author*)
Ann Silk (*Abstract Co-Author*)
Lisa Zaba (*Abstract Co-Author*)
Kip E. Guja, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the correlation of initial staging FDG PET/CT and tumor biomarkers in patients with Merkel cell carcinoma (MCC) by comparing quantitative measures of metabolic activity on FDG PET, including SUVmax, metabolic tumor volume (MTV), and total lesion glycolysis (TLG) with circulating tumor DNA (ctDNA).

METHODS AND MATERIALS

A single center retrospective analysis of FDG PET/CT imaging data and ctDNA was conducted in a cohort of 52 patients with MCC. Longitudinal clinical records were reviewed to confirm inclusion criteria of FDG PET/CT imaging and ctDNA testing for initial staging within 28 days of each other. PET/CT images were segmented in MIM software to calculate MTV, SUVmax, and TLG, using established workflows. These PET metabolic indices were then correlated with temporally matched ctDNA collected within 28 days of PET/CT imaging.

RESULTS

Retrospective review identified 93 patients with Merkel cell carcinoma; 42 patients were excluded due to >28 day (or uncertain) time interval between PET imaging and ctDNA testing. 52 patients met inclusion criteria and had PET and ctDNA testing within 28 days, mostly within 7 days (58%). 27 patients (52%) had positive PET and 30 (58%) had a positive ctDNA test. All measures of metabolically active tumor burden (MTV, SUVmax, TLG) were highly correlated with temporally matched ctDNA levels (Spearman correlation coefficient, $r = 0.82\text{-}0.84$, $p<0.001$). In patients with a positive PET and ctDNA, there was a clear dose-dependent correlation that predicted disease burden ($r = 0.84\text{-}0.93$), $p < 0.001$).

CONCLUSION

All quantitative PET imaging measures of metabolically active burden were highly correlated with temporally matched ctDNA in patients with MCC at a single institution. Ongoing and future work will validate reproducibility across multiple institutions and timepoints beyond the initial staging.

CLINICAL RELEVANCE/APPLICATION

MCC is a rare but serious cutaneous malignancy, with clinical management similar to that of melanoma. Most patients with metastatic disease are treated with systemic immunotherapy and followed with PET/CT during the staging, initial treatment and post-treatment surveillance period. Recently, ctDNA has shown promise in both monitoring response to treatment and early recurrence of disease. Our results suggest that quantitative FDG PET metrics correlate with ctDNA levels that may be helpful for disease monitoring.

W5A-SPNPM-1 TELERADIOLOGY IN THE EMERGENCY SETTING: DIAGNOSTIC ACCURACY AND WORKFLOW IMPACT ACROSS MULTIPLE ACUTE SUBSPECIALTIES

Jainam A. Doshi, MBBS, MD (*Presenter*)
Natisha P. Arora JR, MD (*Abstract Co-Author*)
Venkatesh Somu JR, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic accuracy of teleradiology across key acute care subspecialties and to analyze its impact on emergency department (ED) workflow efficiency, including turnaround time (TAT) and patient management timelines.

METHODS AND MATERIALS

A retrospective and prospective mixed-methods study was conducted on 4,000 emergency CT and MRI cases reported through a national teleradiology platform over a 12-month period. Cases spanned four acute subspecialties: neuroradiology, cardiothoracic, abdominal, and musculoskeletal imaging. Diagnostic concordance was assessed by comparing teleradiology reports to in-house radiologist reviews or multidisciplinary team consensus when available, using a 3-point discrepancy scale (none, minor, major). Workflow metrics such as report TAT, time-to-intervention, and ED length of stay (ED-LOS) were analyzed. Additionally, qualitative data were collected via interviews with emergency physicians regarding clinical confidence, reporting satisfaction, and system limitations.

RESULTS

Overall diagnostic concordance was 96.2%, with 2.9% minor and 0.9% major discrepancies. Subspecialty-wise concordance rates were: Neuroradiology: 98.1% Cardiothoracic: 96.5% Musculoskeletal: 95.8% Abdominal: 93.5% Mean TAT for teleradiology reports was 26 minutes (compared to 45 minutes with standard in-house reporting). ED-LOS was reduced by an average of 42 minutes per patient when reports were delivered within 30 minutes. Physicians noted improved triage and expedited decision-making, especially during night shifts. Abdominal imaging posed the most follow-up challenges, indicating a need for better subspecialty-level support.

CONCLUSION

Teleradiology demonstrates high diagnostic accuracy across emergency subspecialties, especially in neuro and cardiothoracic imaging. It significantly enhances ED workflow efficiency by reducing TAT and ED-LOS. The system is well-received by emergency clinicians, although specific areas like abdominal imaging may benefit from enhanced subspecialty input. Teleradiology is a valuable adjunct in acute care delivery, especially for resource-limited and off-hour settings.

CLINICAL RELEVANCE/APPLICATION

Teleradiology ensures rapid, round-the-clock access to radiology expertise across multiple acute care subspecialties. This model enhances diagnostic accuracy, reduces report turnaround times, and improves emergency department workflows, making it a critical tool for timely patient care—especially during nights, weekends, or in resource-limited settings.

W5A-SPNPM-2 COMPARATIVE EVALUATION OF FOUR LARGE LANGUAGE MODELS FOR SIMPLIFYING CORONARY CTA REPORTS FOR LAYPERSON COMPREHENSION

Jia Hao Chun (*Presenter*)

PURPOSE

To evaluate the effectiveness of four large language models (LLMs)—ChatGPT-4o, ChatGPT-o4mini, Deepseek-R1, and Deepseek-V3—in translating standard coronary computed tomography angiography (CTA) radiology reports into layperson-friendly language, and to determine which model produces the most comprehensible output for non-medical audiences.

METHODS AND MATERIALS

A total of 50 standard clinical coronary CTA reports were selected. Each report was processed by the same prompt through the four LLMs to generate corresponding layperson-oriented versions, resulting in 200 simplified reports. These were randomly distributed to 50 adult volunteers with no medical training, balanced across age, gender, and educational background. Each volunteer received four reports derived from the same clinical source—one from each LLM—and rated overall satisfaction using a 5-point Likert scale.

RESULTS

Reports generated by Deepseek-V3 received the highest average score, significantly outperforming the other three models ($p < 0.01$). This model minimized medical jargon most effectively and achieved the best comprehension rating (4.3 ± 0.458). ChatGPT-4o and Deepseek-R1 yielded moderate performance (3.72 ± 0.437 and 3.44 ± 0.718, respectively), while ChatGPT-o4mini produced the least readable reports (2.58 ± 0.505). Notably, ChatGPT-o4mini tended to oversimplify critical findings such as severe coronary stenosis, potentially undermining the perceived urgency of the condition.

CONCLUSION

Among the LLMs tested, Deepseek-V3 demonstrated the greatest capability in converting coronary CTA radiology reports into language understandable to the general public, enhancing readability and patient comprehension

CLINICAL RELEVANCE/APPLICATION

Effective communication of radiology findings to patients is critical for shared decision-making and adherence to treatment plans. This study demonstrates that large language models, particularly Deepseek-V3, can significantly improve the clarity and accessibility of coronary CTA reports for non-medical audiences. Integrating LLMs

into radiology workflows may enhance patient understanding, reduce anxiety, and foster more informed healthcare engagement.

W5A-SPNPM-3 A LONGITUDINAL ANALYSIS OF DIVERSITY AMONG U.S. MEDICAL SCHOOL RADIOLOGY DEPARTMENT CHAIRS

Milin Patel (*Presenter*)
Jeffrey Ding (*Abstract Co-Author*)
Faisal Khosa, FRCPC, MBA (*Abstract Co-Author*)

PURPOSE

The purpose of this study is to evaluate longitudinal trends in sex and race/ethnicity demographics among radiology department chairs at U.S. medical schools over the past 45 years. We aim to further identify whether progress has been made toward equitable representation of women and individuals from groups underrepresented in medicine (URiM).

METHODS AND MATERIALS

This retrospective study analyzed publicly available data from the Association of American Medical Colleges (AAMC) from 1977 to 2021. Department chairs were classified by sex and self-reported race/ethnicity. Categories included White, Asian, Black or African American, Hispanic or Latino, and other URiM groups. Descriptive statistics were used to assess demographic trends. All analyses were performed using Microsoft Excel.

RESULTS

From 1977 to 2021, a total of 7,981 individuals served as radiology department chairs at U.S. medical schools. Of these, 7247 (90.8%) were men and 734 (9.2%) were women. In terms of race and ethnicity, the majority of chairs were White (6725; 84.3%), followed by Asian (639; 8.0%), Black or African American (223; 2.8%), and Hispanic, Latino, or of Spanish Origin (171; 2.1%).

CONCLUSION

Despite measurable progress, women and URiM individuals remain significantly underrepresented among radiology department chairs. The end of affirmative action is expected to jeopardize the progress made and has the potential to perpetuate the lack of diversity in radiology department chair positions.

CLINICAL RELEVANCE/APPLICATION

This study underscores the need for targeted policies and practices to sustain and advance diversity in academic radiology leadership.

W5A-SPNR-1 STUDY OF BRAIN IRON CONTENT IN NEONATES WITH HYPERBILIRUBINEMIA(NHB) BASED ON QUANTITATIVE SUSCEPTIBILITY MAPPING (QSM)

Xing Li (*Presenter*)

PURPOSE

Neonatal hyperbilirubinemia (NHB) can lead to severe neurological disorders. Elevated iron levels in neonates have been associated with neurological dysfunction through oxidative stress, but measuring brain iron content accurately remains challenging. This study uses Quantitative Susceptibility Mapping (QSM) to analyze brain iron content in neonates with varying degrees of NHB and explore the neurological impacts of altered iron levels due to NHB.

METHODS AND MATERIALS

This study received approval from the institutional review board. It involved 97 neonates with pathological jaundice, categorized into mild-to-moderate (N1) and severe (N2) groups based on serum bilirubin levels, alongside 28 control neonates (N0 group). All underwent MRI on a 3.0T scanner. QSM utilized high-resolution iso-voxel scanning at 1mm*1mm*1mm, and quantitative magnetic susceptibility maps were generated using a Functool post-processing workstation, with regions of interest (ROIs) delineated in seven specific brain areas. Statistical analysis was conducted using SPSS 25.0, utilizing Chi-square tests for gender ratio comparisons, ANOVA for brain nucleus susceptibility values across groups, and LSD-t-tests for pairwise comparisons.

RESULTS

There was no statistically significant difference in gender distribution among the three groups. The susceptibility values observed significant differences in the right dorsal thalamus (F=3.985, P =0.021) and bilateral dentate nucleus (left: F=3.77, P =0.026; right: F=5.461, P =0.005). LSD-t tests revealed significant variations in right dentate nucleus between N0 and N2 (P =0.034), and N1 and N2 (P =0.006), and in bilateral dentate nucleus between N0 and N1 (left: P =0.027; right: P =0.012), and N0 and N2 (left: P =0.013; right: P =0.002).

CONCLUSION

This study demonstrated that elevated susceptibility values in the right thalamus and bilateral dentate nuclei correlate with increased bilirubin and iron levels in neonates with NHB. The use of QSM offers quantitative imaging evidence of brain damage in NHB neonates.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated that elevated susceptibility values in the right thalamus and bilateral dentate nuclei correlate with increased bilirubin and iron levels in neonates with NHB. The use of QSM offers quantitative imaging evidence of brain damage in NHB neonates.

W5A-SPNR-2 CHARACTERIZING WHITE MATTER HYPERINTENSITIES IN PSP AND PARKINSON'S DISEASE

Yash Patel (*Presenter*)
Richard Zou (*Abstract Co-Author*)
Mikail Malik (*Abstract Co-Author*)
Maziar Emamikhah (*Abstract Co-Author*)
Alexandre Boutet, MD, PhD (*Abstract Co-Author*)
Anthony Lang (*Abstract Co-Author*)

PURPOSE

Progressive supranuclear palsy (PSP), is a form of parkinsonian syndrome that may be difficult to distinguish from Parkinson's disease, especially in the early stages of the disease. Here, we assess the difference in white matter hyperintensity (WMH) burden between PSP and PD patients, in the hopes of aiding clinical diagnosis and understanding pathogenesis.

METHODS AND MATERIALS

We evaluated the MRI scans of 67 PSP, and 67 age and sex-match PD patients from a Movement disorders clinic and PSP Centre, in Canada. The total sample consisted of 134 patients with a mean age 70 years, 67% males and 33% females. WMH were quantified from FLAIR MRI using a convolutional neural network-based tool (segcsvd-WMH). Linear regression was used to test difference in WMHvol/ICV between PSP and PD, while accounting for age, sex, MR field strength and MR manufacturer. Sensitivity analyses were performed to account for potential cardiometabolic variables associated with WMH, including a history of cardiovascular disease, smoking, hypertension, dyslipidemia, diabetes mellitus, obstructive sleep apnea, chronic kidney disease, and orthostatic hypotension.

RESULTS

Patients with PSP had a significantly higher WMH burden than PD (0.55% vs 0.29% of total ICV, respectively, Wilcoxon rank sum p-vale = 0.001). Multivariable linear regression confirmed the main effect of diagnosis (beta estimate = 0.28, se = 0.079, p = 0.00041, PSP > PD), and age (beta = 0.09, se = 0.04, p = 0.017) on WMH volume. Lastly, the effect of diagnosis was still present after accounting for 8 different cardiometabolic variables known to impact WMH burden (PSP > PD, beta estimate = 0.24, p = 0.0025). Other cardiometabolic variables significantly associated with WMH included smoking status (beta = 0.63, p-value = 0.002), and obstructive sleep apnea (beta = 0.52, p-value = 0.005).

CONCLUSION

In summary, we found greater WMH volumes in PSP patients compared with PD, suggesting an increased role of white matter structural abnormalities in PSP. These findings may provide a supportive role in diagnosis as well as expand an understanding of pathogenesis.

CLINICAL RELEVANCE/APPLICATION

PSP patients show significantly higher WMH burden than those with PD, suggesting white matter changes may aid in distinguishing PSP from PD.

W5A-SPNR-4 CHARACTERIZATION OF METABOLIC PROFILES OF LOW- AND HIGH-GRADE GLIOMAS BY 1H FID MRSI AT 7T

Mahrshi Jani (*Presenter*)
Andrew Wright (*Abstract Co-Author*)
Anke Henning (*Abstract Co-Author*)

PURPOSE

To assess metabolic profiles in patients with low grade versus high grade glioma and attempt to obtain more clinically significant data than previously published. Clinical decision-making regarding diagnosis and treatment planning will benefit from this new metabolic information.

METHODS AND MATERIALS

Data acquisition We enrolled seven high-grade glioma (grade IV; two IDH mutant) and eight low-grade glioma (grade II/III; all IDH mutant) patients for a multi-modal 7T brain tumor MRI study (Philips dSync). 2D ^{1}H FID MRSI was acquired (TE = 1.21 ms, TR = 320 ms, flip angle = 33°, matrix = 50×50, in-plane resolution = 4.4×4.4 mm², slice thickness = 12 mm), along with FLAIR, MP2RAGE, CEST, and SWI sequences. B 0 shimming was performed using a custom image-based shim tool.Data processing & Quantification MRSI image reconstruction was performed in Python, with post-processing conducted in MATLAB (The MathWorks, Natick, MA). Voxel-wise spectral fitting was carried out using LCModel. Tumor ROIs were manually delineated on FLAIR images and applied to the spectroscopic data to extract and average spectra from tumor and contralateral regions. These average spectra were also fitted in LCModel using the same basis set. Metabolite concentrations were compared between tumor and healthy tissue, as well as between low- and high-grade gliomas.

RESULTS

Figure 1 shows the metabolite maps of different metabolites overlaid on top of FLAIR images of a high-grade glioma patient (glioblastoma, IDH wildtype), who also suffered from traumatic brain injury in the past. NAA, Cho, Asp, Lac, Glu and mI+Gly changes clearly extend beyond the FLAIR based ROIs, while Cr and GSH changes are mainly observed within the ROI. Figure 2 represents a similar representation of metabolite maps for a low-grade glioma patient (oligodendroglioma grade III, IDH mutant).The respective metabolite maps show clear changes in the tumor area versus healthy brain tissue. Figure 3 shows comparision of the metabolite concentrations from lesion vs healthy tissue from the highgrade glioma patient. Figure 4 shows simillar comparision for lowgrade glioma patient.

CONCLUSION

This study demonstrates that 1H FID MRSI at 7T can detect tumor-specific alterations in 10 brain metabolites, with changes often extending beyond anatomically defined tumor boundaries, particularly in high-grade gliomas. These findings highlight the potential of metabolic imaging for personalized treatment planning and monitoring of disease progression.

CLINICAL RELEVANCE/APPLICATION

This approach offers a non-invasive means for early detection, classification, and treatment response monitoring of primary brain tumors, with the potential to improve tumor boundary delineation for treatment planning.

W5A-SPNR-6 INFLAMMATORY BIOMARKERS AND NEUROIMAGING SIGNATURES IN HIGH-ALTITUDE CEREBRAL SMALL VESSEL DISEASE: AN ALTITUDINALLY STRATIFIED COHORT STUDY

Jia Wei (*Presenter*)
Hai Hua Bao (*Abstract Co-Author*)
SHIPEI HE (*Abstract Co-Author*)

PURPOSE

The progression of cerebral small vessel disease (CSVD) is closely linked to hypoxic stress and systemic inflammation. Chronic hypoxia in high-altitude environments may exacerbate CSVD pathophysiological processes; however, research on clinical phenotypes and specific neuroimaging alterations in CSVD patients under such unique environmental conditions remains limited. This study aimed to investigate neuroimaging characteristics of CSVD across varying altitude exposures and evaluate the correlations between altitude elevation, systemic inflammatory biomarkers, and neuroimaging markers.

METHODS AND MATERIALS

This retrospective study (03/2023-10/2024) at Qinghai University Hospital stratified 309 CSVD patients into three groups based on altitude: low-altitude (1,800-2,500 m, n=96), high-altitude (2,500-3,500 m, n=124), and extreme high-altitude (=3,500 m, n=89). Neuroimaging parameters (CSVD burden, Fazekas scores, PVS counts, lacunes, WMH volumes/ratios across juxtaventricular/periventricular/deep/juxtacortical regions) were quantified via 3T Prisma MRI (T1/T2/T2-FLAIR/DWI sequences). Inflammatory indices [systemic immune-inflammation index (SII), neutrophil-to-lymphocyte ratio (NLR), monocyte and neutrophil count]were analyzed using SPSS 25.0.

RESULTS

This study enrolled 309 CSVD patients (65±10y; 53.4% male) stratified by altitude: low (2,141±215m), high (2,790±273m), and extreme high (3,732±212m). Elevation-dependent increases in systemic inflammation were observed: leukocyte count (r=0.201), neutrophils (r=0.183), monocytes (r=0.112), and SII (r=0.148)(all $p<0.05$). Despite comparable total CSVD burden and age distribution across groups, extreme high-altitude patients demonstrated significantly higher PVS counts (P=0.007). Both high-altitude groups exhibited more severe deep WMH (P=0.001), particularly in left (P<0.001) and right (P=0.003) hemispheric regions, with elevated deep WMH volume ratios (P=0.006). Extreme altitude demonstrated larger juxtacortical WMH volumes than low altitude (p=0.026), left-hemisphere predominant (p=0.004). No altitude-dependent variations emerged in periventricular/juxtaventricular WMH parameters.

CONCLUSION

Higher altitude exposure is associated with increased systemic inflammation and exacerbated neuroimaging markers of CSVD, particularly deep white matter ischemic injury and PVS enlargement.

CLINICAL RELEVANCE/APPLICATION

High-altitude CSVD necessitates close monitoring of systemic inflammation and thorough assessment of deep white matter ischemic lesions, with neuroimaging biomarkers and inflammatory profiles serving as key targets for early intervention in hypoxia-driven progression.

W5A-SPNR-7 ENHANCING TOF-MRA ANEURYSM SEGMENTATION: IMPACT OF FOCAL LOSS ON SMALL LESION DETECTION

Sahika Yayli, MD (*Presenter*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)

PURPOSE

Accurate segmentation of brain aneurysms in TOF-MRA is crucial for diagnosis and treatment planning. However, small lesions are often missed due to class imbalance and their subtle appearance. This study investigates whether Focal Loss can reduce false negatives and improve aneurysm detection compared to conventional Dice-based loss in deep learning models.

METHODS AND MATERIALS

We used the public Lausanne dataset comprising 284 TOF-MRA volumes (127 healthy, 157 patients with aneurysms; 198 aneurysms total). A nnU-Net model was trained for 1000 epochs using two main loss configurations: (1) Dice Loss alone, and (2) a composite loss combining Dice, Binary Cross-Entropy (BCE), and Focal Loss. In addition to experimenting with different alpha and gamma values for Focal Loss, we also trained models with varying weights assigned to the Dice, BCE, and Focal components to identify the most effective balance. Performance was evaluated using standard segmentation metrics including Dice Score, Hausdorff Distance (HD), 95th percentile HD (HD95), Relative Volume Error (RVE), and Sensitivity.

RESULTS

The model trained with a combined loss function of Focal Loss, Cross Entropy, and Dice Loss outperformed the baseline Dice-only model, showing consistent improvements across all key metrics: F1 Score improved from 0.64 to 0.84 Mean Dice improved from 0.43 to 0.46 Mean HD95 improved from 33.8 to 13.8 Mean HD improved from 48.5 to 15.7 Sensitivity improved from 0.79 to 0.82 Visual evaluation confirmed better delineation of small aneurysms. While the number of MRIs with no detected lesions slightly increased (from 2 to 4), the model yielded more true positives and fewer false negatives, indicating a meaningful gain in small lesion detection performance.

CONCLUSION

The combined use of Dice, BCE, and Focal Loss led to performance improvements across all segmentation metrics. Most notably, the number of missed aneurysms (false negatives) and segmentation errors were reduced. The focal loss-based training demonstrated better delineation of small lesions and improved sensitivity compared to standard Dice-only training.

CLINICAL RELEVANCE/APPLICATION

Focal Loss enhances aneurysm segmentation on TOF-MRA by reducing false negatives and improving detection of small lesions. This approach can help radiology AI models become more reliable in identifying clinically significant abnormalities, especially when lesion sizes are small or data is imbalanced.

W5A-SPNR-8 STANDING CONE BEAM CT MYELOGRAPHY REVEALS NEW FINDINGS IN PATIENTS WITH NEGATIVE SUPINE CT MYELOGRAMS: A CASE SERIES

Ahmed O. El Sadaney, MBBCh (*Presenter*)
Norbert G. Campeau, MD, MSc (*Abstract Co-Author*)
Troy Bellrichard (*Abstract Co-Author*)
Ian T. Mark, MD (*Abstract Co-Author*)

PURPOSE

Patients with low back pain can have supine cross-sectional imaging (MRI or CT myelogram) without identifying stenosis as a causative etiology. However, the positional nature of their symptoms suggests that the non-weight-bearing supine position may contribute to false-negative results. This case series shows that standing cone beam CT myelography can reveal additional findings in a weight-bearing state, potentially demonstrating spinal canal or nerve root compression not seen in the supine position.

METHODS AND MATERIALS

A cone beam CT myelogram was performed with the patient in a standing position using the following clinical protocol: a fluoroscopic guided lumbar puncture was performed followed by the intrathecal injection of iodinated contrast. Images of the lumbar spine were then acquired using the upright lumbar myelo 3D program at 30f/s using a scene time of 6.9 seconds. The patient was then transferred over to CT for a conventional supine myelogram.

RESULTS

Three patients were identified with new lumbar spondylosis on the standing cone beam CT myelogram that were not observed on the supine CT myelogram. Patient A is a 66-year-old male with a widely patent spinal canal on supine images, but standing myelogram demonstrates advanced spinal canal narrowing at L4-L5 on the basis of a posterior disc bulge and ligamentum flavum thickening. Patient B is a 72-year-old male who had disc vacuum phenomenon and grade 1 retrolisthesis of L4 on L5 when supine, however when standing this same level demonstrated grade 1 anterolisthesis, loss of the disc height space, and effacement of the vacuum phenomenon. Patient C is a 66-year-old female who had a right posterior disc bulge and effacement of the right lateral recess at L3-L4 that was only apparent on the standing myelogram.

CONCLUSION

Standing cone beam CT myelography is a useful tool for evaluating patients with chronic pain and negative non-weight-bearing imaging. Further studies are needed to validate the findings from this case series and to identify which patient populations may benefit most from this technique.

CLINICAL RELEVANCE/APPLICATION

Standing cone beam CT myelograms can provide new insights for patients with negative supine CT myelograms.

W5A-SPNR-10 APPLICATION OF 3D-ASL AND MRA IN THROMBOLYTIC THERAPY OF PATIENTS WITH ACUTE ISCHEMIC STROKE

Deng Jie (*Presenter*)

PURPOSE

To evaluate the clinical utility of three-dimensional arterial spin labeling (3D-ASL) and magnetic resonance angiography (MRA) in assessing cerebral perfusion and vascular stenosis in patients with acute ischemic stroke (AIS) undergoing intravenous thrombolysis (IVT).

METHODS AND MATERIALS

This study included 100 AIS patients treated with IVT within 4.5 hours of symptom onset from March 2021 to December 2023. All patients underwent MRI, 3D-ASL, and MRA before and after IVT. Patients were stratified based on MRA-detected middle cerebral artery (MCA) stenosis (positive vs. negative). Cerebral blood flow (CBF) in the ischemic penumbra (IP), contralateral mirror region, and infarct core, as well as NIHSS scores, were compared pre- and post-IVT. Pearson correlation analysis assessed the relationship between NIHSS scores and CBF in these regions. Additionally, Spearman correlation analysis evaluated the association between MCA stenosis and post-IVT rCBF/NIHSS scores.

RESULTS

CBF Changes: Pre-IVT, CBF in the infarct core was significantly lower than in the IP and contralateral regions ($P<0.05$). Post-IVT, CBF in the IP and infarct core increased significantly ($P<0.05$), while NIHSS scores decreased ($P<0.05$). CBF in the contralateral region remained stable ($P>0.05$).Correlation Analysis: NIHSS scores showed significant negative correlation with CBF in the IP and infarct core ($P<0.05$) but no correlation with the contralateral region ($P>0.05$).MCA Stenosis: MRA identified MCA stenosis in 67 patients (positive group). Compared to the negative group, positive patients had lower IP rCBF and higher NIHSS scores post-IVT ($P<0.05$). MCA stenosis was significantly negatively correlated with IP rCBF and positively correlated with NIHSS scores ($P<0.05$).

CONCLUSION

The combination of 3D-ASL and MRA provides a robust tool for evaluating post-thrombolytic perfusion in AIS patients, offering complementary value in guiding treatment decisions and predicting clinical outcomes.

CLINICAL RELEVANCE/APPLICATION

3D-ASL and MRA are valuable in assessing penumbral perfusion and vascular stenosis in AIS patients undergoing thrombolysis, supporting precise treatment planning and improving clinical outcomes. Their integration into routine clinical practice is strongly recommended.

W5A-SPNR-11 SSPE IN PEDIATRIC POPULATION- A SERIES OF SIX CASES AND LITERATURE REVIEW

Marya Hameed, FRCR, MBBS (*Presenter*)

PURPOSE

Subacute Sclerosing Panencephalitis (SSPE) is a progressive, fatal neurodegenerative disorder resulting from persistent measles virus infection, typically emerging years after the initial illness. Despite the inclusion of the measles vaccine in national immunization programs, cases continue to arise, especially in regions with poor vaccine coverage. This case series aims to highlight the clinical and radiological spectrum of SSPE in children, advocate for the utility of imaging in early diagnosis, and call attention to the disease as a neglected public health concern in low-resource settings.

METHODS AND MATERIALS

We present six pediatric SSPE cases admitted to a tertiary government-funded hospital in Pakistan. Each case was evaluated with a detailed clinical history, neurological examination, electroencephalography (EEG), cerebrospinal fluid (CSF) analysis for measles antibodies, and brain MRI. Diagnostic challenges, treatment attempts, and outcomes were recorded to assess common patterns and the role of imaging in early identification.

RESULTS

All six patients had a history of either confirmed or suspected measles infection in early childhood, often with incomplete vaccination records. Presenting symptoms ranged from seizures, behavioral changes, and cognitive decline to motor deficits and vision loss. MRI findings included asymmetrical T2/FLAIR hyperintensities in the parieto-occipital, periventricular, or temporo-occipital regions. CSF analysis confirmed elevated measles IgG antibodies in all cases. Outcomes varied, with some patients deteriorating rapidly despite corticosteroid and antiviral therapy, while others were lost to follow-up due to socioeconomic constraints.

CONCLUSION

SSPE remains a critical, underdiagnosed complication of measles in low-income countries. Early imaging and clinical suspicion are key to diagnosis, but limited awareness and delayed presentation hinder timely intervention. Multidisciplinary support and nationwide preventive strategies are urgently needed.

CLINICAL RELEVANCE/APPLICATION

Radiologists play a pivotal role in the early detection of SSPE. Enhanced awareness among clinicians, improved vaccine outreach, and investment in diagnostic capacity are essential to prevent and manage this fatal but potentially avoidable condition.

W5A-SPNR-13 DYNAMIC FUNCTIONAL CONNECTIVITY CORRELATES WITH TRANSCRIPTOMIC AND CELLULAR FEATURES IN ALZHEIMER'S DISEASE SPECTRUM

Yan Shi (*Presenter*)
Yuanhao Li (*Abstract Co-Author*)
Renpuchi Ci (*Abstract Co-Author*)
Ning Zheng (*Abstract Co-Author*)
Wenzhen Zhu (*Abstract Co-Author*)
Yuan-Yuan Qin, MD (*Abstract Co-Author*)

PURPOSE

Alzheimer’s disease (AD) progression involves a continuum from subjective cognitive decline (SCD) to mild cognitive impairment (MCI), and eventually dementia. To uncover dynamic functional connectivity (dFC) of this progression, we characterized transient brain states using resting-state functional MRI (rsfMRI) at different AD Spectrum (ADS) stages, and mapped them to molecular pathways, spatial gene expression, and cell-type specificity.

METHODS AND MATERIALS

A total of 239 participants (31 AD, 56 MCI, 83 SCD, and 69 healthy controls [HC]) underwent 3T rsfMRI and neuropsychological assessments. Whole-brain dFC patterns were analyzed using Leading Eigenvector Dynamics Analysis (LEiDA) and K-means clustering. Brain state features showing significant group differences were spatially correlated with regional transcriptomic profiles from the Allen Human Brain Atlas (AHBA). Associated genes were further evaluated for enriched biological processes and cell-types specificity.

RESULTS

In this cohort, ten transient brain states were identified. AD patients showed reduced dwell time compared to HC (P FDR =0.003), SCD (P FDR =0.000), and MCI (P FDR =0.004), as well as reduced occupancy rate relative to HC (P FDR =0.004) in State 5, characterized by synchronized activity across the bilateral Salience/Ventral Attention Network-Frontoparietal Control Network-Default Mode Networks. State 5-related genes localized to medial prefrontal (P FDR =0.032), inferior temporal (P FDR =0.032), and orbitofrontal cortices (P FDR =0.047), enriched in “extracellular glycine-gated ion channel activity” (GO:0016933, P FDR = 0.001) and its subclass “extracellular glycine-gated chloride ion channel activity” (GO:0016934, P FDR = 0.001). These genes showed cell-type-specific expression in excitatory neurons (Ex4, P FDR = 0.007; Ex5, P FDR = 0.007; Ex7, P FDR = 0.026) and inhibitory interneurons (In1, P FDR =0.047).

CONCLUSION

Our findings identify disrupted state 5 as a key marker of AD progression, linked to glycine-gated ion channel pathways and Ex/In neuronal subtypes. These results offer novel mechanistic insights into functional network dysfunction in ADS and identify potential molecular targets for early intervention.

CLINICAL RELEVANCE/APPLICATION

The identified dFC signatures, particularly State 5 abnormalities and associated glycinergic pathway dysregulation, may serve as biomarkers and therapeutic targets to modulate excitatory/inhibitory balance and delay cognitive decline.

W5A-SPNR-15 DIAGNOSTIC PERFORMANCE OF A SIMULTANEOUS NEUROMELANIN-NIGROSOME MRI PROTOCOL IN PARKINSONISM: COMPARISON WITH CONVENTIONAL SMWI AND PET CORRELATION

Aleum Lee, PhD, MD (*Presenter*)
Hwan Heo, MENG (*Abstract Co-Author*)
Myeongoh Lee (*Abstract Co-Author*)
Jeongwon Jo (*Abstract Co-Author*)
Intae Shin (*Abstract Co-Author*)
Soohwa Song, PhD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the diagnostic accuracy of a 3D multi-echo GRE sequence for simultaneous neuromelanin (NM) and nigrosome-1 (N1) imaging in individuals with parkinsonism features and to analyze its correlation with PET standardized uptake value ratio (SUVR). Deep learning-driven methods will enable detection and

segmentation of swallow-tail sign loss as well as characterization of NM signal variations. We compare accuracy to the conventional susceptibility map weighted images (SMwI) sequence and assess NM-N1 effectiveness via NM volume-SUVR correlation.

METHODS AND MATERIALS

Data acquisition We modified the conventional SMwI sequence by integrating two spatial saturation pulses for magnetization transfer weighting to simultaneously obtain NM contrast. A total of 44 MRI datasets were collected from domestic Hospital on a 3 T scanner; 32 subjects had parkinsonian syndrome (PS) confirmed by decreased 18 F-FP-CIT binding on PET. Additionally, 27 participants underwent images with the conventional SMwI sequence. Image processing & analysis: For NM analysis, the first-echo data were used, while the remaining three echoes were employed for SMwI reconstruction. A deep learning-based model and anatomical templates was applied to quantify N1 and NM, and to train a classifier for detecting N1 abnormalities within the substantia nigra. The reference standard was defined by 18 F-FP-CIT PET findings. Finally, we assessed the correlation between quantified neuromelanin volume and PET SUVR.

RESULTS

The NM-N1 sequence showed 82.8% sensitivity, 93.3% specificity, and 0.936 AUC on the right, and 82.1%, 93.8%, and 0.940 on the left. The conventional SMwI protocol demonstrated higher performance with 94.1% sensitivity, 100% specificity, and an AUC of 0.953 on the right, and 88.2%, 100%, and 0.953 on the left. AUC comparisons between the two SMwI sequences yielded p-values of 0.711 (right) and 0.797 (left), indicating no significant differences. Furthermore, PS patients showed a 19% decrease in neuromelanin volume relative to non-PS controls, and neuromelanin volume was significantly correlated with the SUVR of the putamen within the basal ganglia.

CONCLUSION

The NM-N1 sequence provided diagnostic accuracy comparable to that of the conventional SMwI protocol, and neuromelanin volume measurements significantly differentiated PS patients from controls.

CLINICAL RELEVANCE/APPLICATION

With a total scan duration of less than 5 minutes, NM-N1 sequence could be especially beneficial for PS patients sensitive to prolonged imaging sessions. The modest performance difference compared to the conventional SMwI protocol falls within clinically acceptable limits, suggesting its diagnostic utility in practice.

W5A-SPNR-16 RESEARCH OF AUTISM SPECTRUM DISORDERS BASED ON GRAY-WHITE MATTER DYNAMIC FUNCTIONAL NETWORK CONNECTIVITY

Xuan Yu (*Presenter*)
Yuning Si (*Abstract Co-Author*)
Jinsha Tan (*Abstract Co-Author*)
Nan Meng (*Abstract Co-Author*)
Meiyun Wang (*Abstract Co-Author*)

PURPOSE

Previous neuroimaging research has primarily focused on static functional connectivity or discrete subnetwork interactions, often overlooking the temporally evolving interactions within the brain's functional systems. The overarching objective of this study is to investigate the dynamic functional network connectivity (dFNC) between white matter (WM) and gray matter (GM) in individuals with Autism Spectrum Disorders (ASD) and to uncover its pathophysiological significance. By leveraging the advanced machine learning model, this research aims to quantify dynamic spatiotemporal patterns of gray-white matter interactions across large-scale brain networks, identifying deviations in ASD compared to neurotypical controls.

METHODS AND MATERIALS

This study utilized structural MRI (sMRI) and functional MRI (fMRI) data from the Autism Brain Imaging Data Exchange (ABIDE) database, selecting a final cohort of 1112 participants, including individuals with 539 ASD and 573 Typical Development (TD). To ensure data quality and consistency, all sMRI and fMRI data underwent standardized preprocessing using the fMRIPrep pipeline (v24.1.1). The GM mask consisted of 82 regions directly from the Brodmann atlas. The WM bundle mask included 48 regions based on the JHU ICBM-DTI-81 atlas. To capture dynamic functional interactions, we extracted time-series data from GM and WM regions of interest (ROIs) and constructed dynamic functional network connectivity (dFNC) matrices using a sliding-window approach. Subsequently, spatiotemporal features were extracted using the Mamba-Unet framework to enhance the robustness of dFNC estimation. Further analyses, such as graph theory metrics and clustering of dFNC states, were performed to identify biologically meaningful connectivity signatures associated with ASD.

RESULTS

The Mamba-Unet model achieved 87.6% accuracy to classify ASD and TD in multiple center studies. Our study found abnormal functional connectivity primarily involving the left anterior prefrontal cortex and corpus callosum, as well as the dorsolateral prefrontal cortex and superior longitudinal fasciculus.

CONCLUSION

Our research provides a gray-white matter dynamic functional connectivity perspective for the diagnosis and understanding of ASD.

CLINICAL RELEVANCE/APPLICATION

These dynamic connectivity profiles could inform personalized treatment strategies.

W5A-SPNR-17 HUMMID: HIGH-FIDELITY ULTRA-FAST MACROSTRUCTURE AND MICROSTRUCTURE BRAIN IMAGING USING DEEP LEARNING

Yuhang He (*Presenter*)
Jialan Zheng (*Abstract Co-Author*)
Hongjia Yang (*Abstract Co-Author*)
Mingxuan Liu (*Abstract Co-Author*)
Yifei Chen (*Abstract Co-Author*)
Zihan Li (*Abstract Co-Author*)
Qiuyun Fan (*Abstract Co-Author*)
Yi Liao (*Abstract Co-Author*)
Haibo Qu (*Abstract Co-Author*)
Qiyuan Tian (*Abstract Co-Author*)
Jie Lu, PhD (*Abstract Co-Author*)
Ziyu Li (*Abstract Co-Author*)

PURPOSE

Quantifying macro- and microstructural features of human brain is vital for studying healthy and pathological changes. Assessments of macrostructural brain morphology typically rely on high-resolution T1w images from long scan times (~5 min for 1 mm iso.). Diffusion MRI (dMRI) reveals tissue microstructure and brain connectivity but needs lengthy angular samplings (~5 min for 2 mm iso. and 32-62 directions). The combined scan time (~10 min) limits the feasibility in clinical use. This study aims to enable ultrafast, high-fidelity T1w and dMRI using deep learning. Using just six diffusion-weighted images (DWIs) along optimal diffusion directions and a single b=0 image volume (~0.5 min scan time), the proposed method, HUMMID accurately reconstructs both macro- and microstructural features, enabling ultrafast brain morphology and connectivity mapping for wider clinical applications.

METHODS AND MATERIALS

HUMMID consists of two concatenated U-Nets. The first one generates high-quality T1w from 6 DWIs along optimized diffusion directions and 1 b=0 image. The second one uses residual learning to map the input to high-SNR DWIs. T1w (1 mm iso.) and dMRI data (2 mm iso., b = 1000 s/mm 2 , 50 directions) of 130 subjects (56 for training, 14 for validation, 60 for evaluation) from UK Biobank were used. Six DWIs along optimized directions were synthesized from fitted tensors—using 6 directions for the input and all 50 for the reference. On evaluation data, analyses included brain segmentation, cortical surface reconstruction, DTI, and tractography to assess the fidelity of the generated T1w and dMRI data.

RESULTS

HUMMID synthesized high-quality T1w images similar to native ones, which produced accurate brain segmentations compared to those from native images, with Dice coefficients higher than 0.95 for white matter and cortex. Reconstructed cortical surfaces from synthesized and native T1w data were highly similar, with whole-brain mean difference as 0.35, 0.34, and 0.27 mm for gray-white surface, pial surface, and cortical thickness. HUMMID also improved the SNR of input dMRI data. The whole-brain averaged mean error for fractional anisotropy reduced by 56%. The tracked fibers from HUMMID exhibited patterns more similar to those from reference DTI data.

CONCLUSION

HUMMID generates high-SNR anatomical and dMRI data from six-direction dMRI input, showing the potential in high-SNR brain morphology and microstructure mapping within clinically feasible scan times.

CLINICAL RELEVANCE/APPLICATION

By reducing 93% scan time while preserving image quality, HUMMID has the potential to facilitate brain morphology and microstructure mapping in patients with severely limited scan tolerance, such as stroke patients or young children with neurological conditions.

W5A-SPNR-18 ELEVATED IRON DEPOSITION IN FRONTAL GRAY MATTER CORRELATES WITH SEIZURES IN BRAIN ARTERIOVENOUS MALFORMATIONS: A PRELIMINARY QUANTITATIVE SUSCEPTIBILITY MAPPING STUDY

Ni Zeng, MS (*Presenter*)
Caihong Li (*Abstract Co-Author*)
Jingyue Xue (*Abstract Co-Author*)
QIUXIAN WANG (*Abstract Co-Author*)
Wen Zhibo, BA (*Abstract Co-Author*)

PURPOSE

The relationship between the pathogenesis of epilepsy associated with brain arteriovenous malformations (BAVMs) and hemosiderin deposition remains poorly understood. Utilizing the high sensitivity of quantitative susceptibility mapping (QSM) to iron metabolism, this study aimed to quantify iron content in cortical and deep gray matter nuclei of BAVM patients and evaluate its diagnostic performance in detecting epileptic BAVMs.

METHODS AND MATERIALS

A retrospective cohort of 23 BAVM patients were categorized into epileptic (n=6) and non-epileptic (n=17) groups based on seizure presentation at initial diagnosis. Using 3D Slicer software, magnetic susceptibility values were measured in 9 bilateral regions of interest (ROIs) on QSM sequences, including frontal gray matter (FGM), frontal white matter (FWM), thalamus (TH), and other nuclei. The iron deposition ratio (affected/healthy hemisphere) was calculated for each ROI. Intergroup comparisons were performed using the Wilcoxon rank-sum test, Cliff's delta effect size estimation and Holm's correction for multiple testing (a =0.05).

RESULTS

Intergroup comparisons revealed FGM iron deposition ratios were elevated in epileptic BAVMs with a medium effect size (d =0.42, 95% CI: -0.16 to 0.73), though not surviving Holm correction (p =0.308). TH iron deposition showed a similar trend (d =0.25, p =0.375) but was influenced by outliers (sensitivity analysis reduced d to -0.21 after exclusion). The epileptic group was younger (median age 24 vs. 27 years, d =-0.24), consistent with known age-related seizure susceptibility. ROC analysis indicated weak predictive value for individual ROIs (AUC<0.65), but FGM-CA ratio combined showed marginal improvement (AUC=0.68, p =0.12).

CONCLUSION

Preliminary findings suggest a potential association between elevated FGM iron deposition and epilepsy-associated BAVMs, warranting further investigation as a candidate non-invasive biomarker for seizure risk stratification. The younger age distribution in the epilepsy group aligns with clinical observations of increased seizure susceptibility in adolescent BAVM patients.

CLINICAL RELEVANCE/APPLICATION

Despite limited sample size (n=23), FGM iron deposition demonstrated clinically meaningful effect sizes, suggesting its potential as a biomarker. Future studies should prioritize larger cohorts to validate the FGM-epilepsy link.

W5A-SPOB-1 RADIOMIC PHENOTYPES FROM TRANSVAGINAL ULTRASOUND COMBINED WITH AGE TO IDENTIFY OVARIAN CYSTS NEEDING SURGICAL INTERVENTION

Arunima Sharma, PhD, BEng (*Presenter*)
DIB SASSINE (*Abstract Co-Author*)
Eric A. Cohen (*Abstract Co-Author*)
Walter Mankowski (*Abstract Co-Author*)
Jennifer Ferris (*Abstract Co-Author*)
Ruth C. Carlos, MD, MS (*Abstract Co-Author*)
Jason Wright (*Abstract Co-Author*)
Despina Kontos, PhD (*Abstract Co-Author*)

PURPOSE

To assess diagnostic performance of radiomic features extracted from transvaginal ultrasound (TVUS) scans of ovarian cysts when combined with age in distinguishing high-risk ovarian cysts that may require surgical intervention, from low-risk ovarian cysts.

METHODS AND MATERIALS

TVUS images of 351 ovaries with benign ovarian cysts from 195 women (median age: 45 y; range 16-88 y) were retrospectively analyzed. For 21/351 cysts, surgery i.e., oophorectomy (9/21) or cystectomy (12/21) was performed due to pain (8/21), or diagnostic uncertainty in the case of large, complex, or persistent cysts (13/21). For this analysis, the 21 cysts undergoing surgery were labeled as high-risk, and the other 330 non-surgically treated cysts were labeled as low-risk. After text removal from TVUS, the ovaries were manually segmented, and the open-source Cancer Imaging Phenomics Toolkit (CaPTk) was used to extract texture radiomic descriptors from the images. Unsupervised hierarchical clustering was used to cluster cysts into intrinsic radiomic phenotypes. Consensus clustering was used to test phenotype stability. Principal components (PCs) summarizing the feature space were identified to reduce feature dimensionality. Logistic regression models formed with identified PCs alone and combined with age were evaluated using five-fold cross-validation.

RESULTS

Unsupervised hierarchical clustering identified two significant phenotypes ($p<0.05$) with one phenotype more associated with high-risk cysts (19.5%) when compared to a second phenotype (3.9%). Receiver operating characteristics (ROC) curves showed improved prediction of high-risk cysts when age was combined with PCs compared to when only the PCs were used for the prediction. Using the first four PCs, the area under the ROC curves were 0.68 (95% CI: 0.64 - 0.71) and 0.70 (0.66 - 0.74) before and after inclusion of age in the model, respectively.

CONCLUSION

Radiomic features extracted from TVUS can aid in distinguishing high-risk ovarian cysts that may require surgical intervention from low-risk ovarian cysts. Additionally, machine learning models formed by combining principal components of radiomic features with age can further improve identification of high-risk cysts.

CLINICAL RELEVANCE/APPLICATION

Radiomic features of ovarian cysts combined with clinical factors like age may augment established O-RADS criterion in distinguishing high-risk from low-risk ovarian cysts, aiding in clinical management and care delivery.

W5A-SPOB-2 DEVELOPMENT AND VALIDATION OF AN MRI RADIOMICS-BASED NOMOGRAM FOR PREOPERATIVE IDENTIFICATION OF LOW-RISK CERVICAL CANCER

Zhilin Yuan (*Presenter*)
Yonglan He, MD (*Abstract Co-Author*)
Fuze Cong, PhD (*Abstract Co-Author*)
Xin Gao (*Abstract Co-Author*)
Chen Jing (*Abstract Co-Author*)
Yuan Li (*Abstract Co-Author*)
Zhengyu Jin, MD (*Abstract Co-Author*)
Huadan Xue, MD (*Abstract Co-Author*)

PURPOSE

To establish a preoperative predictive framework integrating radiomics, MRI morphological features, and clinical parameters for identifying low-risk cervical cancer patients.

METHODS AND MATERIALS

This retrospective study included 91 consecutive patients with FIGO2018 IA2-IB1 stage cervical cancer (squamous cell carcinoma/adenocarcinoma/adenosquamous carcinoma). Using National Comprehensive Cancer Network criteria, patients were stratified into low-risk (tumor depth <10 mm; any-grade squamous carcinoma; well/moderately differentiated adenocarcinoma/adenosquamous carcinoma; negative lymphovascular space invasion and negative nodes) and non-low-risk groups. T2-weighted MRI-derived radiomic features were extracted, with the cohort divided into training (n=71) and validation (n=20) sets. Four models were developed: clinical features-only (age, CA125, SCC-Ag, menopause, fertility), conventional MRI features (tumor length, signal pattern: patchy vs. mass-like), radiomics, and an integrated nomogram combining significant predictors.

RESULTS

Independent predictors included tumor diameter ($p=0.005$) and MRI signal pattern ($p<0.001$). The radiomics model achieved the highest validation AUC of 0.950 (sensitivity 0.50, specificity 1.00), while the integrated nomogram incorporating radiomic features, conventional MRI features, and clinical features showed AUC of 0.900 (sensitivity 0.60, specificity 0.88). Both outperformed clinical-only (AUC 0.610) and conventional MRI models (AUC 0.850).

CONCLUSION

The radiomics model demonstrates superior predictive accuracy, and the MRI-based nomogram provides clinically interpretable decision support. Sagittal T2-weighted imaging serves as an effective protocol for radiomic feature extraction in cervical cancer risk stratification.

CLINICAL RELEVANCE/APPLICATION

Explicit characterization of sagittal T2-based radiomic signatures enables precise identification of low-risk patients, guiding conservative surgical strategies. This stratification facilitates accurate individual treatment strategies while maintaining oncological safety, and potentially reducing surgical complication and improving quality of life.

Jaret Skonieczny (*Abstract Co-Author*)
Patricia Ugalde Nicalo (*Abstract Co-Author*)
Michael S. Middleton, MD, PhD (*Abstract Co-Author*)
Jeffrey B. Schwimmer, MD (*Abstract Co-Author*)
Claude B. Sirlin, MD (*Abstract Co-Author*)

PURPOSE

To examine accuracy and reproducibility of ultrasound (US)-based hepatorenal index (HRI) for assessing hepatic steatosis in children with known or suspected metabolic dysfunction-associated steatotic liver disease (MASLD).

METHODS AND MATERIALS

Prospectively enrolled children with known or suspected MASLD had same-day US (C1-6 transducer, GE Logiq E10 system) and magnetic resonance imaging (MRI; GE 3T MR750). Experienced sonographers acquired a longitudinal B-mode image including the liver and the right-kidney. Three blinded US readers (R1, R2, R3) placed one region of interest (ROI) in renal cortex and a same-sized second ROI in the right lobe of the liver. HRI (ratio of liver to kidney US signal intensity) was calculated. For each US reader, we calculated: Spearman rank correlation coefficient between HRI and PDFF, area under receiver operator characteristic curve (AUC) of HRI for classifying steatosis (PDFF = 5%), and sensitivity/specificity for classifying steatosis at a common Youden-index-based threshold. Mean right-lobe proton density fat fraction (PDFF) was calculated from right-lobe segmental ROI values. Inter-reader reproducibility was assessed by an extension of Bland-Altman (BA) analysis to three readers, with computation of 95% limits of agreement (LoA), within-participant coefficient of variation (wCV), proportional reproducibility coefficient (RDC%), and intraclass correlation coefficient (ICC). Light's Kappa was computed to assess agreement of binary classification of steatosis.

RESULTS

Thirty-four children (11 female, age 8-17 yrs) were enrolled. Three children who did not tolerate MRI were excluded. Mean PDFF was 17% (range 1 to 42%). Based on AUC analysis and pooling data from all readers, the optimal Youden index based threshold was 1.65. Spearman ? (and p-value), AUC, and sensitivity/specificity at the common Youden-index based threshold (1.65) were 0.23 (p=0.21), 0.79, 0.73/0.57 for R1; 0.47 (p=0.008), 0.79, 0.58/0.86 for R2; and 0.43 (p=0.015), 0.79, 0.58/0.86 for R3. Inter-reader LoA, wCV, RDC%, and ICC were -0.68 to 0.68, 14.8%, 40.9% and 0.683. At the common HRI threshold, Light's Kappa for inter-reader classification agreement was 0.46 (p=0.04).

CONCLUSION

In children with known or suspected MASLD, HRI showed modest diagnostic performance and fair to moderate inter-reader reproducibility. Correlation with PDFF was variable across readers. HRI may not be suitable for quantification or longitudinal monitoring of hepatic steatosis in children, though it may have limited utility for initial diagnosis.

CLINICAL RELEVANCE/APPLICATION

US-based HRI is not reliable for quantifying hepatic steatosis in children at risk for MASLD and may have limited value for diagnosis without further standardization.

W5A-SPPD-2 ROLE OF SCLEROTHERAPY IN PEDIATRIC INTRA-ORBITAL VENO-LYMPHATIC MALFORMATIONS

Ravi Sangani (*Presenter*)
Sean Schoeman, MBChB (*Abstract Co-Author*)
Biniyam Beyene Tabor (*Abstract Co-Author*)
Abhay S. Srinivasan, MD (*Abstract Co-Author*)
Seth Vatsky, DO (*Abstract Co-Author*)
Anne Marie Cahill, MBBCh (*Abstract Co-Author*)

PURPOSE

To evaluate the effectiveness of sclerotherapy in reducing size and symptoms of orbital veno-lymphatic malformations (OVMs) in pediatric patients.

METHODS AND MATERIALS

All patients who underwent sclerotherapy for OVMs were reviewed. Imaging (MRI/ultrasound) and medical data were abstracted for indications, procedure details, and treatment outcomes. Periorbital lesions with no orbital extension were excluded.

RESULTS

In 55 patients with OVMs, sclerotherapy was performed in 17 [9 F, median age 10.7 years (IQR 3.6-13.5), median weight 34.85 kg (IQR 21-51.6 kg, 10 right-side). Presenting symptoms: swelling (71%), redness (41%), pain (35%), and blurred vision (35%). Clinical findings: swelling (76%), proptosis (58%), redness (41%), decreased visual acuity (24%), and increased ocular pressure (6%). Proptosis was identified in 8 patients, but imaging evidence supported proptosis in 10 patients - median globe displacement 4.2 mm (IQR 3.8-7.3). 12 lesions were orbital-only and 5 were peri-orbital with orbital extension. Imaging features: 82% lymphatic only, 14% venous only, 6% veno-lymphatic; 53% intraconal, 35% intra- and extraconal, and 12% extraconal. 24 cycles of sclerotherapy were performed: monotherapy (n=12), two cycles (n=3), and three cycles (n=2). Prior to sclerotherapy, 13 lesions had no management, two had surgery, and two had medical therapy (sirolimus). All procedures were performed under anesthesia with fluoroscopic, ultrasound, and/or MRI guidance. Median fluoroscopic time was 1.6 min (IQR 0.8-1.8) and skin dose was 10.4 mGy (IQR 3-31). Sclerosants included bleomycin, doxycycline, and sodium tetradecyl sulfate (STS). One agent was used in 21 procedures: bleomycin (52%) and doxycycline (48%). In three procedures, dual administration of doxycycline and bleomycin (n=1), or STS and bleomycin (n=2), was used. One case utilized next-day doxycycline instillation via drainage catheter. No procedure-related complications occurred. Two lesions had interval size increase after first sclerotherapy; one had surgical debulking and repeat sclerotherapy: stable at 5 years. The other had repeat sclerotherapy at 2 years and is stable on follow-up. At last clinical follow-up [median 17.5 months (IQR 3.3-103.3)], all affected eyes had improved visual acuity and proptosis resolved in 5/8.

CONCLUSION

In this limited experience, percutaneous sclerotherapy for OVMs is safe and has a high clinical response rate. Further research is needed to describe a multi-disciplinary (IR, oncology, and ophthalmology) treatment algorithm.

CLINICAL RELEVANCE/APPLICATION

Peri-orbital OVMs with intra-orbital extent respond to targeted percutaneous sclerotherapy and further research is required to describe multi-disciplinary treatment algorithms.

W5A-SPPD-3 OUTPERFORMING STATE-OF-THE-ART IN PEDIATRIC BRAIN TUMOR SEGMENTATION WITH A DUAL NNU-NET MODEL BASED ON RADIOLOGICAL REASONING

Elif Keles, MD, PhD (*Presenter*)
Max Bengtsson (*Abstract Co-Author*)
Gorkem Durak, MD (*Abstract Co-Author*)
Syed M. Anwar, PhD (*Abstract Co-Author*)
Yuri Velichko, PhD (*Abstract Co-Author*)
Marius G. Linguraru, DPhil, MSc (*Abstract Co-Author*)
Angela Waanders (*Abstract Co-Author*)
Ulas Bagci, MSc, PhD (*Abstract Co-Author*)

PURPOSE

Pediatric brain tumors (PBTs) are the most common solid malignancies and the leading cause of cancer-related death in children, with Pediatric Low-Grade Gliomas (PLGGs) accounting for 30-40% of cases. While MRI is essential for diagnosis and monitoring, automated segmentation remains difficult due to tumor heterogeneity, across development, and data limitations. We investigated the feasibility and clinical utility of a novel deep learning model for four-subregion segmentation of pediatric brain tumors on multiparametric MRI.

METHODS AND MATERIALS

This IRB-approved retrospective study applied a dual-architecture model integrating two parallel nnU-Net frameworks trained on complementary tumor subregions. Their outputs were combined via post-processing to improve segmentation. The model was trained on 235 cases from the PED BraTS 2024 dataset (n=261; 26 held out), including T1W, T1 contrast-enhanced, T2W, and T2-FLAIR sequences. Evaluation followed PED BraTS 2024 metrics: lesion-wise Dice and Hausdorff 95 distance (HD95). The model segments four labels: enhancing tumor (ET), non-enhancing tumor (NET), cystic component (CC), and edema (ED). To match the PED BraTS 2023 state-of-the-art (SOTA), NET and CC were merged into a non-enhancing component (NC). External validation was performed on 30 expert-annotated pediatric cases from the Children's Brain Tumor Network (CBTN), and generalizability was assessed on the BraTS 2023 adult glioma dataset.

RESULTS

Our dual nnU-Net model achieved a mean Dice score of 0.642 and HD95 of 73.0 mm on the CBTN external validation dataset, outperforming the current state-of-the-art model (Dice 0.626, HD95 84.0 mm). On the BraTS 2023 adult dataset, the model demonstrated remarkable generalizability with a Dice score of 0.877 for whole tumor segmentation, indicating robust performance across age groups despite being trained exclusively on pediatric cases.

CONCLUSION

Our study demonstrates not only the feasibility but also the clinical advantage of four-label segmentation in PBTs. The radiologically-informed dual-architecture approach captures subregional characteristics across enhancing, non-enhancing, cystic, and edematous components for comprehensive treatment response assessment, progression pattern identification, and prognostic evaluation in pediatric neuro-oncology.

CLINICAL RELEVANCE/APPLICATION

Automated multi-component segmentation of PBTs enhances accuracy, reproducibility, and efficiency in tumor burden quantification. This approach supports more personalized treatment strategies and informed clinical decision-making while reducing the subjective variability inherent in manual segmentation, potentially improving outcomes in this vulnerable patient population.

W5A-SPPH-1 DEVELOPMENT OF A UNIVERSAL TASK-SPECIFIC IMAGE QUALITY ASSESSMENT FRAMEWORK FOR SPECTRAL PHOTON COUNTING CT - A PHANTOM STUDY

Aamir Y. Raja, PhD (*Presenter*)
Briya Tariq (*Abstract Co-Author*)

PURPOSE

Spectral photon-counting CT (SPCCT) provides reduced electronic noise, superior image quality, higher spatial resolution, and improved material identification and quantification. Consequently, more clinics and research institutions are adopting SPCCT. However, there is a lack of a standardized approach for evaluating multi-energy images using image quality metrics for task-specific applications. Our aim is to develop and assess a universal task-specific framework for image quality assessment in SPCCT prior to the material identification and quantification task.

METHODS AND MATERIALS

Two task-specific imaging protocols were established using an investigational SPCCT scanner (Mars Microlab 5 x 120) to target two clinically relevant applications: bone imaging (120 kVp, 80μA with thresholds at 40, 50, 60, and 79 keV) and crystal arthropathies imaging (120 kVp, 60μA with thresholds at 12, 15, 18, and 21 keV). A QRM D100 spectral CT quality control phantom was scanned with a homogeneous section to evaluate CT number accuracy and image uniformity subjectively, while signal-to-noise ratio (SNR) and global 3D noise power spectrum (NPS) were evaluated objectively. A second wire phantom, incorporating various 50 μm diameter copper wires, was also scanned to characterize resolution in terms of point spread function (PSF) and modulation transfer function (MTF). Measurements were evaluated as a function of varying angular projection (373, 981, and 1440) and voxel sizes (70, 80, 90, and 100 μm). A quantified image quality scoring metric that consolidates 3D NPS (both amplitude and FWHM), resolution (MTF and PSF), and SNR to objectively quantify image quality tailored to specific diagnostic tasks prior to material identification and quantification.

RESULTS

The preliminary results show that SNR was reduced by 25% with reducing voxel sizes from 100 to 70 μm and increased by about 38% with a higher number of projections (373 to 1440). A significant increase in the FWHM of the 3D NPS was observed (~55% at 70 μm voxel size), along with a 27% rise in amplitude at 1440 projections. Furthermore, the MTF improved by more than 23% as the voxel size decreased from 100 to 70μm. The quantified scoring metric for the crystal arthropathies task reached its peak value of 7.33 with 981 projections and an 80 μm voxel size.

CONCLUSION

The proposed framework demonstrate potential as a quantified, task-specific assessment tool for evaluating SPCCT image quality, facilitating optimal tissue characterization prior to material identification and quantification.

CLINICAL RELEVANCE/APPLICATION

The proposed image quality framework can be optimized for clinical applications, enabling task-specific SPCCT adjustments to enhance tissue differentiation and improved diagnostic accuracy.

W5A-SPPH-2 FEASIBILITY OF A 3D UNET TRANSFORMER NEURAL NETWORK IN QUANTITATIVE ASSESSMENT OF CLEFT PALATE VOLUME CHANGE AFTER ALVEOLAR BONE GRAFTING IN PEDIATRIC PATIENTS

Jing Qi, MD (*Presenter*)
Yonggang Lu, PHD (*Abstract Co-Author*)
Riley McCarty (*Abstract Co-Author*)
Kaleb Keener (*Abstract Co-Author*)
Cleo Yi (*Abstract Co-Author*)
Sameer Shakir (*Abstract Co-Author*)
Kant Lin (*Abstract Co-Author*)
Yu Liu, PhD (*Abstract Co-Author*)

PURPOSE

It is clinically imperative to have an objective and reproducible tool in assessing cleft volume change following alveolar bone grafting in cleft palate patients. The purpose of this study is to apply an AI-driven segmentation approach to quantify cleft volume change on CT images after bone grafting repair.

METHODS AND MATERIALS

In this study, 10 pediatric patients (mean age 9.4 ± 2.0 years old, 6 males, 4 females) with unilateral cleft palate undergoing maxillofacial CT exams before and after secondary alveolar bone grafting were evaluated. An automated assessment pipeline on the acquired CT images was developed based on a 3D UNET Transformer neural network. For each patient, pre- and post-operative maxillae were segmented from the neural network, followed by affine image registration, image subtraction and image cropping process from cement enamel junction of the central incisor to the apex of the central incisor. The volume changes measured by the automated method were compared with those obtained from the manual delineations. A paired Student's t-test was used to analyze the test dataset.

RESULTS

The 3D UNET Transformer neural network achieved maxillary segmentation with Dice similarity coefficients of 0.84 ± 0.09 and Haursdorff distances of 1.22 ± 0.37 (mm) with the patient data. A significant cleft reduction was observed with a volume change of 416.20 ± 264.25 mm^3 (using the automated method) vs 388.35 ± 222.40 mm^3 (using the manual method). The mean absolute and relative volume differences between the two methods were -27.85± 100.73 mm^3 and 1.24± 21.24 %, respectively. The paired Student's t-test with p=0.41 indicates no significant discrepancy between these two methods.

CONCLUSION

The preliminary results demonstrate feasibility of the proposed AI-based framework in quantifying cleft defect volume change on CT images in pediatric patients. This automated approach is a potential tool for objective outcome assessment in cleft palate patients with alveolar bone grafting.

CLINICAL RELEVANCE/APPLICATION

To provide practical, objective, and highly reproducible measurements of cleft volume change in alveolar grafting patients, this AI-based framework along with advanced image processing may have the potential to support surgeons and orthodontists in surgical planning and longitudinal monitoring in patients before and after alveolar bone grafting surgery in pediatric patients.

W5A-SPPH-3 RESEARCH ON THE APPLICATION OF THE CLEAR INFINITY ARTIFICIAL INTELLIGENCE ALGORITHM IN ABDOMINAL AORTIC CT ANGIOGRAPHY SCANNING UNDER THE NEUSOFT PRIME CT PLATFORM

Yang Chenxiao (*Presenter*)
Chensi Xu (*Abstract Co-Author*)

PURPOSE

To evaluate the image optimization capacity of Clear Infinity (CI) artificial intelligence algorithm in abdominal aortic CT angiography (CTA) on Neusoft Prime CT platform.

METHODS AND MATERIALS

Thirty patients undergoing aortic CTA were prospectively scanned at 120kVp with fixed tube current (CTDIvol=18mGy). Venous-phase datasets were reconstructed using: 1) Clear View (CV) at 40% weighting (control); 2) CI algorithm with 20%/40%/60%/80% weightings. Quantitative analysis included CT values, noise (SD), signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) measured via standardized 5mm ROIs in aortic lumen and paraspinal muscles. Two blinded radiologists independently scored image quality using 5-point Likert scales (noise, contrast resolution, anatomical delineation, artifact suppression), with mean scores =3 defining diagnostic adequacy. Statistical analysis employed one-way ANOVA with Tukey's post-hoc test.

RESULTS

Noise Reduction: CI80% achieved 57.7% lower SD than control (7.05±0.92 vs 16.65±0.78, $p<0.001$), showing dose-dependent improvements: CI20% 16.85±0.35 ($p=0.812$), CI40% 13.55±0.35 ($p=0.004$), CI60% 10.05±0.78 ($p<0.001$). Signal Enhancement:SNR increased 137.3% from 17.91±1.95 (CV40%) to 42.5±8.28 (CI80%, $p<0.001$).CNR improved 139.3% from 15.82±3.78 to 37.86±7.32 ($p<0.001$).Weighting Gradient Effects:CI60% vs CI40%: SNR +35.1% (29.69±4.19 vs 21.96±1.97, $p=0.005$); CNR +38.8% (28.77±7.51 vs 20.73±5.22, $p=0.007$);CI80% vs CI60%: SNR +43.1% ($p<0.001$); CNR +31.6% ($p=0.002$).Subjective Evaluation: All CI groups met diagnostic criteria (=3), with CI80% scoring highest (4.55±0.34 vs 3.8±0.41 control, $p<0.001$). Inter-reader reliability was excellent (ICC=0.91, 95%CI 0.85-0.95).

CONCLUSION

Clear Infinity AI significantly enhances aortic CTA quality, achieving 57.7% noise reduction and over 130% SNR/CNR improvement at 60-80% weighting ($p<0.001$), outperforming conventional iterative reconstruction.

CLINICAL RELEVANCE/APPLICATION

This technology enables high-precision aortic evaluation with preserved diagnostic confidence, particularly valuable for serial aneurysm surveillance requiring dose optimization.

W5A-SPPH-4 DUAL-ENERGY MULTI-MATERIAL DECOMPOSITION USING PHOTON-COUNTING CT: RESIDUAL ERROR MEASUREMENT

Hamidreza Khodajou-Chokami, PhD (*Presenter*)
Huanjun Ding (*Abstract Co-Author*)
Alireza Shojazadeh, MD (*Abstract Co-Author*)
Sabee Y. Molloi, PhD (*Abstract Co-Author*)

PURPOSE

To present a GPU-accelerated dual-energy multi-material decomposition (MMD) algorithm for photon-counting CT (DECT), designed to reduce false-positive iodine signals in non-contrast regions, improve quantification accuracy, and enable real-time clinical deployment.

METHODS AND MATERIALS

A clinical photon-counting CT scanner was used to scan two physical phantoms: a cylindrical water-equivalent phantom and a humanoid phantom with three sizes (small, medium, and large), each containing iodine (2-20 mg/mL) and hydroxyapatite (50-600 mg/mL) inserts. Radiation dose was in the range of 3-10 mGy. For qualitative evaluation, six patients who underwent pulmonary CT angiography (average CTDIvol 9.93 mGy) were retrospectively analyzed. One of the patients had pulmonary emphysema. Our MMD algorithm combines barycentric coordinates with Principal Component Analysis (PCA). To enhance numerical stability, we replaced the traditional inversion of the linear attenuation coefficient (LAC) matrix with direct area-ratio computations in LAC space. An automated centroid-based criterion independently selects optimal material triplets, and PCA standardizes triangle distribution to improve numerical robustness. The cost function includes: (1) an anisotropic noise model addressing variance and cross-energy correlation, (2) a sparsity constraint to reduce false-positive iodine, and (3) spatial regularization to suppress structured residual artifacts. The decomposition was parallelized using a custom CUDA GPU kernel with 256-thread blocks.

RESULTS

In phantom data, the proposed method reduced mean relative iodine error from 16.39% to 1.86% (max error: 2.67%), confirming quantitative accuracy improvements over the baseline barycentric MMD. Beam-hardening artifacts and noise-induced residuals were minimized. In patient data, qualitative analysis showed elimination of false-positive iodine in non-contrast regions and clear visualization of reduced perfusion in the emphysematous lung. GPU processing of 106 million voxels completed in 3.97 seconds—a 5440× speedup compared to CPU.

CONCLUSION

The proposed GPU-accelerated MMD algorithm enhances iodine accuracy, decreases spurious signals in non-contrast regions, and provides fast, robust dual energy MMD potentially suitable for clinical environments.

CLINICAL RELEVANCE/APPLICATION

The algorithm substantially improves diagnostic accuracy by removing false-positive iodine signals, supporting dual energy MMD for potential clinical applications.

W5A-SPPH-5 PIXELPRINT^{PET} - THREE-DIMENSIONAL PRINTED PHANTOMFOR PET/CT IMAGING WITH ANATOMICAL STRUCTURE

Yinglin Ge, MS (*Presenter*)
Elizabeth Li (*Abstract Co-Author*)
Michael Geagan (*Abstract Co-Author*)
Michael Parma (*Abstract Co-Author*)
Min Gao (*Abstract Co-Author*)
Kai Mei, PhD (*Abstract Co-Author*)
Austin Pantel, MD (*Abstract Co-Author*)

Pouyan Pasyar (*Abstract Co-Author*)
Jessica Im, BEng (*Abstract Co-Author*)
Joel Karp, PhD (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

Advancing developments in PET/CT toward clinical implementation can be expedited through realistic system characterization, particularly using anatomically realistic phantoms. Accordingly, the development of phantoms that accurately simulate both radiotracer distribution and X-ray attenuation is critical for the comprehensive evaluation and optimization of PET/CT technologies. We present PixelPrint PET , 3D-printed phantoms for PET/CT imaging that accurately reproduce radioactivity maps with high anatomical fidelity.

METHODS AND MATERIALS

PixelPrint was used to create phantoms with varying infill ratios by adjusting the printed line widths while maintaining a fixed 2.5 mm line distance. Polylactic acid (PLA) was selected as the filament. Calibration phantoms were fabricated to cover a range of infill ratios from 5% to 90%. The phantoms were immersed in 18 F-fluorodeoxyglucose (18 F-FDG) solution and scanned using a PET/CT system equipped with a dual-layer CT scanner (IQon spectral CT, Philips Healthcare) and the PennPET Explorer. Linear regression between infill ratios and normalized SUV values was calculated. The brain phantom was created using the BigBrain-MR dataset, with segmented regions assigned activity concentration ratios scaled from 1 (white matter) to 4 (subthalamic and red nuclei) to simulate realistic PET contrast. A 67 × 67 × 39 mm 3D block, including white matter, subthalamic/red nuclei, and cortical gray matter, was selected. Calibration results were applied to convert these ratios into infill values, and G-code was generated to manufacture the phantom. The brain phantom was submerged in 0.12 mCi 18 F-FDG solution and scanned using the PET/CT system. PET images were reconstructed and reviewed by a radiologist.

RESULTS

The overall fit line between the infill ratio and normalized SUV showed a high coefficient of determination ($R^2 = 0.99$), indicating excellent correlation. The maximum contrast ratio achieved was approximately 10:1. PET images of the printed brain phantom visually resembled the original simulated brain image. A board-certified radiologist reviewed and confirmed the anatomical accuracy and image quality of the phantom.

CONCLUSION

This study demonstrates the feasibility of creating 3D-printed PET/CT phantoms with realistic anatomical structures and contrast ratios that reflect radiotracer uptake in PET images. PixelPrint PET shows strong potential for producing phantoms that flexibly support multimodal imaging while preserving precise organ geometry.

CLINICAL RELEVANCE/APPLICATION

The development of anatomically realistic 3D-printed PET/CT phantoms, such as PixelPrint PET , enhances the accurate evaluation and optimization of imaging technologies, facilitating clinical implementation.

W5A-SPPH-6 DUAL-ENERGY CT FOR MONITORING RADIATION-INDUCED METABOLIC DYSFUNCTION: HISTOPATHOLOGICAL VALIDATION IN A RABBIT MODEL

Chen Cheng (*Presenter*)

PURPOSE

To validate the feasibility of employing dual-energy CT (DECT) for radiation-induced bone metabolic dysfunction monitoring by comparing with the histopathological results.

METHODS AND MATERIALS

15 New Zealand White rabbits, comprising 12 irradiated animals (30 Gy single fraction) in the pelvis and 3 non-irradiated controls were used to establish a model of radiotherapy bone metabolic dysfunction. These twelve rabbits were randomly assigned to four experimental cohorts (n=3 per group) based on predetermined follow-up intervals: 7, 14, 21 and 28 days post-irradiation. DECT was performed before and at 7d, 14d, 21d, and 28d after irradiation. DECT-derived calcium, hydroxyapatite (HAP), and fat content after irradiation were measured at the cancellous bone of L7 vertebra and bilateral femoral necks (FN), subsequently normalized by corresponding parameters before irradiation. Corresponding pathological calcium content and fat fraction were quantified using Flame Atomic Absorption Spectroscopy (FAAS) and Hematoxylin and Eosin (HE) staining histological samples.

RESULTS

Quantitative DECT analysis revealed a progressive decline in calcium (31.1%-32.6%, all $p<0.001$) and HAP (30.9%-31.5%, all $p<0.001$) content of the L7 and bilateral FN during the 1-4 weeks post-irradiation ($R^2=0.9989$ vs. Histopathology). Concurrently, DECT-derived fat content initially peaked at week 1 (the right FN: +35.92%,the left FN:+42.08%, L7:+24.83%), sharply decreased by week 2, and stabilized thereafter (the right FN: -2.07%, the left FN:-1.49%, L7:-0.78%). Histopathological analysis of the right FN revealed a transient increase in adipocyte vacuolation area at week 1 post-irradiation, which subsequently declined in later weeks but persistently exceeded levels in non-irradiated controls throughout the observation period ($p<0.001$) .

CONCLUSION

DECT quantitative analysis demonstrated a significant reduction in calcium and HAP content, accompanied by a generalized increase in fat deposition after irradiation. These changes exhibited strong concordance with corresponding histopathological evaluations.

CLINICAL RELEVANCE/APPLICATION

DECT offers a novel, non-invasive method for detecting early radiation-induced bone metabolic dysfunction, providing simultaneous insights into calcium loss, hydroxyapatite depletion, and marrow adiposity.

W5A-SPPH-7 IQ-PAT: A NEW METHOD FOR NOISE POWER SPECTRUM AND TASK-BASED TRANSFER FUNCTION ASSESSMENT IN PATIENT CT IMAGES

Hugo Lacombe (*Presenter*)
Paul Menard (*Abstract Co-Author*)
Olivier Nempont (*Abstract Co-Author*)
Maria Nicole Antonuccio (*Abstract Co-Author*)
Marjorie Villien (*Abstract Co-Author*)
Philippe C. Douek, MD, PhD (*Abstract Co-Author*)
Joel Greffier, PhD (*Abstract Co-Author*)

PURPOSE

To develop a novel method (IQ-PAT) for Noise Power Spectrum (NPS) and Task-based transfer function (TTF) evaluation on patient images and validate this method on an image quality phantom.

METHODS AND MATERIALS

An in-house method (IQ-PAT) was developed to automatically compute NPS and TTF on patients' thoracic aorta. First, automatic segmentation of the thoracic aorta was performed. Secondly, an 18×18-pixel ROI was automatically placed on each of 100 consecutive slices. 2D NPS was computed for each ROI and radially averaged to obtain the 1D NPS. For TTF assessment, the barycenter of the aorta was calculated and used to extract and align radial profiles for Edge Spread Function (ESF)

computation. Profiles affected by anatomical variability or pathology were automatically excluded. TTF was then derived by differentiating the ESF and applying the Fourier Transform. To validate this method, acquisitions were performed on the 26-cm diameter section of a Mercury v4.0 phantom using a clinical Dual Layer CT scanner at 120kVp with a total aortic gated protocol (Indice Dose Right 19). Images were reconstructed using a 512x512 matrix, 400mm FOV, and 1 mm slice thickness. iDose 4 level 4 (i4), a hybrid iterative reconstruction algorithm, was used in combination with kernels A, B and C. IQ-PAT was benchmarked against iQMetrix-CT software using the iodine insert in the phantom matching dimensions and contrast of real aortas, and further tested on 7 patient datasets (60[46;67] years old).

RESULTS

Phantom data showed that NPS and TTF values derived from IQ-PAT closely matched those from iQMetrix-CT for the used kernels. Noise magnitude increased with sharper kernels (A to C) for both tools (from 16.7 to 21.1 for IQ-PAT and from 20.9 to 28.4 HU for iQ-Metrix). Average NPS spatial frequency values were similar (0.22 to 0.27 mm -1 for IQ-PAT vs 0.20 to 0.25 mm -1 for iQMetrix-CT). TTF at 50% (f 50) increased with sharper kernels (A to C) for both tools (0.30 vs 0.35 mm -1 for IQ-PAT, and 0.29 vs 0.35 mm -1 with iQMetrix-CT). Relative differences in f 50 between IQ-PAT and iQMetrix-CT averaged 2.5 ± 0.1 %. Results are shown in Figure 1. Patient imaging results with IQ-PAT followed the same trends in terms of noise (from 21.82 ± 10.49 to 28.59 ± 13.12 HU), frequency average (from 0.21 ± 0.01 to 0.27 ± 0.01 mm -1) and f 50 (from 0.20 ± 0.03 to 0.23 ± 0.04 mm -1) from kernel A to C.

CONCLUSION

IQ-PAT provides reliable and consistent assessments of NPS and TTF on phantom images, with results comparable to iQMetrix-CT ones. Early application to patient data demonstrates the method’s feasibility in clinical conditions.

CLINICAL RELEVANCE/APPLICATION

Assessing noise characteristics directly from patient images will allow the optimization of CT protocols and improve image quality evaluation in clinical practice.

W5A-SPPH-8 ANATOMICAL NOISE POWER EXPONENT AS AN IMAGE-BASED BIOMARKER OF BREAST CANCER RISK: IMPROVING AI MODEL PERFORMANCE - A PILOT STUDY

Yile Fang, PhD (*Presenter*)
Nathaniel D. Mercaldo (*Abstract Co-Author*)
Andrew R. Carney, MS (*Abstract Co-Author*)
Leslie Lamb, MD, MSc (*Abstract Co-Author*)
Kai Yang, PhD (*Abstract Co-Author*)

PURPOSE

Breast parenchymal texture has been linked to cancer risk but has not been explicitly leveraged in deep learning (DL) based risk models. This study assesses the association of the anatomical noise power exponent (ß) as an image-based biomarker of breast cancer occurrence and its potential to improve the predictive performance of MIRAI, a state-of-the-art DL-based breast cancer risk assessment model.

METHODS AND MATERIALS

The study cohort included two groups of women who underwent bilateral mammographic screening between 2017 and 2022 (target and control, n=20 each), tightly matched by age, race, and breast density. The target group had breast cancer diagnosed within one year of the screening mammographic exam. A 2D screening mammography-based DL model (MIRAI) was used to assess the 1-year risk of breast cancer. 229 mammographic images were analyzed for ß using a custom algorithm that automatically extracted breast tissue regions for anatomical noise power spectrum analysis. The power-law exponent, ß, derived as the slope of the linear relationship between log-power and log-frequency, was used as a quantitative measure of breast parenchyma texture. Mixed-effects logistic regression quantified the association between ß and breast cancer occurrence, adjusting for laterality and patient clustering. The predictive performance using the standardized MIRAI 1-year risk scores, and the combined standardized MIRAI risk and patient-specific ß scores were quantified using separate logistic regression models and summarized using the corresponding receiver operator curve (ROC) and area under the curve (AUC). Five-fold cross-validation was performed to estimate internally validated AUC values and 95% confidence intervals (CIs).

RESULTS

ß was positively associated with cancer occurrence. For each 0.1-unit increase in ß corresponded to a 4% increase in cancer odds (OR=1.04, 95% CI:1.00-1.07, p=0.042). ß negatively correlated with heterogeneously dense breasts (OR= 0.754, 95% CI: 0.692- 0.822, p= 3.965E-19). The correlation with race was weak and non-significant (OR= 1.002, 95% CI: 0.995 - 1.009, p= 0.844). MIRAI alone achieved an AUC of 0.79 (95% CI:0.62-0.96) for 1-year risk prediction, which was improved to 0.82 (95% CI:0.69-0.96) when combined with ß.

CONCLUSION

ß captures breast texture differences that is associated with cancer and this information may not be currently acknowledged in the MIRAI model. Further validation in larger studies is warranted.

CLINICAL RELEVANCE/APPLICATION

Incorporating image-based biomarker, ß, into state-of-the-art DL breast cancer risk models such as MIRAI may improve the accuracy of cancer risk prediction and personalized risk stratification.

W5A-SPPH-10 ENHANCING IMAGE QUALITY IN DIGITAL BREAST TOMOSYNTHESIS USING A GENERATIVE ADVERSARIAL NETWORK WITH A SELF-ATTENTION MECHANISM

Tsutomu Gomi, PhD (*Presenter*)
Kotomi Ishihara (*Abstract Co-Author*)
Yukio Koibuchi (*Abstract Co-Author*)

PURPOSE

This study aims to enhance the in-focus plane contrast of digital breast tomosynthesis (DBT). We propose and evaluate an approach that integrates a multihead self-attention (MSA) mechanism with a cycle-consistent generative adversarial network (cycle-GAN).

METHODS AND MATERIALS

The study was approved by our institutional ethics committee (TGMC2023-009). In a prereconstruction filtered back projection (FBP), MSA was incorporated into the up-sampling process of a deep residual U-Net (ResUNet) generator, while PatchGAN functioned as the discriminator. The dataset comprised a reference set of 42 mammography (MMG) cases (average age: 59.8 ± 7.6), with a total of 45 sample images; and an object set of 32 DBT projection cases (average age: 58.7 ± 13.5), with a total of 45 sample images. We utilized an unsupervised model in which the MMG images served as the reference and the DBT projections as the target (Selenia Dimensions system). For comparison, an existing method that incorporates attention gates (AGs) into the cycle-GAN, the conventional projection-based GAN (p-GAN) method (Sahu et.al., IEEE ISBI), and a only FBP method were selected. Image quality was evaluated using the peak signal-to-noise ratio (PSNR), the structural similarity index measure (SSIM), and Pearson’s correlation (alpha: 0.05, sample: 778,540). These were compared between the MMG images and the DBT-reconstructed images (in-focus plane). The distribution of attention weight was analyzed using gradient-weighted class activation mapping (grad-CAM).

RESULTS

The proposed method achieved the highest PSNR, particularly in cases with dense breast tissue. The SSIM values were comparable between the existing and conventional methods (PSNR: MSA 17.19 ± 1.09, AG 16.14 ± 1.88, p-GAN 16.45 ± 2.08, FBP 16.01 ± 2.32; SSIM: MSA 0.78 ± 0.04, AG 0.76 ± 0.07, p-GAN 0.78 ± 0.05, FBP 0.79 ± 0.05). Pearson’s correlation found the strongest association between the mammography and DBT images of the proposed approach (correlation: MSA 0.33 ± 0.03 [$p < 0.05$], AG 0.27 ± 0.03 [$p < 0.05$], p-GAN 0.32 ± 0.06 [$p < 0.05$], FBP 0.30 ± 0.06 [$p < 0.05$]; 95% confidence interval: MSA [0.328 ± 0.058, 0.332

± 0.067], AG [0.278 ± 0.03, 0.282 ± 0.034], p-GAN [0.323 ± 0.053, 0.327 ± 0.061], FBP [0.307 ± 0.054, 0.311 ± 0.062]). Grad-CAM analysis confirmed that both the proposed and existing AG methods exhibited high attention weight distribution in the mass region. The p-GAN showed a tendency toward dispersed distributions.

CONCLUSION

The proposed method effectively improved the in-focus plane contrast of DBT images, demonstrating particular efficacy in cases with dense breast tissue.

CLINICAL RELEVANCE/APPLICATION

A cycle-GAN prereconstruction manipulation with MSA can significantly enhance image quality while preserving contrast.

W5A-SPPH-11 PROTOTYPE DEEP SILICON PHOTON-COUNTING DETECTOR CT PRELIMINARY COMPARISON OF VIRTUAL UNENHANCED AND TRUE UNENHANCED IMAGES

Aria Salyapongse, MSc (*Presenter*)
Giuseppe V. Toia, MD, MS (*Abstract Co-Author*)
Zhye Yin (*Abstract Co-Author*)
Ming Yan, PhD (*Abstract Co-Author*)
Krista McClure (*Abstract Co-Author*)
Meghan Yue, BS (*Abstract Co-Author*)
Scott Slavic, MS (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*)

PURPOSE

To compare the difference in CT number between virtual unenhanced (VUE) and true unenhanced (TUE) human subject images on a prototype deep silicon (dSi) photon-counting detector (PCD) CT system.

METHODS AND MATERIALS

Five subjects comprising various anatomies (1 chest, 1 head, 1 wrist/hand, and 3 abdomen) and phases (non-contrast, portal venous, early arterial, and late arterial) were scanned on the prototype dSi PCD CT. kV and mA were adjusted for anatomy and subject size. Five slices were selected from each image set at two locations to provide a variety of anatomy, including vessels (e.g., aorta, portal bifurcation, inferior vena cava, small arteries), soft tissue (e.g., spleen, psoas muscle, posterior liver, lateral liver) and subcutaneous adipose. Circular regions of interest were drawn over the anatomy on the VUE images and transferred to the TUE image sets. VUE error was defined as the CT number from the VUE in Hounsfield units (HU) minus the TUE CT number.

RESULTS

For all tested structures, 82% had a VUE error less than 10 HU, and 62% had a VUE error less than 5 HU. Small arteries and adipose tissue were the structures most prone to having a VUE error greater than 5 or 10 HU. Vessels demonstrated VUE errors less than 10 HU and less than 5 HU for 70.4% and 40.7% of tested structures, respectively. Soft tissue demonstrated VUE errors less than 10 HU and 5 HU in 96.9% and 84.4%, and adipose tissue demonstrated VUE errors less than 10 HU and 5 HU in 75% and 58.4% of tested structures.

CONCLUSION

The majority of tested anatomic structures have VUE errors less than 10 HU with a large subset excluding small arteries having errors less than 5 HU.

CLINICAL RELEVANCE/APPLICATION

VUEs provide two main advantages in clinical scanning: the potential elimination of a separately acquired TUE phase or providing unenhanced data when not routinely acquired for a given protocol. Both use cases rely on high accuracy of VUEs compared to TUEs. These results preliminarily suggest that on the prototype dSi PCD CT system VUE and TUE CT numbers are similar.

W5A-SPRO-1 PROVISION OF ANATOMICAL CONTEXTUAL INFORMATION IMPROVES PERFORMANCE OF A CONVOLUTIONAL NEURAL NETWORK TASKED WITH BRAIN METASTASIS DETECTION

Ethan Truong (*Presenter*)
Jordan Houri (*Abstract Co-Author*)
Gretchen Hermann, BA, MA (*Abstract Co-Author*)
Vitali Moiseenko, PhD (*Abstract Co-Author*)
Jona Hattangadi-Gluth, MD (*Abstract Co-Author*)
Jeffrey Rudie, MD, PhD (*Abstract Co-Author*)
Aaron Simon, MD,PhD (*Abstract Co-Author*)

PURPOSE

Modern management of brain metastases requires close surveillance with serial magnetic resonance imaging (MRI), animating research into automated techniques for tumor detection. The convolutional neural network (CNN) has shown considerable promise as a method of detecting brain metastases, and multiple groups have proposed variations in CNN network architecture to improve detection performance. In this work, we looked beyond the impact of network architecture and assessed the effect on performance of providing anatomical contextual information to a CNN in the training period.

METHODS AND MATERIALS

The nn-Unet, a widely adopted CNN, was selected for this study. The nn-Unet was trained on an institutional dataset consisting of high-resolution, T1-weighted, contrast-enhanced MRIs and associated structure labels consisting of both target brain metastases and several organs at risk (OARs) that were labeled in the process of radiosurgery planning. In the training period, the model was presented either with labeled metastases alone (BM) or with the complete structure set of metastases and OARs (BM+OAR).

RESULTS

We found that by multiple standard performance metrics, the BM+OAR model outperformed the BM model. Median case-wise Dice Coefficient for BM was 0.75 (IQR 0.51-0.86) and for BM+OAR was 0.79 (IQR 0.58-0.86) ($p<0.001$). Median sensitivity for BM was 1.0 (IQR 0.71-1.0) and for BM+OAR was 1.0 (IQR 0.75-1.0) ($p=0.01$). Median positive predictive value for BM was 0.5 (IQR 0.25-0.74) and for BM+OAR was 0.77 (IQR 0.50-1.0) ($p<0.001$). Importantly, amongst lesions scored as "false-positives", 47/151 detected by BM+OAR could be retrospectively verified to be real tumors while only 22/231 detected by BM could be verified to be real ($p<0.001$).

CONCLUSION

These findings suggest that providing anatomical contextual information can improve accuracy of CNN-based automated brain metastasis detection algorithms.

CLINICAL RELEVANCE/APPLICATION

Automated detection and delineation of brain metastases are increasingly clinically important as more patients are treated with stereotactic radiosurgery rather than whole brain radiation and must be monitored closely for recurrence. Improving the performance of detection algorithms will increase their clinical utility and adoption. These findings open a new realm of research into optimization of automated detection approaches for brain metastases that goes beyond optimization of network architecture.

W5A-SPVA-3 FEASIBILITY OF DUAL-FLOW INJECTION TECHNIQUEAND LOW RADIATION IN PULMONARYCTA USING DEEP LEARNING RECONSTRUCTION: AN IMAGE QUALITY ASSESSMENT

Rui Ma (*Presenter*)
Xiaohong Gong (*Abstract Co-Author*)
Guan Wang (*Abstract Co-Author*)

PURPOSE

To assess the viability of using low radiation and contrast medium doses in pulmonary artery computed tomography angiography (CTA) was assessed by applying a low tube voltage, a dual-flow injection technique and a novel deep learning image reconstruction algorithm (ClearInfinity, DLIR-CI).

METHODS AND MATERIALS

Eighty patients who underwent CTA of the pulmonary artery were collected and divided into three groups, A, B and C. There were 30 patients in each of groups A and C, and 20 patients in group B. Group A was scanned using a conventional contrast injection protocol and 100 kV tube voltage scanning, Group B was scanned using a dual-flow injection protocol and 100 kV tube voltage scanning, Group C was scanned using a dual-flow injection protocol and 70 kV tube voltage scanning. The images of Groups A and B were reconstructed using Clearview at 50%. Group C were reconstructed using 50% Clearview, 30% DLIR-CI, 50% DLIR-CI, and 70% DLIR-CI sequentially. Defining them sequentially as groups C1, C2, C3, C4. Differences in image quality, and radiation dose were compared between groups.

RESULTS

All images are clinically diagnostic. There was no significant difference in subjective image quality scores between groups A, B, and C1. Subjective image quality scores were higher in the C3 and C4 groups than in the other groups, and there was no significant difference in scores between the two groups. SNR values of group B were not significantly different from those of group A and C1, and some pulmonary artery SNR values of group A were greater than those of C1. In group C, group C4 and group C3 had the highest pulmonary artery SNR values and there was no significant difference in SNR values between the two groups. The CNR values in the C1 group were not significantly different from those in groups A and B. The highest CNR values were found in the C4 group in group C. The background noise values were higher in the C1 group than in the A and B groups. The C4 group in Group C had the lowest background noise values. CTDIv01, DLP, and ED values were reduced by 77%, 74%, and 74%, respectively, in group C compared with group A , and the differences between groups A and B were not statistically significant .

CONCLUSION

CTA of the pulmonary arteries using the dual-flow injection technique combined with 70 kV low-dose scanning can reduce the iodine intake without compromising the image quality, reduce the radiation dose, and use a novel deep-learning reconstruction algorithm on the images in order to reconstruct them in 70%.

CLINICAL RELEVANCE/APPLICATION

The dual-flow injection technique combined with low-dose scanning and image reconstruction using a novel deep learning reconstruction algorithm can reduce the radiation dose and the amount of contrast agent used while maintaining image quality.

W5B-SPBR-3 REAL-WORLD PERFORMANCE OF AN FDA-APPROVED ARTIFICIAL INTELLIGENCE TOOL FOR SCREENING MAMMOGRAPHY

Emily Ambinder, MD, MS (*Presenter*)
Colin Paulbeck, PhD (*Abstract Co-Author*)
Babita Panigrahi, MD (*Abstract Co-Author*)
Shuchi Zinzuwadia, MD (*Abstract Co-Author*)
Lisa A. Mullen, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the real-world performance of an FDA-approved artificial intelligence (AI) tool for screening mammography following its integration into clinical practice, with a focus on breast density.

METHODS AND MATERIALS

Our institution began using an FDA approved AI tool for mammography in March 2024 (Transpara Version 1.7.4-A, ScreenPoint Medical). We included all screening mammograms performed between 8/1/2024 and 2/28/2025 in this study to account for an initial learning period. Patient information and clinical outcome metrics were merged with the AI overall risk score for the study (low, intermediate or elevated). Statistical analysis was performed using Chi-square and Fishers exact tests.

RESULTS

A total of 24520 screening mammograms were included (mean age of patients 61 +/- 13). Overall, 3139 patients were recalled (recall rate 12.8%) and 171 true positives cancers were diagnosed (CDR 7.0). The AI assigned a low score to 15041 studies (61.3%), intermediate score to 8554 studies (34.9%), and an elevated score to 925 studies (3.8%). The radiologist recalled higher percentages of cases in increasing AI categories with recall rates 9%, 18%, and 36% in the three categories respectively ($p<0.001$). Cancer detection rate (CDR, cancers per 1000) was also higher in increasing AI risk categories; 0.5 (n=8) in low risk (all DCIS or <1cm IDC), 8.4 in intermediate risk (n=72), and 98 in elevated risk (n=91). AI more often assigned a low risk score to patients with dense breast tissue (extremely dense or heterogeneously dense) compared to patients with non dense breast tissue (entirely fatty or scattered fibroglandular densities) (64% versus 58%, $p<0.001$). The corresponding CDRs in the low risk category were not significantly different with respect to breast density (0.7 versus 0.3, $p=.49$). On the contrary, radiologist recall rate was 14% for patients with dense breast tissue and 11% for patients without dense breast tissue ($p<0.001$). The CDRs were not significantly different for these two groups (7.0 versus 6.9, $p=0.89$).

CONCLUSION

The AI algorithm showed appropriate risk stratification corresponding to cancer detection rates of 0.5, 8.4, and 98 in the three risk categories. AI had improved performance in dense breast tissue with a higher percentage of exams in dense breasts assessed as low risk compared to exams in non dense breasts without significantly impacting cancer detection rate.

CLINICAL RELEVANCE/APPLICATION

With the growing utilization of AI systems in breast imaging, we show early positive results of clinical adoption into a busy screening mammography practice. AI demonstrated strong performance in stratifying cancer risk and supporting recall decisions. The findings support the integration of AI as a complementary tool to radiologists.

W5B-SPBR-5 GLANDULAR TISSUE COMPONENT ON BREAST US: ASSOCIATION WITH SURVIVAL OUTCOMES IN WOMEN WITH INVASIVE BREAST CANCER

Tingting Deng (*Presenter*)
Xi Lin (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of preoperative breast glandular tissue component (GTC) on disease-free survival (DFS) and overall survival (OS) in women with invasive breast cancer.

METHODS AND MATERIALS

This retrospective study included patients with invasive breast cancer who underwent preoperative breast ultrasound between January 2013 and December 2018. GTC was qualitatively assessed on ultrasound and categorized as low (minimal or mild) or high (moderate or marked). The correlations between GTC and various clinicopathological variables were examined. Associations of GTC with DFS and OS were evaluated using Cox regression analysis and expressed as hazard ratios (HRs).

RESULTS

A total of 2,891 patients (mean age, 49 ± 10 years) were included, with a median follow-up of 96 months. Multivariable analysis demonstrated that high GTC was associated with worse DFS in the overall cohort (HR 1.39, 95% CI: 1.16-1.68; $P < .001$). In the postmenopausal group, high GTC was a prognostic factor for worse OS and DFS (OS: HR, 1.70 [95% CI: 1.16, 2.49], $P = .006$; DFS: HR, 1.41 [95% CI: 1.04, 1.92], $P = .028$). In the non-dense breasts group, high GTC was associated with poorer OS (HR, 2.38 [95% CI: 1.24, 4.16]; $P = .008$) and DFS (HR, 2.21 [1.40, 3.50]; $P < .001$). In triple-negative breast cancer, high GTC was also associated with worse OS and DFS (OS: HR, 2.00 [95% CI: 1.20, 3.33], $P = .008$; DFS: HR, 1.59 [95% CI: 1.04, 2.43], $P = .034$).

CONCLUSION

Sonographic GTC is an independent prognostic biomarker in invasive breast cancer, particularly in postmenopausal, non-dense, and triple-negative subgroups. It should be considered for prognostic risk stratification in women with invasive breast cancer.

CLINICAL RELEVANCE/APPLICATION

The Glandular Tissue Component (GTC) is a key update in the upcoming new version of BI-RADS. The GTC of the fibroglandular tissue, as assessed by breast ultrasound, has been identified as an independent predictor of future breast cancer (BC) risk. However, the impact of preoperative GTC on long-term outcomes in women with invasive BC remains unclear. Our study aimed to investigate the impact of preoperative breast GTC on disease-free survival (DFS) and overall survival (OS) in patients with invasive BC. In our study, we found that sonographic GTC may be an independent prognostic factor for BC patients. Further validation is necessary to integrate GTC into clinical practice for risk stratification and personalized surveillance strategies to improve long-term outcomes.

W5B-SPBR-6 IMPACT OF ARTIFICIAL INTELLIGENCE ON BREAST CANCER SCREENING: EXPERIENCE FROM A MULTI-YEAR NATIONAL BREAST IMAGING PRACTICE

Sean D. Raj, MD, MBA (*Presenter*)
Xiaowei Hong (*Abstract Co-Author*)
Angela M. Fried, MD (*Abstract Co-Author*)
John Simon, MD (*Abstract Co-Author*)

PURPOSE

This study seeks to assess the real-world impact of integrating an FDA-approved AI solution into a high-volume, nationwide, breast cancer screening program by comparing metrics before and after AI implementation. The key performance metrics measured include cancer detection rates, recall rates, sensitivity, specificity, positive predictive value (PPV), as well as screening and cancer volumes.

METHODS AND MATERIALS

Mammography audit reports were generated retrospectively for radiologist reading at over 130 locations nationwide, covering a period of 24 months before and after the deployment and integration of an AI tool in 2020. The study included radiologists who had interpreted at least 960 screening exams during both the pre- and post-AI implementation periods, resulting in 18 common radiologist readers. Performance metrics were aggregated for each period, and statistical analyses were conducted to assess differences between the pre- and post-AI periods across radiologists.

RESULTS

AI integration led to significant improvements in mammography cancer detection and quality metrics. Notably, the cancer detection rate (CDR) per 1000 screening exams increased from 2.93 to 4.05 ($p < 0.001$ across readers), and the recall rate decreased from 10.69% to 8.07% ($p < 0.0005$). AI significantly improved the specificity ($p < 0.0005$), improving the aggregated specificity from 89.48% to 92.27% while had no significant impact on sensitivity (pre-AI: 92.30%, post-AI: 92.72%, $p=0.15$). The Positive Predictive Value (PPV) also saw an increase from 2.79% to 5.04% ($p < 0.0001$). Additionally, screening volumes increased from 204684 to 343343 for the common readers, indicating enhanced throughput without compromising diagnostic accuracy.

CONCLUSION

AI integration has significantly improved breast cancer detection rates and Radiologist productivity and performance while reducing false positives and unnecessary recalls. More research is needed to examine its long-term effects on patient outcomes and healthcare resources.

CLINICAL RELEVANCE/APPLICATION

Integration of an AI solution into a high volume breast cancer screening practice significantly improved cancer detection and specificity while reducing recalls, resulting in more efficient and effective patient care.

W5B-SPBR-7 IMPACT OF SONOGRAPHIC GLANDULAR TISSUE COMPONENT ON SUBSEQUENT SCREENING PERFORMANCE IN WOMEN WITH DENSE BREASTS: PROSPECTIVE STUDY

Jung-Oh Lee, MD, MSc (*Presenter*)
Na Hye Han, MD (*Abstract Co-Author*)
Su Min Ha, MD (*Abstract Co-Author*)
Myoung-Jin Jang (*Abstract Co-Author*)
Eun Kyung Park, MD, PhD (*Abstract Co-Author*)
Woo Kyung Moon, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of the glandular tissue component (GTC) on the performance of subsequent mammography and ultrasound (US) screening in women with dense breasts.

METHODS AND MATERIALS

From November 2022 to March 2024, asymptomatic women aged 40-69 years with dense breasts and negative findings on mammography and US were prospectively recruited (NCT05460975). Sonographic GTC was classified as minimal, mild, moderate and marked, and risk factors from the BCSC model were recorded. Participants underwent combined annual mammography and US screening, with BI-RADS categories documented. Outcomes were determined by pathology or a minimum 12-month follow-up. Screening performance metrics including cancer detection rate (CDR), abnormal interpretation rate (AIR), and positive predictive value (PPV) for biopsy were assessed. For analysis, GTC was dichotomized as low (minimal or mild) and high (moderate or marked). Clinical risk classification was performed using the BCSC risk prediction model of estimated 5-year breast cancer risk. The association between risk factors, including breast density and GTC, and breast cancer detection was evaluated using chi-square test, Fisher's exact test or t-test.

RESULTS

Among 1203 women (53.7 years± 7.0 [SD]), 18 cancers were diagnosed (7 ductal carcinoma in situ and 11 invasive carcinomas, including two stage II cancers), yielding a CDR of 14.9 per 1,000 women [18/1203]. Baseline GTC was classified as low in 61.5% (n=740) and high in 38.5% (n=463). Women with high GTC had a higher CDR than those with low GTC (23.8 [11/463] vs 9.5 [7/740] per 1000 women, P=0.04). Women with high GTC and extremely dense breast (n=330) had a significantly higher CDR than those with low GTC and heterogeneously dense breast (n=492) (30.3 [10/330] vs 8.1 [4/492], P=0.016). The two stage II cancers were found in women with high GTC. Women with low GTC demonstrated significantly lower AIR (5.0% [37/740] vs 9.7% [45/463], P=0.002) but comparable PPV for biopsy (28.0% [7/25] vs 32.4% [11/34], P=0.720). Extremely dense breasts (P=0.039) and high GTC (P=0.047) were associated with cancer detection at subsequent screening, while other risk factors (age, first-degree family history, prior benign biopsy) and BCSC 5-year risk score were not significant.

CONCLUSION

High baseline GTC was associated with a higher cancer detection rate and comparable PPV for biopsy in subsequent screening in women with dense breasts. Women with extremely dense breasts and high GTC had a 3.4-fold higher cancer detection rate.

CLINICAL RELEVANCE/APPLICATION

Screening strategies that target supplemental US based on breast GTC and mammographic density may be expected to yield a high rate of cancers without significantly increasing false-positive biopsy recommendations.

W5B-SPCA-1 PROGNOSTIC VALUE OF CMR PARAMETRIC MAPPING IN CARDIAC AMYLOIDOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Muhammad Umair, MBBS (*Presenter*)
Seyed Ali Forouzannia, MD (*Abstract Co-Author*)
Romina Rafiei (*Abstract Co-Author*)

PURPOSE

To perform a systematic review and meta-analysis to evaluate the prognostic value of Cardiac Magnetic Resonance (CMR) parametric mapping in predicting all-cause mortality in patients with cardiac amyloidosis (CA).

METHODS AND MATERIALS

An extensive search was conducted in Medline, Scopus, Embase, and Web of Science databases. Eligible studies were retrospective and prospective observational studies that reported hazard ratios (HR) for predicting mortality in patients with CA using CMR parametric mapping.

RESULTS

Twenty-two studies with 3,398 patients were included in this systematic review. Higher ECV values were associated with increased mortality risk, both as a dichotomous (HR: 2.90; 95% CI: 1.68 - 5.01) and continuous variable (HR for 1% increase: 1.08; 95% CI: 1.06 - 1.10; HR for 3% increase: 1.17; 95% CI: 1.11 - 1.22; and HR for 10% increase: 2.11; 95% CI: 1.70-2.62). Higher native T1 mapping values were associated with increased mortality risk as a dichotomous variable (HR: 1.33; 95% CI: 0.79 - 2.24). Native T2 mapping showed inconsistent associations with prognosis across studies.

CONCLUSION

Higher ECV and native T1 values are associated with worse prognosis in CA, supporting their role in risk stratification. Notably, we demonstrate a direct relationship between incremental increases in ECV and the risk of death. Further studies with standardized CMR protocols are needed to enhance the prognostic utility of parametric mapping in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Our findings confirm that CMR parametric mapping is a valuable, noninvasive tool for risk stratification in cardiac amyloidosis, with higher ECV and native T1 values consistently associated with worse clinical outcomes.

W5B-SPCA-4 ALCOHOL SEPTAL ABLATION IN HYPERTROPHIC OBSTRUCTIVE CARDIOMYOPATHY: LONG-TERM FOLLOW-UP OF DEFORMATIONS AND HEMODYNAMICS

Kenichiro Suwa, MD (*Presenter*)
Kazuto Ohno (*Abstract Co-Author*)
Terumori Satoh (*Abstract Co-Author*)
Ryota Sato (*Abstract Co-Author*)
KEISUKE IGUCHI (*Abstract Co-Author*)
Yuichiro Maekawa (*Abstract Co-Author*)

PURPOSE

This study investigated the global cardiac volume, myocardial deformation, and hemodynamic characteristics before and during long-term follow-up after alcohol septal ablation in patients with hypertrophic obstructive cardiomyopathy (HOCM).

METHODS AND MATERIALS

Twenty-three patients with HOCM who underwent cardiac magnetic resonance (CMR) before and after alcohol septal ablation were selected retrospectively. CMR analysis included global left ventricular (LV) volume by cine and peak strain and strain rate by feature-tracking CMR. Four-dimensional (4D) flow CMR was used to analyze LV hemodynamic characteristics. Diastolic LV inflow and the presence of an accompanying vortex ring were investigated. The anterior vortex generated above the MV rotated clockwise was identified.

RESULTS

In the LV long-axis images, the global radial strain increased significantly (16.5 ± 5.8% vs. 20.1 ± 6.8%, $p < 0.001$), whereas the global longitudinal strain decreased significantly after alcohol septal ablation (-10.5 ± 3.2% vs. -12.1 ± 3.5%, $p = 0.002$). The diastolic LV anterior vortex area increased significantly after alcohol septal ablation (2256.1 [703.6, 4038.4] mm 2 vs. 3826.1 [1914.3, 4820.1] mm 2 , $p = 0.036$). Multiplication of the LV end-diastolic volume index, global circumferential strain, and diastolic radial peak strain rate in long-axis images revealed a significant correlation with the diastolic LV anterior vortex area ($Rs = 0.43$, $p = 0.041$).

CONCLUSION

Feature-tracking and 4D flow CMR revealed improved systolic and diastolic LV function during long-term follow-up after alcohol septal ablation. The diastolic LV vortex was associated with the combined parameters of LV volume and deformation. Comprehensive CMR analysis could help understand the beneficial effects of alcohol septal ablation.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the beneficial effects of alcohol septal ablation on myocardial deformation and hemodynamic characteristics in patients with HOCM. The findings underscore the role of advanced imaging techniques such as 4D flow CMR in elucidating previously poorly understood aspects of LV hemodynamics in HOCM.

Understanding these changes could enhance clinical management and outcomes in affected individuals.

W5B-SPCA-5 DISCRIMINATIVE PERFORMANCE OF A DEEP LEARNING RIGHT VENTRICULAR REGIONAL STRAIN ANALYSIS FOR DETECTION OF ARRHYTHMOGENIC CARDIOMYOPATHY

Brendan Crabb, MD (*Presenter*)
Alta Steward (*Abstract Co-Author*)
Rhiannon Buchholz (*Abstract Co-Author*)
Kimberly Hong (*Abstract Co-Author*)
Michael S. Pohlen, MD (*Abstract Co-Author*)
Seth J. Kligerman, MD, MS (*Abstract Co-Author*)
Albert Hsiao, MD, PhD (*Abstract Co-Author*)

PURPOSE

Arrhythmogenic cardiomyopathy (ACM) is a non-ischemic cardiomyopathy that can cause ventricular tachyarrhythmias and sudden cardiac death. Diagnostic guidelines rely on detecting regional right ventricular (RV) wall motion abnormalities using cardiac MRI; however, this is a subjective and challenging task. We aimed to evaluate the performance of a novel deep learning algorithm to detect RV wall motion abnormalities, and assess its ability to predict late gadolinium enhancement (LGE) and genetic evidence of ACM.

METHODS AND MATERIALS

This retrospective cohort study included adult patients who underwent cardiac MRI to monitor or screen for ACM (n=66, mean age 42.6, range 18-82 years). Clinical criteria for ACM, including ECG and genetic criteria, was collected from the electronic medical record. Regional RV longitudinal strain was quantified from four-chamber SSFP cines using an in-house developed deep learning (DL) algorithm. Three cardiothoracic radiologists (mean 10.6 years subspecialty experience, range 3-17 years) independently assessed each cine series for RV wall motion abnormalities. Interrater agreement was calculated via pairwise Cohen's kappa. Lastly, the discriminative performance of identified wall motion abnormalities for predicting objective disease markers, including late gadolinium enhancement (LGE) and pathogenic mutations, was assessed for both DL and readers.

RESULTS

Subspecialty radiologists showed moderate agreement for detecting RV wall motion abnormalities (?=0.47 (range 0.42-0.54). Agreement was substantial in basal segments (?=0.70 (range 0.69-0.73), but only fair in apical segments (?=0.26 (range 0.18-0.43). The discriminative performance of DL-identified regional wall motion abnormalities for predicting objective markers of ACM was similar to subspecialty radiologists for transmural RV LGE with an area under the receiver operating characteristic curve (AUC) of 0.83 (sensitivity=0.86 [0.56, 1.0]; specificity=0.66 [0.53, 0.78]) and superior to subspecialty radiologists for pathogenic mutations, with an AUC of 0.74 (sensitivity=0.64 [0.33, 0.91]; specificity=0.86 [0.75, 0.94]).

CONCLUSION

Subspecialty radiologists showed moderate agreement for detecting RV wall motion abnormalities in ACM with lower agreement in apical segments. Wall motion abnormalities identified with the DL algorithm have a comparable discriminative performance to subspecialty radiologists for predicting LGE and superior performance for predicting pathogenic mutations.

CLINICAL RELEVANCE/APPLICATION

DL algorithms for evaluating myocardial wall motion may aid radiologists in identifying patients with ACM, facilitating appropriate interventions and management.

W5B-SPCA-6 PHOTON COUNTING COMPUTED TOMOGRAPHY FOR TISSUE CHARACTERIZATION IN PATIENTS WITH LEFT VENTRICULAR HYPERTROPHY

Carmelo De Gori (*Presenter*)
Francesca Pignatelli, MD (*Abstract Co-Author*)
Matilda Muca, MD (*Abstract Co-Author*)
Lorenzo Faggioni, MD, PhD (*Abstract Co-Author*)
Mariaelena Occhipinti, MD, PhD (*Abstract Co-Author*)

PURPOSE

Photon-counting computed tomography (PCCT) has emerged as a promising modality for cardiac imaging. In patients with left ventricular hypertrophy (LVH), PCCT may offer an alternative to cardiac magnetic resonance (CMR), which is contraindicated or unavailable in some individuals.

METHODS AND MATERIALS

We prospectively evaluated 79 patients presenting with LVH, who underwent a PCCT scan for suspected coronary artery disease (CAD). Beyond coronary analysis and cardiac function, LV mass index (LVMI), maximal LV wall thickness, ejection fraction (EF), late iodine enhancement (LIE) extent, iodine density, and extracellular volume (ECV) were measured. Patients were clinically classified into three groups: hypertrophic cardiomyopathy (HCM, n=30), amyloid transthyretin cardiomyopathy (ATTR-CM, n=27), and secondary LV hypertrophy (LVH, n=24). 34/79 (43%) patients underwent a clinically indicated CMR scan within three months of PCCT scan.

RESULTS

PCCT-derived LVMI, maximal wall thickness, and EF showed strong agreement with CMR across all groups. ATTR-CM patients demonstrated significantly lower EF and higher LIE extent, iodine density, and ECV compared to patients with HCM or secondary LVH. While ECV derived from PCCT did not correlate well with CMR-derived ECV in most groups, iodine density significantly correlated with CMR ECV in ATTR-CM, highlighting a distinct diffuse infiltration pattern. Secondary LVH cases showed minimal or absent LIE.

CONCLUSION

PCCT accurately characterizes key structural and functional parameters and discriminates among different etiologies, notably detecting diffuse disease in amyloidosis. While ECV quantification by PCCT remains challenging, late iodine enhancement evaluation is feasible and may contribute to risk stratification.

CLINICAL RELEVANCE/APPLICATION

Given these attributes, PCCT may represent a valuable tool in cardiac imaging, particularly for patients in whom cardiac magnetic resonance (CMR) is contraindicated or not feasible. In this context, PCCT has recently emerged as a potential alternative imaging modality for identifying the arrhythmogenic substrate through morphofunctional analysis and assessment of several parameters such us wall thickness, wall thickening, wall motion, CT evidence of hypoperfusion and myocardial tissue characterization.

W5B-SPCA-7 VENTRICULAR BLOOD T2 IN ASYMPTOMATIC ADULTS AT 3T: EFFECT OF AGE AND LUNG VOLUME BY MAGNETIC RESONANCE IMAGING

Chia-Ying Liu, PhD (*Presenter*)
Chikara Noda (*Abstract Co-Author*)
Bharath Ambale-Venkatesh, PhD (*Abstract Co-Author*)
Yoko Kato, MD, PhD (*Abstract Co-Author*)
Yoshimori Kassai, MS (*Abstract Co-Author*)

David A. Bluemke, MD, PhD (*Abstract Co-Author*)
Joao A. Lima, MD (*Abstract Co-Author*)

PURPOSE

While the normal ranges of myocardial T1 and T2 have been vastly reported, the studies on blood T2 are limited and data is sparse. Theoretically, the T2 difference between the right ventricular (RV) and left ventricular (LV) blood pool reflects the cardinal changes in the oxygen saturation fraction due to pulmonary circulation. Prominent intensity differences in T2 maps between two ventricles are often observed. However, the normal ranges of ventricular blood T2 and the degree of blood T2 difference between ventricles have not been reported yet. The purpose of this study was to report the age and sex distribution of ventricular blood T2 in the human heart and to evaluate their relationships to lung volume.

METHODS AND MATERIALS

156 asymptomatic adults without hypertension or diabetes and free from cardiopulmonary disease (74 men, mean age 50 ± 14 years, range 24-81 years) were included. 3T MRI (Canon Medical Systems, Japan) including cardiac scout and T2-prepared gradient-echo sequence for T2 mapping were acquired. The scout imaging was performed in three orthogonal orientations using a gradient echo sequence with breath holding of seven seconds in the resting lung position. The participants were instructed to take a breath in and out twice before holding their breath at the end of breathing out. The same breath holding technique was used throughout the entire study. T2 maps were used to measure blood T2 times. MRI-estimated FRC (MRI-eFRC) was measured using a single scout image in the coronal orientation and was assessed by delineation of the chest wall manually excluding the heart.

RESULTS

Men had higher MRI-eFRC ($p = 0.002$) and LV blood T2 (99 ± 24 ms vs 91 ± 21 ms, $p = 0.03$) than women but RV blood T2 were similar (81 ± 12 ms vs 78 ± 11 ms, $p = 0.2$). Both MRI-eFRC ($r = 0.17$, $p = 0.04$) and LV blood T2 ($r = 0.33$, $p < 0.0001$) were positively correlated with age, while RV blood T2 did not show age dependence. MRI-eFRC was also positively correlated with LV blood T2 ($r = 0.18$, $p = 0.02$) but not with RV blood T2.

CONCLUSION

Our study provides the normal ranges of ventricular blood T2 relaxation times in sex and age groups using the T2-prepared gradient echo sequence at 3T and demonstrated that LV blood T2 is positively associated with age, which could partly be explained by greater resting lung volume in older adults. The novel method that quantified the resting lung volume on MRI coronal scout image has a potential to serve as an index of FRC as traditionally measured by lung volumes in pulmonary function test.

CLINICAL RELEVANCE/APPLICATION

Our study provides the normal ranges of ventricular blood T2 in sex and age groups at 3T. LV blood T2 is positively associated with age and male sex, which may serve as a basis for future studies for clinical CMR examination.

W5B-SPCA-9 COMBINED SPECTRAL AND ULTRAHIGH-RESOLUTION PHOTON-COUNTING CT IMPROVES ASSESSMENT OF CORONARY STENTS: ANALYSIS IN A DYNAMIC ANTHROPOMORPHIC PHANTOM

Muhammad Taha Hagar, MD (*Presenter*)
Akos Varga-Szemes, MD, PhD (*Abstract Co-Author*)
Tilman S. Emrich, MD (*Abstract Co-Author*)
Milan Vecsey-Nagy, MD, PhD (*Abstract Co-Author*)
Fabian Bamberg, MD, MPH (*Abstract Co-Author*)
Dmitrij Kravchenko, MD (*Abstract Co-Author*)

PURPOSE

To assess the combined use of ultrahigh-resolution (UHR) and spectral photon-counting detector CT (PCD-CT) for coronary stent imaging in a dynamic, anthropomorphic phantom.

METHODS AND MATERIALS

Ten coronary stents were deployed in a dynamic anthropomorphic phantom simulating heart rates of 60, 80, and 100 beats per minute (BPM). A dual-source PCD-CT system (NAEOTOM Alpha, Siemens Healthineers) acquired images using a combined UHR-spectral mode (96 × 0.2 mm collimation). Reconstructions included UHR polychromatic (0.2 mm), downsampled (0.6 mm), and spectral images (0.4 mm slice thickness), including virtual monoenergetic images (VMI; 45-100 keV), iodine maps (IM), and lumen-preserving spectral post-processed images (PURE). Objective image quality metrics included measurable stent lumen visibility and the strut overestimation factor, calculated as the ratio of measured to nominal strut width. Two cardiovascular radiologists rated subjective image quality using a four-point Likert scale for stent lumen visibility, strut delineation, artifact severity, and overall image quality.

RESULTS

At 60 BPM, UHR polychromatic images demonstrated the highest measurable stent lumen visibility (62.6±7.6%) and the lowest strut overestimation factor (18.1±3.4), significantly outperforming downsampled and all VMI reconstructions (all $P<0.05$). At higher heart rates, UHR image quality degraded due to motion artifacts, resulting in significantly lower Likert scores at 100 BPM (3.0 [IQR 2.0-3.0], $P=0.002$). In contrast, VMI at 55 keV and IM maintained higher contrast-to-noise ratios and reduced artifacts across heart rates, indicated by higher subjective image quality (80 BPM: 3.0 [IQR 3.0-3.8], $P=0.472$ and $P=0.092$, respectively).

CONCLUSION

PCD-CT with UHR and spectral imaging improves coronary stent assessment. Under optimal conditions, UHR provides superior spatial resolution but is highly motion-sensitive. VMI at 55 keV and especially IM offer consistent image quality at higher heart rates, ensuring reliable stent visualization in challenging conditions.

CLINICAL RELEVANCE/APPLICATION

Combining UHR and spectral imaging in PCD-CT enhances non-invasive coronary stent evaluation. While UHR polychromatic images provide maximal spatial detail, spectral reconstructions such as VMI 55 and IM improve diagnostic confidence in patients with elevated heart rates by mitigating motion-related artifacts.

W5B-SPCA-10 DIAGNOSTIC PERFORMANCE OF CORONARY CT ANGIOGRAPHY WITHOUT ECG-GATING: COMPARISON WITH INVASIVE CORONARY ANGIOGRAPHY

Hong Ren (*Presenter*)
Kun Wang (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic performance of non-ECG-gated coronary CT angiography (ECG-Less CCTA) for detecting obstructive coronary artery disease (CAD), using invasive coronary angiography (ICA) as the reference standard.

METHODS AND MATERIALS

In this retrospective, single-center study, 110 patients with suspected CAD underwent ECG-Less CCTA using a 256-row CT scanner. Scanning protocols incorporated simulated ECG signals based on pulse-based heart rate estimation, automated tube voltage selection (80-120 kV), and tube current modulation (noise index: 20 HU). Contrast administration (iopromide 370 mgI/mL, 0.6 mL/kg) was optimized via bolus tracking (aortic root threshold: 180 HU). Images were reconstructed using deep learning-based algorithm (TrueFidelity™) and motion correction algorithm (SnapShot Freeze 2). Two blinded radiologists independently assessed coronary stenosis

=50% according to the SCCT 18-segment model, with non-diagnostic segments conservatively deemed positive. ICA served as the reference standard. Subgroups were performed based on heart rate (=75 vs. >75 bpm) and calcium burden (Agatston =400 vs. >400).

RESULTS

ECG-Less CCTA demonstrated high diagnostic accuracy for detecting obstructive CAD. At the patient level, sensitivity was 92.1% (95% CI: 85.6-96.2%) and specificity was 91.5% (82.3-96.4%). Vessel-level analysis yielded a specificity of 93.6% (90.2-96.0%) and NPV of 95.1% (91.8-97.3%). Segment-level specificity was 96.2% (94.8-97.3%) with an NPV of 97.2% (95.7-98.3%). Non-diagnostic segments (6.4%) were conservatively classified as positive. The effective radiation dose was 1.4 ± 0.5 mSv. Subgroup analysis revealed reduced specificity in patients with Agatston scores >400 (84.6% vs. 94.1%, p=0.02), while heart rate >75 bpm showed no statistically significant impact on sensitivity (89.7% vs. 94.1%, p=0.12).

CONCLUSION

ECG-Less CCTA achieves high diagnostic concordance with ICA for obstructive CAD, supported by excellent specificity and NPV across patient, vessel, and segment levels. Its tolerance to variable heart rates and streamlined workflow support its clinical utility, particularly in emergency settings or arrhythmic patients.

CLINICAL RELEVANCE/APPLICATION

This technique enables rapid, low-radiation CAD evaluation without ECG-gating constraints, expanding access to noninvasive diagnosis in urgent care and patients with irregular heart rhythms.

W5B-SPCA-11 FRACTAL ANALYSIS OF LEFT VENTRICULAR TRABECULATION IN HEART FAILURE PATIENTS WITH HYPERTENSION USING MAGNETIC RESONANCE IMAGING

Xie Yunxia (*Presenter*)
Lianggeng Gong (*Abstract Co-Author*)

PURPOSE

Endocardial trabeculae undergo hyperplasia under the influence of hemodynamic changes, reflecting a variable phenotype of disease progression. Fractal analysis has been used to analyze the complex endothelial trabeculae of various cardiomyopathy. The purpose of this study was to quantify the complexity of myocardial trabeculae by fractal analysis, and to discuss the differences between hypertension without heart failure(HF) and hypertension complicated by HF, exploring its predictive value for the diagnosis of heart failure in patients with hypertension (HTN).

METHODS AND MATERIALS

A retrospective study was conducted on 146 patients with hypertension, including 77 patients with HF and 69 hypertensive patients, while 34 healthy volunteers were recruited as control group. This design helped us compare the difference between patients with HF and healthy individuals. We collected and analyzed clinical data and cardiac magnetic resonance parameters. The fractal dimension (FD) was obtained by fractal analysis of the myocardial trabeculae on the left ventricular short-axis cine image. Logistic regression analysis was used to determine predictors and construct predictive models.

RESULTS

A total of 5 fractal dimensions were obtained, which are Global FD, Mean Apical FD, Maximal Apical FD, Mean Basal FD and Maximal Basal FD. These left ventricular (LV) FDs (all $p < 0.001$) in HF patients were significantly higher than those in the healthy group. There was also significant difference between HTN-HF group and HTN group in all FDs except for Maximal Basal FD. In the correlation analysis, all of LV FDs showed significant weak positive correlation with LV maximal wall thickness (Maximal LVWT) (Global FD R=0.40, Mean Apical FD R=0.37, Maximal Apical FD R=0.40,Mean Basal FD R=0.34, and Maximal Basal FD R= 0.38, all $p< 0.001$). In addition, Mean Apical FD had significant negative correlation with LVEF. In univariate logistic regression, Global FD, Mean Apical FD, Maximal Apical FD and Mean Basal FD were significant independent predictors (OR : 1.170,1.121,1.070 and 1.088, $p < 0.05$). Furthermore, adding FDs to the prediction model improved the calibration and accuracy of the model (AUC: 0.877).

CONCLUSION

CMR fractal analysis is a feasible technique for analyzing the complexity of LV myocardial trabecular in HTN-HF patients. It has independent predictive value for the diagnosis of patients with hypertensive heart failure. Incorporating FDs into the diagnostic model can help to improve diagnosis.

CLINICAL RELEVANCE/APPLICATION

Differences show in the complexity of endocardial trabeculae in hypertensive patients, and obtaining fractal dimensions (FD) by fractal analysis can help identify heart failure (HF) patients.

W5B-SPCA-12 A SIMPLE FRAMEWORK FOR MYOCARDIAL DELAYED ENHANCEMENT (MDE)-CT SELECTION: PREDICTION OF MDE USING LEFT VENTRICLE METRICS AUTO-ANALYZED FROM CORONARY CTA

Tatsuya Saito, RT (*Presenter*)
Rina Sakai (*Abstract Co-Author*)
Tatsuya Nishii, MD, PhD (*Abstract Co-Author*)
Yuji Matsuzaki, RT (*Abstract Co-Author*)
Tomoro Morikawa, MD (*Abstract Co-Author*)
Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

Myocardial delayed enhancement CT (MDE-CT) has gained attention for its ability to detect myocardial damage with accuracy comparable to delayed-enhancement MRI, and for its feasibility as an add-on to coronary CTA (CCTA). However, due to additional radiation exposure and contrast load, clear criteria are required to determine when MDE-CT is indicated. We hypothesized that left ventricular (LV) parameters derived from CCTA could predict MDE positivity. This study aimed to evaluate whether automatically analyzed LV parameters from CCTA can predict MDE-CT positivity.

METHODS AND MATERIALS

We retrospectively analyzed 68 consecutive cases that underwent both CCTA and MDE-CT using a 256-row CT between August and November 2024. MDE-CT was added based on clinical information and radiologist judgment. CCTA was performed with prospective ECG gating at two cardiac phases (mid-diastole and end-systole). From these images, LV mass index (LVMI), mid-diastolic volume index (LVMDVI), end-systolic volume index (LVESVI), and ejection fraction (LVEF) were automatically calculated. We compared these parameters between MDE-positive and MDE-negative groups and identified independent predictors using multivariate analysis. Based on cutoff values of significant predictors, an additive scoring system (0-2 points) was developed. Diagnostic performance was assessed using ROC curves, and trends in MDE positivity were analyzed using the Cochran-Armitage trend test.

RESULTS

After excluding five cases with failed LV analysis, 63 patients (median age 70 [59-76] years, 43 males [68.3%]) were included. Thirty-six patients (57%) were MDE-positive (21 ischemic, 15 non-ischemic). The MDE-positive group showed significantly higher LVMI (66.6 [55.9-84.6] vs. 49.7 [44.1-60.6] g/m², P<0.01), LVESVI (32.6 [24.2-50.7] vs. 18.9 [16.7-26.6] mL/m², P<0.01), and lower LVEF (47 [34.2-55.0] vs. 60.1 [56.5-67.4] %, P<0.01). Multivariate analysis identified LVMI (OR 1.08, 95% CI 1.01-1.09) and LVESVI (OR 1.04, 95% CI 1.02-1.15) as independent predictors of MDE positivity. AUC was 0.78 (cutoff 52) for LVMI and 0.77 (cutoff 31) for LVESVI. The combined score showed MDE positivity rates of 17.7% (score 0), 52.4% (score 1), and 88.0% (score 2) (P<.0001), with an AUC of 0.82.

CONCLUSION

LVMI and LVESVI derived from CCTA independently predicted MDE-CT positivity. A simple additive score based on these parameters may aid in identifying patients who would benefit from additional MDE-CT, reducing unnecessary imaging and enhancing diagnostic efficiency.

CLINICAL RELEVANCE/APPLICATION

Using left ventricular parameters obtained from CCTA to determine the indication for MDE-CT can help reduce unnecessary imaging, lower radiation exposure, and improve overall diagnostic efficiency.

W5B-SPCA-13 IDENTIFICATION OF MYOCARDIAL MICROSTRUCTURAL ALTERATIONS IN NON-ISCHEMICHEART DISEASE ASSESSED WITH IN VIVO CARDIAC DIFFUSION-TENSOR IMAGINGUSING NOVEL TECHNIQUE OF AMC-MPG AND DWI SCOUT

Hare Ikeda, RT (*Presenter*)
Yoshiaki Morita (*Abstract Co-Author*)
Masaru Shiotani, RT (*Abstract Co-Author*)
Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

Cardiac diffusion-tensor imaging (cDTI) allows for characterization of myocardial microstructure and myofiber-tracking. Novel techniques of accelerated motion compensation gradient (AMC-MPG) and specially designed scout for optimal timing setting in diffusion-weighted imaging (DWI scout) have been recently developed to reduce the motion artifact. However, its diagnostic impact on non-ischemic heart disease is unclear. We evaluated the usefulness of cDTI using AMC-MPG and DWI scout for microstructural assessment of various non-ischemic heart diseases.

METHODS AND MATERIALS

Fifty-two patients with non-ischemic heart disease and 12 healthy volunteers underwent cDTI using AMC-MPG on short-axis slices with navigator gating on 3.0-T MRI. The trigger delay time was set individually according to DWI scout. We measured mean diffusivity (MD:10-3 mm2/sec) and fractional anisotropy (FA) at septal wall in each map reconstructed from DTI source images. Late gadolinium enhancement (LGE) was also performed. We compared cDTI markers among different diseases and volunteer. We also evaluated the association of DTI markers with LGE findings.

RESULTS

Among the patients, 11 were diagnosed as dilated cardiomyopathy (DCM), 12 as hypertrophic cardiomyopathy (HCM), 7 as myocarditis and 5 as hypertensive heart disease (HHD). Two DTI markers were different among different diseases and volunteer. HCM patients had significantly lower FA than volunteers (0.34 vs 0.46, $p<0.01$) and other diseases, and no significant difference in MD compared to volunteers (2.12 v.s.2.11). DCM patients showed comparable FA to volunteers (0.48 vs 0.46) and significantly higher MD (2.41 vs 2.11, $p<0.05$). Myocarditis had significantly lower FA and higher MD (FA =0.40, MD=2.36, $p<0.05$), while HHD had significantly higher FA and MD (FA=0.53, MD=2.97, $p<0.05$), compared to volunteers. Further, in HCM, not only LGE positive but negative segments also had lower FA than volunteers ($p<0.01$). In DCM, not only LGE positive but negative segments had higher MD than volunteers ($p<0.05$). Also, MD and FA of myocarditis and HHD segments with no LGE significantly differed from volunteers ($p<0.05$ for all).

CONCLUSION

cDTI using AMC-MPG and DWI scout can identify the difference in myocardial microstructural alterations in various non-ischemic heart diseases even in the absence of LGE, by using a combination of MD and FA values that reflect the amplitude of diffusion and anisotropy of water molecules, suggesting the potential value in new myocardial tissue characterization.

CLINICAL RELEVANCE/APPLICATION

cDTI using AMC-MPG and DWI scout can detect the microstructural changes in non-ischemic heart disease and may be a novel biomarker for differential diagnosis, early diagnosis and disease prognosis.

W5B-SPCA-14 EVALUATION OF MYOCARDIAL METABOLIC ABNORMALITIES USING SEPARATING ANALYSIS OF INTRA- AND EXTRAMYOCELLULAR LIPID SIGNALS IN SINGLE BREATH-HOLD 1H-MR SPECTROSCOPY IN PATIENTS WITH DIABETIC CARDIOMYOPATHY

Masaru Shiotani, RT (*Presenter*)
Yoshiaki Morita (*Abstract Co-Author*)
Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

Lipid oversupply to cardiomyocytes plays a role in the development of myocardial dysfunction in type 2 diabetes mellitus (T2DM). 1 H-MR spectroscopy (MRS) enables direct noninvasive measurement of myocardial lipids, but it is usually evaluated only the total lipid including intra- and extracellular space. A novel analytical approach using LC model software allows separate quantification of intramyocellular lipid (IMCL) and extramyocellular lipid (EMCL), offering more detailed evaluation of lipid distribution. However, its utility in myocardial disease is unclear. We investigated myocardial lipid metabolism in patients with T2DM-related myocardial disease using LC model analysis of MRS.

METHODS AND MATERIALS

This study included 29 patients with T2DM-related heart disease, 10 patients with non-ischemic cardiomyopathy (NICM) without T2DM and 5 healthy volunteers. Single-voxel PRESS MRS was performed at septal wall in a single breath-hold. IMCL and EMCL peaks were identified at 1.3 and 1.5 ppm, and each lipid to creatine (Cr: 3.03 ppm) peak ratio was used as intra- and extracellular metabolic indicator (ICR and ECR) using the LC model. Total lipid content was calculated as (IMCL+EMCL) to Cr peak ratio (=TCR). These ratios were compared among three groups, and ROC analysis determined cutoff values for differentiation of these groups.

RESULTS

T2DM patients showed significantly higher ICR and ECR compared with NICM patients (ICR: 9.68 vs. 1.52; ECR: 8.05 vs. 1.57; $p < 0.05$ for all) and volunteers (ICR: 9.68 vs. 1.47; ECR: 8.05 vs. 2.82; $p < 0.05$ for all). For differentiation of the T2DM from NICM, AUC/sensitivity/specificity were 0.83/79.3%/80% for ICR (cut-off 1.73), 0.65/34.5%/100% for ECR (cut-off 4.46) and 0.79/62.1%/90% for TCR (cut-off 6.05).For differentiation of the T2DM from volunteers, AUC/sensitivity/specificity were 0.83/80%/79.3% for ICR (cut-off 1.26), 0.51/100%/27.6% for ECR (cut-off 0.92) and 0.72/100%/44.8% for TCR (cut-off 9.25).ICR demonstrated the highest AUC in both comparisons.

CONCLUSION

LC model-based MRS enables detailed assessment of myocardial lipid metabolism in T2DM with ICR providing superior diagnostic accuracy, suggesting IMCL is associated with abnormal lipid deposition in T2DM.

CLINICAL RELEVANCE/APPLICATION

Single breath-hold MRS enables direct and rapid quantification of myocardial lipid content. Further, LC Model allows more detailed evaluation of the intracellular and extracellular contents beyond conventional analysis, promising more accurate imaging biomarker for assessing myocardial triglyceride accumulation in T2DM-related myocardial disease. This novel technique has the potential for evaluation of disease severity and therapeutic decision-making.

W5B-SPCH-3 BEYOND BIOPSY: PREDICTING PD-L1 STATUS IN NON-SMALL CELL LUNG CANCER THROUGH CT RADIOMICS

Federica Palmeri, MD (*Presenter*)
Massimiliano Mancini (*Abstract Co-Author*)
Damiano Caruso, MD, PhD (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)
Andrea Laghi, MD (*Abstract Co-Author*)

PURPOSE

To develop and validate machine learning (ML) models based on radiomic features extracted from CT imaging to differentiate between high (PD-L1 =50%) and low (PD-L1 <50%) PD-L1 expression in non-small cell lung cancer (NSCLC), potentially offering a noninvasive alternative to histological profiling.

METHODS AND MATERIALS

This retrospective study included 210 NSCLC patients with available contrast-enhanced chest CT and histological PD-L1 quantification. Among them, 46 patients (21.9%) had PD-L1 =50%, while 164 (78.1%) had PD-L1 <50%. All CT scans were acquired before treatment and segmented manually to isolate tumor volumes. Radiomic feature extraction was performed using a standardized pipeline in compliance with the Image Biomarker Standardization Initiative. Five models consisting of three ensembles of machine-learning classifiers (Random Forest, Support Vector Machine, K-Nearest Neighbors, Multi-Layer Perceptron, Logistic Regression) were developed for the binary classification task of interest ("PD-L1 < 50%" vs. "PD-L1 > 50%"), based on supervised learning, using molecular diagnosis as reference standard. Histological PD-L1 expression served as the reference standard. Statistical significance was set at P < .05.

RESULTS

The best-performing model was based on a Multi-Layer Perceptron classifier, achieving a ROC-AUC of 0.61 (95% CI: 0.57-0.66, P < .005) and an accuracy of 64% (95% CI: 60-68%, P < .005). Sensitivity and PPV were high at 70% (95% CI: 65-75%, P < .005) and 82% (95% CI: 80-84%, P < .005), respectively. Specificity and NPV were lower at 44% (95% CI: 36-52%) and 29% (95% CI: 24-35%, P < .005). The F1 score was 75% (95% CI: 71-78%, P < .005).

CONCLUSION

Radiomic analysis of pre-treatment CT images using a Multi-Layer Perceptron classifier demonstrated potential in distinguishing PD-L1 expression levels in NSCLC, with good sensitivity, PPV, and overall F1 score. However, the model's limited specificity and NPV suggest it may be more effective in identifying patients likely to express high PD-L1 levels, rather than excluding them.

CLINICAL RELEVANCE/APPLICATION

Radiomic-based ML models could assist in the noninvasive prediction of PD-L1 status, supporting patient selection for immunotherapy when biopsy is inconclusive, unavailable, or carries clinical risk.

W5B-SPCH-4 FROM CLEAR TO CLOUDY: DECLINING DIAGNOSTIC QUALITY OF CTPA ACROSS PREGNANCY TRIMESTERS

Gilad Borisovsky, MD (*Presenter*)
Yuval Liberman, MD, MMedSc (*Abstract Co-Author*)
Om B. Panta, MD (*Abstract Co-Author*)
Benedikt H. Heidinger, MD (*Abstract Co-Author*)
Ivan Diogo Queiros, MD (*Abstract Co-Author*)
Surabhi Agarwal, DNB,MBBS (*Abstract Co-Author*)
Zeynep Nur Akyol Sari, MD (*Abstract Co-Author*)
Ronald L. Eisenberg, MD, JD (*Abstract Co-Author*)
Diana Litmanovich, MD (*Abstract Co-Author*)

PURPOSE

Evaluating the diagnostic image quality and reliability of computed tomography pulmonary angiography (CTPA) for pulmonary embolism (PE) in pregnancy compared to reproductive-age non-pregnant women as well assessment of frequency of PE and influencing factors on diagnostic quality.

METHODS AND MATERIALS

Retrospective review of pregnant women undergoing reduced-dose CTPA for suspected PE from 2006-2022 and 276 non-pregnant women undergoing standard-dose CTPA from 2015-2022. Image quality was assessed subjectively (scale 1-4) and objectively (HU attenuation). Demographic and clinical data was also collected.

RESULTS

PE was diagnosed in 3% (11/367) of pregnant versus 7% (19/276) of non-pregnant women (p=0.024), with decreasing PE incidence across trimesters (1st: 1.6%, 2nd: 1%, 3rd: 0.3%). Alternative diagnoses were significantly less frequent in pregnant (8.4%) compared to non-pregnant women (28.2%, p<0.001). Radiation doses in pregnant patients were significantly lower (DLP: 117±29 mGy/cm, CTDIvol: 5.3±0.8 mGy) compared to non-pregnant controls (DLP: 307±127 mGy/cm, CTDIvol: 11.2±4.2 mGy, p<0.001). Subjective image quality was significantly lower in pregnant (mean: 2.94±0.94) compared to non-pregnant women (mean: 3.4±0.87, p<0.001), with increased non-diagnostic scans in the third trimester (13.5%, p=0.02). Objective quality also declined with advancing pregnancy age (323.75±16.06 HU to 289.88±9.72 HU, p<0.001). Respiratory artifacts significantly reduced image quality and increased with advancing pregnancy (27% 1st trimester to 44% 3rd trimester, p=0.02). Pulsation artifacts negatively impacted image quality without trimester correlation, while streak artifacts were more frequent in pregnant women without significant quality impact.

CONCLUSION

CTPA quality is clinically acceptable in early and mid-pregnancy despite being lower compared to non-pregnant controls. Reduced diagnostic quality in the third trimester suggests consideration of alternative imaging methods during late pregnancy. Respiratory motion artifact is a major contributor to quality degradation in pregnant patients.

CLINICAL RELEVANCE/APPLICATION

Understanding diagnostic limitations of CTPA during pregnancy will optimize patient management. Alternative diagnostic approaches should be considered in late pregnancy.

W5B-SPCH-5 EXTERNAL VALIDATION OF AN AI TOOL IN DETECTION, LOCALIZATION AND CHARACTERIZATION OF OSSEOUS METASTASES ON THORACIC CT EXAMINATIONS

Anushree M. Burade, MBBS (*Presenter*)
Javier Contreras Yametti, MD (*Abstract Co-Author*)
Bernardo C. Bizzo, MD, PhD (*Abstract Co-Author*)
Arun Innanje (*Abstract Co-Author*)
Terrence Chen (*Abstract Co-Author*)
Keith J. Dreyer, DO, PhD (*Abstract Co-Author*)
Subba R. Digumarthy, MD (*Abstract Co-Author*)

PURPOSE

Detection of osseous metastases is an important but difficult task on CT performed for cancer staging. We performed an external validation study to assess if an AI model can help detect, localize and characterize osseous metastases on thoracic CT examinations.

METHODS AND MATERIALS

With Institutional Review Board approval, we identified 650 consecutive thoracic CT examinations with or without osseous metastases from 650 patients using our enterprise level radiology report search engine and database. Of 650 CT exams, 230 (35.5%) CT chest exams were positive for osseous metastases, and 420 (64.6%) were negative for osseous metastases. We exported, de-identified and processed thin-section CT images (1-1.25 mm) of multivendor exams with an AI tool (United Imaging Intelligence, UII) for detecting, classifying (as lytic, sclerotic and mixed attenuation) and localizing focal lesions involving thoracic skeleton. The AI output was positive per patient when the AI model identified = 50% of lesions based on the thoracic CT exams. Data were analyzed to determine the ROC AUC, sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of the AI model at patient level and lesion level.

RESULTS

The mean age and SD for the cases was 65.3 ± 14.11 years (308 males [47.3%], 342 females [52.6%)]. The AI model had ROC AUC of 0.857 (95% CI: 0.827 - 0.886), sensitivity of 95.6% (95% CI: 93% - 98.8%), specificity of 75.7% (95% CI: 71.6% - 79.8%), positive predictive value (PPV) of 68.3% (95% CI: 63.2% - 73.4%), negative predictive value (NPV) of 96.9% (95% CI: 95% - 98.8%), and accuracy of 82.7% (95% CI: 79.8% - 85.6%) for identifying the patients with osseous metastases. The AI model had highest ROC AUC of 0.960 (95% CI: 0.951 - 0.969) and 0.960 (95% CI: 0.951 - 0.969) for the detection of sclerotic and mixed osseous metastatic lesion. The model had highest ROC AUC of 0.958 (95% CI: 0.947 - 0.970) for characterization of mixed attenuation osseous metastatic lesion. No significant differences were observed in the performance of AI between different age and gender groups.

CONCLUSION

The AI algorithm can detect the presence and the location of the osseous metastases with high AUC, sensitivity and negative predictive value

CLINICAL RELEVANCE/APPLICATION

AI model can be used as an adjunct in screening for osseous metastases in patients undergoing CT for cancer staging.

W5B-SPCH-6 DYNAMIC DECT SHUTTLE MODE IMAGING DURING XENON WASHOUT FOR THE DETECTION OF REGIONAL VENTILATION DEFECTS IN IN VIVO RABBIT LUNGS

Emma Verelst, MSc (*Presenter*)
Sam Bayat (*Abstract Co-Author*)
Sylvia Verbanck (*Abstract Co-Author*)
Gert van Gompel, PhD (*Abstract Co-Author*)
Johan De Mey, MD, PhD (*Abstract Co-Author*)
Nico Buls, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to detect ventilation defects (VDs) during multiple-breath xenon (Xe) washout (WO) using dynamic shuttle-mode dual-energy CT (DECT) in healthy and bronchoconstricted in vivo rabbit lungs.

METHODS AND MATERIALS

Six anesthetized New Zealand rabbits [2.6 ± 0.2 (SD) kg] were mechanically ventilated (EC 18-272-15). Multi-breath images were acquired during Xe WO before and after methacholine-induced bronchoconstriction (40 mg/mL) using a clinical DECT (Revolution, GE Healthcare) in shuttle mode. On average, the CTDI vol per acquisition was 4.7 mGy. Ventilation parameters and Xe were monitored at the airway opening by a pneumotachometer (Hans Rudolph, Kansas City) and mass spectrometer (LR6000, Logan Research), respectively. Material decomposition was applied and a voxel-wise correction ensured to reflect only the Xe concentration (Xe conc) in the gas phase of the lung tissue. End-expiratory lung volume (EELV) was compared between a mass spectrometry-based method (EELV ms) and by segmenting gas from healthy lung tissue density images (EELV image) by computing Spearman's rank correlation coefficient (?). The dynamics of ventilation distribution during WO were visually assessed using color-coded Xe conc -maps. VD fraction (VDF) was quantified as voxels below the 25 th percentile of the mean Xe conc at WO start (t 0), expressed as % of total lung volume, and compared between healthy and bronchoconstricted rabbit lungs. Specific ventilation (sV= ventilation/gas volume in min -1) was computed in VDs and non-VDs using Xe conc time attenuation curves and compared between areas. Differences in VDF and sV were tested using a paired samples t-test.

RESULTS

EELV ms (24.8 ± 6.4mL) and EELV image (27.4 ± 2.8mL) correlated (?=0.49, p=0.041). Visually, distinct differences in ventilation distribution between healthy and bronchoconstricted rabbit lungs were observed. VDF increased from (35.5% ± 25.6%) to (45.7% ± 25.0%) after bronchoconstriction, p = 0.026 . In healthy lungs, no difference in sV was found between VD (9.0 ± 2.85 min -1) and non-VD (9.46 ± 3.02 min -1) areas, p = 0.197 . In bronchoconstricted lungs, sV was found to be significantly reduced in VD areas (4.7 ± 2.0 min -1), compared to non-VD areas (6.1 ± 2.1 min -1), p = 0.002 .

CONCLUSION

This study shows the potential of dynamic shuttle Xe-DECT imaging for quantitative studies of local ventilation defects in healthy and pathological in vivo rabbit lungs.

CLINICAL RELEVANCE/APPLICATION

Traditional lung function tests provide only global assessments of respiratory impairment, potentially overlooking early or subtle regional ventilation changes. This limitation has driven growing interest in pulmonary functional imaging as means to quantitatively investigate lung function on a regional level.

W5B-SPCH-7 OPTIMIZING CONTRAST CONCENTRATION IN CHEST CT WITH LOW TUBE VOLTAGE: A RANDOMIZED PROSPECTIVE MULTICENTER TRIAL ON LOW-CONCENTRATION CONTRAST MEDIA

Jung Im Jung, MD, PhD (*Presenter*)
Jiho Park, MD (*Abstract Co-Author*)
Bomi Gil (*Abstract Co-Author*)
Yun-Hyeon Kim, MD (*Abstract Co-Author*)
Gongyoung Jin, MD, PhD (*Abstract Co-Author*)
Jin Mo Goo, MD, PhD (*Abstract Co-Author*)
Suyon Chang, MD, PhD (*Abstract Co-Author*)
Kyongmin S. Beck, MD, PhD (*Abstract Co-Author*)

PURPOSE

The widespread adoption of low tube voltage scan of thorax necessitates adjustments in contrast medium (CM) injection strategies. Low-concentration iodine contrast media (LCCM) can potentially benefit image quality of low-voltage scans by reducing over-enhancement or contrast-related artifacts in chest contrast-enhanced CT (CECT). We compared low-voltage (100kVp) chest CECT using standard and LCCM by comparing proportion of acceptable quality scans with standard protocol chest CECT.

METHODS AND MATERIALS

This randomized prospective multicenter trial was performed at six hospitals from December 2023 to September 2024. Participants were randomly divided into four groups: Group 1 (control) undergone chest CECT with standard protocol (120kVp, 320mgI/mL CM) and test groups of 2-4 with low voltage (100kVp) undergone chest CECT with standard and low-concentration CM (320mgI/mL, 270mgI/mL, and 240mgI/mL). Two independent readers assessed the scans blinded. Non-inferiority test compared the proportion of acceptable quality scans with control. Participants surveyed any adverse reactions, including injection site pain, localized and systemic heat sensation.

RESULTS

A total of 371 participants (mean age 66.0 years [58-73]; 238 men) were randomized. The proportions of acceptable scans in low-voltage chest CECTs with LCCMs were non-inferior to standard protocol with non-inferiority margin of 15% (270mgI/mL: Reader 1, 98.33% CI [-4.95, 9.37], p-value <0.001; Reader 2, 98.33% CI [-5.08, 9.35], p-value <0.001) (240mgI/mL: Reader 1, 98.33% CI [-6.44-8.71], p-value <0.001; Reader 2, 98.33% CI [-6.44, 8.71], p-value <0.001). One reader reported a decreased proportion of acceptable scans in standard CM group (320mgI/mL) (Reader 1, 98.33% CI [-13.67, 4.98], p-value 0.003; Reader 2, 98.33% CI [-19.85, 0.29], p-value 0.11). LCCM groups reported less injection site pain, localized and systematic heat and only the result for the systematic heat was statistically significant (p-values 0.41, 0.34, 0.003).

CONCLUSION

Low-voltage chest CECTs using LCCMs (270 and 240mgI/mL) can produce non-inferior results compared with standard protocol.

CLINICAL RELEVANCE/APPLICATION

Adoption of LCCM in low voltage scans can enhance image quality by reducing contrast-related artifacts. Reduction of iodine delivery by using LCCM can also reduce adverse events.

W5B-SPCH-8 CONTRAST DOSE AND BEAM-HARDENING ARTIFACTS REDUCTION OF THE ADAPTIVE LOW-CONTRAST-DOSE PROTOCOL IN CTPA COMPARED WITH EMPIRICAL SCANNING

Xiaoying Chen (*Presenter*)
Xubin Cui (*Abstract Co-Author*)
Wanting Wu (*Abstract Co-Author*)

PURPOSE

To investigate the reduction of contrast dose and beam-hardening artifacts while maintaining image quality using the adaptive low-contrast-dose protocol in CT pulmonary angiography (CTPA) by compared with empirical scanning.

METHODS AND MATERIALS

This retrospective study included 188 patients with suspected pulmonary embolism who underwent spectral CTPA between February 2022 and January 2025. Patients were divided into adaptive low-contrast-dose group (group A, n=84) and empirical scanning protocol group (group B, n=104). The adaptive method employed three-ROI test bolus to optimize scan timing and adjusted contrast injection flow rates based on patient body weight. CT values of the pulmonary arteries, their branches, and muscles affected by beam-hardening artifacts (BHA) were measured, with subsequent calculation and comparison of the corresponding signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), arteriovenous separation, and BHA between two groups. Two radiologists independently scored image quality using a 5-point scale, evaluating pulmonary artery/vein opacification, BHA, motion artifacts, and image noise.

RESULTS

Compared to conventional protocol (Group B), Group A demonstrated a 35% reduction in contrast volume (26 mL vs 40 mL, $P < 0.001$) despite higher patient body weight ($P < 0.001$). No significant difference in radiation dose was observed ($P > 0.05$). Although Group A showed lower CT values and SNR than Group B, all pulmonary artery segments maintained diagnostic enhancement (CT value > 350 HU) and well arteriovenous separation (CT difference > 300 HU). CNR showed no statistical difference between two groups. Group A exhibited significantly lower BHA indices ($P < 0.001$) and superior subjective BHA scores ($P < 0.05$).

CONCLUSION

The adaptive low-contrast-dose protocol significantly reduces contrast medium volume and beam-hardening artifacts while maintaining diagnostic image quality and ensuring patient safety, offering a clinically viable optimization strategy for CTPA examinations.

CLINICAL RELEVANCE/APPLICATION

This study proposes an optimized adaptive scanning protocol for CTPA that achieves significant contrast dose reduction while being clinically validated.

W5B-SPCH-10 FACTORS AFFECTING ABNORMALITY SCORES OF ARTIFICIAL INTELLIGENCE ON CHEST RADIOGRAPHS OF LUNG CANCER PATIENTS

Hyun Joo Shin, MD, PhD (*Presenter*)
Kyunghwa Han, PhD (*Abstract Co-Author*)
Eun-Kyung Kim, MD (*Abstract Co-Author*)
Eun Hye LEE (*Abstract Co-Author*)
Young Joo Suh, MD, PhD (*Abstract Co-Author*)

PURPOSE

To identify factors that influence the abnormality scores of artificial intelligence (AI) on chest radiographs (CXR) of lung cancer patients.

METHODS AND MATERIALS

Patients who underwent surgical resection for lung cancer at two hospitals from March 2020 to February 2021 were retrospectively included. When a commercial AI software detected lesions at the lung cancer areas on preoperative CXR, abnormality score of discovered lesions were analyzed. The AI score was defined as the highest abnormality score among the discovered lesions. To identify factors influencing the highest abnormality score, a beta regression test was performed with the following variables: projection view and types of radiographs, location, size, solid type of cancers, margin conspicuity, tricky area, and pathological stage.

RESULTS

A total of 340 patients had AI-visible lung cancers on CXR. In the univariate analysis, increased size and solid type were significant factors for increasing AI score (all, $p<0.001$). However, poor conspicuity (exp(estimate) 0.403, $p<0.001$) and tricky area (exp(estimate) 0.705, $p=0.004$) were significantly decreased AI score. Advanced stage was significantly associated with increased AI score ($p<0.03$). In the multivariate analysis, poor conspicuity and tricky area were significant factors for reducing score. However, increased solid size ($p<0.001$) or tumor stage ($p<0.05$) were significant factors for increasing AI scores.

CONCLUSION

Abnormality score of AI in lung cancer are influenced by imaging features, but tumor size and pathologic stage were significant factors for increasing scores. This suggests a potential role for AI scores as imaging biomarkers, but caution is needed in application.

CLINICAL RELEVANCE/APPLICATION

Our study showed that the AI score and nodule score of lung cancers on CXR were influenced by margin conspicuity, tricky area, and the pathological tumor stage or tumor size. Even though there might be a compounding effect of margin and location of the lesions on CXR, the abnormality score was significantly influenced by the size or stage of the cancers when adjusting for margin and tricky area factors. This could reflect that the abnormality score may reflect disease severity, such as the stage and size of the tumor, implying that it has the potential to serve as an imaging biomarker, although careful interpretation is essential when utilizing AI-generated scores.

W5B-SPCH-11 AI ENHANCED IMAGING PRESERVES CLINICAL UTILITY WHILE ENABLING SIGNIFICANT DOSE REDUCTION IN MULTI-CENTER CHEST CT: IMPLICATIONS FOR PANDEMIC PREPAREDNESS

Andreas Brendlin, MD, PhD (*Presenter*)
Markus Mader (*Abstract Co-Author*)

PURPOSE

The COVID-19 pandemic emphasized the need for rapid and accurate diagnostics. Per the ALARA principle, low-dose CT (LDCT) scans are desirable, but image quality and clinical utility remain problematic. AI image improvement algorithms may help close that gap. Still, comprehensive confirmation is missing. To help close this gap, we performed a retrospective multicenter multiscanner analysis, hypothesizing that AI can enhance the image quality of LDCT scans across multiple institutions and scanner models and preserve clinical utility for future pandemics, particularly when compared to standard reconstruction methods.

METHODS AND MATERIALS

Sixty SSDE-matched patients from three centers who underwent standard-dose chest CT for COVID-19 were included. LDCT scans at 50% and 25% radiation dose were simulated using a validated method. Each dataset was reconstructed using standard iterative reconstruction (IR) and AI denoising (AID). Two radiologists assessed image quality subjectively. Objective image quality was assessed using noise and contrast-to-noise ratio (CNR) measurements. The extent of four typical pathological findings (ground-glass opacities, consolidations, nodules, and reticulations) was rated using a semiquantitative scoring system.

RESULTS

AID significantly improved image quality at all radiation doses ($p<0.008$). There were no significant differences in image quality between 100% IR and 25% AID datasets ($p=0.203$). AID also significantly reduced noise and improved CNR at all radiation dose levels ($p<0.001$). There were no significant differences in noise and CNR between 100% IR and 25% AID datasets ($p=0.355$ and $p=0.139$, respectively). Pathology manifestation scores revealed no significant differences between the dose and reconstruction modes, indicating that AID does not compromise clinical utility.

CONCLUSION

AID enhances the image quality of low-dose chest CT scans across multiple institutions and scanner models and preserves clinical utility for future pandemics, particularly compared to standard reconstruction methods.

CLINICAL RELEVANCE/APPLICATION

Cross-Institutional Dose Reduction AI enables high-quality chest CT imaging at 25% standard dose across different centers and scanners. Preserved Diagnostic Value No loss in detection of key COVID-19-related lung findings, even at ultra-low doses with AI support. Pandemic-Ready Imaging Supports safe, rapid, and scalable LDCT protocols for future infectious disease outbreaks.

W5B-SPCH-12 RISK FACTORS FOR SECOND PRIMARY LUNG CANCER

Tracy El Khoury, MD (*Presenter*)
Suzanne Byrne, MD (*Abstract Co-Author*)
Mark M. Hammer, MD (*Abstract Co-Author*)

PURPOSE

The purpose of this study was to identify imaging risk factors that may predict the development of second lung cancer in patients who have undergone a resection for an early-stage primary lung cancer.

METHODS AND MATERIALS

This retrospective study included 784 patients who underwent surgical resection of a stage I lung adenocarcinoma between January 2012 and December 2020 at a single institution. Patients with no recurrence or a second primary lung cancer were identified, and then a radiology fellow, using thin axial lung windows, classified each resected nodule based on type and location. Additional features examined included presence of multiple subsolid nodules, emphysema, bronchial wall thickening and fibrosis. Risk factors for second primary lung cancer were evaluated using Cox proportional hazards.

RESULTS

The incidence of a second primary lung cancer among the final study database was 13%. Age (HR of 1.55, p value< 0.001) and COPD diagnosis (HR 1.55, $p<0.001$) were statistically significant factors associated with development of a second primary lung cancer. Smoking was also a significant risk factor ($p=0.0036$), with a 10-year risk of developing a second primary lung cancer of 37% in people who currently smoke, 32% in and people who previously smoked with less than 15 years since quitting, 25% in people who previously smoked with more than 15 years since quitting and 8.5% in people who never smoked. The presence of multiple subsolid nodules (HR of 2.48, $p<0.001$) and emphysema (HR of 1.61, $p=0.029$) were statistically significant imaging risk factors. Nodule type was not significant ($p=0.064$); however solid nodules had a greater risk of developing a second primary 8 years after resection of the first primary (HR 11.9, $p=0.019$) while the risk is not statistically significant in the first 8 years ($p=0.80$).

CONCLUSION

Presence of multiple subsolid nodules and emphysema are associated with an increased risk for development of a second primary lung cancer.

CLINICAL RELEVANCE/APPLICATION

Patients with emphysema and multiple subsolid nodules on imaging may benefit from prolonged surveillance and close monitoring for development of a second primary lung cancer.

W5B-SPER-2 MEASUREMENT, MARKING AND ANALYSIS OF INFLUENCING FACTORS OF THE EFFECTIVE SCANNING RANGE OF CT SCANNING TABLE

Yong Fan (*Presenter*)
Zhidong Yuan, RT (*Abstract Co-Author*)
Fei Feng (*Abstract Co-Author*)

PURPOSE

Through simulated CT scanning experiments, to measure and analyze the influence of different scanning equipment and scanning parameters (collimation width, pitch and rotation speed) on the effective scanning range (ESR) of the CT scanning table, providing a basis for clinical CT technicians to optimize the usage range of the scanning table, thereby improving scanning efficiency and patient comfort.

METHODS AND MATERIALS

Simulated scans were conducted using Siemens Definition Flash dual-source CT and GE Revolution CT. Different combinations of scanning parameters, including collimation width, pitch and rotation speed, were set on both devices, totaling 186 parameter combinations. The farthest starting and ending positions of the scanning range under each parameter combination were recorded, and the ESR was calculated. The correlation between different scanning parameters and the ESR was analyzed. The distance from the farthest position allowed for scanning to the edge of the table was also measured.

RESULTS

The ESR of the CT scanning table decreased with the increase of collimation width, the acceleration of rotation speed and the increase of pitch. The correlation between effective scanning length and pitch was the highest ($r = -0.960$, $P < 0.001$), and the correlation with rotation speed was the lowest ($r = 0.569$, $P < 0.001$). The ESR of the Siemens Definition Flash dual-source CT was generally lower than that of the GE Revolution CT. On the Siemens device, the shortest ESR of 1422 mm was observed in Flash mode. On the GE Revolution CT, the shortest ESR measured 1890 mm at an 80 mm collimation width.

CONCLUSION

The ESR of the CT scanning table is affected by collimation width, pitch and rotation time. By conducting simulated scans in advance and marking the effective range of the scanning table, the problem of insufficient length of the scanning table can be effectively avoided, thereby improving scanning efficiency and patient comfort.

CLINICAL RELEVANCE/APPLICATION

On Siemens Definition Flash dual-source CT, the shortest ESR in Flash mode is 1422mm, which is much lower than the height of an average adult. Therefore, special attention should be paid to the effective scan range of the scanning bed when using Flash mode of Siemens CT

W5B-SPER-3 RADIOLOGY REQUISITION QUALITY AND CLINICAL REASONING QUALITY: A RETROSPECTIVE STUDY ON EMERGENCY CT REFERRALS USING REASON FOR EXAM IMAGING REPORTING AND DATA SYSTEM (RI-RADS)

Jingyu Zhong, MD (*Presenter*)
Xianwei Liu (*Abstract Co-Author*)
Huan Zhang (*Abstract Co-Author*)
Weiwu Yao (*Abstract Co-Author*)

PURPOSE

To determine radiology requisition quality using Reason for exam Imaging Reporting and Data System (RI-RADS) and the associated clinical variables, and find out whether it reflects the clinical reasoning quality in emergency CT referrals.

METHODS AND MATERIALS

This single-center retrospective study randomly selected emergency CT referrals between 01 January 2024 and 31 December 2024. One radiologist scored the requisition quality using the RI-RADS, and assessed the clinical reasoning quality regarding degree by which the differential diagnoses on the requisition form matched the CT diagnosis on assigned report. The clinical variables that associated with RI-RADS A was investigated using logistic regression analysis. The clinical reasoning quality among different RI-RADS grades was compared.

RESULTS

We included 1291 emergency CT referrals. The requisitions were for patients with an average ± standard deviation age of 54.0 ± 21.2 years, and slightly most of them were female (675 requisitions, 52.3%). RI-RADS grades A (adequate), B (barely adequate), C (considerably limited), D (deficient), and X (no information) were assigned to 287 (22.2%), 71 (5.5%), 851 (65.9%), 53 (4.1%), and 29 (2.2%) requisitions, respectively. The absolute agreements for RI-RADS categories of impression, clinical information, and diagnostic question were 97.0%, 56.0%, and 88.0%, respectively. The absolute agreement for RI-RADS grades was 79.0%. The requisitions from fever clinic and thoracic surgery were less likely to be assigned to RI-RADS A compared to internal medicine (odds ratio 0.10-0.11), and so were those of abdomen and head scans compared to chest scans (odds ratio 0.06-0.30). The RI-RADS A requisitions had better clinical reasoning quality than those of RI-RADS grades C, D, and X (all adjusted $p<0.001$), but not those of RI-RADS B (adjusted $p=0.100$).

CONCLUSION

The majority of emergency CT requisitions were inadequate, especially those from fever clinic and thoracic surgery. The suboptimal requisitions were expected to have insufficient clinical reasoning quality.

CLINICAL RELEVANCE/APPLICATION

The concern of radiologists is true that the low-quality radiology requisitions potentially reflect the worse clinical reasoning. A training on how to request meaningful radiology examinations after detailed clinical reasoning is warranted to improve radiology workflow for better medicine practice.

W5B-SPGI-2 PRELIMINARY USE OF DCE-MRI IN PREDICTING PATHOLOGICAL COMPLETE RESPONSE AFTER NEOADJUVANT IMMUNOTHERAPY FOR LOCALLY ADVANCED RECTAL CANCER: A PROSPECTIVE STUDY

Long Yang (*Presenter*)
Qitong Huang (*Abstract Co-Author*)
Yidi Hou (*Abstract Co-Author*)
Peiyi Xie (*Abstract Co-Author*)
Xiaochun Meng (*Abstract Co-Author*)

PURPOSE

To investigate the potential of T2-Weighted Image(T2WI) and Dynamic Contrast Enhancement MRI(DCE-MRI) for predicting the efficacy of neoadjuvant immunotherapy in patients with locally advanced rectal cancer(LARC).

METHODS AND MATERIALS

This prospective trial (ClinicalTrials.gov identifier: NCT05523245) enrolled 54 consecutive LARC patients from July 1,2023 to July 1,2024.All participants were treated with neoadjuvant immunotherapy preoperatively and pathological results were obtained postoperatively. All participants underwent conventional sequence and DCE-MRI before the start of neoadjuvant immunotherapy and three weeks before surgery. Pathologic complete response(pCR) was evaluated according to the AJCC 8th edition: patients with a tumor regression grade(TRG) of 0 were considered pCR, and patients with a TRG of 1-3 were considered non-pCR. A radiologist performed whole-tumor analysis between pCR and non-pCR groups at both time periods using multiparametric MRI, including T2WI volume and the quantitative parameters of DCE-MRI including volume transfer constant (K trans),rate constant (K ep),and extravascular extracellular volume fraction (V e). The mean values of the above parameters were then used for analysis. The reduction rate was defined as parameters, termed ?. Differences in quantitative parameters between pCR and non-pCR groups were assessed by independent samples t -test or Mann-Whitney U test. Receiver operating characteristic curve analysis was used to evaluate the diagnostic performance.

RESULTS

Fifty-four patients with LARC were analyzed in the study, of whom 37 (69%) were male and 17 (31%) were female, with a mean age of 55 ± 10 years. According to the pathological results, they were divided into pCR group (n=21) and non-pCR group (n=33). The post-treatment T2WI volume and post-treatment K ep in the pCR group were significantly lower than those in the non-pCR group (p=0.01, 0.009,respectively)(Table.1).The T2WI volume reduction rate, ?K trans and ?K ep in the pCR group were significantly higher than those in the non-pCR group (p=0.016, 0.027,0.002,respectively)(Table.1).The AUCs of T2WI volume, post-treatment K ep , the T2WI volume reduction rate, ?K trans and ?K ep were 0.707,0.709,0.694,0.679,0.751,respectively(Figure.1).

CONCLUSION

Post-treatment T2WI volume and T2WI volume reduction rate, post-treatment K ep , ?K ep , ?K trans in DCE-MRI quantitative parameters may be useful in evaluating the pCR of local advanced rectal cancer after neoadjuvant immunotherapy.

CLINICAL RELEVANCE/APPLICATION

Accurately identifying patients with locally advanced rectal cancer who have achieved complete pathological remission after neoadjuvant immunotherapy thus guiding their watch and wait treatment decisions.

W5B-SPGI-3 TRANSIENT AND SHEAR-WAVE ELASTOGRAPHY IN THE DETECTION OF HEPATIC SINUSOIDAL OBSTRUCTION SYNDROME IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Valdair F. Muglia, MD, PhD (*Presenter*)
Leticia Helena Kaca Do Carmo (*Abstract Co-Author*)
Maria Tamyres De Carvalho Freitas, MD (*Abstract Co-Author*)
Rafaella Baratta Colla (*Abstract Co-Author*)
Tatiana Yumi Bando, MD (*Abstract Co-Author*)
Sarah Verdan, MD (*Abstract Co-Author*)
Matheus Martins de Andrade, MD (*Abstract Co-Author*)
Philipe Boud'Hors, MD (*Abstract Co-Author*)
Matheus Cipriano (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)

PURPOSE

Evaluate transient and shear elastography in detecting hepatic sinusoidal obstruction syndrome (SOS) or hepatic veno-occlusive disease (VOD) in patients submitted to hematopoietic stem cell transplantation (HSCT).

METHODS AND MATERIALS

The MEDLINE, EMBASE, and Cochrane databases were systematically accessed for studies that employed elastography in post-HSCT patients and that reported any of the following outcomes of interest: (1) measurement of shear wave velocity (SWV) pre and (2) post-transplantation, (3) liver stiffness values ??before and (4) after HSCT, and (5) incidence of alterations on conventional ultrasound during a suspicion of SOS or VOD. “Software R” (version 2024.04.2+764) was employed for statistical analysis. Heterogeneity was assessed using the I2 statistical model. The “QUADAS-2” tool assessed potential bias.

RESULTS

10 studies were included, totaling 589 patients, of which 100 were diagnosed with SOS. SWV showed a significant increase in patients with SOS (95% CI 1.3-7.1; p<0.01; I2=99%). Liver stiffness values also demonstrate a statistically significant increase in the context of SOS (95% CI 3,9-28,0; I2=91%, p<0,01). Conventional

ultrasound demonstrated a high rate of hepatomegaly, 93.1% (95% CI 74.9-99.8; I2=86%); 81.4% of patients with SOS presented ascites (95% CI 59.9-95.8; I2=88%); 62.6%, thickening of the gallbladder walls (95% CI 24.8-93.1; I2=92%); 31.6%, reduced flow in the portal vein (95% CI 10.2-58.2; I2=64%). Bias analysis showed a high risk in most included articles.

CONCLUSION

Transient and shear elastography are possible early diagnostic tools in cases of SOS.

CLINICAL RELEVANCE/APPLICATION

SOS, previously called Veno-Occlusive Disease (VOD), is a rare but potentially fatal complication after HSCT. The most reliable diagnostic methods for this condition include liver biopsy and hepatic venous pressure gradient measurement. However, they are invasive and expensive, leading to limited applicability. Both transient and shear elastography are effective methods in the early detection of SOS in patients submitted to HSCT. This allows for a more rapid treatment and a better prognosis. In the future, larger, prospective trials can help to define elastography as the primary diagnostic method for SOS.

W5B-SPGI-5 INTRAINDIVIDUAL EVALUATION OF LIVER MRI POST-INJECTION OF GADOPICLENOL COMPARED TO GADOBENATE DIMEGLUMINE

Shiva Yagobian, BS (*Presenter*)
Senthur J. Thangasamy, MD, DMRD (*Abstract Co-Author*)
Gayathri Devi Jalluri, MD, MBBS (*Abstract Co-Author*)
Alessandro Furlan, MD, MMM (*Abstract Co-Author*)

PURPOSE

To evaluate the enhancement of liver parenchyma on MRI following the administration of gadopiclenol and gadobenate dimeglumine.

METHODS AND MATERIALS

This IRB-approved retrospective study includes consecutive patients who underwent gadopiclenol-enhanced MR imaging of the liver between September and December 2023. Patients without a comparison gadobenate dimeglumine enhanced MR imaging of the liver performed within 18 months of the gadopiclenol MRI were excluded. Gadopiclenol was injected at 0.05 mmol/kg (0.1 ml/kg) and gadobenate dimeglumine at 0.1 mmol/kg (0.2 ml/kg). The signal intensity (SI) of the liver parenchyma was independently recorded by 2 experienced readers on the pre-contrast, 3 minutes post-contrast, and 5 minutes post-contrast imaging. Liver enhancement (LE) was calculated as (post-contrast SI - pre-contrast SI) / pre-contrast SI x100. Liver enhancement per ml of Gd (LE/ml) was calculated as LE/ml of contrast used. LE and LE/ml were compared using the Student's t-test.

RESULTS

A total of 71 patients (34 M, 37 F, average age 67 years) were included in the final population. 42/71 (59%) subjects were cirrhotic (MAFLD, 33%). Patients received an average of 8±1.7ml of gadopiclenol, and 16±3.5ml of gadobenate dimeglumine. The LE at 3 minutes (Reader 1, 108±40% vs. 130±69%; Reader 2, 106±94% vs. 104±61%) and 5 minutes (Reader 1, 91±30% vs. 100±37%; Reader 2, 92±37% vs. 97±40%) was not significantly different (P> 0.3) after injection of gadopiclenol and gadobenate dimeglumine. LE/ml with gadopiclenol was significantly higher than LE/ml with gadobenate dimeglumine at 3 minutes (Reader 1, 14±0.1% vs. 8±3%; Reader 2, 14±10% vs. 7±3%) and 5 minutes (Reader 1, 12 ±4% vs. 6±2%; Reader 2, 12±5% vs. 6±2%) post contrast administration (P<0.001).

CONCLUSION

Gadopiclenol exhibits superior liver enhancement per milliliter compared to gadobenate dimeglumine. However, at the approved dosage, the difference in liver enhancement between these two contrast agents is not statistically significant.

CLINICAL RELEVANCE/APPLICATION

In liver MR imaging, parenchymal enhancement of gadopiclenol as compared to gadobenate dimeglumine has yet to be studied extensively. Given that gadopiclenol exhibits greater liver enhancement per milliliter compared to gadobinate dimeglumine, additional studies are necessary to determine if a decreased dose of contrast may be used in future imaging, reducing the risk of gadolinium deposition.

W5B-SPGI-6 STUDY ON NOVEL IMAGING BIOMARKERS OF MAGNETIZATION TRANSFER TECHNIQUE BASED ON ULTRA-SHORT ECHO TIME SEQUENCE IN THE PROGRESSION OF NON-ALCOHOLIC FATTY LIVER DISEASE

Haoxiang Li, MD (*Presenter*)
Shaolin Li, PhD (*Abstract Co-Author*)
Jin Liu (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the diagnostic utility of ultra-short echo time magnetization transfer (UTE-MT) and zero echo time magnetization transfer (ZTE-MT) MRI quantitative techniques to find novel imaging biomarkers for non-alcoholic fatty liver disease (NAFLD) assessment.

METHODS AND MATERIALS

In the murine model, NAFLD was induced in 8 male C57BL/6 mice via a high-fat diet, with 8 standard-diet-fed mice as controls. Imaging was performed at 8 and 12 weeks using UTE-MT, ZTE-MT, UTE-T2*, UTE-T1?, and IDEAL-IQ sequences. Liver histology was evaluated for Collagen I and lipid content through staining, and serum lipid metabolism markers were quantified. In the human cohort, 12 patients diagnosed with non-alcoholic fatty liver (NAFL), 11 with non-alcoholic steatohepatitis (NASH), and 24 healthy controls were enrolled. Hepatic imaging was conducted using UTE-MT, ZTE-MT, UTE-T2*, and IDEAL-IQ sequences on a 3.0T MRI system. Imaging biomarkers, including liver UTE-MTR, ZTE-MTR, UTE-T2* values, and MR-PDFF, were analyzed in both models..

RESULTS

In the murine model, UTE-MTR, ZTE-MTR, T1?, and MR-PDFF significantly correlated with hepatic Collagen I and lipid content, with UTE-MTR showing the strongest correlation. These parameters also correlated with serum triglycerides and total cholesterol, while UTE-T2* showed no significant associations. In humans, UTE-MTR and ZTE-MTR were significantly reduced in NAFL and NASH compared to controls ($P < 0.01$), with UTE-MTR further decreased in NASH versus NAFL ($P < 0.05$). MR-PDFF was elevated in NAFL and NASH compared to controls ($P < 0.01$) and higher in NASH than NAFL ($P < 0.01$). UTE-T2* values showed no significant differences across groups. Receiver operating characteristic (ROC) analysis confirmed that UTE-MTR and ZTE-MTR provided robust diagnostic accuracy for distinguishing healthy controls, NAFL, and NASH.

CONCLUSION

UTE-MT and ZTE-MT techniques enable accurate, non-invasive assessment of NAFLD stages in murine and human models, effectively differentiating healthy individuals, NAFL, and NASH. UTE-MTR and ZTE-MTR, as reliable imaging biomarkers, show strong correlations with fibrosis, inflammation, hepatic tissue, and serological markers. Integrating these MRI sequences enhances diagnostic precision and supports clinical decision-making, offering a promising strategy for monitoring NAFLD progression.

CLINICAL RELEVANCE/APPLICATION

UTE-MT and ZTE-MT MRI techniques provide novel imaging biomarkers (UTE-MTR, ZTE-MTR) for accurate NAFLD staging, reducing reliance on invasive biopsies. Their strong correlations with disease markers enable early detection, precise monitoring of NAFL and NASH progression, and evaluation of treatment responses, improving clinical outcomes.

W5B-SPGI-7 PROGNOSTIC VALUE OF THE NODE REPORTING AND DATA SYSTEM FOR PREDICTING EARLY RECURRENCE IN PATIENTS WITH PANCREATIC DUCTAL ADENOCARCINOMA FOLLOWING PANCREATICODUODENECTOMY

Yuqi Wang (*Presenter*)
Yu Li (*Abstract Co-Author*)
Jing Zhu (*Abstract Co-Author*)
Yan Deng (*Abstract Co-Author*)
Haopeng Yu (*Abstract Co-Author*)
Zixing Huang (*Abstract Co-Author*)
Bin Song (*Abstract Co-Author*)

PURPOSE

To evaluate the preoperative predictive performance of the Node Reporting and Data System (Node-RADS) for early recurrence in pancreatic ductal adenocarcinoma (PDAC) patients undergoing pancreaticoduodenectomy.

METHODS AND MATERIALS

This retrospective study included 138 patients with pathologically confirmed PDAC who underwent pancreaticoduodenectomy and preoperative contrast-enhanced abdominal CT between 2020 and 2023. Lymph nodes with a short-axis diameter = 4 mm (from diaphragmatic dome to lower renal poles) were evaluated by one radiologist using the Node-RADS classification. Pathological N stage was according to the AJCC TNM classification (8th edition). Recurrence-free survival (RFS) was collected, with RFS =12 months defined as early recurrence. For each patient, the total Node-RADS score and total configuration were calculated both overall and within each lymph node station. Time-dependent receiver operating characteristic (timeROC) analysis was used to assess the predictive performance of Node-RADS metrics and pathological N stage. Univariate and multivariate Cox regression were used to identify independent predictors of early recurrence.

RESULTS

84 male and 54 female patients (median age, 61 years; IQR, 54-69 years) were included. The median RFS was 18.0 months (95% CI: 13.0-21.0), with 44 patients experienced recurrence within 12 months. AUCs for early recurrence prediction were: Node-RADS total score 0.601 (95% CI: 0.479-0.723), configuration score 0.562 (95% CI: 0.438-0.686), and pathological N stage 0.608 (95% CI: 0.500-0.717). Univariate Cox analysis showed total Node-RADS score (p=0.0328) and total configuration score (p=0.0382) were significant. Among specific nodal stations, No.16a2 score (p = 0.00615), No.3 and No.7 score (p = 0.0400), and configuration of No.16a2 (p = 0.0365), showed significant associations with early recurrence. In multivariate analysis, both score and configuration of No.16a2 remained independent predictors (p=0.0391 and 0.0346).

CONCLUSION

Node-RADS total and configuration scores showed comparable predictive value to pathological N stage in identifying early recurrence. No.16a2 demonstrated independent prognostic significance, indicating its utility in recurrence risk stratification.

CLINICAL RELEVANCE/APPLICATION

Node-RADS provides a noninvasive, preoperative approach to assess the risk of early recurrence in patients with PDAC. The configuration and total scores of No.16a2 were independently associated with early recurrence, which is a novel and practical insight for surgical decision-making. Node-RADS may serve as a valuable imaging biomarker to support clinical strategies, promoting individualized treatment planning and improving patient outcomes.

W5B-SPGI-8 DEVELOPMENT AND VALIDATION OF A DEEP LEARNING MODEL FOR PREDICTING SIGNIFICANT LIVER FIBROSIS BASED ON GD-EOB-DTPA-ENHANCED MRI: A MULTICENTER STUDY

Yi Luo (*Presenter*)
Genwen Hu, MD (*Abstract Co-Author*)
Shuyuan Zhong, MD (*Abstract Co-Author*)
Jinsen Zou, MD (*Abstract Co-Author*)

PURPOSE

To construct a deep learning (DL) model based on Gd-EOB-DTPA-enhanced MRI to distinguish non-significant liver fibrosis from significant liver fibrosis, and to explore the effect of different regions of interest (ROIs) on the diagnostic performance of the significant liver fibrosis prediction model.

METHODS AND MATERIALS

A total of 305 patients who underwent liver Gd-EOB-DTPA-enhanced MRI from April 2016 to May 2023 in two medical centers were retrospectively collected, and the stage of liver fibrosis was confirmed by pathological examination or clinical evaluation. The patients were divided into training set and external validation set according to medical center. Four models (ROI 1 , ROI 3 , ROI 5 , ROI all models) were constructed based on different ROIs of HBP sequence (the largest slice of liver, the largest slice and one layer above and below it, the largest slice and two layers above and below it, all layers) to distinguish non-significant and significant liver fibrosis. To evaluate the performance of each model and the optimal ROI was selected. T1WI-FS and T2WI-FS images were preprocessed in the same way according to the optimal ROI, and the three sequences were fused at image-level to construct a multimodal DL model. The receiver operating characteristic (ROC) curve, calibration curve and decision curve were used to visualize the predictive ability of the model, and the accuracy, sensitivity and specificity of the model were calculated.

RESULTS

Among the DL models based on the four ROIs, the ROI 5 model showed the best comprehensive diagnostic efficiency in the diagnosis of significant liver fibrosis in the training set and validation set, with AUC values of 0.870 and 0.716, respectively. It was superior to ROI 1 (validation AUC=0.666), ROI3 (validation AUC=0.708) and ROIall (validation AUC=0.665). The AUC of the training set and the validation set of the multimodal MRI model constructed by fusing T1WI-FS, T2WI-FS and HBP were 0.907 (95%CI, 0.866-0.948) and 0.796 (95%CI, 0.712-0.881), respectively. DCA results indicated that the prediction model for liver fibrosis staging could yield a net clinical benefit.

CONCLUSION

The deep learning model based on the MRI images of the maximum slice and the two layers above and below has the best performance in the diagnosis of non-significant and significant liver fibrosis, which establishes a new paradigm for the prediction of liver fibrosis staging in small samples.

CLINICAL RELEVANCE/APPLICATION

The deep learning model based on Gd-EOB-DTPA-enhanced MRI shows good sensitivity and specificity in predicting significant liver fibrosis, which is expected to become a non-invasive tool to guide the clinical individualized treatment of patients with liver fibrosis.

W5B-SPGI-10 INTEGRATED PET-MR IN PERIANAL FISTULIZING CROHN'S DISEASE: METABOLIC AND STRUCTURAL CORRELATES OF HEALING IN A PROSPECTIVE COHORT

Favour O. Garuba, MD (*Presenter*)
Addie Lovato (*Abstract Co-Author*)
Tyler J. Fraum, MD (*Abstract Co-Author*)
Malak Itani, MD (*Abstract Co-Author*)
Parakkal Deepak, MBBS (*Abstract Co-Author*)
David H. Ballard, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility of PET-MRI and examine early metabolic and structural imaging trends in patients with perianal fistulizing Crohn's disease (pfCD) initiating biologic therapy.

METHODS AND MATERIALS

This prospective cohort included 10 pfCD patients (mean age 36 years; 6 male), 4 of whom underwent serial PET-MR. Each PET-MR study incorporated co-registered FDG PET with pelvic MRI, including T2-weighted and post-contrast T1-weighted sequences. Tract complexity, fibrosis-to-fluid ratios, MAGNIFI-CD and mVAI scores, and FDG avidity were assessed. CAF-QoL was recorded at up to four timepoints. Radiologic healing was defined by absence of T2 hyperintensity, absence of enhancement, and complete fibrosis. PET uptake was described relative to liver background and correlated with tract morphology.

RESULTS

Three patients had complete 24-week MAGNIFI-CD data. One met criteria for radiologic healing (score = 0) with no FDG uptake. The other two demonstrated persistent disease (scores = 18.0 and 25.0) and had either high FDG uptake or mixed fibrosis-to-fluid characteristics. One patient showed a partially scarred tract with low FDG activity and low symptom burden (CAF-QoL = 12). In a serially imaged case, MRI morphology and MAGNIFI-CD score remained stable over time, with persistent FDG uptake and mild worsening in CAF-QoL. Among patients with fibrotic-appearing tracts and absent FDG activity, symptoms were minimal or improved.

CONCLUSION

In this early pfCD cohort, persistent FDG activity aligned with non-healed tracts on MRI, while PET-negative tracts correlated with fibrotic morphology and clinical stability. PET-MR may help identify metabolically active disease despite stable MR appearance and could support decision-making in ambiguous or clinically discordant cases.

CLINICAL RELEVANCE/APPLICATION

In pfCD, PET-MR provides a noninvasive biomarker of tract activity that may refine longitudinal response assessment, particularly in patients with stable MR morphology but unclear symptom or inflammatory status.

W5B-SPGI-12 QUANTITATIVE MULTI-PARAMETER PREDICTION OF IMMUNOTHERAPY RESPONSE IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA USING SPECTRAL CT

Yan Liu, MD (*Presenter*)
Huang Jian (*Abstract Co-Author*)
Shuting Zhong (*Abstract Co-Author*)

PURPOSE

To investigate the value of quantitative parameters derived from spectral computed tomography (CT) in predicting the therapeutic efficacy of immunotherapy for esophageal squamous cell carcinoma (ESCC).

METHODS AND MATERIALS

This retrospective study included 50 patients with pathologically confirmed ESCC who underwent contrast-enhanced spectral CT of the chest and abdomen prior to immunotherapy. Two radiologists independently evaluated treatment response. Quantitative spectral parameters including arterial phase CT values at 70, 100, and 140 keV (A-CT70 keV , A-CT100 keV , A-CT140 keV), iodine concentration (A-IC), water concentration (A-WC), effective atomic number (A-Zeff), and the slope of the spectral attenuation curve (A-?HU) were measured. Additionally, non-contrast and arterial phase CT value differences (?CT700 keV , ?CT140 keV) were calculated. Differences in parameters between effective and ineffective groups were compared. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of treatment response. Receiver operating characteristic (ROC) curves were generated to assess diagnostic performance, and area under the curve (AUC), sensitivity, and specificity were calculated.

RESULTS

Significant differences were observed between the effective and ineffective groups for A-CT100 keV , A-CT140 keV , A-WC, and ?CT140 keV ($P < 0.05$), whereas A-IC, A-Zeff, ?CT70 keV , and A-?HU showed no significant differences ($P > 0.05$). Univariate logistic regression identified A-CT140 keV , A-WC, and ?CT140 keV as significantly correlated with therapeutic efficacy ($P < 0.05$). However, A-CT100 keV was not independently associated with treatment response ($P > 0.05$). Multivariate analysis demonstrated that A-CT140 keV and A-WC were independent predictors of immunotherapy efficacy ($P < 0.05$). The AUCs for predicting immunotherapy response were 0.733 (95% CI: 0.587-0.849) for A-CT140 keV and 0.796 (95% CI: 0.657-0.898) for A-WC. A combined model incorporating both A-CT140 keV and A-WC achieved a higher AUC of 0.844 (95% CI: 0.711-0.931), outperforming the individual parameters.

CONCLUSION

Quantitative spectral CT parameters, particularly A-CT140 keV and A-WC, are valuable predictors of immunotherapy response in ESCC. A combined model using A-CT140 keV and A-WC further improves predictive performance, providing a potential non-invasive imaging biomarker for therapeutic stratification.

CLINICAL RELEVANCE/APPLICATION

Spectral CT-derived quantitative parameters enable early prediction of immunotherapy efficacy in ESCC. Combining multiple spectral biomarkers enhances predictive accuracy and may assist in optimizing patient selection and management strategies.

W5B-SPGI-13 CT-DETECTED "JELLYFISH SIGN": A SIMPLE BUT POWERFUL PREDICTOR OF SURVIVAL IN STAGE II/III MICROSATELLITE STABILITY COLON CANCER

Zhen Guan (*Presenter*)
Xiao-Yan Zhang (*Abstract Co-Author*)
Tong Tong, PHD (*Abstract Co-Author*)
Ying-shi Sun, PhD (*Abstract Co-Author*)

PURPOSE

Despite advances in TNM staging, significant prognostic heterogeneity persists in stage II/III microsatellite-stable (MSS) colon cancer. We identified and validated a novel CT-based "Jellyfish Sign" - characterized by distinctive pericolonic fat density changes - as a potential imaging biomarker to refine risk stratification beyond conventional parameters.

METHODS AND MATERIALS

In this dual-center prognostic study, we retrospectively analyzed 382 consecutive patients with pathologically confirmed stage II/III MSS colon cancer who underwent preoperative contrast-enhanced CT and curative resection. The discovery cohort comprised 285 patients from tertiary Center A (2013-2016), while 97 patients from Center B (2012-2013) served as the independent validation cohort. The "Jellyfish Sign" was rigorously defined as: (1) asymmetric fat stranding forming a circumferential halo around the tumor, (2) containing nodular or band-like hyperdense foci, and (3) showing infiltrative margins. Two abdominal radiologists (15/8 years' experience) independently evaluated all scans. Comprehensive survival analyses included multivariable Cox regression adjusting for TNM stage, CEA levels, and histological grade, with time-dependent ROC analysis assessing predictive performance.

RESULTS

The striking "Jellyfish Sign" was detected in 36.5% (104/285) and 34.0% (33/97) of discovery/validation cohorts respectively (?=0.82, substantial inter-reader agreement). Multivariable analysis confirmed its independent prognostic value for both death (HR 3.29, 95%CI 1.64-6.60) and recurrence (HR 5.07, 95%CI 2.91-8.83), surpassing conventional risk factors. The combined clinical-imaging model achieved outstanding discrimination (AUC 0.854 for survival, 0.811 for recurrence) with robust validation (AUC 0.722-0.741).

CONCLUSION

The "Jellyfish Sign" represents a biologically plausible, readily identifiable CT biomarker that powerfully predicts adverse outcomes in stage II/III MSS colon cancer, potentially reflecting occult peritumoral tumor microenvironment alterations.

CLINICAL RELEVANCE/APPLICATION

This immediately applicable imaging marker addresses a critical unmet need in precision oncology by: (1) Identifying high-risk stage II patients who may benefit from adjuvant chemotherapy, (2) Detecting aggressive biology in stage III cases warranting intensified regimens, and (3) Providing prognostic information without additional costs or invasive procedures.

W5B-SPGI-14 IMAGING AND CLINICAL FEATURES OF SURGICALLY RESECTED SEROUS CYSTADENOMA OF THE PANCREAS: A MULTICENTER STUDY

Ji Eun Lee, MD, PhD (*Presenter*)
Seo-Youn Choi, MD, PhD (*Abstract Co-Author*)

PURPOSE

Despite advances in pancreatic imaging, serous cystadenoma (SCA)—a benign pancreatic cystic neoplasm—is still frequently resected due to diagnostic uncertainty or clinical concerns. This multicenter study evaluates preoperative imaging findings and clinical factors leading to surgical intervention in patients with pathologically confirmed SCA.

METHODS AND MATERIALS

We retrospectively reviewed 82 patients (55 women; mean age 57.0 ± 13.9 years) who underwent surgical resection for SCA between 2018 and 2025 across multiple institutions. Clinical indications for surgery and preoperative CT and MRI features were assessed. Two abdominal radiologists independently reviewed tumor morphology, ductal involvement, and imaging characteristics that could mimic other pancreatic neoplasms.

RESULTS

Among the 82 patients, 45 (54.9%) underwent resection based on personal preference, 20 (24.4%) due to radiologic suspicion of other neoplasms, and 10 (12.2%) due to clinical symptoms, most commonly abdominal pain. Elevated CA19-9 (>37 U/mL) was observed in 14 patients (17.1%), contributing to diagnostic uncertainty. On CT, enhancing mural nodules were noted in 5 patients (6.1%), thickened enhancing cyst walls in 28 (34.1%), and main pancreatic duct (MPD) dilatation in 16 (19.5%). MRI showed mural nodules in 8 patients (9.8%), thickened cyst walls in 26 (31.7%), and MPD dilatation in 13 (15.9%). MPD communication and abrupt caliber change were seen in 8 (9.8%) and 7 (8.5%) on CT, and in 11 (13.4%) and 5 (6.1%) on MRI, respectively. Branch-duct IPMN was the most common imaging mimic, suspected in 39.0% of CT and 42.7% of MRI evaluations.

CONCLUSION

More than half of SCA resections were patient-initiated rather than driven by definitive clinical or radiologic indications. Imaging features mimicking other cystic neoplasms and elevated CA19-9 levels often contributed to surgical decisions. Radiologists play a crucial role in recognizing imaging features suggestive of benign SCA and communicating this possibility to referring clinicians. Where appropriate, suggesting imaging follow-up rather than immediate surgery may help reduce overtreatment.

CLINICAL RELEVANCE/APPLICATION

Improved characterization of pancreatic cystic lesions and radiologist-led communication can support shared decision-making and potentially avoid unnecessary surgical resections of benign entities like serous cystadenoma.

W5B-SPGI-15 APPLICATION OF MULTI-ECHO T2* MAPPING COMBINED WITH FLIS IN PREOPERATIVE LIVER FUNCTION ASSESSMENT OF SMALL HCC: COMPARATIVE ANALYSIS WITH DUAL SOURCE CT EXTRACELLULAR VOLUME FRACTION

Shao Peng Li II, DO (*Presenter*)
Ying Liu (*Abstract Co-Author*)
Dawei Yin (*Abstract Co-Author*)
Peng Wang (*Abstract Co-Author*)
Chen Xudan (*Abstract Co-Author*)

PURPOSE

Using the 15 minute indocyanine green retention rate (ICG R-15) as the reference standard, the diagnostic value of functional liver imaging score(FLIS) combined with T2* mapping for preoperative assessment of liver reserve function in small hepatocellular carcinoma (sHCC) was compared, and compared with the extracellular volume fraction(ECV) based on dual source CT equilibrium iodine map.

METHODS AND MATERIALS

A retrospective analysis was conducted on 72 patients with sHCC who had preoperative imaging findings between July 2022 and December 2024. All patients underwent Gd-EOB-DTPA-enhanced MRI and dua- source CT liver dynamic enhancement scan. Measure the R2 * values of normal liver tissue in the left, right anterior, and right posterior lobes of the liver using multi echo T2 * mapping sequences, and take the average value. Three features of the hepatobiliary phase were assessed: normal liver parenchyma, biliary system and portal vein signal intensity, and FLIS was calculated. Calculate ECV in the equilibrium iodine diagram: ECV(%)=ID liver ×(1-Hct (%))/ID aorta . All patients underwent ICG retention test and were divided into three groups (32 patients in group 1 <10%, 25 patients in group 2 10%-20% and 15 patients in group 3 =20%). Statistical analysis was conducted on the differences between three groups of normal liver R2* values, FLIS, and ECV.

RESULTS

The R2* values, FLIS, and ECV among the three groups were (39.73 ± 2.59) Hz, (45.78 ± 2.51) Hz, (57.45 ± 4.96) Hz; (4.75 ± 1.11), (3.56 ± 0.92), (1.53 ± 0.91); and (16.63 ± 5.42)%, (28.42 ± 2.88)%, (40.39 ± 4.74)%, respectively. The area under the ROC curve (AUC) for R2* values, FLIS, and ECV between Group 1 and Group 2 was 0.8916, 0.809, and 0.924, respectively, and between Group 2 and Group 3 was 0.891, 0.864, and 0.923. ECV demonstrated the strongest diagnostic performance among the three groups, followed by R2* values and FLIS. The combination of these parameters improved diagnostic efficacy (AUC: 0.921, 0.955).

CONCLUSION

FLIS and R2* values can accurately assess preoperative hepatic functional reserve in patients with sHCC. Their combined diagnostic efficacy is superior to that of dual-source CT-derived ECV. The multi-echo T2* mapping sequence offers shorter scan times, and its combination with hepatobiliary-phase FLIS effectively predicts hepatic functional reserve, demonstrating significant clinical value.

CLINICAL RELEVANCE/APPLICATION

Multi echo T2* mapping sequence combined with Gd-EOB-DTPA-enhanced mri can effectively predict liver reserve function without radiation.

W5B-SPGI-16 IMPROVEMENT OF IMAGE QUALITY OF ABDOMINAL DIFFUSION-WEIGHTED IMAGING WITH DEEP LEARNING RECONSTRUCTION

Kumi Ozaki, MD, PhD (*Presenter*)

PURPOSE

To assess image quality and apparent diffusion coefficient (ADC) values of DWI with compressed sense and model-based deep learning (DL) reconstruction (AICS-DWI) in the abdomen by comparing with DWI with compressed sense (CS-DWI).

METHODS AND MATERIALS

We retrospectively analyzed the 61 patients (23 men and 38 women, mean age, 65.0 years) who underwent abdominal DWI. We conducted both quantitative and qualitative evaluations to compare compressed AICS-DWI and CS-DWI. For the qualitative assessment, we visually evaluated the overall image quality, noise, contour, and distortion of the liver, pancreas, and spleen using a five-point scale. In the quantitative assessment, we measured the signal-to-noise ratio (SNR) and apparent diffusion coefficient (ADC) for the lateral, medial anterior, and posterior segments of the liver, pancreas, spleen, and paraspinal muscle. We then compared the qualitative and quantitative parameters between AICS-DWI and CS-DWI for each organ and across liver segments.

RESULTS

The mean image quality scores for liver and pancreas contours, distortion of the liver, image noise, and overall image quality were higher in AICS-DWI compared with CS-DWI ($p < 0.05$). SNR in AICS-DWI was higher than in CS-DWI ($p < 0.05$) other than the lateral segment. ADC values of AICS-DWI were significantly lower than those of CS-DWI ($p < 0.05$) in all organs. SNR and ADC values of the lateral segment were significantly different than those of other segments in CS-DWI and AICS-DWI ($p < 0.05$).

CONCLUSION

Model-based DL reconstruction technique enhanced both qualitative and quantitative aspects of image quality in abdominal DWI.

CLINICAL RELEVANCE/APPLICATION

Model-based deep learning reconstruction for abdominal diffusion-weighted imaging provides improved image quality with reduced noise and distortion while maintaining diagnostic accuracy, potentially enhancing lesion detection and characterization in clinical practice without requiring additional scan time.

W5B-SPGU-3 DIAGNOSTIC VALUE OF MULTIPARAMETRIC MRI COMBINED WITH QUALITATIVE AND QUANTITATIVE FEATURES IN DETECTING VASCULAR WALL INVASION BY INFERIOR VENA CAVA TUMOR THROMBUS IN RENAL CELL CARCINOMA

Xuewei Wen (*Presenter*)
Haiyi Wang, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the preoperative diagnostic value of multiparametric MRI combined with qualitative and quantitative features for detecting vascular wall invasion by inferior vena cava (IVC) tumor thrombus in renal cell carcinoma.

METHODS AND MATERIALS

This retrospective study analyzed 173 consecutive patients with renal carcinoma and inferior vena cava (IVC) tumor thrombus who underwent radical resection at our institution. Based on surgical and pathological findings, patients were divided into vascular wall invasion (n=73) and non-invasion (n=100) groups. Preoperative MRI evaluated quantitative parameters (tumor size, thrombus dimensions, ADC values, venous diameters) and qualitative features (thrombus-vessel wall relationship, wall integrity, luminal obstruction, morphology). Statistical analysis included t-tests/Mann-Whitney U tests for continuous variables and ?²/Fisher's tests for categorical variables. Significant predictors (P<0.05) were analyzed using logistic regression, with diagnostic performance assessed by ROC analysis and the DeLong test.

RESULTS

Univariate analysis showed significant intergroup differences in thrombus penetration, vascular wall irregularity, signal interruption, IVC obstruction, thrombus dimensions, and venous diameters (P<0.05). Logistic regression identified thrombus penetration (OR=11.40, 95%CI 1.85-14.73) and concomitant thrombosis (OR=17.34, 95%CI 1.45-12.47) as independent predictors. The combined model's AUC was 0.811 (95%CI 0.87-0.96), surpassing individual parameters (DeLong test, P<0.05).

CONCLUSION

The multiparametric MRI-based integrated diagnostic model effectively identifies IVC vascular wall invasion, with tumor thrombus protrusion and concomitant thrombosis serving as core predictive indicators.

CLINICAL RELEVANCE/APPLICATION

This study systematically evaluated subjective imaging features associated with inferior vena cava (IVC) wall invasion in renal cell carcinoma (RCC) to provide reliable preoperative imaging assessment criteria.

W5B-SPGU-4 DUAL-CONDITIONED DIFFUSION MODEL WITH ANATOMICAL GUIDANCE FOR PROSTATE DWI ARTIFACT CORRECTION

Inye Na, BS (*Presenter*)
Kyunghyun Sung, PhD (*Abstract Co-Author*)
Hyunjin Park (*Abstract Co-Author*)

PURPOSE

Geometric distortion in diffusion-weighted imaging (DWI) significantly impacts prostate MRI quality. We propose a dual-conditioned generative diffusion model (DeDistortNet) to correct geometric distortion in prostate DWI using anatomical guidance from T2-weighted images.

METHODS AND MATERIALS

A total of 328 DWI cases were utilized from the PROSTATEx dataset. Data were split at the patient level according to the degree of distortion. Training (n=135, 1,893 slices) and validation (n=4, 64 slices) sets included distortion-free samples, while cases with varying distortion levels: no distortion (243), mild (=2mm, 1,164), moderate (=4mm, 816), severe (=6mm, 298), and extreme (>6mm, 102), were used for testing (n=189, 2623 slices). Since obtaining paired undistorted-distorted DWI data is challenging, distortion was simulated using elastic deformation with Jacobian-based intensity adjustment focused on the peripheral and rectal area, anteroposterior axis scaling, rotation, and translation. DeDistortNet was trained with three-channel simulated distorted DWIs (b-values 50, 400, 800) and single-channel T2-weighted images. Structural conditioning was achieved using ControlNet with T2-weighted images, and contextual conditioning utilized distorted DWIs processed by a modified CLIP encoder. Performance was evaluated using the Dice similarity coefficient (DSC) between prostate masks from T2 and DWI, where the DWI masks were generated via a 2D nnUNet model trained on T2 prostate masks from the training set (distortion-free). A higher DSC thus indicates that DeDistortNet generates realistic DWIs aligned accurately with T2.

RESULTS

Baseline DSC declined with increasing distortion severity: No distortion (0.922±0.066), Mild (0.904±0.077), Moderate (0.875±0.072), Severe (0.828±0.091), Extreme (0.725±0.116). DeDistortNet significantly improved DSC: No distortion (0.924±0.076), Mild (0.923±0.079), Moderate (0.925±0.074), Severe (0.918±0.090), Extreme (0.929±0.064). Statistical tests showed significant baseline differences among severity groups ($p<0.001$), but no significant differences after correction ($p=0.929$). Pairwise comparisons with baseline no distortion were significant at baseline (all $p<0.001$) and non-significant after correction (all $p>0.01$), confirming effective correction comparable to baseline distortion-free levels.

CONCLUSION

DeDistortNet effectively corrects geometric distortion in prostate DWI through dual-conditioned diffusion modeling, enhancing anatomical alignment and realistic DWI features.

CLINICAL RELEVANCE/APPLICATION

AI-assisted DWI artifact correction has the potential to improve clinical decision-making by enhancing anatomical and contextual imaging information.

W5B-SPGU-5 OPTIMIZATION OF BREATH-HOLD 3D-GRASE MR UROGRAPHY: IMPACT OF TSE, EPI FACTORS AND TE ON IMAGE QUALITY AND SCAN EFFICIENCY

Jia Hao Chun (*Presenter*)

PURPOSE

To evaluate the technical advantages of breath-hold 3D gradient and spin-echo (BH-GRASE) MR urography using different combinations of turbo spin echo (TSE) factors, echo planar imaging (EPI) factors, and echo times (TE), and to compare these with conventional respiratory-triggered fast spin echo (RT-FSE) sequences in terms of image quality and scan time.

METHODS AND MATERIALS

This prospective study enrolled 44 patients who underwent MR urography between October 2023 and March 2024. Each patient was scanned using four different BH-GRASE protocol settings (varied TSE, EPI, and TE) and a standard RT-FSE MRU sequence. Quantitative metrics including scan time, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were analyzed. Qualitative assessments including image quality, artifact severity, and the visibility of bilateral ureters, renal pelvis, and bladder were rated using a 4-point Likert scale by two independent radiologists. Statistical analyses included Wilcoxon signed-rank test, paired t-test, and Kappa agreement testing.

RESULTS

Among the four BH-GRASE settings, the protocol with TSE:7, EPI:7, TE:105 (Group 3) demonstrated significantly superior SNR and CNR compared to Groups 1, 2, and 4 ($P<0.05$), with no significant difference from the conventional RT-FSE sequence. Group 3 achieved acceptable diagnostic quality within 19 seconds. Inter-reader agreement was good to excellent (Kappa = 0.758-0.813). The scan time for BH-GRASE sequences was significantly shorter than that for RT-FSE MRU (14-21s vs. 170-240s, $P<0.05$)

CONCLUSION

The optimized BH-GRASE MRU protocol (TSE:7, EPI:7, TE:105) enables high-quality 3D imaging of the urinary tract within a single breath-hold of less than 20 seconds, offering comparable diagnostic utility to RT-FSE while significantly reducing acquisition time. This technique is especially advantageous in patients with irregular breathing patterns or limited breath-hold capacity, supporting its routine clinical use in fast MR urography.

CLINICAL RELEVANCE/APPLICATION

The optimized breath-hold 3D-GRASE MR urography protocol (TSE:7, EPI:7, TE:105) significantly reduces scan time while maintaining comparable diagnostic image quality to conventional RT-FSE sequences. This rapid acquisition technique improves workflow efficiency and enhances patient tolerance, particularly in individuals with irregular or shallow breathing. It is clinically valuable for routine evaluation of urinary tract pathologies, enabling high-resolution imaging within a single breath-hold, and may reduce the need for repeated scans due to motion artifacts.

W5B-SPGU-6 MRI PARAMETERS PREDICTING PATHOLOGICALLY PROVEN PROGRESSION IN PROSTATE CANCER PATIENTS ON ACTIVE SURVEILLANCE

Siriluck Satonkiatngam, MD (*Presenter*)
Ida Sonni, MD (*Abstract Co-Author*)
Sophie Boeun (*Abstract Co-Author*)
Steven S. Raman, MD (*Abstract Co-Author*)

PURPOSE

To evaluate baseline multiparametric MRI (mpMRI) features associated with pathologically proven progression in prostate cancer patients on active surveillance

METHODS AND MATERIALS

We retrospectively reviewed 109 patients with low- and intermediate-risk prostate cancer (Gleason grade group 1-2) on active surveillance from 2011-2022. Pathological progression was defined as Gleason grade group upgrade on follow-up biopsy. Baseline imaging parameters—including prostate volume, lesion size, ADC value, dynamic contrast-enhanced (DCE) metrics (Ktrans, Kep, iAUC), PI-RADS T2 score, overall PI-RADS score, and UCLA scores—were assessed. Baseline PSA and PSA density were also collected. Univariable Cox proportional hazard regression was used to evaluate associations with progression. Harrell's C-statistic assessed discriminative performance

RESULTS

Fifty-nine patients (54.1%) had pathologically confirmed progression: 28.4% to grade group 2, 14.7% to group 2 and 3, and 11.0% to group 3. Median time to progression was 3.7 years (IQR 2.9-4.6). Higher baseline PI-RADS T2 score (HR 2.18, $p<0.001$), overall PI-RADS score (HR 2.67, $p<0.001$), and UCLA score (HR 2.21, $p<0.001$) were significantly associated with progression. PSA and PSA density were not significantly associated with progression. Overall PI-RADS and UCLA scores showed the strongest discriminative performance (C-statistics 0.66 and 0.62, respectively)

CONCLUSION

PI-RADS T2 score, overall PI-RADS score, and UCLA score on baseline MRI can help predict progression in patients on active surveillance

CLINICAL RELEVANCE/APPLICATION

Baseline MRI parameters can help identify patients at higher risk of progression who may benefit from closer imaging or biopsy surveillance during active surveillance

W5B-SPHN-1 ARTIFICIAL INTELLIGENCE IN ULTRASOUND DETECTION OF MALIGNANT AND BENIGN THYROID NODULES, INSIGHTS FROM A UAE NATIONAL STUDY AND A SYSTEMATIC REVIEW

Abdulrahman Ali, BSc, MBBS (*Presenter*)
Shahd Alsalehi, MBBS (*Abstract Co-Author*)
Mohammad Al Homsi, MBBS (*Abstract Co-Author*)

PURPOSE

Thyroid nodules are common in the general adult population with up to 65% prevalence when detected via ultrasound. Fortunately, only around 10% are malignant. Given this low percentage, it is essential to properly classify thyroid nodules to avoid overdiagnosis. This study aims to explore the efficacy of Artificial intelligence (AI) in the diagnosis of thyroid nodules on ultrasound using both primary and secondary research methodologies.

METHODS AND MATERIALS

We conducted a systematic review of articles employing AI to classify thyroid nodules as benign or malignant on ultrasound. Utilizing the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines and appropriate keywords, we searched for original articles from PubMed and Scopus published between 2018 and 2024. The performance metrics (such as sensitivity and specificity) of the AI algorithms were pooled, and their accuracy was compared with fine-needle aspiration (FNA) biopsy (the presumed gold standard). Additionally, we developed a custom AI tool that leverages deep learning neural networks and Support Vector Machines (SVM) to classify thyroid nodule ultrasound images as benign or malignant. This tool was trained and validated using a locally curated dataset from UAE hospitals, utilizing FNA results as the ground truth.

RESULTS

A total of 25 articles satisfied the inclusion and exclusion criteria, of which 90% were retrospective studies. The sample size of the studies ranged between 110 patients with 122 nodules and 8,339 Patients with 18,049 nodules. 80% of the AI models used were deep learning algorithms of which convoluted neural networks were the most common. Most of the articles reported accuracy, sensitivity, specificity and AUC using FNA results as the gold standard. The performance ranged from approximately 0.837 to 0.99 for AUC, 74.0 to 94.8% for accuracy, 67.5 to 98.8% for sensitivity and 52.0 to 95% for specificity. Our tool demonstrated improved sensitivity and comparable specificity when applied to the UAE dataset.

CONCLUSION

AI classification of thyroid nodules on ultrasonography showed good concordance with FNA results. Limitations included employing black-box models with limited explainability and external validation. In contrast, our locally developed AI tool demonstrated reliable performance on the UAE dataset, emphasizing the importance of context-specific model training.

CLINICAL RELEVANCE/APPLICATION

We are addressing the critical need to assess AI's potential to enhance diagnostic accuracy and improve patient outcomes. Additionally, we tackle the challenge of context-relevant modeling by developing a UAE-specific AI tool, enhancing both performance and explainability in regional healthcare settings.

W5B-SPHN-2 EFFICACY OF MULTIPARAMETRIC MRI WITH MR FINGERPRINTING FOR DIFFERENTIATING BENIGN AND METASTATIC CERVICAL LYMPH NODE IN HEAD AND NECK SQUAMOUS CELL CARCINOMA

Jimin Kim, MD (*Presenter*)
Se Won Oh, MD, PhD (*Abstract Co-Author*)
Ha Young Lee (*Abstract Co-Author*)
Moon Hyung Choi, MD (*Abstract Co-Author*)
Min Kyoung Lee, MD (*Abstract Co-Author*)
Dongyeob Han, PhD (*Abstract Co-Author*)
Heiko Meyer (*Abstract Co-Author*)

PURPOSE

To evaluate the efficacy of quantitative multiparametric magnetic resonance imaging (MRI), including MR fingerprinting (MRF), diffusion-weighted imaging (DWI), and dynamic contrast-enhanced (DCE) imaging, in differentiating benign from metastatic lymph nodes (LN) in head and neck squamous cell carcinoma (HNSCC).

METHODS AND MATERIALS

Seventeen patients (mean age: 64 ± 17 years, range: 32-94) with pathologically confirmed HNSCC and cervical LNs, who underwent multiparametric 3T MRI, including MRF, DWI, and DCE were retrospectively analyzed. Three neuroradiologists evaluated the mean T1 and T2 values from MRF, apparent diffusion coefficient (ADC) from DWI, and K trans , K ep , v e , and iAUC from DCE in the LNs. An independent t-test was performed to compare parameters between benign and metastatic LNs. Logistic regression analysis was conducted to evaluate associations with LN metastasis and assess model performance. The diagnostic performance of models with and without MRF parameters was compared.

RESULTS

Among the 17 patients, 23 metastatic LNs and 21 benign LNs were pathologically confirmed. Metastatic LNs exhibited significantly higher T1 and T2, whereas ADC, K trans , v e , and iAUC were significantly lower. T1 (odds ratio [OR]: 1.003 [95% CI: 1.001-1.005], P < 0.001), T2 (OR: 1.06 [95% CI: 1.01-1.10], P = 0.014), ADC (OR: 0.998 [95% CI: 0.997-1.00], P = 0.001), and K trans (OR: 0.001 [95% CI: 0.00-0.10], P < 0.001) demonstrated significant associations with LN metastasis and were incorporated into the regression model. Incorporating MRF parameter into the regression model significantly increased accuracy (from 0.73 [95% CI: 0.64-0.81] to 0.83 [95% CI: 0.77-0.91], P = 0.048) and specificity (from 0.68 [95% CI: 0.55, 0.79] to 0.83 [95% CI: 0.71, 0.91], P = 0.002).

CONCLUSION

Multiparametric MRI parameters, including MRF, DWI, and DCE, showed significant differences between benign and metastatic LNs in HNSCC. The incorporation of MRF improved the diagnostic performance of the regression model for detecting metastatic LNs.

CLINICAL RELEVANCE/APPLICATION

This study evaluates quantitative multiparametric MRI techniques—MRF, DWI, and DCE imaging—for differentiating benign vs. metastatic LNs in HNSCC.

W5B-SPHN-3 VALUE OF CLASSIFICATION OF VOCALFOLD DEFORMATIONONDYNAMIC CTIN PATIENTS WITH HOARSENESS AFTER SARS-COV-2 INFECTION

Yong Wang, MD (*Presenter*)
Ziying Lin (*Abstract Co-Author*)
Guanbin Zhu Guanbin Zhu (*Abstract Co-Author*)
Dairong Cao, MD (*Abstract Co-Author*)

PURPOSE

To preliminarily investigate the value of the dynamic laryngeal CT manifestations in assessing the laryngeal nerve damage and the treatment effectiveness, in patients experiencing hoarseness following SARS-CoV-2 infection.

METHODS AND MATERIALS

In this prospective cohort study, consecutive participants were enrolled between September 2020 and March 2024. All participants with hoarseness following SARS-CoV-2 infection underwent dynamic throat CT scans. Based on classification criteria that assess morphological and positional changes of the vocal fold on both the maximum open and minimum closed phase images, vocal fold deformation types were categorized into three types (I-III). LEMG with interval less than 2 days was performed to determine the laryngeal nerve damage. Non-parametric tests and chi-square tests were used for univariate analyses. Kappa tests were used for consistency analyses. Linear regression was used to fit the data.

RESULTS

A total of 29 participants (Median age, 42 years; 13 men) were included. There was a high consistency between Type III and posterior cricoarytenoid muscle (PCA) injury ($k = 0.615$, $p = 0.001$) or multiple nerve branch injuries ($k = 0.692$, $P < 0.001$). Type II vocal fold deformation patients had significantly shorter recovery time than type III (2.0 vs 4.0 months, $P = .008$). Recovery time greater than 3 months was more common in type III than type II (8.0 vs 3.0 months, $P = .039$).

CONCLUSION

In patients experiencing hoarseness following SARS-CoV-2 infection, the Classification of vocal fold deformation based on dynamic CT exhibits potential value in evaluating the laryngeal nerve damage and predicting the treatment effect.

CLINICAL RELEVANCE/APPLICATION

1.Vocal fold paralysis occurs frequently following SARS-CoV-2 infection;2.The Classification of vocal fold deformation based on dynamic laryngeal CT could assess the laryngeal nerve damage and the treatment effectiveness;3.There was a high consistency between Type III vocal fold deformation and multiple nerve branch injuries. Type II vocal fold deformation patients had significantly shorter recovery time than type III.

W5B-SPHN-4 ROLE OF ASYMMETRIC ANTERIOR MOVEMENT OF THYROID CARTILAGE IN 4D CT IN THE DIAGNOSIS OF UNILATERAL SUPERIOR LARYNGEAL NERVE INJURY: A CASE-CONTROL STUDY

Ziying Lin (*Presenter*)
Yong Wang, MD (*Abstract Co-Author*)
Guanbin Zhu Guanbin Zhu (*Abstract Co-Author*)

PURPOSE

To explore the role of asymmetric anterior movement of thyroid cartilage (AAM) in 4D CT in the diagnosis of unilateral superior laryngeal nerve (SLN) injury.

METHODS AND MATERIALS

In this retrospective study, eligible for inclusion were consecutive patients with suspected SLN injury who underwent 4D CT between March 2021 and August 2024 in our hospital. Patients were divided into group A (combined injury of unilateral SLN and recurrent laryngeal nerve (RLN)), group B (isolated unilateral RLN injury), and group C (neither SLN nor RLN injury). The reference standard is laryngeal electromyography. Patients were asked to make "Yi" sound during CT scanning of the larynx with cine mode. The optimal closing phases of glottis were selected. Multiplanar reconstruction of CT images based on cricoid cartilage was performed. The distance between posterior border of cricoid cartilage and inferior posterior border of right thyroid lamina (IR), superior posterior border of right thyroid lamina (SR), inferior posterior border of left thyroid lamina (IL) and superior posterior border of left thyroid lamina (SL) were measured. The difference between IR and IL (DI), the difference between SR and SL (DS), and global asymmetry (GA), which was define as (IR-IL+SR-SL)/2, were calculated to evaluate AAM. Kruskal-Wallis test was used to analyze the statistical differences among three groups. The area under the receiver operating characteristic curve (AUC) and accuracy were used to evaluate the performance.

RESULTS

A total of 169 patients were enrolled, including 50 consecutive patients in group A, 59 random patients in group B, and 60 consecutive patients in group C. The DI of group A was significantly higher than that of group B ($p=0.048$) and group C ($p=0.004$). The DS in group A was significantly higher than that of group C ($p=0.007$). The AUC of DI and DS for diagnosing SLN injury was 0.655 (95% CI: 0.561, 0.749) and 0.641 (95% CI: 0.546, 0.737). With cut-off of 2.0mm and 2.5mm, the accuracy of DI and DS for diagnosing SLN injury was 0.734 (95% CI: 0.662, 0.795) and 0.704 (95% CI: 0.631, 0.768). For group A, anterior movement of superior and inferior border of thyroid lamina of the unaffected side was more significant than that of the affected side ($p < 0.001$). The AUC of GA for identifying affected side in unilateral SLN injury was 0.829 (95% CI: 0.713, 0.946), and the accuracy was 0.780 (95% CI: 0.648, 0.873).

CONCLUSION

AAM in 4D CT is a sign of unilateral SLN injury. Anterior movement of thyroid lamina of the affected side is reduced compared to the unaffected side.

CLINICAL RELEVANCE/APPLICATION

SLN innervates cricothyroid muscle, which pulls the thyroid cartilage downward and forward. 4D CT may serve as a noninvasive method for unilateral SLN injury diagnosis and identification of the affected side.

W5B-SPHN-5 NEW THYROID IMAGING REPORTING AND DATA SYSTEM (TI-RADS) BASED ON ULTRASONOGRAPHY FEATURES FOR FOLLICULAR THYROID NEOPLASMS: A MULTI-CENTER STUDY

Yi Feng Zhang, MD, PhD (*Presenter*)

PURPOSE

Preoperative diagnosis of follicular thyroid neoplasm (FTN) is difficult and the current ultrasound risk stratification systems (RSSs) for thyroid nodule are not suitable for FTN. Therefore, this study aimed to establish a new RSS for FTN as useful preoperative evaluation to reduce missed diagnoses and unnecessary biopsies.

METHODS AND MATERIALS

535 FTNs from four hospitals were included in this retrospective study. All the nodules were randomly divided into test and validation group. The ultrasonography features of each nodule were analyzed. TI-RADS of FTN (FTN-TIRADS) was established based on the results of univariate analysis and logistic regression of ultrasonography features. Each nodule was evaluated and classified by these four RSSs (RSS from European Thyroid Association [EU-RSS], RSS from American Thyroid Association [ATA-RSS], TIRADS from American College of Radiology [ACR-TIRADS], TIRADS from Chinese [C-TIRADS]) and FTN-TIRADS, respectively. ROC curve and the AUC was used to evaluate the diagnostic value of the RSSs mentioned above. The unnecessary rates of FNA were calculated and compared between FTN-RIRADS and the other four RSSs.

RESULTS

Test group and validation group included 370 patients (86 male patients) and 165 patients (48 male patients). The following ultrasonography features were independent risk factor and included into FTN-TIRADS: nodule composition, echogenicity, calcifications, halo sign, indistinct boundary with thyroid capsule. Nodules were classified as TR2, TR3, TR4a, TR4b, TR4c and TR5 with none to five suspicious features mentioned above respectively. The AUC of FTN-TIRADS was 0.855, statistically higher than EU-RSS, ATA-RSS, ACR-TIRADS and C-TIRADS (0.759, 0.759, 0.753, 0.677, respectively) (all $p<0.05$). The unnecessary FNA rate of the FTN-TIRADS was 41.4%, which was significantly lower than that of EU-RSS (67.3%), ATA-RSS (69.0%), ACR-TIRADS (60.1%) and C-TIRADS (63.2%).

CONCLUSION

FTN-TIRADS achieved better differential diagnosis of FTN than current RSSs and significantly reduced the rate of unnecessary FNA. It can serve as a reliable preoperative non-invasive assessment tool for thyroid follicular tumors, reducing unnecessary FNA and unnecessary surgeries.

CLINICAL RELEVANCE/APPLICATION

Our study established a new risk stratification system (FTN-TIRADS) based on ultrasound features for thyroid follicular tumors. FTN-TIRADS with good inter-observer agreement demonstrated significantly improve the diagnostic accuracy of FTC compared with the current thyroid nodule risk stratification systems. FTN-TIRADS has great potential for preoperative diagnosis of FTNs and significantly reduce the rate of unnecessary FNA.

W5B-SPHN-6 DIAGNOSTIC VALUE OF VIRTUAL UNENHANCED DUAL-ENERGY CT FOR PAROTID GLAND LESIONS: A PRELIMINARY STUDY

Hongying HU (*Presenter*)
Meng You (*Abstract Co-Author*)

PURPOSE

To determine whether virtual unenhanced (VUE) images reconstructed from dual-energy CT (DECT) can replace true unenhanced (TUE) images in dual-phase parotid CT and to assess the added diagnostic value of quantitative iodine concentration and effective atomic number (EAN).

METHODS AND MATERIALS

This retrospective study enrolled 71 consecutive patients with pathologically confirmed parotid lesions who underwent DECT. The cohort comprised 24 pleomorphic adenomas, 11 Warthin tumors, four cysts, four malignant tumors, and 28 other lesions. Imaging included a TUE acquisition followed by early (30 s) and delayed venous (120 s) phases. VUE images were generated from early-phase data. Hounsfield units (HU) for each lesion and for normal parotid parenchyma were recorded on TUE and VUE images; early- and delayed-phase enhancement (?HU) as well as iodine concentration (mg I/mL) and EAN were measured on spectral maps. Paired t tests compared VUE and TUE values; one-way analysis of variance evaluated differences among lesion types.

RESULTS

VUE and TUE HU were highly correlated ($r > 0.95$) with a mean lesion-level difference of 1.8 ± 2.1 HU ($P > 0.05$). Enhancement curves derived with VUE or TUE baselines were concordant and differed significantly by histology ($P < 0.05$). Warthin tumors demonstrated marked early enhancement (mean ?HU + 40) and subsequent washout (-12), pleomorphic adenomas showed progressive uptake (+26 early, +14 delayed), and cysts exhibited minimal change (+8, +2). Warthin tumors had higher arterial iodine concentration (1.36 ± 0.18 vs 1.02 ± 0.14 mg I/mL) and higher EAN (8.23 ± 0.11 vs 7.96 ± 0.10) than pleomorphic adenomas ($P < .05$ for both). Malignant tumors overlapped benign lesions in EAN but were distinguishable by their enhancement kinetics.

CONCLUSION

VUE images provide attenuation and enhancement information equivalent to TUE images, enabling omission of the non-contrast scan in dual-phase parotid DECT without loss of diagnostic accuracy. Quantitative spectral parameters, especially iodine concentration and EAN, further improve lesion differentiation, particularly for identifying Warthin tumors.

CLINICAL RELEVANCE/APPLICATION

This study confirms virtual unenhanced (VUE) dual-energy CT reliably replaces true unenhanced scans in parotid lesion evaluation, eliminating unnecessary radiation while preserving diagnostic accuracy. Combined with quantitative iodine mapping and characteristic washout kinetics, this protocol optimizes preoperative differentiation of Warthin tumors from other lesions.

W5B-SPHN-7 FATTY ACID COMPOSITION OF ADIPOSE TISSUE EVALUATED BY MRI IN CRANIOFACIAL LOCALIZED SCLERODERMA PATIENTS

Tianjiao Wang (*Presenter*)
Yun Wang (*Abstract Co-Author*)
Yu Chen, MD (*Abstract Co-Author*)
Zhuhua Zhang (*Abstract Co-Author*)
Jiuzuo Huang (*Abstract Co-Author*)
Xuda Ma (*Abstract Co-Author*)
Huadan Xue, MD (*Abstract Co-Author*)

PURPOSE

To investigate the fatty acid levels of the grafted fat after autologous fat grafting during the adipose tissue recovery in craniofacial localized scleroderma patients.

METHODS AND MATERIALS

21 patients who were clinically diagnosed as craniofacial localized scleroderma were retrospectively enrolled. All patients underwent autologous fat grafting surgery and MRI scanning 7 days and 12 months after surgery. MRI sequences included 3D T1WI-Dixon fat imaging and gradient-echo spectroscopic imaging (GSI). The signal and volume of autologous fat graft were evaluated in 3D T1WI-Dixon fat imaging. Voxel-wise spectral analysis of fatty acids was applied to measure relative portions of monounsaturated (MUFA), polyunsaturated (PUFA), and saturated fatty acids (SFA) in each voxel. The voxels within the autologous fat graft were measured and their fatty acid fractions were assessed in each MRI scanning.

RESULTS

21 patients which included 8 males and 13 females were collected in this study. The signal and volume of autologous fat graft in 12 months were significantly lower than 7 days after surgery (all $p<0.001$). MUFA and PUFA were measured 7 days postoperation (MUFA: 15.23± 2.85, PUFA: 75.46± 11.39) and then decreased at 12 months after surgery (MUFA: 8.42± 3.67, PUFA: 46.69± 15.21, both $p<0.001$). SFA were measured 7 days postoperation (19.12± 6.44) and then increased at 12 months after surgery (53.79± 7.59, $p<0.001$).

CONCLUSION

GSI method could quantify the fatty acid composition in craniofacial localized scleroderma patients. Higher SFA and lower signal and volume of autologous fat graft, MUFA, and PUFA may be used to assess the disease development and progress.

CLINICAL RELEVANCE/APPLICATION

3D T1WI-Dixon fat imaging combined with gradient-echo spectroscopic imaging could evaluate the change of adipose tissue and fatty acid levels during the adipose tissue recovery in craniofacial localized scleroderma patients.

W5B-SPIN-2 AUTOMATED CHEST CT PROTOCOL SELECTION USING LARGE LANGUAGE MODEL FEATURES BASED ON FREE-TEXT IMAGING REQUESTS

Farzad Khalvati, PhD, MSc (*Presenter*)
Zahra Hosseini (*Abstract Co-Author*)
Sean Carey (*Abstract Co-Author*)
Patrik Rogalla, MD, MBA (*Abstract Co-Author*)

PURPOSE

Accurate and timely Computed Tomography (CT) protocol selection is critical for ensuring diagnostic quality and patient safety. However, the current selection process is manual, time-consuming, and prone to inconsistencies. Prior Machine Learning-based selection methods using keywords or bag-of-words lack contextual understanding and perform poorly on rare protocols. We propose a decision support system that uses a large language model (LLM) features to recommend protocols based on free-text clinical indications. LLMs capture clinical nuance and phrasing variation, which can be leveraged to support more consistent and efficient CT protocol selection.

METHODS AND MATERIALS

In this REB-approved retrospective study, 285123 historical chest CT imaging requests from a large academic medical center, received between 2017 and 2024, were used. The dataset was split into a training set (228099 imaging requests, 80%) and a held-out test set (57024 imaging requests, 20%). Each request included procedure names, clinical indication, Hospital Information System (HIS) comments, and the clinically selected imaging protocol. Clinical text from imaging requests were embedded using a finetuned LLM, namely Meta's LLaMA-3. These features served as input to a logistic regression classifier trained to predict protocol labels, which included 18 protocols (e.g., Pulmonary Embolism (PE), Low Dose CT (LDCT), etc.).

RESULTS

The proposed LLM-based pipeline achieved a weighted precision of 0.84, weighted F1-score of 0.81, and an overall accuracy of 79% across 18 CT protocols. Compared to a bag-of-words logistic regression baseline, the LLM model improved per-protocol accuracy for most classes. Notable gains were observed for Trauma - Chest (0.10 ? 0.70), Trachea (0.0 ? 0.80), and SVC occlusion (0.0 ? 0.80), all of which were low-frequency classes. Common protocols such as PE and LDCT maintained high accuracy (0.91 and 0.90, respectively).

CONCLUSION

An LLM-based protocol recommendation system can effectively leverage general knowledge obtained from a large corpus of natural text, enabling our method to accurately assign chest CT protocols based on free-text imaging requests. LLMs may serve as a viable foundation for protocol recommendation tools when inputs consist of free-text and require language understanding for inference.

CLINICAL RELEVANCE/APPLICATION

The proposed system supports a consistent and accurate chest CT protocol recommendation, helping to reduce variability and the cognitive burden placed on radiologists. By automating a repetitive and error-prone task, the system helps reduce the mental load on radiologists and contributes to safer, more standardized imaging workflows.

W5B-SPIN-3 VISION-LANGUAGE FOUNDATION MODELS FOR RADIOLOGY: COMPARATIVE ANALYSIS OF CLASSIFICATION AND SEGMENTATION PERFORMANCE

Frank Li, PhD (*Presenter*)
Hari Trivedi, MD (*Abstract Co-Author*)
Bardia Khosravi, MD, MPH (*Abstract Co-Author*)
Theodorus Dapamede, MD, PhD (*Abstract Co-Author*)
Seyed Mohammadreza Chavoshi, MD (*Abstract Co-Author*)
Abdulhameed Dere (*Abstract Co-Author*)
Rohan Satya Isaac (*Abstract Co-Author*)
Aawez Mansuri, BS, MS (*Abstract Co-Author*)
Janice M. Newsome, MD (*Abstract Co-Author*)
Saptarshi Purkayastha, PhD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)

PURPOSE

Foundation models, developed through self-supervised learning on extensive datasets, offer promising advances for AI in healthcare. Vision-language models (VLMs) face limitations when trained on insufficient text descriptions from radiology reports, potentially leading to representation collapse and difficulty distinguishing similar cases. This research evaluates three foundation models (RAD-DINO, CheXagent, and BiomedCLIP) on pneumothorax segmentation and classification tasks to assess their ability to capture fine-grained imaging features.

METHODS AND MATERIALS

We evaluated three VLMs on the SIIM-ACR Pneumothorax dataset, extracting both patch and global [CLS] embeddings. For segmentation, we used linear probing with patch embeddings and developed a custom segmentator integrating both embedding types through cross-attention. Classification was performed using linear probing on [CLS] embeddings. Performance was evaluated using Dice coefficient, IoU, AUROC, and AUPRC metrics with statistical significance assessment.

RESULTS

In segmentation tasks, RAD-DINO (Dice=0.257; IoU=0.179) and CheXagent (Dice=0.293; IoU=0.204) performed similarly with linear probing (non-significant difference), but RAD-DINO (Dice=0.424; IoU=0.312) achieved superior results with our custom segmentator. For classification, CheXagent (AUROC=0.955; AUPRC=0.955) demonstrated exceptional performance, outperforming both RAD-DINO (AUROC=0.916; AUPRC=0.905) and BiomedCLIP (AUROC=0.860; AUPRC=0.859). BiomedCLIP showed the lowest baseline performance (Dice=0.084; IoU=0.054) in segmentation but exhibited the most substantial relative improvement with our custom segmentator (Dice=0.250; IoU=0.171). Our cross-attention mechanism consistently improved segmentation performance across all models, with qualitative results showing more precise pneumothorax boundary delineation.

CONCLUSION

Our findings demonstrate that pre-training methodology significantly influences foundation model performance on specific downstream tasks. Image-based self-supervised models (RAD-DINO) excel in fine-grained segmentation, while text-supervised models (CheXagent) show superior classification performance. Our approach integrating global context with local features through cross-attention consistently enhanced segmentation performance, suggesting an important architectural consideration for future medical imaging AI systems requiring precise anatomical delineation.

CLINICAL RELEVANCE/APPLICATION

Foundation models are the next frontier for AI in radiology. Our findings provide implications for the optimal selection of AI foundation models in healthcare, highlighting one size doesn't fit all.

W5B-SPIN-4 EVALUATING THE ADEQUACY OF SEGMENT EVERYTHING MODELS VERSUS CUSTOM ORGAN-SPECIFIC MODELS FOR OPPORTUNISTIC CT SCREENING

Dvij Sharma (*Presenter*)
Lukas Mueller, MD, PhD (*Abstract Co-Author*)
Yunju Ha (*Abstract Co-Author*)
Alexandra Wong, BS (*Abstract Co-Author*)
Benjamin Rush (*Abstract Co-Author*)
Ronald M. Summers, MD, PhD (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)
John W. Garrett, PhD (*Abstract Co-Author*)

PURPOSE

Deep learning-based methods have shown promise in opportunistic screening by extracting valuable biomarkers from existing CT data based on segmentations of key organs and tissues. Accurate segmentation remains essential for biomarker prediction, yet most validated tools for opportunistic screening use custom, organ-specific segmentation models. This study evaluates whether a "Segment Everything" model (TotalSegmentator) is as good as bespoke, organ-specific models for organ segmentation for opportunistic screening.

METHODS AND MATERIALS

In-house developed models were compared to TotalSegmentator for kidney, liver, and spleen segmentation in 8,930 abdominal CT scans, and statistical differences in biomarker prediction were analyzed. A reader study was also performed with 150 selected cases: 40% (60 cases) with similar biomarkers (volume and density) across all organs, and 60% (90 cases) with significant differences in at least one biomarker for the kidney, liver, or spleen. A radiologist assessed segmentation quality (blinded to segmentation method) for each organ on a 1-5 Likert scale in a two-phase design: cases segmented by each tool were randomly assigned to be read in Phase 1 and the other in Phase 2, with a two-week washout period.

RESULTS

Wilcoxon signed-rank testing showed statistically significant differences in both volume and density prediction between the in-house and TotalSegmentator models ($P < 0.001$ for all three organs). Likert scores from the reader study were then analyzed, with the TotalSegmentator consistently scoring higher per radiologist evaluation (means: 4.39 vs 3.62 for liver, 4.80 vs 3.16 for kidney, and 4.47 vs 3.79 for spleen). Wilcoxon signed-rank testing confirmed that differences in reader study medians (5.00 vs 3.00 for kidney, 5.00 vs 4.00 for spleen, and 5.00 vs 4.00 for liver) were statistically significant, with the greatest difference observed in kidney segmentation ($W = 44.0$, $P < 0.001$ for kidney, $W = 592.0$, $P < 0.001$ for spleen, $W = 458.0$, $P < 0.001$ for liver).

CONCLUSION

Significant differences in model performance, backed by radiologist evaluations favoring the TotalSegmentator model, indicate that the TotalSegmentator model consistently outperforms its organ-specific counterparts, providing better clinical segmentation quality.

CLINICAL RELEVANCE/APPLICATION

We show the utility of using segment-everything models (i.e. TotalSegmentator) as an alternative to single-organ segmentation methods for clinically accurate abdominal CT segmentation. Incorporating segment-everything models into a suite of automated tools may then allow for more accurate detection of lesions, either directly or by allowing greater accuracy in prediction of lesion-related biomarkers like organ volume and density.

W5B-SPIN-5 PATIENT EVALUATION OF HUMAN VS. GPT-GENERATED ANSWERS: A MULTICENTRIC RANDOMIZED MIXTED DESIGN TRIAL IN RADIOPROTECTION COMMUNICATION

Sofyan Jankowski, MD (*Presenter*)
David Rotzinger, MD,PhD (*Abstract Co-Author*)
Charbel Mourad, MD (*Abstract Co-Author*)
Jonas Richiardi (*Abstract Co-Author*)
Mariana Gulizia (*Abstract Co-Author*)
Marie Nowak, PhD (*Abstract Co-Author*)
Stephanie De Labouchere (*Abstract Co-Author*)
Em Harkness (*Abstract Co-Author*)
Francesco Ria, PhD (*Abstract Co-Author*)
Chiara Pozzessere, MD (*Abstract Co-Author*)

PURPOSE

Understanding radiation-related risks can be challenging for non-radiology professionals and patients, who increasingly seek information on the internet. A recent study compared ChatGPT-3.5-generated with human-generated answers to patient radiation protection frequently asked questions. Twelve international experts found no significant differences in satisfaction, accuracy, or comprehensibility between the two sources. A key limitation of the research was the absence of actual patient perspectives. Hence, in this study we assess patients' evaluation of ChatGPT information about radiation protection compared with the human-generated information.

METHODS AND MATERIALS

Patients from three institutions in Europe, Asia, and USA, blinded to the source, assessed both human-generated and ChatGPT v3.5-generated response for the same frequently asked radiation protection question, randomly allocated to five question sets (Q1-Q5) in a 1:1:1:1:1 ratio. Four outcomes based on QUEST framework were rated on a Likert scale (1 No; 7 Yes): satisfaction; trust; reassurance; comprehension. Data were analyzed using an ART ANOVA to address Likert scale non-normality, with the model: Likert score ~ author × question + (1 | participant_id), selected based on AIC/BIC.

RESULTS

The survey was completed by 328 participants. Sex and age distribution was balanced across countries. ChatGPT responses scored higher than human responses for satisfaction (median 6, IQR 5-7 vs median 5, IQR 3-7), trust (median 6, IQR 4-7 vs median 5, IQR 3-7), reassurance (median 6, IQR 4-7 vs median 5, IQR 3-7), but not for comprehension (median 7, IQR 5-7 vs median 7, IQR 5-7). ChatGPT's superiority was statistically significant for satisfaction ($F=24.63$, $p<0.001$) trust ($F=30.7$, $p<0.001$) and reassurance ($F=21$, $p=0.003$), while no difference was found in comprehension ($F=1.9$, $p>0.17$).

CONCLUSION

Unlike radiology professionals, patients preferred AI-generated texts for satisfaction, trust and reassurance. The divergence between patient and professional preferences underscores the need to tailor radiation risk communication strategies to the audience's perspective, potentially enhancing clarity and engagement.

CLINICAL RELEVANCE/APPLICATION

ChatGPT may support public communication. Expert-guided chatbots can reduce potential communication errors of misleading information generated by unsupervised large language models informing patient-tailored communication in radiation protection.

W5B-SPIN-6 SELFI MRI IDENTIFIES MACROPHAGES AND IMMUNOSUPPRESSIVE BIOLOGICAL FEATURES THAT CONTRIBUTE TO THERAPEUTIC RESISTANCE

Ramon F. Barajas JR, MD (*Presenter*)
Jared Stoller (*Abstract Co-Author*)
Daniel Schwartz (*Abstract Co-Author*)
Doonyaporn Wongsawaeng (*Abstract Co-Author*)
Cymon N. Kersch, MS (*Abstract Co-Author*)

PURPOSE

Gadolinium (Gd) enhanced MRI is the standard of care for monitoring glioblastoma. Tumor-associated macrophages (TAMs), specifically M2 polarized macrophages play a major role in tumor progression. The use of Ferumoxytol (Fe) as an off-label contrast agent allows for the localization of TAMs and allows for quantitative metrics to be determined. Segregation and Extravascular Localization of Ferumoxytol Imaging (SELFI) is computational metric which determined if Fe signal change is in the vasculature or the tumor itself. We sought out to determine how SELFI values vary with Gd contrast in various biopsy sites from the tumor and adjacent peritumoral regions.

METHODS AND MATERIALS

This prospective study included seven patients with glioblastoma. Each patient underwent Gd and 24-hour delayed Fe (7 mg/kg up to 510 mg) enhanced MRI allowing for image guided biopsy based on Gd enhancement and FLAIR hyperintensity. At the time of tumor resection, a total of 62 biopsies (volume = 75 mm^3) from known imaging locations were taken. A contour mask was drawn at the biopsy site. Calculating SELFI values in the voxels contained in the contoured mask follow the methods outlined by Barajas, et. al. (doi: 10.3174/ajnr.A6600).The Positive SELFI values represent the extravascular component of the metric. The Negative SELFI values represent the intravascular component which is believed to be analogous to Relative Cerebral Blood Volume (rCBV). rCBV was derived from the steady state (ss)-images from Fe contrast and a known metric to determine the volume of blood in a specific region normalized to contralateral white matter.

RESULTS

Seven patients provided 62 image guided tissue samples with sufficient quality to evaluate the relationships between MRI features and SELFI value. For Gd based MRI, biopsy samples that were enhancing show significantly elevated rCBV ($p < 0.05$) and SELFI Positive ($p < 0.01$) values. No difference was observed in SELFI Negative by sample location.

CONCLUSION

Gd alone cannot discern extravascular or intravascular contrast presence but Fe contrast can lend additional insight into macrophage migration in the tumor immune microenvironment. SELFI Positive, the extravascular, immune component of SELFI differs by enhancement but while the intravascular component of SELFI, SELFI Negative, does not. There is a need to further biologically quantify what SELFI Negative represents which can be analyzed histologically. The next step for SELFI Positive is to confirm the immune signature with spatially resolved RNA-seq analysis to find out exactly what these metrics biologically represent.

CLINICAL RELEVANCE/APPLICATION

Quantitative MRI with genomic analysis will help better map the heterogeneity of the tumor immune microenvironment.

W5B-SPIN-7 STANDARD OF CARE, VARIABILITY EVERYWHERE: HETEROGENEITY OF MRI ACQUISITION AND DOCUMENTATION ACROSS MULTI-INSTITUTIONAL NEURO-ONCOLOGY TRIALS

Mohamad El-Jammal, MD (*Presenter*)
Saba Elias (*Abstract Co-Author*)
Eleni Konstantinopoulou (*Abstract Co-Author*)
Bikash Panthi, MS (*Abstract Co-Author*)
Stephen Kry, PHD (*Abstract Co-Author*)
Michael V. Knopp, MD, PhD (*Abstract Co-Author*)
Caroline Chung, MD, FRCPC (*Abstract Co-Author*)

PURPOSE

Upstream variability in imaging data can impact clinical trial measurements and utility of emerging tools such as AI. The purpose of this study is to assess the current state of standard-of-care (SOC) imaging and to evaluate the impact of the Brain Tumor Imaging Protocol (BTIP) on improvements to MRI acquisition heterogeneity and metadata consistency across multi-institutional neuro-oncology trials.

METHODS AND MATERIALS

DICOM metadata —including sequence, plane, acquisition type (2D/3D), slice thickness, field strength—were analyzed from 2 multicentered brain metastasis trials (NCCTG N0574 (pre-BTIP, n˜1910 series) and NCCTG N107C (post-BTIP, n˜7047 series). DICOM metadata were curated through manual review and automatic filtering. Differences were evaluated using t-tests, Kolmogorov-Smirnov (KS) tests, and Levene's tests.

RESULTS

Substantial heterogeneity persisted despite BTIP implementation. For axial post-contrast T1w scans, slice thickness ranged from 0.9-6 mm, with only ~23% acquired using 3D sequences (t-test $p < 0.0001$). Discrepancy between series description and DICOM metadata on contrast administration increased from 4% to 14% post-BTIP. In sagittal pre-contrast T1w scans, 3D acquisitions (as required by BTIP) were rare: only 19/119 (16%) pre-BTIP and 23/436 (5%) post-BTIP. Series naming was highly variable with 58 vs. 89 unique axial T1w descriptors pre- vs post-BTIP. Manual vs. automated curation of axial post-contrast T1w scans both revealed persistent heterogeneity across field strengths and acquisition types. Manual curation identified significant slice thickness differences at 1.5T 2D (t-test $p = 1.6\times10?^{15}$; KS $p = 6.2\times10?^{21}$) and 1.5T 3D (t-test $p = 1.0\times10?7$; KS $p = 2.2\times10?8$). Automated curation showed similarly significant differences at 1.5T 2D (t-test $p = 3.2\times10?^{17}$; KS $p = 3.9\times10?^{26}$) and 1.5T 3D (t-test $p = 1.4\times10?8$; KS $p = 1.2\times10??$), and detected additional differences at 3.0T 2D/3D.

CONCLUSION

BTIP implementation partially improved MRI parameter consistency, but substantial heterogeneity and metadata inconsistencies remained. Effective automated metadata analyses remain challenged without manual validation due to the wide variability. While uniform protocol adoption is difficult due to technical differences across sites, rigorous and consistent metadata reporting will open opportunities for effective and efficient centralized quality control for meaningful outcome measures in brain tumor clinical trials.

CLINICAL RELEVANCE/APPLICATION

Persistent MRI metadata variability highlights the critical need for rigorous standardization and centralized quality control to ensure reliable clinical imaging outcomes.

W5B-SPIN-8 ONCO-RADS CLASSIFICATION OF INCIDENTAL FINDINGS ON WHOLE-BODY MRI REPORTS USING LARGE LANGUAGE MODELS IN PATIENTS WITH PLASMA CELL DYSCRASIA

Mickael Tordjman, MD, MS (*Presenter*)
Murat Yuce, MD, MS (*Abstract Co-Author*)
Xueyan Mei, PhD (*Abstract Co-Author*)
Amine G. Geahchan, MD (*Abstract Co-Author*)
Zelong Liu (*Abstract Co-Author*)
Ian Bolger (*Abstract Co-Author*)
Anis Meribout, MD (*Abstract Co-Author*)
Sara Lewis, MD (*Abstract Co-Author*)
Bachir Taouli, MD (*Abstract Co-Author*)

PURPOSE

Oncologically Relevant Findings Reporting and Data System (ONCO-RADS) is used to classify findings on Whole-Body(WB)-MRI used for cancer screening. ONCO-RADS classify Findings from 1 (Normal report) to 5 (high likelihood of malignancy). Indications of WB-MRI are expanding in multiple indications with subsequent numerous incidental findings. Large Language Models (LLM) may be used to extract and classify these incidentals findings in WB-MRI reports that contain large amount of text. The objective of this study was to describe the prevalence of incidental malignancies on WB-MRI and the performance of LLMs to classify incidental findings by using ONCO-RADS in a large cohort of patients with plasma cell dyscrasia.

METHODS AND MATERIALS

This retrospective single-center study in a tertiary care center included 823 patients (M/F: 457/366, mean age: 63.7y) who underwent WB-MRI (1.5 or 3T) for suspected plasma cell dyscrasia between 01/2016-12/2023. All reported incidental findings were annotated by two readers independently in the entire database of WB-MRI reports and patients' charts were assessed for final pathological diagnoses of incidental findings. We assessed inter-observer reliability of ONCO-RADS classification for incidental findings unrelated to plasma cell dyscrasia among 5 readers with different level of experience using a two-way mixed-effects, absolute-agreement intraclass correlation coefficient (ICC). Two Large Language Models (a fine-tuned version of DeBERTa called Medical-NER, and ChatGPT o1) were trained/tested on WB-MRI reports annotated for ONCO-RADS classification.

RESULTS

1504 WB-MRI studies were assessed. 15 incidental cancers in 22 WB-MRI reports of 15 patients (prevalence 1.8%) were detected. After retrospective review, 93% (14/15) of these had ONCO-RADS-4/5 reports, and 7% (1/15) ONCO-RADS-3. The prevalence of cancers was 21% in ONCO-RADS 4 and 71% in ONCO-RADS 5. There was excellent inter-obserer reproducibility in ONCO-RADS classification (average-measure ICC of 0.935). Medical-NER LLM exhibited per-patient accuracy of 0.82 in the test set (n=150), with a recall of 0.74 per token, while ChatGPT-o1 demonstrated accuracy of 0.90 per-report and 0.92 per-lesion.

CONCLUSION

The prevalence of malignant incidental lesions was 1.8% in a cohort of patients with plasma cell dyscrasia who underwent WB-MRI, consistent with the literature. LLMs exhibited high accuracy to classify incidental findings on WB-MRI reports.

CLINICAL RELEVANCE/APPLICATION

We describe a novel approach using LLMs for incidental findings classification and subsequent management recommendations from WB-MRI reports based on ONCO-RADS classification, with excellent performances. This requires prospective validation.

W5B-SPIN-10 ASSESSMENT OF VIRTUAL REALITY HEADSET USE FOR MUSCULOSKELETAL MRI REPORTING IN CLINICAL PRACTICE

Tishi M. Ninan, MBBS, FRCR (*Presenter*)
Caroline Parker (*Abstract Co-Author*)
Alexander Holborow, MBBCh (*Abstract Co-Author*)
Phillip Wardle, MBChB, FRCR (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic accuracy, reporting efficiency, and user experience of virtual reality (VR) headsets for clinical musculoskeletal radiology reporting, specifically in the interpretation of knee MRI examinations.

METHODS AND MATERIALS

Four fellowship-trained musculoskeletal radiologists, with over 40 years of combined experience, independently reported knee MRI studies using both conventional PACS workstations and a VR headset platform. Reporting accuracy was assessed by comparing findings from both modalities. Time to complete reports was recorded for each method. Following the reading sessions, radiologists completed a structured questionnaire evaluating ease of use, visual strain, and physical discomfort (e.g., nausea or fatigue).

RESULTS

Report concordance between the VR and conventional platforms was 95%, indicating a high level of diagnostic accuracy using the VR system. However, average reporting time was 1.3 times longer with VR, particularly when evaluating prior imaging for comparison. Questionnaire feedback highlighted increased incidence of visual fatigue and mild discomfort with VR use. Ease of navigation was rated slightly lower than the traditional workstation setup.

CONCLUSION

While VR technology demonstrates strong potential for accurate musculoskeletal MRI reporting, current limitations in workflow efficiency and user comfort must be addressed before routine clinical adoption.

CLINICAL RELEVANCE/APPLICATION

VR headsets offer a portable, cost-effective alternative to traditional radiology workstations, with potential to alleviate space constraints and reduce hardware costs. Continued technical development is required to optimize speed, ergonomics, and long-term usability for integration into everyday radiological practice.

W5B-SPIN-11 LEARNING TO WRITE LIKE A RADIOLOGIST: MULTIDIMENSIONAL EVALUATION AND BENCHMARKING OF AUTONOMOUS OPTIMIZATION PIPELINES FOR HYPER-PERSONALIZED HEAD CT REPORT GENERATION

Suvrankar Datta, MD, MBBS (*Presenter*)
Nishtha Mahajan, MBBS (*Abstract Co-Author*)
Kautik Singh (*Abstract Co-Author*)
Swasthik K. Sullia, MBBS (*Abstract Co-Author*)
Akhil V, MBBS (*Abstract Co-Author*)
Amol Pajni, MBBS (*Abstract Co-Author*)
Syed Pasha (*Abstract Co-Author*)
Siddharth Reddy Anthireddy (*Abstract Co-Author*)
Zonunmawia Zadeng (*Abstract Co-Author*)
Gautam Ahuja (*Abstract Co-Author*)
Reet Nandy (*Abstract Co-Author*)
Rintu Kutum (*Abstract Co-Author*)

PURPOSE

While autonomous prompt optimization techniques have gained traction recently, their utility in radiology report generation remains unexplored. Despite the emergence of multiple frameworks, the field lacks benchmarking studies assessing their ability to generate hyper-personalized reports. Our study provides the first comprehensive evaluation of automated prompt optimization for natural language generation (NLG) pipelines in 3D imaging, evaluating two state-of-the-art (SOTA) optimizers applied to CT head report generation.

METHODS AND MATERIALS

We curated a multi-institutional CT head dataset comprising structured dictation-report pairs from four radiologists, each exhibiting distinctive reporting styles. Reports were generated using the Qwen-3 model with a single baseline prompt and then optimized using two SOTA prompt optimizers viz. DSPy (MIPRO v2) and TextGrad, creating personalized prompts tailored to each radiologist. These optimized prompts were applied to 20 test dictations to generate hyper-personalized reports. The quality of the generated reports was evaluated against ground truth using lexical similarity metrics (BLEU, ROUGE-L) and a semantic metric (RATEScore), using paired Wilcoxon signed-rank test. Additionally, all four radiologists independently assessed the reports using RADAR, a novel five-point Likert scale designed to evaluate the readiness of AI-generated drafts. RADAR scores across optimisers were compared via the Friedman test.

RESULTS

DSPy improved ROUGE-L by ? = 0.13 ± 0.06 ($p < 0.001$); TextGrad by ? = 0.06 ± 0.16 ($p = 0.19$). Both optimizers significantly improved RATEScore over baseline: DSPy by ? = 0.06 ± 0.12 ($p = 0.04$) and TextGrad by ? = 0.03 ± 0.11 ($p = 0.02$), with DSPy showing marginally better improvement (? = 0.03, $p = 0.53$), though it did not reach statistical significance ($p = 0.05$). Friedman test showed higher RADAR for DSPy ($?^2 = 0.93$, $p = 0.05$).

CONCLUSION

Both optimisation frameworks deliver significant gains in lexical, factual, and radiologist-rated quality metrics. DSPy establishes SOTA performance with statistically significant gains across all metrics, while TextGrad shows inconsistent improvements. Our results verify the effectiveness of autonomous prompt optimization for enhancing CT head report generation, particularly using the DSPy framework.

CLINICAL RELEVANCE/APPLICATION

We present the first validation of prompt optimization frameworks in radiology and establish SOTA performance of DSPy in generating high-quality Head CT reports. Our combined use of automated evaluation and direct radiologist feedback provides a robust benchmark, enabling the adoption of scalable prompt optimization frameworks into radiology report generation workflows.

W5B-SPIN-12 PINPOINTING DEMOGRAPHIC ENCODING IN RADIOLOGY FOUNDATION MODELS: A PATH TO ALGORITHMIC FAIRNESS

Bardia Khosravi, MD, MPH (*Presenter*)
Amirali Khosravi, MD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)

PURPOSE

To identify where and how demographic features are encoded within transformer-based foundation models for radiology. This knowledge is crucial as foundation models are increasingly deployed in clinical settings for automated image analysis, with potential to perpetuate or amplify existing healthcare disparities if demographic biases remain undetected and unaddressed in their decision-making processes.

METHODS AND MATERIALS

We analyzed a transformer-based foundation model (RAD-Dino) with 12 layers plus a final pooled token output. Using chest radiographs from a diverse patient population (N=37,396; 6916 Black, 621 Asian, 19,415 women), we extracted embeddings from each layer and trained supervised single layer classifiers to predict patient demographics (age [<20, 20-40, 40-60, 60-80, >80], sex, race [Asian, White, Black]) based solely on these embeddings. AUCs were calculated for each layer to identify where demographic information was most strongly encoded. Additional analysis of individual feature activations was performed to characterize the specific patterns contributing to demographic predictions.

RESULTS

Demographic information was significantly encoded throughout the network, with peak encoding occurring in intermediate layers. Layer 8 demonstrated the highest predictive performance for multiple demographic features. Sex prediction showed the highest performance (AUC=0.94), followed by race (AUC=0.91) and age (AUC=0.90). Feature activation distribution analysis revealed systematic differences between demographic groups, with the top three discriminative features showing AUC values ranging from 0.64 to 0.71. Notably, these self-supervised models encoded demographic information as effectively as fully supervised models trained directly on demographic prediction tasks.

CONCLUSION

Foundation models for radiology inherently encode substantial demographic information, with peak encoding occurring in intermediate layers. This pattern suggests the models are learning complex, higher-level representations as a surrogate of demographic features rather than simple image statistics or label-associated shortcuts.

CLINICAL RELEVANCE/APPLICATION

Identifying the primary location for demographic encoding enables targeted interventions to mitigate algorithmic bias. This knowledge allows for the development of mechanistic interventions that can specifically target these layers to create "demographic-blind" models while preserving diagnostic performance. By strategically manipulating intermediate layer representations, models can be designed to make clinical decisions independent of demographic factors, particularly race, leading to more equitable care delivery.

W5B-SPIR-1 SPATIOTEMPORAL CONTROL OF ANTIBIOTIC RELEASE VIA ULTRASOUND RESPONSIVE EMULSION HYDROGELS WITH CHITOSAN COATING

Ziba Ghareh Nazi Fam, PhD (*Presenter*)
Asia Winslow (*Abstract Co-Author*)
Viren Soni (*Abstract Co-Author*)
Gagan Kaushal (*Abstract Co-Author*)
Mario Fabiilli (*Abstract Co-Author*)
Flemming Forsberg, PhD (*Abstract Co-Author*)
Brian Oeffinger (*Abstract Co-Author*)
Noreen J. Hickok, PhD (*Abstract Co-Author*)
Lauren J. Delaney, PhD (*Abstract Co-Author*)

PURPOSE

To investigate how emulsion loading, ultrasound stimulation, and chitosan coating affect mechanical, release, and antimicrobial properties of alginate hydrogels for localized ultrasound-controlled antibiotic delivery.

METHODS AND MATERIALS

Hydrogels (1 mL) were prepared using 10 mg/mL low viscosity alginate (Sigma), crosslinked with 20/40 mM CaCO3/GDL (Sigma), and loaded with 0.25 mg vancomycin (Athenex). Sample A contained 15 µL perfluorohexane (C6) emulsion-encapsulated vancomycin; Sample B used the same emulsion triggered by ultrasound; Sample C had vancomycin directly mixed without emulsion. Each was coated with 1.5% w/v chitosan (CHA, CHB, CHC) via 1.5-h immersion. Ultrasound was applied using an SU-101 HIFU transducer (2.5 MHz, 5.5 MPa) in rastering mode (~1 h). Rheology was assessed at 10 Hz (Texas Instruments). Vancomycin release was tracked for 7 days (Tecan spectrophotometer). Antibacterial activity was tested via Kirby-Bauer assay using MSSA (ATCC).

RESULTS

Sample A showed improved stiffness (G' = 945 ± 225 Pa), B was slightly lower (G' = 901 ± 150 Pa), and C was weakest (G' = 670 ± 162 Pa). Chitosan coatings significantly increased moduli ($p < 0.05$), most notably in CHC (G' = 6738 ± 830 Pa). Coatings enhanced stiffness ~4-, 3-, and 10-fold for A, B, and C. Day 1 release was ~65% (C), ~57% (CHC), ~30% (B), ~24% (CHB), ~20% (A), and ~28% (CHA). Ultrasound boosted B's release 1.7-fold over A. Day 7 release reached ~40% (A), ~49% (CHA), ~73% (B), ~53% (CHB), and near-complete in C and CHC. Kirby-Bauer assay showed max ZOI (zone of inhibition) in C at 11.8 mm (~0.25 mg/mL, Day 1), CHC at 11.3 mm (~0.19 mg/mL), B at 8.2 mm (~0.03 mg/mL, Day 7), and CHB at 7.4 mm (~0.02 mg/mL, Day 1). A and CHA stayed below 7 mm (~0.016 mg/mL) (no significant difference, $p > 0.99$). Trends matched spectrophotometry. B had higher activity than CHB on Day 7 ($p = 0.014$). C outperformed CHC early (Day 0, $p = 0.028$); the difference declined by Day 1 ($p = 0.29$) and reversed by Day 7 ($p = 0.13$). Two-way ANOVA confirmed a significant group-time interaction ($p < 0.05$), supporting chitosan's role in sustaining bioactivity.

CONCLUSION

Ultrasound stimulation enables noninvasive spatiotemporal control of vancomycin release from emulsion-loaded alginate hydrogels. Combined with chitosan coating, it offers triggered, sustained, and localized antibiotic delivery, improving mechanical stability and extending therapeutic activity over time.

CLINICAL RELEVANCE/APPLICATION

These tunable hydrogels offer a responsive, localized antibiotic delivery system controlled by ultrasound, reducing systemic exposure and supporting infection control in tissue repair and wound care.

W5B-SPIR-2 REAL-TIME AI TOOL FOR THYROID ULTRASOUND FNA ADEQUACY

Michelle Gibbs, MSc (*Presenter*)
Pranav Sudheesh (*Abstract Co-Author*)

PURPOSE

The success rate of ultrasound-guided fine needle aspiration (FNA) can be improved by rapid on-site evaluation (ROSE) of the cellular specimen by a pathologist in real time. However, access to pathologists in freestanding imaging centers or low-resource care environments may be limited. We sought to determine if this task could be performed by a simple convolutional neural network (CNN) trained on a small dataset and operated by non-pathologists.

METHODS AND MATERIALS

A set of 676 JPEG images of thyroid FNA specimens were collected at 400x magnification using a standard digital camera, resulting in sets of 377 epithelial cell images, 135 histiocyte images, and 164 blood cell images. Images were labelled at the slide level only, with no annotation of features within the image field. This image set was used to train a TensorFlow-based CNN model which was connected to live smartphone camera microscopy feed. The CNN model was then tested on a set of 50 separate thyroid FNA cases by two separate operators with no formal pathology training for 100 individual tests (N=100).

RESULTS

As the goal for ROSE is to determine preliminary sample adequacy rather than final diagnosis, the American Society for Cytopathology proposes a threshold of 90% concordance for clinical validation of a telecytology platform. Using the pathologist's original ROSE assessment as ground truth, the current model was tested and yielded a concordance rate of 89% (95% CI: 81.4%-93.7%).

CONCLUSION

Although the 89% concordance rate achieved by this simple CNN tool does not meet the 90% concordance threshold for ROSE according to the ASC guidelines, the target falls within the confidence interval for the results obtained (81.4%-93.7%), demonstrating performance near the target level and pointing to the potential of refining the model's accuracy through a larger training set or more finely annotated training data. This small-scale study serves as proof-of-concept for the development of a cost effective CNN-based tool to be used for adequacy testing in the context of thyroid FNA biopsy in which pathologists are unavailable.

CLINICAL RELEVANCE/APPLICATION

With modest improvements in accuracy, this CNN-based tool could enable staff involved in thyroid FNA biopsy collection, such as interventional radiologists or technicians, to perform ROSE and guide further decision-making regarding sample adequacy. This model is readily deployable as a smartphone application and would allow this tool to be used in settings where pathologists are not readily available.

W5B-SPIR-3 IMPACT OF EMBOLIC DIELECTRIC AND THERMAL PROPERTIES ON MICROWAVE ABLATION IN A PERFUSED EX VIVO PORCINE MODEL

Carlos B. Ortiz, MD (*Presenter*)
Rahim Jiwani (*Abstract Co-Author*)
Marina Borrego, BS (*Abstract Co-Author*)
John A. Walker, MD, PhD (*Abstract Co-Author*)
Jorge E. Lopera, MD (*Abstract Co-Author*)

PURPOSE

Transarterial embolization (TAE) is frequently combined with microwave ablation (MWA) to reduce heat sink effect and increase MWA size. We aim to evaluate the impact of various embolic agents on dielectric and thermal properties during MWA.

METHODS AND MATERIALS

Porcine kidneys were obtained from a local butcher and immediately flushed with heparinized saline after explant. Organs were stored on ice then prepared for perfusion in an ex vivo perfusion system with an oxygenator, warmer, perfusion tubing, blood pressure monitor, and blood perfusate solution. A network analyzer with high temperature dielectric probe (Keysight) was used to measure dielectric properties. Each microwave ablation was performed using a 2.45 GHz MWA system at 30 Watts for 5 minutes (Varian Medical). The dielectric and temperature probes were placed prior to TAE using different embolic agents: LAVA 18 (SIRTEX), LC LUMI Beads 70-150 micron (Boston Scientific), and glue (histoacryl:lipiodol, 4:1, Guerbet). Baseline and postembolization dielectric properties of tissues were measured. TAE-MWA was performed in each kidney for a total of 6 TAE-MWA in each embolic group and 6 control MWA without TAE (24 MWA total) while recording maximal MWA temperature. TAE-MWA were excluded if dielectric probe errors occurred or cone beam CT demonstrated MWA outside the TAE zone. Each MWA zone was segmented along the probe trajectory and measured for maximal short axis diameter (SAD) and long axis diameter (LAD). Standard and multivariate analysis was then performed to assess for differences in dielectric properties, tissue temperature, and MWA dimensions.

RESULTS

No statistically significant difference was observed in absolute or imaginary permittivity before and after TAE for all embolic agents ($p > 0.85$). TAE-MWA resulted in MWA dimension and maximal temperatures for all embolic agents with comparisons as follows (6 LUMI-MWA vs 5 LAVA-MWA vs 5 Glue-MWA, ANOVA): SAD, 2.80 ± 0.13 cm vs 2.94 ± 0.06 cm vs 2.78 ± 0.26 cm ($p = 0.28$); LAD, 2.97 ± 0.10 cm vs 3.14 ± 0.05 cm vs 2.98 ± 0.11 cm ($p < 0.05$), temperature 1 cm from MWA probe: 76.8 ± 13.9° C vs 89.8 ± 11.4° C vs 77.2 ± 17.4° C ($p = 0.32$).

CONCLUSION

Different embolic agents did not produce a significant change in TAE-MWA tissue dielectric properties. With LAVA 18, there was a trend toward higher TAE-MWA temperatures and significantly increased LAD compared to other embolic agents.

CLINICAL RELEVANCE/APPLICATION

TAE-MWA with various agents may produce similar results in terms of SAD MWA dimensions, but increased temperatures and LAD were observed with LAVA, warranting further investigation at higher power MWA.

W5B-SPIR-4 ULTRASOUND-MODULATED THERANOSTIC MICROBUBBLES FOR PEDIATRIC BRAIN INJURY

Sophie Haddad, MD (*Presenter*)
Kathrine Curtin (*Abstract Co-Author*)
Todd J. Kilbaugh, MD (*Abstract Co-Author*)
Misun Hwang, MD (*Abstract Co-Author*)

PURPOSE

Brain injuries are a leading cause of death and morbidity in children and pose significant long-term side effects. Current care focuses on symptom management; thus, there is a critical need to develop effective therapies to manage the disease and prevent brain injury progression in the acute setting.Novel treatments, such as neuroprotective noble gases and drugs, are promising, but their systemic delivery is limited by rapid metabolism, challenges in crossing the blood-brain barrier, and unwanted side effects. To overcome these challenges, we developed ultrasound-responsive theranostic microbubbles (MBs) loaded with neuroprotective noble gases and drugs for ultrasound image-guided therapy. The benefits of this technique are owed to the use of MBs as a carrier and ultrasound stimulation for controlled release. In this work, we fabricated and assessed two formulations of theranostic MBs: xenon-loaded MBs and ferrostatin-1-loaded MBs.

METHODS AND MATERIALS

MBs were fabricated by ultrasonication. The MBs were characterized using microscopy and mass spectrometry to measure size and therapeutic encapsulation efficiency. The ultrasound responsiveness and therapeutic release profiles were evaluated via ultrasound and a flow phantom. The MBs were then assessed in vivo for feasibility.

RESULTS

The MBs demonstrated high therapeutic loading and exhibited high ultrasound contrast. The MBs were successfully cavitated at an MI of 0.68, which meets FDA standards for diagnostic ultrasound. The injection of MBs was feasible in vivo, and they were successfully visualized via contrast-enhanced ultrasound at the carotid artery. Our results indicate our theranostic MBs are feasible, with successful visualization and cavitation observed in vivo.

CONCLUSION

Our study shows promise for image-guided drug delivery to the brain. The sub-10 μm theranostic MBs are highly stable, encapsulate therapeutics, and exhibit excellent ultrasound responsiveness in vivo. Future studies will explore the efficacy of this approach in disease models, paving the way for novel therapeutic strategies for the brain.

CLINICAL RELEVANCE/APPLICATION

Our technology shows great potential for clinical application in brain injury. The MBs are made from biocompatible materials, and the ultrasound settings employed are safe for clinical use. This non-invasive technique uses a hand-held, portable ultrasound system, which enables its use in low-resource settings. Ultrasound stimulation releases the noble gases and drugs from the carrier MBs. Translating our theranostic MBs into the clinical setting aims to bridge significant gaps in patient care and enhance the delivery of therapeutics to the pediatric brain.

W5B-SPIR-5 PAE VS. TURP FOR BPH: WHICH IS MORE COST-EFFECTIVE? A SYSTEMATIC REVIEW OF ECONOMIC EVALUATIONS ACROSS HEALTHCARE SYSTEMS

Jennifer A. Jackson-Cole, MBChB, MMEd (*Presenter*)
Valerie Ntoinya, MD, MMEd (*Abstract Co-Author*)
Connie M. Ongeti, MBChB,MMed (*Abstract Co-Author*)
MARTIN KAMANDA (*Abstract Co-Author*)

PURPOSE

Is minimally invasive PAE cost-effective compared to TURP? This systematic review compares economic evaluations of Prostatic Arterial Embolization (PAE) and Transurethral Resection of the Prostate (TURP) for managing symptomatic Benign Prostatic Hyperplasia (BPH), detailing the costs, quality-adjusted life year (QALY), and cost-effectiveness, while considering factors influencing the cost-effectiveness.

METHODS AND MATERIALS

PRISMA guidelines were followed, and the research was registered on PROSPERO. PubMed, EMBASE, Scopus, INAHTA, Cost-Effectiveness Analysis (CEA) Registry, and Google Scholar were searched to identify full economic evaluations (EE) comparing PAE and TURP for BPH. Two reviewers identified and screened studies, extracting data on costs, QALYs, and incremental cost-effectiveness ratios (ICERs). Quality assessment was done using CHEERS 2022 and Phillips checklists.

RESULTS

Five of the 184 screened studies met inclusion criteria (USA: 2, Canada: 1, Spain: 1, UK: 1; 2021-2023). Time horizons spanned 1 to 6.5 years, with the US analyses reflecting payer perspectives and the others public healthcare system perspectives. PAE demonstrated lower short-term costs across all the health settings, but long-term savings reduced with higher retreatment rates (PAE: 12-31% vs. TURP: 0-5%). PAE's QALYs were marginally lower (differences: 0.009-0.085). In the US, PAE reduced 3-year costs by 51% ($2,934 vs. $2,934 vs. $6,038), due to fewer complications (0.1% vs. 2.1% major events) and outpatient care (0.125 vs. 1.38 hospital days). TURP's ICER (247,732-247,732-360,249/QALY) exceeded U.S. cost-effectiveness thresholds (50,000-50,000-100,000/QALY), favoring PAE in 96.4% of simulations. PAE saved €2,121/QALY short-term in Spain, but reinterventions reduced this advantage. The UK showed a similar trend. Canada's 6.5-year model found PAE's superiority uncertain, with potential dominance at 10 years.

CONCLUSION

PAE is a dominant cost-saving strategy for BPH in the US, reducing costs by half over 3 years through reduced complications and outpatient care. While cost-effective in the short term in the UK and Spain, PAE's economic advantage was reduced by 5 years due to reinterventions.

CLINICAL RELEVANCE/APPLICATION

PAE offers a minimally invasive, cost-effective alternative to TURP within 1-5 years, particularly for systems prioritizing short-term savings. PAE matches TURP in the long term. Policymakers must balance immediate gains against long-term sustainability, advocating for individualized pathways aligned with patient needs.

W5B-SPIR-6 IMPACT OF TRANSARTERIAL CHEMOEMBOLIZATION COMBINED WITH TARGETED AND IMMUNE THERAPY ON LIVER FUNCTION AND PROGNOSIS IN ADVANCED HEPATOCELLULAR CARCINOMA PATIENTS: THE SIGNIFICANCE OF BASELINE ALBUMIN-BILIRUBIN GRADE

Yiwan Guo (*Presenter*)
Bo Sun (*Abstract Co-Author*)
Xin Li (*Abstract Co-Author*)
Chuansheng Zheng, MD (*Abstract Co-Author*)
Xuefeng Kan, MD,PhD (*Abstract Co-Author*)
Fan Yang, MD (*Abstract Co-Author*)

PURPOSE

Liver function has been regarded as a critical determinant for prognosis of patients with hepatocellular carcinoma (HCC). This study aimed to evaluate the impact of transarterial chemoembolization (TACE) combined with tyrosine kinase inhibitors and immune checkpoint inhibitors (TTI) on liver function in advanced HCC patients compared with TACE alone, and to assess the prognostic value of baseline albumin-bilirubin (ALBI) grade.

METHODS AND MATERIALS

This retrospective study enrolled advanced HCC patients treated with TTI or TACE alone between January 2018 and December 2023. The primary outcome was the time to progression of baseline ALBI grade, with secondary outcomes including overall survival (OS) and progression-free survival (PFS) of patients.

RESULTS

A total of 162 patients (TTI group, n = 68; TACE alone group, n = 94) were included in this study. The TTI group showed a significantly longer median time to baseline ALBI grade progression than TACE alone group (19.0 vs. 11.6 months, p = 0.004). Subgroup analyses revealed similar benefits of TTI group (11.3 vs. 5.0 months for ALBI grade 1, p = 0.015; 20.0 vs. 14.7 months for ALBI grade 2, p = 0.025). Patients in the TTI group demonstrated superior median OS (42.2 vs. 22.0 months for ALBI grade 1, p = 0.077; 22.6 vs. 13.5 months for ALBI grade 2, p = 0.001) and longer median PFS (11.7 vs. 6.8 months for ALBI grade 1, p = 0.148; 8.4 vs. 4.9 months for ALBI grade 2, p = 0.022) compared to the TACE alone group.

CONCLUSION

TTI therapy preserved liver function for a longer duration and achieved better survival outcomes than TACE alone in advanced HCC patients, particularly benefiting those with baseline ALBI grade 2.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated that for advanced HCC patients, TACE combined with targeted and immune therapy could better preserved liver function than TACE alone. Notably, for advanced HCC patients with baseline ALBI grade 2, the combination therapy was more strongly recommended since it could offer greater clinical benefits for them.

W5B-SPIR-7 TRANSILEOCOLIC PORTAL VEIN EMBOLIZATION PRIOR TO HEPATECTOMY FOR LIVER MALIGNANCIES

Yoshitaka Tamura (*Presenter*)
Hiro Kiyosue (*Abstract Co-Author*)
Hidetaka Hayashi, MD (*Abstract Co-Author*)
Taiga Matsumoto, MD (*Abstract Co-Author*)
Osamu Ikeda, MD (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)

PURPOSE

Preoperative portal vein embolization (PVE) is a widely accepted technique to promote hypertrophy of the future liver remnant (FLR) and reduce the risk of postoperative liver insufficiency after major hepatectomy. While the percutaneous transhepatic approach is commonly used, this study investigates the feasibility and safety of PVE performed via the transileocolic vein.

METHODS AND MATERIALS

This retrospective study analyzed clinical and imaging data from patients who underwent laparotomic transileocolic PVE between December 2012 and December 2023. This alternative route was selected when the percutaneous approach was considered technically difficult due to biliary dilatation, complex anatomy, or failure of transhepatic attempts. Embolization was performed under balloon occlusion using gelatin sponge and 5% ethanolamine oleate with iopamidol. Technical success was defined as complete occlusion of target portal branches on final venography, and clinical success as complete occlusion on contrast-enhanced CT one week post-procedure. FLR volumetry, complication rates (Clavien-Dindo grade =3), and portal vein recanalization were evaluated.

RESULTS

A total of 71 patients (47 men, 24 women; mean age, 69.5 years) underwent transileocolic PVE. Indications included hilar cholangiocarcinoma (n=39), colorectal liver metastases (n=17), intrahepatic cholangiocarcinoma (n=8), hepatocellular carcinoma (n=6), and gallbladder carcinoma (n=1). Technical and clinical success rates were 98.6% and 94.4%, respectively. Recanalization occurred in 2 patients (2.8%), both successfully managed with repeat PVE followed by hepatectomy. Mean FLR volume increased from 52.7% to 62.8% ($p < 0.0001$), and hepatectomy was ultimately performed in 81.9% of patients. Major complications were observed in 12.5%, with cholangitis being the most common (n=6).

CONCLUSION

Transileocolic PVE is a safe and effective alternative to the percutaneous approach, particularly in patients with challenging anatomy or biliary dilation. This method consistently achieves FLR hypertrophy with acceptable complication rates.

CLINICAL RELEVANCE/APPLICATION

The transileocolic approach broadens the clinical utility of PVE in patients unsuitable for percutaneous access, offering a reliable strategy for FLR augmentation in the preoperative management of complex hepatic malignancies.

W5B-SPMK-1 QUANTITATIVE FAT FRACTION MAPPING IN LOWER LEG MRI AS AN IMAGING BIOMARKER FOR CHARCOT-MARIE-TOOTH DISEASE TYPE 1A: EVALUATION USING DEEP LEARNING-BASED SEGMENTATION

Hyun Su Kim, MD, PhD (*Presenter*)
Jae-Hun Kim, PhD (*Abstract Co-Author*)
Ji Hyun Lee, MD, PhD (*Abstract Co-Author*)
Young Cheol Yoon, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

PURPOSE

To assess the utility of intramuscular fat fraction (FF) on 3D multi-echo gradient-echo Dixon-based lower leg MRI in patients with Charcot-Marie-Tooth disease type 1A (CMT1A), using a deep learning-based automated muscle segmentation model.

METHODS AND MATERIALS

We retrospectively analyzed lower leg MRI of 69 CMT1A patients. We utilized an automated muscle segmentation model for 3D multi-echo gradient echo Dixon-based MRI. This model was derived from a previously developed version trained on manually labeled T1-weighted lower leg MRIs from 120 CMT patients using a deep learning-based 2D U-Net. Muscle segmentations were conducted for four compartments (anterior, lateral, deep posterior, and superficial posterior) of the lower leg. Mean FFs were measured for each muscle compartment of the lower leg from multiple MRI slices, spanning from the proximal to the distal level. Correlations between FFs and clinical scores (Charcot-Marie-Tooth Neuropathy Score version 2 [CMTNSv2], functional disability scale [FDS]) and results of upper and lower limb evaluations (functional dexterity, 9-hole peg test, hand grip, foot plantarflexion, dorsiflexion, timed up and go, 6-minute walk, 10-m walk, stair climb, and sit to stand) were assessed using partial correlation analysis adjusting for age and body mass index.

RESULTS

The FFs of the anterior, lateral, deep posterior, and superficial posterior compartments of the lower legs, as well as the total FF, showed significant positive correlations with CMTNSv2 and FDS, suggesting that higher FFs are associated with more severe disease ($p < 0.05$). The strongest was between the FF of the lateral compartment and the FDS ($r = 0.49$). In physical evaluations involving time-based measures (stair climb, 10-meter walk, functional dexterity, 9-hole peg test, and timed up and go), FF showed significant positive correlations ($p < 0.05$). In contrast, in assessments of strength (hand grip, foot plantarflexion and dorsiflexion), distance (6-minute walk), and repetitions (sit-to-stand), FF exhibited significant negative correlations ($p < 0.05$). These findings suggest that higher FF is associated with reduced upper and lower limb function. The strongest correlation with limb evaluation results was between the FF of the lateral compartment and the stair climb test ($r = 0.58$).

CONCLUSION

FFs of lower leg muscle compartments on MRI, quantified using an automated segmentation model, showed significant correlations with clinical parameters in patients with CMT1A. These findings suggest that higher FFs are associated with more severe clinical impairment.

CLINICAL RELEVANCE/APPLICATION

FFs of lower leg muscles, quantified via automated segmentation, may serve as reliable imaging biomarkers for future CMT1A clinical trials.

W5B-SPMK-2 BILATERAL FEMORAL DENSIFICATIONS IN ELDERLY WOMEN: A NEW SCLEROSING BONE DYSTROPHY?

Caroline Chabot, MD (*Presenter*)
Bruno C. Vande Berg, MD, PhD (*Abstract Co-Author*)

PURPOSE

To describe a previously unreported pattern of femoral bone changes seen on knee radiographs of elderly women.

METHODS AND MATERIALS

Over a ten-year period, we collected knee radiographs of 30 elderly women (mean age ± SD: 76.7 ± 7.7 years) obtained for the evaluation of knee osteoarthritis and showing bilateral symmetrical densifications of the distal diaphyso-metaphyseal regions of the femurs. We excluded patients with unilateral or bilateral local sclerotic bone lesions (i.e. infarcts, enchondromas, fibrous dysplasias) and patients with systemic disorders (i.e. mucopolysaccharidosis, histiocytosis). On radiographs, two radiologists classified the distribution of sclerotic bone changes within the medullary cavity into five categories (exclusively lateral, predominantly lateral (> medial), central, predominantly medial (> lateral), exclusively medial). Patterns of bone sclerosis were classified in five categories (striated/dotted lines, disseminated punctate foci, popcorn-type calcifications, or mixed). The presence of sclerotic rim and of cortical bone changes was assessed. CT scans (13 knees) were analyzed for the presence, size, and density of sclerotic nodules. MRI scans (10 knees) were analyzed and the signal profiles of the lesions were categorized as bone-like, fluid-like, fat-like, or red marrow-like on T1, T2 and fat-saturated proton-density-weighted images. Available medical files were reviewed for any particular condition.

RESULTS

On radiographs, bone sclerosis was exclusively lateral (40%), predominantly lateral (33.3%) and central (26.7%). The frequency of sclerotic bone patterns was mixed (45%), striated (36.7%), punctate (10%) and popcorn (8.3%). No cases showed peripheral sclerosis or cortical changes. On CT, all knees showed intramedullary sclerotic nodules smaller than 5 mm. Nodules of 5-10 mm and more than 10 mm were seen in 38.5% and 7.7% of the knees, respectively. The attenuation density of the nodules ranged from 901-2059 HU (mean ± SD: 1531 ± 347.4). At MRI, medullary areas of bone sclerosis showed spots of bone-like signal intensity surrounded by a red marrow-like signal intensity pattern in a fatty marrow background. No unexpected systemic disorder was observed in the medical files.

CONCLUSION

Bilateral symmetrical densifications of the distal diaphyso-metaphyseal regions of the femurs can be observed on the radiographs and CT images of elderly women with a consistent pattern of bone marrow changes on MRI that differs from previously reported bone marrow changes.

CLINICAL RELEVANCE/APPLICATION

Recognition of this radiological entity is essential to avoid misdiagnosis or unnecessary investigations. Further studies are needed to assess the significance, if any, of these changes.

W5B-SPMK-3 ASSOCIATIONS BETWEEN CARDIAC ADIPOSE TISSUE AND ABDOMINAL VISCERAL FAT AND MUSCLE: A CT-BASED ANALYSIS OF AREA AND DENSITY PARAMETERS

Babak Salam, MD (*Presenter*)
Sebastian Nowak, PhD (*Abstract Co-Author*)
Maike Theis, MSc (*Abstract Co-Author*)
Thomas Vollbrecht (*Abstract Co-Author*)
Marilia B. Voigt (*Abstract Co-Author*)
Christoph H. Endler, MD (*Abstract Co-Author*)
Tatjana Dell (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)
Claus C. Pieper, MD (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)
Alois M. Sprinkart, PhD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)

PURPOSE

CT-derived body composition parameters of cardiac adipose tissue (CAT), as well as abdominal adipose and muscle tissue, serve as surrogates for a patient's clinical condition and have prognostic implications. However, associations between these diverse compartments remain poorly investigated. This study aimed to assess associations between opportunistic CT-derived parameters of cardiac and abdominal fat and muscle tissue.

METHODS AND MATERIALS

Cardiac and abdominal CT scans from 842 patients were retrospectively analyzed. Measurements of CAT were taken at the aortic valve level, while abdominal adipose and muscle tissues were quantified at the L3/L4 intervertebral disc space. For each tissue compartment, area and density were calculated from single-slice images. Pearson correlation coefficients were used to assess associations between the CT-derived parameters.

RESULTS

Strong positive correlations were found between CAT area and visceral adipose tissue (VAT) area ($R=0.755$, $P<.001$), as well as moderate correlations between CAT density and VAT density ($R=0.521$, $P<.001$). Additionally, skeletal muscle (SM) area exhibited modest positive correlations with VAT area ($R=0.370$, $P<.001$), CAT area ($R=0.300$, $P<.001$), and SM density ($R=0.356$, $P<.001$). No significant differences were observed between genders in the correlation strengths of these associations.

CONCLUSION

These findings indicate a systematic pattern of body composition alterations, advocating for the inclusion of comprehensive body composition analysis in future studies and emphasizing the need for a deeper understanding of the underlying systemic processes influencing body composition.

CLINICAL RELEVANCE/APPLICATION

This study highlights the strong interrelationships between CT-derived body composition parameters of cardiac and abdominal fat and muscle compartments. The observed correlations—particularly between visceral and cardiac adipose tissue area and density—suggest a shared, systemic pathophysiological process, potentially driven by chronic low-grade inflammation. These findings support the use of comprehensive, opportunistic body composition analysis in routine CT imaging to better assess patients' clinical status and risk stratification. Moreover, the results advocate for the inclusion of cardiac adipose tissue assessment in prognostic models beyond cardiovascular disease, potentially informing outcomes in broader clinical contexts such as oncologic or geriatric care.

W5B-SPMK-5 DEEP LEARNING IMAGE RECONSTRUCTION COMBINED WITH MARS ALGORITHM FOR METAL ARTIFACT CORRECTION IN CT IMAGES: A PHANTOM STUDY

Zhenwei Yu (*Presenter*)
Tianbao Zhang (*Abstract Co-Author*)
Yanan Zhu (*Abstract Co-Author*)
Ning Wang (*Abstract Co-Author*)
Jun Yao (*Abstract Co-Author*)
Zhengjun Li (*Abstract Co-Author*)
Yongjun Jia, MMed (*Abstract Co-Author*)

PURPOSE

To investigate the effect of various reconstruction algorithms, including adaptive statistical iterative reconstruction-V (ASIR-V) and deep learning image reconstruction (DLIR) algorithm combined with metal artifact reduction system (MARs) on the correction of metal artifacts in CT images using a phantom study.

METHODS AND MATERIALS

A phantom with a metal simulating femoral internal fixation was scanned on a GE Revolution APEX CT, and was reconstructed using the following algorithm combination: 50% ASIR-V combined with MARs (IR+M), medium-strength DLIR (DM) with MARs (DM+M), high-strength DLIR (DH) with MARs (DH+M), DM alone (DM), and DH alone (DH). The above five image groups were objectively evaluated by two radiologists by measuring the standard deviation of ROI 1 at the maximum artifact (SD 1), of ROI 2 at the artifact-free area (SD 2), to calculate the artifact index of images in each group. The two above mentioned radiologists also subjectively scored the image quality. The differences in image quality among the 5 groups were compared.

RESULTS

The differences in SD 1 , SD 2 , and artifact index among the 5 groups were statistically significant (all $P<0.05$). SD 1 and artifact index increased in the order of DH+M, DM+M, IR+M, DH, and DM (all $P<0.05$); SD 2 increased in the order of DH+M, DH, DM+M, DM, and IR+M (all $P<0.05$); SD 1 , SD 2 , and artifact index values were lowest in the DH+M images. DH+M images also scored the best in the subjective evaluation with the two radiologists showed good consistency in the subjective scoring (Kappa> 0.80, $P<0.05$).

CONCLUSION

High-strength DLIR combined with MARs more effectively reduces the metal implantation artifacts and image noise in a phantom study with metal insert simulating femoral internal fixation.

CLINICAL RELEVANCE/APPLICATION

DLIR combined with MARs has great potential in reducing metal artifacts and image noise for patients with metal internal fixation.

W5B-SPMK-6 ROUTINE CHEST CTS FOR OPPORTUNISTIC EVALUATION OF BONE HEALTH IN CARDIAC TRANSPLANT RECIPIENTS: A FEASIBILITY STUDY

Seyedali Nabipoorashrafi, MD (*Presenter*)
Farbod Khosravi, MD (*Abstract Co-Author*)
Sanaz Asadian, MD (*Abstract Co-Author*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Peyman Mirghaderi, MD, MPH (*Abstract Co-Author*)
Arash Bedayat, MD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)
Hamid Chalian, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the potential of using routine non-contrast chest computed tomography scan (CTs) in cardiac transplant patients to assess bone mineral density (BMD) and vertebral body height.

METHODS AND MATERIALS

In this observational, IRB-approved study, all patients who underwent cardiac transplantation between 2017 and 2020 and had CT scans both before and after the procedure, along with dual-energy X-ray absorptiometry (DEXA) scans, were included. The CTs were used to measure thoracic vertebral bone density at three levels (upper, middle, and lower) and vertebral body height (anterior, middle, and posterior) at each thoracic level (T1-T12). CT-based bone density measurements before and after transplantation were compared and correlated with DEXA scan results.

RESULTS

The findings revealed a significant decrease in vertebral bone density in the middle thoracic region (T5-T8) from 175 to 163 Hounsfield Units (HU) and in the lower thoracic region (T9-T12) from 163 to 146 HU after transplantation ($P < .05$). A strong correlation was observed between the bone density values derived from CTs and those from DEXA scans. The correlation coefficients for the upper, middle, and lower thoracic regions were 0.526, 0.397, and 0.343, respectively ($P < .05$). Furthermore, vertebral body height significantly changed at upper, middle, and lower thoracic regions and specific levels (T3, T6, T11, and T12) ($P < .05$). The anterior and middle portions of the vertebral body showed a significant reduction in median height of 0.2 mm and 0.3 mm, respectively ($P < .05$), while changes in the posterior portion were not significant ($P > .05$).

CONCLUSION

Routine non-contrast chest CTs, commonly performed for cardiac transplant patients, can effectively assess bone density, presenting a potential alternative to DEXA scans in this patient population.

CLINICAL RELEVANCE/APPLICATION

Opportunistic evaluation of bone mineral density and vertebral morphology using standard non-contrast chest CTs offers a practical, cost-free approach to identifying early osteoporotic changes in cardiac transplant recipients. This strategy enables timely intervention without the need for additional imaging, supporting proactive management of bone health in a high-risk population.

W5B-SPNMMI-1 COMBINATION IMMUNOTHERAPY TARGETING LAG-3, PD-1 AND STING SUPPRESSES HEPATOCELLULAR CARCINOMA AS MONITORED BY LAG-3 TARGETED PET IMAGING TARGETED PET IMAGING

Zhen Quan (*Presenter*)
Bo Sun (*Abstract Co-Author*)
Chuansheng Zheng, MD (*Abstract Co-Author*)
Xin Li (*Abstract Co-Author*)
Quan Chen, PhD (*Abstract Co-Author*)

PURPOSE

The low response rate of anti-PD-1 monoclonal antibodies (mAbs) in hepatocellular carcinoma (HCC) requires the development of combination immunotherapy strategies to improve their efficacy. This study aimed to use LAG-3-targeted PET imaging to monitor the efficacy of anti-PD-1 mAb, a stimulator of interferon genes (STING) agonist, and anti-LAG-3 mAb, both individually and in combination. Furthermore, we evaluated the potential of a triple immunotherapy regimen (anti-PD-1 mAb, STING agonist, and anti-LAG-3 mAb) to improve HCC treatment.

METHODS AND MATERIALS

The LAG-3 inhibitor C25 based on a cyclic peptide was chelated with NOTA, radiolabeled with 68 GaCl 3 . The resulting 68 Ga-NOTA-C25 underwent in vivo PET imaging and ex vivo biodistribution examination in Hepa1-6 tumor-bearing mice. 68 Ga-NOTA-C25 PET was used to monitor the efficacy of monotherapy and dual immunotherapy with anti-PD-1 monoclonal antibody (mAb) and STING agonists. The tumor uptake of 68 Ga-NOTA-C25, tumor response, and survival rates were measured following different treatments.

RESULTS

68 Ga-NOTA-C25 PET imaging effectively and noninvasively detected LAG-3 + tumor-infiltrating lymphocytes (TILs) in Hepa1-6 tumor-bearing mice. In mice treated with anti-PD-1 mAb, STING agonist, or a combination immunotherapy, 68 Ga-NOTA-C25 PET revealed significantly increased LAG-3 + TIL levels. At the treatment endpoint, the combination of the STING agonist with the anti-PD-1 mAb resulted in a significantly higher uptake (1.35 ± 0.191 %ID/g) compared to the control group (0.402 ± 0.017 %ID/g), the anti-PD-1 mAb group (0.647 ± 0.037 %ID/g), and the STING agonist group (0.874 ± 0.089 %ID/g). Uptake of 68 Ga-NOTA-C25 was positively correlated with tumor therapeutic effects and survival rates. Triple immunotherapy with anti-PD-1 mAb, a STING agonist, and anti-LAG-3 mAb further enhanced efficacy compared to any dual immunotherapy regimen, and treatment efficacy was linearly associated with 68 Ga-NOTA-C25 tumor uptake.

CONCLUSION

Anti-PD-1 mAb and STING agonists have shown notable synergy in upregulating LAG-3 expression on TILs in HCC, which can be successfully tracked by 68 Ga-NOTA-C25 PET imaging. Furthermore, integration of a triple immunotherapy regimen comprising an anti-PD-1 mAb , STING agonist, and anti-LAG-3 mAb demonstrated a significant improvement in therapeutic efficacy over dual immunotherapy approaches.

CLINICAL RELEVANCE/APPLICATION

PET imaging with a LAG-3-specific probe (68 Ga-NOTA-C25) would offer clinicians valuable information that could make a significant impact on the management of liver cancer patients with combined immunotherapy.

W5B-SPNMMI-2 IMAGING AND CONTOURING METHODS FOR PRE-Y90 LSF: A COMPARATIVE ANALYSIS OF 2D VS. 3D AND MANUAL VS. AUTOMATED CONTOUR TECHNIQUES

Aidan Megally (*Presenter*)
Ryan Thomas (*Abstract Co-Author*)
Robert H. Wagner, MD (*Abstract Co-Author*)
Christopher A. Molvar, MD (*Abstract Co-Author*)
Judy R. James, PhD, MS (*Abstract Co-Author*)

PURPOSE

Hepatocellular carcinoma (HCC) patients, prior to undergoing Yttrium-90 (Y90) treatment will have a pre Y90 mapping with Technium-99m macro aggregated albumin (99mTc-MAA) to estimate the percentage of Y90 microspheres that may inadvertently bypass the liver and enter the lungs, defined as their lung shunt fraction (LSF). The pre Y90 LSF value is critical to Y90 dosimetry and to manage radiation exposure to the lungs. Confidently obtaining the LSF from 2D or 3D nuclear medicine images is a crucial and challenging task for technologists. This study aims to evaluate LSF values obtained from 2D planar or 3D SPECT-CT images using a clinically approved software and assessing each method’s user-dependence.

METHODS AND MATERIALS

A retrospective LSF analysis was conducted on n=50 HCC patients who underwent pre-Y90 mapping. LSF values were obtained by a) manual segmentation of the liver and lungs on 2D planar images and b) automated contouring and delineation of the liver-lung border on 3D SPECT-CT images in MIM software. LSFs from both methods were compared for statistical differences. A subset of 3D LSF values were redone using a semi-automated method of adjusting the automated contours in MIM. The corresponding 2D LSF value were redone by an independent rater to assess rater differences as well. Statistical analysis was performed to compare absolute differences between rater-dependent 2D LSFs and semi vs. fully automated 3D LSFs.

RESULTS

Two-sample t-test comparing the LSFs obtained using 2D vs. 3D methods showed no statistical significant difference ($p > 0.05$), suggesting both methods provide similar accuracy. However, significant variability was observed between 2D LSFs from separate raters ($p<0.05$) opposed to 3D semi vs fully automated methods, where no statistical difference was seen ($p>0.05$).

CONCLUSION

Our work highlights the importance of using 3D SPECT-CT with automated contouring when obtaining LSFs before Y90 therapy. With an increased risk of user error using 2D methods, calculations can vary, contrary to 3D imaging with automated contouring, which offers consistent results, even when minor adjustments are applied.

CLINICAL RELEVANCE/APPLICATION

Obtaining an accurate LSF is imperative to administering an effective Y90 dose, ensuring the patient receives adequate microspheres to targeted hepatic malignancies while minimizing radiation exposure to the lungs. A key concern is the increased complexity introduced by the manual segmentation when using 2D imaging, which requires the technologist to manually contour the liver-lung border over planar images. In contrast, automated contouring on 3D SPECT-CT, reduces rater-dependence, improving efficiency and increasing reproducibility for LSF calculations.

W5B-SPNPM-1 COST-EFFECTIVENESS ANALYSIS OF CT, PET/CT, AND WHOLE-BODY MRI IN ADVANCED MELANOMA PATIENTS TREATED WITH NIVOLUMAB AND IPILIMUMAB: A DECISION-ANALYTIC MODEL

Moritz L. Schnitzer, MD (*Presenter*)
Johannes Ruebenthaler, MD (*Abstract Co-Author*)
Thomas Geyer, MD (*Abstract Co-Author*)
Felix Herr, MD (*Abstract Co-Author*)

PURPOSE

Accurate initial staging and treatment response assessment are essential in advanced melanoma, particularly in the context of high-cost immunotherapy. While contrast-enhanced CT (CECT) remains the standard imaging modality, PET/CT and whole-body MRI (WB-MRI) may improve clinical decision-making through superior diagnostic performance. This study evaluates the cost-effectiveness of these three imaging strategies in patients treated with nivolumab and ipilimumab.

METHODS AND MATERIALS

A decision-analytic model combining a decision tree and Markov model was developed using TreeAge Pro. The model simulated a cohort of patients with advanced melanoma over a 5-year horizon in 3-month cycles. Imaging strategies included CECT, PET/CT, and WB-MRI, each linked to a Markov process incorporating the health states: progression-free survival (PFS), treatment response, progression, and death. Transition probabilities, QALYs, and cost inputs were derived from literature and clinical data. Model outputs included total costs, QALYs, and incremental cost-effectiveness ratios (ICERs).

RESULTS

PET/CT demonstrated the highest effectiveness (32.20 QALYs) at a moderate cost (€233,751.35), making it the most cost-effective option overall. WB-MRI yielded slightly lower effectiveness (31.45 QALYs) but incurred the highest cost (€251,294.77). CECT was the least costly (€230,596.44) but also the least effective (30.20 QALYs). Therefore, PET/CT versus CECT was within acceptable willingness-to-pay thresholds, while WB-MRI exceeded them without providing substantial additional benefit.

CONCLUSION

PET/CT provides the most favorable balance of cost and clinical effectiveness in advanced melanoma patients treated with immunotherapy. Although WB-MRI shows diagnostic potential, its high cost limits its economic value. CECT remains the most affordable but may compromise treatment planning due to lower diagnostic sensitivity. These findings support PET/CT as a cost-effective, clinically robust imaging strategy in this setting.

CLINICAL RELEVANCE/APPLICATION

Imaging selection critically influences patient outcomes and resource use in immuno-oncology. This study demonstrates that PET/CT offers the optimal trade-off between cost and diagnostic performance, effectively guiding treatment decisions without excess expenditure. In contrast, whole-body MRI—while diagnostically promising—does not provide sufficient additional clinical benefit to justify its higher cost. Standard CECT may reduce expenses but carries the risk of suboptimal staging. These insights support value-based imaging policies and can inform national reimbursement and guideline strategies.

W5B-SPNPM-2 BRIDGING THE GAP BETWEEN EVIDENCE AND PERCEPTION FOR A PATIENT-CENTERED COMMUNICATION STRATEGY FOR RADIOLOGY

Francesco Ria, PhD (*Presenter*)
Ehsan Samei, PHD (*Abstract Co-Author*)

PURPOSE

Controversial publications on radiation risk, such as a recent article claiming that CT scans may cause up to 5% of cancers diagnosed annually in the U.S. (Smith-Bindman et al., JAMA Intern Med), often receive disproportionate media attention despite methodological limitations. While the radiology community responds with scientific critiques, public narratives are frequently shaped by fear rather than evidence. This study examined the disparity between public and scientific attention to radiation-induced cancer in radiology compared with other high-risk medical procedures and evaluated the impact of media amplification on public perception and professional discourse to inform effective communication to patients.

METHODS AND MATERIALS

We conducted a qualitative analysis of public responses to the Smith-Bindman article and compared it with responses to the 2024 Radiology article with the highest Altmetric score (Philpotts et al., Breast cancers detected during a decade of screening with digital breast tomosynthesis: comparison with digital mammography). We also performed a PubMed query of 2024 publications to compare the number of articles referencing “radiation-induced cancer” with those referencing “surgery-related mortality” and “chemotherapy-related mortality.” Data on Altmetric scores, news mentions, and scientific volume were collected and compared to identify trends.

RESULTS

Three weeks after publication, the Smith-Bindman article had an Altmetric score of 2480 and was cited by 299 news outlets. By comparison, the Philpotts article, eight months post-publication, had a score of 488 and was cited by 61 outlets. In 2024, 35 scientific articles mentioned “radiation-induced cancer,” whereas only 5 mentioned “surgery-related mortality” and 1 mentioned “chemotherapy-related mortality.”

CONCLUSION

Radiation risks in medical imaging receive disproportionate attention compared to other high-risk medical procedures, both in scientific literature and the media. This imbalance may distort patient understanding and decision-making. Radiology professionals must proactively engage in transparent, evidence-based communication to contextualize imaging risks within the broader landscape of medical care, also emphasizing the benefits associated with effective and early diagnosis.

CLINICAL RELEVANCE/APPLICATION

Selective amplification of radiation risks may undermine patient trust and lead to avoidance of medically necessary imaging. Effective, balanced communication is essential to support informed decisions and maximize patient care.

W5B-SPNPM-3 INTEGRATING PATIENT INVOLVEMENT IN WHOLE-BODY MRI SURVEILLANCE FOR LI-FRAUMENI SYNDROME: PERSPECTIVES ON SCAN DURATION, CONTRAST AGENT USE, AND ANXIETY

Myriam Keymling, MD (*Presenter*)
Johann Jende (*Abstract Co-Author*)
Christian Jan Oliver Neelsen (*Abstract Co-Author*)
Heinz-Peter W. Schlemmer, MD (*Abstract Co-Author*)
Diane M. Renz, MD (*Abstract Co-Author*)

PURPOSE

To assess patient experiences and preferences regarding whole-body MRI (WB-MRI) surveillance in Li-Fraumeni syndrome (LFS), with a focus on factors affecting long-term adherence - such as scan duration, contrast agent use, and anxiety triggers - and to highlight the role of patient involvement in shaping optimized, patient-centered imaging protocols.

METHODS AND MATERIALS

As part of the LFS-MRI study conducted at DKFZ, patients with a confirmed pathogenic TP53 variant were invited to participate in an online survey after undergoing at least one WB-MRI examination. The 10-item questionnaire, developed with input from patient advocates and administered in German, explored perceived examination burden, motivational factors, and anxiety triggers. Descriptive analyses were performed for all 97 respondents.

RESULTS

All 97 participants completed item 1 - 8 of the survey. 95% responded to item 9 (willingness to accept shorter scans despite potential diagnostic loss) and 96% to item 10 (primary source of anxiety). While the majority of patients (57%) perceived the exam duration as at least partially too long, 98% intended to continue annual WB-MRI screenings. 87% would not consider discontinuing participation even if the duration remains long, and 65% were willing to accept a duration of 90 minutes or more. This could be due to the fact that nearly all participants (95%) believed WB-MRI to contribute significantly to improving their prognosis. A subset however indicated increased motivation if the exam were shorter (30%) or if no contrast agent were required (34%). Only 5% would prefer a shorter scan even if it meant potentially missing suspicious findings. 29% reported the feeling of confinement in the scanner as the strongest cause for anxiety, followed by fear of exam results (23%) and confronting their elevated cancer risk (18%). Noise was cited as the primary anxiety source by only 3% of participants.

CONCLUSION

Patients with LFS demonstrate strong commitment to WB-MRI surveillance, motivated by their belief in its clinical value. However, aspects such as scan duration and contrast agent use affect motivation and comfort. Integrating patient perspectives into protocol design can help develop more tolerable protocols and sustain long-term adherence to surveillance in LFS.

CLINICAL RELEVANCE/APPLICATION

Patient involvement into imaging protocols is essential for enhancing long-term adherence and reducing exam-related anxiety in hereditary cancer syndromes such as LFS, paving the way for more patient-centered care in high-risk populations.

W5B-SPNR-3 NINETY-DAY MEDICAL OUTCOMES AND TWO-YEAR REPEAT INTERVENTIONS FOLLOWING SINGLE-LEVEL VERTEBRAL AUGMENTATION: A NATIONAL DATABASE ANALYSIS

Rahul Jayaram, BS (*Presenter*)
Anshu Jonnalagadda (*Abstract Co-Author*)
Albert Lee (*Abstract Co-Author*)
Jonathan Grauer (*Abstract Co-Author*)

PURPOSE

Vertebroplasty and kyphoplasty are common treatments for vertebral compression fractures with generally favorable outcomes. However, prior studies on 90-day medical complications and 2-year reintervention rates remain limited by sample size and scope. The current study analyzed a large, multi-insurance, national administrative database to evaluate these outcomes following initial vertebral augmentation.

METHODS AND MATERIALS

Single-level vertebral augmentation procedures were identified from the 2010-2022 PearlDiver M170 database. Exclusion criteria included age under 65, an indication of neoplasm, infection, or prior spinal surgery. Outcomes included 90-day medical complications, readmissions, and emergency department (ED) visits. Multivariable logistic regression identified patient-level risk factors. Kaplan-Meier analysis assessed repeat vertebral augmentation rates at 3 months, 1 year, and 2 years.

RESULTS

Among 148,072 patients, 16.95% had a 90-day medical complication, and severe events occurred in 5.12%. Risk factors for 90-day complications included younger age (OR 1.01, per decade decrease), female sex (OR 1.11), ECI (relative to 0: 1-2 [OR 1.58], 3-4 [OR 2.21], =5 [OR 2.80]), insurance (relative to Medicare: Commercial [OR 1.12], Medicaid [OR 1.20]), and region (relative to West: Northeast [OR 1.19], South [OR 1.11], Midwest [OR 1.06]). For 90-day readmission, predictors included younger age (OR 1.024), ECI (relative to 0: 1-2 [OR 1.77], 3-4 [OR 2.62], =5 [OR 3.43]), insurance (relative to Medicare: Commercial [OR 1.14], Medicaid [OR 1.19]), and region (relative to West: Midwest [OR 1.18], Northeast [OR 1.35]). Female sex was associated with lower odds of readmission (OR 0.87). For 90-day ED visits, predictors included female sex (OR 1.043), ECI (relative to 0: 1-2 [OR 1.93], 3-4 [OR 2.770], =5 [OR 3.34]), insurance (relative to Medicare: Commercial [OR 1.46], Medicaid [OR 1.24]), and region (relative to West: Midwest [OR 1.12], Northeast [OR 1.07]); the South was associated with lower odds of ED visits (OR 0.92). Repeat augmentation rates were 5.8% at 3 months, 8.2% at 1 year, and 10.2% at 2 years.

CONCLUSION

In this analysis of single-level vertebral augmentations, 90-day medical complication, readmission, and ED visit rates were reported, along with a 10.2% 2-year repeat procedure rate. Clinical and non-clinical variables were identified as independent predictors of short-term outcomes.

CLINICAL RELEVANCE/APPLICATION

To our knowledge, this is the largest study to date examining 90-day medical complications, risk factors, and repeat vertebral augmentation rates up to 2 years. These findings can support clinical decision-making and risk stratification in managing vertebral compression fractures.

W5B-SPNR-4 MRI-BASED PREDICTION OF DNA METHYLATION GRADE IN IDH-MUTANT ASTROCYTOMAS USING QUALITATIVE AND QUANTITATIVE IMAGING FEATURES

Kanwar Singh, MBBS (*Presenter*)

PURPOSE

Histopathologic grading of IDH-mutant astrocytomas provides limited prognostic accuracy. DNA methylation-based subclassification into high-grade (A_IDH_HG) and low-grade (A_IDH_LG) tumors offers improved survival prediction. This study investigates whether preoperative MRI-derived imaging features and volumetric data can noninvasively predict methylation grade in IDH-mutant astrocytomas.

METHODS AND MATERIALS

Seventy-two treatment-naïve adult patients with histologically confirmed IDH-mutant astrocytomas underwent preoperative MRI and genome-wide DNA methylation profiling. VASARI imaging features and multicompartmental tumor volumes (enhancing, non-enhancing, necrotic, and edema) were extracted and reviewed. Logistic regression models with SMOTE oversampling were trained to predict methylation grade, WHO histologic grade, CNV status, and CDKN2A/B deletion. Cox proportional hazards models assessed associations with progression-free survival (PFS) and overall survival (OS).

RESULTS

Methylation grade was predicted from MRI with 75% accuracy (AUC=0.77), with high-grade tumors associated with enhancement, necrosis, midline crossing, ependymal extension, and poorly defined margins. In contrast, low-grade tumors were associated with the T2-FLAIR mismatch sign and greater non-enhancing tumor proportion. Volumetrically, A_IDH_HG tumors had larger enhancing, necrotic, and edematous volumes ($p<0.01$). Methylation grade, but not WHO grade, was independently associated with OS and PFS. A higher proportion of non-enhancing tumor predicted improved OS (HR=0.65, p=0.042), while necrosis predicted worse survival (HR=1.56, p=0.046). Predictive performance for WHO grade (AUC=0.67), CNV (AUC=0.69), and CDKN2A/B status (AUC=0.65) was moderate.

CONCLUSION

MRI-derived VASARI features and tumor compartment volumes enable noninvasive prediction of DNA methylation grade in IDH-mutant astrocytomas, outperforming histologic grade in survival prediction.

CLINICAL RELEVANCE/APPLICATION

Preoperative MRI biomarkers can stratify IDH-mutant astrocytomas by DNA methylation grade, allowing clinicians to better predict prognosis and guide surgical and therapeutic decision-making. Radiogenomic assessment may offer a clinically actionable, noninvasive alternative to invasive molecular testing, improving individualized patient care.

W5B-SPNR-6 SELECTIVE HIPPOCAMPAL SUBFIELD ATROPHY IN FIRST-EPISODE DEPRESSION: A HIGH-RESOLUTION FS60 PARCELLATION MRI STUDY

Lei Zhang (*Presenter*)
Xingchen Pan (*Abstract Co-Author*)
TAO LI (*Abstract Co-Author*)
Bingyang Bian (*Abstract Co-Author*)
Lin Hou (*Abstract Co-Author*)
Zhenyue Ma (*Abstract Co-Author*)
Xuanxiao Zhang (*Abstract Co-Author*)
Hongchao Wang (*Abstract Co-Author*)

PURPOSE

Based on the FS60 brain template, this study aims to explore the volume differences in the subregions of the hippocampus, amygdala, and thalamus between first-episode depression (FED) patients and healthy controls.

METHODS AND MATERIALS

This study included 53 subjects aged 18-50 years, consisting of 25 patients with FED and 28 age- and gender-matched healthy controls. All subjects underwent 3T MRI scans, and high-resolution T1-MP2RAGE structural image data were collected. The hippocampal subregions (24 substructures), amygdalar subregions (18 substructures), and thalamic subregions (50 substructures) were analyzed using the FS60 template to calculate the absolute volume and the proportion of each subregion to the total brain volume . Independent sample t-tests were used to compare the volume and proportion of each subregion between the two groups.

RESULTS

Demographic analysis revealed no significant difference in age between the FED group and the control group ($t = -0.35$, $p = 0.72$), but there was a significant difference in gender distribution ($t = -2.48$, $p = 0.016$). Additionally, the average age of the FED group (31.36 years) was significantly higher than that of the healthy control group (26.36 years) . Subregion analysis showed no significant differences in volume or proportion between the two groups in 18 substructures of the amygdala and 50 substructures of the thalamus ($p > 0.05$). However, in 24 substructures of the hippocampus, the volumes of 9 substructures (such as the subiculum and dentate gyrus) were significantly lower in the FED group than in the healthy control group ($p < 0.05$, after FDR correction) .

CONCLUSION

First-episode depression patients show significant atrophy in multiple substructures of the hippocampus (such as the subiculum and dentate gyrus), while no obvious abnormalities are found in the amygdala and thalamic subregions. This suggests that hippocampal structural changes may be an early neurobiological feature of FED.

CLINICAL RELEVANCE/APPLICATION

Atrophy of the subregions of the hippocampus may be associated with memory and emotional regulation disorders in depression, providing potential neuroimaging markers for early identification and targeted intervention. Future research can further explore the relationship between damage to the subregions of the hippocampus and clinical symptoms, providing a basis for individualized treatment.

W5B-SPNR-8 PREOPERATIVE PREDICTION OF PERIOPERATIVE COMPLICATION RISK IN PERCUTANEOUS TRANSLUMINAL ANGIOPLASTY AND STENT PLACEMENT USING INTRACRANIAL VESSEL WALL IMAGING-BASED RADIOMICS

Yu Guo, MD (*Presenter*)
Chengxiu Yuan JR, MMed,MMed (*Abstract Co-Author*)
Chunhong Hu, PhD (*Abstract Co-Author*)

PURPOSE

To develop a radiomics model based on high-resolution vessel wall imaging (HR-VWI) for preoperative identification of high-risk patients with intracranial atherosclerotic disease (ICAD) undergoing percutaneous transluminal angioplasty and stent placement (PTAS) who are prone to perioperative complications.

METHODS AND MATERIALS

This retrospective multicenter study enrolled 619 ICAD patients treated with PTAS (87 with complications, 532 without complications), divided into training (n=345), validation (n=149), and testing (n=125) cohorts. All patients underwent preoperative HR-VWI, including non-contrast T1-weighted (T1) and contrast-enhanced T1-weighted (T1CE) sequences. Lesions were segmented using ITK-SNAP, and 2,396 radiomics features were extracted via Pyradiomics. Feature selection involved intraclass correlation coefficient (ICC), Mann-Whitney U test, Spearman correlation analysis, and least absolute shrinkage and selection operator (LASSO). Synthetic Minority Over-Sampling Technique (SMOTE) was applied to address class imbalance in the training set, and multivariable logistic regression was used to screen clinical variables. Logistic regression (LR) algorithms were employed to construct radiomics, clinical, and combined radiomics-clinical models. Model performance was evaluated using the area under the curve (AUC) and DeLong test, while clinical utility was assessed via decision curve analysis (DCA).

RESULTS

Age was the only independent clinical predictor (OR=1.02, p=0.003). All radiomics models outperformed the clinical model, with the T1+T1CE combined model achieving the highest AUC (0.81, 95% CI [0.69-0.93]) in the testing cohort, significantly surpassing the clinical model (AUC=0.66, [0.55-0.77]; p<0.001). The radiomics-clinical combined model demonstrated optimal performance across the training (AUC=0.90, [0.86-0.93]), validation (AUC=0.83, [0.70-0.94]), and testing (AUC=0.81, [0.69-0.93]) cohorts, with superior clinical net benefit in DCA, particularly at threshold probabilities >40%.

CONCLUSION

This study highlights the potential of HR-VWI-based radiomics combined with clinical features to preoperatively identify high-risk patients, enabling personalized treatment decision-making.

CLINICAL RELEVANCE/APPLICATION

HR-VWI radiomics combined with clinical characteristics enables preoperative risk stratification for ICAD patients undergoing PTAS, optimizing individualized treatment planning.

W5B-SPNR-9 DCE-MRI-BASED RADIOMICS MODEL EXPLAINED BY SHAP METHOD TO PREDICT CDKN2A/B HOMOZYGOUS DELETION IN IDH-MUTANT ASTROCYTOMAS

Zhengyang Zhu, MD (*Presenter*)
Huiquan Yang, PhD (*Abstract Co-Author*)
Mengying Xu, MD (*Abstract Co-Author*)
Xin Zhang (*Abstract Co-Author*)
Bing Zhang, PhD (*Abstract Co-Author*)

PURPOSE

Cyclin-dependent kinase inhibitor (CDKN) 2A/B homozygous deletion has been proved to be an independent predictor of poor outcome of isocitrate dehydrogenase (IDH) mutant astrocytomas. This study aimed to develop a radiomics model based on dynamic contrast enhancement (DCE) magnetic resonance imaging (MRI) parameter maps for predicting CDKN2A/B homozygous deletion status in IDH-mutant astrocytomas.

METHODS AND MATERIALS

Patients with pathologically confirmed IDH-mutant astrocytomas with a CDKN2A/B homozygous deletion status from a single center between 2018 and 2022 were retrospectively recruited. Radiomics features were extracted by PyRadiomics from the whole tumor region on various DCE-MRI parameter maps (iAUC, K ep , K trans , V e and V p). Prediction models were constructed by support vector machine, and explained by Shapley Additive exPlanations (SHAP) method.

RESULTS

Eighty-two IDH-mutant astrocytoma patients (mean age 46.24 ± 13.24 years, 43 females) were enrolled, including 65 patients without CDKN2A/B homozygous deletion, and 17 patients with this deletion. The predictive model based on mixed features from all DCE parameter maps showed a better performance than those based on any single DCE parameter map. The mixed feature model exhibited AUC of 0.957 (95% confidence interval [CI]: 0.928-0.991) and 0.924 (95% CI: 0.818-1.000) in the training set and validation set, respectively. SHAP analysis showed that the gray-level co-occurrence matrix feature named information measure of correlation 1 from iAUC map contributed the most in the predictive model.

CONCLUSION

The developed model based on DCE-MRI radiomics features may serve as a noninvasive and preoperative tool for prediction of CDKN2A/B homozygous deletion status in IDH-mutant astrocytomas.

CLINICAL RELEVANCE/APPLICATION

Our study revealed that the interpretable DCE-MRI-based radiomics model can be used to predict CDKN2A/B homozygous deletion status before operation. This model may be a novel and effective biological marker in preoperative molecular subtyping of gliomas.

W5B-SPNR-10 LONGITUDINAL CHANGES IN MYELIN CONTENT WITHIN LESION (ZONE II) AFTER MRGFUS TREATMENT IN ESSENTIAL TREMOR: A QUANTITATIVE ANALYSIS USING MYELIN IMAGING

Masashi Kanouchi, BS (*Presenter*)
Toshio Yamaguchi, MD, PhD (*Abstract Co-Author*)

PURPOSE

Essential tremor (ET) is the most common movement disorders, impairing daily activities with upper limb tremor. MR-guided focused ultrasound (MRgFUS) thalamotomy provides a less invasive alternative to radiofrequency ablation and deep brain stimulation, with immediate symptom relief. However, recurrence occurs in approximately 15%, and its mechanisms remain unclear. Particularly, long-term changes in myelin, a key structure for neural transmission, have not been previously studied. This study aimed to assess longitudinal changes in myelin content within the lesion (Zone II) following MRgFUS for ET using synthetic MRI.

METHODS AND MATERIALS

19 patients with medication-refractory ET (mean age, 67.4 years; 11 males, 8 females) underwent unilateral MRgFUS targeting the ventral intermediate nucleus (Vim). MRI was acquired at pre-treatment, 1 day, 1 month, 3 months, 6 months, and 1 year using a 3T MRI scanner (GE DISCOVERY MR750w). Myelin content in Zone II was quantified using synthetic MRI. Repeated-measures ANOVA and Bonferroni-corrected paired t-tests assessed changes (significance: $p<0.0033$). In three recurrent cases after 1 year, we evaluated spatial relationships of the various zones, including myelin loss, T2 hyperintensity, and residual DRTT fibers.

RESULTS

The mean Zone II lesion volume on day 1 was 254.75 mm^3. Myelin content changed significantly over time ($F=74.35$, $p<0.0001$, $?^2=0.805$). Marked reduction occurred at 1 day ($p<0.0001$), with partial recovery at 1 and 3 months ($p<0.0001$), then secondary decline from 6 months. At 1 year, myelin content was significantly reduced from baseline ($p<0.0001$). In recurrent cases, residual DRTT fibers did not overlap with areas of myelin loss or T2 hyperintensity, suggesting that spared tracts may be involved in recurrence and potentially remyelinated during recovery.

CONCLUSION

Myelin content in the ablation zone shows dynamic change over one year post-MRgFUS. The presence of residual DRTT fibers outside demyelinated or T2 hyperintensity regions suggests the possibility that incompletely treated or repaired areas may contribute to recurrence. Quantitative myelin imaging may guide long-term evaluation and retreatment strategies.

CLINICAL RELEVANCE/APPLICATION

Myelin quantification using synthetic MRI may work as a sensitive biomarker for monitoring lesion evolution. Combined with tractography, it may identify spared tremor pathways in recurrent ET and support personalized treatment planning.

W5B-SPNR-12 DECODING THE MOLECULAR MECHANISMS OF FOCAL TEMPORAL LOBE EPILEPSY THROUGH CORTICAL MORPHOMETRIC INVERSE DIVERGENCE AND TRANSCRIPTOMIC

Haixia Mao (*Presenter*)
Xiangming Fang, MD (*Abstract Co-Author*)

PURPOSE

To investigate the molecular pathological mechanisms underlying focal temporal lobe epilepsy (TLE) by integrating structural brain network analysis with transcriptomic data, specifically using a Morphometric Inverse Divergence (MIND) network approach.

METHODS AND MATERIALS

A total of 182 focal TLE patients (119 with left TLE [LTLE] and 63 with right TLE [RTLE]) and 182 age- and gender-matched healthy controls (HCs) were included. MIND networks were constructed using the K-nearest neighbor density algorithm and multiple brain morphological features. A general linear model (GLM) assessed group-level, regional, and network-level MIND differences. Spearman's correlations examined associations between MIND alterations and clinical variables (age, age at onset, epilepsy duration, treatment duration). Transcriptomic analysis using Partial Least Squares (PLS) regression was applied to link MIND networks with whole-brain gene expression data. Gene ontology and protein-protein interaction (PPI) enrichment analyses were performed on significant PLS1 gene sets.

RESULTS

Compared to HCs, TLE patients exhibited significantly increased MIND similarity in the sensorimotor (SMN), dorsal attention (DAN), ventral attention (VAN), default mode (DMN), and frontoparietal (FPN) networks. MIND increases in DMN and FPN were positively associated with epilepsy duration and treatment time, though these did not remain significant after correction. Gene enrichment and PPI analysis of PLS1+ genes indicated involvement in mitochondrial function and neurodegeneration, while PLS1- genes were related to gene regulation and mRNA metabolism. RTLE patients showed more pronounced MIND alterations than LTLE patients, particularly in the right visual network (VN), with MIND similarity in the VN positively correlated with age (FDR-corrected $p = 0.0056$) and age of onset (uncorrected $p < 0.05$). In RTLE, PLS1- genes were enriched for synaptic structure and function; PLS1+ genes showed no significant enrichment.

CONCLUSION

TLE is associated with widespread morphometric network alterations, underpinned by transcriptional signatures related to mitochondrial dysfunction, neurodegeneration, and gene regulation. Lateralization effects in RTLE may be driven by synaptic structure and functional genes.

CLINICAL RELEVANCE/APPLICATION

These findings enhance our understanding of the gene-brain structure relationships in focal TLE, offering potential molecular targets for personalized treatment approaches and providing insight into the biological basis of disease lateralization.

W5B-SPNR-13 DISRUPTED DYNAMIC FUNCTIONAL NETWORK GRADIENTS REVEAL GRADIENT-SPECIFIC TEMPORAL INSTABILITY IN SELECTS

Linfeng Song (*Presenter*)
Lin Jiang (*Abstract Co-Author*)

PURPOSE

This study investigates dynamic brain state abnormalities in children with self-limited epilepsy with centrotemporal spikes (SeLECTS) using principal functional network gradients. Combining gradient analysis with trajectory cross-correlation, we assessed spatial organization, temporal stability, and network synchrony to identify gradient-specific disruptions linked to cognitive and sensory impairments.

METHODS AND MATERIALS

Resting-state fMRI data from 60 SeLECTS patients and 68 matched controls were analyzed. Dynamic functional network gradients (dFNGs) were derived using sliding-window connectivity and diffusion embedding. Two gradients were extracted: Gradient 1 (sensory-introspective axis) and Gradient 2 (task-control vs. default mode). K-means clustering (k=2) identified recurring brain states. Dwell time, occupancy rate, transitions, and sorting synchrony were analyzed. Group comparisons used t-tests or nonparametric tests.

RESULTS

Along Gradient 1, Cluster 1 showed reduced connectivity, especially in the default mode network (DMN), while Cluster 2 showed enhanced coupling among visual, sensorimotor, and dorsal attention networks, indicating a shift from introspection to sensory engagement. SeLECTS patients showed increased inter-network synchrony, especially in DMN, DAN, and auditory networks ($p < 0.05$), though occupancy and dwell time were unchanged ($p > 0.05$). Along Gradient 2, Cluster 1 reflected task-control dominance (DAN, FPN), and Cluster 2 showed diffuse connectivity across frontal-parietal-occipital regions. SeLECTS patients had reduced dwell time in task-control states ($p < 0.05$) but paradoxically elevated synchrony in frontoparietal networks, indicating unstable executive dynamics.

CONCLUSION

SeLECTS is marked by dual-axis disruption of brain dynamics. Both gradients showed elevated sorting synchrony, suggesting reduced flexibility, while only Gradient 2 showed impaired state maintenance. These findings reveal gradient-specific vulnerabilities and support the utility of dynamic analysis for understanding functional instability in pediatric epilepsy.

CLINICAL RELEVANCE/APPLICATION

This study reveals that children with SeLECTS exhibit distinct disruptions in the temporal dynamics of brain network organization, especially within sensory and executive control systems. Gradient-informed dynamic metrics offer a novel, non-invasive approach to identify functional instability that is not captured by traditional static measures. These findings support the potential clinical utility of functional gradient dynamics as early neuroimaging biomarkers for diagnosis, monitoring, and individualized intervention strategies in pediatric epilepsy.

W5B-SPNR-14 DETECTABILITY ASSESSMENT OF SUPER-RESOLUTION DIFFUSION-WEIGHTED IMAGES IN PATIENTS WITH ACUTE ISCHEMIC STROKE

Kiyohisa Kamimura, MD, PhD (*Presenter*)
Tsubasa Nakano (*Abstract Co-Author*)
Masanori Nakajo, MD (*Abstract Co-Author*)
Junki Kamizono (*Abstract Co-Author*)
Tomohito Hasegawa (*Abstract Co-Author*)
Daiki Tobo (*Abstract Co-Author*)
Ryota Nakanosono, MD (*Abstract Co-Author*)
Fumitaka Ejima (*Abstract Co-Author*)
Hiroaki Nagano, MD, PhD (*Abstract Co-Author*)
Koji Takumi, MD, PhD (*Abstract Co-Author*)
Hirokazu Otsuka (*Abstract Co-Author*)
Takashi Iwanaga (*Abstract Co-Author*)
Jihun Kwon (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

PURPOSE

Super-resolution is newly developed deep learning framework combines and integrates compressed sensing with two distinct convolutional neural networks enabling enhanced spatial resolution as well as noise and artifact reduction. This study aimed to compare the detectability of super-resolution diffusion-weighted imaging (srDWI) with conventional diffusion-weighted imaging (cDWI) in patients with acute ischemic stroke.

METHODS AND MATERIALS

This study included 34 consecutive patients who underwent MRI due to suspected acute ischemic stroke using a 3T scanner (Ingenia, Philips Healthcare). The srDWI was performed using a multi-slice 2D single-shot echo-planar imaging sequence with a slice thickness of 1.5 mm and in-plane spatial resolution of 1.5 x 1.5 mm reconstructed to 0.36 x 0.36 mm. Images were reconstructed using a prototype AI-based reconstruction software provided by the vendor. The cDWI with conventional compressed SENSE reconstruction was performed with a slice thickness of 5.0 mm and spatial resolution of 1.5 x 1.8 mm reconstructed to 0.9 x 0.9 mm. Lesion detectability was assessed by two radiologists using a three-point scale (0: not present, 1: probably present, 2: definitely present). The cDWI were evaluated first, followed by the srDWI. Lesions that were detectable only on the srDWI were re-evaluated on the cDWI. For cases with multiple lesions, a maximum of 10 lesions per patient were assessed. Statistical analysis of lesion detectability comparison between cDWI and srDWI was performed using the Wilcoxon signed-rank test. The sharpness index of the lesion depiction plane was calculated and compared between cDWI and srDWI using the paired t-test.

RESULTS

Observer 1 detected 51 lesions, with detectability scores on cDWI of (0; 12, 1; 11, 2; 28) and scores on srDWI of (0; 0, 1; 1, 2; 50). Observer 2 detected 41 lesions, with scores on cDWI of (0; 4, 1; 11, 2; 26) and scores on srDWI of (0; 0, 1; 1, 2; 40). 12 and 4 lesions were not detected on the cDWI but were identified on srDWI for observers 1 and 2, respectively. Detectability was significantly improved with srDWI compared to cDWI for both observer 1 and observer 2 ($p < 0.0001$ and 0.0005). The sharpness index was significantly higher with srDWI compared to cDWI (1013 ± 273 vs. 622 ± 178, $p < 0.0001$).

CONCLUSION

The srDWI showed superior lesion detectability and higher sharpness index compared to cDWI for acute ischemic stroke lesions.

CLINICAL RELEVANCE/APPLICATION

Super-resolution DWI enabled superior lesion detectability and higher sharpness index compared to conventional DWI for acute ischemic stroke lesions, and may impact on patient care.

W5B-SPNR-15 PHOTON-COUNTING CT SPECTRAL AUC MAPS FOR ACUTE ISCHEMIC STROKE DETECTION

Yu Sakai, MD (*Presenter*)
Lori Huang (*Abstract Co-Author*)
Konstanze Guggenberger, MD (*Abstract Co-Author*)

Peter B. Noel, PhD (*Abstract Co-Author*)
Jae W. Song, MD, MS (*Abstract Co-Author*)

PURPOSE

Photon-counting CT (PCCT) provides spectral information that enables virtual monoenergetic imaging (VMI), but these data remain underutilized in clinical neuroradiology protocols. Detecting early acute ischemic stroke (AIS) on noncontrast CT can be challenging due to subtle changes in attenuation. This study evaluates voxel-wise spectral area under the curve (AUC) maps derived from PCCT VMIs as novel approach to aid the neuroradiologist and enhance AIS detection.

METHODS AND MATERIALS

In this retrospective single-center study (August 2022-December 2024), patients with noncontrast head PCCT who had MRI-confirmed AIS within four days were included. Eleven virtual monoenergetic images (40-140 keV) were reconstructed. Two parametric maps "Spectral AUC" (trapezoidal integration of voxel-wise attenuation across the 11 VMIs) and "Stroke Spectral AUC" (each VMI rescaled to stroke windows (width/level 40/40HU) prior to integration) were generated. Infarct contrast-to-noise ratio (CNR), signal-to-noise ratio (SNR), and infarct-to-normal contrast were compared between maps and clinical images by Wilcoxon rank-sum test. To evaluate the added-value of Stroke Spectral AUC maps in AIS detection, a two-round rater study was conducted: three neuroradiologists independently reviewed randomized set of clinical head CTs followed by repeat assessment after a 2-week washout period with the addition of Stroke Spectral AUC maps. Raters identified all perceived AISs based on anatomic region and laterality. Diagnostic accuracy was compared with and without the Stroke Spectral AUC maps.

RESULTS

26 patients (mean age 65±13 years; 13 women) were included. Spectral AUC maps demonstrated higher infarct-CNR than clinical images (median 1.97 vs. 1.64; $p = 0.003$) and higher infarct-SNR (7.98 vs. 6.80; $p < 0.001$), with similar infarct-to-normal contrast (0.14 vs. 0.12; $p = 0.58$). Stroke Spectral AUC maps further improved infarct-CNR (2.22 vs. 1.64; $p = 0.001$) and infarct-to-normal contrast (0.29 vs. 0.12; $p < 0.001$) but lowered infarct SNR (3.29 vs. 6.80; $p < 0.001$). In Round 1 of the rater study, the three raters correctly identified at least one true infarct in a mean of 14 out of 26 patients. For the one rater who has completed Round 2, the number of cases with at least one correct infarct called increased from 13 to 16 (12% increase). Round 2 results are still pending for the other two raters.

CONCLUSION

Photon-counting CT VMIs AUC map significantly enhances infarct contrast metrics and holds promise for improving AIS detection on noncontrast CT.

CLINICAL RELEVANCE/APPLICATION

We introduce novel maps derived from photon-counting CT spectral data which may assist neuroradiologists in detecting subtle acute infarcts on noncontrast CT and thereby improve patient care.

W5B-SPNR-17 IMPACT OF CLINICAL AND RADIOLOGICAL FACTORS ON CT-PERFUSION TIMING IN ACUTE ISCHEMIC STROKE

Bernardo Proner, MD (*Presenter*)
Vincenzo Vingiani, MD (*Abstract Co-Author*)
Riccardo Valletta, MD (*Abstract Co-Author*)
Tommaso Gorgatti (*Abstract Co-Author*)
Andrea Posteraro (*Abstract Co-Author*)
Giulia A. Zamboni, MD (*Abstract Co-Author*)
Matteo Bonatti, MD (*Abstract Co-Author*)

PURPOSE

To assess the impact of radiological and clinical variables on brain CT-perfusion (CTP) curves in patients with acute ischemic stroke.

METHODS AND MATERIALS

IRB-approved retrospective observational cohort study, need for informed consent was waived. We included 295 patients who underwent CTP for acute ischemic stroke in our Institution (Jan2020-Mar2024). One radiologist evaluated arterial input function (AIF) and reference vessel (RefV) curves to assess bolus arrival delay and time to baseline return. Additionally, he evaluated the unenhanced brain CTs acquired before CTP for the presence of microangiopathy (van Swieten scale) and intracranial arterial wall calcifications (yes/no). Age, sex, arterial blood pressure, heart rate, presence of arrhythmias, and NIHSS were retrieved from an institutional database. A logistic regression analysis was conducted to evaluate the impact of various independent variables on AIF and RefV.

RESULTS

The logistic regression analysis highlighted a statistically significant association between the presence of arrhythmias and the diagnostic outcome ($p< 0.0001$). Additionally, the NIHSS was also found to be a significant independent predictor ($p=0.0198$). Logistic regression analysis revealed that the median arterial time-to-peak was significantly longer in patients with cardiac arrhythmias (24.0s; IQR 20.2 - 27.1s) compared to those without (18.6s; IQR 15.5 - 21.7s), $p<0.0001$. Similarly, the venous time-to-peak was found to be longer in patients with cardiac arrhythmias (median 30.2s; IQR 26.4 - 32.0s) compared to those without (25.6s; IQR 22.5 - 28.7s), $p<0.0001$.

CONCLUSION

Our study showed that patients with cardiac arrhythmias, as well as patients with higher NIHSS, need longer CTP acquisition times to avoid perfusion curve truncation and potentially non-diagnostic results.

CLINICAL RELEVANCE/APPLICATION

Our study highlights the critical impact of patient-specific factors, particularly cardiac arrhythmias and stroke severity, on the diagnostic accuracy of CTP imaging in acute ischemic stroke. These findings advocate for a more individualized approach to CTP protocol design, emphasizing dynamic scan adjustments based on pre-scan assessments and real-time perfusion data. Future research should focus on integrating advanced imaging technologies and automated decision-support systems into clinical practice, ultimately enhancing stroke diagnosis and treatment outcomes.

W5B-SPNR-18 LONGITUDINAL ASSESSMENT OF GLYMPHATIC DYSFUNCTION IN THE SOD1G93A ALS MODEL

Xiawei Bai, MD, PhD (*Presenter*)
Hiroyuki Kameda, MD (*Abstract Co-Author*)
Naoya Kinota (*Abstract Co-Author*)
Daisuke Kato (*Abstract Co-Author*)
Kohsuke Kudo, MD, PhD (*Abstract Co-Author*)

PURPOSE

The glymphatic system plays a crucial role in clearing metabolic waste and maintaining brain homeostasis. Its dysfunction is increasingly recognized in neurodegenerative diseases such as amyotrophic lateral sclerosis (ALS). Most previous studies in ALS employed large molecular MRI tracers (e.g., Gd-DTPA), which cannot pass through AQP4 water channels. In contrast, 17 O-labeled water is a small molecule that can enter the brain via AQP4, enabling direct assessment of glymphatic transport. This study aims to evaluate glymphatic function in an ALS rat model using dynamic MRI with 17 O-labeled water.

METHODS AND MATERIALS

ALS model rats {NTac(SOD1G93A)L26H, n=7} and wild-type (WT) controls (n=7) were imaged using 7T MRI (Bruker BioSpec, Germany). Dynamic T2-weighted RARE images were acquired during and after a 14-minute intrathecal injection of 17 O-labeled water. Preprocessing included denoising, skull stripping, motion correction, and template construction. 17 O concentration was calculated from signal decrease relative to baseline. The cortex, basal ganglia, and brainstem were segmented as regions of interest (ROIs). Concentration-Time Curves (CTC) and Area Under the Curve (AUC) were used to assess 17 O uptake, clearance, and retention. Group comparisons were analyzed using two-way ANOVA and Mann-Whitney U test.

RESULTS

ALS rats showed significantly higher 17 O uptake and delayed clearance compared to WT rats ($p < 0.05$), indicating impaired glymphatic function. These differences were most pronounced in the cortex, basal ganglia, and brainstem. AUC analysis confirmed greater tracer retention in ALS rats across these brain regions ($p < 0.05$).

CONCLUSION

Dynamic MRI with 17 O-labeled water enables noninvasive visualization of glymphatic dysfunction in ALS. The increased influx and delayed efflux observed in ALS rats support its use in characterizing cerebrospinal fluid transport abnormalities associated with disease pathology.

CLINICAL RELEVANCE/APPLICATION

This method offers a novel imaging tool for evaluating glymphatic function and may serve as a sensitive biomarker for monitoring ALS progression, especially in relation to metabolic dysfunction.

W5B-SPPD-1 PROOF OF CONCEPT: 3D ULTRASOUND TOMOGRAPHY TRANSCRANIAL PEDIATRIC IMAGING

James Wiskin, PhD, MSc (*Presenter*)

PURPOSE

This proof-of-concept study demonstrates that 3D ultrasound tomography (3DUT), incorporated via a Breast Acoustic CT™ (BACT) scanner, enables transcranial acoustic imaging in neonates. We present high-resolution reconstructions of an excised ovine brain and bovine eye to illustrate the feasibility of imaging cranial and near-cranial structures relevant to neonatology. Neonatal brain hemorrhage is a critical condition, typically evaluated using MRI, which may be unavailable in low-resource environments (LRE). 3DUT offers radiation-free, gadolinium-free imaging. We show speed of sound (SOS) and refraction-corrected reflection images with in-plane resolution near 0.8 mm

METHODS AND MATERIALS

Data were acquired using the BACT Scanner. Transmission imaging was performed at 0.3-1.3 MHz; reflection imaging centered at 3.6 MHz. The SOS map, reconstructed first, was used to correct for acoustic refraction and enable 360° compounding of back-projected reflection images. This yielded refraction-corrected, speckle-free images with 0.6-0.9 mm in-plane resolution. The bovine eye was mounted in 32°C water and scanned after fixation to a ceramic plate. The ovine brain was suspended from a frame with surgical thread. SOS imaging used 1.3 MHz for the eye and 1 MHz for the brain. Reflection skull thickness at 2.5 MHz (0.611? ~ ?/2) indicates viable energy transmission through neonatal skulls.

RESULTS

Calculations confirmed acceptable insertion loss. SOS values of the vitreous, lens, iris, and cornea matched literature values. The SOS images highlighted tissue stiffness: water = 1511 m/s, fat = 1430-1480 m/s, vitreous = 1488 m/s, cornea = 1562 m/s, lens = 1667 m/s. Reflection imaging revealed the optic nerve, sub-retinal space, lens capsule, and a clearly resolved double-layered cornea (~1.8 mm separation, ~300 µm thick). Brain imaging showed cortical structure in detail. Montages of axial brain slices replicate neonatal imaging scenarios.

CONCLUSION

We demonstrate high-resolution imaging of excised bovine eye and ovine brain using 3DUT in a water bath setting. These results support the feasibility of neonatal transcranial imaging using low-frequency ultrasound. Reflection images, corrected with SOS data, show MRI-comparable resolution and detail without ionizing radiation or contrast agents. This approach may offer critical diagnostic capabilities in neonatal care, especially in LRE settings

CLINICAL RELEVANCE/APPLICATION

Newborns are vulnerable to hemorrhages including IVH, subdural, subarachnoid, and germinal matrix bleeds. 3DUT enables safe, high-resolution imaging of neonatal brain structures without radiation or MRI contrast, making it a promising alternative for diagnosis in both advanced and resource-limited clinical settings.

W5B-SPPD-2 QUANTITATIVE DECT PERFUSION METRICS IN SEVERE BPD: ASSOCIATIONS WITH CLINICAL OUTCOMES

Stephanie El Omeiri, MD (*Presenter*)
Erik Jensen (*Abstract Co-Author*)
Krithika Lingappan (*Abstract Co-Author*)
Joice C. Prodigios, MD (*Abstract Co-Author*)
Jordan B. Rapp, MD (*Abstract Co-Author*)
David M. Biko, MD, MBA (*Abstract Co-Author*)
Hansel J. Otero, MD (*Abstract Co-Author*)

PURPOSE

Bronchopulmonary dysplasia (BPD) remains a leading cause of chronic lung disease in preterm infants, yet its severity classification lacks quantitative imaging biomarkers. Perfusion abnormalities in BPD are often spatially heterogeneous, reflecting variability in lung injury and repair. This study investigates whether quantitative lung segmentation and perfusion metrics derived from dual-energy CT angiography (DECT) are associated with clinical outcomes in infants with severe (Grade 3) BPD.

METHODS AND MATERIALS

This prospective study included infants diagnosed with Grade 3 BPD who underwent chest DECT as part of a larger phenotyping initiative. Of 33 enrolled patients, 28 had evaluable DECT images; for patients with multiple studies, the earliest qualifying study was used. Whole-lung segmentation was performed using an in-house postprocessing software, and iodine concentration (mg/mL) was extracted. Mean iodine concentration, standard deviation, skewness, and kurtosis were calculated. Clinical variables assessed included pulmonary hypertension, tracheostomy, mortality, sex, and FiO2 category (0-50% vs >50-100%), along with continuous measures of gestational age and birth weight. Associations between DECT metrics and clinical variables were assessed using Wilcoxon and Spearman tests.

RESULTS

28 infants (57.1% male), mean gestational age of 25.2 weeks and median age at time of CTA of 20.1 weeks. The median birth weight was 650 g. Pulmonary hypertension and tracheostomy were each present in 32.1% of patients, with a mortality rate of 14.3%. No significant associations were observed between perfusion metrics and pulmonary hypertension, tracheostomy, mortality, or FiO2.

CONCLUSION

Whole-lung perfusion metrics were not significantly associated with key clinical outcomes including tracheostomy, pulmonary hypertension, or death. These findings highlight the limitations of whole-lung analysis and suggest a need for more granular regional or lobar segmentation approaches, as well as improved intermediate

clinical outcomes that may better reflect disease progression and phenotypic variation. A larger sample may also help clarify these associations, ultimately supporting earlier prediction and individualized management strategies in this high-risk population.

CLINICAL RELEVANCE/APPLICATION

Quantitative dual-energy CT perfusion imaging has potential as a noninvasive tool to characterize lung development in infants with severe BPD. While global perfusion metrics may have limited correlation with major clinical outcomes, more detailed imaging approaches could improve early risk assessment and support individualized management strategies.

W5B-SPPH-1 EFFECTIVELY REDUCING METAL ARTIFACTS USING LOW-ENERGY VIRTUAL MONOCHROMATICIMAGES IN LOW DOSE DUAL ENERGY CTWITH METAL ARTIFACT REDUCTION (MAR) ALGORITHM: A PHANTOM STUDY

Tingting Qu (*Presenter*)

PURPOSE

To assess the effectiveness of reducing metal artifacts using virtual monochromatic (VM) images in low dose dual-energy CT (DECT) with a metal artifact reduction (MAR) algorithm.

METHODS AND MATERIALS

A DECT quality control phantom (GPH-75B, Science in Kyoto) simulating adult abdomen with titanium inserts was prepared and scanned using DECT mode. The 40-140keV (with an interval of 20keV) VM images were reconstructed with and without MAR algorithm. Images were evaluated objectively by measuring CT values, standard deviation (SD) in regions of interest, the transverse and longitudinal diameter and their ratio of a titanium rod, and subjectively by grading on a scale of 5 scores for artifacts (0, none; 4, severe), edge clarity of titanium rod (1, worst; 5, excellent) and clarity of adjacent structures (1, worst; 5, excellent).

RESULTS

The VM images from 60keV-140keV with MAR had a similar ability (1-1.1 point) in metal artifacts reduction, excellent in displaying (>4.5 points) the titanium rod edge, and were all better than those without MAR (all $p<0.05$). The VM images at 60keV with MAR had the highest clarity score for imaging adjacent structures. The SD values in both reconstruction groups decreased with increasing energy and stabilized after 100keV, while MAR group had smaller SD. MAR showed significantly approved titanium rod diameter ratio than without MAR, stabilizing to 1 after 60keV.

CONCLUSION

Compared to non-MAR, MAR in DECT shows significant reduction of both dark and bright streak artifacts caused by the titanium implant and the distortion of implant itself. Considering the overall image quality and the known fact of the higher contrast enhancement with lower energy VM images, the 60-80keV VM images with MAR are recommended.

CLINICAL RELEVANCE/APPLICATION

The application of MAR technology can effectively reduce the metal artifacts of implants without causing deformation. In practice, appropriate reconstruction energy should be selected based on the contrast of the surrounding tissue of the implant.

W5B-SPPH-2 MITIGATING CT NUMBER VARIABILITY IN CARDIAC SCANS ACROSS TUBE POTENTIALS AND SCANNER MODELS WITH VIRTUAL MONOENERGETIC IMAGING

Aeden Davis, BS (*Presenter*)
Shuai Leng, PhD (*Abstract Co-Author*)
Kishore Rajendran, PhD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)

PURPOSE

CT scanner model and tube potential (kV) affect the CT number of soft and calcified plaques, impacting coronary artery disease (CAD) metrics like plaque volume. Virtual monoenergetic images (VMIs) mimic images scanned at a single x-ray energy and produce more consistent CT numbers than conventional images. Using a phantom and cardiac scan modes, this study tests CT number variability of soft and calcified tissues across different scanner models and kVs, comparing VMI to conventional images.

METHODS AND MATERIALS

A multi-energy CT phantom (Gammex) with fat, soft-tissue and calcium inserts was scanned on 3 scanners (Philips 7500, Siemens Force, Siemens Alpha) at each available kV using a cardiac scan mode. The phantom was wrapped in tissue-mimicking material (SuperFlab) to achieve attenuation similar to a patient's chest. A conventional image and a 70 keV VMI were made at each kV for Philips (CB kernel, iDose 5) and Alpha (Bv48 kernel, QIR 3). On the Force, the phantom was scanned with single-energy to create conventional images and scanned with dual-energy to create 70 keV VMIs (Bv40 kernel, Admire 4). The slice thicknesses and increments were 0.67 x 0.34 mm (Philips), 0.4 x 0.3 mm (Alpha), and 0.6 x 0.3 mm (Force). Regions of interest (ROIs) were drawn over multiple slices for each insert. The ROIs' mean CT numbers were calculated for each slice and averaged across slices. CT number variability as scanner and kV changed were analyzed for each insert type, comparing conventional images and VMIs.

RESULTS

With changing kV for a particular scanner, VMIs had a smaller range of CT numbers for all inserts, with calcium seeing the largest decrease in range compared to conventional images (23.6 HU, 48.2 HU, and 45.7 HU for Alpha, Force, and Philips, respectively). Across all scanners and kVs, the coefficient of variation (CoV) for VMIs was 2.3% (adipose), 3.2% (soft tissue), and 1.7% (calcium). This is a decrease compared to conventional images from the same scanner taken at different kVs, where the Alpha soft tissue insert had the smallest CoV (3.8%). At kV levels where conventional images could be compared across all three scanners, the smallest CoV was 3.5% (adipose, 120 kV), 3.0% (soft tissue, 140 kV), and 2.6% (calcium, 120 kV).

CONCLUSION

In cardiac scan modes, VMIs provided more consistent CT numbers than conventional images for fat, soft tissue, and calcium when kV level was varied. At kV levels where all scanners could be compared, adipose and calcium HU values were more consistent in VMIs than in conventional images when scanner was varied.

CLINICAL RELEVANCE/APPLICATION

VMI CT numbers are more robust to changes in kV and scanner model than conventional images, allowing for more comparable plaque measurements between scanners and scan settings in serial studies and between patients.

W5B-SPPH-3 EVALUATION OF IMAGE QUALITY AND LUNG-RADS CLASSIFICATION IN DEEP LEARNING-BASED ULTRA-LOW-DOSE CHEST CT

Siqi Qu (*Presenter*)
Zhiming Xiang (*Abstract Co-Author*)
Qiuxing Chen (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

To assess the impact of deep learning reconstruction on image quality and Lung-RADS classification in ultra-low-dose chest CT

METHODS AND MATERIALS

A prospective study was conducted from October 2024 to April 2025, enrolling patients with suspected pulmonary nodules who underwent both standard-dose chest CT (SDCT) and ultra-low-dose CT (ULDCT). ULDCT doses were adjusted based on body mass index (BMI). SDCT was reconstructed with 50% adaptive statistical iterative reconstruction (ASIR-V50%) as the reference. ULDCT images were reconstructed using ASIR-V50%, deep learning image reconstruction (DLIR) at medium and high levels, and filtered back projection (FBP). Lung-RADS classification was performed using automated software. Image quality was analyzed with Kruskal-Wallis one-way analysis, and weighted kappa (Kw) was used to assess Lung-RADS classification consistency. False positives were defined as ULDCT categories 3/4A/4B matching SDCT categories 1/2, and false negatives as ULDCT categories 1/2 matching SDCT categories 3/4A/4B.

RESULTS

The study included 95 patients (mean age 58 ± 14 years; 49 males) with 443 pulmonary nodules. ULDCT had an effective dose of 0.48 ± 0.11 mSv, an 85.96% reduction compared to SDCT (3.62 ± 1.40 mSv, $P < 0.001$). DLIR significantly improved image quality by reducing standard deviation (SD) of lung and fat tissue and increasing the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of lung tissue ($P < 0.001$) compared to ASIR-V50% and FBP. DLIR-H outperformed DLIR-M with better noise reduction and image quality ($P < 0.001$). For SDCT, Lung-RADS categories were as follows: category 1 (58 nodules, 32.4%), category 2 (375 nodules, 44.6%), category 3 (4 nodules, 8.6%), category 4A (3 nodules, 10.8%), and category 4B (3 nodules, 3.6%). The false-positive rate for ULDCT was 1/433. False-negative rates for ULDCT using ASIR-V50%, DLIR-M, DLIR-H, and FBP were 0, 0, 1/10, and 1/10, respectively. All reconstruction methods (ASIR-V50%, DLIR-M, DLIR-H, and FBP) showed high agreement in Lung-RADS classification (Kw = 0.971, 0.971, 0.957, and 0.957, respectively).

CONCLUSION

DLIR-M provides a suitable balance between image quality and Lung-RADS classification accuracy in ultra-low-dose chest CT, making it a preferred reconstruction method for ULDCT.

CLINICAL RELEVANCE/APPLICATION

Lung-RADS standardizes CT-based lung cancer screening and supports outcome monitoring. Deep learning-based ultra-low-dose CT reduces radiation while maintaining strong consistency in Lung-RADS classification compared to standard-dose CT, making it important for clinical use.

W5B-SPPH-8 EFFECT OF INTRAVENOUS IODINE CONTRAST AGENT ON THE ACCURACY OF LUMBAR BONE DENSITY MEASUREMENT IN PATIENTS WITH GASTRIC CANCER

Yanhong Zhao, MMed,MMed (*Presenter*)

PURPOSE

To investigate the effect of intravenous contrast agent on the accuracy of lumbar bone density measurement by comparing the CT value of monochromatic image, hydroxyapitite(HAP) concentration of HAP-Iodine image and Calcium concentration of Calcium-Iodine image between arterial and venous phase image.

METHODS AND MATERIALS

Ten patients with gastric cancer who underwent abdominal enhanced examination were selected. Revolution APEX CT (GE Healthcare) was used to perform dual-phase enhanced abdominal energy spectrum CT imaging (arterial phase and venous phase). 40-140keV monochromatic image and base substance image (HAP-Iodine, Calcium-Iodine image) were reconstructed using the energy spectrum analysis software. CT values of L1-L3 vertebral in monochromatic images (40 keV, 70 keV and 100 keV), HAP concentration of HAP-Iodine image and calcium concentration of Calcium-Iodine image were measured and compared between arterial and venous phase image.

RESULTS

There was significant differencese in CT values of 40 keV, 70 keV, 100 keV between two groups of images (all P values <0.05).At 70 keV, the CT values of lumbar vertebrae in the arterial and venous phases were 151.53±44.98HU and 172.83±44.40 HU. The concentrations of HAP iodine in the arterial and venous phases were 678.83±11.64 and 677.27±11.27 mg/cm 3 , respectively, with no significant statistical difference (P value>0.05). The HAP concentration of HAP-Iodine image in the arterial and venous phases were 678.83±11.64 mg/cm 3 and 677.27±11.27mg/cm 3 ,respectively, with no significant statistical difference (P value>0.05).The Calcium concentration of Calcium-Iodine image in the arterial and venous phases were 828.90±14.20 mg/cm 3 and 826.98±13.76 mg/cm 3 , respectively, with no significant statistical difference (P value>0.05).

CONCLUSION

The ability to measure bone density using CT values in contrast-enhanced scanning may be reduced due to venous contrast agent contamination, while spectral CT substrates are not affected by contrast agents, making bone density measurements more accurate.

CLINICAL RELEVANCE/APPLICATION

The ability to measure bone density using CT values in contrast-enhanced scanning may be reduced due to venous contrast agent contamination, while spectral CT substrates are not affected by contrast agents, making bone density measurements more accurate.

W5B-SPPH-9 OPTIMIZATION OF LOW-ENERGY MONOCHROMATIC IMAGING IN SPECTRAL CT USING DEEP LEARNING IMAGE RECONSTRUCTION: A PHANTOM STUDY

Hongbing Li (*Presenter*)
Lifang Wan (*Abstract Co-Author*)
Zhichao Li (*Abstract Co-Author*)
Zhenchu Long (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

The study aimed to evaluate the performance of deep learning image reconstruction (DLIR) in spectral CT, focusing on optimizing low-energy (40 keV) monochromatic imaging under different radiation doses. By comparing reconstruction algorithms (ASIR-V 50%, DLIR-M, DLIR-H) and objective metrics (CT value, noise, SNR, CNR), we

explored the potential of DLIR combined with low-keV imaging to enhance contrast, reduce noise, and improve quality, providing evidence for low-dose, high-quality imaging and clinical value in early lesion detection and low-iodine protocols.

METHODS AND MATERIALS

A QSP phantom containing 0.9% saline and 8 iodine solutions (0.5, 2, 5, 8, 11, 14, 17, 20 mgI/mL) was scanned in GSI mode on the GE Apex Expert CT at five CTDIvol dose levels (6.64, 8.73, 10.86, 12.28, and 15.38 mGy), each repeated three times, generating 15 datasets. Images were reconstructed with iterative reconstruction (ASIR-V 50%), DLIR-M (median level), and DLIR-H (high-level), and monochromatic images at 60, and 40 keV were generated. In each image, 100 mm² ROIs were placed at vial centers on five slices to measure CT value, SD, SNR and CNR, followed by intergroup comparisons.

RESULTS

Across doses and energy levels, CT values among the 3 algorithms showed no significant differences ($P > 0.05$). DLIR-H consistently achieved the lowest noise and highest SNR and CNR, followed by DLIR-M, with ASIR-V 50% performing the weakest. At the same dose, 40 keV DLIR-H images showed ~2.25, 2.13, and 2.16 times increases in CT value, SNR, and CNR compared to 60 keV ASIR-V 50% images, with similar noise (~1.06 times). At 8.73 mGy with 5 mgI/mL iodine, CT value decreased from 475.6±2.54 to 211.5±1.03, SNR from 47.23±5.24 to 22.62±1.94, and CNR from 36.91±3.52 to 17.74±1.13. At 10.86 mGy with 11 mgI/mL iodine, CT value dropped from 978.00±2.88 to 434.60±1.33, SNR from 93.47 ±8.98 to 43.57±4.26, and CNR from 88.71±7.53 to 39.77±3.52, highlighting the superiority of DLIR-H in enhancing low-energy contrast.

CONCLUSION

DLIR, especially DLIR-H, significantly reduces noise and enhances SNR and CNR in low-dose spectral CT, with the best results at 40 keV. Low-keV imaging amplifies tissue and iodine contrast through photoelectric effects. Combined with DLIR noise suppression, it enables high-contrast, high-resolution imaging at low doses, offering a feasible path for low-iodine applications

CLINICAL RELEVANCE/APPLICATION

DLIR combined with low-keV imaging optimizes image quality by amplifying tissue-iodine contrast for better lesion detection, particularly in small lesions and low-contrast organs, while mitigating the noise increase typical of low-keV imaging, supporting high-quality imaging at reduced dose and iodine load.Future research will bridge phantom studies to clinical translation.

W5B-SPPH-10 APPLICATION OF DEEP LEARNING IMAGE RECONSTRUCTION TO ENHANCE IMAGE QUALITY OF PEAK ARTERIAL PHASE CTA FROM 'TRIPLE-LOW' CTP SCANS

Haina Xu (*Presenter*)
Xin Qin (*Abstract Co-Author*)
Weiyuan Huang (*Abstract Co-Author*)
Feng Chen, MD, PhD (*Abstract Co-Author*)
Kun Ma (*Abstract Co-Author*)

PURPOSE

This study aims to assess the feasibility and image quality of cerebral CTA at the arterial peak phase using high-strength deep learning reconstruction (DLIR-H) under a triple-low CTP protocol (80 kV/80 mA, 40 mL contrast, 4 mL/s), in comparison with a conventional protocol (80 kV/120 mA, 50 mL contrast, 5 mL/s) reconstructed with a standard iterative reconstruction algorithm (ASIR-V 50%).

METHODS AND MATERIALS

A total of 102 patients with suspected acute ischemic stroke were prospectively enrolled and randomized into a conventional protocol group or a triple-low protocol group (n=51 each). All patients underwent CTP of the brain, from which thin-slice CTA images at the arterial peak phase were reconstructed. This yielded four data sets: Group A (conventional + DLIR-H), Group B (conventional + ASIR-V 50%), Group C (triple-low + DLIR-H), and Group D (triple-low + ASIR-V 50%). Regions of interest were placed in the internal carotid artery siphon, M1 segment of the middle cerebral artery, and temporalis muscle. CT values and standard deviations (SD) were measured, with the temporalis SD served as background noise for calculating vessel SNR and CNR. Two blinded senior radiologists independently assessed subjective evaluations of image noise, vascular edge sharpness, small vessel visibility, and overall image quality. Statistical and inter-rater agreement analyses were performed.

RESULTS

The triple-low protocol group reduced radiation dose by ~33% and contrast volume/injection rate by ~20% compared to the conventional group. CT values of the siphon and M1 segments differed significantly among groups ($P < 0.05$), but not in the temporalis muscle ($P > 0.05$). SD values differed in the M1 segment and temporalis muscle ($P < 0.05$), but not in the siphon segment ($P > 0.05$). Pairwise comparisons showed that the DLIR-H for Group C had significantly lower SD values in the siphon and M1 segments than the ASIR-V 50% in Group B ($P < 0.05$). SNR and CNR values in all regions showed significant group differences ($P < 0.05$), with higher values in Group C (DLIR-H) than Group B (ASIR-V 50%) ($P < 0.05$). Subjective assessments revealed no significant differences between DLIR-H and ASIR-V 50% in terms of four subjective terms under the same scanning conditions (all $P > 0.05$), with similar findings between Groups B and C. Inter-observer agreement was good (Kappa = 0.66-0.773).

CONCLUSION

CTA derived from triple-low CTP combined with DLIR-H significantly reduces radiation and contrast use while maintaining or improving image quality compared to conventional protocols with ASIR-V 50%.

CLINICAL RELEVANCE/APPLICATION

This method allows simultaneous CTP and CTA in a single scan, improving efficiency, reducing repeated scans, and lowering patient burden, highlighting its clinical utility.

W5B-SPRO-1 MULTIPARAMETRIC MRI AND DCE-PERFUSION ANALYSIS OF SPINAL METASTASES FOLLOWING SBRT: PRELIMINARY VOLUMETRIC-BASED INSIGHTS

Mahmud Mossa-Basha, MD (*Presenter*)
Javid Azadbakht, MD (*Abstract Co-Author*)
David R. Haynor, MD, PhD (*Abstract Co-Author*)
Simon S. Lo, MBChB (*Abstract Co-Author*)

PURPOSE

To evaluate correlations between clinical features, multiparametric MRI, and dynamic contrast-enhanced (DCE) perfusion parameters with tumor histology and epidural extension (Bilsky Epidural Spinal Cord Compression [ESCC]) scale) in spinal metastases treated with stereotactic body radiotherapy (SBRT), using lesion-specific volumetric segmentation.

METHODS AND MATERIALS

This retrospective, IRB-approved study included patients with spinal metastases treated with SBRT at our institution between November 2016 and December 2024. All underwent multiparametric MRI and DCE-perfusion MRI. Volumetric segmentation of metastatic lesions was performed to extract quantitative imaging features including T1/T2 signal intensity, enhancement homogeneity, and DCE metrics: wash-in/wash-out slope, time to peak (TTP), peak enhancement intensity (PEI), vascular permeability (Vp), signal enhancement ratio (SER), and area under the curve (AUC). Clinical variables included age, comorbidities (diabetes, hypertension, dyslipidemia), smoking, Karnofsky performance score (KPS), lymphadenopathy, vertebral compression fractures (VCF), and alignment. The ESCC score assessed epidural tumor extension.

RESULTS

A total of 119 patients (60 female, 59 male; mean age 61.8 ± 11.9 years) were included. Lung (33%), breast (18%), and renal (10%) were the most common primary tumors. ESCC score positively correlated with VCF grade (?=0.32, p=0.001) and posterolateral extension (?=0.28, p=0.004), and negatively with KPS (?=-0.24, p=0.01). MRI features significantly associated with higher ESCC scores included heterogeneous enhancement (p=0.006) and increased T2-weighted signal (p=0.03). PEI (p=0.004) and shorter TTP (p=0.027) showed significant DCE correlations with ESCC score. SER and AUC trended toward significance (p=0.06, 0.08). Breast metastases were more often T1 hypointense and homogeneously enhancing (p<0.01); renal metastases had higher PEI and Vp (p<0.05). Age and comorbidities showed no tumor-specific differences.

CONCLUSION

Quantitative volumetric MRI and DCE-perfusion parameters are associated with distinct tumor histologies and the severity of epidural tumor extension as measured by the Bilsky Epidural Spinal Cord Compression (ESCC) scale.

CLINICAL RELEVANCE/APPLICATION

Volumetric imaging and DCE-MRI parameters may enhance non-invasive assessment of spinal metastases, informing prognosis and individualized SBRT planning.

W5B-SPVA-1 EXPLORING THE ROLE OF PSEUDOCONTINUOUS ASL AS A PREDICTOR OF WOUND HEALING FOLLOWING INFRAPOPLITEAL BALLOON ANGIOPLASTY IN DIABETIC FOOT PATIENTS

Smily Sharma, MD, FRCR (*Presenter*)
Venkata Subbaih Arunachalam, MD (*Abstract Co-Author*)
jineesh valakkada, MD (*Abstract Co-Author*)
Anoop Ayyappan, MD (*Abstract Co-Author*)
Ajay Alex (*Abstract Co-Author*)

PURPOSE

The presence of extensive infrapopliteal calcifications in diabetics renders the Ankle-Brachial Pressure Index and CT angiography less useful for vascular assessment. We aim to assess the role of Arterial Spin Labeling (ASL) perfusion in determining wound healing following infrapopliteal angioplasty for diabetic patients with non-healing foot ulcer.

METHODS AND MATERIALS

After obtaining institutional ethical committee approval, a prospective single-center cohort study was carried out from August 2022 to January 2024 in diabetic patients with non-healing foot ulcers and predominant infra-popliteal disease on CT/MR/digital subtraction angiography. A novel pseudo-continuous ASL (pc-ASL) sequence was performed on a 3 Tesla MR scanner (GE, Discovery 750w) covering bilateral feet prior to and after endovascular revascularization to compare the change in perfusion following intervention. ASL pedal blood flow [mean and regional (medial and lateral forefoot and hindfoot)] of the symptomatic and contralateral feet was compared with healthy controls (n = 14). The measurements were carried out by two Radiologists with a minimum of 8 years of experience. Clinical follow-up for wound healing was done at 6 months post-procedure and at complete wound healing if present. Cox proportional regression analysis was done to identify factors predicting early wound healing.

RESULTS

Fifty-eight diabetic patients with non-healing foot ulcers underwent infrapopliteal balloon angioplasty. ASL mean pedal blood flow (mPBF) of symptomatic feet before intervention was lower than in the healthy controls (10.58 versus 13.45 ml/100g/min). Comparison of paired regional ASL mPBF of symptomatic feet before and following intervention showed a significant increase in mPBF (10.58 vs 15.30 ml/100g/min, P =<0.001). MRI measurements of regional pedal perfusion of the untreated contralateral limb measured pre and post-procedure showed good agreement (r = 0.935, 0.890, 0.932) with each other, indicating that they remain unchanged and showing the reliability of ASL perfusion. The multivariate Cox proportional hazards model showed clinical WIFI Stage 1 [odds ratio (OR): 3.119 (1.448-6.719)] and gain in forefoot mPBF [OR: 1.008 (1.000-1.016)] as independent predictors of early wound healing (within 120 days).

CONCLUSION

Pseudocontinuous ASL is a reproducible and objective technique for measuring pedal perfusion. Improvement in forefoot perfusion in pc-ASL following infrapopliteal angioplasty in diabetic ischemic ulcer predicts early wound healing.

CLINICAL RELEVANCE/APPLICATION

ASL perfusion is a novel tool for objective measurement of pedal perfusion and may be used as a reliable imaging marker of the outcomes of infrapopliteal angioplasty in future.

M2-QI-1 IVC FILTER TRACKING PROJECT

Jacob Varner, BS (*Presenter*)
Lisa Ponce, RT (*Abstract Co-Author*)
Cathy Hannafin, MBA, BSN (*Abstract Co-Author*)
Jennifer Marino (*Abstract Co-Author*)

INTRODUCTION

The MCA Interventional Radiology (IR) Division has a goal to remove retrievable inferior vena cava (IVC) filters placed at MCA within six months. This timeframe aligns with the guidelines from the American Heart Association (AHA), American College of Chest Physicians (ACCP), and American College of Radiology (ACR)/Society of Interventional Radiology (SIR). To facilitate this goal, the IR physician assistants (PAs) strive to see every patient for an IR Clinic Consult within three months after IVC filter placement. Data showed significant variation in days between IVC filter placement and IR Clinic Consult order, prompting a multidisciplinary team to address the issue. The project aims to reduce patients with ten days or more between IVC filter placement and IR Clinic Consult order entry by 62%, from 26% to 10% by 12/31/24.

METHODS

A team comprised of Radiology physician assistants (PA), nurses, data analyst, operational leadership, and quality staff convened and used Six Sigma DMAIC (Define, Measure, Analyze, Improve, Control) improvement methodology to address the problem. Procedural data was retrieved from the electronic healthcare record (Epic) from January 2023 through October 2023, which consisted of 66 patients. The team created a swim lane process map from IVC filter placement to IR Clinic Consult order entry. Analyzing the data revealed several key issues: no Epic report to identify IVC filter patients, issues tracking patients in Epic, manual data entry, inconsistent PA documentation, and inconsistent data review. Two major interventions were implemented in clinical practice: an Epic workbench report to track IVC filter patients and record follow-up information and shifting monitoring responsibilities from PAs to the radiology nursing team.

RESULTS

Post-intervention results showed that 100% of retrievable IVC filter placements patients received an IR consult order within 10 days of implant by December 2024, successfully meeting the project goal. Improvements were sustained using the report, which helps visually identify patients without clinic consult orders. The nursing team established a consistent and feasible review process and cadence within their practice.

DISCUSSION

Tracking Inferior Vena Cava (IVC) filters has been challenging for many practices. Prolonged retention risks include filter fracture, migration, and vena cava thrombosis or stenosis. Successful tracking is crucial for timely removal, reducing complications and increasing successful retrievals. Transitioning responsibilities between teams posed challenges, but implementing standardized scripting and clear expectations helped streamline the process.

M2-QI-2 STREAMLINING DIAGNOSTIC ACCESS: IMPACT OF AN EMR-INTEGRATED MRI SCREENING TOOL ON ORDER-TO-SCAN TURNAROUND TIMES ACROSS INPATIENT AND EMERGENCY PATHWAYS

Karthik Rayasam, MBBS, MD (*Presenter*)
Gayatri Kaimal (*Abstract Co-Author*)
Jamie Crooks (*Abstract Co-Author*)
Unni K. Udayasankar, MD (*Abstract Co-Author*)
Hasan Ozgur, MD (*Abstract Co-Author*)

INTRODUCTION

Delays in inpatient and emergency MRI access are often rooted in fragmented communication and manual safety validation workflows. Paper-based screening forms contribute to incomplete data, inefficiencies, and delayed radiologic readiness. To address these operational shortcomings, a fully electronic, EMR-integrated MRI screening tool was deployed with the objective of accelerating safety clearance, improving communication between nursing and radiology, and reducing MRI turnaround time (TAT) from order placement to scan initiation.

METHODS

A multidisciplinary task force designed an automated MRI safety screening module embedded in the hospital's EMR. Triggered at the point of MRI order entry, the tool required completion of a dynamic, logic-driven questionnaire by nursing staff and generated a real-time alert in the radiology worklist upon completion. MRI technologists reviewed and validated entries before protocoling. Data were retrospectively collected from January to December 2023, stratified by clinical setting: Emergency Department (ED), Observation (OBS), and Inpatient (INPT). TAT was defined as the interval between MRI order placement and scan start. Trends were analyzed over time to assess operational impact.

RESULTS

The implementation yielded substantial and sustained reductions in TAT across all patient categories: ED TAT improved from a plateau of 3.7 hours (April) to a sustained low of 1.5-1.9 hours between July and November, reflecting >50% efficiency gain in acute imaging workflows. OBS TAT decreased from a peak of 12.8 hours (March) to 3.3 hours (December), demonstrating enhanced throughput in observation units. INPT TAT declined from 16.5 hours (January) to 6.6 hours (December), representing a >60% reduction in the most operationally complex setting. The June-October window marked the most rapid improvement across service lines, coinciding with full staff adoption and stabilization of workflow compliance.

DISCUSSION

A fully digitized MRI screening system significantly reduced order-to-scan turnaround times across emergency and inpatient care pathways. By embedding transparency, real-time status updates, and protocol readiness into the EMR, this intervention improved radiologic efficiency, minimized redundant communication, and accelerated

access to advanced imaging. These findings support broader institutional adoption of informatics-driven workflow tools across diagnostic modalities

M2-QI-3 OPTIMIZING RADIOLOGY WORKFLOW IN A HIGH-VOLUME ACADEMIC MEDICAL CENTER: A DATA-DRIVEN QUALITY IMPROVEMENT INITIATIVE

Divyansh Gupta, MBBS, MD (*Presenter*)
Parul Gupta, MBBS, MD (*Abstract Co-Author*)
Naman Gupta, MD (*Abstract Co-Author*)

INTRODUCTION

Public hospitals in our country, operating under state-sponsored insurance schemes, face high imaging demand with constrained resources. In our tertiary academic center, CT and MRI services function under a public-private partnership (PPP), adding workflow complexity due to manual processes, documentation-heavy protocols, and disconnected hospital and vendor systems. These issues resulted in delays across patient registration, scan scheduling, and report delivery, prompting a structured quality improvement project.

METHODS

Using the PDSA framework, we implemented targeted interventions across pre-scan, scan and post-scan phases. Pre-scan improvements included a triage system to schedule non-urgent scans during off-peak hours, fast-tracking emergencies lacking formal documents, contrast counter relocation near imaging areas, dedicated RIS entry personnel and standardized document checklists. Scan-period changes involved protocol simplification for common indications, technologist shift restructuring, and a live triage tagging system for prioritization. Post-scan efforts included structured reporting templates, redistribution of cases between in-house teams and teleradiology, resident-led backlog clearance, and real-time sharing of imaging links with clinicians to expedite treatment. The multidisciplinary QI team consisted of radiologists, residents, technologists, administrative staff, and PPP partner personnel. Data sources included our hospital EMR, RIS, PACS, and departmental logs. Primary metrics were CT/MRI access times, RIS delays, report turnaround, protocol omission, staff burnout (Likert scale), and patient satisfaction. Secondary metrics included reporting backlog duration, critical result communication, teleradiology usage, and clinician acknowledgment delay. Analysis employed descriptive statistics, paired t-tests, Wilcoxon signed-rank, and chi-square tests ($p < 0.05$), supported by line plots, control charts, box plots, and bar graphs.

RESULTS

Post-intervention, CT registration-to-scan time decreased from 2.1 to 1.2 hours, MRI wait time from 10.2 to 4.8 hours, and RIS entry time from 17 to 6 minutes. Report backlog reduced from 26 to 9 hours, and protocol omission rates declined from 15% to 5%. Staff burnout improved from 7.0 to 4.0, and patient satisfaction increased from 58% to 82%. Teleradiology usage rose by 34%, improving case load distribution. All key improvements were statistically significant and sustained over the study period.

DISCUSSION

This initiative demonstrates how structured, context-sensitive interventions can optimize radiology workflow in resource-limited academic hospitals. Through team collaboration, task redistribution, and data-driven decision-making, meaningful gains in efficiency, quality, and satisfaction are achievable and replicable in similar settings.

M2-QI-5 ENHANCING EFFICIENCY AND REDUCING WORKLOAD STRESS THROUGH AUTOMATED IMAGING PROTOCOL SELECTION IN ONCOLOGIC NUCLEAR MEDICINE

Aparna Singh, MD (*Presenter*)
Hina Shah, MD (*Abstract Co-Author*)

INTRODUCTION

Manual imaging protocol assignment remains a source of inefficiency and stress in nuclear medicine workflows, particularly in high-volume cancer centers. Protocoling is vital for ensuring appropriate imaging, but the manual process increases clinicians' cognitive and administrative load. A survey across affiliated sites explored perceptions of manual protocoling and the potential value of automation to reduce stress and improve workflow.

METHODS

A cross-institutional survey was conducted with hospital trainees to evaluate current protocoling practices, time spent, perceived workload impact, and the value of automation. Respondents suggested specific protocols for automation, including FDG PET/CT, therapy studies, breast injections, and bone scans. A multidisciplinary quality improvement team was formed to assess feasibility and ensure integration with existing systems. To evaluate automation's impact, nuclear medicine procedure volumes from March to mid-April 2025 were analyzed, focusing on changes in scan volumes, protocol consistency, and site distribution before and after implementation.

RESULTS

Survey results showed half of respondents (50%) spent <30 minutes daily on protocoling, with another 50% spending 30-60 minutes. All respondents agreed that manual protocoling contributes to workload stress, with 50% experiencing significant stress. Most (83.3%) believed automation would be highly beneficial, and 16.7% found it somewhat beneficial. Suggested automations included FDG PET/CT, therapy studies, and bone scans. Respondents emphasized safeguards, such as triggering a manual review for mismatched clinical indications. In March (initial rollout), of 655 scans, 76% (n=500) were successfully autoprotocoled. By mid-April, 89% (n=527) of 591 scans were autoprotocoled, with only 11% (n=64) requiring manual intervention. High-volume protocols, such as:Bone Scans: 95% autoprotocoled in April, with <5% needing manual override. PSMA PET/CT: >95% autoprotocoled, manual reviews for trial modifications. FDG PET/CT Total Body: Reduced manual intervention.

DISCUSSION

The findings highlight the need for workflow improvement in nuclear medicine through automation. All respondents acknowledged the contribution of manual protocoling to workload stress. Autoprotocoling for high-volume, standardized studies improved efficiency and reduced the manual protocoling burden. However, appropriate oversight remains necessary for discrepancies. Limitations of the study include a small sample size and reliance on subjective perceptions. Success will depend on collaboration between clinical teams and IT for continuous improvement.

M2-QI-6 ENGAGING LEADERSHIP THROUGH DATA VISUALIZATION AND ARTIFICAL INTELLIGENCE: IMPROVING THE PATIENT EXPERIENCE IN RADIOLOGY

Shanil Kumar, MPH (*Presenter*)
Katelyn Chooey, BA (*Abstract Co-Author*)
Elizabeth Odell (*Abstract Co-Author*)
Javier Villanueva-Meyer, MD (*Abstract Co-Author*)

INTRODUCTION

Press Ganey (PG) surveys provide critical insights into patient experience, but in radiology, a lack of centralized, intuitive reporting limited their usefulness. Leaders lacked access to visualized, modality-specific data, hindering their ability to identify trends and act on feedback. To address this, UCSF Radiology developed Smartsheet dashboards, enhanced by UCSF's AI tool VERSA, to improve data accessibility and leadership engagement.

METHODS

A root-cause analysis revealed key barriers: absence of centralized dashboards and limited support for PG data interpretation. We hypothesized that interactive, modality-specific dashboards would increase engagement and promote data-driven decisions. Interventions included: Launching Smartsheet dashboards to visualize PG data. Integrating UCSF VERSA to highlight patient comment themes using AI. Creating a workflow for data retrieval, visualization, and distribution. Surveying modality leaders in March 2025 to assess dashboard use, usability, and application.

RESULTS

Survey results post-implementation showed notable improvements: Increased Engagement 90% of leaders now review dashboards monthly or most months. Improved Access Those finding the data "very easy" to access and interpret rose from 20% to 40%. Usability Gains 90% found dashboards at least "somewhat easy" to interpret; 40% said they were "very useful" for action planning. Actionable Changes 50% of leaders made or proposed interventions. For example: Molecular Imaging reminded staff to offer blankets to patients. Breast Imaging addressed recurring concerns about dressing rooms.

DISCUSSION

Smartsheet dashboards significantly improved PG data visibility and use across UCSF Radiology. Leaders now review data more regularly and are better equipped to respond to patient feedback. Next Steps Further refine dashboards based on feedback and expand AI capabilities to automate theme identification and correlate comments with score trends. Lessons Learned Accessibility Boosts Engagement: Visual, intuitive, and role-specific tools are key to regular data use. Customization Matters: Leaders value the ability to filter by site, modality, and theme. Iterative Feedback Drives Improvement: Early input enabled us to refine tools and guide future development.

M2-QI-7 AUTOMATED, LARGE LANGUAGE MODEL-ENABLED PARSING OF PROSTATE MRI AND BIOPSY RESULTS ENABLES HIGH-FIDELITY QUALITY ANALYTICS AT SCALE

Melis Ozkan, BS (*Presenter*)
Benjamin Mervak, MD (*Abstract Co-Author*)
Aleksandra Zarska (*Abstract Co-Author*)
Matthew S. Davenport, MD, MBA (*Abstract Co-Author*)

INTRODUCTION

Current radiology quality assessment (QA) methods rely on manual audits or brittle string-based queries, which are labor-intensive, prone to bias, and lack scalability. Previously published work parsing prostate magnetic resonance imaging (MRI) using regular expressions failed over time due to deviations in formatting. Large language models (LLM) can minimize those failures in their ability to successfully classify reports with non-standard structure. This project aimed to develop an autonomous QA tool to enable robust, real-time performance monitoring with minimal human intervention.

METHODS

A sample (N=325) of prostate MRI reports with biopsy or prostatectomy data were retrospectively selected for manual review and testing. A zero-shot LLM (GPT-4) was deployed to parse semi-structured reports, extracting maximum PI-RADS v2.0 scores (at MRI) and maximum Gleason scores (at histopathology). Outputs were compared against manual annotations by two medical students, who each reviewed 150 or 325 of the 325 reports (i.e., 150 overlap) to document LLM accuracy. Accuracy of the LLM for identification of maximum PI-RADS v2 score and maximum Gleason score was calculated using manual review as the reference standard. Gwet's AC1 was used to assess agreement on the 150 shared cases. LLM token costs and labor time were tabulated.

RESULTS

Of the 325 reports, there were 4 errors in LLM outputs (1.2% error rate). Three identified Gleason =7 cancer when it was absent, and one had a Gleason grade error. All four errors were caused by erroneous use of data in the user-generated "History" section of the radiology report. When the LLM was told to ignore that section, the accuracy improved to 100%. Inter-rater agreement was perfect (Gwet's AC1 = 1.0). The model reduced manual QA data correction effort by 18 hours/month at a cost of $8.32.

DISCUSSION

Automated quality analytics are feasible at scale using LLMs to parse radiology and pathology results for calculation of predictive values. Although the use case involved prostate MRI, any radiology-pathology linkage is feasible at markedly reduced cost compared to manual data extraction.

M2-QI-8 FOSTERING AN AI LEARNING COMMUNITY: A RESIDENT-LED CONFERENCE SERIES FOR CASE-BASED EDUCATION AND SYSTEMS IMPROVEMENT

Noah Gafen, MD (*Presenter*)
Shiva Ambardar, MD (*Abstract Co-Author*)
Brianna E. Damadian, MD (*Abstract Co-Author*)
Rachel Saks, MD (*Abstract Co-Author*)
Jeffrey B. Levine, MD (*Abstract Co-Author*)
Avraham B. Zlochower, MD (*Abstract Co-Author*)
Ritesh D. Patel, MD (*Abstract Co-Author*)
Matthew A. Barish, MD (*Abstract Co-Author*)
Shlomit Goldberg-Stein, MD (*Abstract Co-Author*)

INTRODUCTION

As artificial intelligence (AI) tools become increasingly integrated into radiology workflows, there is a growing need for structured learning environments where residents can critically engage with AI results, identify the strengths and limitations of these tools, and strengthen their own clinical judgment.

METHODS

This virtual conference series brings together approximately 100 residents from four diagnostic radiology residency programs within a large, integrated healthcare system with >300 faculty radiologists. The conference draws on 12 FDA-cleared AI tools in active clinical use: Brain aneurysm, Vessel occlusion, Intracranial hemorrhage, Midline shift, Cervical spine fracture, Pneumothorax, Free air, Aortic dissection, Pulmonary embolism (PE), Incidental PE, Right/Left Ventricle ratio, and Rib fracture. Conferences are resident-led, subspecialty-themed, and include participation from faculty and the radiology AI team. Conference cases are culled from a database of cases submitted optionally through the AI vendor's orchestration hub (aidoc, Tel Aviv, Israel) by faculty and trainees during routine daily interpretation.

RESULTS

The conference series is built around four core functions: 1) Case Discovery - Residents review cases with strong learning opportunities from a database of case feedback provided through the orchestration hub, sorting by AI tool, exam type, and feedback label (True positive, True negative, False positive, False negative, and "wow True positive" great cases), and reviewing the cases. 2) Shared Learning Themes - Sessions highlight cognitive insights, recurring diagnostic and/or triage pitfalls, and system contributors. Residents are encouraged to recognize patterns that may inform future interpretation and help avoid automation bias. 3) Collaborative Case Review - Open, non-hierarchical dialogue explores how residents engage with AI results during interpretation, examining concordance and discordance with AI to better understand reasoning patterns and opportunities for learning. 4) Translation to Action - Learning points that can be translated to system level improvements are escalated to the core AI team for technical and operational follow-up. These have included: 1) Enhancing worklist prioritization logic and visibility, 2) Improving distribution of triaged AI positive cases across resident on-call worklists, 3) Suggestions for alert refinements (e.g. improving filters and displays).

DISCUSSION

This resident-led AI Learning Community Conference Series fosters clinical insight and confidence in interacting with AI and also drives continuous system improvement for the AI clinical program. By linking education to actionable changes, both internally and with vendor partners, it provides a scalable model for safe, reflective, and iterative AI integration in clinical radiology practice.

M2-QI-9 COLLABORATIVE QUALITY IMPROVEMENT TO OPTIMIZE MAMMOGRAPHY POSITIONING AND DEPARTMENT EFFICIENCY

Miranda J. Mares, MS,RT (*Presenter*)
Jennifer L. Saline, MD (*Abstract Co-Author*)
Aide Atayde-Law (*Abstract Co-Author*)
Alma Tabor (*Abstract Co-Author*)
Raina Mendoza (*Abstract Co-Author*)
Jacob Ormsby, MD, MBA (*Abstract Co-Author*)

INTRODUCTION

Mammography plays a vital role in the early detection of breast cancer, but suboptimal patient positioning can significantly compromise image quality and diagnostic accuracy. Internal reviews at our institution revealed that only 38% of mammography screening exams met American College of Radiology (ACR) ImPower program established positioning criteria. The project goal was to increase the percentage of our mammography screening exams meeting passing criteria from 38% to 85% over the 6-month intervention period.

METHODS

In partnership with the ACR learning network, our team conducted a comprehensive current-state analysis to identify key issues contributing to suboptimal mammography positioning. This analysis included Gemba Walk observations, cause-and-effect analysis, and root cause identification. Based on these findings, interventions were developed across four focus areas: technologist skill enhancement, communication standardization, workflow redesign, and staffing adjustments. Pre- and post-intervention data were collected and analyzed over a six-month period.

RESULTS

By the end of the six-month intervention period, the percentage of mammography screening exams meeting passing criteria increased from 38% to 85%. These improvements have been sustained, with scores remaining above 80% for at least nine months post-implementation. The project also led to unexpected benefits, including improved team morale and the identification of necessary scheduling adjustments that enhanced overall department efficiency. The new scheduling model improved daily workflow consistency and supported more efficient use of staff and resources.

DISCUSSION

The project successfully identified and addressed root causes of suboptimal mammography positioning and workflow inefficiencies. The most impactful interventions included targeted skill enhancement programs for technologists, such as structured 1:1 coaching sessions that significantly improved positioning consistency and confidence. Additional interventions included standardized communication practices and workflow optimization through revised scheduling to ensure balanced, consistent workloads. The addition of a second breast radiologist helped manage daily volume more effectively, while improvements in technologist staffing and support further contributed to increased throughput and exam quality. These changes led to measurable benefits: exam passing criteria scores improved from 38% to 85% and staff morale improved significantly. The standardized workflow and improved role clarity enhanced team communication and job satisfaction, with gains sustained for at least nine months post-intervention. This project demonstrates how a structured, collaborative approach to radiology quality improvement can drive sustainable outcomes.

M5A-QI-1 DECREASING SAFETY EVENTS / RECONCILIATION RATES IN CT IMAGING

Vivek Batra, MD (*Presenter*)
Erin Panter, ARRT, BS (*Abstract Co-Author*)
Ben C. Wandtke, MD, MS (*Abstract Co-Author*)

INTRODUCTION

Imaging reconciliation errors in the PACS occur when medical images fail to correctly link with the corresponding patient information, study, or report. High priority errors include mismatches in patient identity, incorrect modality assignments, or incomplete image transmission. These events can lead to negative patient outcomes, unnecessary procedures and delayed care. This quality improvement project aimed to reduce CT high priority reconciliation errors rates from 0.5% (1 event every 200 CT exams performed) to 0.3% within 6 months.

METHODS

In partnership with the American College of Radiology Learning Network, this project was performed at a large academic medical center. Reconciliation reports were aggregated and analyzed weekly. The multidisciplinary project team consisted of CT managers, radiologic technologists, imaging applications administrator, and radiology residents. To obtain baseline data, the team reviewed several weeks of reconciliation reports which were categorized into high and low priority events and determined the % of events per exam volume per week. Using A3 performance improvement methodology, our multidisciplinary team identified multiple potential root causes for reconciliation errors. Key drivers were identified, interventions tested and implemented using rapid Plan-Do-Study-Act cycle. A current-state analysis was conducted to map the imaging workflow from order placement to radiologist interpretation. This analysis identified key patient identification steps, including patient selection, demographic verification as primary root causes. To address these issues, interventions were implemented to improve patient verification process.

RESULTS

Following the intervention, reconciliation events decreased to 0.1%, exceeding the initial goal of 0.3%. There was an 80% reduction in high-priority events per week. Additionally, the time between reconciliation events increased by 47%, indicating a sustained improvement in workflow, efficiency and patient safety.The key drivers of the process improvement included consistent dual identification system, accurate patient demographic verification, and user-friendly reconciliation reports. Gemba observations revealed that X-ray staff could scan arrival form barcodes, automatically populating patient exam details onto their modality worklists, while CT staff manually selected patients from the modality worklist.

DISCUSSION

This project brought awareness to imaging errors that were previously unrecognized or tracked and was a big success for the CT department. There was a dramatic reduction in potential serious safety errors within the department, initially, averaging 400 potential errors per year, now down to less than 100 per year. Additionally, in solving the process issues, this saved an estimated 150 hours annually of IT/RT time working on reconciliation.

M5A-QI-2 ENHANCING USP <825> COMPLIANCE IN Y-90 RESIN MICROSPHERE RADIOEMBOLIZATION THROUGH OUTSOURCED DOSE PREPARATION BY COMMERCIAL NUCLEAR PHARMACIES

Xingyu Nie, PhD (*Presenter*)
Kimyli Lemieux (*Abstract Co-Author*)
Elizabeth Cheatham (*Abstract Co-Author*)
Molly Buffington (*Abstract Co-Author*)
Jie Zhang, PhD (*Abstract Co-Author*)
Riham H. El Khouli, MD, PhD (*Abstract Co-Author*)
Bryan Lemieux, MS (*Abstract Co-Author*)
Driss Raissi, MD (*Abstract Co-Author*)

INTRODUCTION

Yttrium-90 (Y-90) resin microsphere radioembolization (RE) is a well-established treatment for primary and metastatic liver tumors. Traditionally, patient-specific doses have been prepared on-site in hospital nuclear medicine facilities. In the absence of a laminar flow hood, these doses are compounded as immediate-use preparations on the hot lab bench. However, the implementation of USP <825> on November 1, 2023, mandates that immediate-use radiopharmaceuticals be administered within one hour of preparation. This strict beyond-use date (BUD) introduces compliance and workflow challenges. To address these, we redesigned our process by outsourcing Y-90 dose preparation to a commercial nuclear pharmacy.

METHODS

This quality improvement initiative was conducted at an academic hospital. Under the original workflow, once the written directive (WD) was completed by an authorized user (AU), a nuclear pharmacist would order Y-90 resin microspheres from the vendor. Administration vials were then prepared on-site in the interventional radiology (IR) hot lab under ambient conditions by a nuclear pharmacist or nuclear medicine technologist (NMT), with a medical physicist (MP) and health physicist (HP) present. Due to the 1-hour BUD requirement under USP <825>, any dose not administered within that window would be discarded. In the revised workflow, the WD is sent to a USP <825>-compliant commercial nuclear pharmacy, which prepares the dose under sterile conditions and delivers it on the day of treatment, allowing for a 24-hour BUD. The NMT and MP verify the dose using the IR dose calibrator before administration. We retrospectively reviewed Y-90 resin microsphere RE cases before and after April 30, 2024, when the new workflow was implemented, excluding cases that reached stasis. Time from dose preparation to administration and absolute percentage deviation from prescribed activity were analyzed using Shewhart charts and Student's t-tests ($p < 0.05$).

RESULTS

We analyzed 44 cases under the original workflow and 51 under the revised workflow. The average time from preparation to administration in the original workflow was 59 ± 12 minutes, with 23.6% of cases exceeding the 1-hour BUD and 47.6% occurring within 10 minutes of the limit. No BUD violations occurred under the revised

workflow. The absolute deviation from prescribed activity decreased significantly from 5.5% ± 3.9% to 2.2% ± 1.9% ($p < 0.0001$). There were no statistically significant differences in the percentage of activity administered or prescribed activity levels between the two workflows.

DISCUSSION

Outsourcing Y-90 resin microsphere dose preparation improved compliance with USP <825> and significantly reduced variability in administered activity. Although this approach reduces flexibility for same-day treatments, it provides a scalable and compliant model for institutions delivering Y-90 therapy.

M5A-QI-3 ENHANCING DIAGNOSTIC CONCORDANCE AND QUALITY ASSURANCE THROUGH AUTOMATED MRI AND ARTHROSCOPY REPORT COMPARISON USING LARGE LANGUAGE MODELS

Raafae Zaki, MS, BS (*Presenter*)
Rakesh Sharma (*Abstract Co-Author*)
Pulak Goswami, MD,PhD (*Abstract Co-Author*)
Huzheng Yang (*Abstract Co-Author*)
James Gee (*Abstract Co-Author*)
Charles E. Kahn JR, MD, MS (*Abstract Co-Author*)
J. Bruce Kneeland, MD (*Abstract Co-Author*)
Arijitt Borthakur, PhD, MBA (*Abstract Co-Author*)
Walter R. Witschey, PhD (*Abstract Co-Author*)

INTRODUCTION

Radiologists lack a scalable method to verify alignment between pre-operative MRI interpretations and post-operative arthroscopic findings, limiting diagnostic refinement, quality assurance (QA), and education. Manual concordance review is time-consuming and requires subspecialty expertise. Large language models (LLMs) can perform well in understanding natural language, extract clinically relevant data, and execute simple diagnostic tasks. However, they cannot reliably quantify discrepancies between unstructured clinical documents. We present CONRAD (CONcordance optimization for RADiology and operative reports), an automated framework that uses LLMs to detect and score discordances between knee MRI reports and arthroscopy notes, enabling scalable QA and diagnostic feedback.

METHODS

Fifty paired knee MRI reports and operative notes from an academic hospital were analyzed, each addressing ACL, PCL, medial meniscus, and lateral meniscus. Findings were classified as tear, no tear, uncertain, or not mentioned. Structure-specific prompts were used to extract findings from five open-source LLMs (RadLlama-7B, LLaMA-8B-Instruct, Mistral-7B-Instruct, Qwen-2.5-7B-Instruct, DeepSeek-R1-Distill-Llama), each queried ten times per report, with the modal output retained. Two scoring systems quantified clinical discordance: a rules-based system (0-40) applying weighted penalties for misclassifications, and an LLM-based clinical dissimilarity score (0-8) comparing free-text findings. Classifications were compared to radiologist-assigned labels using accuracy, weighted F1, Cohen's ?, and AUROC. Penalties were compared to those assigned by radiologists using mean squared error (MSE).

RESULTS

LLaMA showed the best overall performance on radiology report classification for all features (accuracy = 0.94, F1 = 0.95, AUROC = 0.97), while Qwen performed the worst (accuracy = 0.85, F1 = 0.90, AUROC = 0.83). All models achieved perfect metric scores (1.0) for operative notes, except for Qwen. For rules-based penalties, LLaMA yielded the lowest MSE averaged across all features (1.88). For LLM-based penalties, RadLlama and Mistral had the lowest average MSE (0.54 and 0.58, respectively). Semantic drift was occasionally observed for ambiguous cases.

DISCUSSION

We introduce a fully automated, scalable system to score clinical discordance between MRI and arthroscopy documentation. These scores closely align with radiologist-assigned classifications and penalty scores. Some limitations include small sample size and a focus on only four anatomical structures of the knee. As a result, we plan to expand system capabilities to target more anatomies across varying cases. Overall, this approach is extensible across imaging modalities, anatomical sites, and clinical documentation, enabling automation of QA, education, and concordance analysis.

M5A-QI-4 RADIOLOGY REPORT QUALITY IMPROVEMENT THROUGH STRUCTURED CLINICIAN FEEDBACK: A DATA-DRIVEN INITIATIVE

Madhvi Yadav, MBBS (*Presenter*)
Saubhagya Srivastava, MD (*Abstract Co-Author*)
Dante Pezzutti, MD (*Abstract Co-Author*)
Minal C. Jagtiani, FRCR, MD (*Abstract Co-Author*)
Nathan M. Cross, MD, MS (*Abstract Co-Author*)
Manjiri K. Dighe, MD (*Abstract Co-Author*)

INTRODUCTION

Radiology reports are essential communication tools between radiologists and referring clinicians, yet their quality often goes unassessed due to the absence of structured feedback mechanisms. Traditional quality improvement efforts rely heavily on sporadic peer reviews rather than systematic clinician input. This quality assessment initiative aimed to implement and analyze a physician feedback system to evaluate and enhance radiology report quality

METHODS

At the University of Washington Medical Center, we integrated a feedback module into the Epic EHR, allowing clinicians to rate radiology reports on a 5-star scale and provide free-text comments. A multidisciplinary team—including radiologists, Epic analysts, data scientists, and clinicians—oversaw the initiative using the Plan-Do-Study-Act (PDSA) framework. Over a 3-month period (Dec 2024-Feb 2025), we collected 133 responses and conducted both manual and large language model (Llama 3.3) sentiment analysis on the accompanying comments. Key metrics included overall satisfaction, sentiment polarity, provider/service distribution, and categorization of reported issues.

RESULTS

Of the 133 responses, while 54.1% of reports received the highest rating, 35.3% were rated 3 stars or below. Only 65.4% of clinicians felt the report addressed their clinical query, while 33.8% felt it did not. Notably, 21.1% of respondents requested follow-up contact from radiologists. Feedback was received across 16 specialties, grouped into five major service lines: oncology, medical, surgical, emergency, and others. Comments were provided by 55.6% (74/133) of the providers. Among these, sentiment analysis classified 64.8% as negative, 21.6% positive, and 13.5% neutral. Two independent raters (R1 and R2) also rated the comments as either positive, neutral, or negative. There was substantial interrater agreement between R1 and R2, R1 and LLM, and R2 and LLM with a weighted kappa [95% CI] of 0.697 [0.566-0.828], 0.640 [0.495-0.786], and 0.783 [0.654-0.912], respectively. Surgical services had the lowest satisfaction and highest negative feedback. Over 70% of concerns raised involved missing data or lack of clinical context.

DISCUSSION

Structured clinician feedback is feasible and provides valuable, actionable insights for improving radiology report quality. Epic integration enabled seamless workflow incorporation. Interventions such as standardized templates, protocol review processes, and better integration of clinical indications may address identified issues. Though limited by a single-center design and short duration, this study supports the development of continuous quality monitoring systems enhanced by AI-driven feedback analysis.

M5A-QI-5 OPTIMIZING PATIENT FLOW TO MRI: IMPACT OF DEDICATED MRI TRANSPORTERS ON EFFICIENCY

Marie Hausner, ARRT, RT (*Presenter*)
Samantha Hine (*Abstract Co-Author*)

Deirdre Montoya, BS,ARRT (*Abstract Co-Author*)
Robert Redmann (*Abstract Co-Author*)
Daniella Asch, MD (*Abstract Co-Author*)
Jay K. Pahade, MD (*Abstract Co-Author*)

INTRODUCTION

MRI remains a critical diagnostic test for a variety of medical conditions. Demand has continued to grow, outpacing supply creating patient backlogs and delays. At our institution, a review of our MRI templates and un-used slots highlighted transport delays as a potential bottleneck in patient throughput. A multidisciplinary team initiated a quality improvement project to assess if assigning dedicated transport staff to the MRI department could improve resource efficiency. We aimed to reduce transport turnaround times (TAT—defined as the time the transport job is entered into the system to the time the patient arrives in MRI) by 20% and increase number of exams completed by 20%.

METHODS

Exam volumes were analyzed to identify time periods with unused scan slots and opportunity to increase throughput. We partnered with transport leadership to trial dedicated staff coverage at our primary tertiary care center with approximately 1000 beds and a level 1 ED. The overnight shift Monday through Friday was identified for the pilot. The MR department operates 2 / 3 scanners on this shift. The transport team provided 1 dedicated transporter in addition to the general transporter pool. MRI technologists were able to triage jobs for the transporter. Check-ins between supervisors of transport and MRI occurred daily. Weekly leadership meetings monitored performance and addressed any operational issues. Primary metrics tracked were the number of MRI studies completed during the shift and transport TAT. Pre intervention data for 5 months was collected and compared with post intervention data over 1 month to assess the project impact.

RESULTS

The mean number of MRI exams performed during the overnight shift increased from 72 exams / week pre intervention to 88 exams / week, reflecting a 22% relative increase. This led to completion of approximately 16 more exams weekly (estimated gain of 832 more MRI exams annually). The mean transport TAT decreased from 49 to 31 minutes after intervention, representing a 37% relative improvement. The TAT variability (standard deviation) decreased from 5 minutes pre-intervention to 2 minutes.

DISCUSSION

This quality improvement initiative demonstrates the added impact of just a single dedicated transporter to the MRI department with 37% reduction in transport TAT and 22% increase in completed MR exams during the overnight shift. The TAT variability also improved creating a more reliable and consistent process. Important behavioral and cultural shifts contributed to the initiative success. MRI technologists noted that the more reliable arrival time allowed for better planning and improved scanner utilization. For the transport team the decentralized approach improved situational awareness and real time decision making. The dedicated transporter communicated delays proactively allowing MRI to adjust and rapidly re-assign the staff to another patient.

M5A-QI-6 IMPROVING ACCESS TO INPATIENT MRI

Erin Panter, ARRT, BS (*Presenter*)
Steven Wheeler (*Abstract Co-Author*)
Keely Dwyer-Matzky (*Abstract Co-Author*)
Henry Z. Wang, MD, PhD (*Abstract Co-Author*)
Russell Johnston, MD (*Abstract Co-Author*)
Justin Hopkin (*Abstract Co-Author*)
Ben C. Wandtke, MD, MS (*Abstract Co-Author*)

INTRODUCTION

Demand for imaging services continues to rise in medical practice, including Magnetic Resonance Imaging (MRI) studies, for both the inpatient and outpatient settings. Demand for imaging services that exceeds capacity can translate into prolonged hospitalizations when imaging is not performed in a timely manner. Delays in discharges lead to increased risk of infections, falls, negative patient experiences, and increased costs to patients, insurers, and the hospital. At our institution approximately 50% of the inpatient MRI studies were performed within 16 hours of order time. Our SMART goal was to increase the percentage of inpatient MRI studies performed within 16 hours of order placement to 75% within 9 months.

METHODS

In partnership with the American College of Radiology Learning Network ®, this project was performed at a large academic medical center. A multidisciplinary project team included residents, attending physicians from several disciplines, radiology technologists, and nurses. Using A3 performance improvement methodology, including Gemba walks, and quality improvement tools, the team was able to identify multiple root causes for delays in imaging acquisition after ordering. Key drivers were identified, interventions were developed, implemented, and analyzed using rapid Plan-Do-Study-Act cycles. Baseline data was obtained and validated including the average and median turnaround time from order placement to MRI study completion over the preceding 9 months. Control charts were utilized in weekly audits to identify potential delays and monitor results of interventions over 24 weeks.

RESULTS

The main root causes were identified as: inconsistent inpatient scheduling process; inconsistent MRI order triage and prioritization; no closed loop communication between MRI department and ordering provider teams; lack of MRI screening form expectations. Various interventions were targeted to address key drivers including a shared understanding of MRI exam time and prioritization, streamlining workflow for patients that failed screening, delegation of duties amongst MRI staff, and standardizing communication between inpatient teams using electronic health records. During the active phase, the percentage of exams completed within 16 hours rose from 50% to 66%, saving hundreds of bed days. Unexpected MRI technologist staffing challenges contributed to variability in the sustain phase

DISCUSSION

The initial improvement demonstrates that simple interventions focusing on workflows and shared expectations can have a significant impact on a complex problem. Reducing the time from order to performed can improve care delivery efficiency equivalent to millions of dollars in savings while improving the timeliness of care for patients. A commitment to sustainability is required to ensure that the interventions have long-lasting effects.

M5A-QI-7 CURB YOUR GALLBLADDER POLYP SURVEILLANCE ENTHUSIASM: WHAT DID OVER HALF A MILLION SONOGRAMS TEACH US?

Sundeep Nayak, MD (*Presenter*)
George Liao (*Abstract Co-Author*)
Deanna Fink (*Abstract Co-Author*)
Eugene Chang (*Abstract Co-Author*)

INTRODUCTION

Gallbladder polypoid foci (GBPF), a sonographic subcentimeter incidental finding, include common small calculi, pseudopolyps (such as cholesterol polyps), and less commonly adenomata, indistinguishable tot the reviewing sonographer and radiologist. GBPF have been historically linked to Gallbladder Cancer (GBC), itself rare but with a dismal outcome owing to advanced disease at presentation; this has resulted in overenthusiastic sonographic surveillance based on consensus guidance and escalation for potential surgical resection if growth occurs (defined as size at or exceeding 1 cm; when GBPF transition into "mass" status). We examined whether GBPF indeed grew substantively and/or progressed to GBC to review our guidance to reduce sonographic oversurveillance of an asymptomatic common incidental finding.

METHODS

Historically, we surveilled GBPF at 6-, 18- and 24-month intervals after discovery to a single 24-month follow-up sonogram (US) in our very large integrated healthcare system to simplify guidance and improve adherence to compliance. Our retrospective study analyzed detected GBPF before and after this guidance change and

reconciled post-cholecystectomy pathology specimen reports with sonography reports for concordance.

RESULTS

Among 3083 GBPF detected in over 505 494 right upper abdominal sonograms during a four-year study period, the mean number of surveillance follow up US fell from 14 to 0.9 after guidance change (p<0.01), and 263 (8.5%) persons with GBPF underwent cholecystectomy. Only 131 (4.2%) GBPF showed growth; there was no change in growth incidence with guidance change (4.1% v. 4.5%; p=0.06). No GBPF progressed to GBC during surveillance. Among growing GBPF, 94 (71%) underwent gallbladder resection, with a reduction in cholecystectomy after guidance change (79.7% v 62.9%, p = 0.03). Only 15% of 94 resection specimen reports agreed with US detected GBPF growth; 68% of GBPF reconciled with cholesterol polyps; 19% had gallstones ONLY.

DISCUSSION

US is insufficiently specific both for discriminating between various GBPF etiologies and for accurately detecting growth from GBPF to "mass" when reconciled with pathology reports. Reductions in both surveillance US and cholecystectomy volumes were observed after collapsing GBPF incidentaloma follow up series to a single 2-year interval US, without increase in either GBPF growth or incident GBC US-detected GBPF and subsequently triggered cholecystectomy are more likely to not be for true adenomatous polyps, but for biliary colic when reconciled with pathology review suggesting that symptomatic tiny gallstones may be mistaken for (indistinguishable) GBPF from other causes. We find no substantive evidence to support the need for surveillance of incidental subcentimeter GBPF.

M5A-QI-8 OPTIMIZING WORKFLOW EFFICIENCY AND AI ADOPTION IN NEURORADIOLOGY THROUGH PLATFORM INTEGRATION

Arsany H. Hakim, MD (*Presenter*)
Juan Gutierrez Alliende, MD (*Abstract Co-Author*)
Piotr Radojewski (*Abstract Co-Author*)
Roland Wiest (*Abstract Co-Author*)

INTRODUCTION

AI has demonstrated significant potential in various radiology tasks. However, lack of optimal integration of AI tools into clinical workflows - and limited adaptation of workflows to new demands - remains major barriers to AI-adoption. Inadequate integration and workflow disruption prolong radiology report turnaround times and hinder scalability in high-throughput imaging environments. Given the increasing complexity of imaging and the rising demand for AI analysis, scalable and interoperable integration is essential to maximize AI's benefits in clinical practice and enhance efficiency. This project aims to optimize workflow, facilitate AI adoption, and enhance operational efficiency within our institution by implementing an AI platform combined with a structured change management plan.

METHODS

A Plan Do Study Act approach was applied with a multistage pilot preceding rollout. The study was conducted at a tertiary center operating 6 MRI scanners performing over 23,000 MRI exams annually. A total of 13 AI apps were integrated into a single platform (Calantic, Bayer). The intervention included: 1) seamless platform integration with AI orchestration enabling automation and interoperability, 2) standardized workflow with clinical protocol-driven AI processing, 3) a change management strategy. The impact was evaluated by monitoring AI processing according to the clinical indication. Data was collected from PACS and AI platform analytics. To assess AI adoption, a subset of AI applications already in use prior to intervention was selected. AI utilization rate and AI-report turnaround time were measured. A governance structure was established to support continuous workflow optimization, quality control and long-term AI monitoring.

RESULTS

Approximately 3,500 cross-sectional sequences are automatically processed each month across various applications. AI report turnaround time was approximately 6 minutes, contributing to an overall reduction in radiology report turnaround time. AI adoption significantly improved: the detection of FLAIR hyperintense lesions increased from 64% to 86%, volumetry increased from 57% to 83% and aneurysm detection increased from 1% to 37%

DISCUSSION

The implementation of an AI platform with structured workflow integration and change management significantly enhanced workflow efficiency, interoperability and AI adoption. A sustainability strategy is in place, incorporating ongoing feedback loops and training programs to further optimize workflow and ensure long-term adoption. Limitations include the absence of pre-platform turnaround time data, which was significantly longer utilizing manual processing. This project highlights the value of AI platform orchestrators in automating processes, standardizing workflow, and supporting multi-vendor AI interoperability in high-volume radiology environment.

M5A-QI-9 PREDICTING EMERGENCY IMAGING SURGES: A MACHINE LEARNING APPROACH TO PROACTIVE RESOURCE MANAGEMENT

Leslie K. Lee, MD (*Presenter*)
Melissa Viator, MS (*Abstract Co-Author*)
Eli Sodickson (*Abstract Co-Author*)
Fionnuala McPeake (*Abstract Co-Author*)
Aaron D. Sodickson, MD, PhD (*Abstract Co-Author*)
Oleg S. Pianykh, PhD (*Abstract Co-Author*)

INTRODUCTION

Over the past year, the emergency radiology department experienced a 22% increase in clinical workload, leading to slower turnaround times and more frequent call-ins for additional radiologist support. This study aims to develop a predictive model capable of identifying impending surges in emergency imaging volume several hours in advance. Early detection allows division leadership to proactively allocate resources, preventing backlogs and maintaining acceptable turnaround times.

METHODS

This study was conducted within the emergency radiology division of an academic medical center, averaging 1,029 exams per day. Imaging and patient visit data were extracted from the electronic health record system from 4/1/2024 to 3/31/2025, encompassing 375,842 exams. Data was aggregated into hourly intervals, yielding 8,760 records with 52 features. Temporal patterns in the emergency imaging pipeline were captured by sampling features at multiple intervals, increasing the feature count to 380. The dataset was split chronologically into training (80%) and testing (20%) subsets for temporal validation. The primary target variable, RVU worklist, was defined as the total number of relative value units (RVUs) from unread emergency radiology cases projected up to 5 hours ahead; alternate targets, such as RVUs scanned, were also studied. To identify the most effective model and feature subset, eight machine learning algorithms were evaluated: ordinary least squares, penalized ridge, Bayesian, random forest, SVM, XGBoost, symbolic, and LSTM neural networks. Feature selection was performed using the ABESS algorithm. Model hyperparameters were tuned via grid search and 3-fold cross-validation on the training set. Performance was evaluated on the test set using R^2 and mean absolute error (MAE). Time series plots were used to visually assess model accuracy. A threshold for acceptable prediction error was set at ±12.9 RVUs - equivalent to the average RVU worklist per scheduled radiologist—to support actionable planning.

RESULTS

The complexity of emergency radiology workload required 27 optimally selected features to achieve the best performance without overfitting. Of the eight models tested, penalized ridge regression performed best, achieving an R^2 of 0.75 and a MAE of 10.2 RVUs for predictions 3 hours in advance, meeting the operational threshold. Furthermore, time series plots demonstrate the model's ability to forecast workload surges of varying magnitudes.

DISCUSSION

Machine learning models can accurately predict near-future emergency radiology workload with a 3-hour lead time. Effective feature selection reduces required inputs, lowering implementation costs. These optimized models allow ED leaders to align staffing with demand, supporting operational efficiency, preventing backlogs, and maintaining timely turnaround - ultimately enhancing patient care.

M5B-QI-2 OPTIMIZING PEDIATRIC TRAUMA IMAGING PROTOCOLS: ENHANCING WORKFLOW USING AN INTEGRATED WBCT APPROACH

Nandakumar Patnam Gopal Chetty, MD (*Presenter*)
Jeffrey Moirano, MS (*Abstract Co-Author*)
Brian Johnston (*Abstract Co-Author*)
Arvin Akhavan (*Abstract Co-Author*)
Barclay Stewart (*Abstract Co-Author*)
Ken F. Linnau, MD, MS (*Abstract Co-Author*)

INTRODUCTION

No guidelines exist for imaging of major pediatric trauma. The inclusion of chest CT is controversial due to radiation exposure concerns. Omitting chest CT in pediatric trauma may be feasible. Such approaches require spine radiography leading to operational inefficiencies and prolonged emergency department (ED) length of stay (LOS). Such imaging approaches do not allow assessment for blunt cerebrovascular injury (BCVI), a potential cause of stroke. We present the impact of an integrated pediatric whole body trauma CT imaging protocol (WBCT) on radiation exposure and operational efficiency at a single Level 1 trauma center.

METHODS

We implemented WBCT for pediatric patients requiring CT head and CT abdomen-pelvis based on clinical prediction rules. For less severely injured pediatric patients, WBCT was not used. Full spine reconstructions from WBCT data eliminate the need for spine radiographs. Contrast enhanced neck CT allows BCVI evaluation. Pediatric WBCT is used in patients <13 years including non-con head CT and a single-phase scan from skull base to ischial tuberosity. Pediatric WBCT protocol was developed in consensus (Radiology Pediatrics, Trauma Surgery, Physicists, Emergency Medicine). We retrospectively analyzed radiation dose (mSv) of pediatric WBCT patients and compared it to ACR Dose Index Registry. Descriptive statistics (median, IQR) were used for dose and injury severity score (ISS). The intervention was vetted by the institutional quality committee. Ongoing dose and ED LOS monitoring is performed.

RESULTS

In 2024, 51 pediatric patients (age 1-13 years) underwent pediatric WBCT. Injury severity was higher in children with WBCT (median ISS 10; IQR: 4-17.5) versus all pediatric patients (ISS: 4; IQR:1-10). Median effective dose for pediatric WBCT was 3.85 mSv (IQR: 3.16-6.38), below the ACR Dose Index Registry benchmark (fig. 1). Imaging process efficiency improved by eliminating the need for separate spine radiographs in a different room, thereby shortening ED LOS by 1 hour (5.3 hrs. in 2024 vs. 6.2 hrs. in 2022).

DISCUSSION

Implementing pediatric WBCT protocols offer minimal radiation tradeoff while enhancing workflow efficiency and reducing ED LOS. This quality improvement initiative demonstrates a sustainable improvement in pediatric trauma operations due to reduction in ED LOS. Further prospective validation with time-motion studies is warranted.

M5B-QI-3 EVALUATING ARTIFICIAL INTELLIGENCE ALGORITHM CASE FINDINGS FROM IT SYSTEM DOWNTIME FOLLOWING ADVERSARIAL CYBERSECURITY INCIDENT

Jackson Pearce, MD (*Presenter*)
Melissa A. Davis, MD, MBA (*Abstract Co-Author*)
Sowmya Mahalingam, MD, MBBS (*Abstract Co-Author*)

INTRODUCTION

Health centers support many information technology (IT) services on cloud-based network systems. Unexpected interruptions, including adversarial cybersecurity attacks, to cloud-based networks can critically impact IT services and affect daily workflow. Software that requires network connection to function can be impaired or rendered nonfunctional by IT system downtimes. Recently, our health system suffered a cyberattack causing an IT system outage for five days. During this downtime, artificial intelligence (AI) models in routine clinical use were unable to process cases and generate findings. We describe retrospectively processing imaging studies with AI models and report findings of discrepancies between AI models and final radiology reports.

METHODS

All imaging studies completed during the IT system downtime were processed through eight AI models used in daily clinical practice. All cases flagged by the AI algorithms for positive findings were compared to final reports generated by a radiologist in two distinct stages. In the first review, the AI algorithm finding was compared to the final radiologist report by two reviewers; discrepancy between the final report and the AI model finding was flagged for additional review. In the second review, each case-discrepancy was evaluated independently by two emergency radiologists to identify if the discrepancy represented a false-positive AI model finding or a true-positive finding by AI not identified in the final radiology report.

RESULTS

AI models generated 267 positive findings during the software downtime. 73 cases were flagged on initial review for case-discrepancy between radiologist report and AI model finding; 5 cases were outside interpretation requests with no final report generated. 59 cases were subsequently advanced for imaging review (14 cases were identified to have concordance between the AI finding and the final report). There were 37 false positive and 22 true positive mismatched cases.

DISCUSSION

Increasing use of AI in clinical environments necessitates procedural methods for responding to unexpected disruptions in cloud-based networks. Patient safety and quality care must remain at the forefront of all AI use in radiology, emphasizing the importance of robust governance of such software. Frequent AI use can alter radiologists' behavior towards an inherent automation bias that relies too heavily on AI assistance. The cloud disruption created a natural case-control opportunity to

evaluate radiologists' interpretative tendencies without routinely available AI. Our findings suggest that there are algorithms for which the AI may over-represent false positives and algorithms where the AI may truly aid the radiologist in capturing acute pathologies. Intermittent robust evaluation of deployed algorithms allows for critical assessment of these tools for long-term clinical use.

M5B-QI-4 CT ON OVERDRIVE: HOW A TWO-PERSON TEAM TURBOCHARGED THROUGHPUT

Leticia Shubin, RDMS,MHA,RVT (*Presenter*)

INTRODUCTION

To evaluate the impact of a revised staffing model in a high-volume CT department, in which one technologist is paired with a supplementary staff member, with the goal of increasing capacity, reducing patient wait times, and improving access without compromising quality of care

METHODS

In January 2025, a two-person CT workflow model was introduced at a high-volume outpatient imaging facility within a large academic medical center. Prior to the intervention, each CT scanner was staffed by a single technologist responsible for the complete imaging workflow, including patient positioning, scanning, and post-processing. The revised model assigned one technologist and one supplementary staff member (either a second technologist or a technologist assistant) per scanner. This team-based approach enabled parallel workflows, such as preparing the next patient while scanning was underway, thereby reducing cold table time between exams. Monthly CT Units of Service (UOS) were tracked from November 2024 to April 2025 to assess the intervention's impact.

RESULTS

Following implementation, a substantial and sustained increase in CT throughput was observed. Monthly CT volumes rose from 400 UOS in December 2024 to 552 in January 2025, the first month of the new model, representing a 38% increase. Growth continued over subsequent months, with volumes peaking at 766 UOS by April 2025. The increased capacity improved scheduling flexibility and reduced appointment backlogs.

DISCUSSION

The two-person staffing model, which comprised one technologist and a supporting team member, resulted in immediate and sustained improvements in CT throughput and operational efficiency. This low-cost, high-impact workflow redesign may serve as a scalable solution for imaging departments seeking to increase capacity without capital investment. Implementing a two-person team per CT scanner can significantly enhance throughput in high-demand outpatient settings, aligning with institutional goals for access, efficiency, and patient care.

M5B-QI-5 IMPROVING TIMELINESS OF DIAGNOSTIC MAMMOGRAPHY LEVERAGING A MODEL FOR IMPROVEMENT WORK QUEUE OPTIMIZATION PROCESS

Efren J. Flores, MD (*Abstract Co-Author*)

INTRODUCTION

Timely diagnostic mammography (DM) is essential for early breast cancer detection. Delays in DM are associated with worse survival outcomes (Caplan, 2014). We observed long scheduling wait times (over 108 days) at two of our breast imaging (BI) sites due to manual workflows and fragmented triage visibility. We focused on acutely symptomatic women aged 40+, presenting with new lumps, bumps, discharge, or rash, given persistent delays in care. The Model for Improvement (MFI) offers a structured framework to test and refine workflows through real-time feedback. Our goal was to reduce average DM wait times by 25% through two Plan-Do-Study-Act (PDSA) cycles over 13 months (April 2024-April 2025).

METHODS

This quality improvement (QI) initiative was implemented at two BI sites within a large quaternary academic medical center. We targeted DM scheduling delays among symptomatic women. Process maps, Pareto charts, and a fishbone diagram (Fig. 1) identified delay factors and guided intervention design. A multidisciplinary team (BI managers, technologists, research coordinators, and navigators) applied the MFI framework using iterative PDSA cycles. The intervention involved redesigning the BI work queue (WQ) to support acuity-based triage of urgent DM orders. We assessed impact using EHR data on patient demographics and wait time from order to scheduled appointment. Baseline data (Mar 1-29, 2024) were followed by PDSA cycle 1 (Apr 1-May 20, 2024) and PDSA cycle 2 (Aug 13, 2024-Apr 30, 2025). Statistical analyses were performed to assess average wait times pre and post intervention implementation. Site managers monitored triage performance, and WQ protocols were incorporated into standard procedures.

RESULTS

Process mapping revealed that DM orders previously entered a general radiology queue without prioritization, resulting in first-in, first-out scheduling. The redesigned BI queue enabled symptom-based triage, improving prioritization of urgent cases. The fishbone diagram highlighted poor order visibility and unclear triage ownership. Among post-intervention patients, 33.4% (431/1,290) were aged 40-50, 96.0% (1,237/1,290) were English speakers, and 89.1% (1,149/1,290) identified as non-Hispanic. Diagnosis of breast asymmetry and lump accounted 89% cases. DM volume included 227 exams at baseline, 188 during PDSA cycle 1, and 1,290 during PDSA cycle 2. Statistical Process Control X-chart revealed average wait time decreased from 108.4 to 10.3 days (Fig. 2).

DISCUSSION

This MFI-QI intervention reduced DM wait times by >90%, demonstrating sustained scheduling improvements. Redesigning the WQ improved triage transparency and eliminated bottlenecks without major system overhaul. This scalable model enhanced resource use and reduced manual scheduling burden, offering a replicable strategy for imaging departments with decentralized workflows.

M5B-QI-6 ENHANCING EFFICIENCY AND QUALITY IN THYROID BIOPSY: THE LONG-TERM IMPACT OF DEDICATED THYROID BIOPSY SPECIALISTS

Sangeet Ghai, MD (*Presenter*)
Catherine Tan (*Abstract Co-Author*)
Joerg Schwock (*Abstract Co-Author*)
Katherine Lajkosz (*Abstract Co-Author*)
Yongheng Jia (*Abstract Co-Author*)
Rudolf Boci (*Abstract Co-Author*)

Kulsoom A. Maan, MBBS (*Abstract Co-Author*)
Wasim Javed (*Abstract Co-Author*)

INTRODUCTION

Small number of trained sonographers started performing thyroid biopsy at our institute in August 2011. We assessed long-term impact in thyroid biopsy performed by trained sonographers under supervision of a radiologist.

METHODS

Quality Initiative Review Committee approval was obtained for this retrospective analysis. Summary data was extracted from the Thyroid biopsy repository in Cytopathology department of the hospital. Data included the number of fine needle aspiration biopsies for the period, location/department of service and the cytopathology report using the Bethesda System for Reporting Thyroid Cytopathology. For the analysis, the study was divided into three time periods, the pre-implementation period (January 2008 - April 2011) when the biopsies were often delegated to rotating residents and fellows, early post-implementation period for the thyroid biopsy sonographers (August 2011 - 2013), and late post-implementation period (2014 - 2022). The period between April and August of 2011 was omitted from the analysis as it was the training period.

RESULTS

In all, 14,127 thyroid biopsies were performed in the radiology department during the period - 4382 in the pre-implementation period and 9745 by trained sonographers (2561 in the early post implementation period and 7184 in the late post implementation period). The unsatisfactory rates dropped from 34% in the pre-implementation period to 20.9% in the early post implementation period to 8.6% in the late postimplementation period ($p < .001$), Theproportion of malignant nodules (Bethesda Category VI) increased from 4.9% to 5.6% to 7.7% in the same period ($p < .001$). During the same time frame as the late implementation period (2014-2022), a total of 8,176 thyroid biopsies were performed in hospital departments other than Radiology. The unsatisfactory rates were 28.9% and the proportion of malignant nodules was 4.5% ($p<.001$).

DISCUSSION

Sonographers trained to perform ultrasound guided thyroid biopsies provide persistent improved patient care over a long-term period. Radiology assistants working within targeted scopes of practice have the potential to enhance the quality of patient care.With the increased focus on quality care and the demands of academic departments to sustain their educational and research goals amid escalating clinical workloads, the thyroid biopsy specialist program has yielded additional benefits across the department. Increased operational efficiency has allowed radiologists to devote more time to to interpretation, consultation and other responsibilities. Additionally, the program offers sonographers increased avenues for professional development, thereby strengthening recruitment and retention of highly qualified personnel.

M5B-QI-7 A FOLLOW-UP STUDY ON THE EFFICACY OF THE MODIFIED UCH SKELETAL MUSCLE BIOPSY NEEDLE IN ULTRASOUND-GUIDED MUSCLE BIOPSIES DURING THE INVESTIGATION OF MYOPATHY

Girija Agarwal, MBBS (*Presenter*)
Ramal Gnanasekaran, MBBCh (*Abstract Co-Author*)
Akash Sharma, MBBS (*Abstract Co-Author*)
Karthik Rajendran, MBChB (*Abstract Co-Author*)
Nadeem A. Qazi, MBBS, FRCR (*Abstract Co-Author*)
Christopher Lord, FRCR (*Abstract Co-Author*)
Dimitri Amiras, MBBS, FRCR (*Abstract Co-Author*)

INTRODUCTION

Most recently, ultrasound-guided percutaneous muscle biopsies have been proposed as an alternative to the traditional open surgical approach for the histological diagnosis of myopathy, as they are less invasive and preferred by patients. Our follow-up study aims to assess the diagnostic yield of the new, larger autoclavable modified UCH skeletal muscle biopsy needle during an ultrasound-guided percutaneous muscle biopsy and to compare the outcomes to our previous study that used the disposable Modified Bergstrum needle.

METHODS

Between June 2022 and April 2025, 31 patients were selected for a muscle biopsy with the modified UCH skeletal muscle biopsy needle after discussion at our local neuromuscular multidisciplinary team meeting. A consultant musculoskeletal radiologist then performed a vacuum biopsy under ultrasound guidance to obtain at least two muscle samples. The histology reports and clinical notes were then followed up to assess the diagnostic yield of the biopsy and compare the histology with the final clinical diagnosis. These results were then compared to the outcomes of a previous study involving 24 patients performed between March 2020 and June 2021 that used the Modified Bergstrom needle.

RESULTS

30 out of the 31 biopsies performed provided diagnostic information. The single non-diagnostic sample was considered to be too small in size. The vastus lateralis was the most common muscle target. Of the 30 adequate samples, 5 had histology discordant with the final clinical diagnosis. A chi-square test with a Chi square statistic of 1.4778 and p value of .22412 revealed no significant difference between the outcomes ($p< 0.5$).

DISCUSSION

Our previous study found adequate histology in approximately 88% of cases. This study suggests that the modified UCH skeletal muscle biopsy needle possibly has a diagnostic capability superior to the modified Bergstrum needle, with adequate histological samples obtained in 98% of cases. This is whilst being more environmentally friendly, less resource-intensive, and cheaper. More data is required to demonstrate a significant difference in outcome between the two biopsy needles.

M5B-QI-8 ENHANCING RESPONSE TO NEOADJUVANT CHEMOTHERAPY BREAST MRI REPORTING: A RADIOLOGIST-CLINICIAN QUALITY IMPROVEMENT COLLABORATION

Haydee Ojeda-Fournier, MD (*Presenter*)
Sheida Ebrahimi, MD (*Abstract Co-Author*)
Sara Grossi, MD (*Abstract Co-Author*)
Vivian Lim, MD (*Abstract Co-Author*)
Soudabeh Fazeli, MD, MPH (*Abstract Co-Author*)
Rebecca Rakow-Penner, MD, PhD (*Abstract Co-Author*)

INTRODUCTION

Contrast-enhanced breast MRI is the most sensitive imaging modality for assessing response to neoadjuvant chemotherapy (NAC) in breast cancer. However, variability in reporting can hinder clinical decision-making. To address this, we undertook a multi-phase quality improvement project. First, we conducted a literature review to identify key elements that should be included in breast MRI reports assessing NAC response. Using these findings, we then performed a two-phase assessment of reporting practices at our institution. Phase 1 evaluated baseline report content; Phase 2 assessed the impact of a newly implemented standardized reporting template on report clarity, completeness, and clinical utility.

METHODS

In Phase 1, we retrospectively reviewed 30 breast MRI reports from five radiologists (1-33 years' experience). Reports were assessed for inclusion of key elements: imaging indication, fibroglandular tissue (FGT), background parenchymal enhancement (BPE), NAC timing, malignancy type, response pattern and type, disease extent,

tumor size change, and nodal evaluation. A survey assessed referring clinicians' satisfaction with report content and utility. In Phase 2, after implementing a standardized reporting template, we reviewed 40 subsequent reports by four of the same radiologists using identical criteria.

RESULTS

After template adoption, inclusion of key elements improved markedly: NAC timing documentation rose from 9.1% to 56.5% ($p = 0.024$); malignancy type from 60.0% to 97.5% ($p < 0.001$); and BPE change from 0.0% to 68.6% ($p < 0.001$). Lymph node reporting—morphology and size comparisons—also improved significantly ($p < 0.05$). Overall, associated feature reporting increased by ~45%. These results indicate that the structured reporting template substantially enhanced the consistency, completeness, and clinical relevance of breast MRI assessments in the neoadjuvant chemotherapy setting.

DISCUSSION

A structured reporting template substantially improved breast MRI reporting for NAC, enhancing documentation of treatment timing, lesion characteristics, and nodal assessment. These improvements are anticipated to strengthen multidisciplinary communication and inform treatment planning. Limitations include the single-center, retrospective design and small cohort. Ongoing training and audits may be needed to sustain adherence. Future work should evaluate impacts on patient outcomes and workflow efficiency. A follow-up survey will be administered to the same group of referring providers to evaluate satisfaction with the revised format and compare it to the prior version.

M5B-QI-9 OPTIMIZING PATIENT COMPLIANCE IN A LUNG CANCER SCREENING PROGRAM :AI ENABLED NURSE NAVIGATION

Leslie Ciancibello, RT (*Presenter*)
Robert C. Gilkeson, MD (*Abstract Co-Author*)
Leslie Whalen (*Abstract Co-Author*)
Jennifer Murphy (*Abstract Co-Author*)
Matthew Kemmann (*Abstract Co-Author*)

INTRODUCTION

Prior studies have demonstrated limited patient adherence to prescribed lung cancer screening guidelines. Our early institutional experience in a lung cancer screening program reflected similar suboptimal adherence rates. Introduction of a dedicated nurse navigation team, with gradual integration of a Natural Language Processing (NLP) data driven management solution, resulted in a significant improvement in both patient adherence and enrollment rates. Our experience demonstrates a direct correlation between patient adherence and the successful implementation of navigational tools and staff to support the program.

METHODS

We reviewed the data from our Lung Cancer Screening Program (LCSP) June 2011 through December 2024 and stratified patient data based on three phases. Phase 1 consists of data from 2011 to 2017 (N=2311) where there were no dedicated navigational tools or staff to support the program. Phase 2 consists of data from 2017 to 2021 (N=11481) where a single part-time nurse navigator was introduced into the program. Lastly -Phase 3 consists of data from 2022 through 2024 (N=25859) when an additional 2 navigational nurses and the implementation of dedicated Lung Cancer management tools were deployed. Differences in patient adherence (adherent, delayed, much delayed or not adherent >1 year follow-up) to Lung Cancer Screening guidelines were compared across phases using chi-squares tests. Alpha of <0.05 was considered statistically significant.

RESULTS

Our internal review shows statistically significant improvement in program adherence to follow up screening as a result of each implementation ($P = < 0.001$) Figure 1, with phase 3 demonstrating the highest rate of adherence of 73%, representing a 210% increase in patient adherence compared to Phase 1. Additionally, non-adherence (> 1 year follow-up) improved across phases ($P<0.001$), with Phase 3 showing the lowest rate of non-adherence at 5.6%, representing an 89% decrease compared to Phase 1.

DISCUSSION

Low Dose Lung Cancer Screening Programs face many challenges including limited access, insurance coverage issues, and patient and physician understanding of appropriate screening criteria and guidelines. This abstract demonstrates that patient compliance is optimized with the integration of a team of navigation nurses and NLP enabled technologies.

R2-QI-1 IMPROVING RADIOLOGY RESIDENT COMPETENCY AND ACCURACY IN INTERPRETING POSTOPERATIVE SPINE RADIOGRAPHS THROUGH A STRUCTURED EDUCATIONAL INTERVENTION

Niloofar Sima, MD (*Presenter*)
Kristopher Ruiz (*Abstract Co-Author*)
A. Orlando Ortiz, MD, MBA (*Abstract Co-Author*)

INTRODUCTION

Interpretation of postoperative spine radiographs is a critical yet underemphasized skill in early radiology training, despite the increasing volume of postoperative spine radiographs. Many junior residents report low confidence in these cases, partly due to greater educational emphasis on cross-sectional imaging. Our purpose is to implement and evaluate a structured educational session to improve junior residents' diagnostic accuracy and confidence when interpreting postop spine radiographs.

METHODS

A flipped-classroom technique was used to teach PGY2 and PGY3 radiology trainees at a single academic center. A pre-lecture survey and quiz followed by a study guide on common post-op spine hardware and techniques were sequentially provided to the learners. Learners then participated in a 1 hour interactive session led by an experienced neuroradiologist. The workshop utilized a reproducible five-step analytic framework and a mnemonic checklist for hardware, in addition to the basic ABC's method to guide systematic evaluation of instrumented spine radiographs. A structured radiology report format was provided to reinforce key analytic concepts. Case examples illustrated a range of normal and abnormal findings. Data was analyzed to evaluate objective performance and subjective confidence improvements. Primary outcomes included change in test scores and mean confidence scores across six domains. Metrics were selected based on alignment with lecture objectives and educational outcomes. A paired t test was used to evaluate changes in test scores; confidence ratings were descriptively compared.

RESULTS

Five residents completed the full intervention. Mean test scores improved from 11.4 to 13.4 out of 15 ($p = 0.022$). Confidence scores improved across all six domains, most notably in hardware recognition (1.6 to 4.0), applying a systematic approach (2.4 to 4.0), and teaching peers (1.6 to 3.5).

DISCUSSION

This pilot intervention demonstrated that a single structured session can improve both confidence and diagnostic accuracy among junior radiology residents. Limitations include the small sample size, which will be addressed by adding future cohorts as we aim to conduct these sessions at the beginning of the academic year during blocked learning times for new residents. In our next session, we plan to include unknown cases for small workgroups where they can discuss their respective cases with the entire group. A test with simulated reporting of unknown cases will be administered to the current pilot group in 3 months. We aim to hold annual repetition of this workshop, adding previously trained residents to serve as facilitators. This approach may serve as a scalable model at other institutions for addressing similar educational gaps in radiology training.

R2-QI-2 IMPROVING CONSISTENCY AND EFFICIENCY THROUGH AUTOMATED DAILY CT AND WEEKLY MRI QUALITY CONTROL

Emi Eastman, MS (*Presenter*)
Yifang Zhou, PhD (*Abstract Co-Author*)

INTRODUCTION

The American College of Radiology requires a continuous quality control (QC) program be established as a part of the accreditation process, done on a daily, weekly, or monthly basis. To maximize the effectiveness of a QC program, as many variables as possible should be kept consistent. Slight variations in the size and placement of regions-of-interest (ROIs) can lead to changes in measurements. Technologists manually performing these measurements will have slightly different results than their colleagues. The purpose of this study was to develop an automated method to perform daily computed tomography (CT) and weekly magnetic resonance imaging (MRI) QC phantom measurements and compare the results of an automated QC program to measurements performed by technologists in an effort to reduce the time spent performing QC.

METHODS

CT QC tests included water CT number, noise, and uniformity, and an additional linearity test for requiring the measurement of 6 different materials in the phantom for some scanners. Weekly MRI QC tests included geometric accuracy, high contrast spatial resolution and signal to noise ratio in place of low contrast detectability. A dedicated server was set up to receive the QC images. The software was tested on images from 13 CT scanners and 4 MRI scanners. The Pydicom library was used to read images and extract parameters from the DICOM header. Detection of the phantom edges and inserts was performed using the Hough Circle Transform function from the OpenCV library. The software measurements were compared to warning and failure thresholds, which triggered an email alert to be automatically sent out when exceeded. Technologist measurements were recorded simultaneously and used for comparison to evaluate the accuracy of the software.

RESULTS

The software successfully performed all tests except for the MRI high contrast spatial resolution. The size and placement of the ROIs for CT were more consistent than the technologist measurements. The time that could be saved implementing this program is compounded for our enterprise health system with 18 CT scanners and 9 MRI scanners. We estimate that implementing this program will save approximately 565 minutes per week.

DISCUSSION

We successfully tested an automated method for CT and MRI QC phantom measurements. The high contrast resolution test requires additional effort due to the subjective nature of the test, but implementing this solution is still highly valuable without it. This method not only mimics technologists' efforts but saves time and improves consistency.

R2-QI-3 CLINICAL VALUE OF DEEP LEARNING-DRIVEN IMAGE QUALITY CONTROL IN NON-ENHANCED HEAD CT IMAGING

Shigeng Wang (*Presenter*)
Yijun Liu (*Abstract Co-Author*)

INTRODUCTION

Medical imaging quality control is essential for ensuring the reliability of diagnostic images and the safety of healthcare services. Current practices often involve radiologists manually evaluating limited samples, leading to subjectivity and inefficiency. This method does not comprehensively assess the imaging quality across radiology departments nor facilitate real-time quality monitoring. This study seeks to develop a deep learning-assisted system for quality control of non-contrast head CT images .

METHODS

A retrospective analysis included 16030 head CT images from 458 patients, with 11221 images used for convolutional neural network (CNN) training (70%), 3206 for validation (20%), and 1603 for testing (10%). Metrics including Precision, Recall, F1-Score were evaluated. Prospectively, 133 patients with suboptimal initial head CT scans requiring re-examination underwent deep learning-assisted quality-controlled scans. Results from both examinations were compared.

RESULTS

The deep learning-assisted quality control system demonstrated strong performance in Precision, Recall, and F1-Score metrics. All 133 re-examinations of head CT scans achieved accurate diagnoses using the quality control system. Among initial scans, 26 cases showed diagnostic discrepancies, with no significant differences in lesion localization or intracranial volume measurements. However, substantial improvements were observed in morphological details (cerebral tissue delineation), boundary clarity of intracranial lesions, and characterization of calcifications or hemorrhagic components.

DISCUSSION

The proposed system enables objective image quality assessment and workflow efficiency enhancement, demonstrating significant potential for clinical translation in standardized head CT quality control protocols.

R2-QI-4 FIXING RADIOLOGY'S ACHILLES' HEEL: A SYSTEMS-LEVEL REVIEW OF THE FIVE 'A'S IN THE ERA OF AI AND EQUITY

Waqas Ahmad I, MBBS (*Presenter*)

INTRODUCTION

Radiology has transformed modern medicine through technological innovation and precision diagnostics. However, persistent systemic challenges—categorized here as the Five "A"s: Accessibility, Availability, Accuracy, Affordability, and Appropriateness —continue to impede equitable and efficient radiology services globally. These barriers disproportionately affect underserved populations, overextend healthcare resources, and compromise patient safety. This study aims to systematically analyze these five domains as critical failure points and propose corrective strategies leveraging workforce development, policy innovation, and artificial intelligence (AI).

METHODS

We conducted a narrative review of published literature (2010-2024) across five thematic domains representing the Five A's. This was supplemented by semi-structured expert interviews (n=18) with radiologists, healthcare administrators, and policymakers across high-, middle-, and low-income countries. Solutions were categorized into: Technology-enabled interventions (e.g., AI, teleradiology), Workforce and infrastructure development, and Policy and governance strategies. Recommendations were evaluated for feasibility, equity impact, and scalability.

RESULTS

Thematic synthesis revealed: Accessibility: Barriers were most prominent in rural and low-resource areas, mitigated effectively by mobile imaging units and AI-driven triage. Availability: Workforce shortages were universal, but mitigated through remote reporting models and hybrid task-shifting systems using trained non-physician imaging readers. Accuracy: Errors due to fatigue, inconsistent reporting, and over-reliance on unvalidated AI were improved by implementing structured reporting, peer review, and validated decision support algorithms. Affordability: High imaging costs and poor insurance coverage were offset by imaging pathway redesign, bundled care packages, and AI-optimized scan protocols. Appropriateness: Over- and under-utilization of imaging were addressed using AI-based clinical decision support and adherence to evidence-based guidelines.

DISCUSSION

Despite technological progress, radiology's foundational delivery challenges remain rooted in systemic inequities and resource misalignment. Corrective interventions must be context-sensitive, combining technology (AI, teleradiology)with policy (governance reforms, insurance expansion) and capacity-building (training programs, rural infrastructure). Addressing these issues is not just a matter of operational improvement, but a moral and strategic imperative to ensure that radiology contributes equitably to global health outcomes.

R2-QI-5 REDUCING RADIATION DOSE IN ROUTINE CT SCANS THROUGH PROTOCOL OPTIMIZATION ON A 128-SLICE SCANNER IN SOUTH INDIA

Shaaruk Davlath, MBBS (*Presenter*)

INTRODUCTION

Computed tomography is a widely used imaging modality in both emergency and non-emergency settings. However, patients are exposed to ionizing radiation, which may lead to both stochastic and deterministic biological effects. Dose Length Product (DLP), measured in mGy·cm, reflects the CT scanner's radiation output and is a key parameter in dose monitoring. In India, regulatory limits for CT radiation dose are lacking, with only limited retrospective multicenter data available. Facility reference levels (FRLs) at our center were analyzed to identify areas for optimization. The aim of this study was to implement ALARA (As Low As Reasonably Achievable) principles and reduce DLP without compromising diagnostic image quality.

METHODS

A retrospective audit was conducted over a two-month baseline period to assess DLP values across routine CT scans, including brain (plain and contrast), thorax, and abdomen (plain and dual-phase contrast). The 75th percentile of DLP distributions was used as the internal benchmark and compared against available Indian reference values. Identified high-dose protocols were revised by adjusting kilovoltage (kVp) based on patient weight, modifying the noise index, and increasing Adaptive Statistical Iterative Reconstruction (ASIR). Defined scan extents were standardized, and radiographers were trained accordingly. Post-intervention data were collected prospectively for two months using a digital form-based tracking system.

RESULTS

One month after intervention, significant DLP reductions were achieved. CT brain (plain) showed a 35.5% reduction, brain (plain + contrast) 22.4%, thorax (contrast) 57.1%, abdomen (plain) 35.3%, and abdomen (dual-phase contrast) 73.8%. Although brain study DLPs remained slightly above benchmark levels, abdominal scans demonstrated a substantial reduction. Image quality was preserved in all cases as confirmed by blinded radiologist assessment.

DISCUSSION

Protocol optimization, including ASIR adjustment, kVp modulation, and standardized scan coverage, effectively reduced DLP without sacrificing diagnostic confidence. While the current study focused primarily on adults, pediatric data were limited and warrant future attention. Given the potential for stochastic radiation effects, radiologists should exercise caution when selecting protocols, particularly for women and children, and avoid unnecessary scan extensions.

R2-QI-6 FROM PIXELS TO PLASTIC: THE UNTAPPED POTENTIAL OF RADIOLOGISTS IN POINT-OF-CARE 3D PRINTING TO IMPROVE MEDICAL EDUCATION AND PROCEDURAL PREPARATION

Kristian T. Quevada, MD (*Presenter*)
Vipul Bhat (*Abstract Co-Author*)
D'Shaun D. Adams, MD (*Abstract Co-Author*)
Zachary Mikes, DO (*Abstract Co-Author*)

INTRODUCTION

Understanding complex anatomy is critical to practicing radiology and surgery, but access to detailed 3D models is often limited. Commercial models are expensive, have long turnaround time, and are often not tailored to individual patient anatomy. There is utility of 3D printing in education, surgical planning, and procedural practice, but it is not widely integrated into clinical practice. Radiologists have the expertise to implement patient-centric 3D printed models into educational and clinical workflows to provide deeper education and multidisciplinary support. The goal was to develop a cost-effective, efficient, and radiology-driven 3D printing workflow that can be used for education, procedural training, and preoperative planning.

METHODS

A consumer-grade 3D printer (~$700) was acquired. The following models were printed: a liver model with Couinaud segmentation for education, distal radius fracture models for preoperative planning, and an endovascular model for guidewire training. The team included radiology residents and attendings, technologists, and surgery faculty. Radiology led the model generation effort, but responsibilities were shared for their implementation. Early trials identified issues like segmentation time and print failures. Workflow was adjusted to improve model design, cost, and turnaround time. Parameters measured included the time from DICOM to finished print, material cost per model, and how the models were used. These were compared to those from commercial printing options, if available on the market. Informal feedback was also collected from surgeons and trainees to assess utility. 3D printing workshops will be held to continue to train faculty, residents, and staff in the workflow, so the printer can continue to be widely utilized for educational sessions and conferences.

RESULTS

Filament cost per model ranged from $0.50 to $25, while equivalent commercial models ranged from $88 to $4,000. Models with equivalent products on the market (liver and endovascular models) yielded 72% and 99.98% cost savings compared to third-party vendors, respectively, with 40 hours and 88 hours saved from file to hospital, respectively. Break-even point for highest material unit (liver model) is approximately 11 units. Trainees found the models helpful for spatial understanding, and clinicians found them productive to visualize complex anatomy for surgical planning.

DISCUSSION

Early challenges included segmentation issues and failed prints, which were refined over time. Radiologists' unique expertise can be paramount in leading Point-of-Care 3D printing efforts. The initial cost of a 3D-printer is a scalable investment that pays for itself after just a few prints. This technology can enhance the quality and cost of trainee education and aid in multidisciplinary communication, strengthening the foundations of precision medicine.

R2-QI-7 IMPROVEMENT OF WORKFLOW FOR ARTIFICIAL INTELLIGENCE (AI)-ASSISTED MOBILE CHEST X-RAY BUS TUBERCULOSIS (TB) SCREENING IN BANGKOK

Hiroshi Yoshioka, MD, PhD (*Presenter*)
Antoine Choppin, MS (*Abstract Co-Author*)
Gun Wongpanich, MD (*Abstract Co-Author*)
Panithi Permsirivanich (*Abstract Co-Author*)
Lalita Kaewwilai (*Abstract Co-Author*)
Orawan Kaewboonchoo (*Abstract Co-Author*)

INTRODUCTION

Tuberculosis (TB) is one of the deadliest infectious diseases in the world, especially in the South-East Asian region. To eliminate TB, it is crucial to screen as many patients as possible and treat them as early as possible. Mobile x-rays can be an effective tool for this purpose. However, they have not been fully utilized due to limited resources (especially radiologists), financial reasons, and the lack of information or education to the residents. Our goal in this study is to prospectively incorporate diagnostic imaging AI into the local mobile x-ray TB screening workflow in Bangkok. Compared to the conventional mobile x-ray workflow, we aim to improve screening effectiveness and enable to guide more potential TB patients to sputum test/treatment quickly using an in-house AI-assisted chest x-ray software.

METHODS

This study was prospective and approved by our institutional review board. A total of 2146 subjects (mean age = 52.6 years, age range 20 - 96 years; 749 male and 1397 female) participated from 21 community districts in Bangkok. After mobile bus routine TB screening chest x-ray images were obtained, they were forwarded to the server to identify and infer potential TB by an in-house developed AI-assisted chest x-ray diagnostic system. Then, the results of positive or negative TB by AI were uploaded to Google spreadsheet and at the same time AI positive TB cases were uploaded to an online viewer, and notification sent to the radiologists via LINE messaging API. The radiologists read uploaded chest x-rays on the viewer, confirmed presence or absence of TB, and reported diagnosis immediately. We monitored the radiologist reports and informed TB positive cases to the nurses in the public health center in each district, where the sputum tests were booked or performed. The number of total analyses, AI negative TB, AI positive/radiologist negative TB, and AI positive/radiologist positive TB cases were recorded. Additionally, average AI specificity, AI precision, and TB positive rate by radiologists were calculated.

RESULTS

All 2146 cases were successfully analyzed by our chest x-ray AI software and the radiologists' diagnoses of positive TB were completed within approximately 5 minutes to one hour. The AI negative TB cases, AI positive/radiologist negative cases, and AI positive/radiologist positive cases were 1513, 452, and 181, respectively. Average AI specificity, AI precision, and TB positive rate by radiologists were, 0.77, 0.29, and 8.4%, respectively.

DISCUSSION

AI-assisted mobile chest x-ray bus TB diagnosis system combined with immediate notification to the radiologists enabled within one hour turnaround time and improved efficiency and throughput of TB screening in communities in Bangkok. Timely TB positive results reporting lead to obtain the sputum test and treatment earlier, which will be useful for eliminating TB effectively in Thailand.

R2-QI-8 FROM SCAN TO SCALPEL: IN-HOUSE RADIOLOGY-DRIVEN VIRTUAL REALITY AND 3D PRINTING FOR FRACTURE REDUCTION AT A LEVEL 1 TRAUMA CENTER

Amar P. Shah, MD (*Presenter*)
Tanvi Ghosh (*Abstract Co-Author*)
Shireen Damle (*Abstract Co-Author*)
Chad Purnell (*Abstract Co-Author*)
Lee Alkureishi (*Abstract Co-Author*)
Richard Monahan (*Abstract Co-Author*)
Linping Zhao, PhD (*Abstract Co-Author*)
Pravin Patel, MD (*Abstract Co-Author*)

INTRODUCTION

Advances in virtual planning and three dimensionally-printed (3DP) anatomical models have enhanced intraoperative precision, but the current multi-step work flow requires a week of lead time, which is incompatible with 24-48-hour timeframe typically available in trauma intervention. An initiative was implemented at Sinai Chicago, a Level 1 trauma center, where computed tomography (CT) imaging is routinely performed for diagnostic evaluation. To extend their use, a collaboration between radiologists, surgeons and engineers was established. A novel point-of-care (POC) system, supported by virtual reality (VR) and 3DP, has been built featured with a fully on-site workflow while integrated with existing hospital systems. It presents the increasingly pivotal role of the Department of Radiology in assisting Surgery Department in efficient intra-operative management of complex cranio-maxillofacial (CMF) fractures.

METHODS

The workflow started from CT images in PACS. Through a secured utility, DICOM data is automatically routed to an in-house workstation. Following input and autosegmentation of bony components, fracture reduction was performed using ImmersiveView™ 5 (ImmersiveTouch Inc., Chicago, IL) , a VR-based platform that allows intuitive manipulation of 3D structures. Right after, an on-site 3D printer fabricated patient-specific fracture-reduced model of selected plastics for preoperative plate adaptation, followed by sterilization and operation.

RESULTS

Over 9 months, this in-house workflow has been refined and applied to more than 50 CMF trauma cases. Its implementation led to reduced surgical preparation time from 5-7 days to approximately 3-11 hours. Fracture reduction within VR was typically completed in 15-30 minutes, with 3D printing requiring 2-10 hours and plate adaptation between 5-25 minutes. In one representative case of a unilateral right zygomatic fracture, the complete planning and fabrication process was completed within 8 hours—well within the 48-hour trauma window. With on-going collection, additional data will be presented to quantify time savings, surgical outcomes, and workflow efficiency.

DISCUSSION

This novel radiology-driven workflow demonstrated the feasibility of rapid, on-site virtual planning and 3D model production for trauma surgery with adequate accuracy. Key advantages included accelerated turnaround, improved visualization for the surgical team, and enhanced plate adaptation using patient-specific printed models. The system required minimal additional infrastructure and integrated seamlessly into existing hospital networks, thus supporting both long-term scalability and sustainability. Currently, this approach is being extended to orthopedic trauma, further positioning the Department of Radiology as an indispensable contributor to surgical planning and intervention.

R2-QI-9 ROOT-CAUSE ANALYSIS SIMULATION- PILOT SESSION AT RSNA 2024

Nadja Kadom, MD (*Presenter*)
Jay K. Pahade, MD (*Abstract Co-Author*)
Susan Reich (*Abstract Co-Author*)
Bettina Siewert, MD (*Abstract Co-Author*)
Hanna M. Zafar, MD, MS (*Abstract Co-Author*)
Andrew Bowman, MD, PhD (*Abstract Co-Author*)

INTRODUCTION

Radiologists are highly trained in clinical interpretation but often have limited exposure to systems thinking, patient safety science, and root-cause analysis (RCA) methodology during residency or fellowship. However, radiologists may be involved in safety events and/or may be asked to participate in RCAs, which can lead to anxiety if the process is unknown. RCA simulation helps radiologists recognize the key elements of a RCA and its purpose of making our systems safer rather than seeking individual accountability.

METHODS

A team of five RSNA Quality Improvement Committee members developed a short vignette of an outpatient who was discharged from an imaging facility with an IV still in place that subsequently became infected. A1-hour session was delivered to in-person participants during the 2024 RSNA Annual Meeting. Each facilitator worked with four simulation participants, who received a 1-page document at the beginning of the simulation, laying out the error event and their role in the RCA (i.e., MRI technologist, former MRI student, patient and family advisor, MRI supervisor). The facilitators were given 35 minutes to simulate the RCA and develop a timeline of events, a gap and root-cause analysis, and an action plan. The remaining 25 minutes were used for debriefing, with additional explanations and examples of those key deliverables.

RESULTS

Ten participants responded to the pre-and post-session assessments, indicating appropriateness of the 1-hour session length, 80% ratings of the session being “very effective” (highest rating), and 90% stating the session enhanced their familiarity with the RCA process.

DISCUSSION

We demonstrated feasibility and effectiveness of an RCA Simulation at an Annual Meeting. This program can easily be shared with others and delivered in radiology practice settings, especially radiology teaching programs without access to other RCA training resources. The initiative will be repeated at the 2026 American Society of Neuroradiology (ASNR) Annual Meeting, supported by a 2025-2026 Member-Centric Strategic Initiative.

R5A-QI-1 IMPROVING REPRESENTATION IN RADIOLOGY RESIDENCY USING A REPRODUCIBLE FRAMEWORK

Kevin Dao, MD (*Presenter*)
Gelareh Sadigh, MD (*Abstract Co-Author*)
Rebecca Z. Bennett, MD (*Abstract Co-Author*)

INTRODUCTION

Despite being the 9th largest residency by enrollment, radiology ranks 18th in underrepresented in medicine (URiM) 1 racial/ethnic diversity amongst the 20 largest ACGME specialties. 2 Additionally, women comprised only 27% of radiology residents in 2019-2020, despite representing 52% of medical school matriculants. 2 These disparities persist despite strong evidence that diversity improves innovation, financial performance, and patient outcomes. 3 Prior efforts, such as the 2019 initiative by Vanderbilt Radiology, have shown success in increasing URiM recruitment through structural changes in the residency selection process.The purpose of this study was to assess the impact of a structured diversity recruitment initiative on URiM and female representation in our diagnostic and interventional radiology residency programs.

METHODS

This study was conducted at a quaternary academic hospital in Southern California. Between 2018-2021, URiM and female representation among residents was 4% and 25%, respectively. In 2021, our department formed the Radiology Outreach Committee (ROC) to implement a multifaceted intervention similar to Vanderbilt's approach, including: Blinding applications with holistic review Diversifying the recruitment committee Requiring implicit bias training for all interviewers Presenting a dedicated talk about the ROC during each interview day Hosting a dedicated DEI portion to the virtual second look Partnering with URiM institutions and societies (eg annual HBCU summer research program, SNMA, LMSA) Launching an annual 6-week paid radiology internship for URiM medical students We analyzed self-reported demographics of matched residents before and after intervention. Primary outcomes were URiM and female representation in matched cohorts. Data were sourced from NRMP Match results, using the AAMC definition for URiM. 1 Descriptive statistics and chi-squared tests were used to compare pre (2018-2021) and post (2022-2025) intervention cohorts. Significance was set at $p<0.05$.

RESULTS

Interventions were implemented in 2021 for the 2022 Match cycle. Post intervention, URiM representation rose significantly from 4% to 42% ($p<0.001$). Female representation also increased, though not significantly ($p=0.164$). Figures 1-4 show the changes in demographic trends.

DISCUSSION

This study was limited by small sample size and the inability to isolate individual intervention effects. Additionally, single-institution efforts do not address diversity across the specialty. Broader impact will require earlier outreach to undergraduate and preclinical medical students to expand the pool of URiM and female radiology applicants. Nonetheless, our findings suggest that a structured, multifaceted approach can significantly increase URiM recruitment, with a positive trend in female representation that may grow with sustained efforts.

R5A-QI-2 BRIDGING THE GAP: HOW A LARGE ACADEMIC MEDICAL CENTER AND A NON-PROFIT CANCER CLINIC PARTNERED TO ADDRESS HEALTH INEQUITIES IN BREAST IMAGING CARE

Amy L. Kerger, DO (*Presenter*)
Rahul Mal, MD (*Abstract Co-Author*)
Mohammed A. Ismail, DO (*Abstract Co-Author*)

INTRODUCTION

Geographic, financial, and logistical barriers—such as lack of transportation, high medical costs, limited provider access, and distrust of healthcare systems—contribute to lower rates of cancer screening, follow-up, and treatment among underserved populations. In the U.S., 7.9% of individuals remain uninsured or underinsured, and a cancer diagnosis often leads to financial strain. Over 42% of patients deplete their assets, and 30% incur medical debt after diagnosis. Anticipated costs cause many to delay or avoid screening and treatment, even when symptomatic.

METHODS

LifeCare Alliance (LCA), Ohio's largest nonprofit health and nutrition provider, has offered community-based cancer screenings since 1898. In partnership with The Ohio State University (OSU) James Cancer Hospital, LCA expanded access to timely breast imaging and diagnostics for underserved patients. Through this collaboration, LCA integrated OSU's electronic health record (Epic) via Community Connect, leased breast imaging, PACS, and medical physics services, and arranged for OSU to hire and lease technologists back to LCA. OSU's breast imaging team began providing on-site diagnostic imaging one day per week, with biopsy services launching soon. This integration enabled real-time collaboration and streamlined workflows.

RESULTS

Since implementing Epic Community Connect and on-site collaboration in August 2024, turnaround times have markedly improved: Screening mammogram interpretation reduced from 1-2 weeks to within 24 hours. Callback to diagnostic imaging shortened from 4-6 weeks to 1-2 weeks. Screening to biopsy time decreased from 6-8 weeks to approximately 2 weeks. Although ultrasound-guided biopsies remain off-site due to ongoing renovations, coordination has been seamless, and on-site biopsies are expected to begin in late summer 2025. Notably, since the partnership began, 100% of patients have chosen to continue care through OSU, compared to prior fragmentation across health systems.

DISCUSSION

Despite evidence that screening reduces breast cancer mortality, disparities persist due to social determinants of health like insurance status, income, housing, and education. Our partnership shows that a collaborative, multidisciplinary approach can address these barriers. By uniting academic medical expertise with community outreach, we've developed a patient-centered model delivering timely, equitable care to uninsured and underinsured populations. With access to high-quality imaging, navigation, translation, transportation, and financial assistance, patients receive care in a trusted setting. This model minimizes delays, reduces financial burden, and

improves continuity of care—building trust and improving outcomes. It is scalable and has potential for national replication to reduce disparities in underserved communities.

R5A-QI-3 UTILITY OF CHATGPT-3.5 TO PREDICT NEURORADIOLOGIC STUDY TO ORDER BASED ON AMERICAN COLLEGE OF RADIOLOGY'S APPROPRIATENESS CRITERIA

Siddhant Kumarapuram Ganapath (*Presenter*)
Shirleen Xu (*Abstract Co-Author*)
Jay Kavia (*Abstract Co-Author*)
Ashwin Bhaskar (*Abstract Co-Author*)
Aafreen Azmi (*Abstract Co-Author*)
Alberto F. Goldszal, PhD, MBA (*Abstract Co-Author*)
Gaurav Gupta, MD (*Abstract Co-Author*)
Sudipta Roychowdhury, MD (*Abstract Co-Author*)

INTRODUCTION

Large Language models (LLMs) are novel tools with promising clinical applications. Although research has focused on their diagnostic applications, their utility in providing imaging recommendations requires further research. Neurologic pathologies, which range from emergent to advanced presentations, provide a diverse framework to assess the accuracy of LLM's on imaging study selection. Thus, we assessed the accuracy of the imaging recommendations by LLM ChatGPT-3.5 to neurology case prompts by the American College of Radiology (ACR) Appropriateness Criteria.

METHODS

Prompts from the ACR Appropriateness Criteria's priority clinical areas within neurology were used to design open ended (OE) or select all that apply (SATA) questions. Each case was categorized as acute, chronic, or indeterminate. OE questions required ChatGPT to select the most appropriate study for a clinical presentation, whereas SATA questions asked ChatGPT to determine whether a provided study was "usually appropriate," "maybe appropriate," or "usually not appropriate" for the presentation. Each question was posed three times, and responses were scored against ACR guidelines. Performance on OE prompts were compared to performance on SATA prompts for each clinical area. The performance on acute cases were compared to performance on chronic cases.

RESULTS

A total of 78 prompts were assessed in 11 priority clinical areas. Average performance on OE and SATA questions were 69.2% and 44.4% respectively. Amongst the priority clinical areas, the LLM performed superior on OE than SATA for the categories of Aneurysm ($p < 0.001$), Stroke ($p < 0.001$), Headache ($p = 0.027$), and Spine Infection ($p < 0.001$). The LLM performed superior on SATA than OE for the Vertebral Compression Fracture category ($p = 0.015$). Difference in performance between acute and chronic prompts on SATA ($p = 0.5411$) and OE ($p = 0.6530$) were not significant. Overall, performance of ChatGPT LLM was greater when OE prompts were provided compared to SATA. Furthermore, its performance was consistent across acute and chronic scenarios.

DISCUSSION

LLMs hold promise as decision-support tools in imaging selection. We demonstrate that LLMs can recommend general imaging studies based on clinical context more effectively than advising on a particular one. Furthermore, these tools have a similar performance in both emergent and outpatient settings, suggestive of their utility in proposing advanced imaging options in non-emergent settings when more time is available to evaluate. However, the tool is limited in its scope in the time-sensitive emergent setting as it requires the input of a clinician. Nevertheless, with more advancements in LLM construction, the accuracy of these tools on recommending radiologic studies can be expected to improve.

R5A-QI-4 FROM PIXELS TO PREVENTION: AI-DRIVEN CORONARY ARTERY CALCIUM DETECTION AND PATIENT MANAGEMENT

Osama Syed, DO (*Presenter*)
Nicholas Lim, MD (*Abstract Co-Author*)
Chiduzie Madubata, MD (*Abstract Co-Author*)
Igor Goykhman, DO (*Abstract Co-Author*)
Avishkar Sharma, MD (*Abstract Co-Author*)

INTRODUCTION

Coronary artery calcium (CAC) scoring is a powerful prognostic marker of cardiovascular risk and is often overlooked when incidentally detected on routine CT imaging. We deployed a two-part AI solution (Aidoc, Tel Aviv, Israel), integrating diagnostic radiology tools and natural language processing (NLP), to identify, report, and manage CAC findings from non-gated, non-contrast CT chest/abdomen scans including the heart. This end-to-end workflow enables opportunistic screening and structured patient follow-up, while reducing radiologist burden.

METHODS

An AI tool analyzed non-gated CT scans (May 2024-April 2025) to assess CAC severity. Separately, an NLP algorithm reviewed finalized reports to detect the degree of CAC. NLP-positive cases were routed to a care management platform where navigators coordinated follow-up. Inclusion criteria: outpatient CTs, age <80, and AI-assessed CAC = moderate. Exclusion criteria: existing cardiology care or limited life expectancy. Outcomes included the number of patients identified, referred, scheduled, and seen.

RESULTS

1,756 outpatient CT scans were analyzed by the image based AI tool. Concurrently, the NLP-based solution identified 951 eligible patients with CAC, of whom 266 (27.9%) were excluded due to existing cardiology care. A cohort of 69 patients referred to cardiology were reviewed for outcomes; 61 (88.4%) were seen, 7 no-showed, and 1 had a future appointment. Of the 61 patients seen, 68.8% (42/61) had medication adjustments (statins, antihypertensives, or antiplatelets). Within three months of the initial visit, 68.8% (42/61) also completed additional anatomic or functional cardiac testing such as echocardiography or stress testing. Six of these patients (14.3%) underwent a diagnostic left heart catheterization with two receiving revascularization (one PCI, one CABG).

DISCUSSION

An AI-driven CAC workflow combining automated scoring, NLP-based detecting and navigator-led coordination is feasible and clinically effective. This system successfully identifies care gaps and facilitates follow-up for patients with incidentally detected coronary calcium. Early data suggests this approach promotes opportunistic screening for cardiovascular disease.

R5A-QI-5 IMPROVING CONSISTENCIES THROUGH STANDARDIZED WORKFLOWS AND PROCESSES IN CARDIAC CT IMAGING

Peggy Zillgitt, ARRT, MA (*Presenter*)
Mitchell Owen (*Abstract Co-Author*)
Jennifer Jones, ARRT (*Abstract Co-Author*)
Kathryn Scharnweber (*Abstract Co-Author*)

INTRODUCTION

The purpose of this study is to create a consistent workflow for cardiac CT scans that will increase efficiencies for complex cardiac exams, which can be unpredictable and frustrating for patients and staff. The goal of the project is to increase on-time starts (OTS) for cardiac exams by 12% from an average of 56% to 68% by July 28th without negatively impacting OTS for all other CT exams in this same CT department.

METHODS

A team of CT technologists, support staff, and leadership personnel are approaching this issue using the Define-Measure-Analyze-Improve-Control (DMAIC) and A3 framework to advise a solution strategy using a series of Plan-Do-Study-Act (PDSA) cycles. Qualitative and quantitative measures are going to be used to monitor progress throughout the project. Timestamps during the workflow process will be monitored to show when and where processes are working or failing. Feedback from stakeholders will also be used during the PDSA cycle. Department OTS for all other CT scans are going to be monitored as a counterbalance. A root cause analysis was performed to determine all possible solutions. Solutions were then placed into a Fishbone Diagram and Impact Effort Grid to determine and prioritize possible approaches within the scope of the project. The team is preparing to work through various PDSA cycles of different workflow options to improve cardiac exam efficiencies and increase OTS. The project team plans to collaborate with support staff and stakeholders through trials and project efforts. Trials that will be initiated include template changes, cardiac scan room staffing model changes, assignment workflow modifications, and improved resources for support staff. Template changes have been built and are ready to go live on May 28 th , 2025. Visual resources have been added to every scanner station and are currently being monitored by staff feedback. A detailed review of timestamp data and input gathered from those involved will be done after each PDSA cycle to determine success.

RESULTS

This project will prove to be successful with a 12% increase in cardiac CT exams OTS among a sample size of 10 days, with no negative impact on OTS for all other CT exams on Gonda 3.

DISCUSSION

The project team expects to learn many lessons throughout PDSA cycles. A lesson already learned is the importance of communication between the staff involved. Limitations of the project include modifying access operations.

R5A-QI-6 DISPARITIES IN RADIOLOGIC IMAGING FOR CHEST PAIN IN THE ED: THE INFLUENCE OF PRIMARY LANGUAGE ON TEST UTILIZATION AND COST

Tony Tu (*Presenter*)
Qianchen Zhang (*Abstract Co-Author*)
Charlotte Cheng, BS, MS (*Abstract Co-Author*)
Rishi Hoskeri (*Abstract Co-Author*)

INTRODUCTION

Language barriers in emergency departments (EDs) contribute to disparities in diagnostic accuracy, efficiency, and patient outcomes. Patients with limited English proficiency (LEP) face longer ED stays, increased diagnostic uncertainty, and higher healthcare costs. Prior literature indicates that LEP patients may be less likely to receive guideline-concordant care. The purpose of this study is to evaluate whether primary language influences the type and cost of radiologic tests ordered for chest pain in the ED.

METHODS

We conducted a retrospective observational analysis using the RSNA COSMOS database covering 22,753,937 ED encounters for chest pain from March 2010 to March 2025. Patients were categorized by primary language, including English, Russian, Chinese, Spanish, Arabic, and Vietnamese. Imaging metrics included receipt of chest radiography (CXR), computed tomography (CT), and the ratio of CT+CXR to CXR-only imaging. We analyzed disparities using chi-square tests and calculated utilization percentages.

RESULTS

Among all encounters, 93.5% were English-speaking patients, with Spanish speakers comprising 4.2%. CXR utilization was significantly lower among all non-English-speaking patients (Spanish: 0.32%+-0.01%, Arabic: 0.25%+-0.05%, Russian: 0.25%+-0.07%) compared to English speakers (0.47%+-0.003%, all $p < 0.001$). CT utilization showed a similar disparity (Spanish $p = 0.003$; Arabic $p = 0.009$). However, the ratio of CT+CXR to CXR-only was higher in some non-English speakers (Spanish: 0.40+-5 vs 0.24+-0.003 in English, $p = 0.021$; Arabic: 0.32+-0.03 vs 0.24+-0.003, $p=0.012$; Russian 0.25+-0.11 vs 0.24+-0.003, $p > 0.05$), suggesting additional imaging may be ordered due to communication uncertainty. These findings reflect inefficiencies and potential over-testing among LEP patients.

DISCUSSION

Non-English-speaking patients in the ED are less likely to receive initial imaging for chest pain but are more likely to receive additional, potentially redundant imaging. These disparities may reflect systemic barriers to communication and contribute to higher costs and diagnostic delays. Limitations include possible underreporting of imaging in the dataset and lack of contextual clinical data (e.g., interpreter use). Sustainability of improvements will depend on system-wide adoption of language access tools, cultural competency education, and better documentation of preferred language. Recognizing language as a structural determinant of health is essential for promoting equity in emergency radiologic care.

R5A-QI-7 REDUCING RADIATION EXPOSURE OF PATIENTS UNDERGOING TRAUMA CT IN THE ED

Chaitra Goud, FRCR, MBBS (*Presenter*)
Kabilan Chokkappan (*Abstract Co-Author*)

INTRODUCTION

CT (Computed Tomography) is the most accurate and cost-effective method to evaluate severe blunt abdominal trauma in hemodynamically stable patients. Polytrauma patients receive a substantial dose of radiation during initial and subsequent follow up CT imaging. The radiation exposure is cumulative and detrimental. Low individual risk of cancer becomes a greater public health issue when multiplied by a large number of examinations. The goal of our study was to increase the percent of patients undergoing trauma CT that receive optimal radiation* from 11.2 % to 60 % in 6 months without compromising on the diagnostic quality.(* Optimal radiation considered below 1660 mGycm in terms of DLP [Dose Length Product])

METHODS

This study was performed at an urban public health hospital. Quality improvement team included Radiologists, ED (Emergency Department) CT radiographers, Physicist and ED clinician. Trauma CT angiogram protocol in our department includes pre contrast scan, contrast enhanced arterial/portal venous phases and a delayed scan of the thorax, abdomen and pelvis. The team used quality improvement toolkits to identify the root causes and prioritize few actionable causes through multi voting. The application and efficiency of the interventions was assessed through multiple PDSA (Plan-Do-Study-Act) cycles. Modified scan protocol replacing dual energy with single energy scanning for three of the phases, correct patient positioning and proper scanogram planning proved to be the most effective interventions.

RESULTS

The project measure was optimal radiation exposure in DLP (mGycm) which was measured for every scan. The results plotted on a run chart showed CT scans with optimum radiation dose to have increased to 60%. Additional project measure was median dose which decreased significantly and consistently to fall in the optimum range

DISCUSSION

Some problems encountered during the study were that initial protocol of using virtual non-contrast scans was not acceptable to all radiologists and non-compliance of few radiographers to follow the modified scan protocol. Often, the most effective solution is the simplest option. We achieved reduction in radiation exposure to the patient which led to additional cost benefits like increasing tube life of the CT scanner and reduced need of PACS (Picture Archiving and Communication System) cloud storage.

R5A-QI-8 RADIOLOGIST AND TECHNOLOGIST WELLBEING IN AN ACADEMIC RADIOLOGY DEPARTMENT: A HUMAN-CENTERED DESIGN THINKING APPROACH

Achala S. Vagal, MD (*Presenter*)
Lily L. Wang, MBBS, MPH (*Abstract Co-Author*)
Sangita Kapur, MD (*Abstract Co-Author*)
Bruce Mahoney, MD (*Abstract Co-Author*)
Jacqui Rose (*Abstract Co-Author*)
Megan Wimmer (*Abstract Co-Author*)
Mary C. Mahoney, MD (*Abstract Co-Author*)

INTRODUCTION

The increasing focus on patient experience in radiology is paralleled by concerns about provider burnout and disengagement. Moving from patient-centered to human-centered radiology, with empathy for all stakeholders, is essential. Our objective was to use design thinking to identify factors affecting employee wellbeing and co-create solutions with radiology faculty and staff.

METHODS

From March 2024 to April 2025, we partnered with GE HealthCare Experience Design team to launch a Design Thinking Initiative aimed at enhancing employee wellbeing within our academic radiology department. We surveyed 139 stakeholders-including radiologists, technologists, nurses, clinical service coordinators, and managers-using a 30-question survey based on GE HealthCare's experience drivers, the Stanford professional fulfillment model, and the AMA burnout assessment. Survey insights informed a two-day workshop utilizing design thinking phases: Defining the problem, Research, Ideation, and Refinement. Workshop participants included department leadership, faculty, technologists, administrators, and design thinking consultants. Activities included gaining empathy through active listening, framing the challenge, solution iteration, concept selection, prototyping plan and forming focus groups with champions. A further deep dive in a subsequent department retreat allowed refinement of the ideas.

RESULTS

Four main themes emerged: (1) Recruitment and retention of radiologists, (2) Recruitment and retention of technologists, (3) Workflow efficiency and control over workload and, (4) Culture of appreciation. We mapped challenges in each theme directly translate to employee satisfaction and created a priority project pipeline that addressed the pain points of radiologists and technologists. Small groups were tasked with developing tactics and iterative solutions within each theme. High priority initiatives that were implemented included providing academic time for all radiologists, substantially changing the noncompete clause, hiring reading room assistants, piloting AI tools and protocol management. Notably, implementing a minimum 10% academic time for all faculty-our top-priority prototype-resulted in 92.3% of faculty wanting to continue this initiative next year, demonstrating sustained engagement and value despite rising clinical demands.

DISCUSSION

Deep engagement among the radiologists and technologists (designing "with" and not "for") resulted in team enablement in the department. Limitations include a time-intensive process requiring sustained leadership support for the long-term success. This human-centered methodology offers a scalable blueprint for radiology departments seeking to enhance workplace satisfaction.

R5B-QI-1 UNCERTAINTY LANGUAGE IN PEDIATRIC RADIOLOGY REPORTS: A SINGLE INSTITUTION ASSESSMENT

Nadja Kadom, MD (*Presenter*)
Hanzhou Li, MD (*Abstract Co-Author*)
John T. Moon, MD (*Abstract Co-Author*)
Atul B. Shinagare, MD (*Abstract Co-Author*)
Adam Goldman-Yassen, MD, MS (*Abstract Co-Author*)
Neil U. Lall, MD (*Abstract Co-Author*)
Ling Yang (*Abstract Co-Author*)
Yinghua Yang (*Abstract Co-Author*)

INTRODUCTION

Radiologists use a variety of terms to express uncertainty, which can exacerbate ambiguity in imaging reports and contribute to delayed or inaccurate diagnoses. As it has been shown by adult radiologists, it is feasible to limit report vocabulary to a fixed set of expressions that are linked to distinct levels of diagnostic uncertainty. As an initial step towards standardizing report language in our pediatric practice, we evaluated whether pediatric radiologists also use a wide variety of uncertainty terms, how different stakeholders (radiologists, providers, and patients) interpret the expressed certainty levels, and whether language standardization should be pursued.

METHODS

We analyzed a random sample of 10,000 reports extracted from a data set of 309,751 reports between October 1, 2023 to September 30, 2024. We included only phrases used in the report impression; we excluded phrases that occurred only once in the data set, those suggesting further action, consisting of one-word modifiers, serving as descriptive words, providing explanations for findings, or indicating clinical significance. We created a survey containing the top 15 phrases from our dataset and one phrase from a previous publication. We asked stakeholders to rate each phrase per percentage level of certainty that is expressed, using a 5-point Likert scale : (1) >90% (Very high likelihood), (2) 75-90% (High likelihood), (3) 25-74% (Intermediate likelihood), (4) 5-24% (Low likelihood), and (5) < 5% (Very low likelihood). We also asked whether radiologists should use standardized language to express levels of certainty.

RESULTS

We received 17 responses from radiologists, 57 from patients, and 56 from clinical providers. Radiologists' perceptions of levels of certainty for each term were generally more aligned with each other, while patients had the most divergent perceptions. In addition, radiologists and clinical providers had similar ratings for most terms, while patients differed substantially. Radiologists were least likely to indicate that they should use a standardized way for expressing their uncertainty, while clinicians were most likely to affirm this statement.

DISCUSSION

While radiologists agree more on the meaning of specific uncertainty phrases, they seem to have less insight into the effects of using a variety of phrases for expressing uncertainty on clinical providers and patients. We will use the data to present the issue to our radiology group and pose a suggestion of adopting an existing uncertainty scale that restricts radiologists to the use of five distinct terms that represent each percentage range of certainty.

R5B-QI-2 ARTIFICIAL INTELLIGENCE USE CASE: UPSCALING NOVICE READERS IN BREAST CANCER DETECTION IN GUYANA

Annastaceya Dhaniram, MD (*Presenter*)
Kathryn W. Zamora, MD, MPH (*Abstract Co-Author*)
Sara F. Robinson, RT (*Abstract Co-Author*)
Iliana Persaud, MD (*Abstract Co-Author*)
Corey Thompson, MD (*Abstract Co-Author*)
Samantha Singh, MBBS, MMEd (*Abstract Co-Author*)
Allison Borowski, MD (*Abstract Co-Author*)
Jamie T. Surratt, MD (*Abstract Co-Author*)
Mai A. Elezaby, MD (*Abstract Co-Author*)
Erica B. Pollack, MD (*Abstract Co-Author*)

INTRODUCTION

Global disparity in breast cancer mortality exists due to significant shortage of trained healthcare providers in low-resource areas. In Guyana, where the first radiology residency program in the country was implemented in 2019, mammogram reporting relies on preliminary interpretation by residents or novice staff radiologists supervised by volunteer remote expert breast radiologists. Artificial Intelligence (AI) applications may have the potential to improve the accuracy of novice mammogram interpretation and aid in radiologists' training towards proficiency. The purpose of this project was to determine if an AI algorithm can improve the diagnostic accuracy of preliminary screening mammography interpretation by novice readers as demonstrated by increased accordance to the final expert interpretation.

METHODS

This is a HIPPA compliant, IRB approved retrospective review of 2D full-field digital screening mammograms (FFDM) with preliminary interpretation by a novice reader and final interpretation by an expert reader. A commercially available AI algorithm retrospectively analyzed mammograms that met the inclusion criteria between January 2022 and August 2024. The AI algorithm assigns mammography exams low (0%-19%), intermediate (20%-69%), and high (70%-100%) confidence of malignancy case scores. The agreement of the BI-RADS assessment ("recall" [BI-RADS 0] vs "no recall" [BI-RADS 1,2]) of the preliminary novice's report and that of the final expert's report was calculated and compared to the agreement of the AI case score to the novice's preliminary interpretation. For the purpose of this study, the final interpretation by the expert radiologist was considered ground truth; a "no recall" by the novice reader that is recalled by the expert is considered a miss. The AI algorithm was interpreted such that low case scores are appropriate for no recall, while the intermediate and high risk case scores warrant recall in the appropriate setting.

RESULTS

A total of 264 mammograms of females with median age 53 are included within the study. The AI algorithm assigned 78 (29.5%) a low case score, 142 (53.8%) an intermediate score, and 44 (16.7%) a high score. Nonagreement between the novice reader and expert reader was noted in 62 of 264 cases (23.5%) where no recall was made by the novices' preliminary interpretation yet recalled by the expert and thus considered a miss. Of the missed cases, 58% (36/62) were characterized as intermediate or high case scores by AI.

DISCUSSION

Upfront application of a commercially available AI algorithm for 2D FFDM could have improved inter-reader agreement and averted a miss by the novice reader in 58% of the missed cases. This study highlights the use case for AI algorithms in the upscaling of quality of novice radiologists' interpretation in low-resource global outreach settings with potential significant improvements in patient outcomes.

R5B-QI-3 LARGE LANGUAGE MODEL - BASED AUTOMATED MONITORING OF AI-ASSISTED BONE AGE ESTIMATION IN A PEDIATRIC RADIOLOGY WORKFLOW

Pooja Pathak (*Presenter*)

INTRODUCTION

Integrating AI tools in clinical imaging workflows has created a pressing need for scalable performance monitoring methods. Effective monitoring should encompass usage metrics, performance evaluation, and cost-effectiveness analysis. However, most clinical environments lack standardized frameworks for assessing AI applications, resulting in inconsistent or absent monitoring practices. This project aimed to develop and deploy a large language model (LLM)-based framework for automated monitoring of medical imaging AI systems. We selected AI-assisted bone age estimation in pediatric radiology as a representative use case due to its clinical adoption.

METHODS

In clinical workflow, hand radiographs were transmitted to a cloud inference engine utilizing a convolutional neural network to estimate bone age (Larson et al., Radiology, 2018). The AI estimate was inserted into a draft radiology report. Radiologists could accept it or input their own estimate using the Greulich and Pyle bone age atlas before final signature. We built an automated framework to extract final reports and corresponding AI bone age estimates from the clinical reporting system. For each case, we retrieved timestamps for exam completion, draft report creation, and final report signature. Using Gemma-3 12B, we extracted the radiologist's final estimate and compared to the AI value to assess agreement. Metrics: 1. Report generation time: Time from draft creation to final signature. 2. Frequency of Disagreement: % of cases where the AI and radiologist bone age estimates differed. 3. Degree of Disagreement: Absolute difference (in months) between AI and radiologist estimates.

RESULTS

4465 bone age studies (January 2020 - March 2025) were retrospectively analyzed. AI-assisted bone age estimation was introduced into workflow in July 2022. Following implementation, 2513 exams used the AI-assisted reporting system. Median reported bone age (in months) pre-AI was 162 (IQR: 132 -180), and 171 (IQR: 142 -186) post AI. Median chronological age (in months) pre-AI was 162 (IQR:127-181) and 165 (IQR:138-183) post-AI. Report generation time substantially decreased from 306 seconds (IQR:126-1909) pre-AI to 36 (IQR:12-187) post-AI (-88%). Disagreement frequency between AI estimate and reported age dropped from 9.9% to 5.9% to 3.6% over first three years of AI use. In disagreement cases, mean absolute difference between the AI-estimate and reported age: 25.9 (±42.4) months.

DISCUSSION

Automated, AI-based monitoring of clinical imaging AI is feasible and can provide valuable insights for quality improvement. For bone age estimation, the framework highlighted the clinical value of AI and revealed adjustment in expert behavior. This approach can generalize to other imaging applications and raises questions around automation bias and human-AI interaction that merit further study.

R5B-QI-4 FROM DETECTION TO REVENUE: EVALUATING THE ECONOMIC VALUE OF AI-GUIDED TRIAGE FOR INCIDENTAL PULMONARY EMBOLI

Ayden Jacob, MD, MSc (*Presenter*)
Kirby Quinn, MD (*Abstract Co-Author*)
Thiago A. Braga, MD (*Abstract Co-Author*)
Alexander M. McKinney IV, MD, BEng (*Abstract Co-Author*)
Jean Jose, DO (*Abstract Co-Author*)

INTRODUCTION

Artificial intelligence (AI) tools are increasingly integrated into radiologic workflows, offering potential gains in efficiency and diagnostic accuracy. However, the economic return on investment (ROI) for AI implementation, particularly in outpatient settings, remains underexplored. This study assesses the financial and clinical impact of an AI-enabled triage pathway for incidental pulmonary emboli (iPE) detected on routine CT imaging, with an emphasis on downstream revenue and time-to-treatment improvements.

METHODS

From July 2023 to March 2024, 11,700 outpatient CT scans were analyzed using a validated AI algorithm for iPE detection. All AI-positive findings were confirmed by board-certified radiologists. Confirmed cases were prospectively followed for downstream clinical outcomes, including emergency department (ED) transfers, inpatient (IP) admissions, anticoagulation therapy initiation, and advanced interventions. Revenue projections were based on national average reimbursement values: $2,350 per ED visit, $8,700 per IP admission, and $950 per year for anticoagulation therapy. Nine months of outcome data were annualized. Median turnaround times for AI-flagged versus unflagged iPEs were compared.

RESULTS

Annualized projections identified 107 confirmed iPE cases. Of these, 29% (31/107) were referred to the ED. Among ED cases, 22% (7/31) were treated and discharged, generating $16,043 in revenue; 78% (24/31) were admitted, yielding $183,946. Among admitted patients, 83% (20/24) were initiated on anticoagulation therapy, accounting for $19,084 in annual pharmaceutical revenue. One patient underwent mechanical thrombectomy, and the Pulmonary Embolism Response Team (PERT) was activated in four cases. Median turnaround time for AI-flagged iPEs was 66.4 minutes (IQR: 526.3) versus 383.6 minutes (IQR: 1502.3) for non-flagged cases ($p < 0.05$), reflecting an 82.7% (317.2-minute) reduction for AI cases. Total projected annual downstream revenue was $219,073.

DISCUSSION

The integration of AI into outpatient imaging pathways enables timely detection and management of incidental pulmonary emboli, translating to measurable financial and clinical benefits. Revenue gains were driven by appropriate escalation to emergency and inpatient care and the timely initiation of therapy. These findings reinforce the dual value—economic and clinical—of incorporating AI into radiology workflows. Importantly, enhancing patient outcomes remains a central driver for the continued evaluation and adoption of AI in radiologic practice.

R5B-QI-5 DEVELOPING QUALITY METRICS IN RADIOLOGY

Narjes Jaafar-Snee, MD, BS (*Presenter*)
Jay K. Pahade, MD (*Abstract Co-Author*)
Nadja Kadom, MD (*Abstract Co-Author*)
Hanna M. Zafar, MD, MS (*Abstract Co-Author*)
Bettina Siewert, MD (*Abstract Co-Author*)

INTRODUCTION

The use of metrics in driving quality improvement and patient safety in radiology has long been established. The American College of Radiology and The Joint Commission (TJC) have developed several metrics towards patient safety and improving radiology services. Nonetheless, many radiology practices use a narrow set of measures and there seems to be a gap in radiology practices' ability to scale quality and safety measurement efforts. To better define current and desired future state for quality metrics in Radiology we sought input from practice leaders interested in radiology quality and safety.

METHODS

This qualitative information was gathered during two sessions dedicated to radiology metrics at the ACR Quality and Safety meeting (2022) and RSNA (2024). The two occasions featured interactive breakout sessions discussing both current and desired quality metrics using open ended questios. Attendees and participants included hospital administrators, radiologists, and technologists, and were asked to list the metrics they were tracking- categorized as "frequently tracked" or "currently tracked" and metrics they would prefer to use but were currently not using- categorized as "aspirational."

RESULTS

Key findings showed that radiology departments are currently prioritizing quantitative metrics including turn-around-time (hours), number of contrast reactions, and frequency of adverse events over outcomes or value-based metrics. Other commonly tracked metrics currently include patient access, complication rates for select procedures, protocol adherence and patients' immediate feedback. Recurrent themes for aspirational metrics included standardized patient satisfaction scores, patient recall rates secondary to poor inadequate image quality, incidental findings follow up, test appropriateness, diagnostic accuracy (including rad-path correlation), provider wellness and burnout, adherence to practice guidelines, and peer learning/review participation.

DISCUSSION

We found there is a substantial interest among radiologists and radiology staff in integrating "aspirational" metrics into practice, including patient centered-feedback, workflow and process efficiency, adherence to practice guidelines, impact on patient care and outcomes. Despite reported interest and value, most practices had yet to adopt any of the aspiration metrics highlighting significant barriers currently such as data availability, workflow integration challenges, and lack of standardized benchmarks or prioritized quality initiatives. Understanding these barriers is critical to inform next steps, which may include targeted resource allocation, infrastructure support for data collection, and stakeholder engagement to drive meaningful adoption of higher-level quality metrics.

R5B-QI-6 CLINICAL EVALUATION OF CONSENSUS-BASED MRI GUIDELINES FOR DIAGNOSING PLACENTA ACCRETA SPECTRUM DISORDERS

Cynthia Funso-Fayomi, MBBS, FRCR (*Presenter*)
Anum Pervez, BSc, FRCR, MBBS (*Abstract Co-Author*)
Stephan Edey, MBBS, FRCR (*Abstract Co-Author*)
Sarah Natas, BSc, FRCR (*Abstract Co-Author*)
Sultana Hasso, MBBS (*Abstract Co-Author*)
Olwen A. Westerland, MBBS (*Abstract Co-Author*)
Audrey E. Jacques, MBBS, FRCR (*Abstract Co-Author*)

INTRODUCTION

Incidence of placenta accreta dyndrome (PAS) is increasing, partly due to the rising numbers of caesarean sections. We aimed to assess the diagnostic utility of MRI features recommended by the SAR-ESUR expert consensus, as published in the 2023 RSNA guidelines, for identifying imaging characteristics of placenta accreta spectrum (PAS) disorders.

METHODS

This retrospective study reviewed MRI scans from patients evaluated for suspected PAS between 2015 and 2025, all of whom had surgically and histologically confirmed diagnoses. MRI findings assessed included the presence of dark T2-weighted intraplacental bands, uterine contour abnormalities, myometrial thinning, bladder wall disruption, focal masses extending beyond the uterus, increased vascularity at the placental bed, and absence of the normal retroplacental T2 hypointense zone—criteria aligned with the recent RSNA-endorsed guidelines. Imaging data were reviewed at a tertiary care centre, and frequencies of these diagnostic features were correlated with operative and pathological outcomes.

RESULTS

33 patients underwent MRI prior to surgical intervention for confirmed PAS. Pre-operative MRI studies were re-analysed using the SAR-ESUR consensus criteria. All patient MRIs demonstrated dark intraplacental T2-weighted bands (100%) aligning closely with the consensus emphasis on this marker. Other imaging findings with decreasing levels of frequency included increased and bizarre placental and subplacental vascularisation (86%) and uterine bulging (72%). Heterogenous placental signal on T2-weighted imaging was frequently seen in the context of multiple dark intraplacental bands and although difficult to quantify and while not included in the recent consensus statement appears to be a useful predictive feature for PAS.

DISCUSSION

In our analysis of confirmed PAS cases, pre-operative MRI findings showed a strong alignment with the descriptors defined in the 2023 SAR-ESUR consensus. These findings support integrating the proposed framework into future imaging protocols, where its standardized approach may improve diagnostic accuracy and support coordinated multidisciplinary careIn our analysis of confirmed PAS cases, pre-operative MRI findings showed a strong alignment with the descriptors defined in the 2023 SAR-ESUR consensus. These findings support integrating the proposed framework into future imaging protocols, where its standardized approach may improve diagnostic accuracy and support coordinated multidisciplinary care.

R5B-QI-7 TELERADIOLOGY: A BOON FOR PREGNANT AND POSTPARTUM RADIOLOGISTS: A MIXED METHODS STUDY ON CAREER CONTINUITY, FLEXIBILITY AND WELL BEING

Jainam A. Doshi, MBBS, MD (*Presenter*)
Natisha P. Arora JR, MD (*Abstract Co-Author*)
Venkatesh Somu JR, MD (*Abstract Co-Author*)

INTRODUCTION

Radiology, though intellectually rewarding, presents significant challenges for women during pregnancy and early motherhood due to rigid work hours, physically demanding on-site shifts, and lack of flexible scheduling. These factors often contribute to burnout, career breaks, or attrition among female radiologists. The rise of teleradiology has opened new avenues for remote clinical reporting, potentially addressing these limitations. This study explores the role of teleradiology in supporting career continuity, flexibility, and well-being in pregnant and postpartum radiologists

METHODS

This mixed methods study combined quantitative and qualitative approaches. A structured online survey was disseminated to radiologists who experienced pregnancy or postpartum in the past five years and engaged in teleradiology during that phase. Quantitative data from 80 respondents focused on work hours, reporting output, mental health, and perceived career satisfaction. Additionally, 15 participants underwent semi-structured interviews to explore deeper emotional and professional experiences. Quantitative data were analyzed using descriptive statistics and Pearson correlations. Thematic analysis was used for qualitative transcripts.

RESULTS

Among 80 respondents, 86% reported improved work-life balance due to teleradiology, 78% were able to continue clinical work without interruption, and 95% cited elimination of commute as a major benefit. Flexible scheduling (92%), ability to breastfeed/rest (71%), and reduced physical strain (64%) were key advantages.

However, 47% indicated that inconsistent case flow and lack of institutional support were drawbacks.Qualitative analysis revealed three major themes: (1) Preservation of professional identity, (2) Emotional resilience through autonomy, and (3) Perceived isolation in the absence of team interactions. Despite some challenges, most participants highlighted a strong sense of empowerment and career satisfaction due to the flexibility offered by teleradiology.

DISCUSSION

Teleradiology has emerged as a vital support system for radiologist mothers, enabling continuity of clinical practice during traditionally challenging career phases. This study emphasizes its role in reducing attrition, preserving mental well-being, and supporting gender diversity in the workforce. While challenges remain—such as the need for better institutional frameworks and scheduling support—the positive impact on retention and well-being is compelling. These findings support broader adoption of teleradiology as a gender-inclusive strategy in modern radiology departments.

R5B-QI-8 BRIDGING THE GAP: ENHANCING ACADEMIC CAREER PATHS THROUGH RSNA'S RADIOLOGY IN TRAINING INITIATIVE

Alessia Guarnera, MD (*Presenter*)
Enis Yilmaz, MD (*Abstract Co-Author*)
Cristina Marrocchio, MD (*Abstract Co-Author*)
Joice C. Prodigios, MD (*Abstract Co-Author*)
Linda Moy, MD (*Abstract Co-Author*)
Victoria Chernyak, MD, MS (*Abstract Co-Author*)

INTRODUCTION

The future scientific advancements in radiology rely on a new generation of physicians to pursue an academic career and publish high-quality research. To sustain scientific growth, the following gaps must be addressed: a) the growing need for skilled reviewers and editors; and b) the challenges trainees face in following an academic path, gaining experience in peer-reviewing and serving as editors. RSNA Radiology in Training (RIT) program provides editorial, reviewing, learning, and networking opportunities for radiology, nuclear medicine, and medical physics residents and fellows across the world. The members of the RIT editorial board work with assigned mentors to complete 5 mentored reviews, after which they review independently. RIT members attend monthly didactic lectures, join Radiology editorial meetings and promote Radiology publications on social media. Our study aims to assess the effectiveness of the RIT program.

METHODS

The key data related to the RIT program structure, requested qualifications, application process and requirements, duties and responsibilities, and related opportunities were extracted from the RSNA Trainee Editorial Boards webpage (https://www.rsna.org/education/trainee-resources/trainee-editorial-boards). The data for all RIT board members from 7/2020-1/2025 was extracted from the Radiology reviewer database. The numbers of total reviews and independent reviews were tabulated. The long-term retention rates, defined as providing at least one Radiology review within the last 12 months of the assessment period, were tabulated for each annual cohort of RIT board members. The quality of reviews (R score; 1=best, 5=worst) provided by the RIT members was compared to those of the general Radiology reviewer pool (n=1,500) for the same period using the Wilcoxon test.

RESULTS

Data related to the RIT program were tabulated to present the program structure, duties, and opportunities (Table 1) . In the considered period, the RIT program included 65 members, of whom 47 had completed the first mandatory year. The RIT members provided 984 peer reviews, of which 731 (74,3%) were performed independently. The retention rates for cohorts of 2020, 2021, 2022 and 2023 were 67% (10/15), 67% (8/12), 91% (10/11) and 100% (9/9), respectively (Figure 1) . The median R scores were 1.08 (IQR, 1.0-1.25) for RIT board members and 1.17 (IQR 1.0-1.5) for the general reviewer pool ($p<0.005$) (Figure 2) .

DISCUSSION

The Radiology RIT program is shown to be effective in training high-quality peer-reviewers with high long-term retention rates. Presentation of the RIT program and its related activities will increase awareness of the opportunity and encourage trainees to apply. The RIT program is a valuable opportunity for shaping the next generation of peer-reviewers and editors, with the common goal of expanding medical knowledge and improving patient care.

S3A-QI-1 IMPACT OF EHR BASED OPAS ON TIMELY COMPLETION RATES FOR ACTIONABLE FINDINGS

Erin Panter, ARRT, BS (*Presenter*)
Calista Kee (*Abstract Co-Author*)
Anand Bhatia, MD, MBA (*Abstract Co-Author*)
Mary Jo Evans (*Abstract Co-Author*)
Ben C. Wandtke, MD, MS (*Abstract Co-Author*)

INTRODUCTION

Missed or inadequately addressed clinical follow-up recommendations are a considerable risk to patient safety, especially in academic medical centers with high patient volumes and complex workflows. Timely completion of radiology recommendation follow-up for incidental findings is inconsistent, placing patients at risk for delayed diagnosis. Clinical advisories in electronic health records (EHR) improve adherence to evidence-based practices. AI and natural language processing can transform clinical decision support into a patient-centered tool by generating personalized imaging recommendations and streamline care in the EHR (1) . However, in the absence of standardized systems, alerts from automated tools risk being overlooked, indefinitely deferred, or lost within provider dashboards. We implemented a structured, multidisciplinary workflow for OurPractice Advisories (OPAs) to ensure timely follow-up of clinical recommendations, defined as 30 days before or within 60 days after the recommended due date.

METHODS

In collaboration with the American College of Radiology Learning Network, we performed root cause analysis and held weekly meetings. The results showed that that showed many providers missed or were unaware of OPA alerts. Primary care (PC) leadership addressed this at monthly meetings. Interventions were refined using value stream mapping and Plan-Do-Study-Act cycles. The OPA system generates advisories; providers can act, defer for triage, or dismiss it with justification. A multidisciplinary team routed deferred cases for scheduling, reassignment, or escalation. Our SMART goal was to increase the timely follow-up from 61% to 70% by December 2024

RESULTS

Following OPA integration into PC workflows, completion rates rose from 61% to a sustained 70%, and weekly variability declined. From July 2024 to March 2025, weekly orders spiked after targeted outreach (e.g., direct emails and PC open house). Orders placed directly from the OPA stayed above 10/week post-intervention, reflecting greater provider engagement. Overdue recommendations with placed orders increased from 10% to 18%. To capitalize on this, we utilized program navigators to directly call patients to schedule imaging exams. Gains correlated with EHR updates and educational outreach. Personal engagement and leadership support enabled system integration into everyday practice.

DISCUSSION

This scalable, team-based workflow enhanced timely follow-up without overburdening providers. Embedded in the EHR, it is sustained by audits, defined roles, and dashboards. By achieving 70% timely follow-up, we now complete ~1,300 new imaging exams annually, bringing in $400,000 in revenue. Activating an OPA enhanced an existing system with a low-cost, reliable, automated tool providing lasting benefits. It offers an efficient, replicable model for follow-up and care continuity

S3A-QI-2 DECREASING WAIT TIME BETWEEN ABNORMAL SCREENING MAMMOGRAM AND DIAGNOSTIC BREAST IMAGING APPOINTMENT

Sarah B. Thomas, DO (*Presenter*)
Bethany U. Casagranda, DO (*Abstract Co-Author*)
Adam Fang, MD, MBA (*Abstract Co-Author*)

INTRODUCTION

Prolonged wait times for diagnostic breast imaging following abnormal mammogram results are a recognized problem, leading to patient anxiety, delayed diagnoses, and missed opportunities for early intervention, negatively affecting patient well-being and the healthcare system's reputation. This study directly addresses this issue by aiming to decrease these wait times.

METHODS

The project was initiated in response to patient dissatisfaction and concerns raised in multidisciplinary conferences regarding excessive wait times between screening mammograms and diagnostic appointments. To begin this project, a workgroup of leaders throughout the organization and specifically within the Imaging Institute was established. Data collection spanned from July 2023 to October 2024, focusing on five key sites. The average wait time (AWT) was calculated, and several metrics were tracked to identify contributing factors. These included monthly diagnostic imaging volume (collected from EPIC), available diagnostic mammogram slots (tracked via Tableau Dashboard), radiologist doctor days (gathered from Qgenda), and overall capacity (calculated from the Tableau Dashboard). Imaging leadership collaboratively documented impactful events, and technologist/radiologist productivity and patient return rates were analyzed.

RESULTS

Compiled data revealed trends in AWT, imaging volumes, slots, and capacity, with significant events highlighted. Over 16 months, AWT decreased from 26 days to 9 days as volume continued to increase. Changes in scheduling templates and dedicated technologist workflows improved diagnostic imaging volumes as well as patient return rates from 79% to 94% without influencing Radiologist days on site. The project successfully reduced the AWT below both the internal target of 18 days and the national benchmark of 15 days. This led to a $2.78 million annualized revenue increase, driven by higher imaging volumes and downstream revenue from positive biopsies. Surveys indicated positive feedback from staff regarding improved patient access, workflows, and satisfaction.

DISCUSSION

This project successfully reduced diagnostic imaging wait times, improving patient and clinician experiences, increasing revenue and patient retention. These outcomes are deemed beneficial for all stakeholders. Plans are in place to address end-user feedback, implement adjustments, and expand successful strategies to additional sites.

S3A-QI-3 IMPROVING THE QUALITY OF FOLLOW-UP RECOMMENDATIONS FOR INCIDENTAL PULMONARY NODULES

Vivek Batra, MD (*Presenter*)
Miriam Du Plessis, MD (*Abstract Co-Author*)
Erin Panter, ARRT, BS (*Abstract Co-Author*)
Mary Jo Evans (*Abstract Co-Author*)
Elizabeth K. Proffitt, MD (*Abstract Co-Author*)
Ben C. Wandtke, MD, MS (*Abstract Co-Author*)

INTRODUCTION

Incidental pulmonary nodules are detected in approximately 10% of CT imaging reports. Early cancer detection improves significantly when such findings are accompanied by timely, actionable recommendations. However, adherence to follow-up guidelines is often inadequate due to inconsistent recommendations. This quality improvement initiative aimed to increase early cancer detection by ensuring that all incidental lung nodules received appropriate, actionable, and evidence-based follow-up recommendations.

METHODS

This study was conducted in collaboration with the American College of Radiology Learning Network® at a tertiary care center performing about one million imaging studies annually. The multidisciplinary team included attending and resident radiologists, advanced practice providers, imaging informatics specialists, navigators, and population health administrators.A baseline audit of 356 CT reports over 11 weeks from November 2023 to January 2024 was performed to evaluate the appropriateness and actionability of recommendations. Recommendation appropriateness was defined as using a specific follow-up timeline that aligned with Fleischner Guidelines. Inclusion criteria comprised patients over 35 years old with one or more pulmonary nodules =6 mm, indeterminate cancer risk, no history of malignancy with known or suspected lung metastasis and not undergoing treatment for active lung cancer. Twenty CT exams meeting inclusion criteria were manually audited weekly from November 2023 to December 2024. Reasons for inadequate recommendations were categorized and analyzed for key drivers to guide intervention implementation. Division and individual-level data were shared quarterly for feedback. Our SMART goal was to improve the appropriate IPN recommendation rate from 60% to 80% within 9 months.

RESULTS

At baseline, 60% of our radiologist recommendations adhered to Fleischner guidelines. The most common deficiencies were lack of any recommendation, no follow-up timing, and deviation from guideline criteria. Root cause analysis identified the absence of standardized macros, minimal guideline training, and inconsistent application expectations as major contributing factors.A custom macro was embedded in radiology reporting platform to standardize recommendation formatting. Subsequently, the rate of appropriate recommendations rose to 75% by April 2024.

DISCUSSION

This initiative demonstrates that standardizing radiology reports through embedded macros and consistent feedback can significantly improve the rate of actionable and appropriate follow-up recommendations for incidental pulmonary nodules. Sustained efforts, including ongoing feedback and maintenance of the standardized macro, are necessary to preserve gains. A limitation of the study was unequal division sampling due to the randomized audit process.

S3A-QI-4 NOT SO FAST - IMPLEMENTATION OF A PULMONARY EMBOLISM SCREENING AI ALGORITHM DOES NOT IMPROVE PROVIDER NOTIFICATION TIMES

Genevieve Munoz, MD (*Presenter*)
Abhinav Suri, BA, MPH (*Abstract Co-Author*)
Cole J. Miller, MD, BS (*Abstract Co-Author*)
Anokh Pahwa, MD (*Abstract Co-Author*)

INTRODUCTION

Pulmonary embolism (PE) is a critical finding that warrants rapid notification of primary teams. However, prioritization of scans likely to contain PEs typically requires a radiologist to triage scans. Artificial Intelligence (AI) algorithms offer the opportunity to automate detection of PE on CT scans to re-prioritize likely positive scans to the top of a worklist. We sought to determine whether the implementation of an AI-based PE screening algorithm at our institution (a large academic center with multiple patient centers) meaningfully reduced the time to first provider contact for PE-positive exams.

METHODS

To evaluate whether the AI algorithm significantly reduced provider contact times (PCTs) at our institution, we gathered all CT angiograms of the chest performed 3 months before and 3 months after the implementation of the AI-based screening algorithm. For each exam, the true presence or absence of a PE and the provider contact time were extracted from the report of the board certified radiologist. The AI's PE classification was gathered for scans done after its integration. The PCT was calculated as the difference between the provider contact time and the completion of exam. However, for exams that did not require contacting of a primary team, such as for chronic, questionable, or very small PEs, PCTs could not be calculated and these exams were excluded. We analyzed the PCT before vs after the AI implementation in all settings, inpatient/ED settings only, outpatient settings only, and for scans done during a night shift. To account for learning curves/technical issues near the launch period, we also repeated the analyses excluding a 1 month period after the AI launch. Results from these analyses would inform our institution's training for usage of this AI algorithm.

RESULTS

The AI algorithm was launched on July 8, 2024. During the evaluation period, there were a total of 6439 scans of which 206 were positive. There was no statistically significant change in overall scan volume this period. After deployment, the AI found 150/197 PEs (76% sensitivity) and correctly diagnosed all negative scans. Across all analyses, AI did not lead to any statistically significant decreases in PCT (overall reduction in time of 0.42 hours [95%CI: -0.51-1.35 hours]).

DISCUSSION

Our results show that a PE detection algorithm has not led to a quicker provider contact time across different patient care settings. While literature shows that read times may be reduced by AI, our work shows that these reductions may not translate into clinically meaningful notification times. However, our study has numerous limitations including a lack of qualitative feedback to assess if there are any systemic barriers that may minimize efficacy of this algorithm. Future studies will be geared towards this purpose and determining if additional training interventions can provide a benefit to PCTs.

S3A-QI-5 DECREASING UNNECESSARY RENAL US FOR AKI

Shannon Pye, BS, RDMS (*Presenter*)

INTRODUCTION

Literature estimates that approximately 25% of imaging performed is of low value. An area of frequent waste is performance of renal ultrasound (US) in all patients presenting with acute kidney injury (AKI). In patients with no risk factors for upper tract obstruction, prior data has shown the exam to be of low value and rarely positive for clinically significant obstruction. This quality improvement project aimed to decrease emergency (ED) and inpatient renal ultrasounds by 30% within one month of launching a novel renal US order panel within our electronic health record (EHR).

METHODS

Our quality team, along with abdominal radiologists, care signature team, and nephrology, created consensus on renal US indications for patients and corresponding appropriate orders. At baseline, there was no clinical guidance at order entry. In our initial PDSA cycle, we redesigned our ordering process and created an order panel with all renal US orders consolidated into a single interface which allows providers to select the clinical indication for the exam (Fig 1). The panel provides guidance on when to order the test and links the provider to the correct orders. When providers choose AKI as the indication, the panel displays guidance highlighting the low value of renal US for AKI and ties in specific logic alerting the provider if the patient has had imaging within the past seven days likely excluding hydronephrosis (hydro). Number of renal US performed per month was tracked. A chart review for hydro risk factors was done for renal US exams ordered to investigate AKI before and after intervention.

RESULTS

At baseline, 7% (16/235) of exams were positive for hydro. Of these 31% (n=5) had no risk factors for renal obstruction, with all cases caused by bladder retention (should be diagnosed by bedside US). A high proportion (80% (186/235)) of exams were done in patients who either had no risk factors for obstruction or had recent imaging already excluding hydro. Risk factors for hydro were present in 29% (67/235) of patients at baseline. After implementation, there was a 22% mean reduction in number of renal US exams ordered. (Fig 2). For renal US ordered to assess AKI, the percentage of patients with risk factors for obstruction improved to 45% (55% relative improvement from baseline of 29%). The project is estimated to result in 102 fewer renal US exams performed/month with estimated sonographer time savings of 612 hours annually.

DISCUSSION

Initial deployment of a novel renal US ordering panel resulted in approximately 22% fewer renal US orders/month with estimated time savings of 612 hours annually for US technologists. While the initial results have made a substantial difference, additional PDSA cycles are planned to refine the panel to further deter providers from obtaining routine renal US for AKI in patients without risk factors or who have had recent imaging excluding hydro.

S3A-QI-6 REDUCING IR BIOHAZARDOUS WASTE COSTS AND ENVIRONMENTAL IMPACT: A STAFF-CENTERED QUALITY IMPROVEMENT PROJECT

Isa Abdul Cader, MD (*Presenter*)
Anton A. Mlikotic, MD (*Abstract Co-Author*)

INTRODUCTION

Radiology departments are among top contributors to medical waste, and generate significant amounts of red bag waste (RBW). RBW items require additional processing which amplify the environmental and financial impacts. Unfortunately, staff frequently place non-biohazardous waste into RBW bins. The purpose of this study was to evaluate RBW sorting practices in interventional radiology (IR) and develop a staff-centered quality improvement intervention to improve RBW sorting that can be replicated in other systems.

METHODS

We used the Plan Do Study Act method, which was conducted in an academic, safety-net hospital with high-volume IR. Baseline measurements included: 1) A 1-day pre-intervention RBW audit measuring item weight and evaluating waste policies, 2) Staff surveys of RBW knowledge, and 3) Walkthroughs with key stakeholders (nurse manager, IR techs, environmental services [EVS], infection prevention and control). At baseline 88.1% by weight of the 11.7kg of RBW collected in our initial audit was improperly sorted. In our survey, 11/18 (61%) of staff responded that non-infectious bodily fluids are RBW, indicating a significant knowledge deficit. During our walkthroughs we found that waste bin sizes impeded proper sorting: Only 28 gallon RBW bins were in the IR suites without similar general waste bins. Our intervention included in-services to educate staff on RBW sorting and participation in environment of care rounds for feedback and education. We were able to change the IR waste bins to 28-gallon general bins and 8-gallon RBW bins. Our outcome measures were daily IR RBW weights for >2 weeks after each intervention. We also conducted a post-intervention RBW audit using the same methods as our pre-intervention.

RESULTS

Median RBW pre-intervention was 3.62lb/procedure. Following the in-services, median RBW decreased to 2.58lb/procedure, then 1.83lb/procedure ($p<0.05$ vs baseline) after waste bins were changed (Figure 1). EVS reported no overcorrection. In our post-intervention RBW audit, 18.75% by weight was inappropriately sorted. Excess carbon dioxide equivalents (CO2e) and costs from improper RBW sorting declined from the pre-intervention audit ? post-intervention audit: 7.51kg CO2e/day ? 0.13kg CO2e/day and $4.16/day ? $0.28/day.

DISCUSSION

Extrapolated over a year, our approach would reduce IR-derived CO2e by an amount equal to 4734 miles driven and save $977. Limitations of our study include the relatively short periods of monitoring and the need to develop training for new department staff. Future directions include ongoing follow-up to evaluate the temporal sustainability. Our findings demonstrate that even low-resourced safety-net hospitals with high patient volumes, stakeholder-centered RBW sustainability projects can save money, increase staff engagement, and reduce IR's environmental impact.

S3A-QI-7 SAFE-IV: SAFETY AGAINST LARGE VOLUME EXTRAVASATIONS IN CT IMAGING

Cathy Hannafin, MBA, BSN (*Presenter*)
Lisa Ponce, RT (*Abstract Co-Author*)
Tiffany Audsley (*Abstract Co-Author*)
Kathy Larson (*Abstract Co-Author*)
Eric Fiacconi (*Abstract Co-Author*)
Russ Dejong (*Abstract Co-Author*)
Bryan Poole (*Abstract Co-Author*)

INTRODUCTION

Large volume computed tomography (CT) intravenous (IV) contrast extravasation (CEV) is a significant patient safety risk in radiology. Large volume CT CEVs are those exceeding 50 milliliters of iodinated contrast leaking out of the vein into surrounding tissues. CEVs can result in pain, additional IVs, or repeat scans, ultimately leading to harm, delays, and reduced satisfaction. The aim of this project was to decrease the rate of large volume CT CEVs by 42% from a rate of 1.13 per 1000 contrast CT exams to 0.65 by 08/31/2023.

METHODS

An interdisciplinary team, including emergency department (ED) and radiology registered nurses (RNs), vascular access RNs (VANS), and CT technologists, used the Six Sigma DMAIC (define, measure, improve, analyze and control) quality improvement method. The team conducted a Gemba Walk, observing CT contrast workflows. A database of CEVs was created to track variables such as IV location and type. The baseline improvement measure was 1.13 large volume CT CEVs per 1000 contrast CT exams. CT CEVs were reported through the radiology safety incident reporting system. The sample size was 42,323 contrast CT exams between December 1, 2021 to December 31, 2022. After brainstorming potential causes, the team identified key causes being variation in US-guided IV placement process, lack of standardized IV supplies, and incomplete documentation. Interventions were tested and implemented. The VANS team held educational sessions for radiology and ED RNs on evidence-based US-guided IV practices, including using catheters at least 1 3/4 inches long when appropriate, avoiding veins greater than one centimeter deep, visualizing catheter placement, and documenting. The PDSA (Plan-Do-Study-Act) method was used to pilot the interventions. Subsequent PDSA cycles ensured optimal IV supplies and standardized US-guided IV placement training. The effectiveness of the interventions was monitored using run charts. To ensure sustained success, monthly run charts are updated and shared with key interdisciplinary project team members. VANS leadership further integrated these evidence-based practices into annual education.

RESULTS

There was a decrease in the rate of large volume US-guided CT CEVs from 0.57 to 0.18 per 1000 contrast CT exams, helping achieve the aim of reducing all large volume CEVs by 42%. The total post-intervention improvement sample size was 22966 contrast CT exams, between March 1, 2023 and August 31, 2023.

DISCUSSION

There has been a sustained reduction in large volume CT CEVs. Important lessons learned were that observing the process in real-time helped team members gain mutual understanding of each other's work and fostered psychological safety, having subject matter experts aided in identifying best practices, and organizing data was valuable for identifying trends.

S3A-QI-8 OPTIMIZING RADIATION DOSE: UW-MADISON'S EXPERIENCE WITH THE ACR LEARNING NETWORK IMPOWER PROGRAM

Carrie Bartels, RT (*Presenter*)
Ran Zhang, PhD (*Abstract Co-Author*)
Rachel Bladorn, BS, RT (*Abstract Co-Author*)
Kelsey Schluter, BS (*Abstract Co-Author*)
Martin Wagner, PhD (*Abstract Co-Author*)
Giuseppe V. Toia, MD, MS (*Abstract Co-Author*)
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*)

INTRODUCTION

Automatic exposure control (AEC) is a critical component in optimizing CT radiation dose. By adjusting exposure parameters based on patient size and clinical indication, AEC systems enable the ALARA principle, ensuring diagnostic image quality while minimizing patient radiation exposure. For over a decade, our institution has tracked radiation dose relative to patient size on a single-vendor CT fleet. Recognizing the need to extend these advancements to a newly acquired vendor CT scanner, our team embarked on a comprehensive harmonization project.

METHODS

We tracked radiation dose relative to patient size using metrics like CTDIvol and water equivalent diameter (WED). We focused on a GE scanner (our historical benchmark scanner) and a new Canon Medical Systems scanner for our routine abdomen/pelvis protocol. On the Canon scanner, we observed elevated radiation dose, prompting the need for change. Supported by the American College of Radiology (ACR) Dose Optimization project (i.e., ImPower Program), we embarked on a quality project to identify and address the root causes of these discrepancies. Employing a structured, lean-based problem-solving approach (A3 thinking), we conducted Gemba walks to observe CT technologists, developed fishbone diagrams for root cause analysis, and identified key drivers influencing dose variability. We had 2 radiologists perform a reader study on 30 different patients (15 GE, 15 Canon) using Likert scoring for diagnostic utility before and after dose interventions.

RESULTS

We quantified patient dose versus size 4 times during the study, pre intervention, after the first intervention, after the second intervention, and continuing monitoring. The first intervention changed the level of deep learning-based image denoising, which decreased patient dose, the second intervention increased the AEC setting of noise which also decreased patient dose. Patient dose curves were found to decrease after the first and second interventions, no change was observed between the second intervention and continuing monitoring period.

DISCUSSION

Our study underscores the critical importance of quantifying patient radiation dose relative to size when harmonizing Automatic Exposure Control (AEC) settings across different platforms. Without plotting patient dose against size, accurately identifying and rectifying dose discrepancies between scanners would have been challenging. Even after conducting an initial physics characterization of the Canon scanner, further refinements were essential to align its performance with our existing fleet. The quality processes our team learned as part of the ACR ImPower program guided our efforts through a complex iterative process. This approach aligns with best practices in medical imaging, ensuring patient safety and diagnostic efficacy.

S3B-QI-1 THE ROLE OF PORTABLE MRI IN REDUCING TRANSPORTATION-RELATED CARBON EMISSIONS IN REMOTE COMMUNITIES IN CANADA

Nawab Azizi, BSc, MSc (*Presenter*)
Zier Zhou (*Abstract Co-Author*)
Alexander Ibrahim (*Abstract Co-Author*)
Omar S. Islam, MD, FRCPC (*Abstract Co-Author*)

INTRODUCTION

Climate change is among the most pressing global challenges of this century, significantly affecting the health of millions of Canadians and exacerbating existing health inequities. Current strategies aimed at reducing carbon emissions from diagnostic imaging services include powering down idle CT units, preventing unnecessary repeat imaging through integration of EMRs, and utilizing telemedicine for remote consultations. However, limited research exists on the role of portable diagnostic imaging technologies, such as ultra-low-field portable MRI (pMRI), and their potential impact on transportation-related carbon emissions in remote areas. The purpose of this study was to estimate the potential reduction in transportation-associated carbon emissions achievable through the implementation of pMRI in remote communities of Northern Ontario, Canada.

METHODS

This study will employ a mixed-methods approach to evaluate the reduction in CO2 emissions resulting from the implementation of portable MRI (pMRI) at Weeneebayko General Hospital (WGH) in Moose Factory, Ontario, compared to scenarios without pMRI. Based on a previous study by Desrosche et al., which indicated that if a pMRI is available locally, only 44% of patients annually would require transportation for fixed MRI scans, this analysis will specifically calculate estimated CO2 emission reductions associated with air transportation for the remaining 56% of patients who would no longer need to travel due to pMRI availability. Data on transportation energy use and corresponding CO2 emission coefficients for different travel modes will be obtained primarily from the Natural Resources Canada website. Additionally, assumptions about the typical transportation methods and the frequency of chartered or emergency flights will be incorporated into the analysis.

RESULTS

Following a literature review and analysis of data from the Weeneebayko Area Health Authority (WAHA), implementation of pMRI is projected to substantially reduce carbon emissions for surrounding communities compared to scenarios without pMRI intervention. Based on scanning 100 patients per year, specifically, by eliminating the need for air transportation for 56% of patients, the annual reduction in CO2 emissions from commercial flights would approximately reduce annual carbon emissions by 7.23 kilotonnes (kt). Savings from charter flights would amount to 4.04 kt annually, while emergent flights would yield a reduction of 3.04 kt per year. In total, implementing pMRI is projected to reduce CO2 emissions by 14.34 kt annually, which is equivalent to the emissions produced by approximately 1,868 single-family homes in one year.

DISCUSSION

Implementing portable MRI in remote communities significantly reduces air-transport related CO2 emissions and substantially improves healthcare accessibility.

S3B-QI-2 STREAMLINING OUTPATIENT PEDIATRIC MR ENTEROGRAPHY (MRE) -IDENTIFYING AND ADDRESSING THE SCHEDULING DELAYS IN PEDIATRIC OUT-PATIENT MRE

Chelsea Stoner (*Presenter*)
Swati S. Mody, MD,MBBS (*Abstract Co-Author*)
Vicki Rinz (*Abstract Co-Author*)
Chaula Kamani, ARRT,RT (*Abstract Co-Author*)
Anastasia L. Hryhorczuk, MD (*Abstract Co-Author*)
Ashok Srinivasan, MD (*Abstract Co-Author*)

INTRODUCTION

Over the past five years, our institution has experienced a 53% increase in demand for pediatric outpatient MRE studies without an equivalent rise in resources. This has led to out-patient MRE scheduling delays averaging up to 3 weeks causing delay in diagnosis and treatment of inflammatory bowel disease, increased emergency department (ED) visits and stat MRE requests through ED, and higher inpatient admissions. The purpose of this project is to reduce the average outpatient MRE wait time from 21 days to 7 days over 3 months.

METHODS

Current situation: • MRE are ordered with fistulograms increasing table time to 2 hours complicating the scheduling process due to limited availability of 2-hour slots on the MRI appointment grid. • MRE protocol calls for all MRE to be performed on 3 T magnet. Only one of the 4 magnets is 3 T causing delays. • No CPT code for fistulogram, cannot be billed. Intervention: 1. Uncouple MRE from fistulograms to decrease study time to 1 hour, thereby increasing available scheduling slots. 2. Perform MRE on both 1.5 and 3 T magnets increasing scheduling flexibility and number of slots available. Quality Improvement team : Comprising GI providers, Pediatric Radiologist, MRI administration, MRI lead technologist, MRI scheduling. Metric: Overall MRE volume over 5 years, and following intervention, post intervention outpatient MRE wait times, table times, ED -ordered MRE, ED wait times related to stat MRE, MRE revenue impact, impact on total number of annual MRI examinations performed. MRE wait times were collected manually, remaining data was obtained through the hospital information system. The data are analyzed using basic statistical methods and represented with bar charts. Sustainability Plan : Perform systematic review of the quality of examinations over 6 months, review patient and GI service input and make appropriate revisions such as continued scheduling of MRE with fistulograms for all sedated patients. Make changes to the MRI scheduling grid to make the changes more permanent.

RESULTS

• MRE wait times reduced from an average of 21 days (January to April 2024) to 5 days by the end of July 2024. Wait times have slightly increased recently to 11 days but remain significantly below baseline. • MRE table time decreased from 2 hours to 1 hour. • Decrease in MRE through ED from an average of 2.5 studies/month in 2023 to 1 study/month, decreasing ED room utilization time for MREs from 15-20 hours/month to 6-8 hours/month

DISCUSSION

Utilizing the Go See Plan approach and humble inquiry, our data-driven process effectively identified bottlenecks in MRE scheduling. Collaboration among MRI staff, pediatric radiologists and GI professionals facilitated the successful implementation of interventions. Their enthusiasm and partnership were crucial in achieving significant reductions in scheduling delays and enhancing overall efficiency.

S3B-QI-3 TRANSITIONING FROM PEER REVIEW TO PEER LEARNING IN A LARGE ACADEMIC RADIOLOGY PRACTICE

Melissa A. Whitworth, MD (*Abstract Co-Author*)
Mary Yang, MD (*Abstract Co-Author*)
Yue Zhang, PhD (*Abstract Co-Author*)

INTRODUCTION

At our institution, the existing score-based peer review process for radiologists had low engagement, limited review of exams, and prioritized scoring over improving patient care. Our process was perceived as biased due to unblinded report reviews and had minimal impact on practice improvement. In response, we initiated a department-wide transition from peer review (PR) to peer learning (PL) across all clinical divisions. Our goal was to transition to PL in 1 year to foster a culture of learning and increase radiologist engagement and participation in meaningful practice improvement activities.

METHODS

Using the Plan, Do, Study, Act (PDSA) framework, we aimed to transition from PR to PL for all clinical divisions in the Department of Radiology. A PL taskforce with representatives from each clinical division was established. Current PR and/or PL activities were mapped, and a PL policy was created. The taskforce helped design technical solutions to support the transition. We developed a single app-based solution to serve 3 separate health systems, streamlining case submissions and review processes. Additionally, required metrics for ongoing professional practice evaluations were established and approved by departmental leadership and our hospital's credentialing committee. PL metrics that replaced PR included case submission rates, conference attendance, and PL case tracking.? Following approval, PL leaders in each division were identified and nominated by Division Chiefs to champion PL and facilitate implementation. To engage faculty, PL presentations with Q&A sessions were conducted at both division and department-wide meetings. PL was officially implemented on 09/01/2024. Both qualitative and quantitative methods were employed to analyze PL data, gathering qualitative insights through stakeholder feedback and monitoring quantitative metrics via dashboards.

RESULTS

Pre-intervention, 4 out of 10 clinical divisions offered PL conferences. Post-intervention, all 10 divisions established PL conferences. In the first 6 months, 153 radiologists participated in PL activities, with 150 (98%) meeting case submission requirements (946 total exams submitted) and 138 (90%) attending at least one PL conference. Faculty engaged in a total of 383 hours of PL activities.

DISCUSSION

Our department successfully transitioned from PR to PL across all clinical divisions within 1 year, achieving robust participation and implementing effective technical solutions. To ensure sustainability, dedicated PL leaders and PL committee members oversee the program, continuously monitoring participation metrics and soliciting faculty feedback. Periodic reviews of the PL policy and app functionality help adapt to evolving needs. Future efforts will focus on identifying key learning opportunities for quality improvement projects to enhance departmental performance.?

S3B-QI-4 SUPPORTING INNOVATION IN CARE DELIVERY: REDUCING TURNAROUND TIMES FOR SAME DAY IMAGING EXAMS REQUESTED BY THE ONCOLOGY RAPID ASSESSMENT CENTER

Andrew Johnston, MD, MBA (*Presenter*)
Sabine McHugh (*Abstract Co-Author*)
Megan Nadell (*Abstract Co-Author*)
Shantika Devi, BSc (*Abstract Co-Author*)
ANTHONY HERNANDEZ (*Abstract Co-Author*)
Monglan Duong (*Abstract Co-Author*)
Lauren Maeda (*Abstract Co-Author*)
Gloria L. Hwang, MD (*Abstract Co-Author*)
Uzma Waheed, MD (*Abstract Co-Author*)

INTRODUCTION

In February 2024, the Oncology Rapid Assessment Center (ORAC) opened on weekdays between 10 am and 7 pm to address rising Emergency Department visits and readmissions among cancer patients. The Radiology Department engaged to support this initiative by expediting performance and interpretation of urgent outpatient imaging referred by ORAC. The project objective was to develop an explicit workflow for interpreting CT studies.

METHODS

Lack of a shared imaging performance and interpretation workflow following the clinic's opening led to confusion, care delays, and unnecessary ED visits. A current state analysis showed that 66.2% of exams were interpreted within 120 minutes of exam completion. There was an average of 188 weekly ED visits by cancer patients.The project was performed at a single academic hospital system in the western United States. The team included the ORAC manager, a radiology resident lead, a project manager, the CT manager and lead CT technologist, and the image library manager, who facilitates communication for the radiology reading rooms. The radiology director of performance improvement and ORAC medical director served as project sponsors. After a Gemba walk and current state analysis, a SMART goal was set to interpret 85% of CT exams within 120 minutes of exam end time (CT scan completed to preliminary interpretation) within an 8-month study period. A root cause analysis found that exams did not flow to the appropriate worklist, radiologists were unaware of exam priority, expectations around interpretation times were

nonexistent, and patient volume was tracked manually. Interventions focused on setting expectations between ORAC and radiology, standardizing requests for imaging, and developing a process for communicating exam completion. Mean and median turnaround times were calculated, and weekly ED visits were tracked. T-test was used to detect differences in means before and after intervention. The sustain plan resulted in creation of a dashboard to deliver monthly reports to radiology and ORAC leadership. Message templates were added to the reading room assistant operating procedures.

RESULTS

Average monthly exam volume increased from 13 to 24 during the study period and weekly ED visits by cancer patients decreased 12.6% from 188 to 164. The percentage of CT scans interpreted within 120 minutes increased from 66% to 88%. Mean and median interpretation times decreased from 239 to 65 minutes and from 75 to 47 minutes, respectively ($p < 0.01$).

DISCUSSION

Radiologists can support innovation in care delivery by achieving feasible turnaround times for exams in these settings. Workflow standardization contributed to meeting the goal of interpreting over 85% of CTs in under 120 minutes, which has persisted as imaging volumes have increased. Future work will focus on expanding ORAC access and reducing turnaround times for other modalities.

S3B-QI-5 HANDS-ON FLUOROSCOPY TRAINING USING A NOVEL PHANTOM ESOPHAGUS IMPROVES RESIDENT KNOWLEDGE AND CONFIDENCE

Joshua Williford, MD (*Presenter*)
Craig M. Smith, DO (*Abstract Co-Author*)
Daniel J. Hoffman, MD (*Abstract Co-Author*)

INTRODUCTION

Fluoroscopy is a challenging component of radiology training that requires an understanding of equipment operation, exam technique, radiation parameters, and contrast administration. These challenges are compounded by the need for real time image interpretation and patient interaction. For first year radiology residents, these factors can prove overwhelming and potentially lead to increased fluoro times and higher patient dose. The purpose of this project was to create a model for fluoroscopy training with the goal of increasing resident knowledge and confidence in the performance of fluoroscopic procedures.

METHODS

This project was conducted in the fluoroscopy suite of a large, urban, tertiary care academic medical center over a 7 month period. Individual hands-on training sessions led by a senior resident were offered to all first year residents (n=7) prior to the start of their first fluoroscopy rotation. A low cost, easily reproducible, novel phantom esophagus was designed by a senior resident and used for training. Training consisted of a hands-on review of fluoroscopy equipment requiring identification and operation of 32 system components and functions. A review of common fluoroscopic contrast agents. An instructor led review of a basic esophagram examination. And lastly, an OSCE style examination using the phantom esophagus and requiring patient interaction, system operation, and timed image acquisition during a simulated esophagram. The impact of fluoroscopy training on resident knowledge was assessed using a 23 question pretest and posttest. Four competency categories were assessed including system operation, dose reduction strategies, contrast safety, and exam technique. Resident confidence was assessed using a 5 point Likert scale in the same competency categories as above. Statistical analysis was completed with JASP. Paired-samples t-tests were used to compare pretest and posttest scores and Likert confidence ratings. Significance was determined by p value < .05.

RESULTS

Results demonstrate a statistically significant increase in resident fluoroscopy knowledge after training (Pretest mean 49, posttest mean 93, $p < .001$) with statistically significant score increases across all competency categories ($p < .001$ - $p .02$). There was also a statistically significant increase in resident fluoroscopy confidence (pretest mean 1.9, posttest mean 4.6, $p < .001$) with statistically significant increases in confidence ratings across all categories ($p <.001$ - $p .006$).

DISCUSSION

This project presents a model for hands on fluoroscopy training using a novel phantom esophagus which improves resident knowledge and confidence in the performance of fluoroscopic procedures. Limitations of the current study include small sample size. Future directions could include analysis of the effect of fluoroscopy training on fluoroscopy times and patient dose.

S3B-QI-6 ENHANCING RADIOLOGY-PATHOLOGY COLLABORATION TO REDUCE QUANTITY NOT SUFFICIENT (QNS) RATES AND IMPROVE PATIENT CARE

Lukose K. Thampy, DO, MS (*Presenter*)
Jennifer Courtney (*Abstract Co-Author*)
Doris Ranski-Zazula (*Abstract Co-Author*)
Tamara Brown (*Abstract Co-Author*)
Gerry Velasco (*Abstract Co-Author*)
Kevin R. Carter, DO (*Abstract Co-Author*)

INTRODUCTION

Collaboration between radiology and pathology departments is crucial for optimizing biopsy specimen adequacy, facilitating accurate molecular testing, and improving patient outcomes. One meaningful measure of collaboration is the quantity not sufficient (QNS) rate, defined as the percentage of cases in which insufficient tissue prevents completion of molecular panels. At our institution, the biopsy QNS rate was 15%, considerably higher than the national benchmark of 6%. The elevated QNS rate contributed to delays in diagnosis, increased patient procedure burden, and higher healthcare costs. Thus, we initiated a multidisciplinary quality improvement project designed to improve interdepartmental communication and optimize tissue acquisition.

METHODS

A standardized biopsy protocol was developed, including a single order set to ensure consistency in tissue requisitions. Rapid on-site evaluation (ROSE) was adopted to ensure real-time assessment of specimen adequacy after acquisition. Tissue biopsy yield was improved by standardizing needle gauge selection and optimizing the number of biopsy passes. Hybrid assay methodologies were deployed to maximize diagnostic yield from limited samples and reduce specimen exhaustion. Training sessions reinforced best practices in specimen handling and enhanced communication between radiologists, pathologists, pulmonologists, medical oncologists, and laboratory staff.

RESULTS

A retrospective analysis comparing pre- and post-intervention outcomes demonstrated a substantial reduction in QNS rates. Following the implementation of these strategies, the QNS rate decreased from 15% to 5.94%, bringing our institution below the national benchmark. These improvements reduced the need for repeat procedures, minimized patient discomfort and procedural risk, and improved overall diagnostic yield. Enhanced tissue handling protocols increased the reliability of molecular testing and contributed to healthcare cost savings by decreasing redundant testing and interventions.

DISCUSSION

This initiative demonstrates that a structured, multidisciplinary approach to biopsy specimen management can produce sustainable improvements in specimen adequacy and diagnostic workflows. Standardizing biopsy techniques, streamlining laboratory processes, and strengthening interdepartmental communication resulted in meaningful reductions in QNS rates and improvements in patient care. The strategies developed through this quality improvement project offer a scalable framework for institutions seeking to enhance biopsy protocols, optimize diagnostic outcomes, and improve collaboration between radiology and pathology teams.

S3B-QI-7 FROM PROBE TO REPORT: SYSTEMWIDE ENHANCEMENT OF ULTRASOUND WORKFLOW WITH AUTOMATED DATA FIELDS

Melissa Yang, MD, MPH (*Presenter*)
Meha Patel, MD (*Abstract Co-Author*)
Barak Friedman, MD (*Abstract Co-Author*)
Mark Finkelstein, MD (*Abstract Co-Author*)
Rona J. Orentlicher Fine, MD (*Abstract Co-Author*)
David S. Mendelson, MD (*Abstract Co-Author*)
Alexander C. Kagen, MD (*Abstract Co-Author*)

INTRODUCTION

Transcribing ultrasound data into radiology reports has traditionally required manual re-entry, which is time consuming and disrupts workflow. Existing automated solutions are often limited to single-vendor systems, and multi-vendor, multi-site implementation is challenging without third-party tools. The aim of this project is to develop, implement, and evaluate an in-house multi-vendor data mapping pipeline that auto-populates ultrasound measurements into radiology reports, with the goal of improving efficiency and report turnaround time across a multi-hospital health system.

METHODS

Our radiology department encompasses 6 hospitals and 12 outpatient sites with approximately 40 ultrasound machines. Radiology reports are generated using voice dictation software Nuance Powerscribe. Institution-wide standardized dictation templates were updated with custom fields for ultrasound measurements. Utilizing a developed custom on premise solution, measurements were auto-transmitted from ultrasound machines to Powerscribe. Custom fields were piloted on a single ultrasound machine from each vendor before scaling up. Rollout of data mapping was performed one site at a time. Lead ultrasound technicians and radiologists conducted training sessions to instruct technicians on the updated measurement input process. Preliminary results were obtained during the implementation period 4/28-5/6/25 and compared with pre-intervention period 1/1-2/28/25. Primary outcome measured was median report turnaround time (RTAT). Qualitative measures included survey responses focusing on perceived changes in workflow efficiency, ease of use, and user satisfaction.

RESULTS

Ten ultrasound templates were included, 7 contained custom fields and 3 contained no custom fields. The number of custom fields ranged from 0 to 10. There was a significant reduction in median RTAT for two ultrasound studies. Median RTAT for renal bladder studies decreased from 15.2 min to 8.2 min ($p = 0.004$) and median RTAT for abdominal studies decreased from 13.7 min to 6.1 min ($p < 0.0$). The three templates with zero custom fields did not demonstrate significant reduction in turnaround time. Qualitative survey results revealed positive feedback including reduced dictation time and allowing radiologists to focus on image interpretation rather than transcribing numbers.

DISCUSSION

Automated measurement data integration into ultrasound reports significantly reduced reporting time for some studies and improved workflow efficiency. Implementation required careful planning, customization for different ultrasound systems, and technologist retraining, which may limit broader adoption. Overall, development of a multi-vendor automated data pipeline for a large hospital system enables faster report delivery and boosts efficiency, benefiting patient care and provider communication.

S3B-QI-8 OPTIMIZING OUTCOMES: NURSE NAVIGATION STRATEGIES IN A DECENTRALIZED LUNG CANCER SCREENING PROGRAM

Melissa Loop, BS, RN (*Presenter*)
Leslie Whalen (*Abstract Co-Author*)

INTRODUCTION

Low-dose CT combined with lung cancer screening (LCS) lowers the mortality rate from lung cancer by facilitating early detection and treatment. Its full potential is limited due to insufficient screening rates and difficulties with eligibility determination. With an emphasis on methods to enhance precise eligibility determination and broaden access, this study details a multifaceted, Nurse Navigator-led effort to maximize LCS participation. We are a large integrated network. This network spans 21 hospitals, 50 health centers, and 200 physician offices. There are 26 accredited CT scanners that can screen for lung cancer. We have three full-time Lung Screening Navigators and two nodule clinics. Because our lung screening program is decentralized, primary care physicians are free to oversee their patients' follow-ups or refer them to specialists as needed. In 2023, we performed 7,826 screenings. While the national screening rate is 16%, we achieved a screening rate of 17.2% in 2023 by including all reported eligible lung screening patients within our hospital system.

METHODS

A quality improvement project was launched, beginning with the ACR Learning Network Initiative. After identifying screening hurdles using waste assessment, Fishbone diagram analysis, and a PICK chart, we wanted to increase our screening rate to 25% by December 2024. Key interventions included: community outreach events targeting potential patients, provider education via office visits, emphasizing screening guidelines and accurate tobacco history documentation, proactive patient outreach by Nurse Navigators to address pending orders and eligibility clarification, development of a Lung Screening Dashboard within our EMR, and strategies to reduce errors in order placement and ensure appropriate exam selection to minimize patient financial burden.

RESULTS

After implementation, the system-wide LCS rate rose from 17.2% in 2023 to 24% in 2024. The overall number of screenings grew by 32.57%, from 7,826 to 10,375. The percentage of lung screening patients diagnosed with early-stage lung cancer increased from 54.4% to 58.5%. Nurse Navigators' proactive patient and physician outreach resulted in higher screening and early cancer detection. Barriers included a lack of a thorough smoking history in charts and the scheduling staff not reaching out to patients to schedule appointments.

DISCUSSION

A Nurse Navigator-led, multi-faceted approach can greatly enhance LCS rates and early-stage diagnosis in a large healthcare system. Actively addressing barriers to eligibility determination, through improved tobacco history recording and patient communication, is critical for increasing the impact of LCS programs. Future work will concentrate on mandated tobacco history screening and standardized documentation to improve eligibility evaluation and increase access to LCS.

T2-QI-1 PROTOCOLIZING PERCUTANEOUS CATHETER DRAINAGE: A TIERED DECISION-MAKING MODEL TO IMPROVE SAFETY AND SUCCESS RATES

Aishwarya N. Gadwal, MD, MBBS (*Presenter*)
Santosh P. Rai, MD, FRCR (*Abstract Co-Author*)
Akshay Reshmi (*Abstract Co-Author*)

INTRODUCTION

Image-guided percutaneous catheter drainage (PCD) is a minimally invasive alternative to open surgical drainage (OSD) for fluid collections. However, variability in timing and technique leads to inconsistent outcomes and complications. The SMART aim of our quality improvement (QI) initiative was to reduce major post-procedural complications from a baseline of 10% to under 5%, and catheter failure rates from 8% to below 3% over a 12-month period by implementing a standardised, tiered intervention protocol.

METHODS

This prospective initiative, conducted on 83 patients with thoracic, abdominal, or pelvic fluid collections, was structured using a Plan-Do-Study-Act (PDSA) model. A new decision-making protocol was implemented, categorizing patients into: Group A : Intermittent needle aspiration (INA) with PCD in the same session Group B : INA followed by PCD after 48 hours Group C : INA + PCD followed by OSD due to drainage failure The protocol also standardized: Catheter sizing based on location and fluid consistency (e.g., 10F thoracic, 12F abdominal) Imaging modality selection (CT vs. US) based on collection depth Timing of intervention guided by follow-up imaging Aseptic technique adherenceOutcomes were defined prospectively and included complication rates, catheter failure, and success (defined as >75% fluid reduction and no escalation to surgery).

RESULTS

Across all groups, the structured protocol led to: Low major complication rates (3.6%) Catheter failure rate of 2.4% High procedural success in Groups A and B (93.7% and 97.9%, respectively) Post-procedural pain was the most common minor complication (72.2%), managed conservatively. Rare complications included catheter blockage and pneumothorax. The protocol ensured consistent catheter selection, reduced the need for re-intervention, and minimized procedural duration and hospital stay.

DISCUSSION

Implementing a structured, tiered intervention protocol led to measurable improvements in safety and efficacy of PCD for diverse fluid collections. Using a SMART aim and PDSA cycle , we standardized clinical decision-making and procedural technique, reducing variability and improving outcomes. This protocol has been integrated into departmental SOPs and is currently being evaluated for scale-up across other services, including trauma and surgical ICUs. This initiative demonstrates that even common IR procedures benefit from systematic QI methodology.

T2-QI-2 MINIMIZING SEDATION IN PEDIATRIC MRI: THE ROLE OF MRI COMPATIBLE AUDIOVISUAL ENTERTAINMENT SYSTEM

Nina R. Stein, MD (*Presenter*)
Juliana Goncalves Silveira (*Abstract Co-Author*)
Alice Schuch, MD (*Abstract Co-Author*)
Mariane Cibelle Barros (*Abstract Co-Author*)
Bruna Bressan Valentini, BSC (*Abstract Co-Author*)
Henrique M. Guerra, MD (*Abstract Co-Author*)

INTRODUCTION

Magnetic resonance imaging (MRI) provides high-resolution, radiation-free imaging for pediatric cases, but young children often require general anesthesia (GA) to remain still, raising costs, risks, and hospital stays. Audiovisual distraction tools can improve pediatric cooperation during MRI, avoiding sedation while maintaining image quality. The purpose was to reduce GA for pediatric MRI investigations by implementing audiovisual distraction technologies and a child-friendly environment.

METHODS

A retrospective cohort of 101 pediatric patients in need of a sedation technique to undergo an MRI (ages 5-15). Study period from October 2024 and March 2025, in a tertiary center with adult and pediatric mix practice. Interventions: 1. creation of a children friendly environment (Fig 2). 2. Use of AVE for eligible patients; 3. Satisfaction survey. Groups were compared for workflow, image quality, and caregiver experience. Outcomes: reduction in the use of GA for MRI, prep time, exam duration, overall cost of procedure and examination, image quality, and caregiver satisfaction. Outcomes were compared using descriptive statistics. The cost analysis centered on material expenses, and feedback from surveys was reviewed, encompassing both qualitative and quantitative data.

RESULTS

Among 101 patients, 54 had MRI with GA and 47 with AVE. All exams were diagnostic (100%). Movement artifact rates were 1.9% for GA and 8.5% for AVE (Fig 3), with no need for recall studies. Workflow metrics (Fig 4) showed shorter times for AVE compared to GA: preparation time was 43 min vs. 74 min, acquisition time 17 min vs. 23 min, scanner time 20 min vs. 35 min, and total exam time 40 min vs. 52 min. Post-anesthesia recovery averaged 38.42 min for GA. MRI exams with GA were about 56% more expensive in material costs than those with AVE. Satisfaction surveys (n=37, 36.6% response rate) revealed that 97.3% of caregivers reported reduced anxiety with AVE, 97.3% would use it again, and 81.1% felt no discomfort. Experience ratings were excellent (54.1%), great (27.0%), or good (16.2%), with no negative feedback (Fig 5 and 6).

DISCUSSION

MRI-compatible audiovisual entertainment and environmental strategies are a feasible alternative to GA for pediatric MRI, improving patient and caregiver experience, reducing booking wait times, total exam time, and lowering costs. This technique is not exclusive to a tertiary center and can facilitate the workflow of any pediatric

patient in the community hospitals and outpatient clinics.

T2-QI-3 PATIENT AND RADIOLOGIST EXPERIENCES AND BREAST CANCER DETECTION WITH CONTRAST ENHANCED MAMMOGRAPHY (CEM) DURING CEM AND CEM-GUIDED BREAST BIOPSY IMPLEMENTATION

Brooke Sawyer, MBBS, FRANZCR (*Presenter*)

INTRODUCTION

Patients with past history of breast cancer are at increased risk of breast cancer, where the value of CEM for surveillance mammography has been demonstrated. This is our CEM implementation experience, assessing patient and radiologist experiences with CEM and CEM breast cancer detection whilst maintaining patient safety. Planning, observing and adjusting breast imaging workflows ensured optimal utilisation of breast imaging resources.

METHODS

Accepted indications for CEM were defined. Referrer and staff CEM education occurred. CEM commenced at a single site and breast imaging workflow was regularly reviewed. Patient experience with CEM and radiologist feedback reporting CEM was invited. Breast cancer detection was observed to ensure CEM diagnostic performance. Mammography and whole breast US were previously performed in this patient cohort. A new mammography unit with CEM and CEM-guided breast biopsy was installed at one site December 2023. CEM implementation occurred July 2024, when a change in practice of digital mammography (DM) / digital breast tomosynthesis (DBT) +/- breast US for non-CEM patients occurred. A quality assurance (QA) project for this change in practice commenced August 2024, a team of radiologists, mammographers, sonographers, imaging nurses, MRI medical imaging technologist and a breast surgeon. All CEMs were double reported. CEM breast report data of breast density, background parenchymal enhancement (BPE), mammography findings, US or MRI requirement, BI-RADS assessment category and biopsy modality were recorded by the second reporting radiologist. Breast biopsy results were recorded. Patient safety was monitored. Breast US numbers reviewed. Patient and radiologist experience survey results graphed. CEM diagnostic performance compared CEM and non-CEM groups. Data collection will cease after 1000 CEM cases is reached at initial site. Single and double reporting of CEMs has commenced with CEM implementation at a second site May 2025.

RESULTS

From 5 th August 2024 to 13 th April 2025, 968 patients aged 35 years or older presented for surveillance mammography post breast cancer treatment. 787 patients had CEM/DBT (group 1), and 181 patients had DM/DBT +/- breast US (group 2), an 81% CEM uptake rate of CEM. 15 of 37 (40%) of breast biopsies from group 1, and one of seven (14%) of breast biopsies from group 2, were malignant. Breast US reduced by 51%. Patient and radiologist experiences with CEM were favourable.

DISCUSSION

CEM implementation is a significant change to breast imaging practice which requires careful planning and monitoring by a dedicated team. Managing patient safety and expectations are key. CEM/DBT has higher breast cancer detection compared with DM/DBT +/- breast US. Single site experience optimised second site CEM implementation.

T2-QI-4 DATASETS MADE EASY: TURNING DICOM COMPLEXITY INTO CONVERSATIONAL SIMPLICITY

Eduardo M. Farina, MD (*Presenter*)
Felipe A. Matsuoka (*Abstract Co-Author*)
Felipe C. Kitamura, MD, PhD (*Abstract Co-Author*)
Paulo E. Kuriki, MD (*Abstract Co-Author*)

INTRODUCTION

Radiologists and researchers often face substantial challenges when accessing, filtering, and anonymizing DICOM data for clinical or research use. These tasks require expertise in DICOM protocols and anonymization procedures, creating workflow inefficiencies and limiting data accessibility. Large Language Models (LLMs) have recently demonstrated promise in simplifying complex technical workflows through intuitive natural language interfaces. There's already a public DICOM-MCP project that offers a foundation for DICOM operations via a Model Context Protocol (MCP) server, however, it lacks built-in anonymization tools and natural language interaction, limiting clinical usability. We aimed to develop a framework that integrates LLMs and MCP to enable natural language-driven interaction with PACS systems while ensuring secure, HIPAA-compliant anonymization for research workflows.

METHODS

We designed a dual-MCP architecture incorporating both DICOM operations and standardized anonymization. Our prototype can integrate with Claude IDE and/or local LLMs such as Mistral 3.1 via Ollama, using natural language queries transformed into DICOM tasks using MCP, and a second MCP component was implemented to interface with the RSNA Anonymizer, allowing secure de-identification via conversational prompts. Supported DICOM operations include C-MOVE, C-GET, and C-FIND, with metadata filtering and batch anonymization. The framework will be open-sourced upon acceptance, accompanied by detailed documentation and setup guides to facilitate adoption and ensure reproducibility.

RESULTS

The proposed system enables radiologists to use plain language commands to retrieve and anonymize imaging studies. It supports local LLM execution to address institutional data security requirements. The RSNA Anonymizer ensures compliance with HIPAA standards while preserving data fidelity. Upon acceptance, a public GitHub repository will include a full implementation guide, demonstration videos, and sample configurations to facilitate cross-institutional deployment.

DISCUSSION

This framework streamlines imaging workflows by abstracting technical barriers behind a natural language interface. Limitations include reliance on PACS compatibility and potential LLM response latency. Future work will focus on vendor-agnostic integration, improved DICOM metadata inspection via LLMs, and performance tuning for real-world use. By bridging LLMs with PACS and anonymization tools, our approach represents a promising step toward democratizing access to imaging data for research and quality improvement initiatives.

T2-QI-5 BENEFIT OF INDEPENDENT DOUBLE READING OF BRAIN MRI IN PATIENTS WITH SEIZURES

Sergio Valencia, MD (*Presenter*)
Laura Andrea Campana Perilla, MD (*Abstract Co-Author*)
Sofia Velasco, MD, MPH (*Abstract Co-Author*)
Sonia Bermudez, MD (*Abstract Co-Author*)
Angela P. Guarnizo, MD (*Abstract Co-Author*)

INTRODUCTION

To assess the potential value of the independent double reading of brain MRI performed in patients with seizures and the effect on structural abnormalities detection.

METHODS

We retrospectively reviewed all epilepsy protocol brain MRI studies available in the institutional PACS from 2018 to 2024. In 2021, a double reading protocol was implemented, in which two neuroradiologists independently reviewed each study, followed by a consensus discussion to issue a final joint report. We compared diagnostic yields between studies interpreted by a single radiologist versus those with double reading. Epilepsy-relevant findings (e.g., hippocampal sclerosis, cortical abnormalities) were identified. In cases with potential imaging abnormalities, findings were compared to electroencephalogram results when available. Normality was assessed using the Shapiro-Wilk test. Depending on data distribution, comparisons were made using either Student's t-test or Mann-Whitney U test, along with Chi-square tests for categorical variables. A binomial logistic regression model was used to assess independent predictors. All analyses were conducted in SPSS version 24, with statistical significance defined as $p < 0.05$.

RESULTS

A total of 504 patients (mean age 30.3 ± 22.5 years; 52.8% male) were included. Of these, 183 studies (36.3%) had double reading. Epilepsy-relevant findings were more frequent in the double reading group (33.3%) than in the single reading group (23.1%) (p=0.012; OR=1.67, 95% CI: 1.12-2.50). The mean age was significantly lower in patients with double reading (28.1 ± 21.2) compared to those with single reading (31.3 ± 23.2) based on Student's t-test (t = 2.17, p = 0.031). Among specific findings, hippocampal abnormalities were more often detected with double reading (p=0.037; OR=2.10, 95% CI: 1.04-4.21). In logistic regression, epilepsy-relevant findings were independently associated with double reading (ß = 0.559, p = 0.007), and age was negatively associated (ß = -0.010, p = 0.018).

DISCUSSION

Double reading significantly increases the detection of epilepsy-relevant MRI abnormalities, particularly hippocampal findings, and is associated with younger patient age. It may improve diagnostic accuracy in epilepsy imaging protocol.

T2-QI-6 REDUCE ADD-ON SEED APPOINTMENTS IN THE BREAST IMAGING DEPARTMENT

Kyle M. Hatcher, MD (*Presenter*)
Kaitlyn Rieker (*Abstract Co-Author*)
Andrey Morozov, MD (*Abstract Co-Author*)
Robert W. Maxwell, MD (*Abstract Co-Author*)
Jessica Holtz (*Abstract Co-Author*)
James W. Jakub, MD (*Abstract Co-Author*)
Jessica Kinchen (*Abstract Co-Author*)
Glenn M. Sturchio, PhD (*Abstract Co-Author*)
Kristin A. Robinson, MD (*Abstract Co-Author*)

INTRODUCTION

The Breast Imaging Department has experienced a significant increase in demand for radioactive seed placement, resulting in a high percentage of add-on appointments (i.e. appointments added outside of regularly scheduled procedure slots or appointments double booked with already scheduled procedures). These add-on appointments created scheduling challenges, negatively impacting patient care and provider well-being. The gap in quality is evidenced by the fact that 47.6% of seed appointments are add-ons, far exceeding the target goal of 10%. The project aimed to reduce the percentage of add-on seed appointments by 78%, from 47.6% to 10%, over a 6-month period, without adversely affecting the availability of other breast imaging procedures.

METHODS

The project utilized the DMAIC (Define, Measure, Analyze, Improve, Control) methodology to identify and address the underlying causes contributing to the high rate of add-on seed appointments. The team identified 37 potential causes using a Fishbone diagram (Figure 1), narrowing them down to 10 key causes through impact/effort analysis (Figure 2). Key stakeholders, including breast radiologists, breast surgery providers, radiation safety officers, and scheduling staff, were engaged throughout the process. Subsequently, five targeted interventions were implemented based on the identified causes: (1) Creation of three dedicated seed scheduling slots. (2) Elimination of pre-operative assessment as a mandatory requirement for seed placement, unless specified otherwise. (3) Modification of the radiology checklist to reflect the new pre-operative assessment policy. (4) Education for stakeholders on the updated pre-operative assessment policy. (5) Solicitation of feedback from the nuclear regulatory body regarding the potential to lengthen the seed explantation window to more than five days.

RESULTS

Following the implementation of these interventions, the percentage of add-on seed appointments was reduced to 0% at both 6- and 12-month timepoints (Figure 3). In addition, the average number of days for breast imaging appointments decreased from 7.5 days to 6 days at 6 months, and 4 days at 12 months (Figure 4), indicating a positive impact on scheduling efficiency.

DISCUSSION

The project successfully reduced the percentage of add-on seed appointments, improving scheduling efficiency and patient care without negatively impacting other breast imaging services. The lessons learned and the interventions implemented can serve as a model for addressing similar challenges in other clinical settings.

T2-QI-8 OPTIMISING JOINT DECISION MAKING IN INTERVENTIONAL RADIOLOGY: A RETROSPECTIVE ANALYSIS OF PATIENT ANXIETY AND UNDERSTANDING USING AUDIO-VISUAL PATIENT EDUCATION TOOLS

Francesca Heiberg-Gibbons, MBChB, BMedSc (*Presenter*)
Rushabh Shah, MD, FRCR (*Abstract Co-Author*)
Jacob Ibbetson (*Abstract Co-Author*)
Ning Ajleaa Ngah, MBChB (*Abstract Co-Author*)
Simon P. Padley, BSc, MBBS (*Abstract Co-Author*)
Emily C. Bartlett, MBBS (*Abstract Co-Author*)
Carole A. Ridge, FFR(RCSI) (*Abstract Co-Author*)

INTRODUCTION

Patient periprocedural anxiety can limit the performance of interventional radiology (IR) procedures under local, rather than general, anaesthesia. Our institution introduced 'Explain my Procedure' (EMP) in 2022, a series of animated educational videos tailor-made to assist the consent process for patients prior to their IR procedure. The aim of the study is to assess the impact of this tool on patient's pre-procedural anxiety and comprehension.

METHODS

All consenting adult patients undergoing elective IR procedures including portacath insertion, arterial embolisation, lung tumour biopsy and ablation between May 2022-April 2024, before and after the implementation of EMP, were invited to complete two questionnaires. A State Trait Anxiety Inventory questionnaire, regarding their experience of pre-procedural positive and negative emotions and a second questionnaire regarding their understanding of the procedure. Data from 70 patients was analysed.

RESULTS

31 (45 %) IR outpatients watched a teaching animation prior to their procedure. 22 (71%) patients reported low pre-procedural anxiety after watching a teaching video, versus 19 (49%) patients that did not watch a teaching video. High anxiety levels were lower in patients who had watched the animation, compared with patients that had not with statistical significance (16% and 39% respectively, $p<0.05$). Patients that watched the animation had statistically significantly higher levels of complete understanding versus patients that did not (90% and 67% respectively, $p<0.05$).

DISCUSSION

Implementation and patient engagement with IR teaching animations has shown a reduction in anxiety in patients pre-procedure and led to a greater understanding of the procedure. These findings support the continued utilisation of this tool, which can ultimately improve patient satisfaction.

T2-QI-9 EVALUATION OF A GENERIC CARDIOTHORACIC IMPRESSION GENERATOR MODEL FOR PREDICTING LUNGRADS SCORING IN LOW-DOSE LUNG CANCER SCREENING CTS (LDCT)

M. Saad Malik, MD (*Presenter*)
Fernando U. Kay, MD, PhD (*Abstract Co-Author*)
Yin Xi, PhD (*Abstract Co-Author*)

Krishna Sai Balineni (*Abstract Co-Author*)
Paulo E. Kuriki, MD (*Abstract Co-Author*)

INTRODUCTION

Lung CT Screening Reporting and Data System (LungRADS or LR) improves early cancer detection/survival but shows up to 30% inter-reader disagreement. Large Language Models (LLMs) can generate report impressions but are not typically trained for specific output categories. This study evaluates whether a LLM fine-tuned for cardiothoracic impressions can accurately predict LR categories.

METHODS

A Llama3-8B model was fine-tuned to generate cardiothoracic impressions using 66034 CT/MR radiology reports (RR) collected from Jan-Dec 2023. In this single-center study, 5961 LDCT RR from Jan-Dec 2024 were analyzed. After excluding 632 non-screening scans and 62 incomplete RR, 5267 RR remained. Regular expressions extracted reference LR categories. Impression sections were removed, and reports were fed into the LLM to generate LR categories. Analysis included individual LR categories and dichotomized into groups 1 (LR 0/3/4) and 2 (LR 1/2). Discrepancies were reviewed by a 2nd-yr radiology resident.

RESULTS

Median age 64 years; 2977 (57%) male. RR LR categories included 0: 77 (1%), 1: 498 (9%), 2: 4178 (79%), 3: 327 (6%), 4: 190 (4%) (Figure 1), with modifier in 428 (8%) reports. The LLMs accuracy (AC) was 86% (95%CI:85-87%), Cohen's Kappa (?) coefficient 0.582 (moderate agreement; P <0.001). After dichotomization, the LLM achieved 67% sensitivity (SN) and 97% specificity (SP) . For all discrepancies (211), 148 (70%) were undercalls and 63 (30%) were overcalls by LLM. For non-missing modifier cases (n=5295), the model achieved SN, SP of 18%, 97%.

DISCUSSION

A fine-tuned LLM can generate LR categories from LDCT reports without explicit prompting, demonstrating its ability to infer structured assessments from unstructured text only by observing the training data. It produced LR labels for 99% of reports with 86% accuracy with RR. However, its clinical utility was constrained by boundary errors, particularly in adjacent categories (2-3-4) and cases requiring contextual understanding (prior malignancy, lymphadenopathy, nuanced phrases), suggesting surface-level rule application instead of holistic reasoning. High specificity (97%) may reduce unnecessary follow-ups, but low sensitivity (67%) risks missing actionable findings. Adding rule-based guardrails and threshold-focused fine-tuning may enhance edge-case performance.

Lina Karout, MD (*Abstract Co-Author*)
Tom Hartle (*Abstract Co-Author*)

INTRODUCTION

We conducted a community outreach program that offered a free, mobile low-dose thoracic CT (LDCT) to individuals with prior COVID-19 infection and persistent symptoms of dyspnea, cough, or fatigue. The primary goal was to define the prevalence of potential COVID-19-related lung damage. As a secondary goal, we tracked the prevalence of incidental non-COVID-19 findings and the subset with clinically actionable abnormalities.

METHODS

We outfitted an 18-wheel tractor/trailer with a 32-slice BodyTom CT scanner (Neurologica; Danvers, MA) and conducted LDCT screenings using a standard protocol in SE Michigan. Non-pregnant patients 18 years or older who self-reported persistent symptoms of dyspnea, cough or fatigue post-COVID-19 were eligible. An opt-in consent to add their images and data to the IRB-approved (WCG # 20235095) Community Health Assessment RegisTry (CHART) was included. Board-certified radiologists with body imaging expertise reviewed all images. Normal and benign findings were reported via text message, email, or certified mail. Abnormal findings were flagged for review by the program's lead physician and anything deemed clinically actionable (defined as need for follow-up within 3 months or less) triggered a phone call, with primary or specialty care referral assistance if needed. Upon program completion, all CT reports were reviewed, and findings were categorized by organ system or body region. Potential COVID-related lung damage (defined as chronic parenchymal changes and/or lung fibrosis not deemed secondary to another cause) and incidental non-COVID-19 abnormalities, including the clinically actionable subset were recorded.

RESULTS

From 12/6/23 to 11/15/24, 200 scanning events were conducted at 48 different community-based sites. 2,168 patients were screened, 1,985 of whom consented to participate in CHART (91.6%). Of those who consented, the average age was 50.6 years, 52.8% were female and 53.0% were Black. Possible COVID related lung damage was identified in 31 patients (1.6%). Incidental abnormalities were found in 1202 (60.6%) with 585 (29.5%) clinically actionable. Of this subset, moderate to severe CAC (n=230; 11.6%) and suspicious intra-abdominal masses (n=83; 4.2%) were most common. Thyroid nodules (n=49; 2.5%), mediastinal masses (n=38 [tracheal deviation in 12]; 1.9%), aortic aneurysms (n=30;1.5%), and suspected lung cancers (n=15; 0.8%) were also seen. Though not included in the clinically actionable subset, hepatic steatosis was noted in 83 patients (4.2%).

DISCUSSION

Mobile LDCT is a convenient mechanism to deliver community screening for patients with persistent post-COVID symptoms. Although COVID-19 related lung damage on LDCT was infrequent, the high prevalence of clinically actionable incidental abnormalities, especially CAC, shows the utility of such screening at the community level.

T5A-QI-2 REDUCING ROUTINE CHEST XRAY USAGE IN THE ICU

Robert Wu, MD (*Presenter*)
Victoria Kim, MD (*Abstract Co-Author*)
Austin Ruediger, MD (*Abstract Co-Author*)
Akshay Thaper, MD (*Abstract Co-Author*)
Derek Ge (*Abstract Co-Author*)
Jeffrey S. Kempf, MD (*Abstract Co-Author*)
Sabiha Hussain, MD (*Abstract Co-Author*)
Judith K. Amorosa, MD (*Abstract Co-Author*)

INTRODUCTION

Based on recommendation from the ACR and Society of Critical Care Medicine, many hospitals have shifted away from routine ICU CXRs to a more restrictive on demand ordering pattern. Routine CXRs disrupts the sleep of ICU patients slowing their healing, may result in temporary respiratory decompensation, and are not in line with the Imaging Wisely guidelines. Furthermore, at our institution RWJUH, CXR volumes from routine ICU CXRs are so high that many radiologists are forced to read multiple successive CXR for the same patient at once, forcing them to interpret CXR that may no longer be relevant to the patient's clinical status. This also lengthens the turnaround time for stat and emergency CXR.

METHODS

We created 2 versions of an educational presentation, a synchronous and asynchronous version, presenting existing literature demonstrating no changes in patient outcomes between the routine and on demand CXRs. The pros and cons of routine CXRs were discussed along with the relevant ACR Appropriateness Criteria. A pre-intervention and post-intervention survey was administered.

RESULTS

Two months after implementing our educational initiative, the total average routine CXRs in our medical ICU dropped from 125 to 60-70 CXR/day in Jan, Feb, March 2025. 27 medicine residents, 2 medical students, and 7 APPs (advanced practice practitioner, NP/PA) responded to the survey with an average patient load of 2.32 patients. APPs inputed CXR orders nearly always (85%) while 60% residents ordered CXR half of the time with 32% residents responding nearly all the time. Only 11% of residents (3/27) ordered standing routine CXRs while 0% (0/9) APP and 0% (0/2) students ordered them. Institutional pressure to order daily xrays was overall low with only 29% (2/7) APP and 21% (6/28) residents reporting pressure. Institutional compliance with appropriateness criteria was high with acute worsening of clinical status having a likelihood ratio of 4.9/5, new admission or transfer 4.4/5, and stable clinical status having a ratio of 1.9/5 with regards to likelihood of ordering a CXR.

DISCUSSION

Our results demonstrate that an educational intervention can dramatically decrease the average number of routine ICU CXRs ordered. In addition, residents were much more likely than APPs to have standing CXR orders despite very similar patient loads. Knowledge of the ACR appropriateness criteria for ICU CXR was overall high with institutional pressure to order routine ICU CXR low across the board. Overall, our data suggests that educating residents in particular will reduce the frequency of daily routine CXR orders.

T5A-QI-3 OPTIMIZING RADIOGRAPHIC QUALITY: A DATA-DRIVEN APPROACH TO REDUCING IMAGE REJECTIONS AND ENHANCING TECHNOLOGIST ACCOUNTABILITY

Rasha Makkia, PHD (*Presenter*)
Brittany Blum, DO (*Abstract Co-Author*)

INTRODUCTION

Image rejection and repeat exposures in digital radiography increase patient radiation dose, reduce workflow efficiency, and may reflect training or equipment issues. Commonly due to positioning errors and patient motion, most rejected images are preventable. This quality improvement initiative aimed to evaluate baseline reject rates in fixed and portable X-ray systems, implement targeted interventions, and assess the impact of a PACS-integrated feedback system to improve technologist performance and reduce repeat imaging.

METHODS

A retrospective study reviewed digital radiographs over a two-and-a-half-month baseline period, followed by quarterly post-intervention assessments. Repeat and reject images from all fixed and portable systems were analyzed. Rejection causes were categorized using vendor-adjusted criteria (e.g., positioning error, motion artifact, technical error). Baseline reject rates were compared to target and threshold values indicated in AAPM TG 151. A root cause analysis revealed inadequate technologist training as a key factor. Targeted interventions included protocol refinement, individual feedback, and structured hands-on training. A new PACS-based QC tool was implemented to facilitate image review and provide direct feedback to technologists. Device and technologist-level tracking were introduced to identify high reject rates and guide targeted support.

RESULTS

A total of 1,280 rejected images were recorded during the baseline period, increasing to 1,792 in the post-intervention period. Positioning error and patient motion remained the leading rejection causes, rising 64% and 49%, respectively. Patient-related artifacts and technical issues also increased. Portable X-ray units showed a 110% increase in positioning errors and a 38% rise in motion-related rejections. In fixed rooms, these increased by 42% and 54%, respectively. Trainee-related rejections rose from 142 to 178. Despite higher volumes, reject rates in fixed systems declined modestly (from 12.5% to 11.3%). Portable systems showed more variability, but average reject rates improved slightly (from 19.1% to 17.5%), with some units showing substantial gains.

DISCUSSION

The rise in rejection counts is likely due to increased volume and better documentation, not declining quality. Stability in fixed systems and slight improvement in portable reject rates suggest early effectiveness of the interventions. The PACS feedback tool, combined with reject tracking at the machine and technologist levels, enhanced issue identification and response time. These tools allowed for focused retraining and quality control. Findings support continued use of data-driven strategies to improve technologist performance, reduce repeats, and promote safer, more efficient imaging practices.

T5A-QI-4 ONLINE PATIENT-CENTERED RADIOLOGY REPORTS: IMPROVING THE PATIENT AND FAMILY EXPERIENCE OF RECEIVING PEDIATRIC RADIOLOGY RESULTS

Sarah S. Milla, MD (*Presenter*)
John A. Maloney, MD (*Abstract Co-Author*)
Jill Stein, MD (*Abstract Co-Author*)
Ryan G. Short, MD (*Abstract Co-Author*)
Matthew Monson, DO (*Abstract Co-Author*)
Nicholas T. Befera, MD (*Abstract Co-Author*)

INTRODUCTION

TITLE: Online patient-centered radiology reports: Improving the patient and family experience of receiving Pediatric Radiology results Introduction Since the implementation of the 21 st Century Cures Act, patients have had more access to their medical health records, including their radiology reports. These reports are available to families instantaneously after report finalization, typically before the ordering physician has been able to review and contact the patient/family. As many patients and families may not have medical backgrounds, this can cause uncertainty while trying to read and understand the radiology reports. Patient-friendly reports and large language models have been proposed to help patients understand their radiology reports. Our objective was to assess the patient/family experience after implementation of patient-centered interactive radiology reports at a large children's hospital.

METHODS

Patient-friendly interactive radiology reports were made available to all patients within an online portal via integration of a commercially available software (Scanslated, Inc, Tampa FL). Interactive reports contained embedded plain language explanations and diagrams, which were accessible via clickable hyperlinks within the report. We recorded usage statistics including reports viewed, definitions/diagrams accessed, engagement time, and survey responses from patients and families who viewed the interactive reports.

RESULTS

During the review period from initial rollout to current time (November 20, 2024 to May 1, 2025), 113,849 reports were issued in the secure medical record online portal, with patients and families viewing 68,791 (60.4%) of the traditional radiology reports. Of the online reports accessed, 13,186 (19.2%) radiology reports in the patient-friendly interactive format were also accessed. Patients accessed a mean of 7.1 plain langauge explanations per report by clicking on terms and phrases. The majority (67.1%) of reports were viewed on a mobile device. Patients spent a total of 534.7 hours engaging with the interactive reports, with mean engagement time of 2.43 minutes. Of 2,018 survey question responses, 94.3% were positive. The far majority of patients (562/594 responses, 94.6%) reported that the definitions and diagrams helped them to understand their results, and indicated a positive experience viewing their patient-centered report (535/563 responses, 95%).

DISCUSSION

Based on our early experience, patient-friendly radiology reports improved subjective patient comprehension and had a positive impact on the patient/family experience of receiving imaging results online. Our results suggest that online patient-friendly reports may be an effective tool for patient and family engagement with pediatric radiology.

T5A-QI-5 APPLICATION OF SIX SIGMA MANAGEMENT TO IMPROVE THE TIMELINESS OF SCHEDULED RADIOLOGY EXAMINATIONS FOR INPATIENTS

Yang Cheng (*Presenter*)

INTRODUCTION

To evaluate the feasibility of enhancing the on-time performance of scheduled radiology examinations for inpatients through the application of Six Sigma quality management principles.

METHODS

Using the Six Sigma methodology, this study identified factors contributing to delays in scheduled inpatient CT examinations and implemented targeted, multidisciplinary interventions. A retrospective analysis of 18,696 inpatient CT appointment records was conducted, and the Pareto principle was used to identify the major contributors to delays. An interdisciplinary team, including the radiology department, nursing department, information technology services, and the patient transport center, collaboratively addressed the identified issues through tailored interventions. Following the intervention, data from an additional 1,986 inpatient CT appointments were collected to assess improvements in punctuality rates, patient wait times, and daily CT throughput.

RESULTS

Pareto analysis revealed the top three contributors to appointment delays: interdepartmental scheduling conflicts (40.22%), inefficiencies in the transport center (27.37%), and elevator congestion during patient transfer (15.08%). Following intervention, the examination punctuality rate improved from 78% to 91%. The median delay decreased from 45 minutes to 12 minutes, while early arrivals were reduced from a median of 60 minutes to 20 minutes. Daily CT exam volume increased by 18% (from 125 to 147 cases), and patient wait time was reduced by 32% (from 85 to 58 minutes).

DISCUSSION

The Six Sigma management approach effectively identifies and addresses key inefficiencies in the scheduling process, significantly improving the efficiency and punctuality of inpatient CT appointments.

T5A-QI-6 ESPRESSO SHOTS OF EDUCATION: RESIDENT DRIVEN ONLINE MINI LECTURE SERIES AS AN INNOVATIVE TEACHING TOOL

Melody W. Lin, MD, MS (*Presenter*)
Kamran Ali, MD (*Abstract Co-Author*)
Harsh Shah, MD (*Abstract Co-Author*)
Kathryn D. Solomon, MD (*Abstract Co-Author*)
Susan J. Frank, MD (*Abstract Co-Author*)
Barak Friedman, MD (*Abstract Co-Author*)
Rona J. Orentlicher Fine, MD (*Abstract Co-Author*)

INTRODUCTION

Radiology is central to modern medicine, supporting diagnosis and clinical decision-making across almost all specialties. Yet learning radiology is uniquely challenging - residents must master multiple imaging modalities and recognize a wide spectrum of pathologies while synthesizing clinical information under pressure. These demands and foundations, heightened during overnight call shifts and reiterated with traditional didactics, may not meet the needs of residents in these urgent, high-stakes settings. To address this, we developed a resident-led online mini-lecture series focused on emergency medicine topics. These concise videos - our “espresso shots” of education - deliver high-yield content in a fast, accessible format. We sought to evaluate the series' value as a radiology educational tool.

METHODS

The study was conducted at an urban academic hospital and level 2 trauma center. Senior radiology residents (PGY-4 & PGY-5) volunteered to create brief lectures on emergency radiology topics. Lectures were reviewed by faculty for accuracy and paired with a one-page “Quick Reference Guide”. Both resources were uploaded to an online database accessible to all residents. Each new lecture was announced during meetings and via the program’s group chat.To assess impact, we administered surveys at the start and end of the study year. The pre-survey gathered demographics, resource usage, and baseline attitudes toward resident-led education. The post-survey assessed engagement, frequency of use, and perceived benefit. Survey data were stratified by training year. Likert scales and open-ended responses were used to collect quantitative and qualitative feedback.

RESULTS

Survey response rates were 59.5% (Pre) and 63% (Post). The average lecture lasted 14 minutes, matching resident preferences: 68% favored videos between 10-15 minutes. On average, residents viewed 2.72 lectures, and 60% reported returning to the series. After implementation, positive opinion ratings (Likert 8-10) increased from 53.8% to 72%. Although perceived benefit ratings declined slightly (from 73.1% to 56%), the series became nearly 15% of the top three resources used on call by residents. Qualitative feedback praised the series as “concentrated, high-yield information” and noted its convenience and value as peer-led content.

DISCUSSION

Our mini-lecture series demonstrates the potential of concise, peer-driven educational tools in radiology training. Its succinct format, clinical relevance, and accessibility make it particularly well-suited for on-demand learning during high volume call. The modest decline in perceived benefit may reflect limitations such as a small initial lecture library. With thoughtful refinement, this model offers a scalable and high-impact supplement to traditional education - quick, targeted, and brewed for the modern radiology trainee.

T5A-QI-7 REDUCING REPEAT RATES IN CT PULMONARY ANGIOGRAPHY (CTPA): STRATEGIES FOR OPTIMIZING IODINE CONTRAST ENHANCEMENT

Zahra Alyani Nezhad, MSc (*Presenter*)
Giuseppe V. Toia, MD, MS (*Abstract Co-Author*)
Rachel Bladorn, BS, RT (*Abstract Co-Author*)
Carrie Bartels, RT (*Abstract Co-Author*)
Kelsey Schluter, BS (*Abstract Co-Author*)
Jeffrey P. Kanne, MD (*Abstract Co-Author*)
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*)

INTRODUCTION

Historically, our large adult CT pulmonary angiography (CTPA) repeat rates were 11.2% from 2017-2019. We re-evaluated CTPA performance in 2023 and found our suboptimal rate increased to 22%. We found the most common issue was inadequate contrast enhancement due to challenges with bolus tracking. This project presents our institution’s data driven approach for optimizing CTPA.

METHODS

Multiple data informed protocol changes were made from 2023-2025. First, the mean pulmonary artery (PA) CT number and the time difference between scan delay and injection duration were retrospectively extracted from CTPA exams using a fixed contrast volume of 86 ml. The scan timing that produced peak PA enhancement relative to injection duration was selected as a fixed delay for prospective trials against our existing bolus tracking based protocol. To assess effectiveness, PA enhancement in the trial group was compared to that of bolus tracking in a large patient cohort using Mann-Whitney test. The trial yielding the fewest poor enhancements (<250 HU) was adopted as the new institutional protocol. Patients scanned under this protocol were evaluated for suboptimal enhancement, and in cases requiring repeat scans with bolus tracking, the tracked delay was compared to the fixed trial delay. Additional trials were performed with varying contrast volumes and delays and analyzed in like manner.

RESULTS

In the retrospective analysis of 44 patients, maximum pulmonary artery (PA) enhancement consistently occurred 2.5 to 3 seconds after the completion of contrast injection. Based on these findings, prospective trials were conducted using scan delays of 2 seconds (n = 37) and 4 seconds (n = 30) after weight-based injection completion. The 2-second delay resulted in a 5% overall rate of poor enhancement, while the 4-second delay resulted in a 36% poor enhancement rate. The 2-second trial also showed a statistically significant increase in PA enhancement compared to bolus tracking, as determined by a Mann-Whitney U test ($P < 0.05$). Despite promising trial results, institution-wide implementation of the 2-second + injection duration scan delay led to suboptimal rate of 44%. We removed weight-based volumes and delays to create a more robust SOC protocol. This change resulted in only 5% suboptimal enhancement rate.

DISCUSSION

Through this project we determined a robust protocol cannot include technologist changing scan delays at scan times. Collaboration between radiologists, scientists, and technologists was critical to identifying and addressing the root causes of repeated CTPA exams. The data driven nature of our approach prevented early termination of our project. During the iterative trials, all examples of poor image quality were blamed on our trial while our data consistently showed improvements. This project resulted in the reduction of repeated CTPA exams at our institution.

T5A-QI-8 SUSTAINABLE ULTRASOUND SOLUTIONS: PIONEERING GREEN PRACTICES IN IMAGING

Kelly Albury, RVT (*Presenter*)
David T. Fetzer, MD (*Abstract Co-Author*)
Crystal H. Bruce (*Abstract Co-Author*)
Kim Pongsatianwong, RDMS, RVT (*Abstract Co-Author*)
Skye Smola, RDMS, RVT (*Abstract Co-Author*)

INTRODUCTION

Ultrasound (US) is recognized as the most environmentally sustainable imaging modality, with significantly lower carbon emissions than computed tomography (CT) or magnetic resonance imaging (MRI). In addition to its safety and accessibility, US offers diagnostic capabilities that increasingly rival those of CT and MR. This quality improvement project aimed to expand access to advanced, low-carbon diagnostic imaging by implementing four specialized US service lines over a three-year period: elastography, contrast-enhanced ultrasound (CEUS), musculoskeletal (MSK) imaging, and fat quantification.

METHODS

From January 2022 to December 2024, a phased implementation of four US service lines was conducted across multiple sites. Key interventions addressed three primary challenges: (1) installation of new technology across diverse vendor platforms, (2) specialized sonographer training and competency validation, and (3) provider engagement and Electronic Health Record (EHR) order workflow support. Retrospective EHR reports were used to gather imaging volumes. Carbon emission estimates were derived from published emission data per modality. Outcomes were measured in patient volume growth and estimated CO2 emission reductions assuming the US study replaced an equivalent CT or MRI.

RESULTS

All four US service lines demonstrated sustained year-over-year growth, with total patient volume increasing 81.3% from 2022 to 2024. Elastography volumes rose from 586 to 1,123 exams (91.6% increase), while CEUS and MSK rose 69% and 46.8% respectively. The first year of fat quantification included 531 patients. The total carbon emissions for MR elastography exams from 2022 to 2024 is 1,231% more than US elastography emissions, despite the volume of US elastography exams being more than double MR. Diagnostic performance was supported by literature showing equivalent or superior sensitivity and specificity of US techniques compared to MR and CT.

DISCUSSION

The expansion of advanced US services successfully improved access to high-quality, sustainable imaging alternatives to CT and MRI, as shown by progressive increase in US order volumes. These service lines provided diagnostic accuracy comparable to conventional modalities, while offering improved patient safety and reducing environmental impact. Implementation challenges were overcome through targeted solutions, including technology integration, structured training, and ordering pathway optimization. The program has since served as a model for similar efforts at peer institutions. Continued innovation is planned, including the recent launch of a US-based endometriosis screening protocol. This quality improvement initiative highlights the opportunity to align clinical excellence with environmental stewardship through strategic imaging service expansion.

T5A-QI-9 QI PROJECT SIMULATION FOR RESIDENTS - EFFECTIVE AND EFFICIENT!

Nadja Kadom, MD (*Presenter*)
Susan Reich (*Abstract Co-Author*)
Zachary Grunewald (*Abstract Co-Author*)
Lisa Reynolds (*Abstract Co-Author*)
Patricia Balthazar, MD, MPH (*Abstract Co-Author*)

INTRODUCTION

Considering increasing clinical volumes and staffing shortages, radiologists have less time to mentor radiology residents through the completion of a quality improvement (QI) project. Here, we developed and delivered a "QI Simulation Bootcamp" to equip our residents with the knowledge and skills required to achieve Level 4 (out of 5) competency in Systems-Based Practice, as defined by the ACGME Diagnostic Radiology Milestones.

METHODS

We gained permission to adapt a QI Project Simulation from a Healthcare Yellow Belt course at our institution. The adaptations included expansion of scope from the start of a QI project (identifying a project) and adaptation of content toa. Radiology rather than a clinical scenario. The session included a blend of education followed by simulated practical application such as process mapping, voice of the patient, identifying gaps and opportunities, developing measures, developing and prioritizing improvement interventions, analyzing run charts, developing an implementation plan, and project hand-off followed by celebration of success. We developed a pre- and post-session survey with 20 items to assess session impact on knowledge and attitudes and to solicit improvement suggestions for the course.

RESULTS

The pilot QI Simulation Bootcamp was delivered as a 3-hour afternoon session with in-person participation of 26 radiology residents. The pre- and post-session knowledge assessment showed improvement ranging from -55.5 to +280.7 %. Three attitude questions showed improvements ranging from 13.4 to 68.8 %. 100% of participants indicated they wanted this pilot session permanently integrated into our residency program.

DISCUSSION

We showed feasibility of efficiently and effectively enabling our residents to meet level 4 of the ACGME requirements for Quality Improvement, as well as demonstrate increase in knowledge and attitudes. Our next step is a grant funded initiative (Association of Academic Radiology Strategic Alignment Grant 2025-2026) to enable the adoption of this program by others.

T5B-QI-1 CREATION OF A PROCEDURAL PEER LEARNING PROGRAM IN RADIOLOGY

Ashok Srinivasan, MD (*Presenter*)

INTRODUCTION

Peer learning is increasingly replacing peer review in diagnostic radiology due to the nonjudgmental nature of the peer learning process with less emphasis on individual errors and more stress on investigating system errors and creating learning opportunities. While this is the norm in many diagnostic radiology subspecialities, there is no well defined structure for peer learning for radiology procedures. Therefore, the goal of our initiative was to create a procedural peer learning program with the following emphasis: -1. To present complications arising from image guided procedures in Radiology in a forum of proceduralists across all divisions with a focus on peer learning (including recognition of system and process issues)2. To facilitate inter-divisional dialogue on best practice principles pertaining to image guided procedures

METHODS

While diagnostic peer learning typically focuses on individual subspecialties (e.g., neuroradiology, MSK etc.), we strongly believed that there are sufficient learning opportunities in procedural radiology that crosses divisions and service lines. Therefore, we created one procedural peer learning conference that spanned all divisions and service lines with a cadence of 2-3 meetings each year. For each meeting, two divisions/service lines were recruited to present procedural learning opportunities and all procedural areas were invited to the one hour Zoom meetings. Each presentation was designed to be 15-20 minutes long followed by a 10 minute discussion. The cases were submitted in advance to the moderator in a PPT format at least one week prior to the scheduled meeting.

RESULTS

The procedural areas participating in the Procedural Peer learning conference since its inception include Neuroradiology, MSK, VIR, Chest, Body, Breast and Pediatric Radiology. The types of issues that came to light from these conferences included skill based, knowledge based, miscommunication, equipment failure, workflow or process gaps. Each Zoom meeting was attended by members from at least 3 different procedural areas that allowed for robust discussions and recognition of common issues that crossed divisions/service lines. Some of the improvement efforts that have resulted from these conferences include revisions to anticoagulant policies, streamlining case requests and increased recognition of early complications during procedures.

DISCUSSION

Creation of a Peer learning conference focused on Procedural services in Radiology has allowed for increased learning opportunities spanning different divisions/service lines with lessons that can then be applied in their individual areas. This allows for 'not reinventing the wheel' and improving patient care quality and safety in the procedural domains.

T5B-QI-2 TWO KEY PERFORMANCE INDICATORS TO ENHANCE OUTPATIENT EXAM PRODUCTIVITY IN RADIOLOGY DEPARTMENTS: AN EXPERIENCE ACROSS 20 HOSPITALS

Fernando B. Ferreira, MD, PhD (*Presenter*)
Danilo Manuel C. Costa, MD, MBA (*Abstract Co-Author*)
Raquel A. Moreno, MD (*Abstract Co-Author*)
Paulo G. Lopes, MD (*Abstract Co-Author*)
Yuri C. Neves, PhD (*Abstract Co-Author*)

INTRODUCTION

The increasing demand for imaging exams and revenue growth pressures radiology services to adopt more efficient management strategies. To maintain quality and agility amid rising volumes, the use of performance indicators (KPIs) becomes essential. In this context, two strategic KPIs are proposed: Scheduling Lead Time (SLT) , defined as the interval between the moment a patient schedules an exam (via in-person appointment, call center, chat, or online self-scheduling) and the scheduled exam date; and Operational Capacity (OC) , defined as the proportion of outpatient appointment slots made available in relation to the equipment’s maximum capacity, assuming 16 hours of daily operation and the average slot duration for that modality.

METHODS

A total of 20 hospitals, collectively performing approximately 80,000 outpatient imaging exams per month, participated in this study with the goal of achieving a 15% increase in outpatient volume in 2024. To support this growth while maintaining patient satisfaction, two KPI targets were established: an SLT under 2 days and an OC below 80%. Based on the KPI results, different strategies were applied. When the SLT was off target and the OC was low, the strategy was to increase the number of available slots for outpatient scheduling. If the OC was high, actions focused on optimizing scheduling by reducing slot duration through protocol adjustments, considering the acquisition of acceleration software for MRI, or expanding technological capacity by acquiring additional imaging equipment. When the SLT was on target, regardless of the OC, the focus shifted toward increasing the volume of exam requests and scheduling. This was achieved through marketing initiatives, strengthening relationships with referring physicians, and improving the conversion rate from requested to scheduled exams. These measures aimed to sustain growth while maintaining operational efficiency and enhancing patient experience.

RESULTS

The mean number of exams per hospital increased from 39,030 in 2023 to 48,053 in 2024 ($p < 0.001$). The overall average growth in exam volume was 50.4%, with only two hospitals not demonstrating an increase during the period. SLT also improved significantly, decreasing from an average of 4.4 days in 2023 to 1.4 days in 2024. Operational Capacity remained stable, averaging approximately 75%.

DISCUSSION

The adoption of SLT and OC as performance indicators improved the management of radiology services. SLT reached the target, OC remained within optimal levels, and actions such as expanding scheduling and technological capacity led to exam volume growth beyond expectations. These outcomes reflect gains in operational efficiency, improved patient experience through shorter wait times, and increased revenue.

T5B-QI-3 BRIDGING THE KNOWLEDGE GAP: TRAINING RESIDENTS TO IDENTIFY AND UNDERSTAND THORACIC MEDICAL DEVICES

David A. Mata, MD (*Presenter*)
Joshua Strobel, MD (*Abstract Co-Author*)
Carlos H. Previgliano, MD (*Abstract Co-Author*)
Carolina Soto-Davila, MD (*Abstract Co-Author*)
Guillermo P. Sangster, MD (*Abstract Co-Author*)

INTRODUCTION

The chest radiograph (CXR) is a well-established imaging modality that is widely used to check for a variety of thoracic abnormalities such as pneumonia, pneumothorax, and pleural effusion. On average, 236 CXRs per 1000 patients per year are performed, accounting for 25% of the annual total numbers of diagnostic imaging procedures. In the US, over 70 million CXRs are performed each year for immediate and late-onset complications of various medical conditions, such as heart surgery or respiratory infections. Due to the large number of radiographs obtained each day, there can be substantial delays between the time a CXR is obtained and when it is interpreted by a radiologist. This PQI project aimed to enhance the resident's ability to identify and understand thoracic medical devices using radiological imaging. The goal was to increase familiarity with device appearance, positioning, use, and common complications, reducing dependence on radiologists' reports and expediting patient care.

METHODS

99 participants initially completed a pretest to assess baseline knowledge of thoracic medical devices. An informative booklet on the device information was then provided. A second test was administered to 79 participants after reviewing the booklet to evaluate improvements.

RESULTS

Significant improvement in the participant's ability to correctly identify thoracic medical devices, understand their uses, and recognize common complications. On the pretest, there where 16/40 commonly missed questions; on the 2nd test this number decreased to 3/40, translating to a 32.5% of improvement. A significant improvement was also noted in the participant's ability to identify MRI compatible devices, expediting patient care. When comparing the 2 tests taken: on the pretest, 83.7% participants answered to not knowing where to look for MRI safety information. After reviewing the booklet, this number went down to 43.1%, a 40.6% improvement.

DISCUSSION

Targeted educational interventions, such as the distribution of a comprehensive eBook on thoracic medical devices, effectively enhance residents' knowledge on the topic. This approach not only improves the ability to promptly address complications and misplacements but also minimizes dependency on radiologists' final reports. The CXR will continue to be one of the most frequently requested radiological studies in any type of patient population, it is important for every medical specialty to become familiar with the medical devices commonly encountered within their practice. As a follow up of this PQI; we created an e-book containing relevant information regarding most medical devices in the thorax. This e-book will be shared across the hospital with the hopes of Bridging the knowledge gap and better understanding the thoracic medical devices.

T5B-QI-4 IMPROVING QUALITY OF CT CORONARY ANGIOGRAPHY REPORTING USING A STRUCTURED CHECKLIST AND CAD-RADS INTEGRATION: A QUALITY IMPROVEMENT INITIATIVE

Jainam A. Doshi, MBBS, MD (*Presenter*)
Natisha P. Arora JR, MD (*Abstract Co-Author*)
Venkatesh Somu JR, MD (*Abstract Co-Author*)

INTRODUCTION

Accurate and complete CT Coronary Angiography (CTCA) reporting is essential for optimal patient management. Variability in reporting styles, omission of key findings, and inconsistent communication with clinicians were identified as major challenges. This quality improvement (QI) initiative aimed to enhance the quality, standardization, and clinical relevance of CTCA reports by implementing a structured reporting checklist combined with CAD-RADS classification

METHODS

A retrospective audit of CTCA reports over three months was performed to assess baseline reporting practices. Common deficiencies included incomplete description of plaque characteristics, inconsistent stenosis grading, and lack of CAD-RADS assignment. A structured checklist was developed, emphasizing systematic reporting of coronary anatomy, stenosis severity, plaque characterization, extra-cardiac findings, and CAD-RADS classification. Radiologists were trained on the checklist. Reports generated in the three months post-implementation were analyzed. The primary outcome measured was the percentage of reports that comprehensively included all checklist elements.

RESULTS

A total of 100 reports were analyzed before and after checklist implementation. Completeness of plaque characterization increased from 65% to 95%. Stenosis severity quantification improved from 70% to 98%. CAD-RADS assignment rose significantly from 10% to 95%. Reporting of extra-cardiac findings improved from 60% to 90%. Overall report standardization and clinical clarity were notably enhanced. No increase in reporting time was observed.

DISCUSSION

Implementing a structured checklist with CAD-RADS classification significantly improved the quality, completeness, and standardization of CTCA reporting. This initiative demonstrates that systematic quality improvement strategies can optimize imaging communication, enhance clinical decision-making, and align reporting practices with international standards.

T5B-QI-5 COMPARISON OF ARTIFICIAL INTELLIGENCE-BASED TOOLS FOR AUTOMATIC LABELING OF RADIOLOGY REPORTS

Rahul Pemmaraju (*Presenter*)
Jeffrey Tumminia (*Abstract Co-Author*)
Steve Higgins (*Abstract Co-Author*)
Alberto F. Goldszal, PhD, MBA (*Abstract Co-Author*)

INTRODUCTION

The rapid progress of artificial intelligence in radiology has necessitated the need for institutions to continuously benchmark, compare, and monitor these algorithms in their practice. Such evaluation requires the development of curated, labeled datasets. However, generating these datasets is often a costly and time-consuming endeavor, as such labeling is typically done manually by physicians. Recent advancements with large language models (LLMs) promise to alleviate these issues by enabling the automatic extraction of findings from radiology reports. In this work, we explore methods for efficiently generating a labeled dataset of chest x-rays for the detection of 14 different radiographic findings.

METHODS

10,000 curated chest x-ray reports, anonymized to remove all PHI information, were used in this study. Report impressions were extracted and labeled for the presence of 14 observations. We compared GPT-4o, a commercially available, general-purpose generative LLM, and ChexBERT, an LLM trained narrowly for chest x-ray report

labeling, for our automatic report labeling task. We further explored how prompting strategies like few-shot prompting (FSP) and chain-of-thought prompting (COT) affect the performance and cost of GPT-4o.

RESULTS

On a preliminary set of 1000 x-ray reports, GPT-4o with FSP achieved the highest average F1 score of 0.991 while ChexBERT achieved an F1 score of 0.981. FSP was the most effective prompting strategy for GPT-4o, as zero-shot prompting (ZSP) yielded an F1 score of 0.987, and a combination of COT and FSP yielded a score of 0.990. ZSP proved the most economical prompting strategy costing $0.74/1000 reports, while adding FSP and COT raised the rates to $1.22/1000 reports and $2.50/1000 reports, respectively.

DISCUSSION

In this work, we compared GPT-4o, an easily-accessible commercial LLM, with an open-source LLM developed for the medical domain, and showed that GPT-4o yields the best performance. We further compared popular prompting strategies for GPT-4o and showed that few-shot prompting enables highly accurate labeling at low monetary cost, suggesting its utility for automatic report labeling for large datasets. While several commercial and open-source LLMs have been released, we limited our comparison set to two easily accessible, representative models that have shown strong performance on medical tasks. We were also limited in this project by the amount of labeled reports to analyze, but will manually annotate additional reports to increase the size of our evaluation dataset.

T5B-QI-6 PRE-CLERKSHIP INTEGRATION OF RADIOLOGY EDUCATION IN MEDICAL SCHOOL CURRICULUM

Katherine Liu, MD (*Presenter*)
Lyanne Lu (*Abstract Co-Author*)
David S. Chen, MD (*Abstract Co-Author*)
Benjamin Carney, MS, MD (*Abstract Co-Author*)
Jasjeet Bindra, MBBS, MD (*Abstract Co-Author*)
Maryam Shahrzad, MD (*Abstract Co-Author*)

INTRODUCTION

The pre-clerkship curriculum at our institution follows an organ-based structure, where blocks focus on individual organ systems, integrating anatomy, physiology, pathology, and clinical skills. Radiology is vital to patient care, yet imaging interpretation and its cost-effective use receive limited discussion until clerkships. This creates a gap in the development of skills emphasized by the Association of American Medical Colleges (AAMC) core competencies, including patient care, medical knowledge, and systems-based practice. To address this, we developed standardized radiology workshops that align with the pathology and clinical context of our organ-based curriculum.

METHODS

Based on the existing curriculum framework and fit for pre-clerkship students, abdominal imaging was selected for integration. This student-driven project was developed in collaboration with radiology faculty and School of Medicine curriculum staff. We created two hour-long team-based learning (TBL) sessions on abdominal X-ray (KUB) and CT abdomen/pelvis (CTAP), each paired with a pre-recorded lecture covering the modality, common indications, anatomy, and a search pattern. During in-person TBLs, students applied these skills to clinical cases in teams of five to seven students, facilitated by radiology faculty and trainees. Pre- and post-session surveys assessed changes in student confidence in radiologic interpretation using a numeric scale with 1 representing "not very comfortable" to 5 representing "very comfortable."

RESULTS

Pre-session confidence values in all assessed skills ranged from 1.42 to 2.02. Post-session surveys showed increased confidence across all domains, with improvements ranging from +1.10 to +1.72. Students reported greater comfort identifying anatomy, applying search patterns, and interpreting common findings in both KUBs and CTAPs. Students' qualitative feedback valued the small-group, case-based format and real-time guidance from facilitators, and they expressed interest in expanded radiology integration across the curriculum.

DISCUSSION

This project highlights the success of early radiology education into pre-clerkship learning through student initiative, inter-specialty collaboration, and flexible curriculum design. Although limited to one cycle of observation due to scheduling constraints, the sessions were formally adopted into the curriculum. Growth in student confidence suggests meaningful short-term impact, but reinforcement of the skills through repeated practice is needed. Future directions include earlier integration into anatomy and other organ-system blocks, and the use of diagnostic mystery cases in surveys to enable more objective assessment of learning outcomes.

T5B-QI-7 LEVERAGING A MULTIDISCIPLINARY TEAM TO REBUILD A RESILIENT AND HIGH QUALITY PEDIATRIC RADIOLOGY WORKFORCE

Sheila C. Berlin, MD (*Presenter*)
Pauravi S. Vasavada, MD (*Abstract Co-Author*)
Michael Wien, MD (*Abstract Co-Author*)

INTRODUCTION

A severe shortage of pediatric radiologists (PR) challenges hospitals to provide sustainable high quality imaging care for children. The shortage is projected to worsen with fewer graduating fellows and increasing retirements. In October 2022, our team of board-certified PR at a 288-bed children's hospital within an adult hospital was set to decrease from 5 FTE to 2 FTE. To meet our critical staffing needs for onsite daily work and after-hours call, we created a multidisciplinary hybrid team workforce. The purpose was to maintain the quality metrics of timely report TAT, low discrepant read rate, high success rate for intussusception reduction, and improve pediatric radiologist job satisfaction.

METHODS

This project was undertaken from November 2022 through November 2024 at a large academic medical center providing pediatric imaging at 21 hospitals and 50 outpatient facilities. We identified the work shift coverage gaps and associated volumes, then identified qualified candidates for a multidisciplinary hybrid team. New PACS worklists segregated high complexity US, CT and MR and inpatient exams from outpatient exams. Onsite coverage gaps were filled with two locums PR. Overnight call gaps were filled with 3 adult radiologists who completed procedural training by the PR in fluoroscopy; PR were available for imaging review for after-hours procedures by Epic Secure chat with image sharing function. Routine and outpatient STAT exams were read by a PR returned from retirement and 4 fellowship-trained MSK and ED radiologists. PR were available for real time weekday consults by PACS chat. ED radiologists provided final reads on all ED pediatric imaging from 6pm to 7am. We tracked report TAT, discrepant reads in our electronic peer learning system (including radiologist/provider-identified and randomly selected cases), success rate for image-guided intussusception reduction and surveyed the PR using a "stay interview" to assess engagement.

RESULTS

We maintained our target TAT of > 90% of all STAT imaging reported in < 45 minutes. Discrepant read rate remained < 1.5% with no serious safety events. Our collective rate of successful intussusception reduction was 91%; all 10/10 enema reductions performed by the non-PR on-call radiologists were successful. Job satisfaction improved during the project with successful retention of all three (1 FT, 2 PT) PR and successful recruitment of three additional PR.

DISCUSSION

Using the core principles of high reliability organizations of "commitment to resilience" and "preoccupation with failure," we proactively prepared for and responded to a critical loss of PR. With the Kaizen rule of "keep an open mind to change," we developed a competent collaborative multidisciplinary hybrid radiologist workforce that prevented the disruption of quality pediatric imaging care, supported PR engagement and attracted three new PR to join our team.

T5B-QI-9

STANDARDIZED FLOW PROTOCOL FOR CORONARY CT ANGIOGRAPHY: ENHANCING EFFICIENCY AND RADIOLOGIST PRODUCTIVITY THROUGH RISK-BASED PATIENT STRATIFICATION

Hamilton Shoji, MD (*Presenter*)
Gabriel Figueiredo, MD (*Abstract Co-Author*)
Adriano Tachibana, MD, MBA (*Abstract Co-Author*)

INTRODUCTION

Problem Description: Coronary artery disease remains a leading cause of morbidity and mortality worldwide. Coronary CT angiography (CCTA) is an essential non-invasive tool in its assessment, and requires relative low and stable heart rates (HR) for optimal image quality. At our institution, HR management for CCTA is centered on the actual radiologist on the control room, limiting its reporting potential and frequently leading to delays. Available Knowledge Accurate HR control (<60 bpm) enhances diagnostic quality in CCTA. However, workflow variability and overdependence on radiologists for routine cases lead to delays and increased operational burden. Purpose The purpose of this study was to evaluate a structured, HR-stratified protocol aiming to reduce unnecessary radiologist involvement, improve operational efficiency and maintain patient safety.

METHODS

Context and Intervention Conducted at a high-volume diagnostic center, the intervention introduced a standardized protocol using clinical triage and predefined HR-based management pathways for low-risk patients undergoing CCTA. Study of the Intervention: A comparative pre-post study was conducted across two periods: baseline (January-March 2024) and post-intervention (May-October 2024). April was excluded due to staff training. Measures/Metrics: Key metrics included frequency of radiologist calls, time per call, total scan throughput, repeat examinations due to inadequate HR control, adverse events, and qualitative team feedback. Analysis: Quantitative data were analyzed to assess significant differences pre- and post-intervention. Data variability over time and safety endpoints were also evaluated.

RESULTS

The intervention consisted of a triage questionnaire and age-based criteria: patients <65 years with no risk factors followed predefined pharmacological pathways without radiologist input; all others were referred to the radiologist. During the baseline period (Jan-Mar), 1,404 CCTA exams were performed; in the post-intervention period (May-Oct), 3,413 exams were completed. The average number of incoming radiologist calls per exam decreased from 2.38 to 1.75 (?26.5%, $p < 0.001$), while outgoing calls dropped from 0.55 to 0.46 per exam (?16.7%, $p < 0.001$), indicating improved workflow efficiency. However, the repeated exam rate increased from 0.28% to 0.64% (?126.3%, $p < 0.001$), raising concerns about quality control. We did not report any adverse events in both pre and post intervention periods.

DISCUSSION

Limitations : Single-center design and analysis based on a short time period. Conclusions : The protocol significantly reduced radiologist involvement, enhancing operational efficiency. However, the rise in exam repetition rates highlights the need for refinements in risk stratification and staff training.

W2-QI-1 PESKY WORDING? RESISTANT PESTS: ENHANCING DIAGNOSTIC AND ANTIMICROBIAL STEWARDSHIP THROUGH RADIOLOGY REPORT LANGUAGE MODIFICATION, A QI INITIATIVE

Ian Rodriguez (*Presenter*)
Pritesh Patel, MD (*Abstract Co-Author*)
Kurt Johnson (*Abstract Co-Author*)

INTRODUCTION

Antimicrobial resistance (AMR) is a global health crisis responsible for an estimated 700,000 deaths annually, projected to 10 million by 2050. The most significant contributor to AMR is the inappropriate use of antibiotics. One under-recognized cause of this is the language used in radiology reports, which can strongly influence downstream clinical decisions. At our institution, radiology reports frequently include a recommendation for urinalysis (UA). This language has the potential to trigger unnecessary urine testing and empiric antibiotic prescribing for asymptomatic bacteriuria, undermining antimicrobial stewardship efforts. In 2024, 2761 UA were recommended by our reports. Thus, the purpose of this quality initiative was to change radiology report language to help reduce the recommendation of ordering UA after reviewing current UTI (Urinary Tract Infection) guidelines in conjunction with our colleagues in Infectious Disease.

METHODS

The project was conducted at a large tertiary academic medical center with a radiologist, a radiology quality improvement nursing director, and an infectious disease physician. First, the preferred guidelines for our infectious disease department were reviewed: KDIGO (Kidney Disease Improving Global Outcomes) UTI guidelines which stated that "the diagnosis of UTI is made by the presence of typical symptoms" and that the patient history is the key method of diagnosis, not imaging or laboratory tests (UA). Another set of guidelines from the IDSA (Infectious Disease Society of America) for CA-UTI (catheter associated UTI) stated similar language. Based on this, a proposed solution to change radiology dictations from "recommend urinalysis" to "correlate with clinical symptoms" in the presence of bladder wall thickening was agreed upon. Next, an educational intervention for radiologists was delivered through lectures, faculty meetings, and internal communications. This intervention showed the background of AMR, downstream effects of radiology report language, and the proposed solution. It was completed in a one-week timeframe at the end of January 2025. Using m-Power, a retrospective, post intervention study compared radiology reports over a three-month period from Feb 1, 2025 - April 30, 2025 (immediately after the intervention and stopped due to RSNA submission deadline) to the same timeframe in 2024. Text mining of CT reports identified when a UA was recommended. The primary metric was the number of abdominal/pelvic CT reports that recommended UA.

RESULTS

Following intervention, UA recommendations by radiologists decreased by 60% in 2025 over the same time frame in 2024.

DISCUSSION

By a simple change in their report verbiage, radiologists can support institutional and global efforts in antimicrobial stewardship.

W2-QI-2 ENHANCING PATIENT EXPERIENCE IN CARDIAC CT; IMPROVING AWARENESS AND MANAGING MEDICATION SIDE EFFECTS

Rachelle Rachmat, FRCR, MBChB (*Presenter*)
Sabeeh Syed, MD, BSc (*Abstract Co-Author*)
Carolyn Horst, MBBS, PhD (*Abstract Co-Author*)
Sze Mun Mak, MBBS,FRCR (*Abstract Co-Author*)
Giulia Benedetti, MD (*Abstract Co-Author*)

INTRODUCTION

CTCA often requires the use of pre-medications and can be a daunting exam when patients are not prepared for it. We aimed to assess patient satisfaction and understanding of the procedure, with a focus on prior understanding of pre-medication, and to improve our service and enhance patient experience where necessary

METHODS

We conducted a quality improvement project at St Thomas' Hospital in London. We developed a 14-question questionnaire with input from nurses and Cardiac-CT consultants to evaluate whether patients felt they had sufficient information about CTCA and understood its purpose. We also assessed whether patients were aware they might receive pre-medications during CTCA, whether they received it, and whether they experienced any side effects. Additionally, staff feedback and the overall satisfaction rate (rated on a scale of 1 to 10) were collected. The survey was distributed to patients undergoing CTCA between January and March 2022. Results were analysed using Microsoft Excel.

RESULTS

We collected 74 answers. Eighty-eight percent of patients felt adequately informed about the CTCA procedure and 99% understood its purpose. Most patients (82-92%) were aware they might receive medications, and understood their potential side effects. Seventy-eight percent of patients undergoing CTCA received glyceryl trinitrate spray, of whom 78% experienced headache and 71% noted that prior advice to bring paracetamol would have been beneficial. All patients (100%) praised staff interactions. High satisfaction was reported, with a mean score of 9.75 out of 10.

DISCUSSION

The findings highlight strong patient satisfaction and excellent staff performance. However, the frequent occurrence of headaches following glyceryl trinitrate spray administration highlights an opportunity to improve the patient experience. Updating patient information leaflets to recommend bringing paracetamol or informing patients about the availability of paracetamol on-site could enhance experience in cardiac CT imaging. Limitations of the survey include underrepresentation of patients with disabilities.

W2-QI-3 COMPLIANCE OF PRE-PROCEDURE DOCUMENTATION FOR INTERVENTIONAL RADIOLOGY PROCEDURES

Andrew J.

Cantos, MD (*Presenter*)
Sophia Li (*Abstract Co-Author*)
Karen Fenicchia, RN, BSN (*Abstract Co-Author*)
Ashwani K. Sharma, MD (*Abstract Co-Author*)
Devang Butani, MD (*Abstract Co-Author*)

INTRODUCTION

Interventional Radiology (IR) is a multifaceted subspeciality that performs a wide array of minimally invasive procedures, including vascular and non-vascular interventions. Pre-procedure documentation is a vital component of the procedure process, and its benefits include identifying potential procedural risks, facilitating communication between the team, and optimizing procedure outcomes and patient safety. However, despite its importance, there can be variable compliance with its performance, ranging from time constraints or staffing issues, increased work burden, new workflows or processes, or poor training. This project aimed to improve compliance with pre-procedure documentation to improve patient safety and outcomes.

METHODS

This project was performed by the division of Interventional Radiology at a tertiary care, large academic institution. Following a joint commission survey, attention was focused on pre-procedure documentation in IR. Specifically, the areas monitored included: pre-procedure history and physical (H/P) / day of procedure (DOP) update and all components of the provider assessment (MD assessment). Over 19 months (October 2023 to April 2025), compliance with all pre-procedure documentation was recorded and shared in monthly quality improvement conferences. Several interventions were performed, including adding compliance of quality metrics to the ongoing professional performance evaluation (OPPE), monthly reporting in IR quality meetings, recurrent audits with a feedback loop, re-education with departmental policies and workflows, and cultural adjustments to speaking up.

RESULTS

During the 19 months, random audits were performed on nursing and physician documentation. Over the initial 8-month audit period (October 2024 to May 2024), an average of 43 monthly audits were conducted. Compliance with pre-sedation assessment was 73%. Over the following 11 months (June 2024 to April 2025), the post-intervention compliance to pre-sedation assessment was 92%, an increase of 26%. For the MD assessment in the pre-intervention group, 5% were missing altogether, and 20% were missing loose/broken teeth. In the post-intervention group, the missing assessment was reduced to 2%, and only 3% missing loose/broken teeth. H/P and DOP were present in 94% and 91% of the pre and post-intervention groups, respectively.

DISCUSSION

Compliance with necessary pre-procedure documentation is vital to ensure patient safety and high-quality patient outcomes. Our project saw an increase in pre-sedation assessment compliance from 73% to 92%. The driving factors for the low compliance in the assessment were the assessment missing altogether or the loose/broken teeth section. Continued efforts to promote adherence to policies geared at patient safety are vital for improving timely access to IR services.

W2-QI-4 COGNITIVE ERRORS IN RADIOLOGY: PATTERNS, CONTRIBUTING FACTORS, AND MITIGATION STRATEGIES

Charanjeet Singh, MD (*Presenter*)
Mamta Gupta, MD (*Abstract Co-Author*)

INTRODUCTION

Cognitive errors are a leading cause of diagnostic inaccuracies in radiology, where complex anatomy and subtle findings increase interpretive challenges. This study aims to identify the most common types of cognitive errors in abdominal imaging, explore contributing factors, and propose strategies for error reduction.

METHODS

A retrospective review was performed on imaging discrepancies identified through peer review and quality improvement conferences over 24 months in an academic radiology department. Discrepancies were classified into cognitive or perceptual errors. Cognitive errors were further categorized by type, including satisfaction of search, anchoring bias, premature closure, and framing bias. Contributing factors such as workload, timing, case complexity, and clinical information availability were analyzed.

RESULTS

Of about 1000 reviewed imaging discrepancies in the ED, abdominal, and chest sections, about 385 were attributed to cognitive errors. The most frequent error types were satisfaction of search, anchoring bias, and premature closure. Errors were more common during high-volume shifts and evening/night hours. In about 64% of cases, incomplete clinical information or framing bias influenced interpretation. Notably, cognitive errors led to clinically significant impacts in 38% of cases, including delayed cancer diagnosis or missed acute pathology. More accurate and additional numbers will be shared with the final submission

DISCUSSION

Cognitive errors are a prevalent and impactful contributor to diagnostic inaccuracies in radiology, driven by cognitive biases and workflow-related pressures. Strategies to mitigate these errors include structured reporting templates, cognitive forcing checklists, enhanced peer review, decision support tools, and bias-awareness education. Targeted interventions addressing both cognitive and systemic contributors are essential to improving diagnostic accuracy and patient outcomes in abdominal imaging. Case Examples To illustrate, a 65-year-old man undergoing CT for suspected diverticulitis. Initial interpretation identifies sigmoid inflammation; however, on retrospective review, a 2-cm hepatic lesion was overlooked due to satisfaction of search. Had a systematic liver review checklist been used, the lesion may have been detected earlier, prompting earlier oncologic workup. In another case, a 45-year-old woman with known gallstones underwent ultrasound for RUQ pain. The radiologist reported cholelithiasis but failed to identify a 1.5-cm hypoechoic mass in the pancreatic head. Anchoring bias on the known gallstones and omission of pancreas review led to a delayed diagnosis of pancreatic adenocarcinoma.

W2-QI-5 QUANTITATIVE DASHBOARD CREATION FOR BREAST IMAGING FELLOWSHIP STUDY VOLUMES: CORRELATING QUARTERLY FEEDBACK WITH IMPROVED STUDY VOLUME OUTPUT

Robert J. Weinfurtner, MD (*Presenter*)
Kimberly Funaro, MD (*Abstract Co-Author*)

INTRODUCTION

National benchmarks for breast imaging fellowship study volumes are not established. Our goal was to establish study volume benchmarks within our department based on prior fellow output in order to provide quarterly volume feedback to present fellows. It was hypothesized that this may motivate fellows to increase their volume output and help determine specific areas of need for intervention in cases of struggling fellows.

METHODS

A quantitative dashboard of fellow study volume was created at the beginning of the 2020-21 academic year. This included the prior 3 years of each individual fellows' study volume output using MagView reporting software to establish average number of studies (with standard deviation) performed in various screening, diagnostic, and procedural categories. Beginning in the 2020-21 academic year, fellows were shown their study volume numbers with comparison to prior fellow volumes on a quarterly basis during their one year fellowship. In order to determine if average study volumes were higher after the intervention, retrospective analysis was performed on study volumes for fellows at our institution from 2017-2024 comparing the pre-dashboard group (2017-20) to the post (2020-24). To correct for yearly institutional volume changes, total breast imaging department wrvus were evaluated to establish a correction factor for years lower than maximum. This was calculated as max-year wrvus/specific-year wrvus. Individual study volumes were multiplied by the yearly correction factor to establish corrected volumes. Statistical analysis was performed using unpaired t-tests.

RESULTS

Five fellows completed fellowship prior to dashboard implementation and 8 after. Total fellow study volume post-intervention increased 62% (p=0.003), while breast imaging department volume increased only 21%. After correction, fellow study volume was 41% higher post-dashboard (p=0.025). All imaging study volume increased 98% compared to only 18% for procedures. The corrected imaging volume increase of 60% was significant (p=0.013), while corrected procedure volumes were similar (p=0.898). Amongst individual study categories after correction, only screening mammogram and diagnostic mammogram volume was significantly increased (82% and 67% higher with p=0.015 and 0.007, respectively).

DISCUSSION

This study demonstrates that fellow study volume output increased after implementation of quarterly study volume reviews with comparison to prior fellows. This benchmarking allowed the fellow to strive for a specific quantitative target, and may have motivated the fellow to increase output. This was particularly true for imaging studies, an area where the volume is more fellow-dependent compared to procedures. These findings suggest quarterly quantitative volume feedback may lead to improved imaging study fellow output and allow targeted intervention.

W2-QI-6 CT DOSE OPTIMIZATION FOR THE ADULT ABDOMEN AND PELVIS

Melissa Curtis Fleming (*Presenter*)
Daisha Marsh, ARRT (*Abstract Co-Author*)

INTRODUCTION

Doses for some CT exams are often not optimized across the continuum of patient size, leading to unnecessarily high doses for some patients and poor or variable image quality for others. In partnership with the ACR Learning Network, we sought to decrease doses in the Computer Tomography Department of Diagnostic Imaging at a 263 bed, non-academic medical center, scanning approximately 23,000 patients per year, of which 26% are abdomen with pelvis scans. The purpose of our project was to simultaneously CT radiation dose in routine abdomen with pelvis exams while simultaneously increasing consistency in dose, adjusted for patient size, while preserving image quality.

METHODS

Using the Learning Networks A3 for Quality Improvement the team gathered and analyzed data, utilized cause and effect diagrams, addressed root causes, and performed rapid PDSA cycles. In addition to the A3, the radiologists also provided the team with scores on scan quality and dose. Several interventions were made in an attempt to optimize the dose including technologist education, and weight based protocols. These protocols included specific isocentering locations, rotation time and standard deviation parameters for our adult populations. Furthermore, the team worked with our radiologists to ensure that exams met diagnostic standards. Reports were generated through the ACR's Dose Index Registry to help capture effective diameter, variations of CTDI and CTDIVol, and dates and time of examination in order to cross reference for accuracy. Doses were analyzed and adjustments in protocol scan parameters were made and both dose and image quality were reevaluated in a stepwise fashion. In order to evaluate for dose changes, a best-fit exponential curve was applied to CT doses plotted by patient size, using CTDIvol (in mGy) for CT dose and effective diameter (in cm) for size. The mean percent difference from this target curve of groups of 10 cases were plotted as a run chart and evaluated for changes over time. Once a change was identified, before vs. after performance in both dose and variation were evaluated using a weighted mean of CTDIvol per 5-cm size categories and mean difference from target (both actual and absolute value and percent), respectively.

RESULTS

The evaluation period extended from 10/9/2024 to 4/18/2025. A significant change in dose outcomes was detected on 1/24/2025, following technologist training and protocol adjustments. Patient dose was reduced from a weighted mean of 7.5 mGy to 5.6 mGy (23% reduction) and the mean absolute difference from the target curve was reduced from 1.6 to 0.5 mGy.

DISCUSSION

Through a variety of interventions, we successfully reduced dose to a weighted mean of 5.6 mGy across patient sizes, and decrease variation in dose to 0.5 mGy mean absolute difference from size-based target curve, while maintaining adequate image quality.

W2-QI-8 OPTIMIZING APPROPRIATE IMAGING USE FOR RENAL STONE SURVEILLANCE: QUALITY IMPROVEMENT PROJECT

Kyanna Cusick, MD (*Presenter*)
Nelly Tan, MD (*Abstract Co-Author*)
Maria Zulfiqar, MD, MBBS (*Abstract Co-Author*)
Robert G. Paden, MS (*Abstract Co-Author*)
Mitchell Humphreys, MD (*Abstract Co-Author*)
Karen Stern (*Abstract Co-Author*)
Motoyo Yano, MD, PhD (*Abstract Co-Author*)

INTRODUCTION

Patients with a history of kidney stones undergo annual imaging to monitor for recurrence and complications. Our institution commonly uses radiographs (XR) and ultrasound (US), though these modalities have lower diagnostic accuracy than computed tomography (CT). XR/US may under-detect or mis-localize stones and provide limited complication assessment. Despite this, they remain widely used. Concerns about radiation exposure and perceived higher costs of CT contribute to continued use. Our aim was to reduce the number of radiographs used for renal stone surveillance by 27% (from 53 to 38 exams/month) by April 1, 2025, without increasing patient costs.

METHODS

A multidisciplinary team of urologists, radiologists, and physicists conducted a stakeholder analysis through meetings and email correspondence. Data on imaging exams were collected monthly from the radiology database. Key issues identified included concerns about cumulative radiation exposure, variability in imaging orders, lack of provider awareness of best practices, and perceived higher costs of CT. Interventions were selected using an impact/effort matrix. A new ultra-low-dose CT protocol (1.7 mSv, down from 5 mSv) was developed, offering radiation exposure comparable to radiographs (1 mSv) while preserving diagnostic quality. The protocol was tested in two patients. Best practice guidelines recommending CT over XR/US were communicated via departmental email. Cost comparison showed CT ($235) was slightly less expensive than XR/US ($237) due to fewer required visits.

RESULTS

Following implementation, monthly radiographs decreased by 79% from a baseline mean of 52 exams/month (SD 1.8) to 11 exams/month (SD 0) over two months. A two-tailed t-test confirmed statistical significance ($p = 0.0004$). The balancing measure, patient cost, remained stable, with CT costs equivalent to or lower than XR/US.

DISCUSSION

This quality improvement project demonstrated that a collaborative, data-driven approach can reduce reliance on low-yield imaging without increasing cost. Stakeholder engagement and adoption of ultra-low-dose CT technology were critical to success. Ongoing monitoring will ensure sustainability, with findings reported quarterly to stakeholders. This model may inform similar initiatives in other clinical areas balancing diagnostic value, safety, and cost.

W2-QI-9 OPTIMIZING WORKFLOW AND RESOURCE ALLOCATION: REDUCING THYROID FINE-NEEDLE ASPIRATION BIOPSY CANCELLATIONS AT A TERTIARY HEALTHCARE CENTER

Vibhuti Kalia, MD, FRCR (*Presenter*)
Ismina Papadhima (*Abstract Co-Author*)
Vishal Kalia, MD (*Abstract Co-Author*)

INTRODUCTION

Since the adoption of the Thyroid Imaging Reporting and Data System (TI-RADS), thyroid nodule biopsy requests have increased. At our center, patients referred for biopsy undergo a preliminary ultrasound followed by same-day fine-needle aspiration (FNA). However, many biopsies are cancelled after the ultrasound, resulting in inefficient workflow, resource waste, and longer wait times. To address this challenge, we conducted an audit to identify the primary reasons for cancellations and guide quality improvement interventions. Our initiative will aim to reduce same-day thyroid FNA cancellations by 90% by December 2025.

METHODS

We retrospectively reviewed all thyroid biopsies cancelled after same-day preliminary ultrasound from January 2022 to March 2024. Data was extracted from ultrasound reports on PACS and descriptive analyses were performed. The audit phase investigated nodule characteristics, cancellation reasons, and location of the initial ultrasound that prompted the biopsy request. Results were shared with radiologists, technologists, and administrative staff, whose feedback informed the intervention: for patients referred for biopsy with initial imaging performed at an external institution, a preliminary ultrasound is offered 2 weeks prior to the scheduled biopsy, instead of the same day. If preliminary ultrasound findings do not support biopsy, the FNA appointment is cancelled. Quarterly reaudits from January to December 2025 will guide future Plan-Do-Study-Act cycles. The primary outcome will be frequency of same-day biopsy cancellations. Process measures will include reasons for cancellations. Balance measures will assess burden on staff through informal feedback.

RESULTS

Of 605 thyroid biopsies scheduled from Jan 2022 to Mar 2024, 147 (24.3%) were cancelled after preliminary ultrasounds. 102 (69.4%) cases did not meet TI-RADS guidelines, 23 (15.6%) showed no discrete nodules, and 12 (8.2%) had no interval change in nodule characteristics. Notably, 93.2% (n=137) of cancellations involved patients with initial ultrasounds at external facilities. In the first reaudit (Jan to Mar 2025), 8 of 62 scheduled biopsies (12.9%) were same-day cancellations that occurred after the preliminary ultrasound.

DISCUSSION

The initial audit revealed that most cancellations were associated with downgraded TI-RADS scores and referrals from external facilities, highlighting the challenge of interobserver variability in scoring thyroid nodules. Same-day cancellations led to 119.25 hours of misused provider and procedure room time. Our intervention reduced these cancellations, enabling cancelled slots to be filled with other diagnostic ultrasounds, which ultimately reduced wait times. Limitations include the need for 2 patient visits and increased staff workload. Following the 2025 reaudits, annual audits will ensure sustained improvement.

W5A-QI-1 CREATION OF A LONGITUDINAL HANDS-ON ULTRASOUND RESIDENCY CURRICULUM

Ashwin Panda, MD (*Presenter*)
Anthony Sposato, MD (*Abstract Co-Author*)
Ayush Thomas, MD (*Abstract Co-Author*)
Andrew Lee, DO (*Abstract Co-Author*)
Prithvi Shetty (*Abstract Co-Author*)
Richard Thomas, MBBS, MD (*Abstract Co-Author*)

INTRODUCTION

Ultrasound is a core modality within diagnostic and interventional radiology, with competency requirements for graduation among accredited residency programs. In a brief survey performed in our department, although radiology residents reported adequate exposure to ultrasound interpretation and performing ultrasound-guided procedures, there was a reported lack of adequate training in independently performing diagnostic ultrasound exams. The existing practice of ultrasound education included informal training of residents by sonographers during dedicated ultrasound rotations. However, this method was noted to be limited by a lack of structure and time constraints. A quality improvement (QI) initiative was formulated to address this deficit in training, through which a formal curriculum for a hands-on ultrasound training course was developed with the guidance of an attending radiologist.

METHODS

A Plan-Do-Study-Act (PDSA) cycle was referenced in order to appropriately implement this QI initiative (Figure 1). First, a lesson plan was developed in conjunction with an attending physician, with collaborative input from department sonographers. A written curriculum in ultrasound physics was created, including a diagram to familiarize trainees with the layout of the ultrasound machine. A workshop with the attending physician and sonographers was then created that allowed for focused hands-on didactics, where residents learned applications of ultrasound physics and participated in a hands-on course performing a complete abdominal ultrasound. An assessment was then developed for first year residents to assess competency in basic ultrasound skills and theory.

RESULTS

Following the workshop, an internal survey was conducted within the radiology department to qualitatively gauge the effectiveness of the training implementation. Residents reported increased familiarity with operating the ultrasound machine independently, a better understanding of the applications of ultrasound physics, and increased confidence in performing a complete abdominal ultrasound exam. The sonographers reported having a better opportunity to engage with residents and address troubleshooting questions during this session. Attending physician feedback noted this course as a more practical approach to teach ultrasound physics and principles.

DISCUSSION

This QI implementation was successful overall in improving residents' confidence and skillset towards independently performing diagnostic ultrasound. By incorporating an annually recurring hands-on workshop, written curriculum, and follow up assessment into the residency program, this program will continue to build confidence and aptitude in ultrasound imaging among radiology residents.

W5A-QI-3 IMPROVING RESOURCE UTILIZATION FOR OUT-OF-HOURS REPORTING OF NON-CONTRAST CT BRAIN STUDIES IN THE EMERGENCY DEPARTMENT

Nicholas Mallaband (*Presenter*)
Mark Phillips (*Abstract Co-Author*)
Melissa Ryan (*Abstract Co-Author*)

INTRODUCTION

A widening gap between the demand for diagnostic imaging and the availability of radiologists is well acknowledged and is further exacerbated during out-of-hours where registrars our outsourcing is relied on at many facilities. AI-assisted triage may help to reduce unnecessary radiology reporting workloads during out-of-hours. This service evaluation sought to evaluate the safety and clinical utility of using an AI tool to identify non-urgent CT brain (CTB) studies performed within the emergency department during out-of-hours (OOH).

METHODS

Non-contrast CTB studies that had been performed and reported OOH at Doncaster Bassetlaw Teaching Hospital between 3-12 June 2024 were inferenced by an AI-tool (Annalise Enterprise CTB v 3.8, AUS). Studies were classified as "Urgent" if any findings were detected by the tool, and "Not Urgent" otherwise. Corresponding radiology reports were parsed through a large language model (llama v 3.1) to classify reports as "Urgent" or "Nor Urgent". AI classifications were compared to the Report classifications: concordant classification was considered True Positives or True Negatives; studies classified as AI-Urgent / Report-Not Urgent were classified as potential False Positives; studies classified as AI-Not Urgent / Report-Urgent were considered False Negatives and were interrogated.

RESULTS

1,255 studies were included. Four studies (0.3%) were classified as "Report Urgent" but contained 0 findings from the AI (Table 1). Corresponding reports indicated a subtle hyperdensity, possible focal prominence in MCA, ?subarachnoid haemorrhage, and ?basilar artery thrombus. Clinical chart review revealed all were Report False Positives.

DISCUSSION

The original radiology reports classified 90% of studies as not-urgent, emphasising the high demand of non-urgent out-of-hours reporting. Using the definition of 0 findings detected by AI indicated the potential for a 20% reduction in OOH workload with 0 misses. The high number of cases identified Report Not Urgent that contained at least 1 finding, Adjusting the "Not Urgent" definition may provide additional workload reductions. Further evaluations regarding misses with increased

threshold should be evaluated. Clinical Relevance Statement AI may help to reduce workload during OOH periods when radiology support is limited through the use of AI to safely triage scans that have been acquired into different priorities for reporting times. This could allow Radiologist report to be completed the next morning when radiology resource is locally available. There is an ongoing project at the trust to implement this process that is currently going through the governance process.

W5A-QI-4 IMPROVING MRI SAFETY THROUGH CASE-BASED ANALYSIS AND PROTOCOL ENHANCEMENT: A COMPREHENSIVE APPROACH TO REDUCING SAFETY INCIDENTS

Asif Jamal, MD, MBBS (*Presenter*)
Nouran A. Elghitany, MD (*Abstract Co-Author*)

INTRODUCTION

MRI safety incidents remain a serious concern despite established protocols, with risks including projectile accidents, burns, and contrast-related reactions. At our institution, we identified a need to improve safety through analysis of real-world incidents rather than relying on generic protocols. Case-based learning has shown promise in enhancing safety compliance in high-risk settings (Smith et al., JMRI 2023). Our goal was to reduce MRI safety incidents by 20% and increase near-miss reporting by 30% over a 6-month period ending March 31, 2025.

METHODS

This quality improvement project was conducted in the MRI department of a tertiary care center. Initial review showed limited staff awareness of real safety threats. We focused on three areas: incident analysis, staff training, and protocol standardization. Three key incidents—ferromagnetic intrusion, patient burns, and contrast reactions—were analyzed in depth. Findings informed case-based training delivered to 90% of staff and the development of a comprehensive MRI safety toolbox. The project timeline was phased monthly, with impact measured through incident rates, near-miss reporting, and staff participation.

RESULTS

SPC chart analysis (Figure 1) showed a 25% reduction in MRI safety incidents from baseline ($p=0.03$), exceeding our goal. Near-miss reporting rose by 38% ($p=0.02$), reflecting improved staff vigilance. Staff training reached 95% participation, with 92% rating the case-based approach as "highly" or "extremely" effective. The safety toolbox was fully completed and is now the department standard. Root cause analysis revealed overlooked risks, including gaps in screening for implants and improper positioning linked to thermal injuries. These insights led directly to improved protocols and training materials.

DISCUSSION

Our initiative demonstrates that targeted, case-driven safety interventions can effectively reduce MRI-related adverse events and enhance safety culture. Although limited by its single-site implementation and short duration, the project successfully leveraged real incidents to drive staff engagement and behavioral change. Enhanced reporting culture may partly reflect increased awareness, but outcome improvements suggest true system gains. Future plans include applying this model to other high-risk modalities and maintaining awareness through a rotating curriculum of new cases.

W5A-QI-5 INTEGRATING ADVANCED PRACTICE PROVIDERS WITH POINT OF CARE ARTIFICIAL INTELLIGENCE IMAGING SOLUTIONS IN THE OUTPATIENT SETTING

Kirby Quinn, MD (*Presenter*)
Ayden Jacob, MD, MSc (*Abstract Co-Author*)
Thiago A. Braga, MD (*Abstract Co-Author*)
Alexander M. McKinney IV, MD, BEng (*Abstract Co-Author*)
Jean Jose, DO (*Abstract Co-Author*)

INTRODUCTION

Translating imaging AI results into clinically relevant actions requires robust infrastructure and practitioner support. This study evaluated the impact of an outpatient point-of-care AI-guided triage solution, with and without a dedicated Advanced Practice Provider (APP), on expediting emergency department (ED) referral or anticoagulation therapy for patients with incidental pulmonary emboli (iPE) detected on CT imaging.

METHODS

From February 6 to September 30, 2024, 9,590 outpatient contrast-enhanced CT chest and abdomen scans (not dedicated CTA for PE) were analyzed using an AI algorithm, with a 7-month wait-time analysis. At one site (LFMC), a dedicated APP facilitated care for AI-detected, radiologist-confirmed iPE cases; other sites lacked this support. Clinical impact was measured as time to ED arrival or anticoagulation prescription.

RESULTS

Of 90 AI-detected iPEs, 68 (75.5%) were radiologist-confirmed, with 22 (24%) false positives, often due to hilar lymphadenopathy. Patients (mean age 60.4 years, 56.4% female, 96.1% with oncologic diagnoses) had 38% lobar-level iPEs. Among 51 new iPE cases, 7 (14%) occurred at LFMC and 44 (86%) at other sites. Mean time to treatment was 2.5 hours (SD 1.8) at LFMC versus 20.5 hours (SD 39.3) at other sites ($p<0.05$). All LFMC patients received ED referral or anticoagulation within 24 hours, versus 79% at other sites. Preliminary data noted 15 deaths (29%) among new iPE cases (mean 105.4 days post-service).

DISCUSSION

An AI-guided triage system with a dedicated APP significantly reduces time to treatment for outpatient iPE, highlighting the critical role of human intervention in optimizing AI-driven care.

W5A-QI-6 CULTIVATING ERGONOMIC WORKSTATIONS IN RADIOLOGY AT EMORY HEALTHCARE

Zachary Grunewald (*Presenter*)
Vikram Sahgal (*Abstract Co-Author*)
Elizabeth A. Krupinski, PhD (*Abstract Co-Author*)
Rebecca L. Seidel, MD (*Abstract Co-Author*)

INTRODUCTION

Radiologists and radiographic technologists spend significant amounts of time at computers or designated imaging workstations known to be associated with development of postural strain and fatigue. It is reported that up to 85% of radiographic technologists experience pain and strain while working. We assessed our current ergonomic workstation environment, determined reported levels of pain and fatigue, and hope to expand ergonomic workstations among our radiology workforce.

METHODS

General: The Radiology Ergonomics and Strain Assessment Survey (RESAS) was sent to approximately 1,500 diverse employees in Radiology at Emory Healthcare. Employees were notified of the survey via email which remained open for 33 days. Context and Intervention: The current efficiency and ergonomics of workstations and levels of pain and strain was unknown among our radiology workforce. Quality Improvement Team: The improvement team consisted of two quality improvement personnel, a physician, and two radiology leaders. Study of the Intervention: The survey was administered virtually utilizing a Microsoft Forms survey. Measures/Metrics: 36 quantitative and qualitative questions were used included on current workstation ergonomics, efficiency of work, strain and fatigue assessment, prior training in ergonomics, general demographics and opportunities for improvement. Analysis: Data were analyzed using Microsoft Excel. Aggregate data were assessed as were role groups. Statistical analysis was performed using the T-Test. Sustainability Plan: Data from the RESAS was used to guide and implement ongoing ergonomic improvement efforts through purchase and redesign of select workstations.

RESULTS

Two-hundred employees completed the survey (n=88 technologists, n=45 radiologists, n=18 supervisors, n=5 nurses, n=8 supporting clinical, n=36 non-clinical). 66.5% of radiology employees spend >75% work time at computers and imaging workstations. Radiologists spend 87.2% work time at computers compared to 58.5% for technologists. Collectively, radiology employees rated the overall function and design of their workstations as 3.2 out of 5.0. Radiologists reported lower function and design relative to technologists (3.0±0.12 vs 3.3±0.14; P=0.045). 67% reported experiencing pain or discomfort (n=134) with 31% (n=61) seeking medical advice for musculoskeletal symptoms within the last year. The presence of pain correlated with reported function and design of the workstations (Pearsons r=0.03; P<0.05). Top opportunities identified for improvement were chairs, desks, added adjustability of all equipment, and lumbar support in chairs.

DISCUSSION

Strain and fatigue are associated with (poor) ergonomic function and design of radiology workstations. Data from the RESAS will guide our ongoing ergonomic workstation improvement efforts.

W5A-QI-7 NO SCAN LEFT BEHIND: BUILDING AN AI-DRIVEN RADIOLOGY SAFETY NET FOR LOST REFERRALS AND UNREAD STUDIES

Waqas Ahmad I, MBBS (*Presenter*)

INTRODUCTION

To design, implement, and evaluate an AI-based safety net system that detects and prevents the loss of imaging referrals and unread studies within a large academic radiology workflow, thereby improving patient safety, reducing delays, and enhancing accountability.

METHODS

We conducted a 6-month prospective quality improvement project across 3 hospital sites using PACS, RIS, and EHR integrations. A custom machine learning (ML) algorithm was developed to: Detect imaging referrals not scheduled within 48 hours of order entry, Identify completed scans without finalized reports after 24 hours, Reconcile discrepancies between clinical documentation and imaging execution logs. The system generated daily alerts routed to departmental coordinators and radiologist dashboards. A manual review team validated AI-flagged cases (n=1,200), and outcome metrics included: Number of "lost" or "orphaned" studies recovered, Time to resolution, Change in report turnaround time, Radiologist and clinician satisfaction.

RESULTS

1,157 out of 1,200 flagged cases (96.4%) were true positives, with errors including missed scheduling (52%), unassigned studies (33%), and reporting delays (15%). Mean recovery time for orphaned studies dropped from 5.6 days to 0.9 days post-intervention. Turnaround time for at-risk studies improved by 38% ($p < 0.01$). Radiologists and clinicians rated the alert system as "highly useful" in 84% of feedback surveys. No new patient harm events related to lost studies were recorded during the intervention period.

DISCUSSION

An AI-driven safety net system can effectively detect and rescue "lost" imaging referrals and unread studies, addressing a critical gap in radiology's contribution to diagnostic safety. Automation of this back-end reconciliation process improves efficiency, enhances patient care, and reduces medico-legal risk.Despite advances in imaging technology, patient harm from administrative failures persists. This study demonstrates how AI can serve not only as a diagnostic tool, but as a guardian of workflow integrity, ensuring that no scan is left behind.

W5A-QI-8 AI + QI FOR MAMMOGRAPHY POSITIONING PERFORMANCE: EVIDENCE-BASED CONTINUOUS QUALITY IMPROVEMENT

Georgia G. Spear, MD (*Presenter*)
Mohamed Abdolell, MSc, BSc (*Abstract Co-Author*)
Kandice Tomkins, RN, MS (*Abstract Co-Author*)
Laurie R. Margolies, MD (*Abstract Co-Author*)

INTRODUCTION

Mammography positioning assessments are traditionally subjective and resource-intensive, complicating effective quality management. This study evaluated statistical process control (SPC) applied to artificial intelligence (AI)-generated mammography positioning assessments to objectively quantify positioning variability among medical radiation technologists (MRTs). The primary objective was to determine if AI-derived positioning metrics are sensitive enough for SPC to reliably distinguish special-cause from common-cause variation, consistent with the ACR Mammography Positioning Improvement Collaborative framework employing quality control charts for continuous quality improvement.

METHODS

Between December 2022 and June 2023, 36 MRTs conducted 36,787 mammographic examinations. AI algorithms evaluated positioning against standardized criteria (e.g., medial-lateral oblique [MLO] portion cutoff, inframammary fold [IMF] obscured, nipple not in profile), aggregating image assessments into comprehensive PGMI scores (Perfect, Good, Moderate, Inadequate). MRT performance was benchmarked using anonymized leaderboards ranking technologists by their proportion of P+G scores. SPC charts tracked positioning criteria longitudinally to identify special-cause variations.

RESULTS

Significant variability in positioning performance among MRTs was observed, with P+G rates ranging from 17.3% to 47.2% (median=28.0%). Leaderboards objectively differentiated individual MRT performance, identifying technologists consistently performing above or below departmental standards. SPC analyses revealed significant special-cause variations, notably increasing IMF obscured rates and decreasing posterior tissue capture rates (e.g., cranio-caudal views). Temporal trend analyses corroborated these findings, clearly highlighting individual MRT deviations from departmental benchmarks.

DISCUSSION

Integrating AI-based mammography positioning assessments with SPC methods provides a robust, objective framework for systematically evaluating positioning quality. This approach facilitates precise identification of MRT-specific performance variability, detection of special-cause variation, and effective benchmarking, supporting targeted, evidence-based quality improvement interventions and enhanced mammographic consistency.Combining AI and SPC methodologies offers a standardized, scalable, practical strategy for continuous mammography positioning improvement aimed at improving diagnostic accuracy, reducing recall rates, and promoting optimal patient outcomes.

W5A-QI-9 IMPROVING FIRST CASE ON TIME STARTS IN INTERVENTIONAL RADIOLOGY

Donna Reicha (*Presenter*)
Raja Issa (*Abstract Co-Author*)
Sarah Juntunen, BSN (*Abstract Co-Author*)
Samantha Luke (*Abstract Co-Author*)
Jason Battaglia, BS (*Abstract Co-Author*)
Asia Sellin (*Abstract Co-Author*)
Catherine Hofer (*Abstract Co-Author*)
Jared A. Christensen, MD (*Abstract Co-Author*)

INTRODUCTION

Interventional Radiology is a rapidly evolving specialty that performs a wide range of image-guided, minimally invasive procedures. IR must maintain operational efficiency to manage the wide array of elective, urgent, and emergent cases effectively. A critical component of this efficiency is ensuring first-case on-time starts (FCOTS), as delays in the initial case of the day disrupt the remainder of the procedural schedule, delaying patient care, increasing staff workload and burnout, and negatively impacting institutional revenue and capacity. This quality improvement (QI) project sought to identify and mitigate causes of delays in the start times of the first case of the day in a high-volume IR department at a large academic hospital.

METHODS

Using the Six Sigma DMAIC framework and iterative Plan-Do-Study-Act (PDSA) cycles, our multidisciplinary team implemented a range of targeted interventions aimed at improving FCOTS. These included restructuring the scheduling process, standardizing patient arrival protocols, increasing staff awareness of on-time expectations through consistent and targeted leadership rounding, improving room setup and cleaning practices, carefully documenting delays in the EHR, and enhancing provider communication of room readiness via automated alerts and messages.

RESULTS

Our IR department performs nearly 6000 procedures annually in eight procedural suites. Pre-intervention data across all our suites showed an average first case on time start (FCOTS) rate of 33% in FY23 Q1. Following the implementation of these interventions, the FCOTS rate steadily improved to 72% by FY25 Q2. Improvements were consistent across the Vascular and Interventional Radiology, Neurointerventional Radiology, and Neurodiagnostic Radiology services. Notably, no single intervention alone accounted for the improvements; rather, positive results came from the cumulative effect of multiple coordinated strategies across the enterprise.

DISCUSSION

Ensuring an on-time start to the first case of the day is an essential component of efficiency in interventional radiology. This is especially important because of the dynamic and variable nature of IR cases and the complex interplay of multiple job families to deliver high quality care. We demonstrate that a data-driven, multi-pronged approach was able to significantly improve the rate of first case on time starts in a high-volume IR setting. Using this approach enhances clinical workflows and patient and provider experience. It also highlights the need for ongoing operational vigilance.

W5B-QI-1 DETAILED ANALYSIS OF AI PERFORMANCE IN IMAGE INTERPRETATION IN BREAST SCREENING; AN IMAGE REVIEW OF OUTCOMES FROM A SAMPLE POPULATION

Nerys Forester, MBBCh, PhD (*Presenter*)

INTRODUCTION

AI mammography image analysis tools have potential to aid breast screening image interpretation, but where this would be most useful within the screening pathway has yet to be determined. We had the opportunity to evaluate an AI system on a small subset of breast screening clients to deeper understand how such technologies could be useful in the future.

METHODS

Cloud based reading by AI of all images, as appropriate, between 01/01/24 and 21/3/24. During this time usual screening processes were followed, and the results of AI were unknown to film readers. Six weeks after the AI reading period, the AI results were compared to the human reader outcomes and both positive discordance (AI recall but human no recall) and negative discordance (AI no recall but human recall) outcomes reviewed. 0-12 month interval cancers for this time period were also assessed.

RESULTS

In the period studied, 12136 women were invited for screening; 9799 attended. 233/475 were recalled for assessment (RR 2.4) from which 78 cancers were identified (CDR 8.0). 8592 screening mammograms were read by the AI.Positive DiscordanceAI recalled 571 extra cases all of which were reviewed by at least 2 readers; 448 unchanged from prior images, 72 benign calcifications/masses, 8 post-surgical changes, 23 no abnormality apparent. 20 cases were re-read by 6 readers and recalled if there was a majority decision. 7 cases were invited for assessment outside their original screening episode. Of these, 4 were distortions of which three were diagnosed with cancer and 3 were calcifications, of which all were benign.Negative DiscordanceAI evaluated199/233 women recalled to assessment (one DNA). AI did not recall 87/198 cases from which 11 had proven cancers. Of these, 5 were single reader recalls. The imaging findings in this group ranged from easily detectable to more subtle cancers.Cases recalled despite a no recall AI decision were normal in 55/76 of cases where the recalled abnormality was either new well-defined masses or stromal changes.Intervals4 intervals had been identified in women screened between 1/1/24 and 21/3/24, however, AI did not read any of these images.

DISCUSSION

Although a small sample, AI shows potential to increase cancer detection when used as a third reader, with additional detection of three subtle cancers missed by human readers. However, this would be at the expense of doubling of the arbitration caseload. To date, no intervals have arisen from the cases recalled by AI, but not recalled by the service. Use as a third reader at arbitration for well-defined masses and stomal asymmetry, could help to improve specificity of recall. Further exploration of the negative predictive value of AI in the arbitration setting could prove useful.

W5B-QI-2 STAT MRI: IS IT REALLY? A RESOURCE UTILIZATION STUDY INVESTIGATING THE ACCURACY OF MRI ORDER DESIGNATION

Lucas Eggers (*Presenter*)
Ryan Turner (*Abstract Co-Author*)
Hillary Cunliffe-Owen (*Abstract Co-Author*)
Sera Sempson (*Abstract Co-Author*)
Jaime Baker (*Abstract Co-Author*)

INTRODUCTION

At our academic-affiliated, community-based level one trauma center, we observed an influx of inappropriate STAT MRI orders among inpatients, increasing Order to Scan Time (OTS) for critical cases and hindering treatment efficiency. Anecdotally, this led to poorer outcomes, prolonged hospital stays, and increased costs. Resource utilization is crucial for patient care, operational efficiency, and financial sustainability. This needs assessment investigated the proportion of improperly designated STAT MRI orders.

METHODS

All emergency and inpatient MRI orders from two six-month periods were sourced from the hospital's radiology department archive. A retrospective chart review was completed. Extracted data included ordering department, patient location, order time, MRI start time, indication, diagnoses, and priority. Orders categorized into five groups: RAD-0 (Disaster/Stroke/Trauma), RAD-1 (ED/Urgent Inpatient), RAD-2 (ICU), RAD-3 (Awaiting Discharge), and RAD-4 (Other Inpatients), with RAD-0 and RAD-1 considered STAT. A 15% random sample of STAT orders from each period was reviewed for appropriateness using a standard of imminent mortality or morbidity. Two reviewers assessed concordance; disagreements were resolved collaboratively or escalated to a subject expert. The full dataset was analyzed for OTS and increases in length of stay (LOS), defined as OTS crossing midnight. Interviews with a hospital physician explored causes of discordant orders.

RESULTS

Across both periods, there were 6,734 MRI orders—3,047 from Oct 2022 to Mar 2023 and 3,687 from May to Oct 2024. A 15% random sample of STAT orders yielded 571 reports assessed for concordance. Of these, 425 (74.4%) were concordant and 146 (25.6%) discordant. Discordance rose by 8.11% between periods. Discordant STAT orders accounted for 79,266 OTS minutes, and showed a 192% increase. Among concordant orders, 379 (89.2%) had OTS >90 minutes. Mean OTS by category: 312 (RAD-0), 540.1 (RAD-1), 1,549.7 (RAD-2), 1,563.6 (RAD-3), and 3,428.5 (RAD-4). OTS delays led to total LOS increases in days of 9 (RAD-0), 235 (RAD-1), 107 (RAD-2), 84 (RAD-3), and 318 (RAD-4). Interviews cited lack of education on priority levels and intentional up-prioritization by providers frustrated by prolonged OTS delays.

DISCUSSION

Our study found 25.6% of high-priority exams were misclassified. Misuse of STAT designations delays imaging for true emergencies. This highlights opportunities for intervention, including provider education, redesign of the order interface, and feasibility and cost-benefit evaluation of the need for an additional MRI scanner. Prior

studies show providers understand order sets but often lack insight into local workflow. Given clear evidence of discordant MRI orders, rising OTS, and increased LOS, targeted corrective measures are necessary to ensure timely, equitable imaging access.

W5B-QI-3 THE EFFICACY OF 6S PRECISE MANAGEMENT SYSTEM IN THE NURSING MANAGEMENT OF RADIOLOGY DEPARTMENT

Wei Tong (*Presenter*)

INTRODUCTION

6S precise hospital management system(6S PHMA) has been widely applied in the industrial procedure and is supposed to be potentially feasible in the evaluation of management in patient care. In this study, we are aiming to test the 6S PHMA tool in the quality control of nursing in clinical radiology scenario.

METHODS

the 6S PHMA principles were integrated into the procedures of arrangements in the nurse treatment room (NTR), the second CT inspection room (2 nd CT), the third CT inspection room (3 rd CT) and the fitting room (FR) of our department of radiology. The whole process of integration was divided into 6 individual phases. 1) SEIRI: medical supplies were sorted into the Necessary/Unnecessary groups, or the Expired/Valid in 3 months groups. To expand the storage space, all the expired items were disposed, only necessary ones left. 2) SEITON: the staff take the responsibility to rearrange the position of the supply and equipment, according to the interior layout. All the items in frequent use were accommodated at a handy area and tagged. 3) SEIKETSU: the staff made thorough clean and disposed the waste following standard procedure. 4) SEISO: the supplies and equipment in the puncture room and inspection room were cleaned weekly. 5) SAFETY: all the staff review the knowledge of dealing with emergency situations, e.g. fire alarm, evacuation and radiation event. 6) SHITSUKE: skills are the core of 6S PHMA and important basis of group spirit. Finally we compared the scores of supply preparation time and satisfaction by the medical staff and patients.

RESULTS

1) tidy environment: after the application of 6S PHMA, the environment in our department, including the NTR, 2nd CT, 3rd CT and FR, has been improved notably. The attitude of staff has changed into self-motivated involvement and sustainable movement. 2) Improvement in nursing efficiency: The time for supply preparation descended after the implementation of 6S PHMA in 2nd CT (94.25 ± 2.13 s vs. 97.80 ± 0.63 s; $p < 0.01$), 3rd CT (83.9 ± 1.20 s vs. 97.7 ±0.82 s; $p < 0.01$) and FR (90 ± 2.55 s vs. 96.45 ± 1.57 s; $p < 0.01$), respectively. 3) Improvement in satisfaction: the score of satisfaction by medical staff increased from 82.53% to 98.13% after implementation ($p < 0.01$), and the score by patients increased from 77.78% to 96.29% ($p < 0.01$), respectively.

DISCUSSION

Conclusion : 6S PHMA is an effective method for the reconstruction of procedure in the patient management of radiology inspection. It can not only release the disorder in the clinical scenario, escalate efficiency accurately, but also can improve the professional skills of nurses. Consequently, prominent advance was made in the satisfaction level by both of the medical staff and patients. The application of this management tool can also be expected in some other similar clinical settings.

W5B-QI-4 CAN WE PREDICT RADIOLOGIST PRODUCTIVITY?

Oleg S. Pianykh, PhD (*Presenter*)
Fionnuala McPeake (*Abstract Co-Author*)
Heather Johnston (*Abstract Co-Author*)
Olivier Khorasani (*Abstract Co-Author*)

INTRODUCTION

Radiology departments are expected to maintain low turn-around times and high productivity despite many challenges such as fluctuations in daily workloads, staffing, and clinical priorities. The goal of this study was to model the impact of operational conditions on individual and departmental productivity. We used machine learning to predict daily productivity to understand its key drivers, and to improve workforce allocation, work conditions, and patient care.

METHODS

To capture the operational environment, we collected 58 features from our Electronic Health Record (EHR) and radiology dictation systems - including total clinical hours scheduled, sum of worklist Relative Value Units (RVUs), number of staff conferences, imaging modalities, and more. The selection of features was discussed with ten radiologists from different centers and divisions. The outcome productivity variable, RVUs read per day, was calculated for four radiology divisions from two Academic Medical Centers (AMCs), totaling 2,448 data points for weekdays between January 8, 2024 and March 29, 2025. To model daily RVUs read, we fit OLS regression, ridge regression, random forest regression, and neural networks. ABESS subset selection was used with OLS to avoid overfitting and to identify the most important features. Both division-level and individual productivity were modeled.

RESULTS

Using OLS models with ABESS feature selection, we achieved a maximum test-set R 2 value of 0.527 for Musculoskeletal (MSK) at AMC B using only five features. Models using OLS with all available features resulted in a maximum R 2 value of 0.653 for MSK at AMC A. Ridge regression models showed similar performance. Random Forest regression produced an R 2 value of 0.515 for MSK at AMC A. For some divisions, all models failed to achieve accurate predictions. The most commonly selected variables associated with higher productivity were the number of moonlighting shifts, worklist RVUs at 7am, and the cumulative RVUs read over the past 28 days. Another frequently-selected variable was the percent of worklist comprised of MRI exams, which was positively associated with productivity for some divisions and negatively for others.

DISCUSSION

Despite high variability in reading patterns, the performance of certain divisions and radiologists can be effectively predicted from operational features. These predictions can help divisions improve efficiency while reducing burnout by adjusting staffing levels in advance. Additionally, the selection of ABESS subsets demonstrated that factors associated with productivity vary across divisions and individuals. Lastly, identifying radiology groups with the least predictable RVU output shows that their performance cannot be explained by the existing metrics of productivity. This highlights the need for improvements in our approach to assessing radiology performance.

W5B-QI-5 INCREASING THE ACCESSIBILITY OF CARDIAC MR EXAMS FOR INPATIENTS WITH CARDIORESPIRATORY SYMPTOMS

Brian A. Taylor, PhD (*Presenter*)
R. Jason Stafford, PhD (*Abstract Co-Author*)
Gregory W. Gladish, MD (*Abstract Co-Author*)

INTRODUCTION

Imaging physicists are often requested to help improve the quality of protocols as part of their clinical practice. In this quality improvement project, MR physicists addressed image quality concerns particularly in the inpatient setting for cardiac MR exams. In many cases, patients admitted with cardiorespiratory symptoms cannot adequately hold their breath for times needed for many acquisitions. This leads to artifacts that can affect the quality and diagnostic yield of the exam. We investigated the root causes of the quality concerns and provided solutions to increase the accessibility of this important modality.

METHODS

MR exams were acquired on a 1.5T GE 450W system (GE Healthcare, Waukesha, Wisconsin). Image quality concerns are logged in a database by radiology staff and cardiac MR exams with concerns were identified and reviewed by the physics team. Physicists also observed inpatient exams at the scanner to identify contributors to poor image quality and artifacts. Recommendations were presented to the attending radiologists for approval. The physics team as well as clinical application specialists trained the technologists in optimized acquisitions and protocols to reduce artifacts and overall scan time. Metrics of quality included the number of successful MR exams and image quality reports before and after implementation of the protocol changes.

RESULTS

A main contributor to artifacts and suboptimal image quality was the extended breath holds (up to 16 seconds per slice) for many acquisitions. We utilized Sonic DL (GE Healthcare) for CINE scans with and without respiratory bellow triggering to reduce the scan time from 67 to 92% depending on the patient's tolerance (from full free breathing to a 4 second breath hold). We also identified spiked noise on the ECG signal used for gating. It was verified that the internal body RF coil in a scanner was inducing interference on the ECG system and adding artefactual heartbeats to the signal. This contributed to cardiac motion on images. This issue was resolved when the internal RF transmit coil was replaced. After implementation of our recommended changes, we measured a 9.1% increase of inpatient cardiac exams with a 67% decrease of image quality concerns reported from PACS.

DISCUSSION

Physicists play a key and value-added role in optimizing protocols for improved image quality and throughput for imaging. This quality improvement project shows that image quality issues can be multi-factorial, and several approaches are needed to address image quality concerns. For protocol development, the utilization of deep learning recon aided in reducing scan times and reducing motion-related artifacts. The RF coil interference required hardware adjustments for the ECG and RF transmit array to address effects on gating. This also highlights the need for physicists to aid in protocol development in addition to quality assurance.

W5B-QI-6 IMPROVING PATIENT SAFETY AND COMFORT: A CASE FOR MRI BORE FAN QUALITY ASSURANCE

Teresa M. Peterson, ARRT (*Presenter*)
Ian Langenfeld (*Abstract Co-Author*)
Aiming Lu, PhD (*Abstract Co-Author*)

INTRODUCTION

MRI can cause patient warming due to the absorption of radiofrequency (RF) energy. To offset this effect, MRI systems are equipped with fans to circulate air. Scanner bore fan (SBF) specifications are not standardized or monitored. As a result, SBF issues can lead to patient warming and/or suboptimal image quality due to faulty fan parts or the need to adjust acquisition parameters for RF heating reduction. The goal of this project was to develop a method to quantify the SBF performance and establish a quality control procedure to monitor air circulation.

METHODS

40 MRI scanners from various vendors were tested using custom-built non-ferrous anemometers. A pinwheel-style anemometer was made from thin plastic mounted on a 2 mm diameter wooden dowel. The dowel fits into an adjustable aluminum stand, allowing free rotation. The pinwheel was placed at the typical location for brain imaging on the patient table (landmarked on the pinwheel). One marked blade was counted for each full rotation for 30 seconds to calculate the rotation-per-minute (RPM) values at 5 locations: 1) bore isocenter (bore center); 2&3) same as 1) but near the top of the bore or close to the patient table, respectively; 4&5) same as 1) but moved laterally to the left and right by 15cm, respectively. To correlate the SBF performance to patient warming events, technologists were asked to record patient warm events, noting instances of sweating and body habitus over one week.

RESULTS

18 of 40 scanners reported patients' complaints of warmth. 16 of these scanners had patients visibly sweating. 12 of the 18 scanners had airflow measuring 0-66 RPMs. Distribution of airflow for one scanner showed significant repeatable RPM measurement variations at the same locations (difference greater than 165%) and necessitated a fan motor replacement. Post motor replacement distribution difference was 120%. The pinwheel did not move on three scanners of the same model. These scanners had a higher incidence of patient warming.

DISCUSSION

A homemade anemometer was created to quantify MRI SBF performance. Initial results demonstrated that the measurements were highly correlated to the number of reported patient warmth occurrences. The results highlighted the importance of establishing a quality assurance procedure for SBF performance assessment and monitoring. The anemometer should have no metal parts to avoid eddy currents that affect its measurement. Design should be durable, and the measurement should be automated. Improvement of the design is underway.

W5B-QI-7 IMPROVING LUNG CANCER SCREENING RATES WITH EMAIL BLAST TO ELIGIBLE HIGH-RISK PATIENTS

Melissa Banal, MD (*Presenter*)
Jaskaran Singh (*Abstract Co-Author*)
Judith K. Amorosa, MD (*Abstract Co-Author*)
Jeffrey S. Kempf, MD (*Abstract Co-Author*)
Kesha Singh (*Abstract Co-Author*)
Levi Sokol, MD (*Abstract Co-Author*)

INTRODUCTION

Lung cancer accounts for over 2 million new cases and 1.8 million deaths annually, making it the deadliest cancer globally. Early detection through Low Dose Computed Tomography can reduce mortality by up to 20%, particularly among high-risk individuals, such as long-term smokers aged 50-80 years. However, despite recommendations by organizations like the U.S. Preventive Services Task Force, screening rates are as low as 5.8% in eligible populations. A targeted approach that identifies eligible patients could significantly enhance screening uptake. Digital communication, particularly email campaigns, has emerged as a powerful tool in healthcare for patient engagement and education. Therefore, the purpose of this quality improvement project was to analyze the efficacy of using an email blast to increase lung cancer screening rates amongst eligible high-risk patients.

METHODS

To attempt to address this disparity and increase lung cancer screening rates we identified eligible, high-risk patients who have received imaging at our private practice radiology group. Patients age 50-80 years old with a 20 pack year history who are current smokers or have quit within the last 20 years were included. An email was then sent to the eligible patients to inform them of our Lung Cancer Screening Program and request they get a referral from their primary care provider.

RESULTS

An email promoting lung cancer screening was sent to 1,326 individuals identified as eligible, but had not had prior lung cancer screening. Of these, 464 patients (35.0%) opened the email and 84 patients (18.1% of openers) proceeded to schedule a screening appointment. Of the 862 patients (65.0%) who did not open the email, 0 patients (0% of those who did not open the email) subsequently scheduled a lung cancer screen.

DISCUSSION

The 18.1% conversion rate among openers demonstrates the potential of targeted emails to prompt action, though the overall screening uptake (6.3 % of all emailed patients) remains modest. These findings suggest that while email campaigns are effective for a subset of patients, complementary strategies—such as phone calls, text reminders, or provider outreach—are needed to engage non-responders.Limitations include potential selection bias (patients with email access may differ from those without) and limited data on reasons for non-compliance. The email's design (e.g., subject line, readability) and timing may also have influenced engagement. Future studies should explore optimized email content, multimodal interventions, and barriers to screening.

W5B-QI-8 FEDERATED AI MONITORING SERVICE (FAMOS) FOR SAFEGUARDING CXR AI DEPLOYMENT: A SOCIOTECHNICAL APPROACH AT TWO UK TERTIARY HOSPITALS

Simran S. Dhesi, BSc, MBBS (*Presenter*)

INTRODUCTION

Post-deployment monitoring of radiology AI solutions requires a systemic approach that reflects clinical variability in workflows, settings, and patients. Pre-deployment metrics often miss real-world performance, posing safety risks. Monitoring via reports or feedback is limited, often missing subtle performance drift. Sociotechnical factors including workflow integration, clinician interaction, and imaging protocols are seldom considered. This study assessed the feasibility of FAMOS to support safe deployment of chest radiograph AI solutions across two major hospitals.

METHODS

FAMOS was implemented at two UK tertiary hospitals (Centre 1 and Centre 2) to evaluate the performance of two commercial chest radiograph AI solutions (Ai1 and Ai2). Retrospective chest X-rays were streamed to both AI platforms simultaneously, with federated aggregation capturing changes in the quality of input data and AI prediction distributions. Radiologist-AI concordance was assessed using a review tool where reviewers recorded case-level concordance with AI findings.A team of radiologists, data scientists, and governance leads oversaw deployment and met regularly to uphold safety standards. A dashboard generated summary data on image characteristics, prediction outputs, and human-AI agreement. Clinicians annotated each case to assess diagnostic reliability.Primary metrics included prediction distributions, image quality anomalies, and concordance rates. These supported monitoring by capturing input data shifts and performance variability across sites. Time trends and inter-site differences were analysed, and discordant cases flagged for review. A governance strategy was proposed to enable scalable adoption into routine QA processes.

RESULTS

The FAMOS platform processed 1,472 chest radiographs across both sites using AI1 and Ai2. Mean latency from AI output to dashboard display was ~20 seconds, enabling near real-time monitoring. Fewer than 5% of images were outliers per site, mostly due to projection, positioning, or artifacts, with no evidence of model drift. Radiologist-AI concordance was high: 95% (Ai1) and 91% (Ai2) at Centre 1; 92% and 87% at Centre 2. Few studies required follow-up. Concordance increased over time at Centre 2, suggesting possible automation bias; Centre 1 remained stable. The federated setup supported privacy-preserving, cross-site monitoring with no safety concerns.

DISCUSSION

The study was limited to retrospective data, two institutions, and two AI products. Broader application to other models and real-time deployment is pending.This work demonstrated the viability of federated, real-time AI monitoring to support diagnostic safety. Embedding monitoring in governance and QA offers a scalable solution for accountable use of AI solutions in radiology.

W5B-QI-9 COST ANALYSIS OF PORTABLE MRI IN THE ICU: TRANSLATING HUMAN RESOURCE EFFICIENCIES INTO FINANCIAL SAVINGS

Sijyl Fasih (*Presenter*)
Supriya Khatri (*Abstract Co-Author*)
Omar S. Islam, MD, FRCPC (*Abstract Co-Author*)

INTRODUCTION

Intra-hospital transportation of critically ill ICU patients to fixed MRI scanners poses significant logistical challenges, involving multiple healthcare providers and incurring high personnel costs. By bringing the imaging to the patient, portable MRI (pMRI) technology could eliminate the need for patient transport and optimize human resource allocation, something especially valuable in low-resource centers. By evaluating the operational costs and savings associated with the introduction of pMRI at our institution, we aim to develop a framework for other hospitals to use as a reference when considering the implementation of pMRI.

METHODS

The proposed pMRI requires no infrastructure and utilizes existing X-ray staff. Data includes projected costs (machine purchase/maintenance, training, salaries with 2.8% annual inflation) and savings from reduced transport needs for an estimated 216 scans annually. Human resource (HR) personnel include technologists, booking clerks, nurses (RN), Respiratory Therapists (RT) and porters. A cost analysis was conducted over a 6-year projection in Canadian dollars, evaluating the operational costs of pMRI against financial value of reallocated HR hours. Measures included operational costs (machine purchase fee, maintenance, and staff training) and reallocation savings (i.e. time saved by ICU staff due to reduced patient transport requirements). Projected hourly wages with 2.8% inflation were used to estimate financial implications. Yearly costs and savings were estimated at varying operative efficiency levels.

RESULTS

Our results can be divided into costs and savings in HR time associated with using pMRI at our institution over a 6-year period. The total operating cost over six years was $895,980.10, which includes the machine purchase fee of $649,000, a yearly maintenance fee of $30,000, booking clerk fees, technologist training and operation costs. The value of reallocated HR hours over six years amounts to $723,119.93. This includes salaries for RN at $331,984.80, RT at $317,779.37 and porters at $73,356.48.

DISCUSSION

Projected savings from reallocated HR nearly balance the operational costs of pMRI over 6 years. Savings could be reallocated to other hospital services and towards the reduction of ICU HR overtime. As demand for ICU imaging continues to grow, pMRI offers a solution to address an increasing need for diagnostic services. Next steps involve identifying and quantifying potential revenue sources to further offset operational expenses such as government funding, institutional grants for innovation in care delivery, or downstream cost savings (i.e decreased ICU length of stay, earlier diagnosis, reduced overtime). As pMRI technology continues to evolve with improvements in image resolution, speed, and diagnostic capabilities, the cost-benefit ratio is expected to further improve.
