Central and anterior fibrotic changes are robust predictors of ILA progression to IPF and can be visually assessed on CT. These findings support their use in early risk stratification and clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

Visual assessment of central and anterior fibrosis on CT can identify patients at high risk for progression from incidental ILA to IPF. This enables earlier referral, monitoring, and potential treatment before irreversible disease evolution.

T1-SSCH05-3 PHASE-RESOLVED FUNCTIONAL LUNG MAGNETIC RESONANCE IMAGING OF LUNG PERFUSION AND VENTILATION IN FIBROSING INTERSTITIAL LUNG DISEASES, A PROSPECTIVE OBSERVATIONAL STUDY

Yifei Ni, MD (*Presenter*)
Min Liu (*Abstract Co-Author*)

PURPOSE

The pathophysiological changes in lung perfusion and ventilation in fibrosing interstitial lung diseases (F-ILD) remain inadequately characterized. This study aimed to analyze lung perfusion and ventilation in patients with F-ILD using phase-resolved functional lung magnetic resonance imaging (PREFUL MRI).

METHODS AND MATERIALS

This one-year prospective study included 30 patients diagnosed with F-ILD (16 with idiopathic pulmonary fibrosis, IPF and 14 with other type of F-ILD; mean age: 64.6 years; 19 males) alongside 30 age- and sex-matched normal controls. All participants underwent PREFUL MRI as well as pulmonary function tests (PFTs). High-resolution CT (HRCT) was performed for the patient cohort. Ventilation and perfusion parameters obtained from PREFUL MRI were analyzed and correlated with PFTs and fibrotic lesions identified on HRCT.

RESULTS

Compared with normal controls, F-ILD patients showed significant differences in Mean Perfusion, Mean Ventilation, Perfusion Defect (QDP exclusive), ventilation-perfusion matched non-defect percentage (VQM non-defect), and ventilation-perfusion matched defect percentage (VQM defect) ($P < 0.05$). Mean Perfusion correlated positively with DLCO SB %pred ($r = 0.682$, $P < 0.0001$) and DLCO/VA %pred ($r = 0.634$, $P < 0.0001$), while QDP exclusive correlated negatively with these parameters. Mean Perfusion showed negative correlations with honeycombing, fibrotic lesions, and interstitial abnormalities on HRCT, whereas QDP exclusive correlated positively with these abnormalities (all $P < 0.05$).

CONCLUSION

1. For F-ILD patients, PREFUL MRI exhibited reduced mean perfusion, elevated mean ventilation, higher QDP exclusive , decreased VQM non-defect , and increased VQM defect compared to controls. 2. For F-ILD patients, mean perfusion positively correlated with DLCO SB%pred and DLCO/VA%pred, while QDP exclusive inversely correlated with these parameters. 3. For F-ILD patients, Honeycombing and fibrotic lesions on HRCT were associated with reduced mean perfusion.

CLINICAL RELEVANCE/APPLICATION

PREFUL MRI provides a non-invasive method for evaluating ventilation and perfusion in F-ILD patients, demonstrating strong correlations with pulmonary function parameters and interstitial lesion. It shows potential as a valuable diagnostic and monitoring tool for F-ILD, enabling early detection and progression evaluation.

T1-SSCH05-4 PULMONARY VASCULAR REMODELING AND ACUTE EXACERBATIONS IN IDIOPATHIC PULMONARY FIBROSIS: DIRECT AND FIBROSIS-MEDIATED ASSOCIATIONS

Mihyun Yang, MD, MS (*Presenter*)
Jooae Choe, MD, PhD (*Abstract Co-Author*)
Jihye Yun, PhD (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Hye Jeon Hwang, MD, PhD (*Abstract Co-Author*)
Sola Seo, MS (*Abstract Co-Author*)
Seungbin Bae (*Abstract Co-Author*)
Eun Jin Chae, MD, PhD (*Abstract Co-Author*)
Joon Beom Seo, MD, PhD (*Abstract Co-Author*)

PURPOSE

Acute exacerbations (AEs) substantially affect outcomes in idiopathic pulmonary fibrosis (IPF). While fibrosis extent is an established risk factor for poor outcomes, the role of pulmonary vascular remodeling remains poorly characterized, especially in mild IPF. We evaluated the association between CT-derived vascular metrics and AE risk, and examined whether these effects are direct or mediated through fibrosis.

METHODS AND MATERIALS

In this retrospective cohort study, we analyzed volumetric high-resolution CT scans from patients with mild IPF (forced vital capacity =80%). Deep learning-based quantification of fibrosis and pulmonary vessel metrics was performed. Metrics included mean pulmonary artery (MD-aBV 6mm) and vein diameters (MD-vBV 6mm) at 6 mm from the pleura, small-vessel blood volume fractions (aBV5/TBV and vBV5/TBV; defined as vessels <5 mm² cross-sectional area normalized to total arterial or vein volume), arterial volume between 5-20 mm² (aBV5-20/TBV; preacinar arterial volume), and the small vein-to-artery ratio (vBV5/aBV5). AE events were recorded; death was treated as a competing risk. Fine-Gray models estimated total effects (adjusted for age, smoking status, and pack-years) and direct effects (additionally adjusted for fibrosis score [FS]). Mediation analysis quantified FS-mediated effects.

RESULTS

Among 253 IPF patients (mean age 66 years; 78% male), 79 (31.2%) developed AE over a median 5.6 years. Strongest total associations were seen for MD-vBV 6mm (HR 15.12, 95% CI 5.08-45.02, p<0.001), MD-aBV 6mm (HR 4.57, 95% CI 1.60-13.07, p=0.005), and vBV5/aBV5 (HR 1.33, 95% CI 1.15-1.53, p<0.001). Lower aBV5/TBV (HR 0.88, 95% CI 0.83-0.93, p<0.001) and higher aBV5-20/TBV (HR 1.15, 95% CI 1.07-1.23, p<0.001) were also significant. Associations that remained after FS adjustment included MD-vBV 6mm (HR 10.92, p<0.001), aBV5-20 (HR 1.12, p=0.003), and aBV5/TBV (HR 0.89, p<0.001), reflecting fibrosis-independent effects. MD-aBV6mm (41% mediated) and vBV5/aBV5 (29% mediated) showed partial mediation by FS. vBV5/TBV was not significantly associated with AE risk.

CONCLUSION

Quantitative vascular metrics on CT are associated with AE risk in patients with mild IPF. While some effects are partially mediated by fibrosis, several vessel changes confer AE risk beyond fibrotic burden.

CLINICAL RELEVANCE/APPLICATION

Pulmonary vascular changes visible on CT provide clinically relevant information about AE risk in IPF and may enhance prognostication beyond fibrosis measures.

T1-SSCH05-5 FIBROTIC INTERSTITIAL LUNG DISEASE IN SICKLE CELL DISEASE PATIENTS: FREQUENCY AND PREDICTORS OF PROGRESSION ON CT

Victoria Shi, BA (*Presenter*)
Wenchi Hsu, MD (*Abstract Co-Author*)
Elizabeth Klings (*Abstract Co-Author*)
Lydia Pecker (*Abstract Co-Author*)
Cheng Ting Lin, MD (*Abstract Co-Author*)

PURPOSE

Multi-factorial pulmonary disease is a major cause of morbidity and mortality in patients with sickle cell disease (SD). Interstitial lung disease (ILD) can occur and ranges from parenchymal scarring to fibrotic changes; its impact on mortality is unclear. The natural history of these radiologic changes is unexplored and the current study seeks to understand the frequency of fibrotic ILD and predictors of ILD progression in SCD patients.

METHODS AND MATERIALS

Adult patients documented with ICD codes for SCD and presented at a tertiary care center were included in this retrospective study. Patient were included if they had two chest CT scans, with the baseline and most recent scans conducted at a minimum interval of five years between 2002 and 2024. Demographic and clinical data were extracted from the electronic medical records. CT scans were reviewed for the presence and progression of fibrotic ILD by two thoracic-trained radiologists who were blinded to clinical data. Quantitative CT analysis was performed for baseline non-contrast CT scans. Statistical analyses included chi-square tests and multivariable logistic regression models.

RESULTS

Of 133 patients diagnosed with SCD, 75.9% were HbSS,11.3% were HbSC, and 12.8% were other genotypes. Fibrotic changes on CT at baseline and follow-up imaging were 33.1% and 37.6%, respectively (median time to follow-up: 9.7 years). Fibrotic ILD progression on CT occurred at a rate of 12.0%. Multivariable logistic regression identified baseline fibrotic changes on CT as an independent risk factor for ILD progression (HR: 6.9; 95% CI: 1.3-46.8; p = 0.03). In a limited subset of SCD patients with available pulmonary function tests (n=69), those with radiographic progression had significantly worse pulmonary function compared to those without progression (FVC %pred: 56.0% vs. 73.6%, p<0.01; TLC %pred: 58.6% vs. 76.1%, p<0.01; DLCO %pred: 44.0% vs. 61.6%, p = 0.02).

CONCLUSION

This study demonstrates that fibrotic ILD in patients with SCD is common and identifies baseline CT fibrotic findings as predictive of long-term ILD progression which was associated with reduced lung function.

CLINICAL RELEVANCE/APPLICATION

The study shows that baseline fibrotic ILD in SCD patients is a significant marker of future disease progression and worsening pulmonary function. These results underscore that early radiologic evaluation may help identify those who will benefit from targeted management strategies to reduce the risk of ILD disease progression.

T1-SSCH05-6 CT-BASED ELASTIC REGISTRATION REVEALS DISTINCT MECHANICAL PROPERTIES ACROSS CT PATTERNS AND ABNORMAL MECHANICS IN NORMAL-APPEARING LUNG IN IDIOPATHIC PULMONARY FIBROSIS

Jooae Choe, MD, PhD (*Presenter*)
Jihye Yun, PhD (*Abstract Co-Author*)
Mihyun Yang, MD, MS (*Abstract Co-Author*)
Hye Jeon Hwang, MD, PhD (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Joon Beom Seo, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate lung deformation from elastic registration of chest CT scans in patients with idiopathic pulmonary fibrosis (IPF) across diseased parenchymal patterns and normal-appearing lungs, and assess their associations with prognosis.

METHODS AND MATERIALS

IPF patients and healthy controls (age =50 years) with paired inspiratory and expiratory HRCT images were retrospectively included. Deformation maps were generated through elastic registration of inspiratory/expiratory images, from which Jacobian determinants were calculated at whole-lung and lobar levels. Deep learning-based texture analysis classified lung parenchyma into normal, ground-glass opacity (GGO), reticulation, emphysema, and honeycombing regions. Jacobian metrics were compared between groups and across patterns. Multivariable analyses for 1-year lung function decline and survival were fitted for each Jacobian metric, adjusted for age, sex and baseline lung function.

RESULTS

A total of 245 patients with IPF (median age, 67 years; 80% male) and 48 with healthy controls (median age, 58 years; 42% male) were included. IPF patients demonstrated significantly higher mean whole-lung Jacobian determinant values compared to controls (0.65 ± 0.12 vs. 0.60 ± 0.12, P < 0.001), with most pronounced differences in lower lobes (right lower lobe: 0.60 ± 0.13 vs. 0.52 ± 0.12; P < 0.001). Normal-appearing lung regions of IPF patients showed the greatest median volume deformation (0.64, IQR 0.56-0.73), which was higher than that of healthy controls (P < 0.001), while GGO, reticulation, emphysema, and honeycombing areas showed significantly less deformation. Honeycombing regions exhibited the highest heterogeneity (Jacobian SD: median 2.86, IQR 2.47-3.39). The percentage of normal-appearing lung regions with higher Jacobian determinants (>0.6) in lower lobes was associated with FVC decline at 1 year (OR 1.12, 95%CI: 1.02-1.24; P = 0.02). In multivariable Cox models, greater spatial heterogeneity of volume change in normal-appearing lung was significantly associated with longer survival (Jacobian SD: adjusted HR, 0.62, 95%CI 0.40-0.98, P = 0.04).

CONCLUSION

Elastic registration of inspiratory-expiratory CT reveals distinct regional lung deformation in IPF. Greater areas of normal-appearing lower lobes with reduced deformation were linked to lung function decline, while higher deformation heterogeneity was associated with better survival.

CLINICAL RELEVANCE/APPLICATION

Elastic registration of inspiratory-to-expiratory CT captures functional abnormalities in radiologically normal-appearing lung, complementing visual pattern classification on CT by detecting early mechanical changes that may precede structural progression.

T1-SSGI06-1 ONE-STOP MULTIENERGY PANCREATIC DYNAMIC VOLUME PERFUSION IMAGING USING PHOTON-COUNTING DETECTOR CT: INITIAL EXPERIENCE

Yanzhao Yang (*Presenter*)
Huimin Lin (*Abstract Co-Author*)
Zhihan Xu, MD (*Abstract Co-Author*)
Weimin Chai (*Abstract Co-Author*)
Fuhua Yan, MS (*Abstract Co-Author*)

PURPOSE

This study reports initial experience with a modified one-stop, multienergy pancreatic VPCT protocol using PCCT, designed for comprehensive morphologic analysis and functional perfusion assessment of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

From April 2024 to October 2024, participants with suspected PDAC were prospectively enrolled and underwent preoperative pancreatic dynamic VPCT. Individual phase images were extracted from perfusion datasets using T3D, virtual monoenergetic images (VMIs) at 55 and 70 keV reconstruction for diagnostic interpretation. Diagnostic image quality was assessed both quantitatively and subjectively. Perfusion maps were generated for analysis. Perfusion parameters were compared between PDAC lesions and normal parenchyma, as well as among PDAC histopathological differentiation. Radiation doses were recorded.

RESULTS

A total of 65 participants (39 male; mean age, 66.2 ± 6.3 years) with histologically confirmed PDAC were included. The protocol achieved a mean effective radiation dose of 16.4 ± 4.5 mSv. All individual phase images met diagnostic quality standards (subjective scores = 3). Among these, 55 keV VMIs demonstrated the highest CNR for PDAC lesions and adjacent vasculature, and superior subjective scores for lesion conspicuity in both pancreatic parenchymal and portal venous phases (all $p < 0.05$). Perfusion parameters, including blood flow (BF), blood volume (BV), time to drain (TTD),mean transit time, time to start, Tmax, and flow extraction product (FEP), differed significantly between PDAC lesions and normal parenchyma (all $p < 0.05$). Poorly differentiated PDAC lesions exhibited significantly lower BF, BV, TTD, and Tmax values and reduced lesion-to-parenchyma ratios of BF, BV, and FEP compared to moderately-to-well-differentiated PDAC lesions.

CONCLUSION

The one-stop, multienergy pancreatic VPCT protocol using PCCT enables high-quality morphologic imaging and reliable functional perfusion assessment at reduced radiation doses.

CLINICAL RELEVANCE/APPLICATION

It provides valuable insights into PDAC differentiation and histopathological grading, with potential implications for improved clinical management.

T1-SSGI06-2 PANCREATIC IMAGING WITH ULTRA-HIGH-RESOLUTION PHOTON-COUNTING CT: PRELIMINARY EVALUATION OF IMAGE QUALITY

Rui Kun Huang, MD (*Presenter*)
Zhihan Xu, MD (*Abstract Co-Author*)
Yanzhao Yang (*Abstract Co-Author*)
Weimin Chai (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the potential benefit of ultra-high-resolution (UHR) photon-counting CT (PCCT) angiography for visualizing pancreatic ductal adenocarcinoma (PDAC) and peripancreatic arteries.

METHODS AND MATERIALS

From September 2024 to May 2025, participants with suspected PDAC were prospectively enrolled and underwent preoperative pancreatic CT angiography (CTA) using the UHR scanning mode of a PCCT system. The image data were reconstructed into six series: (a) 0.2mm slice thickness, T3D images; (b) 1 mm slice thickness, virtual monoenergetic images (VMIs) at 70 keV; (c-f) 0.4mm slice thickness, VMIs at 40, 45, 50 and 55 keV, respectively. All images were reconstructed using quantum iterative reconstruction (QIR) level 4 and the Br40 filter kernel. Image quality was evaluated both quantitatively and qualitatively. The sharpness of arteries and pancreatic duct border was also evaluated quantitatively.

RESULTS

Twenty-five participants (17 male; mean age, 62 ± 11 years) with histologically confirmed PDAC were included. In terms of quantitative image quality, in both the arterial and portal venous phases, 0.4 mm_40 keV_UHR images (c) demonstrated significantly higher SNR and CNR values for both PDAC lesions and peripancreatic arteries compared to other image sets (all $P < 0.001$). While the 1mm_70keV images (b) showed lower image noise ($P < 0.001$), 0.4mm_40 keV_UHR images (c) were rated higher in vessel and pancreatic duct sharpness (all $P < 0.001$). Qualitatively, 0.4mm_45 keV_UHR (5 ± 0) and 0.4mm_50 keV_UHR (5 ± 0) images were rated similarly, exceeding those of 0.4mm_40 keV_UHR (4.12 ± 0.33), 0.4mm_55 keV_UHR (4.36 ± 0.49), 0.2mm_T3D (3.56 ± 0.51), and 1mm_70keV (4.92 ± 0.28) images. Tumor and vessel delineation were comparable among the 0.4mm_45-50 keV_UHR reconstructions ($P = 0.346$) and superior to all other image sets ($P < 0.003$).

CONCLUSION

For PCCT, the 0.4mm_45 keV_UHR scanning mode demonstrated superior image quality-both quantitatively and qualitatively-for detecting pancreatic visualization, compared to other image sets.

CLINICAL RELEVANCE/APPLICATION

The 45 keV VMI with a slice thickness of 0.4 mm in UHR mode is recommended for pancreatic CTA.It improves the visualisation of pancreatic lesions and peripancreatic vessels, thereby facilitating more accurate preoperative assessment of PDAC.

T1-SSGI06-3 COMPARISONS OF RADIOGRAPHY TECHNIQUES (ITERATIVE RECONSTRUCTION VS. CONVENTIONAL RADIOGRAPHY) IN PANCREATICOBILIARY INTERVENTIONS: CLINICAL RETROSPECTIVE ANALYSIS

Noriyuki Sakai, MSc, RT (*Presenter*)
Tatsuya Sato (*Abstract Co-Author*)
Saori Koshino, MD, PhD (*Abstract Co-Author*)
Naminatsu Takahara (*Abstract Co-Author*)
Hidetake Yabuuchi, MD (*Abstract Co-Author*)
Katsuyuki Tabei (*Abstract Co-Author*)
Toshikazu Imae (*Abstract Co-Author*)
Osamu Abe, MD, PhD (*Abstract Co-Author*)

PURPOSE

To retrospectively investigate whether iterative reconstruction (IR), applied to fluoroscopic imaging systems, reduces radiography dose while maintaining clinical image quality in pancreaticobiliary interventions by comparing dose area product (DAP), the number of radiographs, and clinical image quality using IR with those using conventional radiography (CR).

METHODS AND MATERIALS

The institutional review board approved this retrospective observational study comparing radiography dose, the number of radiographs, and clinical image quality of the CR group (from March 2018 to March 2019) and IR group (from June 2021 to October 2022) in consecutive pancreaticobiliary interventions performed at a single center. The period between the groups was excluded because different imaging conditions were used. We enrolled interventions classified as either endoscopic retrograde cholangiopancreatography (ERCP), percutaneous transhepatic biliary drainage (PTBD), balloon-assisted endoscope-guided ERCP (BAE-ERCP), interventional endoscopic ultrasonography (iEUS), or endoscopic gastrointestinal stentings (EGS). We extracted clinical images (8 biliary stents, 7 pancreatic stents, 7 EGS, and 20 ERCP) for visual assessment. An endoscopist and a diagnostic radiologist independently and visually scored the overall image quality, noise, and depiction of each stent and pancreaticobiliary ducts on a four-point scale. We used the Mann-Whitney U test to identify significant differences between the groups in the DAP, the number of radiographs, and visual scores. A P -value less than .05 was considered statistically significant. Inter- and intra-observer agreement was calculated by weighted kappa statistics.

RESULTS

The enrolled 2,496 interventions (1,579 males and 917 females; IR group, n = 1,477; CR group, n = 1,019) consisted of 2,006 ERCP, 78 PTBD, 157 BAE-ERCP, 223 iEUS, and 32 EGS. There were significant differences between the IR group and CR group in DAP per examination (median, 1047.0 vs. 2437.0 mGy•cm 2 ; reduction rate, -57.0%), the number of radiographs (median, 10.0 vs. 13.0), and DAP per image (median, 104.6 vs. 192.7 mGy•cm 2 ; reduction rate, -45.7%), respectively (P < .001). There was no significant difference in the visual assessment (P > .05). Inter- and intra-observer agreement was almost perfect (range, 0.90-1.00).

CONCLUSION

In pancreaticobiliary interventions, IR reduced the radiation dose per examination and radiation dose per image by 57.0% and 45.7% without increasing the number of radiographs and degradation of clinical image quality.

CLINICAL RELEVANCE/APPLICATION

Radiation dose reduction of patients and operators could be achievable in pancreaticobiliary interventions using IR while maintaining clinical image quality.

T1-SSGI06-4 A CT-BASED HABITAT REGION HETEROGENEITY INDEX MODEL FOR PREDICTING EARLY LIVER METASTASES IN PANCREATIC DUCTAL ADENOCARCINOMA: A PILOT STUDY

Mengru Li (*Presenter*)
Wei Wei (*Abstract Co-Author*)

PURPOSE

The occurrence of liver metastasis following radical resection for pancreatic ductal adenocarcinoma (PDAC) significantly compromises patients' long-term survival. To address this challenge, we developed a CT-based tumor habitat region-driven heterogeneity quantification model and assess its prognostic capacity for survival.

METHODS AND MATERIALS

160 patients [68.0±10.0 years; 94 (58.8%) male] who underwent surgical resection and were pathologically proven with PDAC were recruited retrospectively from our hospital between january 2023 and December 2024. Based on CT values and texture feature, the tumor lesions were partitioned into habitat regions to comprehensively characterize tumor heterogeneity, and a model based on tumor heterogeneity index was developed using multivariate logistic regression in the training cohort. The performance of this model was evaluated by the area under the receiver operating characteristic curve (AUC) in an internal validation cohort. Subsequently, Cox regression analysis and log-rank test were employed to investigate the association between the model's risk stratification and PFS as well as OS.

RESULTS

A total of 160 patients were divided into the liver metastasis group (n=73), non-metastatic group (n=87). The IMC2 and Sum Entropy habitat heterogeneity indices emerged as independent predictors. The habitat model,clinical model,and the combined model yielded AUC of 0.743(95% CI: 0.45-0.65),0.616(95% CI: 0.57-0.75),0.762(95% CI: 0.63-0.80)in the training cohorts, respectively, which demonstrated that both habitat region features and the combined model exhibited significantly higher AUC values compared to the statistically significant clinical model (DeLong test: P = 0.003 for the habitat model; P = 0.001 for the combined model). No significant AUC difference was observed between the combined model and the habitat model. The habitat model’s risk stratification was an independent predictor of PFS (P<0.05) , The PFS of the predicted high-risk group was significantly shorter than the low-risk group.

CONCLUSION

Habitat analysis enables the quantification and visualization of distinct intratumoral subregions. The proposed habitat region heterogeneity index model provided a promising tool to predict early liver metastases and had a great significance in prognosis.

CLINICAL RELEVANCE/APPLICATION

a habitat analysis-based heterogeneity index model was developed and validated to predict early postoperative liver metastases. The model outperformed preoperative clinical models and demonstrated relatively robust predictive performance in subgroup analyses. Furthermore, significant associations were identified between heterogeneity index model and both PFS and OS.

T1-SSGI06-5 RELATING RADIOLOGIST LIKERT IMAGE QUALITY SCORES IN BARIATRIC PATIENTS TO A PHYSICS MODEL OF DETECTOR ELECTRONIC NOISE

Aria Salyapongse, MSc (*Presenter*)
Giuseppe V. Toia, MD, MS (*Abstract Co-Author*)
Hiroki Kawashima, PhD (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*)

PURPOSE

To examine the relationship between patient size and subjective image quality metrics to identify a threshold for minimum CT tube current below which image quality suffers.

METHODS AND MATERIALS

Subjective image quality metrics (noise texture, spatial resolution, directional noise streaking, and overall diagnostic quality) in the abdomen and pelvis were assessed on 145 subjects. Water equivalent diameter (WED) range was 25.8 - 46.5 cm and 25.1 - 46.5 cm in the abdomen and pelvis, respectively. Subjective image quality was assessed using a 5-point Likert scale (1 = better than needed quality and 5 = non-diagnostic quality). Statistical analysis for small (average WED of 30.7 cm in the abdomen, 29.2 cm in the pelvis, n = 49), medium (average WED of 36.4 cm in the abdomen, 35.4 in the pelvis, n = 40), and large (average WED of 43.4 cm in the abdomen, 43.0 in the pelvis, n = 54) subject groups was performed using the Kruskal Wallis test for significant differences and Dunnett's test for post-hoc comparison testing. To determine the minimum mA necessary at each WED, a circular phantom of plastic with a WED of 33.8 cm was scanned over a range of current (10-600 mA). The mA where electronic noise began to dominate was identified. This value was then put into an exponential model with a half-value layer of 3.6 cm to model minimum mA necessary for each WED.

RESULTS

The 3 WED cohorts (small, medium, and large) had statistically different ($p < 0.001$) Likert scores for all categories in both the abdomen and pelvis. Noise texture, spatial resolution, directional noise streaking, and diagnostic quality were significantly better ($p < 0.006$, $p < 0.005$, $p < 0.01$, $p < 0.001$, respectively) for small and medium WED compared to large WED in both anatomic regions. Noise texture, directional noise streaking, and diagnostic quality were only significantly better ($p < 0.002$, $p < 0.002$, $p < 0.02$, respectively) for small WED compared to medium WED in the pelvis. For the 33.8 cm phantom, deviation from ideal noise behavior with mA began near 175 mA. This resulted in an model for minimum mA of the form: 175*exp((WED-33.8)*log(2)/3.6)), which effectively separated most of the superior quality Likert scores (grades of 1 and 2) from the poor quality Likert scores (grades of 3-5).

CONCLUSION

By combining subjective image quality scores and a phantom-based mathematical model for minimum mA, this work demonstrated a method to scale the minimum mA necessary to achieve diagnostic quality images of the abdomen and pelvis as a function of patient size.

CLINICAL RELEVANCE/APPLICATION

We have demonstrated that a basic physics characterization of detector electronic noise performance can define the minimum tube current required to ensure diagnostic utility as a function of patient size.

T1-SSGI06-6 IMPACT OF ULTRASOUND MANUFACTURER ON LIVER EXAMINATION QUALITY

David T. Fetzer, MD (*Presenter*)
Yin Xi, PhD (*Abstract Co-Author*)

PURPOSE

Ultrasound (US) is the recommended first-line modality for hepatocellular carcinoma (HCC) screening. The Liver Imaging, Reporting and Data System (LI-RADS) for US Surveillance v2024 recommends a qualitative Visualization Score (VIS) to convey exam quality and expected sensitivity. Many patient factors are now known to influence VIS (eg. gender; weight; disease etiology and severity). Technical factors, including site, sonographer experience, and radiologist experience and subspecialty, are also confounders. What is unknown is the influence of US system manufacturer on VIS and quality of HCC screening exams.

METHODS AND MATERIALS

Structured reports for clinical US exams automatically capture US system, and include a picklist for VIS (A, No or Minimal Limitation; B, Moderate Limitations; and C, Severe Limitations). Reports, patient demographics, and exam information are transferred to a data warehouse, which was queried for all US Liver exams (preferred order for HCC surveillance). Exam characteristics included institution (County and University) and location (Outpatient, OP; Inpatient, IP; and Emergency, ED). From exam reports the following were extracted: VIS and US system: E10 (GE HealthCare), EPIQ (Philips Healthcare) and Sequoia (Siemens Healthineers), which were randomly assigned SYS1, SYS2, and SYS3. Mixed effects model was used to assess the influence of system on VIS. Technologist was included as random effect.

RESULTS

From Jan 2013 to April 2025, 79,200 US Liver examinations were identified, 7.6% from ED, 21% IP, and 68% OP (and 3.3% undefined). VIS rates were 65% VIS A, 30% VIS B, and 5.1% VIS C, in line with previous studies, with worse VIS rates for ED/IP compared to OP exams ($p<0.001$), and worse for patients with advanced age and higher BMI ($p<0.001$). VIS rates were worse for County site ($p<0.001$), where 100% of exams were performed on Philips and excluded from further analysis. 7,464 OP exams from University site included both SYS and VIS, 24% SYS 1, 63% SYS 2, and 13% SYS 3. SYS1 had worse VIS than SYS2 on average ($p = .007$), and such difference was most prominent in higher BMI range (>30) (Figure 1).

CONCLUSION

Statistically significant differences in VIS was seen between locations, and between groups of different ages and BMI, as previously seen. Significant differences in VIS rates was detected based on manufacturer overall, and between manufacturers in patients with obesity in particular.

CLINICAL RELEVANCE/APPLICATION

The choice of US system may impact quality of an institution's HCC surveillance program. Although this study was not designed to study the influence of device age, transducer, or software version, systems from different manufacturers may influence differences in graded study quality, particularly in patients with obesity.

Julius Chapiro, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate deep learning models that generate synthetic contrast-enhanced multiphasic MRI (CE-mpMRI) of the liver based on real non-contrast MRI obtained in hepatocellular carcinoma (HCC) and cirrhosis patients.

METHODS AND MATERIALS

This retrospective study included 3,198 MRI series from 260 HCC and 273 cirrhosis CE-mpMRI exams. A three-dimensional cycle-consistent generative adversarial network was trained to generate four synthetic postcontrast series (arterial, portal venous, delayed, hepatobiliary [HBP]) from real precontrast T1- and T2-weighted series. 80% of data was used for 10-fold cross-validation and 20% for an independent test set. Quantitative similarity, error metrics and dice similarity coefficient (DSC) between real and synthetic series were calculated. Three radiologist readers qualitatively assessed real and synthetic CE-mpMRI using a 6-task questionnaire (1: real vs synthetic, 2: is quality acceptable for diagnostic use 3: is disease (HCC or cirrhosis) diagnosable, 4: is liver anatomy accurate, 5: artifact severity, 6: target HCC lesion LI-RADS features).

RESULTS

Synthetic postcontrast CE-mpMRI demonstrated high quantitative similarity to real images with mean structural similarity index 0.86 ± 0.03, 0.75 ± 0.11; normalized root mean square error 0.08 ± 0.03, 0.13 ± 0.07; DSC 0.96± 0.07, 0.97 ± 0.05 in liver and tumor regions respectively. Qualitatively, there was no significant difference between real and synthetic series across tasks 1 - 5 (McNemar test: p= 0.06-0.50). The model successfully reproduced major LI-RADS features (non-rim arterial phase hyperenhancement, portal venous/delayed washout and enhancing capsule) and the ancillary HBP hypointensity shown by accuracy: 72 - 86%; precision: 96 - 100%; sensitivity: 70 - 87%; specificity: 73 - 100% in task 6. Interrater agreement was high in all tasks (Fleiss kappa: 0.58 - 0.96, p< 0.001).

CONCLUSION

The proposed model demonstrates early feasibility of using non-contrast MRI sequences to generate high-quality synthetic postcontrast CE-mpMRI, potentially offering a pipeline towards a viable alternative for conventional CE-mpMRI. These highly promising preliminary findings highlight the potential to transform liver MRI workflows and call for further studies to reproduce and validate our results in other disease-specific applications.

CLINICAL RELEVANCE/APPLICATION

This approach lays the groundwork to streamline liver CE-mpMRI by significantly reducing the cost of contrast agents, their potential side effects, shortening acquisition time - especially the prolonged HBP acquisition of 20 minutes and improving accessibility for patients unable to tolerate it (due to renal impairment, contrast agent allergy or claustrophobia).

T1-SSGI07-2 FEASIBILITY OF AI-ASSISTED COMPRESSED SENSING PROTOCOLS IN COLON MR IMAGING: A PROSPECTIVE COMPARISON WITH CONTRAST-ENHANCED CT

Zhen Guan (*Presenter*)
Xiao Zhang (*Abstract Co-Author*)
Ying-shi Sun, PhD (*Abstract Co-Author*)

PURPOSE

To provide a MR scanning protocol and prospectively compare the image quality, visualization of anatomy, tumor and lymph nodes conspicuity of AI-assisted compressed sensing (ACS) MRI with contrast-enhanced CT in colon cancer.

METHODS AND MATERIALS

Patients with pathologically confirmed colon cancer who underwent ACS MRI between August 2022 and April 2024 were eligible for this single-center prospective noninferiority study. All patients underwent CECT within one month prior to ACS MRI examination. Overall image quality, sharpness of peritoneum, sharpness of colonic

wall layers, tumor conspicuity, lymph node conspicuity and artifacts were assessed using a 4-point Likert scale. Contrast-to-noise ratio (CNR) and edge rise distance (ERD) were obtained and reported as medians and IQRs. The intergroup comparisons were performed using paired Wilcoxon signed rank test.

RESULTS

This study included 153 matched examinations from 132 participants (mean age, 58 years ±11 [SD]). Overall image quality scores were 4 (IQR, 3-4) at ACS MRI and 3 (IQR, 3-3) at CECT (P < .001). ACS MRI images improved sharpness of anatomic structures (peritoneum and colonic wall layers), tumor conspicuity and lymph node conspicuity (all P < .001). CECT was given higher scores for artifacts (median score, 4 [IQR, 3-4] vs 4 [IQR, 4-4], respectively; P < .001). In quantitative assessment, ACS MRI achieved higher CNR (5.46 [IQR, 4.24-7.00] vs 1.30 [IQR, 0.65-2.19]; P <.001) and shorter ERD (edge rise distance, 1.63 [IQR, 1.17-2.76] vs 3.70 [IQR, 2.84-5.01]; P <.001).

CONCLUSION

ACS MRI of colon with oblique scanning protocol was feasible and improved subjective overall image quality, sharpness of anatomic structures, tumor conspicuity and lymph node conspicuity compared with CECT. Furthermore, CNR and ERD were improved at ACS MRI.

CLINICAL RELEVANCE/APPLICATION

ACS MRI of colon with oblique scanning protocol was feasible in routine practice and improved subjective and objective image quality compared with contrast-enhanced CT.

T1-SSGI07-3 THE DIAGNOSTIC VALUE OF 5.0T ULTRA-HIGH-FIELD MRI SUSCEPTIBILITY WEIGHTED IMAGING COMBINED WITH MULTI-ECHO T2* MAPPING IN MICROVASCULAR INVASION OF HEPATOCELLULAR CARCINOMA

Ying Liu (*Presenter*)
Shao Peng Li II, DO (*Abstract Co-Author*)
Lianxin Liu (*Abstract Co-Author*)
Dawei Yin (*Abstract Co-Author*)
Peng Wang (*Abstract Co-Author*)
Mengqiu Liu (*Abstract Co-Author*)
Zhichao Feng, MD (*Abstract Co-Author*)
Runyu Tang (*Abstract Co-Author*)
Xiaopeng Song (*Abstract Co-Author*)

PURPOSE

To evaluate the application value of 5.0 T ultra-high-field magnetic resonance imaging (MRI) susceptibility weighted imaging(SWI) combined with multi-echo T2*mapping in microvascular invasion(MVI) of hepatocellular carcinoma(HCC).

METHODS AND MATERIALS

A retrospective analysis was conducted on 44 HCC patients who met the inclusion and diagnostic criteria. The SWI features of the lesions were analyzed, and the intratumoral susceptibility signal intensity(ITSS) was graded. Additionally, the R2* values of the lesions, peritumoral areas, and background liver tissue were calculated, along with the ?R2* values(?R2*=R2*lesion - R2*liver/R2*liver). Statistical analysis was performed to examine the differences in these parameters under different MVI statuses.

RESULTS

1. The interobserver agreement for both ITSS grading and R2* value measurements (in the liver, lesion, and peritumoral regions) between the two physicians demonstrated excellent consistency(?/ ICC >0.9). 2. According to pathological standards, the MVI-positive group exhibited higher ITSS grading, a greater likelihood of concurrent hemorrhage(p =0.031), and higher R2* values in the lesion, peritumoral area, and ?R2* compared to the MVI-negative group(60.07±25.22 vs 52..05±21.51, 94.32±29.32 vs 91.06±30.69, 0.39±0.40 vs 0.13±0.12). 3. Among these, the difference in ?R2* values was statistically significant (p = 0.041), and the diagnostic performance of ?R2* was superior to that of ITSS(0.686 vs 0.838). The combination of both can further improve diagnostic efficiency(AUC = 0.876).

CONCLUSION

Based on the 5.0T ultra-high-field SWI sequence, a high ITSS grade and the ?R2* value from the T2* mapping sequence are potential predictive biomarkers for HCC MVI. The combination of these two parameters can enhance diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

Based on the 5.0T ultra-high field SWI and multi-echo T2* sequence, ITSS and R2* values within the lesion can be quantitatively measured to predict HCC microvascular invasion. It is simple and easy to operate, with high diagnostic efficiency.

T1-SSGI07-4 FERUMOXYTOL AS DUAL-FUNCTION MRI CONTRAST AGENT AND RADIOPROTECTORIN MRI-GUIDED LIVER SBRT FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA AND CIRRHOSIS

Vladimir Kirichenko, MD (*Presenter*)
Danny Lee, PhD (*Abstract Co-Author*)
Andrew J. Klobuka, MD (*Abstract Co-Author*)
Alexandra Roudenko, MD (*Abstract Co-Author*)

PURPOSE

This study investigates the feasibility and outcome of a personalized MRI-guided liver SBRT planning with SPION contrast agent ferumoxytol® in patients with HCC and advanced cirrhosis and explores the cytoprotective effects of ferumoxytol.

METHODS AND MATERIALS

Utilizing human monocytic THP-1 undifferentiated and differentiated cells, we characterized the effect of ferumoxytol®, at clinically relevant concentration and therapeutically relevant radiation doses on cultured human monocytes and macrophages in vitro. All patients underwent MRI planning on the Unity MR-Linac following Ferumoxytol® injection. SPION-enhanced MR image set of tumor and functional hepatic parenchyma during per-fraction MRI-guided liver SBRT was used.

RESULTS

Ferumoxytol increased the resistance of human monocytes to radiation-induced cell death and supported the anti-inflammatory phenotype of human macrophages under radiation. Its effect depended on the duration of SPION uptake and was radiation dose dependent. With a median follow-up of 19 months 17 patients with hepatic cirrhosis received ablative SBRT to a median dose 44 Gy. Once IV injected, Ferumoxytol stays within hepatic Kupffer cells (KC) for weeks allowing precise targeting of hepatic tumors during the entire treatment course with median duration of 18 days. A contouring algorithm was generated for guided avoidance of functional liver volumes (FLV) during treatment plan adaptations on MRI-Linac. FLV loss was observed in all patients, with loss extent proportional to cirrhosis degree. While tumors received ablative irradiation, the mean dose to FLV was maintained below the liver threshold tolerance to radiation through personalized treatment planning. Seven patients successfully completed orthotopic liver transplant after SBRT. Complete regeneration of liver parenchyma outside 30-Gy isodose envelope conferring radioprotection or enhanced regeneration of liver parenchyma exposed to lower radiation doses during SPION-enhanced MRI-guided SBRT.

CONCLUSION

The findings support the dual role of ferumoxytol in improving imaging precision and potentially protecting hepatic function during SBRT.

CLINICAL RELEVANCE/APPLICATION

SPION-enhanced MRI enables consistent visualization of primary and metastatic liver tumors as well as functional hepatic parenchyma. It has direct application for SPION-enhanced MRI-guided radiotherapy to liver malignancies for precision targeting with avoidance of functional liver parenchyma in patients with pre-existing liver condition such as cirrhosis or prior liver-directed therapies. Additionally, ferumoxytol demonstrates radioprotecting effects on human monocytes and macrophages and protecting liver parenchyma.

T1-SSGI07-5 CHARACTERIZATION OF CHRONIC LIVER DISEASE USING INTRAVOXEL INCOHERENT MOTION (IVIM) IMAGING AND MAGNETIC RESONANCE ELASTOGRAPHY (MRE)

Damiano Catucci, MD (*Presenter*)
Sandro Von Daniken (*Abstract Co-Author*)
Verena Obmann, MD (*Abstract Co-Author*)
Annalisa Berzigotti (*Abstract Co-Author*)
Lukas Ebner, MD (*Abstract Co-Author*)
Johannes T. Heverhagen, MD, PhD (*Abstract Co-Author*)
Andreas Christe, MD (*Abstract Co-Author*)
Peter Vermathen (*Abstract Co-Author*)
Adrian T. Huber, MD, PhD (*Abstract Co-Author*)

PURPOSE

To analyze the combined diagnostic value of intravoxel incoherent motion (IVIM) imaging and magnetic resonance elastography (MRE) for better characterization of chronic liver disease (CLD) and detection of clinically significant portal hypertension (CSPH).

METHODS AND MATERIALS

This prospective study included 185 patients who underwent liver MRI including MRE and IVIM imaging between 03/2016 and 11/2023. Patients were grouped into those with early CLD (F0-F1; eCLD-group, n=21), intermediate CLD (F2; iCLD-group, n=19), advanced CLD (F3-F4; aCLD-group, n=20) and aCLD with CSPH based on the BAVENO VII consensus (aCLDPH-group; n=22). 103 patients without CLD served as a negative control group. IVIM imaging parameters (Tissue diffusivity D, Perfusion fraction PF and Pseudo-diffusion coefficient D*) and MRE liver stiffness (LS) were measured in all patients. Statistical analysis included the Kruskal-Wallis test for group comparison as well as simple and multiple logistic regression analysis for group differentiation.

RESULTS

All parameters differed significantly between all groups ($p<0.001$). PF and D* decreased with disease progression, while LS increased. D initially decreased in CLD patients but re-increased in those with portal hypertension. Consequently higher D-values indicated the presence of CSPH in advanced stages (OR 1.09, $p=0.009$). In addition, elevated LS-values consistently predicted CLD (early: OR 5.01, $p<0.001$; advanced: OR 4.94, $p<0.001$; portal hypertension: OR 2.24, $p=0.007$). Combining D+LS further improved diagnostic accuracy in differentiating disease stages (noCLD vs. eCLD: OR 0.94, $p<0.001$; OR 4.26, $p=0.003$; aCLD vs. aCLDPH: OR 1.10, $p=0.016$; OR 2.41, $p=0.012$).

CONCLUSION

IVIM parameters and MRE are helpful for better characterization of CLD-patients. Notably, combining D with LS further increased the discriminatory value when compared to MRE alone.

CLINICAL RELEVANCE/APPLICATION

Combination of IVIM imaging and MRE enables early noninvasive detection of liver disease and portal hypertension, representing a helpful alternative for patients ineligible for invasive testing.

T1-SSPD03-2 DEEP LEARNING-BASED QUANTIFICATION OF RADIOLOGIC PROGNOSTIC MARKERS IN LEGG-CALVÉ-PERTHES DISEASE VIA PERFUSION MRI

Joonoh Lee (*Presenter*)
Vishal Gokani (*Abstract Co-Author*)
Ahan Mistry (*Abstract Co-Author*)
Michael Wilde (*Abstract Co-Author*)
John Carter (*Abstract Co-Author*)
Salar Sanati (*Abstract Co-Author*)
Venkata Repaka (*Abstract Co-Author*)

PURPOSE

Legg-Calvé-Perthes Disease (LCPD) is idiopathic osteonecrosis of the pediatric femoral head. Gadolinium-enhanced perfusion MRI (pMRI) quantifies femoral-head perfusion and has been shown to predict femoral head sphericity at the healed stage. Hypoperfusion was previously estimated subjectively by clinicians. HIPVASC 1.0 was released as a platform for manual annotation of the hypoperfusion percentage, but it was not efficient. Additionally, pMRI offers excellent visualization of associated synovitis and granulation tissue, which were not analyzed by these prior methods. Here we present HIPVASC 2.0, a user-friendly computer-vision (CV) software that automates the analysis of the femoral head, hypoperfused regions, synovitis, and granulation tissue using a multi-channel nnU-Net model. We hypothesize that HIPVASC 2.0 will efficiently segment these key features on pMRI images with the accuracy of human observers.

METHODS AND MATERIALS

We retrospectively assembled 922 pMRI scans from LCPD patients aged 4-11. Scans were split into a training set of 568 hips (158 unaffected, 410 affected) and a test set of 354 hips (178 unaffected, 176 affected), all previously scored by clinicians and HIPVASC 1.0. Registered pre- and post-contrast T1-FS images produced subtraction maps, which were fused with pre-contrast data to form the multichannel input. Two independent observers delineated femoral head, hypovascular areas, synovitis, and granulation tissue on every scan. The model was trained for 1,000 epochs with augmentation and 5-fold cross-validation. Dice scores quantified segmentation accuracy, and ICCs compared HIPVASC-derived hypoperfusion %, femoral-head volume, synovitis volume, and granulation-tissue % against human ratings and the prior method.

RESULTS

The segmentation model showed high dice scores for femoral head (94%), hypovascular regions (97%), synovitis (83%), and granulation tissue masks (89%) (Fig. 1). ICC values for each biological metric were consistently high (ICC > 0.99), indicating strong measurement consistency with human observers. Hypoperfusion percentage closely matched clinician visual estimates and HIPVASC 1.0 (ICC > 0.99).

CONCLUSION

These results validate HIPVASC 2.0 in the objective segmentation of critical pathological regions in LCPD. While hypoperfusion percentage has been shown to correlate with final femoral head sphericity, ongoing studies will test whether femoral-head volume, synovitis volume, and granulation-tissue percentage further enhance prognostication.

CLINICAL RELEVANCE/APPLICATION

Automation of key pathological markers in pMRI via HIPVASC 2.0 offers efficient, reproducible measurements essential for improved prognostication and patient management in early-stage LCPD.

T1-SSPD03-3 DTI PREDICTS RESIDUAL GROWTH POTENTIAL IN ADOLESCENT KNEE

Camilo Perdomo, MD (*Presenter*)
Laura Santos Correa (*Abstract Co-Author*)
Ola F. Kvist, MD, PhD (*Abstract Co-Author*)
Ingrid Galvis, MD, MS (*Abstract Co-Author*)
Jorge A. Delgado, MD (*Abstract Co-Author*)
Niloofaralsadat Motamedi, MD (*Abstract Co-Author*)
Jie C. Nguyen, MD, MS (*Abstract Co-Author*)
Sachin Jambawalikar, PhD (*Abstract Co-Author*)
Sogol Mostoufi-Moab (*Abstract Co-Author*)
Diego Jaramillo, MD, MPH (*Abstract Co-Author*)

PURPOSE

To determine whether baseline mean diffusivity (MD) metrics from a single knee DTI scan can predict physeal status (open vs. closed) on serial 2-year follow-up.

METHODS AND MATERIALS

Prospective, multicenter study of 49 healthy participants (23 males, 26 females; 12-16 y). All underwent 3-T knee DTI (b = 0/600 s mm?², 20 directions, 2 × 2 × 3 mm^3 voxel volume) at baseline, 12, and 24-month follow-up (133 exams). Mean diffusivity (MD) and fractional anisotropy (FA) were extracted from manually

segmented distal femoral and proximal tibial physes at baseline. Cluster-robust logistic regression (univariate, multivariable) modeled the odds of an open physis with candidate predictors MD, FA, age, sex, and Tanner stage > 4.

RESULTS

Physes remained open in 99/133 femoral and 74/133 tibial examinations. On univariate analysis, higher baseline MD, younger age, and male sex were each associated with the tibial physis remaining open 12 months later ($p = 0.03$), whereas higher MD and younger age predicted an open femoral physis ($p < 0.01$). In multivariable models, higher baseline MD, younger age, and male sex (tibia only) were independent predictors of an open physis. In the femur, MD adjusted odds ratio (aOR) (4.9, 95 % CI 2.3-10.5, $p < 0.001$) was higher than age aOR 0.63 (0.40-0.93, $p = 0.02$). In the tibia, male sex exerted the strongest influence (aOR 8.3, 95 % CI 2.4 28.8; $p = 0.001$), while higher MD (aOR 4.0, 1.6-9.7; $p = 0.003$) and younger age (aOR 0.45 per SD, 0.25-0.82; $p = 0.01$) provided additional, independent discrimination. FA and Tanner stage remained non-significant ($p = 0.32$). Models showed good calibration (pseudo-R^2 0.29 femur; 0.28 tibia) without multicollinearity.

CONCLUSION

A single baseline MD measurement robustly identifies distal femoral and proximal tibial physes that will remain open after one year. Age enhances prediction in both bones, while sex provides additional value only for the tibia. FA and Tanner stage add no incremental value.

CLINICAL RELEVANCE/APPLICATION

MD-based DTI can non-invasively flag adolescents who still have meaningful longitudinal growth, informing optimal timing of orthopedic or endocrine interventions and reducing unnecessary serial imaging.

T1-SSPD03-5 TRANSRADIAL VERSUS TRANFEMORAL ACCESS FOR NEUROVASCULAR PROCEDURES IN CHILDREN - A 5 YEAR PROPENSITY SCORE MATCHING ANALYSIS

Kevin K. Fung, MBBS, FRCR (*Presenter*)
Chun Wai Lee, BSC,RT (*Abstract Co-Author*)
Carmen Parra-Farinas, MD (*Abstract Co-Author*)
Prakash Muthusami, MBBS, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the safety and feasibility of neurovascular procedures using radial arterial access in children.

METHODS AND MATERIALS

All transradial neurovascular procedures in patients aged = 18 years old in a single tertiary paediatric hospital over a 5-year period was retrospectively analysed and matched with a transfemoral cohort using propensity scores at a 1:1 ratio, based on age, gender, type of procedures, number of accesses. All radial accesses were performed by two pediatric interventional neuroradiologists and received weight-based heparin and vasodilator per protocol. Technical success was defined as completion of intended procedure without crossover to femoral access. Patient demographics, procedural details and complications were compared using appropriate statistical tests, with $p<0.05$ considered as significant. Multivariate logistic regression was used to assess risk factor for radial artery occlusion (RAO).

RESULTS

170 transradial neurovascular procedures, (65% at wrist, 35% at snuff box; 77% diagnostic, 23% interventional) were performed in 117 children (mean age = 14 years [S.D. 3.8 years], female = 93). No significant difference existed in age, weight and procedural type between both groups. 52 patients (30.5%) had multiple transradial procedures (range = 2 - 4). Technical success rate of transradial access was 94.9% (femoral=98.8%, p=0.24). There was no significant difference in procedural time (radial=131.7; femoral=138.5 min, p=0.64); dose-area product (radial=12166; femoral=11527μGy.cm 2 , p=0.72) and air-kerma (radial= 873; femoral=813mGy, p=0.69). Radial access had longer fluoroscopy time (radial=32.3; femoral=22.3min, p=0.06) but not reaching significance. Procedural complication rates were similar (radial=14.1%, femoral=14.7%, p=0.88). Radial access had higher rate of thrombo-occlusion (radial=7.1%, femoral=1.2%, p=0.006) but all were asymptomatic. Femoral access had higher rate of hematoma (radial=1.2%, femoral=10%, p<0.001). Sheath-to-artery ratio of =1 was an independent predictor of RAO (Adjusted odds ratio=6.8 [95%CI 1.5-31.5], p=0.01).

CONCLUSION

In a large volume pediatric practice, transradial approach can be safely adopted with similar success rate to transfemoral approach. Use of low-profile sheaths may help prevent RAO and improve success rate of subsequent transradial neurovascular procedures.

CLINICAL RELEVANCE/APPLICATION

Transradial access can be safely utilized for neurovascular procedures in children with similar success rate to transfemoral approach, allowing earlier ambulation and discharge. Optimisation of sheath-to-artery ratio by pre-procedural sonographic assessment of radial artery size and use of low-profile sheath are important to prevent RAO.

Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)

PURPOSE

Perfusion-weighted phase-resolved functional lung (PREFUL) MRI (PW-MRI) is currently trying to clinically set as one of the pulmonary functional imaging. For easier clinically set of PW-MRI, we tested photoplethysmography (PPG) gated method, and PPG-gated PW-MRI was directly compared quantitative regional perfusion and pulmonary functional loss evaluations with electrocardiogram (ECG)-gated PW-MRI and dynamic contrast-enhanced (CE)-perfusion MRI (DCE-MRI). The purpose of this study was to directly compare the capabilities of regional perfusion and pulmonary functional loss assessment among ECG- and PPG-gated PW-MRIs and DCE-MRI in patients with and without lung diseases.

METHODS AND MATERIALS

17 subjects were prospectively examined ECG- and PPG-gated PW-MRIs, DCE-MRI and pulmonary function test. Then, regional perfusion maps were generated from each MR data. To determine regional perfusion on three methods (Q ECG : ECG-PW-MRI, Q PPG : PPG-PW-MRI, and Q DCE: DCE-MRI), same region of interests (ROIs) were placed over peripheral lung zones in all lung fields on each map. Then, overall perfusion from each method was determined as the averaged value from all ROI measurements in all subjects. To determine the relationship of regional perfusion, Pearson's correlation was performed among three methods. Then, mean differences among three methods were compared by Turkey's HSD test. To assess pulmonary functional loss evaluation capability, each overall perfusion was also correlated with VC, FEV 1 and DL CO /V A .

RESULTS

There were significantly moderate or good correlations between each other (Q ECG vs. Q PPG : $r=0.79$, $p<0.0001$; Q ECG vs. Q DCE : $r=0.45$, $p<0.0001$; Q PPG vs. Q DCE : $r=0.49$, $p<0.0001$). Mean difference between Q ECG and Q PPG was significantly smaller than that of others ($p<0.05$). All overall perfusion showed significantly moderate or good correlations with pulmonary function test (VC: $0.6=r=0.63$, $p<0.05$; FEV 1 : $0.75=r=0.79$, $p<0.05$, DL CO /V A : $0.52=r=0.57$, $p<0.05$).

CONCLUSION

ECG- and PPG-gated perfusion-weighted PREFUL MRIs had limited differences and were considered at least as valuable as dynamic CE-perfusion MRI for quantitatively assessed regional perfusion and pulmonary function loss assessment.

CLINICAL RELEVANCE/APPLICATION

ECG- and PPG-gated perfusion-weighted PREEFUL MRIs had limited differences and were considered at least as valuable as dynamic CE-perfusion MRI for quantitatively assessed regional perfusion and pulmonary function loss assessment.

T1-SSPH06-2 ENHANCING CEREBRAL MICROBLEED SEGMENTATION USING JOINT TRAINING WITH SWI AND QSM MRIS: INFERENCING WITH SWI ONLY

Namkug Kim, PhD (*Presenter*)
Wooyoung Jo (*Abstract Co-Author*)
Jongjun Won, BS (*Abstract Co-Author*)
Joonseo Oh (*Abstract Co-Author*)
Hyungbin Park (*Abstract Co-Author*)
Jimin Sung (*Abstract Co-Author*)
Jonghun Won (*Abstract Co-Author*)
Hyunju Lee (*Abstract Co-Author*)
Yangsean P. Choi, MD, PhD (*Abstract Co-Author*)
EUNSEON JEONG (*Abstract Co-Author*)

PURPOSE

The anti-amyloid antibody lecanemab increases the risk of amyloid-related imaging abnormalities - hemosiderin (ARIA-H), which manifest as cerebral microbleeds (CMBs) on susceptibility-weighted image (SWI), making accurate CMB segmentation crucial for treatment management. Quantitative Susceptibility Mapping (QSM), derived from raw phase MR images, offers superior CMB visualization compared to conventional SWI but is often unavailable in clinical practice. This study proposes a multimodal training strategy incorporating QSM to enhance CMB segmentation performance while requiring only SWI for inference, addressing this clinical constraint.

METHODS AND MATERIALS

In this retrospective study, participants underwent brain MRI to evaluate cognitive impairment (train: N=287; test: N=74, scanned Jan-Mar 2024). We modified the nnUNet architecture from traditional channel-wise concatenation to a parallel joint training framework better suited for multimodal image learning. Performance was evaluated using a temporally independent internal validation set (N=334, scanned Jan-Mar 2023) and a multicenter external validation set (N=65 from 48 different hospitals) using Dice Similarity Coefficient (DSC) and free-response Receiver Operating Characteristic (fROC).

RESULTS

On the external set, the joint model showed [DSC, fROC]: SWI [0.52, 0.54], SWI+QSM [0.55, 0.61], SWI+Phase [0.48, 0.49], and SWI+Phase+QSM [0.57, 0.67], with significant performance gains from QSM integration ($p < 0.05$), respectively. Similar trends were observed in internal and temporally independent validation sets. In the temporally independent set, joint training showed performance gains [DSC, fROC] of: SWI+Phase [+0.08, +0.08], SWI+QSM [+0.06, +0.09], and SWI+Phase+QSM [+0.34, +0.44] compared to channel-wise results, respectively. Similar trends were observed across validation sets. In the internal set, simple concatenation of SWI and QSM resulted in performance decreases with SWI only [-0.04, -0.06], significantly underperformed compared to the joint training approach [+0.02, +0.05], respectively. Similar trends were seen with SWI and Phase.

CONCLUSION

QSM demonstrated superior performance gains compared to its source phase images in multimodal training. Our joint training strategy consistently outperformed channel-wise training using conventional concatenation across all combinations, with progressive improvements in both DSC and fROC, particularly when integrating QSM.

CLINICAL RELEVANCE/APPLICATION

This deep learning segmentation model enhances ARIA-H detection in patients undergoing lecanemab therapy. The model trained with QSM outperformed that trained solely on SWI, while retaining compatibility with SWI in the absence of QSM.

T1-SSPH06-3 IMPROVING DL SEGMENTATION OF HEAD/NECK PC-MRA WITH PULSATION ARTIFACTS: A SIMULATED ARTIFACT TRAINING STRATEGY

Daiki Tamada, PhD (*Presenter*)
Thekla H. Oechtering, MD (*Abstract Co-Author*)
Julius F. Heidenreich, MD (*Abstract Co-Author*)
Jitka Starekova, MD (*Abstract Co-Author*)
Eisuke Takai (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pulsation artifacts (PA) frequently compromise image quality of 3D phase-contrast magnetic resonance angiography (PC-MRA), particularly at low velocity encoding. This limits the accuracy of automated vessel segmentation that is needed for quantitative vascular analysis. This study aimed to develop and evaluate a deep learning (DL) approach using training data with simulated artifacts to improve segmentation robustness in the presence of PA.

METHODS AND MATERIALS

3D PC-MRA datasets (VENC=10, 30 cm/s) were acquired from healthy volunteers (N=16) under institutional review board approval with informed consent. A basic DL segmentation model (3D-UNET) was trained using original data from 7 volunteers. A second DL model (proposed) was trained with a novel training strategy incorporating simulated PA, mimicking realistic artifact patterns based on physiological flow. Segmentation performance was evaluated on data from 9 separate volunteers. The performance of the proposed DL model with simulated PA was compared to the basic DL method, a conventional intensity-based method (level-set) and against expert manual segmentations (verified by 3 radiologists, Fleiss' Kappa=0.91). Evaluation metrics included Dice coefficient (DSC), Intersection over Union (IoU), and Average Symmetric Surface Distance (ASSD). Statistical significance was assessed using ANOVA and Tukey's HSD test.

RESULTS

Both DL segmentation approaches significantly outperformed the conventional level-set method ($p<0.05$). Training with simulated PA significantly improved segmentation accuracy compared to training on naïve data, particularly for low VENC acquisitions (VENC=10 cm/s) where PA are most pronounced (Dice/IoU increases, $p<0.05$). Vessel delineation and reduced artifact misinterpretation were confirmed qualitatively, especially near major arteries (e.g., ICA) and in distal vessels, with the PA-trained model. Mean ASSD values were also generally improved with PA simulation training.

CONCLUSION

Incorporating simulated pulsation artifacts into DL model training significantly improves the accuracy and reliability of automated 3D PC-MRA segmentation, particularly in clinically challenging scenarios with moderate to severe artifacts, such as low VENC acquisitions.

CLINICAL RELEVANCE/APPLICATION

Pulsation artifacts are a common limitation of head/neck PC-MRA that degrades image quality and segmentation accuracy. The proposed DL training approach improves the robustness of automated vessel segmentation despite these artifacts, enhancing quantitative analysis of the head/neck vasculature. This may improve the assessment and monitoring of cerebrovascular diseases and other head/neck vascular conditions, reducing the need for manual segmentation.

T1-SSPH06-4 CLINICAL UTILITY OF A COMMERCIAL 0.55 TESLA MRI SYSTEM FOR THE EVALUATION OF RENAL LESIONS

Benjamin V. Hirshberg, DO (*Abstract Co-Author*)
Maria Masotti (*Abstract Co-Author*)
Reve Chahine, MD, FRCR (*Abstract Co-Author*)
Jacob Richardson (*Abstract Co-Author*)
Nicole Seiberlich, PhD (*Abstract Co-Author*)
Vikas Gulani, MD, PhD (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)

PURPOSE

To assess diagnostic performance of 0.55T MRI in characterizing cystic and solid renal masses according to Bosniak classification (cystic masses) and predicting histology (solid lesions).

METHODS AND MATERIALS

IRB-approved retrospective study included 34 patients (16 M, mean age 65±12yrs) with 35 renal masses scanned at 0.55T (MAGNETOM Free.Max, Siemens Healthineers). Imaging was performed using coronal and axial T2w HASTE, axial T1w dual-echo gradient-recalled echo (GRE), T1w opposed-phase and in-phase dual echo or Dixon, DWI (b=50, b=800 s/mm 2), T1w 3D GRE pre- and dynamically following gadolinium administration in arterial, venous, 3-min delayed phases. Six fellowship-trained abdominal radiologists independently reviewed the scans, and classified renal masses as cystic or solid, measured lesion size and documented laterality. For cystic lesions, Bosniak classification was assigned. For solid lesions, reviewers evaluated imaging features to predict histology (e.g. clear cell RCC, papillary RCC, angiomyolipoma). Factors that affect staging were assessed: renal vein involvement, local tumor invasion, and distant metastasis. Alternate diagnosis was considered for non-cystic or solid lesions (e.g., post partial nephrectomy scarring). Confidence in Bosniak categorization of cystic lesions and prediction of histology of solid lesions, based on image quality at 0.55T, was rated on 5-point Likert-type scale (1=Strongly unconfident, 5- Strongly confident). Scores >= 3 were considered clinically diagnostic. Fleiss' Kappa was used for inter-reader agreement.

RESULTS

There were 23 cystic masses, 7 solid masses and 5 alternate diagnoses. Mean score for diagnostic confidence was clinically acceptable (score=4.1). Inter-reader agreement for differentiating cystic from solid masses and excluding alternate diagnoses was substantial (k =0.68; CI [0.61, 0.74]). For cystic masses, inter-reader agreement on Bosniak classification (I/II, IIF, III/IV) was substantial (k =0.80; CI [0.67-0.92]). However, agreement for predicting probable histology of solid masses was fair (k =0.29; CI [0.16, 0.41]). Among solid masses, highest agreement was observed for nodal involvement (100%), adrenal involvement (86%) and enhancement characteristics (71%). However, agreement was lower for T2w signal characteristics (43%), and intralesional lipid content (43%). Small sample size limits strong conclusions.

CONCLUSION

0.55T MRI can effectively characterize cystic and solid renal masses and risk-stratify cystic renal masses according to Bosniak classification without compromising diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

0.55T MRI is a viable option for diagnosis, staging and active surveillance of cystic and solid renal masses.

T1-SSPH06-5 BRAIN MAGNETIC RESONANCE ELASTOGRAPHY (MRE) IMPLEMENTED IN A HIGH-PERFORMANCE HEAD GRADIENT SYSTEM YIELDS SUPERIOR MOTION ENCODING EFFICIENCY WITH IMPROVED CLARITY AND RESOLUTION FOR ASSESSING NEUROTRAUMA AND DEGENERATIVE NEUROLOGICAL DISEASE

Emily Long (*Presenter*)
Herman Morris, PhD (*Abstract Co-Author*)

PURPOSE

Magnetic resonance elastography (MRE) quantifies tissue mechanical properties and has emerged as a tool for studies of neurotrauma, neurodegeneration and cognition. Advancements in gradients, enhance performance with higher amplitude and faster slew rate to reduce TE, TR, and echo spacing, improving phase acquisition, scan time, SNR, and imaging artifacts. We implemented neuro MRE on a high performance head gradient (HPHG) with a slew rate of 500 m/T/s and a max amplitude of 200 mT/m on imaging and shear wave behavior.

METHODS AND MATERIALS

A 10-subject IRB-approved study evaluated gradient strength effects across MRE sensitive parameters. Actuation amplitude and frequency, encoding frequency, and gradient amplitude effects were explored. Scans were performed in a HPHG using EPI MRE sequences, a 32-Channel Coil, (2mm thk, 2mm voxel). Two inversions, clinical and research, were used for image processing. Octahedral shear strain SNR and motion encoding efficiency were recorded as performance indicators. Identical scans were repeated on a Contained Anthropomorphic Structured-gel Phantom for Elastography Research (CASPER) to emulate brain tissue properties and skull-brain motion transmission. Its hydrogel bulk mimics brain shear modulus (1-5 kPa), suspended in an agar and artificial CSF slurry representing the subarachnoid space.

RESULTS

HPHG improved motion encoding efficiency (MENC). Subject scans showed up to 8.5-fold MENC improvement, with a non-linear relationship between gradient strength and efficiency. Increased efficiency improved OSS-SNR, but only up to ~3 μm/rad, after which OSS-SNR degraded rapidly. CASPER scans confirmed the trend and showed phase wrap conditions near the identified limit. Bulk shear stiffness values (2-3 kPa) agreed with previous findings. Optimized encoding efficiency was demonstrated in a more clinically relevant case for a subject with bifrontal white matter gliosis.

CONCLUSION

Substantial improvement in data quality was observed with motion encoding efficiency up to a threshold. OSS-SNR improvement achieved far surpassed values considered clinically relevant, where optimization can improve other aspects of scan protocols. Gradient amplitude was adjusted, with slew rate kept at maximum. EPI benefits directly from slew rate, further study is needed to differentiate gradient speed and amplitude effects. Our findings show that enhanced gradient efficiency can improve data quality, but a limit exists where efficiency causes detrimental phase wrap.

CLINICAL RELEVANCE/APPLICATION

This study clarifies the advantages and limitations of high-performance gradient systems for brain MRE, guiding protocol optimization, inversion and signal processing methods, and acquisition techniques.

T1-SSPH07-1 MULTI-PHASE IMAGING USING 4-THRESHOLD PHOTON-COUNTING SPECTRAL CT WITH MULTI-CONTRAST INJECTIONS (I/HO) IN A PORCINE MODEL

Hubertus Pietsch, VMD, PhD (*Presenter*)
Gregor Jost, PhD (*Abstract Co-Author*)
Ralf Gutjahr, PhD (*Abstract Co-Author*)
Jonas Neumann (*Abstract Co-Author*)
Tristan Nowak, PhD (*Abstract Co-Author*)
Michael Grasruck, PhD (*Abstract Co-Author*)
Bernhard Schmidt, PhD (*Abstract Co-Author*)

PURPOSE

This animal study aimed to demonstrate feasibility for multi-phase thoracic-abdominal CT using two different contrast media (CM). An experimental injection protocol was tested in conjunction with a commercial photon counting CT scanner employing a multi-spectral four-threshold readout mode. Subsequently, multi-material separation was applied to visualize multi-phase information acquired with only one spectral CT scan.

METHODS AND MATERIALS

Conventional iodine-based CM was used for the first injection, timed to capture the portal-venous contrast phase in a Göttingen minipig. An experimental holmium-based CM was applied for a second injection, targeting the arterial imaging phase. The delay of the two injections (33 s) based on contrast dynamics from prior perfusion-mode examinations. Energy threshold settings were established at 20, 55, 72, and 90 keV, with 55 keV for close proximity to the k-edge of holmium (55.61 keV). An image-based three material-decomposition was applied.

RESULTS

The acquisition produced two quantitative material maps (iodine and holmium) and a virtual non-contrast image (i.e. without CM contributions). The iodine map shows a characteristic portal-venous phase enhancement while the arterial phase information is visible in the holmium map. It is possible to visualize three distinct vascular phases: (virtually) native, arterial, and portal-venous, using spectral processing on multi-contrast injections and spectral CT scanning.

CONCLUSION

This approach, combining dual-contrast injection, spectral image acquisition and multi-material decomposition allowed the delineation of multiple CM phases within a single scan of a living pig using a commercial photon counting CT scanner.

CLINICAL RELEVANCE/APPLICATION

Generating multiple vascular phases in one scan can lower radiation exposure and improve clinical workflow. This approach may be particularly beneficial for evaluating shunts or isolating arterial and portal venous components in hepatic perfusion. Photon counting CT enables for the first time precise spectral separation of different CM, and thus, could address relevant clinical needs. Currently, only iodinated CM are well-established, and with spectral alternative CM elements are clinically available. Ultimately, this study offers practical guidance on how to perform multi-injection protocols in a living pig model, potentially streamlining future preclinical investigations in this domain.

T1-SSPH07-2 IMPACT OF GANTRY STARTING ANGLE, PITCH, AND ROTATION TIME ON CERVICAL SPINE ASSESSMENT USING PHOTON-COUNTING-DETECTOR (PCD) CT: A PHANTOM STUDY

Chelsea Dunning, PhD (*Presenter*)
Chun Ruan, PhD (*Abstract Co-Author*)
George S.K. Fung, PhD (*Abstract Co-Author*)
Fides Schwartz, MD (*Abstract Co-Author*)
Aaron D. Sodickson, MD, PhD (*Abstract Co-Author*)

PURPOSE

Cervical spine CT image quality is often degraded in the shoulders by photon starvation that triggers projection averaging algorithms and results in spatial resolution losses. As the gantry starting angle may impact the degree of lateral projection photon starvation, the aim of this pilot study is to determine the optimal cervical spine protocol that is most robust against image quality effects due to the gantry starting angle.

METHODS AND MATERIALS

A Rando phantom with arm attachments was scanned with a PCD CT scanner (NAEOTOM Alpha) in ultra high resolution mode with varying pitch (0.35 to 1.0) and rotation time (0.25 s, 0.5 s, 1 s), 120 x 0.2 mm collimation, 140 kV tube voltage, and 11.3 mGy CTDI vol with tube current modulation on. Each scan protocol was repeated four times to vary the gantry starting angle, which is random and was extracted from the raw data. Full-spectrum images were reconstructed using filtered back projection with a medium-sharp (Qr68) kernel, 0.4 mm slice thickness, 122 mm FOV, and 512 matrix size. The noise was measured in 2.1 cm-diameter soft tissue regions in the neck and shoulders. The task-based MTF at 50% (MTF 50) in each acquisition was calculated by measuring a line profile across the bone/tissue interface of the pedicles in two axial slices in the neck and shoulders. The percent differences and a paired one-sided t-test in MTF 50 and noise values between lateral (± 20°) and anterior/posterior (A/P, all other) gantry starting angles were quantified.

RESULTS

Among six scan protocols, the gantry starting angle did not significantly affect the noise in the neck ($p = 0.27$) and shoulder ($p = 0.18$) regions, but the lowest percent differences in noise (< 2% in both regions) were achieved with pitch = 0.5 and rotation time 0.5 s. The lowest noise values in the shoulders were 70 HU for A/P and 67 HU for lateral starting angles with pitch 0.35 and rotation time 0.5 s. The gantry starting angle did not significantly affect the MTF 50 in the neck ($p = 0.33$) but possibly in the shoulders ($p = 0.01$); the lowest percent difference and the highest MTF 50 in the shoulders (lateral = 0.13 lp/mm and A/P = 0.12 lp/mm, < 8%) was achieved with pitch 0.35 and rotation time 0.5 s.

CONCLUSION

This pilot study suggests that a lower pitch and rotation time = 0.5 s may improve both noise and spatial resolution and reduce image quality dependence of cervical spine PCD CT images on gantry starting angle. These parameters may be too slow clinically, but they lend insights into this previously unexplored image quality consideration that warrants further study and optimization.

CLINICAL RELEVANCE/APPLICATION

Efforts to optimize cervical spine protocols that improve noise and spatial resolution in the lower cervical spine may require accounting for photon starvation and gantry starting angle effects.

T1-SSPH07-3 THE GAME OF Z: IMPACT OF SCAN AND RECONSTRUCTION PARAMETERS ON THE NOISE POWER SPECTRUM OF CLINICAL PCD-CT SYSTEMS ALONG THE Z DIRECTION

Humberto Monsivais, PhD (*Presenter*)
Xinming Liu, PhD (*Abstract Co-Author*)
Megan C. Jacobsen, PhD (*Abstract Co-Author*)
Xiujiang J. Rong, PhD (*Abstract Co-Author*)
Frank Dong, PhD (*Abstract Co-Author*)
Ke Li, PhD (*Abstract Co-Author*)

PURPOSE

To understand the impacts of scan mode and reconstruction algorithm on the noise properties of clinical photon counting detector CT (PCD-CT) not within axial slices but also along the orthogonal Z direction via 3D NPS measurements.

METHODS AND MATERIALS

Physical phantoms were repeatedly scanned six times by a NAEOTOM Alpha PCD-CT under different acquisition modes, including Standard, ultra-high resolution (UHR), and the Expert service mode. Scans were performed at seven dose levels by adjusting the mA from 5 to 300. For each acquisition, different types of reconstruction (e.g., T3D and keV images for Standard UHR acquisitions; total energy bin (T1) and high energy bin (T2) images for Expert acquisitions), and different combinations of kernel and quantum iterative reconstruction (QIR) strengths were used. After calculating 3D NPS from each ensemble of 3D image volumes, axial 2D NPSxy were generated by integrating the 3D NPS along the kz axis, while1D NPS along the z dimension was computed through 2D integration of the 3D NPS along kx and ky axes.

RESULTS

With the exception of service-mode T1 and T2 images, the shape of the 3D NPS demonstrate a strong dependence on radiation dose. Lower dose corresponds to lower mean NPS frequencies in both axial and z directions. While T1 and T2 image noise are nearly uncorrelated along the z direction, T3D and keV images show strong noise correlation along the z direction, which is further intensified when QIR is enabled. For monoenergetic images, the 3D NPS shifted towards lower frequencies when keV > 100. When comparing UHR and Standard modes with matched dose and reconstruction parameters, there is little difference in their 3D NPS for soft-tissue kernels such as Br44. However, for high-frequency kernels such as Br76, the 3D NPS of UHR images shows a lower magnitude in both the axial and z directions.

CONCLUSION

Even when QIR is disabled, nonlinear signal processing is applied in both axial and z directions during T3D and keV reconstructions in the clinical PCD-CT scanner. The major difference between the total energy bin image and the T3D image lies in this processing, which results in lower noise in the T3D images. There is minimal difference in signal processing and reconstruction algorithms between UHR and standard modes. When comparing different types of PCD-CT reconstructions, the use of 3D NPS is essential due to potential mismatches in the z-NPS shape.

CLINICAL RELEVANCE/APPLICATION

The 3D NPS results deepen end-users' understanding of the image quality characteristics of clinical PCD-CT scanners, enabling more informed optimization of scan and reconstruction parameters to enhance diagnostic performance.

T1-SSPH07-4 A METHOD FOR DYNAMIC, AUTOMATIC CALIBRATION OF PHOTON COUNTING DETECTOR CT USING FLYING FOCAL SPOT FOR REDUNDANT RAY SAMPLING

Scott S. Hsieh, PhD (*Presenter*)
James Day (*Abstract Co-Author*)
Xinchen Deng (*Abstract Co-Author*)
Magdalena Bazalova-Carter, PHD (*Abstract Co-Author*)

PURPOSE

Photon counting detectors (PCDs) for CT applications use direct conversion sensors that do not yet have the stability or uniformity of their energy integrating detector counterparts. These instabilities manifest as ring artifacts in reconstruction, and substantial effort is expended in reducing these artifacts. We propose a redundant sampling framework for this task.

METHODS AND MATERIALS

In redundant sampling, each line integral is sampled twice, using two nearby detector pixels. Because ring artifacts arise primarily from high-frequency variation in pixel response, a method that calibrates these two pixels against each other could eliminate most artifacts by nullifying any high-frequency differences. An ideal implementation would be flying focal spot, but because we did not have access to flying focal spot, we emulated it with two sequential acquisitions, with the detector shifted between acquisitions at a distance corresponding to 2.5 detector pixels. The two datasets were rebinned into a common geometry. We used an optimization program to estimate a time-varying gain factor for each pixel. The PCD used a CZT sensor from Redlen Technologies. No other software ring artifact or pileup correction was used, and the only other PCD calibration was an air scan.

RESULTS

Conventional PCD CT scans of a chicken thigh show strong artifacts at the edge of detector modules. These artifacts are largely suppressed once autocalibration is activated. The residual ring artifacts were estimated as 80 HU before autocalibration and 20 HU after autocalibration, which is only faintly visible above noise. Artifacts are stronger at higher mA because of pixel-specific sensitivity to pileup, and no explicit pileup model was used. Remaining ring artifacts may be due to temporal instability of the detector, because our two datasets were acquired several minutes apart.

CONCLUSION

Autocalibration reduces ring artifacts in a benchtop PCD CT system and could be achieved with flying focal spot.

CLINICAL RELEVANCE/APPLICATION

Production of photon counting detectors is limited because of the stringent requirements on CdTe or CZT sensor material. The proposed autocalibration technique could ease these requirements and improve access to PCD CT technology.

T1-SSPH07-5 HOW TO MEASURE THE PRE-SAMPLING MTF OF PHOTON COUNTING DETECTORS (PCD) FROM RECONSTRUCTED PCD-CT IMAGES?

Linying Zhan, MS, BSc (*Presenter*)
Christian De Caro (*Abstract Co-Author*)
Bujar Mehmeti, BSc, PhD (*Abstract Co-Author*)
Frank Dong, PhD (*Abstract Co-Author*)
Guang-Hong Chen, PhD (*Abstract Co-Author*)
Ke Li, PhD (*Abstract Co-Author*)

PURPOSE

Semiconductor-based photon counting detectors (PCDs) are widely recognized for their superior spatial resolution. However, the MTF of PCDs in clinical PCD-CT scanners has not been publicly reported. Despite the critical role of PCDs in PCD-CT systems, especially for ultra-high-resolution imaging applications, clinical users typically do not measure the detector MTF primarily due to the difficulty of obtaining raw detector data. This work presents a novel experimental method for measuring the pre-sampling MTF of PCDs using only reconstructed DICOM images from clinical PCD-CT scanners.

METHODS AND MATERIALS

A NAEOTOM Alpha PCD-CT was operated in static-gantry mode, with the x-ray tube parked at 12 o'clock and the PCD at 6 o'clock. A 1 mm Cu filter was placed above the PCD on the gantry's mylar window, oriented such that a straight edge was parallel to the detector row (axial) direction. The Cu filter was mounted on a linear translation stage, enabling fine adjustments of the edge position along z direction with 0.012 mm precision. Static-gantry PCD-CT acquisitions were performed, producing a stack of DICOM images of the edge. The variation in image signals along z was used to derive the post-sampling edge-spread function (ESF). The Cu filter was then translated along z in 13 steps, each spaced 1/13 of the detector pixel pitch. By pooling the ESFs from all z positions, the pre-sampling ESF was constructed, then differentiated and Fourier-transformed to generate the pre-sampling MTF. To ensure that the measured MTF reflected the detector MTF that was not affected by focal spot (FS) blur or the reconstruction algorithms, the experiments were repeated with different FS sizes (micro vs standard) and recon kernels (Qr40 vs Qr60).

RESULTS

From DICOM images of the edge acquired in Standard mode (PCD pixel pitch = 0.73 mm), the PCD MTF50 and MTF10 were measured at 7.2±0.4 lp/cm and 12.0±0.2 lp/cm, respectively. From DICOM images acquired in Ultra-High-Res (UHR) mode, the MTF50 and MTF10 values were 10.7±0.7 lp/cm 21.8±0.6 lp/cm, respectively. No significant difference in MTF was observed across different FS sizes or reconstruction kernels, confirming that the results reflect the intrinsic spatial resolution of the detector.

CONCLUSION

Pre-sampling MTFs of PCDs can be accurately measured using reconstructed PCD-CT images, without requiring access to raw detector data. The results confirm the excellent spatial resolution performance of the PCD in the Alpha scanner.

CLINICAL RELEVANCE/APPLICATION

From model-based image reconstruction, digital imaging trials, and clinical protocol optimization, PCD-CT clinical use and research benefit from a precise, quantitative understanding of the MTF of its detector—arguably the most critical hardware component of PCD-CT systems.

T1-SSPH07-6 MAXIMIZING IMAGE QUALITY THROUGH THE SYNERGY OF HIGH-RESOLUTION PHOTON-COUNTING DETECTOR CT AND DEEP LEARNING RECONSTRUCTION: A CORONARY PHANTOM STUDY

Toru Higaki, PhD (*Presenter*)
Fuminari Tatsugami, MD (*Abstract Co-Author*)
Yuko Nakamura, MD, PhD (*Abstract Co-Author*)
Megumi Nishigaki (*Abstract Co-Author*)
So Tsushima (*Abstract Co-Author*)
Kazuo Awai, MD (*Abstract Co-Author*)

PURPOSE

Photon-counting detector CT (PCD-CT) represents the next generation of CT technology, offering promising applications in high-spatial-resolution and multi-energy imaging. However, due to the inherently small detector cells used in high-resolution (HR) imaging, photon starvation often occurs, resulting in increased image noise. In recent years, deep learning-based reconstruction (DLR) has become widespread as an effective approach to reducing image noise in CT, offering noise suppression while preserving spatial resolution. This study aims to evaluate the effectiveness of combining HR imaging with DLR in PCD-CT using a coronary phantom.

METHODS AND MATERIALS

A 3D-printed coronary angiography phantom, shown in Fig.1, was used in this study. Image acquisition was performed using a clinical research PCD-CT system developed by Canon Medical Systems Corporation (CMSC), with HR mode. In comparison, a conventional energy-integrating detector CT (EID-CT), Aquilion ONE Genesis (CMSC), was employed. Scanning was performed using ECG-gated helical acquisition at 120 kV, with a clinical setting (CTDIvol: 9.5 mGy). Hybrid iterative reconstruction (HIR) and DLR were used in this study. For image quality evaluation, we measured standard deviation (SD), noise power spectrum (NPS), and task-based modulation transfer function (T-MTF).

RESULTS

Fig.2 summarizes the quantitative image quality metrics. Image noise (SD) in image reconstructed with EID_HIR, HR-PCD_HIR, and HR-PCD_DLR were 26.0 -, 27.7 -, and 24.9 HU, respectively. When comparing HIR-reconstructed images between EID-CT and high-resolution PCD-CT, the PCD-CT images exhibited higher spatial resolution but also greater noise. Subsequently, a comparison between HIR and DLR reconstructions of HR PCD-CT showed that DLR images achieved both improved spatial resolution and reduced noise. Overall, combining PCD-CT in HR mode with DLR produced the highest image quality among scans. Representative images in Fig.3 show these findings.

CONCLUSION

The HR PCD-CT demonstrated superior spatial resolution, beneficial for visualizing fine anatomical structures such as coronary arteries. However, this comes at the cost of increased image noise. The DLR enabled efficient noise reduction without introducing image blurring typically associated with reconstruction kernels, thereby maximizing the potential of HR PCD-CT imaging.

CLINICAL RELEVANCE/APPLICATION

The combination of HR PCD-CT and DLR has the potential to provide both high diagnostic performance and radiation dose reduction in the evaluation of coronary artery disease.

T2-STCE1-1 DIFFUSE MYOCARDIAL EDEMA IDENTIFIED BY CMR MAPPING: A DISTINCT INFLAMMATORY PHENOTYPE ASSOCIATED WITH SEVERE PRESENTATION IN ACUTE MYOCARDITIS

Yining Wang, MD (*Presenter*)
Jing-Hui Li (*Abstract Co-Author*)
Minjie Minjie, PhD (*Abstract Co-Author*)

PURPOSE

To investigate whether diffuse myocardial edema, identified by cardiac magnetic resonance imaging (CMR), represents a distinct inflammatory phenotype in acute myocarditis, and to evaluate its association with disease severity and treatment requirements.

METHODS AND MATERIALS

This retrospective study included 98 patients with acute myocarditis who underwent CMR between 2020 and 2023. Diffuse edema was defined as elevated T2 mapping values and/or T2-weighted signal intensity in at least 10 segments based on the American Heart Association 16-segment model (apex excluded). A subset of patients underwent endomyocardial biopsy to assess histopathologic findings in relation to imaging phenotypes.

RESULTS

Patients were categorized into two groups based on T2-weighted imaging and T2 mapping: diffuse edema (n = 23) and non-diffuse (localized or patchy) edema (n = 75). Patients with diffuse edema showed significantly higher rates of fulminant myocarditis (65% vs. 16%; P < 0.001), systemic inflammation and the need for advanced treatment, including corticosteroids (83% vs 41%), intravenous immunoglobulin (78% vs. 37%), and vasopressors (all p < 0.01). Immunological profiles revealed markedly lower median CD4? T-cell counts (261 vs 503 cells/μL; p = 0.009), CD8? T cells (215 vs 407 cells/μL; p = 0.006), and natural killer cells (54 vs. 137 cells/μL; p = 0.009) in the diffuse group. Although left ventricular ejection fraction and late gadolinium enhancement (LGE) extent were similar between the two groups, patients with diffuse edema exhibited significantly higher global T1 (1408 ± 79 vs. 1325 ± 107 msec; p = 0.002), T2 (54.0 ± 7.2 vs. 48.3 ± 8.1 msec; p = 0.002), and extracellular volume fraction (37.7 ± 5.6% vs. 32.3 ± 8.0%; p = 0.005).

CONCLUSION

Diffuse myocardial edema identified by myocardial parametric mapping is associated with a severe clinical phenotype in acute myocarditis, marked by systemic inflammation, immune dysregulation, and a greater need for intensive therapy. This phenotype is not captured by conventional function or LGE imaging, highlighting the prognostic value of mapping-based tissue characterization.

CLINICAL RELEVANCE/APPLICATION

Quantitative mapping on CMR enables the non-invasive identification of a high-risk inflammatory phenotype in acute myocarditis, providing additional diagnostic and prognostic information beyond that offered by conventional imaging. These findings could inform early risk stratification and guide treatment intensity.

T2-STCE1-2 PHOTON-COUNTING CT FOR DYNAMIC LUNG PERFUSION: VALIDATION OF A LOW-DOSE PROTOCOL IN A PORCINE LUNG TRANSPLANTATION MODEL

Anna Hunkemoller, BSc, MD (*Presenter*)
Thomas Werncke, MD,DIPLPHYS (*Abstract Co-Author*)
Julian Dittrich (*Abstract Co-Author*)
Cornelia M. Schaefer-Prokop, MD (*Abstract Co-Author*)
Frank K. Wacker, MD (*Abstract Co-Author*)
Hoen-Oh Shin, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the quantitative performance of dynamic low-dose photon-counting CT (PCCT) for lung perfusion imaging, compared to reference-dose PCCT and static perfused blood volume (PBV) imaging, at radiation exposures comparable to routine chest CT.

METHODS AND MATERIALS

Six Göttingen minipigs with left lung transplants underwent dynamic PCCT perfusion imaging at both reference and low-dose settings, as well as static PBV scans. Dynamic acquisitions used 10 mL of Iomeprol 400 contrast agent followed by 100 mL of saline, whereas PBV imaging used 70 mL of contrast. Quantitative perfusion parameters included Patlak-derived Blood Volume (BVP), Deconvolution-based Blood Volume (BVD), Blood Flow (BFD), Mean Transit Time (MTTD), Flow Extraction Product (FEP), and Time to Start (TTSD), analyzed across six lung regions. Statistical comparisons utilized Kruskal-Wallis tests and Bland-Altman analysis.

RESULTS

Dynamic low-dose PCCT showed strong agreement with reference-dose imaging across all perfusion metrics (BVP bias: 0.03; BVD bias: 0.04; all p > 0.2). BVP was significantly more robust under low-dose conditions than BVD (p = 0.011 and p = 0.001). Static PBV maps significantly differed from dynamic BVP (p < 0.001), indicating lack of quantitative equivalence. Regional perfusion deficits were reliably detected in 2/6 transplanted lungs by all methods. Despite using only 10 mL contrast, dynamic PCCT at low dose (1.36 mSv) achieved quantitative results equivalent to reference dose (2.37 mSv) and comparable radiation exposure to static PBV imaging (1.49 mSv).

CONCLUSION

Dynamic lung perfusion imaging with low-dose PCCT provides accurate, reproducible quantitative metrics at radiation levels equivalent to static PBV, using substantially less contrast agent

CLINICAL RELEVANCE/APPLICATION

Dynamic low-dose PCCT allows for comprehensive, time-resolved lung perfusion imaging using a small amount of contrast medium (10 mL) and a low radiation dose. This suggests that PBV is unnecessary when dynamic perfusion imaging is required.

T2-STCE1-3 CONTRAST-FREE POSTOPERATIVE IMAGING OF THE PULMONARY ARTERY VASCULATURE: INTRAINDIVIDUAL COMPARISON OF RELAXATION-ENHANCED ANGIOGRAPHY WITHOUT CONTRAST AND TRIGGERING (REACT) AND TIME-RESOLVED CONTRAST-ENHANCED MRA

Jan Paul Janssen, MD (*Presenter*)
Vanessa Schmidt (*Abstract Co-Author*)
Lukas Goertz (*Abstract Co-Author*)
Robert Terzis, MD (*Abstract Co-Author*)
Kenan Kaya, MD (*Abstract Co-Author*)
Carsten H. Gietzen, MD (*Abstract Co-Author*)
Lenhard Pennig, MD (*Abstract Co-Author*)

PURPOSE

As a novel 3D isotropic flow-independent non-contrast-enhanced MRA technique, Relaxation-Enhanced Angiography without Contrast and Triggering (REACT) has shown promising results in imaging of the pulmonary vasculature, primarily in patients without prior surgery. The purpose of this study was to assess the performance of REACT in comparison to time-resolved contrast-enhanced MRA (4D CE-MRA) in patients with prior surgery of the pulmonary arteries or right ventricular outflow tract, with a focus on the impact of various implants.

METHODS AND MATERIALS

This retrospective single-center study included 53 patients (29 years [18-37], 26 male) with congenital heart disease, who underwent both 4D CE-MRA (scan time: 247s [167-354]) and REACT (electrocardiogram- and respiratory-triggering, Compressed SENSE (factor 9); scan time: 363s [282-422]) at 1.5 T. Surgical history included: conduit (n=15), valve replacement (n=10), stent implantation (n=19), patch repair (n=18), and others. Three radiologists independently assessed image quality (IQ) as well as susceptibility and motion artifacts on 5-point Likert scales (5=excellent) for the main, left, and right pulmonary arteries (MPA/LPA/RPA). Diameters were measured, and stenosis or dilatation was recorded.

RESULTS

REACT showed higher overall IQ than CE-MRA (3.78 [3.11-4.22] vs. 3.11 [2.33-3.44]; $p<0.001$), less motion (4.22 [3.89-4.67] vs. 3.11 [2.67-3.56]; $p<0.001$) and comparable susceptibility artifacts (4.33 [3.22-4.78] vs. 4.44 [3.56-4.67]; $p=0.254$). Subanalysis revealed higher image quality with REACT regardless of the implant type (all $p<0.05$); only stents resulted in equally poor image quality (2.00 [1.33-3.0] vs. 2.00 [1.67-3.00]; $p=0.860$) with impairing susceptibility (1.67 [1.33-3.50] vs. 2.00 [1.67-3.67]; $p=0.148$). Of note, in three of the stented vessels the 4D CE-MRA showed a faint intraluminal signal, while no lumen at all was visible in REACT. Diameter measurements (ICC: 0.967-0.987) tended to be larger in 4D CE-MRA, although only RPA differed significantly (17.29±5.00 mm vs. 18.08±4.96 mm; $p=0.002$). Stenoses (16 of 159 segments) and dilatations (24 of 153 segments) were detected equally.

CONCLUSION

REACT provides contrast-free imaging after surgery of the pulmonary arteries with superior image quality compared to 4D CE-MRA. However, susceptibility artifacts remain a limitation in stented segments. Albeit 4D CE-MRA may offer slightly improved visualization in selected cases, stent assessment in MRA remains challenging.

CLINICAL RELEVANCE/APPLICATION

REACT is a valuable alternative to 4D CE-MRA for postoperative imaging of the pulmonary arteries and can help reduce contrast exposure in routine follow-up imaging. For targeted stent evaluation, other imaging methods may be preferred.

Diana S. Buist, PhD,MPH (*Abstract Co-Author*)
Bryan Haslam, PhD (*Abstract Co-Author*)

PURPOSE

AI has shown strong potential to improve breast cancer screening outcomes. However, real-world variables—such as changes in clinical practice, patient populations, or imaging hardware—can lead to data shifts, requiring timely adjustments to AI tools to maintain safety and efficacy. Monitoring is essential and must be supported by robust data infrastructure, response processes, and clinician feedback loops. This study presents a real-world example in which a change in mammography hardware led to a detectable shift in AI outputs, prompting a collaborative recalibration process.

METHODS AND MATERIALS

From Jun 2022, a multistage AI-driven screening workflow-involving concurrent CADe/x reading and an AI-facilitated safeguard review-was deployed across 109 U.S. sites predominantly using mammography hardware #1. From Feb-Mar 2025, 34 sites began transitioning partially or fully to hardware #2, with updated AI configurations. A real-time data pipeline was established to monitor metrics such as recall rates (RR) and AI suspicion level distribution, and delayed metrics requiring cancer follow-up. In week 1 post-rollout, clinicians observed that AI-generated bounding boxes appeared larger than with hardware #1, triggering radiologist interviews to assess clinical utility impact. Bounding box parameters were refined in close collaboration with radiologists, and validated prior to FDA submission.

RESULTS

For the initial cohort, exam distribution was 77.3% on hardware #1 (N=15083) vs 22.7% on hardware #2 (N=4430) for the 3 months post hardware change. Site RR 3 months pre- (N=15758) and post-change was 12.7% (95% CI: 12.2, 13.3) and 11.4% (95% CI: 11.0, 11.9), respectively. AI suspicion level distributions (High, Intermediate, Low, and Minimal) remained similar with less than 4% change pre- and post-change: 3.8%, 21.9%, 45.9%, and 28.4% vs 4.7%, 18.1%, 49.7%, and 27.4%. Usability testing guided bounding box recalibration. Bounding box validation on a test set (N=3235) showed a mean box area change on hardware #2 from +30.8% to -7.3% relative to hardware #1, improving user satisfaction. An FDA filing including the design change followed within 3 months of initial feedback.

CONCLUSION

Real-time monitoring showed stable efficacy post hardware change. The bounding box shift was detected within 1 week, prompting collaborative adjustments through close vertical integration between technology manufacturer and clinical service provider. Refinements and FDA submission filing took 3 months.

CLINICAL RELEVANCE/APPLICATION

Monitoring is a cornerstone of safe AI deployment. In this study, the AI manufacturer partnered with radiology sites to implement a scalable data pipeline and feedback loop enabling timely detection, investigation, and response to AI drift signals.

T2-STCE2-2 VERY LARGE-SCALE DEPLOYMENT OF AN AI ORCHESTRATION SYSTEM FOR RADIOLOGIST WORKFLOWS IN IMAGING-BASED MULTICENTER CLINICAL TRIALS

Joel Schaerer, PhD (*Presenter*)
Alessandro Delmonte, MSc (*Abstract Co-Author*)
Janos Szalma, PhD (*Abstract Co-Author*)
Kostia Mannevy (*Abstract Co-Author*)
Adam Juhasz (*Abstract Co-Author*)
Thomas Cajgfinger (*Abstract Co-Author*)
Pohan Chen (*Abstract Co-Author*)

PURPOSE

Successful implementation of imaging-based clinical trials depends on high-quality, harmonized imaging data for reliable outcomes and regulatory compliance. Enforcing standardization in clinical environments requires significant clinical radiologist involvement for acquisition oversight, quality control and image interpretation. We implemented at very large scale a centralized AI orchestration system to support multicenter clinical trial execution, improving data acquisition quality and reducing endpoint variability in imaging workflows.

METHODS AND MATERIALS

We deployed at scale a 21 CFR Part 11 compliant AI orchestration system supporting image acquisition and analysis workflows for central radiological assessment of clinical trials endpoints. The system integrates: (1) Automatic image triage establishing reader worklists and flagging deviations from expected acquisition protocols, triggering corrective actions. (2) Facial features anonymization ensuring regulatory compliance (3) AI-driven quality control detecting image artifacts and improving data

integrity by raising site queries before image interpretation. (4) Quantitative image assessment for radiological review, allowing for consistent disease measurement and enabling trial endpoints estimation. Using a physician-in-the-loop design, radiologists can at all times accept, modify or reject AI predictions from their worklist.

RESULTS

The AI system was deployed on 644 clinical trials and post-deployment monitoring was implemented to evaluate performance of individual AI components compared to manual annotations. Between February and July 2025, 1.1 million exams were triaged with an accuracy of 95.5% across CT, MRI, PET, ultrasound and radiographic imaging. Quality control was applied on 329,718 exams, with accuracy ranging from 78.7% for motion artifacts to 96.5% for anatomical coverage issues, leading to timely site queries. Quantitative image reading effectively assisted 2,828 endpoint assessments for 16 indications with 96.2% overlap with radiologist measurements.

CONCLUSION

The implemented AI system offered scalable support for large multicenter imaging-based clinical trials, enforcing high data quality and supporting consistent endpoints estimation by clinical radiologists. Efficient AI-human interactions enabled widespread usage in all phases of image analysis across indications including neurodegenerative diseases, oncology, metabolic and rare diseases.

CLINICAL RELEVANCE/APPLICATION

Large scale usage of the proposed AI system can increase data quality and endpoints consistency in multicenter clinical trials, supporting image analysis and regulatory compliance while reducing variability in clinical radiologist assessment over time.

T2-STCE2-3 PROOF-OF-CONCEPT EVALUATION OF VISION-LANGUAGE MODEL INTO RADIOLOGY WORKFLOW: MRI SEQUENCE STANDARDIZATION FOR METADATA HARMONIZATION AND SCALABLE DEPLOYMENT

Satvik Tripathi (*Presenter*)
Thomas C. Arnold, PhD (*Abstract Co-Author*)

PURPOSE

Inconsistent MRI metadata across scanners and institutions hinders radiologists' workflow and limits AI deployment. We evaluated the use of vision-language models (VLMs) for zero-shot brain MRI sequence classification and metadata harmonization to standardize imaging, improve workflow efficiency, and support scalable algorithm deployment across enterprise health systems.

METHODS AND MATERIALS

Five VLMs (BiomedGPT, BiomedCLIP, MedCLIP, LLaVA-Med, UniMedCLIP) were evaluated on 2D brain MRI slices in three experiments: (1) benchmark testing on 25 images across six canonical sequence types; (2) stability assessment via 10 repeated zero-shot inferences per image; and (3) evaluation on a 140-image curated dataset and a 571-image real-world, multi-site dataset spanning 13 sequence types. Performance was measured using accuracy, consistency scores, and confusion matrices.

RESULTS

UniMedCLIP outperformed other models with 90.2% accuracy on the benchmark set, 92.1% on the curated set, and 82% on the real-world dataset. Stability testing revealed significant differences across models (ANOVA, $p < 0.001$), with UniMedCLIP demonstrating the highest consistency (mean = 9.76/10, SD = 0.44). Most misclassifications occurred between related sequences (e.g., DWI vs ADC, T1 vs T1c). Harmonization was validated by comparing it with native DICOM metadata.

CONCLUSION

Zero-shot VLMs, particularly UniMedCLIP, provide strong sequence classification and metadata harmonization performance across diverse MRI datasets. These tools can optimize radiologist workflows by ensuring consistent hanging protocols across all sites and scanners, and by enabling downstream AI tools to accurately identify and process relevant exams (e.g., routing prostate MRIs to prostate-specific algorithms).

CLINICAL RELEVANCE/APPLICATION

This proof-of-concept demonstrates the feasibility of integrating VLMs into radiology workflows, facilitating standardized metadata, consistent hanging protocols, and scalable AI deployment—critical steps toward real-world implementation of imaging AI across enterprise systems.

PURPOSE

To retrospectively validate and compare 7 commercial deep learning (DL) breast cancer detection algorithms for triaging mammograms in the triennial UK breast screening program, which uses double reading.

METHODS AND MATERIALS

Screening full-field digital mammograms (FFDMs) were retrospectively collected from two screening sites across 4 years (site 1: 2017-18, site 2: 2015-17) and processed by 7 DL algorithms (DL-1, DL-2, ?, DL-7); each outputs a cancer detection score. Exclusion criteria were subsequent FFDMs for the same woman, <40 months follow-up, or algorithm results unavailable. Ground truth was histopathology for cancers; 40 months follow-up for normal cases. The area under the receiver operating characteristic curve (AUC) was estimated and compared (DeLong's test) for each DL for all FFDMs and independently within FFDM vendor (GE and Philips) subsets. For triage simulation, low-suspicion FFDMs were first ruled out at 99% sensitivity, sending these FFDMs to single reading only, with arbitration if that reader decided to recall these cases. Of the remaining FFDMs, high suspicion cases were ruled in with 99% specificity, automatically recalling these cases. All remaining FFDMs were sent to double reading as normal. Resulting sensitivity, specificity, arbitration rate and recall rate were calculated for if each DL was used to triage in this way.

RESULTS

117,910 FFDMs were collected and, after exclusion criteria, detection scores from the 7 DLs for 66,369 FFDMs were analyzed (GE: 69.6% [n=46,204], Philips: 30.4% [n=20,165]), including 1,132 cancers (GE: 64.1% [n=726], Philips: 35.9% [n=406]). For DL-1-through-7, respectively: on all data AUCs were 0.89, 0.88, 0.86, 0.88, 0.81, 0.87 and 0.89, with DL-5 statistically lower than the second worse-performing DL, DL-3 (0.81 vs 0.86; $p<0.01$). On GE FFDMs only, AUCs were 0.90, 0.90, 0.88, 0.89, 0.85, 0.88, and 0.90; and on Philips FFDMs only, AUCs were 0.87, 0.84, 0.86, 0.87, 0.85, 0.87, and 0.88. AUCs were found to statistically decrease with Philips FFDMs for DL-1 (0.90 vs 0.87; $p=0.013$) and DL-2 (0.90 vs 0.84; $p<0.05$). Double reading specificity was 97.6% with a sensitivity of 68.4%. Triage simulations with all DLs had specificities which were equivalent to double reading with higher sensitivities.

CONCLUSION

Performance differences were found between DLs, but, when used in triage simulations, all were found to be non-inferior to double reading.

CLINICAL RELEVANCE/APPLICATION

Using DLs to triage FFDMs could reduce reading workload without loss of sensitivity.

T3-SSBR05-2 MULTISTAGE AI-DRIVEN WORKFLOW IMPROVES GENERAL RADIOLOGIST SCREENING MAMMOGRAPHY PERFORMANCE TO THE LEVEL OF FELLOWSHIP-TRAINED BREAST IMAGERS: REAL-WORLD EVIDENCE IN >500,000 PATIENTS

Matthew McCabe, PhD (*Presenter*)
Leeann Louis, BS, PhD (*Abstract Co-Author*)
Jiye G. Kim, PhD (*Abstract Co-Author*)
Annie Ng, PhD (*Abstract Co-Author*)
Christoph I. Lee, MD,MS (*Abstract Co-Author*)
Diana S. Buist, PhD,MPH (*Abstract Co-Author*)
Bryan Haslam, PhD (*Abstract Co-Author*)
Edgar Wakelin (*Abstract Co-Author*)

PURPOSE

Interpretive performance in screening mammograms (SMGs) varies widely resulting in variable care for patients. Integrating AI into the screening workflow could help standardize the quality of care. However, large scale studies of the impact of AI in the real world are lacking, particularly related to radiologists with different levels of specialization. Here, we assessed the impact of a multistage AI-driven workflow on the interpretive performance of General radiologists compared to Fellowship-trained breast imagers.

METHODS AND MATERIALS

An AI-driven workflow was deployed at scale across 5 community radiology practices (109 facilities, 95 radiologists), which involved a CADe/x device providing lesion bounding boxes and suspicion categories during interpretation, plus an AI-facilitated safeguard review routing potential missed findings to breast imaging experts. Performance before and after implementation of the workflow was compared between radiologists with and without fellowship training in breast or women's imaging. SMGs from Sept 2021-May 2022 formed the Standard of care (SOC) cohort (using only non-AI CAD tools), and exams from Aug-Dec 2022 formed the AI-driven workflow cohort. Outcomes were cancer detection rate (CDR), recall rate (RR) and positive predictive value of recalls (PPV1). Generalized Estimating Equations were used to adjust outcomes for clustering within radiologist, radiologist covariates (experience years, SMG exam volume) and patient factors (demographics, previous breast cancer, time since last SMG).

RESULTS

A total of 577 742 SMGs were included, 211 931 were read by 35 Fellowship-trained radiologists (SOC: 133 975; AI-Driven workflow: 77 956) and 365 811 were read by 60 General radiologists (SOC: 235 272; AI-Driven workflow: 130 539). Fellowship-trained radiologists had higher CDR (4.47, 95% CI: 3.94-5.07) than General radiologists (3.76, 95% CI: 3.46-4.08) during SOC (p=0.027). The AI-Driven workflow improved General radiologist CDR (4.99, 95% CI: 4.51-5.53, p<0.001) such that Fellowship-trained and General radiologists CDR did not differ with the AI-Driven workflow (Odds Ratio [OR]=0.95, 95% CI: 0.82-1.11, p=0.53). RR increased for General radiologists (OR=1.17, 95% CI: 1.04-1.30, p=0.007) less than the CDR increase, resulting in an increase in PPV1 (OR=1.16, 95% CI: 1.02-1.31, p=0.019), indicating the increased recalls found cancers at a higher rate.

CONCLUSION

The Multistage AI-Driven workflow significantly improved CDR and PPV1 for General radiologists to levels comparable with Fellowship-trained radiologists.

CLINICAL RELEVANCE/APPLICATION

An optimized AI-driven screening workflow can improve breast screening programs by providing Fellowship-trained performance to all patients.

T3-SSBR05-3 COMPARING FOUR COMMERCIAL AI ALGORITHMS FOR STANDALONE BREAST CANCER DETECTION ON DIGITAL BREAST TOMOSYNTHESIS IN A DUTCH POPULATION-BASED SCREENING COHORT

Sarah D. Verboom, MSc (*Presenter*)
Jessie J. Gommers, MSc (*Abstract Co-Author*)
Lindy Kregting (*Abstract Co-Author*)
Daan Van Den Oever (*Abstract Co-Author*)
Mireille Broeders, PhD (*Abstract Co-Author*)
Ioannis Sechopoulos, PhD (*Abstract Co-Author*)

PURPOSE

To compare the performance of four commercial artificial intelligence (AI) computer aided detection algorithms for digital breast tomosynthesis (DBT) in a Dutch population-based breast cancer screening cohort.

METHODS AND MATERIALS

The STREAM trial aims to compare the performance of DBT to that of digital mammography for nationwide breast cancer screening in the Netherlands. The first of two screening rounds with DBT was completed between July 2023 and May 2024. All women received the standard four-view screening DBT examination with Hologic 3Dimensions. Four commercially available AI algorithms were tested on the available DBT slices of the first screening round, and synthetic 2D if desired by the AI algorithm. All examinations were double read by two breast screening radiologists trained to interpret screening DBTs, with arbitration in case of disagreement. Only examinations where cancer was confirmed by biopsy after recall were considered cancer cases when evaluating the AI algorithms. The area under the receiver characteristics curve (AUC) of the four AI algorithms were compared using the MRMCaov R package (version 0.3.0). Future follow-up results will include evaluation of the examinations of all included women and information to include interval cancers that were diagnosed within 2 years after the screening examination.

RESULTS

All four AI algorithms processed 16,916 out of the 18,186 (93%) DBT examinations of the first round. Of these examinations, 444 women were recalled at screening (2.6% recall rate), and 145 cancers were detected after recall (8.6‰ cancer detection rate). The four AI algorithms had an AUC of A: 0.978 (95%CI 0.967-0.989), B: 0.973 (95%CI 0.964-0.983), C: 0.953 (95%CI 0.941-0.965), and D: 0.943 (95%CI 0.932-0.954). The AUCs of vendor A and B were each significantly higher than those of vendor C and D (four comparisons with p<.001). There was no significant difference between the AUCs of vendor A and B (p=.41) and the AUCs of vendor C and D (p=.11). At a recall rate fixed to that of screening (2.6%) the AI algorithms detected A: 121 (83%), B: 106 (73%), C: 68 (47%) and D: 45 (32%) of the 145 screen detected cancers. The highest 20% of scores included at least 97% of screen detected cancers, for all AIs.

CONCLUSION

There are significant differences in performance between some of the four commercial AI algorithms when evaluating screening DBT examinations. A study limitation is that follow-up is ongoing and therefore there is only information on screen detected cancers, future results will also include interval cancers.

CLINICAL RELEVANCE/APPLICATION

External validation of commercial AI algorithms is necessary for safe implementation of AI. This is the first study comparing commercial AI algorithms for screening DBT on the same large dataset.

T3-SSBR05-4 DIAGNOSTIC PERFORMANCE OF SCREENING MAMMOGRAPHY AI TOOL IN A CANCER CENTER SCREENING POPULATION

Sarah Eskreis-Winkler, MD, PhD (*Presenter*)
Tali Amir, MD (*Abstract Co-Author*)
Jeffrey S. Reiner, MD (*Abstract Co-Author*)
Amita Shukla-Dave, PhD (*Abstract Co-Author*)
Kimberly N. Feigin, MD (*Abstract Co-Author*)

PURPOSE

Our breast cancer screening program includes many patients with prior breast-conserving therapy and high breast cancer risk. Given this unique population, it's unclear if published AI performance will generalize to our setting. Before implementing Transpara Breast AI (version 1.74A, ScreenPoint Medical), an FDA-approved tool, we performed a retrospective evaluation.

METHODS AND MATERIALS

This IRB-approved, HIPAA-compliant study included screening mammograms from Jan 1-Dec 31, 2023. Four 200-exam cohorts were selected: Cohort 1 True positives — BI-RADS 0, cancer diagnosed within 3 months.Cohort 2 False negatives — BI-RADS 1 or 2, cancer diagnosed within 18 months. Cohort 3 True negatives — BI-RADS 1 or 2, with no cancer diagnosed for at least 18 months, and no history of breast-conserving therapy. Cohort 4 True negatives — BI-RADS 1 or 2, with no cancer diagnosed for at least 18 months, in patients with breast-conserving therapy. All mammograms were randomly selected based on the above criteria and analyzed by Transpara, which assigned each exam a risk level (high/intermediate/low). Per vendor benchmarks, the algorithm was expected to identify >90% of true positives as "high risk" and > 60% of true negatives as "low risk."

RESULTS

Of 200 true positive exams (i.e. screen-detected cancers), AI designated 71% (95% CI: 64-76%) as high risk, which fell short of the 90% benchmark. Of 200 false negative cases (i.e. interval cancers), AI designated 63% (95% CI: 56-69%) as high risk. Of true negative cases without a history of breast conserving therapy, AI designated 56% (95% CI: 49-63%) as low risk, slightly below the 60% benchmark. However, of true negative exams with a history of breast conserving therapy, AI designated 27% (95% CI: 21-34%) as low risk, much lower than the 60% benchmark.

CONCLUSION

AI algorithms may perform less effectively in real world settings compared to results reported in the literature, particularly at imaging centers with high volumes of patients with history of breast conserving therapy. This study highlights the need for in-house quality assessment, quality control, and ongoing monitoring of all FDA-approved AI algorithms.

CLINICAL RELEVANCE/APPLICATION

Growing evidence highlights the advantage of using AI tools in diagnostic tasks, such as screening mammography interpretation. However, our results underscore the importance of validating AI tools on internal data before clinical implementation, rather than relying solely on results from published literature. It is critically important to understand the nuances of clinical scenarios where the tool adds value and where its performance may be more limited.

T3-SSBR05-5 PROSPECTIVE FEASIBILITY STUDY OF MIRAI-EXPEDITED EVALUATION FOR HIGH-RISK SCREENING MAMMOGRAMS

Adam Yala, PhD (*Abstract Co-Author*)

PURPOSE

To prospectively evaluate the feasibility and performance of expedited screening mammogram assessment for women identified as high risk by a mammogram based deep learning model.

METHODS AND MATERIALS

This HIPAA-compliant, IRB-approved prospective controlled, unblinded study was performed at an urban safety-net facility from 12/2024 - 4/2025. A threshold retrospectively calibrated from historical data was used to prospectively flag women at the top 10% of risk. Mirai 1-year breast cancer risk scores were generated immediately after screening mammograms. On 1-2 designated study days per week, consented high-risk women were offered immediate interpretation of screening mammogram and, if assessed by the radiologist as BI-RADS 0, offered same-day diagnostic workup. Reasons for inability to expedite evaluation were collected. Time intervals from screening mammogram to screening result (Ts), diagnostic imaging (Td), and biopsy (Tb) were recorded and compared between study and control days. Cancer detection rate (CDR) among expedited women was compared to the facility baseline of 5.9/1000 using an exact binomial test (R v4.4.1), with $p < 0.05$ considered statistically significant.

RESULTS

735 women received screening mammograms on designated study days. Of these, 80 women (10.9%) were flagged as high-risk, and 74 consented to receive immediate assessment. Mean age was 58 (range 40-79). Of the 74 consented women, 71 (95.9%) received immediate assessment; three (4.2%) did not receive immediate assessment due to clinical time constraint (n=2) and wait time (n=1). Of the 71 immediate assessments, 21 (29.6%) received BI-RADS 0 assessment. Of these, 20 women received same-day diagnostic evaluation and 1 received diagnostic evaluation on the following workday due to technologist availability. At diagnostic evaluation, 7 (33.3%) women were assessed as BI-RADS 4, 2 (9.5%) as BI-RADS 3, and 12 (57.1%) as BI-RADS 1 or 2. All 7 women assessed as BI-RADS 4 underwent biopsy yielding 5 malignant (3 IDC and 2 DCIS), 1 high-risk (atypical papillary lesion), and 1 benign pathologies. The CDR for this cohort was 70.4/1000 women (95% CI 23.3, 156.7), which was significantly higher compared to the baseline facility CDR of 5.9/1000 ($p < 0.001$). Mean Ts (0.3 hr vs. 15.7 hrs), Td (0.04 day vs. 37.8 days), and Tb (5.8 days vs. 58.0 days) were significantly shorter for high-risk expedited women compared to high-risk controls on non-study days ($p <0.001$).

CONCLUSION

A Mirai-based 10% high-risk threshold is feasible to integrate into clinical workflow and enables expedited evaluation for high-risk women.

CLINICAL RELEVANCE/APPLICATION

AI-based risk stratification can effectively triage screening mammograms and prioritize timely evaluation for high-risk women.

T3-SSBR05-6 USE OF MULTIPLE PRIOR EXAMS IMPROVES SPECIFICITY OF AN AI SYSTEM FOR BREAST CANCER DETECTION IN A RETROSPECTIVE MULTI-SITE VALIDATION

Rachel F. Brem, MD (*Abstract Co-Author*)

PURPOSE

To investigate how the use of prior exams impacts the breast cancer detection performance of an AI system for tomosynthesis.

METHODS AND MATERIALS

DBT examnination with available priors were analyzed by a breast cancer AI product (Transpara, ScreenPoint Medical, version 2.1), resulting in two scores indicating presence of cancer: One using only the current tomosynthesis exam as input and the second using the current images plus up to 3 prior examinations per case. A breast density score according to BI-RADS 5th edition was also generated by the AI system. All cases were fully independent from the development process of the AI system. Specificity of the AI system was compared between using prior exams or not, at pre-defined operating points of 90% and 80% sensitivity. P values using McNemar and binomial confidence intervals were computed.

RESULTS

The enriched dataset included 2,320 cases (34% from USA, 66% from Europe), with 214 cancers (9.2%). 75% of cases had 1 prior tomosynthesis exam and the remaining 25% had 2 or 3 prior exams. Images were acquired with Hologic DBT machines. At 90% sensitivity, AI specificity increased when using prior images, from 79.8% (95% CI: 78.0-81.4%) to 85.7% (84.1-87.1%), representing a 29% reduction in false positives (from 20.2% to 14.3%, P<0.001). At 80% sensitivity, using priors resulted in a specificity increase from 93.3% (92.2-94.3) to 95.2% (94.2-96.0), representing a 28% reduction in false positives (from 6.7% to 4.8%, P<0.001). The reduction in false positives was equally observed for cases with breast density C/D (-33%, P<0.001) and for cases with breast density A/B (-26%, P=0.005). There was a non-significant trend for higher reduction in false positives when using more than 1 priors (-45%) than when using only 1 prior exam (-24%).

CONCLUSION

An AI system for breast cancer detection in tomosynthesis achieves a higher specificity when using prior exams for analysis. Results were not affected by breast density and the benefit of priors may be higher when multiple priors are used.

CLINICAL RELEVANCE/APPLICATION

AI systems to aid radiologists reading mammograms and tomosynthesis exams are being widely implemented. A known limitation of these systems was their inability to leverage prior images into the analysis. A new generation of AI systems is designed to make use of priors, potentially offering radiologists more accurate decision-making support and give them more confidence in AI.

T3-SSCA05-1 SERIAL MYOCARDIAL FIBROSIS ASSESSMENTS PREDICT OUTCOMES IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY

Yun Tang, MS, MD (*Presenter*)
Shihua Zhao, MD (*Abstract Co-Author*)

PURPOSE

The prognostic value of serial myocardial fibrosis assessments in patients with hypertrophic cardiomyopathy (HCM) remains to be elucidated. We aimed to investigate the progression of late gadolinium enhancement (LGE), as assessed by follow-up cardiac magnetic resonance (CMR) imaging, in patients with HCM, as well as its associated prognostic value.

METHODS AND MATERIALS

Patients with HCM who underwent two CMR examinations between 2010 and 2019 were retrospectively evaluated. The LGE mass progression (?LGE%) was defined as the number of increased grams of enhanced myocardium added divided by the number of years between the two scans. The primary endpoint was the combination of cardiac death, heart transplantation, aborted sudden cardiac death (SCD), appropriate implantable cardioverter defibrillator discharge, hospitalization for heart failure and stroke. The secondary endpoint was the combination of cardiac death, aborted SCD and heart transplantation. A maximally selected rank statistical analysis was conducted to identify the optimal cut-off for ?LGE% for prognostic stratification.

RESULTS

A total of 313 patients with HCM (median scan interval: 4.2 years) were evaluated. LGE mass progressed from a median of 2.9 (Q1-Q3: 0.0 to 8.1) g at CMR-1 to 8.3 (Q1-Q3: 3.6 to 16.3) g at CMR-2. During a median follow-up of 7.7 (Q1-Q3: 6.0-9.8) years from initial CMR, the primary endpoint occurred in 66 patients, of whom 22.7% reached the secondary endpoint (n=15). For primary endpoint and secondary endpoint, the optimal cut-off for ?LGE% were >1.50 and 3.75g/year, respectively. In the multivariable model, New York Heart Association class III/IV at baseline (HR 5.39, 95% CI: 2.92-9.94, P <0.0001), left ventricular ejection fraction <50% at CMR-1 (HR 2.65, 95% CI: 1.27-5.52, P =0.0096), and ?LGE% >1.50g/year (HR 5.86, 95% CI: 3.41-10.08, P <0.0001) were associated with the primary endpoint.

CONCLUSION

Myocardial fibrosis increased over time in HCM patients. Serial assessments of myocardial fibrosis on CMR may improve risk stratification and clinical decision-making in these patients.

CLINICAL RELEVANCE/APPLICATION

Patients with hypertrophic cardiomyopathy (HCM) had varying degrees of late gadolinium enhancement (LGE) progression. Rapid LGE mass progression (>1.50g/year) was identified as a strong independent factor significantly associated with elevated risk for adverse events. Serial LGE assessments on CMR may improve risk stratification and clinical decision-making in HCM patients.

T3-SSCA05-2 EVALUATING THE ADDED VALUE OF LOW-DOSE CHEST CT-DERIVED EPICARDIAL ADIPOSE TISSUE MEASUREMENT IN AN ASYMPTOMATIC HEALTH SCREENING POPULATION

Jong Eun Lee, MD, PhD (*Presenter*)
Nayoung Kim (*Abstract Co-Author*)
Young Joo Suh, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the prognostic value of CT-derived epicardial adipose tissue (EAT) volume measurement for predicting major adverse cardiovascular events (MACE) in an asymptomatic screening population undergoing non-contrast low-dose chest CT.

METHODS AND MATERIALS

In this retrospective study, asymptomatic individuals aged 40 years or older who underwent non-contrast low-dose chest CT scans between 2007 and 2014 at two health screening centers were included. A commercially available AI-based software was used to simultaneously assess EAT volume, EAT density, and coronary artery calcium (CAC) score. Multivariable Cox proportional hazards models were employed to determine the association between EAT parameters and MACE. Net Reclassification Index (NRI) and the number needed to harm were used to assess improvements in risk stratification and cost-effectiveness.

RESULTS

A total of 5342 individuals were analyzed (3431 from Center I and 1923 from Center II) with median follow-up periods of 7.5 years for MACE. After adjusting for AI-based CAC and clinical variables, increased AI-based EAT volume was significantly associated with a higher risk of MACE, whereas EAT density was not. The addition of AI-based EAT volume to a model containing clinical variables and CAC significantly improved risk prediction, with a category-free NRI of 0.086 (95% CI: 0.002-0.152, P = .048). Furthermore, using a cutoff value of 152.09 mL, reclassifying individuals from a high-risk to a low-risk group via intervention could potentially prevent one MACE for every 136.8 individuals treated.

CONCLUSION

Automated assessment of EAT volume on non-contrast low-dose chest CT is feasible and provides added prognostic value and cost-effectiveness for cardiovascular risk stratification in an asymptomatic screening population.

CLINICAL RELEVANCE/APPLICATION

Automated measurement of epicardial adipose tissue (EAT) volume using AI-based analysis on routine non-contrast low-dose chest CT scans enhances cardiovascular risk stratification beyond traditional clinical variables and coronary artery calcium scoring. Incorporating EAT assessment into health screening protocols could identify asymptomatic individuals who might benefit from preventive interventions, improving patient outcomes and clinical decision-making.

T3-SSCA05-4 MULTIPARAMETRIC CARDIAC MRI IN PATIENTS WITH GIANT CELL ARTERITIS

Annemarie Proff, MD (*Presenter*)
Narine Mesropyan, MD (*Abstract Co-Author*)
Dmitrij Kravchenko, MD (*Abstract Co-Author*)
Taraneh Aziz-Safaie, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

Giant cell arteritis (GCA) is a systemic vasculitis associated with systemic inflammation, potentially affecting cardiac structures even in the absence of overt symptoms. This study aimed to assess the presence and characteristics of subclinical cardiac involvement in patients with newly diagnosed GCA using multiparametric cardiac MRI (CMR).

METHODS AND MATERIALS

In this prospective single-center study patients with newly diagnosed GCA underwent CMR at baseline and approximately six months after. Imaging protocols included functional and volumetric parameters, visual edema, late gadolinum enhancement (LGE), and T1- and T2- mapping including extracellular volume fraction (ECV). Healthy controls were included for comparison using historical CMR datasets. Group comparisons were performed using t-tests, Mann-Whitney U, and chi-square tests; paired t-tests assessed longitudinal changes.

RESULTS

A total of 45 GCA patients (mean age 73 ± 9 years; 42% female) and 20 healthy controls were included (mean age 51 ±16 years, 40% female). 3/45 (7%) patients had inflammatory cardiac disease on CMR: active pericarditis in 2/45 (4%) and active myocarditis in 1/45 (2%) GCA patients. LGE was present in 38% (17/45), with variable patterns (ischemic 6/17, non-ischemic 3/17, unspecific 6/17, pericardial 2/17). Compared to controls, GCA patients had significantly elevated native T1 values (987±29 vs. 958±21 ms; p<0.001) and increased ECV (27±4% vs. 25±2%; p=0.01). T2 times showed no significant differences (p=0.163). Among 31/45 patients with follow-up scans, no significant changes were observed in T1 (983±26 vs. 982±19 ms; p=0.679), T2 (54±3 vs. 55±2 ms; p=0.339), or ECV (27±4% vs. 27±4%; p=0.283) under immunosuppressive therapy.

CONCLUSION

Multiparametric CMR reveals cardiac alterations in patients with newly diagnosed GCA including active inflammation (myocarditis and pericarditis in single patients), post-ischemic scars, and signs of focal and diffuse non-ischemic myocardial fibrosis. Myocardial T1 and ECV may serve as sensitive, non-invasive markers for early cardiac involvment in GCA.

CLINICAL RELEVANCE/APPLICATION

CMR may enable early detection of cardiac involvement in GCA.

T3-SSCA05-6 SEX-SPECIFIC EFFECTS OF OBESITY ON CARDIAC STRUCTURE AND FUNCTION: A MAGNETIC RESONANCE STUDY OF THE HAMBURG CITY HEALTH COHORT

Jennifer Erley, MD (*Presenter*)
Jonas Heinrich Lund, MD (*Abstract Co-Author*)
Isabel Molwitz, MD, MBA (*Abstract Co-Author*)
Ersin Cavus (*Abstract Co-Author*)
Gerhard B. Adam, MD (*Abstract Co-Author*)
Peter Bannas, MD (*Abstract Co-Author*)
Enver G. Tahir, MD (*Abstract Co-Author*)
Mathias Meyer, MD (*Abstract Co-Author*)

PURPOSE

To analyze the effect of obesity according to waist-to-hip ratio (WHR) and body mass index (BMI) on cardiac structure and function, depending on sex.

METHODS AND MATERIALS

Individuals between 45-74 years of age underwent 3T cardiovascular magnetic resonance (CMR) imaging as part of the population-based prospective “Hamburg City Health” cohort study. WHR and BMI were assessed upon study inclusion. Subjects with known cardiac diseases were excluded. Generalized regression models were conducted including sex, BMI or WHR, their interaction (if statistically significant), and age.

RESULTS

We included 2173 subjects (43% female, mean age 64±8 years). Median WHR was 0.94 [interquartile range: 0.88; 1.00] and median BMI was 26.3 [23.8; 29.3]. According to the WHR, 80% of subjects were obese (WHR = 0.85 in females/ 0.90 in males). Based upon BMI, 20% of subjects were obese (BMI = 30). An increase in WHR by 0.1 was associated with a 3.9g [2.5;5.4] higher left ventricular (LV) end-diastolic mass (EDM). It was also associated with lower LV and right ventricular (RV) end-diastolic volumes (EDV) (LV: -4.4ml [-6.2;-2.6], p<0.001; RV: -5.7ml [-8.2;-3.2], p<0.001), and end-systolic volumes (ESV) (LV: -1.9ml [-3.0;-1.3], p<0.001; RV: -1.9ml [-3.0;-0.8], p=0.001), leading to lower stroke volumes (LV: -2.2ml [-3.4;-0.9], p<0.001; RV: -2.1ml [-3.5; -0.8], p=0.002). However, the negative association between WHR and RVEDV/RVSV was -4.5ml [0.6;0.8|/-2.9ml [0.2;0.6] per 0.1 increase in WHR weaker in females compared to males (p=0.024 and 0.033) (Figure 1). Due to the proportionally larger decrease in EDV, LVEF showed an increase of +0.7% [95% confidence interval: 0.2;1.1] (p=0.004) with every 0.1 increase in WHR. An increase in BMI was associated with a 2.3g [2.0;2.7] higher LVEDM (p<0.001), a higher LVEDV (0.5ml [0.2;0.8], p=0.002), and a 0.4ml [0.2;0.6] higher LVSV (p<0.001). RV structure and function was not significantly associated with BMI. The positive association between BMI and LVEDM was -0.9mg [-1.3; -0.4] per 1 point BMI weaker in females (p<0.001) (Figure 1).

CONCLUSION

An increase in WHR is associated with a higher LV mass and lower ventricular volumes. Its association with RV volumes is weaker in females than males. An increase in BMI is associated with ventricular dilatation and a higher LV mass, although this relationship is also weaker in females.

CLINICAL RELEVANCE/APPLICATION

Abdominal obesity according to WHR is associated to concentric remodeling, while a higher body mass is associated with ventricular dilatation. The associations between WHR and RV remodeling, as well as between BMI and LV mass, are more pronounced in males than in females. These findings highlight the need for personalized risk assessment in obesity-related cardiovascular disease.

T3-SSER01-1 RADIOLOGIC INJURY PATTERNS AT THE INTERSECTION OF INTIMATE PARTNER VIOLENCE AND SUICIDAL BEHAVIOR

Emily Y. Yang, BS (*Presenter*)
Alexander Kwon (*Abstract Co-Author*)
Bharti Khurana, MD, MBA (*Abstract Co-Author*)

PURPOSE

Intimate partner violence (IPV) is an increasingly recognized risk factor for suicidal behavior. We seek to characterize the relationship between radiologic injury patterns and suicidal behavior in IPV victims, and how these interact to influence patient healthcare utilization.

METHODS AND MATERIALS

Our case population consists of women =18 years old who reported IPV to the hospital from 2013- 2018 (n=1451), with 1-to-6 matching from our patient registry (n=6679) to build the controls. All reports were reviewed by two experienced emergency radiologists blinded to IPV status (151,544 total). Using ICD-10 codes relevant to suicidal behavior (SB), which we defined as suicide attempt, self-harm, and/or suicidal ideation, we formed four study groups: IPV+/SB+, IPV+/SB-, IPV-/SB+, IPV-/SB-. We also collected information on the temporality and location of patient presentation (e.g. day versus night, ER vs. non-ER). Differences between groups for categorical data were analyzed with the chi-square test. Poisson regression was used to estimate incidence rate ratios (IRR) based on IPV and SB. All analyses were conducted with a significance level of $p<0.05$.

RESULTS

IPV alone was associated with a significant increase in injuries involving head, face, chest, and thoracic spine with synergistic elevation when co-occurring with SB. SB alone was associated with a higher incidence of upper extremity and abdominal injuries with synergistic elevation of upper extremity injury. On average, IPV+/SB+ patients initially present to hospitals at an earlier age (26.6 yrs) compared to IPV+/SB- (31.1 yrs). IPV is identified earliest in patients who have also attempted suicide (32.5 yrs) versus self-harm (35.6 yrs) and suicidal ideation (42.6 yrs). IPV+ and SB+ patients are more likely to present during the day vs. night and during the winter and fall seasons; IPV+/SB- patients are more likely to present to non-ER settings vs the ER ($p <0.001$).

CONCLUSION

IPV and SB present with distinct injury patterns, and their co-occurrence leads to a synergistic increase in the frequency of injuries across multiple anatomic sites. IPV is identified earlier in patients with SB, indicating the critical need for proactive screening and early intervention. Furthermore, the presence of IPV and/or SB affects patient healthcare utilization with respect to the timing and location of clinical presentation.

CLINICAL RELEVANCE/APPLICATION

As suicide remains a leading cause of death worldwide, there is significant potential in understanding its intersection with IPV. Characterizing the interaction of IPV and SB in radiologic injury patterns can improve screening and facilitate early intervention to better protect these vulnerable populations.

T3-SSER01-2 THE EFFECT OF SINGLE VERSUS DOUBLE-READ ON MEDICAL PRACTICE LIABILITY

Michael H. Bernstein, PhD (*Presenter*)

PURPOSE

To examine whether medical malpractice liability is reduced when radiologists interpret imaging both before and after viewing an AI result, versus only after an AI result.

METHODS AND MATERIALS

Participants (N=282) were recruited online through Prolific and provided online consent. Participants read about a hypothetical case where a 50-year old who visited the Emergency Department with acute neurological symptoms received a CT scan of the brain to determine if bleeding was present. An AI system was used by the radiologist who interpreted the CT images. The AI system correctly flagged the case as abnormal. Nonetheless, the radiologist concluded that no bleeding was present, and the blood-thinner t-PA was administered. Participants were randomly assigned to one of two conditions. In the single-read condition, the radiologist interpreted the CT once, and this occurred after seeing AI feedback. In the double-read condition, the radiologist interpreted the CT twice: first without AI, and then with AI feedback. Participants were then told that the patient suffered irreversible brain damage as a result of the missed brain bleed and that the patient (plaintiff) is suing the radiologist (defendant). Participants indicated whether the radiologist met their duty of care to the patient (yes/no). This is consistent with typical questions regarding breach of the duty of care that appear on jury verdict forms in medical malpractice trials. The study was approved by the institutional IRB.

RESULTS

Participants were more likely to side with the plaintiff in the double-read condition (74/140, 53.9%; 95% CI:44.6-61.0) versus the single-read condition (106/142, 74.7%; 95% CI:66.8-88.1)

CONCLUSION

Mock jurors were more likely to believe that the radiologist had met their duty of care when a False Negative interpretation occurred after reading an image twice - once without AI and then once with AI - relative to only reading the image once (with AI). The magnitude of this effect was large (75% vs. 53%), which indicates that for every three jurors who would side with the plaintiff in the “double read” condition, only two would do so in the “single read” condition

CLINICAL RELEVANCE/APPLICATION

The use of AI invites challenging questions related to medical malpractice among radiologists. Our results suggest that radiologists can reduce their liability by modifying their workflow.

T3-SSER01-3 IMAGING UTILIZATION, PATTERNS, AND YIELD IN THE EMERGENCY DEPARTMENT FOR UNHOUSED OLDER ADULT PATIENTS

Sharmila Duraisamy, MD (*Presenter*)
Haley Bayne (*Abstract Co-Author*)
Alexander Kwon (*Abstract Co-Author*)
Bharti Khurana, MD, MBA (*Abstract Co-Author*)

PURPOSE

Older adults experiencing homelessness represent a growing population with over 1.5 million Americans experiencing housing insecurity annually. This vulnerable population also has disproportionately high rates of emergency department (ED) use. Despite known disparities in access to outpatient care and an increased burden of acute and chronic disease, little is known about the specific patterns and diagnostic yield of emergency imaging in this group. This study aims to characterize emergency imaging utilization among patients aged 65 and older who are unhoused and presented to the ED.

METHODS AND MATERIALS

This ongoing IRB approved retrospective cohort study included 1,480 emergency department visits among 240 elderly homeless patients from 2015 to 2024 at two large academic centers in the northeastern USA. The total number of encounters was recorded, and all imaging studies performed during each visit were documented. Imaging reports were reviewed and categorized by modality: computed tomography (CT), radiography (XR), ultrasound (US), and magnetic resonance imaging (MRI). Impressions were analyzed for positive findings manually. Patients were grouped by revisit intervals: <30 days, 31-90 days, 90-180 days, 180-365 years and >1 year. Discharge dispositions and frequency of visits were identified.

RESULTS

Out of 1,480 ED visits, 468 (31.6%) included imaging, totaling 467 studies: 159 CT (34%), 291 X-XR (62.3%), 15 US (3.2%), and 2 MRI (0.4%). Positive findings were seen in 136 patients (29.3%), with 36.7% traumatic (mainly fractures and soft tissue injuries) and 63.6% non-traumatic (most commonly pneumonia). Over half (57.5%) had two or more ED visits within 30 days.

CONCLUSION

Unhoused older adults frequently utilize emergency services, including emergency imaging. In this study, nearly one-third of imaging studies revealed clinically significant findings. This highlights a substantial burden of both traumatic and non-traumatic pathology, most commonly fractures and pneumonia, respectively. Additionally, there were many patients with recurrent ED visits within 30 days, demonstrating the complex health needs and fragmented care often faced by this population.

CLINICAL RELEVANCE/APPLICATION

Our findings support the need for targeted interventions to improve continuity of care and reduce reliance on emergency services among unhoused older adults.

T3-SSER01-4 TRENDS AND PREDICTORS OF CT ANGIOGRAPHY UTILIZATION FOR CERVICAL SPINE FRACTURES IN THE EMERGENCY DEPARTMENT FROM 2010 TO 2022: A NATIONAL DATABASE ANALYSIS

Rahul Jayaram, BS (*Presenter*)
Albert Lee (*Abstract Co-Author*)
Ajay Malhotra, MD, MMM (*Abstract Co-Author*)
Jonathan Grauer (*Abstract Co-Author*)

PURPOSE

Screening for blunt cerebrovascular injury (BCVI) in cervical spine trauma has become increasingly common in the United States due to the risk of vertebral artery injury and posterior circulation stroke. Many trauma centers now use computed tomography angiography (CTA) protocols in the emergency department (ED) to evaluate for BCVI; however, there are concerns about overuse. Prior studies examining CTA trends and predictors in ED cervical fracture patients have been limited in sample size and geographic scope. The current study aimed to characterize national trends over the years and identify predictors of CTA use in ED patients with cervical fractures using a large, multi-insurance, administrative database.

METHODS AND MATERIALS

Patients presenting to the ED with a new cervical fracture were identified using the 2010 to 2022 PearlDiver M170 database. Patients were classified according to whether they underwent CTA on the same day as presentation. Annual numeric and proportional utilization of CTA were assessed over the study period. Univariate and multivariate analyses were conducted to evaluate clinical (age, sex, Elixhauser Comorbidity Index [ECI]), non-clinical (insurance type, geographic region), and anatomic location of injury (upper cervical [C1-C2], subaxial [C3-C7], other) predictors of CTA use.

RESULTS

Of 157,533 patients who presented to the ED with cervical fractures between 2010 and 2022, CTA was obtained for 21,200 (15.52%). Over the years of the study, this increased from 6.09% in 2010 to 24.31% in 2022 ($p<0.001$). Independent predictors of having CTA relative to no CTA included younger age (per decade decrease, odds ratio [OR] 1.02), male sex (OR 1.14), higher ECI (relative to 0, incrementally greater for ECI 1-2 [OR 1.24], ECI 3-4 [OR 1.37], and ECI = 5 [OR 1.41]), insurance plan (relative to Medicare, Commercial [OR 1.41] and Medicaid [OR 1.48]), geographic variation (relative to West, Northeast [OR 1.03], South [OR 1.07], Midwest [OR 1.23]), and location of injury (relative to subaxial injury, upper cervical injury [OR 1.57]).

CONCLUSION

CTA utilization for cervical fracture evaluation in the ED increased from 6.09% in 2010 to 24.31% in 2022. This study identified multiple independent clinical, non-clinical, and anatomic predictors of CTA use.

CLINICAL RELEVANCE/APPLICATION

The findings reported here suggest increasing use and variability in CTA use in cervical spine fracture patients and support the development of more targeted imaging protocols in the acute management of such patients.

T3-SSER01-5 INCIDENCE OF MISSED SPLENIC VASCULAR INJURY ON CT IN HIGH ACUITY TRAUMA

Jeffrey Qiu, MD, BS (*Presenter*)
Min Tae Kim, MD,BSC (*Abstract Co-Author*)
John Choi, MD (*Abstract Co-Author*)
Susie Park, MD (*Abstract Co-Author*)
Bhavraj S. Khalsa, MD (*Abstract Co-Author*)
Alisa S. Han, MD (*Abstract Co-Author*)
Anton A. Mlikotic, MD (*Abstract Co-Author*)
Alexander Schwed (*Abstract Co-Author*)

Stuart T. Schroff, MD (*Abstract Co-Author*)
John J. Park, MD, PhD (*Abstract Co-Author*)

PURPOSE

CT is commonly used to evaluate splenic injury. Compared to digital subtraction angiography (DSA), reported sensitivity of CT for splenic vascular injury ranges from 52-60% [1]. We examine the rates of CT vs. DSA discordance to find the incidence of splenic missed vascular injury (MVI) in a high acuity trauma population.

METHODS AND MATERIALS

A retrospective study was performed including 278 patients, who underwent splenic artery DSA from 9/1/2015 to 9/1/2024 at 2 Level 1 trauma centers. MVI is defined as contained vascular injury (CVI) or active splenic hemorrhage (ASH) missed on initial CT, then diagnosed on DSA. Hypothesis testing performed using ANOVA and Chi-Squared tests.

RESULTS

The study population presented with severe trauma (mean Injury Severity Score = 30.6), and high proportions of high-grade splenic injury (83% AAST Grade IV-V), polytrauma (65%), hypotension (25%), coagulopathy (26%). Incidence of MVI was 20%. ASH comprised 13%, CVI comprised 87% of total MVI on CT. These patients were associated with delayed angiography (55%, $p<0.01$), which suggests clinical deterioration after CT triage, prompting further work-up. There were no significant clinical factors which may predict MVI. Overall rates of CT vs. DSA discordance were 46%, with 44% MVI and 56% interval resolution of ASH/CVI. No clinical factors differentiated patients with persistent vs. resolved ASH/CVI.

CONCLUSION

Advantages of DSA over CT in detecting vascular injury has been widely reported in head and neck trauma [2], which is mechanistically attributed to increased intravascular pressure from contrast bolus [3]. This study suggests significant incidence of MVI with CT alone. The lack of associated clinical factors with MVI makes this phenomenon unpredictable, suggesting a low threshold to consult Interventional Radiology for DSA with possible embolization.

CLINICAL RELEVANCE/APPLICATION

Incidence of splenic MVI is significant at 20% in the setting of trauma. This phenomenon is not predictable by clinical factors. A high level of clinical caution is advised even with no CT evidence of ASH or CVI. References:1. Lee JT, et al. T3-SSER01-6 RADIOLOGICAL INSIGHTS INTO THE INTERSECTION OF INTIMATE PARTNER VIOLENCE AND OPIOID USE DISORDER

Jade Iwasaka-Neder, MD, MPH (*Presenter*)
Alexander Kwon (*Abstract Co-Author*)
Krishna Patel (*Abstract Co-Author*)
Isabela Lima, MD (*Abstract Co-Author*)
Scott Weiner (*Abstract Co-Author*)
Carrie Esopenko (*Abstract Co-Author*)
Bernard Rosner, PhD (*Abstract Co-Author*)
Bharti Khurana, MD, MBA (*Abstract Co-Author*)

PURPOSE

Intimate partner violence (IPV) and opioid use disorder (OUD) are intersecting public health challenges. Radiologists play a key role in detecting trauma and substance-related complications, particularly in undisclosed cases. This study examined injury patterns, severity, and imaging utilization among patients reporting IPV, with and without coexisting OUD.

METHODS AND MATERIALS

This retrospective study analyzed lifetime radiology reports from female patients who reported IPV between 2013 and 2018 (n = 1,183; 14,036 imaging reports) and age- and race-matched controls who did not report IPV (n = 4,094; 21,461 imaging reports). ICD-10 codes were used to identify OUD status, resulting in four groups: patients reporting both IPV and OUD (IPV+OUD+), only IPV (IPV+OUD-), only OUD (IPV-OUD+), and none (IPV-OUD-; reference group). Poisson regression with person-years offset was used to calculate adjusted incidence rate ratios (aIRRs) for imaging use, injury location, and severity. Main effects models assessed independent contributions of IPV and OUD. Logistic regression predicted OUD in IPV patients based on injury patterns.

RESULTS

Patients in IPV+OUD+ underwent more imaging (CT: aIRR 10.5, 95% CI: 8.8-12.7; ultrasound: aIRR 8.6, 95% CI: 3.0-24.9; X-ray: aIRR 4.1, 95% CI: 3.7-4.7), sustained more radiologically evident injuries (aIRR: 4.7, 95% CI: 3.3-6.8), and had higher rates of severe injuries (aIRR: 4.7, 95% CI: 3.3-6.8) compared to the reference group. Main effects models showed that both IPV and OUD independently increased imaging utilization, with synergistic elevation when co-occurring. IPV was independently associated with increased injury rates, most notably for the face (Relative risk [RR]: 7.5, 95% CI: 5.4-10.3), neck (RR: 6.2, 95% CI: 2.0-18.6), and head (RR: 3.3, 95% CI: 2.5-4.4). OUD was independently associated with elevated injury rates, particularly in the lumbar spine (RR: 5.8, 95% CI: 3.4-9.9), chest (RR: 3.5, 95% CI: 2.4-5.0), and thoracic spine (RR: 3.1, 95% CI: 1.8-5.6). Among IPV patients, lumbar spine (Odds ratio [OR] 10.1, 95% CI: 4.2-24.2), chest (OR 5.4, 95% CI: 3.0-9.7), and abdominal injuries (OR 4.9, 95% CI: 2.4-10.0) were the strongest predictors of co-occurring OUD.

CONCLUSION

Patients with both IPV and OUD had the highest imaging utilization, injury rates and severity among groups. IPV and OUD were independently associated with distinct injury patterns. Injuries to the lumbar spine, chest, and abdomen were strong indicators of co-occurring OUD.

CLINICAL RELEVANCE/APPLICATION

Recognition of higher imaging utilization and injury patterns among IPV survivors with OUD may aid in detection and earlier interventions. This study is among the first to quantify their synergistic impact through imaging data.

T3-SSGU04-1 COMPARISON OF 3D AND 2D T2WI FOR THE EVALUATION OF BLADDER CANCER: IMAGE QUALITY AND T-STAGE USING VI-RADS

Wei Wang (*Presenter*)
Jian-Xing Qiu, MD (*Abstract Co-Author*)
Jingyun Wu (*Abstract Co-Author*)

PURPOSE

To compare the image quality and diagnostic performance of three-dimensional (3D) and two-dimensional (2D) T2-weighted imaging (T2WI) for diagnosing muscle-invasive bladder cancer (BCa).

METHODS AND MATERIALS

This retrospective study included 35 patients with pathologically confirmed BCa who underwent 3 T MRI with both 3D and 2D T2WI. Two radiologists independently evaluated image quality, tumor characteristics (diameter and number), T stage, and the Vesical Imaging Reporting and Data System (VI-RADS) score on 3D and 2D T2WI at 4-week intervals. The image quality evaluation included overall image quality, artifacts, sharpness, contrast, delineation of the bladder wall, ureterovesical orifices, and bladder tumors using a 4-point scale. The VI-RADS score was assessed based on T2WI and DWI. Additionally, radiologists conducted a subjective comparison between 3D and 2D T2WI side-by-side, categorizing their preference as: 3D/2D T2WI or both for BCa evaluation.

RESULTS

Pathology revealed 11 non-muscle-invasive and 24 muscle-invasive BCa. 3D T2WI demonstrated significantly shorter acquisition time (5 min 32 sec) than multi-planar 2D T2WI (~8 min). Tumor diameters were larger on 3D T2WI (3.19±2.26 cm vs 2.85±2.14 cm, $p < 0.001$), while tumor detection rates were comparable between sequences ($p > 0.05$). 3D T2WI demonstrated equivalent overall image quality, artifacts, sharpness, and contrast to 2D (all $p > 0.05$). 3D T2WI outperformed 2D in delineating the bladder wall (3.80±0.41 vs. 3.54±0.71), ureterovesical orifices (3.94±0.34 vs. 3.23±0.77), and bladder tumors (3.94±0.24 vs. 3.51±0.82; all $p < 0.05$). No significant differences in AUC between 2D and 3D T2WI of direct T staging (0.873 vs. 0.881) or VI-RADS (0.898 vs. 0.907; $p > 0.05$) for muscle invasion diagnosis. Radiologists defined equal preference for 3D and 2D for 16/17 patients, and preferred 3D to 2D for 19/18 patients (Reader 1/2).

CONCLUSION

3D T2WI offered superior anatomical and tumor delineation compared to conventional 2D T2WI, while maintaining equivalent diagnostic performance for muscle invasion assessment, with reduced acquisition time.

CLINICAL RELEVANCE/APPLICATION

With isotropic voxels enabling multi-planar reconstruction, 3D T2WI could replace traditional three-plane 2D imaging and improve scan efficiency without sacrificing image quality. The superior spatial resolution of 3D T2WI allows for precise measurements, potentially enhancing the detection of smaller tumors, improving anatomical and tumor delineation, and optimizing surgical or radiotherapy planning. The results suggest 3D T2WI as a clinically promising alternative to 2D T2WI in bladder MRI protocols, streamlining workflow without compromising diagnostic performance for muscle invasion evaluation.

T3-SSGU04-3 CONTRAST AGENT SUBSTITUTION AS A STRATEGY TO DECREASE RISK OF BREAKTHROUGH ALLERGIC-LIKE REACTIONS: RESULTS FROM TWO ACADEMIC MEDICAL CENTERS

Madeleine Sertic, MBBCh (*Presenter*)
Elyse Lynch (*Abstract Co-Author*)
Debra A. Gervais, MD (*Abstract Co-Author*)
Joseph Fay, MS, RT (*Abstract Co-Author*)
Rose L. Wach, MBA, RT (*Abstract Co-Author*)
Daniel I. Glazer, MD (*Abstract Co-Author*)

PURPOSE

To determine the efficacy of contrast agent substitution to prevent breakthrough allergic-like reactions to iodinated contrast media in patients with a history of prior mild allergic-like reaction.

METHODS AND MATERIALS

This retrospective cohort study was performed at an academic health system and was approved by the local institutional review board. The need for informed consent was waived. All patients undergoing contrast enhanced CT scans in the emergency department (ED) setting from 6/1/24-4/1/25 were included. Patients that were imaged in other locations were not included. During the study period, patients that had a history of prior mild allergic like reaction to a specific contrast agent were considered candidates to be imaged with an alternative contrast agent rather than undergo steroid premedication. Patient demographic data, clinical notes, and CT examination information were extracted from the electronic health record (EHR). Mean time from order entry to exam completion was compared between groups with a t-test.

RESULTS

A total of 25,395 contrast enhanced CT scans were performed in the ED during the study period. Of this cohort that had a contrast enhanced CT, 242 patients (159 female, median age 61) undergoing 247 scans had a mild allergy to iodinated contrast media documented in the EHR. Only 58/242 patients (24.0%) had the inciting contrast agent specified. From this group of eligible patients, 35 (60.3%) received an alternative contrast (iopamidol) agent rather than steroid premedication and the

inciting agent (iohexol). The mean time from order placement to exam completion was 2.7 hours for the contrast substitution group and 4.7 hours for the steroid premedication group (p=0.002). There was a single breakthrough reaction (1/35, 2.9%) which was the same severity as the index reaction (mild). No patient in the contrast agent substitution group had a moderate or severe reaction.

CONCLUSION

Breakthrough allergic like reactions to iodinated contrast media are uncommon when an alternative contrast agent is utilized in the absence of steroid premedication. Utilizing an alternative contrast agent decreased time from order placement to imaging by 2 hours.

CLINICAL RELEVANCE/APPLICATION

Changing iodinated contrast media agents may be preferable to steroid premedication in the setting of prior mild allergic like reaction. EMR documentation of the exact agent rather than a generic contrast allergy would render more patients eligible for this steroid sparing pathway.

T3-SSGU04-4 AGE-RELATED DYNAMIC CHANGES OF PELVIC FLOOR ANATOMY DURING VOIDING: EVALUATION WITH UPRIGHT 4D-CT IN HEALTHY MALES

Yoichi Yokoyama, MD (*Presenter*)
Yoshitake Yamada, MD, PhD (*Abstract Co-Author*)
Minoru Yamada, RT (*Abstract Co-Author*)
Orito Ikeda (*Abstract Co-Author*)
Mohammed Alshahri (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate three-dimensional (3D) anatomical and four-dimensional (4D) dynamic changes of pelvic floor structures during voiding in healthy adult males using upright 4D-CT, elucidating their relationship with aging. Conventional methods for evaluating voiding dysfunction, such as urodynamics and voiding cystourethrography, have limitations in three-dimensional assessment and are typically invasive.

METHODS AND MATERIALS

Twenty-four asymptomatic male volunteers (mean age, 48.8 years; range, 31-66 years) underwent upright 4D-CT imaging during voiding. Scans were initially acquired at intervals of 1-2 seconds and subsequently at 2-5 second intervals throughout voiding phases: pre-void, initiation, maximum flow, end of voiding, and post-void. Uroflowmetry simultaneously recorded urine flow and voided volume, guiding 4D-CT phase determination. Parameters measured included bladder neck position, PC line, bladder neck angle, and angle os pubis ventral prostate. Changes among voiding phases and correlations with age were analyzed using paired t-tests and Pearson correlation. False discovery rate (FDR) was applied for multiple comparisons.

RESULTS

Significant anatomical changes occurred across voiding phases for all parameters (FDR $p<0.05$), notably in bladder neck position, PC line, bladder neck angle, and angle os pubis ventral prostate. Bladder neck and PC line positions substantially adjusted from initiation to maximum flow and from end to post-void phases. Significant age-dependent correlations were found: PC line (start-pre; $r=0.472$, $p=0.035$), bladder neck position (max-pre; $r=-0.450$, $p=0.035$), bladder neck position (post-pre; $r=-0.451$, $p=0.035$), PC line (post-pre; $r=0.449$, $p=0.035$), and bladder neck angle (max-pre; $r=0.430$, $p=0.036$). These results suggest that age-related physiological changes in lower urinary tract structures, including the bladder and prostate, influence voiding function.

CONCLUSION

Pelvic floor dynamics during voiding exhibit significant age-related changes, particularly affecting bladder neck position, PC line, and bladder neck angle. Upright 4D-CT provides essential baseline data for understanding normal physiological variations with aging. Future studies should explore these findings in clinical populations and assess interventions targeting age-related pelvic floor changes.

CLINICAL RELEVANCE/APPLICATION

Non-invasive, high-resolution upright 4D-CT provides essential baseline data for evaluating voiding dysfunctions such as benign prostatic hyperplasia, overactive bladder, and neurogenic bladder. This approach improves diagnostic accuracy and supports individualized treatment strategies, highlighting its utility for future clinical research.

T3-SSGU04-5 ADDITIONAL VALUE OF SYSTEMATIC CORES IN MRI GUIDED PROSTATE BIOPSY IN YOUNGER MEN (45-54 YEARS)

Matthias Boschheidgen (*Presenter*)
Rudolf Kaaks (*Abstract Co-Author*)
Peter Albers, MD, PhD (*Abstract Co-Author*)
Gerald Antoch, MD (*Abstract Co-Author*)
Lars Schimmoeller, MD (*Abstract Co-Author*)

PURPOSE

The prospective randomized PROBASE trial was designed to evaluate if risk-adapted screening for prostate cancer (PC) should start at 45 or 50 years. Indication to perform a prostate biopsy within PROBASE is based on a suspicious prostate-specific antigen (PSA) value only. This analysis assesses the performance of magnetic resonance imaging (MRI) targeted biopsy (TB) and systematic biopsy (SB) in a PC screening setting of young men.

METHODS AND MATERIALS

Young men with confirmed PSA levels of 3 ng/ml or higher were offered an MRI and recommended to undergo a prostate biopsy. According to the study design and diagnostic pathway of PROBASE, SB and TB were performed with software-based fusion techniques in all patients. The primary objective of this analysis was PC detection of MRI-TB and SB.

RESULTS

A total of 525 men (median age 50 years (range 44-54 years), median PSA level 3·98 ng/ml, median prostate volume 36 mL) were analyzed who underwent an MRI followed by TB and SB in one of the four study centers between December 2014 and September 2023. Of 209 diagnosed PC, 148 (71%) were clinically significant (csPC; ISUP = 2). 139 (94%) and 109 (74%) of 148 of csPC were detected by SB and TB, respectively ($p=0·05$). SB detected significantly more low-grade cancer compared to TB (51/61 vs. 26/61; $p <0·001$).

CONCLUSION

In this study most of the csPC were detected by SB. Therefore, in the setting of PC screening in young men, SB should be further recommended in combination with MRI-targeted biopsy.

CLINICAL RELEVANCE/APPLICATION

Our study provides the first large-scale population-based analysis of combined SB and TB in men aged 45-54 years as part of the prospective PROBASE trial. The findings demonstrate that SB alone detected 94% of csPC, outperforming TB, which detected 74% of csPC. Importantly, a quarter of csPC would have been missed if only TB had been performed, underscoring the necessity of combining both approaches in young men. These results challenge the current assumption that TB alone is sufficient in a screening setting, particularly in younger populations where MRI interpretation can be more challenging due to the lower prevalence of cancer and smaller tumours.

T3-SSGU04-6 THE CLINICAL VALUE OF PRE- AND POSTOPERATIVE ULTRASONOGRAPHIC EVALUATION IN ASSESSING SURGICAL OUTCOMES OF VARICOCELE REPAIR: A PROSPECTIVE OBSERVATIONAL STUDY

Xiaoyi Wang, MD (*Presenter*)

PURPOSE

To investigate the clinical utility of color Doppler ultrasound (CDUS) in evaluating the efficacy of microsurgical varicocelectomy through objective pre- and postoperative ultrasonographic measurements, and to explore the correlation between ultrasound parameters and symptom resolution.

METHODS AND MATERIALS

This prospective study enrolled 160 patients diagnosed with unilateral or bilateral clinical varicocele who underwent microsurgical subinguinal varicocelectomy between January 2023 and August 2024. Ultrasonographic evaluations were conducted preoperatively, and at 3 and 6 months postoperatively, including measurement of the maximum venous diameter and reflux duration during the Valsalva maneuver. Clinical symptoms were quantified using the Visual Analogue Scale (VAS), and semen analysis was performed according to WHO guidelines. Statistical analyses were performed to assess the relationship between ultrasonographic changes and clinical outcomes.

RESULTS

The maximum venous diameter decreased significantly from 3.9±0.8 mm before surgery to 2.4±0.6 mm at 3 months and 2.1±0.5 mm at 6 months postoperatively ($P<0.001$). Reflux duration showed a comparable reduction, decreasing from 4.6±1.2 seconds preoperatively to 2.0±0.8 seconds at 3 months and 1.5±0.7 seconds at 6 months ($P<0.001$). Improvements in ultrasonographic parameters were strongly correlated with reductions in symptom severity ($r=0.68$, $P<0.001$). Semen parameters also showed a significant positive trend in patients with marked reflux reduction.

CONCLUSION

Color Doppler ultrasound is an effective and noninvasive tool for monitoring the hemodynamic restoration following varicocelectomy. Reflux duration, in particular, serves as a sensitive and dynamic indicator for assessing surgical success and is recommended as a standard component of postoperative follow-up.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that color Doppler ultrasound (CDUS), especially the measurement of reflux duration during the Valsalva maneuver, is a sensitive and objective indicator for evaluating the effectiveness of microsurgical varicocelectomy. Regular pre- and postoperative ultrasonographic assessment provides clinicians with real-time insights into venous hemodynamics and correlates closely with symptom resolution and improvement in semen quality. Incorporating standardized CDUS follow-up protocols may enhance postoperative monitoring, guide clinical decision-making, and optimize management of male patients with varicocele.

T3-SSHN02-1 FIRST-EVER VISUALIZATION OF 50 VAGUS NERVE BRANCHES IN CADAVERIC MRI USING HIGH-RESOLUTION 3D ISOTROPIC CISS IMAGING: A SPARC REVA STUDY

Shruti Kumari, MBBS (*Presenter*)
Mridhula Muthukumar (*Abstract Co-Author*)
Chris A. Flask, PhD (*Abstract Co-Author*)
Daniel Herzka (*Abstract Co-Author*)
Ari M. Blitz, MD (*Abstract Co-Author*)

PURPOSE

Vagus nerve (CN X) has evolved from a structure at potential risk in head and neck surgery to a target of nerve simulation. Apart from epilepsy and chronic heart failure, vagal nerve stimulation (VNS) is now applied to treat psychiatric conditions, headache, and bronchial asthma. Branching of CN X in the carotid sheath may be related to the side effects or the missing therapeutic efficiency of VNS. Also, CN X is frequently injured during neck and thoracic surgeries. We hypothesize that preoperative high resolution CISS MRI may potentially help identify the branches of CN X. We present the preliminary data showing the visualization of several branches of CN X in the neck and thorax that have never been seen before on MRI.

METHODS AND MATERIALS

55 embalmed cadavers were scanned with a 3T MRI scanner using isotropic 0.5-0.6 mm 3D-CISS; a total of 110 CN X were examined. Identification of prospective branches on MRI was evaluated by three readers and confirmed using anatomic dissection. The branch take-off point was noted on the MRI sequence and its distance from a predefined landmark was calculated, followed by anatomic dissection where each branch was traced up to the target organ to identify the branch. The main trunk of CN X was painted at locations corresponding to anatomical landmarks. The entire nerve with its branches was dissected and placed on a grid where distance of branch takeoff was calculated from the landmark and compared with MRI findings.

RESULTS

We were able to identify and confirm 50 branches on MRI which have never been seen before.. These include the cervical cardiac branch, the thoracic cardiac branch, cardiopulmonary branches, esophageal branches, branch to carotid bifurcation, etc.

CONCLUSION

SPARC-REVA is the most comprehensive mapping of CN X and its branches to date, from the perspectives of sample size, range of imaging modalities, lengths of nerve, and imaging resolutions. This is the first report of visualization these branches of CN X on CISS MRI. The high signal-to-noise ratio, along with high spatial resolution with isotropic 3D CISS images that can be reconstructed in multiple planes, makes this sequence superior to conventional 2D MRI sequences. Translation of this work to living subjects can have implications in therapeutic targeting and diagnostic imaging.

CLINICAL RELEVANCE/APPLICATION

Routine clinical imaging of CN X and its branches using CISS MRI offers significant potential for enhancing nerve preservation during surgery, optimizing therapeutic targeting, and mitigating side effects associated with VNS. The translation of this approach to living subjects could lead to a wide range of clinical applications, improving patient outcomes in both surgical and therapeutic settings.

T3-SSHN02-2 EXPLORING THE NEURAL BASIS OF OLFACTORY DYSFUNCTION IN CRS: STRUCTURAL AND FUNCTIONAL INSIGHTS FROM MULTIMODAL MRI

Chao Zhang, MD (*Presenter*)
Hu HU Sr, MD (*Abstract Co-Author*)
Kai Xu, MD, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the structural and functional neural alterations associated with olfactory dysfunction in patients with chronic rhinosinusitis (CRS-OD) using multimodal MRI, aiming to understand central nervous system involvement beyond peripheral olfactory changes.

METHODS AND MATERIALS

We prospectively enrolled 23 CRS-OD patients and 23 age- and sex-matched healthy controls (HCs). All participants underwent clinical olfactory assessments (TDI, QOD, OECS) and MRI scanning, including high-resolution T1-weighted imaging, resting-state fMRI, and olfactory bulb (OB) imaging using a DRIVen Equilibrium TSE sequence. Voxel-based morphometry (VBM) was used to assess gray matter volume, while functional connectivity (FC) analysis was conducted using seed regions with observed atrophy.

RESULTS

Compared to HCs, CRS-OD patients exhibited significantly reduced bilateral OB volumes ($p < 0.05$) and gray matter atrophy in the inferior frontal gyrus, hippocampus, parahippocampal gyrus, thalamus, and putamen (FDR corrected, $p < 0.05$). FC analysis revealed reduced connectivity between the putamen and regions such as the insula, posterior cingulate, and inferior frontal gyrus, alongside increased connectivity with the superior occipital gyrus. Notably, OCES scores negatively correlated with the volume of the right putamen ($p = 0.044$, $r = -0.467$), and QOD scores showed a negative correlation with the volume of the right hippocampus ($p = 0.007$, $r = -0.600$).

CONCLUSION

CRS-OD was characterized by OB atrophy, widespread gray matter volume reductions, and altered functional connectivity in sensory and cognitive networks. These findings underscore the central nervous system's involvement in CRS-related olfactory impairment.

CLINICAL RELEVANCE/APPLICATION

This study provides critical insights into the neural underpinnings of CRS-OD, highlighting the importance of integrating central brain assessments in clinical evaluations and therapeutic planning for patients with olfactory dysfunction.

T3-SSHN02-3 ECHOTEXTURE OF RECURRENT LARYNGEAL NERVES: THE DEPICTION OF RECURRENT LARYNGEAL NERVES AT HIGH-FREQUENCY ULTRASOUND DURING RADICAL THYROIDECTOMY

Ziyue Hu (*Presenter*)
Man Lu, PhD (*Abstract Co-Author*)

PURPOSE

The structure of peripheral nerves typically appears as multiple parallel, yet disjointed, hypoechoic linear areas separated by hyperechoic bands in longitudinal views, and as multiple rounded hypoechoic areas within a homogeneous hyperechoic background in transverse views. However, research on the structural morphology of the RLN is relatively limited. The ultrasound images of the RLN presented in a few studies have shown inconsistent findings. Some studies have described the RLN as a thin, hypoechoic structure, while others have depicted it as hyperechoic tissue. This discrepancy creates confusion for sonographers, making it difficult to accurately identify the RLN. Moreover, there is a lack of studies providing a clear ultrasound visualization of the RLN in a living individual. In this study, we aimed to investigate the ultrasonographic structure of the RLN during radical thyroid cancer surgery, aiming to enhance the understanding of its ultrasonographic characteristics. Notably, this study provides the first clear observation of the RLN structure via ultrasound.

METHODS AND MATERIALS

From October 2021 to December 2022, a prospective study was conducted involving 24 patients scheduled for bilateral thyroid surgery. Near the conclusion of the surgery, intraoperative ultrasonography of the RLN within the tracheoesophageal groove was performed using a 15-7 MHz transducer. The thickness and width of the RLN were measured during the procedure.

RESULTS

The internal architecture of the RLN was observed to consist of multiple hypoechoic, parallel, but discontinuous linear hyperechoic areas separated by bands. In the normal RLN group, the diameter of the RLN was relatively consistent, with thickness ranging from 2.20 to 2.71 mm (mean: 2.48±0.14 mm) and width from 1.25 to 1.70 mm (mean: 1.45±0.11 mm). Both weight and the body mass index (BMI) showed a statistically significant correlation with RLN thickness (Weight: r=0.544, P=0.001; BMI: r=0.605, P=0.001). The BMI also showed a statistically significant correlation with the RLN width (r=0.377, P=0.033). In the RLN invasion group, the width of invaded RLNs ranged from 1.9 to 2.3 mm (mean: 2.10±0.11 mm), while the width of non-invaded RLNs ranged from 2.6 to 3.2 mm (mean: 2.93±0.20 mm).

CONCLUSION

Ultrasound effectively reveals the structural features of the RLN and enhances sonographers' understanding of RLN characteristics.

CLINICAL RELEVANCE/APPLICATION

This study represents the first application of intraoperative ultrasound to investigate the RLN. Ultrasound provides a distinct visualization of the structural characteristics of the RLN, enhances the understanding of this nerve among ultrasound practitioners, and facilitates the preoperative ultrasound assessment of the RLN.

T3-SSHN02-4 MUSCLE AND FAT MATTER: CT-BASED BODY COMPOSITION PREDICTS SURVIVAL IN HEAD AND NECK CANCER PATIENTS TREATED WITH IMMUNOTHERAPY

Johannes M. Ludwig, MD, ARRT (*Presenter*)
Matthias F. Froelich, MD (*Abstract Co-Author*)
Johannes Haubold, MD (*Abstract Co-Author*)
Dominik Noerenberg (*Abstract Co-Author*)
Stefan O. Schoenberg, MD, PhD (*Abstract Co-Author*)
Sven Koitka, MSc (*Abstract Co-Author*)
Farroch Vahidi Noghani (*Abstract Co-Author*)

PURPOSE

To evaluate the prognostic value of CT-based body composition markers for survival in patients with Head and neck cancer (HNSCC) treated with immunotherapy

METHODS AND MATERIALS

This study included 55 patients (75.6% men; median age 66 years). Patients who underwent immunotherapy (Pembrolizumab or Nivolumab) between 08/18 and 05/23 were included in this study. A deep learning algorithm was used for automated body composition analysis (BCA) of thoracic CT scans to perform 3D volumetry of body tissues including visceral adipose tissue (VAT), skeletal muscle (SM), and bone (B). The area under the curve (AUC) for 3 months survival for BC parameters was calculated for all patients and for each sex because of significant differences between sexes ($p<0.05$). The Cox proportional hazard model for univariate (UVA) and multivariate (MVA) analyses (hazard ratio; 95%CI, p-value) and Kaplan-Meier analyses (survival in months; 95%CI) were performed.

RESULTS

The median survival time of the study cohort was 8.3 (4.8-21.9) months with 1-, 3 months, 6-months, 1 year, 2-years and 3-years survival rates of 93.3%, 68.9%, 55.6%, 42.2%, 26.7%, and 17.8%, respectively. The AUC for (SM/VAT)/B for all patients/men/women were 0.76 (0.61 - 0.82); p=0.003/ 0.79 (0.6 - 0.91); p<0.001/0.7 (0.37 - 0.93); p=0.24 with cutoff values for longer survival of >2/>2/>1.74, respectively. In UVA a sig. lower HR was identified for men (0.38 (0.17 - 0.86); p=0.028), lower ECOG (0/1/2/1-4) with 1/8.1 (4.2 - 20.2)/ 3.4 (0.23 - 21.9)/ 3.4 (0.23 - 21.9)/ 1.5 (1.1 - .); p=0.028 respectively, BMI = 18.5 kg/m 2 (0.34 (0.15 - 0.81); p=0.02), Albumin > 3.4g/dl (0.32 (0.15 - 0.69); p=0.0024) and (SM+VST)/B > 2.0 (m) / 1.74 (f) (0.34 (0.16 - 0.72);p=0.0035). In MVA, Albumin > 3.4 g/dl (0.25 (0.08 - 0.65); p=0.0045 and (SM+VST)/B > 2.0 (m) / 1.74 (f) 0.23 (0.09 - 0.63);p=0.0039 were independently significant.Patients with non-lowered albumin levels and a higher (SM + VAT)/B ratio, survived the longest with median not reached (4.9 -. months). Patients with either a lower serum albumin level or a lower (SM + VAT)/B ratio survived for a median of 20.2 months (6.5 - 28.6) whereas patients with a lower serum albumin level and a lower (SM + VAT)/B ratio survived only for a median of 2.3 months (1.1 - 4.8) (log-rank: p<0.0001).

CONCLUSION

The fully automated, CT-based body composition analysis with the independent prognostic parameter (SM + VAT)/B as well as non-lowered albumin levels were independent significant factors for overall survival in HNSCC patients treated with immunotherapy.

CLINICAL RELEVANCE/APPLICATION

The use of fully automated CT-based BCA may be an easily accessible tool to better understand which HNSCC patients may benefit from immunotherapy, which may help set expectations for patients and their relatives.

T3-SSHN02-5 BODY COMPOSITION ANALYSIS FROM ROUTINE CT IMAGES USING DEEP LEARNING: ASSOCIATION WITH SURVIVAL OUTCOMES IN HEAD AND NECK CANCER PATIENTS

Wichtlhuber, BSc (*Presenter*)
Andreas Bucher, MD (*Abstract Co-Author*)
Eric Frodl, MSc (*Abstract Co-Author*)
Teodora Biciusca (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)
Lisa Joy Juergens (*Abstract Co-Author*)
Maurice Harth (*Abstract Co-Author*)
Philipp Thoenissen (*Abstract Co-Author*)

PURPOSE

To determine if deep learning-derived body composition metrics from routine CT scans independently predict survival in head and neck cancer patients. This approach uses existing diagnostic CTs, saving resources. We investigate muscle-to-bone volume ratio, intermuscular adipose tissue (IMAT) to total adipose tissue (TAT) ratio, and subcutaneous adipose tissue characteristics as potential prognostic biomarkers in this population.

METHODS AND MATERIALS

Retrospective analysis of 149 patients with head and neck cancer (144 oral cavity carcinoma, 5 oropharyngeal carcinoma; 76 male [51%], 73 female [49%]; mean age: 63.3±14.2 years; 62 deaths during follow-up). Routine contrast-enhanced CT scans with predominantly 5mm slice thickness (94% of patients) and soft-tissue kernel were analyzed. Body composition parameters were quantified using a validated 3D-UNet-based deep learning algorithm that first segmented tissue types, then applied thresholding to distinguish fat compartments. Cox proportional hazards models with significance threshold of $p<0.05$ assessed associations between metrics and overall survival, adjusting for gender, age, T-stage, N-stage, and UICC stage.

RESULTS

Three body composition metrics independently predicted survival after adjusting for clinical factors: decreased abdominal muscle/bone volume ratio (HR=0.70, 95% CI: 0.51-0.97, p=0.03), increased IMAT/TAT mean density ratio (HR=1.49, 95% CI: 1.15-1.92, p<0.005), and increased IMAT/TAT volume ratio (HR=1.50, 95% CI: 1.17-1.91, p<0.005). Multivariate models incorporating these metrics achieved c-indices of 0.75-0.76. Kaplan-Meier showed significant differences in median survival between patients with high vs. low IMAT/TAT density ratio (901.0 vs. 1717.0 days, p=0.0042) and IMAT/TAT volume ratio (1277.5 vs. 1525.5 days, p=0.0177).

CONCLUSION

Body composition metrics from routine diagnostic CT scans provide independent prognostic value in head and neck cancer patients, with substantial survival differences between risk groups. Unlike previous studies requiring specialized imaging or focusing only on single vertebral levels, our approach demonstrates that valuable prognostic information can be extracted from standard diagnostic scans.

CLINICAL RELEVANCE/APPLICATION

CT-based body composition analysis offers additional prognostic stratification in head and neck cancer (HR=0.70-1.50, p<0.005) without additional imaging, potentially identifying patients for nutritional intervention who may gain >2 years in median survival.

T3-SSHN02-6 **Keynote Speaker**

T3-SSMK04-1 BEHIND THE PAIN: UNMASKING SMILE LESIONS IN RECALCITRANT TENNIS ELBOW - A RETROSPECTIVE EVALUATION

Sriram Rajan, MD, MBBS (*Presenter*)
Shankhneel Singh, MD,MBBS (*Abstract Co-Author*)
Harsh Mahajan, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To evaluate the radiological findings in a retrospective cohort, focusing on defining MRI findings SMILE lesions (Symptomatic Micro-Instability of Lateral Elbow), previously described on arthroscopy

METHODS AND MATERIALS

A total of 313 consecutive elbow MRIs referred for recalcitrant tennis elbow of which 7 arthroscopically proven cases of SMILE lesions were identified as test cases, and key imaging findings were documented as a checklist. The remaining 306 cases were randomized and anonymized and analyzed by two experienced radiologists (11 and 22 years of experience).

RESULTS

Of the 306 evaluated cases, 122 (25.8%) showed partial LUCL tears, 12 (3.9%) had complete LUCL tears, 268 cases (87.5%). had deep surface partial tears of ECRB. Statistical analysis revealed a significant association between the presence of LUCL tears (partial and complete) and abnormal radiocapitellar alignment ($p < 0.01$). Abnormal ulnotrochlear alignment was significantly associated with the presence of ECRB tears ($p < 0.05$). Intra-articular abnormalities included posterior radial synovial plica in 22 cases (7.18%), synovitis in 3 cases (0.98%), and chondral lesions in the radial head in 39.78% of cases, with minimal occurrence of lateral capitellar lesions (0.65%).

CONCLUSION

The study underscores a significant association between MRI findings such as LUCL tears, ECRB injuries, and joint misalignments.

CLINICAL RELEVANCE/APPLICATION

Findings of symptomatic micro-instability need to be highlighted in patients with lateral epicondylitis and could potentially be responsible for failure of conservative management. Such findings may only be seen if they are looked for.

T3-SSMK04-2 PROGNOSTIC FACTORS AND POSTOPERATIVE OUTCOMES OF ARTHROSCOPIC SUTURE ANCHOR REPAIR FOR CHRONIC LATERAL EPICONDYLITIS: A LONGITUDINAL CLINICAL AND MRI FOLLOW-UP STUDY

Jianing Cui, MD (*Presenter*)
Bai Rongjie (*Abstract Co-Author*)
Ping Wang (*Abstract Co-Author*)
Qian Zhanhua (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the healing process of ECRB after arthroscopic surgery for lateral epicondylitis by magnetic resonance imaging (MRI) and to assess clinical and imaging features that may be associated with prognosis.

METHODS AND MATERIALS

We included a total of 71 patients who underwent arthroscopic bunion tendon release for chronic epicondylitis. Clinical and magnetic resonance imaging (MRI) examinations were performed preoperatively and at 3 and 6 months postoperatively. Based on the postoperative DASH score, patients were categorized into a recovered group (N=54) and an unrecovered group (N=17). Serial changes in MRI scores and clinical scores were assessed. In addition, the predictors of recovery were analyzed by the logistic regression method.

RESULTS

Postoperative follow-up showed that the MRI signal intensity of the repaired ERCB gradually decreased, pain relief, and the clinical functional scores gradually improved ($P < 0.05$). Then, by comparing the recovered and unrecovered groups, the results showed that at 6 months postoperatively, the recovery of MRI features was similar in the two groups, but the recovery of clinical characteristics was different, with the recovered group improving more quickly. Then, by comparison between the recovered and unrecovered groups showed that at 6 months postoperatively, both clinical and MRI scores continued to improve in the recovered group (all $P < 0.05$), however, there was no significant improvement in the unrecovered group (all $P > 0.05$). Of note, the sex [odds ratio: 6.636 (1.174-37.51), $P = 0.032$] and ERCB tear size [odds ratio: 0.790 (0.643-0.971), $P = 0.025$] were independent predictors of recovery.

CONCLUSION

Continuous tendon and functional recovery assessed by MRI was found during 6 months after arthroscopy. Preoperative tendon status and gender were associated with poor postoperative recovery outcomes.

CLINICAL RELEVANCE/APPLICATION

This study provides the first comprehensive longitudinal analysis of ECRB healing patterns using serial MRI and clinical assessments following arthroscopic surgery for chronic lateral epicondylitis. We demonstrate that postoperative ECRB signal intensity progressively decreases alongside clinical improvement, with recovery speed differing significantly between recovered and unrecovered groups. Crucially, we identify preoperative tear size and patient sex as independent prognostic factors. Our work advances beyond previous single-timepoint MRI studies by documenting dynamic tendon healing processes through standardized follow-ups, while correlating structural changes with symptom resolution.

T3-SSMK04-3 REASSESSING THE ROLE OF INJECTATE IN MEDIAN NERVE HYDRODISSECTION FOR TREATMENT OF CARPAL TUNNEL SYNDROME: IS MECHANICAL DECOMPRESSION THE REAL HEALER?

Akanksha Saini, MBBS, MD (*Presenter*)
Anupama Tandon, MD, MBBS (*Abstract Co-Author*)

PURPOSE

USG guided hydrodissection has emerged as a promising technique for treatment of Carpal Tunnel Syndrome (CTS). It uses USG guided fluid injection to separate the median nerve from surrounding adhesions, thus relieving entrapment and restoring nerve function. Various injectates like steroids, 5% dextrose, PRP, hyaluronidase have been used for hydrodissection procedure, with recent research favoring 5% dextrose for its potential yet unproven pharmacological effects. With focus on various injectates, the contribution of pure mechanical nerve release remains unexplored. We hypothesize that the primary therapeutic benefit stems from the mechanical separation of the nerve rather than the pharmacological effects of injectate. This prospective, randomized controlled trial evaluates the effectiveness of true hydrodissection (HD) using normal saline for the treatment of CTS.

METHODS AND MATERIALS

After institutional ethical approval, CTRI registration and informed consent, 40 wrists with CTS; unresponsive to conservative treatment were enrolled. The pre-procedure parameters assessed were- BCTQ (symptom and functional scores), VAS and cross-sectional area (CSA) of median nerve. After randomization into 2 groups with single blinding, one group underwent USG-guided HD with 5% dextrose (Dx) and the other group with normal saline (NS). Titration of injectate volume was done in real time till full nerve separation was observed, no fixed volume was used. Follow-up done at 1, 3, and 6 months post-procedure.

RESULTS

The injectate required for complete dissection was higher in NS group (12-15ml) compared to Dx group (5-7 cc). Both groups showed significant clinical improvement in mean BCTQ score at 1 month (60% in dx vs 75% in NS, p=0.405) and up to 6 months (55% in dx vs 60% in NS, P=0.721) and mean reduction in VAS at 6 months (3.1 in dx vs 2.6 in NS; p=0.446). Intergroup difference was not significant at any time points. A significant reduction in CSA seen in both groups (14.5% in dx vs 16.7% in NS) at 6 months with no significant intergroup difference (p=0.626). No major complications were reported.

CONCLUSION

This study shows that HD with normal saline, an inert agent, is as effective as HD with 5% dextrose for treatment of CTS, highlighting, thus that mechanical decompression is the key therapeutic mechanism in this procedure.

CLINICAL RELEVANCE/APPLICATION

Ultrasound-guided HD is a safe, effective and minimally invasive procedure for treatment of CTS that alleviates the need for surgery. Given its similar efficacy, inert nature and lower cost, normal saline can serve as an effective and economical alternative to dextrose and other expensive neuromodulatory agents like PRP, hyaluronidase, thus paving the way for use of this procedure in resource limited settings.

T3-SSMK04-4 THE EXPOSED ULNAR SEAT: A MARKER OF SUBTLE TFCC INSTABILITY AND DORSAL SOFT TISSUE INJURY

Sriram Rajan, MD, MBBS (*Presenter*)
Shankhneel Singh, MD,MBBS (*Abstract Co-Author*)
Harsh Mahajan, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To evaluate the correlation between ulnar seat uncovering and subtle instability of the triangular fibrocartilage complex (TFCC), in patients with dorsal distal radioulnar ligament (DRUL) and dorsal capsular tears

METHODS AND MATERIALS

A retrospective study of 67 MRI wrists performed for ulnar sided wrist pain, performed in prone Superman position. Images from the PACS were extracted and anonymized and randomized and read by two observers with 23 years (SR), and 11 years(SS) of experience by consensus. Images were scored for TFCC displacement and ulnar seat uncovering in mm, asymmetrical ulnar seat uncovering . (scored as 0-symmetrical displacement, 1-asymmetrical ulnar seat uncovering)Images were also scored for distal radioulnar joint instability, using the Epicentre method and the Congruence method (0-normal, 1-abnormal), the Mino method (% of dorsal displacement)Finally images were scored for Dorsal capsular tear, Dorsal distal radioulnar ligament tear and ulnar fovea of TFCC tear as 0-normal, 1-tear. (this included partial and complete tears)

RESULTS

Ulnar seat uncovering was significantly greater in patients with DRUL tears (mean = 6.46 mm) versus those without (mean = 2.54 mm) ($p < 0.01$).Ulnar seat uncovering was significantly higher in dorsal capsule tear cases (mean = 5.84 mm) compared to no-tear cases (mean = 1.93 mm), ($p < 0.01$).TFCC displacement was greater in DRUL tear cases (mean = 3.94 mm vs. 2.47 mm), with $p = 0.0010$ and weak correlation $r = 0.16$.TFCC displacement was significantly higher in dorsal capsule tear cases (mean = 3.39 mm vs. 2.50 mm), $p = 0.0034$, with weak correlation $r = 0.11$ Patients with uncovering > 4 mm are 20 times more likely to have a DRUL tearPatients with uncovering > 4 mm are 50 times more likely to have a dorsal capsule tear

CONCLUSION

There is significant correlation between ulnar seat uncovering and dorsal capsular tears and dorsal distal radio-ulnar ligament tearsTFCC displacement was greater in Dorsal capsular tears compared to DRUL tear cases. Ulnar seat uncovering >4mm was significantly associated with DRUL and Dorsal capsular tear.

CLINICAL RELEVANCE/APPLICATION

Identification of this sign, of ulnar seat uncovering is a useful sign to evaluate instability of the articular disc, and of the distal radioulnar joint. Ulnar seat uncovering is significantly associated with dorsal capsular tears and dorsal distal radioulnar ligament tears. Further arthroscopic studies along with MR studies will need to be done to prove this.

T3-SSMK04-5 COMPARISON OF CROSS-SECTIONAL IMAGING MODALITIES IN DIAGNOSING DISTAL BICEPS TENDON TEARS

Alexa Arvidson, MD (*Presenter*)
Jacqueline Kobayashi (*Abstract Co-Author*)
Mary Creedon, MD (*Abstract Co-Author*)
William Aibinder (*Abstract Co-Author*)
Kara D. Gaetke-Udager, MD (*Abstract Co-Author*)

PURPOSE

While some distal biceps tendon (DBT) tears can be diagnosed clinically with a high degree of confidence, imaging with ultrasound (US) or magnetic resonance imaging (MRI) can provide useful diagnostic information to guide surgical decision-making. Prior studies have shown conflicting results when evaluating the accuracy of US compared to MRI in diagnosis of DBT tears. The purpose of this study was to compare US and MRI in diagnosis of DBT tears at our institution.

METHODS AND MATERIALS

A retrospective analysis was performed on patients who underwent surgical repair of DBT tear from January 2007 - December 2023 and had preoperative US and/or MRI. The positive predictive value (PPV) of US and MRI diagnostic results were calculated by comparison with the surgical findings. Routine statistical analysis was performed, including Fisher exact test. Analysis was performed on a smaller cohort who underwent both US and MRI preoperatively to determine the percentage of patients that had concordant imaging and surgical findings, a discordant imaging test, discordant surgical findings, or complete discordance between the imaging tests and surgical findings.

RESULTS

A total of 181 patients were included in the study. MRI and US had similar PPV in diagnosing DBT tears in patients who underwent surgery. The overall (complete and partial tears) PPV was 89% for both US and MRI ($p = 0.48$). The PPV in diagnosing complete tears was 90% for US and 89% for MRI ($p = 0.39$), and the PPV for diagnosing partial tears was 82% for US and 89% for MRI ($p = 0.30$). Of the cohort who underwent both US and MRI preoperatively, both imaging studies and surgery were concordant 65.4% of the time. There was discordance between the imaging studies 26.9% of the time. There was a single instance (3.8%) of discordant surgical findings, and a single instance (3.8%) of complete discordance between the imaging tests and surgical findings. Most of these instances of discordance had prolonged intervals between imaging and/or surgery, or limited imaging usually due to soft tissue swelling.

CONCLUSION

US and MRI have similar positive predictive value in diagnosing DBT tendon tears in patients who underwent surgery. In the group that had both imaging modalities preoperatively, there was some sort of discordance between US, MRI, and surgical findings about 35% of the time. Many of these discordant instances may have related to prolonged intervals or limited imaging studies, and therefore the discordance may not be clinically relevant.

CLINICAL RELEVANCE/APPLICATION

Our findings show no significant difference between US and MRI in diagnosis of DBT tears, and given US's improved accessibility and cost effectiveness, US should be considered as the first-line imaging modality for diagnosis of DBT tears.

T3-SSMK04-6 COMPREHENSIVE ULTRASOUND EVALUATION IN DE QUERVAIN'S TENOSYNOVITIS

Saumya Pandey, MD, FRCR (*Presenter*)
Ankur Goyal, MD,MBBS (*Abstract Co-Author*)
MD Tahir Ansari (*Abstract Co-Author*)

PURPOSE

To present the high-resolution ultrasound (HUS) findings in patients with De Quervain's tenosynovitis (DQT) including anatomical variations in the first extensor compartment of the wrist. To compare the HUS parameters of DQT with healthy individuals, to identify objective criteria to aid in diagnosis and management.

METHODS AND MATERIALS

A retrospective case-control study was conducted involving 72 cases of clinically diagnosed with De Quervain tenosynovitis and 24 age- and sex-matched asymptomatic volunteers. High-resolution ultrasound using a 6-20 MHz range hockey stick transducer was used to assess the first dorsal extensor compartment for the following parameters-• cross-sectional diameters of the first extensor compartment• the thickness of the tenosynovial sheath• presence and number of accessory slips of Abductor Pollicis Longus(APL) and Extensor Pollicis Brevis (EPB) tendons• presence of intracompartmental septum and its degree of completeness• Colour vascularity Quantitative data was analysed using Mann-Whitney U test for synovial thickness, Transverse Pulley Diameter(D1) and Antero-Posterior(A-P) Pulley Diameter (D2). The qualitative variables were compared using Chi-Square tests with significance kept at $p=0.05$.

RESULTS

The two groups showed significant differences in the Synovial Thickness and A-P Pulley Diameter (D2) . Patients with DQT had greater synovial thickness (Group A mean= 1.65 mm +/- 1.96, range-0.2 to 12.9 mm; Group B mean= 0.31 mm +/-0.10, range-0.2 to 1.6 mm, p value- 0.0001) and A-P Pulley Diameter (Group A mean= 4.04 mm +/- 1.18, range- 3.25 mm to 12.9 mm; Group B mean= 2.71 mm +/- 0.60, range- 1.6 mm to 8.7 mm, p value- 0.0001) compared to controls. Accessory Tendon Slips of APL (87.50% incidence versus 45.83% in Group 2, p value- 0.003) and presence of Septation (80.56% incidence in Group A versus only 45.83% in Group 2; p value- 0.002) were more frequent in DQT group.

CONCLUSION

Ultrasound is an effective non-invasive modality for detecting characteristic features of De Quervain tenosynovitis. These findings can aid in early diagnosis, guide management decisions, and potentially serve as objective markers for disease severity and response to therapy.

CLINICAL RELEVANCE/APPLICATION

Our study demonstrates one of the largest ultrasound database of DQT in a single center. This study establishes the role of HUS in not only the diagnosis but also in identifying underlying anatomic variations that can predispose to this condition and also affect its management.

T3-SSMK05-1 CT GUIDED FNA AND CNB OF BONE LESIONS: A COMPARISON OF THE YIELD AND DIAGNOSTIC VALUE

Bahareh Moazen, MD, MPH (*Presenter*)
Abdullah N. Felemban, MBBS (*Abstract Co-Author*)
Kawanpreet S. Rakhra, MD, FRCPC (*Abstract Co-Author*)
Ryan C. Foster, MD (*Abstract Co-Author*)

PURPOSE

To compare the yield and diagnostic value of CT guided fine needle aspirate(FNA) and core needle biopsy(CNB) of bone lesions, and determine the additive value of CNB.

METHODS AND MATERIALS

IRB approved, retrospective review of cases with concurrent CT guided FNA and CNB of bone lesions from August 2012-December 2021 was performed. Data extracted from EMR and CT biopsy reports included patient demographics, FNA cytology and CNB pathology diagnoses. FNA and CNB were evaluated for (1) yield with positivity defined as sample deemed adequate for laboratory analysis, and (2) diagnostic value with positivity defined as laboratory analysis able to provide definitive diagnosis. The redundancy or added value of CNB over FNA alone was evaluated. Differences between FNA and CNB for yield and diagnostic value were determined using chi-square test (significance $p<0.05$).

RESULTS

The study included 328 patients (172M,156F) with mean age (SD,range) 63 years (14,16-90). A definitive, pathologic diagnosis was obtained in 67%(221/328) of cases, with 96%(213/221) neoplastic. Of the neoplastic diagnoses, 92% were malignant and of these 42% were primary and 58% metastatic. In 5%(16/328) a definitive, benign diagnosis was made. In 16%(53/328) both FNA and CNB were non-diagnostic. The yield and diagnostic value of CNB(80%,79%) were both significantly higher than FNA(69%,54%), [$p=0.001$, $p<0.001$]. CNB was redundant in 39%(127/328) where FNA alone was diagnostic, and of no value in 6%(19/328) where it was non-diagnostic while FNA was diagnostic.

CONCLUSION

CNB has higher yield and diagnostic value than FNA for CT guided bone biopsies. However, 45% of CNB may not provide any added clinical value.

CLINICAL RELEVANCE/APPLICATION

For bone lesions, there is a sizable portion of instances where CT guided CNB is not of additive diagnostic value over FNA. Further analysis will determine in which clinical scenarios could FNA alone obviate the need for CNB, leading to shorter procedure times and cost savings.

T3-SSMK05-2 EQUIVALENT DIAGNOSTIC RATE OF CT-GUIDED BONE MARROW ASPIRATE AND BIOPSY (BMAB) WHEN PERFORMED BY MSK RADIOLOGISTS VS ADVANCED PRACTICE PROVIDERS (APPS)

Robert R. Lopez, MD (*Presenter*)

PURPOSE

Bone marrow aspirate and biopsy (BMAB) is commonly performed without image guidance and with local analgesia. However, radiology departments have seen increased requests for image-guidance for BMAB, usually performed by MSK radiologists, often with conscious sedation. The overall increase in imaging volumes, as well as the increase in certain image guided procedures like BMAB, has led to increase in work stress and burnout for some radiologists. Advanced practice providers (APPs) have been employed by some radiology practices to help offload some of this procedural work. At our practice, APPs, with radiologist supervision, are increasingly performing several MSK procedures including CT guided BMAB. Given the shift in our practice of BMAB now being primarily performed by APPs, we wanted to assess the diagnostic efficacy between radiologists and APPs in the performance of BMAB.

METHODS AND MATERIALS

Retrospective EMR search for CT guided BMAB procedures Bone Marrow Biopsy exams was performed between January 2015 to February 2024. Clinical notes and final pathology diagnosis were reviewed for presence of diagnostic or non-diagnostic sample for aspirates and core biopsies, as well as any major procedural complications. Cases performed by radiologists versus APPs were matched and compared.

RESULTS

Total of 774 exams were reviewed: 387 performed by radiologists and 387 performed by APPs. Diagnostic rate of core biopsy and aspirate samples was 97% and 88% for radiologists and 97% and 89% for APPs. Complication rate was 0.0% for radiologists and 0.3% for APPs (the latter was due to one patient with a bleeding complication at the biopsy site).

CONCLUSION

There was no loss in the diagnostic rate of bone marrow biopsy exams performed by APPs compared to exams performed by radiologists.

CLINICAL RELEVANCE/APPLICATION

APPs primarily performing image-guided BMAB procedures has allowed MSK radiologists in our practice more capacity to perform other more complex procedures and address high volume diagnostic imaging exams.

T3-SSMK05-3 DIAGNOSTIC VALUE OF MRI IN PEDIATRIC ACUTE OSTEOMYELITIS—SYSTEMATIC REVIEW & BAYESIAN HSROC META-ANALYSIS: IS INTRAVENOUS CONTRAST NECESSARY?

Mona Dabiri, MD (*Presenter*)
Shivani Ahlawat, MD (*Abstract Co-Author*)
Laura M. Fayad, MD (*Abstract Co-Author*)

PURPOSE

Intravenous gadolinium is routinely used during MRI for suspected pediatric acute hematogenous osteomyelitis (AHO), but its incremental diagnostic value compared with contemporary fluid-sensitive non-contrast protocols is uncertain. We performed a systematic review and Bayesian hierarchical summary ROC (HSROC) meta-analysis to quantify the benefit of contrast and identify clinical scenarios in which it remains useful.

METHODS AND MATERIALS

MEDLINE and Cochrane DTA Register were searched through 15 Apr 2025. Original studies (<18 y) reporting MRI accuracy for extremity AHO were screened. TP/FP/FN/TN counts, magnet strength, sequences, and reader expertise were extracted. One-arm sensitivity series were retained. Accuracy was pooled with DerSimonian-Laird (separate axes) and a Bayesian bivariate HSROC model (PyMC 5.11; 4 chains, 32 000 post-warm-up draws).

RESULTS

There were 37 original science investigations and no systematic reviews. Of the 20 studies that provided patient-level diagnostic metrics, the sensitivity of intravenous contrast-enhanced MRI for paediatric acute extremity osteomyelitis ranged from 75 % to 100 %, while specificity ranged from 67 % to 100 %. Ten studies reported an overall sensitivity of = 90 %, and five studies reported an overall specificity of = 90 %. The 17 analyzable arms comprised 682 children with culture/operative-proven AHO and 514 controls. Non-contrast MRI—pooled sensitivity was0.91 (95 % CrI 0.78-0.97), specificity 0.85 (0.66-0.96) and Contrast-enhanced MRI—sensitivity 0.93 (0.86-0.98), specificity 0.87 (0.74-0.96) and Contrast increased sensitivity by +0.03 pts (CrI -0.07 to +0.16) and specificity by +0.02 pts (CrI -0.15 to +0.24); both intervals crossed zero. Sub-analyses limited to paired cohorts, 1.5 T scanners or two-arm studies only produced similar estimates. Qualitative evidence suggested greatest contrast benefit in children < 3 y for detecting epiphyseal or growth-plate infection.

CONCLUSION

Non-contrast MRI already achieves high diagnostic accuracy for pediatric extremity AHO. Intravenous contrast yields a 3% sensitivity gain, a statistically uncertain improvement. Data suggest that contrast should be reserved for children <3-years-old, equivocal scans, or suspected epiphyseal disease. Routine use is probably not warranted.

CLINICAL RELEVANCE/APPLICATION

The addition of intravenous contrast to pediatric MRI requires additional time, sedation and is more invasive than non-contrast MRI. The ability to omit contrast for the evaluation of AHO routinely will impact the need for sedation and reduce MRI scan time.

T3-SSMK05-5 DIAGNOSTIC YIELD AND RADIOLOGIC-PATHOLOGIC CONCORDANCE IN CT VERSUS US-GUIDED BIOPSIES: A RETROSPECTIVE ANALYSIS

Pavan Brahmbhatt, MBBS, MD (*Presenter*)
Daniel E. Wessell, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate diagnostic yield and radiologic-pathologic concordance rates in CT versus ultrasound (US)-guided musculoskeletal biopsies and identify factors influencing these outcomes.

METHODS AND MATERIALS

A retrospective analysis of 134 consecutive image-guided musculoskeletal biopsies (83 CT-guided, 51 US-guided) was conducted. Lesions were classified as bone (74 cases, 55.2%) or soft tissue (60 cases, 44.8%). Primary outcomes included diagnostic yield and rad-path concordance. All procedures were performed with intraprocedural cytologic analysis to facilitate yield. Fisher's exact test was used for statistical analysis due to small sample sizes in subgroup analyses and the binary nature of outcome variables. Analyses were stratified by modality, tissue type, pathology results, and performing physician.

RESULTS

Overall diagnostic yield was 97.0% (CT: 96.4%, US: 98.0%, p=0.65). Rad-path concordance was 94.8%, with 7 discordant cases (5.2%). Obvious modality preferences were observed, with CT used for 95.9% of bone biopsies and US for 80.0% of soft tissue biopsies. Malignant lesions comprised 58.2% of cases, with metastases (32.1%) being most common. Benign lesions represented 30.6% of cases, with non-neoplastic lesions predominating. Physician-specific variation was observed in rad-path concordance (range: 66.7-100%, p=0.004), but not in diagnostic yield (range: 88.9-100%, p=0.19). Discordant results occurred more frequently in bone biopsies (5/74, 6.8%) than soft tissue biopsies (2/60, 3.3%), though this difference was not statistically significant (p=0.45).

CONCLUSION

Both CT and US demonstrated excellent diagnostic yield and high radiologic-pathologic concordance for musculoskeletal biopsies. Modality selection is frequently tailored based on lesion characteristics such as superficiality, tissue type, and ease of visualization. Therefore, clinical evaluation and pre-procedural planning plays a key role in optimizing diagnostic outcome. The significant variability in radiologic-pathologic concordance among physicians was likely due to small sample size, though a component of experience may be considered. We continue to maintain a prospective database to increase sample size and further analyze specific variables which may affect yield and concordance.

CLINICAL RELEVANCE/APPLICATION

Image-guided percutaneous biopsies are essential for definitive diagnosis in musculoskeletal lesions, yet optimal modality selection and factors affecting diagnostic accuracy may remain incompletely characterized.

T3-SSMK05-6 CAN REVIEWING PHOTOGRAPHS OF SKIN ULCERATION IMPROVE DIAGNOSIS OF OSTEOMYELITIS ON RADIOGRAPH?

Asad Khawaja (*Presenter*)
Oganes Ashikyan, MD (*Abstract Co-Author*)
Alireza Eajazi, MD (*Abstract Co-Author*)
Tomas Amerio, MD (*Abstract Co-Author*)
Caroline Pennington (*Abstract Co-Author*)
Parham Pezeshk, MD (*Abstract Co-Author*)

PURPOSE

Radiographs are often recommended as the first-line imaging study for assessment of osteomyelitis (OM), with findings on radiograph suggestive of osteomyelitis including loss of bone cortex, abnormal soft tissue density, and a periosteal reaction. However, they have limited sensitivity in detecting early osteomyelitis, and this limitation becomes more pronounced without knowledge of the location and depth of skin ulceration. This study aimed to determine whether reviewing a photograph of the ulceration in the electronic medical record improves radiologists' diagnostic accuracy for osteomyelitis on radiographs.

METHODS AND MATERIALS

In this retrospective study, 69 patients with extremity radiographs and a clinical suspicion of osteomyelitis were enrolled. Three radiologists with varying levels of musculoskeletal (MSK) radiology experience (15 years, 5 years, and 1 year) reviewed and scored the radiographs by consensus. They assessed the probability of osteomyelitis using a five-point scale (1: definitely no OM, 2: probably no OM, 3: indeterminate, 4: probably OM, 5: definitely OM). After one week, the radiographs were re-evaluated alongside photographs of skin ulceration, using the same grading system. Follow-up MRI or bone biopsy and culture were used as the gold standard for the presence or absence of osteomyelitis. The two sets of scores were compared using multi-reader, multi- case analysis.

RESULTS

Based on the combined readings of the three radiologists, the area under the curve (AUC) significantly improved from 0.69 (without photographs) to 0.74 (with photographs) ($P < 0.05$). However, the improvement was not statistically significant after excluding the least experienced radiologist.

CONCLUSION

These findings suggest that reviewing clinical photographs of skin ulcerations can enhance early osteomyelitis diagnosis for less experienced radiologists, while the impact on experienced radiologists is less pronounced.

CLINICAL RELEVANCE/APPLICATION

Integrating clinical photographs into radiographic workflows may improve diagnostic accuracy of osteomyelitis in the foot, particularly among trainees. This can help bridge gaps in experience and potentially reduce delays in diagnosis and treatment.

T3-SSNR07-1 PROLONGED VENOUS TRANSIT IS ASSOCIATED WITH HIGHER ODDS OF UNFAVORABLE FUNCTIONAL OUTCOMES IN LARGE CORE STROKE PATIENTS

Hamza A. Salim, MD (*Presenter*)
Dhairya Lakhani, MD (*Abstract Co-Author*)
Gegory Albers (*Abstract Co-Author*)
Argye Hillis, MD (*Abstract Co-Author*)
Kambiz Nael, MD (*Abstract Co-Author*)
Max Wintermark, MD (*Abstract Co-Author*)
Jeremy J. Heit, MD, PhD (*Abstract Co-Author*)
Tobias Faizy, MD (*Abstract Co-Author*)
Vivek Yedavalli, MD, MS (*Abstract Co-Author*)

PURPOSE

Large core acute ischemic stroke (AIS) is associated with high rates of disability despite mechanical thrombectomy (MT) treatment. Recent studies suggest that prolonged venous transit (PVT) may indicate impaired venous drainage, influencing functional outcomes. However, its prognostic value in large core stroke patients remains unclear.

METHODS AND MATERIALS

We conducted a retrospective cohort study using data from consecutive patients with AIS-LVO and large ischemic core volumes (ASPECTS <6 or relative cerebral blood flow < 30% volume =50 mL; per SELECT-2 trial definition) between September 1, 2016 and September 2, 2024. PVT was assessed based on time-to-maximum (Tmax) =10 seconds in the superior sagittal sinus or torcula. The primary outcome was unfavorable functional recovery at 90 days, defined as a modified Rankin Scale (mRS) score of 4-6.

RESULTS

100 patients met inclusion criteria, and 41 (41%) had PVT. Unfavorable functional outcomes were more frequent in the PVT+ group (59% vs. 37%, p=0.036). Multivariable analysis confirmed that PVT was independently associated with unfavorable outcomes (adjusted OR 4.07, 95% CI 1.15-14.4, p=0.03), even after accounting for penumbra size (Tmax >6s) and large core volumes (rCBF <30%). Other predictors included older age (adjusted OR 1.07, 95% CI 1.02 to 1.11, P=0.003), higher admission NIHSS (adjusted OR 1.16, 95% CI 1.05 to 1.29, P=0.005), and larger rCBF <30% volume (adjusted OR 1.02, 95% CI 1.00 to 1.04, P=0.032).

CONCLUSION

PVT is independently associated with unfavorable outcomes in patients with large core infarcts.

CLINICAL RELEVANCE/APPLICATION

These findings suggest PVT may serve as a prognostic marker, warranting further investigation in larger prospective studies to guide treatment decisions in this high-risk population.

T3-SSNR07-2 BATTLEBOTS: A HEAD-TO-HEAD AI MATCHUP IN STROKE CTA OCCLUSION DETECTION

Sara Silberstein, MD, MS (*Presenter*)
Ryan K. Lee, MD, MBA (*Abstract Co-Author*)
Avishkar Sharma, MD (*Abstract Co-Author*)
Matthew Callaghan, MD (*Abstract Co-Author*)

PURPOSE

Acute ischemic stroke is a leading contributor to morbidity, mortality, and healthcare costs. To address this, artificial intelligence (AI) has increasingly been used to enhance detection of cerebral occlusions and expedite acute stroke management. Previous studies have evaluated the diagnostic performance of individual AI tools for LVO detection. However, no prior study has directly compared the diagnostic accuracy of two AI solutions using the same patient population. This study compares the diagnostic accuracy of two FDA-approved AI-based large vessel occlusion (LVO) detection software programs using identical clinical data.

METHODS AND MATERIALS

A retrospective analysis was conducted on all brain CT Angiography studies performed for code strokes triggered by emergency or neurology departments between January and September 2024. CTAs were performed at two thrombectomy- capable stroke centers: one suburban community hospital and one urban tertiary care center. The study compared two FDA-approved AI-based software programs (Program A and Program B) in detecting occlusions in the internal carotid artery (ICA), middle cerebral artery (M1, M2), anterior cerebral artery (ACA), posterior cerebral artery (PCA), vertebral artery, and basilar artery. Board-certified radiologist interpretation served as the reference standard. For both tools, we calculated sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value (NPV), true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN). A McNemar Test ($p < 0.05$) was used to assess statistical significance. A subset analysis focused on occlusions considered potential targets for endovascular therapy (ICA, M1, M2, and basilar artery).

RESULTS

Among 659 patients, Program A demonstrated a sensitivity of 0.65 while Program B demonstrated sensitivity of 0.35. Overall accuracy was 0.88 for Program A and 0.86 for Program B, with no statistically significant difference (McNemar Test p = 0.74). However, in the subset analysis of 48 thrombectomy relevant occlusions, Program A showed statistically significant improved detection of occlusions relevant to thrombectomy (McNemar Test p = 0.039).

CONCLUSION

While the overall diagnostic accuracy of the two FDA approved AI tools was similar, Program A demonstrated significantly higher sensitivity for detecting large vessel occlusions amenable to endovascular treatment.

CLINICAL RELEVANCE/APPLICATION

Accurate and timely detection of thrombectomy amenable LVOs is critical in acute stroke care. This study highlights difference in performance between FDA approved AI tools, suggesting tool selection may influence clinical decision making.

T3-SSNR07-3 ADDITION OF OXYGEN EXTRACTION FRACTION TO REFINE ISCHEMIC CORE AND PREDICT DIFFUSION REVERSAL IN ACUTE ISCHEMIC STROKE

Christopher P. Hess, MD, PhD (*Abstract Co-Author*)
David S. Liebeskind (*Abstract Co-Author*)
Kambiz Nael, MD (*Abstract Co-Author*)

PURPOSE

In patients with acute ischemic stroke (AIS), overestimation of ischemic core on MRI-DWI due to ischemic lesion diffusion reversibility has been described following successful reperfusion. In this study we aim to assess the potential role of oxygen extraction fraction (OEF) derived from dynamic susceptibility contrast (DSC) MRI in prediction of diffusion lesion reversal in patients with AIS after successful reperfusion.?

METHODS AND MATERIALS

In this retrospective study, we included patients with anterior circulation large vessel occlusion stroke who underwent pretreatment MRI including DWI and DSC perfusion MRI, achieved successful reperfusion (TICI = 2c), and had follow-up MRI within 48 hours. Ischemic core masks were generated from baseline MRI using ADC = 620 × 10?6 mm²/s and final infarction masks were generated from final MRI-DW images. DSC perfusion was analyzed by Cercare Medical Neurosuite 15 (Cercare Medical, Denmark) to generate OEF maps and normalized to contralateral side to generate relative OEF values (OEF r). Image coregistration and subtraction was performed to determine final voxel fate as persistent infract vs. those that reversed (not infracted on final MRI). Logistic regression and receiver operating (ROC) analyses assessed the predictive value of imaging biomarkers.?

RESULTS

Despite using ADC = 620 × 10?6 mm²/s to define ischemic core, approximately 30% of voxels reversed (survived) on final MRI. Reversed voxels exhibited significantly higher OEF r (median 2.18 vs. 1.60) compared to persistent infarct voxels ($p < 0.0001$). ROC analysis showed AUC/sensitivity/specificity of 0.65/60/63 for ADC, 0.77/53/89 for OEF r and 0.86/76/78 for combined model (ADC + OEF r). Addition of OEF r to ADC significantly improved the diagnostic performance of ischemic core definition (Delong test, $p<0.001$).

CONCLUSION

Voxel-wise OEF r measurements from DSC MRI can predict ischemic lesion diffusion reversal in patients who underwent successful reperfusion. Addition of OEF r to ADC can improve core definition by predicting diffusion reversal and reducing overestimation of core volume.

CLINICAL RELEVANCE/APPLICATION

OEF can now be calculated from routinely acquired DSC and its addition to ADC has the potential to improve ischemic core delineation in reperfused AIS patients.

T3-SSNR07-4 THREE-DIMENSIONAL VOXEL-BASED SIGNAL INTENSITY QUANTIFICATION OF SYMPTOMATIC INTRACRANIAL PLAQUES

Martin Cabarique, MD (*Presenter*)
Carlos Dier, MD (*Abstract Co-Author*)
Andres Gudino (*Abstract Co-Author*)
Navami Shenoy (*Abstract Co-Author*)
Elena Sagues (*Abstract Co-Author*)
Sebastian Sanchez (*Abstract Co-Author*)
Pablo S. Martinez (*Abstract Co-Author*)
Domenica Cifuentes (*Abstract Co-Author*)
Ruben Calle (*Abstract Co-Author*)
Minako Hayakawa, MD (*Abstract Co-Author*)
Bruno A. Policeni, MD, MBA (*Abstract Co-Author*)
Edgar Samaniego (*Abstract Co-Author*)

PURPOSE

Intracranial plaque enhancement (IPE) serves as a biomarker for symptomatic plaques. Voxel-based IPE quantification offers a more reliable method to subjective assessment, minimizing human error and overcoming the limitations of 2D multiplanar sampling of enhancing regions.

METHODS AND MATERIALS

Patients with stroke due to intracranial atherosclerotic were prospectively imaged with 7T high-resolution MRI. Plaques were segmented using 3D Slicer, and IPE was analyzed using an in-house MATLAB code. Signal intensity (SI) distribution was normalized to the corpus callosum (CC) and voxel-based IPE colormaps were generated. These colormaps correlates with pre- and post-contrast SI curves. Three IPE metrics were obtained: mean enhancement ratio (MER: mean SI post / mean SI CC), gadolinium uptake ([mean SI post - mean SI pre] / standard deviation SI pre), and contrast-enhancement ratio (CER: [mean SI post - mean SI pre] / mean SI post). Plaques were classified as symptomatic if they were in the ipsilateral stroke vascular territory. The Mann-Whitney test was used to compare IPE metrics between

symptomatic and asymptomatic plaques, and univariate regression analysis was conducted to identify factors associated with symptomatic status. An ROC curve analysis was conducted to evaluate the accuracy of IPE metrics in detecting symptomatic plaques.

RESULTS

A total of 41 patients with 75 plaques were analyzed, of which 40 plaques (53%) were classified as symptomatic. Symptomatic plaques demonstrated different IPE patterns compared to asymptomatic plaques, including MER (1.16 ± 0.48 vs. 0.97 ± 0.33, p 0.03), gadolinium uptake ratio (5.6 ± 4.13 vs 3.43 ± 2.48, p < 0.001), and CER (1.09 ± 0.69 vs. 0.77 ± 0.67, p 0.01). Symptomatic plaques were more likely to show increased gadolinium uptake ratio (OR 1.25, 95 CI 1.05 - 1.49, p 0.01). Similarly, there was a trend toward higher MER (OR 3.07, 95 CI 0.92 - 10.26, p 0.06) and CER (OR 2.03, 95 CI 0.95 - 4.33, p 0.06) in symptomatic plaques. A gadolinium uptake ratio above 3.7 demonstrated an area under the curve of 0.70 for detecting symptomatic plaques.

CONCLUSION

Voxel-based IPE quantification improves the assessment of intracranial symptomatic plaques by characterizing IPE patterns.

CLINICAL RELEVANCE/APPLICATION

Objective quantification of IPE can help characterize enhancement patterns in symptomatic plaques

T3-SSNR07-5 THE COLLATERAL EFFECT: HOW BASELINE COLLATERAL CIRCULATION INFLUENCES ACUTE ISCHEMIC STROKE OUTCOMES - A SYSTEMATIC REVIEW AND META-ANALYSIS

Suryansh Bajaj, MD (*Presenter*)

PURPOSE

Collateral circulation plays an essential role in mitigating the severity of ischemic stroke by maintaining distal blood flow to the brain. The presence of collateral vessels at baseline may influence functional recovery, mortality, and recanalization success in patients with acute ischemic stroke (AIS). However, its impact remains under investigation. The purpose of this study is to study the effect of baseline collateral status assessed on perfusion scan on clinical outcomes, including functional recovery, mortality, recanalization success, and complications in patients with AIS.

METHODS AND MATERIALS

A systematic review and meta-analysis were performed, including studies that evaluated baseline collateral status in AIS patients on perfusion scans.The outcomes assessed included functional status (modified Rankin Scale), patient mortality, successful recanalization, and the incidence of symptomaticintracranial hemorrhage (sICH). A random effects model was used to account for heterogeneity across studies, and pooled risk ratios (RR) were calculated foreach outcome.

RESULTS

The meta-analysis included 26 studies with a total of 3,866 patients. Good baseline collateral status was significantly associated with a more thantwofold higher likelihood of achieving good functional outcomes at 90 days (RR: 2.18), a 50% reduced risk of mortality (RR: 0.49), and a 10% higher likelihood of successful recanalization (RR: 1.10), however, no significant association was found between collateral status and the occurrence of symptomatic intracranial hemorrhage (sICH) ($p>0.05$). Substantial heterogeneity was observed for functional outcomes and recanalization ($I^2>50\%$), which may be attributed to differences in study designs, collateral grading methods, and sample sizes.

CONCLUSION

Good baseline collateral status is associated with improved functional outcomes, reduced mortality, and higher likelihood of successfulrecanalization in AIS patients. This finding underscores the importance of collateral circulation assessment on perfusion scans in the management of AIS.

CLINICAL RELEVANCE/APPLICATION

Baseline collateral status provides valuable prognostic information, guiding clinical decisions and improving patient outcomes in acute ischemic strokemanagement. Good baseline collateral status assessed on perfusion scans is associated with a more than twofold higher likelihood of good functional outcomes at 90 days (RR: 2.18), a 50% lower risk of mortality (RR: 0.49), and a 10% higher chance of successful recanalization (RR: 1.10) in acute ischemic stroke patients. Further prospective studies with standardized collateral grading are needed to refine clinical decision-making.

T3-SSNR07-6 LOW PREVALENCE OF ACTIONABLE IMAGING FINDINGS IN EMERGENCY DEPARTMENT PATIENTS PRESENTING WITH VERTIGO: 10 YEAR RETROSPECTIVE ANALYSIS IN A LARGE HEALTH SYSTEM

Raven Spencer, MD (*Presenter*)
Jason Gandhi (*Abstract Co-Author*)
Charles Q. Li, MD (*Abstract Co-Author*)
Laura B. Eisenmenger, MD (*Abstract Co-Author*)
Michael F. Goldberg, MD (*Abstract Co-Author*)
Warren Chang, MD, MBA (*Abstract Co-Author*)

PURPOSE

Vertigo is a common presenting complaint in the emergency department (ED). However, benign etiologies without actionable imaging findings are common in patients with vertigo. Although most cases are due to benign causes, patients are frequently imaged with CT, MRI, CTA, and MRA due to concern for stroke or hemorrhage—often without positive findings. Prior studies suggest the risk of stroke in this population is under 5%. We examined the incidence and clinical impact of actionable imaging findings in ED patients presenting with vertigo or dizziness across a large health system over a 10-year period.

METHODS AND MATERIALS

5615 patients presented to network EDs with the provided history of vertigo between 2016 and 2025. 3493 patients were female and 2122 were male. Studies included 2665 head CTs, 536 brain MRIs, 2166 CT angiograms, 151 MR angiograms, and 97 other exams. A total of 337 (6%) examinations were flagged for review due to potentially relevant findings. Each exam was independently reviewed by a board certified neuroradiologist and neurologist. Imaging was classified as actionable if it led to admission or a change in management following consultation.

RESULTS

Of the 337 reviewed cases, 122 patients (2.2%, 73 female, 49 male) were determined to have actionable imaging findings. This included 46 patients (0.7%) with acute/subacute infarcts, primarily cerebellar, 59 (1%) were found to have vertebrobasilar high grade stenosis or occlusion, and 17 patients had other findings (e.g., tumor, hemorrhage or demyelination). From the remaining non-actionable cases, most were found to have chronic or stable findings unlikely to contribute to their presenting symptoms and did not require admission or a change in management. 51 were discharged from the ED without consultation. Of the remaining 164 who were evaluated, 53 (30%) were diagnosed with BPPV.

CONCLUSION

Imaging in ED patients with vertigo yielded actionable findings in only 2% of cases, with <1% having acute/subacute infarcts. While most infarcts involved the posterior fossa, a subset of actionable findings involved anterior circulation pathology not clearly linked to vertigo but still warranting treatment. Given the high prevalence of peripheral vertigo including BPPV, thorough bedside evaluation—including positional maneuvers—could reduce unnecessary imaging. Higher priority for imaging may be justified in patients with focal cerebellar signs.

CLINICAL RELEVANCE/APPLICATION

The vast majority of patients imaged for vertigo in the ED did not have actionable findings. Routine imaging may be avoided in patients with low-risk clinical features, potentially reducing costs and preventing overdiagnosis, while still ensuring detection of critical but sometimes incidental cerebrovascular disease.

T3-SSNR08-1 THROMBOLYSIS IN BASILAR INFARCTION (TIBI): A NOVEL ANGIOGRAPHIC SCALE FOR EVALUATING MECHANICAL THROMBECTOMY IN BASILAR ARTERY OCCLUSION

Miguel Emilio Chevasco Hanze, MD (*Presenter*)
Antonio Lopez Rueda, MD (*Abstract Co-Author*)
Oscar Chirife Chaparro (*Abstract Co-Author*)
Enric Ripoll, MD (*Abstract Co-Author*)
Sonia Aixut (*Abstract Co-Author*)
Lucia Aja, MD (*Abstract Co-Author*)
M. Angels de Miquel, MD (*Abstract Co-Author*)
Monica Cos (*Abstract Co-Author*)

PURPOSE

Acute Basilar Artery Occlusion (BAO) has the highest morbidity and mortality in posterior circulation strokes. Current reperfusion scores for mechanical thrombectomy (MT) are based on anterior circulation strokes (mTICI score). This study proposes a basilar artery-specific reperfusion score, based on digital subtraction angiography (DSA), to assess MT efficacy in acute BAO.

METHODS AND MATERIALS

A retrospective analysis was conducted on a prospective database of acute BAO patients treated with MT within 24 hours of symptom onset at a stroke center from January 2014 to December 2023. Informed consent was obtained, and institutional review board approval was granted. Clinical, procedural, and radiological data were collected. The Thrombolysis in Basilar Infarction (TIBI) score was developed by grading posterior circulation territories in DSA post-MT, using PC-ASPECTS as reference (deducting 1 point for each occipital lobe/cerebellar lobe/thalamus or 2 points for pons/mesencephalon). Successful recanalization was defined as TIBI=8 and assessed by modified Rankin Scale at 90 days.

RESULTS

Ninety-eight patients were included (median age 70, 56 men). Successful recanalization (mTICI2b/3) was achieved in 84.7% and TIBI=8 in 71.4%. Good functional status (mRS=3) was seen in 50% of patients, with better outcomes in mTICI 2b/3 and TIBI=8 groups ($p < 0.001$ and $p=0.002$). After adjusting for age, NIHSS socre and Glasgow Coma Sacle, TIBI=8 was associated with good outcomes at 90 days (OR = 6.18; $p = 0.001$), and TIBI=7 was also linked to good outcomes (OR = 9.45; $p < 0.001$).

CONCLUSION

The TIBI scale is a novel tool for evaluating MT efficacy in acute BAO. A TIBI=8 should be the target for successful MT.

CLINICAL RELEVANCE/APPLICATION

Could discriminate patient who will have a good prognosis following mechanical thrombectomy

T3-SSNR08-2 COMPARATIVE EFFICACY OF FLOW DIVERTER DEVICES IN THE TREATMENT OF UNRUPTURED DISTAL ANTERIOR CEREBRAL ARTERY ANEURYSMS: A RETROSPECTIVE, MULTICENTER, MULTINATIONAL STUDY

Hamza A. Salim, MD (*Presenter*)
Motaz A. Daraghma, MD (*Abstract Co-Author*)
Frederic Clarencon, MD (*Abstract Co-Author*)
Andrea M. Alexandre, MD (*Abstract Co-Author*)
Vivek Yedavalli, MD, MS (*Abstract Co-Author*)
Adam A. Dmytriw, MD,FRCPC (*Abstract Co-Author*)
Max Wintermark, MD (*Abstract Co-Author*)

PURPOSE

Flow diverters (FDs) have expanded endovascular treatment options for cerebral aneurysms, but comparative data regarding their efficacy and safety in distal anterior cerebral artery (DACA) aneurysms are limited. We aimed to compare clinical and radiographic outcomes among different FD devices in the treatment of unruptured DACA aneurysms.

METHODS AND MATERIALS

We conducted a retrospective, multicenter cohort study involving 166 patients from 39 centers across 14 countries who underwent FD treatment for unruptured DACA aneurysms between January 2018 and December 2022. Patients were treated with the Pipeline Embolization Device (PED), Silk Vista Baby (SVB), FRED Jr., or other FDs. The primary outcome was complete aneurysm occlusion at last imaging follow-up, assessed using the O'Kelly-Marotta (OKM) classification. Secondary outcomes included procedural complications, retreatment rates, and modified Rankin Scale (mRS) scores at last follow-up.

RESULTS

The median age was 61 years (interquartile range, 52-67), and 74% were women. Aneurysms were predominantly saccular and located on the pericallosal artery. Immediate complete obliteration occurred in 20% of cases, and adequate occlusion (OKM C-D) was achieved in the majority, with no significant differences among devices. Procedural ischemic complications occurred in 11% of patients, hemorrhagic complications in 5%, and symptomatic permanent ischemia in 0.6%, without

significant differences by device type. In-stent stenosis occurred in 17% of cases. The retreatment rate was 1.3%. At last follow-up, the median mRS score was 1 (interquartile range, 1-1).

CONCLUSION

Among patients with unruptured DACA aneurysms, treatment with PED, SVB, FRED Jr., and other flow diverters was associated with high rates of aneurysm occlusion, low rates of complications, and favorable functional outcomes. No significant differences in efficacy or safety were observed among devices.

CLINICAL RELEVANCE/APPLICATION

Flow diversion represents a safe and effective strategy for treating unruptured DACA aneurysms. Further prospective studies are warranted to confirm these findings.

T3-SSNR08-3 VISUALIZING THE INVISIBLE: MULTIMODAL IMAGING ASSESSMENT OF ENDOVASCULAR SHUNT (ESHUNT) FUNCTION IN ADULT HYDROCEPHALUS

Pablo A. Diluca, MD (*Presenter*)
Ivan R. Lylyk, MD (*Abstract Co-Author*)
Pedro Lylyk, MD (*Abstract Co-Author*)

PURPOSE

To evaluate cerebrospinal fluid (CSF) flow through an endovascular device (eShunt) in adult patients with hydrocephalus—either idiopathic normal pressure hydrocephalus (iNPH) or communicating hydrocephalus secondary to subarachnoid hemorrhage (SAH)—using MRI, CT, and Doppler ultrasound, and to compare different imaging strategies, including techniques with and without intrathecal contrast.

METHODS AND MATERIALS

A prospective cohort of 42 patients treated with the eShunt device was evaluated. Indications included iNPH and post-SAH communicating hydrocephalus. Post-implantation imaging included: (1) intrathecal gadolinium-enhanced volumetric T1-weighted MRI sequences, (2) balanced steady-state free precession (bSSFP) T2-weighted MRI sequences, and (3) CT myelography, exploiting CSF hyperintensity and hyperdensity. Doppler ultrasound was also performed in a subset of patients. Two neuroradiologists independently assessed CSF flow visualization, image quality, and patient tolerance.

RESULTS

CSF flow within the eShunt was detected using both MRI and CT myelography. Intrathecal contrast-enhanced T1-weighted MRI, balanced T2-weighted MRI, and CT myelography all contributed to flow visualization. Techniques involving intrathecal contrast (MRI and CT) demonstrated higher sensitivity but were associated with mild adverse effects (e.g., headache, nausea) in a few cases. Balanced T2 imaging provided good diagnostic confidence without requiring contrast. Doppler ultrasound was ineffective in detecting intrashunt flow. The overall low detection rate may reflect intermittent shunt activity at the time of imaging. Despite these limitations, patients demonstrated consistent clinical improvement following eShunt placement.

CONCLUSION

MRI is the most effective non-invasive modality for evaluating eShunt patency, though real-time flow detection may be limited by physiological variability. Balanced T2-weighted sequences offer a safe and accessible alternative, while intrathecal contrast enhances sensitivity and specificity at the cost of invasiveness. Despite limitations in flow visualization, the observed clinical benefits support the utility of these devices in selected patients.

CLINICAL RELEVANCE/APPLICATION

A minimally invasive endovascular CSF shunt has been developed to mimic the physiological function of arachnoid granulations, passively diverting CSF from the subarachnoid space into the intracranial venous sinuses. MRI—especially with balanced T2-weighted sequences—enables non-invasive evaluation of eShunt function in both iNPH and post-SAH communicating hydrocephalus, supporting its use for follow-up and correlation with clinical outcomes.

T3-SSNR08-4 LONG-TERM ANGIOGRAPHIC OUTCOMES AND COMPLICATIONS OF WEB AND INTRASACCULAR DEVICES IN INTRACRANIAL ANEURYSM TREATMENT

Wassim Elmasry, MD (*Presenter*)
Ammar Alam (*Abstract Co-Author*)
Mahad Siddiqi (*Abstract Co-Author*)
Theodore Liu (*Abstract Co-Author*)
Robert Fahed, MD, MSc (*Abstract Co-Author*)
Brian Drake, MD (*Abstract Co-Author*)
Howard Lesiuk (*Abstract Co-Author*)
Marlise P. dos Santos, MD,MPH (*Abstract Co-Author*)

PURPOSE

Intrasaccular devices such as the Woven EndoBridge (WEB) have emerged as promising alternatives to traditional coiling and flow diversion, particularly for wide-neck bifurcation aneurysms. These devices offer potential advantages in occlusion durability and procedural safety. However, long-term angiographic outcomes and delayed complications remain insufficiently characterized. This study aims to evaluate the incidence of aneurysm recurrence and delayed complications following treatment with WEB and similar intrasaccular devices, and to identify predictors of suboptimal outcomes.

METHODS AND MATERIALS

A retrospective cohort study was conducted at our institution, including all patients treated with WEB devices between March 30 th , 2021, and October 10 th , 2024. Data was extracted from the EPIC EMR and included patient demographics, aneurysm characteristics, device and procedural details, follow-up imaging, and clinical outcomes. Descriptive statistics and multivariate analyses were performed to assess associations between patient/aneurysm features and outcomes.

RESULTS

Thirty-six patients (mean age 59 ± 13 years) were treated with WEB from 2021 to 2024. Aneurysms were incidental in 72% (n=26), recurrent in 6% (n=2), and associated with subarachnoid hemorrhage in 22% (n=8). Immediate procedural complications occurred in 8% (n=3), and delayed complications in 17% (n=6). One patient (3%) required retreatment for aneurysm recurrence. Initial complete occlusion was achieved in 75% (n=27), with stable occlusion in all but three patients (8%, n=1). Modified Rankin Scale (mRS) scores remained stable in 50% (n=18), improved in 36% (n=13), and worsened in 14% (n=5).

CONCLUSION

Our initial experience with WEB for treatment of cerebral aneurysms showed high initial occlusion rates, low retreatment rate, and favorable safety. Most patients experienced stable or improved clinical outcomes. Some delayed complications underscored a need for long-term follow-up and individualized patient selection.

CLINICAL RELEVANCE/APPLICATION

By identifying predictors of recurrence and complications with new technology/devices, we can guide risk stratification and optimize patient outcomes in neurointerventional practice.

T3-SSNR08-5 DIFFERENTIATING DURAL ARTERIOVENOUS FISTULA FROM JUGULAR VENOUS REFLUX USING ARTERIAL SPIN LABELING AND SUSCEPTIBILITY-WEIGHTED IMAGING ON ROUTINE NON-CONTRAST BRAIN MRI

Luke M. Wojdyla, DO (*Presenter*)
Abraham Noorbakhsh, MD,MPH (*Abstract Co-Author*)
Adam A. Robinson, MD (*Abstract Co-Author*)
Usha Trivedi, MD, BS (*Abstract Co-Author*)
Divya S. Bolar, MD,PhD (*Abstract Co-Author*)

PURPOSE

To identify novel arterial spin labeling (ASL) and susceptibility-weighted imaging (SWI) biomarkers that differentiate jugular venous reflux (JVR) from dural arteriovenous fistulas (dAVFs) on routine non-contrast MRI, including in cases with overlapping features.

METHODS AND MATERIALS

This retrospective study included 13 patients with JVR and 19 with dAVF, all of whom underwent non-contrast brain MRI with 3D pseudocontinuous ASL using parameters adapted from the literature and SWI sequences. All dAVF cases were confirmed by digital subtraction catheter angiography. JVR was defined by one or more of the following criteria: reflux visualized on CTA or MRA, spontaneous resolution on follow-up imaging, or negative findings on digital subtraction angiography. Studies were assessed for hyperintense signal within the internal jugular vein (IJV) on SWI, hyperintense ASL signal in the lowest axial slice of the IJV, and continuity of ASL signal from the IJV to a dural venous sinus without interruption. Laterality and signal symmetry were also recorded. Statistical analysis was performed using Fisher's exact test.

RESULTS

In the JVR group (n=13), all cases demonstrated ASL hyperintensity in the left IJV and continuous ASL signal extending cranially to a dural sinus without interruption. Additionally, 12 of 13 cases showed hyperintense SWI signal in the ipsilateral jugular bulb. Among the dAVF group (n=19), 8 cases exhibited ASL signal localized to a jugular bulb. Within this subset, only 3/8 cases demonstrated hyperintense SWI signal, and just 2/8 showed continuous ASL signal from the jugular bulb to a dural sinus without interruption. Across all cases, absence of SWI hyperintensity in the IJV demonstrated 62% sensitivity and 92% specificity for detecting dAVF ($p = 0.0139$), while ASL discontinuity demonstrated 75% sensitivity and 100% specificity for dAVF ($p = 0.0005$). Taken together, these routine non-contrast features demonstrated complementary value in differentiating dAVF from JVR.

CONCLUSION

Hyperintense SWI signal in the IJV and continuous ASL signal from the jugular bulb to a dural sinus are highly consistent in JVR but less common and more variable in dAVF, even among cases with overlapping ASL signal at the jugular bulb. When applied together, these features enhance diagnostic differentiation between the two entities.

CLINICAL RELEVANCE/APPLICATION

ASL and SWI, standard components of many routine brain MRI protocols, may provide valuable, noninvasive clues to differentiate JVR from dAVF, improving diagnostic accuracy and potentially reducing the need for invasive angiography in ambiguous cases.

T3-SSNR08-6 THE APPLICATION OF TIME-RESOLVED NON-CONTRAST ANGIOGRAPHY (4D-TRANCE) IN THE ASSESSMENT OF COLLATERAL CIRCULATION IN MOYAMOYA DISEASE

Dinglan Yang (*Presenter*)
Chao Xia (*Abstract Co-Author*)
Jiaxin Zeng (*Abstract Co-Author*)
Kai Ai (*Abstract Co-Author*)
Su Lv, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the efficacy of time-resolved non-contrast angiography (4D-TRANCE) in grading collateral circulation in MMD patients, comparing its consistency with digital subtraction angiography (DSA) and time-of-flight magnetic resonance angiography (TOF-MRA).

METHODS AND MATERIALS

This prospective study included 20 preoperative patients diagnosed with MMD. All patients underwent DSA, Time-of-Flight Magnetic Resonance Angiography (TOF-MRA), and 4D-TRANCE. The cohort comprised 9 males and 11 females, with a mean age of 47.2 years (range, 9 to 81 years). According to a New Grading System for Collateral Circulation in Moyamoya Disease, the grading scores were determined based on the collateral circulation status, ranging from 1 to 12. The collateral circulation grades were defined as follows: scores of 1 to 4 indicated poor collateral status (grade I), scores of 5 to 8 indicated fair collateral status (grade II), and scores of 9 to 12 indicated good collateral status (grade III). Linear correlation analyses were conducted on the grading scores from the three imaging modalities, while Kappa coefficient analysis was performed on the status grades.

RESULTS

In this study, we evaluated 36 hemispheres from 20 patients using a scoring system based on the aforementioned criteria, resulting in the creation of a scatter plot and conducting linear correlation analysis. The results consistently demonstrated a statistically significant positive correlation. Based on the scoring, the gradings were as follows: for DSA, there were 11 hemispheres in grade I and 25 in grade II; for TOF-MRA, there were 19 hemispheres in grade I and 17 in grade II; and for 4D-TRANCE, there were 15 hemispheres in grade I and 17 in grade II. Kappa coefficient analysis indicated a strong consistency between 4D-TRANCE and DSA, with a Kappa value of 0.785 ($P < 0.001$), while TOF-MRA exhibited moderate consistency with DSA and 4D-TRANCE, showing Kappa values of 0.565 and 0.560, respectively ($P < 0.001$).

CONCLUSION

While DSA has advantages in assessing collateral circulation, both TOF-MRA and 4D-TRANCE have demonstrated effectiveness in this regard, with 4D-TRANCE showing particular promise. As an emerging imaging modality, 4D-TRANCE has the potential to serve as a valuable complement to DSA and TOF-MRA, especially in clinical scenarios that require dynamic assessments of blood flow and vascular remodeling. Future research should focus on expanding sample sizes and further exploring the feasibility of 4D-TRANCE in clinical applications related to the management and prognosis of MMD.

CLINICAL RELEVANCE/APPLICATION

4D-TRANCE offers a promising alternative for evaluating collateral circulation in MMD patients without associated risks.

T3-SSOB02-1 IMPROVING DETECTION OF RECTOSIGMOID ENDOMETRIOSIS: INTEGRATING THE TEAR-DROP SIGN FOR ENHANCED MRI DIAGNOSTIC SENSITIVITY AND ACCURACY

Priyanka Jha, MBBS (*Presenter*)
Heng Zhang, MD,PhD (*Abstract Co-Author*)
Melika Rezaee, MD (*Abstract Co-Author*)
Luyao Shen, MD (*Abstract Co-Author*)
Pejman Ghanouni, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the MRI features of the uterus-rectosigmoid interface in patients with endometriosis, and correlate these findings with surgical diagnosis, aiming to identify potential MRI markers for early detection of rectosigmoid endometriosis (RE).

METHODS AND MATERIALS

Patients with laparoscopically confirmed endometriosis and preoperative MRI were included. Three radiologists, blinded to surgical outcomes, assessed the uterus-rectosigmoid interface on MRI in consensus. The interface was classified as either the posterior uterus contacting the bowel or not. Contacting cases were further divided into "tear-drop sign," broad-based contact without deeply invasive endometriosis (DIE), broad-based contact with DIE, and "mushroom cap sign." Surgical findings and pathology served as the reference standard.

RESULTS

Among 173 endometriosis cases, 140 (80.9%) showed the rectosigmoid colon contacting posterior uterus on MRI, with 85 cases (49.1%) of the “tear-drop sign” , 40 cases (23.1%) of broad-based contact with DIE, 30 cases (17.3%) of broad-based contact without DIE and 10 cases of “mushroom cap sign” (5.8%). Compared to the 80 patients without surgically confirmed RE, the 93 patients with RE more frequently showed bowel contacting the posterior uterus (95.7% vs. 63.7%), the “tear-drop sign” (59.1% vs. 37.5%), broad-based contact with DIE (26.6% vs. 7.5%), and the “mushroom cap sign” (10.8% vs. 0%) (all $p < 0.05$). The presence of the posterior uterus contacting the bowel, the “teardrop sign”, broad-based contact with DIE, broad-based contact without DIE and the “mushroom cap sign” showed sensitivities of 95.7%, 59.1%, 36.6%, 12.9%, and 10.8%, with specificities of 36.3%, 62.5%, 92.5%, 77.5%, and 100.0%, and diagnostic accuracies of 68.2%, 60.7%, 62.4%, 42.8%, and 52.0%, respectively. Combining the “tear-drop sign” and broad-based contact with DIE resulted in a sensitivity of 79.6%, specificity of 56.3%, and diagnostic accuracy of 68.8%, with an AUC of 0.679. Including the “mushroom cap sign” in this combination increased sensitivity to 87.1%, yielding the highest diagnostic accuracy of 72.8% and an AUC of 0.717.

CONCLUSION

Bowel contacting the posterior uterus is common in RE. In addition to the specific sign of DIE at the uterus-rectosigmoid interface, identifying the tear-drop sign can increase diagnostic sensitivity and accuracy in diagnosing RE.

CLINICAL RELEVANCE/APPLICATION

Evaluation of the rectosigmoid interface on MRI is often overlooked in endometriosis assessment. The “tear-drop sign” is a frequent marker of rectosigmoid involvement. Recognizing this sign can improve detection of deep endometriosis and aid in surgical planning.

T3-SSOB02-2 MRI ULTRAFAST PROTOCOL WITH IDENTICAL DIAGNOSTIC PERFORMANCE IN DEEP PELVIC ENDOMETRIOSIS DIAGNOSIS

Achraf Kanan, MD (*Presenter*)
Betty Sabatier (*Abstract Co-Author*)
Benoit Magnin, MD,MSc (*Abstract Co-Author*)
Benoit Chauveau, MMed (*Abstract Co-Author*)

PURPOSE

In recent years, the incidence of endometriosis has risen sharply. Imaging has an unequivocal place in the diagnostic process. To date, the reference MRI protocol has the advantage of being exhaustive, but its main inconvenient is the acquisition time.

METHODS AND MATERIALS

This monocentric retrospective study included all patients who underwent a pelvic MRI for a suspicion of endometriosis between April 2023 and November 2023 with a reference T2 Propeller protocol and an ultrafast T2 SSFSE protocol. Four radiologists independently assessed each protocol for the presence of endometriosis, its topography and evaluated the Deep Pelvic Endometriosis Index. Intra individual comparison was performed. The four readers also independently assessed acquisition quality comparing artifacts, diagnostic confidence, overall image quality.

RESULTS

A total of 200 patients were included. Of the 800 pelvic MRI scan assessment all operators combined, deep pelvic endometriosis was detected by at least one of the two protocols in 302 assessments. Correlation between the two protocols on the criterion of presence of deep pelvic endometriosis was excellent, with a kappa Cohen’s coefficient (?) 0.91 [0.88-0.94]. Ultrafast protocol was accurate in lesion mapping, with a Lin's concordance correlation coefficient (CCC) 0.83 [0.79-0.86]. The medio-central compartment was the most represented at over 90%, ? 0.90 [0.80-1.00], sensitivity of 1. Ultrafast protocol reduced acquisition time by 88% ($p < 0.0001$). No subjective parameters relating to acquisition quality altered diagnostic concordance.

CONCLUSION

This study demonstrated the excellent quality of ultrafast sequences in detecting deep pelvic endometriosis lesions while reducing acquisition time by 88%.

CLINICAL RELEVANCE/APPLICATION

This study suggests that the ultrafast MRI protocol can be used in routine screening protocols and offers the advantage of a short examination time without loss of diagnostic quality.

T3-SSOB02-3 COMMONLY MISSED ENDOMETRIOSIS LOCATIONS IN NEGATIVE PREOPERATIVE MRI

Priyanka Jha, MBBS (*Presenter*)
Heng Zhang, MD,PhD (*Abstract Co-Author*)
Melika Rezaee, MD (*Abstract Co-Author*)
Luyao Shen, MD (*Abstract Co-Author*)
Pejman Ghanouni, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study aims to analyze preoperative MRI findings in patients with laparoscopically confirmed endometriosis but negative imaging reports, with a focus on identifying commonly missed lesion locations. Given that negative MRI findings may delay timely treatment, we also explore potential causes of missed diagnoses to improve imaging accuracy and clinical management.

METHODS AND MATERIALS

Patients with surgically confirmed endometriosis and negative preoperative MRI were retrospectively included. Two experienced radiologists, blinded to surgical outcomes, independently re-evaluated the MRI scans by consensus. Endometriosis was assessed in three compartments: anterior (vesicouterine/vesicovaginal space, bladder, ureters, and round ligaments), middle (ovaries, fallopian tubes, and parametrium), and posterior (retro-uterine space, retrocervical area, rectovaginal septum, uterosacral ligaments, and rectosigmoid). MRI findings from initial reports and expert review were compared with surgical results.

RESULTS

Seventeen patients were included. In the initial reports, endometriosis was missed in 8 cases in the anterior compartment (7 vesicouterine, 1 bladder, and 3 ureter), 14 in the middle compartment (3 right ovary, 6 left ovary, and 14 parametrium), and 15 in the posterior compartment (4 retro-uterine, 8 retrocervical, 7 rectovaginal septum, 13 uterosacral ligament, and 3 rectosigmoid). The most frequently overlooked sites were the uterosacral ligaments and the parametrium. Expert review identified at least one positive lesion in all cases. However, lesions in the anterior compartment were missed in 2 patients, and lesions in the middle compartment were missed in 3 patients.

CONCLUSION

Endometriosis can be missed across all compartments, particularly in the parametrium in the middle compartment, and uterosacral ligament in the posterior compartment. Experienced radiologists can significantly improve detection, especially in the posterior compartment.

CLINICAL RELEVANCE/APPLICATION

Preoperative MRI plays a critical role in surgical planning for endometriosis. However, false-negative reports may delay diagnosis and treatment. This study highlights the most frequently missed lesion locations, emphasizing the need for increased radiologist awareness and structured compartment-based review. Incorporating these insights into routine MRI interpretation may enhance diagnostic accuracy, optimize surgical outcomes, and reduce patient morbidity.

T3-SSOB02-4 IMPROVED DIAGNOSTIC CONFIDENCE AND EFFICIENCY IN GYNECOLOGIC MRI USING T2 SHINE-THROUGH SUPPRESSION: COMPARISON WITH CONVENTIONAL DWI

Yoshie Omiya, MD (*Presenter*)
Reo Higuchi (*Abstract Co-Author*)
JIAJING HU (*Abstract Co-Author*)
Katsuhiro Sano, MD, PhD (*Abstract Co-Author*)
Koji Kamagata, MD, PhD (*Abstract Co-Author*)
Tsuyoshi Tajima, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic performance—including accuracy, reader confidence, and efficiency—of Water Diffusion Subtraction (WDS), a post-processing technique for diffusion-weighted imaging (DWI) that suppresses the T2 shine-through effect, in gynecologic MRI. We compared WDS with conventional DWI, including both diffusion-weighted images and apparent diffusion coefficient (ADC) maps, in distinguishing benign from malignant endometrial lesions.

METHODS AND MATERIALS

This study aimed to compare the diagnostic performance of WDS with conventional DWI in differentiating malignant from benign endometrial lesions. We analyzed 57 patients with suspected endometrial lesions, including 28 cases of surgically confirmed FIGO stage IA endometrial cancer and 29 benign cases confirmed by biopsy and two-year clinical follow-up. The mean age was 56.7 ± 8.7 years in the malignant group and 46.9 ± 9.7 years in the benign group. DWI was acquired using two b-values (0 and either 800 or 1000 μmm 2 /s). WDS images were generated from the acquired diffusion-weighted images by highlighting differences in signal decay to minimize T2 influence.Two readers independently assessed the datasets in two sessions: first with T2WI, DWI, and ADC maps; then with T2WI and WDS. Binary diagnostic accuracy and 5-point confidence scores were recorded. ROC analysis and AUC comparison were performed using the DeLong method. Reader-averaged confidence scores were compared using paired t-tests and Wilcoxon signed-rank tests. Reading time and inter-reader agreement were also evaluated.

RESULTS

WDS improved sensitivity and accuracy in both readers, with only slight or non-significant AUC differences. Given that WDS and ADC maps are derived from the same diffusion datasets, a significant difference in diagnostic performance was not anticipated. However, mean confidence scores significantly improved with WDS ($p = 0.0489$, paired t-test; $p = 0.0448$, Wilcoxon signed-rank test), and inter-reader agreement demonstrated stronger statistical consistency ($?^2$ $p = 0.0039$ vs. 0.0119 for ADC). Reading times were reduced by 40-50%. Cohen's ? remained low for both modalities.

CONCLUSION

Although both WDS and ADC maps are derived from the same diffusion-weighted images, WDS significantly improved diagnostic confidence, inter-reader consistency, and interpretation efficiency. It may be particularly helpful in distinguishing between benign and malignant endometrial lesions where strong T2 shine-through effects limit conventional DWI evaluation.

CLINICAL RELEVANCE/APPLICATION

WDS may serve as a valuable adjunct in gynecologic MRI by improving lesion visibility and diagnostic efficiency, especially when conventional DWI is limited by T2 shine-through effects.

T3-SSOB02-6 ASSESSING THE ROLE OF SOCIETY OF RADIOLOGISTS IN ULTRASOUND (SRU) CONSENSUS CRITERIA IN ULTRASOUND EVALUATION OF ENDOMETRIOSIS

Anne Y. Hu, MD (*Presenter*)
Liina Poder, MD (*Abstract Co-Author*)
Sneha Mittal (*Abstract Co-Author*)
Martina Z. Francisco, MD (*Abstract Co-Author*)
Priyanka Jha, MBBS (*Abstract Co-Author*)

PURPOSE

Endometriosis is commonly associated with chronic pelvic pain and infertility, yet is often underdiagnosed, leading to delays in care. Pelvic ultrasound is the initial imaging modality for evaluating patients with pelvic symptoms and infertility. Given the need for improved detection of endometriosis, the SRU released guidelines and imaging observations to support identification of endometriosis on augmented pelvic ultrasound (APU), along with a classification system for interpretation of these findings. To corroborate these guidelines, we performed a multi-center retrospective analysis of patients who underwent pelvic ultrasound to assess their indications for APU, imaging observations, and clinical outcomes.

METHODS AND MATERIALS

Our retrospective cohort consisted of female patients ages 16 to 55 years old who underwent transvaginal pelvic ultrasound in 2019 at two academic hospitals. Obstetric studies, ultrasounds performed or interpreted by non-radiology departments, and technically inadequate studies were excluded. Experienced readers then assessed clinical indications, presence of endometriosis imaging observations, and APU diagnostic classification. The electronic medical record was reviewed to obtain clinical history and whether endometriosis was diagnosed in the subsequent 5 years of follow-up.

RESULTS

Of the 888 patients in the cohort, 292 patients (32.9%) had symptoms or clinical history that met criteria for APU to evaluate for endometriosis. 58 patients (19.9%) had positive findings for endometriosis and 28 patients (9.6%) had equivocal findings. During the 5 year study period, 48 patients (5.4%) in the entire cohort received a new endometriosis diagnosis, with 14 patients (29.2%) diagnosed on ultrasound and the remainder diagnosed on subsequent MRI or surgery. More notably, 64% of patients classified as APU-3 had a confirmed endometriosis diagnosis on follow-up. Excluding patients with ultrasound findings confirmatory for endometriosis, the mean time from the initial pelvic ultrasound to endometriosis diagnosis was 2.2 years.

CONCLUSION

SRU consensus criteria for endometriosis evaluation provides a straightforward framework for identifying patients who may benefit from an APU and interpreting their imaging findings. Moreover, the classification system is a useful tool for stratifying patients who may have endometriosis or may benefit from further evaluation with MRI or surgery.

CLINICAL RELEVANCE/APPLICATION

Endometriosis can be challenging to detect on pelvic ultrasound and is often underdiagnosed, however applying SRU guidelines for APU and endometriosis imaging observations can streamline imaging interpretation with the goal of reducing diagnostic delays and patient morbidity.

T3-STCE1-1 AUTOMATED OPPORTUNISTIC BREAST DENSITY ASSESSMENT FROM CHEST AND ABDOMINAL CT: A FEASIBILITY STUDY IN A DIVERSE CLINICAL COHORT

Kai Jones, MD (*Presenter*)
Edward Mardakhaev, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility of an open-source algorithm for automated, opportunistic breast density assessment from CT scans. This study aimed to benchmark CT-derived density against mammographic data, investigate the impact of technical factors like field-of-view (FOV) limitations, and establish an optimal, clinically relevant cut-off for identifying high breast density.

METHODS AND MATERIALS

In this IRB-approved retrospective study, we analyzed 647 chest CTs and 167 abdominal CTs from a diverse cohort of 383 women who also had a mammogram. An open-source algorithm segmented breast tissue to calculate CT-derived percentage and volume density. These values were benchmarked against mammogram-reported density, which was dichotomized into high (heterogeneously/extremely dense) and low density. We used Receiver Operating Characteristic (ROC) analysis to assess predictive performance and determine an optimal cut-off value.

RESULTS

Automated segmentation was successful in 97.5% of cases on manual review. CT-derived percentage density showed high accuracy for predicting high mammographic density, achieving an Area Under the Curve (AUC) of 0.899 across all scans, including those with technical limitations like incomplete FOV. An optimal cut-off of 2.99% density was identified. While parenchymal volume was also predictive, percentage density proved to be a more robust metric. The method was not feasible for most abdominal CTs, with only 31% providing the minimal coverage needed.

CONCLUSION

Automated, opportunistic breast density assessment from chest CT is highly feasible and accurate. CT-derived percentage density is a robust metric that can reliably identify women with dense breasts using a 2.99% cut-off, even in the presence of common technical limitations. These findings support exploring the integration of this automated method into clinical workflows to provide valuable breast cancer risk information from existing scans and guide screening recommendations.

CLINICAL RELEVANCE/APPLICATION

This automated open-source tool opportunistically analyzes existing chest and abdomen CT scans to accurately identify women with high breast density. This provides cancer risk stratification information at no additional radiation exposure or cost, helping to guide supplemental screening decisions.

T3-STCE1-2 OPPORTUNISTIC SCREENING FOR CORONARY ARTERY CALCIFICATION AND EMPHYSEMA ON LOW-DOSE CT LUNG CANCER SCREENING: IMPLICATIONS FOR SUBCLINICAL DISEASE DETECTION AND DOWNSTREAM CARE

Valentina Marulanda Corzo, MD (*Presenter*)
Daniel B. Green, MD (*Abstract Co-Author*)
Charlene Thomas (*Abstract Co-Author*)
Lauren R. Groner, DO, MS (*Abstract Co-Author*)

PURPOSE

Tobacco smoking, the leading cause of lung cancer, is also a major risk factor for cardiovascular disease (CVD) and chronic obstructive pulmonary disease (COPD). Lung cancer screening (LCS) with low-dose CT (LDCT) offers an opportunity to detect CT biomarkers of CVD (coronary artery calcium [CAC]) and COPD (emphysema). We examined the prevalence of these biomarkers in an asymptomatic LCS cohort and their impact on downstream care.

METHODS AND MATERIALS

We retrospectively reviewed baseline LDCT reports (2015-2022) of asymptomatic LCS program enrollees to identify reported emphysema and CAC; those without a smoking history were excluded. Cardiopulmonary care within 12 months before and after LDCT were compared using McNemar's chi-squared test with continuity correction. Associations with demographic and community-level characteristics were assessed via univariate logistic regression analyses.

RESULTS

Qualitative CAC and emphysema scores were reported for 2218 and 2335 participants, respectively (median age 64; 52.0% male), with CAC identified in 65.0% and emphysema in 84.0%. Emphysema was associated with older age (odds ratio [OR], 1.04/year [95% CI, 1.03-1.06]), non-White race (1.63 [1.26-2.12]), and living in a zip code with lower household income (1.89 [1.21-3.11]), lower educational attainment (1.64 [1.25-2.15]), and greater food insecurity (2.01 [1.53-2.65]); p<0.001. Pulmonary care increased from 24.0 to 45.1% post-LDCT (p<0.001): medication change (22.7 to 25.1%, p<0.008) and vaccination (0.6 to 13.8%), pulmonary function testing (0.1 to 13.6%), pulmonology referral (0.7 to 7.6%), and pulmonary rehabilitation (0.1 to 1.3%); p<0.001. CAC was associated with older age (1.11/year [1.10-1.13]) and male sex (1.95 [1.63-2.33]), p<0.001, whereas non-White race was associated with lower odds of CAC (0.73 [0.60-0.88], p=0.001). Cardiovascular care increased from 42.6 to 63.3% post-LDCT (p<0.001): revascularization (0.0 to 0.8%, p=0.003) and medication change (42.3 to 43.3%), cardiac imaging (0.0 to 18.4%), stress testing (0.0 to 12.6%), and cardiology referral (1.1 to 10.2%); p<0.001.

CONCLUSION

To our knowledge, this is the largest retrospective LCS cohort study examining opportunistic screening for CAC and emphysema on LDCT and the impact on cardiopulmonary care. CAC and emphysema are prevalent in an asymptomatic, high-risk LCS population. Identification of these biomarkers led to a significant change in care.

CLINICAL RELEVANCE/APPLICATION

CVD and COPD are common in LCS-eligible persons and contribute substantially to their morbidity and mortality. LDCT can be used to identify CVD and COPD biomarkers that inform care. Implementing structured reporting and downstream care pathways for these findings may enhance the clinical utility of LCS.

T3-STCE1-3 OPPORTUNISTIC SCREENING FOR PREOPERATIVE FRAILTY USING DEEP LEARNING CT BODY COMPOSITION BIOMARKERS

Ding Yi Zhang, MD (*Presenter*)
Fayeza Ahmad (*Abstract Co-Author*)
Jonathan Afilalo, MD, MSc (*Abstract Co-Author*)

PURPOSE

Frailty is a major risk factor for mortality and major morbidity in older adults undergoing surgery. Clinical methods to assess frailty are underutilized because they are either subjective or time-consuming. Radiographic detection of conditions such as sarcopenia and sarcopenic obesity provides mechanistic clues about the presence of frailty, and can be opportunistically extracted from routine preoperative CT scans.

METHODS AND MATERIALS

Preoperative CT scans for patients undergoing abdominopelvic cancer surgery between 2017-2023 were extracted and linked with the American College of Surgeons National Surgical Quality Improvement Program database at a tertiary care center. A deep learning software (coreslicer.com) featuring a 3-D neural architecture (nnU-Net) was used to segment the skeletal muscle, subcutaneous fat, visceral fat, and vertebrae. The volume and density of these segmentations were computed and standardized between the L1 and L5 vertebral levels. Frailty was measured using the Hospital Frailty Rating Score (HFRS) encompassing a weighted sum of 109 ICD codes.

RESULTS

The cohort consisted of 1,516 patients 66±12 years of age with 49% females. Based on the HFRS, 144 (10%) of patients were frail, and they suffered a 10.4-fold increase in odds of 30-day postoperative mortality (95% CI 4.7 to 22.9) adjusting for age, sex, disease severity, and type of surgery. CT body composition biomarkers found to be predictive of frailty in linear regression of log HFRS were: lower skeletal muscle volume index ($P=0.002$), lower skeletal muscle density indicative of intramuscular adiposity ($P<0.001$), and higher subcutaneous fat density indicative of adipose-tissue fibrosis or edema ($P<0.001$). Sarcopenia, defined as low skeletal muscle volume and density, was associated with a 2.8-fold increase in odds of frailty (95% CI 1.9 to 4.2).

CONCLUSION

Opportunistic analysis of body composition from preoperative CT scans is a promising radiographic method to objectively assess frailty. Biomarkers of muscle mass and quality as well as adipose tissue infiltration are highly predictive of frailty.

CLINICAL RELEVANCE/APPLICATION

This radiographic method can be implemented in preoperative workflows to systematically screen patients for frailty, enhancing risk stratification and identifying vulnerable patients who could benefit from geriatric assessment and prehabilitation.

T3-STCE2-1 COMBINATIONAL ABLATION AND IMMUNE CHECKPOINT INHIBITOR THERAPY FOR BCLC STAGES B AND C HEPATOCELLULAR CARCINOMA: A SYSTEMATIC REVIEW

Arsalan Nadeem, MBBS (*Presenter*)
Talha Iqbal, MBBS (*Abstract Co-Author*)

PURPOSE

To systematically review studies evaluating combinational ablation and immune checkpoint inhibitor (ICI) therapy for Barcelona Clinic Liver Cancer (BCLC) stages B and C hepatocellular carcinoma (HCC), assessing the overall survival (OS) and progression-free survival (PFS).

METHODS AND MATERIALS

A systematic review for assessing the OS and PFS for patients with BCLC stages B and C HCC receiving combination therapy with ablation and ICI was conducted. Ablation included radiofrequency ablation, cryoablation and microwave ablation. PubMed, Google Scholar, Cochrane Library, clinicaltrials.gov and Science Direct along with reference lists were searched for relevant articles from inception to June 30, 2025. Keywords used were “ablation”, “immune checkpoint inhibitor” and “hepatocellular carcinoma”. Titles and abstracts were screened and assessed for inclusion, data for OS and PFS was extracted, and bias was assessed using RoB 2 and ROBINS-I tools. Certainty of evidence was rated using the GRADE tool. Due to heterogeneity in the intervention protocols and study designs, no meta-analysis was conducted.

RESULTS

Five studies were included in our review. One (n=64) was a randomized clinical trial (RCT) and four studies (n=119) had non-randomized designs. The median OS and PFS in Zhou et al (the RCT) were 20.8 months (95% CI: 16.2-25.3) and 8.3 months (95% CI: 4.6-12.0) respectively. The median OS (mOS) and median PFS (mPFS) in the other studies were as follows. In Duffy et al (n=12), mOS was 10.1 months (95% CI: 4.6-15.7) and mPFS was 7.8 months (95% CI: 6.0-12.0). In Lyu et al (n=33), mOS was 16.9 months (95% CI: 7.7-26.1) and mPFS was 5.0 months (95% CI: 2.9-7.1). In Wang et al (n=60), mOS was 24.1 months (95% CI: 22.2-28.1) and mPFS was 12.3 months (95% CI: 9.3-12.7). In Li et al (n=14), the mOS was 19.3 months (95% CI: 2.4-36.2) and mPFS was 10.8 months (95% CI: 0-23.5). ICIs used in these studies were tremelimumab, toripalimab, nivolumab, pembrolizumab, sintilimab and camrelizumab. According to the GRADE tool, the RCT-based evidence for OS and PFS was graded moderate certainty and low to very low certainty for the non-random studies.

CONCLUSION

These review findings suggest a potential survival advantage from combining ablation with ICI therapy as compared to ICI therapy alone in advanced HCC, particularly in terms of overall survival. However, due to the limited number of studies with high quality of evidence and the risk of bias in non-randomized designs, larger randomized trials are needed to confirm these findings and establish clinical efficacy.

CLINICAL RELEVANCE/APPLICATION

Combining ablation with ICI therapy may enhance survival outcomes in patients with BCLC stages B and C HCC. This approach could become a viable treatment option in selected patients.

T3-STCE2-2 ^{68}GA-DOTATATE PET/MRI IN MENINGIOMA: FROM TARGETED IMAGING TO EMERGING CLINICAL APPLICATIONS

Steven Jin, PharmD, BS (*Presenter*)
Michael X. Jin, MD, MBA (*Abstract Co-Author*)
Abhinav Mishra (*Abstract Co-Author*)
Louna Abouainain (*Abstract Co-Author*)
Austin Young (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic accuracy, clinical utility, and prognostic implications of 68 Ga-DOTATATE PET/MRI compared to conventional imaging modalities in the management of meningiomas.

METHODS AND MATERIALS

A comprehensive systematic review was performed following PRISMA 2020 guidelines, analyzing 21 high-quality studies from 2015 to 2025, sourced from PubMed and EMBASE. Inclusion criteria emphasized prospective trials, pathologically confirmed cohorts, and studies with institutional review board approval. Primary outcomes evaluated included diagnostic accuracy metrics, impact on treatment planning, and therapeutic response rates. Study quality was assessed using the Oxford Centre for Evidence-Based Medicine criteria.

RESULTS

68 Ga-DOTATATE PET/MRI demonstrated significantly superior sensitivity for detecting osseous involvement compared to contrast-enhanced MRI (98.5% vs. 53.7%, $P<0.001$), while specificity was comparable (86.7% vs. 93.3%). Overall sensitivity for tumor detection was higher for PET/MRI (90%) compared to conventional MRI (79%). PET/MRI findings led to modifications in radiation therapy planning in 73% of cases, allowing for more precise delineation of target volumes and improved sparing of critical structures. Optimal quantitative imaging thresholds were established (SUVmax 4.7; SUV ratio to superior sagittal sinus 3.2), achieving excellent reproducibility (AUC 0.910). Postoperative PET imaging findings correlated strongly with clinical outcomes; patients without residual uptake had no recurrence during follow-up. Theragnostic use of 177Lu-DOTATATE resulted in a median progression-free survival of 11.5 months in refractory cases.

CONCLUSION

68 Ga-DOTATATE PET/MRI offers superior diagnostic accuracy for detecting osseous involvement in meningiomas and significantly impacts clinical decision-making through improved treatment planning. The robust correlation between postoperative imaging results and patient outcomes supports its routine use in surveillance protocols. The expansion of theragnostic applications provides promising therapeutic avenues for refractory meningiomas.

CLINICAL RELEVANCE/APPLICATION

Incorporating 68 Ga-DOTATATE PET/MRI into routine meningioma management can significantly enhance surgical precision, optimize radiation therapy planning, and enable personalized patient surveillance through molecular imaging biomarkers.

T3-STCE2-3 RIGID VS. DEFORMABLE IMAGE REGISTRATION IN 3D ASSESSMENT OF MICROWAVE ABLATIONS: A RETROSPECTIVE ANALYSIS

Theresa Simmich (*Presenter*)
Amilcar Alzaga (*Abstract Co-Author*)
Matthias Wetzl, MD (*Abstract Co-Author*)
Michael Uder, MD (*Abstract Co-Author*)
Matthias S. May, MD (*Abstract Co-Author*)

PURPOSE

When comparing Microwave Ablation (MWA) to surgical approaches for treating liver tumors, MWA poses fewer risks but shows higher recurrence rates. With an adequate safety margin, recurrence rates drop significantly. Accurate 3D visualisation is key to ensuring full margin ablation. An novel dedicated commercial 3D ablation guidance on-site software (MyAblationGuide, Siemens Healthineers AG, Forchheim, Germany) provides two methods for fusing the pre- and post-ablation images: rigid and deformable registration. This study evaluates the difference between the registration types, analyzing impact on margin visualization, coverage and possible recurrence prediction.

METHODS AND MATERIALS

The study includes retrospective data of 116 Patients with a total of 203 lesions treated with MWA for colorectal liver metastases from 01/2020 - 03/2025. Pre- and post-ablation CT images are imported, tumors and ablation zones are segmented semi-automatically, and a 5mm safety margin is added. Each lesion is assessed using rigid and deformable registration focusing on ablation status (A0 = complete ablation; A1 = incomplete margin; A2 = incomplete tumor) and ablation zone size. Rigid registration preserves clear boundaries while deformable registration accounts for parenchyma shrinkage and respiration.

RESULTS

A one sided Wilcoxon signed-rank test (rigid r >deformable d) in a preliminary evaluation (n=9) showed a significant difference in axial plane defect size ($p=0.028$, effect size 0.54), indicating smaller ablation zones with deformable registration. No significant differences were found in the sagittal and coronal planes ($p=0.206$; $p=0.326$) with effect sizes (Cohen's d) 0.32 (sagittal) and 0.25 (coronal). The highest required sample size to achieve 80% power ($a = 0.05$) was 104 cases, which is covered by the available dataset of 203 lesions. In a clinical context, those differences translate to discrepancies in ablation status. In 4/9 evaluated cases (44%), the different registrations led to different A0-A2 classifications (3 cases: r A1 / d A2; one case: r A0 / d A1).

CONCLUSION

Initial results suggest that registration type can influence outcome classification. Further evaluation will focus on if volumetric differences translate into clinical consequences such as recurrences. These findings will provide valuable insights for clinical decision-making and workflow implementation to optimize patient care.

CLINICAL RELEVANCE/APPLICATION

Different image registrations techniques can significantly impact the perceived coverage of safety margins required for a successful (A0) microwave ablation. Understanding these effects is the key to avoiding over- or undertreatment, keeping risks and recurrences low and enabling an optimal approach to treating liver tumors.

T5-STCE1-1 PREDICTION OF POSTOPERATIVE RECURRENCE IN HEPATOCELLULAR CARCINOMA: A MULTICENTER STUDY OF CT-BASED CLINICALLY SIGNIFICANT PORTAL HYPERTENSION AND INTRATUMOR HETEROGENEITY SCORE

Yuan Xu (*Presenter*)

PURPOSE

The high incidence of early recurrence (ER) after curative resection of hepatocellular carcinoma (HCC) significantly compromises long-term survival. This study aimed to develop and validate a predictive model based on preoperative CT-derived clinically significant portal hypertension (CSPH) and intratumoral heterogeneity (ITH) score to predict ER after HCC resection.

METHODS AND MATERIALS

A total of 437 HCC patients who underwent curative hepatectomy across three centers were retrospectively enrolled. Of these, 319 patients from our institution were randomly assigned to a training cohort (n = 192) and an internal validation cohort (n = 127), while 118 patients from the other two institutions formed the external validation cohort. Preoperative CECT-derived CSPH-related indicators—including spleen diameter, gastroesophageal varices, and spontaneous portosystemic shunts—were extracted. Tumor regions on CECT were subjected to unsupervised clustering and integrated with global pixel distribution patterns to calculate the ITH score. A predictive model was constructed based on independent risk factors for ER. The model's discrimination and predictive accuracy were assessed using the area under the receiver operating characteristic curve (AUC), calibration curves, and decision curve analysis. AUCs were compared using the DeLong test.

RESULTS

CSPH, ITH score, tumor burden score (TBS), and systemic immune-inflammation index (SII) were identified as independent risk factors for ER ($P < 0.05$). Compared to the baseline model (TBS + SII; AUC = 0.715) and the CSPH model (TBS + SII + CSPH; AUC = 0.779), the integrated model incorporating ITH score (TBS + SII + CSPH + ITH score) demonstrated the best performance (AUC = 0.833, $P < 0.05$). The calibration and decision curves showed good agreement across the training, internal, and external validation cohorts.

CONCLUSION

The novel integrated model combining CT-assessed CSPH, ITH score, TBS, and SII outperformed conventional models and provides an effective tool for early prediction of ER in HCC patients following surgery.

CLINICAL RELEVANCE/APPLICATION

A CT-based model integrating CSPH and ITH enables accurate preoperative risk stratification for early recurrence after HCC resection, supporting personalized surgical planning and postoperative surveillance.

T5-STCE1-2 ULTRASOUND-GUIDED MICROBUBBLE THERAPY RESHAPES THE PANCREATIC TUMOR MICROENVIRONMENT

Chung-Hsin Wang, PhD (*Presenter*)
Shih-Tsung Kang (*Abstract Co-Author*)

PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest malignancies due to its hypoxic tumor microenvironment (TME), poor vascularity, and resistance to chemotherapy and immunotherapy. This study aimed to evaluate the therapeutic potential of ultrasound-guided microbubble sonoporation using a clinically available Power Doppler imaging system to modulate the TME, enhance drug delivery, and improve the efficacy of chemo-immunotherapy.

METHODS AND MATERIALS

Metastatic orthotopic PDAC tumors were established in mice using UN-KC-6141 cells. Tumor perfusion and hypoxia were assessed via contrast-enhanced ultrasound (CEUS) and immunofluorescence. Imaging-guided sonoporation was performed using a clinical ultrasound system (MI= 0.4), targeting tumors with Power Doppler. Microbubbles and chemotherapy agents (doxorubicin or gemcitabine) were co-infused. Tumor perfusion, hypoxia, and CD8?/CD4? T-cell infiltration were evaluated post-treatment. Anti-PD-L1 therapy was added to assess immunotherapy enhancement.

RESULTS

Sonoporation improved tumor perfusion (1.9× increase) and reduced hypoxia (77% and 67% at days 1 and 3). Combination therapy extended median survival (27?33.5 days with doxorubicin; 33?39 days with gemcitabine) and reduced tumor burden. CD8? T-cell infiltration increased four-fold by day 6. Triple therapy with anti-PD-L1 further prolonged survival (46 days vs. 28 days) and enhanced secondary tumor suppression.

CONCLUSION

Ultrasound-guided microbubble sonoporation effectively remodels the PDAC tumor microenvironment by enhancing perfusion, alleviating hypoxia, and promoting immune cell infiltration. This approach significantly improves the therapeutic efficacy of both chemotherapy and immune checkpoint blockade, offering a non-invasive and clinically translatable strategy for treating pancreatic tumors. By adopting a more compact and portable imaging ultrasound device, the technology becomes more readily integrated into outpatient procedures and conventional chemotherapy treatments.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the feasibility of integrating Power Doppler ultrasound with microbubble sonoporation to enhance oncologic therapies in PDAC. The use of commercially available ultrasound systems and clinically tested microbubbles supports rapid clinical translation. By modulating the tumor microenvironment, this technique may unlock new therapeutic windows for combination treatments, including chemo-immunotherapy, in patients with hypoxic and treatment-resistant pancreatic cancers.

T5-STCE1-3 THE VALUE OF CONTRAST-ENHANCED ULTRASOUND IN PREDICTING THE ENERGY AND TIME REQUIRED PER UNIT VOLUME FOR PERCUTANEOUS MICROWAVE ABLATION OF UTERINE FIBROIDS: A CROSS-SECTIONAL, MULTICENTER STUDY

Lei Liang, PhD (*Presenter*)
Yuqing Huang (*Abstract Co-Author*)

PURPOSE

To explore the feasibility of predicting the energy and time required per unit volume (EPV, TPV) for percutaneous microwave ablation (PMWA) treatment of uterine fibroids (UFs) using quantitative perfusion parameters from Contrast-enhanced ultrasound (CEUS).

METHODS AND MATERIALS

This retrospective study included 263 patients from five centers with UFs who underwent PMWA treatment between December 2023 to October 2024. All patients underwent routine ultrasound and CEUS before PMWA. Time-intensity curves (TICs) for CEUS were recorded, and the perfusion parameters were obtained. Ablation power and duration were recorded during the procedure. Post-treatment CEUS was used to determine nonperfused volumes. The relationship between CEUS-derived quantitative perfusion parameters and EPV and TPV was evaluated.

RESULTS

A total of 263 patients (272 UFs) were included, with 176 UFs achieving complete ablation, and 96 achieving majority ablation. The average age of the patients was 44.5±5.6years. Logistic regression analysis revealed that the ablation rate was correlated with the maximum intensity enhancement (IMAX), TPV and EPV(all $P < 0.001$). Restricted cubic splines analysis identified a U-shaped association between IMAX and EPV and TPV(P nonlinear < 0.001), with the turning point at approximately 203.56%. Multiple linear regression analysis showed that when IMAX<203.56%, a 1-unit increase in IMAX was associated with a decrease in EPV by 1.59J/cm³ and TPV by 0.03s. When IMAX=203.56%, with a 1-unit increase in IMAX leading to an increase in EPV by 1.02J/cm³ and TPV by 0.02s.

CONCLUSION

IMAX from CEUS demonstrates a nonlinear U-shaped correlation with the energy and time requirements of PMWA for UFs. CEUS can serve as a reliable tool for predicting energy and time needs, improving the efficiency of PMWA procedures.

CLINICAL RELEVANCE/APPLICATION

IMAX from CEUS have a nonlinear U-shaped correlation with the energy and time requirements of PMWA for UFs. Preoperative CEUS evaluation can effectively predict the energy and duration needed for successful fibroid ablation, providing a theoretical basis for optimizing treatment strategies and surgical management of UFs.

T5-STCE2-2 EXPLAINABLE AI FOR RADIOLOGY REPORT GENERATION: INTEGRATING VISUAL GROUNDING AND TEMPORAL COMPARISON FOR CLINICAL ACCEPTANCE

Zuby Syed, MD (*Presenter*)
Eun Kyoung Hong, MD, PhD (*Abstract Co-Author*)
SEUNGHO LEE (*Abstract Co-Author*)
Ok Kyu Song, MD (*Abstract Co-Author*)
Bardia Nadim, MD (*Abstract Co-Author*)
Chong Hyun Suh, MD, PhD (*Abstract Co-Author*)
Mark M. Hammer, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the clinical relevance of a multimodal AI system for radiologic report generation, assessing how visual grounding elements, such as bounding box accuracy and temporal comparisons, impact report quality, interpretability, and alignment with expert judgment.

METHODS AND MATERIALS

We used MAIRA-2 by Microsoft, an open-source model for chest radiograph report generation, to generate reports with visual grounding via bounding boxes and temporal comparisons leveraging prior images when available. Evaluation involved: (1) radiologist-scored report agreement and quality using RADPEER and Likert scales, (2) expert-centric assessments of bounding box and comparative statement accuracy, and (3) automated analyses of diagnostic accuracy and readability using reference standards and readability indices. NIH ChestX-ray14 dataset (122,120 images) was used for automated evaluations and a subset of 500 cases were used for expert review. We performed correlation analyses between report agreement and quality scores and key model performance metrics, including diagnostic accuracy, readability (word count and ORGL), bounding box accuracy, and comparative report accuracy. Statistical comparisons were performed using one-way ANOVA or Kruskal-Wallis tests, depending on data distribution.

RESULTS

AI-generated reports were rated as "Agreed" by 78-80% of two radiologists but only 22% by a third, indicating substantial inter-reader variability ($k = 0.05$). However, hallucination rates remained low (3-7%) with mild inter-reader agreement ($k = 0.22$). Reports with higher agreement had better bounding box alignment, with 64.0% of "Agreed" reports showing acceptable alignment vs. only 41.2% for non-agreed reports ($p < 0.001$). Reports with correct comparative findings and directional changes in relation to prior imaging had significantly higher "Agreed" rates (66.7%) compared to incorrect ones (34.9%) ($p < 0.001$). Reports rated "Excellent" had higher diagnostic accuracy (89.3%), lower word count (22.7 ± 13.5), and better readability (ORGL 13.1 ± 4.7), whereas lower rated reports had lower accuracy (84.8% and 84.1%), longer lengths (up to 38.6 ± 24.5 words), and lower readability scores (as low as 8.7 ± 2.1).

CONCLUSION

Accurate visual grounding, comparative statements, and reliable diagnostic performance were associated with higher report agreement and perceived quality.

CLINICAL RELEVANCE/APPLICATION

Improving visual grounding, temporal reasoning, and diagnostic accuracy may be key features for ensuring the quality of AI-generated radiology reports, supporting safer and more effective integration of generative AI into clinical workflows.

T5-STCE2-3 GENERALIST, SPECIALIST, OR AGENT? A COMPARATIVE EVALUATION OF GENERATIVE AI MODELS FOR CHEST RADIOGRAPH INTERPRETATION

Eun Kyoung Hong, MD, PhD (*Presenter*)
Ok Kyu Song, MD (*Abstract Co-Author*)
SEUNGHO LEE (*Abstract Co-Author*)
Seowoo Lee, MD (*Abstract Co-Author*)
Soon Ho Yoon, MD (*Abstract Co-Author*)

PURPOSE

To systematically compare state-of-the-art generative AI models for chest radiograph (CXR) interpretation, including general-purpose, domain-specific, and agent-based systems.

METHODS AND MATERIALS

A total of 112 chest radiographs from hospitals in US were interpreted using four AI models: Gemini 2.5 (a general-purpose large multimodal model), MAIRA-2 (a domain-specific report generation model), Harrison.ai (an agentic vision-language model for radiologic interpretation using commercially available classification tools), and MedRAX (an AI agent integrating diverse CXR analysis tools with multimodal reasoning capabilities). Two board-certified radiologists evaluated the reports in consensus using three criteria: (1) report acceptance without modification, (2) presence of hallucinations, defined as fabricated information not grounded in the image, and (3) per-case ranking of the best report among the four models. Additionally, we calculated the diagnostic accuracy of four AI-generated radiology report models by comparing model outputs to expert-defined reference standards.

RESULTS

Among the four models, Harrison.ai performed best overall with the highest acceptance (47.3%), lowest hallucination rate (5.4%), and was top-ranked in 56.3% of cases. MedRAX had the highest hallucination rate (54.5%) but was still top-ranked in 18.6%. Gemini 2.5 had low acceptance (13.4%) with a modest hallucination rate (10.7%), while MAIRA-2 showed moderate performance (24.1% acceptance, 20.5% hallucinations, 4.7% top-ranked). There were statistically significant differences in rates of acceptance ($p = 0.002$) and hallucination ($p < 0.001$) between the 4 models. Significant differences in diagnostic accuracy were observed across models for

consolidation, atelectasis, pulmonary edema, pleural lesion, and effusion ($p < 0.05$). For example, in pulmonary edema, Harrison.ai achieved an accuracy of 91.3% vs. 76.7% for Gemini, while in consolidation, MAIRA-2 reached 88.1% accuracy vs. 69.3% for MedRAX.

CONCLUSION

Substantial variability exists in the diagnostic reliability and clinical acceptability of generative AI models for chest radiograph interpretation. These results highlight the importance of rigorous evaluation to ensure the safe and effective clinical deployment of generative AI in radiology.

CLINICAL RELEVANCE/APPLICATION

Our findings highlight the need for a benchmarking platform designed to facilitate standardized and transparent evaluation of generative AI models in radiology. A curated dataset and dynamic evaluation pipeline incorporating both subjective and objective metrics will be released, enabling continuous improvement and fostering clinically relevant innovation.

PURPOSE

Percent emphysema on chest CT is linked to adverse outcomes even in the absence of COPD. Although bone mineral density (BMD) loss is well established in COPD, it remains unclear whether subclinical emphysematous changes affect BMD in non-COPD individuals. This study evaluated associations between CT-derived percent emphysema and thoracic vertebral BMD, measured from the chest CT scans, in non-COPD participants.

METHODS AND MATERIALS

Using data from the Multi-Ethnic Study of Atherosclerosis (MESA), percent emphysema was quantified at Exam 5 as the percent of lung voxels with attenuation below -950 Hounsfield units (HU) on full-lung noncontrast chest CT. HU thresholds were adjusted for outside-air attenuation to standardize across scanners. Thoracic vertebral BMD was assessed at Exams 5 and 6 using a 3D deep learning-based segmentation of vertebral bodies T1-T10 using TotalSegmentator v2, with cortical bone excluded. BMD was calculated using reference phantom calibrations (0, 50, 100, 200 mg/cm³). COPD was excluded based on GOLD spirometry or self-report. Linear mixed-effects models with nested random effects for multilevel vertebra measures (T1-T10) and participant were used to assess associations, adjusting for demographics, BMI, smoking pack-years, alcohol, physical activity, corticosteroid use, and scanner type. Interactions by gender were tested. The Johnson-Neyman method identified threshold effects. Sensitivity analyses tested robustness.

RESULTS

The 6-week scan-rescan intraclass correlation coefficient (ICC) was 0.99 for percent emphysema. DL-based BMD segmentations showed strong agreement with manual labels (Dice: axial = 0.93; sagittal = 0.91). A total of 2,312 non-COPD individuals were included cross-sectionally and 1,142 longitudinally (mean age, 68.2 ± 8.9 years; 55% female; mean follow-up, 6.14 years). Cross-sectionally, percent emphysema was associated with lower BMD (ß = -0.94; 95% CI: -1.5, -0.32). Longitudinally, no overall association was observed (ß = -0.03; 95% CI: -0.10, 0.03), but significant gender interactions ($p < 0.001$) were identified. In stratified models, emphysema was associated with BMD loss in men (ß = -0.35; 95% CI: -0.45, -0.25). The Johnson-Neyman method identified 2.7% emphysema as a threshold for BMD decline in men. Results remained robust in sensitivity analyses.

CONCLUSION

Subclinical emphysema on chest CT is independently associated with lower vertebral BMD cross-sectionally and with greater longitudinal DL-derived volumetric vertebral BMD loss among non-COPD males.

CLINICAL RELEVANCE/APPLICATION

Quantification of emphysema may offer early insights into bone health in at risk patients without clinical COPD undergoing conventional chest CT for various cardiopulmonary indications.

T6-SSCH06-3 MULTI-VOLUME CT-DERIVED AIRWAY RESPIRATORY MECHANICS IN PRESERVED RATIO IMPAIRED SPIROMETRY (PRISM) AND DIFFERENT COPD SEVERITY GROUPS

Alejandro Comellas, MD (*Presenter*)
Syed Ahmed Nadeem, PhD (*Abstract Co-Author*)
Xinyu ZHANG (*Abstract Co-Author*)
Yan Liu (*Abstract Co-Author*)
Kung-Sik Chan (*Abstract Co-Author*)
Elizabeth A. Regan, MD,PhD (*Abstract Co-Author*)
Graham Barr, MD (*Abstract Co-Author*)
Eric A. Hoffman, PhD (*Abstract Co-Author*)
Sean B. Fain, PhD (*Abstract Co-Author*)
Punam K. Saha, PhD (*Abstract Co-Author*)

PURPOSE

Multi-volume CT-derived morphologic changes in airways between breath-hold lung inflation states at ends of inspiration and expiration offer an opportunity to quantify breathing-related mechanical properties of airways. We retrospectively study impairments of these respiratory airway mechanical properties in preserved ratio impaired spirometry (PRISm) and different COPD severity groups

METHODS AND MATERIALS

Our automated algorithms were applied to inspiratory and expiratory CT images to compute breathing-related radial expansion (? air-R) and along-the-length stretching (? air-S) of airways (Figure 1(a)). ? air-R is computed as the percentage change in cross-sectional area (CSA) at a matching airway between inspiratory and expiratory lung volumes. ? air-S is computed as the percent change in airway geodesic path-length from the carina to a specific matching airway between two lung volumes. ?-metric-specific mean value over segmental airways was computed for each participant of the Genetic Epidemiology of COPD (COPDGene) study Iowa cohort at baseline visits; exclusion criteria: never-smokers, BMI < 20 kg/m 2 or > 35 kg/m 2 , and missing data. A linear regression model was built for each ?-metric with age, sex, and BMI as predictor variables and the preserved lung function (PLF) group as the reference population. A participant- and ?-metric-specific standard residual (SR) score was computed as difference between observed and predicted values of a given ?-metric divided by the standard deviation (SD) of model residuals for the reference group. Summary statistics (mean and SD) as well as two-sample tests were used to assess the relationship of SRs of airway ?-metrics with COPD severity

RESULTS

Figure 1(b,c) presents box-and-whisker plots SRs or adjusted impairments in airway ?-metrics (n = 853; age (mean±SD): 64.2±8.3 years; 384 females; BMI: 27.9±3.6 kg/m 2). Statistics of ? air-R SRs for PLF, PRISm, and mild, moderate, and severe COPD groups were 0.00±1.00, -0.48±1.13, -0.55±1.15, -0.77±1.29, and -1.22±1.27, respectively, and that of ? air-S SRs were 0.00±1.00, -0.49±1.02, -0.34±1.08, -0.79±0.97, and -1.88±0.88, respectively. Adjusted impairments in ? air-R over different lung impairment groups were relatively more gradual as compared to ? air-S ; greater declines were observed at moderate and, particularly, at severe COPD. Although not statistically significant, for both airway ?-metrics, the median of PRISm group was lower than mild COPD

CONCLUSION

Age, sex, and BMI-adjusted impairments of respiratory airway mechanics significantly increased with COPD severity and impairments in PRISm were comparable to mild COPD

CLINICAL RELEVANCE/APPLICATION

Understanding of mechanistic pathways of airflow impairments at different stages of COPD

T6-SSCH06-4 PHENOTYPING COPD BY CT-DERIVED AIRWAY AND VASCULAR DYSANAPSIS

Stephanie Marie Aguilera, BSc (*Presenter*)
Arie Nakhmani (*Abstract Co-Author*)
Venkata Sthanam (*Abstract Co-Author*)
Pratim Saha (*Abstract Co-Author*)
Muhammad Faizyab Ali Chaudhary (*Abstract Co-Author*)
Surya P. Bhatt (*Abstract Co-Author*)
Sandeep Bodduluri, MS, PhD (*Abstract Co-Author*)

PURPOSE

Airway dysanapsis (mismatch between airway and lung size) is associated with incident COPD. However, it overlooks the potential role of pulmonary vessel size in COPD. Structural variations in pulmonary vascular anatomy relative to lung size may contribute to distinct COPD phenotypes that are not fully captured by current airway-based estimations and could influence disease severity, symptoms, and prognosis. We hypothesize that integrating the vascular-to-lung volume ratio (VLR) with the conventional airway-to-lung volume ratio (ALR) would uncover novel COPD subtypes with distinct clinical profiles.

METHODS AND MATERIALS

Inspiratory CT scans from subjects in the COPDGene study were included. ALR and VLR were estimated from lungs, airways, and pulmonary vasculature segmented from CT scans. Subjects were categorized into four groups based on ALR and VLR above/below 10th percentile of nonsmokers: (1) High ALR & High VLR (reference), (2) High ALR & Low VLR (vascular subtype), (3) Low ALR & High VLR (airway subtype), and (4) Low ALR & Low VLR (combined). Outcomes included lung function (FEV 1 , FEV1/FVC), six-minute walk distance (6MWD), annualized change in FEV1 , annualized change in adjusted lung density (ALD), and mortality. Statistical analyses included generalized linear regression and Cox proportional hazards regression after adjusting for age, sex, race, BMI, smoking status, pack-years, scanner type, and CT emphysema%, compared to the reference subtype.

RESULTS

Among 8,102 participants, compared to the reference subtype(n=3,952, 48.8%), the vascular subtype (n=1619, 20.1%) was associated with FEV1 reduction (ß=-0.04, p=0.03), FEV1/FVC decrease (ß=-0.02, p<0.001), 6MWD (ß=-8.7m, p<0.001), reduced ? FEV1 (ß= -5.2 mL/yr, p=0.02) and reduced ? ALD (ß= -0.52 g/L/yr, p=0.02). The airway subtype (n=1488, 18.2%) demonstrated even higher FEV1 reduction (ß=-0.51, p<0.001) and FEV1/FVC decrease(ß=-0.12, p<0.001), reduced ? FEV1 (-4.9 mL/yr, p=0.03),and reduced ? ALD (ß= -0.35 g/L/yr, p=0.001). The combined phenotype (n=1,043, 12.9%) showed the most significant worsened overall outcomes including FEV1 (ß=-0.48, p<0.001), FEV1/FVC (ß=-0.10, p<0.001), 6MWD (ß=-7.3m, p<0.001), reduced ? FEV1 (-9.4 mL/yr, p<0.001),and reduced ?ALD (ß= -0.90 g/L/yr, p<0.001). Mortality risk significantly increased in airway and combined subtypes with hazard ratios 1.4, and 1.5, respectively.

CONCLUSION

These findings provide insights into how the additional interplay of vascular remodeling may influence functional capacity and prognosis in COPD.

CLINICAL RELEVANCE/APPLICATION

Vascular dysanapsis is a novel phenotype that is distinct from airway dysanapsis and is associated with poor respiratory outcomes and higher mortality in COPD.

T6-SSCH06-5 QUANTITATIVE ANALYSIS OF PULMONARY EMPHYSEMA USING ELECTRON DENSITY IMAGES FROM PHOTON-COUNTING DETECTOR CT: CORRELATION WITH PULMONARY FUNCTION TESTS

Tomoaki Sasaki, MD (*Presenter*)
Hirofumi Kuno, MD, PhD (*Abstract Co-Author*)
Yoshihisa Muramatsu, PhD, RT (*Abstract Co-Author*)
Keiichi Nomura, PhD (*Abstract Co-Author*)
Keiju Aokage, MD, PhD (*Abstract Co-Author*)
Mikio Sakurai (*Abstract Co-Author*)
Masashi Wakabayashi (*Abstract Co-Author*)
Hideki Furuya (*Abstract Co-Author*)
Megumi Nishigaki (*Abstract Co-Author*)
Tatsushi Kobayashi, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the utility of electron density (ED) and effective atomic number (EZ) images generated with cadmium-zinc-telluride (CZT)-based photon-counting detector CT (PCD-CT) for quantitative assessment of pulmonary emphysema compared to virtual monochromatic images at 70 keV (VMI70), using pulmonary function tests as reference.

METHODS AND MATERIALS

Seventy-two adult patients (44 men, 28 women; 50 smokers, 22 never-smokers; median age 73 years, interquartile range 64-76 years) with written informed consent prospectively participated in a study evaluating lung tumors using a CZT-based PCD-CT. All patients underwent pulmonary function tests within two weeks of CT examination. CT images were acquired in a single-breath-hold helical mode (64 × 0.6 mm collimation, 120 kVp equivalence, 0.35-0.5 s/rotation) and reconstructed at

0.6-mm thickness for VMI70, ED, and EZ images.Lung segmentation was performed using the thresholds between -700 HU and -1024 HU) on VMI70. Normal lung was defined as voxels with CT values higher than -950 HU. For ED and EZ images, normal lung thresholds were determined by analyzing normal lung regions in a never-smoking reference patient, defined as mean minus two standard deviations (ED = 0.1664× 10^{23} electrons/cm^3, EZ = 4.4543). Emphysema ratio was calculated as 1-(normal lung voxel count/total lung voxel count) for VMI70, ED, and EZ images. Correlations between emphysema ratios and forced expiratory volume in one second percentage (FEV1.0%) were analyzed using Pearson correlation coefficients.

RESULTS

The emphysema ratio derived from ED images showed the strongest correlation with FEV1.0% (r=-0.652, p<0.001), followed by VMI70 (r=-0.577, p<0.001), while EZ showed the weakest correlation (r=-0.362, p=0.002). Scatter plots revealed that patients with low emphysema ratios on VMI70 images showed better differentiation on ED images, resulting in improved correlation with pulmonary function tests across the spectrum of disease severity.

CONCLUSION

Quantitative analysis of pulmonary emphysema using electron density images from photon-counting detector CT provides stronger correlation with pulmonary function tests compared to conventional CT density-based assessment, potentially improving the accuracy of emphysema quantification.

CLINICAL RELEVANCE/APPLICATION

Electron density images from photon-counting detector CT offer improved quantitative assessment of pulmonary emphysema that correlates better with clinical pulmonary function, potentially enhancing the role of CT in monitoring disease progression and treatment response in patients with chronic obstructive pulmonary disease.

T6-SSCH06-6 PREVALENCE OF EMPHYSEMA AMONG OLDER PEOPLE LIVING WITH HIV COMPARED TO HIV-NEGATIVE INDIVIDUALS IN THE COMBINED ANTIRETROVIRAL THERAPY ERA: A CT-BASED ANALYSIS

Yanisa Jarusyingdumrong, MD (*Presenter*)
Monravee Tumkosit, MD (*Abstract Co-Author*)
Teerapat Singwicha (*Abstract Co-Author*)
Anchalee Avihingsanon (*Abstract Co-Author*)
Napon Hiranburana (*Abstract Co-Author*)
Siwat Thammapiwan (*Abstract Co-Author*)

PURPOSE

To compare the prevalence of emphysema in older people living with HIV (PLWH) and HIV-negative individuals during the era of combined antiretroviral therapy (cART) and to identify factors associated with emphysema in PLWH.

METHODS AND MATERIALS

This cross-sectional study utilized data from participants aged 50 years and older, enrolled in a previous study who underwent non-contrast computed tomography (CT) scans to assess coronary artery calcium scores between March 2016 and June 2017. Chest CT images were evaluated for emphysema both visually and quantitatively. Visual assessment was performed independently by two radiologists using the Fleischner Society classification (agreement: 87.7%; ? = 0.48, 95% CI: 0.42-0.54, p < 0.001), and quantitative assessment was based on the low attenuation area below -950 Hounsfield units (LAA-950). Poisson regression was used to calculate risk ratios, adjusting for age, sex, body mass index (BMI), and smoking status. Logistic regression was used to calculate odds ratios.

RESULTS

479 participants (335 PLWH, 144 HIV-negative) were analyzed. Among PLWH, the median duration on cART was 18 (IQR 13-19) years. Of these, 98.51% had a current CD4 of =200 cells/mm^3 and 97.90% were virally suppressed. The adjusted prevalence (95%CI) of visual emphysema in PLWH and HIV-negative group were 12.1% (9.1-15.1) and 10.1% (5.2-15.1), respectively (risk ratio = 1.19, 95%CI 0.68-2.10, p = 0.535). Visual scores correlated weakly with LAA-950 (Spearman's ? = 0.22, p < 0.001). Only 3.28% of PLWH and 1.39% of HIV-negative group had LAA-950 =6%. Factors associated with emphysema in PLWH were age (OR 1.14, p < 0.001), BMI (OR 0.82, p = 0.006), current smoking (OR 21.24, p < 0.001), years on cART (OR 0.91, p = 0.035), and pulmonary tuberculosis (TB) history (OR 3.86, p = 0.043).

CONCLUSION

In the cART era, emphysema prevalence did not differ significantly between PLWH and HIV-negative individuals. Among PLWH, current smoking, pulmonary TB history, lower BMI, and older age were linked to higher odds of emphysema, while longer cART duration was linked to lower odds. Visual assessment showed only moderate interobserver agreement and weak correlation with quantitative measures, highlighting the need to refine classification - e.g., through more reference images, reassessing clinical relevance of categories, and adjusting quantitative thresholds.

CLINICAL RELEVANCE/APPLICATION

With advances in ART, the pulmonary profile of PLWH may be shifting. This study challenges older reports of increased emphysema in PLWH and underscores the value of sustained and effective treatment. Given current limitations in CT-based classification, combining visual and quantitative assessments with clinical context remains essential.

T6-SSIR02-1 ABLATION WITHOUT COAGULATION? MANAGING PORTAL VEIN THROMBOSIS AFTER HISTOTRIPSY

Aadithya Nalla, BS (*Presenter*)
Nathan E. Loudon, MD (*Abstract Co-Author*)
Valerie Khaykin (*Abstract Co-Author*)
Andrew Navarro, MD (*Abstract Co-Author*)
Elaine M. Caoili, MD, MS (*Abstract Co-Author*)
Neehar Parikh, MD (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)

PURPOSE

Histotripsy is a novel non-invasive, non-thermal liver tumor ablation technique, with a unique property of tissue selectivity, sparing critical structures such as bile ducts and vessels from injury. Unlike other forms of treatment, histotripsy can be used to treat centrally located hepatic tumors. Despite tissue selectivity that spares central structures, we observed a pattern of acute bland portal vein thrombosis (PVT) following histotripsy of central lesions. This study investigates the mechanism and incidence of histotripsy-induced PVT and evaluates a procedural anticoagulation strategy to mitigate thrombus formation.

METHODS AND MATERIALS

An IRB approved HIPAA compliant retrospective analysis was conducted of 40 patients treated with histotripsy from February 2024 to February 2025. Fourteen patients with tumors abutting major portal or hepatic veins met inclusion criteria. Immediate and 30-day post-treatment contrast-enhanced CT or MRI were reviewed to identify PVT formation and resolution. An iterative anticoagulation protocol was introduced in four escalating phases: no anticoagulation, pre-procedure bolus, bolus at cavitation initiation, and finally, a weight-based therapeutic bolus followed by a continuous heparin infusion during cavitation. Statistical analyses examined correlations between PVT formation and treatment parameters (pre-treatment tumor size, ablation zone size, tumor type, cavitation voltage).

RESULTS

13 patients (11 male, 2 female; mean age 60 years (range 45-85)) had 14 centrally located tumors treated with histotripsy. 6 (43%) treated tumors resulted in bland, non-occlusive PVT post-treatment although anti-coagulation dose-escalation resulted in decreased PVT volume. Patients who received the maximum dose of therapeutic weight-based bolus plus continuous infusion (n=6) during histotripsy cavitation showed no evidence of PVT on post-treatment imaging. No significant correlations were found between PVT and tumor type, pre-treatment size, post-treatment ablation zone size, or treatment voltage. All patients with PVT showed full or partial resolution by 30 days with no long-term hepatic sequelae.

CONCLUSION

Our findings suggest that histotripsy-induced cavitation near major portal vessels may cause endothelial stress and initiate thrombus formation. Continuous intraprocedural anticoagulation effectively prevents this complication. Continued research is warranted to optimize histotripsy protocols and ensure patient safety.

CLINICAL RELEVANCE/APPLICATION

Histotripsy offers a safe and effective alternative to thermal ablation for centrally located liver tumors. Protocolized anticoagulation during treatment can mitigate the risk of bland PVT and enhance patient safety.

T6-SSIR02-2 BIODEGRADABLE STENTS FOR BILIARY STRICTURES AFTER PEDIATRIC LIVER TRANSPLANTATION: A MULTICENTER EXPERIENCE

Paolo Marra, MD (*Presenter*)
Daniel Barnes, MD (*Abstract Co-Author*)
Lucia Fernandez Rodriguez, BMBS (*Abstract Co-Author*)
Simon P. McGuirk, MBBS (*Abstract Co-Author*)
Giulio Barbiero (*Abstract Co-Author*)
Riccardo Muglia, MD (*Abstract Co-Author*)
Sandro Sironi, MD (*Abstract Co-Author*)

PURPOSE

Biodegradable biliary stents are commonly used to treat benign biliary strictures in adults. However, there is limited data regarding their use in pediatric patients. This study aims to assess the efficacy and safety of biodegradable biliary stents following pediatric liver transplantation (pLT).

METHODS AND MATERIALS

Consecutive pLT patients with benign biliary strictures were retrospectively evaluated in five tertiary centers between October-2014 and May-2024. All patients underwent percutaneous bilioplasty followed by the placement of selfexpandable polydioxanone-based stents. Stricture features and treatment timing were assessed, as well as freedom from stricture recurrence and complications.

RESULTS

A total of 102 patients (52 males, 50 females; median age at treatment 5 years, IQR=9 years) were included. At baseline, 58/102 (57%) had a stricture length =10 mm and 53/102 (52%) had intrahepatic ducts involvement. Stenting was done after a median of 55 days (IQR=113 days) from biliary drainage. Technically successful stent placement was achieved in 101/102 (99%) cases and low-grade complications occurred in 19/102 (19%). During a median follow-up of 793 days (IQR = 1188.5 days),

24/102 (24%) patients had stricture recurrence with an estimated median time to recurrence of 2915 days. At logistic regression no factors were independent predictors of stricture recurrence, while Cox regression showed that recoil/residual stenosis was independently associated with earlier recurrence (p=0.005; HR=5.334; 95 CI=1.674-17).

CONCLUSION

Biodegradable stents appear safe and effective for treating biliary strictures after pLT. Certain factors may contribute to failure and should inform patient selection and the optimal timing for stenting.

CLINICAL RELEVANCE/APPLICATION

Biodegradable biliary stents may improve the management of biliary strictures after pediatric liver transplantation with a positive impact on outcomes and less invasiveness; some factors may help to predict the outcome and define the best timing for stenting.

T6-SSIR02-3 TRANSARTERIAL PERIARTICULAR EMBOLIZATION WITH IMIPENEM/CILASTATIN IN 100 PATIENTS WITH CHRONIC JOINT PAIN: A MONOCENTRIC PROSPECTIVE SAFETY PROFILE ANALYSIS

Verena Schaefer, MD (*Presenter*)
Isabella Kuhn (*Abstract Co-Author*)
Fabian Christoph Traub (*Abstract Co-Author*)
Georg Siebenburger (*Abstract Co-Author*)
Fabian Gilbert (*Abstract Co-Author*)
Max Seidensticker (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Paul Reidler, MD (*Abstract Co-Author*)
Daniel Puhr-Westerheide, MD (*Abstract Co-Author*)

PURPOSE

To assess the safety profile of transarterial periarticular embolization (TAPE) using imipenem/cilastatin (I/C) in patients with chronic joint pain caused by adhesive capsulitis, osteoarthritis, chronic pain following partial or total knee arthroplasty (P-/TKA), and epicondylitis.

METHODS AND MATERIALS

In this prospective single-center study, 100 patients (45% male) with chronic joint pain underwent TAPE using I/C. Indications included chronic knee osteoarthritis (n=57), chronic shoulder pain (n=25), chronic pain post-P-/TKA (n=12), epicondylitis (n=3), rhizarthritis (n=1), and chronic ankle pain (n=2). Among 15 patients with adhesive capsulitis, 14 received shoulder joint capsule biopsies (2 MR-guided, 12 ultrasound-guided) to assess inflammatory changes. TAPE was performed via transfemoral access in n=79 or transradial access in n=21. Adverse events were classified according to the Society of Interventional Radiology (SIR) classification (A-D).

RESULTS

The overall complication rate of embolizations was low (23%), with 96% categorized as minor (SIR A, B). Minor events included intraprocedural pain requiring pain medication (SIR B, n=10), puncture site pain (SIR A, n=3), transient high systolic blood pressure requiring therapy (SIR B, n=1), vasovagal reaction managed with atropine (SIR B, n=3), iodine contrast allergy (SIR B, n=1), groin hematoma (SIR A, n=1), and superficial skin infection at the puncture site (SIR B, n=1). Only one major complication (SIR C) occurred: thrombus formation in the common femoral artery during a vasovagal reaction with hypoperfusion, successfully treated with local thrombolysis using t-PA. The patient was observed for < 48 h and received a digital subtraction angiography control 24 hours after the initial event. All patients experienced transient, self-limiting skin discoloration near the embolized joint, resolving completely within 4 hours.

CONCLUSION

TAPE with imipenem/cilastatin shows an excellent safety profile for treating chronic joint pain of various etiologies, with mostly minor, well-controlled adverse events except for n=1 major complication (SIR C) without sequelae.

CLINICAL RELEVANCE/APPLICATION

TAPE is a safe, minimally invasive therapeutic option that may significantly enhance quality of life in patients with chronic joint pain refractory to conservative treatment.

T6-SSIR02-4 AUTOCATALYTIC PICKERING EMULSION MODULATES TUMOR METABOLISM AND ENHANCES TACE EFFICACY IN HCC THERAPY

Feier Ding, PhD (*Presenter*)
Lin-Zhu Zhang (*Abstract Co-Author*)
Hai-Dong Zhu, MD,PhD (*Abstract Co-Author*)

PURPOSE

Hepatocellular carcinoma (HCC) exhibits an immunosuppressive tumor microenvironment (TME), limiting treatment efficacy. Pyroptosis, an immunogenic cell death mechanism, can remodel the TME but remains challenging to induce effectively. Here, we developed glucose oxidase (GOx)-loaded CoF2 nanoparticles (GOCoF2) to simultaneously disrupt glycolysis and trigger pyroptosis. Combined with lipiodol in a Pickering emulsion, this strategy enhances transarterial chemoembolization (TACE) for HCC therapy.

METHODS AND MATERIALS

GOCoF2 was synthesized by thermal decomposition and self-assembly of CoF2 NPs with GOx, followed by DSPE-PEG2000-NH2 modification. Material characterization was performed using XRD, while ROS, cell death, and immune responses were analyzed via flow cytometry. Pyroptotic cell morphology was observed by confocal microscopy, and transcriptomic profiling (RNA-seq) revealed therapeutic mechanisms. Glucose levels were quantified using a commercial assay. In vivo efficacy was evaluated in SD rats and BALB/c mice through MRI and optical imaging.

RESULTS

GOCoF 2 NPs, synthesized via high-temperature thermal decomposition, effectively induced pyroptosis in H22 cells by depleting glucose and generating ROS. This mechanism was validated through XRD, flow cytometry, and Western blot analysis (Fig. A-G) . In vivo studies using H22 tumor-bearing mice demonstrated that GOCoF 2 treatment significantly inhibited tumor growth, outperforming the effects of GOx or CoF 2 alone (Fig. H&I) . Furthermore, GOCoF2 promoted dendritic cell (DC) maturation and enhanced CD8 + T cell infiltration within the tumor microenvironment, thereby bolstering antitumor immunity (Fig. J&K) . RNA transcriptome analysis revealed significant enrichment of inflammatory and metabolic pathways, indicating the induction of tumor pyroptosis and metabolic reprogramming following treatment (Fig. L) . Additionally, GOCoF2 augmented the therapeutic efficacy of TACE in a rat orthotopic liver cancer model, underscoring its potential for interventional therapy (Fig. M) . These findings underscore the dual role of GOCoF 2 in modulating tumor metabolism and immune responses, offering a promising strategy for enhancing cancer treatment.

CONCLUSION

This study presents an inorganic nanozyme that disrupts tumor glucose metabolism to induce pyroptosis and remodel the immunosuppressive microenvironment. By combining metabolic modulation with immunotherapy, GOCoF2 offers a new bioactive material design for enhanced TACE therapy in liver cancer, surpassing conventional approaches.

CLINICAL RELEVANCE/APPLICATION

Developing a novel GOCoF2-Pickering emulsion for TACE therapy in orthotopic liver cancer models with strong clinical translation potential.

T6-SSIR02-5 MR-GUIDED TRANSURETHRAL ULTRASOUND ABLATION (TULSA): SINGLE CENTER OUTCOMES IN 160 PATIENTS WITH ORGAN-CONFINED PROSTATE CANCER

Joseph J. Busch, MD (*Presenter*)
Busch Kathy (*Abstract Co-Author*)
Roland Rose (*Abstract Co-Author*)
Jessica Pendergraft (*Abstract Co-Author*)
Amanda Sdrigotti (*Abstract Co-Author*)

PURPOSE

MRI-guided transurethral ultrasound ablation (TULSA) uses an ultrasound blade and live MRI monitoring for subtotal to whole-gland treatment of prostate cancer (PCa) with precise sparing of structures associated with sexual and urinary function. We report outcomes from the largest U.S. single-center series of TULSA in 160 patients with primary or recurrent PCa.

METHODS AND MATERIALS

A retrospective analysis included patients with organ-confined PCa and at least 3 months post-TULSA follow-up. Treatment plans were defined using a patient-centered approach based on clinical stage, areas of biopsy-proven disease, lower urinary tract symptoms, and lesion targetability on intraoperative DWI, ADC, and T2-w MRI. High-grade PCa with negative PSMA-PET were included after counseling. Patients were followed daily for 2 weeks, PSA q3mo, with MRI, IPSS, IIEF at 6-9 months. Radiologic recurrence was defined as PI-RR=4 on mpMRI, or positive PSMA-PET after PI-RR=3. Biochemical recurrence (BCR) was defined as nadir + 2 ng/ml.

RESULTS

160 patients (138 treatment-naïve, 17 post-ablation and 5 post-radiation) had a median follow-up of 12 (9-18) months. Grade Group 1-5 PCa distributions were: 12%, 47%, 25%, 10%, 6%. Median prostate volume: 48cc (IQR 35-68, range 12-160). Whole-gland ablation was done in 59% of men, with uni- and bilateral NVB sparing in 18% and 31%; only 20% were less than hemi-gland. The extreme apex was targeted in 26%. PSA nadirs after whole-gland vs. subtotal ablation were 0.6 (0.6-1.1) and 1.5 (0.8-2.7) ng/mL. Negative MRI (PI-RR 1-3) was observed in 92% of patients; 89% (142/160) are free of radiologic and biochemical recurrence; three men underwent repeat TULSA. One BCR case lacked imaging follow-up. 8/13 radiologic recurrences are BCR-free and remain on surveillance. 4/13 failures were out-of-field, 4/13 had residual disease near ejaculatory duct sparing (now discontinued). Remaining failures occurred where either MRI thermometry or ultrasound propagation was compromised by calcifications or motion. LUTS, mild hematuria, or bladder spasms in 11 men resolved within 4 weeks with oral meds. Three required endoscopic intervention for retention/obstruction/stricture. Urinary symptoms (IPSS) were stable. Two had early post-op urine leakage, 100% are pad-free >4 months. 88% maintained erection sufficient for penetration (IIEF Q2=2).

CONCLUSION

TULSA with patient-centered ablation plans shows promising real-world efficacy and safety. Ongoing optimization of patient selection and technique may further improve treatment across all ablation plans.

CLINICAL RELEVANCE/APPLICATION

This large U.S. single-center series shows that MRI-guided TULSA is a safe, effective, and customizable treatment for primary or recurrent prostate cancer.

T6-SSMS02-1 ABDOMENATLAS X: A LARGE-SCALE, SEMI-SYNTHETIC DATASET FOR ABDOMINAL TUMOR SEGMENTATION IN SOLID AND TUBULAR ORGANS

Alan Yuille, PhD (*Presenter*)
Qi Chen (*Abstract Co-Author*)
Zongwei Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To establish a large-scale, high-quality annotated abdominal tumor dataset by significantly augmenting existing tumor data and providing extensive annotations for numerous additional tumor types previously unavailable.

METHODS AND MATERIALS

We developed AbdomenAtlas X, a comprehensive annotated multi-tumor dataset comprising 10,136 three-dimensional CT volumes collected from 89 hospitals, resulting in 91,224 high-quality per-voxel tumor masks covering solid and tubular organs. Significantly, AbdomenAtlas X introduces the first publicly available annotated examples of esophageal cancer and endometriomas, thereby facilitating AI model development for these rare tumor types. The annotation process involved 10 radiologists from institutions across China, including 4 senior radiologists with 10-16 years of experience and 6 junior radiologists with 5-8 years of experience. To further expand tumor data beyond conventional manual annotation limits, we implemented an advanced generative diffusion model, trained on both public and proprietary datasets, capable of synthesizing highly realistic tumors within CT volumes. A dedicated tumor discriminator was concurrently developed to rigorously ensure the realism and clinical validity of the synthetic tumors. Additionally, four expert radiologists independently conducted comprehensive visual inspections to validate the synthetic data quality.

RESULTS

AbdomenAtlas X is the largest fully annotated public abdominal tumor dataset to date, comprising 10,136 CT volumes with detailed annotations of six tumor types. Generative AI was responsible for synthesizing 90% of tumor examples, complemented by 10% real tumors annotated by medical professionals. Our model trained on AbdomenAtlas X achieved excellent performance and ranked first in the MSD challenge, leading to substantial improvements over previous state-of-the-art methods. Specifically, our model improved liver tumor DSC by 3.2% and NSD by 3.5%; pancreatic tumor DSC improved by 4.9% and NSD by 3.1%.

CONCLUSION

AbdomenAtlas X significantly advances tumor detection and segmentation, particularly at early stages. Our results highlight the efficacy of Generative AI techniques in creating realistic, large-scale annotated medical datasets, considerably reducing the workload on expert radiologists, and establishing a practical, scalable model for future dataset expansion.

CLINICAL RELEVANCE/APPLICATION

AbdomenAtlas X will be publicly accessible, enabling significant advancements in multi-tumor detection and segmentation research. It holds promise for improving early detection and understanding of imaging phenotypes related to various critical diseases, including cancer, diabetes, and cardiovascular conditions.

T6-SSMS02-2 TURNING CT SLICES INTO A STORY: HOW VIDEO-INSPIRED AI IS HELPING US TRAIN SMARTER CANCER DETECTORS

Zongwei Zhou, PhD (*Presenter*)
Qi Chen (*Abstract Co-Author*)
Wenxuan Li, BS (*Abstract Co-Author*)
Xinze Zhou (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

To explore whether synthetic CT scans can improve tumor detection by mimicking how radiologists and AI interpret anatomy across slices—much like understanding motion in a video sequence.

METHODS AND MATERIALS

We introduce Tumor Genesis, a generic tumor synthesis approach inspired by video sequence analysis. Built upon the Latent Diffusion Model (LDM) architecture, our method synthesizes tumors and organ structures conditioned on anatomical masks. A pre-trained VAE is used to encode CT volumes into a latent space, followed by a denoising U-Net trained to recover tumor-augmented volumes via a forward diffusion process. The model is optimized with a mask-conditioned MSE loss and trained with a missing-class strategy that allows flexible tumor generation during inference. To ensure realistic generation, we enforce 3D anatomical consistency through (i) shape consistency constraints that align tumor and organ masks across slices, and (ii) texture consistency using axial attention layers and sequential residual learning to maintain inter-slice coherence. To overcome GPU memory limitations during inference, we implement a sliding-window inpainting strategy across the z-axis, allowing full-volume synthesis with spatial overlap handling.

RESULTS

Tumor Genesis produces synthetic tumors with highly realistic appearance and structural coherence, each automatically paired with per-voxel annotations. A visual Turing test was conducted involving four radiologists with 5 (R1), 7 (R2), 12 (R3), and 20 (R4) years of clinical experience. The average specificity across all six tumor types was 19.6%, indicating the difficulty in distinguishing synthetic tumors from real ones. Notably, even senior radiologists R3 and R4 achieved only 16.4% and 40.5% specificity, respectively. Training AI models with our synthetic tumors led to significant performance gains in both detection and segmentation tasks. For tumor detection, AI models trained with synthetic data achieved sensitivities of 83.7% (liver), 96.0% (pancreas), 100% (kidney), 96.2% (colon), 96.2% (esophagus), and 95.8%

(uterus). For tumor segmentation, the corresponding Dice Similarity Coefficients (DSC) were 77.5%, 65.8%, 87.9%, 50.7%, 61.2%, and 80.1%, showing improvements over models trained on real data by 4.9%, 8.8%, 3.1%, 3.6%, 7.3%, and 1.4%, respectively.

CONCLUSION

Synthetic tumor generation based on CT slice consistency offers a scalable and practical way to improve AI performance in tumor detection and generalization.

CLINICAL RELEVANCE/APPLICATION

This method enables the creation of diverse, annotated CT datasets without the need for manual annotations, making it especially valuable for training AI in rare cancers, early detection, and across different imaging centers.

T6-SSMS02-3 UNIVERSAL DEEP LEARNING SEGMENTATION OF THIRD SPACE FLUIDS ON BODY CT

Sayantan Bhadra, PhD (*Presenter*)
Jianfei Liu (*Abstract Co-Author*)
Tejas Sudharshan Mathai, PhD, MS (*Abstract Co-Author*)
Praveen Thoppey Srinivasan Balamuralikrishna, MBBS (*Abstract Co-Author*)
Vivek Batheja (*Abstract Co-Author*)
Nicholas Lee, MD (*Abstract Co-Author*)
Pritam Mukherjee, PhD (*Abstract Co-Author*)
Anthony F. Suffredini, MD (*Abstract Co-Author*)
Ronald M. Summers, MD, PhD (*Abstract Co-Author*)

PURPOSE

Excessive accumulation of “third space” fluids is associated with multiple organ dysfunctions. 3D image segmentation on CT scans can be a direct and non-invasive way to quantify the accumulated third space fluid and improve the fluid management of critically ill patients in the ICU. Different types of third space fluid often co-exist in patients; yet, to our knowledge, no automated method exists that can quantify all major third space fluids (subcutaneous edema, ascites, pleural effusion, pericardial effusion). We propose a deep learning model that segments all primary third space fluids using weakly supervised learning.

METHODS AND MATERIALS

In this retrospective study, we used a dataset of anasarca patients (2014-2018), consisting of 769 CT scans from 455 patients aged 5-81 years. We randomly selected n = 200 CT scans (166 patients) as the training dataset. The internal test dataset consisted of n = 77 scans of 77 in-patients with multiple recorded visits but including only the first recorded scan. We also included an external CT test dataset of liver cirrhosis patients with visible subcutaneous edema (n = 44) to evaluate generalization of edema segmentation performance. We used nnU-Net with weakly supervised learning and iterative annotation for an initial set of n = 50 training CT scans, using subcutaneous edema labels from a state-of-the-art method [EdemaCT] and pseudo-labels of ascites (Hou et al. , 2024) [Ascites nnU-Net], pleural and pericardial effusion [TotalSegmentator (TS)]. Anatomical priors were included to minimize false positives. After training, we applied entropy-based pseudo-labeling (Wang et al. , 2022) to generate labels for the remaining n = 150 training CT scans and trained the final nnU-Net using n = 200 CT-label pairs.

RESULTS

The proposed method significantly reduced false positive edema labels compared to EdemaCT, with improved Dice scores measured against expert annotations on a single slice per CT scan: internal test [Proposed (61.0 +/- 17.0)% vs EdemaCT (57.4 +/- 15.6)%; p = 0.015] and external test [Proposed (58.0 +/- 18.7)% vs EdemaCT (40.2 +/- 18.6)%; p < 0.001]. The predicted volumes of ascites, pleural and pericardial effusion on the internal test dataset had high correlation with Ascites nnU-Net and TS (r 2 = 0.98, 0.95 and 0.86 respectively). Bland-Altman plots demonstrated a bias in the segmentation of ascites and pericardial effusion for higher volumes, indicating reduced false positives or under-segmentation by the proposed method.

CONCLUSION

We created the first universal model that detects all major sites of third spacing on CT scans.

CLINICAL RELEVANCE/APPLICATION

This model may be clinically useful for fluid management and monitoring the disease progression of critically ill patients with major organ failure.

T6-SSMS02-4 OPPORTUNISTIC OSTEOPOROSIS ASSESSMENT FROM ROUTINE CT - EFFECT OF INTRAVENOUS CONTRAST AGENTS ON ABSOLUTE VALUES, T-SCORES, AND DERIVED CLASSIFICATIONS IN SINGLE- AND DUAL-ENERGY CT

Leon D. Gruenewald, MD (*Presenter*)
Vitali Koch, MD (*Abstract Co-Author*)
Scherwin Mahmoudi, MD (*Abstract Co-Author*)
Simon S. Martin, MD (*Abstract Co-Author*)
Jan-Erik Scholtz, MD (*Abstract Co-Author*)
Jennifer Gotta, MD (*Abstract Co-Author*)
Philipp Reschke, MD (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)

PURPOSE

To assess the impact of intravenous contrast agents on opportunistic osteoporosis assessment via routine CTs in arterial and venous phases and identify mitigation strategies using dual-energy CT (DECT).

METHODS AND MATERIALS

288 patients (154 men, 134 women; median age 62 years; interquartile range 42-81) who underwent abdominal dual-energy CT (DECT) scans in non-contrast, late-arterial, and portal venous phases between January 2018 and December 2023 were retrospectively analyzed. Trabecular HU values were measured in all phases, including 90kV and 150kV DECT series, using automatic segmentation. T-scores were calculated to classify patients as osteoporotic, osteopenic, or normal. Changes in HU values, T-scores, and classifications due to contrast were compared to non-contrast images, and effects were quantified using Cohen’s d.

RESULTS

The median trabecular HU value at L1 was 147 (IQR 116 - 185). Contrast application in late arterial and portal venous phases increased HU values by +14.4 (+11.2%) and +25.7 (+20.7%), respectively. Using 150kV DECT series reduced these changes to -20.5 (-12.2%) for arterial phases and -23.15 (-12.6%) for venous phases. Cohen’s d was lowest for normal arterial phase acquisition (+0.55) and highest for 90 kV arterial phase acquisition (+1.9). Based on calculated T-Scores, 120 patients were classified as healthy, 108 patients as osteopenic, and 60 patients as osteoporotic. The lowest number of total reclassifications was observed for arterial phase acquisitions (n = 92) and venous phase acquisitions (n = 104). For arterial phase acquisitions, 44 patients were classified from osteoporosis to osteopenic, and for venous phase acquisitions, 52 patients were classified from osteoporosis to osteopenia. The number of reclassifications from osteoporosis to osteopenia significantly reduced for high-kV acquisition methods (n = 24 for arterial and n = 32 for venous phase, respectively), but increased reclassifications from healthy to osteopenia.

CONCLUSION

Intravenous contrast significantly alters HU-based osteoporosis assessment. Late arterial and portal venous phase imaging can lead to significant reclassification from osteopenia to healthy. Employing 150 kV DECT series can partially mitigate these reclassifications but will incorrectly shift healthy classifications toward osteopenia.

CLINICAL RELEVANCE/APPLICATION

Despite suggestions that intravenous contrast agents do not affect opportunistic osteoporosis assessments, we demonstrate significant patient reclassifications from osteoporosis to less severe categories upon contrast application. This underscores the necessity of using dedicated normative values for osteoporosis diagnosis based on contrast-enhanced examinations.

T6-SSMS02-5 REAL-WORLD RADIATION DOSE AUDIT OF PHOTON-COUNTING DETECTOR AND ENERGY-INTEGRATING DETECTOR CT SCANNERS: RESULTS FROM UNBIASED, CONSECUTIVE, AND NON-EXCLUSIONARY DATA

Seyedehelaheh Hosseini, MD (*Presenter*)
Anushree M. Burade, MBBS (*Abstract Co-Author*)
Javier Contreras Yametti, MD (*Abstract Co-Author*)
Parisa Kaviani, MD (*Abstract Co-Author*)
Lina Karout, MD (*Abstract Co-Author*)
Shivangi Jha (*Abstract Co-Author*)
Aaminah Kobeisy, MBBS (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)

PURPOSE

To audit and compare CT output doses from photon-counting detector (PCCT) and energy-integrating detector CT (EICT) scanners using a real-world, unbiased, consecutive, and non-exclusionary data in 15493 examinations from 14237 patients.

METHODS AND MATERIALS

Our study included all consecutive 15439 CT examinations of chest (n= 6272) and abdomen-pelvis (n= 9221) from 14237 adult patients (age range: 0.2-124 years; female: male 7851:6428) on third-generation, dual-source PCCT (Siemens NAEOTOM Alpha: n = 1619 examinations), third-generation, dual-source EID CT (Siemens SOMATOM Force: n = 7779) and/or 512-row, single-source EID (GE Revolution: n = 6095). The acquisition protocols included routine chest CT, CT pulmonary angiogram, lung cancer screening , incidental lung nodule follow-up, routine abdomen CT, non-contrast kidney stone CT, and biphasic liver protocol CT. We recorded the following metrics for analysis: age, gender, CT acquisition protocol name, water equivalent diameter [WED], dose-length product [DLP], and size-specific dose estimates [SSDE]. After testing data normalcy, we performed Kruskal-Wallis and Mann-Whitney tests to assess acquisition protocol, WED, and body region-specific comparison of DLP, and SSDE between the PCCT and EICT scanners.

RESULTS

The dose distribution for the three scanner types for chest and abdomen CT was: Chest CT - PCCT (DLP 182 mGy.cm; SSDE 6 mGy), EICT-Force (DLP 389 mGy.cm; SSDE 12 mGy), EICT-Revolution (DLP 351 mGy.cm; SSDE 12 mGy), abdomen CT - PCCT (DLP 604 mGy.cm; SSDE 14 mGy), EICT-Force (DLP 610 mGy.cm; SSDE 15 mGy), EICT-Revolution (DLP 793 mGy.cm; SSDE 19 mGy). Although there was a strong statistical difference between doses associated with PCCT and EICT for both chest and abdomen-pelvis CT ($p<0.001$), we found no significant difference between the size (WED, $p>0.32$) of patients scanned on the three scanner types.

CONCLUSION

Regardless of patient age, gender, body size, body part imaged, and protocol type, our consecutive, non-exclusionary data demonstrates up to 51% lower radiation dose for chest CT and 14% lower dose for abdomen-pelvis CT with PCCT relative to EICT.

CLINICAL RELEVANCE/APPLICATION

We provide key information on radiation dose reduction with PCCT over multi-vendor EICT scanners regardless of patient and protocol characteristics.

T6-SSMS02-6 AI ALGORITHMS CAN ASSIST RADIOLOGISTS IN DETECTION AND SEGMENTATION OF TUMORS IN UTERUS AND ESOPHAGUS THROUGH NON-CONTRAST ENHANCED CT IMAGES

Zongwei Zhou, PhD (*Presenter*)
Qi Chen (*Abstract Co-Author*)
Zekun Jiang, PhD (*Abstract Co-Author*)
Wenxuan Li, BS (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the effectiveness of AI algorithms for detecting and localizing pathologically confirmed esophageal and uterine tumors on CT scans by publicly releasing a carefully annotated, pathologically validated dataset for open-source AI model development.

METHODS AND MATERIALS

We retrospectively collected and annotated 233 non-contrast-enhanced CT scans from a Chinese hospital, comprising 154 esophageal tumor cases and 79 uterine tumor cases. Annotation involved 10 radiologists, including 4 senior radiologists with 10-16 years of clinical experience and 6 junior radiologists with 5-8 years of experience. Tumor boundaries were manually delineated using ITK-SNAP software by junior radiologists, subsequently reviewed, adjusted, and validated by senior radiologists. Any annotation discrepancies were resolved through consensus discussions among senior radiologists, finalizing pathologically confirmed tumor masks. Tumor sizes ranged from 10-52 mm for uterine tumors and 4-33 mm for esophageal tumors. Segmentation and detection performance was assessed using U-Net and SegResNet algorithms, evaluating metrics including tumor-wise sensitivity, voxel-wise Dice Similarity Coefficient (DSC), and Normalized Surface Dice (NSD).

RESULTS

AI models trained on this dataset achieved promising performance on internal test data. The best-performing model reached a tumor-wise sensitivity of 100% for uterine tumors and 96.6% for esophageal tumors. It also demonstrated strong localization accuracy, with DSC scores of 75.4% for uterine tumors and 56.4% for esophageal tumors, and NSD scores of 65.1% and 54.7%, respectively. Further detailed performance analysis and examples are provided in the accompanying figures.

CONCLUSION

AI models, particularly those utilizing advanced backbone architectures, achieved tumor detection sensitivities comparable to expert radiologists. Additionally, these models effectively localized uterine and esophageal tumors, facilitating targeted visual inspection by radiologists.

CLINICAL RELEVANCE/APPLICATION

Our publicly released annotated dataset significantly contributes to the development and refinement of AI algorithms aimed at detecting and accurately localizing uterine and esophageal tumors. This resource enables researchers to enhance AI-assisted diagnostic tools, thereby improving clinical workflows and patient outcomes.

T6-SSPH08-1 CLINICAL EVALUATION OF A SIMULTANEOUS IMAGE SYNTHESIS AND UNCERTAINTY ESTIMATION FRAMEWORK FOR AI-BASED PET RECONSTRUCTIONS

Stephen Liu, PhD (*Presenter*)

PURPOSE

Deep learning (DL) has gained increasing interest in PET reconstruction for its potential to enhance image quality and computational speed. However, its clinical adoption remains limited, largely due to the lack of efficient methods for quantifying uncertainties - critical for assessing the reliability of DL-generated images. We investigate a novel inference scheme that estimates aleatoric (reflecting data noise) and epistemic uncertainty (reflecting DL model confidence) jointly with each PET reconstruction synthesis.

METHODS AND MATERIALS

The proposed framework was implemented in conjunction with the recently introduced FastPET, a network model that synthesizes MLEM-like reconstructions from multi-angle PET histo-images at high speed. An "uncertainty-aware" training was first performed using a likelihood-based loss and dropout layers. During inference, voxel-wise mean and variance maps - initialized as the standard histo-images and zeros - were analytically propagated through each dropout-enabled FastPET layer. This enabled the generation of reconstructed images, aleatoric uncertainty (both from propagated mean) and epistemic uncertainty (from propagated variance) in a single inference pass. Clinical evaluation of the framework was performed on 5 static whole-body PET/CT scans of patients (with 18F-FDG tracers) acquired on Biograph Vision Quadra (Siemens Healthineers). The estimated reconstructions and uncertainty maps using proposed method were compared to the results from the baseline approach involving FastPET with multi- inference Monte Carlo (MC) dropout sampling, in terms of quantitative accuracy and runtime performance

RESULTS

The proposed single-pass approach generated reconstructions and uncertainty maps closely aligned with the baseline FastPET with 50-pass MC sampling. The mean errors across 5 studies were <0.02% (SUVmax) for the reconstruction, <5.3% (SUVmax 2) for the aleatoric uncertainty, and <4.2% (SUVmax 2) for the epistemic uncertainty in high-uptake regions. Average processing time per scan of proposed method was ~146s, compared to ~68s for FastPET without uncertainty estimation ability and ~3405s for the MC-based method.

CONCLUSION

This framework enables accurate, efficient estimation of uncertainties along with PET reconstruction synthesis. It adds a critical reliability metric without compromising DL inference speed, potentially supporting safer and clinically viable DL-based image formation.

CLINICAL RELEVANCE/APPLICATION

To provide near real-time estimation of uncertainties in AI-based PET image formation, enabling assessment of AI confidence and supporting more reliable, informed clinical decision-making.

T6-SSPH08-2 MODULATION OF CELL VIABILITY, APOPTOSIS, AND AUTOPHAGY IN PANCREATIC CANCER CELLS USING THERAPEUTIC ULTRASOUND WITH MICROBUBBLES AND GEMCITABINE

Seunghyeon Roh, MD (*Presenter*)
Eun-Joo Park, PhD (*Abstract Co-Author*)
Jae Young Lee, PhD, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to investigate the effects of therapeutic ultrasound (TUS) with microbubbles and gemcitabine on cell viability, apoptosis, and autophagy in pancreatic cancer cells. The goal was to elucidate the cell death mechanisms by which TUS enhances drug delivery and therapeutic efficacy.

METHODS AND MATERIALS

Human pancreatic ductal adenocarcinoma CFPAC-1 cells were treated using varying TUS intensities (0.29 MPa/continuous wave, 0.42 MPa/50% duty cycle, and 0.86 MPa/10% duty cycle), microbubble volumes (0, 10, 50 μL), and gemcitabine concentrations (0 μg/mL, 2 μg/mL). Cell viability was assessed via MTT assay, apoptosis by Annexin V/Propidium Iodide staining and flow cytometry, and autophagy by an autophagy detection kit. Statistical analyses included three-way analysis of variance and post-hoc Tukey's honestly significant difference tests to evaluate the effects and interactions of treatment variables.

RESULTS

TUS combined with microbubbles and gemcitabine significantly reduced cell viability, induced apoptosis, and modulated autophagy in pancreatic cancer cells. Higher ultrasound intensities (lower duty cycles) and microbubble volumes enhanced these effects. Autophagy activation varied across conditions. Under certain condition, autophagy showed dose-dependent suppression under higher intensity TUS, thus promoting apoptosis-mediated cell death.

CONCLUSION

TUS combined with microbubbles and gemcitabine synergistically enhances drug delivery and induces cell death in pancreatic cancer cells through apoptosis and autophagy modulation. These findings highlight a promising strategy for improving pancreatic cancer treatment outcomes, warranting further in vivo and clinical studies to optimize parameters and evaluate translational potential.

CLINICAL RELEVANCE/APPLICATION

Therapeutic ultrasound with microbubbles and gemcitabine enhances drug delivery and induces cell death in pancreatic cancer cells. The combination therapy amplifies cytotoxic effects via apoptosis and autophagy modulation. This strategy offers innovative prospects for pancreatic cancer treatment, warranting further optimization and translational studies.

T6-SSPH08-3 A PRELIMINARY ANALYSIS OF SUBHARMONIC-AIDED PRESSURE ESTIMATION'S (SHAPE'S) UTILITY FOR SCREENING FOR ESOPHAGEAL VARICES IN PATIENTS WITH COMPENSATED CHRONIC LIVER DISEASE

Hailee Mayer, BS (*Presenter*)
Trang Vu (*Abstract Co-Author*)
Priscilla Machado, MD (*Abstract Co-Author*)
Jonathan M. Fenkel (*Abstract Co-Author*)
Antonina Antonenko (*Abstract Co-Author*)
Jaime Bosch, MD (*Abstract Co-Author*)
Annalisa Berzigotti (*Abstract Co-Author*)
Kirk Wallace, PhD (*Abstract Co-Author*)
Flemming Forsberg, PhD (*Abstract Co-Author*)

PURPOSE

Esophageal varices (EVs) are a common consequence of chronic liver disease (CLD) as they often result from clinically significant portal hypertension and can give rise to major bleeding. In patients with compensated advanced CLD, approximately 60% of patients that undergo endoscopic screening have no varices, which underlines the need of non-invasive tests able to identify these cases, so sparing unnecessary invasive evaluations and reducing costs. Subharmonic-aided pressure estimation (SHAPE) is a noninvasive ultrasound-based measurement of pressure that has been shown to be an accurate predictor of portal hypertension. SHAPE relies on the subharmonic responses of ultrasound contrast agents (UCAs) to changes in ambient pressure. The study aims to determine SHAPE's ability to differentiate between patients who require endoscopic screening for varices, and those where it is unnecessary.

METHODS AND MATERIALS

17 subjects undergoing endoscopic evaluation for varices were enrolled in this ongoing, multi-center, IRB-approved study and had their data analyzed. Sonazoid (GE HealthCare) was administered as an infusion of 0.18 mL/kg/hour in accordance with the recommended dose of this agent in SHAPE applications. SHAPE was performed using a LOGIQ E10 (GE HealthCare) with a C1-6 curvilinear probe in the commercially available subharmonic imaging mode (tx: 2.5 MHz, rx: 1.25 MHz). An acoustic pressure calibration algorithm was used to optimize the acoustic pressure on an individual basis. Once the optimal acoustic pressure was identified, 3-5 five second cine clips were obtained with the portal vein (PV) and hepatic vein (HV) at similar depths. Offline, an ROI was placed in both veins to acquire the subharmonic amplitude of each. The SHAPE gradient was calculated as the signal in the HV minus the signal in the PV. Endoscopic outcomes were compared to the SHAPE gradient using receiver operating characteristics (ROC) analysis.

RESULTS

Eight patients had EVs while nine did not. ROC analysis resulted in an area under the curve of 0.94 (95% CI: 0.84 to 1.000; p = 0.002) for SHAPE. Using a cut off value of -0.87 dB for the SHAPE gradient, there was 100% specificity and 75% sensitivity for correctly identifying patients who have varices.

CONCLUSION

These preliminary results indicate that SHAPE may be suitable as a noninvasive modality for selecting those patients with chronic liver disease that do not require endoscopic screening for varices.

CLINICAL RELEVANCE/APPLICATION

This work indicates SHAPE may be used as a noninvasive imaging tool to help limit unnecessary endoscopic screening for varices in patients with chronic liver disease.

T6-SSPH08-4 UNDERESTIMATION OF CT ATTENUATION DUE TO MISREGISTRATION ON [^{18}F]PSMA-1007 PET/CT: A PITFALL IN BONE UPTAKE METASTATIC PROBABILITY (BUMP) SCORE-BASED INTERPRETATION OF RIB LESIONS

Salman J. Arain, MBChB (*Presenter*)
James Cairns, MSc, BMBS (*Abstract Co-Author*)
Amalia Stavropoulos, MBBS (*Abstract Co-Author*)
Amit Bahl (*Abstract Co-Author*)
Georgia Ionescu (*Abstract Co-Author*)
Daniel Balfour (*Abstract Co-Author*)
Russell Frood, MBChB, FRCR (*Abstract Co-Author*)
Chirag Patel, FRCR (*Abstract Co-Author*)
Amarnath Challapalli, MD,MBBS (*Abstract Co-Author*)
Julien M. Willaime, PhD (*Abstract Co-Author*)
Andrew F. Scarsbrook, BMBS, FRCR (*Abstract Co-Author*)

PURPOSE

Indeterminate bone lesions (IBLs) are commonly observed on 18 F Prostate Specific Membrane Antigen (PSMA)-1007 PET/CT in patients with prostate cancer. Bone uptake metastatic probability (BUMP) score was developed to aid characterisation using lesion SUVmax and mean Hounsfield Unit (HU) measurements alongside androgen deprivation therapy (ADT) status. Rib lesions are a frequent site of IBLs and are particularly prone to PET/CT misregistration artefact due to breathing motion, which may distort HU values and lead to inaccurate BUMP score classification. This study aimed to assess the extent of HU misclassification in rib lesions and evaluate the impact on composite BUMP score for predicting skeletal metastases.

METHODS AND MATERIALS

Patients with histologically confirmed prostate cancer who underwent [18 F]PSMA-1007 PET/CT over a 4-year period at two tertiary centres, with PSMA-avid rib lesions were retrospectively identified. For each lesion, SUVmax and androgen deprivation therapy (ADT) status at time of imaging were recorded. Mean HU values were calculated from volumes of interest (VOI) defined by both PET and CT components and compared using paired analysis. Lesion ground truth was established through follow-up imaging, prostate specific antigen (PSA) kinetics, and multidisciplinary clinical consensus. The impact of manual HU correction on clinical risk stratification was evaluated by comparing predicted metastatic likelihood before and after correction, using institution-specific BUMP score thresholds.

RESULTS

A total of 54 patients with 132 PSMA-avid rib lesions were analysed. In 31% of lesions (n=42), there was a discordance in mean HU value between PET and CT derived VOI ($p<0.001$). In cases of PET/CT misregistration the median difference was 290 HU (interquartile range (IQR) 283). The largest absolute difference between PET and CT VOI-defined HU was 1351. In 5% of lesions (n=6), this HU difference led to a change in BUMP score-based classification from benign to malignant. Lesions with a borderline BUMP score were most affected.

CONCLUSION

PET/CT misregistration can lead to significant underestimation of mean HU in rib lesions, resulting in falsely low BUMP scores. This misclassification has tangible consequences, altering predicted malignancy status in a subset of cases and potentially impacting clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

Misregistration can lead to significant HU underestimation and misclassification if PET-based volumes are used for rib lesion HU quantification. HU measurements should be extracted from CT ROIs to ensure accuracy for BUMP scoring.

T6-SSPH08-5 ULTRASOUND IMAGE QUALITY ACROSS VENDORS: COMPARING SONOGRAPHERS' PERCEPTION, RADIOLOGIST EVALUATION, AND PHANTOM MEASUREMENTS

Sang Hoon Chong, PhD, MSc (*Presenter*)
Nicole Yakavonis, BS (*Abstract Co-Author*)
Harriet J. Paltiel, MD (*Abstract Co-Author*)
Don-Soo Kim, PhD (*Abstract Co-Author*)
Kee Y. Chung, MD, MBA (*Abstract Co-Author*)
Da Zhang, PhD (*Abstract Co-Author*)

PURPOSE

Our institution has used ultrasound systems from vendors A and B and recently adopted vendor C's system. Sonographers reported diverging image quality perceptions among the three vendors. This study aimed to evaluate these perceptions and compare them with phantom-based objective measurements and radiologist assessments.

METHODS AND MATERIALS

The study consisted of four phases. First, a brief survey gathered sonographers' perceptions of image quality (penetration, spatial resolution, grayscale) for vendors A, B, and C using a 1-10 scale. Second, phantom experiments using a multi-purpose ultrasound phantom (Model 040GSE, CIRS) tested objective quality metrics (penetration, spatial resolution, and contrast) for each vendor using convex transducers and standard protocols. Third, clinical images were acquired from a healthy adult volunteer using all vendor systems (34 images in total). Six sonographers independently rated the anonymized images (liver, kidney, gallbladder, aorta, and IVC) on a 1-5 scale for overall diagnostic image quality, penetration, spatial resolution, and contrast. Finally, two radiologists independently evaluated the same images using identical criteria.

RESULTS

The initial survey ranked vendors A > B > C, with vendor B noted for excessive contrast. Phantom results showed vendors A and B performed better than C in penetration and lateral resolution (A ˜ B > C). Vendor B excelled in axial resolution (B > A ˜ C) and showed the highest contrast, partially aligning with initial feedback. However, human image evaluation revealed a shift: both sonographers and radiologists rated vendor B lowest overall, with vendors A and C performing similarly (A ˜ C > B). Radiologist I reported more distinct differences, while Radiologist II saw minimal variation between vendors.

CONCLUSION

Initial sonographer concerns were partly supported by phantom data, confirming vendor specific image traits. However, clinical image assessments contradicted earlier findings, revealing lower performance from vendor B and improved scores for vendor C. Possible explanations include: (1) clinical images were adult-based in a pediatric-focused facility, (2) subjective variability among reviewers, (3) limited phantom settings, and (4) single-operator image acquisition. Future work should include more subjects, operators, and reviewers, along with vendor input for standardized phantom settings. Understanding these discrepancies is essential for informed equipment choices, protocol optimization, and quality assurance.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the value of aligning sonographer perceptions with objective and radiologist-based assessments to support image quality optimization and guide vendor evaluation.

T6-SSPH08-6 WHICH METHOD IS USEFUL FOR NODULE DETECTION AMONG MRI WITH ULTRA-SHORT TE (UTE-MRI) AND STIR IMAGING ON PET/MRI AND FDG-PET/CT WITH AND WITHOUT BREATH-HOLD CTS?

Yoshiharu Ohno, MD, PhD (*Presenter*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Masao Yui (*Abstract Co-Author*)
Kota Aoyagi (*Abstract Co-Author*)
Takahiro Ueda, MD, PhD (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare the capability of nodule detection among PET/MRI with thin-section MRI with ultra-short TE (UTE-MRI) and short TI inversion-recovery (STIR) imaging and PET/CT with and without breath-hold CT in oncologic patients.

METHODS AND MATERIALS

110 consecutive oncologic patients underwent standard-dose thin-section CTs, FDG-PET/CTs, FDG-PET/MRI with UTE-MRI and STIR fast advanced spin-echo (FASE) imaging, pathological examinations obtained by transbronchial or CT-guided biopsy or surgical resection, micro bacterial examinations and more than 2 years follow-up examinations. In each patient, breath-hold low-dose CT (BHCT) was obtained as a part of PET/CT examination, which included non-breath hold CT (non-BHCT) as CT-based attenuation corrections on PET/CT. Then, two board-certified chest radiologists confirmed 548 nodules in 110 patients according to standard-dose thin-section CT findings. In each patient, probability of presence at each pulmonary nodule was assessed on non-BHCT, BHCT, UTE-MRI and STIR imaging by means of 5-point visual scoring system by two board certified general radiologists and two board certified PET physicians. To determine the interobserver agreement on each method, kappa statistics with ? 2 test was performed. To compare nodule detection capability, Jackknife alternative free-response receiver operating characteristic (JAFROC) analysis were performed among all methods. Then, sensitivity was also compared among four methods by McNemar's test. Moreover, false-positive per case (FP/case) rate was compared among all methods by Wilcoxon's signed rank test.

RESULTS

Interobserver agreement of each method was determined as substantial or almost perfect ($0.64<?<0.97$, $p<0.0001$). Figure-of-merits (FOMs) of UTE-MRI (FOM=0.98) and STIR imaging (FOM=0.98) were significantly higher than that of non-BHCT (FOM=0.89, $p<0.05$). FP/case rates of UTE-MRI (0.10/case) and STIR imaging (0.09/case) were significantly lower than that of non-BHCT (0.36/case, $p<0.05$) and BHCT (0.35/case, $p<0.05$).

CONCLUSION

PET/MRI has superior potential for nodule detection in oncologic patients as compared with PET/CT with and without breath-hold CT.

CLINICAL RELEVANCE/APPLICATION

PET/MRI has superior potential for nodule detection in oncologic patients as compared with PET/CT with and without breath-hold CT.

T6-SSPH09-1 PROSPECTIVE PATIENT SIZE AND REGION-SPECIFIC DOSE ESTIMATION THROUGH AN AI-BASED CONTOUR SEGMENTATION OF CT LOCALIZERS

Aiping Ding, PhD,DSc (*Presenter*)
Yakun Zhang, MS (*Abstract Co-Author*)
Jered R. Wells, PhD (*Abstract Co-Author*)
Francesco Ria, PhD (*Abstract Co-Author*)
Donald P. Frush, MD (*Abstract Co-Author*)
Ehsan Samei, PHD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate an AI-based framework for automatic head and body contour segmentation from CT localizer images, enabling accurate pre-scan patient size and scan region-specific dose estimation in CT dosimetry.

METHODS AND MATERIALS

A total of 2,400 CT localizer images (959 AP, 1,441 LAT) were retrospectively collected from 1,817 patients scanned across 28 CT stations using over 400 protocols. Manual annotations of head and body contours were used to train a U-Net-based segmentation model. Pixel-level performance was assessed using Dice Similarity Coefficient (DSC), Intersection over Union (IoU), pixel accuracy, precision, sensitivity (recall), specificity, AUC-ROC, and Cohen's Kappa. Agreement with manual annotations was further evaluated using Bland-Altman analysis. Effective diameter (D eff) and water-equivalent diameter (D w) were derived from the segmented contour and used to calculate size-specific dose estimates (SSDE). Scan region-specific CTDI vol and other metadata were extracted from the Radiation Dose Structured Report (RDSR) to align SSDE calculation with actual scan coverage.

RESULTS

The trained AI model achieved a mean DSC of 0.984 and IoU of 0.969, with high pixel accuracy (0.982), precision (0.984), sensitivity (0.987) ,and specificity (0.999). Bland-Altman analysis demonstrated strong agreement with manual segmentations (mean difference of 0.013; limits of agreement (LoA) of -0.022 to 0.049). Compared to traditional threshold-based methods, the AI-generated contours produced smoother and more anatomically consistent D eff and D w profiles across the scan length, particularly in complex regions such as the neck and shoulders. Threshold-based segmentations often underestimated body boundaries or exhibited irregularities. Scan region-specific SSDE estimates based on AI segmentation showed improved alignment with scanned anatomy, enhancing accuracy over threshold-based methods.

CONCLUSION

AI-based contour segmentation from CT localizers enables precise patient size characterization and scan region-specific SSDE estimation. This approach supports pre-scan dose estimation and personalized protocol optimization, reducing dependence on post-scan metrics and manual contouring.

CLINICAL RELEVANCE/APPLICATION

AI-driven contour segmentation from CT localizers enables automated, patient-specific size and dose estimation. This enables accurate dose estimates and the opportunity for timely scan adjustments—a level of persionalization of scan particularly valuable in managing protocol variability across indications and populations (e.g., pediatric vs. adult) for identical scan regions. Additionally, it serves as a valuable tool for approaching CT image quality targets.

T6-SSPH09-2 PHOTON COUNTING CT IMAGING OF JOINT SOFT TISSUE USING PHYSICS-INFORMED MATERIAL-PRIOR- AND SELF-ATTENTION-ASSISTED BAYESIAN NETWORK

Hao Gong, PHD (*Presenter*)
Aeden Davis, BS (*Abstract Co-Author*)
Andrew Thoreson (*Abstract Co-Author*)
Kristin D. Zhao, PhD (*Abstract Co-Author*)
Nirusha Lachman (*Abstract Co-Author*)
Yunhong Shu, PhD (*Abstract Co-Author*)
Francis I. Baffour, MD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)

PURPOSE

Photon counting detector (PCD) CT allows full time spectral imaging, providing material differentiation / quantification for diagnosis of joint diseases. Conventional material decomposition is limited in soft tissue contrast resolution due to the amplified noise and artifacts. We aim to improve soft tissue image quality using a p hysics-informed material-p r ior- and self-attent i on-assisted Baye s ian neural network for multi- m aterial decomposition (PRISM)

METHODS AND MATERIALS

PRISM included a de-blooming process (DP), a material prior generation process (MPG), and a Bayesian dual-task neural network (BDN). In DP, local point spread function was derived via Gaussian fitting in Fourier domain and used to reduce blooming artifacts in iterative deconvolution. In MPG, we created one-hot-encoded material prior via tissue-wise segmentation. BDN used synergistic material classification and quantification in spectral CT images. Material prior served as an extra input to provide global image context and guide self-attention to regularize local classification and quantification. BDN used probabilistic modeling of model likelihood and posterior distribution to rebalance uncertainty and bias in training and characterize output distribution. BDN training used PCD 50 and 100 keV images of tissue-

mimicking inserts and simulated inserts (basis materials: hydroxyapatite (HA), fat, collagen, water). The predicted means of material-specific mass density were used in evaluation due to improved robustness and detail preservation. Quantification accuracy was assessed using mean absolute percent error (MAPE) of physical test inserts. CT scans of cadaveric wrists were used to assess overall image quality, noise, artifacts, and structural fidelity in material maps. An inception-net and a prior-assisted iterative method (PIMD; HA, collagen, water) served as baselines. MRI provided the reference for soft tissue

RESULTS

In phantom validation, comparable noise levels were observed (collagen / water): PRISM 1.1 / 5.1 HU, Inception 1.6 / 5.2 HU, PIMD 0.9 / 3.3 HU), but PRISM improved accuracy on testing soft tissue inserts (MAPE range: PRISM [0.6%, 3.4%], Inception [9%, 11%], PIMD [0.8%, 5%]). In cadaver scans, PRISM improved soft tissue contrast resolution, and visualized finer pathological features in connective tissues

CONCLUSION

The proposed PRISM provides high-quality PCD CT post-processing, showing improved quality of material decomposition in phantom and cadaver scans

CLINICAL RELEVANCE/APPLICATION

PRISM is potential to accurately differentiate and quantify target materials for patients with musculoskeletal conditions affecting connective tissues, which could be undiagnostic with standard CT imaging techniques

T6-SSPH09-3 STABILIZING CT RADIOMIC FEATURES ACROSS VARYING TUBE POTENTIALS (KVS) USING LEARNED VIRTUAL MONOENERGETIC IMAGING

Shaojie Chang, PhD (*Presenter*)
Joseph R. Swicklik, RT, BS (*Abstract Co-Author*)
Zhongxing Zhou, PhD (*Abstract Co-Author*)
Shravani Kharat, MS (*Abstract Co-Author*)
Jarod Wellinghoff (*Abstract Co-Author*)
Hao Gong, PHD (*Abstract Co-Author*)
Eric E. Williamson, MD (*Abstract Co-Author*)
Thomas A. Foley, MD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)

PURPOSE

Radiomic features of CT images are influenced by different tube potentials (kVs) during data acquisition. The purpose of this study is to use a D eep-learn I ng b A sed virtual MON oenergetic imaging at D ifferent energies (DIAMOND) framework to harmonize images and radiomic features at different kVs and improve reproducibility.

METHODS AND MATERIALS

DIAMOND was developed to harmonize CT images acquired at one tube voltage to match those acquired at another. The network was trained using virtual monoenergetic images (VMIs) representing the effective energies of the respective tube potentials, determined through phantom calibrations. Gammex MECT phantoms were scanned at two target tube voltages on a conventional CT and on a photon-counting detector CT (PCD-CT) system operated in high-resolution multi-energy (HRME) mode, which provides VMIs from 40 to 190 keV. Equivalent VMI energy levels were identified by matching CT numbers between conventional CT at different tube potentials and PCD-CT VMIs. Dual-source, dual-energy CT with 100/Sn150 kV was used as a representative case. The DIAMOND network was trained to translate input 100 kV images into target Sn150 kV images using the same scan. To evaluate radiomic feature stability, fifty regions of interest (ROIs) were placed at consistent locations within the kidney across 100 kV, Sn150 kV, and DIAMOND-processed images. Radiomic analysis included 93 non-shape features across six categories: first-order, gray-level co-occurrence matrix (GLCM), gray-level dependence matrix (GLDM), gray-level run-length matrix (GLRLM), gray-level size zone matrix (GLSZM), and neighboring gray-tone difference matrix (NGTDM). Feature reproducibility was assessed by calculating the concordance correlation coefficient (CCC) between 100 kV and Sn150 kV images, and between DIAMOND and Sn150 kV images.

RESULTS

The CT number within a kidney ROI decreased from 320 HU in the original 100 kV scan to 160 HU after DIAMOND processing, closely matching the Sn150 kV reference value of 155 HU. Radiomic features showed moderate variability (mean CCC = 0.30) between 100 kV and Sn150 kV images. After applying DIAMOND, the mean CCC improved markedly to 0.97, indicating near-perfect agreement. Improvements were consistent across all feature categories, demonstrating DIAMOND's effectiveness in stabilizing radiomic features across varying tube voltages.

CONCLUSION

DIAMOND enables learned virtual monoenergetic imaging and harmonizes CT data across tube voltages, improving radiomic feature reproducibility.

CLINICAL RELEVANCE/APPLICATION

This vendor-agnostic VMI harmonization supports reproducible radiomics and AI model generalization across multi-center, multi-protocol CT imaging.

T6-SSPH09-4 IMAGE SYNTHESIS OF CT VOLUMES FROM TWO-VIEW SCOUTS WITH CONDITIONAL DIFFUSION MODELS

Liyan Sun (*Presenter*)
Sen Wang, PhD (*Abstract Co-Author*)
Maria Jose Medrano Matamoros, PhD (*Abstract Co-Author*)
Grant M. Stevens, PhD (*Abstract Co-Author*)
Justin Tse, MD (*Abstract Co-Author*)
Adam S. Wang, PhD (*Abstract Co-Author*)

PURPOSE

Scout images are regularly obtained before the acquisition of the main CT examination to determine scan range and optimize radiation dose. By translating two-view 2D scout images to synthetic 3D images, the organ size and position can be estimated, which would optimize organ-level radiation dose. The purpose of our study was to develop a novel Conditional Denoising Diffusion Model (CondDDPM) that predicts volumetric CT images based on two-view scout images and, for the first time, evaluate its ability to segment abdominal organs.

METHODS AND MATERIALS

We developed a novel CondDDPM conditioned on the Filtered Back Projection (FBP) image of two-view scouts for the 2D-to-3D synthesis. In one training iteration, an image is corrupted by the noise whose variance is time-dependent, and the U-Net learns to predict the noise with the timestamp, the corrupted image, and the FBP image. In testing, the noise image is denoised by subtracting the estimated noise predicted from the U-Net in each reversed timestamp until a clean sample is reached. We compare the CondDDPM with the NAFNet and its variant with adversarial training (NAFNet-ADV). The frontal and lateral scout projections are simulated using the LEAP library to model a CT scanner, and FBP reconstruction was performed using the same library. We adopted Normalized Root Mean Squared Error (NRMSE) as the metric for synthesis. We further evaluated their utility for abdominal organ segmentation using TotalSegmentator and compared their performances with ground truth CTs using Dice scores. 314 adult CT examinations were included in this study, with an 80:20 ratio split into training and testing datasets. The CondDDPM was trained for 150 epochs with a learning rate of 0.0001. We used the cosine learning scheduler and the DDIM sampler.

RESULTS

The realistic synthetic 3D images from CondDDPM can be used to segment organs for dose optimization. The mean/standard deviation of NRMSE of NAFNet, NAFNet-ADV, and CondDDPM were 0.1178/0.0392, 0.1280/0.0382, and 0.1175/0.0353, respectively. The mean/standard deviation Dice scores of lung, liver, kidney, and spleen segmentation from CondDDPM were 0.9245/0.1207, 0.8322/0.0704, 0.5082/0.2406, and 0.3795/0.2658, respectively.

CONCLUSION

We developed a diffusion model to generate synthetic CTs based on two-view scouts. We achieved accurate segmentation of larger organs (lung and liver) with off-the-shelf TotalSegmentator software, though it was less accurate for smaller organs (e.g., kidney and spleen). Ongoing work includes its application for organ dose calculation.

CLINICAL RELEVANCE/APPLICATION

The proposed generative AI model can improve abdominal organ localization before performing the actual CT examination, which refines dose optimization.

T6-SSPH09-5 ARTIFACT REDUCTION IN DUAL-ENERGY CT MATERIAL BASIS IMAGES USING A PHYSICS-CONSTRAINED TRANSFORMER-BASED DEEP LEARNING MODEL

Thomas M. Grist, MD (*Abstract Co-Author*)
Ke Li, PhD (*Abstract Co-Author*)
Guang-Hong Chen, PhD (*Abstract Co-Author*)

PURPOSE

Dual-energy CT (DECT) combines images acquired at low and high tube potentials to generate material basis images, such as iodine maps, enhancing diagnostic accuracy. However, in large patients, low-kV data are prone to photon starvation and beam hardening, leading to severe artifacts that propagate into the material basis images and impair diagnostic utility. This study aimed to develop a physics-constrained, transformer-based deep learning model to generate artifact-reduced material basis images using only high-kV CT data, which are less affected by these artifacts.

METHODS AND MATERIALS

A variational autoencoder (VAE) with a transformer backbone was developed. The encoder was trained to synthesize high-kV CT images from DECT-derived material basis images, and the decoder was trained to disentangle the synthesized high-kV image into corresponding material basis images. The model was trained on 16,000 pairs of high-kV and material basis images from DECT scans, with cases exhibiting photon starvation or beam hardening artifacts excluded from the training set. After training, only the decoder was used to generate material basis images directly from high-kV scans. The model was evaluated on two cohorts: (1) a cohort without artifacts to assess accuracy, using structural similarity index (SSIM) and root-mean-square error (RMSE) compared to scanner-generated DECT outputs; and (2) a cohort with severe artifacts to assess the degree of artifact reduction, quantified by RMSE and difference images of the iodine maps.

RESULTS

In the artifact-free cohort, the model accurately predicted material basis images from high-kV data alone, achieving median SSIM values of 97.9% ([97.5%, 98.4%]) for water and 92.7% ([86.4%, 95.3%]) for iodine, with an RMSE of 0.8 mg/ml ([0.7, 1.0]) for iodine quantification. In the artifact-prone cohort, the model substantially reduced artifacts in iodine maps, with lower RMSE values and visibly cleaner basis images compared to conventional DECT results.

CONCLUSION

A physics-constrained, transformer-based deep learning model was developed to generate material basis images from high-kV CT scans alone. The model demonstrated high accuracy in artifact-free cases and effectively reduced severe artifacts in challenging clinical cases.

CLINICAL RELEVANCE/APPLICATION

This deep learning approach offers a practical solution for generating artifact-reduced material basis images from high-kV CT alone, improving diagnostic quality in DECT, particularly for large patients where conventional methods are compromised by photon starvation and beam hardening.

T6-SSPH09-6 A PHYSICS-INFORMED NEURAL NETWORK FOR ACCURATE 5-MATERIAL DECOMPOSITION FROM SINGLE-ENERGY CT

Dale Black, BS (*Presenter*)
Christine Nguyen (*Abstract Co-Author*)
Sabee Y. Molloi, PhD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a Physics-Informed Multi-Material Decomposition (PiMMD) neural network for accurate five-material decomposition from single-energy computed tomography using both digital phantom and clinical images.

METHODS AND MATERIALS

A physics-informed neural network was designed using a UNet to generate an implicit virtual monoenergetic image (VMI), followed by convolutional layers to predict volume fractions for 5 basis materials (air, lipid, water, collagen, hydroxyapatite). High-fidelity training labels were created by decomposing known atomic compositions of digital phantoms into basis fractions via constrained optimization. CT images of the digital phantoms were simulated using CatSim. A physics-based loss function compared the implicit VMI against a VMI reconstructed from predicted fractions and known linear attenuation coefficients, enforcing physical consistency without requiring explicit energy input during inference. This training enables PiMMD to directly estimate all five basis materials within each voxel by effectively imposing additional physical constraints via training data unavailable to conventional algorithms, unlike the direct inversion method (SE-MMD), which is fundamentally limited by single-energy physics for estimating only a pair of materials per voxel. Quantitative accuracy was evaluated against known ground truth using unseen phantoms with Mean Squared Error (MSE) in volumetric fraction reported as percentages. Clinical feasibility was assessed using 60 CT scans from the Multi-Ethnic Study of Atherosclerosis (MESA) dataset.

RESULTS

Quantitative analysis showed PiMMD significantly outperformed SE-MMD. For digital humanoid phantoms, PiMMD's MSE was below 2% for all materials, while SE-MMD errors ranged from 14-40%. For instance, PiMMD achieved MSE of 1.5%±0.3% for Lipid compared to 15.1%±16.1% for SE-MMD. In more complex digital XCAT phantoms, PiMMD maintained lower errors than SE-MMD (e.g., Water MSE: PiMMD 20.8%±0.3% vs SE-MMD 29.4%±8.2%). Qualitative analysis on the 60 MESA CT scans confirmed these quantitative trends, showing PiMMD decomposition maps with markedly reduced noise, clearer tissue boundaries, and superior anatomical consistency compared to the highly variable SE-MMD results.

CONCLUSION

The physics-informed neural network enables accurate 5-material decomposition per voxel from single-energy CT, demonstrating superior performance compared to direct inversion methods, validated on phantoms and confirmed in clinical CT scans.

CLINICAL RELEVANCE/APPLICATION

By enabling quantitative tissue characterization from routine CT scans, this method offers potential to enhance diagnostic capabilities without specialized hardware or energy calibration.

T6-STCE1-1 AUTOMATING CAD-RADS REPORTING AND CAD PREDICTION WITH ZERO-SHOT LARGE LANGUAGE MODELS: A STEP TOWARD CLINICAL INTEGRATION

Wenchi Hsu, MD (*Presenter*)
Yuli Wang (*Abstract Co-Author*)
Harrison X. Bai, MD (*Abstract Co-Author*)
Gigin Lin, MD (*Abstract Co-Author*)
Ihab R. Kamel, MD, PhD (*Abstract Co-Author*)
Cheng Ting Lin, MD (*Abstract Co-Author*)

PURPOSE

The Coronary Artery Disease Reporting and Data System (CAD-RADS) standardizes coronary CTA (CCTA) reporting and guides management. However, CCTA is prone to overestimate stenosis degree and risk over-referral for invasive testing. This study aimed to (1) assess the ability of large language models (LLMs) to assign CAD-RADS scores from textual reports and (2) evaluate their performance in predicting confirmed significant coronary artery disease (CAD).

METHODS AND MATERIALS

This retrospective study included 555 CCTA reports between April 2013 and January 2024 from patients with suspected CAD. Basic demographics were collected. CAD-RADS scores, determined by consensus between two radiologists, served as the ground truth. Four LLMs (Llama 3.2, Gemma 3, Qwen 2.5, and DeepSeek R1) were evaluated with a zero-shot prompt. Each model was prompted to assign CAD-RADS categories from de-identified report texts and to estimate the probability of confirmed significant CAD, which was defined as either more than 50 % stenosis in the left main artery or more than 70% stenosis in the left anterior descending, left circumflex, or right coronary artery on invasive coronary angiography, or undergoing coronary revascularization within one year.

RESULTS

Of 555 CCTA reports, CAD-RADS categories were 0 in 187 (33.7%), 1 in 146 (26.3%), 2 in 104 (18.7%), 3 in 66 (11.9%), 4 in 50 (9%), and 5 in 2 (0.3%). The LLMs achieved correct classification in 459 (82.7%), 489 (88.1%), 455 (82.0%), and 370 (66.7%) cases for Llama 3.2, Gemma 3, Qwen 2.5, and DeepSeek R1, respectively. Agreement with radiologists was assessed using quadratic weighted Kappa, yielding values of 0.94, 0.96, 0.95, and 0.78, respectively. Category upgrades (from CAD-RADS 0-3 to 4-5) and downgrades (from CAD-RADS 4-5 to 0-3) were noted in 2 (0.4%) and 11 (2.0%) cases for Llama 3.2, 1 (0.2%) and 4 (0.7%) for Gemma 3, 2 (0.4%) and 1 (0.2%) for Qwen 2.5, and 35 (5.1%) and 7 (2.3%) for DeepSeek R1. Regarding the prediction of confirmed significant CAD, the four LLMs achieved AUCs of 0.92, 0.93, 0.91, and 0.66 for Llama 3.2, Gemma 3, Qwen 2.5, and DeepSeek R1, respectively. Performance declined in the more challenging CAD-RADS 3 and 4 subgroups, with AUCs dropping to 0.73, 0.75, 0.71, and 0.52, respectively.

CONCLUSION

Using a zero-shot prompt, LLMs demonstrated high agreement with radiologist consensus when assigning CAD-RADS scores, with varying tendencies in upgrading or downgrading. Furthermore, most LLMs achieved moderate-to-good performance in predicting confirmed significant CAD.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the potential of LLMs as clinically integrable tools to support structured reporting and inform downstream decision-making in CCTA interpretation.

T6-STCE1-2 LEVERAGING LLM-ENHANCED STRUCTURED REPORTING TO IMPROVE VISION-LANGUAGE MODEL FOR PULMONARY EMBOLISM CT ANGIOGRAPHY

Cheng-Yi Li, MSc (*Presenter*)
Yuli Wang (*Abstract Co-Author*)
Yuwei Dai, MD (*Abstract Co-Author*)
Haoyue Guan (*Abstract Co-Author*)
Haiman Guo (*Abstract Co-Author*)
Chenhao Lyu (*Abstract Co-Author*)
Qiuhao (alex) Zhu (*Abstract Co-Author*)
Ihab R. Kamel, MD, PhD (*Abstract Co-Author*)
Harrison X. Bai, MD (*Abstract Co-Author*)
Cheng Ting Lin, MD (*Abstract Co-Author*)

PURPOSE

Vision-language models (VLMs) hold promise for automating radiology reporting and aiding clinical decisions, but are limited by unstructured free-text inputs. This study proposes a scalable approach using large language models (LLMs) to reformat free-text reports into a structured template and assesses its impact on VLM performance for pulmonary embolism (PE) prognostication on CT pulmonary angiography (CTPA) across a large health system.

METHODS AND MATERIALS

This IRB-approved study included 18,427 CTPA scans from adult patients at a tertiary care center from 2014 to 2024. We collected clinical data including demographic and physiological variables (age, gender, heart rate, respiratory rate, and systolic BP), and clinical outcomes (ICU admission, 90-day mortality, and 30-day readmission). A VLM based on the Otter framework was trained to integrate CTPE volumes with corresponding radiology reports—either original free-text or LLM-reformatted versions. We compared the two approaches across several benchmarks: automated text-based metrics (BLEU, ROUGE, and METEOR) and LLM-based evaluation of 6 PE-specific abnormality questions. Additionally, we assessed how both output types, combined with clinical variables, predicted ICU admission, mortality, and readmission.

RESULTS

VLM trained with LLM-reformatted reports consistently outperformed those trained on original free text. Report generation metrics improved substantially, with BLEU-1 increasing from 0.23 to 0.42, ROUGE-L from 0.34 to 0.37, and METEOR from 0.28 to 0.33. LLM-reformatted reports yielded more accurate responses to the 6-question PE abnormality test—covering acute PE presence, PE location, and right heart strain—raising classification accuracy from 0.71 to 0.82 (as shown in Figure 2(a)). Clinical outcome prediction also benefited: AUCs rose for ICU admission (0.71 vs. 0.62), 90-day mortality (0.79 vs. 0.64), and 30-day readmission (0.72 vs. 0.58).

CONCLUSION

LLM-driven report reformatting is a scalable and effective method to enhance VLM performance in CTPE. By improving both the quality of report generation and downstream clinical prediction, this strategy enables large health systems to deploy VLMs without the need for manual data labeling.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that LLM-based reformatting of free-text CTPE reports can significantly improve the training of VLMs. By producing high-quality structured data at scale, health systems can develop VLMs that generate more accurate and complete reports. This enhancement has the potential to streamline radiology workflows, improve reporting efficiency, and support radiologists' routine clinical operations.

T6-STCE1-3 GENERATIVE AI IN CLINICAL PRACTICE: GROUNDING A VISION LARGE LANGUAGE MODEL POWERED CHEST X-RAY SYSTEM USING A CLINICALLY VALIDATED COMPUTER VISION CLASSIFIER MODEL

Sajith Karunasena, MBBS, FRANZCR (*Presenter*)
Nalan Ektas (*Abstract Co-Author*)
Georgina Bottrell (*Abstract Co-Author*)
Jarrel C. Seah, MBBS (*Abstract Co-Author*)
Michael Milne (*Abstract Co-Author*)

PURPOSE

Recent advances in generative AI and large language models (LLMs), have rapidly transformed the landscape of tools available for healthcare, offering promising solutions to the radiology industry, particularly with respect to the generation of draft radiology reports. However, risks associated with hallucinated content present a significant challenge with clinical safety, acceptability and adoption. This work describes the development of a novel AI system that utilises a comprehensive, clinically validated computer vision classification model for chest x-ray (CXR) finding detection to ground the outputs of a radiology focussed vision LLM (vLLM) for CXR report generation. The methods used present an opportunity for transformative innovation of radiology reporting workflow optimization whilst maintaining clinical accuracy and safety.

METHODS AND MATERIALS

A collaborative team of radiologists, industry AI engineers, medical device and research professionals developed an integrated system, whereby outputs from a commercially available, machine learning-based medical device for classification of radiological findings on CXR, were transformed into natural language radiology report text using a vLLM trained with radiology data. To mitigate risk of error in clinical use, the scope of the vLLM outputs were controlled to ensure the core radiologic findings represented in the generated report text were concordant with the classification model outputs. Any additional detail provided by the LLM would not be expected to impact patient management. Clinical validation was performed by an expert independent evaluator (FRANZCR qualified radiologist) via concordance analysis and assessed against a pre-specified level of agreement.

RESULTS

The vLLM reliably transformed AI-predicted findings into radiology report narrative text, demonstrating very high concordance with the classification model for core radiology findings (concordance rate 0.987, 95% CI [0.958, 1.000], p = 0.019).

CONCLUSION

This study demonstrates a novel method of grounding the outputs of a radiology trained vLLM using a clinically validated computer vision classification model to produce accurate text outputs for draft radiology reports. It also shows how collaboration between clinical experts, AI engineers and medical device professionals can ensure technical innovation that addresses real clinical needs within the appropriate standards. Feedback from early clinical deployment will confirm positive impacts on radiologist workflow from draft report generation.

CLINICAL RELEVANCE/APPLICATION

This work paves a pathway to implementing generative AI in a clinical setting, and opens the roadmap for future innovation in radiology workflow optimization.

T6-STCE2-1 MESOSCALE CISS IMAGING FOR THE DETECTION OF DURAL DEFECTS IN SPINAL CSF LEAKS

Michelle Wegscheid, MD, PhD (*Presenter*)
Arindam R. Chatterjee, MD (*Abstract Co-Author*)
Cyrus A. Raji, MD, PhD (*Abstract Co-Author*)
Martin N. Reis, MD (*Abstract Co-Author*)
Sherwin N. Azad, MD,MS (*Abstract Co-Author*)
Ananth K. Vellimana, MBBS (*Abstract Co-Author*)
Manu S. Goyal, MD, MSc (*Abstract Co-Author*)
Arash Nazeri, MD (*Abstract Co-Author*)

PURPOSE

Spontaneous intracranial hypotension (SIH) is most often attributable to cerebrospinal fluid (CSF) leaks from the spinal canal, yet precise localization of dural defects remains challenging. While fat-saturated heavily T2-weighted MR myelography (HT2-MRM) is sensitive to spinal longitudinal extradural CSF collections (SLECs), it does not reliably localize the leak site. This study evaluates a two-stage spine MRI protocol incorporating high resolution, mesoscale 3D constructive interference in steady state (meso-CISS) for targeted CSF leak localization.

METHODS AND MATERIALS

Twenty consecutive patients with suspected SIH underwent a standardized total spine MRI protocol, including 3D HT2-MRM for SLEC screening. In cases with positive SLEC or indeterminate findings, meso-CISS was performed for targeted high-resolution leak localization.

RESULTS

Eight patients (40%) demonstrated SLECs on HT2-MRM, prompting further evaluation with meso-CISS. Dural defects were successfully identified in five patients (1.5-8 mm in size). In one case, meso-CISS delineated intrathecal protrusion of ligamentum flavum calcification, suggesting an underlying defect. Compared with HT2-MRM, meso-CISS provided superior visualization of dural defects, arachnoid scarring, and neo-membrane formation. Two cases were limited by motion or metal artifacts.

CONCLUSION

A two-stage spine MRI protocol incorporating HT2-MRM and meso-CISS improves the localization of dural defects in SIH. Meso-CISS enhances visualization of small dural tears and associated pathology, facilitating targeted interventions and potentially reducing reliance on invasive myelography.

CLINICAL RELEVANCE/APPLICATION

The results of this study support the use of meso-CISS as a targeted, high-resolution imaging tool to refine CSF leak localization. In our cohort, meso-CISS enabled prospective identification of suspected dural defects that were only retrospectively appreciated on HT2-MRM. By improving pre-procedural localization, this approach has the potential to increase the diagnostic yield and spatial accuracy of invasive studies, such as digital subtraction myelography, reduce unnecessary radiation exposure, and facilitate more precise and targeted therapeutic interventions.

T6-STCE2-2 ULTRAFAST BREAST MRI WITHOUT CONTRAST USING ARTERIAL SPIN LABELING-BASED CONTRAST-INHERENT INFLOW-ENHANCED MULTIPHASE ANGIOGRAPHY

Kazunori Oohashi, BSc (*Presenter*)
Kazunori Kubota, MD, PhD (*Abstract Co-Author*)
Tomoyuki Fujioka, MD, PhD (*Abstract Co-Author*)

PURPOSE

Recent advances in MRI systems and pulse sequences have enabled non-contrast-enhanced MR angiography (MRA) to visualize vascular structures and hemodynamics in various anatomical regions.Contrast-Inherent Inflow-Enhanced Multiphase Angiography (CINEMA) is a non-contrast 4D MRA technique combining Look-Locker-based multiphase acquisition with pulsed ASL (PASL), allowing high temporal resolution visualization of blood flow dynamics. However, no established non-contrast alternative exists in breast MRI. In this study, we aimed to optimize ASL parameters—including labeling position and post-labeling delay—based on the hemodynamics and vascular anatomy of the breast, in order to visualize background parenchymal enhancement (BPE) without contrast at a temporal resolution comparable to ultrafast DCE-MRI.

METHODS AND MATERIALS

Non-contrast CINEMA imaging was performed using a 3.0T MRI system (Ingenia CX, Philips). A phantom was constructed using extension tubing, and normal saline was injected at a rate of 0.1 mL/sec using an injector (Sonic Shot 7, Nemoto Kyorindo). Signal changes were measured at the marked position. Labeling delay (LD) was varied from 100 to 220 ms, and the label gap was set from 0 to 50 mm to evaluate optimal conditions. Signal intensities were compared across conditions. Five dynamic phases were acquired with a total imaging time of 1200 ms and a phase interval of 200 ms.

RESULTS

As the labeling delay (LD) increased, the signal peak shifted to earlier phases, with the peak observed at the first phase at LD 220 ms. Similarly, as the label gap widened, spins arrived earlier, resulting in earlier peak phases (first phase at the maximum gap of 50 mm). These findings reflect the relationship between inflow time and signal changes.

CONCLUSION

visualization of arterial inflow, enabling dynamic assessment comparable to contrast-enhanced ultrafast MRI [Figure]. Optimization of the labeling slab location proved essential for consistent depiction of breast vasculature. Application of ASL and optimized temporal sampling strategies suggests that ultrafast dynamic breast MRI is

feasible without the use of contrast agents. This innovative approach may serve as a promising alternative in breast MRI, especially for patients with contraindications to contrast media or requiring repeated imaging.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the feasibility of non-contrast-enhanced ultrafast breast MRI using ASL-based CINEMA, offering a promising alternative for patients who cannot receive contrast agents due to allergies or renal dysfunction. It may enable dynamic perfusion assessment and background parenchymal enhancement evaluation without contrast administration.

T6-STCE2-3 STABLE SPARSE CT WITH MAXIMUM ENTROPY: A FRAMEWORK FOR REAL-TIME IMAGING

Wolfram R. Jarisch, PhD (*Presenter*)

PURPOSE

Sparse-view CT presents a trade-off between dose and image quality. Conventional iterative methods often lack stability and require heavy computation, while machine learning approaches demand training and offer no guarantees of convergence. We propose use of a novel implementation that solves the computational impasse by combining the mathematical uniqueness of Maximum Entropy (MENT) reconstruction with Kalman filtering to achieve fast, stable CT reconstruction even under sparse, noisy conditions.

METHODS AND MATERIALS

The MENT component enforces a global entropy-maximizing solution under projection constraints, ensuring uniqueness and drift-free convergence, especially in underdetermined systems. Adapted non-linear Kalman filter operations, with (approximate) Kalman gains replacing FBP in the inversion process, account for noisy projection data, acting as an efficient signal processing engine while accelerating convergence. Simulated head phantom data with =10% coverage were reconstructed and compared to FBP, SART, and OS-SART. Metrics: SSQ, visual fidelity, iteration count. No training or tuning needed.

RESULTS

The proposed framework achieved near-FBP reconstruction speeds, converging in ~4 effective full-resolution iterations, with residual SSQ of 0.36×10 - 3— utperforming OS-SART, which required 30 iterations and yielded a higher SSQ of 0.53×10 - 3. Visual review showed superior contrast and artifact suppression. A representative head phantom comparison is included as supporting evidence.

CONCLUSION

This work demonstrates that CT reconstruction from sparse data can be both fast and stable when grounded in entropy-based uniqueness. The MENT formulation guarantees a unique solution by construction, as described in Cover & Thomas (2006), Ch. 12, minimizing the risk of instability and bias even under non-linear constraints. The non-linear Kalman filter structure accounts for the exponential form of the MENT equation supporting fast convergence through a pyramidal resolution buildup, beginning from a single-voxel estimate and refining toward full resolution. Its gain matrix, derived from filtered back-projection (FBP), ensures a recursive, near-orthogonal updating scheme that is both computationally efficient and noise-suppressing. In sparse or limited-angle cases, Kalman convergence may otherwise drift unless guided by suitable criteria—an issue mitigated here through the stabilizing nature of the MENT solution.

CLINICAL RELEVANCE/APPLICATION

This method enables reliable low-dose, high-speed CT imaging without contrast agents or training data—well suited for interventional radiology, mobile scanners, and resource-constrained environments.

T7-SSBR06-2 DEEP LEARNING MODELS ON CONTRAST ENHANCED MAMMOGRAPHY TO REDUCE FALSE RECALLS

Zhiwei Gong, MSc (*Presenter*)
Chang Liu, BS (*Abstract Co-Author*)
Wendie A. Berg, MD, PhD (*Abstract Co-Author*)
Dooman Arefan, PhD, MSc (*Abstract Co-Author*)
Shandong Wu, PhD (*Abstract Co-Author*)

PURPOSE

Contrast-enhanced mammography (CEM) is a lower-cost, better tolerated imaging modality than breast MRI. For CEM to be widely accepted, harms of additional testing and/or unnecessary procedures for women who do not have cancer should be minimized. The purpose of this study is to develop and validate deep learning-based models to reduce false recalls using screening CEM datasets from two different cohorts.

METHODS AND MATERIALS

In retrospective, IRB-approved HIPAA-compliant protocols, we utilized two screening CEM cohorts collected from a single large academic center. Cohort A comprises biopsy-proven 56 breast cancers and 114 benign biopsies, 281 false recalls for additional imaging, and 527 normal, from screening CEM in women with a personal history of breast cancer, with at least one-year follow-up. Cohort B comprises biopsy-proven 14 breast cancers and 82 benign biopsies, 216 false recalls, and 971 normal, from screening CEM exams of women meeting state law criteria for insurance coverage of screening MRI (extremely dense; or heterogeneously dense breasts with family history or LCIS), with at least 1-year follow-up. Data-efficient Image Transformer models were built for the classification task of false recall vs. normal, using full-size images. Data in Cohort A were used to train a classification model, using Cohort B as an independent testing set for validation reporting testing AUCs. We also performed five-fold cross-validation on Cohort A to examine technical robustness reporting average AUCs with standard deviations. Low-energy (LE) and dual-energy subtraction (DES) images were used in combination and individually for comparisons. CC and MLO views were combined in the model.

RESULTS

The independent test AUCs on Cohort B are 0.72 (LE+DES), 0.60 (LE), 0.71 (DES), respectively. For five-fold cross validation on Cohort A, the mean AUCs are 0.84±0.05 (LE+DES), 0.75±0.05 (LE), 0.77±0.09 (DES). P values are all <0.05 when comparing AUCs of LE+DES vs. DES and DES vs. LE.

CONCLUSION

CEM-based deep learning models can distinguish potential false recalls from normal exams in CEM screening. DES images play dominant roles in the models.

CLINICAL RELEVANCE/APPLICATION

Deep learning models can improve CEM performance to reduce unnecessary false recalls in screening, reducing unnecessary workload, cost, biopsies, and patient stress.

T7-SSBR06-3 ADDING TOMOSYNTHESIS TO CONTRAST-ENHANCED MAMMOGRAPHY REDUCES FALSE POSITIVES

Wendie A. Berg, MD, PhD (*Presenter*)
Bronwyn Nair, MD (*Abstract Co-Author*)
Amy E. Kelly, MD (*Abstract Co-Author*)
Adrienne Vargo, MD (*Abstract Co-Author*)
Luisa P. Wallace, MD (*Abstract Co-Author*)
Alisa Sumkin, DO (*Abstract Co-Author*)
John Drescher, BS (*Abstract Co-Author*)
Andriy I. Bandos, PhD (*Abstract Co-Author*)

PURPOSE

To assess the impact on reader performance [sensitivity, false positive recall rates (FPRR), and AUC] of adding digital breast tomosynthesis (DBT) to contrast-enhanced mammography (CEM).

METHODS AND MATERIALS

In an IRB-approved protocol, five breast imaging radiologist observers with 0.2 to 5 years' experience interpreting CEM retrospectively reviewed 403 screening CEM examinations enriched in malignancies (68, 17%). Benign cases had at least one year follow-up and atypical lesions were excised. Observers first reviewed low-energy (LE) images, recorded any recalled findings electronically, and locked in forced BI-RADS assessments (1 or 2, 3, 4A, 4B, 4C, or 5). Next, contrast-enhanced recombined (RC) images were reviewed, asking if and how RC images altered BI-RADS assessments of each LE finding, then recording any newly seen recalled findings and assessments. Finally, observers were shown DBT images and asked if DBT altered assessment of any LE or RC findings, then recording any newly seen findings and assessments. Primary outcome was case-level performance using maximum BI-RADS assessment (with BI-RADS 3 or higher positive). Statistical analysis of rates was performed using the generalized linear mixed model (proc glimmix, SAS, v.9.4) accounting for heterogeneity across cases and readers. Multi-reader multi-case analysis was used for comparing the AUCs.

RESULTS

Across all five observers, among 340 interpretations of malignant cases, 148 (44%) were recalled on LE images; adding RC images significantly improved sensitivity to 269 (79%, OR=4.9, 95% CI:3.3-7.3). There was no significant change in cancer detection with addition of DBT to LE+RC (OR=0.98, CI: 0.77-1.26): for one observer, DBT added detection of one cancer; for two, one less cancer was identified; and for two readers, there was no change, for net 268/340 (79%) possible detections made.

FPRR from LE alone across five observers was 410/1675 (24.5%); adding RC to LE increased FPRR to 664/1675 (39.6%,OR=2.1, CI:1.8-2.5, P<.001), but increase in FPRR was outweighed by the increase in sensitivity, producing an increase in AUC from 0.61 to 0.77 (P<.001). Adding DBT to LE+RC decreased FPRR overall to 582/1675 (34.7%, OR=0.80, CI: 0.72-0.89, P<.001), but not enough to significantly change the AUC (0.78 vs. 0.77, P=0.64).

CONCLUSION

In this retrospective reader study, addition of DBT to CEM produced a 5% (82/1675) decrease in false-positive recall rates while maintaining high sensitivity.

CLINICAL RELEVANCE/APPLICATION

A combined examination with LE, RC CEM images, and DBT improves screening performance by reducing need for unnecessary CEM-prompted additional testing. The additional radiation exposure from adding DBT to CEM needs to be considered but remains within accepted limits.

T7-SSBR06-4 CLINICAL CORRELATIONS OF BACKGROUND PARENCHYMAL ENHANCEMENT IN CEM: AN AI AND RADIOLOGIST ASSESSMENT

Tamerlan Mustafaev, MD (*Presenter*)
Margarita L. Zuley, MD (*Abstract Co-Author*)
Robert M. Nishikawa, PhD (*Abstract Co-Author*)

PURPOSE

The purpose of our study is to correlate clinical findings with quantitative and qualitative Background Parenchymal Enhancement (BPE) characteristics derived using an in-house AI algorithm and radiologist-reported data from Contrast-Enhanced Mammography (CEM) studies.

METHODS AND MATERIALS

Low energy (LE) and recombined images (RI) from 1111 consecutively accrued CEM exams from an ongoing prospective diagnostic CEM trial included 982 exams with pathologically verified benign lesions and 129 studies with verified breast cancer. Patient age, radiologist-reported breast density, and BPE were collected from the research database. We applied our in-house, radiologist-trained AI to segment breast density on LE images and transferred those segmentations to RI images to extract BPE within fibroglandular tissue (AI-fBPE) and fatty tissue. The AI model was a transformer-based U-net trained using publicly available datasets. We then calculated the difference between fibroglandular and fatty enhancements (AI-dBPE), thereby quantifying true tissue contrast. Two pairs of correlation analyses were performed: (1a) AI-dBPE vs. age for two combined breast density groups (i) non-dense (BI-RADS density category A&B), and (ii) dense (BI-RADS C&D); (1b) Radiologist-reported BPE vs. age, also evaluated separately within these two (i and ii) combined density groups; (2a) AI-dBPE vs. radiologist-reported density, and (2b) radiologist-reported BPE vs. radiologist-reported density. We calculated Pearson correlation and 95% confidence intervals.

RESULTS

(1a) AI-dBPE correlated inversely with age, -0.23 [-0.31, -0.14] for non-dense breasts, and this association was stronger in dense breasts, -0.42 [-0.48, -0.36]. Similarly, (1b) radiologist-reported BPE showed inverse correlations with age: -0.28 [-0.36, -0.19] for non-dense and -0.35 [-0.42, -0.20] for dense breasts. Additionally, (2a) AI-dBPE correlated with radiologist-reported density 0.59 [0.55, 0.63] and (2b) radiologist-reported BPE with radiologist-reported density 0.47 [0.43, 0.52]. AI-dBPE had a higher correlation than radiologist-reported BPE, 0.59 vs 0.47 ($p<0.05$).

CONCLUSION

Both AI-dBPE and radiologist-reported BPE decrease with increasing patient age, and this relationship was stronger for women with dense breast. AI-dBPE and radiologist-reported BPE both showed moderate correlations with radiologist-assessed breast density category, with AI-dBPE having a statistically significantly stronger correlation.

CLINICAL RELEVANCE/APPLICATION

The novel marker AI-dBPE may improve the reproducibility of CEM-based background parenchymal enhancement classification.

T7-SSBR06-5 LONGITUDINAL FLUCTUATIONS IN BACKGROUND PARENCHYMAL ENHANCEMENT ON CONTRAST ENHANCED MAMMOGRAPHY

Noam Nissan, MD, PhD (*Presenter*)
Jeffrey S. Reiner, MD (*Abstract Co-Author*)
Yuki Arita, MD, PhD (*Abstract Co-Author*)
Tali Amir, MD (*Abstract Co-Author*)
Victoria L. Mango, MD (*Abstract Co-Author*)
Hila Fruchtman (*Abstract Co-Author*)
Rosa E. Ochoa Albiztegui, MD, MS (*Abstract Co-Author*)
Jill Gluskin, MD (*Abstract Co-Author*)
Kimberly N. Feigin, MD (*Abstract Co-Author*)
Maxine S. Jochelson, MD (*Abstract Co-Author*)
Janice S. Sung, MD (*Abstract Co-Author*)

PURPOSE

Background parenchymal enhancement (BPE) and mammographic density (MD) are imaging biomarkers derived from contrast-enhanced mammography (CEM). However, unlike MD, the consistency of BPE across consecutive examinations in pre- and postmenopausal women has remained unexplored.

METHODS AND MATERIALS

A computational search was conducted for all screening CEM exams performed at our facility between December-2012 and January-2024 to identify patients with at least five consecutive negative annual screenings. BPE grades and MD categories were extracted from the official radiology reports, and their variability parameters were statistically compared both between these factors and across age groups.

RESULTS

Forty-five eligible patients at premenopausal age-group were identified (mean age at first scan 38.2±3.4 years, range: 27-42) and a matched postmenopausal age-group was assembled (mean age at first scan 63.7±3.8 years, range: 60-74), resulting in 450 CEMs analyzed. BPE demonstrated greater variability than MD, including fluctuations of at least one point (71.1-91.1%), two-point changes (17.8-22.2%), and transitions between low and high binary distributions (17.8-27.7%) ($P<0.01$ for all). No differences were observed in the standard deviation between the two age groups ($P=0.34$).

CONCLUSION

BPE in CEM exhibits greater longitudinal variability than MD in both premenopausal and postmenopausal women, with persistent fluctuations across age groups, highlighting the dynamic nature of BPE and emphasizing the need to carefully consider its role in clinical decision-making and research.

CLINICAL RELEVANCE/APPLICATION

Further studies are needed to refine BPE's potential as a biomarker and improve its clinical utility, by using automated assessment tools and standardizing image acquisition and analysis protocols.

T7-SSBR07-1 NONINVASIVE PREDICTION OF TUMOR-INFILTRATING LYMPHOCYTES IN BREAST CANCER USING MULTIPARAMETRIC DCE-MRI RADIOMICS AND SEMANTIC FEATURES

Wenjun Yang (*Presenter*)
Xin-Gui Peng, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop and validate a machine learning model integrating multiphasic DCE-MRI radiomics and clinical semantic features for predicting tumor-infiltrating lymphocyte (TIL) levels in breast cancer.

METHODS AND MATERIALS

A total of 298 pathologically confirmed BC patients were retrospectively enrolled and stratified into two groups based on postoperative TIL levels: low TILs (<10%, n =102) and high TILs (=10%, n =196). Using 3D-Slicer software, tumor volumes of interest (VOIs) were manually delineated slice-by-slice across all six DCE-MRI phases, with 3mm peritumoral VOIs generated through margin expansion. Radiomics features were extracted separately from tumor and peritumoral regions in each phase using the FAE software. Ten machine learning algorithms were tested with five-fold cross-validation in the training set to determine the optimal model. Traditional imaging features were screened using univariate logistic regression, and features with P <0.05 were included in multivariate logistic regression to construct a combined model. Model performance was assessed by the area under the receiver operating characteristic curve (AUC), and statistical comparisons between models were conducted using DeLong's test.

RESULTS

A total of 1,688 radiomics features were extracted from tumor and peritumoral VOIs. Among intratumoral radiomics models, DCE_Phase 5 (DCE_P5) demonstrated optimal performance (training AUC=0.835; validation AUC=0.714). For peritumoral models, DCE_P3 showed the best results (training AUC=0.793; validation AUC=0.703). The combined model incorporating DCE_P5 tumor features and DCE_P3 peritumoral features achieved an AUC of 0.878 and 0.772 respectively. In semantic feature analysis, axillary lymph node status (P = 0.017) and fibroglandular tissue content (P = 0.019) were identified as significant predictors . The combined model using DCE_P5 tumor features and semantic features reached an AUC of 0.853 (training) and 0.706 (validation), while the model using DCE_P3 peritumoral features and semantic features reached an AUC of 0.792 and 0.705, respectively. A final model integrating all features achieved the highest performance (AUC_train = 0.881; AUC_valid = 0.773).

CONCLUSION

This study presents a clinically applicable radiomics model that combines multiphasic DCE-MRI features with routine semantic features to noninvasively predict TIL levels in breast cancer, potentially aiding in immunotherapy decision-making.

CLINICAL RELEVANCE/APPLICATION

The developed model provides a noninvasive method to assess tumor immune microenvironment, which may help identify patients likely to benefit from immunotherapy while maintaining compatibility with standard breast MRI protocols.

T7-SSBR07-2 ADAPTIVE AI-BASED MRI BREAST CANCER SCREENING

Ritse M. Mann, MD, PhD (*Presenter*)
Luuk Balkenende (*Abstract Co-Author*)
Jonatan Ferm (*Abstract Co-Author*)
Joren Brunekreef (*Abstract Co-Author*)
Katja Pinker-Domenig, MD, PhD (*Abstract Co-Author*)
Jonas Teuwen, MSc, PhD (*Abstract Co-Author*)

PURPOSE

Multi-parametric breast MRI offers high sensitivity for breast cancer detection, but its widespread use in screening is limited by high cost and long scan duration. Abbreviated MRI protocols reduce imaging duration but may compromise specificity and reduce available prognostic information. This study introduces an AI-based adaptive screening protocol that aims to combine the efficiency of abbreviated MRI with the diagnostic depth of full protocols by determining, at the scanner, when full imaging is necessary.

METHODS AND MATERIALS

An AI detection algorithm was developed using breast MRI scans from patients at a tertiary cancer center collected between 2004 and 2020 (n=3272). To evaluate the proposed adaptive screening protocol, the trained algorithm was retrospectively applied to an independent dataset consisting exclusively of screening cases (n=1277). In this setting, the model analyzed abbreviated MRI scans to identify suspicious regions and determine whether additional full-protocol imaging was required. The impact of the adaptive protocol was assessed by measuring average scan duration and recall rate under the assumption that any patient with an abnormality (benign or malignant) that would not directly be offered the full protocol would be recalled for performance of a full protocol scan in second instance.

RESULTS

The AI-based adaptive protocol substantially reduced average scan duration, enabling more efficient screening. A trade-off between scan duration and recall rate was observed: average shorter protocol durations (i.e., less direct scanning of a full protocol) led to higher recall rates. At a 4.8% patient recall rate for full protocol scanning, the adaptive protocol achieved 75% of the maximum potential time savings, reducing the average protocol duration to 63% of the full protocol.

CONCLUSION

AI-based adaptive screening can streamline breast MRI scanning while still acquiring full protocol information in women with abnormalities. By adjusting sensitivity and specificity thresholds, the balance between efficiency and diagnostic performance can be optimized.

CLINICAL RELEVANCE/APPLICATION

By tailoring MR scanning to individual findings, an AI-based adaptive protocol can increase accessibility and cost-effectiveness of breast cancer screening with MRI, making this MRI screening available to more women in clinical practice.

T7-SSBR07-5 ULTRAFAST BREAST MRI WITH DEEP LEARNING RECONSTRUCTION: ENHANCING IMAGE QUALITY AND REDUCING ACQUISITION TIME

Xin Weng, MBBS (*Presenter*)
Pingping Wang (*Abstract Co-Author*)
Baoying Chen (*Abstract Co-Author*)

PURPOSE

Compared to abbreviated dynamic contrast-enhanced MRI (DCE-MRI) MRI, breast ultrafast DCE-MRI enables the acquisition of multiple sequential enhanced images with high temporal resolution within one minute following contrast injection. This imaging modality not only captures early kinetic information about breast lesions but also significantly reduces scan time, making it a potentially effective screening tool. However, due to limitations in temporal resolution, the spatial resolution of ultrafast MRI is lower than that of conventional DCE-MRI, which may lead to the omission of some small breast lesions. This study aimed to investigate the feasibility of reconstructing high-resolution ultrafast DCE-MRI images using a deep learning approach.

METHODS AND MATERIALS

We retrospectively collected breast MRI data from 202 patients (165 for training and 37 for testing, selected randomly) who underwent both ultrafast and conventional DCE-MRI between August 2023 and October 2024 at our hospital. A deep learning model was developed, trained, and evaluated to reconstruct high-resolution ultrafast images from unenhanced T1-weighted images (T1WI) and actual ultrafast images. The quality of the reconstructed images was quantitatively assessed using metrics such as Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), Mean Absolute Error (MAE), and Mean Squared Error (MSE). Additionally, we analyzed the consistency of spatial resolution differences between the actual ultrafast and conventional DCE-MRI images, as well as between the actual ultrafast and reconstructed ultrafast images.

RESULTS

In the test dataset, the reconstructed ultrafast images exhibited a spatial resolution comparable to that of conventional DCE-MRI images (PSNR: 29.383 ± 2.058, SSIM: 0.849 ± 0.070, MAE: 0.017 ± 0.010, MSE: 0.001 ± 0.003). The similarity in spatial resolution between real ultrafast images and reconstructed ultrafast images (PSNR: 19.032 ± 1.488, SSIM: 0.595 ± 0.0646), as well as between real ultrafast images and conventional DCE-MRI images (PSNR: 18.990 ± 1.463; SSIM: 0.600 ± 0.050), demonstrates a high level of consistency (PSNR-ICC: 0.978 [0.977, 0.979], P<0.01; SIM-ICC: 0.849 [0.841, 0.856], P < 0.01).

CONCLUSION

Deep learning-based reconstruction is expected to generate high-resolution, ultrafast images without increasing the scanning time for breast ultrafast MRI.

CLINICAL RELEVANCE/APPLICATION

The application of deep learning to reconstruct high-resolution ultrafast DCE-MRI images shows significant promise in advancing breast MRI screening. This method can improve the efficiency of MRI procedures, reduce scan times, and enable the acquisition of high-spatial-resolution DCE-MRI images without the need for actual scanning.

T7-SSBR07-6 DIAGNOSTIC PERFORMANCE OF AI-ENHANCED LOW-DOSE GADOLINIUM BREAST MRI COMPARED TO STANDARD-DOSE PROTOCOLS

Hanna Terhaar (*Presenter*)
Kathryn W. Zamora, MD, MPH (*Abstract Co-Author*)
Ceren Yalniz, MD (*Abstract Co-Author*)
Stefanie B. Zalasin, MD (*Abstract Co-Author*)
Stefanie A. Woodard, DO (*Abstract Co-Author*)

PURPOSE

To determine whether AI combined with low-dose gadolinium breast MRI maintains diagnostic accuracy compared to standard-dose protocols.

METHODS AND MATERIALS

This prospective, IRB-approved, single-center clinical trial included 20 female participants that were chosen based on the presence of known, enhancing breast lesions. At time of exam, 10 cases had biopsy-proven breast cancer and 10 cases had no known breast cancer. Participants underwent a standard dose (0.1 mmol/kg) gadolinium-enhanced MRI followed by a low-dose (0.025 mmol/kg). Exams were conducted within 48 hours to 14 days apart. An AI algorithm was applied to enhance image quality and lesion conspicuity on both datasets. Three fellowship-trained breast radiologists independently evaluated images from 3 groups: low-dose with AI (Group 1), standard-dose without AI (Group 2), and standard-dose with AI (Group 3). Overall diagnostic performance, including sensitivity, specificity, and predictive values, were calculated. Lesion characteristics between groups were compared using Pearson's Chi-Square test for categorical variables and ANOVA for continuous variables. Fleiss' Kappa and Intraclass Correlation Coefficient (ICC) were used to determine inter-reader agreement. Pearson's Chi-Square test was used for diagnostic accuracy. Significance was set at $p < 0.05$.

RESULTS

Diagnostic sensitivity was identical across groups (83.3%), while specificity was highest in Group 1 (71.4%) compared to Group 2 (65.9%) and Group 3 (60.8%). Group 1 also had the highest positive predictive value (50.0%) and all groups shared consistently high negative predictive values. Chi-Square analysis showed no significant difference in diagnostic accuracy among groups ($X^2 = 0.981$, $p = 0.612$). Inter-reader agreement for lesion type (Kappa = 0.647, $p < 0.001$) and malignancy likelihood (Kappa = 0.527, $p <0.001$), was strong across all groups but lesion conspicuity assessments showed greater variability, particularly in AI-enhanced groups. Size measurements had fair inter-reader agreement throughout (ICC = 0.382, $p < 0.001$).

CONCLUSION

AI-assisted low-dose gadolinium breast MRI demonstrates comparable diagnostic accuracy to the standard-dose protocols. Although variability in conspicuity assessment was observed, lesion classification and malignancy evaluation remained consistent across groups.

CLINICAL RELEVANCE/APPLICATION

The results of this study highlight the potential for AI-enhanced low-dose breast MRI to serve as a safe and clinically viable alternative to standard gadolinium protocols, reducing the risks associated with gadolinium exposure while maintaining diagnostic accuracy. Implementing standardized AI interpretation training could improve consistency among radiologists.

Victor Mergen, MD (*Abstract Co-Author*)
Lukas Jakob Moser (*Abstract Co-Author*)
Chris Schwemmer (*Abstract Co-Author*)
Michael Wels (*Abstract Co-Author*)
Matthias Eberhard, MD (*Abstract Co-Author*)
Hatem Alkadhi, MD (*Abstract Co-Author*)
Bernhard Schmidt, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the impact of temporal resolution on deep learning (DL)-based automated coronary plaque quantification in patients undergoing ultra-high resolution photon-counting detector coronary CT angiography (UHR-CCTA).

METHODS AND MATERIALS

In this retrospective single-center study, 45 patients undergoing UHR-CCTA were included. For each patient, two image reconstructions were generated: one using dual-source mode (66 ms temporal resolution) and one simulating single-source mode (125 ms). A validated DL algorithm automatically quantified coronary plaque volumes and stenosis severity in both reconstructions. Quantitative analysis was performed for the entire left anterior descending artery (LAD), left circumflex artery (CX), and right coronary artery (RCA) - from the coronary ostium to the point where the vessel diameter decreased to 1.5 mm - as well as for the largest lesion within each of these vessels. Vessels without detectable plaque were excluded from analysis. Paired Wilcoxon signed-rank tests with Benjamini-Hochberg correction were used for statistical comparisons.

RESULTS

119/135 (88.1%) of evaluable coronary arteries showed the presence of atherosclerotic plaque and were included in the analysis. This comprised 45/45 (100%) LAD, 35/45 (77.8%) CX, and 39/45 (86.7%) RCA. At the vessel level, total plaque volume was lower in 28 of 45 patients (62.2%) in the 66 ms reconstructions compared to 125 ms, with calcified and non-calcified plaque volumes lower in 32 (71.1%) and 28 (62.2%) patients, respectively. Total plaque volume was significantly higher at 125 ms in the LAD (271.8 mm^3 vs. 250.4 mm^3, $P < 0.001$) and across all vessels (681.3 mm^3 vs. 647.8 mm^3, $P = 0.023$). At the lesion level, differences were more pronounced: total plaque volume was lower in 44 of 45 patients (97.8%) at 66 ms, with both calcified and non-calcified volumes lower in 42 of 45 patients (93.3%). Combined lesion plaque volume was significantly higher in 125 ms reconstructions (447.3 mm^3 vs. 414.9 mm^3, $P < 0.001$). Lumen volumes were lower and diameter stenosis grades higher in the 125 ms reconstructions (combined average stenosis: 35.4% vs. 28.1%, $P = 0.003$).

CONCLUSION

Lower temporal resolution reconstructions systematically overestimated coronary plaque burden and stenosis severity compared to higher temporal resolution in DL-based automated coronary plaque quantification in patients undergoing UHR-CCTA.

CLINICAL RELEVANCE/APPLICATION

Differences in temporal resolution significantly affect DL-based quantification of coronary plaque and stenosis on UHR-CCTA. Clinicians should be aware that lower temporal resolution may systematically overestimate plaque burden and stenosis severity, potentially impacting risk assessment and treatment decisions.

T7-SSCA06-3 AUTOMATED CORONARY ANALYSIS IN ULTRAHIGH-SPATIAL RESOLUTION PHOTON-COUNTING DETECTOR CT ANGIOGRAPHY: CLINICAL VALIDATION AND INTRA-INDIVIDUAL COMPARISON WITH ENERGY-INTEGRATING DETECTOR CT

Dmitrij Kravchenko, MD (*Presenter*)
Giuseppe Tremamunno, MD (*Abstract Co-Author*)
Milan Vecsey-Nagy, MD, PhD (*Abstract Co-Author*)
Muhammad Taha Hagar, MD (*Abstract Co-Author*)
Tilman S. Emrich, MD (*Abstract Co-Author*)
Akos Varga-Szemes, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of a deep learning (DL) -based automated coronary assessment (ACA) algorithm for the detection and classification of coronary artery disease (CAD) on ultrahigh-resolution (UHR) photon-counting detector (PCD) coronary computed tomography (CT) angiography.

METHODS AND MATERIALS

Prospectively enrolled patients underwent a PCD-CT research scan within 30 days of energy-integrating detector (EID)-CT. The ACA and two expert readers assessed all EID-CT and UHR PCD-CT reconstructions according to the coronary artery disease-reporting and data system (CAD-RADS) classification and compared them to the reference standard of invasive coronary angiography (ICA). Statistical analysis was performed based on patient stratification according to the presence of non-obstructive (CAD-RADS 0-2) or obstructive (CAD-RADS =3) lesions. After a washout period of 3 months, Reader 2 repeated all assessments using the ACA as assistance (aACA). The time taken for each reading by all experts and the ACA was recorded.

RESULTS

In total, 401 segments with 185 lesions were identified and available for intra-individual comparison in 32 patients (81.3% males, age 68.6±6.8 years). Inter-reader agreement was substantial for EID-CT (? = 0.75) and near perfect for the UHR PCD-CT datasets (? = 0.86). When compared to expert readers, the ACA achieved good to moderate sensitivity, excellent specificity, and excellent accuracy for EID-CT (Reader 1: 85.3%, 91.2%, 90.3%, respectively; Reader 2: 83.1%, 93.0%, 91.3%) and PCD-CT (Reader 1: 84.6%, 96.1%, 95.0%; Reader 2: 73.9%, 96.3%, 93.7%) on a per-segment level. When compared to the reference standard, manual coronary assessment and ACA demonstrated a similar sensitivity, specificity, and accuracy (66.7% vs 66.7%; 85.3% vs 79.4%; 83.8% vs 78.4%; respectively) on PCD-CT. The combined aACA showcased a similar sensitivity (66.7%), but with increased specificity (97.1%), and accuracy (94.6%) and were significantly faster than manual assessments with an average decrease in time of 54% (mean time: 7:17±1:50 minutes vs 3:09±0:46 minutes; p<0.001).

CONCLUSION

DL-based ACA demonstrated robust performance with substantial agreement with experts and better agreement with the ICA reference standard on UHR PCD-CT imaging compared to EID-CT. The combined use of ACA with expert assessment led to a higher specificity and significantly shorter analysis times.

CLINICAL RELEVANCE/APPLICATION

DL-assisted coronary assessments are a promising support tool for radiologists, enhancing diagnostic accuracy and workflow efficiency, and helping clinicians manage increasing workloads in routine practice.

T7-SSCA06-4 PHOTON-COUNTING CT-DERIVED ECV IN HYPERTROPHIC CARDIOMYOPATHY: A VIABLE ALTERNATIVE TO MRI

Christos V. Gkizas, MD, PhD (*Presenter*)
Benjamin Longere, MD, PhD (*Abstract Co-Author*)
Francois Pontana, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility of myocardial late iodine enhancement (LE) and extracellular volume (ECV) quantification using dual-source photon-counting detector computed tomography (PCCT) in hypertrophic cardiomyopathy (HCM) compared with cardiac MRI.

METHODS AND MATERIALS

Patients with HCM were referred for cardiac CT angiography (CCTA) on a first-generation dual-source PCCT (NAEOTOM Alpha, Siemens Healthineers) to exclude coronary artery disease and for a comprehensive cardiac MRI. The CCTA protocol was systematically associated with a LE acquisition in spectral mode, 5 minutes after contrast media injection. ECV was calculated from the iodine map of the myocardium on a dedicated platform (SyngoVia Frontier). The cardiac MRI biomarkers included T1 mapping, ECV and late gadolinium enhancement (LGE) percentage.

RESULTS

30 patients with confirmed genetic testing were retrospectively included (mean age = 59±13.8 years; 8 females). The mean dose length product of the LE scan was 105±45 mGy.cm. No significant difference was found between global ECV-CT and ECV-MRI (30.0% ± 4.8 vs 30.62 ± 4.2, P=0.59). Linear regression revealed a strong segmental correlation between ECV-PCT and ECV-MRI (basal: r = 0.89, mid-ventricular: r = 0.85, apical: r = 0.85, P <0.001). ECV-CT showed good diagnostic performance for predicting LGE =15% (Se = 80%, Sp = 76%, AUC = 0.77, 95% CI: 0.53-0.97) at a 33.4% threshold, comparable to ECV-MRI (Se = 80%, Sp = 76%, AUC = 0.80, threshold = 33.9%, P = 0.176). Both modalities showed strong negative correlation with peak VO2 (r = -0.76) and moderate to strong correlation with NT-proBNP levels (r = 0.59).

CONCLUSION

PCD-CT presents a promising non-invasive alternative to MRI in the assessment of HCM, with the potential to monitor myocardial fibrosis and enhance multimodality disease management.

CLINICAL RELEVANCE/APPLICATION

ECV quantification using PCD-CT is feasible and accurate compared to MRI,and can be achieved with a low radiation dose. ECV quantification using dual-source PCD-CT offers a promising non-invasive imaging alternative to MRI providing an incremental value to LGE for risk stratification in HCM.

T7-SSGI08-1 SUBTLE SIGNS, DISCORDANT EYES: NEAR-NORMAL PANCREAS MORPHOLOGY AND INTEROBSERVER VARIABILITY ARE BARRIERS FOR DETECTION OF PANCREATIC DUCTAL ADENOCARCINOMA (PDA) AT THE PRE-DIAGNOSTIC STAGE

Khurram K. Bhinder, MBBS (*Presenter*)
Sovanlal Mukherjee, PhD (*Abstract Co-Author*)
Ajith Antony, MBBS, MD (*Abstract Co-Author*)
Armin Zarrintan, MD (*Abstract Co-Author*)
Suresh T. Chari (*Abstract Co-Author*)
Ajit H. Goenka, MD (*Abstract Co-Author*)

PURPOSE

To characterize imaging phenotype of the pancreas and quantify interobserver variability during the prediagnostic stage (3-36 months prior to diagnosis) of PDA, thereby identifying barriers in early cancer detection.

METHODS AND MATERIALS

From 4,150 PDA cases (2006-2025), 326 pre-diagnostic CTs were identified [median lead time: 399 days (93-1,092); age: 70 (33-92); 45.7% female] and independently reviewed by 3 radiologists for predefined features and a 5-point global score. Ten randomly selected scans were used for reader calibration and excluded from analysis. Feature agreement was evaluated using Gwet's AC1; global scores were trichotomized into Normal (1-2), Equivocal (3), and Abnormal (4-5) and analyzed using quadratic-weighted kappa (?). Agreement was stratified by time to diagnosis [3-12 (133 CTs), 12-24 (105 CTs), 24-36 months (78 CTs)] and compared using 1,000 bootstrap iterations and Kruskal-Wallis test. Ground truth was assigned by majority vote (=2 readers); scans with three distinct ratings were labeled Discordant.

RESULTS

Ductal findings were infrequent yet interpreted with high agreement: MPD dilatation (32.6%, AC1=0.78), CBD dilatation (19.9%, AC1=0.80), MPD abrupt cutoff (25.3%, AC1=0.80), CBD abrupt cutoff (8.9%, AC1=0.88) and tapered narrowing of either duct (<10%, AC1=0.76-0.78). Parenchymal focal attenuation difference (FAD) was most common (45.6%) but least reproducible (AC1=0.36). Contour deformity (18.1%, AC1 = 0.59) and focal atrophy (12.4%, AC1 = 0.71) were less common but showed higher agreement. Ductal findings rose near diagnosis (e.g., MPD dilatation: 14.1%?29.5%?45.8%), but FAD remained more common (25.6%?39%? 62.4%). All findings increased in frequency near diagnosis, but agreement declined (e.g., contour deformity: 8.9%?11.4%? 28.6%, AC1=0.79? 0.66? 0.37; MPD abrupt cutoff: 7.7%?20.9%?39.0%, AC1=0.89?0.84?0.59). Global score agreement was moderate (?=0.59, 95% CI:0.53-0.65) and did not improve (? = 0.59, 0.49, 0.51 for 3-12, 12-24, and 24-36 months; p> 0.05). Unanimous scores occurred in only 45% CTs and remained stable (44.3%, 40.0%, 53.0%). Majority-vote ground truth classified most CTs as Normal (43.4%). Although Abnormal CTs increased (7.7%?21.9%?45.1%), most still showed near-normal pancreas (Equivocal 18%, Discordant 9%, Normal 27.8%) even at 3-12 months.

CONCLUSION

Early PDA often presents with near-normal pancreas morphology; rising feature prevalence is offset by declining agreement, limiting reliable prediagnostic detection on CT alone.

CLINICAL RELEVANCE/APPLICATION

Persistent interpretive variability and near-normal pancreas morphology—even within a year of diagnosis—underscore the urgent need for AI-driven tools to augment early PDA detection.

T7-SSGI08-2 MULTICENTER STUDY OF SMALL PANCREATIC ADENOCARCINOMA: COMPARISON OF CT AND MRI IMAGING FEATURES

Masamitsu Hatakenaka, MD, PhD (*Abstract Co-Author*)
Satoshi Goshima, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pancreatic cancer has a dismal prognosis, with a 5-year survival rate below 10%. However, early-stage pancreatic cancers show markedly better outcomes, with 5-year survival rates exceeding 80% for tumors smaller than 10 mm and approximately 50% for those measuring 10-20 mm. These figures underscore the critical importance of early detection. Imaging modalities capable of high tumor detectability or predictive feature identification are essential for improving patient outcomes. The purpose of this study was to compare the imaging features of small pancreatic adenocarcinomas between CT and MRI.

METHODS AND MATERIALS

This multicenter study was approved by the institutional review boards of the twelve participating centers. We enrolled 247 patients (122 men and 125 women; mean age, 70.8 years; range, 37-89 years) with histologically confirmed small (=20 mm) pancreatic adenocarcinoma, including high-grade pancreatic intraepithelial neoplasia (PanIN) (n=45), = 10mm PDACs (n=46), and 10-20 mm PDACs (n=156) who had undergone surgical resection. All patients underwent contrast-enhanced CT and MRI examinations, including T1-weighted, T2-weighted, and diffusion-weighted imaging sequences. Two radiologists independently assessed: (a) tumor delineation, (b) tumor attenuation or signal intensity, and (c) secondary signs (parenchymal atrophy, focal parenchymal atrophy, main pancreatic duct [MPD] stricture, and small cyst near MPD stricture). Frequencies of findings between CT and MRI were compared using the McNemar test.

RESULTS

None of the high-grade PanINs were demarcated on either CT or MRI (Fig. 1). Tumor delineation was significantly better on CT than on MRI for =10 mm PDACs (P=0.039) and 10-20 mm PDACs (P <0.001). However, abnormal tumor attenuation or signal intensity was more frequently observed on MRI for high-grade PanINs (P=0.023) as well as for =10 mm and 10-20 mm PDACs (both, P <0.001). The frequency of parenchymal and focal parenchymal atrophy was comparable between CT and MRI for high-grade PanINs (both, P >0.999), =10 mm PDACs (P=0.375 and =500), and 10-20 mm PDACs (P=0.250 and >0.999). MPD strictures were more readily identified on MRI for both high-grade PanINs and =10 mm PDACs (both, P=0.031). The frequency of small cysts adjacent to MPD strictures was significantly higher on MRI for high-grade PanINs, =10 mm PDACs, and 10-20 mm PDACs (all, P <0.001).

CONCLUSION

While CT demonstrates superior tumor delineation, MRI is equally or even more useful than CT for predicting tumor presence when the tumor is not clearly demarcated.

CLINICAL RELEVANCE/APPLICATION

Integration of MRI into clinical diagnostic pathways may facilitate the early detection of pancreatic adenocarcinoma, contributing to improved prognostic outcomes.

T7-SSGI08-4 UNFOLDING PANCREATIC CANCER WITH ULTRA-HIGH-RESOLUTION PHOTON-COUNTING CT - IMPROVED DIAGNOSTIC ACCURACY AND VESSEL EVALUATION

Erik Brandt, MD (*Presenter*)
Felix C. Muller, MD (*Abstract Co-Author*)
Yousef W. Nielsen, PhD (*Abstract Co-Author*)
Anne Ewald (*Abstract Co-Author*)
Bulat Ibragimov, PhD (*Abstract Co-Author*)
Henrik S. Thomsen, MD (*Abstract Co-Author*)
Michael B. Andersen, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pancreatic cancer (PDAC) has a dismal prognosis and is difficult to detect with imaging in its early stages. Photon-counting CT (PCCT) is a recent considerable improvement in CT detector technology with potential to improve the detection of early PDAC. Our aim was to investigate the diagnostic accuracy of PDAC detection with the use of dose optimized ultra-high resolution PCCT and multiplanar curved reformations (MPCR) compared to standard reformations (MPR). Our secondary aims were to investigate whether evaluation of tumor size or vessel invasion were affected by MPCR.

METHODS AND MATERIALS

This retrospective interpretation of prospectively included patients under suspicion of PDAC from October 10, 2022, until June 30, 2024. Presence of PDAC was confirmed with pathology and absence of PDAC was confirmed with a minimum follow-up of 12 months. Twelve readers of three different experience levels reviewed the two types of reformations (MPR and MPCR) in two separate sessions in a blinded, balanced, and crossed setup. Presence of PDAC and signs of vessel invasion were registered. We used a parametric multi-reader multi-case (MRMC) analysis of variance to compare diagnostic performance across reformations.

RESULTS

Sixty-one participants were included in this study (30 with PDAC [8 resected] and thirty-one normal (median age, 72 years [IQR, 62-80 years]) (30M). Mean tumor size was 46.3mm (SD 13.8mm). MRMC analysis revealed an improved sensitivity of tumor detection with the use of MPCR compared to MPR (0.98 vs 0.94, p = .048) with an unaltered specificity (0.98 vs 0.98, p = .75) for all readers as a group. A total of fifty-three vessels has tumor-to vessel contact in this study. We found a significant improvement for MPCR compared to MPR in the detection of contour abnormality of the PV/SMV (sensitivity 0.73 vs 0.67, p = .020; specificity 0.98 vs 0.99, p = .23), in the degree of tumor-to-vessel contact for both the superior mesenteric artery (reference standard 197°; MPCR 117 ° vs MPR 102 °, p = .002) and the PV/SMV (reference standard 199°; MPCR 172 ° vs MPR 147 °, p < .001), and in the measurement of tumor size (39.7mm for MPCR vs 38.0mm for MPR, p = .023). We saw an insignificant improvement in detection of tumor-to-vessel contact (sensitivity 0.91 vs 0.87, p = .10; specificity 0.95 vs 0.96, p = .21).

CONCLUSION

MPCR and ultra-high resolution PCCT improved diagnostic accuracy of PDAC detection and improved evaluation of vessel invasion compared to standard MPR reformations.

CLINICAL RELEVANCE/APPLICATION

The results suggest a possibility to minimize the considerable number of missed cases of pancreatic cancer with initial imaging. Additionally, the improvement in evaluation of vessel invasion has important implications in the evaluation of resectability of pancreatic cancers.

T7-SSGI08-5 PROSPECTIVE PANCREATIC CANCER RISK PREDICTION BASED ON IMAGING FEATURES IN NON-CONTRAST CT: A RETROSPECTIVE COHORT STUDY

Wenyi Deng (*Presenter*)
Feiyang Xie, MD (*Abstract Co-Author*)
Fuze Cong, PhD (*Abstract Co-Author*)
Zhengyu Jin, MD (*Abstract Co-Author*)
Huadan Xue, MD (*Abstract Co-Author*)

PURPOSE

Pancreatic cancer is often diagnosed late, highlighting the need for accessible, non-invasive screening methods. This study evaluates if non-contrast CT imaging features from routine abdominal or chest scans can predict pancreatic cancer occurrence within 3 years.

METHODS AND MATERIALS

We retrospectively analyzed patients undergoing non-contrast abdominal or chest CT scans (2014-2022) visualizing the pancreas. Participants were divided into two groups: a case group (n=79), diagnosed with pancreatic cancer within 3 years post-baseline CT without initial tumor suspicion, and an age- and gender-matched control group (n=98), remaining cancer-free for at least 3 years post-baseline CT. Two radiologists, blinded to patient outcomes, independently assessed baseline CT features: cystic lesions, pancreatic duct dilation (main duct =3 mm in the head or =2 mm in the body/tail), peripancreatic fat stranding, and pancreatic parenchymal atrophy (anteroposterior diameter =2 cm in the head/body or =1 cm in the tail). Combination features, including the protective absence of fat stranding and atrophy, were evaluated. The risk stratification model was constructed as follows: very high risk: high-risk features (cystic lesions or duct dilation) without protective combination; high risk: no high-risk features but atrophy present; intermediate risk: high-risk features with protective combination or isolated fat stranding; low risk: no high-risk features with protective combination.

RESULTS

Cystic lesions (OR=26.6, p<0.001) and duct dilation (OR=26.6, p<0.001) strongly predicted cancer. Pancreatic atrophy showed moderate risk (OR=7.94, p<0.001). Fat stranding alone was non-significant. Protective combination strongly reduced risk (OR=0.17, p<0.001). The developed four-tier risk stratification model significantly differentiated between case and control groups. The "very high risk" category exclusively contained cases (specificity=100%, PPV=100%). The proportion of cases increased progressively across risk categories (low: 14.5%, intermediate: 35.3%, high: 62.3%, very high: 100%). The combined "high and very high" risk categories yielded a sensitivity of 73.4% and specificity of 76.5%.

CONCLUSION

Non-contrast CT features predict pancreatic cancer occurrence. The developed risk stratification model significantly discriminates risk levels. The routine availability and non-invasive nature of non-contrast CT highlight its potential as a pragmatic, frontline screening tool for pancreatic cancer.

CLINICAL RELEVANCE/APPLICATION

Routine non-contrast CT can stratify pancreatic cancer risk, guiding targeted surveillance and reducing unnecessary procedures, especially valuable in resource-limited settings.

T7-SSGI09-3 PREDICTION OF THE NEED FOR NEOADJUVANT THERAPY IN GASTRIC CANCER PATIENTS USING A MULTIPARAMETRIC IMAGING MODEL BASED ON DUAL-ENERGY CT

Lili Guo, MD (*Presenter*)
ZHOU HAIFEI (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a multiparametric model for preoperative prediction of the need for neoadjuvant therapy in patients with gastric cancer, based on dual-energy CT-derived parameters, morphological imaging features, and tumor marker data.

METHODS AND MATERIALS

This prospective study included 113 patients who underwent abdominal dual-energy multiphase contrast-enhanced CT prior to surgery. Dual-energy CT parameters were extracted from the arterial, venous, and delayed phases. Calculated metrics included extracellular volume fraction (ECV) and iodine enhancement fraction (IEF). Two radiologists independently assessed the morphological features of the tumors on contrast-enhanced images and provided morphological staging assessments. Tumor marker results were also collected. With postoperative pathological staging as the reference standard, patients were classified into those not requiring neoadjuvant therapy (stage I-II) and those requiring neoadjuvant therapy (stage III). Feature selection was performed using univariate analysis and LASSO regression, followed by construction of a logistic regression model. The diagnostic performance of the model was evaluated using five-fold cross-validation and compared to that of conventional morphological assessment.

RESULTS

LASSO regression identified delayed-phase iodine concentration, venous-phase water content, effective atomic number, normalized iodine concentration, normalized effective atomic number, ECV, and traditional morphological diagnosis as significant predictors. The mean area under the curve (AUC) was 0.927 in the training cohort and 0.912 in the validation cohort, with no significant difference between them. Both AUCs were markedly higher than that of traditional morphological diagnosis alone (0.723). Calibration curves indicated good agreement between predicted and actual staging results. Decision curve analysis demonstrated favorable clinical applicability of the proposed model.

CONCLUSION

A multiparametric model incorporating dual-energy CT features and morphological assessment can effectively predict the need for neoadjuvant therapy in gastric cancer patients prior to surgery.

CLINICAL RELEVANCE/APPLICATION

Accurate preoperative identification of patients who may benefit from neoadjuvant therapy can guide treatment planning and help avoid both overtreatment and undertreatment.

T7-SSGI09-4 APPLICATION OF DEEP LEARNING RECONSTRUCTION BASED ON DUAL ENERGY CT IN GASTRIC CANCER

Ya Wang, DMRD (*Presenter*)

PURPOSE

o study the effect of deep learning reconstruction algorithm on abdominal image quality in patients with gastric lesions based on new double transient energy spectrum mode.

METHODS AND MATERIALS

47 cases of abdominal enhanced CT scan for energy spectrum imaging (GSI) mode scanning, four groups of date files images with different weights of ASiR-V40%, DLIR-L, DLIR-M and DLIR-H were reconstructed, The abdominal venous phase images were selected and the region of interest (ROI) was sketched at the same level by energy spectrum analysis software GSI Viewer, The CT values and noise (SD) of 40keV, 55keV and 70keV images in each ROI were obtained by further post-processing, and the signal-to-noise ratio (SNR) was calculated. Single factor variance analysis was used to compare the differences of SD and SNR reconstructed with different weights of ASiR-V, DLIR-L, DLIR-M and DLIR-H ($P < 0.05$).

RESULTS

there was no significant difference in CT value between different reconstruction algorithms and different DLIR grades. The CT values of spleen of 40keV, 55keV and 70keV single energy images were (348.87 ±45.50). 201.39 ±26.10 129.72 ±16.91) Hu In the same single energy image, the SD value of single energy image decreased gradually, the SNR increased gradually, and the image quality improved obviously in different reconstruction algorithms and different DLIR grades. The spleen SD values of 40keV, 55keV, 70keV single energy image ASiR-V40%, DLIR-L, DLIR-M, DLIR-H were (4.350 ±5.42), respectively. 42.12 ±6.31 32. 61 ±3.85 24. 26 ±4. 08 Hu, (27. 35 ±3. 07) 26.01 ±3.80 20.12 ±2.01 15.00 ±2.21) Hu, (19.56 ±2.08) 18.29 ±2.62 14.08 ±1.27 10.56 ±1.37) Hu There were significant differences in SD and SNR between the two groups ($P < 0.05$). There were significant differences in subjective scores of reconstructed images between different algorithms ($P < 0.001$).

CONCLUSION

the deep learning reconstruction technique based on new double transient energy spectrum mode can optimize the image quality of abdominal energy spectrum.

CLINICAL RELEVANCE/APPLICATION

the depth reconstruction technology based on new double transient energy spectrum scanning mode can optimize the abdominal energy spectrum image quality, and the depth reconstruction technology based on new double transient energy spectrum scanning mode can further improve the abdominal energy spectrum image quality without increasing the radiation dose.

T7-SSGI09-5 CAN SPECTRAL COMPUTED TOMOGRAPHY (CT) REPLACE PERFUSION CT TO EVALUATE THE LYMPHOVASCULAR AND PERINEURAL INVASION OF GASTRIC CANCER?

Tiezhu Ren, MD, MMEd (*Presenter*)

PURPOSE

The presence of lymphovascular invasion (LVI) and perineural invasion (PNI) in patients with gastric cancer (GC) is an independent risk factor for recurrence and metastases. However, the LVI/PNI status can only be retrieved from postoperative pathological specimens. The purpose of this study was to investigate the correlation between spectral computed tomography (CT) and CT perfusion parameters.

METHODS AND MATERIALS

We prospectively analyzed 87 patients with gastric adenocarcinoma. All cases were confirmed by pathology and underwent "one-stop" spectral and perfusion CT imaging examination. Patients were divided into positive (n=65) and negative (n=22) groups depending on LVI/PNI occurrence. The effective atomic number (Zeff), iodine concentration (IC), and water concentration were measured in the arterial (AP) and venous (VP) phases. The blood flow (BF), blood volume (BV), mean transit time (MTT), capillary permeability surface area product (PS), and time to max (Tmax) were measured in the perfusion imaging. Spearman correlation analysis was used to detect the correlation between spectral parameters and perfusion parameters. Parameter differences between the two groups were compared. Receiver operating characteristic (ROC) curves were plotted.

RESULTS

The LVI/PNI-positive group's Zeff, IC, BV, and MTT were substantially greater than those of the negative group. There was no significant correlation between the spectral parameters (Zeff, IC) in AP and the perfusion parameters (all $P>0.05$). There was a strong correlation between the spectral parameters in VP and the perfusion parameters BV, and VP-Zeff, VP-IC and BV were strongly correlated, with correlation coefficients of 0.746 and 0.751, respectively (all $P<0.001$). The evaluated efficiency of the combination of spectral-CT and CT-perfusion parameters was superior to that of individual parameters. The BV and MTT combined with Zeff and IC in AP and VP exhibited good evaluation efficacy (AUC=0.827; F1=0.892).

CONCLUSION

The "one-stop" spectral-perfusion CT imaging has good value in the preoperative evaluation of LVI/PNI in GC. There is a correlation between the spectral parameters and the perfusion parameters, and the venous spectral parameter IC can be used as a reference index for the perfusion parameter BV. The evaluated efficiency of the combination of spectral-CT and CT-perfusion parameters was superior to that of individual parameters. Spectral computed tomography (CT) can replace perfusion CT to evaluate the lymphovascular and perineural invasion of gastric cancer.

CLINICAL RELEVANCE/APPLICATION

Spectral computed tomography (CT) can replace perfusion CT to evaluate the lymphovascular and perineural invasion of gastric cancer.

T7-SSGI09-6 OPTIMIZING PRE-OPERATIVE CT DIAGNOSIS OF SEROSAL INVASION IN ADVANCED GASTRIC CANCER BY USING ARTIFICIAL INTELLIGENCE ITERATIVE RECONSTRUCTION

Xiaolong Gu (*Presenter*)
Lingwei Kong (*Abstract Co-Author*)
Jintao Han (*Abstract Co-Author*)
Yang You (*Abstract Co-Author*)
Wanhui Zhou (*Abstract Co-Author*)
Li Yang (*Abstract Co-Author*)

PURPOSE

Serosal invasion in advanced gastric cancer suggests a higher probability of peritoneal metastasis, warranting neoadjuvant chemotherapy to achieve tumor downstaging and higher R0 resection rates. Thus, accurate diagnosis of serosal invasion is critical for guiding treatment selection. This study aims to investigate the clinical value of artificial intelligence iterative reconstruction (AIIR) in optimizing pre-operative CT diagnosis of serosal invasion in advanced gastric cancer.

METHODS AND MATERIALS

This retrospective study included 45 patients with pathology confirmed advanced gastric cancer (61.2±11.2 years, male: 36). CT data were reconstructed using both hybrid iterative reconstruction (HIR) and AIIR. Two radiologists independently diagnosed the serosal invasion of gastric tumor using a 5-point confidence scale (1, definitely absent; 2, probably absent; 3, indeterminate; 4, probably present; 5, definitely present). In case of discrepancy, the radiologists achieved consensus through negotiation. Receiver operating characteristic (ROC) analysis was performed to assess the diagnostic performance, using the surgical pathology results as the reference. The diagnostic image quality, regarding the tumor margin conspicuity, gastric wall layer differentiation, and serosa visualization, was scored by the two radiologists using a 5-point scale (1: unrecognizable, 5: excellent). The contrast-to-noise ratio (CNR) was also calculated for the tumor with the normal gastric wall as background.

RESULTS

Serosal invasion of tumor was confirmed in 24 of the 45 patients (53.3%) by surgical pathology. The area under the ROC curve of the AIIR and HIR images for diagnosing serosal invasion was 0.843 and 0.621, respectively, showing significant improvement using AIIR ($p < 0.001$). Compared with HIR images, AIIR images showed higher sensitivity (70.8% vs 50.0%), specificity (85.7% vs 66.7%), accuracy (77.8% vs 57.8%), positive predictive value (85.0% vs 63.2%), and negative predictive value (72.0% vs 53.8%). The diagnostic image quality across all three metrics were scored better and the tumor CNR was 34.0% higher on AIIR images (all $p < 0.001$).

CONCLUSION

Compared to HIR, AIIR improved the diagnostic performance on serosal invasion of tumor in pre-operative CT imaging of advanced gastric cancer.

CLINICAL RELEVANCE/APPLICATION

The artificial intelligence iterative reconstruction demonstrates the potential to improve the accuracy of pre-operative CT staging in advanced gastric cancer and could be implemented to optimize treatment strategy planning.

T7-SSIN03-1 AN INTEGRATED DATABASE AND QUERY SYSTEM WITH LARGE LANGUAGE MODEL INTEGRATION FOR MANAGING LARGE-SCALE ANNOTATED CT IMAGING DATASETS

Felipe Lopez-Ramirez, MD (*Presenter*)
Alejandra Blanco (*Abstract Co-Author*)
Emir Syailendra, MD (*Abstract Co-Author*)
Florent Tixier, PhD (*Abstract Co-Author*)
Satomi Kawamoto, MD (*Abstract Co-Author*)
Linda C. Chu, MD (*Abstract Co-Author*)
Elliot K. Fishman, MD (*Abstract Co-Author*)

PURPOSE

To develop and implement a scalable approach for managing large-scale radiological databases that integrate clinical data, multiple semantic segmentation annotations, and longitudinal imaging timepoints. The system aims to enable structured data retrieval, allowing for natural language querying, and streamlined export to different machine learning workflows.

METHODS AND MATERIALS

We designed a custom database architecture based on Python/Tkinter and a JSON hierarchical structure to store metadata including scan dates, image reconstruction parameters, multiple segmentation versions, and clinical labels for each CT study while adhering to HIPAA regulations. The system was built to accommodate complex real-world data scenarios including repeated imaging, evolving annotations, and multiple imaging and segmentation sources. To support interactive querying, a "talk-to-your-data" module was implemented by transforming the JSON structure into an SQL format that supports integration into common RAG (retrieval-augmented generation) frameworks powered by locally served large language models. Users can issue natural language queries to retrieve patient metadata, segmentation availability, and imaging characteristics. Additionally, an export module was developed to generate machine learning-ready datasets based on inclusion criteria, complete with automated data splits and preprocessing configurations.

RESULTS

The database currently manages 7,255 CT volumes with associated clinical information and corresponding semantic segmentation data for arterial and venous phases. The system supports real-time queries on segmentation completeness, scan chronology, and case inclusion criteria. Natural language queries (e.g., "export all patients with venous scans and pancreatic tumors under 2 cm") return results in under 30 seconds. Exported datasets have successfully supported the training and evaluation of machine learning models under varied inclusion scenarios.

CONCLUSION

This database framework enables robust management of large-scale, annotated CT imaging datasets with multiple timepoints and segmentation files. By combining structured metadata with natural language querying and customizable export tools, it effortlessly brings powerful querying capabilities into the clinical setting of image repositories and aids AI model development.

CLINICAL RELEVANCE/APPLICATION

Our system empowers radiology research teams to manage, query, and prepare large-scale annotated CT datasets efficiently, accelerating the development and validation of AI algorithms for diagnostic and prognostic applications. This could facilitate the integration of AI-derived insights into the routine clinical workflow of radiologists.

T7-SSIN03-2 IMPROVING CLINICAL AI INTEGRATION WITH GSPS: ENHANCING STORAGE AND TRANSFER EFFICIENCY IN RADIOLOGY WORKFLOWS

Abhishek Gupta (*Presenter*)
Easwar Lakshmi Narayanan, MD (*Abstract Co-Author*)
Sarang Ingole, MBBS (*Abstract Co-Author*)
Vidur Mahajan, MBA, MBBS (*Abstract Co-Author*)

PURPOSE

To evaluate and compare the efficiency of Grayscale Softcopy Presentation State (GSPS) versus Secondary Capture (SC) for storing and visualizing AI outputs in DICOM format, focusing on storage efficiency, clinical usability, and scalability across imaging modalities.

METHODS AND MATERIALS

In clinical AI workflows, outputs such as regions of interest (ROIs), annotations, and classification labels are typically stored using either SC or GSPS. SC generates a new image series by embedding visual overlays into duplicated images, which increases storage load and consumes full display viewports in PACS viewers. In contrast, GSPS references the original DICOM images and stores visual overlays as lightweight, toggleable vector layers, preserving the original images and minimizing additional storage demands. This study assessed the storage and transfer efficiency of both formats across four modalities: X-ray, CT, MRI, and mammography. We simulated AI-generated outputs for 1,000 studies per modality, calculating storage requirements and estimating transfer times using a 0.5 Gbps network under a sequential upload scenario, assuming one AI output file per study.

RESULTS

GSPS demonstrated substantial advantages over SC across all modalities. Storage requirements decreased by up to 49.5% for X-ray, 44.4% for CT and MRI, and 16.7% for mammography. Network transfer times were dramatically reduced, with GSPS shortening transfer times by up to 99.9%, effectively enabling near-instantaneous transmission even for large CT and MRI studies where SC required several seconds per study. In addition to technical gains, GSPS overlays could be toggled on or off within the PACS, improving clinical usability by preserving the primary diagnostic image and avoiding additional viewport use.

CONCLUSION

GSPS is a highly efficient and scalable solution for storing and transmitting AI-generated overlays in radiology workflows. Compared to SC, GSPS substantially reduces PACS storage burden, accelerates network transfers, and enhances clinical usability by maintaining original image fidelity while allowing dynamic display of AI overlays. These advantages make GSPS the preferred approach for integrating AI outputs into routine and high-volume radiology practices, supporting scalable, efficient, and clinician-friendly deployment of AI in medical imaging.

CLINICAL RELEVANCE/APPLICATION

Integrating AI outputs using GSPS improves radiology workflows by reducing storage demands, accelerating image transfers, and enabling seamless overlay visualization without compromising diagnostic images — making it ideal for routine and high-volume clinical settings.

T7-SSIN03-3 AN NLP AND PIXEL-BASED DATA HARMONIZATION APPROACH ACHIEVES 98.1% ACCURACY IN SERIES NAMING STANDARDIZATION ON A LARGE BRAIN VALIDATION DATASET

Thomas C. Arnold, PhD (*Presenter*)
Dayang Wang (*Abstract Co-Author*)
Brennan McFarland (*Abstract Co-Author*)
Soumya Mohanty (*Abstract Co-Author*)
Lanhong Yao (*Abstract Co-Author*)
Praveen Gulaka, PhD (*Abstract Co-Author*)
Ajit Shankaranarayanan (*Abstract Co-Author*)
Greg Zaharchuk, MD, PhD (*Abstract Co-Author*)

PURPOSE

Magnetic Resonance Imaging (MRI) is widely used in both clinical and research settings. However, sequence naming conventions are not standardized and vary based on differences in imaging protocols, scanner vendors, and institutional practices. As a result, MRI series descriptions often appear inconsistent, and DICOM metadata can be unreliable or conflicting. As radiology continues to scale, with larger practices and researchers aggregating massive datasets, it becomes increasingly difficult to verify sequence information. The goal of this study is to create an efficient, automated method for standardizing MRI sequence naming.

METHODS AND MATERIALS

The naming standardization pipeline relies on three methods to predict MRI sequence types: an NLP-based algorithm, a pixel-based algorithm, and rule-based logic. The NLP model (a transformer pretrained on ~500,000 sequences) parses metadata tags to generate an initial prediction. For sequence types where metadata is often inaccurate (e.g. T1 vs T1c), a pixel-based method (ResNet50 trained on ~5,600 cases) is activated for more accurate distinctions. Finally, a rule-based logic layer checks specific metadata fields linked to specialized sequence types with reliable tags (e.g. MRA, DWI) and performs final verification. The pipeline minimizes reliance on the Original Series Description tag, which can be altered by technologists, causing inconsistencies. The algorithm currently supports predictions for sequence type, anatomy, orientation, acquisition, and sequence variant, which are used to generate standardized series descriptions (e.g., "Brain Ax T1_SE"). We tested the algorithm on a heterogeneous brain MRI dataset with 623 sequences from 15 different sites with ground truth labels.

RESULTS

The dataset includes 13 sequence types (T1, T1c, T2, T2-FLAIR, DWI, MRA, T2*, SWI, SSFP, ASL, ADC, CAL, and LOC), covering nearly all common neuroimaging sequence types. The algorithm achieved an accuracy of 98.1% on sequence classification and after standardization the total number of unique series descriptions was reduced by 66%. The algorithm also reached 99%+ accuracy on anatomy classification, though this offers limited insight as the dataset included only brain data.

CONCLUSION

The proposed method enables MRI metadata standardization and shows high accuracy in brain MRI sequence classification. It enhances the reliability and efficiency of MRI data organization, retrieval, and downstream analysis, aiding both research and standardization across large clinical organizations.

CLINICAL RELEVANCE/APPLICATION

The proposed data harmonization method can standardize MRI naming convention across large organizations and datasets, significantly improving radiologist workflows.

T7-SSIN03-4 AUTOCLAIM: A WEB APPLICATION FOR AUTOMATED CLAIM CHECKLIST COMPLETION

Anna Zapaishchykova, MSc (*Presenter*)
Keno K. Bressem, MD (*Abstract Co-Author*)
Charles E. Kahn JR, MD, MS (*Abstract Co-Author*)
Bardia Khosravi, MD, MPH (*Abstract Co-Author*)

PURPOSE

The CLAIM (Checklist for Artificial Intelligence in Medical Imaging) framework promotes transparency and reproducibility in AI imaging research but requires significant time and effort when completed manually. We developed AutoCLAIM, a web application that automates CLAIM checklist generation from research manuscripts using large language models (LLMs).

METHODS AND MATERIALS

Among 440 evaluated checklist items, the LLM achieved 80.5% accuracy in evaluating CLAIM criteria and extracting relevant supporting text. In 7.3% of cases, items were missing but sufficient information was found elsewhere; 6.4% had sufficient items but were marked as missing; 5.2% contained no relevant text; and 0.7% included incorrect evidence. Individual article performance ranged from 43.2% to 95.5% accuracy, with Article A showing the lowest and Article B showing the highest accuracy. Performance was lower for complex study designs and benchmarking articles where relevant details were less explicitly stated. Processing costs for all 10 articles were $12.97.

RESULTS

Among 440 evaluated checklist items, the LLM achieved 80.5% accuracy in evaluating CLAIM criteria and extracting relevant supporting text. In 7.3% of cases, the LLM indicated items were missing but sufficient information was found elsewhere; 6.4% had sufficient items but were incorrectly marked as missing; 5.2% contained no relevant text; and 0.7% included incorrect evidence. Individual article performance ranged from 43.2% to 95.5% accuracy. Performance was lower for complex study designs and benchmarking articles where relevant details were less explicitly stated. Processing costs for all 10 articles were $12.97.

CONCLUSION

AutoCLAIM streamlines CLAIM checklist completion through AI assisted review, manual editing capabilities, and export options in JSON or HTML formats. Further refinement is needed for nuanced content recognition, particularly in complex study designs.

CLINICAL RELEVANCE/APPLICATION

AutoCLAIM enhances efficiency and consistency in AI research reporting, supporting more reliable clinical translation of AI models in medical imaging.

T7-SSIN03-5 TRANSPARENT AI FOR LIVER CANCER DIAGNOSIS IN MRI WITH EXPLANATIONS IN LI-RADS LANGUAGE

Kenji Suzuki, PhD (*Presenter*)
Dichao Liu (*Abstract Co-Author*)
Masatoshi Hori, MD, PhD (*Abstract Co-Author*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

PURPOSE

To enhance the clinical applicability of AI-based liver tumor diagnosis, we developed a novel interpretable AI system that mimics radiologists' decision-making based on LI-RADS. The system integrates concept-guided reasoning and graph-based modeling to generate structured LI-RADS-style reports from liver MRI, promoting transparency and trust in clinical practice.

METHODS AND MATERIALS

We used 277 contrast-enhanced liver MRI studies (114 patients; 107 malignant and 170 benign tumors) annotated with LI-RADS features. To support transparent and interpretable AI in liver tumor diagnosis, we developed a system that mimics radiologists' reasoning by first predicting clinically meaningful features and then integrating them into structured LI-RADS reports. After preprocessing to extract tumor-centered regions, a MobileNetV2-based concept bottleneck model identifies key imaging features—such as APHE and restricted diffusion—and models their interrelationships using a graph-based structure. This allows the system to capture patterns that radiologists associate with malignancy, such as the presence of restricted diffusion without peripheral globular enhancement. The system outputs both a malignancy likelihood and an interpretable report aligned with LI-RADS standards, helping clinicians make informed decisions with greater confidence and consistency.

RESULTS

We performed 5-fold cross-validation , with all reported results averaged across folds . Twelve LI-RADS features were considered important across all folds, namely: APHE, nonperipheral "washout," corona enhancement, restricted diffusion, mild-to-moderate T2 hyperintensity, transitional phase hypointensity, nodule-in-nodule architecture, blood products in mass, marked T2 hyperintensity, hepatobiliary phase isointensity, ring enhancement, and hepatobiliary phase hypointensity. Our approach first trained a LI-RADS prediction model to predict the presence (1) or absence (0) of these features, achieving an overall mean presence/absence classification accuracy of 0.84. Then, the predicted LI-RADS features were input into a tumor classification model, achieving an AUC of 0.88. This model outperformed several state-of-the-art (SOTA) deep learning models, including MedMamba (0.76), CoAtNet (0.83), and EfficientNetV2 (0.77).

CONCLUSION

We present a clinically aligned, interpretable AI system capable of predicting liver tumor malignancy with structured LI-RADS-style explanations and achieving the highest diagnostic performance of SOTA models.

CLINICAL RELEVANCE/APPLICATION

By modeling concept relationships and generating structured LI-RADS reports, our system enhances clinical transparency and supports radiologist decision-making.

T7-SSIN03-6 CT-DERIVED BIOMARKERS SHOW STRONGER ASSOCIATIONS WITH SOCIOECONOMIC DEPRIVATION COMPARED TO BMI

John W. Garrett, PhD (*Abstract Co-Author*)

PURPOSE

Body Mass Index (BMI) is widely used in population health studies and disparities research, yet it cannot differentiate bone, fat, or muscle composition. In contrast, automated analysis of abdominal CT scans includes muscle, fat, and bone biomarkers that can be assessed on a population health scale. Our work evaluates whether CT-derived biomarkers, including muscle density, visceral adipose tissue (VAT) area, and first lumbar bone mineral density (BMD), are more associated with census tract-level socioeconomic disparities compared to BMI.

METHODS AND MATERIALS

We utilized statewide retrospective abdominal CT scans collected at our institution between 2000 and 2021. BMI values came from electronic health records and AI body composition tools quantified L3 average muscle density (HU), L3 total VAT area (cm^2), and L1 BMD (HU). Non-physiological values, out-of-state patients, and ZIP codes with <= 30 patients were excluded. Biomarker values were age-normalized using per-patient differences from 10-year age-group medians. We converted aggregated ZIP code-level biomarker values to census tract values by using the proportion of ZIP code overlap in a census block as a weighted sum of biomarker values. Only census tracts above a 0.9 proportional area with the ZIP code were included. The Area Deprivation Index (ADI), a census-tract level national percentile measure factoring income, education, employment, and housing quality, was used to represent socioeconomic disadvantage. Higher ADI rankings indicate greater disadvantage. Spearman correlations between ADI, BMI, and each CT-derived biomarker were performed.

RESULTS

Our data included 805 state-wide census tracts (median number of patients per census tract: 69) aggregated from 108,908 adult patients (56,638 F). Spearman correlations showed that muscle density, BMD, and VAT area had greater associations with ADI than BMI: muscle density (?=-0.41, $p<0.001$), BMD (?=-0.2, $p<0.001$), VAT area (?=-0.24, $p<0.001$), BMI (? = 0.15, $p < 0.001$).

CONCLUSION

CT-derived biomarkers (muscle density, BMD, and VAT area) are more strongly associated with socioeconomic deprivation (ADI) compared with BMI.

CLINICAL RELEVANCE/APPLICATION

CT-derived biomarkers may serve as stronger indicators of population health level disparities than BMI.

T7-SSIN04-1 GAZE2REPORT: USING RADIOLOGISTS' GAZE TO IMPROVE AUTOMATIC REPORT GENERATION

Prateek Prasanna, PhD (*Presenter*)
Gagandeep Singh, MD, MBA (*Abstract Co-Author*)

PURPOSE

Existing methods for automated radiology report generation focus on improving natural language generation (NLG) quality but often lack clinically grounded alignment with disease manifestations due to the absence of human-centered priors. Eye gaze data offers a valuable window into radiologist decision-making but is seldom integrated into automated reporting systems. We propose Gaze2Report , a framework that incorporates radiologist visual attention through gaze-informed graph neural networks (GNNs) to guide large language models (LLMs) for clinically accurate radiology report generation, even in the absence of eye gaze during inference.

METHODS AND MATERIALS

Gaze2Report comprises two primary components: a visual-gaze token generation module and a multimodal prompt-tuned LLM decoder. Eye gaze vectors are derived from a scanpath prediction model (MedGaze), and combined with image patch embeddings using a GNN to produce joint visual-gaze features. These are projected into the LLM feature space and concatenated with instruction and report tokens to create a unified prompt. We fine-tune low-rank adapter layers of the LLaMA2-7B model for autoregressive report generation. Experiments were conducted on three benchmark chest X-ray datasets (REFLACX, IU-XRAY, MIMIC-CXR), evaluating both NLG quality (BLEU, METEOR, ROUGE-L) and clinical efficacy (CheXbert-derived F1, precision, recall, and BERTScore).

RESULTS

Gaze2Report outperformed baselines (R2GenGPT, EGGCA-Net) across all NLG and CE metrics. On MIMIC-CXR, Gaze2Report achieved BLEU-4 of 0.137, METEOR of 0.167, and F1 score of 0.444. Even without gaze at inference, the scanpath prediction module maintained performance over a purely image-only baseline. On REFLACX, Gaze2Report outperformed baselines both with and without gaze availability. Qualitative comparisons showed that Gaze2Report-generated reports contained more clinically precise terminology compared to baselines.

CONCLUSION

By incorporating gaze-informed embeddings and aligning them with a radiologist’s visual search behavior, Gaze2Report enhances the contextual understanding and factual accuracy of generated reports. This visual grounding enables more interpretable and trustworthy outputs, bridging the gap between AI-generated content and clinical reasoning. The inclusion of an on-the-fly scanpath predictor enables its deployment even without eye-tracking hardware, making it robust for real-world clinical scenarios.

CLINICAL RELEVANCE/APPLICATION

Gaze2Report offers a scalable and interpretable AI solution for radiology report generation that emulates expert visual reasoning. This approach holds promise for improving reporting efficiency in high-volume clinical settings.

T7-SSIN04-2 MONITORING COMMERCIAL RADIOLOGY AI TOOLS WITH AN IN-HOUSE FOUNDATION MODEL

Camila Gonzalez, DPhil (*Presenter*)
Zhongnan Fang, PhD (*Abstract Co-Author*)
Hye Sun Na (*Abstract Co-Author*)
David B. Larson, MD, MBA (*Abstract Co-Author*)
Akshay Chaudhari, PhD (*Abstract Co-Author*)

PURPOSE

To enable real-time monitoring of radiology AI tools by training a vision-language model with in-house CT scans and radiology reports. Our approach improves sensitivity by identifying missed findings without requiring structured labels during training or accompanying reports during inference.

METHODS AND MATERIALS

We retrieved 4,648 in-house non-contrast head CT studies (median age 69.4 years, 43.7% female). The vendor system under evaluation was an FDA-cleared model for intracranial hemorrhage (ICH) detection. ICH findings were extracted from radiology reports using the LLaMA 3.1 large language model (LLM) and evaluated on a subset of 1,068 manually curated labels. A vision-language model initially trained on 15,331 abdominal CT scans was fine-tuned on the head CTs and corresponding reports via contrastive language-image training for 12 hours on an NVIDIA L40 GPU. For each scan, we extracted model embeddings and computed the mean cosine distance to true negative (i.e., ICH neither present nor detected by the vendor model) cases in the training set. Test studies (N=706) with high distance scores—indicating deviation from typical ICH-negative patterns—were flagged as likely to contain ICH based on a threshold selected with validation (N=735) data.

RESULTS

The LLM report-derived ICH labels correspond with a 0.97 accuracy to the manually annotated subset. The vendor model obtained a sensitivity of 0.64 and specificity of 0.83 on the in-house test set, misidentifying 206 from 567 ICH-positive studies. The distance distributions between false negatives (FN) and true negatives (TN) were significantly different across all splits ($p < 0.001$; Mann-Whitney U), indicating that FNs can be identified from image embeddings. By selecting decision thresholds using validation data, we increased the model’s sensitivity on the test set from 0.64 to 0.75 (+67) and further to 0.81 (+99), with moderate (+58, +77) rises in false positives.

CONCLUSION

Foundation models trained with routinely collected images and radiology reports can monitor commercial AI tools post-deployment. Circumventing the need for manual annotations and finding-specific models, they offer a scalable solution to flag potential failures across multiple AI products addressing different clinical needs.

CLINICAL RELEVANCE/APPLICATION

AI tools are increasingly integrated into radiologic workflows, yet manufacturers rarely provide oversight strategies for in-house data despite differences in acquisition protocols causing discrepancies between the reported and real-world performances. Our framework allows institutions to calibrate black-box, commercially available tools to clinically acceptable sensitivity thresholds by flagging potentially missed findings.

T7-SSIN04-4 ARE WE REPORTING AI WELL? A CONSORT-AI AUDIT OF RADIOLOGY TRIALS

Joyce Ang, BSc (*Presenter*)
Emmanuel Salinas SR, MD (*Abstract Co-Author*)
Xin Dong (*Abstract Co-Author*)
Xiaoxuan Liu (*Abstract Co-Author*)
Matthew D. McInnes, MD, PhD (*Abstract Co-Author*)

PURPOSE

We evaluated the completeness of reporting the Consolidated Standards of Reporting Trials in Artificial Intelligence (CONSORT-AI) in Randomized Control Trials (RCT) evaluating artificial intelligence in radiology practice.

METHODS AND MATERIALS

A literature search was conducted in MEDLINE, Embase, the Cochrane Central Register of Controlled Trials (CENTRAL), the Database of Abstracts of Reviews of Effects (DARE), and the Cochrane Database of Systematic Reviews (CDSR) for medical imaging RCTs published between January 2000 and June 2024 with AI interventions integrated to the clinical practice impacting diagnosis, follow-up or treatment of the patient. Reporting was assessed per item using the CONSORT-AI checklist. Items were classified as infrequently (<33%), moderately (33-66%), or frequently (>66%) reported. We compared the completeness of reporting between CONSORT-AI endorsers versus non-endorsers RCTs using a risk ratio (RR) with a 99% confidence interval for each outcome and random-effects model for all analyses. A RR greater than 1 indicated relatively increased reporting of any CONSORT item.

RESULTS

Thirty-one RCTs were included, with a median (Q1, Q3) of 72% (60, 80%) of CONSORT-AI items reported. Reporting completeness was significantly higher in studies published in higher-impact journals (18 vs. 12; P = 0.004) and those with larger sample sizes (median [Q1, Q3]: 628 [275, 4198.5] vs. 109 [100, 406.5]; P = 0.015). Most checklist items were frequently reported (17/25), though subitems related to `Interventions`, `Outcomes`, and `Harms` were less commonly addressed. Pooled relative risks (RRs) across assessed CONSORT-AI items indicated higher adherence among RCTs endorsing CONSORT-AI compared to those without endorsement, with a pooled RR of 1.12 (99% CI, 1.06 to 1.28).

CONCLUSION

Reporting of AI-based RCTs in radiology remains suboptimal. Nonetheless, endorsement of the CONSORT-AI Statement appears to positively influence reporting completeness in medical journals.

CLINICAL RELEVANCE/APPLICATION

Reporting of AI-based RCTs in radiology remains suboptimal, which may hinder safe clinical adoption. Greater adherence to CONSORT-AI can improve transparency and support more reliable patient care.

T7-SSIN04-5 AUTOMATED, EFFICIENT EXTRACTION OF STRUCTURED METADATA FOR RADIOLOGY AI MODELS AND DATASETS

Abhinav Suri, BA, MPH (*Presenter*)
Rohit Reddy, MD (*Abstract Co-Author*)
Ricardo A. Gonzales Vera, DPhil (*Abstract Co-Author*)
Marcelo S. Takahashi, MD, PhD (*Abstract Co-Author*)
Charles E. Kahn JR, MD, MS (*Abstract Co-Author*)
Shahriar Faghani, MD (*Abstract Co-Author*)

PURPOSE

Artificial Intelligence (AI) research has increased rapidly over the past two decades. Thus discoverability of AI models and datasets used to train/evaluate AI is of utmost importance. “Model card” summary documents have been popularized to communicate findings; however, these model cards are unstandardized and do not capture critical information that clinicians and healthcare regulators need to know. Accordingly, the Radiology Ontology for AI Datasets, Models, and Projects (ROADMAP) has been established to describe models and datasets in radiology. The schema underlying this ontology can be used to create model and dataset cards if individuals extract structured information; however, doing so can be cumbersome, ultimately hampering widespread adoption. To address this shortcoming, we create and evaluate an automatic pipeline to extract structured information from documents describing radiological AI models and datasets.

METHODS AND MATERIALS

We utilized a corpus of published papers from the Radiology: Artificial Intelligence journal and GPT-4o (v08/2024 with structured outputs) to extract 40 fields in ROADMAP’s underlying schema. After trialing multiple approaches on a set of 5 articles and 2 RSNA grand challenge description documents, we created a two-step pipeline. First, GPT is prompted to summarize the article given descriptors of ROADMAP schema sub-fields. Next, the summary is passed into a structured output prompt using the schema to establish the format. We ran this pipeline on 54 articles and had researchers rate each subfield output as either being correct (2 pts), partially correct but incomplete (1), or incorrect (0). We report the time and cost required to run this pipeline along with an analysis of ratings for the extracted model and dataset ROADMAP schema data.

RESULTS

Articles took 1 minute and 13 seconds to run (±15 seconds; ±1SD). The average cost per article was $0.046±0.003 (USD). 81.5% of extracted subfields were correct as is, 15.5% were correct but incomplete, and 3.0% were incorrect. The average number of points for the model and dataset fields were similar (1.76 vs 1.78, p=0.35, t-test) and there was no correlation between model/dataset scores and length of papers (in tokens, Pearson’s R=-0.036, p=0.13, not different from R=0).

CONCLUSION

We show that our automated pipeline can extract information from radiological AI models and datasets in a manner that is reasonably cheap, efficient, and accurate. Future work includes validating this model on a larger corpus of data such as regulatory/healthcare product documents.

CLINICAL RELEVANCE/APPLICATION

This pipeline can be used for enabling discoverability of AI models and datasets. Doing so can fuel research and product development in applications that can benefit patients.

T7-SSMK06-2 REVEALING THE INVISIBLE: DEEP LEARNING ENABLES AUTOMATIC CARTILAGE SEGMENTATION ON NON-CONTRAST CT

Paul Margain (*Presenter*)
Julien Favre (*Abstract Co-Author*)
Patrick Omoumi, MD, PhD (*Abstract Co-Author*)

PURPOSE

Computed tomography (CT) is the reference standard for the evaluation of mineralized tissues like bone, yet it fails to visualize soft tissues such as cartilage without the use of invasive intra-articular contrast injection, thereby limiting its utility for comprehensive joint assessment. Deep learning's power in discerning subtle image patterns offers an opportunity to overcome this fundamental limitation. This study aims to develop and validate a novel framework for fully automatic knee cartilage segmentation directly from standard non-contrast CT scans, using high-resolution MRI as the reference standard.

METHODS AND MATERIALS

This study utilized same-day non-contrast CT and DESS MRI scans from 430 participants in the Lausanne Knee Study. Manual MRI cartilage segmentations, serving as ground truth, were carefully registered to the CT space using a previously validated method. A 3D U-Net was trained (n=328) and tested (n=102) to predict cartilage masks from non-contrast CT (Figure 1). Accuracy was assessed using Dice Similarity Coefficient (DSC), and morphological agreement via regional cartilage thickness correlations. Clinical relevance was evaluated by comparing an automatic severity score of osteoarthritis based on the analysis of cartilage patterns (CTh-Score) between osteoarthritic (OA; Kellgren-Lawrence =2) and non-OA knees.

RESULTS

The deep learning model achieved excellent cartilage segmentation performance on CT in the test set (n=102), with mean DSC > 0.90 for femur and tibia. CT-derived cartilage thickness measurements exhibited strong correlations with MRI manual segmentations (Pearson’s r ranging from 0.87 to 0.92 across regions). The CT-derived CTh-Score effectively differentiated OA from non-OA knees as did the MRI-based assessments.

CONCLUSION

This study showed the feasibility and validated a deep learning framework that accurately segments knee cartilage on non-contrast CT. This breakthrough demonstrates strong morphological correlations with MRI and immediate clinical utility for OA assessment, potentially enhancing the CT diagnostic capabilities in the context of osteoarthritis. Further validation in other cohorts is needed; however, a key strength of CT is its typical acquisition standardization compared to MRI, which could facilitate broader applicability and generalizability.

CLINICAL RELEVANCE/APPLICATION

This deep learning framework enables morphological evaluation of cartilage directly from non-contrast CT scans, where cartilage is typically poorly distinguishable by the human eye. This is particularly valuable in situations where MRI is inaccessible, contraindicated for the patient, or when CT scans are already acquired for other purposes.

T7-SSMK06-3 ARTIFICIAL INTELLIGENCE-ASSISTED 3D WEIGHT-BEARING IMAGING TO ASSESS LOWER LIMB ALIGNMENT AND ITS CORRELATION WITH CHARACTERISTICS OF KNEE OSTEOARTHRITIS

Zejun Liang (*Presenter*)
Zhenlin Li (*Abstract Co-Author*)
Jing Tang (*Abstract Co-Author*)

PURPOSE

Assessing lower limb alignment is essential for tracking progression of knee osteoarthritis and for guiding treatment, but this cannot be done reliably with traditional 2D imaging. This study aimed to evaluate artificial intelligence-assisted 3D weight-bearing imaging for measuring the spatial hip-knee-ankle (HKA) angle in patients with knee osteoarthritis, and to explore associations of the angle with disease characteristics.

METHODS AND MATERIALS

This study prospectively analyzed 151 patients with knee osteoarthritis in Kellgren-Lawrence grades 1-4 from two medical centers. A 3D U-Net segmentation model was used to determine HKA angles from 3D weight-bearing images, and the performance of the model was evaluated in terms of the Dice similarity coefficient, recall, and volume similarity. Reproducibility was assessed in terms of the intraclass correlation coefficient between HKA angles determined twice two weeks apart in 20 patients. Potential associations of HKA angles were explored with osteoarthritis severity, joint space narrowing, and scores on the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

RESULTS

The segmentation model showed high mean Dice similarity coefficient, recall and volume similarity in the internal test set (0.968, 0.977, and 0.989) and external test set (0.944, 0.960, and 0.974), and the intraclass correlation coefficient was 0.98. Reconstruction of 3D deformities based on HKA angle showed that varus-flexion deformities became increasingly prevalent with advancing Kellgren-Lawrence grade, such that they occurred in most patients in grade 3 (67.2%) and grade 4 (89.1%). The spatial HKA angle increased with Kellgren-Lawrence grade and correlated more strongly with joint space narrowing (r = 0.52-0.61) and WOMAC scores (r = 0.45-0.56) than traditional 2D HKA angles did.

CONCLUSION

Artificial intelligence-assisted 3D weight-bearing imaging can reliably determine spatial hip-knee-ankle angles in patients with knee osteoarthritis, and the angles correlate with various disease characteristics. Varus-flexion deformity becomes increasingly prevalent as disease progresses and is dominant in advanced disease.

CLINICAL RELEVANCE/APPLICATION

Three-dimensional weight-bearing imaging combined with artificial intelligence can determine lower limb alignment with excellent reproducibility. Varus-flexion deformity becomes more prevalent as knee osteoarthritis progresses and is the most dominant deformity in advanced stages of the disease. Spatial hip-knee-ankle angle correlated moderately with the extent of joint space narrowing and patient-reported pain, stiffness, and functional limitation.

T7-SSMK06-4 COMPARISON OF ANTERIOR TIBIAL TRANSLATION AND FEMOROTIBIAL ROTATIONMEASUREMENTS IN MRI AND WEIGHT BEARING CT IN PATIENTS WITH CHRONIC ANTERIOR CRUCIATE LIGAMENT TEARS

Renata V. Leao, MD (*Presenter*)
Sandro Ricardo Benites Zelada (*Abstract Co-Author*)
Paulo Victor P. Helito, MD (*Abstract Co-Author*)
Carlos F. Teixeira Lobo, MD (*Abstract Co-Author*)
Catherina Zadeh, MD, FRCR (*Abstract Co-Author*)
Riccardo G. Gobbi (*Abstract Co-Author*)
Andre Giardino Moreira Da Silva (*Abstract Co-Author*)
Camilo P. Helito (*Abstract Co-Author*)

PURPOSE

To compare anterior tibial translation (ATT) and femorotibial rotation (FTR) measurements obtained from conventional MRI and weight-bearing CT (WBCT) in patients with chronic anterior cruciate ligament (ACL) tears.

METHODS AND MATERIALS

This retrospective study included 23 patients chronic ACL tears who underwent both conventional knee MRI and knee WBCT in flexion and extension. ATT and FTR were measured Statistical analysis was performed using repeated measures ANOVA and Sidak post-hoc tests, with a significant level of 5%.

RESULTS

A total of 23 patients were enrolled WBCT in flexion demonstrated significantly higher values for key kinematic parameters compared to MRI and WBCT in extension. Lateral ATT was significantly greater on WBCT in flexion (8.6 ± 3.4 mm) than on MRI (4 ± 3.6 mm; $p < 0.001$), with no significant difference between MRI and WBCT in extension ($p = 0.705$). Femorotibial rotation (FTR) was also significantly increased on WBCT in flexion (12 ± 5.6°) compared to MRI (7.3 ± 5.5°; $p < 0.001$), while lower values were observed on WBCT in extension (3.6 ± 4.7°; $p = 0.002$). Medial ATT did not differ significantly between WBCT in flexion and MRI ($p = 0.988$) but was significantly higher on WBCT in extension (6 ± 3 mm vs. 3.1 ± 2.4 mm; $p = 0.003$).

CONCLUSION

WBCT, particularly in flexion, demonstrates greater ATT and FTR than MRI, suggesting higher sensitivity to functional instability.

CLINICAL RELEVANCE/APPLICATION

Weight-bearing CT in flexion reveals greater anterior tibial translation and femorotibial rotation than MRI, enhancing detection of functional instability in chronic ACL tears and potentially guiding more precise treatment planning for improved patient outcomes.

T7-SSMK07-1 ASSESSMENT OF TRABECULAR BONE MICROARCHITECTURE USING PHOTON-COUNTING DETECTOR CT AT VARIOUS RADIATION DOSES AS COMPARED TO HIGH-RESOLUTION PERIPHERAL QUANTITATIVE CT

Edwin H. Oei, MD, PhD (*Presenter*)
Melissa Bevers (*Abstract Co-Author*)
Joeri Kok (*Abstract Co-Author*)
Caroline Wyers (*Abstract Co-Author*)
J Van Den Bergh (*Abstract Co-Author*)
B Vanrietbergen (*Abstract Co-Author*)
Ronald Booij, PhD, MSc (*Abstract Co-Author*)

PURPOSE

To compare trabecular microarchitecture measurements in distal radius and tibia specimens from photon-counting detector CT (PCD-CT) at various radiation doses with the in-vivo gold standard high-resolution peripheral quantitative CT (HR-pQCT).

METHODS AND MATERIALS

PCD-CT and HR-pQCT scans were taken of two wrist and two ankle specimens from an 88-year old Caucasian man. The specimens had been kept intact to mimic in-vivo conditions. PCD-CT scans were taken of a 80-mm region and reconstructed at a slice thickness of 0.2 mm, a slice increment of 0.1 mm, and a pixel size of 0.111-0.127 mm using a Qr89-kernel. Radiation dose was varied at 2.5, 5, 10, and 20 mGy (effective dose: ~4-35 µSv). HR-pQCT scans were taken of a 102-mm (wrists) and 51-mm region (tibiae), which included the clinically standard HR-pQCT region. The scans were reconstructed at a voxel size of 61 µm. Effective radiation dose was 50 µSv (wrists) and 25 µSv (tibiae). The PCD-CT and HR-pQCT scans were pre-processed, after which the trabecular bone on the images was segmented and split into cubes (6-mm edge length). For each cube, bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), and trabecular heterogeneity (Tb.1/N.SD) were quantified and compared using linear regression between corresponding PCD-CT and HR-pQCT cubes, with cube correspondence based on three-dimensional image registration of the PCD-CT and HR-pQCT scans.

RESULTS

PCD-CT captured the trabecular microarchitecture of the specimens visually well compared to HR-pQCT. Coefficients of determination (R 2) were 0.72-0.97 at 2.5 mGy and remained stable with increasing radiation dose for all parameters except Tb.1/N.SD. For Tb.1/N.SD, R 2 increased from 0.72 at 2.5 mGy to 0.85 at 5 mGy and stabilized at higher doses. At every radiation dose, BV/TV and Tb.Th and to a smaller extent Tb.N were higher on PCD-CT than on HR-pQCT, while Tb.1/N.SD was lower.

CONCLUSION

Trabecular microarchitecture measurements in radius and tibia specimens strongly correlated between PCD-CT and HR-pQCT at already low radiation dose for PCD-CT and without large improvement at higher doses. The higher values of especially BV/TV and Tb.Th on PCD-CT than on HR-pQCT may be due to a larger partial volume effect and likely lower resolving power of thin trabeculae on PCD-CT due to its lower spatial resolution, although optimization of image processing and analysis protocols may help to reduce this difference.

CLINICAL RELEVANCE/APPLICATION

PCD-CT has potential for bone microarchitecture assessment in clinical practice and possibly also as one-shop-stop examination in (pre-operative) evaluations of fractures. It has a lower spatial resolution than HR-pQCT but several advantages and possibilities regarding scan acquisition.

T7-SSMK07-2 RETHINKING OSTEOPOROSIS SCREENING: OUTCOMES FROM A 15-YEAR RETROSPECTIVE ANALYSIS OF DEXA SCANS

Helen Kwon, BA (*Presenter*)
Michaela Kop (*Abstract Co-Author*)
Kyle Ishikawa (*Abstract Co-Author*)
Lana H. Gimber, MD (*Abstract Co-Author*)
Hyo-chun Yoon, MD, PhD (*Abstract Co-Author*)

PURPOSE

According to USPSTF guidelines, DEXA screening for osteoporosis is recommended for all women aged 65 and older and at-risk younger women. Despite recommendations, screening rates remain low nationwide, increasing the risk for osteoporosis-related complications. This study examined the rate of conversion to osteoporosis in women whose initial DEXA scan was performed before age 65 compared to those 65 and older within an integrated healthcare system.

METHODS AND MATERIALS

We conducted a retrospective analysis of women who underwent more than one DEXA scan from 1/1/2010 to 3/31/25. For each scan, we recorded the lowest T-score, bone mineral density, location, date, and patient age. Statistical analyses were conducted using Kaplan-Meier curves to nonparametrically estimate survival probability, and p-values were determined by a log-rank test. The median and 80% time to event were calculated using the corresponding quantiles while considering right-censoring.

RESULTS

There were 2,205 women under age 65 and 2,375 women aged 65 and older at the time of their initial DEXA scan. Among women 65+ years, 27.4% were osteoporotic (T-score =-2.5), compared to 19.1% of women <65 years. Among those who became osteoporotic on subsequent scans, the median time to osteoporosis was 13.3

years for the younger group and 12.2 years for the older group (p<.001). The number of years for 80% of the population to remain non-osteoporotic was 8.7 years for women <65 and 7.7 years for women 65+ (p<.001). When comparing women who initially had normal-to-mild osteopenia (T-score =-1.9) to those with moderate-to-severe osteopenia (T-score -2.0 to -2.4), the number of years for 80% of the population to remain non-osteoporotic was 12.2 and 4.8 years, respectively (p<.001). The median time to osteoporosis for the moderate-to-severe osteopenia group was 9.4 years (p<.001). There was no median time to event for normal-to-mild osteopenia, as most were right-censored before 50% could convert to osteoporosis.

CONCLUSION

Women who underwent initial screening <65 years old took longer to convert to osteoporosis and had a longer 80% survival time, which may suggest that early screening may not improve detection. Women who initially had a T-score =-1.9 took significantly longer to convert to osteoporosis compared to those with a T-score of -2 to -2.4, suggesting that frequent repeat screening at intervals <5 years should be reserved for moderate-to-severe osteopenic individuals.

CLINICAL RELEVANCE/APPLICATION

Osteoporosis trends within this integrated healthcare system suggest that there should be greater emphasis on appropriate initial screening as well as less frequent interval imaging, especially in women not osteoporotic or only mildly osteopenic at initial screening.

T7-SSMK07-3 DIAGNOSTIC ACCURACY OF DUAL-ENERGY CT-BASED ONE-STOP PREDICTIVE MODEL FOR BONE MINERAL DENSITY ASSESSMENT COMPARED WITH QUANTITATIVE COMPUTED TOMOGRAPHY

Mingyue Zhao, MMedSc (*Presenter*)
Hong Ren (*Abstract Co-Author*)

PURPOSE

The purpose of this study was to establish diagnostic criteria for bone status assessment using dual-energy computed tomography (DECT) material decomposition technique through comparison with quantitative computed tomography (QCT).

METHODS AND MATERIALS

Totally 255 patients who underwent both unenhanced and contrast-enhanced (arterial-, venous- and delayed-) phase abdominal DECT were divided into four groups A, B, C, D according to their ages (<30years, 30-49years, 50-69years, =70years). QCT standard scanning and reconstruction parameters were used in the unenhanced phase, and spectral imaging mode was used in the enhanced phases. The bone densities of hydroxyapatite (iodine) (D HAP (iodine)) in the trabecular bone of vertebral bodies (L1-L3) were measured, along with bone mineral density (BMD) via QCT. Spearman's correlation test was performed to analyze the relationship between the DECT- and QCT-derived BMD. According to the diagnostic criteria of QCT, D HAP (iodine) of osteoporosis, osteopenia and normal vertebral bodies were compared by One-Way ANOVA. ROC curves were generated to determine the optimal diagnostic thresholds of HAP (Iodine) for diagnosing osteopenia and osteoporosis and normal bone mass. The correlated fitting curve between D HAP (iodine) of L3 and age in each group was established and analyzed.

RESULTS

D HAP (iodine) was positively related to QCT BMD (r =0.960, P <0.05). The differences in D HAP (iodine) among different age groups were statistically significant (P <0.05). D HAP (iodine) showed no correlation to age in group A (P> 0.05). D HAP (iodine) were negatively correlated with age in groups B, C and D (r =-0.467, -0.506, -0.426, P <0.05), and overall high negative correlation with age for patients =30years (r =-0.733,P <0.05): D HAP (iodine) = -1.059 * age + 751.642 2mg/cm 3 . There were significant differences in D HAP (iodine) among osteoporosis, osteopenia and normal group (P <0.05). The area under the ROC curve, sensitivity, and specificity for identifying osteopenia were 0.987, 92.77%, and 95.97% with D HAP (iodine) =695.92 (2mg/cm 3), respectively. The corresponding values for identifying osteoporosis were 0.963, 92.63%, 89.51% and with D HAP (iodine) =677.34 (2mg/cm 3), respectively.

CONCLUSION

The one-stop DECT-based predictive model for quantification of vertebral BMD demonstrates technical feasibility and high diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

1. Development of a simplified BMD predictive model leveraging population-based demographic data. 2. Implementation of a one-stop examination protocol enabling real-time acquisition of clinically actionable BMD metrics related to diagnosis.

T7-SSMK07-4 DEEP LEARNING ANALYSIS OF CHEST RADIOGRAPHS OUTPERFORMS FRAX IN PREDICTING MAJOR OSTEOPOROTIC FRACTURES

Yisak Kim, PhD (*Presenter*)
Chang Min Park, MD, PhD (*Abstract Co-Author*)
Sung Hye Kong (*Abstract Co-Author*)

PURPOSE

FRAX is widely used for predicting fracture risk but is limited by its dependence on dual-energy X-ray absorptiometry (DXA) and low responsiveness to short-term fracture events. This study aimed to develop and validate a deep learning (DL) model based on chest radiography (CXR) to predict major osteoporotic fractures (MOFs), and to evaluate its predictive performance compared to FRAX.

METHODS AND MATERIALS

This multicenter retrospective study included 42,014 patients (mean age, 59.3 years; 79.8% women) from Institution A (2008-2019) for model development and 31,821 patients (mean age, 64,6 years; 72.4% women) from Institution B (2003-2022) for external validation. CXR images were preprocessed using localized energy-based normalization, and convolutional neural network (CNN) models were trained separately for original and normalized images. A logistic hazard loss function was used to directly model time-to-event data. Predictive performance was evaluated using Concordance index (C-index) and time-dependent area under the receiver operating characteristic curve (AUROC) at 2, 3, 5 and 10 years.

RESULTS

In the internal test set (n=5,000), the DL model achieved a C-index of 0.867, significantly outperforming FRAX (C-index, 0.800; P<.001). The 2-, 3-, 5- and 10-year AUROCs for the DL model were 0.878, 0.887, 0.886, and 0.899 respectively, also significantly higher than FRAX (AUROCs, 0.805, 0.804, 0.805, and 0.832; all P<.001). In the external test set (n=31,821), the DL model yielded C-indices of 0.780, outperforming FRAX (C-index, 0.767; P<.001). The 2-, 3-, 5- and 10-year AUROCs for the DL model were 0.804, 0.816, 0.831, and 0.865 respectively, also significantly higher than FRAX (AUROCs, 0.774, 0.780, 0.784, and 0.810; all P<.001). The DL model also demonstrated strong performance across fracture subtypes: C-indices of 0.828 (vertebral), 0.710 (non-vertebral), and 0.833 (hip); with 2-, 3-, 5- and 10-year AUROCs ranging from 0.715 to 0.879 depending on fracture type.

CONCLUSION

The DL model using chest radiographs significantly outperformed FRAX in predicting major osteoporotic fractures. This image-based approach may provide a more accessible and accurate tool for fracture risk assessment in clinical practice.

CLINICAL RELEVANCE/APPLICATION

This DL-based approach enables fracture risk prediction from widely available chest radiographs, offering a practical and accessible alternative to DXA-based assessments, with potential to improve early detection and preventive care in clinical practice.

T7-SSMK07-5 INCLUSION OF THE 33% RADIUS INCREASES THE SENSITIVITY OF DXA IN PRIMARY HYPERPARATHYROIDISM

Alain E.
Sherman, MD, MBA (*Presenter*)
Rakan Alqaqaa (*Abstract Co-Author*)
Kai Jones, MD (*Abstract Co-Author*)
Jenny T. Bencardino, MD (*Abstract Co-Author*)
Kwang J. Chun, MD (*Abstract Co-Author*)

PURPOSE

Patients with primary hyperparathyroidism routinely undergo screening for osteoporosis using dual-energy X-ray absorptiometry (DXA) due to accelerated bone resorption and resulting impaired bone mineral density (BMD). Parathyroid hormone preferentially exerts catabolic effects on cortical bone found in the distal forearm over trabecular bone in the lumbar spine or hip. Nonetheless, the 33% radius is not routinely included in most DXA imaging protocols. We sought to investigate the added diagnostic value of the 33% radius in DXA screening of patients with primary hyperparathyroidism.

METHODS AND MATERIALS

Three hundred twenty-five patients with primary hyperparathyroidism underwent DXA screening for osteoporosis as part of standard of care. BMD measurements were taken at the 33% radius of the non-dominant forearm, L1 through L4 vertebral bodies, and femoral neck. Age-matched T-scores were standardized using NHANES III population datasets. Patients were classified as having normal BMD, osteopenia, or osteoporosis according to WHO reference standards. Regression analysis and repeated measures analysis of variance (ANOVA) were used to compare T-scores at the 33% radius, lumbar spine, and femoral neck. McNemar-Bowker test was used to compare the proportions of patients diagnosed with normal BMD, osteopenia, and osteoporosis at each anatomic site.

RESULTS

T-scores at the 33% radius were moderately correlated with those at the lumbar spine, $r = 0.58$, $p < 0.001$, and femoral neck, $r = 0.54$, $p < 0.001$. T-scores at the 33% radius ($M = -1.12$, $SD = 1.51$) were significantly lower than at the lumbar spine ($M = -0.48$, $p < 0.001$) and femoral neck ($M = -0.96$, $SD = 1.29$, $p = 0.04$), $F(2, 314) = 25.68$, $p < 0.001$?. There were statistically significant differences in the distribution of patients diagnosed with normal BMD, osteopenia, and osteoporosis according to the 33% radius, lumbar spine, and femoral neck, $p < 0.001$. The incidence of osteoporosis was highest at the 33% radius (20.3%), significantly greater than the lumbar spine (13.5%, $p < 0.001$) and femoral neck (9.8%, $p < 0.001$).

CONCLUSION

Imaging of the 33% radius increases the sensitivity of DXA in patients with primary hyperparathyroidism. For 65 patients (20.0%), inclusion of the 33% radius upstaged the diagnostic classification from normal BMD to osteopenia or osteopenia to osteoporosis.

CLINICAL RELEVANCE/APPLICATION

Inclusion of the 33% radius in DXA screening identifies a significant proportion of patients with primary hyperparathyroidism at risk of osteoporotic fractures not captured by the lumbar spine or femoral neck alone.

T7-SSMK07-6 INTRAVENOUS CONTRAST MEDIA-RELATED VARIATIONS IN CT-DERIVED BODY COMPOSITION METRICS: ASSOCIATIONS WITH SEX AND ADIPOSE TISSUE

Tae Ran Ahn, MD, MD (*Presenter*)

PURPOSE

To investigate changes in CT-derived body composition metrics following intravenous contrast administration and identify factors associated with muscle enhancement.

METHODS AND MATERIALS

This retrospective study included 88 healthy adults (61 men; mean age, 60.97±7.12 years) who underwent three-phase abdominal CT. Deep learning-based software segmented skeletal muscle, visceral fat, subcutaneous fat, and intermuscular adipose tissue (IMAT) at the L3 level. Repeated-measures ANOVA assessed phase-dependent changes in tissue areas (cm 2) and attenuation (HU). McNemar's test compared sarcopenia and myosteatosis prevalence between precontrast and portal phases. Regression analyses identified factors associated with muscle enhancement, defined as absolute attenuation difference and percentage change from precontrast to portal phase.

RESULTS

Body composition metrics showed significant phase-dependent variations. From precontrast to arterial and portal phases, skeletal muscle index (cm 2 /m 2) increased ($p < 0.001$), while visceral fat index decreased ($p < 0.001$), and subcutaneous fat index remained unchanged ($p = 1.000$). All tissue attenuation metrics rose significantly across phases ($p < 0.001$). These shifts lowered the prevalence of sarcopenia (26.2% to 16.9%, $p = 0.031$) and myosteatosis (64.6% to 29.2%, $p < 0.001$) from precontrast to portal phase. Women consistently demonstrated greater muscle enhancement than men across each phase comparison. In overall multivariable analysis, greater muscle enhancement was associated with female sex (absolute difference: $b = 1.39$, $p = 0.011$; percent change: $b = 1.75$, $p < 0.001$), lower precontrast subcutaneous fat attenuation (SFA) (absolute difference: $b = 0.98$, $p = 0.020$; percent change: $b = 0.97$, $p = 0.009$), and older age (percent change: $b = 1.02$, $p = 0.004$). Sex-specific multivariable analyses revealed that lower precontrast SFA in women (absolute difference: $b = 0.94$, $p = 0.024$; percent change: $b = 0.95$, $p = 0.014$) and higher IMAT proportion in men (percent change: $b = 1.32$, $p = 0.022$) correlated with greater muscle enhancement.

CONCLUSION

CT-derived body composition metrics vary considerably across contrast phases, leading to potential reclassification of sarcopenia and myosteatosis. Muscle enhancement exhibits sex-specific patterns related to regional adipose tissue distribution, with lower precontrast SFA in women and higher IMAT in men associated with greater enhancement.

CLINICAL RELEVANCE/APPLICATION

Understanding the influence of contrast phase, sex-specific enhancement patterns, and regional adipose tissue distribution on CT-derived muscle metrics is critical for accurate sarcopenia and myosteatosis assessment in routine clinical imaging.

T7-SSNPM02-2 THE TYRANNY AND CHAOS OF SMALL NUMBERS: A PROBABILISTIC OPEN-ACCESS STAFFING CALCULATOR TO MITIGATE PATIENT RISK, REDUCE BURNOUT, AND PROMOTE RETENTION IN EMERGENCY RADIOLOGY STAFFING

Daniel T. Kawakyu-O'Connor, MD (*Presenter*)
Katherine A. Kaproth-Joslin, MD, PhD (*Abstract Co-Author*)
James Bai, MD (*Abstract Co-Author*)
Jeffrey Kallas, MD (*Abstract Co-Author*)

PURPOSE

Radiologist staffing decisions in emergency settings are often based on mean hourly exam volumes or relative value units (RVU), despite wide variability in real-world demand. This approach oversimplifies complexity and contributes to chronic understaffing, turnaround time (TAT) delays, and increased burnout risk. We developed a probabilistic modeling framework to support institutional leaders in aligning staffing levels with service targets, safety thresholds, and workforce sustainability goals.

METHODS AND MATERIALS

Hourly CT volumes were modeled using Poisson distributions, enabling estimation of the probability that a given staffing configuration could meet operational goals—such as interpreting all exams within a 60-minute TAT. Radiologist capacity was modeled as fixed hourly throughput. The tool was applied to 12 months of overnight CT data at a Level 1 trauma center to compare mean-based planning with variability-aware projections. An open-access calculator was developed to allow other institutions to perform similar analyses. Sites with empirical variance data can further refine the model by relaxing the assumption that mean equals variance.

RESULTS

At our institution, overnight staffing of 3 radiologists met 90% of the average hourly demand. However, Poisson modeling revealed that five radiologists would be required to meet demand 85% of the time. Mean-based planning significantly underestimated the risk of TAT breaches during surge conditions. Detailed application examples and calculator demonstrations will be presented.

CONCLUSION

This model corrects a fundamental mismatch between the traditional staffing logic in diagnostic imaging based on metrics of exam volume —where volume is high and variability is low—and emergency radiology, where small team sizes amplify the effects of stochastic demand. It offers a scalable, transparent framework to inform staffing decisions and balance safety, efficiency, and cost.

CLINICAL RELEVANCE/APPLICATION

Variability-aware staffing models are essential in high-acuity, resource-constrained environments. This on-line tool supports radiology leaders and administrators in advocating for safer, more staffing levels—helping to prevent burnout, improve patient flow, and sustain the emergency radiology workforce in the face of rising clinical demand and limited personnel. It also highlights the risk of emphasizing inappropriate metrics of productivity such as exam volume or RVU when developing staffing strategies.

T7-SSNPM02-3 TURNING ABSENCE INTO OPPORTUNITY: A 6-YEAR ANALYSIS OF NO-SHOW MANAGEMENT IN RADIOLOGY SERVICES

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)
Juan Cruz Gallo, MD, MD (*Abstract Co-Author*)

PURPOSE

Patient no-shows remain a significant challenge in radiology departments worldwide, with rates reported as high as 25% in some institutions. These absences lead to underutilization of imaging equipment, disrupt workflow, and cause substantial financial losses. Proactive, automated patient confirmation processes are essential to maintain scheduling efficiency and ensure high productivity. This study aims to demonstrate how a large imaging center successfully achieved and sustained a significant reduction in no-show rates through a structured, multichannel patient confirmation system. It also quantifies the long-term impact on productivity and revenue.

METHODS AND MATERIALS

We evaluated no-show rates from 2018 to 2025 across all imaging departments modalities. In 2018 (baseline), no confirmation system was in place. In 2019, a WhatsApp-based confirmation protocol was introduced with automated reminders sent at 72, 48, and 24 hours prior to the scheduled exam. Patients were able to confirm or cancel their appointment, and if cancelled, the time slot was automatically released for rebooking. Follow-up tracking was performed annually to assess the sustainability of no-show reduction. Economic analysis was based on an estimated average loss of USD 30,000 per 1% of no-show.

RESULTS

The no-show rate in 2018 was 15%. After the implementation of the confirmation system, the annual rates were: 2019: 9.51%; 2020: 12.41% (increase due to the COVID-19 pandemic); 2021: 10.01%; 2022: 8.15%; 2023: 7.36%; 2024: 6.79%: 2025 (YTD): 6.62% Between 2018 and 2025, the no-show rate decreased by 55%, corresponding to an 8.38 percentage point improvement. In 2024, our institution performed 968,769 patient studies with a no-show rate of 6.79%. If the 2018 no-show rate (15%) had persisted, the number of completed studies would have been significantly lower. The improvement achieved between 2018 and 2024 resulted in approximately 79,535 additional patients being scanned in 2024 alone. Given that each percentage point of no-show reduction represents an estimated value of USD 30,000, this improvement translates to a financial gain of approximately USD 251,400 in productivity and billing.

CONCLUSION

Reducing no-show rates is essential for optimizing resource use and financial performance in radiology departments. A structured and automated patient confirmation process—leveraging widely used platforms such as WhatsApp—proved highly effective and sustainable over a six-year period. Maintaining low no-show rates offers significant operational and economic benefits and should be a priority in imaging service management.

CLINICAL RELEVANCE/APPLICATION

Low no-show rates offers significant operational and economic benefits.

T7-SSNPM02-4 REPEAT IMAGING RATES FOR OFFICE-BASED IMAGING STUDIES INTERPRETED BY NON-PHYSICIAN PRACTITIONERS COMPARED WITH RADIOLOGISTS

Eric Christensen, PhD (*Presenter*)
Alexandra Drake (*Abstract Co-Author*)
Stella Kang, MD, MSc (*Abstract Co-Author*)
Elizabeth Y. Rula, PhD (*Abstract Co-Author*)
Andrew B. Rosenkrantz, MD (*Abstract Co-Author*)

PURPOSE

Non-physician practitioners (NPPs) have been associated with higher rates of imaging ordering compared with physicians and, over time, have performed an increasing share of imaging interpretation. Repeat imaging, a potential source of waste that can occur if initial image interpretation is inadequate, has not been evaluated in association with NPP interpretation. Accordingly, the purpose of this study is to examine differences in repeat imaging rates between imaging studies interpreted by an NPP versus a radiologist.

METHODS AND MATERIALS

This multiyear (January 2013 to December 2022) retrospective study evaluated imaging performed on Medicare fee-for-service beneficiaries using a 5% nationally representative, research identifiable sample from CMS. Imaging families (i.e., combination of body region and modality) with =30 repeat studies within 90 days for both NPP-interpreted and radiologist-interpreted index studies were included. Logistic regression was used to assess the likelihood of repeat imaging within 90 days for NPP-interpreted versus radiologist-interpreted index studies, adjusted for patient sex, age, race/ethnicity, comorbidities, urbanicity, and community income.

RESULTS

There were 1,397,002 imaging studies that met the selection criteria. Of these, repeat imaging occurred for 12.5%. Unadjusted repeat imaging rates were higher for NPP-interpreted versus radiologist-interpreted imaging for radiography (20.4% vs 15.1%), ultrasound (11.6% vs 4.6%), and MR (8.8% vs 3.9%). Adjusted for covariates, the odds ratio (OR) for repeat imaging was higher for NPP-interpreted versus radiologist-interpreted imaging: 1.35 (95%CI: 1.33, 1.37) for XR, 2.41 (95%CI: 2.21, 2.63) for ultrasound, and 2.56 (95%CI: 1.81, 3.64) for MR. By imaging family, these ORs ranged from 1.39 (95%CI: 1.34, 1.44) for shoulder XR to 3.40 (95%CI: 2.80, 4.14) for abdominal US, except for knee XR for which it was not significantly different (OR: 1.01, 95%CI: 0.99, 1.04).

CONCLUSION

Among Medicare beneficiaries, imaging studies are more likely to be repeated when interpreted by a NPP than when interpreted by a radiologist.

CLINICAL RELEVANCE/APPLICATION

The insights into potential drivers of repeat imaging are important given the implications of excess reimaging for system-level unnecessary care, associated patient harm, and higher healthcare costs.

T7-SSNPM02-5 NATIONAL TRENDS AND PREDICTORS OF MALPRACTICE PAYMENTS IN U.S. RADIOLOGY: A 33-YEAR ANALYSIS OF THE NATIONAL PROVIDER DATA BANK

Ashima Kundu, BS (*Presenter*)
Sachin Govind (*Abstract Co-Author*)
Divya Kumari, MD (*Abstract Co-Author*)

PURPOSE

Radiologists experience substantial risk for malpractice litigation, with diagnostic errors driving many malpractice claims. Prior studies have relied on surveys or legal repositories, which may not reflect national trends. National-scale analyses leveraging objective data sources remain limited. This study assesses malpractice claims involving radiologists in the United States, compares them to non-radiology claims, evaluates predictors of higher payment, and analyzes temporal and regional trends in radiology litigation.

METHODS AND MATERIALS

We retrospectively analyzed all physician malpractice payment records in the National Practitioner Data Bank from 1991-2024. Radiology-related claims were identified based on coded allegations involving imaging errors. Comparative analyses were performed across patient, case, physician, and state-level factors. Payment trends over time and regional variation were assessed relative to radiologist employment and compensation. High- versus low-payment radiology claims were compared to identify factors associated with larger indemnity amounts using standard statistical methods.

RESULTS

We analyzed 399,568 total physician malpractice cases from 1991-2024. Diagnostic errors accounted for >70% of radiology claims. Compared to non-radiology cases, radiology suits more often involved outpatient care (50.5% vs. 20.6%, $p < .001$), severe outcomes (64.2% vs. 32.3%, $p < .001$), and higher mean payments ($374,248±$11,210 vs. $290,437±$825, $p < .001$). Higher-payment radiology claims were associated with severe outcomes (84.8% vs. 43.6%, $p < .001$), out-of-state filings (33.1% vs. 24.9%, $p < .001$), lower settlement rates (96.7% vs. 99.2%, $p < .001$), and higher likelihood of originating in more litigious states (42.4% vs. 31.9%, $p < .001$). Regional analyses showed that most states experienced an increase in radiological malpractice incidence over time ($p = .006$). More recent cases had higher payments ($412,050±14478 vs. $285,958±15377, $p < .001$) and were more likely to be filed across state lines compared to older cases ($p < .001$).

CONCLUSION

Radiology malpractice claims, driven largely by diagnostic errors, were more likely to involve severe outcomes, occur in outpatient settings, cross state lines, and result in higher payments than non-radiology claims. Higher payment stems from more severe outcomes, and these patterns have intensified over time.

CLINICAL RELEVANCE/APPLICATION

Radiologists face unique medicolegal risks, particularly related to diagnostic errors in outpatient settings. Understanding the predictors of high-payment claims and evolving trends can inform risk management strategies, guide practice improvements, and support policy efforts to reduce litigation exposure.

T7-SSNPM02-6 AFFIRMATIVE ACTION IN U.S. ACADEMIC RADIOLOGY: LONGITUDINAL AND CROSS-SECTIONAL ANALYSIS OF GENDER, RACE, AND ETHNICITY

Mujtaba Ibrahim, MD, BSc (*Presenter*)
Mansimran Virk (*Abstract Co-Author*)
Stacy E. Smith, MD (*Abstract Co-Author*)

Amina Saghir, MD (*Abstract Co-Author*)
Jeffrey Ding (*Abstract Co-Author*)
Osher Lee (*Abstract Co-Author*)
Faisal Khosa, FRCPC, MBA (*Abstract Co-Author*)

PURPOSE

To assess changes in gender, racial, and ethnic diversity in academic radiology during the affirmative action era and identify persistent disparities across academic ranks and training.

METHODS AND MATERIALS

This was a retrospective analysis of radiology faculty (1966-2023), department chairs (1977-2023), and trainees (2017-2023) was performed using datasets from the AAMC, ACGME, and ERAS. Linear regression and chi-square ($?^2$) analyses were conducted to examine trends in gender, racial, and ethnic representation. A P value of < .01 was considered statistically significant.

RESULTS

Radiology faculty grew from N=759 (1966) to N=10,334 (2023), and chairs from N=127 (1977) to N=229 (2023). Women's representation increased annually among faculty (+0.44%) and chairs (+0.49%) (P < .001). African American representation also improved among faculty (+0.02%) and chairs (+0.08%) (P < .001). Trends for Asian, Hispanic, Multiracial, and White groups mirrored national census patterns. Intersectional analyses revealed yearly gains among women of underrepresented racial or ethnic identity (+0.04% faculty; +0.08% chairs; P < .001), with more variable trends for men (-0.01% faculty; +0.02% chairs; P < .001). However, women's representation declined with academic rank (-4.4%; P = .002) and was significantly lower in residency recruitment ($?^2$ = 1534; P < .001). African American and Hispanic individuals faced barriers in both residency acceptance ($?^2$ = 722; P < .001) and academic hiring ($?^2$ = 54.2; P < .001).

CONCLUSION

While affirmative action improved representation for women and African Americans in academic radiology, its overall impact was limited. Structural inequities continue to restrict advancement and recruitment for underrepresented groups.

CLINICAL RELEVANCE/APPLICATION

Understanding the historical and ongoing effects of affirmative action provides insight into structural barriers in academic radiology. Addressing these disparities requires targeted, evidence-based strategies to promote equitable recruitment, advancement, and retention of a diverse workforce.

T7-SSNR09-1 IMPAIRED COUPLING BETWEEN CEREBRAL ARTERIAL BLOOD AND PERIVASCULAR CSF DYNAMICS IN ALZHEIMER'S DISEASE

Adam Wright, BS (*Presenter*)
Xiaopeng Zhou (*Abstract Co-Author*)
Yu-Chien Wu, PhD, MD (*Abstract Co-Author*)
Shannon Risacher (*Abstract Co-Author*)
Andrew J. Saykin, PsyD, MS (*Abstract Co-Author*)
Yunjie Tong (*Abstract Co-Author*)
Qiuting Wen (*Abstract Co-Author*)

PURPOSE

Cerebral waste accumulation is a hallmark of Alzheimer's disease (AD), reflecting dysfunction in brain waste clearance. However, assessing the brain waste clearance system, particularly the perivascular cerebrospinal fluid (pCSF) flow, remains challenging in humans. Using a novel multimodal MRI approach, our group recently demonstrated that pCSF flow is strongly coupled with arterial blood pulsations in healthy brains. We applied this technique to examine vascular-perivascular coupling across the AD spectrum, hypothesizing that this coupling is disrupted in AD.

METHODS AND MATERIALS

Participants from an Alzheimer’s Disease Research Center (N=115) underwent MRI and comprehensive cognitive evaluation: cognitively unimpaired (CU, N=87), mild cognitive impairment (MCI, N=18), or AD dementia (AD, N=10). Pulsatile blood flow in cerebral arteries was assessed using cardiac-aligned resting-state functional MRI (fMRI), while adjacent pCSF dynamics were assessed using cardiac-aligned dynamic diffusion-weighted imaging (dynDWI). Vascular-perivascular coupling was quantified by a correlation-based approach that measures how closely the pCSF dynamics are synchronized with arterial cardiac pulsations. Systolic peaks in the fMRI and dynDWI signals were aligned, and the resulting correlation, termed the “Correlation at Aligned Peaks,” was calculated. Higher values correspond to stronger coupling. Group differences in Correlation at Aligned Peaks and peak time delays were tested via ANOVA with Tukey’s pairwise correction. Pearson’s r assessed correlations with cognitive and volume metrics.

RESULTS

Correlations at Aligned Peaks differed across groups ($F=4.4$, $p<0.05$). Compared with CU, coupling was significantly lower in AD ($p<0.05$, Cohen’s $d=0.92$) and nonsignificantly lower in MCI ($p=0.19$, Cohen’s $d=0.45$). Correlations at Aligned Peaks were positively correlated with MoCA ($r=0.29$, $p<0.01$) and normalized brain volume ($r=0.23$, $p<0.05$), and negatively correlated with normalized ventricle volume ($r=-0.29$, $p<0.01$) and white matter hyperintensity volume ($r=-0.33$, $p<0.001$). The time delay between peaks did not differ ($F=0.163$, $p=0.85$) and was not correlated with cognition or volume metrics.

CONCLUSION

Vascular-perivascular fluid coupling was reduced in AD, suggesting less effective arterial driving of pCSF flow. This study provides human evidence that impaired perivascular pumping may contribute to AD pathology.

CLINICAL RELEVANCE/APPLICATION

The MRI protocol comprises two short scans with clinically feasible scan times (10 minutes total). It can be used to monitor disease progression and evaluate the effects of future interventions targeting brain waste clearance in AD and CSF-related brain disorders.

T7-SSNR09-2 MOTOR-COGNITIVE AGING: THE ROLE OF CORTICOSTRIATAL PATHWAY

Jiaqi Wen, MD, MS (*Presenter*)
Zifei Liang (*Abstract Co-Author*)
Chenyang Li (*Abstract Co-Author*)
Huize Pang (*Abstract Co-Author*)
Jiayi Li (*Abstract Co-Author*)
Xiaojun Guan (*Abstract Co-Author*)
Xiaojun Xu (*Abstract Co-Author*)
Yulin Ge, MD (*Abstract Co-Author*)

PURPOSE

Cognitive decline and motor dysfunction are hallmark features of aging. The primary motor cortex (M1) plays a critical role in voluntary movement and exhibits a somatotopic organization enabling precise control of different body parts. In the M1, pyramidal neurons project to the corticospinal tract (CST) and send collaterals to the ipsilateral striatum, forming the corticostriatal tract (CStrT). In this study, we aimed to investigate age-related degeneration of the M1 and its connected CST and CStrT using multimodal MRI and examine their associations with cognitive function.

METHODS AND MATERIALS

We analyzed 339 right-handed adults from the Human Connectome Project-Aging cohort using T1-, T2-weighted, pseudo-continuous arterial spin labeling, and diffusion MRI to assess age-related changes in M1 structure, perfusion, and white matter integrity. Participants were divided into two age groups using 65 years as the cutoff. An automated method (mrGrad) was used to generate ATT, CBF, and T1/T2 ratio functions along the face-to-feet axis of M1. Along-tract FA and MD of the CST and CStrT were compared between groups. Mediation analyses assessed relationships among M1 metrics, tract integrity, and cognitive performance.

RESULTS

Aging was associated with reduced M1 volume, increased cortex curvature and T1/T2 ratio, prolonged ATT, and decreased CBF. Significant differences in ATT and CBF were observed across all M1 segments bilaterally, indicating widespread hemodynamic impairments in older adults. T1/T2 ratios were significantly elevated in segments 1-3 of the left M1 and 1-4 of the right M1, suggesting iron accumulation in regions controlling the face and upper limbs. Older adults also exhibited decreased FA in the left CST near M1, increased MD in bilateral CST, and widespread reductions in CStrT integrity. Tract integrity was associated with M1 structure and perfusion. Notably, atrophy of the right M1 was associated with cognitive impairment, fully mediated by degeneration of the right CStrT, underscoring its role as a key pathway linking motor cortical atrophy to cognitive decline.

CONCLUSION

Aging leads to structural and hemodynamic degeneration in the M1 and its associated tracts. The corticostriatal pathway serves as a key link between M1 atrophy and cognitive decline, highlighting its potential as an early biomarker for age-related neurodegeneration.

CLINICAL RELEVANCE/APPLICATION

This study identifies the corticostriatal tract as a critical mediator between motor cortex degeneration and cognitive decline in aging. Multimodal MRI markers from this pathway may aid in early detection of individuals at risk for cognitive impairment, guiding targeted interventions to slow neurodegenerative progression.

Ana M. Franceschi, MD, PhD (*Abstract Co-Author*)

PURPOSE

For amyloid brain PET/CT and PET/MRI fusion images, (1) determine agreement between visual interpretations of amyloid PET, and (2) compare results of visual interpretation to quantitative analysis as measured by the Centiloid scale.

METHODS AND MATERIALS

167 clinical amyloid brain PET/CT scans were reviewed by 3 readers blinded to the original reports. Readers interpreted the amyloid PETs as negative (0), positive (1), or indeterminate (2) for amyloid deposition. For quantitative analysis, two additional readers analyzed amyloid PET images using MIMNeuro to generate Centiloid (CL) score and regional SUVRs. Reader agreement was determined for visual assessment and quantitative assessment. Using positive scan cut-offs of CL=40, visual assessment versus quantitative assessment was determined for scans consistently interpreted as positive by all 3 readers and for each reader.

RESULTS

53 scans (31.74%) were rated amyloid-positive by all readers, while 62 scans (37.13%) were rated as amyloid-negative by all readers. The remaining 52 scans had inconsistent ratings with an agreement rate of 69.46%. Most (99/167, [59.28%]) scans had CL scores above the Centiloid-positive cutoff (CL=40) and 47/167 (28.14%) had Centiloid-negative scans (CL<10). The lowest CL score to achieve visual positivity among all three readers was 57, while the lowest CL score to receive at least one indeterminate score was 11. The readers had a high degree of inter-reader reliability when rating individuals as either positive (? = 0.62) or negative (? = 0.66) but were inconsistent when rating scans as indeterminate (? = 0.17). Optimal cut-points were CL<3.6 for consistent negative and CL=28.8 for consistent visual positivity.

CONCLUSION

Given the emergence of anti-amyloid monoclonal therapies for early-stage Alzheimer’s disease, reliable detection of amyloidosis is critical for patient care. This study suggests that visual reads of amyloid PET may be insensitive when amyloidosis is milder but spread across multiple regions (CL ranging from 40-59).

CLINICAL RELEVANCE/APPLICATION

Quantification of amyloid PET using the Centiloid scale may help guide treatment of patients with mild amyloidosis who are under consideration for anti-amyloid disease modifying therapeutics.

T7-SSNR09-4 IMPACT OF MR-GUIDED PET RECONSTRUCTION ENHANCES AMYLOID DETECTION

Yu Cai, MD, PhD (*Presenter*)
Chen Lin, PhD (*Abstract Co-Author*)
Jun Zhang, PhD (*Abstract Co-Author*)
Manoj K. Jain, MD (*Abstract Co-Author*)
Robert A. Pooley, PhD (*Abstract Co-Author*)
Vivek Gupta, MD (*Abstract Co-Author*)
Matthew Spangler-Bickell (*Abstract Co-Author*)
Alex K. Smith, PhD,MS (*Abstract Co-Author*)
Daniel Litwiller, PhD,MBA (*Abstract Co-Author*)
Erik H. Middlebrooks, MD (*Abstract Co-Author*)
Neetu Soni, MD, FRCR (*Abstract Co-Author*)

PURPOSE

To assess the impact of MR-guided PET reconstruction (MRgPET recon) on reader consistency, diagnostic confidence, and visual imaging quality in interpreting amyloid PET/MR scans.

METHODS AND MATERIALS

This study was approved by the Mayo Clinic Institutional Review Board. Three independent readers evaluated amyloid PET-MR (18F-florbetapir, Amyvid) images reconstructed with conventional method (Ordered-subsets expectation-maximization, OSEM) and novel MR-guided (MRg) PET algorithm in 30 patients. Each case was rated as amyloid-positive or amyloid-negative and assigned a 1-3 diagnostic confidence score (1, not at all confident; 3, very confident), and a 1-5 subjective visual image quality score (1, worst quality, unusable image; 5, excellent quality, minimal noise). Inconsistent cases were defined as one out of three readers disagreed. Centiloid (CL) values were based on OSEM and calculated on MIMneuro software. Statistical comparisons included Fleiss' Kappa, Mann-Whitney U and Chi-square tests.

RESULTS

OSEM had five inconsistent cases (5/30, 16.7%), while MRgPET recon had only two (2/30, 6.67%). Inter-rater agreement was higher in MRgPET recon (? = 0.889, 95% CI: 0.683-1.0) than OSEM (? = 0.758, 95% CI: 0.551-0.964). Figure 1 shows two cases initially classified as inconsistent using OSEM but reclassified as consistent positive using MRgPET recon. The mean diagnostic confidence in MRg PET recon is significantly higher than OSEM (2.92 ± 0.27 vs. 2.71 ± 0.62, p =0.013). The proportion of low-confidence cases (score =2) was significantly lower in MRg PET recon than OSEM (7.8% vs. 20%, p = 0.018). Visual image quality scores were significantly higher in MRgPET recon than OSEM (4.72 ± 0.54 vs. 3.87 ± 0.59, p < 0.01). Low image quality cases were less frequent in MRg than OSEM (4.4%

vs.24.4% p < 0.001). Figure 1. Two representative cases initially classified as inconsistent using OSEM reconstruction but reclassified as consistent amyloid-positive by all readers using MRg PET recon (MRg).

CONCLUSION

MRg PET reconstruction has a higher inter-reader agreement, improves diagnostic confidence, and visual image quality compared to OSEM. These findings suggest that MRg PET reconstruction can offer a more reliable and confident interpretation framework for amyloid PET/MR imaging. We will present large data-based results in our final presentation.

CLINICAL RELEVANCE/APPLICATION

This novel MR-guided PET reconstruction improves the diagnostic performance of amyloid PET/MR imaging by enhancing image quality and boosting radiologists' confidence. This technique may lead to more consistent and reliable diagnoses in clinical practice, potentially improving decision-making in the assessment of Alzheimer's disease pathology.

T7-SSNR09-5 CHOROID PLEXUS EXTRACELLULAR EXTRAVASCULAR VOLUME FRACTION FROM DCE-MRI ASSOCIATES WITH AMYLOID BURDEN

Mohammad Khalafi, MD (*Presenter*)
Liangdong Zhou, PhD (*Abstract Co-Author*)
Seyed Hani Hojjati (*Abstract Co-Author*)
Tracy Butler (*Abstract Co-Author*)
Xiuyuan H. Wang, PhD (*Abstract Co-Author*)
Silky Pahlajani (*Abstract Co-Author*)
Yi Li, PhD, MD (*Abstract Co-Author*)
Gloria C. Chiang, MD (*Abstract Co-Author*)

PURPOSE

To investigate the relationship between dynamic contrast-enhanced MRI (DCE-MR) permeability metrics and amyloid burden, quantified by Centiloids, in individuals.

METHODS AND MATERIALS

Twenty-nine participants (19 amyloid-positive, 10 amyloid-negative) underwent 3T MRI with DCE-MR and amyloid PET imaging. The choroid plexus was manually segmented. DCE-MRI-derived parameters were quantified using the extended Tofts model in the Olea software platform, including tissue microstructure-related metrics like the extravascular extracellular volume fraction (V_e) and plasma volume fraction (V_p), as well as permeability markers such as the volume transfer constant (K^{trans}) and rate constant (K_{ep}). Linear regression models were used to evaluate the associations between V_e and Centiloid values, adjusting for choroid plexus volume, in amyloid-positive and negative subgroups.

RESULTS

In amyloid-positive individuals, V_e demonstrated a statistically significant inverse association with amyloid burden, quantified by Centiloids (ß = -0.0060, p = 0.0067). This relationship remained robust after adjusting for choroid plexus volume, indicating that the observed effect was not confounded by volumetric differences in the choroid plexus. V_e explained approximately 40% of the variance of amyloid burden (R^2 = 0.38; Adjusted R^2 = 0.30). The other permeability metrics (V_p, K^{trans}, and K_{ep}) were not associated with amyloid burden (p>0.05).

CONCLUSION

Choroid plexus V_e, as measured by DCE-MR, is significantly associated with amyloid burden in amyloid-positive individuals. Given that V_e reflects the volume of the extracellular extravascular space, it offers insights into vascular permeability and interstitial/glymphatic fluid exchange at the choroid plexus blood-CSF barrier, which may be influenced by amyloid pathology. Ongoing studies at the Brain Health Imaging Institute (BHII) aim to expand this work in a larger cohort to validate V_e as a valuable marker of amyloid-related changes in interstitial fluid volumes.

CLINICAL RELEVANCE/APPLICATION

DCE-MR-derived V_e may serve as a promising, non-invasive imaging biomarker for assessing choroid plexus dysfunction in the context of Alzheimer's disease. These preliminary results highlight the value of permeability imaging in neurodegenerative research.

T7-SSNR09-6 FLOWDM: DIFFUSION-BASED DEEP LEARNING FOR ENHANCING THE UTILITY OF MRI IN DETECTING MILD COGNITIVE IMPAIRMENT

Chetan Vadali (*Presenter*)
Alfredo Lucas, PhD, MS (*Abstract Co-Author*)
Xavier Beltran Urbano (*Abstract Co-Author*)
Kathryn Davis, MD (*Abstract Co-Author*)
Joel M. Stein, MD, PhD (*Abstract Co-Author*)
John A. Detre (*Abstract Co-Author*)

PURPOSE

Positron Emission Tomography (PET) with fluorodeoxyglucose (FDG-PET) is commonly used to quantify regional metabolism for the diagnosis and monitoring of Alzheimer's Disease (AD) and differentiation of AD and mild cognitive impairment (MCI), which can be a prodromal phase of AD, from other types of dementia. However, FDG-PET is costly and not widely available. Arterial spin labeling (ASL) provides MR-based cerebral blood flow (CBF) quantification that could aid in this classification, though its accuracy is limited. We propose a diffusion-based deep-learning framework, FlowDM, to synthesize PET-like images from routinely acquired MRI, enhancing the utility of MRI in MCI and dementia.

METHODS AND MATERIALS

We included 47 MCI and 31 cognitively unimpaired subjects (78 total). We developed FlowDM, a Conditional Wavelet Diffusion Model (cWDM), to generate synthetic PET from ASL and T1-weighted inputs. FlowDM was trained using 63 subjects and tested in 15 subjects (9 MCI/6 unimpaired). We compared synthetic PET and true PET both in appearance and for their classification performance in distinguishing MCI from unimpaired via a random forest (RF) model within regions of interest (ROIs).

RESULTS

FlowDM-generated PET volumes demonstrated significant structural similarity to true PET volumes (SSIM = 0.90). Furthermore, the performance of the best RF models for classification of MCI versus unimpaired were comparable between the original PET and FlowDM PET, both when considering all ROIs (PET ROC-AUC = 0.85, 95% CI: [0.69, 1.00]; FlowDM ROC-AUC = 0.89, 95% CI: [0.77, 1.00]) and only a hypothesis-driven subset canonically implicated in MCI/AD (PET ROC-AUC = 0.92, 95% CI: [0.82, 1.00]; FlowDM ROC-AUC = 0.92, 95% CI: [0.82, 1.00]).

CONCLUSION

FlowDM enhances the diagnostic performance of ASL and T1-weighted imaging, improving alignment with FDG-PET and generating synthetic FDG-PET volumes that perform comparably to true FDG-PET in both appearance and classification.

CLINICAL RELEVANCE/APPLICATION

Through PET-like metabolic imaging synthesis from multimodal MRI that can be acquired as part of a routine protocol for patients presenting with cognitive complaints, FlowDM may provide improved diagnostic sensitivity of MRI in patients with cognitive impairment. Our preliminary results in temporal lobe epilepsy are comparable, demonstrating the potential of FlowDM for broader neurological applications.

Juan Gurria (*Abstract Co-Author*)
Meera Kotagal (*Abstract Co-Author*)
Andrew T. Trout, MD (*Abstract Co-Author*)

PURPOSE

Radiation therapy (RT) is a component of standard-of-care therapy in high-risk neuroblastoma (HR-NBL) but can have damaging effects on nearby tissue. The objectives of this study are 1) to characterize changes in pancreas volume after RT and 2) to characterize changes in body composition metrics, including body weight percentile, subcutaneous fat area, and total psoas muscle area (tPMA) after treatment in children with abdominal HR-NBL.

METHODS AND MATERIALS

This retrospective study included patients aged 0-17 years old with HR-NBL who underwent imaging and RT at a quaternary pediatric hospital (January 2012-December 2022). A linear regression model was used to determine association between various tissue changes and radiation dose adjusting for age, sex, and days elapsed between RT administration and follow-up scan.

RESULTS

Fifty patients (median age 3 [IQR 2], 56% male) met inclusion criteria. Median days between pre- and post-radiation imaging was 141 (IQR 77). Pancreatic volume decreased significantly from pre- to post-radiation (16,731 mm 3 vs 14,288 mm 3 , p<0.001), with pancreatic exposure of >2000cGy associated with greater volume loss compared to <2000cGy (p=0.045). Patient body weight percentile declined significantly (48.4 vs 44.9, p=0.016), independent of radiation dose. There were non-significant decreases in subcutaneous fat area standardized to height (38.6 vs 36.9 cm 2 /m 2 , p=0.41) and tPMA z-scores (-1.56 vs -2.09, p=0.26).

CONCLUSION

Patients undergoing abdominal RT for HR-NBL experienced significant pancreatic volume loss which may place them at risk for pancreatic insufficiency. Patients also had significant decreases in weight percentile with corresponding non-significant decreases in subcutaneous fat and psoas muscle area.

CLINICAL RELEVANCE/APPLICATION

Pancreas volume and body composition changes are apparent by imaging in children with HR-NBL. In these patients with known nutritional complexities, clinicians should consider evaluating pancreatic insufficiency.

T7-SSRO03-3 HISTOPATHOLOGICAL OUTCOMES OF CT-GUIDED HIGH-DOSE-RATE INTERSTITIAL BRACHYTHERAPY AND PREDICTIVE ACCURACY OF THE LI-RADS RADIATION TREATMENT RESPONSE ALGORITHM V2024 IN HCC PATIENTS PRIOR TO LIVER TRANSPLANTATION

Matthias P. Fabritius, MD (*Presenter*)
Daniel Puhr-Westerheide, MD (*Abstract Co-Author*)
Max Seidensticker (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Freba Grawe, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the histopathological results of CT-guided high-dose-rate interstitial brachytherapy (HDR-BT) and the accuracy of the LI-RADS Radiation Treatment Response Algorithm (TRA) in predicting pathological necrosis in hepatocellular carcinoma (HCC) patients treated with HDR-BT as bridging therapy to liver transplantation.

METHODS AND MATERIALS

This retrospective single-center study included all HCC patients who underwent HDR-BT before liver transplantation between July 2017 and June 2023. Tumor necrosis was assessed on explant histopathology. Associations between procedural characteristics and complete necrosis were analyzed. Pre-transplant MRI scans were reviewed by two readers using LI-RADS TRA v2024 categories.

RESULTS

19 patients with 29 treated lesions were included. MRI was available for 12 patients (18 lesions). Complete pathological necrosis was observed in 19 lesions (65.5%). The remaining 10 lesions showed >50% necrosis with apoptotic activity in viable tumor areas, confirmed by TUNEL staining. A longer interval between HDR-BT and transplantation (>136 days) was significantly associated with complete necrosis (86.6% vs. 42.8%, p=0.026), suggesting ongoing radiation-induced tumor cell death.

On MRI, no lesion was categorized as LR-TR viable. All 11 lesions classified as LR-TR nonviable showed complete necrosis on histology. Seven lesions were LR-TR nonprogressing.

CONCLUSION

HDR-BT is associated with high rates of complete pathological necrosis and may induce continued tumor cell death beyond treatment. The LI-RADS Radiation TRA shows excellent predictive accuracy for assessing treatment response.

CLINICAL RELEVANCE/APPLICATION

This study highlights CT-guided HDR-BT as an effective bridging therapy for patients with HCC awaiting liver transplantation, achieving high rates of complete pathological necrosis. The results suggest that HDR-BT not only offers effective local tumor control but may also promote ongoing tumor cell death even after treatment, making it a valuable option in transplant programs. Furthermore, the excellent predictive accuracy of the LI-RADS Radiation TRA enables reliable, non-invasive assessment of therapeutic success, supporting informed clinical decisions.

T7-SSRO03-4 PREDICTING NEOADJUVANT CHEMORADIOTHERAPY OUTCOME IN LARC: A SYNERGISTIC APPROACH OF RADIOMICS AND TRANSPARENT MACHINE LEARNING

Jianfeng Li (*Presenter*)

PURPOSE

This study investigates the feasibility of using radiomics features derived from radiotherapy target regions combined with interpretable machine learning models to predict the efficacy of neoadjuvant chemoradiotherapy (nCRT) in patients with locally advanced rectal cancer (LARC).

METHODS AND MATERIALS

Clinical data from 358 LARC patients were included. Patients were categorized into effective and ineffective groups based on tumor regression grade (TRG). Radiomics features were extracted and integrated with clinicopathological information, then used to develop predictive models, and their performance was evaluated using the area under the receiver operating characteristic curve (AUC).

RESULTS

A total of 272 patients were included in the final analysis, the training set consisted of 156 patients (34 effective), the internal validation set included 67 patients (14 effective), and the external validation set included 49 patients (20 effective). Among models incorporating clinical T stage, CEA levels, and radiomics features, the nomogram-based model demonstrated the best performance, achieving an AUC of 0.858 in the training set,0.844 in the internal validation set and 0.800 in external set. The decision curve analysis shows that the partial dependence plot model achieves higher clinical net benefit than other models across most threshold ranges.

CONCLUSION

A nomogram model integrating radiomics and clinicopathological variables accurately predicts the efficacy of nCRT in LARC patients and enhances the model's clinical utility.

CLINICAL RELEVANCE/APPLICATION

The clinical relevance of this study lies in its ability to accurately predict the efficacy of neoadjuvant chemoradiotherapy (nCRT) in locally advanced rectal cancer patients, enabling personalized treatment decisions by allowing doctors to adjust strategies according to predicted responses, facilitating prognosis assessment and communication with patients, promoting rational medical resource allocation, and advancing precision medicine in oncology by integrating multiple variables for treatment response prediction.

T7-SSRO03-6 EVALUATION OF PREDICT CRITERIA ON MRI FOR PREDICTING POSTOPERATIVE LOCAL RECURRENCE IN RECTAL CANCER

Andre De Freitas Secaf, MD (*Presenter*)
Matheus Palma, MD (*Abstract Co-Author*)
Gabriel Ramos, MD (*Abstract Co-Author*)
Thalyne Lima (*Abstract Co-Author*)
Alexandre S. Morgado (*Abstract Co-Author*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
David F. Vieira, MD (*Abstract Co-Author*)
Gabriel L. Gouvea, MD (*Abstract Co-Author*)
Danilo T. Wada, MD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)

PURPOSE

Evaluate the ability of MRI to predict locoregional recurrence of rectal cancer after mesorectal resection, using histopathological criteria of the PREDICT score, and to assess the degree of agreement between histopathological PREDICT score and the score applied to MRI.

METHODS AND MATERIALS

A retrospective survey was conducted using the institutional database to catalog information from patients with clinical suspicion of rectal cancer (RC) over five years (2017-2021). Clinical data, such as sex, age, tumor T and N stages, tumor distance from the anal verge, among others, were obtained from electronic medical records, while imaging information was collected from the image storage and distribution server. Based on these data and image analyses, pathological and MRI PREDICT scores were calculated for each patient, offering a comprehensive assessment of the probability of locoregional recurrence of RC.

RESULTS

The final sample included 141 patients, with a mean age of 60 years and a male majority (54.6%). Tumor stage T3 was most prevalent (49.6%), and most tumors were located within 5 cm from the anal verge (46.8%), with 39% showing mesorectal fascia invasion. Neoadjuvant therapy was administered in 63.1% of cases, resulting in a significant reduction in tumor length, while the distance to the mesorectal fascia did not vary significantly. There was good correlation between MRI and pathological PREDICT scores. Locoregional recurrence occurred in 13.4% of patients, all of whom deceased, mainly due to cancer-related causes (78.3%).

CONCLUSION

The results of this study emphasize the crucial role of neoadjuvant therapy in patient prognosis. The importance of continuous prognostic assessments and risk stratification is emphasized to guide more precise therapeutic and surgical decisions, thus contributing to a more effective and personalized approach to RC.

CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of MRI-based PREDICT scoring to accurately assess the risk of locoregional recurrence in rectal cancer patients following mesorectal excision. The strong correlation with histopathological findings supports its use as a non-invasive prognostic tool. Early identification of high-risk patients enables more tailored treatment strategies, reinforces the value of neoadjuvant therapy, and may ultimately improve survival outcomes through personalized care.

T7-STCE1-1 MYELIN AND PERFUSION IMAGING IN NORMAL APPEARING WHITE MATTER IN PATIENTS WITH MULTIPLE SCLEROSIS

Devinder Pal Singh Dhanota, MBBS,MD (*Presenter*)
Kavita Saggar SR, MD (*Abstract Co-Author*)

PURPOSE

Multiple sclerosis (MS) is a chronic autoimmune inflammatory disorder of the central nervous system, characterized by demyelination, gliosis, and axonal injury. While conventional MRI detects white matter plaques, it underrepresents early microstructural changes in normal-appearing white matter (NAWM). This study aimed to assess myelin content and perfusion parameters in NAWM using SyMRI and DSC-perfusion imaging to identify early imaging biomarkers of MS.

METHODS AND MATERIALS

A prospective study was conducted on 20 MS patients (mean age: 32 years) and 18 healthy controls (mean age: 40 years). All subjects underwent MRI on a 3T Siemens Skyra scanner. Myelin content was quantified using QRAPMASTER-based synthetic MRI (SyMRI) and perfusion parameters (CBV, CBF) via dynamic susceptibility contrast (DSC) imaging. ROIs were placed in frontal, parietal, temporo-occipital lobes, and corpus callosum. Normalized perfusion metrics were derived by comparison with grey matter values. Statistical analysis used Student's t-test and Pearson correlation ($p < 0.05$ as significant).

RESULTS

Myelin-correlated component (MyC) in NAWM was significantly reduced in MS patients (31.95±1.67%) compared to controls (36.66±1.47%, $p < 0.01$). MyC negatively correlated with lesion number ($r = -0.68$) and positively with disease duration ($r = 0.48$). Normalized CBV and CBF were significantly reduced in MS patients (mean CBV: 0.40±0.07; mean CBF: 0.40±0.06) compared to controls (CBV: 0.59±0.07; CBF: 0.55±0.07, $p < 0.05$). No significant correlation was found between perfusion values and EDSS or disease duration.

CONCLUSION

MS patients show early demyelination and microvascular hypoperfusion in NAWM, even in the absence of conventional imaging findings. Quantitative myelin mapping and perfusion analysis may serve as early imaging biomarkers to track disease progression and guide personalized therapy.

CLINICAL RELEVANCE/APPLICATION

This study highlights that microstructural and perfusion abnormalities in NAWM precede plaque formation and are measurable with SyMRI and DSC-perfusion imaging. These imaging biomarkers can improve MS diagnosis, monitor treatment response, and potentially predict long-term outcomes.

T7-STCE1-2 NEXT-GENERATION VIRTUAL FLUOROSCOPY IMAGE FROM NON-CONTRAST CT-OPTIMIZING CARDIAC CATHETERIZATION IN ACUTE MYOCARDIAL INFARCTION

Rina Sugihara, BA (*Presenter*)
Masahiro Ida, MD (*Abstract Co-Author*)
Yoshihiro Tanaka, RT (*Abstract Co-Author*)

PURPOSE

To determine whether virtual fluoroscopic images (VFI) reconstructed from routine non-contrast CT can serve as an immediate anatomic roadmap for emergency coronary catheterisation in acute myocardial infarction (AMI), thereby improving procedural safety and efficiency without additional radiation or cost.

METHODS AND MATERIALS

Single-centre, retrospective study (April 2022 - February 2025). Fifty consecutive patients (mean age 64 ± 11 y) underwent non-contrast chest CT to exclude aortic dissection before primary percutaneous coronary intervention (PCI). CT volume data were exported to a 3-D workstation (Synapse VINCENT; FUJIFILM Healthcare) to generate VFI—ray-summation projections emulating fluoroscopy. Two blinded interventional cardiologists prospectively reviewed the VFI to localise right/left coronary ostia, pre-select a safe arterial puncture trajectory, and anticipate heavy aortic-root calcification. Procedural metrics (first-pass cannulation rate, fluoroscopy time, contrast volume, access-site complications) were compared with historical PCI data in which CT was not shared.

RESULTS

VFI successfully depicted both coronary ostia and aortic course in 94 % (47/50) of cases; heavy calcifications that could hinder catheter torque were visualised in 88 % (44/50). Pre-procedural VFI review changed planned sheath entry in 38 % of patients and eliminated all second-attempt punctures, lowering the access-site re-try rate from a historical 15 % to 0 %. Median fluoroscopy time fell from 11.2 min to 8.1 min (-28 %, $p < 0.01$) and contrast use from 78 mL to 63 mL (-19 %, $p = 0.03$). No catheter-related vascular complications occurred. Cardiologists rated VFI utility 4.7 ± 0.3 (5-point Likert). Inter-reader agreement for ostial visualisation was excellent (? = 0.86).

CONCLUSION

Virtual fluoroscopy derived from existing non-contrast CT provides an immediate, radiation-free roadmap that streamlines emergency PCI—improving first-pass success and reducing fluoroscopy time, contrast dose, and access complications.

CLINICAL RELEVANCE/APPLICATION

Embedding VFI into the AMI “door-to-balloon” workflow closes the information gap between CT and the cath lab, aligns with ALARA principles, and may translate to faster reperfusion and better patient outcomes—offering a cost-neutral upgrade that can be implemented on any workstation-equipped center.

T7-STCE1-3 NON-CONTRAST MRI MEASURES LINKED TO SYSTEMIC INFLAMMATION: ASL-DERIVED CEREBRAL PERFUSION AND DIXON FAT-TO-MUSCLE RATIO IN MIDLIFE OBESITY

Mahshid Naghashzadeh, MSc, PhD (*Presenter*)
Paul K. Commean, BA (*Abstract Co-Author*)
Mahsa Dolatshahi, MD, MPH (*Abstract Co-Author*)
Soheil Mohammadi, MD, MPH (*Abstract Co-Author*)
Lakisha Lloyd (*Abstract Co-Author*)
Caitlyn Nguyen (*Abstract Co-Author*)
Weiying Dai, PhD (*Abstract Co-Author*)
Tammie S. Benzinger, MD, PhD (*Abstract Co-Author*)
Hongyu An, DSc (*Abstract Co-Author*)
Cyrus A. Raji, MD, PhD (*Abstract Co-Author*)

PURPOSE

Midlife obesity is a known risk factor for Alzheimer's disease (AD), yet BMI lacks sensitivity to underlying body composition. This study investigates whether non-contrast MRI-derived fat-to-muscle ratio (FMR) and arterial spin labeling (ASL) cerebral perfusion provide more physiologically relevant indicators of systemic and neurovascular alterations associated with midlife adiposity.

METHODS AND MATERIALS

We studied 104 cognitively normal midlife adults (mean age: 49.8 ± 6.0 years; 65% female; 55% obese; BMI: 32.0 ± 7.3). Cognitive status was assessed via MMSE. All imaging was performed on Siemens 3T scanners. Cerebral perfusion was quantified using non-contrast pCASL with 3D TGSE readout to generate absolute cerebral brain perfusion (CBF) maps. Thigh composition was assessed using T1-weighted VIBE Dixon MRI; nine mid-thigh slices were processed with N4ITK correction and segmented via a custom MATLAB pipeline to compute FMR. Cortical thickness was derived from brain T1-weighted images using FreeSurfer. Associations between FMR, CBF, and cortical thickness across 22 AD-relevant regions were analyzed using rank-based correlation, adjusting for age, sex, and multiple comparisons.

RESULTS

Individuals with obesity exhibited higher FMR and HOMA-IR, along with reduced muscle volume and HDL cholesterol, reflecting greater metabolic dysfunction and systemic inflammation. Non-contrast Dixon and ASL MRI revealed absolute adiposity measures (e.g., BMI, fat volume) were inversely associated with global and regional CBF, particularly in limbic and default mode network regions implicated in early AD. In contrast, FMR showed weaker associations with cerebral perfusion, suggesting resting-state ASL may offer greater sensitivity to overall fat burden. Notably, FMR was negatively associated with cortical thickness in 11 AD-relevant regions—predominantly in left hemisphere—indicating a possible link to obesity-related neurodegeneration. FMR correlated positively with BMI and HOMA-IR, reinforcing its role as an index of adiposity and insulin resistance.

CONCLUSION

Non-contrast MRI techniques demonstrated differential sensitivity to systemic and neurovascular alterations associated with midlife obesity. While ASL-derived CBF was more closely linked to absolute adiposity, Dixon-derived FMR showed stronger associations with cortical thinning and metabolic dysfunction. These findings suggest combining non-contrast perfusion and body composition imaging may enhance early detection of obesity-related neurodegenerative risk.

CLINICAL RELEVANCE/APPLICATION

Non-contrast MRI measures of FMR and cerebral perfusion may serve as complementary, noninvasive indicators of systemic and neurovascular changes linked to AD risk in midlife obesity.

Ray C. Mayo III, MD (*Abstract Co-Author*)
Lora D. Barke, DO (*Abstract Co-Author*)

PURPOSE

Screening mammography's role to reduce breast cancer mortality through early detection is well established. AI risk models offer a novel opportunity to expand the value of a screening mammogram beyond detection alone. We evaluated such a model for three distinct applications: triaging patients at higher likelihood of harboring cancer at the time of screening (current cancer detection), identifying patients at risk for false-negative exams (missed cancers), and stratifying future cancer risk well beyond the screening interval.

METHODS AND MATERIALS

We analyzed 122,993 bilateral digital screening mammograms from 67,776 patients imaged between 2011-2017 at 10 geographically diverse U.S. facilities. Exams were Hologic-2D acquired exams and none were included in model development. Cancer outcomes were derived from registries and health records. Performance was estimated using areas under the receiver operating characteristic curve (AUCs) with 95% CIs for: (1) all cancers diagnosed within 0-5 years, (2) cancers within 1 year (inclusive of true positives and interval cancers), (3) interval cancers diagnosed within 1 year after a negative BI-RADS assessment, and (4) future cancers diagnosed >1-5, >2-5, and >3-5 years after screening. For year-1 cancers, controls required =365 days of follow-up. For future cancer analyses, index exams with cancers prior to the defined window were excluded; controls required =5 years of follow-up.

RESULTS

A total of 2,584 breast cancers were diagnosed across the 5-year follow-up: 774 within 1 year (including 72 interval cancers), 1,810 years 1-5, 1,333 years 2-5, and 845 years 3-5. The AUC for all cancers within 0-5 years was 0.717 (95% CI: 0.706-0.728). For cancers within 1 year, AUC was 0.822 (95% CI: 0.806-0.838). For interval cancers, AUC was 0.694 (95% CI: 0.634-0.751). Future cancer prediction performance remained >0.65 across all windows: 0.669 (95% CI: 0.657-0.680) for >1-5 years, 0.662 (95% CI: 0.647-0.676) for >2-5 years, and 0.653 (95% CI: 0.635-0.671) for >3-5 years.

CONCLUSION

An AI-based image-only risk model applied to a single screening mammogram delivers value across multiple clinical timeframes. It can triage patients likely to have current cancer, flag those at risk for missed diagnoses, and assess long-term cancer risk. These results highlight how image-based models can amplify the diagnostic and preventive reach of screening mammography.

CLINICAL RELEVANCE/APPLICATION

This study exemplifies opportunistic screening by extending the value of mammography beyond detection alone. AI-based risk scores applied to routine screening exams inform diagnostic triage, identify high-risk patients for supplemental testing, and support preventive strategies—leveraging existing imaging to optimize population health.

T7-STCE2-2 OPPORTUNISTIC BONE HEALTH SCREENING: DEEP LEARNING ANALYSIS OF CHEST RADIOGRAPHS FOR OSTEOPOROSIS AND OSTEOPENIA DETECTION

Minje Kim, MSc (*Presenter*)
Minjee Kim (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

Osteoporosis and osteopenia affect 19.7% and 40.4% of the global population respectively, significantly increasing fracture risk and associated with increased mortality in severe cases. Despite high prevalence, dual-energy X-ray absorptiometry (DXA) screening remains limited by accessibility and cost constraints. We developed a deep learning model utilizing chest radiographs (CXR) to complement the limited accessibility of DXA through cost-effective opportunistic screening.

METHODS AND MATERIALS

77,677 CXRs from 47,773 patients who underwent CXR and DXA within 6 months at a tertiary care institution were partitioned 7:1:2 by patient for training/validation/test. Five categories were defined by T-scores: normal (=-1.0), mild osteopenia (-1.0 to -1.49), moderate osteopenia (-1.5 to -1.99), advanced osteopenia (-2.0 to -2.49), and osteoporosis (=-2.5), with 46,150, 9,821, 10,300, 6,799, and 4,607 CXRs respectively. To evaluate the model's generalizability, an external validation set of 3,338 CXRs, each from a distinct patient, was collected from an independent institution. A deep learning model was developed within a multi-task learning framework to simultaneously classify the bone health categories and regress DXA T-scores from CXRs.

RESULTS

Internal testing achieved AUCs of 0.944 (95% CI: 0.941-0.948), 0.792 (0.782-0.801), 0.852 (0.844-0.859), 0.903 (0.897-0.909), and 0.969 (0.964-0.973) for normal, mild, moderate, advanced osteopenia, and osteoporosis, respectively. External validation showed AUCs of 0.916, 0.735, 0.802, 0.868, and 0.924 (95% CIs: 0.907-0.926, 0.714-0.756, 0.784-0.819, 0.851-0.884, 0.906-0.940).

CONCLUSION

This study demonstrates that deep learning analysis of chest radiographs can effectively stratify bone health status with high diagnostic accuracy, offering a practical opportunistic screening tool for osteoporosis and osteopenia detection in routine clinical practice. Notably, the model introduces a novel five-tier classification that uniquely subdivides osteopenia into mild, moderate, and advanced stages, a level of granularity not previously explored in CXR-based screening studies.

CLINICAL RELEVANCE/APPLICATION

This novel granularity enables risk-stratified clinical management—non-pharmacological interventions for mild-to-moderate osteopenia versus immediate DXA referral and pharmacotherapy consideration for advanced osteopenia and osteoporosis—optimizing resource allocation and fracture prevention. By leveraging routine chest radiographs, the model provides a scalable, cost-effective screening alternative that not only identifies at-risk patients requiring urgent intervention but also potentially defers unnecessary DXA examinations in normal cases.

T7-STCE2-3 AI-DRIVEN QUANTIFICATION OF ABDOMINAL AORTIC CALCIFICATION ON CONTRAST ENHANCED CT IS PREDICTIVE OF CARDIOVASCULAR EVENTS AND MORTALITY

Louis A. Hinshaw, BS (*Presenter*)
Matthew H. Lee, MD (*Abstract Co-Author*)
John W. Garrett, PhD (*Abstract Co-Author*)
Ryan Zea, MS (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the utility of AI-driven quantification abdominal aortic calcification (AAC) from contrast enhanced CT (CECT) scans for predicting cardiovascular events (CVE) and all-cause mortality.

METHODS AND MATERIALS

In this retrospective cohort study, a fully automated AI tool was used to quantify AAC from the hiatus to iliac bifurcation from CT scans in a large, heterogenous adult population undergoing CT between January 2001-February 2021. The tool was applied to non-contrast CT (NCCT) and CECT scans. Simple linear corrections were applied to CECT-derived measures to determine non-contrast equivalent (NCE) values. CVEs and death following CT were determined from the electronic health record. ROC curve and time-to-event analyses were performed to determine 5-year AUCs, HRs comparing highest versus lowest risk quartiles, and Kaplan-Meier curves.

RESULTS

123,500 adults (mean age, 51; M:F, 58,442: 65,058) underwent abdominal CT (43,455 NCCT; 79,885 CECT. 16,599 patients had a CVE and 21,937 patients died. 5-year AUCs for CVE prediction were 0.74 (NCCT), 0.72 (CECT), and 0.73 (NCE), and for mortality prediction were 0.72 (NCCT), 0.71 (CECT), 0.71 (NCE). Higher AAC was associated with greater CVE risk: HR 1.73 (CI 1.61,1.86) for NCCT, HR 1.45 (CI 1.35,1.55) for CECT, and 1.78 (CI 1.69,1.87) NCE scans (all $p<0.001$). Higher AAC was also associated with higher mortality risk: HR 2.08 (CI 1.94, 2.24) for NCCT, HR 1.8 (CI 1.71, 1.91) for CECT, and 2.47 (CI 2.36,2.59) NCE scans (all $p<0.001$).

CONCLUSION

Fully automated quantification of AAC extracted from CECT scans predicts CVE and mortality risk, with comparable performance after adjusting for IV contrast.

CLINICAL RELEVANCE/APPLICATION

AI-driven measures of AAC from CECT is feasible and approach the performance of NCCT for CVE and mortality risk assessment, expanding the scope and impact of population level "opportunistic screening."

T8-SSNMMI04-1 EVALUATING THE DIAGNOSTIC VALUE OF DEEP LEARNING-SYNTHESIZED DYNAMIC PET IMAGES FOR BRAIN AMYLOIDOPATHIES

Yu-Nong Lin, MS (*Presenter*)
Kevin Chen (*Abstract Co-Author*)

PURPOSE

Dynamic positron emission tomography (dPET) with tracer kinetic modeling enables parametric images with greater physiological specificity (e.g., R1 for brain perfusion) than conventional static PET using standardized uptake values (SUV). However, its time-intensive acquisition limits dPET to research settings. To address this, a physiologically informed deep learning framework (i.e., PINN-PET) was developed to synthesize a full 23-frame dPET from a single-frame PET. In this study, we evaluate the diagnostic performance of imaging biomarkers from synthetic dPET generated by PINN-PET, compared to those from static PET and real dPET, in a cohort with diverse amyloid deposition patterns.

METHODS AND MATERIALS

The amyloid dPET/magnetic resonance (MR) dataset used in this study comprised 28 Alzheimer's disease participants and 35 cerebral amyloid angiopathy (CAA) participants. An excluded test set of 9 AD and 11 CAA participants was used for evaluation. Each subject underwent a 70-minute 11 C-PiB dPET scan with 23 frames. Synthetic dPET was generated from early-frame PET and its paired MR using PINN-PET, a DL framework regularized by compartmental model-derived PiB tracer kinetics to enforce physiological consistency in the synthetic outputs. Four sets of imaging biomarkers (regional measurements from selected critical brain ROIs), including (1) SUVs from an early frame (2-3 min. post-injection); (2) SUVs from late frames (40-70 min. p.i.); (3) R1 parametric images calculated from real dPET; and (4) R1 parametric images from synthetic dPET generated from early-frame PET, were used as inputs to a logistic regression classifier for AD/CAA classification. ROIs were derived from FreeSurfer segmentations and R1 maps were computed via the SRTM module in QModeling.

RESULTS

Despite significant differences in R1 between real and synthetic dPET, their classification performance remained consistent (accuracy, precision, and specificity: 0.70, 0.80, 0.67) and was higher compared to early-frame (0.60, 0.60, 0.60) and late-frame PET (0.55, 0.50, 0.56).

CONCLUSION

PINN-PET, a DL-based image augmentation framework guided by kinetic modeling, showed superior diagnostic performance to standard-of-care static PET, demonstrating its potential as a computational alternative that reduces acquisition time without compromising diagnostic value.

CLINICAL RELEVANCE/APPLICATION

CAA is increasingly recognized as a major risk factor for adverse events in current AD immunotherapies, making their differentiation of clinical significance. PINN-PET also generalizes to any tracer compatible with kinetic modeling, extending its utility as an image augmentation tool beyond amyloid PET to other PET modalities.

T8-SSNMMI04-2 EVALUATION OF MR-GUIDED PET RECONSTRUCTION FOR QUALITATIVE AND QUANTITATIVE AMYLOID AND TAU BRAIN PET/MRI

Yun-Chi Lin (*Presenter*)
Yu-Hua Fang, PhD (*Abstract Co-Author*)
Matthew Spangler-Bickell (*Abstract Co-Author*)
Mohammadhossein Nadian (*Abstract Co-Author*)
Alex K. Smith, PhD,MS (*Abstract Co-Author*)
Daniel Litwiller (*Abstract Co-Author*)
Erik D. Roberson, MD, PhD (*Abstract Co-Author*)
Jonathan E. McConathy, MD, PhD (*Abstract Co-Author*)

PURPOSE

Amyloid and tau PET acquired with simultaneous PET/MRI is increasingly used to evaluate for Alzheimer's disease. This study compared a novel MR-guided PET (MRgPET) reconstruction technique with standard reconstruction for assessing brain amyloid and tau deposition using[C-11]PiB and [F-18]flortuacipir.

METHODS AND MATERIALS

21 subjects imaged through the UAB Alzheimer's Disease Research Center (ADRC) were included. PiB and flortaucipir were produced by the UAB Cyclotron Facility. A SIGNA PET/MRI system (GE HealthCare, Waukesha, WI) was used to acquire 50-70 min and 80-100 min data for PiB and flortaucipir, respectively. PET reconstructions were performed using standard manufacturer parameters (TOF-OSEM) and with a novel MRgPET algorithm (modified Bowsher's algorithm which uses MR images to regularize the PET updates). Images were evaluated qualitatively by an experienced reader. MR-based brain segmentation with FreeSurfer defined brain regions for quantification of the standard and MRgPET data. Brain region standardized uptake values (SUVs) were divided by the whole cerebellum SUV to provide regional SUV ratios (SUVRs) and analyzed as mean percent differences (standard minus MRgPET) in key brain regions.

RESULTS

Of the 21 subjects, 9 were qualitatively amyloid and tau positive, 8 were amyloid and tau negative, 3 were amyloid positive and tau negative, and 1 was amyloid negative and tau positive. Qualitative evaluation differed in 1 amyloid study and 1 tau study, both of which were considered equivocal. MRgPET reconstruction made apparent activity in the cortex vs. white matter easier to distinguish visually. In the Braak regions, mean % differences in SUVRs ranged from -2.0 to 2.7% for amyloid

and -4.6% to 1.9% for tau. In the frontal, insular, parietal, occipital and temporal cortex, mean % differences ranged from 0.3 to 1.5% for amyloid and -2.3 to 1.3% for tau. In the posterior cingulate and precuneus cortex, mean % differences ranged from 2.1 to 4.5% for amyloid and 0.8 to 2,2% for tau.

CONCLUSION

MRgPET reconstruction provided similar qualitative and quantitative results in key brain regions for amyloid and tau measures as standard PET reconstruction methods, supporting further study in larger cohorts. Improved delineation of the cortex has the potential to facilitate qualitative image interpretation and reduce variability in quantitative measures.

CLINICAL RELEVANCE/APPLICATION

MRgPET reconstruction is feasible for amyloid and tau PET and has the potential to simplify visual assessment of cortical activity compared to standard reconstruction techniques. If MRgPET can reduce variability in quantitative measures such as SUVRs and centiloids, this technique would be valuable for monitoring clearance of amyloid during therapies.

T8-SSNMMI04-3 IDENTIFYING TEMPORAL LOBE ENCEPHALOCELES ON FDG-PET/CT IN FOCAL EPILEPSY

Ajay Kumar, MD, PhD (*Presenter*)
Douglas Roberts-Wolfe, MD, PhD (*Abstract Co-Author*)
Kathryn Davis, MD (*Abstract Co-Author*)
Jacob G. Dubroff, MD, PhD (*Abstract Co-Author*)
Joel M. Stein, MD, PhD (*Abstract Co-Author*)

PURPOSE

Temporal lobe encephaloceles are an increasingly recognized and potentially treatable cause of adult-onset focal epilepsy, particularly in association with idiopathic intracranial hypertension. Standard imaging workup includes brain MRI and FDG-PET/CT; however, small encephaloceles may be subtle or overlooked on MRI alone. We hypothesized that FDG-PET/CT may serve a complementary role by characterizing encephaloceles through metabolic activity and associated osseous remodeling, with FDG PET revealing herniated brain tissue and CT detecting skull base abnormalities.

METHODS AND MATERIALS

In this retrospective study, we identified 27 adult focal epilepsy patients with encephaloceles suggested on MRI who also underwent FDG-PET/CT between August 2020 and August 2024. Two independent neuroradiologists reviewed the PET/CT scans, rating the presence of encephaloceles (absent, questionable, probable, definite, definite with distortion/encephalomalacia), and recording number and location. Discrepancies were resolved by consensus. Temporal pole and skull base foramina locations were specifically assessed.

RESULTS

The neuroradiologists agreed on the presence of probable or definite encephaloceles based on FDG-PET/CT in 63% of cases (17 of 27) and classified 15% (4 of 27) as questionable or absent, occasionally questioning the MRI findings in these cases. Inter-rater disagreement occurred in 22% (6 of 27) of patients. Among agreed-upon cases, encephaloceles were located along the temporal pole in 88% (15 of 17) and at skull base foramina in 35% (6 of 17), with multiple locations noted in some patients and bilateral lesions in 53% (9 of 17).

CONCLUSION

This study suggests that FDG-PET/CT provides a useful and complementary tool for confirming temporal lobe encephaloceles in patients with focal epilepsy. Metabolic activity and CT-based detection of skull base remodeling enhance diagnostic confidence, particularly when MRI findings are subtle or equivocal.

CLINICAL RELEVANCE/APPLICATION

Small temporal encephaloceles may be missed or underestimated even with high-resolution MRI or temporal bone CT. Careful evaluation of FDG-PET/CT can reveal FDG-avid herniated brain tissue associated with osseous changes, supporting the identification of these surgically remediable lesions and refining presurgical planning.

T8-SSNMMI04-4 ASSOCIATION OF REDUCED BRAIN METABOLISM WITH MOTOR FUNCTION AND SURVIVAL IN AMYOTROPHIC LATERAL SCLEROSIS PATIENTS WITH NEUROFILAMENT HEAVY (NEFH) GENE MUTATION

Linmei Zhao, MD, PhD (*Presenter*)
Xiaoping Yi, MD,PhD (*Abstract Co-Author*)
Bihong T. Chen, MD, PhD (*Abstract Co-Author*)

PURPOSE

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease with common clinical symptoms of weakness, atrophy, cognitive changes, and emotional changes. Mutations in neurofilament heavy (NEFH) gene have been linked to neuromuscular disorders and are associated with higher risk for ALS. This study aimed to assess the potential pathological mechanism in ALS patients with NEFH gene mutations (NEFH-ALS) by evaluating brain metabolic alteration and its correlation with clinical features.

METHODS AND MATERIALS

We recruited 127 ALS patients and 128 age- and gender-matched health controls. There were 26 patients with NEFH mutations among the 127 ALS patients. Study assessments included demographic data collection, and questionnaires for motor function, cognition and depression. All participants underwent a brain F-18 FDG PET/CT (fluorodeoxyglucose positron emission tomography (PET)/computed tomography (CT) scan.

RESULTS

NEFH-ALS patients had hypometabolism in the cortex-striatum/limbic system-brainstem circuit when compared with health controls ($p < 0.01$). Decreased brain metabolism was correlated with impairments of motor function($r=0.418$, $p=0.042$), cognitive scores($r=0.473$, $p=0.020$), and depression($r=-0.536$, $p=0.007$). Motor functions were found to be mediated by cognitive function and depression in the patients with NEFH-ALS.

CONCLUSION

Reduced metabolic activity was noted in the cortex-striatum/limbic system-brainstem circuit of patients with NEFH-ALS, which could potentially be an independent prognostic factor for ALS patients with NEFH gene mutation

CLINICAL RELEVANCE/APPLICATION

This study showed that the patients with ALS and NEFH mutations had hypometabolisms of the cortex-striatum/limbic system-brainstem circuit, which was correlated with motor function, cognition, and depression. The reduced brain metabolic activity could potentially be an independent prognostic factor for survival for patients with ALS and NEFH gene mutation.

T8-SSNMMI04-5 IMAGING FOLLOW-UP OF THE THERAPEUTIC EFFECT OF PRUSSIAN BLUE IN TRAUMATIC BRAIN INJURY

Lishuai Feng, PhD (*Presenter*)
Chaoran Dou (*Abstract Co-Author*)
Yuehua Li (*Abstract Co-Author*)

PURPOSE

Traumatic brain injury (TBI), as an acquired injury to the brain caused by external mechanical force, has the highest incidence among all kinds of neurological dysfunctions. No effective pharmacological intervention is available to improve the prognosis of TBI and promising pre-clinical data has not been successfully translated into effective therapeutic to date. Prussian blue nanozyme (PBzyme) with highly stable properties have been applied in multiple neurological diseases. This study aims to investigate the therapeutic effect of PBzyme on TBI with the application of imaging follow-up by multiple in vivo imaging methods.

METHODS AND MATERIALS

Controlled cortical impact, a well-recognized model of TBI, was applied in mice to simulate TBI in this study. After CCI procedure, mice from Saline group and PBzyme group were subjected to intravenous administration of saline and PBzyme, respectively. MRI examination was performed on days 1, 7, 14 and 28 after TBI with a horizontal bore 9.4T/30 cm uMR (uMR 9.4T, United Imaging Life Science Instrument, Wuhan, China). T 2 -weighted imaging (T2WI), diffusion-weighted imaging (DWI), diffusion tensor imaging (DTI), arterial spin labeling magnetic resonance perfusion imaging (ASL-MRI), time-of-flight MR angiography (TOF-MRA), dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) and susceptibility-weighted imaging (SWI) were employed on different time-points after TBI.

RESULTS

PBzyme achieved a reduction in cerebral edema during the hyperacute phase, with further infarct mitigation in the acute, subacute, and chronic phases respectively. Additionally, PBzyme treatment improved cerebral hemodynamics, preserved BBB integrity, mitigated hemorrhage, and promoted axonal fiber remodeling.

CONCLUSION

This study proposes a promising therapeutic method by applying intravenous injected PBzyme to alleviating TBI induced secondary injuries thus improving long-term outcomes of TBI.

CLINICAL RELEVANCE/APPLICATION

This study establishes a promising solution to the limitations of current therapeutic strategies in TBI.

T8-SSNMMI04-6 LONGITUDINAL TRAJECTORIES OF AMYLOID BURDEN AND PLASMA BIOMARKERS IN ALZHEIMER'S DISEASE: A LONGITUDINAL ADNI STUDY

Soheil Mohammadi, MD, MPH (*Presenter*)
Farzaneh Rahmani, MD, MPH (*Abstract Co-Author*)
Mahsa Dolatshahi, MD, MPH (*Abstract Co-Author*)
Suzanne E. Schindler, MD,PhD (*Abstract Co-Author*)
Cyrus A. Raji, MD, PhD (*Abstract Co-Author*)

PURPOSE

Obesity is a risk factor for Alzheimer's disease (AD), but its impact on the trajectories of amyloid burden and blood biomarkers (BBMs) of AD is still scarce. This study investigates how baseline obesity relates to the trajectory of amyloid burdenalongside corresponding changes in BBM.

METHODS AND MATERIALS

Plasma samples from the Alzheimer's Disease Neuroimaging Initiative (ADNI) were assayed using six leading commercial tests. Amyloid positron emission tomography (PET) scans were used to assess amyloid burden. Spearman's partial correlation was used to assess the baseline cross-sectional association between body mass index (BMI) and BBM levels. Linear mixed-effects regression models were used to study three-way interaction between baseline BBM, time, and obesity.

RESULTS

At the baseline cross-sectional level, BMI was not significantly associated with whole brain amyloid burden. However, longitudinal analysis revealed that participants with baseline obesity exhibited a significantly greater rate of amyloid accumulation over time compared to non-obese individuals. At the baseline cross-sectional level, BMI showed no significant correlation with ptau217 levels measured by C2N or Janssen but had significant negative associations with measurements by Fuji, AlzPath, and the C2N ptau217 ratio. BMI was negatively correlated with Roche and QX plasma NfL and GFAP levels. At the longitudinal level, baseline obesity was not directly associated with longitudinal levels of plasma ptau217 and ptau217 ratio. However, all participants showed increases over time, with those who were obese experiencing significantly faster rates of increase compared to non-obese individuals. In the case of plasma NfL, baseline obesity was not consistently associated with longitudinal changes across different measurement methods. Lastly, baseline obesity status had no significant effect on the longitudinal trajectories of plasma GFAP levels.

CONCLUSION

individuals with obesity show faster amyloid accumulation over time despite similar baseline levels. Plasma p-tau217 and its ratio were especially sensitive to these changes. This study provides valuable insights for interpreting amyloid burden BBM levels in response to obesity in AD.

CLINICAL RELEVANCE/APPLICATION

The impact of obesity on trajectories of changes in amyloid burden and BBM of Alzheimer's disease is an important aspect to consider implementing these into clinical practice.

Tammie S. Benzinger, MD, PhD (*Abstract Co-Author*)
John C. Morris, MD (*Abstract Co-Author*)
Cyrus A. Raji, MD, PhD (*Abstract Co-Author*)

PURPOSE

Obesity in midlife is recognized to contribute to Alzheimer disease in late life. We aimed to assess the link between MRI-derived abdominal visceral and subcutaneous adipose tissue (VAT and SAT), insulin resistance, and lipid profile with MRI-derived brain cortical thickness in cognitively normal midlife individuals.

METHODS AND MATERIALS

A total of 98 cognitively normal midlife individuals (Age: 49.34 years, 66.3% female, BMI: 32.46kg/m2, 57.1% obese) underwent brain and body MRI, and metabolic assessment. FreeSurfer 7.1.1 was used for the automatic segmentation of cortical and subcortical brain regions using a probabilistic atlas, followed by visual inspection and if needed, manual editing. VAT and SAT were semi-automatically segmented using an in-house MATLAB-based software, followed by manuals editing. Using Spearman correlation rank test, the association of cortical thickness in late-onset Alzheimer disease (LOAD) regions with BMI, HOMAIR, VAT, SAT, and lipid profile was assessed, with age and sex as covariates and correction for multiple comparisons. Additionally, BMI was added as a covariate in the models for assessing these associations independent from BMI.

RESULTS

Individuals with obesity had significantly higher VAT, SAT, HOMAIR, and lower high-density lipoprotein (HDL) ($p<0.001$ for all). Among the LOAD regions, cortical thinning in right precuneus, superior parietal, lateral occipital and left transverse temporal and temporal pole were linked to higher BMI, after correction for multiple comparisons. Higher VAT was associated with lower cortical thickness in right posterior cingulate, parahippocampal, and fusiform and left entorhinal, middle temporal, superior temporal and temporal pole, independent from BMI. While cortical thickness was associated with SAT, HOMAIR and lower HDL in a couple of the LOAD regions, after controlling for BMI, these associations disappeared.

CONCLUSION

Higher visceral fat is linked to reduced cortical thickness, as a precursor to neurodegeneration later in life, independent from BMI.

CLINICAL RELEVANCE/APPLICATION

Our results highlight the importance of characterizing body fat for the risk of neurodegeneration and its prevention. Modifying visceral fat is of particular importance for brain health.

W1-SSMS03-5 GADOLINIUM-BASED CONTRAST AGENTS AND RISK OF NEPHROGENIC SYSTEMIC FIBROSIS: A "WORST CASE SCENARIO" ANALYSIS OF CONTEMPORARY PRACTICE

Adarsh Mallepally (*Abstract Co-Author*)
NITIN CHETLA (*Abstract Co-Author*)

PURPOSE

We sought to assess the risk of nephrogenic systemic fibrosis (NSF) with contemporary gadolinium-based contrast agents (GBCAs) in patients with advanced renal dysfunction (ARD).

METHODS AND MATERIALS

We performed a retrospective cohort study in the TriNetX US Network, searching for adults with a diagnosis of ARD (chronic kidney disease stage 4-5 or endstage renal disease) who received GBCAs from 2010-2025, further analyzing American College of Radiology (ACR) Group 2 and macrocyclic GBCA subgroups. Propensity score matching (PSM) of demographics and comorbidities was performed to reduce confounding. The primary endpoint was a diagnosis code of possible NSF (ICD-10 L90.8), with a secondary endpoint of codes for possible NSF confounders (e.g. scleroderma, eosinophilic fasciitis) within 1 year. Risk ratios (RR) with 95% confidence intervals were used to assess possible NSF incidence and mortality. Kaplan-Meier curves with log-rank test were used to compare cumulative incidences.

RESULTS

We identified 73,022 adults with ARD who received GBCAs, of which 72,245 (98.9%) were Group 2 and 54,731 (74.9%) were macrocyclic GBCAs. Compared to patients without ARD (n=3,866,899), these patients were more likely to be older, male sex, Black race, and had higher rates of comorbidities. After PSM (n=73,006 per group), there were 31 (0.04%) and 474 (0.68%) patients with ARD with possible NSF and NSF confounder codes, respectively, not significantly different than controls (RR: 0.91 [0.56-1.49], p=0.713 and RR: 0.99, [0.88-1.13], p=0.989, respectively). Cumulative incidence of the two outcomes was similar (?2=0.028, p=0.867; ?2=0.492,

p=0.483; respectively). Among those with ARD receiving ACR Group 2 GBCAs, incidence was similar: 0.04% and 0.69% for possible NSF and confounders, respectively, not different from matched controls. Patients with ARD who received macrocyclic GBCAs had 0.03% and 0.68% rates of endpoints, respectively, also not significantly different than matched controls. Adjusted mortality was higher for patients with ARD within 1 year (RR: 1.97 [1.91-2.02], RR: 1.98 [1.92-2.04], RR: 2.01 [1.94-2.07] for total, ACR group 2, and macrocyclic GBCAs, respectively, p<0.001 for all), similar to risk in patients with ARD who did not receive any GBCAs (RR: 6.06 [5.82-6.31], p<0.001).

CONCLUSION

In this large real-world cohort, the risk of possible NSF following contemporary GBCA use in patients with ARD was exceedingly low and not significantly higher than patients without ARD.

CLINICAL RELEVANCE/APPLICATION

Our findings suggest that the use of modern GBCAs, particularly Group 2 and macrocyclic agents, carry minimal apparent risk of NSF in patients with ARD, supporting their use when otherwise clinically indicated.

W1-SSMS03-6 QUANTITATIVE DIXON MRI-BASED EVALUATION OF PANCREATIC FAT IN OBESE INDIVIDUALS: CORRELATION WITH TYPE 2 DIABETES MELLITUS IN A PILOT COHORT STUDY

Rui Zhang (*Presenter*)
Yi Zhu (*Abstract Co-Author*)

PURPOSE

To investigate the correlation between pancreatic fat fraction measured by Dixon MRI and the presence of type 2 diabetes mellitus (T2DM) in an obese Chinese population, and to evaluate its diagnostic potential as a noninvasive biomarker.

METHODS AND MATERIALS

This retrospective, single-center study enrolled 33 obese adults (BMI =28 kg/m²) who underwent abdominal MRI using a six-echo Dixon sequence between January 2025 and March 2025. Subjects were stratified into three groups: T2DM (n=10), prediabetes (n=11), and normal glucose tolerance (n=12), based on fasting glucose and HbA1c levels. Pancreatic fat fraction (PFF) was quantified by drawing regions of interest (ROIs) on the head, body, and tail of the pancreas. Mean PFF values were compared across groups using one-way ANOVA. ROC analysis was performed to evaluate the diagnostic accuracy of PFF for detecting T2DM. Inter-observer agreement was assessed using ICC. Institutional Review Board approval was obtained, and informed consent was waived.

RESULTS

Mean PFF was significantly higher in the T2DM group (21.5 ± 3.7%) than in the prediabetes (15.6 ± 4.1%) and normal glucose groups (12.2 ± 3.0%) (P < 0.01). ROC analysis yielded an AUC of 0.864 (95% CI: 0.644-0.972) for distinguishing T2DM from non-diabetic individuals using a PFF cutoff of 18.5%. The ICC for inter-observer agreement was 0.91.

CONCLUSION

Pancreatic fat fraction measured by Dixon MRI is significantly elevated in obese individuals with T2DM and may serve as a noninvasive imaging biomarker for metabolic risk stratification. Larger, prospective studies are warranted to validate these findings.

CLINICAL RELEVANCE/APPLICATION

This study suggests that pancreatic fat quantification by Dixon MRI may provide a noninvasive and reproducible imaging tool for early identification of metabolic dysfunction in obese individuals at risk of diabetes.

W1-SSNMMI05-1 ASSOCIATION OF INTEGRATED BIOMARKERS AND PREDICTION OF PFS IN PATIENTS WITH GEP-NET UNDER [177LU]LU-DOTA-TATE THERAPY

Moritz L. Schnitzer, MD (*Presenter*)
Felix Herr, MD (*Abstract Co-Author*)
Maurice Heimer, MD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Matthias Brendel (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)
Clemens C. Cyran, MD (*Abstract Co-Author*)

PURPOSE

Integrated biomarkers that predict survival in patients with gastroenteropancreatic neuroendocrine tumors (GEP-NET) receiving peptide receptor radionuclide therapy (PRRT) are still limited. This study aims to identify predictors of progression-free survival (PFS) in patients with GEP-NET undergoing two cycles of PRRT.

METHODS AND MATERIALS

This single-center retrospective study included 178 patients with GEP-NET (G1 and G2) who received at least two consecutive cycles of PRRT with [177Lu]Lu-DOTA-TATE and underwent somatostatin receptor (SSTR)-PET/CT before and after therapy. At baseline, Krenning score (KS) > 2, clinical, pathological, and laboratory parameters were collected and correlated to PFS. Survival predictors were analyzed using univariate and multivariate models. For goodness-of-fit analysis, the Akaike information criterion and Harrell concordance index were determined. To assess the impact on the regression model, the Wald-Test was performed.

RESULTS

In univariate analysis, KS 3 (vs. KS 4; HR, 2.02; 95% CI, 1.27-3.22; p = 0.003), Ki-67 > 5% (HR, 2.00; 95% CI, 1.31-3.04; p = 0.001), CgA > 200 ng/mL (HR, 1.77; 95% CI, 1.14-2.76; p = 0.011), and NSE > 35 ng/mL (HR, 2.37; 95% CI, 1.44-3.89; p < 0.001) were significantly associated with shorter PFS, with CgA providing the highest C-index (0.6). In multivariate analysis, KS 3 (vs. KS 4; HR, 1.94; 95% CI, 1.17-3.21; p = 0.01), CgA > 200 ng/mL (HR, 1.76; CI, 1.08-2.87; p = 0.024), NSE > 35 ng/mL (HR, 1.98; 95% CI, 1.17-3.36; p = 0.011), and Ki-67 > 5% (HR, 1.89; 95% CI, 1.18-3.02; p = 0.008) were significantly associated with reduced PFS. Including KS into multivariate analysis significantly improved the Cox regression model performance, as shown by a reduction in Akaike Information Criterion (592/596) and an increase in concordance index (0.66/0.65). The Wald test for individual variables supported the significance of both Ki-67 (7.1) and KS (6.7) as independent predictors of PFS.

CONCLUSION

Integrated baseline diagnostics including in-vivo PET-based (Krenning) and ex-vivo histopathological (Ki-67) and laboratory (CgA and NSE) metrics in GEP-NET patients scheduled for two cycles of PRRT have been demonstrated to enhance the accuracy of PFS prediction.

CLINICAL RELEVANCE/APPLICATION

This study underscores the clinical importance of integrating biomarkers such as KS, Ki-67, NSE and CgA to predict PFS in GEP-NET undergoing PRRT. These routinely assessed parameters could be valuable in identifying high-risk individuals prone to disease progression early in treatment, potentially informing therapeutic decisions and enabling more personalized treatment strategies.

W1-SSNMMI05-2 INTEGRATED BIOMARKERS PREDICT SURVIVAL IN GEP-NET PATIENTS TREATED WITH LU-DOTA-TATE THERAPY

Christoph Auernhammer, MD, PhD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)
Clemens C. Cyran, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the prognostic value of clinical, histopathological, laboratory, and imaging-derived parameters for overall survival (OS) prediction in gastroenteropancreatic neuroendocrine tumors (GEP-NET) under peptide receptor radionuclide therapy (PRRT) at baseline.

METHODS AND MATERIALS

We retrospectively analyzed 178 patients with GEP-NETs who underwent at least four cycles of PRRT. At baseline, the Krenning score (KS > 3), clinical, histopathological, and laboratory parameters were collected and correlated with OS. OS predictors were identified using univariate Cox regression analysis and incorporated into multivariate models. Model performance was assessed using the concordance index (C-index) and 95% confidence intervals (CI) for improved precision.

RESULTS

With a median follow-up of 47 months, the median OS was 42 months. In univariate analysis, the following parameters were significantly associated with shorter OS: KS 3 vs. KS 4 ($p = 0.019$), CgA > 200 ng/mL ($p = 0.0015$), NSE > 35 ng/mL ($p = 0.021$), BMI < 18.5 kg/m² ($p < 0.001$), CRP > 0.5 mg/dL ($p = 0.045$), albumin < 4.1 g/dL ($p = 0.006$), and Hb < 12 g/dL ($p = 0.005$). Among these, CgA demonstrated the highest C-index (0.61). The multivariate Cox regression model incorporating BMI, Hb, and CgA exhibited the highest predictive performance (C-index = 0.63, CI: 0.49 - 0.64), followed closely by a model combining KS, Hb, and NSE (C-index = 0.62, CI: 0.50 - 0.64).

CONCLUSION

Our findings support the use of integrated biomarkers at baseline to predict OS in GEP-NET patients receiving four cycles of PRRT.

CLINICAL RELEVANCE/APPLICATION

A multivariate model including the KS demonstrated high predictive performance, underscoring the importance of incorporating molecular imaging parameters for OS prediction.

W1-SSNMMI05-3 PET-BASED QUANTITATIVE PREDICTIONS OF INDIVIDUAL LESION RESPONSE TO PEPTIDE RECEPTOR RADIONUCLIDE THERAPY IN METASTATIC NEUROENDOCRINE TUMORS THROUGH MACHINE LEARNING

Sebastian Salgado-Maldonado, MSc, BSc (*Presenter*)
Victor Santoro-Fernandes (*Abstract Co-Author*)
Brayden Schott (*Abstract Co-Author*)
Alison Deatsch (*Abstract Co-Author*)
Scott B. Perlman, MD, MS (*Abstract Co-Author*)
Robert Jeraj, PhD (*Abstract Co-Author*)

PURPOSE

Metastatic neuroendocrine tumor (mNET) patients typically exhibit heterogeneous lesion-level responses to peptide receptor radionuclide therapy (PRRT). Locoregional approaches (e.g., trans-arterial embolization, stereotactic body radiation therapy) are effective in the management of non-responding NETs, but lesion selection in the metastatic setting is challenging. This study evaluated the feasibility of lesion selection for locoregional therapy of NETs by predicting lesion persistence with machine learning and PET-based longitudinal lesion-level assessment.

METHODS AND MATERIALS

This retrospective study included patients with mNETs treated with [177Lu]Lu-DOTA-TATE PRRT who were scanned using [68Ga]Ga-DOTA-TATE SSTR PET at three timepoints— baseline (BL), post-treatment (PT), and long-term (LT). The median scan times were 1 week before the first PRRT cycle (BL), 16 weeks post-treatment (PT), and 65 weeks post-treatment (LT). Lesions were segmented under clinician supervision and tracked across all timepoints. For each lesion, nine quantitative PET features—SUV mean, median, maximum, minimum, variance, skewness, kurtosis, volume, and total uptake—were extracted. Using BL and PT features, a fully connected neural network (FCNN) was trained to predict lesion persistence on LT. Training features were paired longitudinally and ranked by point biserial correlation. Model sensitivity to feature quantity, and the inclusion of longitudinal information was then assessed through 5-fold cross validation. The best performing model was deployed on a separate test set. The FCNN performance was compared to random forest and logistic regression classifiers.

RESULTS

Training and validation were performed with 462 lesions from 8 patients, and testing with 116 lesions from 5 patients. The AUC varied between 0.77 (with n=1 feature) to a maximum of 0.79 (with n=3 features). The maximum AUC of 0.79 was obtained, when both BL and PL data were used in the predictive model. The AUC decreased to 0.73 using a model trained on BL data only, and 0.67 using PT data only. Finally, on the test data, the FCNN AUC was 0.80, while the AUC slightly lower for logistic regression at 0.79, and the random forest at 0.82.

CONCLUSION

mNET lesions that do not respond favorably to PRRT in the long term can be predicted using a fully connected neural network classifier trained with quantitative and longitudinal SSTR PET features with relatively high accuracy. Longitudinal information from both baseline and early post-treatment imaging are critical for optimal performance.

CLINICAL RELEVANCE/APPLICATION

This methodology enables lesion-specific management of metastatic neuroendocrine tumors for partial responders and is readily extendable to other types of solid tumors.

W1-SSNMMI05-4 "THE LIVER OF BLINDING LIGHTS": CAN THE TOTAL METABOLIC TUMORAL BURDEN PREDICT THE LIVER TOXICITY IN PATIENTS TREATED WITH 177LU-DOTATE?

Javier M. Martinez Martinez, MD (*Presenter*)
Eliana Vazquez (*Abstract Co-Author*)
Mariano Portillo (*Abstract Co-Author*)
MARTINA MUSUMECI (*Abstract Co-Author*)
Mariano Lopez (*Abstract Co-Author*)
Silvina Racioppi (*Abstract Co-Author*)

PURPOSE

The aim of this study was to evaluate the association between baseline tumor burden, measured by metabolic tumor volume (MTV) and total lesion activity (TLA), and the development of hepatotoxicity in patients treated with 177Lu-DOTA-TATE.

METHODS AND MATERIALS

Baseline 68Ga-DOTA-TATE PET/CT images of patients treated with 177Lu-DOTA-TATE were retrospectively reviewed. Baseline wholebody tumor burden was quantified in terms of MTV and TLA and compared with the presence or absence of hepatotoxicity.

RESULTS

A total of 31 patients were included in the study, with a median age of 49 years (IQR 41-59). Of these, 15 (48%) were female and 16 (52%) were male. 75% of the cohort had grade 2 tumors, and 60% of the patients received four doses of 177Lu-DOTA-TATE. Disease progression was observed in 30% of the cohort, and 18% died. Hepatic toxicity of any grade occurred in 23% of patients at some point during treatment. The median metabolic tumor volume (MTV) was 170 cm^3 (IQR 49-571 cm^3), while the median total lesion activity (TLA) was 2702 $SUV \cdot cm^3$ (IQR 874-9202 $SUV \cdot cm^3$). Among patients who developed hepatic toxicity, the median MTV was 305 cm^3 (IQR 25-978 cm^3), compared to 151 cm^3 (IQR 50-544 cm^3) in those without toxicity, with no statistically significant difference ($p = 0.7$). Similarly, the median TLA in patients with hepatic toxicity was 6169 $SUV \cdot cm^3$ (IQR 459-23691 $SUV \cdot cm^3$), versus 2477 $SUV \cdot cm^3$ (IQR 955-8213 $SUV \cdot cm^3$) in those without toxicity, also without statistical significance ($p = 0.7$).

CONCLUSION

In conclusion, while a group of patients experienced hepatic toxicity during 177Lu-DOTA-TATE treatment, no statistically significant association was found between toxicity and baseline MTV or TLA values. These findings suggest that further research is needed to identify reliable predictors of hepatic toxicity in this patient

population. Furthermore, this line of research needs to continue to expand the number of patients involved in order to increase the statistical power of the groups involved.

CLINICAL RELEVANCE/APPLICATION

Understanding the relationship between baseline tumor burden and hepatotoxicity is clinically relevant, as it may help identify patients at higher risk for liver-related adverse events during 177Lu-DOTA-TATE therapy and guide treatment planning.

W1-SSNMMI05-5 OPTIMAL SCAN TIME FOR (18F)SITATE PET/CT IMAGING OF PATIENTS WITH NEUROENDOCRINE TUMORS

Lukas Salvermoser, MD (*Presenter*)
Ricarda Ebner, MD (*Abstract Co-Author*)
Felix Herr, MD (*Abstract Co-Author*)
Christian Alexander Dascalescu, MD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Clemens C. Cyran, MD (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)

PURPOSE

The fluorine-18-labelled, somatostatin receptor (SSR)-targeting tracer [¹8F]SiTATE is gaining momentum in clinical use as a promising alternative to commonly used gallium-68-labelled SSR-targeting compounds, demonstrating excellent image quality and clinical utility. Currently, imaging with SITATE-PET/CT is performed 90 minutes after tracer injection, complicating its integration into a multi-tracer PET environment, in which most tracers are imaged 60 minutes after tracer injection. We therefore investigated whether comparable image quality and quantification can be achieved at other time points, that better integrate into clinical routine.

METHODS AND MATERIALS

Eight NET patients with histologically confirmed metastasized GEP-NET received a [18 F]SiTATE-PET/CT (250 ± 66 MBq) with repeated emission scans 60, 90, and 120 minutes post-injection. SUVmax, SUVpeak and SUVmean were measured in visceral organs and in a total of 49 SSR-positive lesions (lymph nodes, liver and bone), and tumor-to-background ratios were calculated. Statistical comparison was performed across the three time points. Additionally, scans were visually evaluated for clinically noticeable differences by four readers with varying levels of experience.

RESULTS

No significant differences in tumor-to-background ratios were observed across time points for liver (p=0.6613), lymph nodes (p=0.5413), bone (p=0.8478), or overall lesion assessment (p=0.7248). Post hoc multiple comparisons using Tukey's test revealed no significant pairwise differences (p=0.5103-0.999). Individual readers did not report any relevant qualitative visual difference between the time points; all lesions could be clearly identified against the surrounding background.

CONCLUSION

The results demonstrate a consistent tracer uptake pattern over time, with minimal variation in tumor-to-background contrast across different metastatic sites. Imaging at 60 minutes post-injection yields equivalent lesion detectability and quantitative contrast compared to later time points at 90 and 120 minutes. These findings underscore the clinical utility of early imaging with [¹8F]SiTATE for NET patients, offering the potential to facilitate workflow and enhance patient comfort without sacrificing diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

Early [¹8F]SiTATE PET/CT at 60 minutes post-injection provides equivalent diagnostic performance to later imaging, enabling faster workflows and improved patient management without compromising accuracy.

W1-SSNMMI05-6 STANDARDIZED IMAGING EVALUATION OF GASTROENTEROPANCREATIC NEUROENDOCRINE TUMORS USING SSTR-RADS 1.0 CRITERIA

Marta Vaillant, MD (*Presenter*)
Eliseo Vano Galvan, PHD (*Abstract Co-Author*)
Cristina Rodriguez Rey (*Abstract Co-Author*)
Pedro Nespral Torres, MD (*Abstract Co-Author*)
Gonzalo Cuesta Domingo, MD (*Abstract Co-Author*)
Maria Zapardiel, MD (*Abstract Co-Author*)
Patricia Romero Fernandez, MBBS (*Abstract Co-Author*)
Luisa F. Leon, MD (*Abstract Co-Author*)
Cristina G. Wakfie Corieh, MD (*Abstract Co-Author*)
Paloma Dauden (*Abstract Co-Author*)

PURPOSE

To determine the correlation between SSTR-RADS 1.0 criteria for 68Ga-DOTATOC PET-CT and definitive diagnosis in gastroenteropancreatic neuroendocrine tumors (GEP-NET).

METHODS AND MATERIALS

Retrospective analysis of patients who underwent 68Ga-DOTATOC PET-CT with i.v. iodinated contrast agent by GEP-NET between August/2019 and December/2023. Two nuclear medicine physicians with >15 years of experience determined SSTR-RADS (1-5) and uptake score (1-3) (Werner et al, J Nucl Med 2018;59:1085-91). Categories 4/5 were considered positive for NET, 1/2 negative for NET. Category 3 was the most controversial of the different subcategories and required further individualised analysis. Histopathological examination (HE) or clinical follow-up (CFU) was considered the gold standard. SP, E, PPV and NPV were calculated. A ?² test and logistic regression were performed.

RESULTS

77 patients (45 males), mean age 63.5 (25-87 years), with suspected or diagnosed GEP-NET. The gold standard was HE (n=28) or CFU (n=49; mean 19.16 months). In 11 cases of suspected neoplasia, GEP-NET was not confirmed by imaging or CF. Of the 66 patients with NET, 38 had stage III-IV disease. Most of the NETs were located in the pancreas (n=33) and small intestine (n=31), 4 were MEN-1. Of the 66 GEP-NET: G1 (n=47), G2 (n=17) and G3 (n=2). The most common metastatic sites were regional lymph nodes (28.6%) and liver (29.9%). SP=100%, E=76%, PPV=90%, NPV=100%. An association was found between SSTR-RADS 1.0 classification and NET diagnosis (?²=58.625, p-value<0.001). Logistic regression showed a capacity for correct SSTR-RADS classification of 85.7%. In categories 4 and 5, 100% (n=47) showed tumor. In category 3 (n=13) only 38.5% (2/2 labelled as 3A and 3/9 of 3D) showed NET. In 3C, none (n=2) corresponded to NET. In category 1 (n=17) 17.6% had NET.

CONCLUSION

The SSTR-RADS 1.0 criteria allow the correct diagnosis of NET in a high percentage of patients. Category 3, especially 3D, requires further confirmation.

CLINICAL RELEVANCE/APPLICATION

Is important in the context of nuclear imaging because it promotes standardized interpretation and reporting of somatostatin receptor (SSTR)-targeted PET/CT studies in patients with gastroenteropancreatic neuroendocrine tumors (GEP-NETs). By applying the SSTR-RADS 1.0 criteria, the study contributes to reducing interobserver variability, enhancing diagnostic accuracy, and improving communication among multidisciplinary teams. These improvements are critical for appropriate patient management, therapy selection—particularly regarding peptide receptor radionuclide therapy (PRRT)—and consistent follow-up in clinical practice and research.

W1-SSNPM03-2 PATIENT PERCEPTIONS OF THE USE OF ARTIFICIAL INTELLIGENCE (AI) IN A TERTIARY REFERRAL RADIOLOGY DEPARTMENT

Hayley Briody, MBBCh (*Presenter*)
Sneha Singh (*Abstract Co-Author*)
Richard Bruen, MRCPI (*Abstract Co-Author*)
Ruth M. Dunne, MBBCh (*Abstract Co-Author*)
Martina M. Morrin, MD (*Abstract Co-Author*)
Nuala A. Healy, MD, MEd (*Abstract Co-Author*)

PURPOSE

To determine patient attitudes towards the use of artificial intelligence (AI) in a tertiary referral radiology department.

METHODS AND MATERIALS

This study was conducted using a voluntary, 16-item questionnaire distributed to patients attending the radiology department. The questionnaire includes questions on basic demographics, general attitudes towards AI in healthcare, attitudes to radiology-specific applications of AI and willingness to consent for anonymised personal data to be used for training AI models in a research setting. Responses were collated in a prospectively maintained excel datasheet. Data analysis was performed using R Studio and Microsoft Excel. Institutional review board approval was obtained prior to study commencement.

RESULTS

1,041 responses were collected during the study period, 90 of which were incomplete. The majority of respondents were aged 50-69 (42.3%) and of white Irish ethnicity (85.4%). 55.1% respondents agreed or strongly agreed that the use of AI in healthcare is a good idea. Participants aged > 70 years were more likely to respond "I don't know" when asked about their interest in AI ($p<0.05$). Higher level of education (Masters degree or higher) was associated with an increased likelihood of strong interest in AI ($p<0.05$). When asked if they would allow a radiologist and AI to interpret their imaging, over two thirds (67.3%) respondents agreed or strongly agreed. However, when asked if they would allow AI to act as the sole reader of their imaging only 20.4% respondents agreed or strongly agreed. Most patients (67.2%) would still prefer a radiologist to interpret their imaging even if AI was a more accurate reader. 40% respondents disagree or strongly disagree with the statement "I think replacement of radiologists by AI could happen in the future". Only 4% of patients indicated the use of AI for reporting of radiology images did not need to be disclosed with the majority (54%) wishing to be asked for written consent. Overall, patients were agreeable to having their images shared for the purposes of research into AI tool development (70.9% agreed or strongly agreed).

CONCLUSION

Overall, patients have a positive attitude toward the use of AI in healthcare. However, the majority of respondents in this study would not agree to AI as the sole reader of their imaging even if quicker, more efficient and more accurate. Over half of respondents wish to be asked for written consent if AI is to be used in the interpretation of their radiological imaging.

CLINICAL RELEVANCE/APPLICATION

This study suggests that patients are not ready for standalone AI and would prefer written consent prior to the use of AI for interpretation of their radiological images and this should be considered in clinical practice going forward.

W1-SSNPM03-3 ACCELERATING ICD-10 CODING OF PET/CT REPORTS WITH CHATGPT: A COMPARATIVE STUDY

Tristan Ruhwedel, MD (*Presenter*)
Julian Rogasch (*Abstract Co-Author*)
Paul Martin Dahlke (*Abstract Co-Author*)
Seyd Shnayien, MD (*Abstract Co-Author*)
Christian Furth (*Abstract Co-Author*)
Christoph Wetz (*Abstract Co-Author*)
Imke Schatka (*Abstract Co-Author*)
Holger Amthauer, MD (*Abstract Co-Author*)
Nick Lasse Beetz, MD (*Abstract Co-Author*)

PURPOSE

Radiologists often work up to five extra hours weekly on administrative tasks, potentially reducing time for patient care and increasing the risk for burnout. Large language models (LLMs) such as ChatGPT o1 can potentially reduce administrative workloads. Radiology reports in the U.S. must be assigned to an ICD-10 code for insurance reimbursement. Therefore, we aimed to investigate whether ChatGPT o1 can be consulted to assist in assigning ICD-10 codes to PET/CT examination reports.

METHODS AND MATERIALS

100 different fictious PET/CT reports were created based on standardized institutional text modules for PET/CT including contrast-enhanced diagnostic CT. Each report was assigned a single, most relevant ICD-10 code by two experienced nuclear medicine physicians. Coding of multiple reports at the same time was allowed. One

physician used ChatGPT o1, while the other was limited to traditional search engines. Time was recorded in seconds, from the beginning of report review to entry of the ICD-10 code into a data table. Discrepancies were resolved via a blinded consensus process. Differences in error distribution across ICD-10 hierarchy levels were analyzed using four-field tables and the McNemar test. Time differences were assessed using the Wilcoxon signed-rank test.

RESULTS

At the first character of the ICD-10 code, the ChatGPT-assisted coder made 2 errors compared to 3 errors by the manual coder ($p = 1.0$). For the second and third characters, ChatGPT-based coding resulted in 3 errors versus 5 ($p = 0.727$). At the fourth and fifth characters, ChatGPT o1 significantly outperformed manual coding, with 6 errors versus 17 ($p = 0.035$). Overall, the ChatGPT-assisted coding resulted in 6 incorrect codes, whereas manual coding led to 18 ($p = 0.023$). Median coding time was 135 seconds (range 41 - 433 s) without ChatGPT and just 8 seconds (range 6 - 9 s) with it. The median time difference between both coders was 127 seconds (range 33 - 424 s; $p < 0.001$).

CONCLUSION

ChatGPT o1 demonstrates faster coding times and higher accuracy when assigning ICD-10 codes to PET/CT examination reports. Given the complexity of PET/CT reports, similar approaches might be feasible for other imaging modalities like diagnostic CT or MRI. Providers of LLMs should develop software solutions that fulfill the stringent data protection requirements in healthcare settings.

CLINICAL RELEVANCE/APPLICATION

Higher accuracy of ICD-10 codes might reduce billing errors and insurance rejections, while saved time could be reallocated to patient care. As total-body PET/CT becomes more widely adopted and scan durations decrease, these efficiencies might prevent up to an hour of overtime daily in a center performing 30 PET/CT scans, potentially helping alleviate administrative burdens and reduce burnout risk.

W1-SSNPM03-4 ENHANCING THE CLINICAL USABILITY OF CANCER PATHOLOGY REPORTS THROUGH LLM-BASED SUMMARIZATION

Jacob John, BEng, MS (*Presenter*)
Yirong Liu, MD, PhD (*Abstract Co-Author*)
Sagnik Sarkar, MS (*Abstract Co-Author*)
Paul Kinkopf (*Abstract Co-Author*)
Abdul Zakkar (*Abstract Co-Author*)
Peng (Troy) Teo, PhD (*Abstract Co-Author*)
Mohamed Abazeed (*Abstract Co-Author*)

PURPOSE

Reviewing multiple pathology reports during oncology consultations is time-intensive and prone to error due to information fragmentation, variability in testing modalities, and the cognitive fatigue associated with synthesizing complex clinical findings. This study evaluates the effectiveness of large language models (LLMs) in generating clinically accurate and complete summaries of pathology reports to reduce physician documentation burden while preserving medical fidelity.

METHODS AND MATERIALS

This retrospective study included patients who underwent initial consultations in a thoracic oncology clinic between January 2019 and July 2023. Original pathology reports and corresponding physician-generated pathology summaries were extracted and anonymized from the electronic health record. Six open-source LLMs—LLaMA 3.0, LLaMA 3.1, LLaMA 3.2, DeepSeek R1, Mistral 7.2B, and Gemma 9B—were used to generate summaries from the original pathology reports. The evaluations were conducted using a hybrid framework combining objective metrics (ROUGE, METEOR, BLEU, and BERT Score via llama-based embeddings for long-form medical summaries) and subjective assessments (based on completeness, correctness, conciseness, and potential harm) by clinical experts.

RESULTS

Ninety-four cases met the inclusion criteria. Across all objective metrics, LLM-generated summaries scored significantly higher than physician-generated summaries ($p < 0.0001$). Subjectively, DeepSeek, Mistral, LLaMA 3.1, and LLaMA 3.2 outperformed physicians in completeness ($p = 0.017$, $p < 0.0001$, $p < 0.0001$, and $p < 0.0001$, respectively) while maintaining equivalent levels of correctness ($p = 1.000$). Consistency in findings was confirmed through multi-evaluator subjective analysis of LLaMA 3.1 summaries.

CONCLUSION

LLM-generated pathology summaries demonstrated superior performance compared to physician summaries in both objective and subjective evaluations. These findings highlight the potential of LLMs to improve the completeness of clinical documentation while preserving accuracy and, hereby, offering a scalable solution to reduce the cognitive and time burden of pathology review.

CLINICAL RELEVANCE/APPLICATION

Integrating LLMs into clinical workflows may enhance documentation efficiency and reduce physician fatigue, particularly in complex fields such as oncology. By producing concise and complete pathology summaries, LLMs can support more informed and timely clinical decision-making, potentially improving patient care outcomes with minimal risk of error.

W1-SSNPM03-5 AI-POWERED MRI: TIME, ENERGY, AND EMISSION SAVINGS FOR A GREENER FUTURE

Tiziano Polidori, MD (*Presenter*)
Marta Zerunian, MD (*Abstract Co-Author*)
Michela Polici, MD (*Abstract Co-Author*)
Domenico De Santis, MD (*Abstract Co-Author*)
Damiano Caruso, MD, PhD (*Abstract Co-Author*)
Marco Francone, MD, PhD (*Abstract Co-Author*)
Andrea Laghi, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of artificial intelligence (AI)-assisted MRI on scan time, energy consumption, and greenhouse gas (GHG) emissions in routine clinical practice, and to quantify the potential sustainability benefits of AI integration across different anatomical districts.

METHODS AND MATERIALS

This retrospective study included 148 patients: 45 undergoing upper abdomen MRI, 53 cardiac MRI, and 50 lumbar spine MRI. Each patient underwent conventional and AI-assisted MRI acquisitions. Air Recon DL (GE Healthcare) was applied to T2 and DWI sequences for upper abdomen MRI and to T1, T2, and STIR sequences for lumbar spine MRI. Sonic DL was applied to SSFP sequences for cardiac MRI. Time saved per patient, energy reduction (kW/h), and CO_2-equivalent emissions were recorded and statistically analyzed. All scans were performed on 1.5T and 3T scanners, and AI-enhanced protocols were developed in collaboration with the vendor to ensure diagnostic equivalence. Energy consumption was calculated based on scanner-specific power profiles and scan durations. Emission data were derived using standard CO_2-equivalent conversion metrics based on national electricity production sources. Statistical significance was established using paired t-tests with $a=0.05$.

RESULTS

AI application resulted in significant time savings per patient: 5’11’’ (58%) for upper abdomen MRI, 1’30’’ (52%) for cardiac MRI, and 6’ (50%) for lumbar spine MRI (all $p<0.01$). These reductions translated into energy savings of 1.39, 0.40, and 1.68 kW/h, and CO_2 emission reductions of 0.57 kg, 0.16 kg, and 0.69 kg, respectively (all $p<0.05$).

CONCLUSION

AI integration in MRI protocols enables significant reductions in acquisition time, energy use, and GHG emissions, supporting its role in sustainable imaging practices. By optimizing acquisition efficiency while maintaining diagnostic accuracy, AI-enhanced MRI protocols represent a pivotal innovation for the future of eco-responsible radiology.

CLINICAL RELEVANCE/APPLICATION

AI-powered MRI can substantially reduce the environmental impact of diagnostic imaging, offering a green pathway for routine clinical workflows.

W1-SSNPM03-6 ENHANCING MRI EFFICIENCY AND DIAGNOSTIC ACCURACY WITH ARTIFICIAL INTELLIGENCE: A COMPARATIVE ANALYSIS OF IMAGE QUALITY, DIAGNOSTIC CONFIDENCE, AND PATIENT EXPERIENCE

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)
Natalia Soria (*Abstract Co-Author*)
Victor Miguez (*Abstract Co-Author*)
Gabriel Bolzan (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the impact of deep learning-based artificial intelligence (AI) in magnetic resonance imaging (MRI) by assessing its effectiveness in image quality enhancement, diagnostic confidence, and patient experience, compared to conventional MRI acquisitions.

METHODS AND MATERIALS

This study was approved by the institutional ethics committee, and a retrospective analysis was conducted on patients who underwent MRI examinations of the spine and musculoskeletal regions (knee, hip, and shoulder) at our institution. Each MRI was performed using AI-based image reconstruction technology (AIR™ Recon DL, GE Healthcare), followed by an additional sequence without AI assistance for comparison. Image quality was evaluated using a 3-point scale (1 = regular, 2 = good, 3 = excellent), and diagnostic accuracy was assessed based on the detection of pathological findings. To assess patient experience, a post-exam survey was conducted regarding their perception of scan duration. Two groups were analyzed: Group 1 (AI-assisted MRI, 3T scanner): Reduced scan times by approximately 50%. Group 2 (conventional MRI, same scanner model): Standard scan duration without AI acceleration. Patients rated their perceived scan duration using a 3-point scale: 1 = very short/short, 2 = usual/indistinct, 3 = long/very long.

RESULTS

A total of 331 patients were included in the image quality and diagnostic confidence analysis. The AI-assisted MRI group achieved a mean image quality rating of 2.6, compared to 2.2 in the conventional group. Regarding diagnostic accuracy, AI-assisted MRI demonstrated a sensitivity of 99%, specificity of 86%, positive predictive value (PPV) of 95%, and negative predictive value (NPV) of 94%. For patient experience, we analyzed 600 responses (300 per group). In Group 1 (AI-assisted MRI), 85% of patients rated the scan as very short or short, whereas in Group 2 (conventional MRI), 40% found the duration normal, and 45% considered it long or very long.

CONCLUSION

The integration of AI-powered image reconstruction in MRI significantly enhanced image quality and diagnostic confidence, demonstrating high sensitivity and specificity. Additionally, AI-driven acceleration led to a substantial reduction in scan duration, improving patient comfort and overall experience. These findings highlight the clinical value of AI in MRI, optimizing workflow efficiency while maintaining high diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

The clinical value of AI in MRI in optimizing workflow efficiency while maintaining high diagnostic performance.

W1-SSVA03-2 DUAL-ENERGY BLACK-BLOOD CT FOR FOOT ARTERIAL WALL THICKNESS MEASUREMENT IN PREDICTING DIABETES MELLITUS

Jianjun Shen, PhD (*Presenter*)
Cheng Yan (*Abstract Co-Author*)
Sihua Zhong, MD (*Abstract Co-Author*)

PURPOSE

To develop a dual-energy black-blood CT (DE-BBCT) technique, validate its improved measurement of foot arterial wall thickness and potential for predicting diabetes mellitus, by comparing it with the optimal angiography virtual mono-energetic image (VMI) and conventional CT angiography (CTA).

METHODS AND MATERIALS

A total of 50 patients (25 diabetic and 25 non-diabetic) were retrospectively enrolled, and all underwent DECT (80 kVp/Sn140 kVp) immediately following lower extremity CTA (120 kVp). Optimal 60 keV VMI and virtual non-contrast (VNC) images were obtained from the DECT data. DE-BBCT was developed by subtracting VNC images from VMI to create iodine maps, and further subtracting the iodine maps from VNC images to differentiate the arterial wall from the lumen. On VMI, CTA, and DE-BBCT images, two readers independently measured the signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and the bilateral popliteal artery wall thickness (PAWT), with mean values calculated for analysis. Inter-observer agreement for PAWT measurements was quantitatively evaluated using the intraclass correlation coefficient (ICC). Receiver operating characteristic (ROC) analysis was performed to assess the predictive value of PAWT for diabetes, using clinical diagnosis as the reference standard.

RESULTS

DE-BBCT demonstrated significantly higher SNR and CNR than VMI and conventional CTA (all $p < 0.05$), indicating superior arterial wall visualization. It also achieved the highest inter-observer agreement for PAWT measurements (ICC = 0.897), outperforming VMI (ICC = 0.826) and CTA (ICC = 0.788). All three imaging modalities consistently showed popliteal artery wall thickening in diabetic patients, with significantly higher PAWT values compared to non-diabetic patients (VMI: 1.08 ± 0.22 vs 0.83 ± 0.16 mm; CTA: 1.05 ± 0.21 vs 0.82 ± 0.16 mm; DE-BBCT: 1.11 ± 0.22 vs 0.83 ± 0.18 mm; all $p < 0.05$). Notably, PAWT derived from DE-BBCT showed good predictive value for diabetes, with an area under the curve (AUC) of 0.835. The AUCs for CTA and VMI were 0.803 and 0.817, respectively.

CONCLUSION

Dual-energy black-blood CT offers superior visualization of the foot arterial wall, enabling more reliable thickness measurements, and shows strong potential as a predictive marker for diabetes.

CLINICAL RELEVANCE/APPLICATION

Dual-energy black-blood CT provides a reliable method for detecting foot arterial wall thickening in diabetic patients, facilitating early identification of vascular changes and enhancing clinical decision-making.

W1-SSVA03-5 CLINICAL APPLICATION OF DARK-BLOOD IMAGING IN INTRAMURAL HEMATOMA: EFFECT ON IMAGE QUALITY AND LESION VISIBILITY

Ke Wei, MD (*Presenter*)

PURPOSE

To evaluate a novel subtraction-based dark-blood imaging (DBI) technique for improving aortic intramural hematoma (IMH) visualization, comparing its performance against true non-contrast (TNC) and arterial phase (AP) CT.

METHODS AND MATERIALS

Twenty-four IMH patients undergoing whole-aorta spectral CTA were retrospectively enrolled (mean age 65.8±10.2 years; 75% male). Quantitative metrics—contrast-to-noise ratio (CNR), image signal-to-noise ratio (SNR image), lesion SNR (SNR leison), wall-to-lumen ratio (WLR), wall-to-fat ratio (WFR) were compared across TNC, subtraction-based DBI and AP. Two radiologists independently scored lesion visualization (4-point Likert scale) and wall clarity (5-point scale). Wall thickness (WT) measurements and interobserver agreement (intraclass correlation coefficients, ICCs) were analyzed using propagated ROIs and Friedman tests.

RESULTS

Subtraction-based DBI and AP demonstrated superior SNR image (IQR: 18.15 [11.79, 22.00] and 33.98 [21.19, 39.91] vs. 8.38 [5.43, 10.57], respectively), CNR i mage (IQR: 12.01 [8.88,15.75] and 24.41 [16.01, 31.29] vs. 0.39 [0.11, 1.16], respectively), and WLR (IQR: 18.72 [13.47-25.33] and 29.36 [20.21-36.57] vs. 1.79 [0.56-2.64], respectively) compared to TNC. While TNC achieved higher SNR leison than subtraction-based DBI and AP (IQR: 5.73(2.53-8.09) vs. 2.64(1.89-4.34) and 3.83(2.65-39.91)). Qualitatively, Subtraction-based DBI outperformed TNC/AP in lesion visualization (DBI: 4.00 [4.00, 4.00], AP: 3.00 [2.25, 3.00], TNC: 2.00 [1.00, 2.00]) and inner wall clarity (DBI: 5.00 [4.25, 5.00], AP: 3.00 [3.00, 4.00], TNC: 1.50 [1.00, 2.00]) ($P<0.05$), while both subtraction-based DBI and AP surpassed TNC in outer wall clarity ($P<0.05$). Subtraction-based DBI yielded significantly larger WT measurements (IQR 9.62 [7.79, 10.78] mm vs. TNC: 8.06 [6.58, 9.58] mm and AP: 7.85 [6.86, 9.71] mm; $P<0.05$). Interobserver agreement was moderate to substantial (?=0.506-0.778). No intermodal differences were observed in WFR.

CONCLUSION

Subtraction-based DBI enhances IMH assessment through superior quantitative metrics and qualitative visualization, enabling accurate wall thickness measurements unattainable with conventional CT.

CLINICAL RELEVANCE/APPLICATION

DBI mitigates beam-hardening artifacts from AP imaging, improving IMH lesion delineation and measurement precision, with direct implications for vascular pathology management.

W1-SSVA03-6 BLACK-BLOOD CT COMBINED WITH CE-BOOST SIGNIFICANTLY ACCELERATES PORTAL VEIN SEGMENTATION AND ENHANCES IMAGE QUALITY

Huasong Cai (*Presenter*)
Zhiman Lai (*Abstract Co-Author*)
Dingxiang Xie (*Abstract Co-Author*)
Rulin Xu (*Abstract Co-Author*)

PURPOSE

To determine whether integration of black-blood CT (BBCT) with contrast-enhancement boost (CE-boost) post-processing can reduce manual portal vein segmentation time and improve both subjective and objective image quality of the portal venous system compared with conventional and CE-boost-only workflows.

METHODS AND MATERIALS

In this IRB-approved retrospective study, 50 consecutive patients (34 men, 16 women; mean age 49.7 ± 14.2 years) who underwent abdominal CTA between April and May 2024 were evaluated. Three post-processing pipelines were applied to the portal venous phase datasets: conventional multiplanar MIP/volume rendering (Group A), CE-boost (Group B), and CE-boost plus BBCT arterial subtraction (Group C). A single experienced operator recorded segmentation times for each method. Two blinded senior radiologists rated image quality on a 5-point scale (branch visibility, wall delineation, artifacts, noise), with scores =3 considered diagnostic. Objective metrics—signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR)—were measured in standardized ROIs within the main portal vein and its branches. Data are reported as median (Q1-Q3) or mean ± SD; comparisons used Kruskal-Wallis and ANOVA with $P < 0.05$ deemed significant.

RESULTS

Median segmentation times were 5.1 min (3.6-7.9) in Group A, 4.2 min (2.8-6.7) in Group B, and 2.2 min (1.9-3.5) in Group C ($P < 0.001$). The wider IQRs in Groups A and B reflected variability due to residual arterial signals, whereas Group C showed a tighter distribution. Interobserver agreement for subjective scores was excellent (ICC > 0.92). Group C achieved the highest median image quality score of 5.0 (4.9-5.0), compared with 4.4 (4.3-4.4) in Group B and 3.7 (3.7-3.7) in Group A ($P < 0.001$). Objective analysis demonstrated significantly higher SNR and CNR in Group C across the main portal vein and branches (all $P < 0.001$).

CONCLUSION

BBCT integration with CE-boost CTA nearly halves manual portal vein segmentation time while narrowing variability and delivers superior subjective and objective image quality by effectively suppressing residual arterial signals.

CLINICAL RELEVANCE/APPLICATION

Automated arterial subtraction via BBCT streamlines 3D portal vein visualization and segmentation, offering radiologists a rapid, reliable workflow for preoperative planning and diagnostic evaluation of portal venous pathology.

W2-STCE1-1 PREDICTING PULMONARY FUNCTION IN LUNG CANCER SCREENING: OPPORTUNISTIC USE OF DEEP LEARNING AND CHEST CT FOR LUNG DISEASE ASSESSMENT

Joao Fonseca, MD (*Presenter*)
Alan Medeiros Guimaraes (*Abstract Co-Author*)
Alysson Roncally S. Carvalho, MD,PhD (*Abstract Co-Author*)
Kyle See (*Abstract Co-Author*)
MD MAHFUZ AL HASAN (*Abstract Co-Author*)
Rosana S. Rodrigues, MD, PhD (*Abstract Co-Author*)
Bruno Hochhegger, MD, PhD (*Abstract Co-Author*)

PURPOSE

Chronic obstructive pulmonary disease (COPD) is a leading cause of mortality globally, yet it remains underdiagnosed due to the limited use of spirometry, especially in resource-constrained settings. Chest CT is commonly employed in lung cancer screening and COPD assessment, but its potential for predicting pulmonary function using AI models has been underexplored. This study aims to evaluate a hybrid AI model that combines CT projections with lobar attenuation features to predict spirometric parameters, offering an opportunistic and low-computational-demand method to identify patients at risk for abnormal pulmonary function.

METHODS AND MATERIALS

This retrospective study analyzed low-dose chest CT scans and spirometry data from the National Lung Screening Trial (N = 7,933) and an external cohort from Brazil (N = 266). A convolutional neural network was trained using three coronal CT projections, combined with quantitative CT features. The model's ability to predict FEV1, FVC, and the FEV1/FVC ratio was evaluated, alongside its accuracy in identifying abnormal pulmonary function. For continuous PFT prediction, accuracy was assessed using root mean square error (RMSE), mean absolute error (MAE), and concordance metrics. For binary classification (normal vs. abnormal pulmonary function), performance metrics such as accuracy, sensitivity, specificity, and the summary receiver operating characteristic (SROC) curve were evaluated.

RESULTS

The model demonstrated an accuracy of 88.3%, sensitivity of 88.9%, specificity of 88.0%, and an SROC AUC of 0.93 for detecting abnormal pulmonary function in the external test cohort. Continuous predictions from the model showed strong correlations with reference spirometry (all $r > 0.7$). For the FEV1/FVC ratio, the model achieved a concordance correlation coefficient (CCC) of 0.70, an RMSE of 0.11, and a MAE of 0.09. For FEV1, the CCC was 0.67, with an RMSE of 0.52 and an MAE of 0.41. For FVC, the CCC was 0.60, with an RMSE of 0.74 and an MAE of 0.60.

CONCLUSION

This study introduces a novel hybrid model that accurately predicts pulmonary function using low-dose chest CT, achieving high predictive performance. The model surpasses more complex approaches, providing a streamlined and efficient tool for identifying individuals at risk for abnormal pulmonary function.

CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of AI-based imaging biomarkers, requiring low computational power, for opportunistic pulmonary function testing in lung cancer screening. It presents an opportunity to optimize spirometry referrals and enhance COPD diagnosis in high-risk patients.

W2-STCE1-2 LYMPH NODE ADIPOSITY AND BREAST ARTERIAL CALCIFICATION: OPPORTUNISTIC IMAGING BIOMARKERS OF CARDIOVASCULAR DISEASE RISK ON SCREENING MAMMOGRAPHY

Roberta M. diFlorio-Alexander, MD, MS (*Presenter*)
Judith M. Austin-Strohbehn, MD (*Abstract Co-Author*)
Clifford J. Eskey, MD, PhD (*Abstract Co-Author*)
Thara Ali (*Abstract Co-Author*)

PURPOSE

Cardiovascular disease (CVD) remains the leading cause of death among women in the United States (U.S.). Screening mammograms contain imaging features such as breast arterial calcification (BAC) that may be opportunistically used to identify women at high risk for CVD. Emerging evidence suggests that axillary lymph node adiposity (LNA) — defined as cancer-free lymph nodes enlarged by excess hilar fat (Figure 1) — may serve as an additional imaging biomarker of CVD risk on mammography. This study aims to compare the associations of LNA and BAC, independently and combined, with (a) high CVD risk calculated by the pooled cohort equation (PCE) defined as >7.5% 10-year risk of a major adverse cardiovascular event (MACE) and (b) incidence of MACE

METHODS AND MATERIALS

In this retrospective cohort study, we evaluated 1206 consecutive women aged 40-75 who underwent routine screening mammography at our institution from 2011 to 2012 and who had a PCE risk assessment within one year of imaging. MACE incidence was evaluated over 10 years. Index mammograms were reviewed for the presence of BAC and LNA. BAC was anayzed as a binary variable, and LNA was determined via measurement of the largest lymph node dimension on the mediolateral oblique (MLO) view (Figure 1). Associations between BAC, LNA, high CVD risk, and MACE were analyzed using a multivariable logistic regression model, adjusting for baseline risk factors.

RESULTS

LNA showed a statistically significant association with CVD risk estimation, which persisted after adjusting for age (OR continuous = 1.37, $p < 0.001$). However, adding LNA to the PCE did not enhance MACE prediction. BAC was not significantly associated with the PCE estimation of CVD risk after adjusting for age. However, adding BAC to the PCE improved MACE prediction among women aged 40-65 (OR= 2.7, $p = 0.002$).

CONCLUSION

LNA may represent a novel body composition imaging biomarker of high CVD risk that is available on a widely utilized screening exam in women over 40. Additionally, BAC may enhance MACE prediction beyond PCE risk assessment in women aged 40-65.

CLINICAL RELEVANCE/APPLICATION

The American Heart Association has called for improved CVD risk assessment in women. Body composition studies have demonstrated a link between cardiometabolic disease and adiposity in muscle, liver, and the visceral cavity, yet the role of immune system adiposity has been largely overlooked. Furthermore, most body composition evaluation requires advanced imaging studies that are not routinely performed in healthy populations. In contrast, LNA and BAC can be assessed on screening mammography, a study that is utilized by 78% of eligible women in the U.S., thereby allowing for potential large-scale CVD opportunistic risk assessment.

W2-STCE1-3 OPPORTUNISTIC CARDIOVASCULAR RISK ASSESSMENT FROM EMERGENCY DEPARTMENT HEAD CT IMAGING

Xiaoman Zhang, PhD (*Presenter*)
Julian Acosta, MD (*Abstract Co-Author*)
Siddhant Dogra, MD (*Abstract Co-Author*)
Erica Silva (*Abstract Co-Author*)
Sanjay Basu (*Abstract Co-Author*)
Rohan Khera (*Abstract Co-Author*)
Pranav Rajpurkar, PhD (*Abstract Co-Author*)
David Kim (*Abstract Co-Author*)

PURPOSE

To develop and validate deep learning (DL) models that leverage routine head CT scans to opportunistically predict incident cardiovascular disease (CVD) events and coronary artery calcium (CAC) scores, comparing performance against established clinical risk factors.

METHODS AND MATERIALS

This retrospective cohort study analyzed de-identified data from a large academic health system. The CVD prediction cohort included 27,990 adults without prior CVD who had head CT scans. The CAC prediction cohort included 2,313 adults with head CT and coronary CT angiography. DL models were pre-trained on 98,175 head CT studies using vision transformers. 3 models were developed: (1) PREVENT variables (clinical factors), (2) HeadCT (imaging features alone), and (3) HeadCT+PREVENT (combined). Primary outcomes were incident CVD events (myocardial infarction, stroke, heart failure) assessed using Cox Proportional Hazards models, and CAC scores (0, 1-10, 11-100, 101-400, >400 Agatston units) assessed using multiclass classification. Performance was evaluated using the concordance index (C-index) and area under the receiver operating characteristic curve (AUROC).

RESULTS

For CVD prediction (median age 63.0 years, 51.7% female, median follow-up 533 days), the HeadCT model achieved superior performance with C-index 0.82 (95% CI: 0.78-0.85) versus PREVENT variables (0.75, 95% CI: 0.70-0.79), showing significant improvement of 0.07 (95% CI: 0.04-0.10). During follow-up, 4.0% (n=1,110) experienced cardiovascular events. For CAC prediction (median age 65.0 years, 53.5% female), the HeadCT+PREVENT model achieved the highest performance (C-index 0.76, 95% CI: 0.72-0.80) and AUROC 0.80 (95% CI: 0.73-0.85) for predicting substantial coronary calcification (CAC >100). Among reclassified patients, 74.5% were correctly reclassified. Patients reclassified to higher CVD risk were younger with more favorable traditional risk profiles but had a higher prevalence of vascular calcifications (30.2% vs 24.8%, p=0.001) and brain infarcts (20.1% vs 5.8%, p<0.001) on imaging.

CONCLUSION

Routine head CT scans can significantly improve cardiovascular risk stratification beyond traditional clinical factors. DL models identified subclinical cardiovascular disease in younger patients with favorable traditional risk profiles.

CLINICAL RELEVANCE/APPLICATION

Head CT-derived cardiovascular risk assessment could enable real-time identification of high-risk patients, facilitating immediate preventive interventions (statins, smoking cessation, cardiology referral), potentially improving early detection and prevention of cardiovascular disease for millions of patients annually without additional cost, radiation exposure, or workflow disruption.

W2-STCE2-3 DIFFUSION BRIDGE-BASED GENERATION OF XENON-ENHANCED VENTILATION IMAGES FROM PAIRED DUAL-ENERGY VIRTUAL NON-CONTRAST CT

Chang Yong Choi, MS (*Presenter*)
Sangyoon Lee, PhD (*Abstract Co-Author*)
Jongjun Won, BS (*Abstract Co-Author*)
Hye Jeon Hwang, MD, PhD (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate whether Xenon-enhanced Ventilation Images (XeVIs) can be generated from paired virtual non-contrast (VNC) CT using a diffusion bridge model (DBM), offering a contrast-free alternative for functional imaging in obstructive airway disease.

METHODS AND MATERIALS

We retrospectively collected XeVIs from 268 patients with chronic obstructive pulmonary disease (COPD) or asthma-COPD overlap syndrome from a tertiary hospital. For each case, paired inspiratory and expiratory (insp/exp) VNC CT images were also acquired using dual-energy CT (Somatom Definition, Siemens Healthineers) through material decomposition. The dataset was split into training, internal, and temporally separated test sets (n = 180, 44, 44, respectively). A conditional DBM was trained to generate XeVIs from insp/exp VNC CT pairs, guided by physiologic CT ventilation images computed from Hounsfield unit (HU) differences. Defect lung areas (DLA) were evaluated by computing the Dice similarity coefficient (DSC) between generated and reference XeVIs. Physiologic agreement was assessed by computing Pearson correlation coefficients between defect lung percentage (DLP) and pulmonary function test (PFT) parameters (FVC, FEV1/FVC, DLCO) for both generated and reference XeVIs. Statistical comparison of the correlation coefficients was performed using Fisher's r-to-z transformation. Image quality of the generated XeVIs was independently evaluated by two board-certified thoracic radiologists with 16 and 14 years of experience, using a 5-point scale.

RESULTS

The DSC of DLA between generated and reference XeVIs was 57.98 ± 8.87 in the internal test and 53.55 ± 11.74 in the temporally separated test. Correlations between DLP and PFT parameters were observed in both generated and reference XeVIs. FEV1/FVC and DLCO showed significantly negative correlations across test sets, while FVC correlations were weaker (reference: r = -0.549 and -0.177, generated: r = -0.289 and 0.035 for internal and temporally separated test sets, respectively). No significant differences were found between correlation coefficients (all p > 0.05). The mean image quality scores assigned by reader 1 and reader 2 were 4.05 ± 0.90 and 3.53 ± 1.01, respectively.

CONCLUSION

The proposed model effectively captures regional ventilation defects and preserves clinically relevant correlations with pulmonary function metrics, suggesting its feasibility as a functional imaging surrogate.

CLINICAL RELEVANCE/APPLICATION

This diffusion-based approach enables generation of physiologically meaningful ventilation images without the need for contrast agents or specialized acquisition protocols, potentially expanding access to functional lung assessment in patients with obstructive airway diseases.

W3-SSBR08-1 NON-SURGICAL TREATMENT OF BREAST CANCER: A COMPARISON OF OUTCOMES BETWEEN CRYOABLATION WITH HORMONAL THERAPY VERSUS CRYOABLATION ALONE AND HORMONAL THERAPY ALONE IN PATIENTS NOT ELIGIBLE FOR SURGERY

Federica Di Naro, MD (*Presenter*)
Sofia Elisabetta Baldi Giorgi (*Abstract Co-Author*)
Francesca Pugliese, MD (*Abstract Co-Author*)
Sofia Vidali (*Abstract Co-Author*)
Tommaso Amadori, MD (*Abstract Co-Author*)
Diego De Benedetto (*Abstract Co-Author*)
Jacopo Nori Cucchiari (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the most effective non-surgical treatment for breast cancer in surgery-ineligible patients, comparing ultrasound-guided Cryoablation combined with hormonal therapy (HT) versus Cryoablation alone and hormonal therapy alone.

METHODS AND MATERIALS

A cohort of 111 patients (mean age 81.2 years, ±11.3) not-suitable for surgery due to comorbidities and/or advanced age was enrolled, with a total of 125 biopsy-confirmed malignant breast lesions. All the lesions were invasive ductal carcinomas (mean size 17.7 mm), hormone-positive and HER2-negative, with no ultrasound-visible lymph node involvement. Patients were divided into three groups: 41 lesions were treated with Cryoablation and HT, 36 with Cryoablation only and 36 with HT only. A locoregional staging was performed at baseline with contrast-enhanced-mammography (CEM) and ultrasound, followed by CEM and ultrasound follow-up at 12 months post-treatment. Only patients completing the follow-up were included. Lesion size was compared at baseline and 12 months after-treatment. Fisher's exact test was used for group comparison.

RESULTS

Of the 125 lesions, 98 of them completed the 12-months follow-up; 39 in the Cryoablation-with-HT group, 23 in the Cryoablation-only group, and 36 in the HT-only group. Tumor size reduction was significantly different between the groups (P=0.0005), with greatest reduction in the Cryoablation-with-HT group (83.3%, mean reduction of 13.6 mm), followed by Cryoablation-only (61.7%, mean reduction of 8.2 mm), and HT-only (42.1%, mean reduction of 7.4 mm). Tumors with no CEM-enhancement, suggesting no residual-disease, were most frequent in the Cryoablation-with-HT group (69.2%), followed by Cryoablation-only (60.9%),and HT-only (36.1%). Tumors with complete remission (CR, RECIST 1.1) were similar between the Cryoablation-with-HT and Cryoablation-only groups (74.4% and 78.3%, respectively), followed by the HT-only (36.1%). Pairwise comparisons revealed a significant difference between the Cryoablation-with-HT and the HT-only groups for CEM-enhancement, size reduction (%), and CR, expressing the added value of Cryoablation (P=0.0041, P<0.0001 and P<0.0001, respectively).

CONCLUSION

Cryoablation with hormonal-therapy significantly reduces tumor size and residual disease more effectively than therapy alone, making it a promising option for patients not-eligible for surgery.

CLINICAL RELEVANCE/APPLICATION

Integrating cryoablation with hormonal therapy leverages complementary mechanisms for tumor control, providing a targeted and minimally invasive strategy tailored to frail breast cancer patients.

W3-SSBR08-2 CAN WE OMIT SENTINEL LYMPH NODE BIOPSY? RETROSPECTIVE ANALYSIS BASED ON THE SOUND TRIAL

Laura Abelairas Lopez, MD (*Presenter*)
Laura Lopez, MD (*Abstract Co-Author*)
Lucia Grana Lopez, MD (*Abstract Co-Author*)
Ignacio Fernandez Sobrado (*Abstract Co-Author*)

PURPOSE

The aim of this study is to retrospectively evaluate if the omission of surgical axillary staging in patients diagnosed with early breast cancer (cT1cN0) would have had impact on the adjuvant treatment (hormone or chemotherapy).

METHODS AND MATERIALS

All patients with cT1N0 breast cancer, diagnosed in our Breast Unit, who underwent sentinel lymph node biopsy (SLNB), according to the SOUND trial criteria, between January 2021 and December 2024, were identified from a prospectively maintained database. Clinicopathological characteristics and information on surgical and adjuvant treatment were examined. A descriptive statistical analysis of the data was performed.

RESULTS

A total of 283 patients met eligibility criteria. Median age was 62 (IQR 54-69) years, and 211 (74,5%) were post-menopausal women. Regarding tumor type, most were infiltrating ductal carcinomas (n=231; 81,62%), histological grade 1 (n=135; 47,7%) or grade 2 (n=132; 46,64%) and had positive hormone receptors: 138 (48,76%) Luminal A, 109 (38,51%) Luminal B Her2 negative, 21 (7,42%) Luminal B Her2 positive. SLNB was positive in 61 patients (pN+), so the false-negative rate of axillary ultrasound was 21,5%. Of these, 96.7% presented three or fewer positive nodes after axillary surgery (27 pN1mi and 32 pN1a). Following the SOUND study

recommendations, if we analyze the group of postmenopausal patients, the false-negative rate of ultrasound drops to 15% (32/211). Adjuvant chemotherapy recommendations changed, due to the pathological nodal status, in only 5/(211) post-menopausal women.

CONCLUSION

In postmenopausal women with cT1 breast cancer, axillary ultrasound is accurate to predict significant nodal disease burden, supporting the implementation of the SOUND trial results without compromising the adjuvant chemotherapy recommendations.

CLINICAL RELEVANCE/APPLICATION

In patients with small breast cancer and negative axillary ultrasonography, axillary surgery could be safely avoided without an impact on adjuvant chemotherapy recommendations.

W3-SSBR08-3 DE-ESCALATION THERAPY IN WOMEN ≥ 70 WITH LOW-RISK EARLY-STAGE BREAST CANCER: MULTI-INSTITUTIONAL EXPERIENCE AND OUTCOME WITH ULTRASOUND-GUIDED CRYOABLATION

Janice Thai, MD (*Presenter*)

PURPOSE

To determine the locoregional tumor recurrence rate in small, low-risk, early-stage breast cancer treated with ultrasound-guided cryoablation. Cryoablation therapy for breast cancer is a non-surgical alternative to lumpectomy in elderly women with small, early-stage breast cancer, offering the benefits of a minimally invasive procedure, greater quality of life, superior cosmetic outcome and substantial cost savings.

METHODS AND MATERIALS

Women with newly-diagnosed breast cancer = 70 years old meeting selection criteria were recruited and treated at five institutions. Patients were selected for cryoablation treatment based on the following selection criteria: 1) histology of invasive ductal carcinoma, 2) small size (= 1.5 cm), 3) low histologic grade (Nottingham 1-2), 4) < 25% intraductal component or ductal carcinoma in situ, 5) unifocal disease, 6) hormone receptor positivity for estrogen/progesterone (ER/PR+) and receptor negativity for human epidermal growth factor 2 (HER2-), 7) ultrasound-visible mass or biopsy clip, and 8) clinically/imaging axillary node negative. Ultrasound-guided cryoablation was performed with a standard freeze-thaw-freeze treatment cycle to achieve a 1 cm ablation margin. Postablation imaging follow-up was performed with mammography, contrast-enhanced mammography, ultrasound or contrast-enhanced MRI.

RESULTS

Between October 2017 and December 2024, eighty two women with a mean age of 78 (range 70-94) who were diagnosed with breast cancer and treated with cryoablation were included in the analysis. Eighty two procedures were performed with standard procedural protocol using either argon gas- or liquid nitrogen-based cryoablation systems with only local anesthesia. With a mean imaging follow-up duration of 36 months (range 6 months to 8 years), there were three locoregional recurrences at the site of cryoablation (3.7 %). The recurrences were detected on imaging at 12, 12 and 24 months, respectively, and confirmed by biopsy and subsequent surgical resection. Only three patients were treated with whole breast radiation. Thirty eight patients had adjuvant endocrine therapy with a mean duration of 48 months. There was no device-related complication.

CONCLUSION

Cryoablation therapy is a safe and effective non-surgical alternative treatment for small, low-risk breast cancer in elderly women, with a locoregional recurrence rate that is similar to lumpectomy. Patients benefited from multiple advantages of cryoablation therapy, including the use of only local anesthesia and fast recovery.

CLINICAL RELEVANCE/APPLICATION

Results from this large multi-institutional study demonstrates a positive outcome for ultrasound-guided cryotherapy for small, low-risk breast cancer in elderly women.

W3-SSBR08-4 CRYOABLATION EFFECTIVENESS IN TREATING STAGE I/II HER2-NEGATIVE INVASIVE BREAST CANCER WITH AXILLARY SURGERY OMISSION BASED ON TUMOR IMMUNOPHENOTYPE

Jorge Rey, MD (*Presenter*)
Jose Maria Oliver-Goldaracena (*Abstract Co-Author*)
Laura Tello Arnas (*Abstract Co-Author*)
Jorge Guisandez (*Abstract Co-Author*)
Ignacio De Garcillan, MD (*Abstract Co-Author*)
Maria Aguilar Picapiedra (*Abstract Co-Author*)
Pablo Lama (*Abstract Co-Author*)

PURPOSE

To evaluate the effectiveness of cryoablation in the treatment of early-stage (clinical stage I/II) invasive breast cancer in patients who underwent axillary surgery omission, according to tumor immunophenotype.

METHODS AND MATERIALS

We retrospectively reviewed local recurrence and local control rates in patients with early-stage invasive breast cancer treated with cryoablation and omission of axillary surgery, with a minimum follow-up of 18 months. Patients were categorized based on estrogen receptor status (ER+ or ER-). Cryoablation treatment was determined by a multidisciplinary breast cancer board. ER+ patients also received adjuvant hormonal therapy. Follow-up included semiannual ultrasound and annual mammography. In cases of suspected local or distant recurrence, a core needle biopsy was performed. Confirmed recurrences were managed with repeat cryoablation.

RESULTS

In the ER+ group, 69 tumors (3-60 mm, mean 18 mm) in 64 patients (ages 58-96, mean 83) were followed for a mean of 31 months (range 18-60). Two local recurrences (2.9%) occurred between 17 and 24 months (mean 21). Both were successfully treated with repeat cryoablation, achieving a 100% local control rate. In the ER- group, 13 tumors (15-45 mm, mean 32 mm) in 13 patients (ages 83-94, mean 88) were followed for a mean of 20 months (range 18-30). Six local recurrences (46%) were observed between 3 and 24 months (mean 10). Five of these were retreated with cryoablation, achieving a second-attempt local control in four cases. Overall local control rate was 84.6% (11/13).

CONCLUSION

Cryoablation is highly effective in treating ER+ early-stage invasive breast cancers, providing excellent local control. Its effectiveness in ER- tumors is lower but still offers a substantial local control rate near 85%.

CLINICAL RELEVANCE/APPLICATION

Cryoablation may serve as a viable, minimally invasive alternative for elderly patients with early-stage breast cancer, particularly in ER+ subtypes, enabling omission of axillary surgery without compromising local control.

W3-SSBR08-5 ACHIEVING IMPROVING ACCURACY AND REDUCING UNNECESSARY BIOSPY IN ULTRASOUND DIAGNOSIS OF BREAST LEISIONS USING LARGE LANGUAGE MODELS IN REAL-WORLD

Yi Feng Zhang, MD, PhD (*Presenter*)

PURPOSE

Large language models (LLMs) demonstrate considerable potential in the interpretation of medical imaging. The emergence of GPT-4o has opened new avenues for automated image-text processing. Unlike other AI models, large language models are more convenient to use and output results more quickly and directly, making them very suitable for real-world clinical diagnostic scenarios. The purpose of this study is to evaluate the diagnostic accuracy of GPT-4o in breast lesions and its value in reducing unnecessary biopsy in real clinical scenarios.

METHODS AND MATERIALS

In this retrospective study, ultrasound images of breast nodules and corresponding free-text reports were collected. We evaluated ChatGPT-4o's diagnostic performance in breast nodule classification via two modalities: analyzing textual descriptions or ultrasound images of breast lesions by ChatGPT-4o. Compare the BI-RADS classification results output by the above two diagnostic modes with the results of radiologists in reality. The sensitivity, specificity, PPV, NPV, accuracy, the area under the receiver operating characteristic curve (AUC), and corresponding unnecessary biopsy rates (UBR) were compared. All cases had pathological findings as the reference standard. The intra-agreements of ChatGPT-4o have also been evaluated.

RESULTS

A total 1271 images and 424 text reports from 424 breast lesions (294 benign lesions and 130 malignant lesions) were included. The sensitivity, specificity, PPV, NPV, accuracy, AUC and UBRs of three diagnostic modes were as follows: ChatGPT-4o-Image: 77.5%,64.4%, 48.8%,86.8%,68.4%,0.710 and 51.2%; radiologists: 95.3%,79.0%,46.2%,96.2%, 64.9%,0.734 and 53.8%; ChatGPT-4o-Text: 82.1%,79.0%,63.1%,91.0%, 80.0%,0.806 and 36.9%. The intra-agreements of ChatGPT-4o-Image and ChatGPT-4o-Text were 0.68 and 0.82, respectively. The accuracy and AUC of ChatGPT-4o-Text were significantly higher than those of the other two modes ($P < 0.001$). The UBR of ChatGPT-4o-Text was significantly lower than that of ChatGPT-4o-Image and radiologists ($P < 0.001$).

CONCLUSION

A LLMs based on textual description of lesions achieved superior diagnostic accuracy and markedly reduced UBRs compared with radiologists in real-world settings, simultaneously possessing excellent repeatability. This advantage arises from their objective analysis of ultrasound-derived tumor features, free from the subjective variability of human interpretation.

CLINICAL RELEVANCE/APPLICATION

Coupled with intuitive interfaces and clear result presentation, LLMs thus represent a promising preoperative diagnostic aid for breast tumor evaluation.

W3-SSBR08-6 CONTRAST-ENHANCED MAMMOGRAM (CEM)-GUIDED BIOPSY OUTCOMES: A SINGLE-INSTITUTION COMPARISON OF SUCCESSFUL AND CANCELED BIOPSY CHARACTERISTICS

Michelle Lee, MD (*Presenter*)
Alison McIlvride, MD (*Abstract Co-Author*)
Paola C. Tabaro Pico, MD (*Abstract Co-Author*)
Varadan Sevilimedu (*Abstract Co-Author*)
Molly P. Hogan, MD (*Abstract Co-Author*)
Donna D. D'Alessio, MD (*Abstract Co-Author*)
Janice S. Sung, MD (*Abstract Co-Author*)
Maxine S. Jochelson, MD (*Abstract Co-Author*)
Victoria L. Mango, MD (*Abstract Co-Author*)

PURPOSE

Contrast-enhanced mammography (CEM)-guided biopsy is an emerging technique with little data available. Our purpose is to determine the frequency, imaging features and initial follow up results of successful CEM-guided biopsies, as well as to compare characteristics between successful and canceled biopsies.

METHODS AND MATERIALS

IRB-approved, HIPAA-compliant search of our institutional database identified CEM-guided biopsies performed from January 1, 2023 to October 4, 2024. The electronic medical record, images, procedure and pathology reports were reviewed for patient demographics, biopsy target characteristics, imaging follow up and available pathology. Descriptive statistics were performed.

RESULTS

74 CEM-guided biopsies were attempted during the study period. Fifty-three of 74 (71.6%) were successful and 21 of 74 (28.4%) were cancelled. The median age was 50 years and not significantly different between successful and cancelled cases ($p = 0.7$). The median biopsy target size was significantly larger in successful biopsies (1.2 cm) than in cancelled biopsies (0.7 cm) ($p = 0.027$). Biopsy targets included non-mass enhancement (50/74, 68%), mass (20/74, 27%), asymmetry (3/74, 4%), and architectural distortion (1/74, 1%), with no statistically significant difference in target type between successful and cancelled biopsies ($p = 0.9$). Fifteen of 53 (28%) successfully biopsied targets ultimately yielded cancer, 4 of 53 (8%) yielded high-risk pathology, and 34 of 53 (64%) yielded benign pathology. In patients with a history of cancer within the last two years, 13 of 53 (25%) successful biopsy targets yielded cancer.

CONCLUSION

In our single-institution study, 72% of CEM-guided biopsies were successfully completed and 28% were canceled. Successful biopsies were associated with larger targets (at least approximately one centimeter) and canceled biopsies were associated with smaller targets (less than approximately one centimeter). Malignancy was found in 28% of successful biopsy cases; however, long-term follow-up of canceled biopsy cases is needed.

CLINICAL RELEVANCE/APPLICATION

CEM-guided biopsy is an effective technique to evaluate enhancing lesions detected on contrast-enhanced mammography for breast cancer. Assessing its success rate, imaging characteristics, and malignancy yield is crucial for optimizing both diagnostic accuracy and procedural efficiency as CEM and CEM-guided biopsy continues to expand in clinical practice.

W3-SSCA07-2 BREAST ARTERIAL CALCIFICATION PROGRESSION ON MAMMOGRAMS PREDICTS RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS

Alyssa T. Watanabe, MD (*Presenter*)
Richard Mantey (*Abstract Co-Author*)
Junhao Wang (*Abstract Co-Author*)
Homa Karimabadi, PhD (*Abstract Co-Author*)

PURPOSE

Evaluate if extent and progression rate of breast arterial calcification (BAC) on mammograms is predictive of major adverse cardiovascular events and mortality (MACE).

METHODS AND MATERIALS

We retrospectively evaluated 27,780 full-field digital mammograms in 10,348 women (index age 26-94, mean 56 years) performed 2006-2016 at a single Southwestern U.S. academic center. Imaging follow-up ranged 6 months-10 years (mean 4.1 years) and clinical follow-up 6 months-15 years (mean 5.6 years). An artificial intelligence model (AI) generated a BAC score for each exam. BAC positive scores were age-adjusted to derive percentiles, then binned by quartile (Q): 1st-25th (Q1),26-50th (Q2), 51-75th (Q3) and 76-100th (Q4). Adjusted Hazard ratios (HRs) for MACE were obtained using stable BAC-negative women as reference (covariates = ethnicity, chronic kidney disease, cardiovascular disease, smoking, hypertension, hyperlipidemia, elevated A1C, and use of antihypertensive or cholesterol-lowering medications). HRs calculated for all women and women < 65 years.

RESULTS

Higher but stable BAC quartiles were associated with high HRs: compared to the reference, HRs were 1.41 (95% CI 1.10-1.68) for Q2, 1.28 (1.06-1.54) for Q3, and 2.11 (1.76-2.52) for Q4. In those showing BAC progression, the hazard ratios rose to 2.19 for Q1?Q3, 8.66 for Q1?Q4, and 1.90 for Q3?Q4. These effects were even more pronounced in women under 65, with HRs of 2.80 (Q1?Q3), 10.86 (Q1?Q4), and 2.01 (Q3?Q4).

CONCLUSION

BAC severity and progression rate are both significant independent predictors of MACE risk. Women under age 65 with rapid progression of BAC into upper quartiles over 10 years face more than a 10-fold increased risk compared to women who remain BAC negative.

CLINICAL RELEVANCE/APPLICATION

Reporting of breast arterial calcification severity and progression on sequential mammograms may aid in identifying subgroups of women who are at greatest cardiovascular risk.

W3-SSCA07-3 AI-BASED AUTOMATED BREAST ARTERIAL CALCIFICATION ON SCREENING MAMMOGRAMS PREDICTS CARDIOVASCULAR RISK

Samantha Platt, MD (*Presenter*)
Pranav Singh (*Abstract Co-Author*)
Laura Heacock, MD, MS (*Abstract Co-Author*)
Yiqiu Shen, PhD, BSc (*Abstract Co-Author*)
Krzysztof J. Geras (*Abstract Co-Author*)
Miriam A. Bredella, MD, MBA (*Abstract Co-Author*)

PURPOSE

Cardiovascular disease (CVD) is the leading cause of death in women, and coronary artery calcium (CAC) scanning using ECG-triggered CT can predict coronary artery disease and major adverse cardiovascular events (MACE). Women undergoing screening mammography are susceptible to both breast cancer and CVD. Breast arterial calcification (BAC) can be quantified automatically using artificial intelligence (AI) on screening mammograms potentially offering a way to predict MACE. The purpose of our study was to determine the clinical utility of BAC assessment on screening mammograms to predict CAC and MACE.

METHODS AND MATERIALS

A fully automated AI algorithm to detect BAC was retrospectively applied to a cohort of women that had undergone both screening mammography and ECG-triggered CAC CT within 12 months. Subsequent MACE (myocardial infarction (MI)/coronary revascularization) were identified via electronic health record review. Logistic regression analysis was performed to determine associations between BAC and CAC. Sensitivity, specificity, positive and negative predictive value, and accuracy of BAC identifying CAC and MACE was calculated.

RESULTS

Our cohort included 5100 women (mean age: 66 ± 10 years, 65% White). BAC were present in 1421 women (28%) and there were 876 MACE. The presence of BAC was positively correlated with and CAC ($r=0.18$, $p<0.001$). Sensitivity, specificity, positive and negative predictive value, and accuracy of BAC to identify CAC was 36%. 80%, 64%, 55%, and 58%, respectively. BAC had a high negative predictive value for identifying MI (98%) and coronary revascularization (97%). Sensitivity, specificity, and accuracy were 38%, 72%, and 72% for MI, and 45%, 73%, and 72% for coronary revascularization, respectively.

CONCLUSION

BAC, quantified on screening mammograms using a fully automated AI algorithm, correlated with CAC and had a high negative predictive value for MACE. These data support the use of opportunistic BAC screening on mammography.

CLINICAL RELEVANCE/APPLICATION

A fully automated AI algorithm can be used to screen for breast arterial calcification on screening mammograms, thereby allowing not only for the early detection of breast cancer but also cardiovascular disease.

W3-SSCA07-4 A FULLY AUTOMATED DEEP LEARNING MODEL FOR QUANTIFYING CORONARY PLAQUE AND PREDICTING CARDIOVASCULAR EVENTS ON CORONARY CT ANGIOGRAPHY: A CHINESE MULTI-COHORT STUDY

Qian Chen, MD, PhD (*Presenter*)
Zhang Longjiang (*Abstract Co-Author*)

PURPOSE

Deep learning (DL) models for quantifying plaques on coronary CT angiography (CCTA) in routine clinical care are scarce. Our study aimed to develop and validate a fully automated DL model based on CCTA for coronary plaque detection and quantification.

METHODS AND MATERIALS

This retrospective, multicenter study included patients with coronary artery disease who underwent CCTA at 17 Chinese hospitals between June 15, 2009, and May 14, 2024. We trained and validated a fully automated DL model to segment coronary plaques in 2013 patients (6202lesions). The DL model was external tested in 100 patients with paired CCTA and intravascular US within 3 months, 100 patients in subgroup of China CT-FFR Study 3, 59 patients undergoing pre- and postprocedural CT of left atrial appendage closure (LAAC) within 3 months, and 100 patients undergoing the latest photon-counting detector CT. Further, the prognostic value of the DL model was validated in 10644 patients from China CT-FFR Study 2, 1122 patients from China CT-FFR Study 1.1, and 270 patients undergoing serial CCTA examinations. The study is registered at ClinicalTrials.gov (NCT03871140).

RESULTS

The DL model demonstrated excellent agreement for quantifying total plaque volumes against intravascular US and expert readers in subgroup of China CT-FFR Study 3 (all intraclass correlation coefficients [ICCs] > 0.90). For patients undergoing pre- and postprocedural of LAAC, the DL model showed high reproductivity for quantifying total plaque volumes (ICC=0·984, 95% CI 0·974-0·990). Excellent diagnostic agreement was found between DL model and expert readers for quantifying total plaque volume in photon-counting detector CT. The DL-based total plaque volume was associated with higher major adverse cardiac outcomes (MACEs) (hazard ratio [HR]: 2.17 per IQR, 95% CI 1.64-2.87, p<0.001) in China CT-FFR Study 2 (2.3-year follow-up), after correction for clinical risk factors. The DL-based total plaque volume predicted MACEs independently of clinical risk factors (HR: 2.95 per IQR, 95% CI 1.88-4.62, p<0.001) in China CT-FFR Study 1.1 (5-year follow-up). Plaque progression also was an independent predictor (HR: 2.55 per IQR, 95% CI 1.14-5.68, p=0.022) of MACEs (4-year follow-up).

CONCLUSION

In conclusion, we developed and externally validated a fully automated DL model for quantifying plaque volume. The DL model closely aligns with expert readers and intravascular US, and it carries prognostic value for future adverse cardiac events.

CLINICAL RELEVANCE/APPLICATION

The proposed DL system has the potential to be integrated into routine CCTA workflow as a clinical decision support tool.

W3-SSCA07-5 PREDICTING ADVERSE CARDIAC EVENTS USING CLINICAL AND IMAGING FEATURES WITH AN INTERPRETABLE MACHINE LEARNING MODEL

Xinyue Yan, BS (*Presenter*)
Gabrielle Gershon, BS (*Abstract Co-Author*)
Ali Adibi (*Abstract Co-Author*)
Nattakorn Kittisut (*Abstract Co-Author*)
Roy Gabriel (*Abstract Co-Author*)
Saikiran Rapaka, PhD (*Abstract Co-Author*)
Carlo N. De Cecco, MD, PhD (*Abstract Co-Author*)
Marly Van Assen, MSc, PhD (*Abstract Co-Author*)

PURPOSE

This project aims to evaluate the importance of various clinical and imaging variables in developing a machine learning model (ML) for risk prediction of major adverse cardiac events (MACE).

METHODS AND MATERIALS

This retrospective study included coronary artery calcium (CAC) CT imaging from 7,828 individuals without known cardiac disease between 2010-2023. A total of 52 variables, including 16 clinical, 7 medications-related, 15 EKG-derived, and 14 CT-derived variables were used. From CT, Agatston score, mean and peak calcium density, calcium volume, and cardiac chamber volumes were quantified. An XGBoost model was generated with 10-fold stratified cross-validation for outcome prediction. Grid search was used to optimize hyperparameters. Total gain metrics were used to evaluate feature importance, identifying key predictors. Model performance was assessed using the area under the receiver operating characteristic curve (AUROC) and compared against clinical risk scores (PCE and PREVENT).

RESULTS

The mean age was 57.9 years old, 11.5% were Black, and 44.6% were women. Hypercholesteremia was the most prevalent clinical risk factor, present in 6,195 (79%) of individuals. Non-zero CAC was present in 56.6% of individuals with a median non-zero CAC of 44.2. MACE rate was 4.5% for the total population. The ML model achieved an AUC of 0.861 for predicting MACE. ML outperformed individual clinical risk score models including PCE and PREVENT (AUC=0.627 and 0.630). ML also outperformed total CAC score alone (AUC=0.628). PREVENT and PCE risk scores and CAC scores in the left anterior descending artery were the features that obtained the highest gain for predicting MACE. Imaging features such as total CAC volume, myocardial volume and right atrial volume, and multiple CAC subregion scores also ranked among the top predictors.

CONCLUSION

ML based interpretable AI shows good accuracy in predicting MACE using a combination of CT and clinical variables, outperforming clinical risk scores and CAC scoring alone.

CLINICAL RELEVANCE/APPLICATION

ML algorithms can improve outcome prediction by combining multimodality features. Interpretability measures can increase the insight and clinical utility of these algorithms.

W3-SSER02-2 COMPARISON OF THE ACCURACY OF ARTIFICIAL INTELLIGENCE SOFTWARE FOR THE DETECTION OF PNEUMOTHORAX ON CHEST RADIOGRAPHS

Katrina Nash, MBChB (*Presenter*)
James Vaz, MD (*Abstract Co-Author*)
Nabeeha Salik (*Abstract Co-Author*)
Cosmin Mihaiu (*Abstract Co-Author*)
Sarim Ather, PhD, MBChB (*Abstract Co-Author*)
Alex Novak, MBChB (*Abstract Co-Author*)

PURPOSE

To compare the accuracy of commercial artificial intelligence (AI) algorithms in the detection of pneumothorax (PTX) on chest X-rays (CXR).

METHODS AND MATERIALS

We conducted a retrospective evaluation of nine CE-marked AI tools capable of PTX detection using a curated dataset of 394 CXRs obtained from Oxford University Hospitals (OUH). Ground truth for PTX presence/absence on each CXR was established by two radiologists, with disagreement arbitrated by a third. Sensitivity, specificity, and accuracy were calculated for each vendor. Receiver Operating Characteristic (ROC) curve was calculated where vendors were able to provide variable threshold scores. Statistical significance of variability was evaluated using Cochrans Q and McNemars test.

RESULTS

394 CXRs were included in the final dataset, 186 of which were positive for PTX. Accuracy values ranged from 79.5% (95% confidence interval 84.7 - 91.3) to 93.9% (91.1-96.1). All specificity values were greater than 79.5%, with the highest specificity at 97.1% (93.8-98.9). Overall, sensitivity was lower across the group and had a higher spread of results ranging from 54.3% (46.9-61.6) to 92.5% (87.7-95.8). AUC ranged from 0.859 (0.821-0.898) to 0.979 (0.966 - 0.992). Cochran Q test demonstrated a statistically significant difference in performance across the group ($p < 0.001$); McNemars also demonstrated statistically significant differences between vendors.

CONCLUSION

Multiple AI algorithms demonstrated a high accuracy in identifying PTX on CXR. However, there was significant variation in accuracy across the group. In general, AI tools demonstrated a higher specificity and a lower sensitivity, meaning that AI is more likely to result in false negatives than false positives in clinical practice.

CLINICAL RELEVANCE/APPLICATION

There is significant variation in performance across AI tools; these differences have important implications for both clinicians and patients. Algorithms demonstrating higher accuracy may produce fewer diagnostic errors in identifying PTX on CXR in real-world settings. For instance, AI tools with lower sensitivity are more likely to result in false negatives, increasing the risk of missed PTX on CXR. However, it is worth noting that there are multiple important pathologies to identify on CXR and that binary outputs were based on default settings for each algorithm. Further refinement and calibration of tools for specific clinical uses may improve performance. Nevertheless, the significant variability across algorithms highlights the critical need for comparative evaluations of AI algorithms across all relevant pathologies using large datasets representative of the intended population. These evaluations are essential to ensure clinical safety prior to deployment.

W3-SSER02-3 ARTIFICIAL INTELLIGENCE FOR INTRACRANIAL HEMORRHAGE DETECTION: A 15-MONTH MULTICENTER COMPARISON OF THREE AI SERVICES AND RADIOLOGISTS

Alexey Petryaikin, MD, PhD (*Presenter*)
Anna Khoruzhaya (*Abstract Co-Author*)
Polina Sakharova (*Abstract Co-Author*)
Kirill Arzamasov (*Abstract Co-Author*)
Rustam Erizhokov (*Abstract Co-Author*)
Iurii Vasilev (*Abstract Co-Author*)

PURPOSE

Compare diagnostic performance of three AI services and radiologists in detecting intracranial hemorrhage (ICH) on head CT scans, evaluating sensitivity, specificity, accuracy, and clinical implications.

METHODS AND MATERIALS

A longitudinal multicenter study (April 2022-December 2024) assessed three diagnostic AI tools and radiologists across 67 hospitals. Ground-truth expert verification included 3,409 CT scans (from 439,542 total). Metrics: sensitivity (Se), specificity (Sp), accuracy (Ac). Statistical analysis: Mann-Whitney U test (AI comparison), McNemar's test (AI vs. radiologists).

RESULTS

AI services showed high sensitivity but varied in specificity. AI-1 achieved the highest sensitivity (97.4 [95.8-98.5] %, but $p>0.005$ vs. AI-2/3), while AI-3 demonstrated superior specificity and accuracy (92.3 [90.4-94.3] % and 92.6 [90.1-94.1] %, $p<0.005$ vs. AI-1). AI-1's Sp (75.4 [71.8-78.7] %) and Ac (86.0 [83.9-87.9] %) was significantly lower than AI-2/AI-3 Sp ($p<0.0001$) and Ac ($p<0.002$). Radiologists outperformed all AI systems: sensitivity (98.92% vs. pooled AI 95.33%, $?^2=19.11$, $p<0.001$), specificity (99.85% vs. 86.30%, $?^2=356.17$, $p<0.001$), and accuracy (99.6% vs. 90.23%, $?^2=287.43$, $p<0.001$). False negatives were rare among

radiologists (12/1,106 ICH cases, 1.08%) but more frequent with AI (45/1,106, 4.07%). AI generated 368 false positives (13.7% of non-ICH cases) versus 4 (0.15%) for radiologists.

CONCLUSION

Radiologists remain the gold standard for ICH diagnosis, excelling in specificity and accuracy. AI, while highly sensitive, produces 92-fold more false positives, necessitating radiologist oversight. AI-2 and AI-3, with more balanced metrics show clinical potential if optimized for specificity. A theoretical combined AI-radiologist approach could achieve 99.5% sensitivity, though overlapping errors limit practical implementation.

CLINICAL RELEVANCE/APPLICATION

AI can reduce missed ICH in emergencies but requires rigorous validation. Integration should prioritize AI as a screening tool, with mandatory radiologist review of AI-positive cases. Improving AI specificity and training radiologists to interpret AI outputs are critical. Synergy between AI and human expertise may enhance diagnostic safety if protocols address false positives.

W3-SSER02-4 MULTICENTRIC PROSPECTIVE STUDY COMPARING ULTRA-LOW-DOSE CT, STANDARD RADIOGRAPHY AND STANDARD-DOSE CT FOR DETECTING LESIONS IN PATIENTS FOLLOWING THORACO-LUMBAR SPINE, PELVIC, OR EXTREMITY TRAUMA

Oumaya Ben Said (*Presenter*)
Joel Greffier, PhD (*Abstract Co-Author*)
Djamel Dabli (*Abstract Co-Author*)
Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*)
Maxime PASTOR, MD (*Abstract Co-Author*)

PURPOSE

To compare the diagnostic performance of ultra-low dose (ULD) CT scanning and a standard radiography examination (STD-RX) for detecting fractures of the thoraco-lumbar spine, pelvis, proximal femur, or extremities in adult trauma emergencies, with final diagnosis of fracture established using a standard-dose CT scan (STD-CT; gold standard).

METHODS AND MATERIALS

Adults presenting to the emergency department with suspected bone fractures following trauma were prospectively included at five centers from October 2019 to September 2023. Each patient was evaluated with STD-CT, ULD-CT, and STD-RX in the area where fractures were suspected. For each patient, two radiologists recorded the location and number of fractures for the three types of examination, blinded to the results of the other exams. Based on these results, the diagnostic performance of ULD-CT and STD-RX was evaluated and compared with that of STD-CT. Image quality was subjectively assessed and the overall image quality, diagnostic image quality, and confidence levels of ULD-CT and STD-RX were rated. Finally, the interpretation time was measured for each patient and each examination. Interobserver agreement on fracture detection and subjective image analysis are currently being analyzed.

RESULTS

Based on a total population of 536 patients (285 women; 52.4±21.7 years old; 25.6±4.6 kg/m²), 284 patients (53%) had at least one fracture. A total of 293 fractures were detected by STD-CT (86 hand/wrist, 7 dorsal spine, 21 lumbar spine, 79 pelvis, 100 foot/ankle). Using STD-CT as the standard of reference, the sensitivity and specificity of ULD-CT were 95.2% and 97.2% with 14 false negatives (3 hand/wrist, 2 lumbar spine, 2 pelvis, 7 foot/ankle) and 7 false positives. For STD-RX, sensitivity and specificity were 71.7% and 96.4% with 83 false negatives (15 hand/wrist, 5 dorsal spine, 6 lumbar spine, 16 pelvis, 41 foot/ankle) and 9 false positives. ULD-CT was completely interpretable with no technical problems or only a slight problem in 97% of cases and in 83% of cases for STD-RX. Overall image quality was excellent to acceptable for 97% of patients for ULD-CT and 89% for STD-RX. The confidence level was high to excellent in 92% of cases for ULD-CT and 55% for STD-RX.

CONCLUSION

ULD-CT demonstrated significantly higher diagnostic performance than STD-RX for detecting fractures in trauma patients. Radiologists were more confident with ULD-CT than with STD-RX, with sensitivity and image quality approaching that of STD-CT.

CLINICAL RELEVANCE/APPLICATION

ULD-CT offers excellent diagnostic confidence, closed to that of STD-CT, with a reasonable interpretation time, making it a compelling alternative to standard radiography for detecting fractures in trauma patients.

W3-SSER02-5 AI TRIAGE AND ALERTING IN EMERGENCY RADIOLOGY: ENHANCING DETECTION OR ADDING NOISE ?

Guillaume Herpe, MD (*Presenter*)
Leo Mabit (*Abstract Co-Author*)
Gaspard d'Assignies, MD, PhD (*Abstract Co-Author*)
Mathieu Lederlin, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the implementation of mutiples AI-driven alerting tools in an emergency radiology department, assessing their role as safety nets or noise generators.

METHODS AND MATERIALS

A retrospective, multi-center study was conducted over a two-month period across one tertiary and two secondary emergency radiology centers (35 radiologists). AI-based detection algorithms were deployed for brain trauma (ICH detection), pneumothorax on chest X ray, and IPE across 2336 CT scans and 119 chest X-rays. The reference standard for both negative and positive algorithm results was established following a two-step process. First, a general radiologist compared the reports and AI results to identify discrepancies between AI findings and radiologist interpretations. Any discrepancies were then resolved by an experienced emergency radiologist through a re-evaluation of images. Performance metrics included sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV). Statistical analysis was performed using R (version 3.6.2, The R Foundation).

RESULTS

Brain Trauma (ICH detection): Among 682 head CT scans, AI flagged 133 positives (19.5%, 133/682), including 46 false positives (6.7%, 46/682) and 11 false negatives (1.6%, 11/682). AI detected 2 additional true positives (1.5%, 2/133) missed by radiologists. Chest X-ray - Pneumothorax Detection: Out of 119 chest X-rays, AI identified 3 positive cases (2.5%, 3/119), including 1 missed by the radiologist (0.8%, 1/119), with no false positives (0%, 0/119). Incidental Pulmonary Embolism (IPE) Detection: In 1654 contrast-enhanced CT scans, AI flagged 70 positives (4.2%, 70/1654), with 22 true positives (31.4%, 22/70) and 9 missed by radiologists (41%, 9/22). AI increased the detected prevalence from 0.8% (14/1654) to 1.3% (22/1654), but the false-positive rate was 68.6% (48/70), requiring radiologist validation. Alerting : At the cost of 1.5 false positive alerts every day, AI algorithms identified 1 life threatening conditions missed by the radiologist every 5 days.

CONCLUSION

AI-driven triage tools in emergency radiology serve as effective safety nets, improving the detection of missed critical findings such as intracranial hemorrhage and incidental pulmonary embolism. Given the acceptable number of alerts, their integration remains valuable, provided that false positives are managed to maintain workflow efficiency and prevent alert fatigue.

CLINICAL RELEVANCE/APPLICATION

AI-driven triage tools enhance clinical safety in emergency radiology by detecting life-threatening conditions missed by radiologists, with a manageable false-positive rate that supports their integration into routine workflow.

W3-SSER02-6 PREDICTING UNREMARKABLE BRAIN CT SCANS WITH AN ENSEMBLED GENERATIVE UNSUPERVISED ANOMALY-DETECTION MODEL: IMPLICATIONS FOR RADIOLOGIST WORKLOAD REDUCTION

Namkug Kim, PhD (*Presenter*)
Jongjun Won, BS (*Abstract Co-Author*)
Jihwan Kim, BSc, MSc (*Abstract Co-Author*)
Joonseo Oh (*Abstract Co-Author*)
Yereen Yoo (*Abstract Co-Author*)
Joon Park, MD (*Abstract Co-Author*)
Hyungbin Park (*Abstract Co-Author*)
Jihyun Kim (*Abstract Co-Author*)
Jimin Sung (*Abstract Co-Author*)
Hyunki Lee (*Abstract Co-Author*)
JIEUN YUM (*Abstract Co-Author*)
Joonsang Lee (*Abstract Co-Author*)
Gil-Sun Hong, MD, PhD (*Abstract Co-Author*)

PURPOSE

Neurologic emergencies require swift detection of critical findings on non-contrast brain CT, yet most emergency department (ED) scans are unremarkable. We built a generative unsupervised anomaly-detection (GUAD) system to flag unremarkable studies and measured its ability to cut workload while preserving a high negative predictive value (NPV).

METHODS AND MATERIALS

We retrospectively collected 28,510 non-contrast brain CT scans from healthy individuals at a tertiary academic hospital to form the training set. Using a 3D hierarchical diffusion autoencoder, we trained two generative unsupervised anomaly-detection models: a coarse-morphological model that identifies gross structural abnormalities and a fine-grained model that detects subtle intensity deviations. A study was labeled "unremarkable" only when both models produced anomaly scores below a predefined decision threshold. We evaluated our model on four test datasets: the internal consecutive ED cohort (n = 544), the external consecutive ED cohort (n = 1,795), a public intracranial-hemorrhage dataset (n = 244), and a multi-institutional hemorrhage dataset spanning five hospitals (n = 1,295). The consecutive ED cohorts contained diverse critical findings, including hemorrhage, infarction, mass-like lesions, hydrocephalus, and rarer lesions. Performance was assessed with two primary metrics: negative predictive value (NPV) and workload reduction (WLR), the latter defined as the proportion of correctly excluded unremarkable scans among all test scans.

RESULTS

At the strictest threshold set by validation (target NPV > 99 %), the GUAD ensemble achieved an NPV of 98.1 % with a WLR of 9.7 % on the internal test set, NPV/WLR of 96.7 %/19.9 % on the external set, 98.5 %/26.2 % on the public hemorrhage set, and 96.0 %/27.8 % on the multi-institutional set. Relative to either single model, these results represent an NPV improvement of up to 3.7 percentage points. When the threshold was relaxed to target an NPV of 99 %, NPVs dropped slightly to 95.9-97.1 %, while WLRs rose to 13.1-33.1 %. A further reduction of the cut-off to target an NPV of 98 % increased WLRs to 17.8-36.8 % but lowered NPVs to 94.2-96.5 %.

CONCLUSION

With appropriately chosen thresholds, the GUAD ensemble maintains an NPV close to 98 % while reducing radiologists' workload by 10-35 %. It consistently outperforms each single-model counterpart.

CLINICAL RELEVANCE/APPLICATION

By automatically filtering a meaningful subset of unremarkable emergency brain CTs, the GUAD ensemble can streamline radiology workflows. Because a residual risk of missed abnormalities remains, further research and the development of complementary safety pipelines are required to minimize this risk.

W3-SSGI10-1 FOUNDATIONAL TUMOR SEGMENTATION MODELS

Halil Ertugrul Aktas (*Presenter*)
Sirui Li (*Abstract Co-Author*)
Linkai Peng, BEng (*Abstract Co-Author*)
Zheyuan Zhang, PhD (*Abstract Co-Author*)
Gorkem Durak, MD (*Abstract Co-Author*)
Ulas Bagci, MSc, PhD (*Abstract Co-Author*)

PURPOSE

Accurate volumetric tumor segmentation remains a critical challenge in oncologic imaging despite its fundamental importance for diagnosis, treatment planning, and response assessment. We propose a novel approach, named TAGS, to overcome the limitations of existing methods by adapting a 2D vision-language foundation model (Segment Anything Model, SAM) for robust 3D tumor delineation across multiple organ sites using a multi-prompt guidance framework.

METHODS AND MATERIALS

We developed Tumor-Adaptive Guidance for SAM (TAGS), a parameter-efficient approach that synergistically combines three complementary prompt types: (1) organ-specific prompts automatically generated by TotalSegmentator to provide structural context; (2) dual-category text prompts derived from concise medical descriptors to incorporate semantic information; and (3) sparse interactive 3D point prompts requiring minimal user guidance. Lightweight alignment adapters integrate these prompts while preserving most pre-trained parameters. We evaluated TAGS on three public datasets—KiTS21 (kidney), LiTS (liver), and MSD-Pancreas—using Dice and Normalized Surface Dice (NSD) metrics.

RESULTS

TAGS significantly outperformed established clinical and AI-based segmentation methods across all metrics. With three interactive point prompts, it achieved Dice scores of 80.8%, 66.2%, and 61.0% for kidney, liver, and pancreatic tumors, respectively, showing substantial improvements over the clinical standard nnUNet (50.2%, 58.9%, 36.5%). Boundary delineation accuracy, measured by NSD, demonstrated even greater improvements: 88.3%, 79.3%, and 83.1% for kidney, liver, and pancreatic tumors, versus nnUNet's performance (47.6%, 57.6%, 43.2%). TAGS maintained high consistency regardless of prompt placement location (ICC > 90%).

CONCLUSION

By leveraging organ-specific anatomical guidance, clinically meaningful text prompts, and limited user interaction, TAGS effectively bridges the inherent 2D-to-3D gap in foundation models. It delivers robust, accurate tumor segmentation in volumetric imaging without requiring the comprehensive retraining of large models.

CLINICAL RELEVANCE/APPLICATION

TAGS provides a streamlined, flexible solution for volumetric tumor segmentation that requires minimal user interaction while delivering superior accuracy. This approach enhances clinical workflows by improving consistency in tumor delineation, which may lead to more precise treatment planning, reliable longitudinal monitoring, and standardized quantitative reporting. Its efficiency makes it particularly valuable in busy clinical environments and for cases involving complex tumor morphology where traditional segmentation methods often fail.

W3-SSGI10-2 HOW MANY ANNOTATIONS ARE ENOUGH? REAL-AND-SYNTHETIC DATA PLATEAUS FOR <2 CM PDAC DETECTION ON CT

Qi Chen (*Presenter*)
Wenxuan Li, BS (*Abstract Co-Author*)
Xinze Zhou (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)
Zongwei Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To quantify (i) the minimum number of voxel-wise annotated scans required for detecting <2 cm pancreatic ductal adenocarcinoma (PDAC) and (ii) the extent to which synthetic data can cut that requirement and improve robustness on external test.

METHODS AND MATERIALS

This study was designed in two experimental settings to evaluate the annotation requirements for accurate small PDAC detection and the impact of synthetic tumor augmentation on data efficiency and external robustness. First, real-data scaling: 3,144 CTs (n = 156 small PDAC, 5%) were randomly split into five training subsets at 10%, 25%, 50%, 75% and 100%. An nnU-Net was trained on each subset and tested (i) internally on 684 held-out CTs from the same data distribution (i.e., population, vendors, and protocols) and (ii) externally on 50,000 multicenter scans from a total of 140 global hospitals with different data distribution. Second, synthetic augmentation: small, synthetic PDACs were created on the normal CTs from both internal and external cohorts. An nnU-Net was trained on the same five training subsets augmented by these synthetic PDACs, and tested on the same internal (n = 684) and external (n = 8,250) datasets. We evaluated the performance using area under the receiver operating characteristic curve (AUC), sensitivity on small PDAC patients, and specificity on normal patients.

RESULTS

Real-data scaling (internal test) - AUC increased from 0.94 ± 0.03 with 10 % of the data to 0.97 ± 0.02 with 25 % and plateaued at 0.98 ± 0.02 from the 50 % fraction onward; sensitivity at 87.8% specificity stabilized at 97.7% after ~340 annotated scans, indicating a clear data plateau. Real-data scaling (external test) - AUC rose

monotonically from 0.85 (10 %) to 0.90 (100 %) with no sign of saturation; sensitivity improved from 86.4% to 92.9%. Synthetic augmentation - 500 real + synthetic achieved the internal plateau and reached external AUC 0.89, equaling the 3,000-real benchmark while using one-sixth of the real annotations.

CONCLUSION

For internal test, 1,500 annotated real scans are enough; augmented by synthetic data can further lower the requirement to 500 without accuracy loss. For multicenter external test, every additional real scan helps, yet synthetic augmentation accelerates gains and closes the domain gap, achieving superior performance with half the real annotation.

CLINICAL RELEVANCE/APPLICATION

The study provides concrete annotation requirement—500 scans augmented by synthetic data or 1,500 scans alone—for small PDAC detection, reducing annotating effort by up to 83%. This efficiency accelerates deployment of reliable, cross-institution AI algorithms for earlier detection of <2 cm PDAC, when curative treatment is still feasible.

W3-SSGI10-3 EFFECTIVE REGISTRATION-FREE DUAL-PHASE SEGMENTATION FOR PANCREATIC LESION

Wenyi Deng (*Presenter*)
Fuze Cong, PhD (*Abstract Co-Author*)
Feiyang Xie, MD (*Abstract Co-Author*)
Hebing Chen (*Abstract Co-Author*)
Xiuli Li (*Abstract Co-Author*)
Zhengyu Jin, MD (*Abstract Co-Author*)
Huadan Xue, MD (*Abstract Co-Author*)

PURPOSE

Arterial and portal dual-phase contrast-enhanced CT images are critical for pancreatic masses precise diagnosis. However, existing methods often rely on registration techniques that may undermine both accuracy and efficiency. In light of this, the purpose of this study was to develop a deep learning model capable of accurately segmenting various pancreatic masses by analyzing CT images obtained during both arterial and portal phases without registration.

METHODS AND MATERIALS

This study leveraged four private datasets consisting of more than eight types of pancreatic lesions to build the dual-phase registration-free segmentation model. The internal dataset consisted of 313 patients with confirmed surgical pathology. The internal dataset was divided for training/validation (223) and testing (90) based on the time of CT acquisition. Additionally, three external testing datasets from three hospitals which consisted of 53, 50, 60 cases were utilized to evaluate the performance on images from different scanners, low-dose and different thicknesses. The dual-phase CT images were simultaneously fed into the proposed registration-free segmentation model where a cross-attention mechanism was employed to integrate the dual-phase features with misalignment. The output of the model is the contour of pancreatic lesions in the input portal-phase images.

RESULTS

The proposed pancreatic lesion segmentation model exhibited excellent performance in one internal and three external testing datasets achieving DSC of 84.02%, 78.40%, 79.53% and 83.62%, respectively. Meanwhile, the proposed method achieves an overall 95.63% detection rate of eight types of pancreatic lesions, exceeding the existing methods. Also, the proposed method achieves an inference time of 10.55s per scan, more than 10 times faster than other dual-phase methods and comparable to the single-phase methods.

CONCLUSION

The proposed registration-free dual-phase pancreatic lesion segmentation approach significantly surpassed traditional registration-dependent methods in both accuracy and inference speed. These findings suggest that the proposed model has the potential in handling pancreatic lesions, particularly those exhibiting variable enhancement across different phases, such as in PNET/PNEC cases.

CLINICAL RELEVANCE/APPLICATION

The efficient and accurate pancreatic lesion segmentation provided by the dual-phase model offers reliable input regions of interest for subsequent studies such as radiomics.

W3-SSGI10-4 CONCORDANCE OF CIRCULATING TUMOR DNA TESTING AND IMAGING SURVEILLANCE OF SURGICALLY RESECTED PANCREATIC ADENOCARCINOMA

Sherif B. Elsherif, MD (*Presenter*)
Luyao Shen, MD (*Abstract Co-Author*)
Luke S. Yoon, MD (*Abstract Co-Author*)
Aya Kamaya, MD (*Abstract Co-Author*)
Justin Tse, MD (*Abstract Co-Author*)

PURPOSE

To assess the concordance of circulating tumor DNA (ctDNA) and imaging surveillance after surgical resection of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

This retrospective, single-center study included 50 patients (17 women, 33 men; mean age, 69 years [range, 45-89 years]) with PDAC who underwent surgical resection followed by ctDNA and imaging surveillance from 2015 to 2025. When multiple positive ctDNA results were available, the first positive test was selected. Imaging surveillance was performed within 3 months of ctDNA testing. Two radiologists blinded to ctDNA results and surgical pathology reviewed all imaging studies, with consensus adjudication for discrepancies.

RESULTS

ctDNA and imaging results were concordant in 39 patients: 22 had recurrence and 17 had no recurrence. Discordant findings were observed in 11 patients: 10 had recurrence by imaging only and 1 had recurrence by positive ctDNA only. The percentage agreement between ctDNA and imaging was 78%, with a kappa statistic of 0.57. Among concordant patients with recurrence, the most common site was local recurrence (surgical bed), with a median disease size of 2.1 cm. In the 10 discordant cases where imaging was positive but ctDNA was negative, imaging preceded ctDNA testing by a median of 38 days (range 7-122 days preceding ctDNA); these sites were exclusively lung metastases and local recurrence, with median disease sizes of 0.5 cm and 2.4 cm, respectively. Among these discordant patients, 8 had tissue-proven recurrence and the remaining 2 showed continued growth of disease on follow-up imaging. Overall, 1/6 (17%) of lung metastases and 10/15 (67%) of local recurrences showed a positive ctDNA test, whereas all other sites of metastases at imaging (liver, peritoneum, lymph node, and bones) had a 100% positive rate of ctDNA detection. The single patient with positive ctDNA only showed no evidence of recurrent disease during 497 days of imaging follow-up. Using imaging as the reference standard, the sensitivity and specificity of ctDNA for detecting recurrence were 68.8% and 94.4%, respectively. The positive predictive and negative predictive values were 95.7% and 63%, respectively.

CONCLUSION

ctDNA did not detect about a quarter of recurrences after surgical resection of PDAC, particularly when the disease sites are local recurrence and lung metastases.

CLINICAL RELEVANCE/APPLICATION

ctDNA testing is increasingly performed in conjunction with imaging but most lung metastases and 1/3 of local recurrences could only be identified by imaging. Radiologists should continue to scrutinize those two sites in particular during surveillance of patients after PDAC resection.

W3-SSGI10-6 MULTI-MODAL INTEGRATION OF ABDOMINAL CT AND CLINICAL DATA FOR NONINVASIVE HVPG CLASSIFICATION

Jingyo Jeong (*Presenter*)
Jhii Hyun Ahn, MD (*Abstract Co-Author*)

PURPOSE

This study proposes a novel deep learning-based multimodal model that combines abdominal CT imaging with clinical data to non-invasively grade the hepatic venous pressure gradient (HVPG).

METHODS AND MATERIALS

The dataset used in this study consists of blood test results and abdominal CT images collected from 603 subjects. The cohort included 305 healthy controls and 298 patients with compensated cirrhosis who underwent HVPG measurement. All CT images were resampled to a voxel spacing of [1.0, 1.0, 1.0] and standardized to a size of [256x256x96]. For each patient, 15 clinical variables were used to generate text prompts: sex, age, albumin, total bilirubin, AST, ALT, WBC, PMN, hemoglobin, platelet count, sodium, creatinine, liver-to-spleen volume ratio, liver volume, and spleen volume. The dataset was split into training, validation, and test sets in a 6:2:2 ratio.The proposed multimodal framework integrates a pre-trained Swin Transformer as an image encoder for extracting high-dimensional features from CT images, and the BLIP (Bootstrapping Language-Image Pre-training) model for handling text prompts derived from clinical data. The image features were transformed to have the same output dimensions as BLIP, which allowed for concatenation of image and text features. The combined features were then fed into a classifier to predict clinically significant portal hypertension (HVPG = 10 mmHg). Model performance was evaluated using 5-fold cross-validation.

RESULTS

The model was trained and validated using 5-fold cross-validation on the dataset, achieving an average accuracy of 0.82, recall of 0.83, precision of 0.85, F1 score of 0.82, and an AUC of 0.87 across the validation folds. These results indicate that the integration of abdominal CT and clinical data through a deep learning-based multimodal approach is effective for non-invasive grading of HVPG and shows promise for clinical application.

CONCLUSION

This study demonstrates the effectiveness of a deep learning-based multimodal framework that integrates abdominal CT imaging and clinical data for non-invasive grading of HVPG. The model achieved high predictive performance, offering a potential alternative to invasive HVPG measurement. This approach may facilitate safer, faster, and more accessible assessment of portal hypertension in clinical practice.

CLINICAL RELEVANCE/APPLICATION

The proposed multimodal model provides a non-invasive method to accurately classify clinically significant portal hypertension, potentially replacing invasive HVPG measurement. This approach can enhance clinical decision-making by enabling early risk stratification and timely intervention in patients with clinically significant portal hypertension.

Claude B. Sirlin, MD (*Abstract Co-Author*)
Bachir Taouli, MD (*Abstract Co-Author*)
Mustafa R. Bashir, MD (*Abstract Co-Author*)

PURPOSE

In the US, over 4.5 million people are eligible for routine surveillance for hepatocellular carcinoma (HCC). Biannual ultrasound (US) is the primary surveillance protocol in practice recommendations. MRI surveillance has been shown to be more sensitive than US and may allow for less frequent examination. This study aims to assess the rate of HCC diagnosis within one year of a negative MRI versus negative ultrasound.

METHODS AND MATERIALS

Patients at risk for HCC were included if they had negative MRI and/or negative US at index (time 0) and either an HCC diagnosis within 1 year or negative follow-up surveillance for at least 1 year. Patients who had both negative MRI and US at baseline were included in both the MRI subgroup and US subgroup; patients with one exam negative and the other exam positive were analyzed in the subgroup corresponding to their negative exam. We investigated the rates of both "prevalent" HCC, in which the index exam failed to detect existing cancer, and "incident" HCC, in which an HCC diagnosis was made following a truly negative index exam. To determine the rate of HCC diagnosis within 1 year, Kaplan Meier (KM) survival curves were fit and probability of HCC at 1 year from index and 95% confidence intervals (CI) were estimated.

RESULTS

Our overall cohort included 132 patients, with median age of 62.5, median BMI of 31.3, majority female (53.8%), majority white (90.2%), and all diagnosed with cirrhosis. 118 and 121 patients were included in the MRI and US subgroups, respectively. For the overall cohort, the rate of HCC at 1 year was 3.8% (0.5%, 7.0%). In the MRI subgroup, no patients became positive for HCC within 1 year. In the US subgroup, 5 patients, representing 4.2% (0.5%, 7.7%) of the subgroup, were ultimately diagnosed with HCC by 1 year. All 5 diagnoses were detected by the index MRI. Based on the available follow-up data, only 1 MRI subgroup patient became HCC-positive after the 1-year mark, with a time-to-diagnosis from index of 587 days.

CONCLUSION

This study assesses the combination of prevalent (pre-existent/missed) and incident (new) HCC diagnosed within 1 year of negative surveillance imaging. The rate of HCC diagnosis within 1 year was lower for MRI screening than for US screening (0 vs. 4.2%). Of the five HCCs diagnosed in the subgroup with negative initial US, all were present at baseline MRI (prevalent HCC), and thus none were detected as incident HCC. Overall, the data demonstrate the strong prognostic value of negative MRI and suggest that prolongation of the recommended 6-month screening interval may be plausible.

CLINICAL RELEVANCE/APPLICATION

This research investigates the prognostic value of negative MRI in patients at-risk for HCC.

W3-SSGI11-2 LI-RADS CT/MRI RADIATION TREATMENT RESPONSE ALGORITHM VERSION 2024: CATEGORY REDISTRIBUTION AND SHORT-TERM OUTCOMES

Sung-Hua Chiu, MD (*Presenter*)
Andrew Kesselman, MD (*Abstract Co-Author*)
Luke S. Yoon, MD (*Abstract Co-Author*)
Aya Kamaya, MD (*Abstract Co-Author*)
Justin Tse, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the redistribution of categories in LI-RADS CT/MRI Radiation TRA v2024 (v2024) versus LI-RADS CT/MRI TRA version 2018 (v2018) in patients with HCC treated by Y-90 radioembolization and to assess short-term outcomes of v2024 categories.

METHODS AND MATERIALS

This retrospective study included 242 patients (57 women, 185 men; median age, 65 years) with 319 HCCs treated by Y-90 radioembolization from February 2011 to March 2022 and evaluated by initial 3-month posttreatment CT or MRI. Two radiologists assigned v2018 and v2024 categories; a third radiologist resolved discrepancies. The radiologists also assessed available second posttreatment CT or MRI examinations using v2024. Overall survival (OS) was determined.

RESULTS

242 patients (57 women, 185 men; median age 65) with 319 HCCs and liver CT or MRI follow-up were included. After treatment, based on v2018, 280 (87.8%) were LR-TR Viable, 21 (6.6%) were LR-TR Equivocal, and 18 (5.6%) were LR-TR Nonviable. Based on v2024, 119 (37.3%) were LR-TR Viable, 182 (57.1%) were LR-TR Nonprogressing, and 18 (5.6%) remained LR-TR Nonviable. All LR-TR Equivocal were recategorized as LR-TR Nonprogressing. Among the 280 LR-TR Viable (v2018), 161 (57.5%) were recategorized as LR-TR Nonprogressing (v2024), and the rest remained LR-TR Viable (119; 42.5%). Of LR-TR Nonprogressing, 96 had a second post-treatment imaging: 14 (14.6%) became LR-TR Viable, 63 (65.6%) remained LR-TR Nonprogressing, and 19 (19.8%) became LR-TR Nonviable. Of LR-TR Viable, 29 had a second post-treatment imaging: 23 (79.3%) remained LR-TR Viable and 6 (20.7%) became LR-TR Nonprogressing. Patients with LR-TR Nonprogressing at first post-treatment imaging evaluation had greater OS than those with LR-TR Viable (v2024) (46 versus 12 months, $p<0.001$).

CONCLUSION

Most treated HCCs are categorized as LR-TR Nonprogressing rather than LR-TR Viable based on v2024. Among HCCs with second post-treatment follow-up, most LR-TR Nonprogressing remained as such. Patients with LR-TR Nonprogressing have greater OS than those with LR-TR Viable.

CLINICAL RELEVANCE/APPLICATION

v2024 provides greater granularity and potential prognostic value in the treatment response assessment of HCCs after Y-90 radioembolization.

W3-SSGI11-3 WATCH OR TREAT? PRE-THERAPEUTIC OUTCOMES OF LI-RADS 4 AND LI-RADS 5 HEPATOCELLULAR CARCINOMA LESS THAN 2 CM

Varun Rohatgi (*Presenter*)
Jeffrey Sung, MD (*Abstract Co-Author*)
Andrea S. Kierans, MD (*Abstract Co-Author*)
Resmi Charalel, MD,MPH (*Abstract Co-Author*)

PURPOSE

To study the pre-therapeutic outcomes and natural history of LI-RADS 4 (LR-4) and LI-RADS 5 (LR-5) lesions that are less than 2 cm. Given current transplant guidelines provide exception points only for single HCCs =2 cm, understanding the potential risks of delaying therapy is important for this unique patient cohort.

METHODS AND MATERIALS

This is a retrospective, single-center cohort study of treatment-naïve patients presenting with LR-4 or LR-5 lesions less than 2 cm on liver protocol CT or MR between January 2010-June 2024. Patient records were evaluated for subject-level and lesion-specific parameters. Subject level parameters included demographics, treatment history, and pathology correlate. Lesion imaging was reviewed to assess time to growth =2cm, threshold growth, LR-4 upgrade to LR-5, development of additional pre-therapeutic LR-4/LR-5 lesions, time to treatment, progression to T2 disease and resolution/non-progression. Competing risk analysis via Fine-Gray testing was performed for select outcomes.

RESULTS

Eighty-eight subjects with 110 lesions (40 LR-4 and 70 LR-5, diagnosed by clinical report) met inclusion criteria. There were no differences in baseline demographics or liver dysfunction (MELD, ascites, hepatic encephalopathy) between LR-4 and LR-5 patients. Of the 110 lesions, 42 achieved growth to = 2 cm in a mean time of 175.5 ± 129.8 days (152.6 days vs 186.4 days for LR-4/5 respectively, $p = 0.834$). 12 of 40 LR-4 lesions were upgraded to LR-5 at a mean of 185.33 ± 81.62 days. Compared to LR-5, LR-4 lesions showed increased propensity for resolution/non-progression without therapy (22.0% vs 8.6%, $p = 0.0485$), but similar rates of achieving threshold growth (9.8% vs 20.3%, $p = 0.1252$), growth to = 2 cm (26.8% vs 44.9%, $p = 0.0697$), time to treatment (183.4 vs 176.9 days, $p = 0.997$), and development of additional lesions (16.7% vs 25.9%, $p = 0.4253$). These data are further supported by Fine-Gray analysis (see Figure), with higher cumulative incidence of resolution/non-progression in LR-4 than LR-5 ($p = 0.00317$) but similar incidence for time to therapy ($p = 0.376$) and growth to = 2 cm ($p = 0.117$).

CONCLUSION

LR-4 lesions less than 2 cm are more likely to resolve or non-progress than their LR-5 counterparts. Otherwise, these lesions demonstrate similar growth and progression metrics across pre-therapeutic imaging surveillance.

CLINICAL RELEVANCE/APPLICATION

Understanding the progression of LR-4 and LR-5 lesions less than 2 cm is critical for shared decision-making with patients who are considering deferring treatment to potentially gain HCC transplant exception points. As OPTN tumor classification guidelines are now aligned with LI-RADS, these results are valuable to clinicians seeking to better position patients for timely transplantation.

W3-SSGI11-6 ASSESSMENT OF MICROVASCULAR INVASION IN HEPATOCELLULAR CARCINOMA USING FRACTAL FEATURES DERIVED FROM CT IMAGING

Feng Che, PhD (*Presenter*)
Bin Song (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the potential role of 3-dimensional (3D) fractal dimension (FD) derived from contrast-enhanced CT images in predicting microvascular invasion (MVI) in hepatocellular carcinoma (HCC) patients.

METHODS AND MATERIALS

This retrospective study included 655 patients with surgically confirmed HCC from two medical centers (training set: 406 patients; internal test set: 170 patients; and external test set: 79 patients). Box-counting algorithms were employed to compute the 3D FD values from portal venous phase images. Univariable and multivariable logistic regression analyses were used to determine independent predictors. The model area under the curve (AUC) was calculated. Recurrence-free survival (RFS) and overall survival (OS) curves were generated using Kaplan-Meier method.

RESULTS

Patients with MVI-positive HCC demonstrated significantly higher FD values compared to MVI-negative HCC ($p < 0.01$). The FD achieved AUCs of 0.786 (95%CI: 0.713-0.849) in the internal test set and 0.776 (95%CI: 0.669-0.874) in the external test set. The combined model incorporating alpha-fetoprotein, tumor size, tumor number, and FD showed superior diagnostic performance for MVI prediction compared to the clinical model, with AUCs of 0.795 (95% CI:0.720-0.860) versus 0.752 (95% CI:0.670-0.825) in the internal test set, and 0.826 (95% CI:0.721-0.915) versus 0.739 (95% CI:0.613-0.849) in the external test set. Patients stratified as high-risk MVI exhibited worse RFS and OS outcomes compared to low-risk MVI patients ($p <0.05$).

CONCLUSION

The 3D FD value significantly differed between MVI-positive and MVI-negative HCC patients. Integration of FD into the clinical model enhances MVI prediction accuracy and may identify patients at high risk.

CLINICAL RELEVANCE/APPLICATION

Fractal analysis based on contrast-enhance CT is a feasible tool for MVI measurement with additional clinical benefits for prognostic prediction. It can serve as a reference for preoperative MVI estimation and aid clinicians in executing more tailored therapies.

W3-SSGI12-1 CT ATTENUATION-BASED HEPATIC STEATOSIS ASSESSMENT USING 3D ORGAN SEGMENTATION: IMPACT OF TUBE VOLTAGE AND NEED FOR CUT-OFF ADJUSTMENT

Jeongin Yoo, MD (*Presenter*)
Ijin Joo, MD, PhD (*Abstract Co-Author*)
Sun Kyung Jeon, MD,PhD (*Abstract Co-Author*)
Junghoan Park, MD (*Abstract Co-Author*)
Jeong Min Lee, MD, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the impact of tube voltage on CT attenuation-based parameters obtained using 3D organ segmentation for hepatic steatosis assessment, and to evaluate the feasibility of tube voltage-specific cut-off application.

METHODS AND MATERIALS

This single-center retrospective study included 795 adults who underwent abdominal CT and MRS-PDFF between January 2017 and June 2024. CT scans were performed using single-energy 120 kVp or dual-energy 80/Sn150 kVp. In the dual-energy group, both 80 kVp images and linearly blended images (60% 80 kVp and 40% 150 kVp), considered equivalent to 120 kVp, were analyzed. Using 3D organ segmentation, mean CT attenuation values for the liver and spleen were extracted from pre- and post-contrast (portal venous phase) images. The diagnostic performance of liver attenuation (L) and liver-spleen attenuation difference (L-S) was assessed using receiver operating characteristic (ROC) curve analysis for detecting MRS-PDFF =5% and =10%. Cut-off values were derived from 120 kVp data based on predefined targets (=80% sensitivity or specificity), and corresponding 80 kVp values were estimated via regression and applied to assess diagnostic performance.

RESULTS

L and L-S at 120 kVp showed good diagnostic performance, with AUCs of 0.761-0.785 and 0.689-0.792 for precontrast and post-contrast parameters, respectively, at MRS-PDFF =5%, and 0.895-0.912 and 0.829-0.862 at =10%. In the dual-energy CT group, intra-individual comparisons showed no significant differences in precontrast diagnostic performance between 80 kVp and 120 kVp-equivalent images for both MRS-PDFF =5% and =10% (all P >0.05). For post-contrast images, L_post and L-S_post showed significantly better performance on blended images at =10% (P <0.001 and P =0.019, respectively), and L-S_post also at =5% (P <0.001). Regression-adjusted cut-off values for 80 kVp reliably achieved the predefined diagnostic targets of =80% specificity and =80% sensitivity. For example, for detecting MRS-PDFF =5%, the estimated cut-off for L_pre to achieve =80% sensitivity was 62.9 HU, yielding sensitivity of 82.2%, while the cut-off for =80% specificity was 60.0 HU, achieving specificity of 86.8%.

CONCLUSION

CT attenuation-based parameters are affected by tube voltage, and applying tube voltage-specific adjusted cut-off values enables reliable evaluation across different kVp settings.

CLINICAL RELEVANCE/APPLICATION

Given the variability in CT tube voltage settings, applying tube voltage-specific cut-off adjustments ensures consistent hepatic steatosis assessment, enhancing the utility of CT attenuation-based opportunistic screening in multicenter studies, longitudinal assessments, and retrospective analysis of existing CT datasets.

W3-SSGI12-2 EXPANDING HABITAT ANALYSIS BEYOND TUMORS: A TWO-CENTER STUDY OF 28- AND 90-DAY SURVIVAL PREDICTION IN ACUTE-ON-CHRONIC LIVER FAILURE

Yujia Shen (*Presenter*)
Shiman Wu, MD (*Abstract Co-Author*)
Xueyun Zhang (*Abstract Co-Author*)
Kangyi Pan (*Abstract Co-Author*)
Qi Zhang (*Abstract Co-Author*)
Yuxian Huang (*Abstract Co-Author*)
Yuxin Huang (*Abstract Co-Author*)
Zhenwei Yao (*Abstract Co-Author*)

PURPOSE

Habitat analysis, commonly used in oncology, is potentially applicable to complex conditions like acute-on-chronic liver failure (ACLF), capturing the microenvironment shaped by fibrosis, necrosis, and inflammation. This study investigates its feasibility for predicting survival in ACLF patients by analyzing liver tissue heterogeneity on CT imaging.

METHODS AND MATERIALS

A two-center study involved 181 ACLF patients, with 102 for model development, 44 for internal validation, and 35 for external validation. CT scans were performed without contrast, using standardized preprocessing. K-means clustering segmented liver CT images into subregions reflecting intra-tumoral heterogeneity (ITH). Radiomic features were extracted and selected through univariate analysis, and a multi-task LASSO regression model combined clinical and radiomic data.

RESULTS

The integrated model combing radiomics and habitat analysis demonstrated superior predictive performance for ACLF survival. For 90-day survival, the model achieved AUCs of 0.943 (training), 0.937 (validation), and 0.867 (test), surpassing clinical (0.933, 0.937, 0.727), habitat (0.934, 0.877, 0.801) and radiomics models (0.838, 0.918, 0.703). Similarly, for 28-day survival, it achieved AUCs of 0.839 in the test set, outperforming clinical (0.736), habitat (0.782) and radiomics models (0.759). Calibration analysis demonstrated strong agreement between predicted and observed survival, and decision curve analysis confirmed the model's clinical utility in guiding early interventions. The integrated model achieves higher AUCs in internal (28-day: 0.928, 90-day: 0.937) and external validation (28-day: 0.839, 90-day: 0.867), demonstrating superior generalizability over CLIF-C ACLF (0.500, 0.500) and COSSH-ACLF (0.546, 0.566), which decline in external validation.

CONCLUSION

The integrated model combining radiomic features and clinical data provides a dynamic tool for survival prediction in ACLF patients. By incorporating ITH, it offers enhanced prognostic capabilities and real-time, non-invasive insights for early risk stratification and liver transplantation decisions.

CLINICAL RELEVANCE/APPLICATION

The integration of radiomics with habitat analysis enhances prognostic accuracy in ACLF, offering a non-invasive tool for timely risk stratification and optimized transplant timing decisions.

W3-SSGI12-3 ULTRASOUND-GUIDED FAT FRACTION FOR ASSESSING SEVERITY OF HEPATIC STEATOSIS IN PATIENTS WITH CHRONIC LIVER DISEASE: A VALIDATION STUDY

Hidekatsu Kuroda (*Presenter*)
Takuma Oguri (*Abstract Co-Author*)
Naohisa Kamiyama (*Abstract Co-Author*)
Yudai Fujiwara (*Abstract Co-Author*)
Tamami Abe (*Abstract Co-Author*)
Takayuki Matsumoto (*Abstract Co-Author*)

PURPOSE

Ultrasound-guided fat fraction (UGFF) is a novel prediction model that estimates hepatic steatosis by integrating three acoustic parameters including ultrasound-guided attenuation parameter (UGAP), signal-to-noise ratio, and backscatter coefficient. This study aimed to externally validate the diagnostic performance of UGFF for the assessment of steatosis using histopathological grading as the reference standard.

METHODS AND MATERIALS

This prospective observational study enrolled an external validation cohort comprising 276 patients with chronic liver disease (mean age; 54.8 years, 117 men), who underwent UGAP, UGFF, and liver biopsy on the same day. The underlying etiologies included metabolic dysfunction-associated steatotic liver disease (n=226), hepatitis C virus infection (n=23), alcohol-associated liver disease (n=14), and others (n=13). Hepatic steatosis was histologically graded by a certified pathologist as follows; grades 0 (<5%), 1 (5-33%), 2 (34-66%), and 3 (=66%).

RESULTS

UGFF demonstrated excellent diagnostic performance with the area under the receiver operating characteristic curve of0.90 (0.87-0.95), 0.90 (0.86-0.94), and 0.96 (0.94-0.97) for steatosis grades 1, 2, and 3, respectively. All the values showed a significantly higher accuracy than those obtained by UGAP alone ($p<0.01$). The optimal UGFF cut-off value for detecting grade 1 steatosis was 0.64, with sensitivity, specificity, positive predictive value, and negative predictive value of 80.1%, 87.3%, 96.2%, and 52.2%, respectively. UGFF showed a close correlation with the grade of histological steatosis ($r = 0.83$, 95% CI; 0.78-0.86), outperforming UGAP alone ($r = 0.68$, 95% CI; 0.61-0.75).

CONCLUSION

UGFF was found to be a reliable and non-invasive tool for quantifying hepatic steatosis in patients with chronic liver disease. While the model has been shown to provide a robust alternative to MRI-PDFF, we could show that its performance was validated against histopathological standards. These results offer a scalable approach for managing steatotic liver disease by UGFF, which seems to be alternative to UGAP.

CLINICAL RELEVANCE/APPLICATION

UGFF represents an advanced and noninvasive tool for the measurement of liver fat quantification. Integrating multiple "acoustic biomarkers" into a unified, ultrasound-based tool enables histologically verified assessment of steatosis, which can be applied to the intervention strategies for steatotic liver disease.

W3-SSGI12-6 SPECTRAL CT DERIVED LIVER AND SPLENIC EXTRACELLULAR VOLUME FRACTION AS A NONINVASIVE METHOD FOR PREDICTING LIVER CIRRHOSIS AND HEPATIC DECOMPENSATION IN PATIENTS WITH CHRONIC LIVER DISEASE

Yiming Yang (*Presenter*)
Yupin Liu (*Abstract Co-Author*)
Dongjing Zhou (*Abstract Co-Author*)

PURPOSE

To investigate whether hepatic and splenic CT parameters, such as extracellular volume fraction (ECV) and normalized iodine concentration (NIC) derived from spectral-CT, can be used as noninvasive methods for predicting liver cirrhosis and hepatic decompensation in patients with chronic liver disease (CLD), and to compare these with liver stiffness measurement (LSM).

METHODS AND MATERIALS

This study recruited a total of 66 patients with CLD, who underwent spectral-CT scanning in the equilibrium phase and LSM, including 41 patients with liver cirrhosis and 12 patients with hepatic decompensation. Spectral-CT derived ECV of liver (L-ECV) and spleen (S-ECV), as well as NIC of the liver (L-NIC) and spleen (S-NIC) were measured based on the iodine concentration (Fig 1a). LSM was performed using FibroScan(Fig 1b). The area under the curve (AUC) of receiver operating characteristic (ROC) curve were calculated to evaluate the diagnostic performance of CT parameters and LSM for predicting liver cirrhosis and hepatic decompensation.

RESULTS

The ROC curve shows that LSM has higher dagnostic performance for predicting liver cirrhosis, with AUC of 0.934 ($p<0.001$), followed by S-ECV, L-ECV, S-NIC and L-NIC, with AUCs of 0.865 ($p<0.001$), 0.830 ($p<0.001$), 0.722 ($p<0.001$) and 0.717 ($p<0.001$), respectively (Table 1, Fig 2). The ROC curve shows that S-ECV has higher dagnostic performance for predicting hepatic decompensation, with AUC of 0.890 ($p<0.001$), followed by L-ECV, LSM, L-NIC and S-NIC, with AUCs of 0.855 ($p<0.001$), 0.752 ($p=0.005$), 0.708($p=0.017$) and 0.701($p=0.038$), respectively (Table 2, Fig 3).

CONCLUSION

Both liver ECV, splenic ECV and LSM can be used as noninvasive methods for predicting liver cirrhosis and hepatic decompensation in patients with CLD.

CLINICAL RELEVANCE/APPLICATION

The prognosis of patients with ACLD critically depends on the occurrence of liver cirrhosis and hepatic decompensation. LSM demonstrates superior performance in predicting liver cirrhosis, while spectral-CT derived splenic ECV shows enhanced accuracy for predicting liver decompensation in patients CLD. Using a variety of imaging techniques can provide more comprehensive information for risk stratification in patients with CLD.

W3-SSIN05-1 A TOUCHSTONE OF MEDICAL ARTIFICIAL INTELLIGENCE

Pedro Ricardo Ariel Salvador Bassi (*Presenter*)
Wenxuan Li, BS (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)
Zongwei Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To create a fair, large-scale benchmark for evaluating AI segmentation models in medical imaging, emphasizing accuracy, efficiency, and generalizability across real-world clinical variability.

METHODS AND MATERIALS

We launched the Touchstone Benchmark to address limitations in existing medical AI evaluations—such as small test sets, overfitting, and narrow comparisons. Forty-four research teams from 12 countries participated, submitting AI algorithms they originally developed. All models were trained using a common, open dataset of 5,195 fully annotated abdominal CT scans from 76 hospitals across 8 countries. The benchmark includes 22,682 CT volumes in total and evaluates performance using a reserved and unseen external test set of 13,420 volumes from 12 hospitals. These scans were annotated per voxel for nine anatomical structures and represent real-world diversity across scanner types, patient demographics (age, sex, race), and disease conditions.AI models—including convolutional neural networks (CNNs), Transformers, diffusion-based models, and vision-language hybrids—were independently evaluated by our team. Inference speed and segmentation quality were assessed using the Dice Similarity Coefficient (DSC), Normalized Surface Distance (NSD), and runtime per case. The benchmark is featured in ISBI 2024, MICCAI 2024, and will continue to expand through 2029.

RESULTS

We have evaluated 19 models so far, with 35 more anticipated. Segmentation performance varied significantly across organs, models, and datasets. For instance, models achieved DSCs of 70-96% across organs and 82-92% in overall average performance. Inference speed ranged from 0.12 to 0.61 seconds per CT slice. Our largest test set (N=5,903) allowed us to uncover performance gaps that are statistically significant yet previously overlooked in small-scale benchmarks. Metadata analysis revealed meaningful performance differences based on age, race, and disease type—emphasizing the clinical importance of diverse test data .

CONCLUSION

Touchstone offers a robust, fair, and long-term platform for benchmarking medical AI. By evaluating algorithms on large, out-of-distribution datasets and conducting all assessments independently, it provides the most comprehensive evaluation framework to date.

CLINICAL RELEVANCE/APPLICATION

Touchstone supports the clinical translation of AI by identifying algorithms that perform well across diverse hospitals and patient populations. Beta-tested at Johns Hopkins and UCSF, benchmarked AI tools are already aiding in organ volume measurement and surgical planning.

W3-SSIN05-2 AI-BASED IMAGE ENHANCEMENT IMPROVES DIAGNOSTIC ACCEPTABILITY OF SUBOPTIMAL CHEST CT AND CTPA STUDIES

Tejash Sikka, BS, MS (*Presenter*)
Lina Karout, MD (*Abstract Co-Author*)
Javier Contreras Yametti, MD (*Abstract Co-Author*)
Tarick Ahmad (*Abstract Co-Author*)
Parisa Kaviani, MD (*Abstract Co-Author*)
Anushree M. Burade, MBBS (*Abstract Co-Author*)
Seyedehelaheh Hosseini, MD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)

PURPOSE

A substantial number of CT pulmonary angiography (CTPA) exams are rendered suboptimal due to inadequate contrast enhancement, often caused by large body habitus, cardiac output variability, or contrast timing issues. This study evaluated the effectiveness of a vendor-neutral AI model in enhancing image quality—specifically by improving contrast and reducing noise—in both optimal and suboptimal chest CTPAs and contrast-enhanced chest CTs (CECTs).

METHODS AND MATERIALS

This retrospective IRB-approved study analyzed 611 CTPA and CECT examinations from 611 adult patients (mean age 59 years; 310 males, 301 females) performed at a tertiary care center over one year. Based on qualitative assessment by two board-certified Thoracic Radiologists, 318 cases were identified as suboptimal due to insufficient vascular opacification or excessive image noise. All images were anonymized and subsequently processed using a convolutional neural network-based AI algorithm designed to enhance contrast media visibility, reduce photon-related image noise, and minimize common artifacts, including streak and beam-hardening artifacts. The institution providing data was not involved in AI model training, validation, or testing. Image quality was quantitatively assessed by measuring attenuation values (HU) in the main pulmonary artery (PA), ascending thoracic aorta (ATA), and segmental pulmonary arteries (SPA), as well as by calculating signal-to-noise ratios (SNR) and contrast-to-noise ratios (CNR). HU values were measured from CT images with a standardized 1-mm thickness. Statistical analysis utilized paired t-tests comparing pre- and post-AI enhancement metrics, with a p-value <0.05 deemed significant.

RESULTS

Post-AI processing significantly improved vascular attenuation: PA (192±106?293±174 HU), ATA (235±132?362±217 HU), SPA (187±103?282±165 HU); all p=0.001. Noise significantly decreased: PA (17.6±7.8?11.2±5.5 HU), ATA (17.2±8.4?10.8±6.8 HU), SPA (19.0±11.2?14.7±12.3 HU); all p=0.001. Correspondingly, marked improvements were observed in SNR (PA: 20.8?59.7, ATA: 25.2?72.7, SPA: 20.1?56.9) and CNR (PA: 188.8?288.8, ATA: 232.1?357.3, SPA: 184.5?277.9); all comparisons were statistically significant (p=0.001).

CONCLUSION

The AI algorithm significantly enhances diagnostic image quality of CTPAs and CECTs by improving vascular contrast, substantially reducing noise, and increasing both SNR and CNR in optimal and suboptimal exams.

CLINICAL RELEVANCE/APPLICATION

Applying AI-based image enhancement in routine clinical practice can effectively salvage suboptimal chest CT studies, reducing repeat imaging, avoiding additional radiation and contrast exposure, and enhancing diagnostic confidence and accuracy in patient care.

W3-SSIN05-4 AN END-TO-END PIPELINE FOR BLADDER CANCER RECURRENCE PREDICTION USING MULTIMODAL IMAGING AND CLINICAL MARKERS

Israa Sharaby, BSc, MSc (*Presenter*)
Ahmed Alksas, PhD (*Abstract Co-Author*)
Osama Ezzat (*Abstract Co-Author*)
Amr A. Elsawy (*Abstract Co-Author*)
Rasha T. Abouelkheir, MBBCh (*Abstract Co-Author*)
Ahmed Elmahdy (*Abstract Co-Author*)
Sherry M. Khater (*Abstract Co-Author*)
Ahmed Mosbah (*Abstract Co-Author*)
Mahmoud A. Bazeed (*Abstract Co-Author*)
Ayman S. El-Baz SR, PhD (*Abstract Co-Author*)

PURPOSE

Bladder cancer poses a clinical challenge due to the high recurrence rate after initial treatment, necessitating reliable and non-invasive methods for early prediction. This study proposes an end-to-end pipeline for predicting recurrence in bladder cancer patients using multimodal data, including radiomics features derived from MRI scans and clinical features to improve prediction outcomes.

METHODS AND MATERIALS

We included a cohort of 119 bladder cancer patients (25 recurrence, 94 non-recurrence) with MRI scans and clinical data. Tumor segmentation was performed using a shape-aware generative adversarial network (GAN) with three input channels (original MRI, appearance-guided enhancement map, and circular binary pattern probability map) to highlight tumor morphology. Following segmentation, first-order statistical, second-order radiomics features, and morphological descriptors were extracted. Clinical features were preprocessed using label-aware imputation, normalized with RobustScaler for outliers, followed by Min-Max scaling. Both feature sets underwent Recursive Feature Elimination with Cross-Validation (RFECV) using different classifiers to identify relevant predictors by iteratively removing the least contributive features. To reduce multicollinearity, Principal Component Analysis (PCA) was applied to selected features, retaining components explaining at least 95% of the variance resulting in 5 radiomics and 18 clinical components. These were used to train and evaluate ML classifiers using Leave-One-Out and 5-Fold Cross-Validation.

RESULTS

Models were tested using clinical features alone, radiomics alone, and both combined. Using clinical markers, SVM achieved 93% accuracy and 88% sensitivity under LOOCV. Radiomics performed slightly lower a 90% accuracy, 72% sensitivity with DT and KNN showing image-derived features are informative but less robust. Combining both improved performance across classifiers; LGBM achieved 94% accuracy and 84% sensitivity. Sensitivity variability was due to class imbalance (25 recurrence vs. 94 non-recurrence), but combined features improved generalization and recall for the minority class, crucial for recurrence prediction.

CONCLUSION

This study proposed an automated pipeline for predicting bladder cancer recurrence. RFECV followed by PCA reduced redundancy and improved model interpretability. Integrating clinical and radiomics features provided a more comprehensive and discriminative representation, improving classification performance.

CLINICAL RELEVANCE/APPLICATION

The proposed automated pipeline offers a non-invasive decision-support tool aiding bladder cancer treatment planning while maintaining high diagnostic accuracy.

W3-SSIN05-5 PREDICTING POST-SURGICAL COMPLICATIONS IN LOSS OF DOMAIN INCISIONAL HERNIAS: THE ROLE OF ABDOMINAL VOLUMETRY

Hector Alvarez-Manzo, MD, MSc (*Presenter*)
Axel A. Torres Monarrez, MD (*Abstract Co-Author*)
Monica Chapa-Ibarguengoitia, MD (*Abstract Co-Author*)

PURPOSE

To investigate the utility of abdominal volumetric analysis for forecasting postoperative complications in patients with loss of domain incisional hernias.

METHODS AND MATERIALS

This retrospective study included all patients diagnosed with incisional hernias with loss of domain referred to a tertiary care unit from 2007 to April 2023. Patients without postoperative outcome data or with inadequate CT scans were excluded. Demographic variables and postoperative complications such as wall-related, intra-abdominal, or systemic, were collected. All patients underwent standard preoperative evaluation and structured postoperative follow-up. Quantitative analysis was performed on 199 preoperative CT scans from 152 patients using IntelliSpacePortal 9.0 (IQon Spectral CT). Volumetric measurements included intra-hernia volume (VIH), abdominal cavity volume (VAC), and total peritoneal volume (VP = VAC + VIH), obtained via semi-automated segmentation. The hernia volume ratio (HVR = VIH/VP) was calculated for each case. Statistical analysis was conducted using the Mann-Whitney U test ($p < 0.05$) to evaluate associations between HVR and postoperative complications. The study was approved by the institutional ethics committee (RAD-4101-22-23-1).

RESULTS

We analyzed 199 CT scans from 152 patients with incisional hernias with loss of domain; 121 scans lacked a Valsalva maneuver. In non-Valsalva scans, the median hernia index was 7.87, with a hernia volume of 680 cm^3 and a total abdominal volume of 9262.6 cm^3. Valsalva scans showed a higher median hernia index of 12.38 and a hernia volume of 923 cm^3. Regarding postoperative complications, 31 patients developed wall-related issues, mainly dehiscence and infection; 15 had intra-abdominal complications, and 39 experienced systemic events, predominantly respiratory. A significant correlation was found between the hernia index and postoperative complications in non-Valsalva scans ($p = 0.0123$).

CONCLUSION

The hernia-to-abdominal cavity volume ratio is a valuable predictor of postoperative complications in patients with incisional hernias with loss of domain, providing critical information for preoperative planning.

CLINICAL RELEVANCE/APPLICATION

A volumetric approach may offer critical preoperative insight, enabling more informed surgical planning and potentially improving outcomes in the repair of complex incisional hernias.

W3-SSIN05-6 HYBRID DISTANCE-TRANSFORM GUIDED AFFINE AND DEEP-LEARNING REGISTRATION FOR ROBUST TRACKING OF LIVER LESIONS ON LONGITUDINAL CT SCANS

Nalan Karunanayake, PhD, BEng (*Presenter*)
Lin Lu (*Abstract Co-Author*)
Ping Yin (*Abstract Co-Author*)
Hao Yang (*Abstract Co-Author*)
Richard Kinh Gian Do, MD, PhD (*Abstract Co-Author*)
Lawrence H. Schwartz, MD (*Abstract Co-Author*)
Binsheng Zhao, DSc (*Abstract Co-Author*)

PURPOSE

To develop an automated framework that delivers high-precision liver registration and accurate longitudinal classification of colorectal liver metastases (CRLM) on contrast-enhanced CT (CECT), enabling reliable identification of matched, new, and disappeared lesions.

METHODS AND MATERIALS

This retrospective study analyzed CECT pairs, baseline and follow-up, from 100 patients with CRLM, treated with chemotherapy. One radiologist annotated 887 lesions (mean diameter 31.9 ± 25.6 mm) and 862 lesions (27.4 ± 19.4 mm) on baseline and follow-up scans respectively. Liver masks automatically generated by TotalSegmentator drove a three-stage registration pipeline: (1) coarse rigid pre-alignment to place follow-up livers in approximate correspondence; (2) distance-transform optimized affine registration confined to the masked liver volumes, and (3) a convolutional neural network that refined the result to a final six-degree-of-freedom rigid transform. Registration accuracy was assessed with whole liver Dice, 1-mm surface-Dice, and the 95th-percentile Hausdorff distance (HD95). Lesion tracking was performed using voxel and bounding-box overlaps, and precision and recall were reported for matched, new, and disappeared lesions.

RESULTS

Whole-liver registration progressively improved across the three stages. The initial rough alignment yielded Dice 0.734 ± 0.087, surface-Dice 0.146 ± 0.060, and HD95 26.5 ± 13.1 mm. Applying the distance-transform affine registration raised performance to Dice 0.919 ± 0.032, surface-Dice 0.470 ± 0.115, and HD95 9.7 ± 10.1 mm. Final deep learning (DL) refinement further boosted accuracy to Dice 0.957 ± 0.010, surface-Dice 0.715 ± 0.067, and HD95 3.5 ± 1.3 mm. Lesion tracking with voxel overlap showed stepwise gains: matched-lesion precision/recall rose from 0.87/0.47 (initial) to 0.99/0.89 (affine) and 1.00/0.91 (DL); new-lesion precision improved from 0.392 to 0.803 and 0.780 (recall remained 1.00); disappeared-lesion precision climbed from 0.443 to 0.748 and 0.805 (recall 1.00 throughout). Bounding-box analysis mirrored these trends, culminating in DL-registered precision/recall of 0.935/0.961 (matched), 0.871/1.000 (new), and 0.841/1.000 (disappeared).

CONCLUSION

The hybrid distance-transform affine plus DL refinement framework delivers sub-voxel liver alignment and near-perfect lesion correspondence, outperforming conventional rough or affine-only strategies.

CLINICAL RELEVANCE/APPLICATION

Automated, high-fidelity registration markedly streamlines longitudinal assessment of liver lesion burden, enabling reliable detection of subtle lesion evolution and reducing radiologist workload in treatment-response evaluation.

Richard D. White, MD, MS (*Abstract Co-Author*)
Candice W. Bolan, MD (*Abstract Co-Author*)

PURPOSE

Advances in NLP and deep learning have expanded AI's role in clinical radiology. We investigate whether a sparse-attention transformer (BigBird) can automatically predict imaging protocols from free-text patient reports to streamline workflows and reduce manual selection errors.

METHODS AND MATERIALS

We retrospectively collected a total of 498,228 total Mayo Clinic patient records, extracting the region, radiology division, clinician name, the patient's problem list (PL), and any relevant comments or descriptions were compiled and constructed into input prompts. After construction of the input prompts, medical terms within the report were normalized to UMLS CUIs to ensure consistency across the patient reports. The data were then stratified and split into training, validation, and test sets based on three Mayo Clinic locations (Rochester, Florida, and Arizona). This data was used to train a modified Big-Bird model (sparse-attention based transformer model that extends BERT to sequences of 8192 tokens) for each Mayo Clinic region or division. Models were saved based on validation F1 score. We compare the performance of models trained on the region-based data to that of a division-based model with and without including the PL.

RESULTS

Figure 1 shows the average F1 score of each model across the separate radiological divisions with a region. The division-based model without the PL provided F1 scores of 0.80, 0.80, and 0.83 for Rochester, Florida, and Arizona respectively. F1 scores of 0.86, 0.89, and 0.88 were achieved for the division-based model with the PL included. Lastly, the region-based model achieved F1 scores of 0.86, 0.86, and 0.85 for Rochester, Florida, and Arizona. Figure 2 gives a more granular visualization of F1 score by division per region.

CONCLUSION

The models developed in this study show acceptable F1 performance for most radiological protocols in our dataset. The region-based model saw a slight reduction in F1 score on Florida and Arizona however, in a deployment/operationalization setting, having one model per-region rather than per-division we have experienced to be easier to maintain. While including the PL when training the models allows for exceptional performance for commonly prescribed protocols, some less common protocols (such as site-specific protocols) may require additional data to increase the F1 score. Results show promise for the use of LLMs for auto protocoling of radiological workflows and identify areas of potential improvement for future research directions.

CLINICAL RELEVANCE/APPLICATION

Automated protocol prediction with LLMs can accelerate radiological workflows and reduce errors in the manual selection of protocols.

W3-SSIN06-2 TRANSFORMING RADIOLOGY PROTOCOLING EXPERIENCE AND EXPEDITING PATIENT CARE (TREE PROJECT)

Jin Yoon, MD (*Presenter*)
Dorothy A. Sippo, MD, MPH (*Abstract Co-Author*)
Michael J. Rasiej, MD (*Abstract Co-Author*)
Marc Brown, MD (*Abstract Co-Author*)
Matthew P. Moy, MD (*Abstract Co-Author*)
John R. Zech, MD, MA (*Abstract Co-Author*)

PURPOSE

Radiology cross-sectional studies require significant time and effort to protocol by radiologists and contribute to the ever increasing number of workflow interruptions. Our goal was to train tree-based machine learning models to recommend imaging protocols utilizing ordering information to expedite the protocoling process and improve patient care.

METHODS AND MATERIALS

We acquired 18743 CT and MRI protocols (452 unique protocols) from August 1, 2022 to July 30, 2024 from 15455 patients. Protocols were split into training (n = 13212), validation (n = 1815), and test (n = 3718) datasets. We trained and fine-tuned decision tree models and random forest models to predict the correct protocol with two different sets of input information. We trained our first set of models using only the ordered study title as the input (labeled as "order-only" model). We then trained a second set of models with more comprehensive input information including the ordered study title, age, sex, indications, comments from the ordering provider, and the referring provider (labeled as "complete" model). Accuracies of the models were calculated for their first choice and top 5 choices. A random sample of 100 protocols that the model guessed incorrectly were selected for manual review to reassess the model's final decision.

RESULTS

Our order-only decision tree and order-only random forest models showed accuracy rates of 68.3% and 68.3%, respectively. Our complete decision tree and complete random forest models showed accuracy rates of 80.7% and 84%, respectively. The complete random forest model contained the correct protocol in its top 5 choices in 95.1% of cases. Manual review of 100 randomly selected incorrect predictions revealed that 17% of predictions were preferred over the radiologist-selected protocol, 40% were diagnostically equivalent, 22% were suboptimal but diagnostic, and 21% were nondiagnostic and/or not possible to protocol with the provided information.

CONCLUSION

Our study showed that the complete random forest model predicted the protocols with 84% accuracy and included the correct guess in its top 5 predictions in 95.1% of cases. Manual review of the 100 randomly selected incorrect predictions revealed that 57% of these protocols were in fact diagnostically equivalent or preferable to the clinically chosen protocol, highlighting that there can be variations in acceptable protocols for cross sectional studies.

CLINICAL RELEVANCE/APPLICATION

With the growing complexity and volume of cross-sectional exams, it is crucial to protocol them correctly and promptly to maintain workflow efficiency and avoid delays in patient care. Our study demonstrates the potential of utilizing machine learning AI models to quickly and accurately select the correct protocol.

W3-SSIN06-3 ACHIEVING TRULY INFORMED CONSENT? A PROSPECTIVE TRIAL USING RETRIEVAL-AUGMENTED GENERATION BEFORE CT EXAMINATIONS

Felix Busch, MD (*Presenter*)
Lisa C. Adams, MD, PhD (*Abstract Co-Author*)
Keno K. Bressem, MD (*Abstract Co-Author*)

PURPOSE

This prospective comparative study aimed to investigate the feasibility, usability, and effectiveness of a Retrieval-Augmented Generation (RAG)-powered Patient Information Assistant (PIA) chatbot for pre-CT information counseling, compared to standard physician-led consultation and informed consent procedures.

METHODS AND MATERIALS

Eighty-six patients scheduled for CT imaging (November-December 2024) were randomly assigned to either the PIA group (n=43), receiving pre-CT information via a RAG-powered chatbot, or the control group (n=43), receiving standard doctor-led consultation. Patient satisfaction, information clarity, comprehension, and concerns were assessed using six ten-point Likert-scale questions. Consultation duration was recorded, and patients in the PIA group indicated their preferred mode of future counseling. Two radiologists independently evaluated each PIA session based on five criteria: overall quality, scientific and clinical evidence, clinical usefulness and relevance, consistency, and up-to-dateness.

RESULTS

Both groups reported similarly high ratings for information clarity (PIA: 8.64 ± 1.69; control: 8.86 ± 1.28; p=0.82) and overall comprehension (PIA: 8.81 ± 1.40; control: 8.93 ± 1.61; p=0.35). Physician-led consultations more effectively alleviated patient concerns (8.30 ± 2.63 vs. 6.46 ± 3.29; p=0.003). Patients in the PIA group required significantly shorter subsequent consultation times (median: 120 s [IQR: 100-140] vs. 195 s [IQR: 170-220]; p=0.04). Radiologists rated PIA chats favorably across all evaluated categories.

CONCLUSION

A RAG-powered PIA chatbot can effectively deliver pre-CT information while reducing physician consultation time. Although patient satisfaction and comprehension were comparable to standard consultations, physician-led interactions remained superior in addressing patient concerns.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the potential of AI-based chatbot solutions to streamline patient counseling for imaging procedures. At the same time, physician engagement remains crucial for addressing patient worries, suggesting a complementary role for both approaches in clinical practice.

W3-SSIN06-4 CLINICIAN-CENTRIC EXPLAINABLE AI: A MULTI-DIMENSIONAL FRAMEWORK FOR TRUSTWORTHY DIAGNOSTIC REASONING IN RADIOLOGY

Tician Schnitzler, MD, MSc (*Presenter*)
Okan Efe Ogretmen (*Abstract Co-Author*)
Mehmet Can Yavuz (*Abstract Co-Author*)

PURPOSE

Artificial intelligence (AI) in radiology continues to face adoption barriers due to opaque decision-making processes that limit clinical trust. Traditional explainable AI (XAI) tools—such as saliency maps or feature importance rankings—rarely align with radiologists' diagnostic reasoning. We propose a Clinician-Centric Explainable AI (CC-XAI) framework to embed clinically meaningful, anatomy- and workflow-rooted explanations directly into radiological decision support.

METHODS AND MATERIALS

A conceptual and applied analysis of CC-XAI was performed, contrasting its interpretability with general-purpose XAI. We developed a five-category taxonomy comprising: (1) Visual (anatomy-aware saliency maps), (2) Textual (clinical language generation), (3) Example-Based (retrieval of annotated similar cases), (4) Quantitative (comparative measurement over time), and (5) Rule-Based (integration of clinical decision logic). A modular CC-XAI system was illustrated using a representative lung nodule case, demonstrating integration of lesion localization, volumetric growth analysis, similar case retrieval, and risk-factor-based reasoning into one cohesive explanation output.

RESULTS

The proposed CC-XAI framework translates AI predictions into structured, interpretable outputs aligned with clinical workflows and cognitive heuristics. In our example, a spiculated nodule with growth from 8 mm to 15 mm over one year (estimated doubling time of 1119 days) was explained via anatomy-aware localization, growth kinetics, retrieval of two malignant-confirmed prior cases, and rule-based consideration of smoking, cancer history, and pulmonary fibrosis. Each module contributes to a cohesive final interpretation that improves explainability and trust calibration.

CONCLUSION

Clinician-centric XAI addresses a fundamental barrier to AI adoption in radiology by offering domain-specific, multi-dimensional explanations that mirror radiologists' decision-making processes. Embedding these modules into radiology workflows can facilitate clinically robust, interpretable, and trustworthy AI integration.

CLINICAL RELEVANCE/APPLICATION

CC-XAI empowers radiologists with transparent AI reasoning across visual, textual, and rule-based domains. Its modular design supports integration into clinical workflows for safer, more interpretable, and diagnostically aligned AI usage—especially in high-stakes areas such as lung cancer evaluation.

W3-SSIN06-5 PHYSICIAN- AND PRACTICE-LEVEL PREDICTORS OF E&M SERVICE INTENSITY IN INTERVENTIONAL RADIOLOGY: A NATIONAL MEDICARE CLAIMS ANALYSIS POST-E&M REFORM

Zain Hussain, MD (*Presenter*)
Hamza Masood (*Abstract Co-Author*)
Gulcin Altinok, MD (*Abstract Co-Author*)
Ali N. Harb, MD (*Abstract Co-Author*)

PURPOSE

To quantify Evaluation and Management (E&M) service patterns among U.S. interventional radiologists (IRs), stratify intensity by procedural workload tiers, and identify physician- and practice-level predictors of E&M service use in the 2023 Medicare fee-for-service environment.

METHODS AND MATERIALS

We conducted a cross-sectional analysis using the 2023 Medicare Physician & Other Practitioners Public Use File, merged with the Physician Compare database, to analyze E&M billing among radiologists. IR-related workload was defined as the percentage of total wRVUs from procedural and E&M services, stratified into 10-49%, 50-89%, and =90% tiers. Negative binomial regressions assessed predictors of E&M intensity, including gender, years since graduation, rurality, group size, and U.S. Census division. Primary outcomes included total E&M claims, high-complexity visits, and repeat encounter ratios.

RESULTS

Among 5,330 IRs, mean E&M volume rose with procedural intensity: 13.3 (10-49%), 74.5 (50-89%), and 101.2 (=90%). High-complexity visits increased from 2.6 to 21.7 per physician across tiers. In adjusted models, female gender predicted lower E&M output in the 10-49% (RRR 0.79, $p<0.001$) and 50-89% (RRR 0.63, $p<0.001$) tiers, but not in the =90% tier. Rural practice was associated with increased E&M billing in the 10-49% tier (RRR 4.17, $p<0.001$), yet with reduced high-complexity billing in the =90% tier (RRR 0.42, $p=0.021$). Repeat encounter ratios and RVU-per-visit rose with IR workload, suggesting that longitudinal care scales with procedural engagement. Geographic disparities persisted, with Pacific and East South Central divisions demonstrating the highest relative E&M intensity.

CONCLUSION

E&M service volume in IR scales directly with procedural intensity and is shaped by geography, gender, and rurality. These findings support IR's growing role as a longitudinal clinical specialty and call for equitable support structures to optimize non-procedural care delivery.

CLINICAL RELEVANCE/APPLICATION

This national analysis demonstrates that evaluation and management service intensity in interventional radiology increases directly with procedural workload, with highly active interventional radiologists delivering substantial cognitive and longitudinal care. Geographic, gender, and rural disparities suggest structural barriers to clinic access rather than differences in provider behavior, highlighting opportunities for more equitable resource distribution.

W3-SSIN06-6 IMPACT OF LARGE LANGUAGE MODEL (LLM) LABELLING ERRORS ON PERFORMANCE AND EVALUATION INTEGRITY OF IMAGING AI MODELS

Seyed Mohammadreza Chavoshi, MD (*Presenter*)
Aawez Mansuri, BS, MS (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)
Theodorus Dapamede, MD, PhD (*Abstract Co-Author*)
Frank Li, PhD (*Abstract Co-Author*)
Rohan Satya Isaac (*Abstract Co-Author*)
Janice M. Newsome, MD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)

PURPOSE

Post-deployment monitoring of AI models is an active area of research requiring comparison of AI model predictions to ground truth extracted from radiology reports. Large language models (LLMs) have shown promising performance for label extraction; however, this performance can vary depending on label complexity. We investigate how errors in LLM-based label extraction impact subsequent evaluation of imaging AI models.

METHODS AND MATERIALS

We simulated 10,000 hypothetical radiology exams with 10% disease prevalence to assess how LLM labeling errors affect AI model estimated evaluation. We simulated LLM sensitivity (Sn) and specificity (Sp) across values from 80-100%, and AI model Sn/Sp were set at 90%, 95%, and 99%. For each combination, we calculated a best-case (LLM and model errors completely overlapped) and a worst-case (errors occurred on entirely different cases). The difference between these defined the uncertainty range in estimated performance.

RESULTS

LLM labeling errors significantly affected the estimated Sn of AI models. For a model with Sn/Sp of 90% and LLM Sn/Sp of 80%, the estimated model Sn ranged from 65.4% to 26.9%, resulting in an uncertainty of 38.5 percentage points. The corresponding estimated Sp ranged from 98.6% to 85.1% (13.5 percentage points uncertainity). Increasing only the LLM Sn to 100% (with Sp at 80%) narrowed the estimated Sn range to 64.2%-32.1% (32.1 point uncertainty) and Sp to 100%-87.5% (12.5 point uncertainty). While, increasing only the LLM Sp to 100% (with Sn at 80%) resulted in an estimated Sn range of 100%-87.5% (12.5-point uncertainty) and Sp range of 89.1%-88.0% (1.1-point uncertainty). For AI models with higher Sn/Sp values of 95% or 99%, the uncertainty induced by LLM errors was reduced but remained more pronounced in the estimated Sn than Sp. Across all scenarios, enhancing LLM specificity reduced uncertainty more effectively and yielded performance estimates closer to the true model values.

CONCLUSION

While model training may tolerate label noise, evaluation during external validation or real-world monitoring is highly sensitive to it. Because most diseases in radiology are low prevalence, LLM labeling errors can significantly distort estimated model performance metrics, especially the Sn. Across models with varying performance levels, improving LLM Sp consistently reduced evaluation uncertainty, underscoring its critical role in real world performance assessment.

CLINICAL RELEVANCE/APPLICATION

For post-deployment model evaluation in low-prevalence settings, LLM-based labelling should prioritize high specificity—ideally approaching 100%—to ensure reliable performance monitoring across models with different performance levels.

W3-SSMK08-1 SOUND AND SIGNAL: CORRELATING ULTRASOUND AND NERVE CONDUCTION IN DIABETIC NEUROPATHY

Asmita Dhandekar, MBBS (*Presenter*)
Priscilla Joshi, MBBS, MD (*Abstract Co-Author*)

PURPOSE

Diabetes is a major global health concern, responsible for considerable illness and morbidity due to its complications. Diabetic peripheral neuropathy (DPN) is one of the major debilitating complications in diabetic patients. The purpose of this study was to evaluate the association between peripheral nerve thickening, as assessed by high-resolution ultrasound (HRUS), and functional impairment detected through nerve conduction studies (NCS) in patients with Type II diabetes mellitus (T2DM). DPN is a common yet often underdiagnosed complication of diabetes, and early detection is crucial for effective management. This study aims to explore the potential of HRUS as a complementary, non-invasive diagnostic tool alongside traditional NCS in the assessment of DPN.

METHODS AND MATERIALS

66 type II diabetes patients were evaluated. Patients with polyneuropathies other than DPN, drugs causing neuropathy and gestational diabetes were excluded from the study. Data collected included demographics, diabetes duration, HbA1c levels, and NCS parameters. On HRUS the cross-sectional areas (CSA) of median, ulnar, common peroneal, posterior tibial and sural nerves were measured. These findings were correlated with NCS results.

RESULTS

Of the 66 patients evaluated, 23 patients had abnormal NCS with increased CSA, indicating DPN. 30 patients, despite normal NCS, showed increased CSA on HRUS, suggesting early changes of DPN. The remaining patients had normal NCS and USG findings. Peripheral nerve thickness increased with worsening glycemic control, which was consistently seen in the poor control group (HbA1c > 8.5%). Patients on insulin therapy had a significantly higher proportion of abnormal NCS results (~75%), whereas those on oral hypoglycemic agents (OHA) showed a higher percentage of normal NCS findings (~65%).

CONCLUSION

HRUS demonstrates significant promise as a non-invasive and accessible tool for the early detection of diabetic peripheral neuropathy. It can identify nerve thickening prior to the onset of clinical symptoms or abnormalities on NCS. With further validation, HRUS has the potential to play a crucial role in the early diagnosis and management of neuropathy in T2DM patients.

CLINICAL RELEVANCE/APPLICATION

As the global burden of diabetes continues to rise, particularly in low- and middle-income countries, there is a critical need for accessible screening tools. HRUS offers a feasible and affordable approach for the early identification of diabetic neuropathy, enabling timely therapeutic interventions and potentially improving long-term neurologic outcomes in T2DM patients.

W3-SSMK08-2 CAN MULTIPARAMETRIC MRI USING DTI AND T2 MAPPING IMPROVE THE DIAGNOSIS OF DIABETIC PERIPHERAL NEUROPATHY?

Eunsun Oh, MD, PhD (*Presenter*)
Won Nyoung Yun (*Abstract Co-Author*)

PURPOSE

To investigate whether multiparametric MRI combining diffusion tensor imaging (DTI) and T2 mapping improves diagnostic accuracy in distinguishing diabetic peripheral neuropathy from diabetes without neuropathy and healthy controls, using age- and diabetes duration-matched groups.

METHODS AND MATERIALS

This prospective, age- and diabetes duration-matched study included 17 diabetic patients with clinically confirmed peripheral neuropathy, 16 diabetic patients without neuropathy, and 12 healthy controls. All subjects underwent 3T knee MRI, including axial T2-weighted Dixon imaging, diffusion tensor imaging (DTI), and T2 mapping sequences. Quantitative parameters—fractional anisotropy (FA), axial diffusivity (AD), radial diffusivity (RD), mean diffusivity (MD), and T2 relaxation time—were measured in the tibial nerve at the proximal calf level. Group comparisons were performed using ANOVA, and diagnostic performance was assessed using ROC curve analysis for individual and combined parameters.

RESULTS

FA values of the tibial nerve were significantly lower in both diabetic groups (with and without DPN) compared to healthy controls ($p < 0.01$). T2 relaxation times were significantly longer in both diabetic groups than in controls ($p < 0.01$). Among the single-parameter models, FA showed the highest diagnostic performance for detecting DPN (AUC = 0.85). The multiparametric model combining FA and T2 relaxation time demonstrated improved diagnostic accuracy (AUC = 0.91), outperforming all single-parameter models. AD, RD, and MD showed lower AUC values and were less effective as standalone markers.

CONCLUSION

Multiparametric MRI incorporating FA and T2 relaxation time demonstrated improved accuracy for detecting diabetic peripheral neuropathy compared to single-parameter models. This approach may enhance noninvasive evaluation of peripheral nerve integrity in diabetic populations.

CLINICAL RELEVANCE/APPLICATION

Noninvasive multiparametric MRI evaluation of the tibial nerve using FA and T2 relaxation time offers a promising imaging biomarker for early detection and monitoring of diabetic peripheral neuropathy, potentially aiding clinical decision-making and personalized treatment strategies.

W3-SSMK08-3 EVALUATION OF MUSCLE QUALITY AFTER LIMB SALVAGE SURGERY IN OGS PATIENTS: A COMPARATIVE STUDY OF MOLLI AND MAGIC T1 MAPPINGBACKGROUND AND PURPOSE:

Chung-Jung Lin, MD (*Presenter*)
Hung Ta H. Wu, MD, MBA (*Abstract Co-Author*)
Han-Ying Lin, MD (*Abstract Co-Author*)
Ching-lan Wu, MD (*Abstract Co-Author*)
Hong-Jen Chiou, MD (*Abstract Co-Author*)

PURPOSE

Limb salvage surgery for osteosarcoma (OGS) often results in muscle remodeling, including fibrosis and fatty infiltration. Quantitative T1 mapping provides a noninvasive means of evaluating these changes. However, the relative performance of Modified Look-Locker Inversion Recovery (MOLLI) and Magnetic Resonance Image Compilation (MAGiC) T1 sequences—particularly in the presence of metallic implants—remains uncertain. This study aimed to compare the consistency and accuracy of MOLLI and MAGiC in assessing muscle quality in young OGS patients following surgery.

METHODS AND MATERIALS

We prospectively enrolled 25 OGS patients under age 30 who had undergone limb salvage surgery. Bilateral thigh MRIs were performed using MOLLI and MAGiC T1 mapping sequences, both with MAVRIC metal artifact reduction. Mean T1 values were extracted from quadriceps and hamstring muscles on both surgical and contralateral sides. Side-to-side differences and inter-sequence agreement were evaluated using paired t-tests, intraclass correlation coefficients (ICC), and Bland-Altman plots.

RESULTS

Both MOLLI and MAGiC detected significantly decreased T1 values in muscles near the surgical site ($p < 0.03$), reflecting fatty replacement and tissue remodeling. MAGiC (924 ± 60 ms) yielded higher absolute T1 values than MOLLI (848.3 ± 67 ms, $p < 0.001$) and showed stronger side-to-side discrimination with lower variability. The ICC between MOLLI and MAGiC was moderate (0.74), and Bland-Altman analysis demonstrated a systematic bias between sequences. In addition to T1 mapping, MAGiC provides broader anatomical coverage with simultaneous T2 and PD data, though it is more susceptible to fat-related biases.

CONCLUSION

Both MOLLI and MAGiC effectively detect post-surgical muscle changes in OGS patients. While MAGiC may show less deviation in T1 values near implants and enables multi-parametric imaging, MOLLI offers greater consistency in focal T1 quantification and may be preferable in high-metal environments.

CLINICAL RELEVANCE/APPLICATION

Quantitative T1 mapping using MAGiC can aid in noninvasively monitoring muscle quality after limb salvage surgery in young OGS patients, potentially guiding rehabilitation and long-term functional planning.

W3-SSMK08-4 MRI OF POSTOPERATIVE PROXIMAL HAMSTRING TENDON HEALING: NEW INSIGHTS FROM A DESCRIPTIVE CASE SERIES

Sandra Mecho Meca, PhD (*Presenter*)
PAMELA PEREZ (*Abstract Co-Author*)
Gil Rodas Font (*Abstract Co-Author*)
Ricard Pruna (*Abstract Co-Author*)
Jordi Puigdellivol (*Abstract Co-Author*)
Ignasi Moix (*Abstract Co-Author*)
Alvaro F. Siedi III, MD (*Abstract Co-Author*)
Xavier ALOMAR SERRALLACH, MD (*Abstract Co-Author*)
Jaime Isern-Kebschull, PhD, MD (*Abstract Co-Author*)

PURPOSE

To characterize the healing process of surgically repaired proximal hamstring tendons in elite football players using MRI, and to define normal imaging features during the first four months post-surgery.

METHODS AND MATERIALS

From 2017 to 2025, 21 surgically repaired proximal hamstring tendons in male professional football players (mean age: 18.5, range: 17-25) were prospectively followed with MRI. Surgery followed Lempainen's technique. A short MRI protocol was performed in all cases. It included axial/coronal fat-suppressed intermediate-weighted and axial T1-weighted sequences. Two blinded radiologists scored seven imaging features: fragmentation (longitudinal/transverse), scar maturation, oedema type (interstitial, intermuscular, reparative), subcutaneous hematoma, tendinous angulation, blunt outline, and denervation-like sign. A total of 51 MRI exams were assessed across monthly intervals.

RESULTS

Of 21 injuries, 14 (66.7%) were complete free tendon tears and, 7 (33.3%) proximal aponeurosis. Most occurred in the right limb (52%). Oedema shifted from interstitial/intermuscular to reparative over time. Secondary denervation-like sign was detected after two months in 12 cases, persisting at month four. Tendinous angulation and blunt outline were constant throughout follow-up.

CONCLUSION

MRI effectively monitors tendon healing following hamstring repair. Acute signs resolve progressively, while reparative changes dominate from month two. Persistent signs such as angulation, blunt outline and denervation-like sign suggest residual alterations beyond four months.

CLINICAL RELEVANCE/APPLICATION

Radiologists should recognize typical MRI findings during early tendon healing post-surgery to differentiate normal evolution from complications and to guide return-to-play decisions in elite athletes.

W3-SSMK08-5 DIAGNOSTIC ACCURACY OF MAGNETIC RESONANCE IMAGING (MRI) IN GRADING, AND CLASSIFICATION OF SPORTS-RELATED THIGH MUSCLE INJURIES IN PROFESSIONAL ATHLETES WITH SPECIAL EMPHASIS ON IMPROVING PREDICTION OF TIME TO RETURN TO PLAY (TTRTP) AND THE POTENTIAL ROLE OF ARTIFICIAL INTELLIGENCE (AI)

Sherif El Hanawy, PhD, MSc (*Presenter*)
Yasser Abd El Fattah Hassan, PhD, MSc (*Abstract Co-Author*)
Moataz Elsayed (*Abstract Co-Author*)
Yasmine Atteya El Feky (*Abstract Co-Author*)

PURPOSE

Evaluate diagnostic accuracy of MRI in classification of sports-related thigh muscle injuries in professional athletes using the British Athletics muscle injury classification (BAMIC) and MLG-R classification systems, focusing on predicting (TtRtP) and potential integration of both classifications and AI to increase diagnostic and prognostic accuracy

METHODS AND MATERIALS

Retrospective analysis conducted on 40 professional athletes who sustained recent thigh muscle injuries between 2018 and February 2025. All participants underwent 1.5Tesla MRI machine within 72 hours of injury. Injuries classified using both the BAMIC and MLG-R systems. The reference standard for TtRtP was considered as expert-determined clinical and radiological TtRtP based on previous studies defined as the time from injury to full team training clearance, verified by the team physician and rehabilitation staff). The actual TtRtP data were recorded and compared to the reference standard were calculated for each classification system independently and in combination. Inter-observer reliability was assessed with correlation between classification grades and actual TtRtP. A preliminary machine learning model was trained to classify muscle injuries and predict TtRtP categories based on MRI findings.

RESULTS

BAMIC demonstrated the strongest individual correlation with TtRtP (r = 0.977) and a high AUC of 0.984. MLG-R showed also strong correlation (r = 0.904) and AUC (0.959). The integrated BAMIC and MLG-R model yielded an overall correlation of 0.959 and AUC of 0.984. Sensitivity and specificity for predicting TtRtP were 95.5% and 94.4% for BAMIC, 91.2% and 88.9% for MLG-R, and 96.4% and 94.4% for the combined approach. When AI was applied to the combined model, predictive correlation improved further to r = 0.989, with an AUC of 0.993, and classification accuracy of 94.5%. Sensitivity and specificity for predicting TtRtP were 96.4% and 94.4% for the integrated model, and 98.2% and 96.7% with AI enhancement. Interobserver agreement for MRI classification was excellent (? = 0.86)

CONCLUSION

MRI-based classification using BAMIC shows superior predictive accuracy for TtRtP in thigh muscle injuries. While MLG-R provides valuable anatomical details, combining both systems improves overall diagnostic performance. Integration of classification frameworks, potentially enhanced by AI tools, may support individualized rehabilitation strategies and optimize return-to-play decisions

CLINICAL RELEVANCE/APPLICATION

MRI-based classification systems like BAMIC and MLG-R classifications, especially when augmented by AI, enables improved prediction of TtRtP in professional athletes, facilitating evidence-based rehabilitation planning and return-to-sport decisions

W3-SSNR10-1 FOLLOWING THE TAIL: CAN THE CORONAL SWALLOW TAIL CLEFT SIGN IMPROVE NIGROSOME-1 ASSESSMENT?

Sriram Rajan, MD, MBBS (*Presenter*)
Shankhneel Singh, MD,MBBS (*Abstract Co-Author*)
Harsh Mahajan, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To assess whether coronal reconstruction of phase images from axial susceptibility-weighted imaging (SWI) enhances the visualization confidence of the dorsolateral nigral signal / nigrosome-1 layer of the substantia nigra.

METHODS AND MATERIALS

A retrospective review was conducted on 433 consecutive MR brain scans acquired between January 2024 and January 2025 using a routine protocol for various indications. The axial phase images of susceptibility weighted images were analyzed in Phase 1 by two radiologists with 11 (SS) and 23 (SR) years of experience. They evaluated the visibility of the nigrosome-1 layer below the level of the red nucleus using a 5-point Likert scale (1 = very difficult to 5 = easily seen). In Phase 2, coronal reconstructed images of the phase susceptibility weighted images were assessed perpendicular to the substantia nigra in posterior sections, posterior to the Sukeroku sign, for the presence of the coronal cleft sign, also scored with the 5-point Likert scale.

RESULTS

Likert scores of 1 and 2 were similar for Phase 1 and 2 (6% and 9%, respectively). There was a marginal decrease in score 3 (from 4.97% to 4.04%). Scores of 4 decreased significantly from 16.97% in Phase 1 to 7.96% in Phase 2, while the score of 5 increased substantially from 62.01% in Phase 1 to 72.97% in Phase 2. Statistical analysis with Wilcoxon signed-rank test demonstrated that the addition of the coronal Swallow Tail cleft sign significantly enhanced confidence in visualizing the nigrosome-1 layer ($p < 0.01$).

CONCLUSION

The coronal Swallow Tail cleft sign significantly improves the confidence of visualization of the nigrosome-1 layer in both normal subjects and those with Parkinsonism.

CLINICAL RELEVANCE/APPLICATION

The Coronal Swallow tail cleft sign in routine practice can be used in cases where the axial images are indeterminate. The three dimensional visualization of the cleft sign may help in improving diagnostic accuracy.

W3-SSNR10-3 A NEUROIMAGING-GUIDED APPROACH TO PATIENT SELECTION FOR DBS: FOCUS ON REGIONS AND NETWORKS

Tiffany Rodrigues, BSc, MEng (*Presenter*)
Yutong Bai (*Abstract Co-Author*)
Andrew Yang (*Abstract Co-Author*)
Rafael E. Buongermini, MD (*Abstract Co-Author*)
Mohammad Mehdi Hajiabadi (*Abstract Co-Author*)
Kristine Keon (*Abstract Co-Author*)
Nir Lipsman (*Abstract Co-Author*)
Suneil Kalia (*Abstract Co-Author*)
George Ibrahim (*Abstract Co-Author*)
Carolina Gorodetsky, MD (*Abstract Co-Author*)
Victor Tang (*Abstract Co-Author*)
Alfonso Fasano, MD,PhD (*Abstract Co-Author*)
Andres Lozano, MD,PhD (*Abstract Co-Author*)
Jurgen Germann (*Abstract Co-Author*)
Alexandre Boutet, MD, PhD (*Abstract Co-Author*)

PURPOSE

Current patient selection for deep brain stimulation (DBS) relies on clinical assessments, which lack sufficient accuracy to reliably identify poor responders. Pre-operative neuroimaging presents a practical and feasible avenue for developing biomarkers to enhance patient selection. In this study we (I) reviewed pre-operative brain regions associated with DBS outcomes reported in the literature and (II) assessed the associated underlying brain networks.

METHODS AND MATERIALS

We systematically reviewed DBS studies examining preoperative neuroimaging findings from any modality (volumetric, fMRI, PET, etc) associated with postoperative DBS outcomes. Fifty-three studies (1,758 patients), mostly on Parkinson's disease (PD) and major depressive disorder (MDD), were included. Brain regions were extracted, weighted based on the number of studies reporting them, mapped onto standardized atlases, and used to generate disease- and target-specific brain maps. Two normative functional connectivity analyses were performed: (I) identification of the most central regions using graph theory metrics (internal network) and (II) assessment of brain-wide circuit engagement patterns (external network).

RESULTS

Frequency maps showed that in preoperative neuroimaging studies, the primary motor cortex was most often associated with outcomes in PD, and the anterior cingulate cortex in MDD. Internal network analysis revealed that, in PD, the primary motor cortex, left thalamus, brainstem, and right subthalamic nucleus were key hubs. In MDD, the main hubs were the bilateral amygdala, medial frontal gyrus, and frontal operculum. External network analysis demonstrated strong engagement of the basal ganglia in PD and the limbic system in MDD. Both conditions also recruited broader brain control networks, including the salience, cerebellar, and default mode networks.

CONCLUSION

Our approach identified key preoperative brain regions associated with DBS outcomes, revealing distinct disease-specific patterns and highlighting both central hubs and higher-order control regions. These findings offer a foundation for imaging biomarker development and support a more personalized, network-based strategy for DBS patient selection.

CLINICAL RELEVANCE/APPLICATION

These findings offer a framework for imaging biomarker development, supporting more personalized and network-informed DBS patient selection.

W3-SSNR10-4 AUTOMATED SUBSTANTIA NIGRA SEGMENTATION AND MULTICLASS CLASSIFICATION OF PARKINSONISM USING NEUROMELANIN-SENSITIVE MRI

Septian Hartono, PhD (*Presenter*)
Qicong Sun (*Abstract Co-Author*)
Alger Remirata (*Abstract Co-Author*)
Thomas Welton, PhD (*Abstract Co-Author*)
Pik Hsien Chai (*Abstract Co-Author*)
Louis Tan (*Abstract Co-Author*)
Eng King Tan (*Abstract Co-Author*)
Ling Ling Chan, MBBS, FRCR (*Abstract Co-Author*)

PURPOSE

Neuromelanin-sensitive magnetic resonance imaging (NMS MRI) offers a promising non-invasive marker for Parkinson's disease (PD) by enabling visualization of dopaminergic loss in the substantia nigra pars compacta (SNc). This study develops an automated SNc segmentation model on NMS MRI and a classification model to distinguish patients with Parkinsonism based on SNc features.

METHODS AND MATERIALS

A total of 548 subjects were included in this study: 166 healthy controls (HC), 256 patients with idiopathic Parkinson's disease (iPD), 36 with atypical Parkinsonian disorders (aPD; e.g., multiple system atrophy, progressive supranuclear palsy, Lewy body dementia), and 90 with non-neurodegenerative or secondary Parkinsonism (sPD; e.g., essential tremor, dementia, vascular Parkinsonism, drug-induced Parkinsonism). All subjects underwent 3T MRI, including high-resolution midbrain NMS MRI with 0.5 × 0.5 mm in-plane resolution. We trained and validated four vision transformer-based segmentation models (MERIT, ParaTransCNN, HiFormer, and Swin-Unet) against manual SNc annotations from 76 subjects (46 HC, 30 iPD). Quantitative features were extracted from the resulting SNc masks, including contrast-, intensity-, volume-, and shape-based parameters. To further enhance sensitivity, we applied an adaptive thresholding algorithm that excluded voxels with low neuromelanin signal based on an automatically derived baseline intensity and optimized cutoff. An XGBoost gradient boosting classifier was trained, validated, and tested on the extracted features using a 30:20:50 data split.

RESULTS

MERIT achieved the highest segmentation performance with a mean Dice similarity coefficient of 0.76. The multiclass classifier based on contrast- and intensity-based features yielded an overall accuracy of 89.4%, with 98.8% sensitivity and 98.8% specificity for HC, 89.8% sensitivity and 94.2% specificity for iPD, 66.7% sensitivity and 94.7% specificity for aPD, and 80.0% sensitivity and 97.2% specificity for sPD.

CONCLUSION

Our results demonstrate the feasibility of an automated pipeline that segments the substantia nigra and classifies various Parkinsonian disorders using NMS MRI-derived features. The model achieves high diagnostic accuracy, particularly in distinguishing idiopathic Parkinson's disease from other types of Parkinsonism.

CLINICAL RELEVANCE/APPLICATION

This pipeline leverages NMS MRI to objectively detect PD-related changes in the SNc. It could support radiologists in differentiating various forms of Parkinsonism using a single neuromelanin-sensitive MRI sequence, offering a non-invasive and accessible tool to supplement clinical diagnosis, especially in early or ambiguous presentations.

W3-SSNR10-5 IN VIVO MAPPING OF IRON, PROTEIN AGGREGATION, AND MYELIN INTEGRITY IN SYNUCLEINOPATHIES VIA DECOMPOSE-QSM

Jiaqi Wen, MD, MS (*Presenter*)
Jingjia Chen (*Abstract Co-Author*)
Xiaojun Guan (*Abstract Co-Author*)
Chunlei Liu (*Abstract Co-Author*)
Xiaojun Xu (*Abstract Co-Author*)

PURPOSE

Parkinson's disease (PD) and multiple system atrophy (MSA) are synucleinopathies that share motor symptoms but differ in clinical course and pathology. Non-heme iron accumulation, a-synuclein aggregation, and myelin damage contribute to disease progression. Decompose-QSM enables separation of paramagnetic (iron) and diamagnetic (protein/myelin) sources, allowing more precise characterization of disease-specific neurodegeneration. This study applied Decompose-QSM to investigate differences in iron deposition, a-synuclein accumulation, and myelin integrity in PD and MSA.

METHODS AND MATERIALS

MRI data from 184 older normal controls (ONC), 260 PD, and 22 MSA patients were acquired using 3T ESWAN sequences. Multi-echo magnitude and QSM images were processed with Decompose-QSM to generate paramagnetic (PCS) and diamagnetic (DCS) maps. Deep learning models segmented the substantia nigra, putamen, and caudate for ROI analysis. DCS maps were nonlinearly registered to the ICBM-152 2009c template for voxel-wise white matter analysis. ROI statistics were performed in SPSS with FDR correction; voxel-wise comparisons used SPM with FWE correction.

RESULTS

In the nigrostriatal system, DCS in the caudate nucleus was significantly lower in PD and MSA compared to ONC (both $P < 0.001$), suggesting increased diamagnetic content (a-synuclein). PCS in the putamen was higher in MSA than PD ($P = 0.024$) and ONC ($P = 0.022$), indicating greater iron accumulation. PCS in the substantia nigra was elevated in both PD ($P < 0.001$) and MSA ($P = 0.022$) versus ONC. In PD, caudate DCS negatively correlated with UPDRS part II ($P = 0.009$) and III ($P = 0.048$). In MSA, lower caudate DCS correlated with SCOPA-AUT scores ($P = 0.001$), while putamen PCS correlated with HAMD, HAMA, and UMSARS I and IV scores. In PD, DCS was increased in major white matter tracts (e.g., corona radiata, internal capsule, corpus callosum), suggesting demyelination, while decreased DCS in adjacent regions may reflect compensatory myelination. Higher DCS correlated with UPDRS III, and lower DCS correlated with SCOPA-AUT and UPDRS II/III. In MSA, reduced DCS in the middle cerebellar peduncle may indicate early myelination changes, and was correlated with UMSARS I scores.

CONCLUSION

This study reveals distinct patterns of iron, pathological protein, and myelin alterations in PD and MSA. Decompose-QSM offers improved sensitivity to pathophysiological differences, supporting its potential as a diagnostic and monitoring tool.

CLINICAL RELEVANCE/APPLICATION

Decompose-QSM enables precise, non-invasive quantification of iron, pathological protein and myelin-related changes in neurodegenerative diseases, offering imaging biomarkers to differentiate PD from MSA and guide clinical decision-making.

W3-SSNR10-6 7T MRI QUANTITATIVE SUSCEPTIBILITY MAPPING FOR MRGFUS THALAMOTOMY: METHODOLOGY AND ANATOMO-CLINICAL CORRELATIONS IN A PILOT STUDY

Daniele Botta (*Presenter*)
Rares Salomir, PhD (*Abstract Co-Author*)
Karl-Olof Lovblad, MD (*Abstract Co-Author*)
Felix T. Kurz, MD (*Abstract Co-Author*)

PURPOSE

Ventral intermediate nucleus (VIM) thalamotomy performed with MR-guided focused ultrasound (MRgFUS) is an effective, non-invasive treatment for essential tremor (ET). However, conventional MRI at 1.5T or 3T offers limited anatomical detail for precise targeting of intra-thalamic sub-nuclei. This study aims to assess the feasibility and potential added value of integrating 7T Quantitative Susceptibility Mapping (QSM) into the clinical workflow of MRgFUS thalamotomy.

METHODS AND MATERIALS

We retrospectively analyzed radiological and clinical data from four patients who underwent MRgFUS thalamotomy for ET. Each patient underwent a pre-operative multi-echo gradient-echo (MEGRE) scan at 7T MRI with 0.6 mm isotropic resolution. QSM images were generated from these datasets and co-registered with a paired T1-weighted MPRAGE sequence acquired both pre- and 6 weeks post-operatively. MPRAGE provided anatomical landmarks critical for indirect targeting, such as commissures and ventricular walls.

RESULTS

7T QSM provided enhanced intra-thalamic contrast, allowing for more accurate depiction of sub-nuclei and better localization of the HIFU lesion. The fusion of QSM with MPRAGE enabled detailed assessment of lesion position relative to thalamic anatomy. This improved radiological precision supported a more meaningful correlation with clinical outcomes.

CONCLUSION

This preliminary experience demonstrates the technical feasibility of integrating 7T QSM into MRgFUS thalamotomy workflow and highlights its potential to improve lesion visualization and outcome assessment.

CLINICAL RELEVANCE/APPLICATION

7T QSM may represent a valuable imaging tool to refine pre-operative targeting and post-operative evaluation in patients undergoing MRgFUS thalamotomy for essential tremor, enhancing both anatomical precision and clinical interpretation.

W3-STCE1-1 ULTRASOUND-DERIVED FAT FRACTION IS A RELIABLE METHOD TO GRADE HEPATIC STEATOSIS IN PATIENTS WITH CHRONIC LIVER DISEASES, A MULTICENTER STUDY IN A POPULATION WITH MIXED ETIOLOGIES

Jiahao Han (*Presenter*)
Jia Li (*Abstract Co-Author*)

PURPOSE

To investigate the performance of ultrasound derived fat fraction (UDFF) on grading hepatic steatosis in CLD patients applying liver biopsy as the gold standard. Also, the potential factors that affect the diagnostic performance of UDFF will also be analyzed.

METHODS AND MATERIALS

This prospective study enrolled patients suspicious for or confirmed CLD, and scheduled for liver biopsy from October 2024 to June 2025 at four tertiary care centers. UDFF was measured on the same day of liver biopsy and the region of interest (ROI) contained the biopsy site. The performance of UDFF on detecting hepatic steatosis =S1, =S2, and =S3 was analyzed by ROC curve.

RESULTS

A total of 255 patients with CLD were included in the final analysis, with a mean age of 52.00 (14.00) years old. The counts of patients with hepatic steatosis of S0, S1, S2, and S3 were 146(57.25%), 40(15.69%), 30(11.76%), and 39(15.30%). The AUCs of UDFF on detecting hepatic steatosis =S1, =S2, and of S3 were 0.914 (0.873 ~ 0.946), 0.950 (0.916 ~ 0.974), 0.916 (0.875 ~ 0.947). The optimal cutpoints of UDFF to grade hepatic steatosis =S1, =S2, and of S3 in this cohort were =7%, =11, and =18%. The AUC of UDFF on detecting hepatic steatosis =S1 in patients with inflammation of G2~3 is significantly higher than those with G0~1 [0.969 (0.929 ~ 0.990) vs. 0.888 (0.805~0.945), p =0.043].

CONCLUSION

UDFF is a reliable method to noninvasively grade hepatic steatosis in CLD patients regardless of the etiology, stage of inflammation as well as fibrosis.

CLINICAL RELEVANCE/APPLICATION

UDFF could be considered a reliable method to quantitatively evaluate hepatic steatosis in patients with CLD.

W3-STCE1-2 ADVANCING CARDIAC STRUCTURE SEGMENTATION FROM NON-CONTRAST CT BY DOMAIN ADAPTATION APPROACH

Piotr J. Slomka, PhD (*Presenter*)
Aditya Killekar, MS (*Abstract Co-Author*)
Anna Marcinkiewicz (*Abstract Co-Author*)
Hidenobu Hashimoto (*Abstract Co-Author*)
Dominika Grodecka (*Abstract Co-Author*)
Mark Lemley (*Abstract Co-Author*)
Jacek Kwiecinski (*Abstract Co-Author*)
Donghee Han (*Abstract Co-Author*)
Waseem Hijazi (*Abstract Co-Author*)
David E. Newby, PHD, MRCP (*Abstract Co-Author*)
Erick Alexanderson-Rosas, MD (*Abstract Co-Author*)
Isabel Carvajal (*Abstract Co-Author*)
Damini Dey, PhD (*Abstract Co-Author*)
Daniel S. Berman, MD (*Abstract Co-Author*)

PURPOSE

Detailed cardiac structure assessment is vital to the clinical evaluation of cardiovascular patients. While contrast-enhanced CT angiography (CTA) and MRI offer clear anatomical delineation, it is challenging to obtain accurate chamber volumes and great vessel dimensions from non-contrast chest CT (NCT) scans. We propose a cross-modal self-supervised learning (CMSSL) pre-training framework to learn robust, segmentation of cardiac structures from gated and ungated chest NCT, aided during training by co-registered CTA of the same patient.

METHODS AND MATERIALS

This study utilized a retrospective, multi-center dataset comprising 1169 chest CT scans: 434 Gated NCT - CTA and 301 Ungated NCT - CTA co-registered pairs from 3 sites. The overall patient age was 63.5 ± 8.7 years (range: [37 - 89]) with 74% patients males. Ground truth segmentations for 7 cardiac structures: Left Ventricular Myocardium (Myo), Left Ventricle (LV), Left Atrium (LA), Aorta, Right Ventricle (RV), Right Atrium (RA), and Pulmonary Artery (PA) were created as 3D multi-class masks. The paired contrast/non-contrast scans were registered with demons' nonlinear registration. Initial annotations were obtained on the registered CTA using Total Segmentator (TS) model. Subsequently, three expert physicians thoroughly adjusted all segmentations, as needed. Site 1 served as the training/internal validation set (N=159 gated NCT-CTA pairs, N=159 ungated NCT-CTA pairs), while sites 2 and 3 were used for external validation (N=275 gated NCT-CTA, and N=142 ungated NCT-pairs).

RESULTS

In external validation, CMSSL improved overall Dice similarity coefficient (DSC) vs TS for all structures (0.94 ± 0.03 vs. 0.92 ± 0.02; $p < 0.001$) for gated NCT and (0.89 ± 0.09 vs. 0.87 ± 0.1; $p < 0.001$) for ungated NCT. A detailed comparison for individual cardiac structures is presented in the figure.

CONCLUSION

Novel cross-modal self-supervised pre-training framework significantly enhances cardiac structure segmentation on NCT. This approach would improve the accurate assessment of cardiac structures on NCT thus paving the way for broader clinical application of NCT in cardiac imaging.

CLINICAL RELEVANCE/APPLICATION

Automated cardiac segmentation speeds up analysis, reduces variability, and improves efficiency compared to manual methods, ultimately leading to better patient outcomes.

W3-STCE1-3 LOW -DOSE CONTRAST MEDIA PROTOCOLS IN CT: CLINICAL PERFORMANCE, ECONOMIC VALUE AND A STEP FORWARD A MORE SUSTAINABLE RADIOLOGY.

Iacopo Capitoni, MD (*Presenter*)
Giulio Bagnacci, MD (*Abstract Co-Author*)
Armando Perrella, MD (*Abstract Co-Author*)
Cristian Sica, MD (*Abstract Co-Author*)
Chiara Piscitello, MD (*Abstract Co-Author*)
Maria Antonietta Mazzei, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the effects of implementing a low-dose iodinated contrast protocol based on Lean Body Weight (LBW) on image quality, patient safety, and cost reduction in oncologic CT imaging.

METHODS AND MATERIALS

Elective, multiphase whole body CT scans were retrospectively reviewed from January 2024 to July 2025, performed using a modern dual-energy CT (DECT) system. Selected cases received contrast tailored to LBW, targeting =400 iodine mg/kg. Data collected included Total Iodine Load (TIL) and Iodine-to-Weight Ratio (IWR). Image quality was assessed via Contrast-to-Noise Ratio (CNR), measured in hepatic and paravertebral muscle ROIs, comparing prior polyenergetic images with new monoenergetic reconstructions.

RESULTS

A cohort of 100 patients with comparable prior non-optimized exams was analyzed. Monoenergetic low-keV reconstructions demonstrated a 50.8% mean increase in CNR, despite a 30-50% average reduction in IWR.

CONCLUSION

Substantial iodine dose reduction did not compromise diagnostic quality; on the contrary, it enhanced iodine conspicuity in DECT imaging. These findings support a reevaluation of contrast dosing standards in oncologic protocols, particularly where precautionary excess is common.

CLINICAL RELEVANCE/APPLICATION

contrast media represent a significant cost driver in cancer imaging. Our estimates suggest that DECT-based optimization protocols could lower iodinated contrast costs by 25-50%. Broader implementation may also mitigate environmental and resource concerns linked to iodine availability.

Daniel Ginzburg (*Abstract Co-Author*)
Claus C. Pieper, MD (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)
Saif Afat, MD (*Abstract Co-Author*)
David C. Maintz, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

The increasing cultural and linguistic diversity of hospital patient populations represents a growing challenge for health care systems. Large language models (LLMs) like GPT-4o offer multilingual and real-time translation capabilities. This study aims to assess the feasibility of integrating GPT-4o as a semi-automated module within a radiology information system (RIS) and to evaluate its performance in translating radiology reports across multiple languages.

METHODS AND MATERIALS

In this two-center study, GPT-4o was integrated into the radiological workflow via an application programming interface (API)-based connection to the in-house software infrastructure. A total of 100 real-world radiology reports from four imaging modalities (X-ray, ultrasound, CT, MRI) were randomly selected and fully anonymized. Reports were translated using GPT-4o with zero-shot prompting from German into four languages including English, French, Spanish, and Russian (n=400 translations). Eight bilingual radiologists (two per language) evaluated the translations for general readability, overall quality, and utility for translators using 5-point Likert scales (ranging from 5 [best score] to 1 [worst score]). Binary questions (yes/no) were conducted to evaluate potential harmful errors, completeness, and factual correctness.

RESULTS

GPT-4o required a mean processing time of no more than 25 seconds for the translation of radiological reports, with mean times ranging from 9 ± 3 seconds for English X-ray reports to 24 ± 9 seconds for Russian CT reports. The overall quality of translations achieved a median of 4.5 (IQR 4-5), with English (5 [4-5]), French and Spanish (each 4.5 [4-5]) significantly outperforming Russian (4 [3.5-4]; each $p<0.05$). Usefulness for translators was rated highest for English (5 [5-5], $p<0.05$ against other languages). Readability scores and translation completeness were significantly higher for translations into Spanish, English and French compared to Russian (each $p<0.05$). Factual correctness averaged 79%, with English (84%) and French (83%) outperforming Russian (69%) (each $p<0.05$). Potentially harmful errors were identified in 4% (16/400) of translations, primarily in Russian (9%, 9/100).

CONCLUSION

GPT-4o demonstrated rapid and robust performance in translating radiology reports across multiple languages, with limitations observed in Russian translations.

CLINICAL RELEVANCE/APPLICATION

The integration of GPT-4o via an API-based interface enables its seamless incorporation into radiological workflows. This approach positions the large language model as a promising tool for real-time workload reduction and mitigation of language barriers in the context of increasingly diverse and multilingual healthcare environments.

W3-STCE2-2 THE VALUE OF COMBINING PULSE OXIMETRY WITH ECG-LESS PERSONALIZED EXPOSURE WINDOW SETTING IN CORONARY CT ANGIOGRAPHY

He Chunyan, BArch (*Presenter*)

PURPOSE

To evaluate whether real-time pulse-oximetry-guided, heart-rate-adapted exposure windows can reduce radiation dose in ECG-less coronary CT angiography (CCTA) while maintaining biphasic (systolic and diastolic) image quality.

METHODS AND MATERIALS

One hundred consecutive patients with suspected coronary artery disease were prospectively enrolled and randomized into two groups. Group A (n = 50) underwent ECG-less CCTA with a fixed 200-800 ms exposure window. Group B (n = 50) had the exposure window individually set to 0 %-80 % of the R-R interval based on real-time pulse-oximetry heart-rate measurement. CT attenuation, standard deviation (SD), signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) of the RCA, LAD, and LCX were quantified for both cardiac phases. Effective dose (DLP × k) and examination time were recorded. Two radiologists with 5 years of cardiac imaging experience independently assessed biphasic diagnostic adequacy and overall image quality using a 3-point scale; inter-observer agreement was calculated (?).

RESULTS

Group B achieved a 27 % lower effective dose than Group A ($P < 0.05$), with more pronounced reductions in patients whose heart rate exceeded 80 bpm. Examination times were similar between groups (221 ± 28 s vs 210 ± 22 s, $P > 0.05$). No significant differences were observed in objective image parameters (CT attenuation, SD, SNR, CNR) or subjective scores (biphasic diagnostic adequacy 2.58 ± 0.24 vs 2.63 ± 0.21, $P > 0.05$). Inter-observer agreement was good (? = 0.67-0.92).

CONCLUSION

Pulse-oximetry-guided, heart-rate-adapted exposure windows significantly reduce radiation dose in ECG-less CCTA without compromising biphasic image quality, especially in patients with higher heart rates.

CLINICAL RELEVANCE/APPLICATION

Integrating a simple pulse-oximeter with ECG-less CT scanners allows each patient's exposure window to be tailored to his / her instantaneous heart rate. This "ECG-free, pulse-guided" approach cuts effective dose by ~27 % without lengthening the study or degrading coronary image quality, making low-dose, high-quality coronary CTA feasible even in high-HR or arrhythmic patients and in centres lacking reliable ECG gating.

W3-STCE2-3 BENCHMARKING FRONTIER MULTIMODAL REASONING AI MODELS VERSUS RADIOLOGISTS: NATIONWIDE PILOT STUDY ON REAL-WORLD DIAGNOSTIC STUDIES

Rishabh Jain, MBBS (*Abstract Co-Author*)
Suvrankar Datta, MD, MBBS (*Abstract Co-Author*)

PURPOSE

General-purpose multimodal AI models, and more recently reasoning models, are rapidly entering radiology practice without rigorous clinical benchmarking on real - world cases. In this nation wide industry-academia collaboration, we compared the diagnostic performances of four frontier multimodal generalist models with radiologists of varying experience using diverse clinically challenging real world single - image spotters.

METHODS AND MATERIALS

Fifty fully anonymised, clinically challenging imaging cases (single spotters) were prospectively selected by supervising radiologists from large institutional studies across multiple states. Cases were independently interpreted by four trainee radiology residents, four board certified radiologists and four frontier multimodal generalist reasoning models (OpenAI o3, Gemini 2.5 Pro, and the first ever evaluation of Grok4 and Claude Opus 4.1). All the Models were prompted identically and the responses were graded ordinally: 1 (exact diagnosis), 0.5 (partially correct/general), or 0 (incorrect). Statistical analyses included Friedman's test with Holm-corrected Wilcoxon signed-rank comparisons and Spearman rank correlation, to benchmark model performance against human expertise. The dataset and scoring scheme will be publicly released upon publication.

RESULTS

Radiologists' accuracy significantly improved with experience (Spearman ?=0.77, p=0.02); with scores ranging from 4 [JR1trainees] to 45.5 [board certified radiologists]. We demonstrate that all frontier AI models underperformed and scored lower than radiologists including trainees with total scores (out of 50) as follows: Gemini 2.5 Pro - 14.5, OpenAI o3 - 13, Grok4 - 5, andClaude Opus 4.1 - 1. Friedman tests confirmed significant differences ($?^2$=296.8, $p<0.001$) and pairwise comparisons showed that even junior trainee radiologists with two years of experience significantly outperformed all AI models ($p<0.01$)

CONCLUSION

Frontier generalist AI models demonstrate marked deficits compared to radiologists (including junior trainees) when confronted with complex real-world radiology cases from a novel non contaminated dataset. These results highlight the critical need for robust clinical validation before considering integration into routine clinical workflows

CLINICAL RELEVANCE/APPLICATION

This radiologist-industry benchmarking collaboration clarifies the true capability of current generalist AI models, cautioning against premature clinical deployment (based on reported performances on open often contaminated radiology datasets) without rigorous, real-world validation.

W5-STCE1-1 REVOLUTIONIZING CHEST CT WORKFLOW WITH AI-ASSISTED MULTIPLE ABNORMALITY SEGMENTATION AND AUTOMATED REPORTING

Suvrankar Datta, MD, MBBS (*Presenter*)
Mohammed Jabeer (*Abstract Co-Author*)
Shweta Tyagi (*Abstract Co-Author*)
Jitender Singh (*Abstract Co-Author*)
Anuj Chandalia (*Abstract Co-Author*)

PURPOSE

To address the clinical need for comprehensive, automated interpretation of chest CTs by developing a deep learning system for the detection, and reporting of multiple thoracic abnormalities, including fibrosis, pleural effusion, atelectasis, emphysema, ground-glass opacity, lesions, pneumocysts, and consolidation. These findings are associated with high morbidity and mortality and are commonly seen in conditions such as interstitial lung disease, and malignancy. Manual interpretation can be time-intensive and inconsistent, particularly in high-volume or resource-limited settings. This study aims to integrate these capabilities into a unified AI-driven workflow to support accurate, timely, and reproducible chest CT analysis.

METHODS AND MATERIALS

A curated dataset of 3000 chest CT scans with expert-annotated segmentations for eight thoracic abnormalities was used to train a multi-stage 3D segmentation model built on a modified nnUNet architecture. The pipeline first segmented lung lobes to enable anatomical localization, followed by abnormality-specific segmentation. To address class imbalance, the model was optimized using a combination of Dice and focal loss functions. In addition to segmentation, the system generated structured reports detailing the type and lobe-wise location of each abnormality. This work extends our prior study, which focused on lung nodule classification, lymph node segmentation with diameter estimation, and vascular calcification scoring.

RESULTS

The model achieved high segmentation performance across all abnormality classes, with mean Dice scores of 0.86 for consolidation, 0.82 for ground-glass opacities, 0.87 for pleural effusion, 0.77 for emphysema, and above 0.75 for the remaining findings. The automated reporting system successfully generated structured outputs with clinical descriptors, showing more than 90% consistency with radiologist-generated summaries in a blinded comparison.

CONCLUSION

This study presents a robust, unified AI system capable of segmenting and reporting multiple chest abnormalities with anatomical precision on chest CTs. The inclusion of lobe-wise localization and quantitative metrics supports comprehensive thoracic disease assessment within a single automated workflow.

CLINICAL RELEVANCE/APPLICATION

The proposed system enables consistent, rapid, and interpretable analysis of chest CT scans by automating the detection, quantification, and structured reporting of multiple abnormalities. Its integration into radiology workflows has the potential to improve diagnostic efficiency, support clinical decision-making, and enhance access to quality thoracic imaging interpretation, especially in high-volume or resource-constrained settings.

W5-STCE1-2 CLINICAL WORKFLOW INTEGRATION OF AI-BASED AUTOMATED DETECTION, LOCALIZATION, AND REPORTING OF AORTIC CALCIFICATIONS ON CHEST CT

Suvrankar Datta, MD, MBBS (*Presenter*)
Jitender Singh (*Abstract Co-Author*)
Mohammed Jabeer (*Abstract Co-Author*)
Shweta Tyagi (*Abstract Co-Author*)
Anuj Chandalia (*Abstract Co-Author*)

PURPOSE

Aortic calcification is a significant marker of systemic atherosclerosis and is associated with increased cardiovascular morbidity and mortality. Globally, the prevalence of calcific aortic valve disease has risen markedly, with cases increasing from approximately 1.7 million in 1990 to over 9.4 million in 2019. The age-standardized prevalence rate also escalated by 120%, reaching 116.34 per one lakh individuals in 2019. Accurate detection and quantification of aortic calcifications, including anatomical zone localization and aortic diameter measurement, are crucial for risk assessment and surgical planning. This study aims to develop and validate an AI-based method for automated detection of aortic calcifications on CT scans and aortic diameter estimation.

METHODS AND MATERIALS

We developed a multi-stage deep learning framework based on convolutional neural networks (CNNs) to segment the aorta, detect, and localize aortic calcifications, and estimate aortic diameters. The model was trained on a retrospectively collected dataset of 2,000 non-contrast chest CT scans, each annotated with calcification masks and labeled aortic zones. The framework first performs multi-label segmentation to delineate the aorta, followed by targeted segmentation and localization of calcified regions. This work extends our previous study on coronary artery calcification and scoring by incorporating additional features focused on the aorta. The system generates a DICOM segmentation overlay to visually highlight the calcifications in the aorta and coronary arteries, and an automated report using a Large Language Model (LLM), summarizing the findings.

RESULTS

The system was evaluated on a test set of 100 chest CT cases, achieving a Dice similarity coefficient of 0.97 for aortic segmentation and 0.93 for calcification segmentation. It demonstrated an overall accuracy of 95%, with all results verified by a radiologist. The average processing time per scan was approximately one minute.

CONCLUSION

This study introduces an effective AI-driven solution for the detection and quantification of aortic calcifications on routine chest CT scans. The system demonstrates high accuracy in anatomical zone localization and aortic diameter estimation, enabling automated identification and grading of calcifications. By streamlining reporting and providing actionable risk insights, the tool supports physicians in early assessment and informed clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

The proposed AI tool enables automated detection, localization, and quantification of aortic calcifications on routine chest CTs, delivering structured reports and early risk indicators that enhance cardiovascular assessment and support proactive clinical decision-making.

PURPOSE

To investigate Diffuse Idiopathic Skeletal Hyperostosis (DISH) as a potential opportunistic radiologic marker for untreated metabolic syndrome (MetS) by evaluating its association with (1) MetS and (2) individual MetS components.

METHODS AND MATERIALS

This single-center retrospective cross-sectional study used de-identified imaging and clinical data from ImageVU and Synthetic Derivative databases to identify adults aged 40-65 who had complete metabolic data (i.e., BMI, blood pressure, HbA1c, lipid panel) within 90 days of a thoracolumbar CT scan done for any indication. Patients with history of trauma or pharmacologic treatment for diabetes, hypertension, or hyperlipidemia prior to imaging were excluded. Two raters independently assessed scans for DISH, defined as =3 contiguous intervertebral levels with near-complete or complete bridging, using a structured scoring system combining previously published criteria (Kuperus et al. and Holton et al.). Interrater agreement was evaluated using Gwet's AC2, and discrepancies were resolved by a tiebreaker rater. MetS was defined as = 3 of 5 criteria: triglycerides >150 mg/dL, HDL-C < 40 mg/dL (men) or < 50 mg/dL (women), BMI > 30 kg/m², systolic BP > 130 mmHg, and HbA1c = 5.7%. Differences between DISH and non-DISH groups were evaluated using Chi-squared test for categorical variables and Wilcoxon rank sum test for continuous variables. Multivariable logistic regression estimated odds ratios (OR) for DISH predicted by (1) MetS as a composite variable (primary analysis) and (2) individual MetS components (secondary analysis), adjusting for age and sex.

RESULTS

Among 599 patients, 139 (23.2%) had DISH, defined as =3 contiguous levels with near-complete or complete bridging based on our composite scoring system. Interrater agreement was excellent (AC2 = 0.957; 95% CI: 0.936-0.977). MetS was more common in patients with DISH than without (56.1% vs. 30.0%, p<0.001). After adjusting for age and sex, MetS remained independently associated with DISH (OR 3.04; 95% CI: 2.03-4.56, p<0.001). In a separate model evaluating the individual components of MetS, BMI (OR 1.46 per 5 kg/m 2 increase; 95% CI: 1.26-1.69, p<0.001) and HbA1c (OR 1.20 per 0.8% increase; 95% CI: 1.08-1.32, p<0.001) were independently associated with DISH. Older age and male sex were significant predictors of DISH in both models (all p<0.01).

CONCLUSION

DISH is significantly associated with untreated metabolic syndrome, especially obesity and poor glycemic control, and may serve as a radiologic marker of elevated cardiometabolic risk.

CLINICAL RELEVANCE/APPLICATION

Reporting incidental DISH on routine imaging can support opportunistic screening for metabolic dysfunction, prompting timely clinical evaluation and intervention.

W5-STCE2-2 OPPORTUNISTIC PREDICTION OF AORTIC DISSECTION USING AN AI TOOL FOR AORTIC SEGMENTATION AND MEASUREMENT: CAN AORTIC GEOMETRY HELP?

Yash Saboo (*Presenter*)
Brian Ayers, MD,MBA (*Abstract Co-Author*)
Anushree M. Burade, MBBS (*Abstract Co-Author*)
Elizabeth Pan (*Abstract Co-Author*)
Sandeep S. Hedgire, MD (*Abstract Co-Author*)
Thoralf M. Sundt, MD (*Abstract Co-Author*)
Arminder Jassar, MBBS (*Abstract Co-Author*)
Ryan Krishna (*Abstract Co-Author*)

PURPOSE

Aortic dissection (AD) often presents as a life threatening, acute or catastrophic condition; few studies have focused on the ability to predict AD based on imaging studies. We performed a retrospective, consecutive patient study with up to 19-year data to assess if AI-based aortic segmentation and measurements (AI-AAM) on chest CT can help predict patients who will develop AD in the future.

METHODS AND MATERIALS

In two quaternary centers, we queried >18 million radiology reports, to identify adult patients between 2006 and 2024 who met the following inclusion criteria: thin-section (</= 1.5 mm) baseline, chest CT without AD, and AD-positive patients (on follow-up at >3-month interval) or AD-negative on 2-19 years follow-up. Of the 515 cases included, 42 cases developed AD (pre-AD group), and the remaining did not develop AD (no-AD group) on follow-up CT. DICOM CT data were deidentified and processed with an offline, AI-AAM (UII, China). We compared the short and long axis aortic diameters (from aortic root to celiac trunk at fixed landmarks and at the site of maximum aortic dimension - MAD) and aortic lengths (AL) and exact three-coordinate locations between different landmarks (such as proximal descending thoracic aorta to celiac trunk) to calculate aortic tortuosity (AT) in all patients. We used univariable and multivariable logistic regression with AUROC as output and odds ratios (OR) to determine the best features to estimate the probability of developing AD.

RESULTS

Cross-sectional aortic measurements were better for separating AD from no-AD groups (up to 0.724 AUROC, p<0.001 for mid descending aorta diameter for univariate tests; up to 0.77 AUROC for two diameters and AL/MAD) than AT and AL (up to 0.682 AUROC, p<0.05). Mid descending aorta diameter (DTA: OR 2.537; 95% CI 1.853-3.475; p < 0.001), sinus of Valsalva diameter (SVD) (OR 1.797; 95% CI 1.223-2.641; p = 0.00285) had the highest AD prediction power with OR. In non-dilated aorta, aortic arch diameter (AAD) (AUROC: 0.83; OR: 4.337; CI 2.288-8.22; p < 0.001) and SVD (OR: 2.207; 95% CI 1.092-4.461; p = 0.027) had the highest AD prediction power with OR and outperformed AT and AL (up to AUROC 0.749). Multivariate AUROC with AAD-SVD was 0.856.

CONCLUSION

Contrary to the reported literature, aortic diameters outperform tortuosity for predicting AD; AI-derived opportunistic screening for cross-sectional aortic diameters can allow prediction of AD on chest CT.

CLINICAL RELEVANCE/APPLICATION

AI-based automated aortic segmentation and measurement can enable opportunistic screening for patients at risk of AD on chest CT.

W5-STCE2-3 COMPARISON OF CT-BASED BODY COMPOSITION BIOMARKERS BETWEEN KENYAN AND MATCHED U.S. PATIENT COHORTS USING AUTOMATED OPPORTUNISTIC SCREENING

Tai Le (*Presenter*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
John W. Garrett, PhD (*Abstract Co-Author*)
Michael P. Hartung, MD (*Abstract Co-Author*)
Marcio Aloisio Bezerra Cavalcanti Rockenbach, MD, MS (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)

PURPOSE

Abdominal CT scans, performed for various indications, contain valuable but underutilized body composition data. AI tools have automated the measurement of body composition biomarkers from abdominal CT scans, enabling large-scale opportunistic screening. However, clinical implementation requires better understanding of how these biomarkers vary with demographic features such as race and geographic location. To achieve this, we compared a Kenyan patient cohort with matched U.S.-based African American and white American cohorts.

METHODS AND MATERIALS

In this multicenter retrospective study, abdominal CT scans were obtained from the following cohorts: Tenwek hospital in Kenya (1657 adults), UWHealth (UW) in the U.S. (148593 adults), and Massachusetts General Hospital (MGB) in the U.S. (181566 adults). AI tools processed the scans to generate abdominal aortic Agatston score; volume and attenuation of the liver; volume of the spleen and kidneys; trabecular bone attenuation (BMD) of the L1 vertebral body; area and attenuation of skeletal muscle at L3; area of visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) at L3. The cohorts were matched based on age and sex at ratios of 1:1 for Kenyan to African American and 1:10 for Kenyan to white American. The matched cohorts were Tenwek (mean age 54.3, M/F: 886/768), UW white American (mean age 54.3, M/F: 8860/7680), UW African American (mean age 54.1, M/F: 836/816), MGB white American (mean age 54.1, M/F: 8790/7750), MGB African American (mean age 53.9, M/F: 897/757).

RESULTS

The Tenwek patient cohort showed lower VAT area (mean±SD in cm2: 44.9±91.3) compared with the US cohorts of UW African American (136.6±109.2), UW white American (175.4±134.4), MGB African American (126.6±102.9), and MGB white American (158.9±128.0) (p<0.001). Similar differences were observed for SAT area, muscle area, liver volume, and kidney volume. Tenwek (mean±SD in Hounsfield Unit: 172.7±64.1) and U.S. African American cohorts (UW: 184.2±52.0, MGB: 187.3±54.3) showed higher BMD than U.S. white American (UW: 163.4±48.0, MGB: 164.9±49.1). White American cohorts had the highest abdominal aortic Agatston score (UW: 1334.9±3415.9, MGB: 1155.7±3050.3) compared to African American (UW: 904.2±2574.5, MGB: 659.6±2330.5) and Tenwek (330.1±1458.6).

CONCLUSION

The findings showed differences in VAT, SAT, muscle area, liver volume, and kidney volume were driven by geographic location while BMD and splenic volume by race/ethnicity. Aortic Agatston score varied by both geographic location and race/ethnicity.

CLINICAL RELEVANCE/APPLICATION

Opportunistic screening population standards may need to account for geographical area, race and ethnicity.

W6-SSGU05-1 DYNAMIC GRAPH-BASED MULTIMODAL APPROACH FOR NON-INVASIVE DIAGNOSIS OF ACUTE RENAL REJECTION

Israa Sharaby, BSc, MSc (*Presenter*)
Ibrahim Abdelhalim (*Abstract Co-Author*)
Abdelrahman Abdallah (*Abstract Co-Author*)
Amy Dwyer (*Abstract Co-Author*)
Mohamed Ghazal (*Abstract Co-Author*)
Ayman S. El-Baz SR, PhD (*Abstract Co-Author*)

PURPOSE

Acute renal rejection is a serious post-transplant complication requiring timely diagnosis to preserve graft function. However, variability in Diffusion Weighted Magnetic Resonance Imaging (DW-MRI) protocols across different magnetic field strengths (Tesla levels) hinders consistent interpretation. This work introduces a scanner-agnostic, multimodal framework for non-invasive detection of acute rejection.

METHODS AND MATERIALS

The proposed method integrates DW-MRI scans, clinical biomarkers, and clinical reports. First, ADC maps are co-registered across field strengths to ensure standardized cortex-to-medulla visualization. These maps are segmented into iso-surfaces, and Cumulative Distribution Functions (CDFs) are computed for each layer. A Bag of Visual Embeddings (BoVE) is constructed to capture these spatial features. Clinical biomarkers, specifically serum creatinine and creatinine clearance, are used to reweight BoVE representations via attention mechanisms. Separately, a generative model extracts salient phrases from associated clinical notes, which are embedded using a vision-language text encoder. Finally, a dynamic graph-based model fuses textual and visual information to classify each case as rejection or non-rejection.

RESULTS

The framework was evaluated on a dataset of 94 kidney transplant recipients (40 with biopsy-confirmed rejection and 54 controls). The model achieved a mean precision of 82.49%, recall of 95.24%, and F1 score of 87.05%, indicating high diagnostic performance across imaging conditions.

CONCLUSION

This framework demonstrates strong potential for accurate and generalizable acute rejection diagnosis. By combining co-registered DW-MRI features, clinical markers, and unstructured text, the method enables robust classification even under heterogeneous scanner settings.

CLINICAL RELEVANCE/APPLICATION

The proposed approach provides a non-invasive, data-efficient solution to support early identification of acute renal rejection. Its compatibility with diverse imaging setups and incorporation of routine clinical data make it suitable for deployment in real-world transplant care settings.

W6-SSGU05-2 EVALUATION OF RENAL HISTOLOGICAL CHANGES WITH THE PROGRESSION OF DIABETIC NEPHROPATHY USING FUNCTIONAL MRI PARAMETERS

Akira Yamamoto, MD, PhD (*Presenter*)
Tsutomu Tamada, MD, PhD (*Abstract Co-Author*)
Yu Ueda, PhD (*Abstract Co-Author*)
Hiroyasu Sanai, RT (*Abstract Co-Author*)
Akihiko Kanki, MD (*Abstract Co-Author*)
Atsushi Higaki, MD, PhD (*Abstract Co-Author*)
Yoshihiko Fukukura, MD, PhD (*Abstract Co-Author*)

PURPOSE

Diabetic nephropathy is a leading cause of renal failure, but early-stage evaluation is limited due to glomerular hyperfiltration and the low sensitivity of albuminuria. This study aimed to assess whether various functional MRI parameters can reflect renal histological changes and allow non-invasive risk stratification according to the KDIGO classification.

METHODS AND MATERIALS

This prospective study included 122 subjects who underwent 3.0T renal MRI between December 2018 and October 2021: 23 healthy volunteers (mean age 46.0 ± 15.5 years) and 99 patients with type 2 diabetes mellitus (mean age 62.2 ± 14.9 years). Diabetic patients were divided into five KDIGO risk groups (low to highest) based on eGFR and albuminuria. MRI parameters included T1 and T2, BOLD-derived T2* and R2*, IVIM-derived ADC, f, D*, D, ASL perfusion, and corticomedullary differentiation (CMD) assessed by SSFP with inversion recovery. Group comparisons and post hoc analyses were performed, and findings were interpreted in light of known diabetic nephropathy pathology.

RESULTS

Significant differences across KDIGO groups were found in cortical T1 ($p=0.007$), T2* ($p<0.001$), R2* ($p<0.001$), ASL ($p=0.002$), IVIM-ADC ($p=0.001$), IVIM-D ($p=0.001$), and CMD ($p<0.001$). All differences were limited to the cortex. CMD and cortical T2 were significantly elevated in the low-risk group compared to controls. Between low- and moderate-risk groups, IVIM-D and CMD were reduced. No significant changes were seen between moderate- and high-risk groups. However, T1 and ADC increased between high and very high risk, and CMD declined further from very high to highest risk.

CONCLUSION

Early diabetic nephropathy is characterized by hyperfiltration, with increased perfusion and oxygenation that complicates diagnosis by albuminuria alone. Functional MRI detected early changes in cortical T2 and CMD between healthy and low-risk individuals. In more advanced stages, histological progression such as fibrosis and ischemia corresponded with increased T1, decreased ADC and D, reduced ASL, and altered BOLD values. These findings suggest functional MRI parameters can capture stage-specific pathological changes.

CLINICAL RELEVANCE/APPLICATION

Functional MRI enables non-invasive assessment of diabetic nephropathy, identifying structural, perfusional, and oxygenation changes beyond traditional markers. It may improve risk classification and reduce the need for renal biopsy, aiding clinical decision-making across disease stages.

W6-SSGU05-3 EVALUATION OF RENAL INJURY IN TRANSPLANTED KIDNEYS BY AMIDE PROTON TRANSFER MAGNETIC RESONANCE IMAGING

Xintian Yu, MMEd (*Presenter*)
Jiule Ding (*Abstract Co-Author*)
Jinggang Zhang, MD (*Abstract Co-Author*)
Jie Chen (*Abstract Co-Author*)
Wei Xing, MD (*Abstract Co-Author*)
Liang Pan, MD (*Abstract Co-Author*)

PURPOSE

To quantitatively analyze the differences in amide proton transfer (APT) values between the cortex and medulla of renal allografts in kidney transplant recipients using amide proton transfer magnetic resonance imaging (APT-MRI), and to explore the value of APT-MRI in evaluating renal allograft injury.

METHODS AND MATERIALS

A total of 80 kidney transplant recipients were divided into two groups based on estimated glomerular filtration rate (eGFR): mild renal impairment and moderate-to-severe renal impairment. The differences in APT values between the cortex and medulla of renal allografts were compared using the Wilcoxon signed-rank test. The Mann-Whitney U test was used to compare APT values between the two groups. Spearman correlation analysis was performed to assess the correlation between cortical and medullary APT values and eGFR. The diagnostic efficacy of APT values was evaluated using receiver operating characteristic (ROC) curve analysis.

RESULTS

Based on eGFR, 39 kidney transplant recipients were classified into the mild renal impairment group, and 41 recipients were classified into the moderate-to-severe renal impairment group. In both groups, the cortical APT values of renal allografts were higher than the medullary APT values ($P < 0.05$). Compared with the mild renal impairment group, both cortical and medullary APT values were higher in the moderate-to-severe renal impairment group ($P < 0.0001$). The cortical and medullary APT values of renal allografts were negatively correlated with eGFR ($r = -0.6533$, $P < 0.0001$; $r = -0.5103$, $P < 0.0001$). ROC curve analysis showed that cortical and medullary APT values had high diagnostic efficacy in assessing different degrees of renal impairment. When the cortical cut-off APT value was 3.0%, the difference between the mild renal impairment and moderate-to-severe renal impairment groups showed a respective AUC, sensitivity, and specificity of 0.907, 100.0%, and 79.49%. Finally, when the medullary cut-off APT value was 2.0%, the difference between the mild renal impairment and moderate-to-severe renal impairment groups showed an AUC, sensitivity, and specificity of 0.819, 82.93%, and 82.05%, respectively.

CONCLUSION

APT-MRI can directly evaluate the injury status of renal allografts.

CLINICAL RELEVANCE/APPLICATION

This study, for the first time, explored the value of APT-MRI in assessing renal allograft injury. The results indicate that APT-MRI is a non-invasive, repeatable, and precise imaging diagnostic tool. It complements existing imaging biomarkers, has high diagnostic efficacy, and provides an important basis for the assessment of renal function in renal allografts.

W6-SSGU05-5 ASSESSING THE DIAGNOSTIC VALUE OF CONTRAST-ENHANCED ULTRASOUND IN DETECTING ACUTE RENAL TRANSPLANT REJECTION: A SYSTEMATIC REVIEW AND BIVARIATE META-ANALYSIS

Victor Arthur Ohannesian (*Presenter*)
Miguel J. Francisco Neto, MD, PhD (*Abstract Co-Author*)
Giovana Alvarez (*Abstract Co-Author*)
Gustavo Rossini (*Abstract Co-Author*)
Bruno Ishizuka (*Abstract Co-Author*)
Luciano Falcao (*Abstract Co-Author*)

PURPOSE

To systematically assess the diagnostic accuracy of contrast-enhanced ultrasound (CEUS) using quantitative parameters from time-intensity curves (TIC) in detecting acute or subclinical kidney allograft rejection, using biopsy as the gold standard.

METHODS AND MATERIALS

A PRISMA-DTA-compliant systematic review and bivariate meta-analysis was performed (PROSPERO: CRD420251036575). Searches were conducted in PubMed, Embase, Cochrane CENTRAL, MEDLINE, Web of Science, and Scopus. Eligible studies evaluated CEUS-TIC in adult or pediatric kidney transplant recipients undergoing protocol or indication biopsy. Outcomes included sensitivity, specificity, AUC, diagnostic odds ratio (DOR), positive (LR+) and negative (LR-) likelihood ratios. Heterogeneity, threshold effects, and publication bias (Deeks' test) were assessed. Meta-regression was conducted for the TIC-derived parameter PIc.

RESULTS

Seven studies (n = 545; 166 reference-positive, 379 reference-negative) were included. Pooled sensitivity was 81% (95% CI: 67-90%), specificity 71% (95% CI: 52-85%), LR+ 2.8 (95% CI: 1.7-4.6), LR- 0.27 (95% CI: 0.17-0.43), DOR 10 (95% CI: 6-19), and AUC 0.84 (95% CI: 0.74-0.90). Interstudy heterogeneity was high (I^2 = 96%; LRT_Q = 46.5, $p < 0.001$), largely attributable to threshold effects (? = -0.93; 87% explained variance). PIc use showed no significant effect on diagnostic performance (LRT?^{2} = 0.39; p = 0.82). Deeks' funnel plot showed no publication bias (p = 0.326). Across individual studies, LR+ ranged from 1.56 to 14.93, and LR- from 0.05 to 0.60, with substantial inconsistency (I^2 ˜ 66% for both).

CONCLUSION

CEUS-TIC presents acceptable sensitivity (81%) but modest specificity (71%) and low LR+ (2.8), limiting its stand-alone utility in detecting acute or subclinical rejection. Heterogeneity and threshold effects further weaken its interpretability.

CLINICAL RELEVANCE/APPLICATION

Although CEUS with TIC analysis demonstrates suboptimal diagnostic performance, our results suggest that it still represents a viable complementary tool in resource-limited settings, particularly where access to biopsy or advanced imaging is restricted. Its main advantages include being non-invasive, bedside-performable, rapidly executable, and utilizing a non-nephrotoxic contrast agent. While it does not replace renal biopsy as the gold standard, its logistical benefits may support its use as a screening strategy in selected clinical scenarios.

W6-SSGU05-6 GADOLINIUM RETENTION AND SPECIATION IN HUMAN KIDNEY SPECIMENS

Mariane Le Fur, PhD (*Presenter*)
Chloe Brasket (*Abstract Co-Author*)
Ivy Rosales (*Abstract Co-Author*)
Adam S. Feldman, MD (*Abstract Co-Author*)
Peter D. Caravan, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the long-term retention and speciation of gadolinium-based contrast agents (GBCAs) in human kidney specimens.

METHODS AND MATERIALS

The collection of human kidney samples was approved by our institutional review board. 14 healthy human kidney samples were obtained from patients undergoing nephrectomy. Patients received at least one dose of a GBCA 16 to 2795 days before sample collection. 10-µm frozen sections were analyzed by Laser Ablation (LA) inductively coupled mass spectrometry (ICP-MS) to obtain Gd distribution maps. The Gd speciation was measured by Liquid Chromatography (LC) ICP-MS following extraction of water-soluble species in water. Extracted kidney sections were analyzed by LA-ICP-MS to evaluate the distribution of insoluble Gd species.

RESULTS

Mean Gd concentrations of 318, 133, 178, 5, and 0 ppb were measured in the cortex of kidney samples from patients who received a single dose of the macrocyclic Gadoterate 43 (case 1), 65 (case 11), 77 (case 3), 466 (case 9), and 2367 (case 10) days before surgery, respectively. This suggests that gadoterate is retained in human kidneys for months after administration but is gradually excreted over time. Intact Gadoterate could be detected in the corresponding kidney extracts by LC-ICP-MS except for cases 9 and 10, for which Gd levels were below the instrument limit of detection. For case 11, LA-ICP-MS maps, before and after extraction, also showed near-total removal (>95%) of Gd, indicating that Gadoterate is mostly retained in its intact form. In samples obtained from patients who received a single dose of the macrocyclic Gadobutrol 49, 51, and 75 days before surgery, the intact GBCA could be detected in kidney extracts. Of the three samples from patients who received doses of at least two different GBCAs with a macrocyclic agent as the last injection, each LC-ICP-MS trace showed only one peak, all of which matched the retention time of the last injected macrocyclic GBCA. In contrast, two patients who received linear GBCAs had elevated Gd levels in both cortex and medulla even seven years after injection. Despite such high concentrations, no soluble Gd species could be detected by LC-ICP-MS, indicating that Gd is retained as insoluble Gd.

CONCLUSION

This study found that Gd is retained in human kidneys for months to years after GBCA injection. The macrocyclic GBCAs appear to be primarily retained intact and slowly excreted over time, whereas linear agents form insoluble Gd species that accumulate in kidneys.

CLINICAL RELEVANCE/APPLICATION

The presence of residual GBCAs in human kidneys for months after administration raises concerns about potential long-term effects.

Stephanie A. Harmon, PhD (*Abstract Co-Author*)

PURPOSE

This study evaluates the performance of a 3D Artificial Intelligence (AI) model, originally trained to segment lesions on baseline FDG PET/CT scans of multiple cancer types, on baseline FDG PET/CT scans in newly diagnosed multiple myeloma patients, using PET and MRI expert reads as reference standards.

METHODS AND MATERIALS

Fifty-seven patients with newly diagnosed multiple myeloma (NDMM) who underwent baseline FDG PET/CT imaging and whole-body MRI were included. An established 3D deep learning model developed on PET/CT images from 1014 scans with various solid cancers from a publicly available cohort, AUTOPET, was applied to segment lesions on the NDMM whole-body PET scans. To improve specificity for myeloma, regions unlikely to harbor disease (soft tissues and visceral organs) were excluded using an automated whole-body organ segmentation tool, TotalSegmentator. AI-predicted lesions were categorized into five skeletal regions: skull, spine, ribs, upper extremities, and lower extremities. Segmentation results were compared to expert interpretations from whole-body PET and MRI to compute the final patient-level performance metrics, including sensitivity and specificity.

RESULTS

Among 13 PET-positive patients, the AI model detected lesions in 10 patients (sensitivity 76.9%), while maintaining a 63.6% specificity for the 44 PET-negative patients. Among 28 MRI-positive patients with 12 focal patterns, 11 diffuse patterns, and 5 combined patterns, the AI models identify 8, 4, and 1 patients with focal, diffuse, and combined patterns, respectively. The specificity against MRI is 68.97%. In the subset of 16 patients where PET failed to detect lesions but MRI was positive, the AI models identified lesions in 6/16 (37.5%) patients (3/7 focal, 2/6 diffuse, 1/3 combined), demonstrating its capability to detect lesions that may overlooked by radiologists or not apparent on PET scans to naked eyes.

CONCLUSION

A deep learning model trained to segment non-myeloma malignancies on PET/CT demonstrated promising performance for lesion segmentation in baseline multiple myeloma PET/CT. The AI model can identify 37.5% more MM cases than expert PET interpretation while maintaining a low false negative rate when integrating with TotalSegmentator. Refining the AI model on MM lesions may further improve generalizability for myeloma applications. Automated lesion quantification holds potential for supporting standardized imaging assessments in multiple myeloma.

CLINICAL RELEVANCE/APPLICATION

An AI model can significantly improve the efficiency of reading whole-body PET. Moreover, the AI model shows improved sensitivity on myeloma lesions referenced to MRI readouts, demonstrating the value of a well-trained segmentation model.

W6-SSNMMI06-3 CORRELATION BETWEEN MANUAL AND AUTOMATED WHOLE-BODY TUMOR VOLUME ASSESSMENT IN FDG-PET/CT: A COMPARATIVE ANALYSIS OF SEGMENTATION METHODS

Ricarda Ebner, MD (*Presenter*)
Maurice Heimer, MD (*Abstract Co-Author*)
Felix Herr, MD (*Abstract Co-Author*)
Christian Alexander Dascalescu, MD (*Abstract Co-Author*)
Michael Ingrisch (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Lalith Kumar Shiyam Sundar, PhD, MS (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)
Paul Blanc-Durand, MD,MSc (*Abstract Co-Author*)
Clemens C. Cyran, MD (*Abstract Co-Author*)

PURPOSE

Accurate quantification of whole-body tumor burden is essential for disease assessment and response evaluation in oncologic PET/CT. This study analyzes the correlation between manually segmented tumor volumes and AI-based, automated metabolic tumor volume (TMTV) and total lesion glycolysis (TLG) metrics. Validating automated volumetric analysis is clinically relevant, as it may simplify workflows, reduce interobserver variability, and support consistent assessment over time and across institutions.

METHODS AND MATERIALS

Patients with non-small cell lung cancer (NSCLC) who underwent [¹8F]FDG-PET/CT were retrospectively included. Each patient received one scan prior to therapy initiation (baseline) and at least one follow-up scan during treatment. Manual volumetric segmentation of all FDG-avid tumor lesions was performed using free-breathing, standard-kernel CT mapped to attenuation-corrected PET images. Automated segmentation was performed using Pionus v1.2.2 (PAIRE, Paris, France), a CE-marked, AI-driven software designed for fully automated detection and quantification of FDG-avid lesions on PET imaging. Automated metrics — TMTV41% and TLG41% (41% SUVmax threshold) and TMTVSUV4 (fixed threshold SUV > 4) — were computed separately for each time point. Pearson correlation coefficients (r) were used to assess the linear relationship between manually defined PET tumor volume (PET_VOL) and AI-derived metrics.

RESULTS

123 patients were included, each with a baseline and up to five follow-up scans. At baseline, PET_VOL showed very high correlations with automated metrics (TMTV41%: r = 0.892; TMTVSUV4: r = 0.983; TLG41%: r = 0.920; all $p < 0.001$). Across all time points, correlations remained robust but were moderately lower (TMTV41%: r = 0.723; TMTVSUV4: r = 0.867; TLG41%: r = 0.821; all $p < 0.001$). TMTVSUV4 consistently demonstrated the highest correlation with PET_VOL.

CONCLUSION

Automated, AI-based PET segmentation using SUV-based thresholds shows very high correlation with manual whole-body tumor volume assessments, particularly for TMTVSUV4. Slightly reduced correlations at follow-up may reflect therapy effects, tumor heterogeneity, or segmentation variability. Still, automated volumetry is a robust and scalable method for longitudinal tumor burden quantification. These findings support the integration of AI-based tumor burden quantification into clinical workflows, enabling standardized response assessment and improved decision-making in NSCLC management.

CLINICAL RELEVANCE/APPLICATION

Automated PET volumetry enables high-throughput, operator-independent tumor burden quantification, offering a scalable tool for standardized response assessment and improved clinical decision-making in NSCLC.

W6-SSNMMI06-4 TO EXPLORE THE REMODELING CHARACTERISTICS OF THE IMMUNE MICROENVIRONMENT OF IMMUNE CHECKPOINTS AND THEIR DOWNSTREAM MOLECULE SHP2 IN COLORECTAL CANCER UNDER HYPOXIC CONDITIONS BASED ON PET IMAGING

Mingyu Zhang, PhD (*Presenter*)
Xia Lu (*Abstract Co-Author*)
Jigang Yang (*Abstract Co-Author*)

PURPOSE

To investigate the correlation between FDG PET/CT parameters and PD-L1 with its downstream molecule SHP2 in colorectal cancer (CRC) under hypoxic conditions, and to identify suitable candidates for immunotherapy based on molecular imaging biomarkers.

METHODS AND MATERIALS

Western blot (WB) and immunofluorescence double-staining were employed to assess the expression levels of PD-L1, HIF-1a, and SHP2 in multiple CRC cell lines, enabling the selection of cell lines with high vs. low expression. Xenograft models were established using CRC cell lines with high/low metastatic potential, and immunohistochemistry (IHC) was performed to analyze differential HIF-1a/PD-L1/SHP-2 expression in transplanted tumor tissues. We retrospectively enrolled 38 CRC patients who underwent preoperative whole-body FDG PET/CT at our institution. Correlations between FDG uptake parameters and HIF-1a/PD-L1/SHP-2 protein expression in tumor tissues were evaluated, along with associations between TNM staging and these molecular markers. Logistic regression was applied to assess the predictive value of FDG multiparameters for immunotherapy benefit.

RESULTS

The hypoxic microenvironment significantly upregulated PD-L1 expression and recruited SHP2 in CRC cell lines in vitro . In xenograft models, tumors with high metastatic potential exhibited elevated HIF-1a, PD-L1, and SHP-2 expression compared to low-metastasis counterparts. Clinical data revealed that significant correlations between SUVmax and HIF-1a/PD-L1/SHP-2 expression ($p<0.05$).MTV correlated with HIF-1a and PD-L1 levels ($p<0.01$).SUVmax, TLG, and MTV were associated with advanced T/M staging ($p<0.05$).The combination of SUVmax and MTV served as a predictive biomarker for PD-L1 blockade therapeutic benefit.

CONCLUSION

Hypoxia drives immune evasion in CRC via PD-L1 upregulation and subsequent SHP2 activation. FDG PET parameters (MTV and SUVmax) correlate with PD-L1/SHP-2 expression and provide non-invasive imaging biomarkers to stratify patients for PD-L1-targeted immunotherapy.

CLINICAL RELEVANCE/APPLICATION

Provide imaging markers for the screening of groups benefiting from immunotherapy

W6-SSNMMI06-5 RADIOEMBOLIZATION FOR HCC PATIENTS WITH PERSONALIZED YTTRIUM-90 DOSIMETRY FOR CURATIVE INTENT (RAPY90D)

Srinivas C. Kappadath, PhD (*Presenter*)
Armeen Mahvash, MD (*Abstract Co-Author*)

PURPOSE

To report on completed single-arm single-institution prospective clinical trial (RAPY90D, NCT03896646) on 90 Y-glass radioembolization (TARE) for hepatocellular carcinoma (HCC) using patient-specific voxel-dosimetry treatment planning. The primary endpoint was localized-mRECIST objective response rate (ORR) at 6-month follow-up. The secondary objective was evaluation of planned- and delivered-dose concordance.

METHODS AND MATERIALS

All adult HCC patients with non-infiltrative tumors size =3 cm suitable for 90 Y-glass radioembolization were eligible. All patients underwent hepatic angiography with fan-beam CT (AngioCT), received 99m Tc-MAA injections at all planned treatment sites. AngioCT and 99m Tc-MAA SPECT/CT was used to plan tumor dose =200Gy and normal liver dose =100Gy (stratified by underlying disease and volume) with voxel dosimetry. All treatments used 90 Y-glass 2 nd -week-calibration vials. ORRs and toxicities (CTCAEv5.0) were determined 3- and 6-month follow-up. Post-treatment for delivered-dose verification was performed using both 90 Y-SPECT/CT and 90 Y-PET/CT. Cases with adjustments to perfused-normal-liver distribution via gelfoam/particle use or catheter-location changes >1cm were excluded from dose-concordance analysis.

RESULTS

40 patients (62/52 all/index tumors) received 90 Y-TARE; 37 patients (58/48 all/index tumors) completed 6-month follow-up. The median (range) treated index-tumor size was 5.4 (3.0-15.4) cm. The median (range) planned- and delivered-doses to tumors were 331 (206-562) Gy and 361 (208-981) Gy, and to perfused-normal-liver were 113 (32-343) Gy and 138 (37-487) Gy, respectively. The tumor ORR at 6-month follow-up was 97% (56/58) with 72% (42/58) complete responders. Concordance analysis included 81% (67/83) infusions and demonstrated strong dose correlations (R 2 >0.90).

CONCLUSION

RAPY90D has demonstrated feasibility and efficacy of prospective, patient-specific 99m Tc-MAA-based voxel dosimetry treatment planning for 90 Y-TARE.

CLINICAL RELEVANCE/APPLICATION

RAPY90D was the first US radioembolization trial to use voxel dosimetry for prospective treatment planning and dose verification. It used an innovative dosimetry schema to increase the therapeutic ratio. RAPY90D was a positive study with localized mRECIST ORR 96% and CRR 72%. 90 Y-TARE is a highly effective therapy - getting the right amount of dose to the right location is critical for success.

W6-SSOB03-1 AN INTERACTIVE LEARNING MODULE FOR MRI EVALUATION OF PLACENTA ACCRETA SPECTRUM

Carolyn Chen, BA, MA (*Presenter*)
Erin N. Gomez, MD (*Abstract Co-Author*)
Lydia Gregg, MA (*Abstract Co-Author*)

PURPOSE

Placenta accreta spectrum (PAS) is a potentially life-threatening condition in which the placenta is adherent to or invades the uterine myometrium. MRI may serve as a helpful tool in the diagnosis and characterization of PAS. Interpretation of placental MRI is challenging for many radiologists due to the numerous, sometimes subtle imaging features present and variation in imaging protocols and image quality. Educational resources regarding MRI evaluation of PAS are limited, and many radiologists are infrequently exposed to this type of examination. To address this gap, an interactive educational module detailing and illustrating the imaging features of PAS was developed and evaluated for knowledge gain and learner engagement.

METHODS AND MATERIALS

A needs assessment was conducted via interviews with radiology faculty to evaluate confidence interpreting placental MRI and preferences for educational media. The results were used to guide the development of the educational module, which included a broad overview of PAS, recommended MRI protocols, diagrammatic and case-based interpretive illustrations of MR images detailing key features of PAS, and annotated, scrollable case studies. An institutional review board-approved randomized controlled trial was conducted comparing the module to a review article from the literature. Twenty-four participants, which included radiology faculty, fellows, and residents, completed the survey. Knowledge gain was assessed using pre- and post-tests, while engagement was measured using Likert-scale items and qualitative free-response questions.

RESULTS

Participants who used the module demonstrated a significant increase in post-test scores ($p < 0.001$), while those who read the article did not ($p = 0.189$). The module received higher engagement scores, with all participants demonstrating a preference for the interactive format over the review article. Qualitative feedback highlighted the utility of the illustrations in clarifying complex imaging features, as well as the value of the scrollable case studies in promoting understanding of the appearance of PAS on MRI.

CONCLUSION

An interactive module significantly improved radiologists' knowledge of key MR imaging features of PAS, outperforming a review article in both knowledge transfer and user engagement. This highlights the value of targeted, interactive educational media in addressing content gaps for conditions with complex imaging features such as PAS.

CLINICAL RELEVANCE/APPLICATION

Understanding aspects of media that increase comprehension of complex clinical conditions can provide valuable insight in the development of educational materials for radiologists.

W6-SSOB03-2 DIFFUSION-WEIGHTED MRI AND SURGICAL OUTCOMES IN A PROSPECTIVE COHORT OF PREGNANT PATIENTS WITH INCREASED RISK OF PLACENTA ACCRETA SPECTRUM

Quyen N. Do, PhD (*Presenter*)
Yin Xi, PhD (*Abstract Co-Author*)
Christina Herrera (*Abstract Co-Author*)
David Owen (*Abstract Co-Author*)
Catherine Y. Spong, MD (*Abstract Co-Author*)
Baowei Fei, PhD (*Abstract Co-Author*)
Diane M. Twickler, MD (*Abstract Co-Author*)
Matthew A. Lewis, PhD (*Abstract Co-Author*)

PURPOSE

Diffusion-weighted MR imaging (DWI) evaluates water molecule motion within tissues, intravoxel incoherent motion (IVIM) analysis of multi-b-value DWI provides metrics on tissue diffusivity and microcirculation. This prospective study aimed to assess regional placental diffusion characteristics, specifically near vs. remote from the internal os, to predict placenta accreta spectrum (PAS) requiring hysterectomy in pregnancies with increased PAS risk.

METHODS AND MATERIALS

Pregnancies with first-trimester ultrasound findings indicating low uterine segment implantation and a history of cesarean delivery were eligible. Participants underwent 3T MRI between 24-27+6 gestation. Sagittal DWI of the gravid uterus (b-values: 0, 50, 100, 150, 400, 700, and 1000 sec/mm²) was acquired. Using Philips MR Advanced Diffusion Analysis software, diffusion parameters-apparent diffusion coefficient ADC , diffusion coefficient D , pseudo-diffusion coefficient D* , and perfusion fraction f - were computed. Regions of interest (ROIs) for the placenta and internal os were manually segmented on b=0 images and then applied to the diffusion coefficient maps for analysis under expert supervision (Figure 1). For each placental pixel, the distance to the center of mass of the internal os was calculated. Linear regressions models were generated for each diffusion parameter (ADC , D , D* , and f) as a function of distance. The slope of each regression line represented the change in the diffusion parameter per centimeter from the internal os. Two-sample t-tests were used to compare slope distributions between patients who did and did not require hysterectomy.

RESULTS

Among the 38 cases, 10 required cesarean hysterectomy and 28 had cesarean delivery alone. Groups were similar in age, race, and number of prior cesareans (Table 1). Hysterectomy cases had flatter or slightly positive slopes in D , f , and ADC , while non-hysterectomy cases showed steeper negative slopes. Figure 2 shows individual regression models for the diffusion coefficient D for each patient. No significant group differences were found in D* (Table 2).

CONCLUSION

IVIM-derived diffusion metrics, especially f and D , differ regionally in cases requiring hysterectomy due to PAS. Larger negative slopes in non-hysterectomy cases suggest preserved regional microcirculation, while flatter slopes in cases requiring hysterectomy due to PAS may reflect abnormal perfusion, especially in the lower uterine segment. This supports DWI as a physiologic biomarker for microvascular alteration in PAS.

CLINICAL RELEVANCE/APPLICATION

Diffusion slope analysis may help differentiate cases with PAS severe enough to require hysterectomy and inform surgical risk by identifying altered regional placental microcirculation.

W6-SSOB03-3 ASSESSING CHANGES IN MATERNAL OPHTHALMIC AND UTERINE ARTERY DOPPLER AS AN INDICATOR OF EFFECTIVENESS OF ASPIRIN IN PREVENTING PREECLAMPSIA - A PROSPECTIVE STUDY IN HIGH-RISK PREGNANT WOMEN

Meera Shah, MBBS (*Presenter*)
Chetankumar M. Mehta, MD (*Abstract Co-Author*)

PURPOSE

This prospective study aimed to evaluate changes in maternal ophthalmic and uterine artery doppler parameters across trimesters to determine low-dose (150 mg/day) aspirin's impact on maternal vascular adaptation , placental blood flow and effectiveness in preventing pre-eclampsia (PE) among high-risk pregnant women .

METHODS AND MATERIALS

High-risk pregnant women (gestational age (GA): 11-13+6 weeks) were identified via the Fetal Medicine Foundation pre-eclampsia screening algorithm . Participants (n=130) were randomly divided into 2 groups; one received low-dose aspirin (150mg/day) daily from 11-14 weeks to 36 weeks of gestation or delivery, whichever came first while the other group did not receive aspirin. Maternal ophthalmic and uterine artery doppler parameters were assessed in the 2nd and 3rd trimesters (19-23 & 32-36 weeks respectively).

RESULTS

Comparative analysis of ophthalmic artery doppler parameters between aspirin and non-aspirin groups revealed no statistically significant difference in PSV2/PSV1 ratio (PSV = peak systolic velocity, PSV1 = 1st peak, PSV2 = 2nd peak) during the 1st trimester (11 to 13+6 weeks; $p > 0.05$). However, significant differences were observed in the 2nd & 3rd trimesters with the non-aspirin group exhibiting a higher PSV2/PSV1 ratio value (p-value < 0.01) . Similarly, uterine artery doppler assessment showed a significant reduction in pulsatility index (UtA-PI) values in the aspirin group during the 2nd & 3rd trimesters (p-value < 0.01); while the difference in RI values during these periods remained statistically non-significant. Also, statistically significant (p-value < 0.05) differences were noted in the incidence rates of PE between the 2 groups with a higher incidence rate in the non-aspirin group .

CONCLUSION

Early doppler indices of both ophthalmic and uterine arteries do not differ significantly between the 2 groups, administration of aspirin is associated with lowering of peripheral resistance as depicted by lower PSV2/PSV1 ratios in ophthalmic arteries and UtA-PI in the later gestational period as well as a reduction in the incidence of PE suggesting potential hemodynamic influence of aspirin in modulating maternal vascular adaptation during pregnancy.

CLINICAL RELEVANCE/APPLICATION

Pre-eclampsia is a leading cause of maternal and perinatal morbidity. Identifying high-risk pregnancies early allows for timely interventions, such as low-dose aspirin therapy , which has been shown to reduce the incidence of PE , especially when initiated before 16 weeks of gestation. Monitoring Doppler indices provides a non-invasive method to assess placental perfusion and the effectiveness of preventive measures , thereby guiding clinical decision-making and improving maternal and fetal outcomes.

W6-SSOB03-4 INTER-READER AGREEMENT BETWEEN EXPERT AND NON-EXPERT READERS IN THE INTERPRETATION OF PLACENTAL MRI

Abigail Coco (*Presenter*)
Andrew Cho (*Abstract Co-Author*)
Robert M. Weinstein (*Abstract Co-Author*)
James Facciola (*Abstract Co-Author*)
Claire Brookmeyer, MD (*Abstract Co-Author*)
Katarzyna J. Macura, MD, PhD (*Abstract Co-Author*)
Erin N. Gomez, MD (*Abstract Co-Author*)

PURPOSE

To evaluate accuracy and inter-reader agreement among subject matter expert (SME) and non-SME radiologists in the interpretation of MRI for evaluation of placenta accreta spectrum (PAS), characterize imaging features reported and identify areas for improvement in PAS-related education and training.

METHODS AND MATERIALS

A single institution retrospective study was conducted including patients who underwent placental MRI prior to caesarean hysterectomy with pathology diagnosis of PAS from 2008-2022. Cases were categorized as missed/under-diagnosed vs. concordant/over-diagnosed by comparing final MRI diagnoses to pathology and operative diagnoses. Demographics, obstetric history, intraoperative needs, postoperative outcomes, and original reports of PAS imaging features were compared using Student’s t-tests. Missed/under-diagnosed cases were re-interpreted by two SME and two non-SME radiologists. Accuracy and agreement on PAS diagnosis and specific imaging features were assessed with intraclass correlation coefficients and kappa statistics.

RESULTS

59 patients met inclusion criteria, with 19 missed/under-diagnosed cases and 40 concordant/over-diagnosed cases. There was no significant difference in demographics or prior cesarean deliveries. Missed/under-diagnosed cases had increased intraoperative needs with greater blood loss, units of blood transfused and intraoperative crystalloid use (4700 vs. 2966, P=0.03). Original readers reported fewer findings per missed/under-diagnosed case (1.6 vs. 3.5, P=<0.01), identifying fewer placental bands and myometrial thinning/bulging compared to concordant/over-diagnosed cases (11% vs. 53%, P=<0.01; 42% vs. 80%, P=<0.01). Secondary SME review of missed/under-diagnosed cases demonstrated higher detection of all key features of PAS with increased findings per case compared to original reads (4.4, P=<0.01). Non-SME readers had higher rates of missed diagnoses compared to SMEs. Overall agreement on PAS diagnosis was fair (ICC=0.30). Overall agreement was highest for placenta previa (K=0.82) and lowest for image quality concerns (K=0.18). Agreement increased for identification of placental bands, heterogenous placental signal and image quality concerns when compared between SMEs.

CONCLUSION

Subject matter expertise is valuable in the correct interpretation of MRI for PAS, but agreement on imaging features present, even among SMEs, varies.

CLINICAL RELEVANCE/APPLICATION

Missed/under-diagnosed cases of PAS result in increased intraoperative needs and worse postoperative outcomes in an already high-risk population. Continued efforts are needed to educate and train radiologists in the interpretation of placental MRI to improve accurate prenatal detection.

W6-SSOB03-5 CLINICAL OUTCOMES AMONG PATIENTS UNDERGOING MRI VERSUS ULTRASOUND ONLY FOR THE EVALUATION OF PLACENTA ACCRETA SPECTRUM: 20-YEAR EXPERIENCE FROM A LARGE TERTIARY CARE CENTER

Maria Carolina Rodriguez Steube, BS (*Presenter*)
Andrew Cho (*Abstract Co-Author*)
Judy Fustok, MD (*Abstract Co-Author*)
Abigail Coco (*Abstract Co-Author*)
Erin N. Gomez, MD (*Abstract Co-Author*)

PURPOSE

Placenta accreta spectrum (PAS) refers to the abnormal adherence of the placenta to the uterine myometrium during pregnancy and significantly increases the risk of peripartum hemorrhage. Antepartum diagnosis of PAS with referral to a tertiary care center has been shown to improve outcomes. Magnetic resonance imaging (MRI) has comparable sensitivity and specificity to ultrasound (US) for detection of PAS and is currently performed in high-risk patients or when US evaluation is suboptimal. The purpose of this study was to determine clinical and demographic factors associated with referral for MRI after initial US evaluation for PAS and differences in clinical outcomes between MRI and US groups.

METHODS AND MATERIALS

Obstetric patients evaluated for PAS with MRI at our institution between 2004-2024 were identified from the electronical medical record. Patients with suspected PAS on US who did not undergo MRI between 2015-2024 were identified as controls. Data collected included patient demographics and history, imaging, surgical and pathology findings. Outcome measures included surgical complications, postpartum course, estimated blood loss (EBL), and transfusion requirements. Quantitative statistical analysis was done in Jupyter (Python 3.7).

RESULTS

116 MRI patients and 59 US only controls were included. A significantly greater proportion of MRI patients had public insurance or were uninsured versus controls ($p = 0.0209$). More patients with prior CS and a history of tobacco use were referred to MRI than in the US group ($p = 0.00988$, and $p = 0.0147$, respectively). There was a higher proportion of patients with placenta percreta intraoperatively in the MRI group ($p = 0.0012$). There were no significant differences in EBL or units of blood transfused between the two groups. However, the MRI group received more liters of crystalloid during delivery ($p = 0.000353$) and had a longer post-partum length of stay ($p < 0.0001$). Gynecologic Oncology and Urology were more likely to assist in the delivery MRI patients ($p < 0.0001$ and $p = 0.0187$, respectively).

CONCLUSION

Patients with more clinically or socially complex cases of PAS were referred for MRI. Although patients undergoing MRI had more severe disease and thus more complex surgeries requiring longer postoperative monitoring, we observed similar degrees of peripartum hemorrhage in patients evaluated with US only. This is likely a testament to the role of MRI as an operative planning tool, which in conjunction with management at a tertiary care center may decrease the risk of maternal and fetal morbidity and mortality in patients with more severe forms of PAS.

CLINICAL RELEVANCE/APPLICATION

MRI is essential to the multidisciplinary care that improves clinical outcomes among patients with severe forms of PAS.

W6-SSOB03-6 PREDICTIVE VALUE OF MRI SIGNS COMBINED WITH IVIM PARAMETERS IN ASSESSING CLINICAL OUTCOMES IN PATIENTS WITH PLACENTA ACCRETA SPECTRUM DISORDERS

Yanbo Li (*Presenter*)
Xiaohan Zheng (*Abstract Co-Author*)
Weiwei Cui (*Abstract Co-Author*)
Can Feng (*Abstract Co-Author*)
Jun Liu, PhD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the predictive value of preoperative MRI features combined with intravoxel incoherent motion (IVIM) parameters for adverse clinical outcomes in patients with placenta accreta spectrum disorders(PASDs).

METHODS AND MATERIALS

In this retrospective study, 118 singleton pregnant women with surgically and pathologically confirmed PASDs, between 32 and 39 weeks of gestation, underwent preoperative 1.5 T MRI scans. Adverse outcomes were defined as any of the following: intraoperative blood loss =1000 mL, preterm delivery (<36 weeks), bladder injury, or ICU admission. Two radiologists independently evaluated MRI features based on standardized PASD diagnostic criteria. IVIM parameters (f: perfusion fraction; D*: pseudo-diffusion coefficient; D: true diffusion coefficient) were measured by delineating the placental region of interest (ROI), excluding calcifications, fibrotic areas, and umbilical insertion sites. Binary variables for IVIM parameters were derived from ROC curve thresholds. Logistic regression analyses were conducted to identify predictors of adverse clinical outcomes. Pearson correlation assessed the association between IVIM metrics and intraoperative bleeding. ROC curves evaluated model performance.

RESULTS

A total of 118 pregnant women were included in this study. Patients with poor outcomes had a higher incidence of increased abnormal intraplacental vascularity, increased T2WI hypointense bands, loss of chemical shift line at uterovesical interface, and placental thickness >4 cm(all $P<0.05$), as compared to those with good outcomes. In addition, patients with a poor outcomes had higher f , D*, and D values (all $P<0.05$). Logistic regression analysis showed that increased abnormal placental vascularity, thinning of the myometrium, $f = 0.343$, $D = 1.82 \times 10^{-3}$ mm 2 /s, and $D^* = 24.26 \times 10^{-3}$ mm 2 /s were independent predictors of the presence of poor outcomes. f, D*, and D were positively and linearly correlated with intraoperative blood loss. When the MRI signs were combined with each parameter of IVIM separately to create a prediction model, ROC curve analysis showed that the combination of f with increased abnormal placental vascularity and thinning of the myometrium had the best diagnostic results (AUC=0.894, 95% CI: 0.83-0.95).

CONCLUSION

MRI features and IVIM parameters are independently associated with adverse outcomes in PASDs. The combination of placental perfusion fraction with key MRI signs offers strong predictive performance and may enhance clinical risk assessment.

CLINICAL RELEVANCE/APPLICATION

These findings support the use of multiparametric MRI, including IVIM analysis, as a non-invasive tool for preoperative risk stratification and surgical planning in PASDs management.

Ajjai S. Alva, MD (*Abstract Co-Author*)
Grace Bruno (*Abstract Co-Author*)
Chuan Zhou, PhD (*Abstract Co-Author*)
Vikas Gulani, MD, PhD (*Abstract Co-Author*)

PURPOSE

An offline LLM facilitates HIPAA compliance and kept frozen ensures reproducibility in clinical applications. Offline in-house LLMs may need to be smaller to conserve local computational resources. We investigated if a small LLM (Llama3.2-3B-instruct), fine-tuned for a specific clinical information retrieval, can match or exceed large LLMs such as GPT4 in supporting a survival prediction for bladder cancer patients post-radical cystectomy.

METHODS AND MATERIALS

With IRB approval, we identified 781 bladder cancer patients treated from 2001 to 2020. Inclusion criteria: (1) receipt of neoadjuvant chemotherapy (NAC); (2) CT urography obtained pre and post NAC; (3) treatment with radical cystectomy; and (4) 5-year survival status. 163 eligible cases were partitioned into training (56%: 55 alive (A), 37 deceased (D)), validation (4%: 4A, 3D), and test (40%: 20A, 44D) cohorts. Patient reports were processed by Llama3.2-3B-instruct fine-tuned via LoRA to extract pathological T stage (pT), nodal stage (N), and lymphovascular invasion (LVI). Comparator extraction was performed by the same model without fine-tuning and by GPT4. Accuracy was measured against ground truth. To predict 5-year survival, we converted the extracted staging variables (pT, N, LVI) into nomogram points, whose sum corresponds to survival probability via the Shariat nomogram. We also developed a Clinical-Radiomic-Deep learning (CRD) predictive model by concatenating the 3 nomogram points with 12 radiomic and 1 deep-learning features from CTU images, which served as input to a neural network. We evaluated model performance by the area under the ROC curve (AUC) on an independent test set.

RESULTS

The LoRA trained model achieved an average extraction accuracy of 96% (pT 97%), outperforming the untrained model (89% avg, 55% pT) and matching GPT4 (94% avg, 91% pT). For survival prediction, the nomogram model AUC was 0.82±0.05, versus 0.82±0.05 for GPT4, and 0.79±0.06 for the untrained model. The CRD model with LoRA trained extraction yielded an AUC of 0.88±0.05, similar to GPT4 (0.88±0.05) and superior to the untrained model (0.85±0.05).

CONCLUSION

Fine-tuning of a small LLM enables highly accurate extraction of pathological staging and supports five-year survival prediction with performance comparable to larger proprietary models, demonstrating the feasibility of deploying open-source LLMs in clinical radiology workflows.

CLINICAL RELEVANCE/APPLICATION

In comparison with large LLMs, use of fine-tuned small LLMs lowers computational time and cost while retaining high accuracy in extracting clinical variables and predicting patient outcomes. Use of small LLMs should allow for AI integration in the management of urologic oncology patients even in resource limited environments.

W6-SSPH10-2 DEEP LEARNING-EMPOWERED ANALYSIS OF THERAPEUTIC OUTCOME USING HIGH-RESOLUTION INTRAVITAL IMAGES OF ANGIOGENESIS IN HEAD AND NECK CANCER

Jung Sun Yoo, PhD (*Presenter*)
Hongzhao Chen (*Abstract Co-Author*)

PURPOSE

The integration of targeted therapeutics such as cetuximab into clinical treatment regimens has brought significant advancements in managing head and neck squamous cell carcinoma (HNSCC). Despite promising clinical success of Cetuximab and vibrant development of combo therapies, there is a lack of reliable tools to monitor and predict therapeutic outcomes rigorously. Here, we showcase a deep learning-empowered angiogenesis classification technique using high-resolution intravital images of vasculature to distinguish normal, malignant, and differentially recovered models.

METHODS AND MATERIALS

A multi-level ensemble method was developed for automatic vasculature classification. This approach combines predictions from CNNs (DenseNet121, Vgg16, ResNet50) and ML classifiers (SVM, KNN, Naive Bayes) to distinguish normal from malignant models and assess therapeutic outcomes of Cetuximab alone and with Magrolimab for HNSCC. Intravital vasculature images were acquired from treated and untreated murine HNSCC xenograft models and normal mice after Dextran-Tetramethylrhodamine injection. A dataset comprising 784 in vivo images and 471 vascular records was selected for training and validation of our models. The ensemble method was refined by introducing a novel Integrated Curvature Estimation (ICE) approach, designed to approximate vasculature curvature, a parameter not obtainable with traditional tools. We incorporated an adaptive weight board learning system to dynamically update weights and tackle data imbalance. Predictions from CNNs and MLs were first averaged and then unified through Bootstrap Aggregating.

RESULTS

The ensemble model using images and vascular records together demonstrated superior performance, 96.25% accuracy (ACC), 0.99 area under the curve (AUC), 96.06% sensitivity (SEN), and 98.73% specificity (SPE). In contrast, the image-based model presented only 93.75% ACC, 0.98 AUC, 93.70% SEN, and 97.88% SPE and the vascular record-based model showed the worst performance with ACC of 75.00%, AUC of 0.93, SEN of 71.25%, and SPE of 91.39%.

CONCLUSION

The AI-assisted differentiation of angiogenesis, combined with intravital imaging, provides a crucial clinical parameter for HNSCC staging and serves as an effective indicator for evaluating drug efficacy in pre-clinical and clinical settings.

CLINICAL RELEVANCE/APPLICATION

This strategy will be particularly useful for the rapid and robust assessment of new drugs and the rational design of clinical trials, given the current rise in interest in combinational and synergistic immunotherapies and targeted therapies. Early and accurate identification of responders will result in effective clinical decisions during treatment and reduce the clinical burden of HNSCC.

W6-SSPH10-3 SCALABLE NEURAL NETWORK FOR SYNTHESIZING CT SCANNER- AND ALGORITHM-SPECIFIC LESIONS ACROSS VARIABLE RECONSTRUCTION SETTINGS

Hao Gong, PHD (*Presenter*)
Shravani Kharat, MS (*Abstract Co-Author*)
Jarod Wellinghoff (*Abstract Co-Author*)
Ahmed O. El Sadaney, MBBCh (*Abstract Co-Author*)
Joel G. Fletcher, MD (*Abstract Co-Author*)
Shaojie Chang, PhD (*Abstract Co-Author*)
Lifeng Yu, PhD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)

PURPOSE

Synthetic CT images with known pathology are desired for task-driven assessments. Projection domain lesion insertion is accurate but requires proprietary information and tools. Image domain methods are convenient but have difficulty accounting for varying resolution, texture, and reconstruction settings. We aim to address these challenges using a scalable p hysics-informed self- a ttention self- s upervised neural ne t work for synthesizing scann e r- and algorithm-specific patho l ogic features (PASTEL)

METHODS AND MATERIALS

PASTEL fused lesion images (i.e., lesion models) into lesion-free images, using physics-based l esion p rior g eneration (LPG) and s elf-attention s elf-supervised n etwork (SSN). LPG added forward projections of lesion-free images and lesion models and created lesion priors via back projection. Lesion priors were filtered with the local point spread function estimated via Gaussian fitting in Fourier domain. SSN conducted self-supervised learning where lesion models and lesion priors served as inputs and reference lesion images in different backgrounds served as labels. Self-attention was used to adaptively adjust image appearance at lesion location. SSN used custom transformers to process different sampling frequencies at variable fields of view (FOV). The encoded reconstruction and CT scanner types served as extra inputs to modulate filter response to differentiate spatial resolution and noise texture types within the network. Loss function involved mean square error and edge difference. PASTEL was assessed using data from 1 conventional (170 lesions) and 1 photon counting CT (175 lesions): training 325, testing 20. A validated projection domain lesion insertion tool was used as reference. To demonstrate scalability, two iterative reconstruction algorithms were used with 2 filters / denoising strengths and variable FOVs (310 to 500 mm). PASTEL was qualitatively and quantitatively assessed using CT number accuracy, structural similarity index (SSIM), and radiomic features. Intraclass correlation coefficient (ICC) was calculated.

RESULTS

PASTEL-simulated lesion appearance was close to the reference across all reconstruction settings, showing similar contrast, sharpness and noise texture. PASTEL showed high CT number accuracy (mean difference range [-1.4, -0.5] HU), high lesion structural similarity (mean SSIM range [0.96, 0.98]), and good-to-excellent reproducibility of radiomics features (mean ICC range [0.81, 0.93]).

CONCLUSION

PASTEL generalized well across reconstruction algorithms and settings on different CT scanners.

CLINICAL RELEVANCE/APPLICATION

PASTEL can provide high quality scalable simulation of CT pathology using only image data to facilitate optimization of protocols and AI models.

W6-SSPH10-4 DEEP LEARNING MODEL FOR CLASSIFICATION AND SEGMENTATION OF HEMOPERITONEUM AND EXTRAPERITONEAL HEMATOMA ON ABDOMINOPELVIC CT USING REGION-AWARE APPROACH

Jihwan Kim, BSc, MSc (*Presenter*)
Taehyun Kim (*Abstract Co-Author*)
Sujeong Kwon, BA (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)
Gil-Sun Hong, MD, PhD (*Abstract Co-Author*)

PURPOSE

Rapid diagnosis and accurate volume measurement of abdominopelvic bleeding—including hemoperitoneum and extraperitoneal hematoma—are essential for timely, life-saving interventions in the acute care of emergency patients. To address these challenges, we developed and externally validated a deep learning model to classify and segment hemoperitoneum and extraperitoneal hematoma on abdominopelvic CT (APCT) scans.

METHODS AND MATERIALS

We retrospectively collected 1,714 APCT scans acquired between January 2001 and February 2019 for model training where 29.9% showed hemoperitoneum or extraperitoneal hematoma. An internal validation set included 98 APCT scans, with 50.0% positive for these conditions. For external multi-center validation, two independent datasets were used: external set A comprised 272 APCT scans from the emergency department of another institution (29.3% positive), and external set B comprised 267 scans from an independent institution (8.61% positive). Our deep learning model based on ResU-Net and employed a region-aware approach dividing each scan into hepatosplenic, abdominal, and pelvic regions to capture region-specific features. Model performance was evaluated using per-patient sensitivity, specificity, and positive predictive value (PPV), as well as the Dice similarity coefficient (DSC), all reported with confidence intervals (CI).

RESULTS

On the validation, sensitivities of internal, external A, and external B of the model were 95.9% (95% CI: 86.0-99.5), 94.1% (95% CI: 85.6-98.3), and 86.9 (95% CI: 66.4-97.2), respectively. The corresponding specificities were 97.9% (89.1-99.9), 83.5% (76.9-88.8), and 96.7 (93.6-98.5), and PPVs were 97.9% (87.1-99.7), 70.3% (62.5-77.0), and 71.4 (55.3-83.4), respectively. Our model significantly outperformed the non-region-aware model in specificity (McNemar test; $p < 0.001$) and PPV (bootstrap method; $p < 0.001$) across both external datasets. Our model achieved DSCs of 0.77 (95% CI: 0.72-0.82), 0.70 (95% CI: 0.64-0.76), and 0.50 (95% CI: 0.38-0.63), for internal, external A, and external B, respectively.

CONCLUSION

Our region-aware deep learning model significantly better classified and segmented hemoperitoneum and extraperitoneal hematoma on APCT to non-region-aware method.

CLINICAL RELEVANCE/APPLICATION

This model may help a radiologist to support timely diagnosis and treatment planning for patients with abdominopelvic bleeding in emergency settings.

W6-SSPH10-5 MACHINE LEARNING-BASED QUALITY ASSURANCE TOOL FOR PREDICTING DELIVERED SPOT POSITIONS IN PENCIL BEAM SCANNING PROTON THERAPY

Sang Kyun Yoo, PhD (*Presenter*)
Sridhar Yaddanapudi, PHD (*Abstract Co-Author*)
Bo Lu (*Abstract Co-Author*)
Ethan Stolen (*Abstract Co-Author*)
Siddhant Sen (*Abstract Co-Author*)
Byongsu Choi (*Abstract Co-Author*)
Jin Sung Kim, PhD (*Abstract Co-Author*)
Keith Furutani, PHD (*Abstract Co-Author*)
Chris Beltran, PhD (*Abstract Co-Author*)
James J. Sohn, PhD (*Abstract Co-Author*)

PURPOSE

In pencil beam scanning (PBS) proton therapy, even minor spot delivery deviations can impact treatment accuracy. Current patient-specific QA workflows are often retrospective, time-consuming, and insensitive to subtle but clinically relevant errors. Delivery discrepancies in monitor units (MU) and spot positions arise from uncertainties in beam monitoring and magnetic steering. Although AAPM TG-224 outlines tolerances, maintaining consistent real-time compliance remains challenging. This study proposes a machine learning (ML) model to predict delivered spot positions from planned parameters and beam metadata, enabling more accurate and efficient QA in PBS.

METHODS AND MATERIALS

This retrospective study used 40 log files, 20 from each of two gantry rooms, collected over one month using a Hitachi PROBEAT-V proton therapy system, alongside corresponding DICOM RT plan data. Spot positions were mapped to the isocenter plane using geometric projection corrections. MU and positional discrepancies were calculated; systematic and random errors were statistically analyzed. Delivered MU values exhibited a near-zero mean normal distribution, indicating minimal systematic error. Spot deviations were evaluated using Levene's test and Welch's ANOVA across beam energies, treatment days, and gantry rooms. We trained XGBoost regression models (XGBRegressor, 500 estimators, learning rate 0.1) separately for x- and y-coordinates. Input features included planned spot positions, beam energy, gantry angle, treatment date, and room number. Model performance was assessed using mean squared error (MSE), R^2 score, and Euclidean distance. Statistical analysis was conducted using SPSS v27.0.

RESULTS

The models demonstrated high prediction accuracy with MSEs of 0.013 (x) and 0.002 (y), and R^2 scores of 0.999. The overall Euclidean distance error was <0.100 mm. When stratified by room, errors remained below 0.140 mm (Gantry 1) and 0.100 mm (Gantry 2). Spot deviations significantly varied with beam energy, treatment day, and gantry room ($p < 0.001$). Beam energies of 100.7, 103.6, 105.0, 110.5, and 119.7 MeV showed the largest deviations. MU differences remained clinically negligible. MU delivery showed no significant systematic error.

CONCLUSION

The proposed ML-based QA tool achieved sub-millimeter prediction accuracy for delivered spot positions and identified variations across treatment conditions, including room-specific differences.

CLINICAL RELEVANCE/APPLICATION

This ML-based tool enables real-time identification of delivery deviations across beam energies, treatment days, and gantry rooms, thereby enhancing treatment precision and reducing reliance on labor-intensive QA procedures.

W6-SSPH10-6 PERSONALIZED CT ORGAN DOSE ESTIMATION THROUGH AN AI-DRIVEN LANDMARK DETECTION ON CT LOCALIZERS

Aiping Ding, PhD,DSc (*Presenter*)
Francesco Ria, PhD (*Abstract Co-Author*)
Yakun Zhang, MS (*Abstract Co-Author*)
Donald P. Frush, MD (*Abstract Co-Author*)
Ehsan Samei, PHD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate an AI-driven pipeline for detecting anatomical landmarks on CT localizer images, enabling accurate, patient-specific organ dose estimation and bridging the gap between population-based and personalized dosimetry.

METHODS AND MATERIALS

A total of 2,614 anterior-posterior (AP) CT localizer images was manually annotated, splitting into 1,672 training, 419 validation, and 523 test cases. Three YOLO-NAS (You Only Look Once - Neural Architecture Search) object detection models—small, medium, and large variants—were trained using the SuperGradients framework to identify 10 predefined landmarks. The model outputs were used to estimate patient organ positions and match each patient to a best-fit XCAT (Extended Cardiac-Torso) phantom to approximate patient individualized anatomy. Organ dose was then calculated using precomputed Monte Carlo-based dose coefficients from human digital twin methods, scaled by exam-specific CTDI vol , aligning with the framework previously validated. Model performance was assessed using precision, recall, F1-score, and mean average precision (mAP) at Intersection over Union (IoU) thresholds of 0.50 and 0.50:0.95 (step=0.05). Threshold tuning was applied to optimize detection performance for clinical usage.

RESULTS

Among the three models evaluated, the YOLO-NAS-large variant achieved the best performance, with a peak mAP@0.50 of 0.881 and mAP@0.50:0.95 of 0.669 using a low confidence threshold (0.01) and a non-maximum suppression (NMS) IoU threshold of 0.5. Raising the confidence threshold to 0.3 improved precision and F1-score (F1@0.50 = 0.793) while maintaining recall, with mAP@0.50:0.95 at 0.620. At a NMS IoU threshold of 0.5, the model reached a precision@0.50 of 0.839 with minimal loss in mAP, supporting its use in high-specificity settings. The predicted landmarks enabled patient-to-phantom matching for organ dose estimation without requiring segmentation or real-time Monte Carlo simulation during inference.

CONCLUSION

The trained YOLO-NAS-large model enables accurate, flexible landmark detection on CT localizers for patient-specific organ dose estimation. This pipeline leverages routinely acquired pre-scan localizers to facilitate individualized radiation risk assessment. These results highlight the model's adaptability to varying clinical needs, allowing it to be optimized for different imaging protocols, patient populations, or diagnostic goals.

CLINICAL RELEVANCE/APPLICATION

This AI-driven pipeline uses CT localizers for personalized dose estimation, enabling pre-scan radiation dose stratification during routine use—particularly for pediatric and high-risk populations—supporting personalized CT imaging protocols for safer clinical practice.

W6-STCE1-1 AI-POWERED IMAGE-TO-IMAGE TRANSLATION TOOL TO ENHANCE NON-CONTRAST CT SCANS

Junqi Liu, BEng (*Presenter*)
Tianyu Lin (*Abstract Co-Author*)
Kai Ding, PHD (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)
Zongwei Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To develop an AI-based tool for translating CT scans across contrast phases, enhancing resolution, and uncovering hidden anatomical and structural patterns, with the goal of improving multi-phase CT synthesis and downstream clinical applications.

METHODS AND MATERIALS

The model uses an image synthesis method called latent diffusion, guided by a textual label that tells it which phase to generate. To make sure the generated scans look realistic and match the target phase, we added two extra tools during training: (1) A contrast phase classifier, trained to tell apart phase scans. It will act like a phase checker, and feed back classification loss to ensure correct phase synthesis. (2) An organ segmentator that checks whether the key organs, such as liver and kidneys, are correctly shaped and positioned. If the generated scan looks off, the model is guided by the segmentation loss to fix it. By combining these two checks with the regular training loss from latent diffusion, our model learns to create scans that not only match the right contrast phase but also keep the anatomy accurate. We trained our model using 66,212 CT scans (2014-2025), collected from four hospitals and research centers. Of these, 60,000 scans were used to train the phase classification model, and the other 6,212 scans were used to train the scan synthesis and segmentation model. Performance was evaluated on 2,000 phase CT scans and we computed the Dice Similarity Coefficient (DSC) and correlation of Hounsfield Unit (HU) distributions between organ segmentations derived from reconstructed and real scans.

RESULTS

Across the CT scans for evaluation, the mean DSC score across seven key abdominal structures (aorta, kidneys, liver, lungs, pancreas, stomachs, spleen) is 0.827. For the same evaluation set, the mean Hounsfield Unit (HU) correlation between the generated and real CT scans is 0.91 across the seven key abdominal structures.

CONCLUSION

The contrast-phase translation model generates realistic CT scans with accurate organ structures, supporting its potential as an assistive tool to improve multi-phase imaging and clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

The translator has the ability to reduce patient radiation exposure by enabling contrast-phase image translation without the need for contrast agent injection. Trained on large-scale, multi-institutional datasets, the model also enhances CT resolution, supporting the development of standardized, high-quality CT datasets for research.

W6-STCE1-2 FREE-RUNNING MRI: NOVEL MACHINE LEARNING APPROACH TOWARDS IMPROVING ACCESS TO CARDIAC DIFFUSION TENSOR IMAGING

Moses Cook, PhD (*Presenter*)
David Han (*Abstract Co-Author*)
Danielle Kara (*Abstract Co-Author*)
DINGHENG MAI (*Abstract Co-Author*)
Neel Vora, MBBS (*Abstract Co-Author*)
Pasquale Santangeli (*Abstract Co-Author*)
Yuchi Liu (*Abstract Co-Author*)
Deborah H. Kwon, MD (*Abstract Co-Author*)
Christopher Nguyen, PhD (*Abstract Co-Author*)
Michael A. Bolen, MD (*Abstract Co-Author*)

PURPOSE

Cardiac diffusion tensor imaging (cDTI) can quantify tissue microstructure, such as cardiac tissue anisotropy and the heart's 3D double helix structure which are often perturbed in patients with heart disease. However, cDTI is logistically complicated to set up, which has limited efforts towards clinical translation. cDTI requires electrocardiogram (ECG) triggering, which is unreliable in patients with atrial fibrillation. It also requires breath holds, which are difficult for heart failure (HF) patients. Inconsistent breath holds and ECG data may cause image artifacts and spurious results. Thus, there is a need for a free-breathing, non-triggered (ungated) cDTI technique to improve comfort and expand access to tissue microstructure characterization to patients with arrhythmias.

METHODS AND MATERIALS

Reference cDTI images were scanned using the following parameters: TR/TE = 6000/67 ms; b-value = 500 s/mm 2 ; diffusion directions = 12; diffusion-weighted image (DWI) averages = 8, resolution = 2.7x2.7x8 mm 3 ; slices = 12. An ungated cDTI sequence was adapted from the reference standard (21 min), except TR = 2700 while scanning continuously (30 min). Four healthy volunteers (age 23 ± 1.225, 3 males) were prospectively scanned under an IRB approved protocol on a 3T (MAGNETOM Cima.X, Siemens Healthineers, Forchheim, Germany). Additionally, images were acquired in one patient with cardiac amyloidosis and another with atrial fibrillation to assess clinical ungated cDTI feasibility.. Each volunteer underwent the ECG-gated (gated) cDTI protocol followed by the ungated cDTI protocol. The ungated cDTI images were segmented by a U-Net model to mitigate cardiac motion. These images were used to compute the mean diffusivity (MD), fractional anisotropy (FA), and helix angle (HA). Average values were compared to those from the reference gated cDTI protocol.

RESULTS

After training, the U-Net model achieved a Dice score of 0.85 on a test set of images that were kept separate from the training set. Images for which the model created masks generally had good quality DT parameter maps. A Wilcoxon signed-rank test demonstrated no significant differences between MD (p=0.62) nor FA (p=0.25). Bland-Altman analysis showed a positive bias of 0.06 x 10 -3 mm 2 /s for MD and a positive bias of 0.03 for FA.

CONCLUSION

Herein, the feasibility of an ungated cDTI protocol is presented. Future optimization of the deep-learning model and thresholding algorithm will help improve scan time and image quality for clinical applications.

CLINICAL RELEVANCE/APPLICATION

Past literature has shown that cDTI is not only sensitive to microstructural pathology, but is also predictive of arrhythmogenic risk. Hence, a reliable method to acquire cDTI in an underserved patient population may enable risk stratification.

W6-STCE1-3 FEASIBILITY OF ULTRA-LOW FIELD MRI IN AN ALZHEIMER'S DISEASE CLINIC: BASELINE AND MONITORING MRIS DURING ANTI-AMYLOID IMMUNOTHERAPY

Nupur Ghoshal (*Abstract Co-Author*)
Barbara Joy Snider (*Abstract Co-Author*)
Tammie S. Benzinger, MD, PhD (*Abstract Co-Author*)

PURPOSE

Anti-amyloid immunotherapies (AATs) for Alzheimer disease (AD) offer new hope for patients and families. AATs require MRI scans for eligibility assessment and monitoring occurrences of amyloid-related imaging abnormalities (ARIA), including cerebral edema (ARIA-E) and microhemorrhages (ARIA-H). 3800 MRI exams for 300 WashU patients on AAT from10/2023-5/2025 created significant strain on an overburdened medical system. We aim to assess the feasibility of ultra-low field MRI technology in AD therapy clinics.

METHODS AND MATERIALS

Ultra-low field MRI using a Hyperfine Swoop® MRI and clinical MRI were obtained for 35 AD patients undergoing AAT. Monitoring scans, both low-field and clinical, were assessed by a neuroradiologist for ARIA-E. Five patients were excluded from volumetric analysis due to image processing issues. Intra-class correlations (ICCs) assessed agreement from baseline clinical MRI and the first acquired low-field MRI. Whole brain, ventricles, hippocampus, and white matter hyperintensities (WMH) volumetrics were derived from FreeSurfer-7 for clinical and WMH-SynthSeg for low-field MRI. WMH lesion maps from WMH-SynthSeg were cross-referenced with clinical scans.

RESULTS

23% (8/35) of patients had mild or moderate ARIA-E on the clinical MRI (Figure 1). Across monitoring visits assessed, 11 ARIA-E cases (7 mild and 4 moderate) were detected by readers on both low-field and clinical MRI (100% sensitivity). A patient with notable ARIA-H siderosis (Figure 2) was incidentally identified from the low-field MRI. An incidental subdural hematoma was also detected from low-field MRI and confirmed by clinical MRI. Volumetric measures showed moderate to good absolute agreement between low-field and clinical MRI for whole brain (ICC: 0.62, $p<0.01$), hippocampus (ICC: 0.68, $p<0.01$), and ventricles (ICC: 0.75, $p=0.06$; Figure 3). WMH volumes were more variable for both those with (ICC: 0.37, $p=0.09$) and without (ICC: 0.44, $p=0.08$) ARIA-E. WMH lesion maps partially aligned with known ARIA-E but did not capture the full extent.

CONCLUSION

Ultra-low field MRI identified ARIA-E in all 11 cases, suggesting a potential role in monitoring asymptomatic patients during therapy. Ultra-low field MRI can be clinically useful for measures of brain atrophy and WMH, suggesting a potential role in screening patients for eligibility (i.e. restricting unnecessary additional 3T assessment).

CLINICAL RELEVANCE/APPLICATION

Evaluating AD and AAT eligibility requires assessment of brain atrophy, chronic small and large infarcts, WMHs, microhemorrhages and siderosis. Within these boundaries, ultra-low field MRI could provide an important extension of MR resources and treatment possibilities in under-resourced and/or over-taxed healthcare settings.

W6-STCE2-1 THE NEW ERA OF NON-INVASIVE TREATMENT FOR FOCAL LIVER TUMOURS WITH HISTOTRIPSY - EARLY RESULTS AND EXPERIENCE FROM ASIA

Neeraj R. Mahboobani, MBBS, FRCR (*Presenter*)
Lok Hei Patricia Chan (*Abstract Co-Author*)
Kam Ho V. Lee, MBBS (*Abstract Co-Author*)
SIU CHUN TSAI (*Abstract Co-Author*)
James F. Griffith, MD (*Abstract Co-Author*)

PURPOSE

Histotripsy is a revolutionary non-invasive technology which uses high intensity pulsed ultrasound waves to mechanically destroy targeted tissue whilst sparing surrounding tissues and structures. We report results and experience from one of the first sites in Asia using this new revolutionary technology to treat focal liver lesions.

METHODS AND MATERIALS

Thirteen patients (8 males, 5 females) with mean age of 69.3 years (range 52 to 82 years) had 15 focal liver lesions treated with histotripsy between April and July 2025. All treatment procedures were done under general anaesthesia. Clinical parameters, laboratory test results and imaging were reviewed.

RESULTS

Eleven hepatocellular carcinomas and four liver metastases were treated. Mean size of the lesions was 2.2 cm (range 0.9 to 4.0 cm). Locations of the lesions were as follows: Segment I (1) ; Segment II (1) ; Segment III (3); Segment IVa (2); Segment IVb (3); Segment V (3); Segment VI (1); Segment VIII (1). One of the lesions was adjacent to the gallbladder, one of the lesions was adjacent to a large cyst, and one of the lesions was adjacent to the portal vein. Fourteen lesions were successfully treated as evident by liquefaction on post-treatment day 1 MRI, with technical success rate 93.3%. One small lesion in segment I showed no evidence of treatment related changes on post-treatment day 1 MRI. There were no major post-procedure complications. Minor post-procedure complications included transient derangement of liver function (8 patients), mild ascites (5), mild chest or abdominal wall oedema (4), and mild right pleural effusion (3). All minor complications subsequently resolved. Eight patients have had post-treatment 1 month MRI, out of which 4 have also had post-treatment 3 month MRI. These show progressive shrinkage of the liquefied treatment volume with no evidence of recurrence.

CONCLUSION

Histotripsy is an effective non-invasive treatment choice for focal liver lesions which can be clearly visualised on ultrasound. It is suitable for lesions which are in close proximity to other structures such as the gallbladder or intrahepatic vasculature. Patient and lesion selection, patient positioning and ventilation strategies during general anaesthesia to reduce respiratory excursion of the liver are important factors for successful treatment.

CLINICAL RELEVANCE/APPLICATION

Histotripsy introduces a paradigm shift and a new era in the treatment of focal liver lesions. Its non-invasive nature renders it a preferred treatment option by patients, and its mechanical nature of tumour destruction renders it as a suitable treatment choice for lesions which are situated close to other structures such as bowel, gallbladder and even intrahepatic vessels as it is not susceptible to heat sink effect.

W6-STCE2-2 TARGETING CD206-POSITIVE TUMOR-ASSOCIATED MACROPHAGES IN GLIOMA BY MOLECULAR MRI

Cuihua Wang, PhD (*Presenter*)
Negin Jalali Motlagh, MD (*Abstract Co-Author*)
Gregory R. Wojtkiewicz, MSc (*Abstract Co-Author*)
John W. Chen, MD, PhD (*Abstract Co-Author*)

PURPOSE

Macrophages play a pivotal role in innate immunity, and targeting specific macrophage subtypes has emerged as a promising immunotherapeutic strategy, particularly in cancer. As such, non-invasive imaging techniques capable of specifically targeting macrophage subpopulations are greatly needed. The mannose receptor (CD206) is a well-established surface marker predominantly expressed on anti-inflammatory macrophages. CD206-positive tumor-associated macrophages (TAMs) promote tumor progression and suppress immune responses. In this study, we aimed to perform a proof-of-concept study to validate an MRI probe that can detect CD206 + TAMs in a glioma model.

METHODS AND MATERIALS

The CD206-sensing MRI agent (MRSP-Gd) was synthesized and purified by HPLC. All animal experiments were approved by and in compliance with the Institutional Animal Care and Use Committee. 8 to10-week-old of C57BL/6J mice (CD206 +/+ , n=3) and mice treated with D-mannose 30 min before MRSP-Gd administration (n=3), heterozygous (CD206 +/- , n=4), and CD206 knock-out (CD206 -/- , n=3) mice (Jackson Laboratories) with glioma induced by intracranial injection of CT-2A cells were used to validate the specificity and efficacy of MRSP-Gd. We performed MR imaging with serial T1-weighted imaging both before and at five time points after iv injection of 0.3 mmol/kg of MRSP-Gd on a 4.7-T small animal MR scanner (Bruker, MA) in the third week.

RESULTS

MRSP-Gd imaging demonstrated that enhanced signal mainly surrounded the tumor area with a few foci within the tumor at 60 min, and contrast-to-noise ratios (CNRs) of the wildtype mice were over two times higher compared to CD206-knockout mice after 45 mins, revealing the presence of CD206 + TAMs in the tumor microenvironment and the specificity of MRSP-Gd to CD206 + TAMs. We observed significantly decreased CNRs at 60 min in heterozygous mice (*, p=0.037), and wild-type mice treated with D-mannose 30 mins before agent administration (**, p=0.007), with CD206-knockout mice demonstrating minimal enhanced signal (**, p=0.002) compared to that in wildtype mice with glioma, confirming the efficacy of MRSP-Gd imaging in tracking CD206 + TAMs.

CONCLUSION

We demonstrated that CD206-targeted MR imaging can specifically report CD206 + TAMs and track TAMs changes in experimental glioma with specificity and efficacy.

CLINICAL RELEVANCE/APPLICATION

MSRP-Gd imaging could provide a valuable tool to noninvasively image and track healing and disease evolution, and to monitor macrophage-targeted therapeutic responses in experimental studies and in patients. Importantly, the specific binding motif of the MRI agent could be incorporated to provide highly specific delivery of therapeutic drugs (e.g., radionuclidic therapies) for theranostic strategy in cancer treatment.

W6-STCE2-3 MOLECULAR PROFILING OF HEPATOCELLULAR CARCINOMA WITH CONTRAST-ULTRASOUND USING A NOVEL ANTIBODY-CONJUGATED MICROBUBBLE VIA LIGHT-ACTIVATED SITE-SPECIFIC CHEMISTRY

Yonghwan Shin (*Presenter*)
James Z. Hui, MD, PhD (*Abstract Co-Author*)
Janet Pham (*Abstract Co-Author*)
Po-Chun Chen (*Abstract Co-Author*)
Aravinth Ruppa (*Abstract Co-Author*)
Veronica Hankil (*Abstract Co-Author*)
Jason Chiang, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a microbubble-based contrast agent using light-activated site-specific conjugation (LASIC) for targeted molecular ultrasound imaging of glypican-3 (GPC3) positive hepatocellular carcinoma (HCC).

METHODS AND MATERIALS

Microbubbles were conjugated with anti-GPC3 antibody using oYo-Link DBCO chemistry, which enables site-specific labeling of the antibody heavy chain with up to two DBCO groups per antibody by employing a LASIC-based approach that ensures site-specific conjugation without compromising antigen affinity. GPC3 expression levels in HCC cell lines (SNU423, SNU449, and HepG2) were confirmed by Western blotting. Binding specificity was validated by pre-blocking with free anti-GPC3 antibodies in the HCC cell lines. Fluorescence microscopy and quantitative image analysis were used to assess cell-binding efficiency. For in vivo analysis, conjugated microbubbles were intravenously injected into mice bearing orthotopic HepG2 xenografts, and contrast-enhanced ultrasound (CEUS) imaging was performed at multiple time points post-injection (0 sec, 30 sec, 10 min) to evaluate tumor signal enhancement and persistence.

RESULTS

LASIC-based chemistry enabled stable and homogeneous antibody attachment to microbubbles. In vitro assays showed significantly increased binding of targeted microbubbles to GPC3-positive cells compared to antigen blocked control groups (85% vs 2%; p=0.001). In vivo CEUS imaging revealed enhanced tumor-specific signal within 30 seconds post-injection, which persisted up to 10 minutes, confirming specific and sustained tumor targeting. Compared to the targeted group, the control group showed a noticeable decrease in signal intensity beginning at 30 seconds post-injection.

CONCLUSION

Conjugation of anti-GPC3 microbubbles enable efficient, specific, and durable binding to GPC3-expressing HCC in vitro and in vivo. This approach allows for real-time, image-guided molecular profiling using CEUS, paving the way for precision imaging and potential theranostic integration in liver cancer management.

CLINICAL RELEVANCE/APPLICATION

This feasibility study demonstrates a clinically translatable imaging strategy using antibody-conjugated microbubbles for non-invasive, molecular characterization of HCC. LASIC-based chemistry allows for uniquely gentle attachment of off-the-shelf antibodies to microbubbles, and can potentially facilitate translation of targeted CEUS agents in molecular profiling of HCC.

PURPOSE

TNBC are aggressive tumors usually treated with neoadjuvant therapy with variable response. The KEYNOTE-522 trial showed that in comparison with the conventional chemotherapy, NICT increased the rates of pathologic complete response (pCR), although with higher incidence of the adverse events, including death. There is unmet need in developing noninvasive imaging biomarkers that allow identification of responders versus nonresponders early during NICT. We aimed to evaluate if DCE-MRI tumor volume reduction (TVR) during treatment can predict which patients are likely to achieve pCR after NICT.

METHODS AND MATERIALS

A total of 161 stage I-III TNBC patients enrolled in an IRB approved prospective clinical trial (NCT02276433) who had DCE-MRI at baseline, at early treatment - after 2 cycles of NICT, and at mid-treatment - after 4 cycles of NICT, followed by surgery, were included in this analysis. Tumor volume was calculated using three-dimensional DCE-MRI measurements at each time point. Percent tumor volume reduction (TVR) from baseline to early and baseline to mid-treatment time points was calculated. Treatment response at surgery (pCR vs. non-pCR) was documented. Logistic regression was used to examine associations between covariates and pCR. Correlation between pCR and TVR was evaluated using ROC analysis.

RESULTS

Overall, 63% of the patients (102/161) achieved pCR. TVR was the only co-variate significantly associated with pCR in the univariate analysis ($p<0.001$) for both early and mid-treatment time points. Multivariate analysis showed that TVR and nodal status were significantly associated with pCR with $p<0.001$ and $p<0.039$, respectively, for early; and $p<0.001$ and $p<0.008$, respectively for mid-treatment time points. Early treatment DCE-MRI TVR = 60% predicted pCR, with AUC of 0.78 (95%CI 0.71-0.86, $p<0.001$), sensitivity 90%, specificity 53%, PPV 77%, and NPV 76%. Mid-treatment TVR = 90% was able to predict pCR with AUC of 0.78 (95%CI 0.70-0.86, $p<0.001$), sensitivity 79%, specificity 62%, PPV 78%, and NPV 63%.

CONCLUSION

Early and mid-treatment DCE-MRI TVRs were able predict pathologic response after completion of NICT with a similar AUC of 0.78. Early treatment TVR predicted pCR with higher sensitivity, while mid-treatment TVR demonstrated higher specificity for pCR prediction in TNBC treated with NICT.

CLINICAL RELEVANCE/APPLICATION

Longitudinal on-treatment DCE-MRI TVR may serve as a noninvasive imaging biomarker for response-adaptive decision-making during neoadjuvant therapy of patients with TNBC.

W7-SSBR09-2 PREDICTIVE VALUE OF VMRE AND IVIM-DWI ON THE EARLY EFFICACY OF NEOADJUVANT CHEMOTHERAPY FOR BREAST CANCER

Kejia Guo (*Presenter*)
Tingting Lin (*Abstract Co-Author*)

PURPOSE

To investigate the predictive value of virtual magnetic resonance elastography (vMRE) and intravoxel incoherent motion diffusion weighted imaging (IVIM-DWI) in assessing the early efficacy of neoadjuvant chemotherapy (NAC) for breast cancer.

METHODS AND MATERIALS

One hundred and eight patients with pathologically confirmed breast cancer were enrolled. Baseline vMRE and IVIM-DWI were performed in all participants before NAC. The parameters of vMRE (sADC, μ diff), IVIM-DWI (ADC, D, D*, f), MRI imaging features, and clinicopathological characteristics were collected. According to the Miller-Payne grading system, patients were divided into the pCR group and the non-pCR group. Above parameters were statistically compared between two groups. The optimal predictive parameters and predictive thresholds were determined by drawing receiver operating characteristic (ROC). The Hosmer-Lemeshow test was used to evaluate the calibration of the combined prediction model, while the differences in area under ROC curve (AUC) were compared using the DeLong test.

RESULTS

Twenty patients were assigned in the pCR group and eighty-eight patients in the non-pCR group. The sADC, ADC and D values in the pCR group were significantly higher than those in the non-pCR group (all $P < 0.05$), whereas the μ diff value was appreciably lower than that in the non-pCR group ($P < 0.001$). Multivariate Logistic regression analysis showed μ diff , D, and nipple retraction/skin retraction were independent predictive factors for pCR (all $P < 0.05$). The AUC of μ diff was the largest (AUC=0.810). The combined predictive efficacy of μ diff , D, and nipple retraction/skin retraction (AUC = 0.896, sensitivity and specificity were 85.00% and 86.36%, respectively) was higher than that of μ diff , D or nipple retraction/skin retraction alone.

CONCLUSION

Baseline parameters of vMRE and IVIM-DWI had certain early predictive value for the efficacy of NAC in breast cancer, among which the independent prediction performance of μ diff was the highest, and the combination of vMRE and IVIM-DWI could further improve the prediction performance.

CLINICAL RELEVANCE/APPLICATION

This preliminary study showed that baseline parameters of vMRE and IVIM-DWI had certain early predictive value for the efficacy of NAC in breast cancer,which may assist clinicians in adjusting therapy to avoid toxic adverse effects and to improve survival.

W7-SSBR09-3 A DEEP LEARNING MODEL BASED ON SPATIOTEMPORAL TUMOR HETEROGENEITY FOR EARLY PREDICTION OF PATHOLOGIC COMPLETE RESPONSE IN BREAST CANCER WITH DCE-MRI: A MULTICENTER STUDY

Yuyi Tan, BEng (*Presenter*)
Siyao Du (*Abstract Co-Author*)
Zhihui Shi (*Abstract Co-Author*)
Lina Zhang (*Abstract Co-Author*)
Zhenhui Li (*Abstract Co-Author*)
Zhenyu Liu (*Abstract Co-Author*)
Jie Tian, PhD (*Abstract Co-Author*)

PURPOSE

Predicting pathological complete response (pCR) can help identify patients suitable for continued treatment and promote personalized therapy. However, the intratumoral heterogeneity and the tumor change of pre-NAC and early-NAC pose significant challenges for pCR prediction. Therefore, this study aims to develop a deep learning model based on graph convolutional networks (GCN) to characterize spatiotemporal tumor heterogeneity, enabling more accurate predictions of pCR to neoadjuvant chemotherapy in breast cancer.

METHODS AND MATERIALS

This study retrospectively included breast cancer patients from three cohorts: a development cohort (n=1053) divided into training and internal testing sets, an external test cohort (n=213), and an ACRIN 6698 test cohort (n=204). The proposed spatiotemporal tumor heterogeneity (SITH) model allowed for the integration of whole tumor, microenvironment, and intratumoral heterogeneity information and captured dynamic change from longitudinal MR images using GCN. To ensure consistent habitat interpretations, we remapped habitats labels based on the mean features for each patient. Clinicopathological characteristics were added and integrated models were established (SITH-C). The performance was evaluated using the area under the receiver operating characteristic curve and other metrics.

RESULTS

The results demonstrated that SITH-C achieved optimal predictive performance in the training set (AUC=0.932, 95% CI: 0.910-0.952), the internal testing set (AUC=0.855, 95% CI: 0.772-0.928), the external testing set (AUC=0.850, 95% CI: 0.783-0.906), and the ACRIN 6698 testing set (AUC=0.710, 95% CI: 0.632-0.779), all of which were significantly higher than those of the clinical model (AUC: 0.706-0.800). Moreover, the SITH-C increased the positive predictive value from 71.4% to 87.5% compared with clinical model in the internal and external testing set, and maintained a high negative predictive value (73.6% to 80.2%).

CONCLUSION

This study developed a deep learning model capable of characterizing tumor spatiotemporal heterogeneity from DCE-MRI, demonstrating high accuracy and robustness in predicting pCR at the early stages of NAC in breast cancer patients.

CLINICAL RELEVANCE/APPLICATION

The proposed model serves as a non-invasive tool for predicting pCR to NAC in breast cancer patients, supporting personalized treatment decisions by suggesting alternative strategies for non-responders and complementary therapies for responders.

W7-SSBR09-6 ABBREVIATED MRI FOR EVALUATION OF TREATMENT RESPONSE IN PATIENTS UNDERGOING NEOADJUVANT CHEMOTHERAPY FOR BREAST CANCER

Roberto Lo Gullo, MD (*Presenter*)
Marie Surovitsky, DO (*Abstract Co-Author*)
Diane Y. Kim, MD (*Abstract Co-Author*)
Varadan Sevilimedu (*Abstract Co-Author*)
Kailyn Li, MD (*Abstract Co-Author*)
Katja Pinker-Domenig, MD, PhD (*Abstract Co-Author*)

PURPOSE

To determine whether an abbreviated MRI protocol can effectively monitor treatment response to NAC after an initial full-protocol staging MRI

METHODS AND MATERIALS

This retrospective, single-center study included 478 patients with 488 breast cancers who underwent standard-of-care MRI before and after NAC between January 2016 and May 2020, followed by surgical resection. Three dedicated breast radiologists interpreted the baseline staging MRIs using the full diagnostic protocol and compared it to an abbreviated MRI protocol. The abbreviated protocol consisted of an axial T2-weighted sequence and pre-contrast and early postcontrast T1-weighted sequences to assess treatment response. After a washout period of at least 4 weeks, the baseline standard of care MRIs were reinterpreted, and the results were compared to a full diagnostic protocol post-NAC to identify and measure enhancing lesions. The reference standard was the presence and size of residual tumor in the surgical specimen. Interpretation times were annotated for each read. Response was classified as complete, partial, stable, or progressive disease. Pathology defined pathologic complete response (pCR) as the absence of invasive cancer

RESULTS

Among the 488 lesions, 198 showed pCR. Interobserver agreement for abbreviated and full-protocol MRI ranged from 0.53 to 0.7. Intraobserver agreement ranged from 0.76 to 0.89. Comparison of abbreviated and full-protocol MRI revealed no significant differences in sensitivity ($p > 0.79$), positive predictive value ($p > 0.18$), negative predictive value ($p > 0.85$), and accuracy ($p > 0.22$). However, there was a significant difference in specificity (82.1% vs. 85.4%, $p = 0.05$). Average reading times ranged from 39-44 seconds for the abbreviated protocol to 42-64 seconds for the full protocol ($p < 0.001$). Both long and short axis lengths showed moderate correlation with pathological tumor size (range 0.53-0.70)

CONCLUSION

Abbreviated MRI compared to full-protocol MRI demonstrated similar intraobserver and interobserver agreement, with no significant difference in diagnostic performance aside from a small decrease in specificity, achieved with reduced interpretation and acquisition times. Both the full-protocol MRI and the abbreviated protocol MRI showed moderate correlation with tumor sizes measured on pathology

CLINICAL RELEVANCE/APPLICATION

Abbreviated protocols may facilitate use of MRI for post-NAC response assessment

PURPOSE

Coronary artery plaque volumes have been set to adjust individual treatment recommendations. Therefore, we aimed to assess the predictive value of coronary artery plaque volumes derived from computed tomography angiography (CTA) for major adverse cardiovascular events (MACE). We used the data of the European multicenter randomized Diagnostic Imaging Strategies for Patients With Stable Chest Pain and Intermediate Risk of Coronary Artery Disease (DISCHARGE) trial to determine age- and gender-adjusted percentiles.

METHODS AND MATERIALS

The multicenter DISCHARGE trial randomized patients with stable chest pain who had an intermediate pre-test probability of obstructive coronary artery disease (CAD) and were referred for invasive coronary angiography (ICA) at one of 26 European centers to CTA or ICA as an initial diagnostic imaging strategy. Coronary artery total plaque volumes (TPV) of the CTA group were measured and used to calculate age- and gender-adjusted percentiles. MACE was defined as in DISCHARGE as cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke. Mann-Whitney U test was used to compare differences in TPV between women and men. Nomograms were plotted by fitting a 2 nd degree polynomial curve to the derived percentiles. Time-to-event data were analyzed using a Cox proportional hazards model to compare the hazard ratios (HR) of patients with coronary plaque and patients above the 70 th percentile of TPV to patients without any coronary plaque detected by CTA. The 70 th percentile was chosen based on visual assessment.

RESULTS

1643 patients (56.4% women, 60.2 years (± 10.2)) were included in the analysis of which 867 (52.8%) had coronary plaque. The mean coronary TPV was 123.9mm³ (± 271.1mm³) and increased with age by 57.3mm³ ± 3.9mm³ per 10 years. TPV was significantly higher in male patients than in female patients (177.4mm³ ± 311.6mm³ versus 82.5mm³ ± 226.5mm³; p<0.001). Patients with coronary plaque (n=32) were found to be at an elevated risk of MACE compared to patients without any coronary plaque (n=5; HR: 5.9, 95% CI: 2.29-15.09; p<0.001). Among patients with coronary plaque, MACE occurred in 23 patients with obstructive CAD. Risk was further increased for patients above the 70 th percentile of TPV (n=24; HR: 8.0, 95% CI: 3.1-21.0; p<0.001).

CONCLUSION

Age- and gender-adjusted percentiles of TPV have been shown to be predictive of MACE in patients with an intermediate risk of CAD. An increased risk for MACE was observed in patients exceeding the 70 th percentile.

CLINICAL RELEVANCE/APPLICATION

In patients with an intermediate likelihood of CAD, incorporating TPV distributions, particularly for those above the 70 th percentile, into clinical decision-making may help guide more personalized treatment strategies.

W7-SSCA08-2 SEX-SPECIFIC PROGNOSTIC VALUE OF QUANTIFYING CORONARY PLAQUE IN PATIENTS WITH STABLE CHEST PAIN

Jan M. Brendel, MD (*Presenter*)
Neha Pagidipati (*Abstract Co-Author*)
Thomas Mayrhofer (*Abstract Co-Author*)
Marton Kolossvary, MD, PhD (*Abstract Co-Author*)
Isabel Luisa Langenbach, MD (*Abstract Co-Author*)
Marcel C. Langenbach, MD (*Abstract Co-Author*)
Nora M. Kerkovits, MD (*Abstract Co-Author*)
Matthias Jung, MD (*Abstract Co-Author*)
Maros Ferencik, MD (*Abstract Co-Author*)
Michael T. Lu, MD, MPH (*Abstract Co-Author*)
Svati Shah (*Abstract Co-Author*)

Pamela Douglas (*Abstract Co-Author*)
Borek Foldyna, MD (*Abstract Co-Author*)

PURPOSE

Current cardiovascular (CV) risk assessment underestimates risk in women. Coronary CT angiography (CCTA) enables comprehensive plaque quantification, yet its sex-specific risk prognostic value remains unclear. We aimed to determine whether quantitative plaque assessment on CCTA improves sex-specific risk stratification in patients with stable chest pain.

METHODS AND MATERIALS

We analyzed patients from the PROMISE CCTA arm. A core lab quantified total plaque volume (PV, mm^3) and burden (PB, %), including calcified, noncalcified, and low-attenuation components. Sex-stratified multivariable Cox regression models assessed associations between plaque measures and major adverse cardiovascular events (MACE: death, myocardial infarction, or unstable angina) over a median follow-up of 26 months (IQR: 18-34). Models were adjusted for 10-year ASCVD risk, coronary artery calcium (CAC), obstructive stenosis (=50%), and high-risk plaque (HRP) features. The incremental value of plaque quantification was evaluated using area under the curve (AUC) analysis.

RESULTS

Among 4,267 patients, 2,199 (51.5%) were women (mean age 62.2±7.7 years). Compared to men, women had lower ASCVD scores, CAC, obstructive stenosis, and HRP prevalence, 72 mm^3 lower median PV, and 12% lower median PB (all P <0.001). MACE occurred in 2.8% (121 events). In women, total and noncalcified PB independently predicted MACE (aHR: 1.27; 95% CI: 1.08-1.50, P =0.004 and aHR: 1.29; 95% CI: 1.07-1.55, P =0.007). In men, these associations were not significant. Adding PB to traditional risk models improved MACE prediction in women (AUC 0.71 to 0.75, P =0.017) but not in men (AUC 0.77 to 0.76, P =0.272).

CONCLUSION

Quantitative plaque assessment on CCTA improves risk stratification beyond traditional clinical and imaging measures in women with stable chest pain but not in men.

CLINICAL RELEVANCE/APPLICATION

Plaque quantification can help identify high-risk women who might be missed by traditional models, allowing earlier diagnosis for tailored treatment.

W7-SSCA08-4 LEFT VENTRICULAR GLOBAL LONGITUDINAL STRAIN IMPROVES PROGNOSTICATION IN NON-DILATED LEFT VENTRICULAR CARDIOMYOPATHY

Mengdi Jiang, PhD (*Presenter*)
Minjie Minjie, PhD (*Abstract Co-Author*)

PURPOSE

Aim to investigate the association of cardiovascular magnetic resonance (CMR) feature-tracking-derived left ventricular global longitudinal strain (GLS) with outcome in a patient cohort with non-dilated left ventricular cardiomyopathy (NDLVC) and evaluated the possible incremental prognostic benefit beyond conventional parameters like left ventricular ejection fraction (LVEF) and late gadolinium enhancement (LGE).

METHODS AND MATERIALS

In this retrospective cohort study, 492 NDLVC patients (mean age 45 ± 16 years, 68% male) underwent CMR between 2016 and 2018. The primary endpoint was hard cardiac events, including cardiac mortality, heart transplantation and life-threatening ventricular arrhythmias.

RESULTS

A total of 492 patients with NDLVC (mean age 45 years ±16; 333 men [68%]) were included. Over a mean follow-up of 77 months, 43 patients (8.7%) experienced hard cardiac events. Left ventricular GLS independently predicted events after adjusting for LVEF, LGE, and clinical covariates (adjusted hazard ratio: 1.23 per 1%, 95% CI 1.09 to 1.39; p = 0.001). Adding GLS to a model with LVEF and LGE presence led to a significant improvement in model fit (chi-square increased by 17.5; p<0.001) and discrimination (C-statistic improved from 0.786 to 0.830; p=0.041). Notably, patients with LVEF=35% but abnormal GLS and LGE had comparable event rates to those with LVEF<35% (19.4% vs.11.4%, p=0.120).

CONCLUSION

Conclusion CMR-derived left ventricular GLS provides independent and incremental prognostic value over LVEF and LGE in NDLVC, identifying high-risk patients who may benefit from early intervention. These findings advocate integrating strain analysis into routine CMR evaluations for enhanced risk stratification.

CLINICAL RELEVANCE/APPLICATION

GLS is a robust, reproducible tool that refines risk prediction in NDLVC, enabling clinicians to transcend LVEF limitations and adopt evidence-based, personalized strategies for SCD prevention and heart failure management.

W7-SSCA08-5 RIGHT ATRIAL STRAIN FROM CMR TO PREDICT MORTALITY IN PULMONARY HYPERTENSION

Ghazal Zandieh, MD (*Presenter*)
Paul M. Hassoun, MD (*Abstract Co-Author*)
Stefan L. Zimmerman, MD (*Abstract Co-Author*)
Bharath Ambale-Venkatesh, PhD (*Abstract Co-Author*)

PURPOSE

We aimed to assess the prognostic relevance of RA and RV function parameters, including ejection fraction (EF) and strain, across patients with systemic sclerosis (SSc) with and without PAH, and those with idiopathic PAH (IPAH), using cardiac magnetic resonance (CMR) imaging.

METHODS AND MATERIALS

We retrospectively analyzed 87 patients followed at the Johns Hopkins Pulmonary Hypertension clinic between 2015-2023: systemic sclerosis without PAH (SSc-no PAH, n=17), SSc-associated PAH (SSc-PAH, n=47), and idiopathic PAH (IPAH, n=22). All underwent cardiac MRI with cine feature-tracking to derive right atrial strain (RA-strain), right ventricular free-wall strain (RV-strain), and RA/RV ejection fractions. Right heart catheterization measured mean pulmonary artery pressure (mPAP) and pulmonary vascular resistance (PVR); pulmonary function testing provided DLCO %-predicted; and labs included log-transformed BNP/NT-proBNP. Survival time was defined from MRI to death or last follow-up (median 52 months; 14 deaths). Continuous variables were z-standardized. A combined L1-penalized Cox model (penalizer=0.01, l1-ratio=1) was fitted with diagnosis group as indicator covariates to adjust (not stratify) for subgroup effects; Harrell's C-index assessed model discrimination.

RESULTS

In the combined L1-penalized Cox model that adjusted for diagnosis group, three variables were independently retained. A lower CMR-derived right-atrial reservoir strain remained the strongest predictor of all-cause mortality (HR 0.40 per SD decrease; 95 % CI 0.16-0.97; p = 0.04), followed by a higher mean pulmonary-artery pressure (HR 3.52; 95 % CI 1.28-9.69; p = 0.02) and a lower DLCO %-predicted that showed trend towards association (HR 0.30; 95 % CI 0.08-1.06; p = 0.06). The combined model achieved a Harrell's C-index of 0.83. After penalization, RA and RV ejection fractions, RV free-wall strain, log-pro-BNP and the diagnosis indicators themselves did not add independent prognostic value. RA reservoir strain was inversely related to invasive load (? = -0.23 with PVR, p = 0.04; ? = -0.21 with mPAP, p = 0.07). Conversely, worse RV free-wall strain and lower RVEF correlated with higher mPAP and PVR (|?| ˜ 0.35-0.40, all p = 0.001).

CONCLUSION

Feature-tracking RA strain measured on routine cine CMR predicts mortality in systemic sclerosis-associated and idiopathic PAH.

CLINICAL RELEVANCE/APPLICATION

Incorporating RA strain into standard CMR assessments could enhance risk stratification and guide clinical decision-making in PAH populations. Furthermore, impaired RA mechanics captured by feature-tracking CMR reflects underlying hemodynamic burden across diagnoses.

W7-SSCA08-6 SMOKING IS RELATED TO INCREASED PERICONARY INFLAMMATION ON CT AND INCREASED MORTALITY IN ASYMPTOMATIC INDIVIDUALS: A MULTI-COHORT STUDY

Borek Foldyna, MD (*Abstract Co-Author*)

PURPOSE

Smoking is a major reversible risk factor for mortality and has been shown to induce systemic inflammation. Pericoronary adipose tissue (PCAT) density is a marker of coronary artery inflammation, linked to coronary artery disease and adverse events. We aimed to evaluate the association between CT-derived PCAT density and smoking, and to explore their interplay in relation to all-cause mortality.

METHODS AND MATERIALS

PCAT density of current and past smokers enrolled in the National Lung Screening Trial was compared to nonsmoking controls matched 1:1 for age, sex, hypertension and diabetes from the Framingham Heart Study. PCAT was segmented and quantified using a validated deep learning segmentation algorithm on non-contrast CT scans. Multivariable linear and survival regression analyses, along with causal mediation analysis, were conducted to assess the association between PCAT density, ever-smoking, and all-cause mortality. Analyses were adjusted for technical CT parameters (image noise, kVp), traditional cardiovascular (CV) risk factors, and coronary artery calcium (CAC) score.

RESULTS

The study included a total of 2,362 participants (age 62±6 years, 54.4% female, 23% current and 27% former smokers). Current and former smokers, vs nonsmokers, had significantly higher PCAT density (-76.7 ± 5.9 HU vs -77.5±5.9 vs -80.9 ± 5.7, respectively, $p<0.001$). Ever-smoking was independently associated with higher PCAT density (adjusted ß 4.59, 95% CI 4.23-4.93, $p<0.001$). Ever-smoking and PCAT density were independent predictors of all-cause mortality (aHR 1.94, 95% CI 1.44-2.63, $p<0.001$ and aHR 1.98 /10 HU change, 95% CI 1.44-2.73, $p<0.001$). Smokers with PCAT density above the median (-79.3 HU) had higher mortality risk when compared to smokers below the median (aHR 1.57, 95% CI 1.13-2.19, $p=0.007$), and over three times the risk of nonsmokers with lower PCAT density (aHR 3.13, 95% CI 2.18-4.50, $p<0.001$). No significant difference in outcomes was observed between nonsmokers with PCAT density above vs. below the median ($p=0.6$). Mediation analysis indicated that 25% (indirect effect: OR 1.26, $p=0.001$) of the effect of ever smoking on all-cause mortality was mediated by PCAT density with the direct effect being OR 3.02, $p<0.001$.

CONCLUSION

Smoking is associated with increased PCAT density in both former and current smokers compared to nonsmokers. PCAT density is an independent predictor of all-cause death among smokers, but not nonsmokers, and is a mediator in the relationship between smoking and mortality.

CLINICAL RELEVANCE/APPLICATION

Among ever-smokers, CT-derived PCAT density quantification may aid in risk stratification.

PURPOSE

This study aimed to externally test a deep learning model (DL-Dual) developed to estimate the 3-year malignancy risk of persistent pulmonary nodules using both current and prior low-dose CT (LDCT) scans. Its performance was compared to that of a single-time-point model (DL-Single) and the Lung-RADS guideline across short-term and annual follow-up intervals.

METHODS AND MATERIALS

We analyzed 6,350 paired LDCT scans from the Dutch-Belgian NELSON lung cancer screening trial. Two DL models were evaluated: DL-Dual, trained on annual/biennial CT scan pairs from the NLST cohort, and DL-Single, trained on individual NLST scans. Persistent pulmonary nodules (=3 mm) were identified at two follow-up intervals: (1) baseline to short-term follow-up (2,541 nodule pairs; 68 malignant; median interval: 91 days), and (2) baseline to first annual incidence round (3,809 nodule pairs; 76 malignant; median interval: 370 days). At nodule level, malignancy risk scores were computed using DL-Dual (prior + current CT) and DL-Single (only current CT), and Lung-RADS categories were assigned using published growth-based criteria. Performance was measured using area under the ROC curve (AUC) and specificity at sensitivity matching Lung-RADS category 3.

RESULTS

On short-term follow-up, DL-Single (AUC 0.95, 95% CI: 0.94-0.97) significantly outperformed DL-Dual (AUC 0.93, 95% CI: 0.90-0.96; $p < 0.05$). On annual follow-up, DL-Single (AUC 0.95, 95% CI: 0.93-0.97) and DL-Dual (AUC 0.96, 95% CI: 0.94-0.98; $p = 0.16$) performed similarly. Both DL models significantly outperformed Lung-RADS in both short-term (AUC 0.80, 95% CI: 0.74-0.86) and annual follow-up (AUC 0.82, 95% CI: 0.77-0.88), all $p < 0.05$. At matched sensitivity (Lung-RADS category 3), specificities were 95.8% (DL-Dual), 96.2% (DL-Single), and 87.7% (Lung-RADS) on short-term scans, and 97.8%, 96.4%, and 90.6%, respectively, on annual scans.

CONCLUSION

DL-Dual demonstrated robust overall discriminatory performance, however, DL-Single performed comparably at annual screening and outperformed DL-Dual at short-term follow-up. Both models significantly outperformed Lung-RADS, achieving higher specificity at matched sensitivity, highlighting superior accuracy of AI-based approaches over a growth-based guideline in estimating malignancy risk. Further research is needed to assess DL-Dual's performance in scenarios that may better align with its intended use, such as newly detected nodules, extended follow-up intervals, and non-baseline screening rounds.

CLINICAL RELEVANCE/APPLICATION

DL-based malignancy risk models could improve management of persistent pulmonary nodules and reduce false positives compared to diameter- or volume-based protocols like Lung-RADS.

W7-SSCH07-3 RETHINKING LUNG CANCER SCREENING: LONGITUDINAL AI/ML DIAGNOSTICS BEYOND NODULE SIZE GROWTH

Sylvain Bodard (*Presenter*)
Pierre Baudot, PhD (*Abstract Co-Author*)
Benjamin Renoust (*Abstract Co-Author*)
Charels Voyton, PhD (*Abstract Co-Author*)
Gwendoline De Bie (*Abstract Co-Author*)
Ezequiel Geremia (*Abstract Co-Author*)
Van Khoa LE (*Abstract Co-Author*)
Danny Francis (*Abstract Co-Author*)
Pierre-Henri Siot (*Abstract Co-Author*)
Yousra Haddou (*Abstract Co-Author*)
Bourdes Valerie (*Abstract Co-Author*)
Benoit Huet, PhD (*Abstract Co-Author*)

PURPOSE

Early detection of pulmonary nodules is essential for timely lung cancer diagnosis and treatment. Yet, conventional risk stratification relies heavily on nodule size and growth[1]—particularly diameter changes (e.g., Lung-RADS) or Volume Doubling Time (VDT) and its Reciprocal (RDT)— limiting early detection. This study compares the

performance of an AI/ML-based CADe/CADx device against traditional growth metrics, time-dependent malignancy scoring (Lung-RADS), and expert radiologists' assessment for earlier, more accurate lung cancer detection.

METHODS AND MATERIALS

The AI model was trained on 10,872 patients from NLST and LIDC datasets[2]. Ground-truth was defined as =6 years of stability for benign nodules and histopathology for malignancy. Evaluation used an NLST test cohort with two low-dose CT scans: T -2 (12-24 months before diagnosis) and T -1 (0-12 months) (n=2,080; 74 cancers). A subset (n=419; 74 cancers) was assessed by 4 thoracic radiologists; another (n=282) was evaluated using Lung-RADS by 6 radiologists with prior scan evolution[3]. All nodules were localized, measured, and paired longitudinally by experts. The model's prediction evolution uses D'Arcy Thompson's growth function: P?1/(P?1-P?2) n .

RESULTS

The evolution of AI predictions (ROC-AUC=0.989) and predictions at T -1 (ROC-AUC=0.992) outperformed all growth metrics (?volume, ?diameter, RDT; p<0.0001). RDT performed worst (ROC-AUC=0.924); ?volume slightly outperformed ?diameter (ROC-AUC=0.969). Compared to Lung-RADS with prior evolution, the model showed higher performance (ROC-AUC=0.967 vs. 0.893, p<0.0001). On NLST using the NELSON protocol, our model achieved ROC-AUC=0.954 on indeterminate NODCATIII nodules, improving sensitivity by 11.9% and specificity by 7.4% over VDT-based criteria. On slow-growing and indeterminate nodules (GROWCAT A+B, VDT=400 days), the model at T -2 outperformed radiologists at T -1 (ROC-AUC=0.908 vs. 0.861, p<0.0001).

CONCLUSION

The AI model consistently outperforms conventional growth metrics, including VDT, and time-dependent Lung-RADS assessments, enabling earlier, more accurate malignancy prediction. These findings challenge the current paradigm positioning VDT as a primary malignancy indicator[1]. On slow-growing, indeterminate nodules, our model's T -2 AUC surpasses radiologist diagnosis at T -1 —offering a potential 1-year lead time for treatment.

CLINICAL RELEVANCE/APPLICATION

This AI malignancy risk model could enhance lung cancer screening by identifying malignant nodules earlier and more accurately, enabling timely clinical decision-making, potentially improving patient outcomes through earlier treatment. 1.Yankelevitz Eur.J.Cancer(2025) 2._,RSNA(2024),1527 3.Ardila.Nat.Medicine(2019)

W7-SSCH07-4 A MULTICENTER EXTERNAL VALIDATION OF LUNG-PNET: CLASSIFICATION OF PURE GROUND-GLASS NODULES INTO INVASIVE ADENOCARCINOMA AND NON-INVASIVE SUBTYPES ON CHEST CT IMAGES

Kexin Wang (*Presenter*)
Xiaodong Zhang, MD, PhD (*Abstract Co-Author*)

PURPOSE

To externally validate a pre-trained artificial intelligence (AI) model (Lung-PNet) for differentiating invasive adenocarcinoma (IAC) from non-invasive subtypes (non-IAC) in pure ground-glass nodules (pGGNs) using multicenter chest CT data.

METHODS AND MATERIALS

Chest CT images of resected pGGNs (n = 720; IAC = 143, non-IAC = 577) from seven hospitals were retrospectively analyzed. The dataset was stratified into a local cohort (four hospitals, n = 334) and a national cohort (three hospitals, n = 386). Using the local cohort, receiver operating characteristic (ROC) curve analysis determined a Youden's index-optimized cutoff threshold for binary classification, which was then validated in the national cohort. Model performance was evaluated using the area under the ROC curve (AUC-ROC). Factors influencing AI diagnostic accuracy were analyzed via random forest and mixed-effects logistic regression??.

RESULTS

Lung-PNet achieved an overall AUC-ROC of 0.800 (95% CI: 0.760-0.839), with comparable performance between the local (0.801, 95% CI: 0.740-0.861) and national (0.832, 95% CI: 0.782-0.881) cohorts (P = 0.438, DeLong test). The negative predictive value (NPV) was 0.930 (95% CI: 0.903-0.952), though hospital-specific NPVs varied (0.700-1.000). Key factors influencing the AI model's accuracy included pGGN type, lesion volume, pixel spacing, and hospital, with hospital modeled as a random effect and pGGN type interacting with lesion volume and pixel spacing as fixed effects.

CONCLUSION

This multicenter validation confirms Lung-PNet's generalizability for distinguishing invasive adenocarcinoma (IAC) from non-invasive subtypes (non-IAC) in pure ground-glass nodules (pGGNs). Its high negative predictive value (NPV) supports its clinical utility as a reliable 'rule-out' tool to reduce unnecessary interventions for non-IAC lesions, while institutional variability underscores the need for standardized imaging protocols.

CLINICAL RELEVANCE/APPLICATION

This AI model offers a practical decision-support tool for multidisciplinary teams managing pGGNs, particularly in avoiding overtreatment of non-IAC lesions. By stratifying low-risk nodules for limited resection or surveillance and high-risk IAC for radical surgery, it may reduce unnecessary procedures by 30-40%. Future implementation requires protocol harmonization and prospective validation to optimize real-world performance across diverse clinical settings.

W7-SSCH07-5 LUNG CANCER RISK PREDICTION MODEL PERFORMANCE SUFFERS IN PATIENTS WITH PRIOR CANCER HISTORY AND/OR ADJUVANT CANCER THERAPY EXPOSURE

Allen Luna, BEng (*Presenter*)
Thomas Z. Li, BS (*Abstract Co-Author*)
Chongyu Qu (*Abstract Co-Author*)
Yuankai Huo, PhD (*Abstract Co-Author*)
Bennett A. Landman, PhD (*Abstract Co-Author*)
Kim L. Sandler, MD (*Abstract Co-Author*)

PURPOSE

Patients with prior malignancy are more likely to develop lung cancer relative to the general population, and exposure to adjuvant cancer therapies further increases this risk. Many models for predicting lung cancer risk have been developed, but data on their performance in these populations is lacking. Thus, we set out to assess model performance on patients with incidental pulmonary nodules (IPNs) and a history of malignancy and/or adjuvant therapy exposure prior to nodule detection.

METHODS AND MATERIALS

Retrospective evaluation of individuals with IPNs representing cancer and benign disease was performed. After excluding patients with poor CT scan quality, missing model inputs, and insufficient prior cancer history, a cohort of 224 patients was identified for analysis. Two published lung cancer risk prediction models were investigated: the Mayo model, which utilizes clinical data as inputs, and the DeepLungIPN (DLI) deep learning model which requires clinical data and a single low-dose CT scan as inputs. The models were run on patients with no history of cancer (n=154), a history of cancer (n=70), a history of cancer who received adjuvant chemotherapy and/or radiation (n=34), and a history of cancer treated with surgical resection alone (n=30). Receiver operating characteristic (ROC) curves were generated, and the area under the curve (AUC) was calculated to quantify model performance. Bootstrapping using 1000 samples with replacement was performed to generate mean AUC and 95% CIs.

RESULTS

Both models underperformed on patients with a history of malignancy (AUC = 0.410 [0.405, 0.416] for Mayo; AUC = 0.866 [0.863, 0.869] for DLI) compared to those with no cancer history (AUC = 0.629 [0.626, 0.633] for Mayo; AUC = 0.908 [0.906, 0.909] for DLI). Both models also underperformed in patients with adjuvant therapy

exposure (AUC = 0.283 [0.278, 0.289] for Mayo; AUC = 0.853 [0.849, 0.857] for DLI) compared to patients who only underwent surgical resection of their tumor (AUC = 0.573 [0.563, 0.583] for Mayo; AUC = 0.939 [0.936, 0.942] for DLI). In all populations, DLI outperformed the Mayo model ($p<0.05$).

CONCLUSION

Lung cancer risk prediction models perform poorly in patients with IPNs and a prior history of cancer, especially in those who received adjuvant therapy. The failure of models to capture these factor's impact on an individual's lung cancer risk profile underscores the need for additional model inputs (e.g. biomarkers) before they can accurately guide IPN risk stratification and management in these patients.

CLINICAL RELEVANCE/APPLICATION

Lung cancer risk prediction models underperform on patients with prior malignancy and adjuvant therapy exposure, emphasizing the need for a more personalized approach to lung cancer surveillance for these patients.

W7-SSCH07-6 REAL-WORLD DIAGNOSTIC PERFORMANCE AND CLINICAL UTILITY OF ARTIFICIAL INTELLIGENCE-ASSISTED INTERPRETATION IN DETECTING PULMONARY METASTASIS ON CHEST CT

Sowon Jang, MD (*Presenter*)
Younbeom Jeong, MD (*Abstract Co-Author*)
Jihang Kim, MD (*Abstract Co-Author*)

PURPOSE

To assess the impact of artificial intelligence (AI) assistance on diagnostic accuracy and clinical decision-making for lung metastasis detection in colorectal cancer patients undergoing chest CT surveillance.

METHODS AND MATERIALS

This retrospective diagnostic cohort study included colorectal cancer patients who underwent chest CT surveillance in two cohorts: before AI adoption (2020; human-alone) and after AI adoption (2022; AI-assisted). A total of 647 patients (mean age, 64 ± 11 years; 394 men) were included in the human-alone cohort, and 663 patients (mean age, 63 ± 12 years; 381 men) in the AI-assisted cohort. Diagnostic performance metrics (sensitivity, specificity, accuracy) and clinical utility measures (diagnostic yield, false referral rate, clinical decision changes) were compared between cohorts using multivariable logistic regression. Net benefit was estimated using decision curve analysis.

RESULTS

The prevalence of new lung metastases was comparable between cohorts (4.3% vs 4.4%; $p > .99$). AI-assisted interpretation significantly improved sensitivity (72.4% vs 32.1%; $p = .008$) and accuracy (98.5% vs 96.0%; $p = .005$) without compromising specificity (99.7% vs 98.9%; $p = .11$). AI alone generated 381 false-positive findings in the AI-assisted cohort, but radiologists successfully disregarded most, resulting in one false-positive report in final interpretations. Diagnostic yield ($p = .30$) and false referral rate ($p = .10$) did not differ significantly. Treatment decision changes due to true-positive detections were more frequent in the AI-assisted cohort (55.2% vs 25.0%; $p = .02$), with a positive net benefit estimated.

CONCLUSION

AI-assisted interpretation enhanced sensitivity and accuracy for detecting lung metastases on chest CT and led to more frequent treatment decision changes, indicating potential clinical utility in metastasis surveillance.

CLINICAL RELEVANCE/APPLICATION

Integrating AI into chest CT interpretation may reduce diagnostic errors and improve decision-making for metastatic lung disease in routine clinical practice.

W7-SSCH08-2 FEASIBILITY STUDY OF PHASE-RESOLVED FUNCTIONAL LUNG MRI FOR EVALUATING PULMONARY VENTILATION PARAMETERS IN HEALTHY VOLUNTEERS

Meng Qin (*Presenter*)

PURPOSE

To investigate the impact and feasibility of phase-resolved functional lung (PREFUL)-MRI in assessing pulmonary ventilation parameters of healthy volunteers under different breathing patterns, in comparison with conventional pulmonary function tests (PFTs).

METHODS AND MATERIALS

Thirty healthy adult volunteers with normal pulmonary function were prospectively enrolled from September 2024 to March 2025. All participants underwent PREFUL-MRI scans during both free breathing and deep breathing using a Siemens Skyra 3.0T MRI system equipped with an 18-channel body phased-array coil. Post-processing was performed to obtain pulmonary ventilation parameters, including regional ventilation (RV), flow-volume loop correlation (FVLc), and ventilation defect percentage (VDP). Correlations between these MRI parameters and PFTs indices, including the percentage of forced expiratory volume in one second to the predicted value (FEV1%), the percentage of forced vital capacity to the predicted value (FVC%), and forced expiratory volume in one second/forced vital capacity (FEV1/FVC), were analyzed. The consistency and correlation of PREFUL-MRI parameters obtained under different breathing modes were also compared.

RESULTS

The RV value obtained during free breathing was significantly lower than that during deep breathing ($Z = -4.782$, $P < 0.001$). However, there were no significant differences in FVLc and VDP between the two breathing modes ($P > 0.05$), and both showed strong positive correlations (FVLc: $r = 0.699$, $P < 0.001$; VDP: $r = 0.510$, $P < 0.01$) and good consistency in Bland-Altman analysis. In free-breathing mode, RV was positively correlated with FVC% ($r = 0.402$, $P < 0.05$) and negatively correlated with FEV1/FVC ($r = -0.442$, $P < 0.05$), while other parameters showed no significant correlation with PFTs indices ($P > 0.05$). Under deep-breathing conditions, no significant correlation was found between PREFUL-MRI parameters and PFTs indices ($P > 0.05$).

CONCLUSION

PREFUL-MRI can provide reliable pulmonary ventilation parameters and result maps consistent with respiratory physiology. The technique demonstrated high stability under different breathing patterns, indicating promising clinical application value.

CLINICAL RELEVANCE/APPLICATION

PREFUL-MRI offers a non-invasive, radiation-free method for assessing regional lung ventilation. Its consistent results across different breathing patterns in healthy individuals suggest that complex breathing maneuvers are unnecessary, enhancing clinical feasibility. PREFUL-MRI may serve as an alternative or complement to PFTs and other functional imaging techniques, such as hyperpolarized gas MRI and oxygen-enhanced MRI, especially when those methods are not feasible.

W7-SSCH08-4 SIMULATION OF DYNAMIC F19 AND SINGLE BREATH HYPERPOLARIZED 129XE MAGNETIC RESONANCE IMAGING

Jeffrey Ord, MD (*Presenter*)
Truc Nguyen (*Abstract Co-Author*)
Courtney Wing, MD (*Abstract Co-Author*)
Jennifer Goralski (*Abstract Co-Author*)
Yueh Z. Lee, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pulmonary CT scans largely provide anatomic information, whereas functional lung data is a vital component to disease diagnosis/monitoring. Inhaled gas MRI with hyperpolarized xenon (129Xe) or perfluoro-propane (PFP/F19) provide functional lung information such as ventilation. The aim of this study is to simulate inhalation and imaging of these gases to delineate their roles.

METHODS AND MATERIALS

A high-resolution lung CT was segmented for lobar volumes and proximal airway structure autonomously in Slicer via the Chest Imaging Platform. This airway segmentation was then skeletonized into a node/branch structure, and the distal airway was algorithmically generated grown into the lobar volumes to generate a virtual lung environment (VLE). Random degrees of branch constriction were applied to the distal airways (normal distribution centered on 80%). This VLE (65,638 branches, 65,639 nodes, 32,820 acinar units) housed multiple breath washout simulations simulating a 30-breath wash-in/wash-out of PFP gas and a single hp-Xe gas breath-hold, with and without an overlayed randomized oxygen decay factor to simulate loss of hyperpolarized signal in the presence of paramagnetic oxygen. For F19, kinetic time constants tau 1 (wash-in) and tau 2 (wash-out) were calculated from tracer gas concentration curve fitting. For 129Xe, a a binary VDP value was generated by setting a threshold of 60% mean of acinar 129Xe concentration. Since the airway geometry/resistances applied was known sensitivity and specificity values were calculated for each modality relative to the degree of airway resistance applied.

RESULTS

In the absence of oxygen decay, both 129Xe and F19 had low sensitivity to flow restriction less than 80%, but sensitivities of 16.7%/81.2% (129Xe) and 5.5%/67.8% (F19) to 80/90% constriction. Addition of randomized oxygen decay for 129Xe lowered sensitivity to 6.7%/49%. Specificity to airway constriction was high for both modalities (in 90% range across 65% to 95% flow resistance), but 129Xe has a significant drop off in specificity to resistance values below 85% with addition of oxygen decay term.

CONCLUSION

Prior in-vivo experiments demonstrate differences in F19- and 129Xe-derived deficits. These ex-vivo simulations closely overlap, until the addition of a randomized oxygen decay term which may explain the in-vivo differences seen. A high degree (>80%) of constriction to the distal airway was needed for these simulated modalities to be sensitive.

CLINICAL RELEVANCE/APPLICATION

Comparison of functional pulmonary MRI techniques via multiple breath washout simulations may help clarify the roles of these techniques in their application to lung pathology.

W7-SSCH08-6 TOWARD PRECISE EVALUATION OF OBSTRUCTIVE PULMONARY DISEASE USING 3D VENTILATION-RELATED MAPPING USING MRI

Seokwon Lee, PhD (*Presenter*)
Sun Hye Shin (*Abstract Co-Author*)
Hyeonha Kim (*Abstract Co-Author*)
Jooae Choe, MD, PhD (*Abstract Co-Author*)
Hocheol Kim (*Abstract Co-Author*)
Hye Yun Y. Park (*Abstract Co-Author*)
Ho Yun Lee, MD, PhD (*Abstract Co-Author*)
Jang-Yeon Park (*Abstract Co-Author*)

PURPOSE

To demonstrate that ventilation-weighted (VW) and ventilation flow capacity-weighted (VFCW) maps obtained from non-contrast ultrashort echo-time (UTE) MRI can effectively differentiate between emphysema-predominant (EP) and airway-predominant (AP) phenotypes in obstructive pulmonary diseases.

METHODS AND MATERIALS

Twenty-nine patients, including seventeen with chronic obstructive pulmonary disease (COPD) and twelve with bronchial asthma, were enrolled and underwent spirometry, CT, and free-breathing Three-dimensional (3D) variable slab-selective UTE MRI.. Six respiratory phase-resolved images were obtained using retrospective respiratory gating. 3D VW maps were computed from the difference between end-inspiratory and end-expiratory images. 3D VFCW maps quantified the rate of change in ventilation between two consecutive respiratory states. A mathematical inequality using FEV1 (forced expiratory volume in 1 second), FVC (forced vital capacity), VW, and VFCW parameters was proposed for diagnostic decisions to differentiate between EP and AP phenotypes.

RESULTS

Based on CT findings, fourteen patients were classified as EP and fifteen as having the AP phenotypes. Qualitatively, patients with the EP phenotype tended to have lower VW and VFCW values ??overall, especially in areas where emphysematous changes were observed on CT. In contrast, patients with the AP phenotype had relatively preserved VW values ??but reduced VFCW. The final linear decision function: $D=-1.38\times FE\ V\ 1\ +0.47\times FVC+3.40\times VW+5.27\times VFCW-3.77$, where $D<0$ indicates EP and $D>0$ indicates AP phenotypes. The decision inequality using FEV1, FVC, VW, and VFCW effectively distinguished EP from AP patients, achieving an accuracy of 83.3%, precision of 85.7%, and an F1-score of 75.0%.

CONCLUSION

3D VW and VFCW maps obtained from UTE MRI offer reliable, radiation-free functional biomarkers, enabling detailed functional assessment and differentiation of EP and AP phenotypes in obstructive pulmonary diseases. This approach enables precise functional characterization and improved clinical decision-making in these patients.

CLINICAL RELEVANCE/APPLICATION

UTE MRI-based VW and VFCW maps allow accurate and non-invasive differentiation of obstructive pulmonary disease phenotypes, enhancing personalized care strategies and minimizing reliance on radiation-based imaging modalities.

Kumi Ozaki, MD, PhD (*Abstract Co-Author*)
Satoshi Goshima, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare the lesion detectability of colorectal liver metastases between gadoxetic acid-enhanced magnetic resonance imaging (MRI) (standard protocol), abbreviated MRI (AMRI), and combined protocol (AMRI + contrast enhanced computed tomography (CE-CT)).

METHODS AND MATERIALS

This multi-institutional, retrospective study was conducted between February 2008 and December 2020. This study included adult patients pre- and post-treatment for colorectal adenocarcinoma. All the patients underwent gadoxetic acid-enhanced MRI and 271 of those patients also underwent CE-CT. Two expert radiologists (21 and 24 years of experience respectively) blinded to the final diagnosis independently graded the presence of liver metastasis on a 5-point scale by reviewing three different image sets to detect liver metastases: set A, AMRI (diffusion weighted, fat-suppressed T2-weighted, hepatobiliary phase images); set B, standard protocol (diffusion weighted, fat-suppressed T2-weighted, in-phase and opposed-phase, pre, arterial, portal venous, transitional and hepatobiliary phase images); set C, combined AMRI and CE-CT images. The five largest lesions were selected for evaluation among patients with multiple lesions. Interobserver agreement regarding lesion detectability and conspicuity was also evaluated.

RESULTS

The final cohort comprised 618 patients (mean age, 66.1 ± 11.5 years; 245 women, 40%) from three institutions. There were 356 patients with liver metastases and 262 patients without. The breakdown of the primary sites was as follows: 31 cecum, 92 ascending, 47 transverse, 27 descending, 162 sigmoid colon and 259 rectum. AMRI demonstrated sensitivity comparable to the standard protocol (94.7%-98.6% vs. 94.7%-95.5%) but had lower specificity (47.7%-49.6% vs. 77.5%-82.4%, $p < 0.001$) and accuracy (74.8%-77.8% vs. 87.9%-89.5%, $p < 0.001$). When CE-CT was added to the AMRI protocol, specificity and accuracy significantly improved (specificity, 79.2%-85.8; accuracy, 89.7%-92.3%). Meanwhile, diagnostic performance of the standard protocol and the combined AMRI and CE-CT protocol were comparable (sensitivity, 92.1%-94.7% vs. 97.4%-98.0%; specificity, 82.5%-83.3% vs. 79.2%-85.8%; accuracy, 88.2%-89.3% vs. 89.7%-92.3%). The interobserver agreement was good (kappa = 0.72 on set A and 0.75 on set B), and excellent (kappa = 0.82 on set C).

CONCLUSION

Although AMRI shows lower specificity and accuracy in detecting liver metastases, the addition of CE-CT resulted in specificity and accuracy comparable to the standard protocol.

CLINICAL RELEVANCE/APPLICATION

With contrast-enhanced CT information, AMRI may be sufficient for detecting liver metastases instead of the standard protocol.

W7-SSGI13-3 IRON DEPOSITION IN SCLEROSED HEPATIC HEMANGIOMAS: A SPECIFIC IMAGING BIOMARKER FOR NON-INVASIVE DIAGNOSIS

Nikhil S. Mirajkar, MBChB, FRCR (*Presenter*)
Ryan K. Campbell, MD (*Abstract Co-Author*)
Masoom A. Haider, MD (*Abstract Co-Author*)
Korosh Khalili, MD (*Abstract Co-Author*)
Ciara O'Brien, FRCPC, MBBCh (*Abstract Co-Author*)

PURPOSE

Sclerosed hepatic hemangiomas (SH) present a diagnostic challenge and may mimic malignant lesions. This study investigates the prevalence of iron deposition in SHs as detected by chemical shift MRI and evaluates its specificity as a diagnostic biomarker.

METHODS AND MATERIALS

We performed a single centre retrospective search of MRI reports containing the terms "sclerosed and/or sclerosing haemangioma" over a 10 year period. Patients with either biopsy proven or imaging features confirmatory of a SH were included. Confirmatory imaging features included: 1. typical enhancement pattern of a hemangioma on MRI or CT, performed prior to the sclerosis of the hemangioma, 2. Shrinkage and absence of typical enhancement on the follow-up MRI. Two independent readers

assessed iron deposition (visual identification of areas of signal loss within the lesion on the in phase images and/or significant difference in ROI signal intensity values) and the presence of any ancillary features (geographic pattern, capsular retraction, THID, rim enhancement, nodular enhancement). Comparison groups included typical hemangiomas (n=18) and histologically confirmed cholangiocarcinomas (n=20).

RESULTS

41 patients formed the final SH cohort, with 6/41(14.6%) being proven by biopsy and the rest by imaging criteria. Signal loss on in phase imaging consistent with iron deposition was identified in 20/41 (48.7%) of SH cases. None of the typical haemangiomas or cholangiocarcinomas demonstrated this finding. Interobserver agreement for identifying iron was excellent (? = 0.91). Rim enhancement of the SH was most strongly associated with iron deposition (OR = 38, p <0.01). Average signal intensity difference (IP-OP/IP) between lesions containing iron was -17.5% (SD 25.2) vs without iron +7.8% (SD 12.4), p <0.01. In 10 cases with serial imaging, none showed iron deposition in the initial typical hemangioma, but all developed signal characteristics of iron after sclerosis occurred (Fig 1 & 2). The presence of iron demonstrated 100% specificity (p <0.01) and 48.8% sensitivity (p = 0.88) for SH diagnosis.

CONCLUSION

Iron deposition detected as signal loss on in-phase chemical shift imaging represents a previously unreported but highly specific imaging biomarker for SH. The temporal relationship between sclerosis and iron accumulation suggests a potential pathophysiologic mechanism related to haemosiderin deposition and fibrosis.

CLINICAL RELEVANCE/APPLICATION

The identification of iron deposition in hepatic lesions with imaging features suggestive of SH provides radiologists with a novel specific biomarker to increase diagnostic confidence and potentially avoid biopsy.

W7-SSGI13-4 ARTIFICIAL INTELLIGENCE MEETS CEUS: PROPOSAL FOR AN AUTOMATED DIAGNOSTIC TOOL FOR LIVER LESION CHARACTERIZATION &STUDY SUMMARIZATION

Derya Gol Gungor, PhD (*Presenter*)
Christine Merrill, BSc (*Abstract Co-Author*)
Cynthia Wolverton (*Abstract Co-Author*)
Ismayil Guracar (*Abstract Co-Author*)
Stephen Metz (*Abstract Co-Author*)
Stephanie R. Wilson, MD (*Abstract Co-Author*)

PURPOSE

This study highlights our initial progress in integrating artificial intelligence (AI) with liver CEUS to develop automated tools for imaging study summarization and lesion characterization, with a focus on washout detection.

METHODS AND MATERIALS

Three key components were developed: 1. System Design Proposal: A framework was developed to preprocess CEUS data for neural networks, tackling the temporal and spatial complexities of CEUS imaging. It includes lesion area selection, precise segmentation, and robust tracking to reduce motion artifacts. The preprocessed images are then used by AI models to extract CEUS characteristics and sent to the study summarization tool for visualization. 2. Study Summarization Tool: This tool provides a one-shot visualization method to summarize single or multiple CEUS studies. It generates a timeline plot for each injection, combining frames from the arterial phase (AP) wash-in video with portal vein phase (PVP) washout images. Regular snapshots highlight AP washin patterns alongside PVP washout images, allowing for comprehensive study summarization. 3. Deep Learning Model for Washout Detection: A dataset of 235 lesions from 202 patients (45% female, median age: 58) was used. Lesions included 53% hepatocellular carcinoma (HCC), 30% focal nodular hyperplasia (FNH), 5% adenoma, 4% LR-M, and 5% other types, with hemangiomas excluded. Washout patterns consisted of 60% weak, 5.5% marked, and 34.5% no washout. The data was partitioned into training (70%), validation (15%), and test (15%) sets. An Attention-Based Deep Multiple Instance Model (ABMIL) with EfficientNet-B0 as the backbone image encoder was used for automatic washout detection. The positive bags were created from weak and marked washout samples versus the negative bags from no-washout samples. The model was optimized using Stochastic Gradient Descent (learning rate: 0.01) in TensorFlow.

RESULTS

The study summarization tool provided concise yet comprehensive visualizations of CEUS studies, clearly highlighting AP washin and PVP washout patterns. The ABMIL-based deep learning model achieved 90% accuracy in detecting washout on the test set (50 lesions), demonstrating its reliability for washout detection.

CONCLUSION

The implemented components of the proposed AI tool achieved effective study summarization and showed promising results for washout detection in early studies, with washout now recognized as the most reliable sign of malignancy.

CLINICAL RELEVANCE/APPLICATION

AI-enhanced CEUS imaging transforms liver lesion evaluation, improving diagnostic accuracy and streamlining workflows. This system equips clinicians with advanced tools for better diagnosis and management of liver diseases, ultimately enhancing patient outcomes.

W7-SSGI13-5 LARGE LANGUAGE MODELS FOR THE DIFFERENTIATION OF BENIGN AND MALIGNANT LIVER NODULES BASED ON MULTIMODAL PROMPTS IN LIVER US CASES

Sijia Lin (*Presenter*)
Lingling Li (*Abstract Co-Author*)
Yu Li (*Abstract Co-Author*)
Jianhua Zhou, MD, PhD (*Abstract Co-Author*)

PURPOSE

Large language models (LLMs) that can process both visual images and text data are increasingly being used in the field of radiology. Their ability in liver US cases remains unclear yet. Therefore, this study aimed to evaluate the performance of LLMs including GPT-4o, Claude, and Gemini in differentiating benign and malignant liver nodules and compare it with that of human readers .

METHODS AND MATERIALS

Four hundred liver US cases with pathologically confirmed liver nodules visible on B-mode US from January 2020 to November 2024 were randomly selected in this retrospective study. They were divided into a development set (n=100) and a test set (n=300).Five prompt groups for LLMs including US image [I-only], image description [D-only], image and description [I+D], image and liver US e-textbook [I+T], and image and medical history [I+H] were evaluated to identify the optimal input in the development set. In the test set, accuracy of LLMs in differentiating benign and malignant liver nodules was compared with that of human readers using McNemar's test.

RESULTS

In the development set, the prompt group I+H for all three LLMs exhibited the highest diagnostic accuracy in differentiating benign and malignant liver nodules, being considering as the optimal input (taking GPT-4o as an example, with I-only, 57.0% [as reference]; D-only, 62.0%, P = .55; I+D, 62.0%, P = .54; I+T, 62.0%, P = .36; I+H, 77.0%, P = .01). In the test set, LLMs with I+H outperformed the junior group and showed similar accuracy to senior group (Junior, 70.0% [as reference1]; Senior, 78.3% [as reference2]; GPT-4o, 83.3%, P1 < .001, P2 = .10; Claude, 77.0%, P1 = .04, P2 = .72; Gemini, 75.3%, P1 = .14, P2 = .36).

CONCLUSION

Large language models with US image and medical history inputs achieved accuracy comparable to senior radiologists and superior to junior radiologists in differentiating benign and malignant liver nodules.

CLINICAL RELEVANCE/APPLICATION

This study showed that large language models, when provided with ultrasound images and medical history inputs, could serve as convenient auxiliary tools for differentiating between benign and malignant liver nodules. The findings highlight their potential to support junior radiologists, particularly in regions with a shortage of experienced specialists.

W7-SSGI13-6 EXPLORING THE LESION DETECTABILITY OF DUAL-ENERGY CT FOR LIVER METASTASES USING A DEEP LEARNING DETECTION MODEL

Satoshi Funayama, MD, PhD (*Presenter*)
Shintaro Ichikawa, MD, PhD (*Abstract Co-Author*)
Prakhar Prakash (*Abstract Co-Author*)
Sei Morikawa (*Abstract Co-Author*)
Michail Fanariotis (*Abstract Co-Author*)
Akio Ito, MD (*Abstract Co-Author*)
Masatoshi Kakuya (*Abstract Co-Author*)
Tatsunori Kobayashi, MS,RT (*Abstract Co-Author*)
Tomoko Hyodo, MD (*Abstract Co-Author*)
Kumi Ozaki, MD, PhD (*Abstract Co-Author*)
Satoshi Goshima, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare the detectability of liver metastases on contrast-enhanced dual-energy (DE) CT between radiologists and a deep learning model, using gadoxetic acid-enhanced MRI as the clinical reference standard.

METHODS AND MATERIALS

This retrospective study included 68 patients with gastrointestinal adenocarcinoma. All patients underwent both contrast-enhanced DE-CT and gadoxetic acid-enhanced MRI for suspected liver metastases. DE-CT was performed using a fast kilovoltage-switching scanner (Revolution CT with Apex edition; GE HealthCare), and images were reconstructed at 70 keV using DLIR (TrueFidelity 2.0; GE HealthCare). Liver metastases were diagnosed based on the MRI findings.Patients were divided into a training set (n = 51) and a test set (n = 17). A 3D U-Net-based convolutional neural network (MetsAI) was trained on the post-contrast DE-CT images using an image cropping method within the liver. For comparison, four radiologists—two experts (Readers 1 and 2) and two residents (Readers 3 and 4)—independently reviewed the pre- and post-contrast DE-CT images. Each reader rated lesion localization confidence on a 5-point scale.Lesion detectability was compared between MetsAI and the radiologists using alternative free-response receiver operating characteristic (AFROC) analysis. Statistical significance was assessed using the bootstrap method, with $p < 0.05$ considered significant.

RESULTS

MetsAI demonstrated a significantly higher area under the AFROC curve (AUC) than Reader 4 (0.955 [95% CI, 0.882-1.000] vs. 0.551 [95% CI, 0.510-0.957]; $p < 0.01$, Figure). No statistically significant differences were observed between MetsAI and Readers 1, 2, or 3 (Reader 1: 0.888 [95% CI, 0.750-1.000], $p = 0.24$; Reader 2: 0.760 [95% CI, 0.500-0.973], $p = 0.06$; Reader 3: 0.811 [95% CI, 0.556-0.984], $p = 0.08$). Lesion localization fractions (sensitivity) were as follows: MetsAI, 1.00 (27/27); Reader 1, 0.69 (9/13); Reader 2, 0.77 (10/13); Reader 3, 0.77 (10/13); and Reader 4, 0.62 (8/13).

CONCLUSION

MetsAI demonstrated high lesion detectability for contrast-enhanced dual-energy CT, with a significantly higher AUC than a radiologist with little experience.

CLINICAL RELEVANCE/APPLICATION

The deep learning detection model (MetsAI) applied to dual-energy CT shows promising lesion detectability for liver metastases from gastrointestinal adenocarcinoma.

W7-SSGI14-3 SEMI-AUTOMATED CLASSIFICATION MODEL FOR SIEWERT TYPING OF ESOPHAGOGASTRIC JUNCTION ADENOCARCINOMA BASED ON NNU-NET MODEL AND 3D BREADTH-FIRST SEARCH ALGORITHM

Yiting Liu (*Presenter*)
Yongai Li, MD,MD (*Abstract Co-Author*)
Zifan Chen (*Abstract Co-Author*)
Heyun Chen (*Abstract Co-Author*)
Wanying Ji (*Abstract Co-Author*)
Xiaoting Li (*Abstract Co-Author*)
Fang-jing Hou (*Abstract Co-Author*)
Kan Xue (*Abstract Co-Author*)
Lei Tang, MD (*Abstract Co-Author*)

PURPOSE

The Siewert typing is critical for surgical planning and prognosis evaluation in adenocarcinoma of the esophagogastric junction (AEG). This study aims to develop a semi-automated typing model (GESNet) integrating nnU-Net-based segmentation and 3D breadth-first search (BFS) algorithms to improve the accuracy and reproducibility of Siewert typing for AEG.

METHODS AND MATERIALS

This study developed a semi-automated Siewert typing model integrating nnU-Net segmentation, 3D BFS path calculation, and endpoint annotation. A multicenter cohort of 470 AEG patients was included. Segmentation is carried out according to the following three core steps (Fig 1-2): For gastric tumor segmentation based on nnU-Net , gastric lumen VOI was segmented using CT thresholds. Tumor-to-lumen distance maps were computed, with mucosal VOI defined as voxels = 2 mm from the lumen (Fig 3). Esophageal tumor length was semi-automated: radiologists manually marked the cranial tumor endpoint (E start) in ITK-SNAP. The distal endpoint (E end) was identified as the closest point on the gastric mucosal VOI to E start (Fig 4). 3D BFS-based longitudinal path calculation for gastric tumor initiated from E end , iteratively expanding a 3×3×3 cube on mucosal VOI (Fig 5). Distance matrices tracked shortest surface paths (voxel-wise Euclidean distance summed along the mucosal curvature). (Fig 6) Path directionality was constrained to align with the gastric longitudinal axis by prioritizing contiguous voxels along anatomical curvature, avoiding circumferential deviations. The tumor center was defined as the midpoint of the longest path, and the Siewert type was determined by the distance between this midpoint and the esophagogastric junction (EGJ). Performance was validated via five-fold cross-validation (Dice coefficient) and accuracy, sensitivity, specificity, PPV, and NPV against surgical pathology.

RESULTS

GESNet achieved Dice coefficients of 0.838-0.891 for gastric tumor segmentation. Siewert typing accuracy ranged from 88.0% to 94.8% across cohorts, with sensitivity 86.8%-98.9% and specificity 63.6%-96.0%. External validation showed stable performance (94.8% accuracy in development cohort). The model outperformed traditional methods in reproducibility and reduced inter-observer variability.

CONCLUSION

We develop a deep learning-based 3D AEG segmentation model, leveraging clinical annotations and spatial analysis to quantify tumor length for Siewert typing. A dual-zone strategy enhances segmentation consistency and typing accuracy.

CLINICAL RELEVANCE/APPLICATION

GESNet integrates nnU-Net and 3D BFS to enhance Siewert typing reproducibility, reducing inter-observer variability and standardizing preoperative planning for AEG.

W7-SSGI14-6 CONSTRUCTION OF CLINICAL NUTRITIONAL-RADIOMICS MODEL TO PREDICT HEALING TIME OF ESOPHAGOJEJUNOSTOMY FISTULA AFTER RADICAL TOTAL GASTRECTOMY

Yuan Xu (*Presenter*)
Liu Bo (*Abstract Co-Author*)
Wence Zhou (*Abstract Co-Author*)

PURPOSE

Esophagojejunostomy fistula (EJAL) occurs in 4-15% of gastric cancer patients undergoing radical total gastrectomy, and its unhealed can lead to mortality rates as high as 60%. Nutritional status plays an important role in the healing of anastomotic fistula, but nutritional information contained in Imaging are often ignored. The purpose of this study is to construct a clinical nutritional combined radiomics model for predicting healing time of EJAL patients.

METHODS AND MATERIALS

We retrospectively collected data from 418 patients with EJAL of grades II, who underwent radical total gastrectomy for gastric cancer at two centers from 2018 to 2025 (training group: 226 cases from Hospital A; validation group: 192 cases from Hospital B). The healing time of EJAL was defined as the time from diagnosis to the abdominal drainage tube removal, and patients were divided into a healing group and a delayed healing group based on the median time. The nutritional characteristics are collected from CT and medical record,radiomics features were extracted after segment the whole anastomotic fistula region in all the slices with the CT. Clinical nutritional model, radiomics signatures and combined nomogram were constructed.

RESULTS

The average healing time of EJAL was 15±6 days (median: 11 days, range 4-63 days). Patients who received combined enteral and parenteral nutrition support, had a systemic immune-inflammation index (SII) <2.93×10^12, a controlling nutritional status score (COUNT) >4, a visceral fat area (VFA) for male or female >114.6 or 91.5 cm2 and a psoas muscle inde (PMI) >3.5 cm2/m2 had a shorter healing time for EJAL. In the validation group,The best model was the clinical nutritional combined radiomics nomogram with AUC of 0.855 (95% CI: 0.739-0.891).

CONCLUSION

The clinical nutritional combined radiomics model constructed based on the two centers can relatively accurately predict the healing time of EJAL.

CLINICAL RELEVANCE/APPLICATION

At present, the study of anastomotic fistula mainly focuses on the occurrence of fistula, and ignores the clinical outcome of anastomotic fistula. This study combines radiomics and imaging nutrition, which will effectively improve clinicians' management and understanding of perioperative complications in gastric cancer.

W7-SSIR03-1 MR GUIDED CATHETER-BASED RADIOTHERAPY/BRACHYTHERAPY OF LIVER TUMOURS - FIRST EXPERIENCE AND FEASIBILITY

Matthias P. Fabritius, MD (*Presenter*)
Max Seidensticker (*Abstract Co-Author*)
Olaf Dietrich, PhD (*Abstract Co-Author*)
Daniel Puhr-Westerheide, MD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)

PURPOSE

To show feasibility and safety of MR guided catheter-based radiotherapy/brachytherapy of primary or secondary liver tumours

METHODS AND MATERIALS

Treatments were performed under conscious sedation and local anaesthesia, utilizing a 1.5T MRI system (Magnetom Solafit, Siemens Healthineers) with a 15 cm loop coil. Each procedure involved administering gadoxetic acid at 0.1 mmol/kg body weight for contrast enhancement, inserting an 18G coaxial needle (Co. ITP) and navigating to the lesion through real-time gradient-echo (TE 3.4ms, TR 7.3ms, FA 30°) fluoroscopy sequences (with iMRI UI Extension, Research Software Package), subsequently exchanging the needle over a nitinol wire for a 6F hydrophilic angiography sheath harbouring a 6F brachytherapy catheter. 3D T1-weighted sequences were sent to treatment planning system in the radiation department for Brachytherapy (BT) with IR192 high-dose-rate (HDR) afterloading unit. Target doses ranged from 15 to 25 Gray (Gy) depending on the tumour entity, including HCC (33.3%), CRC (22.2%), GIST (11%), NET (11.1%) and metastases from other primaries (22.2%). The catheters were removed after BT and the radiation tract was sealed with gelatine sponge.

RESULTS

The average room time was 74 ± 35 minutes, the average time for catheter placement was 19 ± 11 minutes. The mean dose administered per lesion (D100) was 18.9 ± 3.6 Gy. Complications during and after BT were generally rare with only 1 patient (3.7 %.) having a minor bleeding without need for blood transfusion or intervention.

CONCLUSION

Overall, MR-guided catheter-based radiotherapy for liver tumours is feasible and safe, particularly for small lesions. With low complication rates and precise dosimetry achieved through advanced imaging, this approach holds promise for effective tumour management.

CLINICAL RELEVANCE/APPLICATION

MR-guided catheter-based brachytherapy is offering a promising option for minimally invasive, targeted therapy for smal liver lesions (HCC and oligometastatic disease), especially when not targetable in CT or Ultrasound.

W7-SSIR03-2 ONCOLOGICAL OUTCOMES FROM THE COVER-ALL TRIAL: SOFTWARE-BASED VERSUS VISUAL ASSESSMENT OF INTRAPROCEDURAL MINIMAL ABLATIVE MARGINS IN PERCUTANEOUS LIVER THERMAL ABLATION OF LIVER TUMORS

Noreen Siddiqi, MD (*Presenter*)
Jessica A. Marques Silva, MD (*Abstract Co-Author*)
Iwan Paolucci, PhD (*Abstract Co-Author*)
Caleb Oconnor (*Abstract Co-Author*)
A. Kyle Jones, PhD (*Abstract Co-Author*)
Kristy K. Brock, PhD (*Abstract Co-Author*)
Bruno C. Odisio, MD, PhD (*Abstract Co-Author*)

PURPOSE

To report the final oncological outcomes of the COVER-ALL randomized phase 2 trial comparing software-based versus visual assessment of intraprocedural minimal ablative margin (MAM) in CT-guided percutaneous thermal ablation (TA) of liver tumors.

METHODS AND MATERIALS

This single-center, prospective trial enrolled patients with up to 3 histology-agnostic liver tumors (1-5 cm) referred for TA. Patients were randomized 1:1 intraprocedurally after probe placement to software-based MAM evaluation (experimental group) or visual assessment (control group), using Pocock-Simon minimization. Following a planned interim analysis showing superiority of the software in achieving MAM =5 mm, control enrollment was halted, and 50 further patients entered a non-randomized experimental group. Here we report the final oncological outcomes to be completed in October 2025, including the 2-year cumulative incidence of local tumor progression (LTP), local tumor progression-free survival (LTPFS), overall survival, and intra- and extrahepatic progression-free survival, analyzed by Fine-Gray and Kaplan-Meier methods per RECIST 1.1 and ablation-specific reporting standards.

RESULTS

Between June 15, 2020, and October 5, 2023, 100 patients were enrolled (control: n = 26; randomized experimental: n = 24; non-randomized experimental: n = 50). Final analysis included a median follow-up of 24.1 months (95% CI: 18.2-21.3) overall, with 24.8 months (95% CI: 24.4-25.5) in the control group and 22.7 months (95% CI: 19.2-24.2) in the experimental group. LTP occurred in 4/26 (15%) tumors in the control group and 1/24 (4%) in the randomized experimental group. The 2-year cumulative incidence of intrahepatic progression outside the ablation zone for the randomized group was 0·57 (95% CI 0·3-0·7) in the control and 0·79 (95% CI 0·5-0·9) in the experimental group (sHR 0·6; 95% CI 0·3-1·2; p=0·15). The 2-year cumulative incidence of extrahepatic progression was 0·6 (95% CI 0·4-0·8) in the

control arm and 0·67 (95% CI 0·4-0·8) in the experimental arm (sHR 0·8; 95% CI 0·4-1·7; p=0·58). Outcome data for the non-randomized experimental group will be finalized in October 2025.

CONCLUSION

Software-based MAM assessment during liver TA reduces LTP risk compared to visual inspection and supports standardized, precision-guided treatment.

CLINICAL RELEVANCE/APPLICATION

The COVER-ALL trial provides the first prospective evidence that intraprocedural software-based MAM assessment improves local tumor control after TA. By enabling real-time, quantitative feedback, this approach promotes procedural standardization and may establish a new benchmark for precision in liver-directed oncologic therapies.

W7-SSIR03-3 COMPARATIVE ANALYSIS OF SYSTEMIC IMMUNE RESPONSES AND METASTATIC RISKS IN TUMOR ABLATION: AN ANIMAL STUDY OF RADIOFREQUENCY ABLATION AND IRREVERSIBLE ELECTROPORATION WITH IMMUNE MODULATION

Mari Hayashi (*Presenter*)
Katsutoshi Sugimoto, MD, PhD (*Abstract Co-Author*)
Hidehito Honda (*Abstract Co-Author*)
Tatsuya Kakegawa (*Abstract Co-Author*)
Hirohito Takeuchi (*Abstract Co-Author*)
Takao Itoi (*Abstract Co-Author*)

PURPOSE

This study aimed to compare systemic immune responses and metastatic effects induced by radiofrequency ablation (RFA) and irreversible electroporation (IRE) in murine tumor models. We assessed cytokine production, growth of treated and untreated metastatic tumors, and synergy with immune checkpoint inhibitors (ICIs).

METHODS AND MATERIALS

Hep55.1c murine hepatoma cells were implanted in C57BL/6N mice to establish primary tumors. In Experiment 1 (n = 50), RFA or IRE was applied to primary tumors, followed by CD8 + T cell depletion in some groups to assess anti-tumor immune responses. Experiment 2 (n = 45) tested RFA and IRE combined with anti-PD-1 therapy for enhanced abscopal effects. In Experiment 3 (n = 28), anti-IL-6 antibody was administered in IRE-treated mice to examine IL-6's role in secondary tumor growth. Tumor volumes and cytokine/chemokine levels were monitored.

RESULTS

Both techniques induced significant CD8 + T cell-mediated anti-tumor responses, with abscopal effects observed in untreated secondary tumors. CD8 + T cell depletion abolished these effects, confirming their role in systemic tumor control. Anti-PD-1 therapy combination further suppressed secondary tumor growth. However, IRE uniquely elevated IL-6 and other inflammatory cytokines, unexpectedly accelerating secondary tumor growth. Administration of an anti-IL-6 antibody mitigated this effect, reducing secondary tumor progression.

CONCLUSION

The results of this animal study indicate that both techniques promote systemic anti-tumor immunity, though IRE uniquely induces an inflammatory response that risks exacerbating micro-metastases through IL-6. Combining IRE with IL-6 blockade may offer a promising strategy for nonthermal tumor ablation therapies. Further studies are warranted to refine ablation-immune therapy combinations for optimal therapeutic outcomes.

CLINICAL RELEVANCE/APPLICATION

Combining IRE with immune checkpoint inhibitors and IL-6 blockade may enhance systemic anti-tumor immunity while mitigating pro-metastatic inflammatory responses, offering a promising strategy for improving the clinical efficacy of nonthermal tumor ablation.

W7-SSIR03-4 MICROWAVE VS. RADIOFREQUENCY ABLATION FOR HEPATOCELLULAR CARCINOMA: A LARGE COHORT PROPENSITY-MATCHED STUDY INCLUDING NO-TOUCH TECHNIQUE

Dongyeong Kim, MD (*Presenter*)
Hyo Jung Park, MD, PhD (*Abstract Co-Author*)
So Jung Lee (*Abstract Co-Author*)
Sang Hyun Choi, MD (*Abstract Co-Author*)
Hyung Jin Won, MD (*Abstract Co-Author*)
Yong Moon Shin (*Abstract Co-Author*)
So Yeon Kim, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare the therapeutic outcomes between microwave ablation (MWA) and radiofrequency ablation (RFA) for hepatocellular carcinoma (HCC) in a large cohort, with a subgroup analysis focusing on the no-touch ablation.

METHODS AND MATERIALS

This retrospective study analyzed 712 patients (male, 577; mean age: 65.0 years) who underwent MWA (n=220) and RFA (n=492) for HCC between 2021 and 2023. Baseline characteristics were compared between the two groups, including liver function, presence of cirrhosis, tumor characteristics, and previous treatments. Clinical outcomes including 2-year cumulative local tumor progression (LTP), intrahepatic distant recurrence (IDR), extrahepatic metastasis (EM) were assessed before and after propensity score matching (PSM). Cox regression analyses were performed to identify factors associated with LTP. Subgroup analysis was conducted to evaluate the no-touch RFA technique (n=89).

RESULTS

The mean tumor size was 1.6 cm (range, 0.5-4.0), with a medianl follow-up of 25.0 months (range, 2.8-42.6). In the unmatched cohort, the MWA and RFA groups significantly differed in several baseline characteristics (e.g., bilirubin, prothrombin time, platelet count, cirrhosis rate, tumor size, subcapsular location). The 2-year LTP rates were similar between MWA and RFA before PSM (5.9% vs. 5.6%, p=0.82) and after PSM (6.5% vs. 6.0%, p=0.84). No significant differences were observed in IDR (before PSM: 43.6% vs. 43.9%, p=0.98; after PSM: 43.6% vs. 44.3%, p=0.98) and EM (before PSM: 9.7% vs. 6.7%, p=0.26; after PSM: 9.9% vs. 7.7%, p=0.67). Multivariable analysis identified perivascular location (adjusted hazard ratio [HR]=3.616, p<0.001) and history of transcatheter arterial chemoembolization (TACE) (HR=2.617, p=0.02) as significant predictors of LTP. The no-touch RFA technique showed a lower LTP rate (3.0%) compared to MWA (5.9%) and standard RFA (6.2%), although statistically not significant (p=0.59 and 0.40, respectively).

CONCLUSION

MWA and RFA demonstrate similar clinical outcomes. Perivascular location and prior TACE are significant risk factors for LTP. The no-touch technique may reduce LTP rates and warrant further investigations.

CLINICAL RELEVANCE/APPLICATION

This large cohort study provides robust evidence that both MWA and RFA are effective treatment options for HCC. The no-touch technique shows potential for improving local control and should be explored in future research.

W7-SSIR03-5 M2-LIKE MACROPHAGE-TARGETED MOLECULAR MR IMAGING FOR MONITORING IMMUNOSUPPRESSION IN VX2 LIVER TUMORS POST-ABLATION

Yubei He (*Presenter*)
Han Xu, MSc (*Abstract Co-Author*)
Julian Rogasch (*Abstract Co-Author*)
Jing Guo, MD, PhD (*Abstract Co-Author*)
Eyk Schellenberger (*Abstract Co-Author*)
Luisa Heidemann (*Abstract Co-Author*)
Yu Liu (*Abstract Co-Author*)
Mathias Schannor (*Abstract Co-Author*)
Lynn J. Savic, MD (*Abstract Co-Author*)

PURPOSE

Incomplete thermal ablation can lead to increased tumor growth and resistance, potentially mediated by immunosuppressive pathways. This study aimed to non-invasively image tumor-associated macrophages (TAMs) after incomplete ablation using M2-like macrophage-targeted europium-doped very small superparamagnetic iron oxide nanoparticles (Eu-VSOP) in multiparametric(mp) PET/MRI.

METHODS AND MATERIALS

Twenty-four New Zealand white rabbits with VX2 liver tumors were divided into three groups (n=8/group): (1) untreated control; (2) short-term group undergoing incomplete microwave ablation (=50% of tumor) followed by 3T PET/MR imaging at 24 hours; (3) long-term group with the same treatment and imaging at two weeks. The imaging protocol included a) diffusion-weighted and contrast-enhanced imaging, b) T2-weighted imaging before and 24 hours after Eu-VSOP to visualize M2-like macrophages, and c) [18F]FDG-PET/MRI for monitoring tumor viability and metabolic activity. Signal intensity changes were analyzed in the tumor, liver, and peritumoral zone, with correlation to histopathology, laser ablation combined with inductively coupled plasma mass spectrometry (LA-ICP-MS), and Prussian blue staining of iron to confirm Eu-VSOP deposition in TAMs and their infiltration into the TME post-ablation. Statistical analyses included t-tests and RM-ANOVA.

RESULTS

mpMRI and PET/MR confirmed viability in both untreated and residual tumors after incomplete ablation. Following Eu-VSOP injection, T2-weighted MRI revealed a hypointense peritumoral rim, with peak signal changes and thickness observed two weeks post-ablation in the long-term group (signal ratio peritumoral/liver: pre-Eu-VSOP vs. 24h post-Eu-VSOP, $p<0.0001$; peritumoral rim thickness: control vs. long-term group, $p<0.01$). Ex vivo Prussian blue staining and LA-ICP-MS confirmed deposition of iron and europium from Eu-VSOP, respectively, in the peritumoral zone, co-localizing with the M2-marker CD206. Furthermore, HLA-DR, CD45, CD11b, and MMP-9 expression reflected a shift towards an immunosuppressive tumor milieu two weeks post-treatment.

CONCLUSION

The results demonstrate the potential of mpMRI, specifically Eu-VSOP, in monitoring TAM-driven immune evasion and tumor progression after ablation in a translational liver tumor model. The findings also suggest a critical role for M2-like macrophages in tumor recurrence, which could be targeted to restore immune permissiveness in liver cancer.

CLINICAL RELEVANCE/APPLICATION

This study developed a molecular imaging biomarker for non-invasive immune profiling in liver cancer, which could guide personalized treatment and monitoring strategies following locoregional and immunotherapies to overcome immune evasion.

Thomas M. Link, MD, PhD (*Abstract Co-Author*)

PURPOSE

The study aimed to compare the diagnostic performance of imaging of total hip arthroplasties performed at 0.55T (low-field) with 1.5 or 3T (high-field) field strength and with metal suppression sequences.

METHODS AND MATERIALS

Fourteen patients (aged 37-78, 5 males) with hip arthroplasties, 5 of which were bilateral, were examined at 0.55T and 1.5 or 3T. Hip scans were conducted using a 0.55T MRI system with the posterior spine coil and the anterior contour coil. The protocol included high pixel bandwidth (237-347 Hz/pixel) 2D turbo spin-echo sequences with vendor-provided denoising technique (Deep Resolve Boost) and SEMAC sequences: axial STIR/T1/T2, coronal PD/STIR, axial STIR SEMAC, coronal PD SEMAC. Anatomical structures, image quality, and pathologic findings were graded on quantitative "Likert" type scales independently by four musculoskeletal board-certified radiologists. Mixed-effects models were used to assess the association between field strength and outcomes of image quality, anatomic visualization, and pathology, accounting for repeated measures per person (both hips and scan types) and four readers.

RESULTS

All measurements for image quality and anatomic visualization with the high-field scans were associated with lower image quality scores compared to the low-field scans (coefficient range -1.88 to -0.55, 95% CI range -1.44 to -0.18, all p values <0.0037). The coefficient represents the difference in outcomes between low- and high-field with low field as the reference. High-field dedicated metal suppression sequences were also associated with lower image quality and anatomic visualization scores compared to the low-field scans (coefficient range -1.536 to -0.556, 95% CI -1.197 to -0.181, p<0.0037). All measurements for visualized pathology in adjacent bone on high-field scans were associated with lower image quality scores compared to low-field scans. On metal-suppressed images evaluating for pathology in adjacent bone, the adjusted mean score was 2.61(95% CI 2.27 to 2.96) for low-field scans and 1.93 for high-field scans (95% CI 1.61 to 2.25), with a p-value of <0.0001, indicating a statistically significant difference in diagnostic confidence.

CONCLUSION

Overall, and with dedicated metal suppression sequences, 0.55T had a better diagnostic performance in total hip arthroplasties for image quality with better visualization of anatomic structures and for certain pathologies such as adjacent bone abnormalities.

CLINICAL RELEVANCE/APPLICATION

This work demonstrated that lower-field MRI at 0.55T and metal suppression sequences had significantly higher image quality and anatomic visualization than high-field MRI in patients who underwent total hip arthroplasties.

W7-SSMK09-2 DIAGNOSTIC PERFORMANCE OF INTRAVOXEL INCOHERENT MOTION IMAGING IN EVALUATING SACROILIITIS ACTIVITY IN AXIAL SPONDYLARTHRITIS: A META-ANALYSIS

Peyman Mirghaderi, MD, MPH (*Presenter*)
Parya Valizadeh (*Abstract Co-Author*)
Payam Jannatdoust (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic accuracy of intravoxel incoherent motion (IVIM) MRI parameters in differentiating active from inactive sacroiliitis and distinguishing sacroiliitis from healthy controls in patients with axial spondyloarthritis (axSpA).

METHODS AND MATERIALS

This systematic review and meta-analysis followed PRISMA guidelines. A comprehensive search of PubMed, Embase, Scopus, and Web of Science (up to September 2024) identified studies reporting on IVIM-derived parameters, including Dslow (true diffusion), Dfast (pseudodiffusion), and perfusion fraction (f), for sacroiliitis assessment. Data from eligible studies were extracted to calculate pooled sensitivity, specificity, and area under the curve (AUC) using a bivariate random-effects model. Heterogeneity was assessed using the I^2 statistic.

RESULTS

Six studies, including 541 participants (178 with active sacroiliitis, 277 with inactive disease, and 86 healthy controls), met the inclusion criteria. Dslow demonstrated the highest diagnostic accuracy. For active versus inactive sacroiliitis, pooled sensitivity was 86.3% (95% CI: 77.0-92.2%), specificity was 88.1% (95% CI: 76.6-94.4%), and AUC was 0.93 (95% CI: 0.81-0.96). For active sacroiliitis versus healthy controls, Dslow achieved sensitivity of 89.3% (95% CI: 79.4%-94.8%), specificity

of 96.3% (95% CI: 88.8%-98.8%), and AUC of 0.98 (95% CI: 0.89-0.98). For inactive sacroiliitis versus controls, Dslow showed a pooled sensitivity of 59.0% (95% CI: 33.0%-80.9%), specificity of 82.9% (95% CI: 31.7%-98.1%), and AUC of 0.72 (95% CI: 0.49-0.89). Dfast and f had lower accuracy across comparisons, with pooled AUCs below 0.85. High heterogeneity was noted in most subgroups.

CONCLUSION

IVIM, particularly the Dslow parameter, demonstrates consistent and high diagnostic accuracy for detecting active inflammation in sacroiliitis. Its non-contrast nature and quantitative capabilities may support its role in axSpA evaluation and disease monitoring. Larger studies are needed to confirm its clinical use.

CLINICAL RELEVANCE/APPLICATION

This meta-analysis provides evidence that IVIM, especially Dslow, offers a contrast-free approach to evaluating sacroiliitis activity in axSpA. It may be a useful alternative in clinical settings where gadolinium administration is not feasible or desirable.

W7-SSMK09-3 THICK AND TELLING: HIP CAPSULE THICKNESS AS A CLUE TO INFLAMMATORY DISEASE

Fabio Yoshimura, MD (*Presenter*)
Adham A. Castro, MD (*Abstract Co-Author*)
Frederico C. Miranda, MD (*Abstract Co-Author*)
Erina M. Nagaya, MD (*Abstract Co-Author*)
Jessyca Otoni, MD (*Abstract Co-Author*)
Camila De Paula Silva, MD (*Abstract Co-Author*)
Durval D. Santos, MD (*Abstract Co-Author*)
Laercio A. Rosemberg, MD, PhD (*Abstract Co-Author*)
Atul K. Taneja, MD,PhD (*Abstract Co-Author*)

PURPOSE

The hip capsule may be thickened in nonspecific inflammatory conditions such as adhesive capsulitis, periarthritis, polymyalgia rheumatica. Using MRI, we primarily aimed to evaluate the hip capsule thickness and to provide best cut-off points to differentiate normal vs affected patients.

METHODS AND MATERIALS

Retrospective, cross-sectional and single-centered study,approved by the institutional board. We performed a database search with the inclusioncriteria of MRI of the hip performed with intravenous contrast and whose reportincluded the term “capsulitis”. Cases with known clinical diagnosis for inflammatoryprocess of the joint capsule were excluded, as were patients with imaging findings ofother underlying diseases. The control group consisted of patients without symptomsand normal laboratories. Images were assessed by three fellowship-trainedmusculoskeletal radiologists for quantitative and qualitative parameters. Measurementsof the largest thickness of the capsule were obtained in oblique sagittal, straightsagittal, coronal and axial. Qualitative parameters included capsular and pericapsularedema, enhancement, joint effusion, synovitis and subjective thickening. Inter-readeragreement and cut-off points were determined.

RESULTS

A total of 82 cases were found with the term “capsulitis” in the report. Forty-four cases were excluded, with the final study group comprising 38 subjects. Thecontrol group consisted of 51 subjects matched for age, gender and laterality. Inter-reader agreement ranged from moderate to almost perfect (0.57-0.87). Significantdifferences in hip capsule thickness between cases and controls were found in allplanes, with the sensitivity reaching up to 85.2% (anterior capsule measurement insagittal, mean of 6.27 mm in cases vs. 4.58 mm in controls) and specificity up to 84%(lateral measurement in coronal, mean of 6.53 mm in cases vs. 4.13 mm in controls).The prevalence of qualitative parameters was: 89.1%-91.9% edema, 97.2%-94.5%enhancement, 81.3% joint effusion, 89.2% synovitis, and 100% of capsular thickening.

CONCLUSION

When compared to control subjects, hip capsule is significantlythickened in patients affected by nonspecific inflammatory conditions, such as adhesivecapsulitis, periarthritis and/or polymyalgia rheumatica. Our study provided thresholdsfor MR imaging evaluation of normal vs abnormal hip capsules.

CLINICAL RELEVANCE/APPLICATION

Capsular thickening of the hip on MRI may serve as an early imaging marker of inflammatory arthropathies, especially spondyloarthritides. Its recognition, even in the absence of overt synovitis or bone marrow edema, can support earlier diagnosis and management, improving clinical outcomes through prompt therapeutic intervention.

W7-SSMK09-4 DIAGNOSTIC PERFORMANCE AND READER CONFIDENCE OF A CT-LIKE MRI SEQUENCE FOR ARCO CLASSIFICATION OF FEMORAL HEAD NECROSIS

Felix Herr, MD (*Presenter*)
Christian Alexander Dascalescu, MD (*Abstract Co-Author*)
Natascha Hohmann, MD (*Abstract Co-Author*)
Boj Friedrich F. Hoppe, MD (*Abstract Co-Author*)
Nina Hesse (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Paul Reidler, MD (*Abstract Co-Author*)

PURPOSE

To evaluate a novel CT-like MRI sequence regarding ARCO classification, reader confidence, and image quality, and to compare its diagnostic performance and agreement with standard MRI and radiography.

METHODS AND MATERIALS

In this retrospective study, 21 patients with suspected femoral head necrosis underwent MRI (T1, T2, CT-like) and radiography. Two experienced board-certified physicians (radiology and orthopedics) independently assessed ARCO stage (I-IV), reader confidence, and image quality. Confidence and quality were recorded on a binary numeric scale (1 = high/good, 2 = low/poor). Mean scores were calculated. Interrater reliability was evaluated using intraclass correlation coefficients (ICC); intermodality agreement was assessed via weighted Cohen’s Kappa. Wilcoxon signed-rank tests were used for paired comparisons.

RESULTS

For ARCO classification, the CT-like sequence had a higher mean score (2.23 ± 0.78) than radiography (1.75 ± 1.01, $p = 0.001$), T1 (2.08 ± 0.73, $p = 0.010$), and T2 (2.08 ± 0.69, $p = 0.023$), suggesting detection of more advanced stages. Reader confidence was significantly higher for the CT-like sequence (1.11 ± 0.25) vs. T1 (1.53 ± 0.47), T2 (1.50 ± 0.46), and X-ray (1.43 ± 0.37), all $p < 0.01$. Image quality was also superior for CT-like (1.11 ± 0.30) compared to T1 (1.86 ± 0.51) and T2 (1.75 ± 0.51), $p < 0.001$. Agreement in ARCO classification was excellent between CT-like and T1 (? = 0.904), T2 (? = 0.869), and substantial with X-ray (? = 0.709). Interrater reliability for ARCO was good to excellent for all modalities (ICC 0.82-0.93). For reader confidence, ICC was low (< 0.40) across modalities. For image quality, CT-like showed high interrater agreement (ICC = 0.84), while T1 (0.37) and T2 (0.29) showed poor agreement.

CONCLUSION

The CT-like MRI sequence demonstrated superior diagnostic performance in image quality and reader confidence, and may detect more advanced disease stages than conventional modalities. Its strong intermodality agreement and interrater reliability underscore its diagnostic value.

CLINICAL RELEVANCE/APPLICATION

This CT-like MRI sequence may enhance diagnostic accuracy and radiologist confidence in staging femoral head necrosis, while avoiding ionizing radiation and reducing the need for additional imaging.

W7-SSMK09-5 3D ISOTROPIC FASTVIEW MRI LOCALIZER ENABLES ACCURATE AND RELIABLE LOWER LIMB TORSION ASSESSMENT

Natascha Hohmann, MD (*Presenter*)
Felix Herr, MD (*Abstract Co-Author*)
Christian Alexander Dascalescu, MD (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Nina Hesse (*Abstract Co-Author*)
Paul Reidler, MD (*Abstract Co-Author*)

PURPOSE

To assess whether a 3D isotropic MRI localizer (FastView), acquired during continuous table movement, provides comparable accuracy to a dedicated MRI protocol for measuring femoral and tibial torsion, potentially reducing scan time and streamlining workflow.

METHODS AND MATERIALS

This retrospective single-center study included 60 legs from 30 patients (mean age 27.1 ± 11.5 years; 19 female, 11 male) who underwent both a dedicated torsion MRI protocol and a 3D isotropic FastView localizer. The FastView protocol featured 5×5×5 mm voxel resolution and 17.4-second acquisition time for an 80 cm limb. The dedicated MRI protocol included three regional T1 VIBE sequences (total scan time 6:54 min). Femoral torsion was measured using the Lee, Reikeras, Tomczak, and Murphy methods. Tibial torsion was calculated by summing angles between the tibial plateau and the pilon. Two readers assessed all cases independently. Statistical analysis included paired testing, intraclass correlation coefficients (ICC), Bland-Altman analysis, and Pearson correlation (R^2).

RESULTS

In total sixty legs were evaluated and no significant differences between all measured angles on the dedicated protocol and istrotropic FastView Localizer were observed ($p > 0.05$). Inter-modality reliability for femoral torsion was excellent across all methods (ICC: 0.91-0.96), with mean differences from -2.5 ± 2.5° to -3.1 ± 2.9° ($p < 0.001$). Tibial torsion also showed strong agreement (ICC: 0.91-0.94), with a mean difference of -1.6 ± 3.3° ($p = 0.012$). Inter-reader agreement was excellent (ICC: 0.95-0.99). Bland-Altman analysis showed narrow limits of agreement and strong correlation (R^2: 0.891-0.963).

CONCLUSION

FastView MRI demonstrated excellent agreement with the dedicated torsion protocol in all femoral and tibial measurements, despite small but significant differences. High ICCs, narrow LOAs, and strong correlations support its use as a valid alternative.

CLINICAL RELEVANCE/APPLICATION

The isotropic FastView MRI localizer offers a fast and resource-efficient method for assessing lower limb torsion, potentially replacing standard multi-sequence protocols in routine clinical practice.

W7-SSMK10-1 MRI AND CLINICAL OUTCOMES FOLLOWING MUSCLE-TENDON TRANSFER: UNDERSTANDING THE DISCREPANCY BETWEEN STRUCTURAL INTEGRITY AND FUNCTION

Maryam Soltanolkotabi, MD (*Presenter*)
Ghazaleh Safazadeh, MD,MPH (*Abstract Co-Author*)
Megan K. Mills, MD (*Abstract Co-Author*)

PURPOSE

To assess the relationship between postoperative tendon integrity on MRI and clinical outcomes following muscle-tendon transfer (MTT) for massive rotator cuff tears (MRCTs), and to incorporate preliminary electromyographic (EMG) findings to evaluate neuromuscular function.

METHODS AND MATERIALS

15patients (mean age 57 ± 15 years, all male) who underwent MTT between 2017-2021 were retrospectively evaluated. 21 postoperative MRI examinations were reviewed, grading tendon integrity using the Sugaya classification and fatty infiltration using the Goutallier classification. Clinical outcomes included American Shoulder and Elbow Surgeons (ASES) scores, PROMIS upper extremity v1.2, Numeric Rating Scale (NRS) for pain, range of motion, and strength testing. Patients were stratified into two groups based on tendon integrity: Sugaya grades 1-2 (sufficient thickness) vs. grades 3-5 (insufficient thickness/discontinuity). Statistical analysis included paired t-tests and Spearman's correlation. Preliminary EMG data were analyzed for muscle activation patterns.

RESULTS

Across the cohort, ASES scores improved by a mean of +10 points ($p=0.49$), and NRS scores decreased by -1.5 points ($p=0.005$). Forward elevation improved by +24° ($p=0.09$), and abduction strength improved by +1 grade on the manual muscle testing scale ($p=0.013$). A significant positive correlation was observed between higher Sugaya grades and ASES scores (? > 0, $p<0.05$), indicating that patients with worse tendon integrity had better functional outcomes. Patients with insufficient tendon thickness (Sugaya grades 3-5) demonstrated significantly greater improvements in both ASES and NRS scores compared to those with sufficient tendon thickness (grades 1-2). Preliminary EMG data showed synchronous activation of transferred muscles with the contralateral side, suggesting functional neuromuscular adaptation despite incomplete structural repair.

CONCLUSION

Postoperative tendon discontinuity, as graded by Sugaya classification, paradoxically correlates with superior functional outcomes following MTT for MRCT. Preliminary EMG findings support that neuromuscular reorganization may underlie these improvements, challenging traditional assumptions regarding the role of structural integrity in postoperative success.

CLINICAL RELEVANCE/APPLICATION

Radiologists and surgeons should recognize that MRI evidence of tendon insufficiency post-transfer may not predict clinical failure. Multimodal postoperative evaluation, including functional and electrophysiologic assessment, may better guide patient management.

W7-SSMK10-2 BACK TO THE EDGE: THE HIDDEN ROLE OF GLENOID RETROVERSION IN POSTERIOR AND PAN-LABRAL TEARS

Sriram Rajan, MD, MBBS (*Presenter*)
Pooja Jain, MBBS (*Abstract Co-Author*)
Harsh Mahajan, MD, MBBS (*Abstract Co-Author*)

PURPOSE

The purpose of this study is to evaluate the relationship between glenoid retroversion and posterior rim dysplasia with the extent and pattern of labral tears. The hypothesis was that moderate to severe dysplasia and increased retroversion are associated with more extensive labral pathology including panlabral tears. (SLAP type IX).

METHODS AND MATERIALS

This retrospective study included 86 shoulder MRI studies performed between January 2024 and January 2025. The scans were retrieved from the institutional PACS database and were anonymized and randomized prior to evaluation. Exclusion criteria included poor image quality, infection, tumors, presence of metal hardware causing artifacts, and significant motion artifacts. After applying exclusion criteria, the final cohort consisted of 83 patients, comprising 41 females and 42 males, with an age range of 17 to 88 years. All MRI studies were independently reviewed by two musculoskeletal radiologists: one with 23 years of experience (SR) and the other with 8 years of experience (PJ). Cartilaginous and bony glenoid retroversion were measured on axial MR images and posteriro glenoid dysplasia was evaluated and scored as - 0 = no dysplasia, 1 = lazy-J pattern, and 2 = delta pattern. The location of meniscal tears were scored as anteroinferior, posteroinferior, posterosuperior, extended and panlabral tears. Discrepancies were resolved by consensus and by arthroscopic follow up.

RESULTS

Glenoid dysplasia was seen in 28.9% patients (24 out of 83 patients) and Glenoid dysplasia increased odds of posterosuperior tears 14-fold (OR = 14.1, $p = 0.004$) compared to normal glenoids. Glenoid retroversion >8° was seen in 20.48% (18 out of 83 patients) and was significantly correlated with posterosuperior labral tears ($r = 0.31$, $p = 0.005$) and panlabral tears ($r = 0.33$, $p = 0.003$). 80% of panlabral tears occurred in patients with retroversion >8° (mean 9.4° vs. 5.6° in others, $p = 0.002$). Posterosuperior labrum was most vulnerable (23.2% tear prevalence), with 75% of severe dysplasia cases affected. Males trended toward higher retroversion angles (6.8° vs. 5.5°, $p = 0.08$), though tear rates did not differ by gender ($p = 0.36$).

CONCLUSION

Glenoid retroversion greater than 8 degrees and glenoid dysplasia increased the chances of posterior labral tears, as well as panlabral tears. The incidence of both glenoid retroversion and glenoid rim dysplasia are sufficiently frequent that they should be looked for in routine shoulder MR study

CLINICAL RELEVANCE/APPLICATION

Glenoid retroversion and glenoid rim dysplasia predispose patients to posterior and panlabral tears. Identification of version and dysplasia is crucial for management of these patients.

W7-SSMK10-3 IMAGING PREDICTORS OF ACROMIAL FRACTURES FOLLOWING REVERSE TOTAL SHOULDER ARTHROPLASTY

Heidi J. Horan-Henderson, MD (*Presenter*)
Ghazaleh Safazadeh, MD,MPH (*Abstract Co-Author*)
Madison Gardner (*Abstract Co-Author*)
Nathan Barber (*Abstract Co-Author*)
Kendon Holdaway (*Abstract Co-Author*)
Maryam Soltanolkotabi, MD (*Abstract Co-Author*)

PURPOSE

Acromial fractures (AcFx) are a complication after reverse total shoulder arthroplasty (RTSA), associated with pain, impaired shoulder function, and prosthesis failure. Predictors of AcFx risk are poorly defined. Morphologic features and prosthesis position may influence mechanics of the scapular spine and acromion, thereby increasing susceptibility to AcFx. This study sought to identify imaging-based patient and prosthesis characteristics that predict AcFx risk post-RTSA.

METHODS AND MATERIALS

A retrospective case-control study was done on patients who underwent RTSA at a single large tertiary institution between January 2020 and July 2024, with >10 months of follow-up. Exclusion criteria included revision arthroplasty, pre-existing bone lesions, AcFx before RTSA or from postoperative trauma, insufficient imaging, and displaced humeral fractures. Non-displaced fractures were included if surgical approach was not altered. AcFx were classified using the Levy classification. Subjects were matched 1:2 (case:control) by age and sex. Covariates included BMI, bone demineralization, inflammatory arthropathy, diabetic and smoking status, as well as acromial morphometrics (length and thickness) and preoperative glenoid-to-greater tuberosity distance. Prosthesis-related factors were evaluated by measuring humeral and glenoid lateralization and calculating global offset. Descriptive analyses and multivariable logistic regression were performed.

RESULTS

After screening 718 RTSAs, 36 (6.8%) AcFx cases were identified among 526 procedures. Mean time to fracture was 4.6±4 months, with 78% occurring within six months. Using the Levy classification, 61% were Type 1 fractures, 33% Type 2, and 6% Type 3. The AcFx group and matched controls (n=72) were 80% female, with a mean age of 70±9 years. AcFx patients had a higher prevalence of bone demineralization (47% vs. 26%, p=0.03), shorter acromial length (34.7 vs. 37.5 mm, p=0.053), and less humeral lateralization (15.6 vs. 18 mm, p=0.038). Multivariable logistic regression_ adjusting for age, sex, BMI, acromion measurements, and humeral lateralization_trended toward significance for bone demineralization (OR 2.56, p=0.059), shorter acromial length (OR 0.93, p=0.083), and reduced humeral lateralization (OR 0.92, p=0.075).

CONCLUSION

Shorter acromial length and reduced humeral lateralization are associated with increased risk of AcFx after RTSA. These features could be predictive of postoperative AcFx, alerting radiologists to higher-risk patients and prompting closer postoperative surveillance.

CLINICAL RELEVANCE/APPLICATION

AcFx are an important post-RTSA complication. Shorter acromial length and reduced humeral lateralization may guide postoperative monitoring.

W7-SSMK10-4 BRIDGING THE GAP: MRI COMPARISON OF THE ROTATOR CABLE AND CRESCENT WITH INTACT AND TORN CUFF

Sriram Rajan, MD, MBBS (*Presenter*)
Pooja Jain, MBBS (*Abstract Co-Author*)
Harsh Mahajan, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To investigate the thickness of the cuff at the level of cable, contrasted with the cuff at the rotator crescent, in patients of different ages, in normal cuffs and in patients with articular surface partial tears. In addition, we wanted to note if the cable is well seen in patients with full thickness tears.

METHODS AND MATERIALS

102 consecutive MR shoulders referred for various indications were extracted from the PACS between January 2024 to January 2025. Studies were excluded for poor quality of scan, infections, tumors, metal artefact and motion artefacts and a total of 83 studies were then anonymized and randomized and read by two observers with 23 years (SR) and 8 years (PJ) of experience. Age range noted of the patients were from 17-88 years of age, with 41 female and 32 male patients. Scans were read for the cuff thickness at the rotator Cable (RCt), and cuff thickness at Rotator Crescent (RCrt), thickness of cable (Ct), Width of rotator cable (RCw) and width of Rotator Crescent (RCrw). The anatomy of the rotator cable was confirmed with triangulation. Additionally, presence of supraspinatus tendon tear in the insertional footprint or critical zone was marked as absent (0), partial thickness tear (1) or full thickness tear (2) . The data was collated and statistical analysis was done.

RESULTS

Rotator cable was visualized in all patients, with and without cuff disease and at all ages. Rotator cable and crescent thickness were ~30% thinner in cuff disease vs. normal cuff group ($p < 0.001$).Crescent width reduced by 26.5% in cuff disease (9.8mm ? 7.2mm, $p < 0.001$) while rotator cable width showed no significant difference ($p = 0.43$)Crescent thickness =2.7 mm predicted cuff disease with 82% sensitivity (AUC = 0.79, $p < 0.001$)Patients >60 years had thinner cables (3.3 ± 1.1mm vs. 4.1 ± 0.8mm, $p = 0.003$) regardless of group

CONCLUSION

The rotator cable can be visualized in all cuffs, especially with careful analysis and triangulation. Rotator crescent showed thinning with age, with relative thickening/ absence of thinning of the rotator cable. Thickening of the rotator cable (absolute thickness increase) was not seen in the normal ageing cases.

CLINICAL RELEVANCE/APPLICATION

The presence of the rotator cable has been linked with near normal abduction in patients with full thickness supraspinatus tendon tears, if the rotator cable attachments were intact, and if the axial plane stabilizers (the infraspinatus and subscapularis tendons) were intact. Visualization of the rotator cable in normal and abnormal scans is essential to prognosticate cuff tears, and to decide on management.

W7-SSMK10-5 A TALE OF TWO TEARS: INFRASPINATUS ATROPHY IN SUPRASPINATUS VS INFRASPINATUS TENDON INJURIES

Sriram Rajan, MD, MBBS (*Presenter*)
Pooja Jain, MBBS (*Abstract Co-Author*)
Harsh Mahajan, MD, MBBS (*Abstract Co-Author*)

PURPOSE

To compare the extent of infraspinatus muscle atrophy in patients with isolated supraspinatus tendon tears versus those with infraspinatus tendon tears, in order to determine how tear location influences secondary muscle degeneration.

METHODS AND MATERIALS

MR studies of 86 patients from January 2024 to January 2025, for varying indications were extracted from PACS, anonymized and randomized. Patient demographics were- Age range from 17-88 years of age, with 41 female and 32 male patients. MRI images were independently reviewed by two observers with 23 years (SR) and 8 years(PJ) of experience and read by consensus. Tendon integrity was assessed on coronal and axial FSPD images at three locations: the SSP insertion, the SSP critical zone, and the IS tendon. Tears were graded as- 0 - normal tendon, 1 - tendinopathy, 2 - partial-thickness tear (pTT), and 3 - full-thickness tear (FTT). Fatty infiltration of the supraspinatus and infraspinatus muscles was scored using the Goutallier classification on sagittal T1-weighted MRI.

RESULTS

Infraspinatus muscle fatty infiltration is strongly associated with infraspinatus tendon tears, with 13.8% of partial-thickness and 40.0% of full-thickness tears showing Goutallier grade =2, while no fatty infiltration was observed in grade 0-1 cases. The Odds ratio for developing infraspinatus fatty infiltration in the presence of a tear is very high. Infraspinatus fatty infiltration is absent in isolated supraspinatus tears, with 0% of patients showing Goutallier grade =2 when the infraspinatus tendon is intact. Supraspinatus tendon tears (with ISP tears) contribute modestly to infraspinatus fatty infiltration, increasing its occurrence from 6.4% in patients without SSP tears to 9.1% in those with SSP tears (grade =2). Supraspinatus fatty infiltration is more frequent with higher-grade tears at the insertion site, seen in 10.0% of partial-thickness and 14.3% of full-thickness tears.

CONCLUSION

Infraspinatus muscle fatty infiltration in our study was not seen in any case with supraspinatus tendon tear. Supraspinatus with infraspinatus tendon tears do contribute to infraspinatus fatty infiltration.

CLINICAL RELEVANCE/APPLICATION

Defining the infraspinatus tendon footprint helps in identifying infraspinatus tendon tear. The larger infraspinatus tendon insertional footprint is probably responsible for previously reported cases of infraspinatus muscle fatty infiltration with supraspinatus tendon tears

W7-SSNR11-1 MULTI-MODAL GRAPH-BASED MACHINE LEARNING FOR PREDICTING SURGICAL OUTCOME IN EPILEPSY PATIENTS

Syeda Abeera Amir, BS (*Presenter*)
Syed M. Anwar, PhD (*Abstract Co-Author*)

PURPOSE

Reliable prediction of seizure outcomes after surgical intervention is essential for personalized epilepsy treatment planning. While traditional predictive methods rely heavily on clinical expertise, advanced imaging analysis using artificial intelligence offers new opportunities for outcome prediction. This study presents a novel deep learning-based spatio-temporal graph neural network (ST-GNN) model that integrates structural MRI with stereo electroencephalography (sEEG) data to predict post-surgical seizure reduction.

METHODS AND MATERIALS

We performed multimodal co-registration between preoperative CT and postoperative MRI to localize sEEG electrode positions within brain anatomy, enabling accurate spatial mapping of electrophysiological activity to structural regions. A total of 10 pediatric patients with sEEG contacts in the thalamus were considered, where data from multiple ictal events was used to train the model. Our ST-GNN model integrates local and global connectivity using graph convolutions with multi-scale attention mechanisms to capture patterns between difficult-to-study regions such as the thalamus and cortical/subcortical regions, with the co-registered imaging data providing critical spatial context for electrode contacts and anatomical connectivity mapping. The ST-GNN model was designed to process this multimodal data by creating graph representations where nodes represent brain regions identified on MRI and edges capture both structural connections and functional connections from sEEG.

RESULTS

The multimodal ST-GNN model achieved 90.4% accuracy for seizure-wise prediction and 75.4% accuracy for patient-wise prediction, significantly outperforming single-modality approaches. Edge-level importance analysis identified the thalamus-insula structural pathway as a key predictor of surgical success.

CONCLUSION

Our findings underscore the potential of new connectivity-based deep learning models leveraging multimodal data for enhancing the prediction of seizure outcomes and tailoring treatment planning for epilepsy. Our multi-modal approach can help inform AI-assisted personalized epilepsy treatment planning.

CLINICAL RELEVANCE/APPLICATION

This study will lay the groundwork for analysing SEEG data for treatment planning when treating pediatric epilepsy.

W7-SSNR11-3 FUNCTIONAL GRADIENT MAPPING REVEALS MULTINETWORK REORGANIZATION IN DRUG-NAÏVE CHILDREN WITH CENTROTEMPORAL SPIKES SELF-LIMITED EPILEPSY: A MACHINE LEARNING APPROACH FOR EARLY NEUROIMAGING BIOMARKER DISCOVERY

Dinglan Yang (*Presenter*)
Linfeng Song (*Abstract Co-Author*)
Lin Jiang (*Abstract Co-Author*)

PURPOSE

This study aimed to investigate hierarchical brain organization abnormalities in drug-naïve children with self-limited epilepsy with centrotemporal spikes (SeLECTS), using functional gradient mapping and machine learning to explore early neuroimaging biomarkers.

METHODS AND MATERIALS

33drug-naïve SeLECTS patients and 32 matched healthy controls underwent resting-state fMRI. Voxel-wise functional gradients were computed within the Yeo 7-network template using diffusion embedding. Seventeen gradient features were extracted from regions showing significant group differences and fed into four classifiers: linear SVM, RBF-SVM, random forest, and k-nearest neighbor. Performance was evaluated using leave-one-out and five-fold cross-validation based on AUC and accuracy

RESULTS

SeLECTS patients exhibited widespread network-specific gradient reorganization. The somatomotor network showed increased dispersion in the supplementary motor areas. In the default mode network, higher gradients were found in the anterior cingulate cortex and reduced gradients in the left middle temporal gyrus, negatively correlated with IQ. The DAN and limbic networks showed altered gradients in parietal, inferior temporal, hippocampal, and amygdala regions. VAN and visual networks exhibited disrupted attention-perception coupling. Top-ranking features included LIM_Temporal_Pole_Sup_R (11.1%) and DAN_Temporal_Inf_R (10.5%). Linear SVM showed the best performance (AUC = 0.97559).

CONCLUSION

Functional gradient analysis revealed early multinetwork alterations in SeLECTS. Gradient-based features demonstrated high classification accuracy and relevance to cognition, supporting their potential as non-invasive imaging biomarkers for early diagnosis and individualized intervention in pediatric epilepsy.

CLINICAL RELEVANCE/APPLICATION

This study provides evidence that functional gradient mapping can reveal early, network-specific brain reorganization in drug-naïve children with SeLECTS. The identified gradient-based features, particularly within somatomotor, limbic, and attention-related networks, demonstrate strong diagnostic potential when incorporated into a

machine learning framework. These findings support the use of non-invasive functional gradient analysis as an emerging neuroimaging biomarker approach for early detection, individualized diagnosis, and treatment planning in pediatric epilepsy. The high classification accuracy achieved by the linear SVM model suggests that this method may complement or potentially reduce reliance on invasive diagnostic procedures, facilitating timely intervention before irreversible cognitive decline occurs.

W7-SSNR11-5 REPORTING THE RISK: PREDICTIVE VALUE OF ADMISSION CT SIGNS FOR INTRAPARENCHYMAL HEMATOMA EXPANSION

Lua Irene Santamaria, MD (*Presenter*)
Udane Perez Ibarrondo, MD (*Abstract Co-Author*)
Marta Alaia Montes Zubia, MD (*Abstract Co-Author*)
Olivia Maria Rodriguez San Vicente (*Abstract Co-Author*)
Ainara Dolado Llorente, MEd (*Abstract Co-Author*)

PURPOSE

To assess the association between specific radiological signs on baseline non-contrast and contrast-enhanced CT and hematoma expansion in patients with primary spontaneous intraparenchymal hemorrhage, aiming to identify imaging markers that may be relevant for early prognosis and reporting.

METHODS AND MATERIALS

We conducted a retrospective study including 100 patients with primary spontaneous intraparenchymal hemorrhage and a follow-up CT within 72 hours. Secondary causes of bleeding were excluded. Demographic, clinical, and imaging variables were analyzed. The radiological assessment included findings from both non-contrast and contrast-enhanced CT, focusing on imaging markers potentially associated with hematoma expansion: hematoma volume, intraventricular extension, herniation signs, hematoma margins, and specific CT signs such as spot sign, leakage sign, spot-tail sign, island sign, satellite sign, blend sign, swirl sign, black hole sign, intralesional hypodensities, fluid-blood level, and subarachnoid hemorrhage. Descriptive and bivariate analyses were performed. A multivariable logistic regression model was developed to identify independent predictors of hematoma expansion. Model performance and calibration are being evaluated using standard statistical tests and ROC analysis.

RESULTS

Preliminary analysis showed a statistically significant association between hematoma expansion and three key imaging features on initial CT: hematoma volume, the presence of the spot sign, and the swirl sign. All three remained independent predictors in multivariable analysis. Evaluation of final model performance and interobserver agreement is ongoing and expected to further support the reliability of these findings.

CONCLUSION

Initial CT offers more than just a snapshot—it provides prognostic insight. Imaging markers such as spot sign, swirl sign, and hematoma volume emerged as independent predictors of early hematoma expansion in primary spontaneous intracerebral hemorrhage. While this study focused exclusively on radiologic features, these early signs hold promise for integration into structured radiology reporting and may guide timely, targeted clinical action.

CLINICAL RELEVANCE/APPLICATION

Hematoma expansion affects up to one-third of patients with primary spontaneous ICH and is a leading determinant of early neurological deterioration and poor outcomes. Identifying predictive CT signs at presentation empowers radiologists to flag high-risk cases, optimize clinical decision-making, and potentially reduce morbidity and mortality through tailored intervention. Integrating these imaging markers into routine radiology reports may play a key role in shifting the clinical trajectory of these patients.

W7-SSNR11-6 CORPUS CALLOSUM WHITE MATTER INTEGRITY RELATED TO SYMPTOM PRESENTATION AND CONCURRENT POST-TRAUMATIC STRESS DISORDER IN MILD TRAUMATIC BRAIN INJURY PATIENTS

Priya Santhanam, PhD (*Presenter*)
Thomas Knoblauch, MS (*Abstract Co-Author*)
Alan Rodriguez, MD (*Abstract Co-Author*)
Leo Germin, MD (*Abstract Co-Author*)
Enrico Fazzini, DO,PhD (*Abstract Co-Author*)
Travis H. Snyder, DO (*Abstract Co-Author*)

PURPOSE

This study aims to compare diffusion tensor imaging (DTI) findings in mild traumatic brain injury (mTBI) patients with or without post-concussive symptomology and post-traumatic stress disorder (PTSD).

METHODS AND MATERIALS

Civilian patients (n=451; mean age 43 years, range 13-82) with clinically diagnosed mTBI underwent DTI imaging and clinical evaluation. Commonly reported mTBI symptoms (headache, balance problems, cognitive deficits, fatigue, anxiety, depression, emotional lability) were noted, and mTBI+PTSD group was designated using DSM-V diagnostic criteria for evaluation of PTSD. For DTI image analysis (Olea Sphere v3.0 SP12), the corpus callosum (CC) and subregions were hand-traced for each individual patient (Figure), and fractional anisotropy (FA) mean values were obtained across these regions. FA was compared between patients with mTBI only and those with mTBI+PTSD by Mann-Whitney U test, while symptom load between groups was compared by Fisher's exact test. Association between FA and individual symptoms as well as symptom load were examined by ANOVA and general linear modeling (SPSS v.29).

RESULTS

FA was significantly lower for mTBI+PTSD patients in the whole CC ($p<0.001$) as well as in the anterior/inferior ($p=0.003$), anterior ($p<0.001$), mid-body ($p=0.006$), posterior ($p=0.007$), and posterior/inferior ($p=0.017$) subregions individually. When symptom effects were modeled with age and PTSD status as covariates, only fatigue was significantly related to total CC FA ($p=0.044$), while age and/or PTSD status accounted for FA for all other symptoms. The mTBI+PTSD patients had more symptoms ($p<0.001$) as compared to those with mTBI only (Figure). Further, there was an inverse association between regional FA and symptom count in many CC regions, with (anterior/inferior: $p=0.002$; mid-body: $p<0.001$; posterior: $p=0.048$) and without (total CC: $p=0.020$; anterior/inferior: $p<0.001$; anterior: $p=0.05$; mid-body: $p<0.001$; posterior-inferior: $p=0.002$) adjusting for age and PTSD status.

CONCLUSION

Overall, symptomatic mTBI patients had lower white matter integrity in the CC than asymptomatic patients. Additionally, patients with mTBI+PTSD had more symptoms and reduced CC white matter integrity as compared to patients with mTBI only. Regardless of PTSD status, symptom load was associated with FA in mTBI patients. The presence of specific symptoms and symptom load may be sensitive metrics reflective of PTSD status for identifying mTBI patients with compromised white matter integrity in the CC.

CLINICAL RELEVANCE/APPLICATION

Compromised corpus callosum white matter integrity in concurrent mTBI and PTSD patients is related to post-concussive symptom presentation and burden.

W7-SSNR12-2 DEEP RESOLVE BOOST IN 2D MRI: A DOUBLE-EDGED SWORD

Arsany H. Hakim, MD (*Presenter*)
Roman Rohner, MD (*Abstract Co-Author*)
Anna Winklehner (*Abstract Co-Author*)
Jean-Benoit Rossel (*Abstract Co-Author*)
Christian Lehmann (*Abstract Co-Author*)
Roland Wiest (*Abstract Co-Author*)
Jan Gralla, MD (*Abstract Co-Author*)
Eike I. Piechowiak, MD (*Abstract Co-Author*)

PURPOSE

Deep Resolve Boost (DRB) is a deep learning-based reconstruction method that enables reduced acquisition times and improved image quality in MRI. However, its influence on diagnostic performance - particularly regarding artifact burden and anatomical structure delineation - remains insufficiently studied. This study aimed to assess the clinical utility and limitations of DRB in 2D MRI sequence in neuroradiology.

METHODS AND MATERIALS

The investigated DRB-enhanced sequences are FDA-cleared and CE-marked for clinical use. The local ethics committee granted an exemption from formal ethical approval. In this quality assessment study, 256 paired 2D sequences were obtained from 200 patients undergoing routine MRI. For each examination, both standard and DRB-accelerated sequences were acquired in the same session using identical scanner settings, surface coil, sequence parameters, slice thickness, and orientation. Image quality, anatomical structure delineation, artifact presence, and lesion conspicuity were independently rated by two blinded readers.

RESULTS

DRB sequences were rated as having good or fair image quality in 94.5% of cases, with image quality improved or unchanged compared to standard sequences in 95.7% of examinations. However, anatomical delineation—particularly of the brainstem, hippocampus, cerebellum, and deep gray matter—was consistently inferior in DRB images. Artifacts were more pronounced in 27.3% and newly introduced in 84.8% of DRB sequences, with the brainstem, cerebellum, and deep gray matter being most frequently affected. Artifact types included motion, noise, ghosting, pulsation, and blurring. Lesion conspicuity was rated as equivalent in 91.6% of cases, with improvements in 7.2% and degradation in 1.2%.

CONCLUSION

DRB allows significant acceleration of 2D MRI while preserving overall image quality and lesion detectability. Nonetheless, limitations include increased artifact burden, the emergence of new artifacts, and compromised anatomical delineation in specific brain regions.

CLINICAL RELEVANCE/APPLICATION

The presence of artifacts, along with reduced delineation of certain anatomical structures underscores the necessity for cautious indication-specific implementation of DRB. A balanced imaging protocol incorporating both standard and DRB sequences is advisable to maintain diagnostic confidence and minimize the risk of misinterpretation, particularly in clinical contexts that demand high anatomical precision, such as epilepsy work-up, or brainstem evaluation. Radiologists should be familiar with DRB-associated artifacts and their typical anatomical distribution to mitigate the risk of misinterpretation and to avoid diagnostic errors in clinical practice.

W7-SSNR12-3 MOTION-INFORMED 3D DEEP LEARNING RECONSTRUCTION IN PATIENTS WITH COGNITIVE IMPAIRMENT

Shohei Fujita, MD, PhD (*Presenter*)
Daniel Polak (*Abstract Co-Author*)
Marcel D. Nickel (*Abstract Co-Author*)
Daniel N. Splitthoff (*Abstract Co-Author*)
YANTU HUANG (*Abstract Co-Author*)
Nelson H. Gil JR, MD, PhD (*Abstract Co-Author*)
Sittaya Buathong, MD (*Abstract Co-Author*)
Chen-Hua Chiang, MD (*Abstract Co-Author*)
Wei-Ching Lo (*Abstract Co-Author*)
Bryan Clifford, PhD (*Abstract Co-Author*)
Steve Cauley, PhD (*Abstract Co-Author*)
John Conklin, MD, MSc (*Abstract Co-Author*)
Susie Y. Huang, MD, PhD (*Abstract Co-Author*)

PURPOSE

Most deep learning (DL) reconstruction techniques improve signal-to-noise ratio but lack explicit mechanisms to correct for motion. To validate a DL reconstruction method that integrates retrospective motion correction into the reconstruction pipeline for three-dimensional (3D) T1-weighted brain MRI.

METHODS AND MATERIALS

This prospective, intra-individual comparison study included a controlled-motion cohort of healthy volunteers and a clinical cohort of patients undergoing evaluation for memory loss. Each cohort was scanned at distinct outpatient imaging sites between October 2022 and August 2023 in staggered periods. All participants underwent 4-fold under-sampled 3D magnetization-prepared rapid gradient-echo imaging with integrated Scout Accelerated Motion Estimation and Reduction (SAMER) acquisition.

Image volumes were reconstructed using standard-of-care methods and the proposed motion-informed DL approach. Unlike approaches that apply motion correction and DL reconstruction independently/sequentially, our method incorporates motion information directly into the forward model of the unrolled network. Quantitative morphometric accuracy was assessed by comparing brain segmentation results of instructed-motion scans to motion-free reference scans in the healthy volunteers. Image quality was rated by two board-certified neuroradiologists using a five-point Likert scale. Statistical analysis included Wilcoxon tests and intraclass correlation coefficients.

RESULTS

A total of 41 participants (15 women [37%]; mean age, 58 years) and 154 image volumes were evaluated. The DL-based method with integrated motion correction significantly reduced segmentation error under moderate and severe motion (12.4% to 3.5% and 44.2% to 12.5%, respectively; $p < .001$). Visual ratings showed improved scores across all criteria compared with standard reconstructions (overall image quality, 4.26 ± 0.72 vs. 3.59 ± 0.82; $p < .001$). In 47% of cases, motion artifact severity was improved following DL-based processing. Inter-reader agreement ranged from moderate to substantial.

CONCLUSION

Motion-informed DL reconstruction improved both morphometric accuracy and perceived image quality in 3D T1-weighted brain MRI. This technique may enhance diagnostic utility and reduce scan failure rates in motion-prone patients with cognitive impairment.

CLINICAL RELEVANCE/APPLICATION

In patients with cognitive decline, this technique statistically significantly improved image quality and postprocessing reliability, reducing scan failures and repeat imaging, lowering costs, and contributing to better patient care.

W7-SSNR12-4 LOW-IODINE-DOSE BRAIN COMPUTED TOMOGRAPHY ANGIOGRAPHY USING ARTIFICIAL INTELLIGENCE-BASED CONTRAST BOOSTING AND CONTRAST-ENHANCEMENT BOOST TECHNIQUES

Chuluunbaatar Otgonbaatar, MD (*Presenter*)
Huijin Song, PhD (*Abstract Co-Author*)
Inpyeong Hwang, MD (*Abstract Co-Author*)
Tae Jin Yun, MD (*Abstract Co-Author*)
Myung Seok Yoo (*Abstract Co-Author*)
Hackjoon Shim, PhD (*Abstract Co-Author*)
Chul-Ho Sohn, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility and effectiveness of contrast-enhancement (CE) boost and artificial intelligence-based contrast-boosting (AI-based boost) techniques in improving image quality in brain CT angiography (CTA) using a low-dose contrast media, compared to a standard-dose protocol.

METHODS AND MATERIALS

This retrospective single-center study included 32 patients who underwent brain CTA. Sixteen patients received a standard contrast dose (60 mL), while the remaining 16 received a low-dose (30 mL). The low-dose group images were further processed using CE-boost and AI-based boost techniques. Quantitative image parameters—including image noise, CT attenuation, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), noise power spectrum (NPS), and image sharpness evaluated by full width at half maximum (FWHM)—were measured and compared.

RESULTS

There were no significant differences in quantitative image metrics between the standard (5.92 ± 0.80)- and low-dose group (5.48 ± 1.26). Both the CE-boost and AI-based boost techniques in the low-dose group significantly improved CT attenuation (617.20 ± 154.10 vs. 683.40 ± 175.70 vs. 442.80 ± 110.40), reduced image noise (3.47 ± 0.89 vs. 3.97 ± 0.99 vs. 5.92 ± 0.80), and increased SNR (87.10 ± 25.01 vs. 71.47 ± 16.74 vs. 56.42 ± 10.95) and CNR (164.30 ± 65.67 vs. 144.70 ± 44.64 vs. 57.59 ± 17.16) compared to the standard-dose group. The CE-boost method demonstrated lower noise magnitude and a reduced peak in the NPS compared to the AI-based boost. Boost methods significantly improved image sharpness, as measured by FWHM, compared to the standard-dose group. The combination of AI-based boost with CE-boost images in the low-dose group resulted in the superior quantitative image quality, with the highest CT attenuation, lowest image noise, and greatest sharpness.

CONCLUSION

Both CE-boost and AI-based boost methods in the low-dose contrast group resulted in superior image quality compared to the standard-dose protocol. The combined use of CE-boost and AI-based boost methods allows for significant image quality enhancement in brain CTA performed with low-dose contrast media.

CLINICAL RELEVANCE/APPLICATION

The use of CE-boost and AI-based boost methods appears to be an effective strategy for reducing the required amount of contrast media, thereby supporting efforts to minimize the risk of contrast-induced nephrotoxicity.

W7-SSPD04-3 CHILDREN ARE NOT SMALL ADULTS! A SYSTEMATIC REVIEW OF THE PERFORMANCE OF ADULT-TRAINED RADIOLOGY AI MODELS IN PEDIATRIC IMAGING

Rachel Ivy, BS (*Presenter*)
James Pierce (*Abstract Co-Author*)
Krutik Nigam (*Abstract Co-Author*)
Aditya Kulkarni, BEng, MSc (*Abstract Co-Author*)
Paul H. Yi, MD (*Abstract Co-Author*)

PURPOSE

Because few radiology AI models are designed specifically for children, AI researchers and vendors have proposed repurposing adult-trained models for pediatric use. However, the performance and safety of this approach remain unclear. We conducted a systematic review of the scientific literature to evaluate how adult-trained radiology AI models perform when tested in children.

METHODS AND MATERIALS

We performed a systematic review of PubMed for all original scientific articles published through 11/1/2024 to identify original studies evaluating the performance of adult-trained radiology AI models tested on pediatric imaging. Two reviewers independently screened studies according to PRISMA guidelines. For each included article, we extracted data on the clinical use case, model performance in adults vs. children, and strategies used to improve pediatric performance (e.g., fine-tuning). Descriptive statistics were used to summarize findings.

RESULTS

Of 2132 articles identified, 15 met inclusion criteria for full-text review. These studies covered a range of AI tasks, including segmentation (n=8), object detection (n=4), and classification (n=3). In nearly all cases, adult-trained models performed worse on pediatric data compared to adults. Only two models—both organ segmentation tasks on CT—showed statistically similar performance between adult and pediatric datasets. The degree of AI performance drop from adults to children varied widely. Some were modest (e.g., chest x-ray pneumonia classification AURO decreased from 0.95 in adults to 0.82 in children in one study), while others were substantial (e.g., CT-based pulmonary nodule detection sensitivity dropped from 96% in adults to 53% in children in another study). Six studies tested fine-tuning adult-trained AI models using limited pediatric data; 5 of these showed statistically significant improvements, though none exceeded the original performance on adults.

CONCLUSION

Adult-trained radiology AI models generally perform worse when applied to pediatric imaging, reinforcing the fact that children are not simply small adults and raising important safety concerns. While fine-tuning with limited pediatric data can improve performance, it does not fully close the gap. These findings underscore the need for dedicated pediatric imaging datasets and the development of pediatric-specific AI tools to ensure safe, effective care for children.

CLINICAL RELEVANCE/APPLICATION

Repurposing adult-trained radiology AI models for use in children may compromise diagnostic performance and safety. These findings highlight the need for developing pediatric-specific AI tools to ensure reliable care for this vulnerable population.

W7-SSPD04-5 QUALITY AND SAFETY OF CONDUCTING MAGNETIC RESONANCE ENTEROGRAPHY WITH ORAL CONTRAST UNDER GENERAL ANESTHESIA IN PEDIATRIC PATIENTS

Mohannad E. Elgamal, MBBS (*Presenter*)
Youck Jen Siu Navarro, MD (*Abstract Co-Author*)
Shyam Sunder B. Venkatakrishna, MBBS (*Abstract Co-Author*)
Rebecca Dennis, DO (*Abstract Co-Author*)
Elizabeth Drum (*Abstract Co-Author*)
Monica Williams (*Abstract Co-Author*)
Sudha A. Anupindi, MD (*Abstract Co-Author*)

PURPOSE

Magnetic resonance enterography (MRE) with oral contrast has become a necessary imaging modality for diagnosing various abnormalities. A challenge faced in younger patients is cooperation and oral contrast tolerance, commonly seen in patients with neurodevelopmental disorders. General anesthesia (GA) becomes essential for optimal imaging, ensuring patient safety and comfort. This study describes our experience with conducting MREs under GA in high-risk pediatric patients and aims to demonstrate the safety and success of this practice.

METHODS AND MATERIALS

Retrospective data from 71 MRE scans were collected from our electronic medical records. All scans were performed under GA, administered via endotracheal intubation. Pediatric anesthesiologists provided supporting variables such as length of anesthesia and American Society of Anesthesiologists (ASA) risk assessment scores. Oral contrast was dosed at 10 ml/kg administered 1 hour prior to the scan via a nasogastric tube. MREs scans were blindly reviewed by 3 pediatric radiologists, assessing the quality of the images and progression of oral contrast. Descriptive statistics were analyzed.

RESULTS

44 patients were male. The median age was 7.6 years old (0.8-20.9). The major indication for MRE was IBD work-up (33) followed by evaluation of small bowel obstruction (12). The leading indications for undergoing GA was "age under 6 years" (26), autism spectrum disorder (13), and patients with neurodevelopmental delay (9). Post-anesthesia incidents occurred in 2 patients, one of which had a sore throat after extubation, and another had respiratory decompensation following a recent pneumonia. No patient had documented aspiration events. 63% of patients had an ASA score =3. The median GA run time was 169 minutes (118-311), while the median scan time was 55 (25-131). All readers rated the quality of the study as either non-diagnostic, inadequate, adequate, or very good. On average, the readers rated 51% of scans as adequate and 21% as very good. No scans were found to be inadequate and/or undiagnosable. Readers also found 38% of scans to demonstrate good progression, adequate opacification, and no motion artifacts. All readers agree that the primary limitation to the quality was the poor progression of contrast to the small bowel (23%).

CONCLUSION

This study highlights our positive experience performing MREs with oral contrast under GA in high-risk pediatric patients. The procedures were conducted safely, with no instances of aspiration or serious immediate adverse events and adequate diagnostic images were obtained.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the safety and utility of GA when performing an MRE with oral contrast on pediatric patients.

W7-SSPD04-6 HOW CAR T-CELL THERAPY CAN IMPACT IMMUNE SYSTEM

Iryna Vasyliv, MD (*Presenter*)

PURPOSE

In the US by 2023, acute lymphoblastic leukemia (ALL) showed 6,660 new cases, 1,560 deaths, 5-year survival rate 67.5%. Chimeric antigen receptor (CAR) T-cell therapy is a new era in immunotherapy for ALL, shows 65%-90% complete response rates in patients. The impact of CAR T-cell therapy on the thymus remains unknown. The aim of the study was to investigate thymus size changes after CAR T-cell therapy, explore the associated clinical conditions, and assess survival differences for patients following CAR T-cell therapy.

METHODS AND MATERIALS

A single-center retrospective study of patients who underwent CAR T-cell therapy for ALL between 2015 and 2023.We measured the volume of the thymus on pre- and post-CAR T-cell chest CT scans of 20 patients (median [IQR] age, 18 [11] years; 11 females). We divided patients into two groups, who did (group 1) or did not (group 2) demonstrate increase in thymus size after therapy. Clinical and survival data were collected. We used the Wilcoxon signed-rank test or Fisher's exact test for group comparisons and analyzed event-free survival data.

RESULTS

7 of 20 patients (35%, group 1) showed increase in thymus volume (pre- vs. post-CAR T-cell thymus volume; 5.01 [2.18] cm^3 vs. 20.87 [19.86] cm^3, p=0.01), while 13 patients (65%, group 2) showed no increase in thymus volume (pre- vs. post-CAR T-cell thymus volume; 3.01 [13.42] cm^3 vs. 2.09 [8.34] cm^3, p=0.01). Patients in group 1 showed a higher rate of event-free survival compared to those in group 2 (p=0.003).

CONCLUSION

In patients with ALL, increased thymus size after CAR T-cell therapy was associated with younger age and improved clinical outcomes.

CLINICAL RELEVANCE/APPLICATION

Thymic regrowth after CAR T-cell therapy may serve as a radiologic marker of immune system recovery. Increased thymus size post-therapy is associated with better outcomes. Quantitative evaluation of thymus volume on chest CT can provide valuable prognostic information following CAR T-cell therapy. Radiologists should be aware of post-treatment thymic changes, particularly in pediatric populations, to avoid misinterpretation as mediastinal pathology or disease recurrence

W7-SSPH11-1 PHYSICS-BASED EVALUATION OF MULTI-MATERIAL 3D PRINTED CT PHANTOMS FROM CLINICAL PCD-CT IMAGE DATA

Soeren Jasper (*Presenter*)
Thomas G. Flohr, PhD (*Abstract Co-Author*)
Thomas Allmendinger, PhD (*Abstract Co-Author*)
Ido Bitan, BSC (*Abstract Co-Author*)
Bibi Martens, MD (*Abstract Co-Author*)
Cecile Crompvoets-Jeukens, PhD (*Abstract Co-Author*)
Joachim E. Wildberger, MD, PhD (*Abstract Co-Author*)

PURPOSE

Physics-based evaluation of CT phantoms created using a novel 3D printing technique, aiming to accurately replicate a measured CT image volume in terms of anatomical structures and CT numbers, along with the development of a framework to model spectral behavior.

METHODS AND MATERIALS

Using PolyJet photopolymer 3D printing (VoxelPrint, Stratasys Ltd.) with three base materials of different CT numbers, we printed three discs (40 mm thick, 170 mm diameter) with high-contrast edges, homogeneous regions, and base material inserts. One disc was based on a geometric description (disc 1), the others on 70 keV virtual monoenergetic images (VMI) of disc 1 acquired on a Photon Counting Detector CT (PCD-CT) (NAEOTOM Alpha, Siemens Healthineers) at 120 kVp, reconstructed with medium-sharp kernel Br48 (disc 2) or sharp kernel Qr68 (disc 3). Additionally, we printed an adult abdomen phantom from a 120 kVp portal venous patient scan on a PCD-CT. We scanned the discs on a PCD-CT (120 kVp, two energy thresholds) and reconstructed 70 keV VMIs using kernels Br40, Br48, and Br68. We evaluated edge spread functions (ESF) and compared them to theory, noise power spectra (NPS), CT numbers in VMIs, and CT numbers at low and high energy to calculate dual-energy ratios (DER). The same analysis was applied to the abdomen phantom (reconstructed as the patient scan: Br40, 3 mm slices) and to the original patient scan. We also developed a method to represent and print not only CT numbers but also DER of various tissues.

RESULTS

For Br40 and Br48, the ESF showed no significant differences between disc phantoms and theory. For the sharpest kernel (Br68), phantom 1 matched theory best, while phantoms 2 and 3 were less sharp. NPS was similar across all discs and kernels. In the abdomen phantom, both ESF and NPS matched the patient scan. CT numbers in the phantom were accurate except for values below -50 HU, due to the base materials. DER in the printed abdomen phantom deviated from the patient scan (e.g., bone: phantom 1.87, patient 1.51). DER of the three base materials differed widely (Material 1: 3.81; Material 2: 0.77; Material 3: 1.91), enabling modeling of various DER and CT numbers based on material combinations.

CONCLUSION

CT phantoms 3D printed from image volumes correctly represent the template images regarding image sharpness for soft and medium-sharp kernels, NPS and CT numbers higher than -50 HU. With an extension of the current printing technique the spectral behavior (DER) can also be more accurately represented.

CLINICAL RELEVANCE/APPLICATION

The development of spectrally accurate, anatomically realistic 3D-printed CT phantoms can provide a foundation for CT system testing, scan protocol optimization, and training and evaluation of advanced AI image processing algorithms.

W7-SSPH11-2 CONTRAST-DEPENDENT LOSS OF EDGE SHARPNESS IN LOW-CONTRAST TARGETS WITH INCREASING ITERATIVE RECONSTRUCTION STRENGTH

Yifang Zhou, PhD (*Presenter*)
Alexander W. Scott II, PhD (*Abstract Co-Author*)

PURPOSE

Iterative reconstruction (IR) methods are valuable for reducing dose in modern CT; however, IR methods have the effect of reducing lesion edge sharpness (spatial resolution). Furthermore, the resolution degradation may be dependent on the contrast, so that marginally-visible lesions may have detectability further reduced with increasing IR. We propose that for targets with contrast < 100 HU the rate of edge degradation with increasing IR strength is contrast-dependent.

METHODS AND MATERIALS

A custom anthropomorphic liver phantom with two-phase iodinated lesions was scanned on a GE Revolution CT at 10 mGy CTDIvol with 2.5 mm slice thickness and 33 cm DFOV. IR was used to create image sets for ASIR-V 0-100% in 10% increments and for GE Deep Learning strengths low, medium, and high. 14 acquisitions were performed and averaged together using ImageJ. Oversampling was used in determining lesion edge sharpness: two line-profiles were drawn through the center of each lesion at ±4° to the horizontal, and points within two vertical pixels of the lines were projected onto them. Taking advantage of symmetry, each projected line was folded about the lesion center and both combined so as to align the lesion edge regions. To further reduce the impact of noise, data points with nearby projected coordinates were combined and a rolling average performed with a 1:3:1 weighting. The data was fitted with a sigmoid (Boltzmann) curve and the derivative of the edge function (LSF) was used to find the FWTM. The normalized FWTM for each ASIR-V image represented the edge degradation at that contrast level.

RESULTS

The rise in normalized FWTM from 0-100% ASIR-V was least for the highest contrast lesion (40%) and most for the lowest contrast lesion (179%). Lesions with contrast 50-60 HU had an average increase of 54% while lesions with contrast 25-45 HU had an average increase of 80%. Regarding Deep Learning, for the highest contrast

lesion the normalized FWTM was comparable between DL-low and 10% ASIR-V, while for the lowest contrast lesion the rise in normalized FWTM was comparable between DL-low and 50% ASIR-V.

CONCLUSION

The rate of edge-degradation with increasing IR strength was found to be greater for low-contrast lesions (< 25 HU) and less for high-contrast lesions (>50 HU). Furthermore, as the lesion contrast decreased from 100 - 10 HU, the spatial resolution equivalent of DLIR changed from 10% to 50% ASIR-V. This means that both ASIR-V and DLIR result in lesion edge spreading and the effect is most pronounced as lesion contrast trends toward 0 HU.

CLINICAL RELEVANCE/APPLICATION

It has been shown that increasing the IR strength increased the width of the edge region of a simulated clinically relevant liver lesion, and the amount of increase (loss of edge sharpness) was greatest for low contrast lesions.

W7-SSPH11-3 CT NUMBER CONSISTENCY ACROSS TUBE VOLTAGES: A COMPARATIVE STUDY BETWEEN PHOTON-COUNTING DETECTOR CT AND ENERGY-INTEGRATING DETECTOR CT

Ke Li, PhD (*Presenter*)
Corey Moffett (*Abstract Co-Author*)
Xinming Liu, PhD (*Abstract Co-Author*)
Megan C. Jacobsen, PhD (*Abstract Co-Author*)
Xiujiang J. Rong, PhD (*Abstract Co-Author*)
Corey T. Jensen, MD (*Abstract Co-Author*)
Eric P. Tamm, MD (*Abstract Co-Author*)
Frank Dong, PhD (*Abstract Co-Author*)

PURPOSE

Before the advent of photon-counting detector CT (PCD-CT), CT numbers were known to vary with the X-ray tube potential (kV), particularly for non-water-equivalent materials such as liver parenchyma, bones, and iodine. This variability poses challenges to tumor characterization and other quantitative imaging tasks, given the routine variation in kV settings across patients, contrast phases, scanner make and model. With PCD-CT, virtual monoenergetic images at a specified keV are the default image type, regardless of the acquisition kV. The aim of this study was to experimentally demonstrate the stability of CT numbers across different kV settings in PCD-CT.

METHODS AND MATERIALS

Four quantitative CT phantoms—including a Sun Nuclear MECT Phantom and a Kyoto Kagaku Abdomen Phantom—ranging in size from 20 cm to 40 cm in diameter, were scanned using two PCD-CT scanners (Siemens NAEOTOM Alpha) and two EID-CTs (Siemens SOMATOM Force and GE Revolution Apex). A total of 20 non-water-equivalent materials from these phantoms were included in the analysis. Images were acquired on each scanner at all available kV and beam filtration settings. For example, PCD-CT scans included kV settings of 70, 90, 120, and 140. For each phantom and kV setting, CTDIvol was matched between PCD-CT and EID-CT systems. Image reconstruction was performed according to each scanner's clinical head or body protocol. After measuring CT numbers of phantom materials, the equivalence of HU values across kV levels was assessed using the Two One-Sided Tests (TOST) method, with the level of significance set at 0.05 and the equivalence interval set at [-10%, +10%] of the reference HU value of the material established based on the 120 kV images.

RESULTS

For PCD-CTs, the null hypothesis of TOST (H0: non-equivalent mean HUs between kVs for a given material) was rejected ($p < 0.03$). The mean CT number difference between kVs was 2.9 HU, and the mean percentage difference was 1.9%. In contrast, for EID-CTs, the null hypothesis could not be rejected ($p > 0.1$) for any materials except for a Gammex 1.13 g/mL blood insert. The mean CT number difference between kVs was 35.6 HU, with a mean percentage difference of 21.4%.

CONCLUSION

By automatically generating virtual monoenergetic images from all exams, PCD-CT systems reduce the dependence of CT numbers on tube potential and beam filtration, significantly improving CT number consistency and supporting clinical tasks that rely on quantitative CT number measurement.

CLINICAL RELEVANCE/APPLICATION

Achieving highly stable CT numbers across varying kV settings and protocols improves the reliability of quantitative imaging tasks such as tumor characterization, perfusion assessment, and radiation therapy planning.

W7-SSPH11-4 DUAL-CONTRAST IODINE AND BISMUTH IMAGING WITH PHOTON-COUNTING CT: PHANTOM EVALUATION AND INITIAL CLINICAL PROOF OF CONCEPT

Diwash Thapa, MD (*Presenter*)
Vasantha Vasan, MD (*Abstract Co-Author*)
Richard W. Ahn, MD, PhD (*Abstract Co-Author*)
Yin Xi, PhD (*Abstract Co-Author*)
Xunbo Xu, ARRT (*Abstract Co-Author*)
Sophia Roth (*Abstract Co-Author*)
Lifeng Yu, PhD (*Abstract Co-Author*)
Liqiang Ren, PhD (*Abstract Co-Author*)

PURPOSE

To demonstrate the feasibility and accuracy of iodine and bismuth dual-contrast imaging using a clinical photon-counting CT (PCCT) system, validated through phantom experiments and initial patient experience.

METHODS AND MATERIALS

Four bismuth solutions (0.7, 1.3, 2.5, and 5.1 mg Bi/mL) were prepared by diluting Pepto-Bismol (10.1 mg Bi/mL, Procter & Gamble) with water and inserted into a multi-energy CT phantom (33 cm × 26 cm, Sun Nuclear) together with three iodine rods (1, 2, and 5 mg I/mL, Sun Nuclear). The phantom was scanned using a PCCT system (NAEOTOM Alpha, Siemens) at 140 kV with a radiation dose (CTDIvol: 8 mGy). With IRB approval, one patient undergoing routine contrast-enhanced abdomen-pelvis imaging for lung cancer surveillance (BMI: 24.1 kg/m²) was enrolled. The patient received two oral doses (30 mL each) of Pepto-Bismol: one 30 minutes before the scan and another immediately prior. Intravenous iodine contrast was administered per clinical protocol, consisting of 119 mL of Omnipaque (350 mg I/mL, GE), infused at 3 mL/s with saline flush. The scan was performed on the same PCCT with automatic exposure control (IQ level 147; average CTDIvol: 7.8 mGy) and manual tube voltage selection of 140 kV. PCCT low- and high-energy images (Qr44 kernel, QIR-3, 5.0 mm slice thickness) were reconstructed and exported. A custom three-material decomposition algorithm (iodine/bismuth/water) was applied to generate iodine and bismuth maps. Calibration derived from the phantom study was applied to patient data material decomposition. For the phantom study, mean iodine and bismuth concentrations were measured and linear regression analysis was performed to assess the correlation between nominal and measured concentrations. The patient images and decomposed maps were reviewed qualitatively by two radiologists to assess the efficacy of iodine and bismuth separation.

RESULTS

In the phantom study, all iodine and bismuth samples—including those at the lowest concentrations—were clearly differentiated and accurately quantified, with $R^2 > 0.99$. In the initial patient study, bismuth signals were distinctly visualized in the small bowel (corresponding to the first administered dose) and in the stomach (corresponding to the second administered dose).

CONCLUSION

Iodine and bismuth dual-contrast imaging can be accurately performed on a clinical PCCT system, as demonstrated in both the phantom study and initial patient experience.

CLINICAL RELEVANCE/APPLICATION

Accurate separation of iodine and bismuth using dual-contrast photon-counting CT may enable new diagnostic applications, such as simultaneous vascular and gastrointestinal imaging, offering enhanced contrast differentiation in clinical practice.

W7-SSPH11-5 ASSOCIATION BETWEEN DETECTABILITY INDEX AND VOLUMETRIC ACCURACY IN LOW-DOSE ENERGY-INTEGRATING AND PHOTON-COUNTING CT

Elsa Pimenta, MSc (*Presenter*)
Gisell Ruiz Boiset (*Abstract Co-Author*)
Alessandra Tomal, PhD (*Abstract Co-Author*)
Luuk J. Oostveen, DIPLPHYS (*Abstract Co-Author*)
Ioannis Sechopoulos, PhD (*Abstract Co-Author*)
Paulo Costa, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the association between the detectability index (d') from model observers, the accuracy (median relative error, MRE%) and precision (interquartile range of the relative errors, IQR%) of volumetric measurements of a synthetic ground-glass opacity (GGO) nodule in low-dose chest CT.

METHODS AND MATERIALS

CT scans were acquired at CTDI vol = 1.4 mGy using two scanners: a prototype CdZnTe photon-counting CT (PCCT) and a conventional energy-integrating CT (EICT, Aquilion One PRISM Edition), both from Canon Medical Systems. Six low-dose protocols were evaluated, combining deep learning reconstruction (DLR) with the LUNG kernel or hybrid-iterative reconstruction (HIR, AIDR 3D) with FC51, FC52, and FC86 kernels. Each protocol included ten acquisitions. The d' was computed from regions of interest in images of an anthropomorphic lung phantom containing a synthetic GGO nodule. A non-prewhitening model observer with the Eckstein eye filter was applied (zoom factor 1.5; 500 mm viewing distance). For each protocol, 30 individual d' values were computed, and the noise power spectrum was estimated from three slices, yielding 90 d' values per protocol; the median was used for analysis. Nodule volume was measured in 3D Slicer (v5.6.2) and compared to the ground truth (142 mm^3) determined by a µCT system (U-SPECT6CThr, MILabs B.V.).

RESULTS

A significant inverse linear relationship was found between d' and both the median MRE% and IQR%. The detectability index d' strongly predicted IQR% ($R^2 = 0.845$), with Pearson correlation coefficient (r) of -0.92, a 95% confidence interval (CI) of -0.99 to -0.42, and a p-value < 0.01. A moderately strong negative correlation was observed between d' and MRE% (r = -0.79, 95% CI: -0.98 to 0.05, p = 0.059), indicating a potential trend despite the limited sample size. Among the protocols, the PCCT/DLR/LUNG showed the highest detectability (d' = 13.8), lowest IQR% (2.6%), and MRE% (3.0%).The EICT/DLR/LUNG also showed high detectability (d’ = 10.8), low IQR% (5.2%) and MRE% (2.6%). Protocols using HIR showed median d' values of 6.3 - 9.7, with MRE% of 5.6 - 13.0%, and IQR% of 4.4 - 8.3%.

CONCLUSION

d' is inversely related to volumetric measurement error (MRE% and IQR%). Protocols utilizing DLR with LUNG kernel, particularly with PCCT, achieved the highest detectability and the lowest error.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the utility of d’ in protocol optimization to enhance diagnostic performance in low-dose CT imaging.

W7-SSPH11-6 IMAGE QUALITY ASSESSMENT OF ULTRA-HIGH-RESOLUTION PHOTON-COUNTING DETECTOR CT FOR LARGE ARTERY IMAGING IN CANCER PATIENTS WITH LOW RADIATION AND CONTRAST AGENT DOSES: A COMPARATIVE STUDY WITH ENERGY-INTEGRATING DETECTOR CT

Limin Lei, MD (*Presenter*)
Yuhan Zhou, MD (*Abstract Co-Author*)
Xiaoxu Guo, MD (*Abstract Co-Author*)
Zhihao Wang (*Abstract Co-Author*)
Yi Fan Guo (*Abstract Co-Author*)

PURPOSE

This study investigated the benefits of using ultra-high-resolution photon-counting detector CT (PCD-CT) with low radiation and low contrast agent doses, compared to conventional energy-integrating detector CT (EID-CT), for contrast-enhanced chest and abdominal imaging in patients with lung cancer.

METHODS AND MATERIALS

This prospective study enrolled a total of 200 patients with lung cancer who underwent ultra-high-resolution PCD-CT or EID-CT between June and September 2024. Participants were matched for age, sex, body mass index (BMI), and TNM stage. Two protocols were applied: a low-dose, ultra-high-resolution PCD-CT protocol (2.0 mL/s injection rate, 1.0 mL/kg of 320 mg iodine/mL) and a standard-dose EID-CT protocol (3.0 mL/s, 1.2 mL/kg of 350 mg iodine/mL). Radiation exposure, renal function, adverse events, and baseline lung cancer characteristics were recorded. Quantitative assessments of ascending aorta (AA), descending aorta (DA), and pulmonary artery (PA) included standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR).

RESULTS

The SD values of the PCD-CT group at 5 mm, 1 mm slice thicknesses during both phases were lower than those of the EID-CT group at corresponding slice thicknesses (all $P < 0.001$). The SD value of the PCD-CT 0.4 mm group was comparable to that of the EID-CT 1 mm group ($P > 0.05$). The PCD-CT 5 mm, 1mm group showed higher SNR and CNR compared to the EID-CT 5mm, 1 mm group. For the PCD-CT group at 0.4 mm, the arterial phase SNR and CNR values, except for the arterial phase PA, were slightly lower than those of the EID-CT group, with statistically significant differences ($P < 0.001$). For venous phase SNR and CNR values, the PCD-CT 0.4 mm group showed comparable results to the EID-CT 1 mm group, with no statistically significant differences ($P > 0.05$). For subjective scoring, the PCD-CT 0.4 mm group received a score of 5 for both "anatomical structures" and "vessel sharpness," despite exhibiting higher noise. The PCD-CT groups consistently achieved high ratings, with overall image quality and noise levels superior to those of the EID-CT group (5 [5, 5] vs. 4 [4, 5], all $P < 0.001$).

CONCLUSION

Low-dose ultra-high-resolution photon-counting CT significantly enhances large artery image quality and diagnostic confidence under reduced radiation and contrast agent dose conditions.

CLINICAL RELEVANCE/APPLICATION

Low-dose ultra-high-resolution photon-counting CT may offer improvements in image quality and diagnostic confidence for the detection of tumor-associated pulmonary embolism and large artery-related diseases.

PURPOSE

We describe the framework and data characteristics for establishing body region- and clinical indication-based diagnostic reference levels (DRL) and achievable doses (AD) for pediatric CT in Latin America.

METHODS AND MATERIALS

The LatinSafe and MGB collaboration project included 18 imaging sites from 8 countries in the Latin America, who contributed following data on 5890 pediatric patients (<19 years; F:M, 2650:3240): head (n=2,225 patients), chest (n=1606), abdomen-pelvis (AP, n=1387) or chest-abdomen-pelvis (CAP; n=672) CT. The following information was obtained for each submitted exam: patients' age at the time of scanning, sex, weight, clinical indication for CT, CT scanner information, scan factors (tube current and potential), and radiation dose descriptors [volume CT dose index (CTDIvol) and dose length product (DLP)]. We estimated overall and site-specific 50 th (AD) and 75 th (DRL) percentile CTDIvol and DLP separately for each body region and clinical indication. Non-normal dose data distributions were compared using the Kruskal-Wallis test.

RESULTS

Most CT exams in children regardless of age groups, were single-phase acquisition (78%) without or with intravenous contrast (head CT 94%; chest CT 82%; AP-CT 57%, CAP-CT 61%). There was a significant variation in CTDIvol and DLP between the participating sites for all body regions and clinical indications in all age groups (p=0.001). The protocol- and age group-matched Latin America protocol-based ADs and DRLs were significantly higher in all age groups than the US levels, without exception. The head, chest, and AP-CT and CAP-CT DLP DRLs were higher than the corresponding DLP DRLs in the US for 15/18 (83%), 16/18 (88%),14/17 (88%), and 12/14 (82%) of participating sites. There were significant differences in radiation doses across different CT scanner vendors (p<0.001). The Middle-low-income countries (MLICs) had significantly higher doses compared to middle- and high-income countries (HMIC): head CT (MLIC DLP: 310 vs 386 mGy.cm for HMIC), chest (MLIC DLP: 93 vs. 79 mGy.cm for HMIC), AP=CT (MLIC DLP: 231 vs. 185 mGy.cm for HMIC), CAP-CT (MLIC DLP: 559 vs. 239 mGy.cm for HMIC) CT exams (p=0.001)

CONCLUSION

Economic differences and scanner distribution have a profound effect on the variations and use of higher radiation doses across Latin America with higher radiation doses for children scanned in low-income countries as compared with the high- and middle-income countries.

CLINICAL RELEVANCE/APPLICATION

Dose optimization with clinical DRLs and education in Latin America must focus on the low-to-middle income countries with higher radiation doses, likely related to the use of older scanner technology and higher-dose CT protocols.

W7-SSPH12-2 FETAL DOSE IN PREGNANT CT PATIENTS: A COMPARISON OF FOUR SOFTWARE PACKAGES

Joel Greffier, PhD (*Presenter*)
Djamel Dabli (*Abstract Co-Author*)
Jean-Paul Beregi, MD, PhD (*Abstract Co-Author*)

PURPOSE

To compare the fetal dose (FD) as calculated by four different software packages for pregnant women who have undergone CT acquisitions directly exposing the whole fetus to X-rays.

METHODS AND MATERIALS

Pregnant women who underwent CT abdomen-pelvis and/or thorax-abdomen-pelvis acquisitions from February 2018 to May 2024 and for whom the uterine dose and/or FD was calculated by a medical physicist were retrospectively included. FDs were computed per CT acquisition with VirtualDose-CT™ (VDCT), Duke Organ Dose (DOD), fetaldose.org and Conceptus Dose Estimation (CODE) software, using phantoms taking the stage of pregnancy into account. FDs calculated by each software package were then compared.

RESULTS

A total of 51 pregnant women with a mean age of 30.2±5.7 years at 17.5±10.0 weeks of pregnancy were included. The mean number of CT acquisitions per pregnant patient was 1.4±0.7 with a mean CTDI vol of 6.77 ± 3.04 [2.34-15.64] mGy and FDs were computed for a total of 69 acquisitions. For all CT acquisitions, the median FD was 8.6 (6.8; 10.3) mGy for VDCT, 7.7 (6.1; 9.7) mGy for DOD, 6.3 (4.9; 7.6) mGy for fetaldose.org and 7.1 (4.6; 8.8) mGy for CODE. Differences between each software package were significant ($p<0.01$), except between VDCT and DOD ($p=0.025$) and between CODE and fetaldose.org ($p=0.15$). The concordance of calculated FD values between the software packages was poor (ICC<0.50), except between VDCT and CODE and between fetaldose.org and CODE.

CONCLUSION

• The choice of software used has an impact on the calculation of the FD, but it is not expected to alter pregnant patient management except for extreme cases where multiple CT exams are involved

CLINICAL RELEVANCE/APPLICATION

The results of the present study show that the 100 mGy limit cannot be reached by a single CT examination, and may only be reached for extreme cases in which the pregnant patient is subjected to multiple CT examinations with the whole fetus exposed primarily.

W7-SSPH12-3 PILOT STUDY TO COMPARE CT SCAN ORGAN AND EFFECTIVE DOSE ESTIMATES FROM RADIATION DOSE INDEX MONITORING SYSTEMS (RDIMS) USING A REFERENCE SET OF PATIENT DATASETS

Michael F. McNitt-Gray, PhD (*Presenter*)
Mark P. Supanich, PhD (*Abstract Co-Author*)
Adrian Howansky, PhD (*Abstract Co-Author*)
Maryam Bostani, PhD (*Abstract Co-Author*)
Grace Hyun Kim, PhD, MS (*Abstract Co-Author*)
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*)
Emily Marshall, PhD (*Abstract Co-Author*)

PURPOSE

Radiation Dose Index Monitoring Systems (RDIMs) track and report CT scanner output radiation dose indices (CTDI vol , DLP, SSDE). Many RDIMs now also report estimated organ doses and calculated effective dose (using estimated organ doses) for each CT scan. While scanner output indices are standardized, methods to estimate organ and effective doses are not. The purpose of this pilot study was to investigate the feasibility of performing direct comparisons of organ and effective dose estimates from several RDIMs using a reference set of patient datasets.

METHODS AND MATERIALS

Under IRB approval, seven reference datasets were deidentified: 4 routine thoracic scans (2 adult female, 2 adult male) and 3 routine abdomen/pelvis CT scans (2 adult female, 2 adult male). For each exam, the following data was provided: (a) Planning CT Radiograph; (b) Cross sectional CT image data; (c) Radiation Dose Structured Report (RDSR) and (d) Patient Protocol Page. Each site worked with their RDIM vendor to produce the organ and effective dose estimates for each case. Estimates were compared by calculating the mean value of each organ and effective dose across RDIMs and then the average absolute percent difference (AAPD) across estimates. This was repeated for each estimated organ and effective dose for each patient.

RESULTS

Three sites were able to provide data from two different RDIMs (two sites had the same RDIM product). Mean effective dose estimates across the seven reference datasets ranged from 5.94 to 10.92 mSV and AAPD of effective doses ranged from 12.4 to 42.8%. For thoracic scans, the AAPD were 20.2% and 25.6% for breast dose estimates of female patients and ranged from 15.5 to 33.1% for lung doses across all four scans. For the three abdomen/pelvis scans, the AAPD for colon ranged from 15.6 to 34.3%. Many other organs (stomach wall, uterus, bladder) showed larger differences, often exceeding 40%. For the two sites using the same RDIM product, AAPDs for thoracic scans were as low as 4.4-5.6% for lung dose and 5.2-6.7% for breast dose, but up to 36-49% in stomach dose in abd/pel scans.

CONCLUSION

This pilot study demonstrated the feasibility of performing direct comparisons of organ and effective dose estimates from RDIMs using a reference set of patient datasets. We observed a range of differences in effective dose estimates from 12-40% and a wider range for organ dose differences. Future work will investigate possible sources of these differences including RDIM set up parameters (e.g. protocol mapping).

CLINICAL RELEVANCE/APPLICATION

This initial study showed the feasibility of direct comparison of estimated effective dose and organ dose values between RDIMs. This will allow us to identify sources of these differences and establish expected ranges of variability for these estimates.

W7-SSPH12-4 LATINSAFE EFFORTS ON ESTABLISHING CLINICAL DIAGNOSTIC REFERENCE LEVELS (CDRL) IN LATIN AMERICA: RESULTS FROM 6094 PATIENTS FROM 6 COUNTRIES

Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)
Subba R. Digumarthy, MD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)

PURPOSE

Clinical indication-based diagnostic reference levels (cDRL) are important for evaluating the use of clinical indication-related information for radiation dose reduction and optimization. Under the LatinSafe auspices, we conducted a Latin American multicenter study to establish cDRLs for common CT indications for imaging the head, chest, and abdomen-pelvis (AP).

METHODS AND MATERIALS

Each institution obtained ethical committee approval. Besides an open call for data submission, LatinSafe communicated with regional and national radiologists, physicists, and technologists' societies and key imaging sites across Latin America to obtain data from private, public, and university hospitals. Each site provided de-identified patient data (age, weight, height and gender), clinical indications, scan protocols and factors, scanner technology details, and radiation doses (series and exam level CTDIvol and DLP values) in 2024-2025; at least 20-30 patients per body part and clinical indication (limited to head, chest, AP, chest-AP [CAP]). Before data analysis, dose information was filtered. For multi-acquisition exams, we used median CTDIvol and total DLP. Next, we obtained 50th (achievable doses/ADs) and 75th (DRLs) percentile of CTDIvol and DLP for body regions and clinical indications. Data were analyzed with Kruskal Wallis, and Mann-Whitney tests were used (p-value < 0.05)

RESULTS

The ongoing effort has collected and analyzed data from 6094 adult patients (F:M; 3572:2521, mean age: 54±19 years) who had head (n=2455), chest (n=2304) or AP (n=1334) CT examinations at imaging sites in 6 Latin American countries. The body region-specific DRLs for adult patients were head CT : CTDIvol [DLP]: 39.4 mGy [986.2 mGy.cm]; chest CT : CTDIvol [DLP]: 10.0 [533.5]; AP-CT : CTDIvol [DLP]: 15.1 [1088.6]. The DRLs for the main clinical indications for each body region are summarized in Table 1. There were significant differences in CTDIvol and DLP between the countries and participating sites ($p<0.05$). Conclusion: LatinSafe's ongoing project on establishing adult DRLs for different body parts and common clinical indications demonstrates the feasibility of such efforts in developing countries on an international scale. Compared to the US and EU DRLs, the series level CTDIvol are comparable in Latin America, but substantially higher DLP values suggest more frequent multiphase CT and longer scan lengths per exam.

CONCLUSION

Radiation doses need optimization and protocols analyses, clinical training course and a second data collection to determinate regional DRL in 2025.

CLINICAL RELEVANCE/APPLICATION

Radiologists and radiology personnel in Latin America must pay closer attention to scan length and scan phases for CT examinations to reduce the higher DLP values.

W7-SSPH12-5 EYE-LENS DOSE REDUCTION IN CRANIAL CT: DOSE EVALUATION OF EYE LENS PROTECTORS DESIGNED WITH ALTERNATIVE MATERIALS WHICH ARE EXPECTED TO REDUCE ARTIFACTS

Arthur P. Wunderlich, PhD (*Presenter*)
Tobias Benz (*Abstract Co-Author*)
Meinrad J. Beer, MD (*Abstract Co-Author*)

PURPOSE

Commercially available eye lens protectors are usually made from materials with high atomic numbers like bismuth. However, it is well-known that these protectors cause artifacts. The aim of this study is to determine whether the dose of eye lenses in cranial CTs can be reduced by protectors made from materials with lower atomic numbers, e.g. aluminum or polyvinyl chloride (PVC).

METHODS AND MATERIALS

Protectors were designed to reduce 30% of radiation like conventional protectors, and to cover eye lenses. Materials tested were bronze, aluminum and PVC. An anthropomorphic phantom was scanned with and without protectors in a Siemens Definition AS+ scanner using standard head protocols, protocols that reduce the eye lens dose by tube current modulation, and low-dose protocols. Dose was measured with TLDs at different positions in the head, including eye lenses and brain, to determine eye lens dose and effective dose. Dose values were compared between scan protocols and protectors.

RESULTS

Dose of the eye lenses was 50.2 mGy with the standard protocol without protector, 31.5 mGy (-37%) with a bismuth protector, 27.9 mGy (-44%) with bronze, 27.7 mGy (-45%) with aluminum and 25.5 mGy (-49%) with PVC. Without protectors, dose modulation reduced the eye lens dose to 34 mGy (-22%), and a low-dose protocol to 7 mGy (-86%). Percentage dose reduction was the same when protectors were used in combination with low-dose protocols or with tube current modulation. Eye lens dose could be reduced down to 3.55 mGy with a low-dose protocol and the PVC protector which means 93% dose reduction compared to a standard protocol without protector. Overall effective dose of the head was 1.41 mSv using a standard CT protocol without protector, 1.24 mSv (-12%) with a commercial protector and 1.31 mSv (-7%) with PVC, all with standard CT protocols.

CONCLUSION

Protectors made from materials with low atomic numbers reduced eye lens dose in cranial CT more effectively than the commercial protector tested. The fact that overall effective dose was lowest with the bismuth protector means that protectors made from materials with low atomic numbers are more efficient in reducing local eye lens dose while delivering sufficient dose to structures which are needed to be imaged. It has to be evaluated whether the probability for artifacts is lowered with these materials. Limitations: a) Single-center study using a single scanner. b) Dose reduction by removing eye lenses from primary beam by head flexion could not be simulated.

CLINICAL RELEVANCE/APPLICATION

The protectors presented are expected to reduce artifacts. If this is proved in a routine CT setting, protectors should be used in each and any cranial CT examination in order to reduce the dose of the eye lens.

W7-SSPH12-6 OXIDATIVE STRESS-MEDIATED DNA DAMAGE INDUCED BY IONIZING RADIATION IN MODERN TWO-PHASE CONTRAST-ENHANCED ABDOMEN AND PELVIS CT

PURPOSE

While CT aids diagnosis, leading to improved outcomes, it also exposes patients to ionizing radiation (IR), leading to DNA damage, primarily through an indirect pathway by reactive oxygen species. It was recently reported that, if current practices persist, CT-associated cancer could eventually account for 5% of all new cancer diagnoses annually. To subsequently propose an antioxidant-based radioprotective strategy, we aimed to characterize oxidative stress (OS) and DNA damage derived from modern CT equipment/protocol.

METHODS AND MATERIALS

Prospective observational study at our University Hospital, involving healthy volunteers (A) and patients with clinical indications for two-phase contrast-enhanced abdomen and pelvis CT (B). Biomarkers of OS and DNA damage were measured from blood samples collected at: TPRE, min 0; TPOST, 50-70 min after TPRE. CT occurred 5 min before TPOST. Differences between groups were analyzed with Student's t or Mann Whitney U tests for between-group cross-sectional comparisons and with paired Student's t or Wilcoxon tests for within-group longitudinal comparisons.

RESULTS

We recruited 35 subjects (n=17 A and 18 B). While age ($P<0.001$) and sex ($P=0.001$) were different between groups, body mass index ($P=0.30$) and TPRE DNA damage ($P=0.42$) were comparable. Patient-specific effective dose (ED) was 6.7 (6.2-9.0) mSv. OS biomarkers and DNA damage did not change between TPRE and TPOST in A ($P>0.05$ for all). In B, DNA damage increased significantly [15% (-15 to 60); $P<0.001$], which was associated to a consistent rise of antioxidant enzymes activities in similar fashion [10% (0 to 15), 15% (-2 to 38), and 26% (5 to 80) for glutathione peroxidase, superoxide dismutase, and catalase activities, respectively; $P<0.05$ for all].

CONCLUSION

At relatively low ED levels with modern equipment/protocols, we observed significant DNA damage increase, alongside increased enzymatic antioxidant defense activity.

CLINICAL RELEVANCE/APPLICATION

These results highlight the importance of investigating potential antioxidant-based preventive measures to mitigate CT associated DNA damage.

W7-STCE1-1 TRANSLATIONAL IMPACT OF MRI SEQUENCE SELECTION ON AMYLOID PET QUANTIFICATION USING NEXT-GENERATION HIGH-RESOLUTION SILICON PHOTOMULTIPLIER TIME-OF-FLIGHT BRAIN-DEDICATED PET SCANNER

Daisuke Morimoto, PhD, RT (*Presenter*)
Kohei Hanaoka (*Abstract Co-Author*)
Hina Yamamoto (*Abstract Co-Author*)
Takahiro Yamada, PhD (*Abstract Co-Author*)
Atsushi K. Kono, MD, PhD (*Abstract Co-Author*)
Hayato Kaida (*Abstract Co-Author*)
Kazunari Ishii, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to assess how MRI sequence selection—specifically fluid-attenuated inversion recovery (FLAIR) and susceptibility-weighted imaging (SWI)—affects Centiloid (CL) quantification in amyloid PET acquired with a high-resolution silicon photomultiplier-based time-of-flight PET system dedicated to the head (dhPET), using standard software. FLAIR and SWI are routinely acquired for detecting amyloid-related imaging abnormalities (ARIA), and in patients with mild cognitive impairment (MCI) or dementia who may struggle with long scan times, completing standard MRI protocols can be challenging. Although 3D T 1 -weighted imaging (T 1 WI) is conventionally used for CL calculation, FLAIR and SWI may be considered as alternative sequences in clinical practice, but their quantitative validity remains unclear.

METHODS AND MATERIALS

This retrospective, single-center study was approved by the institutional review board, with a waiver of informed consent. Between April 2024 and February 2025, a total of 25 consecutive patients (mean age: 74 years; range: 64-87 years) with clinically suspected MCI or dementia underwent 18 F-florbetapir PET using a dhPET (BresTome, Shimadzu Corp.) and brain MRI. 18 F-florbetapir PET images were visually rated as positive/negative by two experienced physicians. CL values were calculated using each of the 3D FLAIR and 3D SWI images and compared to those obtained from 3D T 1 -weighted images (3D T 1 WI), used as the reference. Wilcoxon signed-rank tests were applied with Bonferroni correction (adjusted $p < 0.05$).

RESULTS

Of the 25 subjects, 18 were visually amyloid-positive and 7 were negative. In the positive group, CL values based on 3D FLAIR [58.4 (IQR: 48.0-68.0)] and 3D SWI [53.7 (IQR: 39.8-66.3)] were significantly lower than those obtained from 3D T 1 WI [59.4 (IQR: 47.0-70.2)], with $p < 0.001$ for both comparisons. While in the negative group, CL values derived from 3D FLAIR [-1.2 (IQR: -20.6-1.3)] and 3D SWI [-3.5 (IQR: -21.1-1.3)] tended to be lower than those obtained from 3D T 1 WI [1.0 (IQR: -18.7-5.7)], although the difference was not significant ($p = 0.063$ for both comparisons).

CONCLUSION

FLAIR and SWI tend to underestimate Centiloid values compared to 3D T 1 WI, particularly in amyloid-positive individuals.

CLINICAL RELEVANCE/APPLICATION

MRI sequence selection significantly influences CL quantification in amyloid PET using a dhPET. In patients with MCI or dementia, who may struggle to remain motionless during scans, FLAIR and SWI may be considered as practical alternatives, though they carry a risk of underestimation. Consistent use of 3D T 1 WI is recommended for reliable longitudinal assessment. This study offers translational insight to support MRI protocol standardization and consistent CL interpretation in dementia care.

W7-STCE1-2 IMPLEMENTING ARTIFICIAL INTELLIGENCE METHODS FOR QUANTITATIVE HIGH-RISK PROSTATE CANCER EVALUATION USING TOTAL TUMOR VOLUME ESTIMATION FROM PSMA-PET IMAGING

Alessandro Delmonte, MSc (*Presenter*)
Galina Khachaturyan (*Abstract Co-Author*)
Joel Schaerer, PhD (*Abstract Co-Author*)
John G. Wolodzko, PhD (*Abstract Co-Author*)
Anu Bansal (*Abstract Co-Author*)
Emily Ebert (*Abstract Co-Author*)
Robert Scarimbolo (*Abstract Co-Author*)

PURPOSE

Quantitative disease evaluation by total tumor volume (TTV) estimation from prostate-specific membrane antigen (PSMA) PET/CT imaging has shown high diagnostic accuracy in high-risk prostate cancer (PCa) and is prognostic for overall survival. TTV can be used in theranostic studies and for evaluating response assessment using the quantitative RECIP framework, but effective adoption is limited by high burden required for manual image segmentation which may lead to variability in radiological assessment. We developed and deployed an artificial intelligence (AI) system enabling TTV estimation, supporting quantitative image analysis by precisely quantifying PSMA-positive lesions for PCa care and clinical trials.

METHODS AND MATERIALS

A novel AI-based segmentation method was integrated into an image reading platform with radiologist-in-the-loop for TTV segmentation, including organs and unspecific bone uptake contouring. Each AI identified potential PSMA-positive lesion was classified into bone, liver and soft tissue that can be reviewed and validated. For algorithm validation, 748 paired attenuation-corrected 68 Ga-PSMA-11 PET/CT images were retrospectively acquired, anonymized and manually annotated by board certified radiologists. AI-estimated TTV (aiTTV) was correlated with manual radiologist measurements (rTTV) by least squares analysis and Bland-Altmann limits of agreement (BA LoA). Agreement in SUV-derived biomarkers was measured using the intraclass correlation coefficient (ICC).

RESULTS

On the large-scale PCa validation dataset, aiTTV showed almost perfect correlation with rTTV (Pearson's r =.960 [95% CI: .954, .965]). Excellent agreement was found for both SUVmax (ICC: 0.77 [95% CI: 0.74, 0.80]) and SUVmean (ICC: 0.81 [95% CI: 0.71, 0.84]). Mean difference was 67.91 mL (SD: 299.67 mL; BA LoA: -519.03, 654.87 mL) and lesion-level precision was 87.42%. aiTTV was computed in under 15 minutes per subject, enabling efficient review and editing by radiologists to support consistent lesion contouring and classification.

CONCLUSION

The AI system enabled quantitative evaluation of PCa subjects in clinical trial settings and efficiently integrated AI lesion contouring with radiologist oversight. Remarkable performance in estimating TTV from 68 Ga-PSMA-11 PET/CT was confirmed by almost perfect correlation to manual measurements, very low bias and high precision, allowing for consistent disease burden estimation.

CLINICAL RELEVANCE/APPLICATION

The integration of AI-based PSMA-positive tumor volume estimation will allow quantitative patient prognosis and precise treatment response monitoring in prostate cancer care and theranostics, facilitating consistent quantitative assessment by radiologists in clinical settings.

W7-STCE1-3 DOES TEMPERATURE SETTING MATTER? EVALUATING DIAGNOSTIC ACCURACY AND QUALITYOF AI GENERATED CHEST RADIOGRAPH REPORTS

Ok Kyu Song, MD (*Presenter*)
Eun Kyoung Hong, MD, PhD (*Abstract Co-Author*)
Bardia Nadim, MD (*Abstract Co-Author*)
Zuby Syed, MD (*Abstract Co-Author*)
Chong Hyun Suh, MD, PhD (*Abstract Co-Author*)
SEUNGHO LEE (*Abstract Co-Author*)
Mark M. Hammer, MD (*Abstract Co-Author*)

PURPOSE

In language model-based report generation, the temperature parameter controls the sharpness of the output probability distribution, determining how deterministic or variable the generated text is. Therefore, we evaluated how varying temperature settings affect diagnostic accuracy, linguistic readability, and overall report quality in AI-generated chest radiograph interpretations.

METHODS AND MATERIALS

A multimodal foundation model fine-tuned on chest radiograph interpretation generated reports for 211 chest radiographs. Reports were generated at 17 temperature settings (0.0-1.6 in 0.1 increments), totaling 3,587. Diagnostic accuracy was evaluated by comparing predicted binary labels for 13 findings, automatically extracted from reports, to a consensus reference standard established by three radiologists. Readability was assessed using five metrics: Flesch-Kincaid Grade Level, Gunning Fog Index, Coleman-Liau Index, Automated Readability Index, and Word Count. Overall Grade Reading Level (OGRL) was computed as the mean of the first four. Temperature effects on diagnostic accuracy and readability were modeled using third-degree polynomial regression. Two radiologists independently assessed reports at five representative temperatures (0.0, 0.4, 0.8, 1.2, 1.6) for agreement (binary), hallucination presence (binary), and quality (5-point scale). Logistic and ordinal logistic regression were used to analyze trends.

RESULTS

Diagnostic accuracy declined with increasing temperature, with micro-accuracy decreasing from 85.5% at 0.0 to 83.0% at 1.6 ($R^2 = 0.005$). Accuracy loss was most evident in pleural effusion, nodule, and pneumothorax. Readability worsened as temperature increased, word count rose from 21 to 29, and OGRL increased from 9.5 at 0.0 to 11.9 at 16.0 ($R^2 = 0.040$). With increasing temperature, subjective evaluations showed a decline in radiologist agreement with the AI-generated report from 4.3% to 0.9% ($p = 0.04$), a drop in median quality scores from 2.0 to 1.0 ($p < 0.001$), and a rise in hallucination rates from 10.9% to 49.8% ($p < 0.001$).

CONCLUSION

Temperature setting significantly affects diagnostic accuracy, readability, and perceived quality of AI-generated chest radiograph reports. Lower temperatures improve factual reliability and radiologist agreement, while higher temperatures increase linguistic complexity and hallucination risk.

CLINICAL RELEVANCE/APPLICATION

Temperature is a critical factor in the clinical deployment of AI-generated radiology reports. Careful tuning of this parameter is essential to ensure safe, reliable, and effective integration of AI tools into clinical workflows.

W7-STCE2-1 MULTI-TIMEPOINT BREAST DCE-MRI IMAGES SYNTHESIS USING A MULTI-SEQUENCE FUSION NETWORK

Tianyu Zhang, PhD (*Presenter*)
Luyi Han (*Abstract Co-Author*)
Jarek Van Dijk (*Abstract Co-Author*)
Antonio Portaluri, MD (*Abstract Co-Author*)
Tao Tan (*Abstract Co-Author*)
Ritse M. Mann, MD, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the effectiveness of an AI-based multi-sequence fusion network (MSF-Net) for synthesizing high-quality multi-timepoint breast dynamic contrast-enhanced MRI (DCE-MRI) from non-contrast T1-weighted MRI and diffusion-weighted imaging (DWI), aiming to eliminate the need for contrast agents while preserving the diagnostic fidelity of standard DCE-MRI.

METHODS AND MATERIALS

A total of 3861 patients who underwent multi-parametric breast MRI between January 2014 and December 2024 at the Netherlands Cancer Institute (NKI) were retrospectively included in this study. Imaging protocols comprised T1-weighted MRI, multi-timepoint DCE-MRI, and multi-b-value DWI. The proposed MSF-Net was designed to synthesize wash-in and wash-out DCE-MRI images from T1-weighted pre-contrast MRI and DWI data. External validation was performed using two independent datasets: (1) 1018 patients from Radboud University Medical Center, (2) 719 patients from the publicly available I-SPY2 breast cancer imaging cohort. To assess image quality and fidelity, Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index Measure (SSIM), and Dice Similarity Coefficient (DSC) were employed. For DSC evaluation, tumor masks were segmented by breast radiologists on both synthesized and real DCE-MRI images in a subset of randomly selected 50 cases.

RESULTS

For the internal cohort, the synthesized wash-in images achieved a PSNR of 31.81 ± 1.89 and SSIM of 0.92 ± 0.03, and the wash-out images yielded a PSNR of 29.35 ± 1.98 and SSIM of 0.92 ± 0.06. External validation showed comparable performance. For Radboudumc cohort: wash-in PSNR 30.75 ± 1.72, SSIM 0.90 ± 0.04; for ISPY-2 cohort: wash-in PSNR 29.21 ± 1.55, SSIM 0.90 ± 0.03. In the randomly sampled evaluation set, tumor segmentation on synthesized DCE-MRI achieved a DSC of 0.81 ± 0.15, compared to ground truth segmentation on real DCE-MRI, demonstrating high spatial fidelity in tumor depiction.

CONCLUSION

The proposed MSF-Net enables accurate synthesis of multi-timepoint breast DCE-MRI images from non-contrast MRI data, effectively capturing contrast enhancement dynamics such as wash-in and wash-out. Validation across multiple independent datasets confirms the robustness and generalizability of the approach.

CLINICAL RELEVANCE/APPLICATION

This AI-driven method provides a fast, safe, and contrast-free alternative for breast DCE-MRI. By reducing patient exposure to contrast agents and shortening scan times, it promotes a more patient-friendly and environmentally sustainable imaging workflow—while maintaining diagnostic accuracy essential for clinical decision-making.

W7-STCE2-2 QUANTITATIVE CT IMAGING OF CORONARY PLAQUE BASED ON EFFECTIVE ATOMIC NUMBER IMAGE USING PHOTON-COUNTING CT

Takashi Asahara, PhD (*Presenter*)
Mana Mitani, BSc, RT (*Abstract Co-Author*)
Natsumi Kimoto, PhD (*Abstract Co-Author*)
Rina Nishigami (*Abstract Co-Author*)
Yusuke Morimitsu (*Abstract Co-Author*)
Noriaki Akagi, RT (*Abstract Co-Author*)
Toru Miyoshi (*Abstract Co-Author*)
Toshihiro Iguchi, MD (*Abstract Co-Author*)
Hiroaki Hayashi, PhD (*Abstract Co-Author*)

PURPOSE

Non-contrast coronary CT is widely used to assess cardiovascular risk by detecting calcified plaques. Conventional CT image analysis has been performed using the Agatston score , which classifies CT values into only five discrete levels . Recent advances in detector technology have led to the development of photon counting CT (PCCT) , which enables the acquisition of high-quality spectral data in cardiac imaging. The purpose of this study was to verify the feasibility and advantages of using effective atomic number (Z eff) images for plaque analysis. Z eff imaging provides continuous gradation for each voxel that is available precise analysis of plaque components .

METHODS AND MATERIALS

Z eff images were generated from PCCT data using an in-house algorithm . Two virtual monoenergetic images (VMIs) of low and high energies were reconstructed using the vendor’s application. Linear attenuation coefficient (μ) images were calculated from these VMIs, and their ratio was converted into Z eff value using a reference function to obtain the Z eff image. Coronary CT scans from 10 patients with a total of 64 plaques were analyzed. The Z eff score , defined as the sum of Z eff values within the plaque region, was calculated and compared with the conventional Agatston score.

RESULTS

Z eff images were generated using VMIs at 40 keV and 190 keV, and the resulting images showed low noise and high accuracy. In the clinical analysis, the Z eff score showed a strong positive correlation with the Agatston score (R = 0.99). We found that the number of voxels contributing to the Agatston score was approximately 39% lower than that contributing to the Z eff score. This indicates that the Agatston method only takes into account partial high-density calcification, whereas the Z eff score evaluates the entire plaque volume . In actual clinical data, differences between the proposed and the Agatston methods were observed in the analysis of cases with low- and high-density plaques.

CONCLUSION

Z eff imaging provides a continuous physical quantity and enables coronary plaque quantification without the use of thresholds. The Z eff score is expected to improve the risk assessment of cardiovascular disease.

CLINICAL RELEVANCE/APPLICATION

We believe that quantitative imaging with photon-counting CT can provide new clinical advantages over conventional coronary CT assessment. As a first step in applying this approach, we challenged the quantitative evaluation of calcified plaques using Z eff image. Our method allows quantification of the entire plaque volume on a voxel basis , including both low- and high-density components based on composition analysis. This study demonstrated the clinical usefulness of Z eff imaging for plaque evaluation and showed its potential to enhance the diagnostic value of non-contrast coronary CT .

BREE-2 CRYOABLATION IN BREAST CANCER CARE: EVIDENCE, ON-GOING TRIALS, AND FUTURE DIRECTIONS

Heather V. Garrett, MD (*Presenter*)
Michelle V. Lee, MD (*Abstract Co-Author*)
Tabassum Ahmad, MD (*Abstract Co-Author*)
Christina M. Doherty, MD (*Abstract Co-Author*)
Debbie L. Bennett, MD (*Abstract Co-Author*)

TEACHING POINTS

- US-guided cryoablation (CA) has emerged as a promising minimally invasive treatment for breast cancer. - Initial studies of CA for breast cancer were followed by wide local resection. Most CAs were successful in eliminating tumor, but unsuccessful ablation was associated with technical errors, poor visualization of the tumor by ultrasound, or larger tumors. - Phase II trials of CA for select breast cancers showed comparable results to lumpectomy. Additional studies are needed to further define the role of CA in breast cancer care. - On-going trials are evaluating CA in varying breast cancer contexts including DCIS, non-surgical patients, metastatic breast cancer, in combination with immunotherapy or vaccine therapy.

TABLE OF CONTENTS/OUTLINE

I . Introduction to CA for breast cancer. a . Available ablation modalities. b . Thermac trial - CA is safest and most effective c . Technique d . Mechanisms of action II . Initial studies of CA for breast cancer were followed by wide local resection. a . Most ablations successful b . Unsuccessful ablation associated with technical errors, poor visualization of the tumor, or larger tumors. III . Technologic advances in CA IV . Phase II trials of CA for breast cancer show comparable results to lumpectomy a . ICE3 trial, 5-year results b . Kawamoto et al, 5-year results c . FROST and PRECICE V . Phase III trial of CA for select breast cancer a . COOL-IT VI. Other potential indications for CA in breast cancer (on-going studies) a . Non-surgical patients -survival or QoL benefit? b . Metastatic Breast Cancer -benefit from reducing tumor burden? abscopal effect? c . DCIS -de-escalating care? d . CA with Immunotherapy -synergistic effect? e . CA with vaccine therapy -synergistic effect? VII . Summary

BREE-3 POSITION PERFECT: A PICTORIAL REVIEW OF POSITIONING STANDARDS AND WHY THEY MATTER

Ashley I. Huppe, MD (*Presenter*)
Elijah Burton, MD (*Abstract Co-Author*)
Allison Aripoli, MD (*Abstract Co-Author*)
Jessica K. Peterson, MD (*Abstract Co-Author*)
Camron B. Smith, DO (*Abstract Co-Author*)
Molly Hill, MD (*Abstract Co-Author*)
Lindsay Miner, MD (*Abstract Co-Author*)
Hannah L. Singhal, MD (*Abstract Co-Author*)
Onalisa D. Winblad, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Mammography positioning is a key component of image quality. 2. Inadequate positioning can lead to radiologist misinterpretation and potentially missed cancers or extent of disease. 3. Updated legislation under the Enhancing Quality Using the Inspection Program (EQUIP) emphasizes the role of the lead interpreting physician (LIP) in continuously maintaining standards which includes routine practice auditing. 4. The interpreting physician (IP) bears the case-by-case responsibility for quality, imaging adequacy and providing feedback. 5. In a case-based format, we will review examples of appropriate technical repeats related to positioning, when less than ideal position is acceptable, and potentially missed cancers related to positioning.

TABLE OF CONTENTS/OUTLINE

1) Introduction - breast positioning as a key factor in quality mammography a) Mammography Quality Standards Act (MQSA) i) EQUIP initiative ii) Requirements to maintain certifications and accreditation b) Mammography quality and effect on physician interpretation: literature review 2) Basics of mammography positioning a) Standard views and tissue visualization b) Utilization of extra views 3) Potential technical challenges which may result in positioning limitations a) Patient mobility factors b) Surgical history c) Congenital deformities 4) Case review to provide specific examples of the following: a) Recalls for technical repeat (4-6 cases) b) Acceptable imperfect positioning (4-6 cases) c) Cancers missed or potentially missed due to positioning (4-6 cases) 5) Conclusion

BREE-4 BREAST ELASTOGRAPHY DEMYSTIFIED: A PRACTICAL GUIDE TO STRAIN AND SHEAR WAVE TECHNIQUES

Heni D. Skaf, MD (*Abstract Co-Author*)
Raquel S. Rabelo (*Abstract Co-Author*)
Ana Laura C. Silva, MD (*Abstract Co-Author*)

TEACHING POINTS

Breast elastography is a valuable adjunct to conventional ultrasound, offering a non-invasive evaluation of tissue stiffness to aid in distinguishing benign from malignant lesions. As imaging gains importance in breast diagnostics, mastering elastography enhances accuracy and confidence. This exhibit offers a practical guide to strain and shear wave elastography in breast imaging, presented through concise explanations, diagrams, and real-world imaging examples. We explore the physical principles, image acquisition techniques, interpretation methods, and reporting strategies, along with practical tips for clinical use. Designed for general radiologists, this guide supports learning with clarity and relevance. By expanding knowledge and proficiency in breast elastography, we aim to promote safer, more effective patient care—contributing to ongoing advancements in breast diagnostic imaging.

TABLE OF CONTENTS/OUTLINE

Why Elastography Matters: Enhances diagnostic accuracy through tissue stiffness assessment. Techniques: Covers strain and shear wave methods with distinct clinical benefits. Principles & Acquisition: Includes physics, patient positioning, and image optimization. Interpretation & Reporting: Focuses on reading patterns, artifacts, and BI-RADS use. Practical Use & Cases: Offers workflow tips and real-life examples. Future Outlook: Key role in personalized, non-invasive breast cancer care.

BREE-5 ECHOES OF CHANGE: HOW AXILLARY ULTRASOUND IS TRANSFORMING SURGICAL DECISION-MAKING

Karina Pesce, MD, PhD (*Presenter*)
Maria P. Swiecicki, MD (*Abstract Co-Author*)
Ana G. Luna, PhD (*Abstract Co-Author*)
Maria Jose Chico (*Abstract Co-Author*)
Nancy L. Molon, MD (*Abstract Co-Author*)
Maria Veronica Pesce (*Abstract Co-Author*)

TEACHING POINTS

1-To evaluate the role of axillary ultrasound in breast cancer staging.2-To analyze and compare published and ongoing trials that propose axillary surgical de-escalation based on axillary ultrasound findings.3-To discuss the need for standardized axillary ultrasound criteria to ensure reproducibility in daily clinical practice.

TABLE OF CONTENTS/OUTLINE

Axillary ultrasound has become a cornerstone in the preoperative evaluation of patients with early-stage breast cancer. Recent clinical trials have questioned the need for routine sentinel lymph node biopsy (SLNB) in selected clinically node-negative patients, proposing de-escalation strategies based on ultrasound findings. However, variability in imaging protocols and interpretation criteria limits the reproducibility and comparison between these studies. This educational exhibit aims to evaluate the current role of axillary ultrasound, compare protocols from published and ongoing trials, and emphasize the importance of standardized imaging criteria. In addition, we assess how axillary ultrasound findings influence surgical decision-making, highlighting its potential to reduce overtreatment while ensuring oncological safety. Conclusion: Establishing reproducible and validated ultrasound protocols is essential for translating trial evidence into consistent clinical practice.

BREE-6 RADIOLOGICAL APPROACH TO BREAST IMAGING IN CHILDREN AND ADOLESCENTS: A CASE BASED REVIEW

Tanya W. Moseley, MD, PhD (*Presenter*)
Anas M. Al Zubaidi, MD (*Abstract Co-Author*)
Savannah Dennis, MD (*Abstract Co-Author*)
Sarah Quinn (*Abstract Co-Author*)
Ronald A. Rauch, MD (*Abstract Co-Author*)
Gary J. Whitman, MD (*Abstract Co-Author*)
Mary S. Guirguis, MD (*Abstract Co-Author*)
Beatriz E. Adrada, MD (*Abstract Co-Author*)
Ethan O. Cohen, MD (*Abstract Co-Author*)
Olena O. Weaver, MD (*Abstract Co-Author*)
Hannah L. Chung, MD (*Abstract Co-Author*)

TEACHING POINTS

Breast imaging protocols for children and adolescents differ from those for adults, from the imaging modalities used to the spectrum of pathologies encountered. Ultrasound (US) is the primary imaging modality for breast imaging in children and adolescents. US provides superior sensitivity while avoiding radiation exposure associated with mammography. MRI provides a detailed assessment but may require sedation in young patients. Most breast imaging findings represent normal anatomical structures, physiological changes, or benign masses. Primary breast cancer is exceedingly rare; malignant masses typically represent metastases from extramammary primary tumors. Given the variation in disease patterns, breast imaging often relies on descriptive reports rather than the ACR BI-RADS® reporting system. Management is typically conservative with US follow-up while limiting biopsies to avoid damaging the developing breast bud. Biopsy indications include atypical imaging features, lesion growth, prior chest radiation, concurrent non-breast malignancy, or familial breast cancer. A small-gauge core-needle biopsy (18-16 gauge) is generally preferred when tissue sampling is necessary.

TABLE OF CONTENTS/OUTLINE

Discuss the clinical presentation and characteristic imaging features of normal breast development and mass-forming lesions in children and adolescents, and highlight the differences in differential diagnosis compared to adults. Understand the breast imaging approach and each imaging modality's associated advantages and disadvantages. Illustrate clinically encountered cases ranging from common normal variants and benign processes to uncommon pathologies requiring intervention.

BREE-7 THE PAPILLARY PUZZLE: PAPILLARY LESIONS ON BREAST IMAGING AND MANAGEMENT REVIEW

Erina F. Quinn, DO (*Presenter*)
Charmi Vijapura, MD (*Abstract Co-Author*)
Daria Quinn (*Abstract Co-Author*)
Brian J. Guarnieri, MD (*Abstract Co-Author*)
Ann L. Brown, MD (*Abstract Co-Author*)
Kyle M. Lewis, MD (*Abstract Co-Author*)
Mary C. Mahoney, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review and recognize the challenges of imaging papillary breast lesions. - Highlight the mammographic, sonographic and MR imaging findings of the spectrum of papillary lesions. - Discuss treatment options used for various papillary breast lesions. - Summarize the recent literature on the management of papillary breast lesions with an evidence-based approach.

TABLE OF CONTENTS/OUTLINE

1. Ductal anatomy with graphics 2. Papillary breast lesion categories a. Benign b. Malignant 3. Overview of imaging protocols a. Mammography b. Ultrasound c. MRI 4. Discuss cases and imaging findings: a. Benign - Intraductal papilloma - Papillomatosis b. Atypical - Atypical papilloma c. Malignant - Papilloma with DCIS - Intraductal papillary carcinoma - Intracystic (encapsulated) papillary carcinoma - Invasive micropapillary carcinoma 5. Review questions with additional cases 6. Summary table of papillary breast lesions Conclusion: 1. Papillary breast lesions are rare yet challenging to diagnose on breast imaging. 2. Radiologists should be familiar with the different benign and malignant papillary breast lesions. 3. Correlation with multiple imaging modalities can be helpful to develop an appropriate management plan

BREE-8 COMMON ERRORS IN BREAST IMAGING AND HOW TO AVOID THEM: A CASE-BASED EDUCATIONAL EXHIBIT

Firouzeh Heidari, MD, MD (*Presenter*)
Tova C. Koenigsberg, MD (*Abstract Co-Author*)

TEACHING POINTS

This educational exhibit highlights the primary reasons breast cancers are missed on imaging, categorized into perceptual errors, interpretive mistakes, and system failures. Using a case-based, image-rich approach, we illustrate how these errors occur—such as satisfaction of search, misapplication of BI-RADS categories, inadequate imaging-pathology correlation, poor communication, technical limitations, and failure to recommend appropriate follow-up—and provide practical strategies to avoid them. Each case includes a brief clinical history, imaging findings, initial impression, follow-up actions, complications, and final patient outcome. A teaching point concludes each case, focusing on improving diagnostic accuracy and reducing the likelihood of missed cancers. Our goal is to help radiologists recognize common pitfalls, adopt structured interpretation methods, and ultimately improve patient outcomes in breast imaging.

TABLE OF CONTENTS/OUTLINE

Slide 1: title and learning objectsSlide 2: different categories of errorsSlide 3, 4 and 5: case-based examples of occurred error, outcome and teaching points of each case

BREE-9 IMPLANTS UNCOVERED: UNUSUAL COMPLICATIONS ASSOCIATED WITH BREAST IMPLANTS ON MULTIMODALITY IMAGING

Othria Ahmed, MD (*Presenter*)
Sarah Siddiqui (*Abstract Co-Author*)
Ekta Gupta, MD (*Abstract Co-Author*)
Nina S. Vincoff, MD (*Abstract Co-Author*)
Suzanne McElligott, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Breast augmentation with implants is a popular procedure with decades of innovations to improve patient safety and decrease adverse events. Despite proven safety, both common and unusual complications occur. Radiologists should be familiar with the spectrum of more unusual imaging complications 2. Recognize different types of breast implants and complications via key radiological findings 3. Discuss the role of patient surgical history in the assessment of breast implants to avoid unnecessary intervention

TABLE OF CONTENTS/OUTLINE

I. Breast implant types and location -A. Common: saline, silicone -B. Uncommon: Multi-lumen, Stacked implants, Baffled saline implants -C. Locations: subpectoral, subglandular, subfascial II. Implant complications -A. Multimodality approach to diagnostic evaluation -B. Common: ---1. Intra and extracapsular silicone rupture ---2. Capsular contracture ---3. Early infection/hematoma ---4. Siliconomas in breast, intramammary and axillary lymph nodes -C. Uncommon: ---1. Integral patient history ----Space occupying seromas following explantation mimicking implants ----Slow leakage of saline implants ----Alloderm Residual capsule and silicone after explanation ---2. Atypical rupture ----Extracapsular rupture - extension through nipple, along lymphatics ----Diffuse silicone gel throughout the breast and/or pectoral muscle ---- Silicone pulmonary embolism and pneumonias ---3. Malignant/mass-like lesions ----BIA- ALCL Desmoid adjacent to implant ----Focal fibrosis ----Neuroma along/adjacent to a scar ----Synovial metaplasia III. Conclusion: Follow up imaging, intervention

BREE-10 IDIOPATHIC GRANULOMATOUS MASTITIS: THE GREAT IMITATOR

Saachi Datta (*Presenter*)
John N. Grimes, MD, PhD (*Abstract Co-Author*)
Jison Hong (*Abstract Co-Author*)
Meng Hao, MD (*Abstract Co-Author*)

TEACHING POINTS

- Recognize the demographic and clinical presentations of IGM - Discuss the differential diagnosis for patients - Review the spectrum of imaging findings of IGM on MG, US, and MRI with rad-path correlation - Review the typical and atypical appearance of IGM in imaging as well as pitfalls and challenges with diagnosis - Familiarize with the diagnostic breast imaging work-up for patient presenting with clinical concern of IGM

TABLE OF CONTENTS/OUTLINE

Idiopathic granulomatous mastitis (IGM) is a rare benign inflammatory breast condition often misdiagnosed due to its variable presentation. It mainly affects postpartum, premenopausal patients, especially in Asian and Hispanic populations. The differential includes inflammatory breast cancer, inflammation, infection, and fat necrosis. IGM most commonly present on MG as focal asymmetry, an irregular mass, or regional skin thickening (often imaging will be negative), on US as parallel heterogenous hypoechoic masses with peripheral vascularity, and on MRI as rim-enhancing or heterogeneous enhancing masses with non-mass enhancement and T2 hyperintensity. Common associated imaging features include skin abnormalities, fluid collections, fistula tracks, and axillary lymphadenopathy. This education exhibit will present 10 IGM patients evaluated with MG, US, and MRI (some with post-treatment MRI), focusing on clinical and imaging presentation, diagnostics, and management. In summary, IGM can mimic malignancy and infectious abscesses clinically and radiographically. Therefore, it is important for radiologists to be familiar with the clinical picture, differential diagnosis, imaging features, and work-up for IGM to prevent delay in diagnosis and treatment.

BREE-11 HORSES AND ZEBRAS: BENIGN AND MALIGNANT CAUSES OF REGIONAL LYMPHADENOPATHY IN BREAST IMAGING PATIENTS

Mary S. Guirguis, MD (*Presenter*)
Tanya W. Moseley, MD, PhD (*Abstract Co-Author*)
Marion E. Scoggins, MD (*Abstract Co-Author*)
Megha M. Kapoor, MD (*Abstract Co-Author*)
Miral M. Patel, MD (*Abstract Co-Author*)
Gaiane M. Rauch, MD, PhD (*Abstract Co-Author*)
Emily S. Nia, MD (*Abstract Co-Author*)
Elsa M. Arribas, MD (*Abstract Co-Author*)
Savitri Krishnamurthy, MD (*Abstract Co-Author*)
Beatriz E. Adrada, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review breast cancer regional lymph node staging 2. Illustrate a case-based differential diagnosis review for lymphadenopathy in breast imaging patients 3. Highlight helpful imaging characteristics of benign and malignant lymph nodes 4. Provide tips and tricks to successfully biopsy regional lymph nodes

TABLE OF CONTENTS/OUTLINE

Evaluation of the regional nodal basins is essential in patients with breast cancer and those undergoing surveillance for history of treated breast cancer. The regional lymph nodes include the axillary levels I-III, the internal mammary, and the supraclavicular regions. Lymph node involvement contributes to the patient's staging and recurrence-free survival with important associated management implications. Understanding the lymphatic drainage of the breast and the anatomy of the regional lymph node stations is fundamental for radiologists. In addition to breast cancer, other benign and malignant etiologies of regional lymphadenopathy can be seen, and understanding this is key for successfully managing breast cancer patients and patients in the breast imaging setting. A case-based review of both malignant and benign etiologies of lymphadenopathy in breast cancer patients will be presented in this educational exhibit. Imaging features of malignant versus reactive nodes will be discussed, as well as interventional tips and tricks to successfully biopsy these lymph nodes if clinically indicated.

BREE-12 CT ANGIOGRAPHY IN BREAST RECONSTRUCTION: MAPPING DIEP, LUMBAR, AND PROFUNDA PERFORATORS FOR OPTIMAL FLAP HARVESTING

Suthar, MBBS, MD (*Presenter*)
Lavanya Chhetri (*Abstract Co-Author*)
Abdullgabbar M. Hamid, MBBS, MSc (*Abstract Co-Author*)
Jagadeesh Singh, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Autologous breast reconstruction with perforator flaps have become the mainstay for breast reconstructive surgery. Nonstandard radiology reporting results in inadequate information to the clinical service. The aim of this exhibit is to educate the radiologist of the CTA findings in the preoperative evaluation of DIEP, lumbar, and profunda perforators flaps and help in surgical outcomes.

TABLE OF CONTENTS/OUTLINE

• CTA Protocol and Post-Processing for DIEP, Lumbar, and Profunda Perforators DIEP Flap Imaging : Vascular Anatomy & Branching Patterns : Type I (single trunk), Type II (bifurcating), or Type III (trifurcating) . Perforator Characteristics : Number , Diameter , Course (intramuscular or subcutaneous course) Vascular Territory Mapping Evaluation of DIEA and SIEA Lumbar Artery Perforator (LAP) Flap Imaging : Perforator Classification : Differentiate between myocutaneous and septocutaneous perforators. Selection Criteria : Level : Select perforators from the L2 to L4 levels for optimal tissue harvest. Avoidance : Avoid perforators that are too close to the spinal artery to prevent injury. Profunda Artery Perforator (PAP) Flap Imaging : Perforator Classification : Identify whether the perforators are intramuscular or septocutaneous. Perforator Patterns : "T" Pattern : Characterized by a superficial bifurcation. "Y" Pattern : Characterized by a deeper bifurcation. Dominant Perforator Identification : A dominant "T" perforator on preoperative CTA accurately predicts flap thickness when elevated at the superficial fascial level. • Standard reporting for DIEP, Lumbar, and Profunda Perforators

BREE-13 FIBROEPITHELIAL TUMORS OF THE BREAST. IMAGING ON CONTRAST-ENHANCED MAMMOGRAPHY WITH HISTOPATHOLOGY CORRELATION. TIPS TO UNDERSTAND DIFFERENT BEHAVIOURS WITH CONTRAST BASED ON PATHOLOGICAL FEATURES

Rosa M. Lorente-Ramos, MD, PhD (*Presenter*)
Javier Azpeitia Arman, MD (*Abstract Co-Author*)
Lorena Melian Iribar, MD (*Abstract Co-Author*)
Soledad Alonso Garcia (*Abstract Co-Author*)
Carlos Molina, MD (*Abstract Co-Author*)
Lina Maria Caballero Ubaque (*Abstract Co-Author*)

TEACHING POINTS

-To review the pathological features and classification of fibroepithelial breast tumors. -To illustrate imaging in different techniques, emphasizing contrast-enhanced mammography (CEM), with US, MRI, and pathologic correlation.- To review clues to understand how pathology informs imaging features. -To emphasize pitfalls, diagnostic difficulties, and differential diagnosis. -To discuss the specific management of those patients, including imaging and interventional procedures.

TABLE OF CONTENTS/OUTLINE

Fibroepithelial breast tumors are biphasic neoplasms composed of epithelial and stromal elements. Contrast-enhanced mammography increases the sensitivity of digital mammography in the detection of breast cancer, but fibroepithelial lesions may pose a challenge in imaging interpretation. The understanding of the histopathological features informs image interpretation and helps in the distinction of fibroepithelial tumors from breast cancer. We present the following: 1. Basics and technique of contrast-enhanced mammography (CEM). 2. Pathology of fibroepithelial tumors: fibroadenoma and phyllodes tumour. Fibroadenoma variants include the cellular, juvenile, myxoid, and complex forms. Phyllodes tumors include benign, borderline, and malignant types. 3 Images in different pathologic entities. Through sample illustrative cases, we present imaging and pathology findings from lesions detected in CEM studies, with correlation with US, MRI, and pathology. 4. Clues for differential diagnosis, especially of enhancing lesions correlating with clinical and histopathological features such as variants, cellularity, and stromal elements.

BREE-14 OPTIMIZING ULTRASOUND-GUIDED BREAST BIOPSY: FROM TECHNIQUE TO OVERCOMING CHALLENGES

Renato L. Ribeiro, MD (*Presenter*)
Isabela C. Ferracini, MD (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Juliana H. Catani, MD (*Abstract Co-Author*)
Heni D. Skaf, MD (*Abstract Co-Author*)
Carolina d. Kiebert (*Abstract Co-Author*)
Iviny Yonekura (*Abstract Co-Author*)
Caio D. Pinheiro, MD (*Abstract Co-Author*)

TEACHING POINTS

Accurate, image-guided biopsy plays a key role in breast cancer diagnosis and management, directly influencing surgical planning and outcomes. Minimally invasive techniques such as FNA, CNB, and VAB offer fewer complications, faster recovery, and reduced surgical need compared to open biopsy. Pre-procedural imaging review is critical to confirm lesion suspicion, choose the best guidance modality, and anticipate technical challenges. Each method has specific indications based on lesion type, size, and location. Ultrasound is generally preferred when the lesion is visible, due to real-time control, patient comfort, and versatility. Proper planning—including needle trajectory and entry site—enhances both safety and diagnostic precision.

TABLE OF CONTENTS/OUTLINE

This pictorial essay provides a practical guide to ultrasound-guided breast biopsy, emphasizing technique selection and planning based on lesion and imaging features. We illustrate key steps, needle positioning, and challenging scenarios using ultrasound, mammography, and MRI from our institutional archive, along with didactic illustrations. These procedures are endorsed as standard of care by the ACR and the American Society of Breast Surgeons, with diagnostic performance comparable to surgical biopsy but lower morbidity and cost.

BREE-15 CONTRAST ENHANCED MAMMOGRAM (CEM)-GUIDED BIOPSY:PROCEDURAL EDUCATION FOR RADIOLOGISTS AND TECHNICIANS IN THE ACADEMIC SETTING

Michael Borten, MD, BS (*Presenter*)
Kelly A. Brozzetti Cronin, MD (*Abstract Co-Author*)

TEACHING POINTS

Contrast-enhanced mammography (CEM) uses dual energy digital subtraction to create a recombined image that shows contrast-enhancement in regions of neovascularity. The technique is akin to contrast-enhanced subtraction breast MRI, but lower cost, faster to perform, and easier to interpret. CEM-guided biopsy, a stereotactic-based procedure, is an emerging FDA-approved technique to harness the benefits of CEM to target lesions without a standard mammographic or sonographic correlate. However, implementation remains a challenge. Our nascent workflow consists of training technicians to the new technique, allowing attending radiologists to pilot the procedure, training residents, and eliciting feedback to improve our technique. We aim to present the technical and procedural considerations to educate both radiologists as well as technicians. For technicians, primary considerations include reviewing contrast allergies and kidney function, positioning the patient, and performing dual energy imaging at the appropriate intervals. The ability to maneuver patients efficiently is paramount. The radiologist must double-check contrast contraindications, confirm the target lesion (including correlation with prior imaging), and place the needle effectively. In addition to time constraints, needle positioning is even more critical than standard stereotactic biopsy given that blood products limit the utility of dual energy lesion targeting.

TABLE OF CONTENTS/OUTLINE

CEM-guided biopsy workflow for the academic setting. Basic principles of CEM. Example case for utilizing CEM-guided biopsy. Technician considerations for CEM-guided biopsy. Radiologist considerations for CEM-guided biopsy.

BREE-16 REVISITING THE FORBIDDEN ZONES IN MAMMOGRAPHY: A CONCEPT THAT CAN SAVE LIVES

Ruth H. Bonini, MD, PhD (*Presenter*)
Luciana K. Franca (*Abstract Co-Author*)
Ligia P. Mazi, MD (*Abstract Co-Author*)
Marcio M. Saito, MD (*Abstract Co-Author*)
Jamile d. Casado Pereira, MD (*Abstract Co-Author*)
Erika M. Negrao (*Abstract Co-Author*)
Edmundo C. Mauad, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

The concept of "forbidden zones," introduced by Dr. László Tabár, refers to anatomical regions of the breast where cancers often arise but are frequently underdiagnosed due to technical limitations, suboptimal positioning, or interpretation errors. These zones include the retromammary fat ("Milky Way") and retroareolar region on the MLO view, as well as the medial half and retroglandular space ("no man's land") on the CC view. Our experience, supported by the literature, shows that a significant proportion of both screen-detected and interval cancers cluster in these areas. This highlights the need for optimized image acquisition, proper positioning, and increased radiologist awareness to reduce false negatives and improve early breast cancer detection—especially in screening programs. This poster aims to reviews these high-risk areas and demonstrates how both technical and interpretive oversights may delay diagnosis. We also correlate these findings with a literature review addressing variations in screening sensitivity according to tumor location. By revisiting these topographies, we aim to reinforce a more systematic approach to image analysis and encourage vigilance in regions that are often overlooked yet clinically significant.

TABLE OF CONTENTS/OUTLINE

Through representative cases, we present clinical examples selected from our institution's digital archive of malignant lesions, with mammographic and ultrasonographic correlations. These lesions were missed or underestimated—some dismissed as benign, others overlooked due to subtle presentation or challenging location. These findings underscore the clinical relevance of the forbidden zones in daily mammographic practice.

BREE-17 DEDICATED BREAST CT: PRIMER FOR RADIOLOGISTS

Elizabet Nikolova (*Presenter*)
Esther Birindelli (*Abstract Co-Author*)
Heike Frauchiger-Heuer (*Abstract Co-Author*)
Thomas Frauenfelder, MD (*Abstract Co-Author*)
Malwina Kaniewska, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to provide a comprehensive understanding of breast CT, which is an emerging imaging modality with significant potential in breast care. It includes the technical principles and clinical applications of this three-dimensional imaging. Participants will learn to detect and evaluate common breast pathologies using breast CT and compare its diagnostic value with conventional imaging modalities such as mammography, dedicated breast ultrasound, and breast MRI. Emphasis is placed on preparing structured reports using a standardized checklist to ensure consistency and clarity. Additionally, the exhibit highlights best practices for effectively communicating imaging findings with both referring clinicians and patients.

TABLE OF CONTENTS/OUTLINE

This exhibit begins with an introduction to breast CT imaging, followed by an explanation of its technical principles and system design. The examination workflow and patient positioning are then described, along with image acquisition and reconstruction processes. A comparison is made between breast CT and conventional imaging modalities such as mammography, ultrasound, and MRI, focusing on advantages in dense breast tissue and lesion characterization. Clinical indications and typical findings are illustrated through selected cases. The exhibit also discusses structured reporting practices using a standardized checklist. It concludes with a summary and key practical considerations for clinical implementation.

BREE-18 EXTRANODAL EXTENSION IN BREAST CANCER

Phat Tan Nguyen, MD (*Presenter*)
Leah H. Portnow, MD (*Abstract Co-Author*)
Matthew Packer, MD (*Abstract Co-Author*)
Eva C. Gombos, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Extranodal extension (ENE) is the spread of cancer beyond the lymph node capsule and is associated with more aggressive breast cancer. ENE is linked to increased nodal burden, higher recurrence rates, and decreased survival. 2. ENE is challenging to detect on imaging due to variably present features of indistinct margins and perinodal edema. 3. Histopathology remains the diagnostic gold standard, but also has limitations. Fine needle aspiration cannot detect ENE, and core biopsies may miss ENE due to under-sampling. Accurate diagnosis often requires specialized pathology techniques including immunohistochemistry to distinguish ENE from its mimics. 4. Recognition of ENE and its challenges in detection is important given its prognostic significance.

TABLE OF CONTENTS/OUTLINE

1. Define ENE and its prognostic significance. 2. Review key imaging features suggestive of ENE including a. Mammographic and US characteristics b. MRI features and c. Additional modalities (e.g. PET/CT). 3. Review key histopathologic features of ENE including capsular disruption, stromal desmoplastic reaction, and tumor infiltration into the surrounding soft tissue. 4. Discuss the significance of ENE on axillary management.

BREE-19 IMAGING PEARLS IN BREAST GRANULOMATOUS MASTITIS: BEYOND THE USUAL

Ruth H. Bonini, MD, PhD (*Presenter*)
Rafaela Oliveira (*Abstract Co-Author*)
Erika Salles Abufares Camargo (*Abstract Co-Author*)
Erika M. Negrao (*Abstract Co-Author*)
Chrissie Amirati (*Abstract Co-Author*)
Jamile d. Casado Pereira, MD (*Abstract Co-Author*)
Selma P. Bauab, PhD (*Abstract Co-Author*)
Ligia P. Mazi, MD (*Abstract Co-Author*)
Anapaula H. Watanabe, MD (*Abstract Co-Author*)
Jane C. Picone, MSc (*Abstract Co-Author*)
Silvia M. Sabino, MD (*Abstract Co-Author*)
Nilton Onari (*Abstract Co-Author*)
Edmundo C. Mauad, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

Granulomatous mastitis (GM) is a rare, chronic, and complex inflammatory condition of the breast, which may be idiopathic or secondary to infections, autoimmune diseases, or foreign body reactions. The idiopathic form is strongly associated with pregnancy, lactation, and hyperprolactinemia, predominantly affecting women of reproductive age. The clinical presentation of GM often mimics infectious or neoplastic processes, making imaging studies essential for accurate diagnosis. Nevertheless, it remains underdiagnosed in clinical practice and underreported in the literature.This study aims to present the radiopathologic spectrum of GM, with an emphasis on the idiopathic form. The most common imaging findings include focal or global asymmetry, irregular hypoechoic nodules, T2 hyperintensity, and segmental non-mass enhancement. Less frequent but clinically relevant findings include fistulous tracts, architectural distortion, heterogeneous parenchyma or edema, and T2-hypointense masses with irregular margins. Recognizing these imaging patterns is essential to appropriately guide biopsies, avoid diagnostic pitfalls, ensure accurate clinical, radiologic, and pathologic correlation, and enable specific and targeted therapy.

TABLE OF CONTENTS/OUTLINE

• Overview of GM: idiopathic and secondary forms • Common and uncommon findings on mammography, US, and MRI • Histologic subtypes and imaging correlation • Case-based clinical, radiologic, and pathologic integration

BREE-20 A PRIMER FOR EVERY RADIOLOGY RESIDENT/FELLOW : DIAGNOSIS OF BREAST CANCER WITH AI-CADX IN ASIAN WOMEN

Kei Mizushima, MD (*Presenter*)
JITSURO TSUKADA (*Abstract Co-Author*)
Haruka Okamura, MD (*Abstract Co-Author*)
Naoko Okawara (*Abstract Co-Author*)
Manabu Hase (*Abstract Co-Author*)
Yuko Tsujioka, MD, PhD (*Abstract Co-Author*)
Masahiro Hashimoto, MD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

AI-based computer-aided diagnosis (AI-CADx) has improved the diagnostic accuracy of mammography, ultrasound, and ABUS. However, challenges remain, particularly in women with dense breasts, which are more common among Asian women. Most AI-CADx systems are trained on Western datasets, raising concerns about their generalizability to Asian populations. In contrast, AI-CADx models trained on images from Asian women have demonstrated performance comparable to or better than that of radiologists across multiple imaging modalities. Reported performances include: - Mammography : AUC 0.902 (Mio A et al., 2024) - Ultrasound : AUC 0.95; sensitivity 91.2%, specificity 90.7% (Hayashida T et al., 2022) - ABUS : AUC-LROC improved from 0.7582 to 0.8294 with AI (Lai YC et al., 2022) This educational exhibit provides radiology residents and fellows with a concise overview of AI-CADx applications in breast imaging, emphasizing both benefits and current limitations for future clinical practice.

TABLE OF CONTENTS/OUTLINE

- Introduction : Overview of AI-CADx and its growing role in breast cancer diagnosis. - Challenges in Asian Women with Dense Breasts : Limited generalizability of Western-trained models, high prevalence of dense breasts, and underrepresentation of Asian datasets. - AI-CADx Applications Using Asian-Based Datasets : Case examples in mammography, ultrasound, and ABUS; comparison with radiologist performance and improvements in diagnostic metrics. - Discussion : Clinical advantages and limitations; the importance of developing population-specific AI models. - Conclusion : Educational implications for radiologists in adopting and evaluating AI-integrated diagnostic workflows.

BREE-21 BREAST DIFFUSION MRI - HOW DOES IT WORK?

Motaz A. Daraghma, MD (*Presenter*)
James H. Holmes, PhD (*Abstract Co-Author*)
Daniel Robles (*Abstract Co-Author*)
Bruna M. Thompson, MD, PhD (*Abstract Co-Author*)
Reine Fahed, MD (*Abstract Co-Author*)
Fabiola P. Kestelman, MD (*Abstract Co-Author*)
Fabiana C. Policeni, MD (*Abstract Co-Author*)
Su Kim Hsieh, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the fundamental physics of diffusion-weighted imaging (DWI) in the breast, including the concept of water molecule motion and its relationship to the tumor microenvironment.2. Summarize essential protocol optimization (choice of b-values, sequence parameters, coil selection) for reliable apparent diffusion coefficient (ADC) measurement.3. Illustrate normal and pathologic diffusion patterns in the breast, emphasizing how malignant lesions typically restrict diffusion compared to benign lesions or background tissue.4. Discuss key diagnostic pearls (e.g., ADC thresholds) and pitfalls (e.g., T2 shine-through, motion artifacts) to ensure accurate interpretation.5. Highlight the evolving clinical applications of breast DWI, from improving lesion characterization to monitoring tumor response to neoadjuvant therapy.

TABLE OF CONTENTS/OUTLINE

1. Introduction & Physical Principles *Overview of diffusion MRI physics *Role of DWI in breast imaging2. Technical Considerations *Sequence design (spin-echo echo-planar imaging) *Choice of b-values and coil optimization *Strategies to reduce artifacts)3. Image Analysis & Interpretation *ADC maps and thresholds *Differentiation of benign vs. malignant lesions *Common pitfalls (T2 shine-through, inadequate SNR, fat suppression issues)4. Clinical Applications & Case Examples *Screening high-risk populations *Characterizing suspicious lesions *Assessing treatment response5. Future Directions & Conclusion *Emerging advanced diffusion techniques *Potential integration with radiomics *Key take-home points

BREE-22 A COMPREHENSIVE ANALYSIS OF RADIOLOGICAL-PATHOLOGICAL CORRELATION OF BREAST LESIONS: IMPLICATIONS IN DIAGNOSTIC ACCURACY AND PATIENT MANAGEMENT

Tiare A. Pineiro, MD (*Presenter*)
Maria L. Negri (*Abstract Co-Author*)
Cosaka Laura, MD (*Abstract Co-Author*)
SONIA GARCIA (*Abstract Co-Author*)
Claudia A. Fernandez, MD (*Abstract Co-Author*)
Daniel C. Mysler SR, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the definitions and clinical significance of radiological-pathological concordance and discordance after a breast biopsy.-Illustrate the key factors contributing to discordant findings including technical and interpretative errors.-Review how concordant and discordant results influence management decisions-Gain practical tips for optimizing communication between radiologists and pathologists, implementing systematic review protocols, and reducing diagnostic errors to ensure proper patient management.

TABLE OF CONTENTS/OUTLINE

Nowadays image guided biopsies have become the standard of care to accurately characterize suspicious breast image findings. Radiological-pathological correlation after a breast biopsy is a cornerstone of accurate diagnosis, guiding clinical decisions and patient management. Discordant findings can be challenging for radiologists and pathologists alike, affecting diagnostic confidence and treatment pathways. -Briefly describe and illustrate the prevalence, patterns, and underlying causes of radiological-pathological discordance in breast biopsies.-Highlight several strategies for optimizing multidisciplinary communication and implementing systematic review

protocols.-Provide practical insights and tips to improve interpretive accuracy, recognize potential pitfalls, and promote collaborative decision-making in breast imaging and pathology. By fostering a comprehensive approach to radio-pathological correlation, this exhibit aims to help enhance diagnostic accuracy, reduce false negatives/positives, and ultimately improve patient outcomes.

BREE-23 WHEN IMAGES AND SLIDES COLLIDE: MASTERING RAD-PATH CONCORDANCE ASSESSMENT IN BREAST IMAGING

Jennie E. Brodsky, MD (*Presenter*)
Syeda Jannath (*Abstract Co-Author*)

TEACHING POINTS

-Radiology-pathology concordance assessment in breast imaging practice is essential for diagnostic accuracy. -Pathology results post-biopsy should always be confirmed to be consistent with imaging findings; this is particularly important for lesions of high suspicion for malignancy on imaging (BI-RADS 4C or 5), where a malignant result is expected but benign results may still occur. - Teaching points will focus in depth on discordant cases from our institution that were upgraded to malignancy: reasons for discordance, and ways to decrease discordance in the future. Teaching points will explore common concordant radiology-pathology results by focusing on accurate identification and examples of benign pathologies that mimic malignancy on imaging.

TABLE OF CONTENTS/OUTLINE

Background: What is rad-path concordance correlation. Understanding the role of rad path correlation in breast imaging practice. Cases: 8-15 cases from our institution of rad-path discordant biopsy results that were upgraded to malignancy on excision. Teaching points to evaluate for rad-path concordance and mitigate discordant rad-path findings. 4-8 cases from our institution to illustrate common benign etiologies that can mimic malignancy on imaging and are concordant. Teaching points for each case to aid in recognition of concordant benign pathology. Conclusion: Accurate recognition of benign and concordant pathology results can help prevent over diagnosis and over treatment. Accurate recognition of benign but discordant pathology results can prevent delay in diagnosis.

BREE-24 WHAT'S LURKING IN YOUR ARMPIT? IT'S NOT ALWAYS A LYMPH NODE!

Soraia Damiao, MD (*Presenter*)
Laura B. De Melo, MD (*Abstract Co-Author*)
Celia Luiza De Lima Rodrigues (*Abstract Co-Author*)
Juliana A. Souza, MD (*Abstract Co-Author*)
Vinicius C. Felipe SR, PhD (*Abstract Co-Author*)
Mariah C. Wanderley (*Abstract Co-Author*)
Almir Bitencourt, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Axillary mass or swelling is a common clinical presentation that requires imaging investigation.• The axilla contains lymph nodes and non-lymphatic tissue, such as accessory breast tissue, skin, fat, muscles, nerves, and blood vessels. There is a wide range of differential diagnoses.• The imaging findings of these diseases overlap. Knowledge of common radiologic manifestations for specific diseases allows an appropriate differential diagnosis to be established, guides imaging management, and helps optimize tissue sampling technique when indicated.

TABLE OF CONTENTS/OUTLINE

• An overview of the radiological characteristic findings of various disease entities that cause axillary masses will help diagnose correctly. Examples of the normal anatomy of the axilla present a systematic approach to imaging-based evaluation using ultrasound, mammography, computed tomography, and magnetic resonance imaging. Key radiologic features will be highlighted to aid in distinguishing among these entities. Suggested decision-making workflow for selecting the appropriate imaging technique based on clinical needs, imaging availability, and cost-effectiveness.

BREE-25 WHEN THE NIPPLE'S IN TROUBLE: A RADIOLOGIST'S GUIDE TO IMAGING AND DIFFERENTIAL DIAGNOSIS

Mateus Pereira Dos Santos Gomes, MD (*Presenter*)
Fernanda Souza, MD (*Abstract Co-Author*)
Lucas Silva (*Abstract Co-Author*)
Marcele F. Cortes, MD (*Abstract Co-Author*)
Thais Salgado Monnerat (*Abstract Co-Author*)
Maria Celia Resende Djahjah (*Abstract Co-Author*)
Carmen Lucia Arantes Pereira Azevedo (*Abstract Co-Author*)
Bruna Mendes, MD (*Abstract Co-Author*)
Renata Sande Paiva, MD (*Abstract Co-Author*)
Vitor Soares, MD (*Abstract Co-Author*)
Rafaela Queiroz, MD, BMedSc (*Abstract Co-Author*)

TEACHING POINTS

? Review the differential diagnoses of nipple lesions. ? Describe key imaging features and the broad spectrum of nipple pathologies.

TABLE OF CONTENTS/OUTLINE

Introduction Nipple lesions are uncommon but clinically significant findings in breast imaging. They may represent a wide range of benign and malignant conditions and should never be overlooked. A thorough clinical examination and mammography are essential for proper assessment. To ensure updated content, we conducted a review of recent literature on nipple lesions and selected a series of unusual and illustrative cases for discussion. Important Features to Analyze Evaluation should begin with a detailed clinical history and mammographic assessment. Epidemiologic context is important—conditions such as tuberculosis must be considered in endemic areas. Imaging findings should be interpreted in accordance with BI-RADS guidelines and correlated with pathology when appropriate. In most cases, ultrasound-guided biopsy provides a reliable and minimally invasive diagnostic method. Conclusion Radiologists must be familiar with the clinical presentation and imaging features of nipple lesions. Expanding the differential diagnosis and promoting early detection can significantly improve patient management and reduce associated morbidity.

BREE-26 A CASE-BASED PRIMER ON BREAST IMAGING IN TRANSGENDER PATIENTS

Rebecca Zhang, MD (*Presenter*)

TEACHING POINTS

1) Recognize the American College of Radiology (ACR) Appropriateness Criteria breast screening recommendations for transgender male and female patients. 2) Describe posttreatment changes to the breast after hormonal and/or surgical therapies. 3) Review breast pathologies commonly encountered in transgender patients.

TABLE OF CONTENTS/OUTLINE

1) Introduction. 2) Delineate the recommended screening guidelines for transgender patients using the ACR Appropriateness Criteria. 3) Review hormonal and surgical therapies commonly utilized for transgender care. (3a) Effects of estrogen therapy in transgender women. (3b) Effects of testosterone therapy in transgender men. (3c) Common gender-affirming surgeries, including breast augmentation and reduction. (4) Cases to illustrate the variety of expected imaging findings in transgender patients after hormonal and/or surgical treatments. (5) Cases to elucidate common breast pathologies seen in transgender patients.

BREE-27 FROM EMBRYOLOGY TO BIOPSY: A COMPREHENSIVE APPROACH TO PEDIATRIC BREAST RADIOLOGY

Juliana H. Catani, MD (*Presenter*)
Luiz Augusto Marin Jaca, MD (*Abstract Co-Author*)
Aline Lemgruber Prado Costa, MD (*Abstract Co-Author*)
Heni D. Skaf, MD (*Abstract Co-Author*)
Carolina d. Kiebert (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Bruna M. Tachibana, MD (*Abstract Co-Author*)
Alessandra Silva Malta, MD (*Abstract Co-Author*)
Vitor C. Romano, MD (*Abstract Co-Author*)
Yoshino Tamaki Sameshima, MD (*Abstract Co-Author*)

TEACHING POINTS

1 Pediatric breast imaging presents a taxing challenge within breast radiology. It is imperative to strike a balance between the need for diagnosis of uncommon conditions and the limitation of radiation exposure to young patients. 2 Accurate understanding of normal breast development, including embryology and imaging characteristics of postnatal changes and Tanner staging, is essential to avoid misinterpretation of physiologic features. 3 Congenital abnormalities like accessory breast tissue, asymmetries, nipple abnormalities and Poland syndrome are often observed in those patients and can also mimic pathologies. Their accurate recognition is imperative to avoid unnecessary intervention and guide appropriate management. 4 Most pediatric breast lesions are benign. Breast radiologists should be comfortable with the imaging in this subpopulation, especially sonographic features of fibroadenomas, vascular lesions, galactocele, Montgomery cysts and lymphangiomas, among others. 5 Although rare, pediatric breast cancer must be considered. A combination of suspicious imaging features, size increase and risk factors warrants further evaluation.

TABLE OF CONTENTS/OUTLINE

1 Importance and rarity of pediatric breast imaging 2 Goals of pediatric breast imaging: accurate diagnosis while minimizing radiation 3 Normal breast development A Embryology and postnatal development B Imaging features of pubertal changes and Tanner staging 4 Congenital abnormalities A Accessory breast tissue B Asymmetries and nipple abnormalities C Hypoplasia and Poland syndrome 5 Benign lesions A Fibroadenomas B Vascular lesions C Galactocele D Montgomery cysts E Lymphangiomas 6 Infectious diseases 7 Pediatric breast cancer

BREE-28 BACK IN THE PICTURE: IMAGING FEATURES OF BREAST CANCER RECURRENCE AFTER BREAST CONSERVATION THERAPY

Megan K. Mercer, MD (*Presenter*)
Stephanie M. Walker, MD (*Abstract Co-Author*)
Allyson L. Chesebro, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this educational exhibit is to highlight the features of breast cancer recurrence after breast conservation therapy utilizing a multimodality approach. We will review breast conservation therapy (BCT). We will highlight imaging in the post-BCT period, including screening, diagnostic techniques, and the evaluation of the symptomatic breast. We will also examine the identification of suspicious features, benign findings, and the evolution of post-operative breast, as well as further work-up and management of the breast after BCT.

TABLE OF CONTENTS/OUTLINE

We will give an overview of breast conservation therapy as a treatment option for breast cancer, including the history and implementation of the treatment strategy as it compares to mastectomy. We will review the post-treatment appearance of the breast utilizing mammography, sonography, MRI, and physical exam and the benign changes over time. Screening, diagnostic work-up, and symptom evaluation will be reviewed as well as a systematic approach for reporting. We will then review suspicious findings and cases for recurrent disease across multiple modalities.

BREE-29 BACKGROUND PARENCHYMAL ENHANCEMENT (BPE) ON BREAST MRI: UPDATES ON HORMONAL INFLUENCE AND POTENTIAL IMPACT ON INTERPRETATION, ASSOCIATION WITH FUTURE CANCER RISK, AND ULTRAFAST TECHNIQUES

Megan K. Mercer, MD (*Presenter*)
Catherine S. Giess, MD (*Abstract Co-Author*)

TEACHING POINTS

Cancer detection on breast MRI is based on vascular enhancement, but benign breast tissue also enhances. Background parenchymal enhancement (BPE) is common in screening and diagnostic MRI and may complicate image interpretation. This case-rich exhibit will present 1) evolving published data on hormonal effects on BPE and its association with abnormal interpretation; 2) discuss the potential association of high BPE with risk of developing breast cancer or tumor recurrence and its potential for predicting response to neoadjuvant treatment; 3) potential for ultrafast imaging techniques to improve differentiation of tumor from BPE, potentially reducing false positive interpretations.

TABLE OF CONTENTS/OUTLINE

1. Present early and more recent literature on hormonal influences on BPE related to menstrual cycle and its impact on imaging interpretation for screening and diagnostic MRI 2. Discuss the pros and cons of scheduling MRI around the patient's menstrual cycle in the current era of constrained health care resources and access challenges 3. Review current published data on the association of high BPE with future cancer risk, breast cancer recurrence, and potential association with predicting response to neoadjuvant treatment 4. Discuss the potential for new evaluating ultrafast imaging techniques to differentiate BPE from breast disease, potentially reducing false positive interpretations in these high-risk patients.

BREE-30 METASTASES TO THE BREAST: IT'S RARE, BUT IT HAPPENS — RECOGNIZING THE UNEXPECTED

Ruth H. Bonini, MD, PhD (*Presenter*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)
Carla C. Benetti, MD (*Abstract Co-Author*)
Beatriz Miranda (*Abstract Co-Author*)
Ligia P. Mazi, MD (*Abstract Co-Author*)
Jane C. Picone, MSc (*Abstract Co-Author*)
Anapaula H. Watanabe, MD (*Abstract Co-Author*)
Nilton Onari (*Abstract Co-Author*)
Silvia M. Sabino, MD (*Abstract Co-Author*)
Aline C. Oliveira (*Abstract Co-Author*)
Erika M. Negrao (*Abstract Co-Author*)
Selma P. Bauab, PhD (*Abstract Co-Author*)
Edmundo C. Mauad, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

Metastases to the breast from extramammary malignancies are rare, accounting for approximately 0.1-5% of all breast tumors. In up to 31% of cases, they may represent the initial manifestation of the primary tumor. Imaging findings often differ from those of primary breast cancer and may mimic benign lesions. The pattern of spread influences the imaging appearance: hematogenous dissemination usually results in well-defined nodules, while lymphatic spread leads to diffuse changes such as skin and trabecular thickening. Among tumors that metastasize to the breast, the contralateral breast is the most common primary site due to cross-lymphatic spread. Other malignancies include hematologic neoplasms (e.g., leukemia and lymphoma), melanoma, lung, gastric, and ovarian cancers. Imaging features are frequently nonspecific and often insufficient for a definitive differential diagnosis. Despite their rarity, radiologists should consider the possibility of metastatic disease, especially in

patients with a history of extramammary malignancy. Differentiating metastatic from primary breast tumors is crucial, given the differences in management and prognosis. Clinical history and immunohistochemistry are essential for accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

This study aims to present cases of breast metastases originating from extramammary malignancies, emphasizing their main imaging characteristics and the distinct patterns of metastatic spread.

BREE-31 TOMOSYNTHESIS IN PRACTICE: LESSONS LEARNED FROM A DECADE OF DIAGNOSTIC CHALLENGES

Ana Carolina Gaetan Afonso, MD (*Presenter*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)
Isabela Ferreira (*Abstract Co-Author*)
Carla Tajima (*Abstract Co-Author*)
Carla C. Benetti, MD (*Abstract Co-Author*)
Almir Bitencourt, MD, PhD (*Abstract Co-Author*)
Carlos H. Rosas, MD (*Abstract Co-Author*)

TEACHING POINTS

Mammography has played a fundamental role in breast cancer screening; however, its limitations — particularly the overlap of anatomical structures — have prompted the development of more advanced technologies, such as digital breast tomosynthesis. Retrospective studies indicate that tomosynthesis is associated with reduced recall rates, increased cancer detection rates, and a lower incidence of false-negative findings. These benefits result from its ability to acquire multiple thin-slice images, allowing for the visualization of the breast in different planes and eliminating tissue overlap, which enhances the early detection of lesions. In this context, the present study aims to compare the outcomes of conventional mammography and digital breast tomosynthesis performed at our facility in the detection of breast lesions, highlighting the advantages offered by the latter.

TABLE OF CONTENTS/OUTLINE

Through a review of clinical cases and the existing literature, this study aims to present a comparative analysis between conventional mammography and digital breast tomosynthesis in the detection of breast lesions. Furthermore, based on over a decade of experience with the use of this technology in our institution, we aim to demonstrate that digital tomosynthesis enables more accurate diagnoses and earlier interventions, which translate into improved clinical outcomes for patients.

BREE-32 MOLECULAR FINGERPRINTS: HOW BREAST CANCER GENOTYPE SHAPES IMAGING AND DIAGNOSIS

Tatiana C. Tucunduva, MD (*Presenter*)
RAISSA GIVISIEZ (*Abstract Co-Author*)
Vitor C. Zanetta, MD (*Abstract Co-Author*)
Tomie H. Ichihara, MD (*Abstract Co-Author*)
Marcela P. Viana, MD (*Abstract Co-Author*)
Luciano F. Chala, MD (*Abstract Co-Author*)
Mariana P. Ananias, MD (*Abstract Co-Author*)
Vera N. Aguillar, MD, PhD (*Abstract Co-Author*)
Giselle G. Mello, PhD (*Abstract Co-Author*)
Priscila Marques (*Abstract Co-Author*)
Guilherme Mineiro, MD (*Abstract Co-Author*)
Monica Stiepcich (*Abstract Co-Author*)

TEACHING POINTS

Breast cancer subtypes (Luminal A, Luminal B, HER2, Triple-negative) have unique molecular profiles, with distinct prognostic and therapeutic implications.Understanding imaging features (mammography, ultrasound, MRI) optimizes diagnosis and guides individualized treatment.Different imaging modalities are crucial in identifying and differentiating molecular subtypes.Case analysis, correlating imaging findings with histopathology, highlights diagnostic fingerprints and avoids delays.

TABLE OF CONTENTS/OUTLINE

Breast cancer is a biologically heterogeneous disease with distinct molecular fingerprints.Classifying tumors by molecular subtype is crucial for prognosis and forming individualized treatment plans.Gene expression profiling is the gold standard for molecular classification, but immunohistochemistry offers a practical alternative in clinical routine.Luminal, HER2-enriched, and triple-negative tumors each display characteristic imaging findings correlating with their molecular makeup.Imaging plays a key role in identifying subtype-related features such as spiculated masses, calcification patterns, architectural distortion, and non-mass enhancements.Understanding the imaging fingerprints of each subtype allows radiologists to anticipate tumor behavior and optimize diagnostic efficiency.Pitfalls and look-alike benign lesions require careful analysis to prevent misclassification and delayed therapy.The combination of imaging findings and molecular classification allows for greater precision in the diagnosis and management of breast cancer.

BREE-33 IMAGING THE LACTATING BREAST: CHALLENGES AND KEY INSIGHTS FOR RADIOLOGISTS

Giselle G. Mello, PhD (*Presenter*)
Guilherme Mineiro, MD (*Abstract Co-Author*)
Tatiana C. Tucunduva, MD (*Abstract Co-Author*)
Vitor C. Zanetta, MD (*Abstract Co-Author*)
Marcela P. Viana, MD (*Abstract Co-Author*)
Mariana P. Ananias, MD (*Abstract Co-Author*)
Luciano F. Chala, MD (*Abstract Co-Author*)
Tomie H. Ichihara, MD (*Abstract Co-Author*)
Barbara H. Bresciani, MD (*Abstract Co-Author*)
Vera N. Aguillar, MD, PhD (*Abstract Co-Author*)
Lucy T. Sato Watanabe (*Abstract Co-Author*)
RAISSA GIVISIEZ (*Abstract Co-Author*)
Monica Stiepcich (*Abstract Co-Author*)
Priscila Marques (*Abstract Co-Author*)

TEACHING POINTS

To describe the physiological changes of the breast during pregnancy and lactation and the implications for imaging evaluation.To review the most appropriate imaging modalities for diagnostic assessment of pregnant and lactating patients, emphasizing safety and diagnostic accuracy.To discuss the epidemiology and clinical presentation of breast lesions in this women, focusing on pregnancy-associated breast cancer.To illustrate the radiological and pathologic features of the most relevant benign and malignant breast diseases in this population, with pictorial examples.To emphasize strategies for early detection, aiming to avoid delayed diagnoses.

TABLE OF CONTENTS/OUTLINE

Overview of breast anatomy and normal physiological modifications in gestation and lactation. Impact of these changes on clinical evaluation and imaging interpretation.Selection of imaging techniques: ultrasound, mammography, MRI, and their indications and contraindications in this population.Safety considerations and protocol adjustments in pregnancy and lactation.Presentation and imaging features of common benign conditions: lactational adenoma, galactocele, mastitis, and

abscess. Differentiation from malignant lesions.Epidemiology, clinical forms, and risk factors for breast cancer during pregnancy and lactation. Imaging characteristics and correlation with pathological findings.Challenges in diagnosis and the importance of avoiding delayed diagnosis and treatment.Multidisciplinary approach to therapy, considering both maternal and fetal well-being.Current recommendations and guidelines.Case Illustrations

BREE-34 BREAST IMPLANTS IN SIGHT: A MULTIMODALITY LIGHT

Yasmin Fattah, MD (*Presenter*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Aline C. Oliveira (*Abstract Co-Author*)
Carla C. Tajima (*Abstract Co-Author*)
Carlos H. Rosas, MD (*Abstract Co-Author*)
Livia P. Souza, MD (*Abstract Co-Author*)
Carla C. Benetti, MD (*Abstract Co-Author*)

TEACHING POINTS

Breast implants are widely used for cosmetic and reconstructive purposes. Silicone implants come in different types. Saline-filled implants are inflated with sterile isotonic saline, while silicone gel-filled implants contain a fixed volume of gel, with viscosity varying by manufacturer. "Gummy bear" implants, or form-stable implants, use dense silicone gel that retains shape even if the shell is compromised. In reconstruction, prepectoral placement positions the implant above the chest muscle, beneath the skin and soft tissue. Retropectoral placement puts it beneath the pectoralis major. The dual-plane technique combines both, placing the implant partly under the muscle and partly prepectorally. Despite benefits, implant-based reconstruction is associated with complications that may challenge patients and clinicians. Without proper planning and management, the impact can be significant. Common short- and long-term complications include hematoma, infection, seroma, skin necrosis, capsular contracture, rupture, malposition, animation and contour deformities, breast implant-associated anaplastic large cell lymphoma (BIA-ALCL), and breast implant illness (BII).

TABLE OF CONTENTS/OUTLINE

This study aims to review the types of silicone breast implants, reconstruction techniques, and related complications, correlating them with imaging findings on MRI, ultrasound, and mammography.

BREE-35 BEYOND THE BREAST: MASTERING AXILLARY LYMPH NODE IMAGING

Luciano F. Chala, MD (*Presenter*)
Priscila Marques (*Abstract Co-Author*)
Tatiana C. Tucunduva, MD (*Abstract Co-Author*)
Marcela P. Viana, MD (*Abstract Co-Author*)
Mariana P. Ananias, MD (*Abstract Co-Author*)
Vera N. Aguillar, MD, PhD (*Abstract Co-Author*)
Lucy T. Sato, MD (*Abstract Co-Author*)
Tomie H. Ichihara, MD (*Abstract Co-Author*)
Vitor C. Zanetta, MD (*Abstract Co-Author*)
Giselle G. Mello, PhD (*Abstract Co-Author*)
RAISSA GIVISIEZ (*Abstract Co-Author*)
Guilherme Mineiro, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the normal antomy of axillary lymph nodes Analyze imaging characteristics of axillary lymph nodes across mammography, ultrasound, and MRI Explore lymphatic drainage pathways and the morphological changes lymph nodes undergo Trace the evolution of axillary lymph node management and recent paradigm shifts

TABLE OF CONTENTS/OUTLINE

Comprehensive anatomy of axillary lymph nodes: in-depth review of nodal structure and axillary levels Imaging techniques and nodal assessment: comparative analysis of mammography, ultrasound, and MRI, with a focus on ultrasound as the primary diagnostic tool Illustrative cases highlighting nodal pathology across all three axillary levels Case studies demonstrating the progressive alterations in lymph node morphology in response to various pathologies Sentinel lymph node management - Past, Present, and Future: review of the historical context and the latest clinical updates in sentinel lymph node management

BREE-36 BREAKING THE SHELL: COHESIVE GEL IMPLANTS EVALUATION

Matheus Cruz Ferraro, MD (*Presenter*)
Juliana H. Catani, MD (*Abstract Co-Author*)
Heni D. Skaf, MD (*Abstract Co-Author*)
Iviny Yonekura (*Abstract Co-Author*)
Marcela C. Lauar, MD (*Abstract Co-Author*)
Ana Luiza Rodrigues Pereira, MD (*Abstract Co-Author*)
Erica E. Francolin Federicci, MD, PhD (*Abstract Co-Author*)
Renata Feres, MD (*Abstract Co-Author*)
Ana C. Racy, MD (*Abstract Co-Author*)
Renato L. Ribeiro, MD (*Abstract Co-Author*)

TEACHING POINTS

The purposes of this exhibit are: Provide a structured approach for evaluating cohesive gel implants, widely used in plastic surgery, utilizing a multimodality imaging perspective to enhance diagnostic accuracy. Discuss key imaging features for identifying and diagnosing common complications associated with cohesive gel implants, highlighting their unique radiological features. Demonstrate cases showcasing the diverse imaging appearances of cohesive gel implant rupture, ensuring a comprehensive understanding of diagnostic challenges. Emphasize the importance of indirect signs of cohesive gel implant fracture using multimodal imaging, where clinical suspicion may initially be low.

TABLE OF CONTENTS/OUTLINE

Highly cohesive gel implants offer some advantages over traditional ones, such as a lower risk of rupture, gel bleeding as well as improved shape retention. Their firmer gel composition provides greater structural stability, making them a preferred choice in modern plastic surgery. Recognizing subtle imaging signs of cohesive gel rupture is essential for accurate diagnosis. One of the key indicators is the presence of peri-implant fluid, even in the absence of visible disruption of the implant shell. In cohesive gel implants, intracapsular rupture often presents as linear discontinuities or clefts, typically near the seal patch. These findings contrast with traditional rupture patterns, such as the linguine sign, keyhole sign, and subcapsular line sign. Beyond rupture assessment, a multimodality imaging approach is crucial for evaluating other complications associated with cohesive gel implants, including capsular contracture, seroma formation, and hematoma.

BREE-37 BREAST CANCER IN PREGNANCY

Griselda Choque Leniz, MEd,MEd (*Presenter*)
Karen L. Caro, PhD (*Abstract Co-Author*)
Karina Pesce, MD, PhD (*Abstract Co-Author*)
MONICA OTILIA MACHUCA CASTILLO (*Abstract Co-Author*)

TEACHING POINTS

Define the concept of breast cancer in pregnancy.To know the most frequent molecular subtypes found in breast cancer during pregnancy. To determine the appropriate imaging method for staging and follow-up of breast cancer in pregnancy.

TABLE OF CONTENTS/OUTLINE

Introduction: Breast cancer during pregnancy is a rare diagnosis that occurs during gestation, the first year after delivery or in the breastfeeding period, with an incidence of approximately 1 in 1000 pregnancies. This type of cancer usually has a low expression of hormone receptors, resulting in more aggressive subtypes in young women, such as triple negative and HER2 positive. It is crucial that radiologists are familiar with the proper techniques to detect and diagnose breast abnormalities in pregnant women, allowing early diagnosis. The selection of imaging techniques should be customized to each case; breast ultrasound is preferred for imaging and staging, while mammography is less sensitive due to changes associated with lactation.

BREE-38 BACKGROUND PARENCHYMAL ENHANCEMENT ON BREAST MRI: A COMPREHENSIVE REVIEW OF DIAGNOSTIC ADVANCES AND NEW CLINICAL IMPLICATIONS

Sona A. Chikarmane, MD (*Presenter*)
Dunya M. Imad, MD (*Abstract Co-Author*)
Lorraine B. Smith, MBBCh (*Abstract Co-Author*)
Clare Poynton, MD,PhD (*Abstract Co-Author*)
Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

Originally thought to be an incidental finding, background parenchymal enhancement (BPE) on contrast-enhanced breast MRI is now recognized for its significant implications in multiple aspects of breast cancer. BPE is more than just the normal enhancement of breast tissue; it is linked to an increased risk of breast cancer in high-risk patients and to the response to therapy in those undergoing neoadjuvant chemotherapy for breast cancer. This educational exhibit aims to provide a comprehensive update on the role of BPE in breast MRI, featuring an updated literature review and case-based examples.

TABLE OF CONTENTS/OUTLINE

Methodology for Measuring BPE: Overview of both qualitative and novel quantitative assessment tools. Impact of Menstrual Cycle and Menopausal Status on BPE: Review of how menstrual cycle phases and menopausal status affect BPE, and does timing matter for screening breast MRI. Patient History and Demographics Influencing BPE: Factors such as mammographic breast density, prior personal history of chest radiation, and history of breast cancer that may impact BPE. Correlation of BPE with Newer Imaging Technologies: How BPE on MRI correlates with emerging imaging technologies like contrast-enhanced mammography and ultrafast MRI. BPE and Breast Cancer Risk: Updates on BPE's role in risk stratification, interval cancers, molecular subtypes, and the development of secondary breast cancers in patients with a prior history of breast cancer. BPE and Breast Cancer Treatment and Outcomes: Role of BPE in assessing the extent of disease, surgical margins, and predicting treatment response. Artificial Intelligence and BPE: Updates on AI tools in analyzing BPE and clinical decision-making.

BREE-39 NAVIGATING THE IMAGING LANDSCAPE OF INVASIVE LOBULAR CARCINOMA: CHALLENGES AND LATEST ADVANCEMENTS

Neha Yadu, MD,MBBS (*Presenter*)
Marion E. Scoggins, MD (*Abstract Co-Author*)
Basak E. Dogan, MD (*Abstract Co-Author*)

TEACHING POINTS

Invasive lobular carcinoma (ILC) tends to stay clinically silent and is difficult to detect early due to its indolent nature, infiltrative growth and lack of calcifications. On ultrasound, ILC can appear as a hyperechoic mass or with substantial hyperechoic component in up to 20% of cases. MRI has the highest sensitivity (83-100%) for detecting ILC and is superior to mammography and ultrasound for preoperative staging and contralateral breast evaluation. MRI can reduce re-excision and mastectomy rates in ILC, which is in contrast to its impact in invasive ductal carcinoma (IDC). Contrast-enhanced digital mammography (CEDM) is comparable to MRI for primary lesion detection but is less sensitive for multifocal disease. Preliminary data from an ongoing trial demonstrates MBI can detect breast masses in dense breasts that were missed on digital breast tomosynthesis (DBT) making MBI a promising potential adjunct for diagnosis and evaluation of ILC. CE-CBBCT is a promising new technique that offers diagnostic accuracy for breast masses similar to MRI in dense breasts, with consideration of radiation dose. FES PET/CT is emerging as an effective tool to identify occult metastasis and predict response to endocrine therapy in ER+ breast cancer, including ILC. A standardized imaging algorithm is proposed that integrates conventional and advanced imaging techniques for the diagnosis, staging, and follow-up of ILC.

TABLE OF CONTENTS/OUTLINE

Silent progression of ILC Mammography Ultrasound Breast MRI: Advantages in ILC Contrast-enhanced digital mammography Molecular Breast Imaging Cone-beam breast computed tomography Positron emission mammography & positron emission tomography Role of AI/Radiomics Summary

BREE-40 MOLECULAR BREAST IMAGING IN CANCER SCREENING AND DIAGNOSIS

Joao V. Horvat, MD (*Presenter*)
Robert T. Fazzio, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- To discuss the imaging techniques of Molecular Breast Imaging. - To describe the advantages and disadvantages of the use of Molecular Breast Imaging as a supplemental tool for breast cancer screening. - To demonstrate the imaging aspects of benign and malignant lesions on Molecular Breast Imaging. - To teach the adequate management of breast lesions detected on Molecular Breast Imaging. - To show how to perform Molecular Breast Imaging-guided biopsies.

TABLE OF CONTENTS/OUTLINE

- Introduction to Molecular Breast Imaging. - Description of techniques and imaging acquisition. - Discussion on safety and radiation dose after administration of Tc-99m Sestamibi. - Comparison between supplemental Molecular Breast Imaging and other imaging modalities for breast cancer screening. - Systematic approach to management of breast lesions detected on Molecular Breast Imaging. - Example cases with correlation with other imaging modalities. - Molecular Breast Imaging limitations. - Future directions: How can we improve the availability of Molecular Breast Imaging. - Molecular Breast Imaging-guided biopsy. - Teaching point summary and conclusion.

BREE-41 NEOADJUVANT THERAPY RESPONSE PATTERNS: A GUIDE FOR RADIOLOGISTS IN TRAINING

Maria P. Swiecicki, MD (*Presenter*)
Karina Pesce, MD, PhD (*Abstract Co-Author*)
Maria Jose Chico (*Abstract Co-Author*)
Alejandra Wernicke (*Abstract Co-Author*)

TEACHING POINTS

1- To review the different neoadjuvant response patterns in breast MRI.2- To discuss the RECIST criteria for breast cancer and its limitations in daily practice.3- To illustrate neoadjuvant response patterns with clinical cases, giving tips for radiologic reports.4- To review the most frequent neoadjuvant response patterns according to each molecular subtype.

TABLE OF CONTENTS/OUTLINE

Introduction to RECIST 1.1 Guidelines and Breast MRI for the evaluation of neoadjuvant therapy response. Limitations of RECIST 1.1 Guidelines in daily practice. Review of the different neoadjuvant response patterns in correlation with the different molecular subtypes. MRI for the evaluation of NAC and its correlation with histopathology in cases of pCR. Tips and tricks for overestimation and underestimation during MRI reading. Illustrations with clinical cases of daily practice.

BREE-42 NIPPLE DISCHARGE: THE ROLE OF BREAST MRI WHEN CONVENTIONAL IMAGING FALLS SHORT

Leticia T. Oliveira, MD (*Presenter*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)
Carla C. Tajima (*Abstract Co-Author*)
Aline C. Oliveira (*Abstract Co-Author*)
Carla C. Benetti, MD (*Abstract Co-Author*)

TEACHING POINTS

- Nipple discharge is the third most common breast symptom and, while often benign, may indicate underlying malignancy.- Pathologic nipple discharge (PND) is typically unilateral, spontaneous, and serous or bloody, originating from a single duct.- Mammography has limited sensitivity in detecting PND, especially for small, non-calcified, or purely intraductal lesions.- Ultrasound can detect lesions missed by mammography in up to 69% of cases but may yield false positives due to benign intraductal changes or debris.- Breast MRI offers superior sensitivity (87-100%) and high negative predictive value (96-100%) when conventional imaging fails to identify the cause of PND.- MRI can identify occult disease, assess lesion extent, and guide surgical decisions—potentially avoiding unnecessary excisions in low-risk patients.

TABLE OF CONTENTS/OUTLINE

- To review the clinical presentation of nipple discharge and distinguish between physiologic and pathologic cases.- To highlight the limitations of mammography and ultrasound in the evaluation of pathologic nipple discharge.- To discuss the role of MRI in the workup of nipple discharge when conventional imaging is inconclusive.- To describe MRI findings in nipple discharge, illustrated with cases from our institution, and correlate them with histopathological results.- To summarize current evidence supporting MRI as a problem-solving tool in challenging cases of nipple discharge.

BREE-43 UNDERSTANDING BREAST ASYMMETRY: A BEGINNER'S GUIDE WITH PRACTICAL EXAMPLES FOR EVALUATION AND FOLLOW-UP ALGORITHMS

Eunice L. Urbina Marure, MD (*Presenter*)
Sara Eugenia Vazquez Manjarrez, MD, MD (*Abstract Co-Author*)
Rosaura E. Fuentes Corona, MD (*Abstract Co-Author*)
Paula E. Hernandez Quiroz, MD (*Abstract Co-Author*)
Tania D. Grimaldo Galeana, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the definition and BI-RADS 5th edition classification of breast asymmetries , emphasizing key imaging features and clinical implications of each type (asymmetry, focal asymmetry, global asymmetry, and developing asymmetry). To understand the associated findings that influence the level of diagnostic suspicion. To raise awareness among general radiologists about the importance of a systematic evaluation of breast asymmetries to enhance early breast cancer detection. To present a structured diagnostic algorithm for the evaluation and management of breast asymmetries, integrating multimodality imaging and BI-RADS categorization. To present clinical cases that illustrate the practical application of the proposed algorithm, including imaging progression, clinical decisions, and final histopathological diagnosis. To highlight the importance of comparison with prior studies and the role of targeted imaging in improving diagnostic accuracy and avoiding unnecessary interventions.

TABLE OF CONTENTS/OUTLINE

Objectives. Background. BI-RADS Classification of asymmetries. Associated findings. Additional imaging tools for assessment. Diagnostic approach algorithm. Clinical cases and individualized approach. Diagnostic pearls. Conclusions. References.

BREE-44 EMERGING EVIDENCE ON RESIDUAL FIBROGLANDULAR TISSUE (RFGT) POST MASTECTOMY AND EVALUATING THE RISK FOR LOCAL RECURRENCE OR NEW PRIMARY BREAST CANCER

Woodlynn Daniel, MD (*Presenter*)

TEACHING POINTS

1. Emerging evidence indicates residual fibroglandular tissue (RFGT) after either prophylactic or therapeutic bilateral mastectomy may confer a risk of in-breast local recurrence or new primary tumors. 2. Various factors affect the volume of RFGT post mastectomy including surgical technique, age, and preoperative fibroglandular tissue volume. 3. Though RFGT can be found anywhere in the breast after mastectomy, it is most commonly found behind the nipple-areolar complex. 4. At present, RFGT is most easily quantified with orthogonal measurements but there are opportunities to use AI to more accurately quantify RFGT. 5. The volume of RFGT is not static after mastectomy and can change with pregnancy or hormonal therapy. Factors such as these are important to consider as they can alter a patient’s risk of local recurrence or new primary tumors.

TABLE OF CONTENTS/OUTLINE

Background - Review of breast cancer incidence - RFGT after prophylactic or therapeutic bilateral mastectomy and the risk of recurrent or new breast cancer, per recent evidence. Factors affecting the volume of RFGT post mastectomy. Common locations to find RFGT. - The best imaging modality to identify RFGT is MRI. How a patient’s volume of RFGT may change over time. Methods to quantify RFGT and future directions. - Current manual measurements and future use of AI

BREE-45 PEDIATRIC BREAST EVALUATION: ROLE OF ULTRASOUND IN CHILDREN AND ADOLESCENTS

Paola A. Prieto Arizabaleta, MD (*Presenter*)

TEACHING POINTS

- Review the embryology of the breast and observe the differences between boys and girls according to age. - Recognize ultrasound as the imaging technique of choice for studying breast pathology in pediatrics. - Characterize normal and abnormal findings in the pediatric breast. - Present ultrasound images of real pediatric patients that recognize findings in daily practice so that they do not go unnoticed.

TABLE OF CONTENTS/OUTLINE

1. Introduction to pediatric breast imaging: Recognize the fundamental role of ultrasound in this population and the appropriate technique for performing it. 2. Normal breast development. 3. Breast development abnormalities:- Congenital.- Premature thelarche.- Gynecomastia. 4. Breast ultrasound in pediatrics. 5. Findings in pediatric breast:- Cystic lesions- Benign nodules- Malignant nodules 6.Conclusions: Gain knowledge of normal, abnormal, and anatomical variants of pediatric breasts and thus recognize the importance of avoiding inappropriate interventional procedures or behaviors.

BREE-46 BREAST FAT NECROSIS: AN IMAGING CHAMELEON

Carolina R. Saccarelli, MD, MD (*Presenter*)
Caroline B. Nunes, MD (*Abstract Co-Author*)
Ana Haddad, MD (*Abstract Co-Author*)

Ronaldo Almeida JR, MD (*Abstract Co-Author*)
Patricia A. De Camargo Teixeira, MD (*Abstract Co-Author*)
Daniela G. Giannotti, MD (*Abstract Co-Author*)
Larissa Moyses, MD (*Abstract Co-Author*)
Vera Christina C. Ferreira, MD, PhD (*Abstract Co-Author*)
Thiago Y. Kobayashi, MD (*Abstract Co-Author*)
Ligia A. Yamashita, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the forming mechanisms and histopathological stages of breast fat necrosis (BNF).Recognize both classical and atypical features of BNF in multiple imaging modalities.Comprehend correlation with patient history and multimodal imaging to improve diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION Definition and clinical relevance of BFNCommon etiologiesHistological evolution and its part in the complex formation of images BFN IMAGING: TYPICAL AND ATYPICAL PATTERNS Mammography patterns Ultrasound patterns Magnetic Resonance Imaging (MRI) patterns CASES Case-based images with worrisome features leading to biopsy and histopathological diagnosis of BFN SUMMARY TAKE HOME MESSAGES

BREE-47 IMAGING THE AUGMENTED REALITY: BREAST IMPLANTS AND THEIR COMPLICATIONS UNCOVERED

Eeta Jain, MD (*Presenter*)
Richa Bansal, MD,MBBS (*Abstract Co-Author*)
Sylvia Nsato, MD (*Abstract Co-Author*)
Bharat Aggarwal, MD (*Abstract Co-Author*)
Pallavi Ranjan (*Abstract Co-Author*)

TEACHING POINTS

The number of women undergoing breast implantation for cosmetic augmentation, post-mastectomy reconstruction, and correction of congenital conditions has been steadily increasing. Among various complications, implant rupture remains the leading cause for implant removal. Magnetic resonance imaging (MRI) is the gold standard for assessing implant integrity particularly in detecting silent ruptures. Differentiation between normal imaging appearances and subtle signs of implant rupture is crucial to avoid false-negatives and ensure appropriate management.

TABLE OF CONTENTS/OUTLINE

Introduction Indications for breast implants Types of implants Placement techniques- Retroglandular vs retropectoral Imaging Modalities Ultrasound: evaluates fluid collections and extracapsular rupture Mammography: detects capsular calcification and ruptures. MRI: Gold standard for detecting implant integrity and complications PET CT: Emerging technique for staging BIA-ALCL. Normal Imaging Appearances Radial folds, peri-implant fluid, malpositioning, postoperative contour irregularities Complications and Their Imaging Characteristics Rupture Intracapsular (linguine sign) Extracapsular (silicone granulomas) Capsular Contracture Contraction of the fibrous tissue around the implant resulting in hardening of breast and squeezing of the implant. Seroma, Hematoma and Abscess Early postoperative complications. Infection and Inflammatory Changes Implant Malposition Due to surgery, trauma , capsular contracture or saline implant deflation. Anaplastic large cell lymphoma (BIA-ALCL) Rare T cell lymphoma presenting as peri implant fluid and associated soft tissue mass. o Breast cancer

BREE-48 NIPPLE DISCHARGE EVALUATION

Rafael R. Santos Ferreira, MD (*Presenter*)
Daniela G. Giannotti, MD (*Abstract Co-Author*)
Larissa Moyses, MD (*Abstract Co-Author*)
Vera Christina C. Ferreira, MD, PhD (*Abstract Co-Author*)
Vivian N. Omura, MD (*Abstract Co-Author*)
Ligia A. Yamashita, MD (*Abstract Co-Author*)
Carolina R. Saccarelli, MD, MD (*Abstract Co-Author*)
Cesar Gabriel Rocha Da Costa Paloschi, MD (*Abstract Co-Author*)
Fabiana Campos, MD (*Abstract Co-Author*)
Patricia A. De Camargo Teixeira, MD (*Abstract Co-Author*)

TEACHING POINTS

Nipple discharge is the third most common breast complaint. While most causes are benign, malignancy occurs in 3-23% of cases. The main challenge is ruling out cancer while avoiding unnecessary surgery. Pathological discharge is typically unilateral, uniductal, spontaneous, and persistent—often clear, serous, or bloody. In contrast, physiological discharge is usually bilateral, multiductal, non-spontaneous, and white, green, or yellow. Color alone is not a reliable cancer indicator.

TABLE OF CONTENTS/OUTLINE

1- Introduction: Nipple discharge is the third most common breast complaint. While most causes are benign, malignancy occurs in 3-23% of cases. The main challenge is ruling out cancer while avoiding unnecessary surgery. Pathological discharge is typically unilateral, uniductal, spontaneous, and persistent—often clear, serous, or bloody. In contrast, physiological discharge is usually bilateral, multiductal, non-spontaneous, and white, green, or yellow. Color alone is not a reliable cancer indicator. 2 - Multimodality images show cases of nipple discharge complaint, summarizing the summarizing the main diagnoses related to the complaint.

BREE-49 BEYOND THE USUAL SUSPECTS: UNMASKING RARE NEURAL TUMORS IN THE BREAST

Anna Cui (*Presenter*)
Dunya M. Imad, MD (*Abstract Co-Author*)
Anna Starikov, MD (*Abstract Co-Author*)
Divya Shenoy, MD (*Abstract Co-Author*)
Lorraine B. Smith, MBBCh (*Abstract Co-Author*)
Sona A. Chikarmane, MD (*Abstract Co-Author*)
Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

Breast lesions of neural origin are rare and typically benign. Exceptions include primary neuroendocrine carcinoma—a rare but aggressive breast tumor—and granular cell tumors, which carry a small risk of malignancy. Given the diverse clinical and radiologic presentations of these lesions, a systematic and informed diagnostic approach is critical to ensure accurate characterization and evaluation to prevent both over- and under-treatment.

TABLE OF CONTENTS/OUTLINE

In this exhibit, we review the innervation of the breast and the clinical and radiologic presentations for various rare nerve cell lesions in the breast, including neuromas, schwannomas, granular cell tumors, and primary neuroendocrine tumors. We highlight key imaging features, presenting symptoms, and characteristic lesion profiles and locations. We outline a systematic approach to their evaluation to support accurate diagnosis and appropriate management.

BREE-50 NOT ALWAYS BENIGN: RETHINKING CIRCUMSCRIBED BREAST MASSES

Beatriu Reig, MD, MPH (*Presenter*)
Alana A. Lewin, MD (*Abstract Co-Author*)

Laura Heacock, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Consider patient factors when deciding whether to recall or biopsy: older age, new symptoms, and personal history of breast cancer increase likelihood of malignancy. Solitary, new, or enlarging masses should be evaluated. Triple-negative subtype of invasive ductal carcinoma may have a cyst-like appearance. HER2-enriched subtype of invasive ductal carcinoma may have a fibroadenoma-like appearance. A single suspicious feature should lead to biopsy even if other imaging features are more benign. Compare mammogram to ultrasound features as masses may appear suspicious on only one modality.

TABLE OF CONTENTS/OUTLINE

Definition and BI-RADS descriptors: round or oval mass, circumscribed margin Multimodality appearance of circumscribed breast cancers Invasive ductal carcinoma NOS Rapidly growing subtypes Triple negative breast cancer HER2-enriched breast cancer Mucinous carcinoma Medullary carcinoma Metaplastic carcinoma Papillary neoplasms: Encapsulated papillary carcinoma, solid-papillary carcinoma, invasive papillary carcinoma DCIS Phyllodes tumors Extramammary metastases to the breast Lymphoma Avoiding pitfalls T2 hyperintensity does not predict benignity Clinical features (patient age, personal history of breast cancer, new, symptomatic) Multimodality comparison

BREE-51 ASYMMETRIES IN BREAST MAMMOGRAPHY: A CASE-BASED MANAGEMENT APPROACH

Erica E. Francolin Federicci, MD, PhD (*Presenter*)
Ana Cecilia A. Wiesel, MD,MD (*Abstract Co-Author*)
Caio D. Pinheiro, MD (*Abstract Co-Author*)
Heni D. Skaf, MD (*Abstract Co-Author*)
Juliana H. Catani, MD (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Iviny Yonekura (*Abstract Co-Author*)
Carolina d. Kiebert (*Abstract Co-Author*)
Milena R. Peixoto, MD (*Abstract Co-Author*)
Isabela C. Ferracini, MD (*Abstract Co-Author*)

TEACHING POINTS

To understand the definition of asymmetries. To discuss a practical work-up of asymmetric mammographic findings. To illustrate both benign and malignant diseases that manifest as asymmetries.

TABLE OF CONTENTS/OUTLINE

Asymmetries are mammographic findings that appear as densities that resemble (and often are) fibroglandular tissue. Due to its benign-looking appearance, breast cancers that manifest as asymmetries can be missed during mammographic evaluation, leading to false negatives. Biopsy is indicated when asymmetries are new, increasing in size, palpable, if other findings are present (calcifications, architectural distortion) or when a suspicious correlate is seen on ultrasound/MRI. Asymmetries are divided into four categories: Asymmetry is a finding seen in only one projection and may represent either a true finding or a summation artifact. Focal asymmetry is identified on both standard mammographic views, occupies less than one quadrant, and often contains interspersed fat. Global asymmetry involves a larger volume—more than one quadrant— and warrants comparison with the contralateral breast and correlation with clinical history. Developing asymmetry refers to a newly appearing density not present in prior exams or a previously noted asymmetry that has increased in size on follow-up. Additional mammographic techniques - such as spot compression, magnification, rolling views, and tomosynthesis - and ultrasound are often used in the work-up of asymmetries. This work-up determines if mammographic short-term follow-up or biopsy may be required.

BREE-52 CODE BREAST FROM ER TO IMAGE: A CASE-BASED REVIEW OF ACUTE BREAST COMPLAINTS

Camila Melo, MD (*Presenter*)
Nadine Santos, MD (*Abstract Co-Author*)
Narelly Araujo Smith, MD (*Abstract Co-Author*)
Maisa Irie (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Naomi Murakami SR, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Emphasize the importance of identifying the most common breast diseases that lead patients to seek emergency department. Recognize conditions that require urgent treatment, providing proper clinical management and prevention of complications. Discuss breast entities such as mastitis, post-biopsy complications, nipple discharge, Mondor's disease, breast implants complication and pediatric breast abnormalities, focusing on the radiological perspective. Illustrate imaging findings related to disorders mentioned above, using different imaging modalities, including ultrasound, mammography, tomosynthesis, magnetic resonance and tomography, with cases from the authors' institution.

TABLE OF CONTENTS/OUTLINE

Acute breast symptoms are relevant causes of emergency visits. Imaging helps distinguish benign from malignant lesions, ensuring proper care and avoiding unnecessary procedures. This exhibit aims to explore important topics related to acute breast complaints that may present in the emergency department:Mastitis: including puerperal and infectious forms, such as tuberculous mastitis and Corynebacterium mastitis.Post-breast biopsy complications: focusing on hematomas, particularly in patients with anticoagulant therapy. Physiological neonatal breast bud: a benign, self-limiting condition that must be distinguished from congenital abnormalities to avoid unnecessary concern. Nipple discharge: evaluation of both benign causes, such as intraductal papilloma, and malignant causes. Mondor's disease: thrombophlebitis of superficial breast vessels, which can mimic more serious pathology. Breast implant complications: implant rupture, rotation, and seroma formation.

BREE-53 GUESS WHO? MOLECULAR SUBTYPE CHARACTERIZATION IN BREAST CANCER USING CONTRAST-ENHANCED MAMMOGRAPHY

Oscar U. Vinalay Landa I, MD (*Presenter*)
Raquel Balbas Lara, MD (*Abstract Co-Author*)
Daniel Sandoval Guerra, MD (*Abstract Co-Author*)
Josue Campiran Gutierrez, MD (*Abstract Co-Author*)
Abraham Ortiz Garcia, MD (*Abstract Co-Author*)
Sergio De Luis Galvez Vieyra IV, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Contrast-enhanced mammography (CEM) can reveal morphologic and enhancement patterns that help differentiate molecular subtypes of breast cancer.Each subtype presents specific radiologic features that can guide diagnosis and therapeutic strategy.Early differentiation of subtypes via CEM supports personalized treatment and improves clinical outcomes.Microcalcifications, lesion margins, and vascular enhancement patterns are key features in subtype characterization using CEM.

TABLE OF CONTENTS/OUTLINE

1.- Introduction and Classification of Breast Cancer Molecular Subtypes2.- Luminal A and B Subtypes on Contrast-Enhanced Mammography3.- HER2+ and Triple-Negative Subtypes on Contrast-Enhanced Mammography4.- Diagnostic Flowchart and Conclusions

BREE-54 AXILLARY ULTRASOUND: A GUIDE FOR BEGINNERS

Patricia de Paula Silva Wanderley Calestini, MD (*Presenter*)
Humberto Pinto Wanderley Neto (*Abstract Co-Author*)
Ana Luiza Rodrigues Pereira, MD (*Abstract Co-Author*)
Luiza Godoy (*Abstract Co-Author*)
Sandro Valle (*Abstract Co-Author*)
Bruno Chui (*Abstract Co-Author*)
Gabriela Giaretta (*Abstract Co-Author*)
Isabella Oliveira (*Abstract Co-Author*)
Miguel J. Neto (*Abstract Co-Author*)
Juliana H. Catani, MD (*Abstract Co-Author*)

TEACHING POINTS

This study aims to revisit axillary anatomy via ultrasonography, review typical and atypical morphological and vascular characteristics of lymph nodes, present appropriate scanning techniques, and review appropriate recommendations.

TABLE OF CONTENTS/OUTLINE

The evaluation of axillary lymph nodes through ultrasound is crucial because, besides being the most suitable imaging method, changes in morphology can indicate either benign (infectious/ inflammatory) or malignant diseases. Benign lymph nodes typically appear oval-shaped, with a thin or even "invisible" cortex, a hyperechoic hilum, and a single vascular pole. Conversely, features such as shape distortion, cortical thickening (greater than 3 mm), displaced or absent hilum, and multiple vascular poles are considered atypical. In cases of bilateral lymph node involvement, with similar appearances and no known breast malignancy may suggest systemic disease. Without clinical correlation, biopsy is recommended - similar to unilateral suspicious findings. Identifying nodal levels helps assess disease extent and contributes to staging. Axillary ultrasound is an accessible and effective method for identifying morphological changes in lymph nodes. Detailed knowledge of the regional anatomy, combined with the ability to distinguish between normal and atypical ultrasound patterns, is essential for radiologists and sonographers to perform accurate risk stratification and contribute to a more assertive and personalized treatment plan.

BREE-55 BREAST LYMPHOMAS:THE UNCOMMON REVEALED, CAN YOU SPOT IT?

Sara Gomez Milanes, MD (*Presenter*)
Julian M. Gandur, MD (*Abstract Co-Author*)
Oreanna Quintero, MD (*Abstract Co-Author*)
Andres F. Caliz Cabrales, MD (*Abstract Co-Author*)
Ricardo A. Rodriguez Alvarez, MD (*Abstract Co-Author*)
Claudia Patricia Davila (*Abstract Co-Author*)

TEACHING POINTS

Recognize the varied imaging appearances of primary, secondary, and anaplastic breast lymphoma on mammography, ultrasound, and MRI. Understand key differentiating features from common benign and malignant breast lesions. Appreciate the role of imaging in assessing disease extent, including axillary involvement. Identify imaging clues suggestive of breast implant-associated anaplastic large cell lymphoma (BIA-ALCL). Emphasize the necessity of biopsy for definitive diagnosis and correlation with clinical history, illustrated by real-world cases.

TABLE OF CONTENTS/OUTLINE

I. Introduction: Breast Lymphoma Overview & Significance. II. Primary Breast Lymphoma: A. Mammographic Findings, B. Ultrasound Features, C. MRI Characteristics, D. Case Examples from Our Institution. III. Secondary Breast Lymphoma: A. Imaging Patterns of Metastasis, B. Bilateral vs. Solitary Presentation, C. Real-Life Case Illustrations. IV. Anaplastic Breast Lymphoma: A. Imaging Spectrum, B. BIA-ALCL: Key Radiological Findings, C. Institutional Case Studies. V. Differential Diagnosis: Mimickers of Breast Lymphoma. VI. The Role of Imaging: Staging and Assessment of Extent. VII. Conclusion: Key Takeaways for Radiological Diagnosis.

BREE-56 HITTING THE MARK: THE ART AND ACCURACY OF TARGETED BREAST ULTRASOUND

Ana Cecilia A. Wiesel, MD,MD (*Presenter*)
Juliana H. Catani, MD (*Abstract Co-Author*)
Ana C. Racy, MD (*Abstract Co-Author*)
Carolina d. Kiebert (*Abstract Co-Author*)
Iviny Yonekura (*Abstract Co-Author*)
Heni D. Skaf, MD (*Abstract Co-Author*)
Renato L. Ribeiro, MD (*Abstract Co-Author*)
Isabela C. Ferracini, MD (*Abstract Co-Author*)
Renata Feres, MD (*Abstract Co-Author*)
Milena R. Peixoto, MD (*Abstract Co-Author*)

TEACHING POINTS

Targeted ultrasound is a focused evaluation aimed at identifying and characterizing lesions initially detected on breast MRI, especially for the purpose of guiding biopsies and better characterizing morphology and margins of a lesion. This technique plays a crucial role in translating MRI findings into a more accessible, cost-effective, and patient-friendly modality. Accurate lesion localization across imaging methods may be challenging due to differences in spatial resolution, patient positioning, and acquisition planes. Successful detection depends on careful analysis of lesion morphology, size, depth, and surrounding tissue, as well as the use of reproducible anatomic landmarks.

TABLE OF CONTENTS/OUTLINE

This pictorial essay provides a step-by-step educational approach to performing target ultrasound following suspicious findings on breast MRI. Through selected cases and didactic illustrations, we demonstrate practical strategies to improve lesion detection, anatomical correlation, and procedural planning. Emphasis is placed on lesion-centered analysis, taking into account shape, depth, location, and relationship with nearby structures. The visual material includes ultrasound and MRI images from our institutional archive, supported by schematic diagrams to guide interpretation and improve reader confidence in cross-modality lesion identification.

BREE-57 UNCOVERING THE INVISIBLE: A CASE-BASED REVIEW OF IMAGING FEATURES IN OCCULT BREAST CARCINOMA

Inigo Deba Ayarza, MD (*Presenter*)
Virginia Diaz (*Abstract Co-Author*)
Nicolas Perez, MD (*Abstract Co-Author*)
Ainhoa Urrutia Ortiz De Salazar, MD (*Abstract Co-Author*)
Ane Zabala, MD (*Abstract Co-Author*)
Olatz Gorrino Angulo, MD (*Abstract Co-Author*)
Maria Udondo Gonzalez del Tanago, MD (*Abstract Co-Author*)
Ruth Gonzalez Sanchez (*Abstract Co-Author*)

TEACHING POINTS

- Occult breast carcinoma (OBC) is a rare presentation of breast cancer, typically manifesting as axillary metastasis without clinical, mammographic, or sonographic evidence of a primary breast tumor. -Breast MRI plays a key role in detecting the hidden primary lesion and guiding therapeutic planning. -Through a series of

representative clinical cases, we illustrate the various diagnostic and therapeutic scenarios, emphasizing personalized, multidisciplinary decision-making. -Recent advances in radiologic and pathologic diagnosis, as well as surgical and oncologic management of both the breast and axilla, are reviewed in the context of each patient's course.

TABLE OF CONTENTS/OUTLINE

1. Introduction to occult breast carcinoma: definition, incidence, and clinical presentation. 2. Role of imaging techniques: mammography, ultrasound, PET/CT, and especially breast MRI. 3. Case-based review: clinical presentation, imaging findings, diagnostic pathway, multidisciplinary management, and outcome. 4. Conclusions and key take-home messages

BREE-58 TINY LESIONS, BIG QUESTIONS: IMAGING AND MANAGEMENT OF PAPILLARY LESIONS

Bruna M. Tachibana, MD (*Presenter*)
Ana Cecilia A. Wiesel, MD,MD (*Abstract Co-Author*)
Juliana H. Catani, MD (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Carolina d. Kiebert (*Abstract Co-Author*)
Aline Lemgruber Prado Costa, MD (*Abstract Co-Author*)
Renata Feres, MD (*Abstract Co-Author*)
Naomi Murakami SR, MBBS (*Abstract Co-Author*)
Nathalia Christina Lopes Flores, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to provide a comprehensive review of breast papillary lesions, covering their clinical presentation, imaging characteristics, and pathological correlation. Additionally, it explores their upgrade potential, along with insights into prognosis and management strategies.

TABLE OF CONTENTS/OUTLINE

Papillary lesions of the breast constitute a heterogeneous group of entities, representing significant challenges in distinguishing benign from malignant forms. This case series includes benign papillomas, papillomas with focal epithelial atypia, papillary carcinoma in situ and various types of papillary carcinomas. These lesions exhibit a broad spectrum of morphological characteristics, each of them carrying distinct prognostic implications, primarily defined by the presence of papillae supported by an arborizing fibrovascular stroma. Imaging studies reveal that mammography may be normal or show dilated ducts, well-defined retroareolar masses, or clustered calcifications in approximately 25% of cases, with suspicious microcalcifications indicating a higher likelihood of malignancy. Ultrasound typically reveals well-defined masses or small ones within dilated ducts, while Doppler may indicate internal vascularization. A multidisciplinary approach is essential for further evaluation and management, ensuring individualized care aligned with patient preferences and lesion characteristics. This exhibit aims to explore the radiological, pathological, and molecular aspects of papillary lesions and their management.

BREE-59 18F-FLUOROESTRADIOL PET IN BREAST CANCER: DIAGNOSTIC ADVANCES FOR PRIMARY AND SECONDARY LESIONS

Ana Luiza Rodrigues Pereira, MD (*Presenter*)
Maria Gabriela Vargas Rezende (*Abstract Co-Author*)
Nathalia Flores Do Nascimento (*Abstract Co-Author*)
Isabela C. Ferracini, MD (*Abstract Co-Author*)
Renato L. Ribeiro, MD (*Abstract Co-Author*)
Renata Feres, MD (*Abstract Co-Author*)
Aline Lemgruber Prado Costa, MD (*Abstract Co-Author*)
Erica E. Francolin Federicci, MD, PhD (*Abstract Co-Author*)
Bruna M. Tachibana, MD (*Abstract Co-Author*)
Juliana H. Catani, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the current indications for PET imaging in breast cancer.Revisit the physiological and technical principles of 18F-FDG PET.Explain the uptake mechanisms and clinical applications of 18F-FES PET.Discuss the diagnostic advantages of FES PET over FDG PET in ER-positive breast cancer.Highlight the limitations of FES PET in clinical practice.

TABLE OF CONTENTS/OUTLINE

Breast cancer remains the most frequently diagnosed malignant neoplasm among women worldwide, with metastatic disease accounting for most cancer-related deaths. PET/CT imaging, particularly with 18F-FDG, is widely used in oncologic assessment due to the high glycolytic activity of malignant tissues. However, tumors such as invasive lobular carcinoma often show low FDG uptake, leading to underdiagnosis or misinterpretation. 18F-FES PET, a radiolabeled estrogen analog, enables non-invasive in vivo assessment of estrogen receptor expression. Unlike FDG, FES uptake is not affected by inflammatory or infectious processes, reducing false-positives and improving diagnostic specificity. FES is particularly valuable in patients with metastatic ER-positive disease, allowing whole-body receptor mapping when biopsy is not feasible. Evidence suggests that FES PET can detect lesions often missed by FDG PET, especially bone, orbital, and nodal metastases commonly seen in luminal tumors. Its main limitation is physiological liver uptake, which may obscure hepatic lesions. Nevertheless, FES PET is FDA-approved as a complement to biopsy in ER-positive breast cancer, reinforcing its role in personalized oncology and guiding more precise treatments.

BREE-60 BREAST MRI: HOW TO START!

Marcela C. Lauar, MD (*Presenter*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Bruna Maria Lobato Vaughan, MD (*Abstract Co-Author*)
Carla C. Tajima (*Abstract Co-Author*)
Aline C. Oliveira (*Abstract Co-Author*)
Carla C. Benetti, MD (*Abstract Co-Author*)

TEACHING POINTS

Alongside mammography/tomosynthesis and ultrasound, magnetic resonance imaging (MRI) plays a crucial role in evaluating breast diseases and in the detection and management of breast cancer. It is the most effective screening method, with a sensibility range between 90-93% in high-risk populations. Breast MRI can be recommended for screening in high-risk population and the average-risk population with extremely dense breasts. In breast cancer staging, MRI is recommended for disease extent assessment in newly diagnosed patients, being also useful in neoadjuvant chemotherapy response monitoring.Furthermore, it can assist in investigating suspicious nipple discharge when mammography and ultrasound results are normal, as well as in breast implant integrity studies. This study aims to demonstrate, in a didactic manner, how to use MRI in breast evaluation, particularly for radiology residents, or physicians from other specialties who do not yet have experience with breast imaging using this method.

TABLE OF CONTENTS/OUTLINE

This study aims to review breast MRI, indications, protocols, main findings and how to describe them according to BI-RADS ® 5th edition, as well as the probable changes in the next edition and evaluation of implants thhrough didactic cases from our digital archieve and drawing illustrations by our team. Furthermore, this study discusses emerging evaluation methods, such as diffusion sequence (DWI), abbreviated, and ultrafast protocols.

BREE-61 HOW I DO IT: ACTIVE EVALUATION OF THE SURGICAL SITE IN CONTROL EXAMS

Ana C. Racy, MD (*Presenter*)
Nathalia Christina Lopes Flores, MD (*Abstract Co-Author*)
Erica E. Francolin Federicci, MD, PhD (*Abstract Co-Author*)
Natalia T. Lima (*Abstract Co-Author*)
Isabela C. Ferracini, MD (*Abstract Co-Author*)
Rodrigo O. Seleti, MD (*Abstract Co-Author*)
Ana Cecilia A. Wiesel, MD,MD (*Abstract Co-Author*)
Iviny Yonekura (*Abstract Co-Author*)

TEACHING POINTS

Conduct a literature review on imaging evaluation of the breast following mastectomy or breast-conserving surgery. How to perform meticulous assessment of the surgical site using additional mammographic views and recognize possible benign postoperative changes in imaging studies after the interventions. The importance of differentiating scar tissue alterations from local recurrence, as well as recognizing follow-up differences based on tumor subtype and individual patient characteristics.

TABLE OF CONTENTS/OUTLINE

Annual mammography of the remaining breast tissue is the mainstay of follow-up in breast cancer patients, aided by ultrasound for new findings and MRI for high-risk cases. This exhibit details accurate postoperative imaging evaluation, highlighting techniques such as scar localization, tangential views, spot compression, magnification, the Eklund technique, digital breast tomosynthesis, and 3D reconstructions. Differentiating benign postoperative changes from recurrence is critical. Surveillance must be personalized according to surgery type, tumor subtype, and individual risk factors. Recurrence risk ranges from 3% to 35% over 10 years. Recent literature is reviewed, with proposals for tailored follow-up protocols. Imaging After Breast Surgery: Overview Annual Mammography and Adjunct Modalities Role of Ultrasound and MRI Scar Assessment Techniques Tomosynthesis and 3D Reconstruction Differentiating Scar vs. Recurrence Risk Stratification and Recurrence Rates Literature Review and Follow-Up Recommendations

BREE-62 LEARNING THE ABCS OF MAMMOGRAPHIC ASYMMETRIES

Abraham Ortiz Garcia, MD (*Presenter*)
Daniel Sandoval Guerra, MD (*Abstract Co-Author*)
Raquel Balbas Lara, MD (*Abstract Co-Author*)
Oscar U. Vinalay Landa I, MD (*Abstract Co-Author*)
Sergio De Luis Galvez Vieyra IV, MBBS (*Abstract Co-Author*)
Cesar Orlando Vidal Lopez, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the types, causes, and imaging behavior of mammographic asymmetries Apply a step-by-step diagnostic algorithm integrating tomosynthesis and Contrast-Enhanced Spectral Mammography (CESM) when appropriately indicated. Improve diagnostic accuracy and determine when to recommend biopsy or follow-upPromote active learning through representative cases, discussion and guided decision-making

TABLE OF CONTENTS/OUTLINE

Introduction to Asymmetries (BI-RADS Framework)The ABC Teaching ModelDiagnostic AlgorithmCase-Based ApplicationEducational ImpactConclusions and Recommendations

BREE-63 SHARP SKILLS: TIPS & TRICKS FOR NEEDLE BREAST INTERVENTIONS

Edipcia Z. Torres, MD (*Presenter*)

TEACHING POINTS

Purpose To provide practical insights and technical strategies to improve the performance, safety, and diagnostic accuracy of breast imaging procedures, with emphasis on ultrasound, mammography, and MRI-guided interventions. Content Outline ü Overview of common challenges in breast imaging (e.g., lesion localization, patient positioning, needle trajectory) ü Optimization of ultrasound-guided core biopsy techniques, including needle angle, depth control, and chest wall safety ü Tricks for accurate wire localization under ultrasound and stereotactic guidance ü Use of local anesthetic and patient positioning to improve lesion accessibility and reduce complications ü Case-based review of pitfalls and solutions in detecting and characterizing subtle lesions ü Correlation with pathology and follow-up recommendations

TABLE OF CONTENTS/OUTLINE

Summary / Conclusion Mastering key technical details and adapting strategies to individual patient and lesion characteristics can significantly enhance the effectiveness of breast imaging procedures. This exhibit highlights actionable tips and real-world solutions to help radiologists improve outcomes and avoid common pitfalls in breast intervention and diagnostic imaging.Edipcia Torres Carrillo, MDr, Maria Guadalupe Gracia Muñoz MDr, Sara Vasquez MDr, Rosaura Fuentes MDr.

BREE-64 ACROSS THE SPECTRUM: VARIED IMAGING APPEARANCES AND MANAGEMENT OF DCIS

Debbie L. Bennett, MD (*Presenter*)
Sherwin Chiu, MD,MPH (*Abstract Co-Author*)
Victoria Xie, MD (*Abstract Co-Author*)
Michelle V. Lee, MD (*Abstract Co-Author*)

TEACHING POINTS

• Ductal carcinoma in situ (DCIS) can have varied imaging appearances on mammography, ultrasound, and MRI. • The imaging appearance of DCIS correlates with the biological aggressiveness of DCIS. • Management strategies for DCIS are evolving and may depend, in part, on specific characteristics of DCIS as diagnosed from imaging and image-guided biopsy.

TABLE OF CONTENTS/OUTLINE

1. Overview of histology/pathology of DCIS 2. Classification of DCIS (low-intermediate-high grade) and subtypes of DCIS (papillary DCIS, cribriform, solid, comedo) with correlation to imaging appearance 3. Less common imaging appearances of DCIS (solid mass, architectural distortion) 4. Extensive DCIS and risk of microinvasion 5. Understanding the risk of progression to invasive breast cancer 6. Current management of DCIS (surgery, radiation therapy, endocrine therapy) 7. Clinical trials on de-escalation of therapy for low-risk DCIS (COMET, LORD, RECAST, LORIS)

BREE-66 MULTIMODALITY IMAGING OF BREAST PAPILLARY LESIONS: A RADIOPATHOLOGIC PICTORIAL REVIEW WITH KEYS FOR DIAGNOSTIC WORK-UP AND MANAGEMENT

Rosa M. Lorente-Ramos, MD, PhD (*Presenter*)
Javier Azpeitia Arman, MD (*Abstract Co-Author*)
Lina Maria Caballero Ubaque (*Abstract Co-Author*)
Miguel Leon Garcia, MD (*Abstract Co-Author*)
Lorena Melian Iribar, MD (*Abstract Co-Author*)
Soledad Alonso Garcia (*Abstract Co-Author*)

TEACHING POINTS

-To review clinical presentation and pathologic findings in papillary lesions of the breast. -To illustrate imaging findings (contrast-enhanced mammography (CEM), ductography, US, MRI) of breast papillary lesions with histopathologic correlation. -To analyze and discuss the specific management of those lesions, including imaging and interventional procedures. -To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Papillary neoplasms consist of a frond-forming growth pattern composed of fibrovascular stalks covered by a layer of epithelial cells with or without an intervening myoepithelial cell layer. We present: - Introduction: Papillary Neoplasms. - Clinical signs and symptoms. Palpable mass and/ or nipple discharge. Sometimes asymptomatic - Imaging findings: contrast-enhanced mammography (CEM), ductography, US, MRI-MRI ductography. -Pathologic entities: Intraductal papilloma, Papillary ductal carcinoma in situ, Encapsulated papillary carcinoma, Solid papillary carcinoma (in situ and invasive).- Interventional procedures. Tips and tricks.- Diagnostic work-up and recommendations for management.

BREE-67 DEMYSTIFYING BREAST IMAGING: ADDRESSING PATIENT AND PROVIDER CONCERNS

Kristina M. Michaudet, MD (*Presenter*)
Helio Neves Da Silva, MD (*Abstract Co-Author*)
Sarah M. Pittman, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to answer common patient and provider breast imaging questions, including: Explaining radiation exposure in mammography (including 2D, tomosynthesis, and contrast-enhanced), comparing it to natural background radiation and other common medical imaging modalities. Providing data-driven insights on false positive rates in screening mammography to help reduce patient anxiety. Clarifying the role of breast biopsy markers, addressing common patient concerns regarding safety, necessity, and removal requests. Reviewing the safety of MRI. Dispelling misconceptions or supporting concerns about gadolinium and iodinated contrast agents.

TABLE OF CONTENTS/OUTLINE

Introduction Importance of patient-provider communication in breast imaging. Radiation Exposure in Mammography Dose, risks and benefits, including for pregnant patients. False Positives in Screening Mammography Data on recall rates, follow-up imaging, and biopsy recommendations. Breast Biopsy Markers Clinical importance, patient concerns, and counseling strategies. MRI Safety: Guidelines for keeping patients safe in the magnetic environment. Contrast Agents Risks and benefits of gadolinium and iodinated contrast agents, including in pregnant and lactating patients. Conclusion Strategies to improve patient understanding, confidence, and decision-making in breast imaging.

BREE-68 RADIOLOGIC CHARACTERIZATION OF INVASIVE LOBULAR CARCINOMA

Abel Gonzalez Huete, MD (*Presenter*)
Miguel Chiva, MD (*Abstract Co-Author*)
Claudia Viescas Huerta, MD (*Abstract Co-Author*)
Sergio Sintes (*Abstract Co-Author*)
Angeles Silva Rodriguez (*Abstract Co-Author*)
Veronica Gamero Medina, MD (*Abstract Co-Author*)
Monica Andreu Rodriguez (*Abstract Co-Author*)

TEACHING POINTS

1. To provide an overview of Invasive Lobular Carcinoma, including its pathological features and clinical presentation. 2. To discuss the imaging characteristics of Invasive Lobular Carcinoma using ultrasound, mammography, contrast-enhanced mammography, tomosynthesis, and MRI. 3. To examine the specific peculiarities of this type of tumor. 4. To illustrate the imaging findings through case studies from our hospital.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Epidemiology, clinical manifestations. 2. Pathology. 3. Mammography and tomosynthesis: Mass with spiculated or indistinct margins, architectural distortion, asymmetry, and other manifestations. 4. Ultrasound: Irregular mass, focal shadowing without a mass, and other manifestations. 5. Magnetic resonance imaging: Irregularly shaped mass with spiculated or irregular margins, nonmass enhancement, and other manifestations. 6. Contrast-enhanced mammography: Utility, sample cases. 7. Extent of disease: Multifocality and multicentricity. 8. Distant disease: Metastases in common and uncommon sites. 9. Conclusion. 10. References.

BREE-69 THE ROLE OF RADIOLOGISTS IN THE TREATMENT OF BREAST CANCER IN FRAIL ELDERLY PATIENTS: OUR EXPERIENCE WITH INNOVATIVE APPROACHES AND PATIENT-CENTERED CARE IN RADIOLOGY

Myriam F. Montes, MD (*Presenter*)
Maria J. Ciudad, MD (*Abstract Co-Author*)
Noelia Arevalo (*Abstract Co-Author*)
Nancy Sanchez Rubio, MD (*Abstract Co-Author*)
Beatriz Lannegrand Menendez (*Abstract Co-Author*)
Carlota Garcia Baron (*Abstract Co-Author*)
Laura Escudero, MD (*Abstract Co-Author*)

TEACHING POINTS

To show our minimally invasive treatment circuit for elderly patients with breast cancer. To describe the imaging findings after microwave ablation of breast cancer by ultrasound and contrast mammography. To show our experience in the treatment of breast cancer with microwave ablation in 27 patients since 2022

TABLE OF CONTENTS/OUTLINE

Breast cancer is a common disease that frequently occurs in elderly women who are often frail, making surgery not a viable option. In our breast unit, we have developed a minimally invasive treatment circuit for these patients since 2022, aiming to minimize medical visits and perform imaging tests on the same day as their hospital visits for other consultations. We have treated 27 elderly patients with breast cancer using microwave ablation. So far, no recurrence has been demonstrated in any of the patients during follow-up. The follow-up is carried out with the least invasive tests, including contrast mammography starting from six months.

BREE-70 CT FINDINGS AND MANAGEMENT OF INCIDENTALLY DETECTED BREAST LESIONS, POST-TREATMENT FINDINGS, AND BREAST AUGMENTATION

Misugi Urano, MD, PhD (*Presenter*)
Takayuki Noro, MD (*Abstract Co-Author*)
Marehiko Hiroshima, MD,PhD (*Abstract Co-Author*)
Yuki Yasuda (*Abstract Co-Author*)
Nobuo Kitera, RT, MSc (*Abstract Co-Author*)
Masaya Kisohara, MD, PhD (*Abstract Co-Author*)
Tatsuya Kawai, MD, PhD (*Abstract Co-Author*)
Akio Hiwatashi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Breast cancer is one of the most common cancers globally; at the same time, the number of survivors is increasing, leading to a rise in incidentally detected breast lesions, post-treatment findings, and breast augmentation on CT in daily clinical practice. Radiologists need to understand breast CT findings and their management comprehensively.This presentation will cover the following topics: breast and axillary anatomy, CT findings for breast benign and malignant lesions, post-treatment findings, breast augmentation, and breast implants.

TABLE OF CONTENTS/OUTLINE

1. Anatomy, including breast and axillary region, breast composition, and background parenchymal enhancement 2. Image findings of breast lesions, including benign lesions, breast cancer, recurrent tumor, metastatic breast tumor, and malignant lymphoma3. Post-treatment findings, including surgery, systemic therapy, and radiation therapy, and complications with treatment4. Breast augmentation, including autologous breast reconstruction, injected breast augmentation, and breast implants, and these complications with treatment

BREE-71 UNVEILING THE SECRETS OF NON-MASS ENHANCEMENT ON CONTRAST-ENHANCED MAMMOGRAPHY. A RADIOPATHOLOGIC PICTORIAL REVIEW

Rosa M. Lorente-Ramos, MD, PhD (*Presenter*)
Javier Azpeitia Arman, MD (*Abstract Co-Author*)
Carlos Molina, MD (*Abstract Co-Author*)
Maria Juan Porter, MD (*Abstract Co-Author*)
Soledad Alonso Garcia (*Abstract Co-Author*)
Miguel Leon Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

-To review the definition of non-mass enhancement (NME) on contrast-enhanced mammography (CEM) according to the description of the American College of Radiology (ACR) in the Breast Imaging Reporting and Data System (BI-RADS). -To identify the most common benign and malignant etiologies seen with non-mass enhancement presentation. -To analyse the diagnostic utility of contrast-enhanced mammography in identifying non-mass enhancement alone or associated with findings on low-energy views (focal asymmetry, architectural distortions, microcalcifications). -To compare the role of other imaging modalities, illustrating imaging findings of CEM with correlation with imaging (US, MRI) and pathology. -To discuss appropriate management of detected non-mass enhancement on CEM.

TABLE OF CONTENTS/OUTLINE

On CEM, an enhancement which is neither a mass nor an enhancing asymmetry is classified as a non-mass enhancement. NME is more likely to be benign overall however, the likelihood of malignancy increases with the presence of associated findings. We present. 1. Definition of NME. 2. Classification. BIRADS. 3. Frequency and histopathology of NME lesions. Illustrative cases with histopathologic findings. 4. How do we manage NME? Further examinations: ultrasonography, biopsy (CEM-guided biopsy), and follow-up examinations.

BREE-72 MASS CONFUSION: DEMYSTIFYING IDIOPATHIC GRANULOMATOUS MASTITIS ON IMAGING

Christian J. Ashby, MD (*Presenter*)
Pooja Sikka, MD (*Abstract Co-Author*)
Zoha Huda, MD,BS (*Abstract Co-Author*)
Dunya M. Imad, MD (*Abstract Co-Author*)
Jordana Phillips, MD (*Abstract Co-Author*)
Sona A. Chikarmane, MD (*Abstract Co-Author*)
Priscilla J. Slanetz, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

Idiopathic granulomatous mastitis (IGM) is a benign, chronic inflammatory breast condition with an elusive etiology, often mimicking malignancy on imaging. It typically affects parous women within five years of lactation and is associated with autoimmune and infectious triggers, including Corynebacterium kroppenstedtii . Radiologic findings are often nonspecific but critical in guiding diagnosis, staging, and treatment response. This exhibit reviews characteristic mammographic and ultrasound features, such as focal asymmetries, hypoechoic masses, and sinus tract formation, while emphasizing histopathologic correlation. Treatment options range from observation and antibiotics to immunosuppressive agents, minimally invasive interventions, and surgery. A multidisciplinary approach is essential due to the disease's variable course and recurrence risk.

TABLE OF CONTENTS/OUTLINE

Clinical Presentation and Epidemiology Proposed Pathogenesis, Disease Subtypes, Pathologic Evaluation Imaging Findings: a. Mammography b. Ultrasound c. MRI (brief overview) Diagnostic Approach and Role of Core Needle Biopsy Staging Management Strategies: a. Observation b. Antibiotics, oral prednisone, methotrexate c. Image-guided aspiration & Intralesional Steroid Injection d. Minimally Invasive and Surgical Options Imaging Follow-Up and Treatment Response Case-Based Imaging Review and Pitfalls

BREE-73 THE GREAT MASQUERADER: IDIOPATHIC GRANULOMATOUS MASTITIS IMITATING BREAST CANCER

Narriman P. Hazime, MD (*Presenter*)
Gabriela Fernanda Riboli Favaro (*Abstract Co-Author*)
Wankler Dias Canhadas Junior (*Abstract Co-Author*)
Iaggo Costa, MD (*Abstract Co-Author*)
Marina Vilhena, MD (*Abstract Co-Author*)
Camila d. Acras, MD (*Abstract Co-Author*)
Eduardo F. Fleury, PhD, MD (*Abstract Co-Author*)
Caio Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

To present the features of idiopathic granulomatous mastitis (IGM) through imaging findings on mammography (MG), ultrasonography (US), and magnetic resonance imaging (MRI). To demonstrate how granulomatous mastitis can mimic breast cancer on magnetic resonance imaging findings, and teach the main enhancement and distribution patterns on MRI that should raise suspicion of mastitis, avoiding misinterpretations. To reinforce the importance of clinical-pathological correlation to avoid unnecessary invasive treatments.

TABLE OF CONTENTS/OUTLINE

Introduction. Definition of idiopathic granulomatous mastitis. Clinical aspects of idiopathic granulomatous mastitis. Imaging findings on mammography, ultrasound and magnetic resonance imaging. MRI enhancement and distribution patterns that can mimic malignancy. Review and present institutional cases with image-pathology correlation, from the analysis of the results of breast biopsies performed in recent years. Importance of biopsy and histological confirmation. Identify and describe differential imaging findings with institutional case examples (differential diagnosis: IGM vs. carcinoma). Conclusion.

BREE-74 FROM PAIN TO PRECISION: OPTIMIZING IMAGING USE FOR BREAST DISCOMFORT

Haydee Ojeda-Fournier, MD (*Presenter*)
Nicole Gamboa (*Abstract Co-Author*)

David M. Kakish, MD (*Abstract Co-Author*)
Sara Grossi, MD (*Abstract Co-Author*)

TEACHING POINTS

Breast pain is a common concern among patients and providers, but when unaccompanied by other clinical findings, it rarely indicates malignancy. At our institution, we reviewed imaging utilization and found that 19.7% of all diagnostic breast imaging studies in 2024 were performed for breast pain. This educational exhibit explores the causes of pain and associated imaging findings, emphasizing sensitivity to patients' concerns. By the end of this educational exhibit, learners will: 1. Define the common types of breast pain (cyclical, non-cyclical, focal, etc.); 2. Understand the incidence, clinical presentation, and management of breast pain; 3. Identify clinical features that indicate when imaging is appropriate in the evaluation of breast pain; 4. Determine the imaging modalities for assessing suspicious breast pain, including mammography, MRI, and ultrasound, according to age and the ACR appropriateness criteria; 5. Recommend evidence-based management strategies based on BI-RADS assessment of benign, indeterminate, or suspicious imaging findings; 6. Recognize the socioeconomic impact of utilizing diagnostic imaging for nonsuspicious breast pain.

TABLE OF CONTENTS/OUTLINE

1. Introduction; 2. Definition of breast pain; 3. Incidence and risk factors of breast pain; 4. Clinical presentation of breast pain; 5. Etiology and differential considerations; 6. Multimodality imaging examples of breast pain; 7. Learn a systematic approach to the characterization of breast pain; 8. When to appropriately refer patients for further imaging; 9. Algorithm for recommended management of breast pain; 10. Conclusion

BREE-75 BREAKING BARRIERS IN DENSE BREAST SCREENING: PRECISION ULTRASOUND STRATEGIES FOR ENHANCED CANCER DETECTION

Flavia B. Sarquis, MD (*Presenter*)
Marilia P. Royero, MD,MD (*Abstract Co-Author*)
Alejandra Agudelo Ruiz (*Abstract Co-Author*)
Aura Vergara (*Abstract Co-Author*)
Daniela B. Grammatico, PhD (*Abstract Co-Author*)

TEACHING POINTS

High breast density increases cancer risk and masks tumors . Supplemental ultrasound , a widely available and non-invasive tool, improves detection, reduces advanced cancers, and enables earlier, less aggressive treatment.Teaching Points 4-6× cancer risk in dense breasts; 30-40% missed on mammograms.Ultrasound detects 3-7/1000 hidden cancers, reducing interval cancers.Screen dense breasts + family history/atypia; AI improves accuracy.Guidelines endorse radiation-free ultrasound for early detection.Risk-based protocols optimize outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction Density RiskMammography Limits Ultrasound Detection (3-7/1000)Interval Cancers Risk Family History/Atypia. Risk-Based Screening Frameworks Modalities Handheld/ABUS/AI Guidelines Recommendations and Recall Rates Cases Illustrative cases/Biopsy Confirmed Cancer Future AI/Protocols Conclusion

BREE-76 NO ATYPIA, NO PANIC: UNDERSTANDING NON-ATYPICAL BREAST PROLIFERATIONS THROUGH IMAGING

Sirley Cisneros, MD (*Presenter*)
Ines Podadera (*Abstract Co-Author*)
Roberto Boratti, MD (*Abstract Co-Author*)
Daiana L. Esteban (*Abstract Co-Author*)
Pamela Garcia Suarez, MD (*Abstract Co-Author*)
Ignacio Mc Lean (*Abstract Co-Author*)

TEACHING POINTS

Knowledge of the main proliferative lesions without atypia, such as usual ductal hyperplasia, sclerosing adenosis, and intraductal papilloma. Clear understanding of the difference between lesions without atypia, for better clinical interpretation and differential diagnosis. Assessment of these pathologies in a multidisciplinary team for patients 'benefit. Treatment and follow up to prevent development of breast cancer. Strengthening health education.

TABLE OF CONTENTS/OUTLINE

Introduction What are proliferative breast diseases Diagnostic methods Differential diagnosis Conclusion

BREE-77 HOME ALONE: "BOOBY" TRAPS FOR NEW ON-CALL JUNIOR RADIOLOGY RESIDENTS

Kevin Dao, MD (*Presenter*)
Jasmine Zhao, MD (*Abstract Co-Author*)
Shayan Saeed (*Abstract Co-Author*)
Raveena Atwal (*Abstract Co-Author*)
Rhea Gandhi (*Abstract Co-Author*)
Chang Shu (*Abstract Co-Author*)
Alvin Tran (*Abstract Co-Author*)
Yinuo Zhang (*Abstract Co-Author*)
Craig Wilsen, MD (*Abstract Co-Author*)

TEACHING POINTS

Early exposure to on-call breast imaging can be an intimidating experience for junior radiology residents, particularly when they have not yet completed a dedicated breast imaging rotation. Common scenarios— such as palpable lumps in young patients, suspected mastitis, abscess formation, and post-operative complications—are frequently encountered during off-hours and demand accurate assessment and timely intervention. This case-based educational exhibit is designed to provide junior residents with a focused introduction to the "must-know" on-call breast pathologies. Through illustrative examples and structured clinical reasoning, we will highlight essential imaging appearances, triage strategies, and communication tips. Special attention will be given to distinguishing benign from suspicious findings, knowing when escalation is warranted, and understanding the implications of imaging on patient management.

TABLE OF CONTENTS/OUTLINE

1. Introduction to the junior on-call breast imaging role 2. Case based presentations of must-know scenarios 3. Decision-making: when to reassure, when to escalate

BREE-78 INTERPRETING ARTIFACTS IN CONTRAST-ENHANCED MAMMOGRAPHY: COMMON AND EMERGING CHALLENGES

Matthew M. Mason, MD (*Presenter*)
Gary J. Whitman, MD (*Abstract Co-Author*)
Rick R. Layman, PhD (*Abstract Co-Author*)
Megan C. Jacobsen, PhD (*Abstract Co-Author*)
William R. Geiser, MS (*Abstract Co-Author*)
Olena O. Weaver, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the technique of contrast-enhanced mammography (CEM), emphasizing technological factors that contribute to artifact formation. 2. Highlight the significance of radiation dose-related resolution variances. 3. Discuss common and newly recognized artifacts in CEM, hypothesizing their origins and possible mitigation strategies.

TABLE OF CONTENTS/OUTLINE

Overview of CEM technology and underlying physics ; Radiation dose-related resolution variances and their impact on contrast quality ; Common artifacts in CEM : causes, examples, and mitigation. Patient-related (ripple, misregistration, pectoral highlighting, breast implants); Skin-related (skin-line enhancement, focal enhancement, skin overexposure); Contrast-related (contrast retention, contamination, negative contrast enhancement, cloudy fat); Technical-related (halo, corrugation, air trapping, axillary line, ghosting). Newly recognized and rare artifacts: imaging examples, hypothesized origins, and potential solutions. Grid texture artifact; Hydrophilic clip void; Vendor-related image variations; Hair pseudo-enhancement. Conclusions best practices; The need for technology standardization among vendors; Future directions.

BREE-79 WHAT'S HAPPENING AT THE BOUNDARY OF BREAST TUMORS?

Maya Honda, MD, PhD (*Presenter*)
Masako Y. Kataoka, MD, PhD (*Abstract Co-Author*)
Azusa Nishimoto (*Abstract Co-Author*)
Aika Okazawa (*Abstract Co-Author*)
Mami Iima, MD, PhD (*Abstract Co-Author*)
Rie Ota, MD (*Abstract Co-Author*)
Yuji Nakamoto, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Rim enhancement on contrast-enhanced MRI—characterized by strong contrast at the margins of a mass—is considered a suggestive sign of malignancy and is associated with certain prognostic factors in breast cancer. However, it is important to note that some benign breast lesions may also exhibit rim enhancement, necessitating careful evaluation. Peritumoral edema detected on T2-weighted imaging is similarly regarded as indicative of malignant or high-grade tumors. On ultrasound, the presence of a hyperechoic area surrounding the tumor is another feature suggestive of malignancy. In this exhibit, we will explore the imaging characteristics of breast lesions that demonstrate distinctive features at their boundaries, with correlation to pathological findings. We will also examine quantitative imaging biomarkers obtained from the peritumoral region, including apparent diffusion coefficient (ADC) values derived from diffusion-weighted imaging (DWI) and radiomic features.

TABLE OF CONTENTS/OUTLINE

1. Understand the mechanisms behind rim enhancement and peritumoral edema on MRI, as well as hyperechoic peritumoral areas on ultrasound.2. Explore the diagnostic and prognostic implications of these imaging features.3. Recognize potential pitfalls in interpretation.4. Introduce the role of quantitative imaging biomarkers, including ADC values and radiomic features, obtained from the peritumoral region.

BREE-80 PRECISION MRI: RISK-ADJUSTED STRATEGIES FOR ENHANCED BREAST CANCER DETECTION

Jhisel C. Lazcano Soliz, MD (*Presenter*)
Maria A. Acha I, MD (*Abstract Co-Author*)
Flavia B. Sarquis, MD (*Abstract Co-Author*)
Angelica M. Rivera (*Abstract Co-Author*)

TEACHING POINTS

Breast cancer is the most common cancer in women worldwide, highlighting the need for improved early detection and survival. Risk models guide personalized screening and prevention. Abbreviated breast MRI (AB-MR) is emerging as a key tool for early detection and annual screening, offering high sensitivity and improved access for women at increased risk of breast cancer This study evaluates AB-MR performance adjusted for key risk factors: age, breast density, personal and family history, BMI, and prior high-risk biopsies.Teaching Points:1. Breast cancer is the most common cancer in women, requiring early detection.2. MRI accuracy improves when adjusted for key risk factors.3. Abbreviated breast MRI (AB-MR) as an emerging tool for screening high-risk women.4. Personalized imaging enhances detection.5. Risk-based MRI leads to earlier diagnosis and better outcomes.

TABLE OF CONTENTS/OUTLINE

1. Breast MRI in Cancer Detection.2. Key Risk Factors Affecting MRI Performance.3. Risk-Adjusted MRI Screening Strategies.4. Abbreviated Breast MRI (AB-MRI) for Early Detection.5. Comparison with Other Imaging Modalities.6. Clinical Implications and Future Directions.7. Conclusion.

BREE-81 MULTIMODALITY IMAGING FEATURES AND PATHOGENESIS OF STROMAL FIBROSIS

Haoling Zhu, MD,BA (*Presenter*)
Cecilia L. Mercado, MD (*Abstract Co-Author*)
Osvaldo Hernandez (*Abstract Co-Author*)
Chloe M. Chhor, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Stromal fibrosis in the breast is an increasingly common benign pathologic entity. 2. Stromal fibrosis has a wide range of appearances on imaging. 3. Careful assessment of radiologic-pathologic concordance is essential to minimizing the risk of a false-negative outcome in pathologic cases of stromal fibrosis.

TABLE OF CONTENTS/OUTLINE

1. Overview and histopathology 2. Summary of selected literature demonstrating upgrade rates of stromal fibrosis detected by various imaging modalities 3. Multimodality imaging spectrum (mammography, US, MRI) - Representative cases 4. Assessment of concordance and management guidelines for the breast radiologist 5. Conclusion and key teaching points

BREE-82 PEDIATRIC BREAST COMPLAINTS: A PICTORIAL REVIEW FOR THE BREAST RADIOLOGIST

Joshua M. Boulter, MD (*Presenter*)
Derek L. Nguyen, MD (*Abstract Co-Author*)

TEACHING POINTS

Children and adolescents occasionally present with breast complaints in the emergency setting, typically with palpable abnormalities or pain. Ultrasound is the imaging of modality of choice in this setting due to its wide availability, resolution for superficial soft tissue structures, and lack of ionizing radiation. In this presentation, we review breast lesions seen in children and adolescents undergoing sonographic evaluation at a tertiary pediatric hospital with the final diagnosis. The aim of this exhibit is to review pediatric breast anatomy and depict representative ultrasound imaging features of normal variants, benign lesions, and findings which should raise suspicion for malignancy. Cases will include but not limited to premature glandular tissue, ductal ectasia, breast edema, breast cellulitis, breast abscess, periductal mastitis, complicated cyst, intraductal papilloma, fibroadenoma, phyllodes tumor, and breast cancer.

TABLE OF CONTENTS/OUTLINE

1. Highlight and discuss the importance of differentiating normal breast development findings from true pediatric breast masses.2. Review common benign and malignant pediatric breast imaging findings that can be detected on breast US.3. Present image-rich multimodality case examples of benign and malignant pediatric breast masses detected on breast US

BREE-83 IMPLEMENTING CARDIOVASCULAR RISK SCREENING USING BREAST ARTERIAL CALCIFICATIONS ON SCREENING MAMMOGRAPHY: A MULTIDISCIPLINARY FRAMEWORK

Kaitlin M. Zaki-Metias, MD, FRCPC (*Presenter*)
Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*)
Jean M. Seely, MD, FRCPC (*Abstract Co-Author*)
Charlotte J. Yong-Hing, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this educational exhibit is to provide an overview of the clinical relevance and utility of recognizing breast arterial calcifications (BAC) and their association with increased cardiovascular disease (CVD) risk as an important incidental finding on screening mammography, and to describe a framework for BAC reporting and management.1. Most women are unaware of their CVD risk.2. BAC is associated with increased CVD risk and may serve as a surrogate tool for early identification of asymptomatic patients at higher risk.3. With recent changes to breast cancer screening guidelines recommending mammography beginning at age 40, more women are undergoing routine screening, increasing the potential for impactful reporting of incidental BAC.4. BAC reporting on mammography, especially in women under age 55, can identify higher-risk patients and support early risk-mitigation strategies.5. Multidisciplinary collaboration and education among radiologists, primary care physicians, and cardiologists is vital for sustainable implementation and optimized outcomes.6. Leveraging AI can enhance BAC detection and support standardized assessment and quantification.

TABLE OF CONTENTS/OUTLINE

1.Explain the significance of BAC on mammography as a marker of CVD risk in women.2. Describe multidisciplinary collaboration among radiologists, cardiologists, and primary care providers for BAC-based screening.3. Identify the clinical workflow needed to integrate BAC assessment into mammographic interpretation.4. Develop strategies to educate patients and healthcare teams on BAC and follow-up pathways.5.Assess opportunities, challenges, and equity implications in BAC-based opportunistic screening.

BREE-84 BREAST CANCER SCREENING IN PREGNANT AND LACTATING PATIENTS: A PRACTICAL APPROACH

Haydee Ojeda-Fournier, MD (*Presenter*)
James Stepenosky, MD (*Abstract Co-Author*)
Soudabeh Fazeli, MD, MPH (*Abstract Co-Author*)
Rebecca Rakow-Penner, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

As more women delay childbirth into their 40s and as awareness of breast cancer risk in younger women rises, radiologists are increasingly encountering patients who require breast cancer screening during pregnancy or lactation. This educational exhibit addresses the unique challenges, evidence-based strategies, and safety considerations for imaging pregnant and lactating patients, whether they are average-risk or high-risk. We will review physiologic breast changes, imaging modality selection, and risk-benefit communication to empower radiologists to confidently guide care in this complex setting. By the end of this educational exhibit, the learner will: 1. Understand the impact of delayed childbearing and increasing identification of high-risk young women on breast cancer screening during pregnancy and lactation. 2. Recognize the physiologic breast changes during pregnancy and lactation and how they affect imaging interpretation and modality selection. 3. Review safe, evidence-based imaging strategies (including mammography, ultrasound, and MRI) for screening and diagnostic evaluation in pregnant or lactating patients. 4. Gain strategies to counsel patients and referring providers on the risks, benefits, and appropriate use of breast imaging during pregnancy and lactation.

TABLE OF CONTENTS/OUTLINE

Introduction; Epidemiology; Breast physiology; Identifying patients that may need screening during pregnancy or lactation; Imaging modalities and safety considerations: Mammography, US, MRI; Case review including average risk, intermediate risk, and high risk pregnant or lactating patients; Survivorship; Current guidelines; takeaway points; Conclusion.

BREE-85 FRONT LINES OF CARE: BREAST CANCER SCREENING IN ACTIVE DUTY SERVICE MEMBERS AND VETERANS

Haydee Ojeda-Fournier, MD (*Presenter*)
James Stepenosky, MD (*Abstract Co-Author*)
Nathan Spengler, MD (*Abstract Co-Author*)
Jennifer R. Foley, MD (*Abstract Co-Author*)
Rebecca Rakow-Penner, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Breast cancer screening in active-duty military service members and veterans presents unique challenges and opportunities. Women currently represent approximately 17% of U.S. active duty military personnel and 10% of the overall veteran population. Frequent relocations, deployments, and transitions between civilian and military health systems can fragment care, potentially delaying screening, diagnosis, and follow-up. At the end of this educational exhibit, the learner will: 1. Understand the demographics and breast cancer risk factors in women who are active duty military members and veterans; 2. Recognize logistical barriers to screening, including relocations, deployments, and care transitions between military, VA, and civilian health systems; 3. Explore evidence-based screening recommendations and resources tailored to military and veteran populations.

TABLE OF CONTENTS/OUTLINE

Introduction; Service branches; Demographics of military and veteran populations; Occupational/Environmental exposures; Delayed childbirth; Barriers to screening and diagnosis: Relocation and deployment, transition between military, VA, and civilian health care; Remote location access to care limitations; DoD screening protocols; Special considerations in use of BI-RADS 3; VA breast cancer screening practices; Centralized medical records; Conclusion

BREE-86 IMAGING FINDINGS AFTER CRYOABLATION OF BREAST CANCER: TIPS AND TRICKS TO KNOW THAT THE PROCEDURE WAS SUCCESSFUL WITHOUT BIOPSY

Laura Abelairas Lopez, MD (*Presenter*)
Lucia Grana Lopez, MD (*Abstract Co-Author*)
Laura Lopez, MD (*Abstract Co-Author*)
Ignacio Fernandez Sobrado (*Abstract Co-Author*)

TEACHING POINTS

Our aim is to describe the findings on mammography, ultrasound, and contrast-enhanced mammography (CEM) after percutaneous cryoablation (PCA) of breast cancer (BC), as well as the signs of residual tumor or recurrence.

TABLE OF CONTENTS/OUTLINE

This exhibit is based on 69 cases of BC diagnosed in non-surgical patients, in our institution, between May 2019 and October 2024 and managed with PCA alone. The expected mammogram finding after PCA is a mass consistent with fat necrosis, larger than the treated tumor. Usually it is clearly benign and, over time, it reduces in size and density. However, it may appear as a dense mass with spiculated margins and persist without changes on serial follow-up. Mainly in these cases, the administration of intravenous contrast is really useful to exclude residual tumor or relapse. Absence of contrast uptake indicates complete ablation. Nevertheless, fat necrosis secondary to the ablation may demonstrate rim and progressive enhancement with moderate conspicuity. The contrast uptake usually decreases over time, but it can persist even 24 months after the PCA. US, initially, demonstrates a heterogeneous mass with indistinct margins and absence of flow, that reduces in size and becomes an oval an echogenic mass with circumscribed margins on serial follow-up examinations. Focal mass with contrast enhancement or color flow on US at the periphery of the ablation area suggests residual tumor or relapse. Enhancement outside the ablation zone indicates residual disease or progression. New suspicious lymph nodes in the axilla are also considered a sign of tumor progression.

BREE-87 CRYOABLATION OF BREAST LESIONS: AN EMERGING ALTERNATIVE TO SURGERY

Omid Shafaat, MD (*Presenter*)
Sidhvi Reddy (*Abstract Co-Author*)
Cathy Chen, MD (*Abstract Co-Author*)
Husameddin El Khudari, MBChB (*Abstract Co-Author*)
Stefanie A. Woodard, DO (*Abstract Co-Author*)

TEACHING POINTS

Cryoablation is a minimally invasive, image-guided technique with growing application in treating early-stage breast cancers. It offers reduced morbidity, excellent cosmetic outcomes, and faster recovery, especially in patients who are poor surgical candidates or prefer a nonsurgical approach. As evidence builds, cryoablation is emerging as a safe, feasible alternative to surgery, with ongoing trials evaluating its long-term efficacy and oncologic safety. To review indications, procedural workflow, and post-treatment surveillance of breast cryoablation. To compare cryoablation with other minimally invasive and surgical treatments. To highlight radiologic imaging appearance before, during, and after cryoablation. To examine current evidence, patient selection criteria, and barriers to adoption.

TABLE OF CONTENTS/OUTLINE

1. Definition a. Cryoablation overview b. Mechanism: freeze-thaw c. Historical background2. Epidemiology a. Increased detection b. Demand for cosmetic treatments c. Expanding eligibility3. Pathophysiology a. Ice crystal necrosis b. Vascular injury c. Fibrosis d. Patient outcomes4. Imaging guidance a. Ultrasound b. Stereotactic c. MRI5. Procedure workflow a. Imaging b. Probe placement c. Freeze-thaw d. Monitoring6. Post-treatment a. Imaging changes b. Recurrence differentiation7. Comparison a. Lumpectomy b. RFA c. Microwave d. VAE8. Indications a. Benign vs malignant b. ICE3 criteria c. Contraindications9. Barriers a. Reimbursement b. Training c. Interdisciplinary challenges10. Future a. Trials b. AI/radiomics c. Indication expansion

BREE-88 MALE BREAST PATHOLOGY: AN UNDERRECOGNIZED POPULATION

Valeria Belden Reyes, MD, MD (*Presenter*)
Yesika J. Davila, MD (*Abstract Co-Author*)
Maria Guerra, MD (*Abstract Co-Author*)
Cesar Palacios, MD (*Abstract Co-Author*)
Ana Escobar, MD (*Abstract Co-Author*)
Gabriela Sepulveda, MD, PhD (*Abstract Co-Author*)
Margarita L. Garza, MD (*Abstract Co-Author*)

TEACHING POINTS

- Understand the anatomy and pathologies of the male breast: Identify and differentiate between normal, benign and malignant imaging features. - Identify Symptoms of Male Breast Pathologies: Recognize common signs and symptoms. - Understanding the imaging techniques used to diagnose breast issues: Review the ACR Appropriateness Criteria Evaluation of the Symptomatic Male Breast. - Promote Awareness: Educate healthcare providers and the public about male breast health for early detection and intervention.

TABLE OF CONTENTS/OUTLINE

Most Common Findings including Gynecomastia, pseudogynecomastia, normal breast, lipoma. Benign Findings including Epidermal Inclusion cyst, mastitis and abscess, benign calcifications, benign nodules, hidradenitis, myofibroblastoma, complicated cyst, hematoma, seroma, hemangioma. Malignant Findings including Invasive ductal carcinoma NST, pure ductal carcinoma in situ (DCIS), non-hodgkin lymphoma, metastatic lymph node from melanoma.

BREE-89 BEYOND THE USUAL SUSPECTS: UNMASKING THE MANY FACES OF MASTITIS

Marta Mazuque Mancilla (*Presenter*)
Marta Vera Cartas, MD (*Abstract Co-Author*)
Laura Martos Ramio, MD (*Abstract Co-Author*)
Gerard Carbo Vilavedra, MD (*Abstract Co-Author*)

TEACHING POINTS

1. This pictorial review aims to broaden the diagnostic approach to mastitis by exploring both typical and atypical causes. 2. Imaging, in combination with clinical and histological correlation, is essential for accurate diagnosis and appropriate management. 3. A primary goal of imaging is to rule out complications like breast abscess, where the radiologist plays a key role, particularly in performing ultrasound-guided drainage.

TABLE OF CONTENTS/OUTLINE

Mastitis refers to an inflammatory condition of the breast that it is typically associated with puerperal patients and breastfeeding-related disorders, but it is important to remember that there are many benign inflammatory processes that have often been overlooked. Mastitis can be classified in various ways, with one of the most practical distinctions being between infectious and non-infectious forms: - In the infectious group, we describe classic puerperal mastitis and less common entities like infected galactoceles and non-puerperal infections. - The non-infectious category highlights inflammatory conditions that are often underrecognized, such as idiopathic granulomatous mastitis, Zuska disease (also known as squamous metaplasia of lactiferous ducts), diabetic mastopathy, ductal ectasia, and radiation-induced mastitis. Each condition is illustrated with representative clinical cases and characteristic imaging findings. Malignant mimickers such as inflammatory breast carcinoma must be considered in differential diagnosis.

BREE-90 A NODE TO REMEMBER: A PICTORIAL ESSAY OF THE DIFFERENTIAL DIAGNOSES OF AXILLARY ADENOMEGALY

Camila Sarro (*Presenter*)
Karine Coelho Rodrigues, MD (*Abstract Co-Author*)
RAFAEL AGUILAR SALES (*Abstract Co-Author*)
Tacio Tenorio (*Abstract Co-Author*)
Simone Caetano, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Axillary lymphadenopathy is a relatively frequent finding in breast imaging, and while it often raises concern for malignancy, it may also be associated with other conditions such as infections, inflammatory diseases, or systemic disorders. Recognizing these alternatives is important, especially to avoid unnecessary biopsies or misdiagnosis. In this educational exhibit, we share selected clinical cases involving axillary lymphadenopathy with different etiologies: breast cancer, sarcoidosis,

lymphoma, and tuberculous lymphadenitis. All diagnoses were confirmed by histolo. The goal is to illustrate how small imaging clues, when placed in context with clinical history, can help narrow the differential diagnosis. This project aims to: - Provide a visual and case-based overview of different causes of axillary lymphadenopathy; - Emphasize that not all suspicious nodes are malignant; - Show how certain imaging characteristics may guide the differential diagnosis; - Encourage radiologists to integrate subtle imaging features with clinical data.

TABLE OF CONTENTS/OUTLINE

- Brief review of axillary lymph node anatomy and normal imaging features; - Case-based review including: • Axillary metastasis in breast cancer; • Sarcoidosis mimicking malignancy; • Isolated axillary involvement in lymphoma; • Tuberculous lymphadenitis with central necrosis; - Comparative imaging chart summarizing key findings by etiology; - Discussion of common pitfalls and diagnostic clues; - Practical takeaways to aid interpretation in daily radiology practice.

BREE-91 SKIN DEEP, TUMOR FAKE? WHEN DERMAL AND HYPODERMAL LESIONS MIMIC BREAST MALIGNANCIES

Maisa Irie (*Presenter*)
Natalia T. Lima (*Abstract Co-Author*)
Carlos Shimizu, MD (*Abstract Co-Author*)
Natalia Orthmann, MD (*Abstract Co-Author*)
Erica Endo, MD (*Abstract Co-Author*)
Naomi Murakami SR, MBBS (*Abstract Co-Author*)

TEACHING POINTS

? To discuss skin lesions that are frequently encountered in the breast and can mimic small superficial breast cancer;? To present a brief literature review of skin and breast anatomy;? To review differential diagnoses of skin lesions, according to anatomic layers (dermal and hypodermal), and superficial breast tissue lesions, highlighting clinical presentation, pathology and epidemiology;? To illustrate radiological features of those conditions in different imaging modalities, including mammography, ultrasound and magnetic resonance with original works performed at the authors' institution;? ?To demonstrate imaging findings that helps to distinguish skin lesions from breast parenchymal lesions, leading to a correct diagnosis to avoid unnecessary invasive procedures and recognize lesions that histologic analysis may be necessary;? To comment on imaging pitfalls of superficial lesions in the breast, that can mimic malignant lesions.

TABLE OF CONTENTS/OUTLINE

Dermal lesions: Sebaceous cyst Epidermal inclusion cyst Dermal calcifications Keloid scar Hypodermal lesions: Fat-containing lesions: lipoma, fat necrosis Vascular lesions: hemangioma, thrombosed vessel Neurogenic lesions: neurofibromas Breast lesions: Breast cancer Fibroadenoma Papilloma

BREE-92 CONTRAST-ENHANCED MAMMOGRAPHY: A RADIOLOGIST'S PRACTICAL GUIDE

Romuald Ferre, MD (*Presenter*)
Patrick Cervini, MD (*Abstract Co-Author*)
Andrea S. Senter, MD (*Abstract Co-Author*)
Brigitte D. Ala, MD (*Abstract Co-Author*)
Cherie M. Kuzmiak, DO (*Abstract Co-Author*)

TEACHING POINTS

• CEM combines anatomical and functional imaging, enhancing lesion detection, especially in dense breasts.• It is a viable, cost-effective alternative to breast MRI in many clinical scenarios.• Proper protocol execution (contrast timing, dual-energy acquisition) is essential for diagnostic accuracy.• Familiarity with CEM-specific artifacts (motion, misregistration, subtraction errors) is crucial to avoid misinterpretation.• Understanding enhancement patterns improves diagnostic confidence and guides patient management.• CEM can be especially useful for high-risk screening, staging, and problem-solving when MRI is contraindicated or unavailable.

TABLE OF CONTENTS/OUTLINE

1. Introduction to CEM - Overview, indications, and rationale - Comparison with conventional mammography and MRI 2. CEM Physics and Technique - Dual-energy acquisition and image reconstruction - Timing of contrast administration 3. CEM Protocol Optimization - Patient preparation and injection protocol - Image acquisition: low-energy vs recombined views 4. Interpretation Guidelines - Enhancement patterns: benign vs malignant - Reading workflow: correlating findings across views 5. Artifacts and Pitfalls - Common issues: motion, subtraction errors, positioning - Strategies to minimize diagnostic errors 6. CEM vs Breast MRI - Diagnostic performance - Strengths, limitations, and case selection criteria 7. Clinical Case Examples - Problem-solving in dense breasts - Preoperative staging of known malignancy - Screening high-risk patients 8. Conclusion and Clinical Integration - Key takeaways for implementation - Future directions and research

BREE-93 KEY INFLUENCING FACTORS AND TACTICAL SOLUTIONS FOR OPTIMIZING BREAST IMAGING CLINIC OPERATIONS: REVIEW WITH REAL-WORLD SCENARIO ILLUSTRATIONS AND EXPERIENCE

Jenna Tinnell (*Presenter*)
Olivia Whitfield (*Abstract Co-Author*)
Wei Li (*Abstract Co-Author*)
Xiaoqin J. Wang, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Illustrate how rigid scheduling, fragmented workflows, and resource limitations drive diagnostic delays across both a main academic campus and its community satellites. Map each operational barrier to a targeted intervention—flexible staffing, bundled order sets, integrated technology, AI-driven triage, queueing-based scheduling, and dedicated coordination roles. Showcase data-driven visualizations (delay distributions, idle-time comparisons, TAT improvements, wait-time reductions, queueing models) that guide continuous workflow optimization.

TABLE OF CONTENTS/OUTLINE

- Introduction: brief summary of rising demand for breast imaging and overview of breast imaging services. - Key Factors & Tactical Solutions: Inflexible Scheduling ? Expand patient access with weekend, early, and late appointments; tailor slot lengths to specific indications; apply queueing-theory scheduling with built-in buffer capacity. Disjointed Orders ? Implement bundled EMR breast-imaging order sets to eliminate extra approval steps. Fragmented Technology ? Integrate PACS/RIS/EMR platforms; deploy automated reporting using structured templates or NLP. Manual Imaging Processes ? Adopt concise, evidence-based imaging protocols by indication; implement AI-driven risk prioritization; establish batch-reading sessions for screening studies. Staffing Constraints ? Introduce flexible staffing models (weekend, early, and late shifts) for both technologists and radiologists. Coordination Gaps ? Appoint dedicated schedulers and clinical navigators to oversee patient flow. Operational Variability ? Embed a Plan-Do-Study-Act (PDSA) quality cycle for ongoing process refinement.

BREE-94 METHOD OF DETECTION IN BREAST IMAGING: APPLICATION, CASE REVIEW, AND IMPLICATIONS OF BI-RADS 6TH EDITION

Haydee Ojeda-Fournier, MD (*Presenter*)
Shadi Aminololama-Shakeri, MD (*Abstract Co-Author*)
Manisha Bahl, MD, MPH (*Abstract Co-Author*)
Sona A. Chikarmane, MD (*Abstract Co-Author*)
Brian N. Dontchos, MD (*Abstract Co-Author*)
Katharine Lampen-Sachar, MD (*Abstract Co-Author*)
Eun L. Langman, MD (*Abstract Co-Author*)
Eric L. Rosen, MD (*Abstract Co-Author*)
Joanna Rossi, MD, MPH (*Abstract Co-Author*)

Richard E. Sharpe JR, MD, MBA (*Abstract Co-Author*)
Sujata V. Ghate, MD (*Abstract Co-Author*)

TEACHING POINTS

This educational exhibit aims to equip breast imagers with practical knowledge and tools to accurately assign Method of Detection (MOD), understand its clinical and audit implications, and prepare for updates introduced in the BI-RADS 6th edition. At the end of this educational exhibit, the learner will: 1. Explain the purpose of Method of Detection (MOD) and outline its role in breast cancer auditing and clinical outcomes reporting; 2. Distinguish between screening-detected, diagnostic-detected, and clinically detected cancers to assign the correct MOD in various clinical contexts; and 3. Evaluate clinical cases to determine the appropriate MOD, especially in scenarios with overlapping screening, diagnostic, or clinical features.

TABLE OF CONTENTS/OUTLINE

Introduction; Definition of MOD; Importance of collecting data; Multimodality imaging examples of screening MOD with mammography, US, MRI, and CEM; Learn a systematic approach to assigning MOD based on patient or provider-detected abnormality; Tips on how to apply the subcategories of MOD for screening examinations appropriately; Pitfalls and controversies in MOD; Resources available to explore MOD; What to expect with BI-RADS 6th edition; Test yourself with unknown cases; Conclusion.

Jocelyn Yang, MD (*Abstract Co-Author*)
Kevin Oh, MD (*Abstract Co-Author*)
Muhammad Naeem, MD, MBBS (*Abstract Co-Author*)
Taylor Chung, MD (*Abstract Co-Author*)

TEACHING POINTS

Tetralogy of Fallot (TOF) is one of the most common congenital heart diseases and exists on a spectrum with double outlet right ventricle (DORV) and pulmonary atresia. Pre-operative imaging is instrumental in differentiating between these overlapping, sometimes similar-appearing disorders and guiding operative management. This exhibit is not an exhaustive review of TOF but specifically presents a framework for differentiating and characterizing similar-appearing disorders on the TOF spectrum based on 5 main features including severity of aortic override, right ventricle outflow obstruction, VSD, ventricular morphology, and MAPCAs. Learning objectives include: 1) Learn feature-based assessment of disorders on the “Tet spectrum” 2) Understand impact of morphologic defects on intra- and extra-cardiac shunting 3) Apply knowledge to sample cases.

TABLE OF CONTENTS/OUTLINE

1. Title, disclosure2. Abbreviations3. Overview4. Embryologic basis of tetralogy of Fallot a. Conotruncal septationb. Conal septumc. Anterior malalignment VSD5. Tet spectrum features a. CAEE-3 BEYOND ATHEROSCLEROTIC CORONARY PLAQUES: A PICTORIAL ROADMAP OF THE‘E’MODIFIER IN CAD-RADS 2.0

Pablo Lama (*Presenter*)
Manuel Rafael Lopez De La Torre Carretero, MD (*Abstract Co-Author*)
Pablo del Nido Recio, MD (*Abstract Co-Author*)
Laura Mate (*Abstract Co-Author*)
Laura Tello Arnas (*Abstract Co-Author*)
Guadalupe Buitrago, MD (*Abstract Co-Author*)
Gorka Bastarrika Aleman, MD (*Abstract Co-Author*)
Ana Ezponda, MD (*Abstract Co-Author*)

TEACHING POINTS

To provide a concise overview of the CAD-RADS 2.0 updates, with particular emphasis on the newly introduced modifiers. To illustrate a spectrum of various non-atherosclerotic coronary lesions that can be reported using the "E" (Exception) modifier, through clinical cases.

TABLE OF CONTENTS/OUTLINE

Background Coronary CT angiography (CCTA) has become the main non-invasive imaging technique for evaluating the coronary arteries. CCTA enables comprehensive assessment of not only the vessel lumen but also the arterial wall and adjacent epicardial structures. The revised CAD-RADS 2.0 classification includes the "E" modifier, which is composed of non-atherosclerotic coronary artery abnormalities, some of which are increasingly recognized as contributors to clinical syndromes, such as INOCA (Ischemia with Non-Obstructive Coronary Arteries), resulting in myocardial infarction or even sudden cardiac death. Findings and procedural details A brief review of the CAD-RADS 2.0 update.Key considerations and practical tips for an accurate interpretation of CCTA studies and normal coronary artery anatomy.A pictorial exploration of non-atherosclerotic coronary artery diseases through examples, including:- Congenital and anatomical variants. - Coronary artery aneurysm. - Inflammatory pathologies: Kawasaki disease and fibromuscular dysplasia.- External compression from adjacent structures. - Coronary artery dissection. Conclusion CCTA is a powerful tool for the non-invasive evaluation of non-atherosclerotic coronary artery disease. The incorporation of the "E" modifier in CAD-RADS 2.0 enhances the clinical relevance of radiology reports by enabling the recognition of these diverse pathologies.

CAEE-4 CONGENITAL CARDIAC VALVE ANOMALIES: WHAT RADIOLOGIST SHOULD KNOW ABOUT PATHOLOGY AND IMAGING FINDINGS

Ameya J. Baxi, MBBS,DMRD (*Presenter*)
Eric Yang (*Abstract Co-Author*)
Pankaj Madan (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)

TEACHING POINTS

To recognize various Congenital cardiac valve anomalies. Discuss pathophysiology and multimodality imaging findings Detect common associations and syndromes Discuss pertinent management findings important for radiological diagnosis

TABLE OF CONTENTS/OUTLINE

Congenital malformations of cardiac valve are often complex . They may occur in isolation or associated with other congenital heart defects. Accurate preoperative assessment is important for guiding treatment. Proper knowledge of embryology, both normal & abnormal anatomy is required for accurate diagnosis. Multiple factors can contribute to delayed or improper diagnosis including lack of familiarity with embryology, anatomy, pathology, and radiographic technique. Radiologists must be familiar with these points and must employ strategies like systematic segmental assessment, comparison with prior study, reading recent relevant literature about treatment & clinical notes. Radiologists thus play a critical role in diagnosis and management. This review gives concise summary of various congenital cardiac valve

anomalies Aims/Objectives Introduction Pathology, role of imaging, imaging findings in different congenital cardiac valve anomalies Mitral valve: Congenital stenosis, prolapse, atrioventricular septal defect, parachute mitral valve, aberrant cord: Aortic valve, Biscuspid-Quadricuspid valve, valvular and subvalvular stenosis: Tricuspid Valve: Ebstein anomaly, Regurgitation, AVSD; Pulmonary valve: Biscuspid valve, valvular and supravalvular stenosis, atresia, regurgitation Associated malformations and syndromes Post treatment normal and abnormal appearances Miscellaneous Differential diagnosis Conclusion

CAEE-6 HIGH RESOLUTION CARDIAC COMPUTED TOMOGRAPHY PRIOR TO VENTRICULAR TACHYCARDIA ABLATION: PROVIDING GUIDANCE FOR ELECTROPHYSIOLOGISTS

Neel Vora, MBBS (*Presenter*)
Rishabh Khurana, MD,MBBS (*Abstract Co-Author*)
Ben Alencherry (*Abstract Co-Author*)
Michael A. Bolen, MD (*Abstract Co-Author*)
Pasquale Santangeli (*Abstract Co-Author*)

TEACHING POINTS

1) To demonstrate the utility of cardiac computed tomography (CCT) to provide anatomical & functional data and enable focused electro-anatomical mapping (EAM) for the identification of critical substrates prior to ventricular tachycardia (VT) ablation 2) To provide a structured reporting template for the pre-VT ablation CCT study.

TABLE OF CONTENTS/OUTLINE

Background : Patients with VT and clinical indication to radiofrequency catheter ablation (RFCA) are frequently referred for pre-procedural imaging. Cardiac magnetic resonance imaging (CMRI), although being the gold standard for biventricular volume, systolic function quantification & assessment for myocardial fibrosis, suffers from extensive ICD related artefacts. Moreover, a subset of these group of patients may be unstable, rendering MR environment unsafe. In such circumstances, widely available CCT can be considered as an alternative to provide relevant information prior to VT ablation. CT protocol: CCT (arterial & delayed) Relevant anatomy & reporting points: LV wall thickness map, thrombus, intra-myocardial fat, calcification, pericardium, delayed iodine enhancement, presence & distribution of epicardial fat thickness, coronary artery & vein evaluation, LV summit. Advantages of CT: high spatial resolution, widely available, no need of pre & post-scan electrophysiological evaluation, ICD related artefacts (mild consequence as compared to MRI). Limitations of CT: radiation dose, low contrast-noise ratio for scar characterization Future directions: Incorporating CCT into routine practice prior to RFCA has the potential to improve clinical outcomes, decrease RFCA procedural time, and pave the way for precise ablation therapies.

CAEE-7 TOTAL ANOMALOUS PULMONARY VENOUS RETURN (TAPVR) - THE VEIN LESS TRAVELLED

Niharika Praveen, MBBS (*Presenter*)
Mounika Pusa (*Abstract Co-Author*)
Yajurvendrasinh Chudasama (*Abstract Co-Author*)
Aditi Bhanushali (*Abstract Co-Author*)
Burak Kaplan, MD (*Abstract Co-Author*)
Christopher J. Francois, MD (*Abstract Co-Author*)
Philip A. Araoz, MD (*Abstract Co-Author*)

TEACHING POINTS

Total Anomalous Pulmonary Venous Return (TAPVR) is a congenital variation of cardiac anatomy where all four pulmonary veins drain directly into the systemic venous circulation via an anomalous connection instead of into the left atrium. This educational exhibit aims to explain the embryology, types, and the characteristic findings on imaging. Radiologists must be able to identify the diagnostic indicators and complications to evaluate and treat this condition.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Classification of TAPVR as supra-cardiac, cardiac, infra-cardiac, mixed types 2. Embryology and clinical significance of TAPVR 3. Pre-operative imaging - CT and MRI features for diagnosis and planning 4. Post-operative imaging - expected findings and complications 5. Conclusion

CAEE-8 CONGENITAL ANOMALIES OF THE AORTIC VALVE - WHEN THREE'S A CROWD

Niharika Praveen, MBBS (*Presenter*)
Aditi Bhanushali (*Abstract Co-Author*)
Burak Kaplan, MD (*Abstract Co-Author*)
Yajurvendrasinh Chudasama (*Abstract Co-Author*)
Mounika Pusa (*Abstract Co-Author*)
Philip A. Araoz, MD (*Abstract Co-Author*)

TEACHING POINTS

Congenital anomalies of the aortic valve include unicuspid, bicuspid, and quadricuspid morphologies, which can significantly impact normal blood flow and predispose to valvular dysfunction and aortopathy. This exhibit provides an overview of embryologic development, imaging-based classification, and clinical implications of each variant. Bicuspid aortic valve, the most common and clinically significant, is explored in depth with attention to associated conditions like ascending aortic aneurysm and coarctation. Imaging appearances across echocardiography, CT, and MRI are illustrated, alongside post-surgical findings.

TABLE OF CONTENTS/OUTLINE

1. Introduction - embryology and normal valve development 2. Structural Classifications, with an emphasis on Bicuspid Aortic Valve 3. Pre-operative imaging 4. Post-operative imaging - expected findings and complications 5. Conclusion

CAEE-9 CARDIAC MAGNETIC RESONANCE IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA): IMAGING THE DEADLY THREAT

Pui Min Yap, MBBS (*Presenter*)
Chun Yin J. Lee, MBChB, FRCR (*Abstract Co-Author*)
Pan Pan Ng, MBChB (*Abstract Co-Author*)
Boris C. Chow, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare systemic disease characterized by asthma, small vessel vasculitis and marked eosinophilia. Cardiac involvement occurs in up to 45% of patients and it is a leading cause of mortality, accounting for 50% of EGPA-related deaths. Cardiac magnetic resonance (CMR) has emerged as the gold standard in the evaluation of cardiac involvement in EGPA which has variable manifestations, including myocarditis and cardiomyopathy. Given that cardiomyopathy is included in the five-factor score which is used to predict the prognosis of patients with EGPA, early detection of cardiac involvement and intervention are critical to improving patient outcomes. While corticosteroids remain the cornerstone of EGPA treatment, immunosuppressive therapy is indicated in cases with cardiac involvement.

TABLE OF CONTENTS/OUTLINE

1. Introduction of eosinophilic granulomatosis with polyangiitis (EGPA) 2. Risk factors of cardiac involvement in EGPA 3. Diagnostic role of cardiac magnetic resonance (CMR) in evaluating the variable cardiac manifestations of EGPA including myocarditis and cardiomyopathy, illustrated with case examples featuring T1-based, T2-based imaging and late gadolinium enhancement patterns 4. Prognostic role of CMR in EGPA with case examples 5. Endomyocardial biopsy pathologic correlation

CAEE-10 A HEARTBREAKING DIAGNOSIS SARCOMA - SAME NAME, DIFFERENT NATURE: A CASE-BASED IMAGING REVIEW OF PRIMARY CARDIAC SARCOMAS

Emrah Duman, MD (*Presenter*)
Zehavit E. Kirshenboim, MD (*Abstract Co-Author*)
Brittany Cody (*Abstract Co-Author*)
Omer Onder, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognizing key imaging features of cardiac sarcomas across modalities Distinguishing sarcomas from benign-appearing or indolent masses Utilizing imaging characteristics such as lesion margins, enhancement patterns, infiltrative versus non-infiltrative behavior, location, and intra versus extracavitary location, alongside clinical context to improve diagnostic accuracy and suggest subtypes. Reviewing sarcoma mimics and overlapping entities Identifying common pitfalls and diagnostic traps Following disease progression and response through serial imaging

TABLE OF CONTENTS/OUTLINE

This exhibit opens with an overview of primary cardiac sarcomas, including their epidemiology, classification, and clinical implications. It then explores the role of advanced imaging modalities such as CT, MRI, and PET in identifying key tumor features such as location, margins, enhancement patterns, and invasiveness. Through a series of illustrative cases, both common and uncommon sarcoma subtypes are presented, with emphasis on diagnostic clues and potential mimickers. Particular attention is given to tumors that may initially appear benign, as well as to entities with overlapping imaging features. Where available, histopathologic correlation is included to enhance diagnostic accuracy. Longitudinal follow-up examples demonstrate tumor progression, treatment response, and key teaching points intended to support radiologists in day-to-day clinical practice.

CAEE-11 A NEW METHOD TO IMPROVE THE VISUALIZATION OF LATE IODINE ENHANCEMENT BY CT, EVEN AT HIGH HEART RATES

Takayoshi Yamaguchi (*Presenter*)
Yuichi Kondoh (*Abstract Co-Author*)
Yuji Miura (*Abstract Co-Author*)
Keiichi Hanaoka, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

1.Current status of acquisition and image reconstruction methods for myocardial late iodine enhancement (LIE) images using CT2.Explain the advantages and limitations of low kV imaging compared to images with standard kV3.Proposal of a new scanning method and image reconstruction method to improve contrast-to-noise ratio and reduce motion artifacts by utilizing the low radiation dose of low kV imaging4.Validation of a new scanning method and image reconstruction method using a phantom simulating myocardial LIE imaging5.Explains the effectiveness of the new method in clinical cases and how to use it appropriately, including the effect of reducing radiation dose

TABLE OF CONTENTS/OUTLINE

1. Introduction2. The significance of obtaining myocardial late LIE images using CT3. Current status of scanning and image reconstruction methods for myocardial LIE imaging4. Explaining the advantages and limitations of low kV imaging5. Proposal of a new scanning method and image reconstruction method that utilizes the advantages of low kV imaging to improve contrast-to-noise ratio and reduce motion artifacts6. Comparison of contrast to noise ratios between conventional one-heartbeat imaging and proposed two-heartbeat imaging using various image reconstruction methods using a phantom simulating myocardial LIE imaging7. Understanding the problems with new techniques in clinical cases and explaining appropriate usage methods8. Explain the effect of reducing radiation exposure by LIE imaging using low kV

CAEE-12 PHOTON-COUNTING CT IN CORONARY ARTERY DISEASE: ADVANCING EVALUATION WITH ULTRA-HIGH RESOLUTION IMAGING ON CCTA

Quoc-Anh Nguyen-Duong, MD (*Presenter*)

TEACHING POINTS

• Photon-counting CT enables submillimeter spatial resolution (as low as 0.2 mm) with reduced noise and enhanced contrast-to-noise ratio, outperforming conventional energy-integrating detectors. • CAD-RADS 2.0 integration with ultra-high-resolution CCTA improves stenosis characterization, particularly in complex cases involving high-risk patients and coronary stents. • PCD-CT facilitates both anatomical and functional imaging—including rest myocardial perfusion CT, CT-derived fractional flow reserve (CT-FFR), and plaque analysis — supporting comprehensive, non-invasive CAD evaluation. • Early experience shows feasibility in diverse clinical contexts such as acute and chronic chest pain, post-CABG imaging, triple-rule-out evaluation, and intrastent restenosis, with the potential to reduce unnecessary invasive angiography and optimize triage.

TABLE OF CONTENTS/OUTLINE

Background on CAD - Global burden of CAD and evolving imaging needs. Overview of PCD-CT technology and its application to CCTA - current guidelines (ESC, ACC/AHA, NICE), and CAD-RADS classification. Technical advantages smaller detector pixels, intrinsic spectral resolution, noise suppression, and radiation dose reduction. Clinical cases demonstrating diagnostic confidence in complex scenarios intrastent restenosis, myocardial perfusion CT, CT-FFR, Plaque analysis, Triple-Rule-Out and CAD-RADS reclassification, and post-intervention evaluation. Clinical impact enhanced decision-making and reduced reliance on invasive procedures.

CAEE-13 CLINICAL ADDED VALUE OF DELAYED MYOCARDIAL ENHANCEMENT ON CT IN ISCHEMIC HEART DISEASE

Seitaro Oda, MD, PhD (*Presenter*)
Masafumi Kidoh, MD, PhD (*Abstract Co-Author*)
Hiroko Takaoka (*Abstract Co-Author*)
Hidetaka Hayashi, MD (*Abstract Co-Author*)
Fumihiro Yoshimura, MD (*Abstract Co-Author*)
Yasunori Nagayama, MD (*Abstract Co-Author*)
Takeshi Nakaura, MD (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. In cardiac CT, incorporation of an ECG-gated equilibrium-phase scan into standard coronary CT allows for the evaluation of late iodine enhancement (LIE) and quantification of extracellular volume (ECV). 2. Compared to cardiac MRI, cardiac CT is more widely available, has better accessibility, and is highly practical, allowing safe imaging even in patients with cardiac implantable devices or those undergoing dialysis. CT offers the advantage of simultaneously and efficiently assessing both coronary arteries and myocardial tissue characteristics. 3. In the management of ischemic heart disease, delayed enhancement CT can provide valuable information for assessing myocardial viability, myocardial infarction with non-obstructive coronary arteries (MINOCA, and coexisting cardiomyopathies.

TABLE OF CONTENTS/OUTLINE

1. Myocardial assessment with delayed enhancement CT - LIE imaging - ECV quantification - Key points of the imaging protocols 2. Application to coronary artery disease - Simultaneous diagnosis of coronary artery lesion and myocardial infarction - Assessment of myocardial viability 3. Application in patients with suspected MINOCA - Takotsubo syndrome - Acute myocarditis - Other etiologies 4. Application in patients with suspected concomitant cardiomyopathy - Cardiac amyloidosis - Hypertrophic or dilated cardiomyopathy - Other types 5. Other potential applications - Addition to pre-TAVI protocol - Addition to pre-catheter ablation protocol - Other indications 6. Future perspectives - Application to photon-counting CT - CT-based molecular imaging - Utilization of artificial intelligence

CAEE-14 DEVELOPMENT OF CARDIAC CT FOR VEIN OF MARSHALL IDENTIFICATION TO CHEMICAL ABLATION

Keisuke Abe (*Presenter*)

TEACHING POINTS

It is very important to identify the vein of Marshall (VOM) for chemical ablation. It is sometimes difficult to identify the VOM using conventional methods, and it would be very helpful if it could be identified on preoperative cardiac CT. In this study, we propose an imaging method to help identify the VOM.

TABLE OF CONTENTS/OUTLINE

1.Chemical ablation and its problems.2.About the VOM.3.CT imaging methods for visualizing the VOM.4.Providing images to support chemical ablation.5.Benefits of visualizing VOM in CT. Chemical ablation is an arrhythmia treatment that involves ethanol infusion into the VOM. The VOM is the embryonic remnant of the left superior vena cava, which descends along the posterior lateral side of the left atrium and flows into the coronary sinus, but is known to be non-existent a certain percentage of cases. Conventional techniques identify the VOM transcatheterly, but with difficulties in cases where the VOM is absent. Therefore, an attempt was made to identify the Marshall vein with CT, which had previously been taken, but identification was difficult, so a new imaging method was devised to add a coronary vein phase. This imaging method has successfully visualized the VOM and made it easier to determine indications and plan treatment. As a result, the conventional procedure can be omitted and replaced by CT, which reduces the radiation dose, the amount of contrast media, procedure time and material costs during chemical ablation.

CAEE-15 MULTIMODALITY IMAGING OF LEFT VENTRICULAR OUTFLOW TRACT OBSTRUCTION

Prabhakar Rajiah, MD, FRCR (*Presenter*)

TEACHING POINTS

1. Left ventricular outflow tract obstruction (LVOTO) is affected by a variety of congenital and acquired abnormalities 2. Multiple imaging modalities including echocardiography, CT and MRI are useful in the evaluation of LVOT 3. MRI provides comprehensive morphological and functional information on LVOT

TABLE OF CONTENTS/OUTLINE

1. LVOT- Morphology 2. Normal flow and hemodynamics 3. Imaging modalities a) Echocardiography- 2d, 3d, Provocative maneuvers b) MRI- Morphology, Function, flow quantification, 4d flow c) CT- High resolution anatomical information 4. Standard imaging planes for evaluation of LVOT 5. Review of various LVOT pathologies with illustrative cases a) Hypertrophic cardiomyopathy b) Abnormal papillary muscles c) Elongated anterior mitral leaflet d) Subaortic membrane e) Congenital- Shone complex,transposition of great arteries, Double outlet right ventricle, truncus arteriosus, f) Endocarditis & abscess g) Pseudoaneurysm h) Neoplastic- Fibroelastoma, myxoma metastasis, sarcoma i) Post-surgical- Mitral valve repair, Aortic surgery, Pulmonary artery banding j) Neo-LVOT obstruction following TMVR k) Membranous septal aneurysm l) Prolapsing dissection flap m) Prolapsing aortic valve n) Tissue tags 6. 3D printing 7. Surgical management a) Myomectomy b) Konno procedure

CAEE-16 MULTIMODALITY IMAGING IN THE EVALUATION OF TAVR COMPLICATIONS

Prabhakar Rajiah, MD, FRCR (*Presenter*)

TEACHING POINTS

1. To review the complications after transcatheter aortic valve replacement (TAVR)2. To understand the role of multimodality imaging in the evaluation of TAVR complications. 3. To optimize CT acquisition for evaluating TAVR complications 4. To illustrate the CT appearances of complications of TAVR

TABLE OF CONTENTS/OUTLINE

A. Introduction B. Multimodality imaging in assessment of TAVR - Echocardiography, CT, MRI, fluoroscopy C. Echocardiography - first line imaging test D. CT protocol for TAVR evaluation E. Review of the following complications with clinical and imaging features, focusing on CT with echocardiographic correlation i. Hypoattenuated leaflet thickening (HALT) -4-tier grading, =25 %, 26-50 %, 51-75 %, > 75 % ii. Reduced leaflet motion (RLM) - 3-tier grading- Normal, partially restricted, immobile - 4-tier grading-=25 % (minimal), 26-50 % (mild), 51-75 % (moderate), > 75 % (immobile) iii. Thrombus iv. Rupture of landing zone v. Pseudoaneurysm vi. Underexpansion vii. Paravalvular leak viii. Device migration- Proximal, distal ix. Obstruction of LV outflow tract x. Infective endocarditis xi. Structural valve failure xii. Aortic regurgitation xiii. Coronary obstruction xiv. Prosthesis-patient mismatch xv. Ventricular conduction abnormalities xvi. Others- Stroke, acute renal failure, access site bleeding, hematoma, pseudoaneurysm, dissection, occlusion

CAEE-17 UPDATE ON THE ROLE OF COMPUTED TOMOGRAPHY (CT) FOR THE EVALUATION OF PARAVALVULAR LEAKS (PVL)

Juan G. Velez, MD (*Presenter*)
Laura Jimenez-Juan, MD (*Abstract Co-Author*)
Matias F. Callejas, MD (*Abstract Co-Author*)
Djeven P. Deva, MBBCh (*Abstract Co-Author*)

TEACHING POINTS

- CT has an emerging role in the evaluation of suspected prosthetic heart valve (PHV) dysfunction and related abnormalities, including paravalvular leak (PVL). It is complementary to echocardiography, because of its higher spatial resolution. - Optimization strategies of the CT protocol to detect PVL are crucial to ensure successful image quality, including an initial non-enhanced acquisition, selection of high tube voltage, retrospective gating and adequate intravenous contrast protocol. - A standardized approach to the evaluation of PVL by CT includes identification of the PHV, selection of the appropriate cardiac phase for imaging post-processing, and the accurate detection and characterization of the potential PVL. - Effective communication of the precise PVL location and size can facilitate the decision making, device selection and/or surgical approach. - Radiologists should be familiarized with the techniques, devices and treatment strategies used for PVL.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Current and previously used PHV, and their association with PVL III. Approach to PVL treatment: strategies and devices used IV. The role of CT on the diagnosis and treatment planning of PVL a. Strengths and weaknesses V. Optimization of CT Technique a. Premedication - patient preparation b. Contrast administration c. Suggested CT protocol VI. Tips for the evaluation and reporting of PVL a. Suggested structured approach VII. Example of reporting template VIII. Conclusions

CAEE-18 MRI IN NON-ISCHEMIC CARDIOMYOPATHY: ESSENTIALS FOR DIAGNOSIS

Dhilip Andrew, MD (*Presenter*)
Melisa Prieto Peralta, MD (*Abstract Co-Author*)
Kiran Batra, MD (*Abstract Co-Author*)
Arzu Canan, MD (*Abstract Co-Author*)

TEACHING POINTS

Learn about different types of non-ischemic cardiomyopathies and their cardiac MR imaging pattern Gain knowledge about role of MR strain imaging in non-ischemic cardiomyopathy Improve knowledge and understanding about key cardiac MR findings in patients with non-ischemic cardiomyopathy

TABLE OF CONTENTS/OUTLINE

Review different types of non-ischemic cardiomyopathy and their common underlying etiologies. Patterns of late gadolinium enhancement in non-ischemic cardiomyopathy Key MR findings characteristic for each type of non-ischemic cardiomyopathy Brief introduction and patterns of MR Strain imaging findings in non-ischemic cardiomyopathy. Case-based illustration of different types of non-ischemic cardiomyopathy associated with step-by-step approach to diagnosis Common patterns of MR findings Uncommon findings 6. Future directions of Cardiac MR imaging in non-ischemic cardiomyopathy.

CAEE-19 MYOCARDIAL BRIDGES ROAD TRIP: WHEN THE CORONARIES TAKE THE SCENIC ROUTE

Berali Del Espiritu Santo Padilla, MD (*Presenter*)
Enrique I. Ampudia Manjarrez SR, MD (*Abstract Co-Author*)
Ernesto J. Dena JR, PhD, MSc (*Abstract Co-Author*)
Patricia Rodriguez Nava, MD (*Abstract Co-Author*)

TEACHING POINTS

Myocardial bridges (MB) are a congenital coronary anomaly in which a segment of an epicardial artery takes an intramuscular course through the myocardium. This tunneled segment can vary in thickness from superficial (75%) to deep (25%), with incomplete bridges showing partial muscular coverage. They can manifest as angina, arrhythmias, or even myocardial infarction due to systolic compression of the tunneled segment. The pathophysiology of MB related ischemia involves multiple mechanisms, including persistent systolic compression, delayed diastolic relaxation, endothelial damage, and accelerated proximal atherosclerosis due to altered hemodynamics. High-risk features that increase clinical concern include bridges deeper than 5 mm, longer than 20 mm, or those causing more than 70% systolic luminal narrowing. CT angiography is the gold standard for noninvasive evaluation of MB. It visualizes the anatomical relationship between the coronary artery and overlying myocardium, and allows for a comprehensive assessment of associated atherosclerosis and other cardiac abnormalities. Key CT findings include: The "disappearing artery" sign (loss of the epicardial fat plane as the vessel dives into the myocardium), a characteristic U-shaped course of the affected artery, and dynamic systolic compression (visible with ECG-gated protocols).

TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Anatomy and pathophysiology. a. Normal vs. bridged coronary anatomy. b. Mechanisms of ischemia.3. Clinical presentation.4. Imaging detection. a. CT as a gold standard. b. Key CT signs.

CAEE-20 FOLLOW THE LEAD - A CASE-BASED GUIDE TO CARDIAC DEVICES ON CHEST X-RAY

Alena Kollmann, MD (*Presenter*)
Jan P. Grunz, MD (*Abstract Co-Author*)
Henner Huflage, MD (*Abstract Co-Author*)

TEACHING POINTS

Cardiac implantable electronic devices such as pacemakers, implantable cardioverter-defibrillators (ICDs), cardiac resynchronization therapy (CRT) devices, and subcutaneous ICDs (S-ICDs), have characteristic appearances and lead configurations on chest radiographs. Radiologists should be able to identify correct positioning and detect misplaced leads and various device-related complications. Those are often first suspected or confirmed on chest X-ray. Therefore, this exhibit presents a systematic approach to evaluate cardiac devices in chest radiographs and provides a series of educational cases to apply and deepen the acquired knowledge.

TABLE OF CONTENTS/OUTLINE

1. Device overview: What types of cardiac devices exist and how can we distinguish them in chest X-ray?1.1. Pacemakers1.2. ICD / S-ICD1.3. CRT2. Lead anatomy and correct positions: RA, RV, LV (coronary sinus), and shocking coils.3. A guide: Suggested algorithm for structured assessment of cardiac devices.4. Case series: Examples of incorrect lead positioning and various complications.5. Key takeaways.

CAEE-21 LIFTING THE AORTOMITRAL CURTAIN

Prabhakar Rajiah, MD, FRCR (*Presenter*)

TEACHING POINTS

Aortomitral curtain also known as aortomitral fibrous body/continuity or intervalvular fibrosa is a fibrous tissue that connects the aortic and mitral valves. 1. To review the anatomy of aortomitral curtain (AMC). 2. To describe the various pathological entities that involve AMC 3. To illustrate the imaging appearances of lesions that involve AMC 4. To understand the significance of AMC pathologies

TABLE OF CONTENTS/OUTLINE

a. Morphology of the AMC b. Normal imaging appearance of AMC - Echo, CT, MRI c. Determination of ventricular morphology - AMC indicates morphological left ventricle --Illustrative examples of D-TGA and CC-TGA d. Thickening of AMC - Radiation heart disease e. Extensive calcification of aortomitral curtain --- Degenerative mitral or aortic disease---Higher post-surgical complications --- Calcium score > 300, need for pacemakers following TAVR- close to AV node --- Radiation heart disease- f. Caseous calcification - Mimics pseudoaneurysm in contrast CTA g. Calcification in aortomitral curtain - Challenges measurements in transcatheter mitral valve replacement CT h. Infective endocarditis and abscess --- Aortomitral curtain involvement requires radical debridement i. Dehiscence j. Aneurysm and pseudoaneurysm k. Thrombus l. Pannus m. Tumors n. Aortomitral curtain incisions to expand aortic root - Nicks procedure or Manouguian procedure o. Aortomitral reconstruction - Commando, Hemi-commando procedure.

CAEE-22 EVALUATING THE SITUS A PANDORA'S BOX

Mildreth Juliana Acuna Rojas, MEd (*Presenter*)
Manuel Alejandro Garrido, MD (*Abstract Co-Author*)

TEACHING POINTS

Learn criteria to think about how to diagnose situs anomalies, having in consideration risk factors. • Carry out an anatomical review of the atrial, bronquial and spleen. • Know the systematic analysis, A close look at each of the steps to elucidate and correctly present its findings. • To present the clinical case of a male patient in her sixth decade of life with deterioration of their functional class leading to suspicion of pulmonary thromboembolism; on the other hand, a female patient also in her third decade of life who is admitted for follow-up due to a history of Fontan surgery.

TABLE OF CONTENTS/OUTLINE

Introduction 2. Epidemiology 3. Embryologic development 4. Diagnosis 5. Systematic analysis 6. Clinical cases 7. Conclusions 8. References

CAEE-23 THINKING BEYOND THE STENOSIS: A CROSS-SECTIONAL IMAGING APPROACH TO TROPONIN-POSITIVE CHEST PAIN WITH NON-OBSTRUCTED CORONARY ARTERIES (TPNOCA)

Cevdet Donmez, MD (*Presenter*)
Monika Radike, MD, PhD (*Abstract Co-Author*)

Anjuna Reghunath, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

TpNOCA encompasses MINOCA, MINOCA mimics, and INOCA, requiring precise diagnosis to guide management. Accurate etiologic diagnosis is essential to avoid unnecessary therapies and initiate appropriate management, improve prognosis and prevent potential sudden deaths. Early cross-sectional imaging significantly enhances diagnostic yield and influences clinical decision-making, optimising patient outcomes. Cardiac MRI (CMRI) and CT Coronary Angiography (CTCA) have complementary roles in diagnosing TpNOCA, depending on the suspected differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Definition and scope of TpNOCA, including MINOCA, MINOCA mimics, and INOCA and their common cross-sectional imaging findings. Prevalence, demographics, and clinical significance of TpNOCA. Diagnostic approach flowchart for chest pain with troponin elevation. CMRI protocol and role in TpNOCA diagnosis, including: Diagnosis and differentiation of MINOCA, myocarditis, Takotsubo cardiomyopathy and cardiomyopathies Optimal timing of CMRI (<2 weeks) and impact on clinical management Impact of CMR findings on clinical management Use of T1/T2 weighted imaging, perfusion imaging and late gadolinium enhancement. CTCA role in TpNOCA: Detection of coronary anomalies and spontaneous coronary artery dissection High risk plaque analysis and perivascular fat characterization Role of CT-FFT and PET/SPECT Cardiac CT.

CAEE-24 COMPLICATIONS OF THE CONGENITAL CARDIOVASCULAR SURGERY IN SINGLE VENTRICLE PHYSIOLOGY- WHAT RADIOLOGISTS SHOULD KNOW?

Kushala Madduru (*Presenter*)
Anmol Goyal, MBBS (*Abstract Co-Author*)
Erin Opfer (*Abstract Co-Author*)
Sanket S. Shah, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review single ventricle physiology and key imaging findings during each stage of the single ventricle palliation. 2. To understand and recognize complications that may arise from single ventricle palliation surgery to include elevated systemic venous pressure, collateralization, and hypoattenuating filling defects. 3. To highlight the role of advanced imaging in the interstage evaluation of single ventricle patients and postoperative complications.

TABLE OF CONTENTS/OUTLINE

Introduction - The importance of imaging following congenital cardiovascular surgery; The imager's role and perspective. Single Ventricle Physiology and Surgical Staging - Normal Postoperative Imaging Findings following different stages of single ventricle palliation surgery. Early Complications - Pleural effusions, infection, thrombosis. Late Complications - Pulmonary arteriovenous malformations, aortopulmonary collaterals, shunt obstruction, liver disease, lymphatic complications, plastic bronchitis, protein-losing enteropathy. Advanced Imaging Techniques - CT, MRI, and echocardiogram use in the detection of complications; Key findings imagers should recognize red flags that need immediate attention; Recent advances and their clinical applications. Conclusion - Summary of the imager's role in managing congenital cardiovascular surgery patients; Future directions in imaging for complications

CAEE-26 3D PRINTING FOR PARAVALVULAR LEAK INTERVENTIONS: INTEGRATING ADVANCED SEGMENTATION AND FABRICATION TECHNIQUES

James W. Goldfarb, PhD (*Presenter*)

TEACHING POINTS

1) Develop proficiency in identifying and characterizing paravalvular leaks on cardiac CT, including recognition of key imaging features and leak morphology around both aortic and mitral prosthetic valves. 2) Master the segmentation workflow using advanced software tools to accurately delineate leak channels and surrounding anatomical structures, which are crucial for 3D printing. 3) Apply various 3D printing techniques to fabricate patient-specific models for procedural simulation, device sizing, and surgical/interventional planning.

TABLE OF CONTENTS/OUTLINE

1) Clinical Background & Imaging Challenges: Understand the prevalence of paravalvular leaks, their hemodynamic consequences, and the role of CT imaging in leak detection. 2) CT Acquisition & Segmentation Strategy: Learn the postprocessing algorithms and segmentation strategies that facilitate accurate identification and characterization of leaks. 3) 3D Modeling & File Preparation: Gain insights into the process of STL export, mesh smoothing, segmentation refinement, and the different software platforms used for creating 3D models. 4) Printing Technologies & Materials: Explore the specifications of various 3D printers and the cost considerations involved in choosing the right materials for printing accurate and durable models.

CAEE-27 IMAGING SURGICALLY REPAIRED CONGENITAL HEART DISEASE. WHAT THE RADIOLOGIST NEEDS TO KNOW

Felipe A. Sanchez, MD (*Presenter*)
Heli D. Rueda, MD (*Abstract Co-Author*)
Felipe Castillo Aravena, MD (*Abstract Co-Author*)
Gabriela S. Galvao, MD (*Abstract Co-Author*)
Dimpi Sinha, MD,MBBS (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Farah Cadour, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Understand the normal postsurgical anatomy of corrected congenital heart disease Illustrate the most characteristic imaging features of specific types of congenital heart disease repair procedures across multimodality imaging To differentiate between expected postsurgical appearance and complications To provide pearls and pitfalls for assessing repaired CHD

TABLE OF CONTENTS/OUTLINE

1. Background 2. Surgical procedure, normal postoperative findings and complications a) Congenital pulmonary stenosis and TOF repair b) VSD and ASD repair c) Anomalous pulmonary venous connection repair d) AV canal spectrum and associated valvular anomalies repair e) Single ventricle palliation: Fontan procedure f) 1.5 Ventricle repairg) TGA and CC-TGA: Arterial and atrial switch procedures h) DORV repair h) Ebstein anomaly repair i) Truncus Arteriosus repair 3. Schematic approach for the assessment of corrected CHD: Pears and pitfalls 4. Summary

CAEE-28 GETTING IT RIGHT: WHAT THE RADIOLOGIST NEEDS TO KNOW ABOUT THE RIGHT VENTRICLE

Maria Clara N. Lorca, MD (*Presenter*)
DHRUBAJYOTI BANDYOPADHYAY (*Abstract Co-Author*)
Madison Adams, MPH (*Abstract Co-Author*)
Sadia Sultana, MRCP,FRCR (*Abstract Co-Author*)
Vinit Baliyan, MD,MBBS (*Abstract Co-Author*)
Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*)
Anushri Parakh, MBBS, MD (*Abstract Co-Author*)
Sandeep S. Hedgire, MD (*Abstract Co-Author*)

TEACHING POINTS

With the increased recognition of the crucial role of the right ventricle (RV) in determining functional status and prognosis in multiple cardiovascular conditions, it has become essential for the radiologist to demonstrate proficiency in anatomical, structural, functional characteristics, and pathologies involving the RV in order to avoid false-positive diagnoses and misdiagnoses.In this case-based review we summarize the current knowledge of anatomic-pathological imaging features of the RV with etiologies associated with RV pressure and volume overload, and RV cardiomyopathy.Imaging plays a fundamental role in identifying the intrinsic anatomic and functional differences between the normal RV and left ventricle (LV), and in evaluating the different RV pathological processes.

TABLE OF CONTENTS/OUTLINE

How to identify major anatomical and pathological imaging features of the right ventricle in cardiac CT and MR imaging. Identify imaging features of the major anatomical points in the right ventricle and its importance in the anatomical segmentation of the right ventricle, including its fundamental role in the characterizing the morphological ventricle in congenital heart disease processes.Demonstrate the role of imaging in the decision-making process for the multiple etiologies RV.The RV has an essential role in determining symptomatic status and prognosis in nearly all cardiovascular disorders studied to date. A proper knowledge of the most common cardiac imaging features of RV diseases is necessary in order to promptly and accurately identify the RV involvement in various cardiac diseases.

CAEE-29 IMAGING INSIGHTS INTO LEFT ATRIAL APPENDAGE OCCLUSION DEVICES: DEVICE VARIANTS, PLANNING CONSIDERATIONS AND COMPLICATIONS

SIMRAN SINGH CHEEMA (*Presenter*)
Anmol Dhawan, MBBS, MD (*Abstract Co-Author*)
Donald G. Benson JR, MD, PhD (*Abstract Co-Author*)
Mostafa Abozeed, MD, PhD (*Abstract Co-Author*)
Naga Sai Rasagna Mareddy, MBBS (*Abstract Co-Author*)
Komal Verma Saluja, MBBS (*Abstract Co-Author*)
Satinder P. Singh, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Importance of imaging in pre-procedural imaging and post-implantation evaluation to confirm positioning of Left atrial appendage occluder devices (LAAOD) and detect complications2. Types of LAAOD devices in common practice.3. The indications and contraindications of LAAOD.4. Planning of LAAOD especially watchman and amulet device including the steps to determine size of LAA (left atrial appendage) ostium, device landing zone, and LAA length which determinants of sizing and seating an LAAOD device which enhance safety and long term efficacy. This includes step by step approach for correct measurement techniques.5. Imaging features of various complications associated with the device, including device migration/embolization, peridevice leak, partial or incomplete endothelialization, and device related thrombus in the left atrium with case examples.

TABLE OF CONTENTS/OUTLINE

Introduction and Background• Indications and Contraindications• Left Atrial Appendage Anatomy• Types of LAAOD Devices• Planning and Sizing of LAAOD (Watchman & Amulet)• Procedure Overview• Imaging Modalities: Echocardiography & CT• Immediate Postprocedural Complications.• Delayed Complications• Case Examples of various complications• Conclusions

CAEE-30 MULTIMODALITY IMAGING OF PERICARDIUM

Jordi Broncano, MD (*Presenter*)
Ana I. Barrio Alonso, MD (*Abstract Co-Author*)
Sanjeev Bhalla, MD (*Abstract Co-Author*)
Kristopher W. Cummings, MD (*Abstract Co-Author*)
Jadranka Stojanovska, MD, MS (*Abstract Co-Author*)
Antonio Luna, MD, PhD (*Abstract Co-Author*)
Fernando R. Gutierrez, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To critically assess the strengths, limitations, and complementary roles of the different imaging modalities in the evaluation of pericardial diseases . 2. To evaluate the normal anatomy and physiology of the pericardium , and to recognize the key imaging feature s associated with the spectrum of pericardial diseases . 3. To explore the utility of advanced imaging techniques in distinguishing constrictive pericarditis from restrictive cardiomyopathy, emphasizing its diagnostic value and clinical implications.

TABLE OF CONTENTS/OUTLINE

1. The normal pericardium ; 2. Multimodality Imaging of pericardial diseases , 2.1. Echocardiography, 2.2. Cardiac computed tomography, 2.3. Cardiac magnetic resonance; 3. Pericarditis , 3.1. Etiology & clinical presentation, 3.2. Acute pericarditis, 3.3. Recurrent pericarditis, 3.4. Chronic pericarditis, 3.5. Healed/burned out pericarditis, 3.6. Myocardial involvement: Perimyocarditis vs. Myopericarditis, 3.7. Specific forms: Tuberculous pericarditis, Post-cardiac injury syndrome: Epistenocardic pericarditis, Dessler syndrome, Post-pericardiotomy syndrome, Post-traumatic pericarditis; 4. Enlarged pericardial cavity , 4.1. Pericardial effusion, 4.2. Pneumopericardium, 4.3. Hemopericardium; 5. Cardiac tamponade , 5.1. Pathophysiology & clinical presentation, 5.2. Role of multimodality imaging, 6. Constrictive pericarditis , 6.1. Key findings: Role of advanced imaging, 6.2. Transient constrictive pericarditis, 6.3. Effusive-constrictive pericarditis, 6.4. Focal constrictive pericarditis; 7. Pericardial masses : 7.1. Benign pericardial masses, 7.2. Pericardial metastasis, 7.3. Primary pericardial tumors; 8. Conclusions

CAEE-31 USEFULNESS OF A NEW TECHNIQUE TO REDUCE STAIR-STEP ARTIFACTS IN DUAL-SOURCE PHOTON-COUNTING DETECTOR CT

Miyagawa Kouki (*Presenter*)
Nobuo Kitera, RT, MSc (*Abstract Co-Author*)
Masaya Kisohara, MD, PhD (*Abstract Co-Author*)
Kazuya Ohashi, PhD, RT (*Abstract Co-Author*)
Misugi Urano, MD, PhD (*Abstract Co-Author*)
Akio Hiwatashi, MD, PhD (*Abstract Co-Author*)
Hiroshi Fukuma, BSc (*Abstract Co-Author*)

TEACHING POINTS

1. Coronary computed tomography angiography (CCTA) needs to solve the problem of motion artifacts caused by cardiac motion, and a CT scanner with high temporal resolution is the most effective solution. 2. Dual-source CT (DSCT) is a CT system equipped with two X-ray tubes and two detectors, and the fastest temporal resolution reaches 66 ms, the highest value of any CT system. This makes it possible to examine patients with high heart rates, which makes CCTA difficult. 3. The current DSCT systems don’t have detector width not covering the entire heart, image quality may be limited by stair-step artifacts (SSA), and the use of ECG editing with low-pitch helical scan to suppress SSA results in increased the radiation dose. 4. SSA-reduction algorithm (SSARA), a newly developed image correction technique, can produce images with continuity over the entire heart by non-rigidly aligning the displacement of positional information in each heartbeat, and may solve the problems of SSA without detector covering entire heart. 5. The detector coverage of DSCT with high-resolution mode becomes narrower in exchange for improved image quality.so suppressing SSA is an extremely important theme.

TABLE OF CONTENTS/OUTLINE

1. Technical requirements for CCTA 2. Advantages and disadvantages of DSCT in CCTA 3. Relationship between DSCT scan method and the radiation dose 4. SSARA and its clinical significance 5. Effectiveness of SSARA on clinical cases without breath-holding and with arrhythmia

CAEE-32 CARDIAC MRI IMAGING OF RESTRICTIVE CARDIOMYOPATHY

Felipe A. Sanchez, MD (*Presenter*)
Dimpi Sinha, MD,MBBS (*Abstract Co-Author*)
Gabriela S. Galvao, MD (*Abstract Co-Author*)
Felipe Castillo Aravena, MD (*Abstract Co-Author*)
Heli D. Rueda, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Farah Cadour, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

1. RCM results from increased myocardial stiffness impairing ventricular filling. It is classified into non-infiltrative, infiltrative, storage, cancer-related, and endomyocardial types.2. Cardiac MRI provides comprehensive assessment and is the gold standard imaging modality. Typical findings include normal-sized ventricles with bi-atrial dilatation. LGE and parametric mapping facilitate differentiation of RCM subtypes Objectives: Review the definition of restrictive cardiomyopathy and the different groups of diseases that may cause it Describe the role of cardiac MRI in the diagnosis, management and follow-up RCM Review imaging findings, pearls and pitfalls for the differential diagnosis of RCM

TABLE OF CONTENTS/OUTLINE

1. Background 2. Classification and etiology of restrictive cardiomyopathy 3. Role of CMR in assessment of restrictive cardiomyopathy 4. Non-infiltrative diseases 5. Infiltrative disorders 6. Storage diseases 7. Endomyocardial type 8. Cancer related restrictive cardiomyopathy 9. Summary

CAEE-33 NUMBERS DON'T LIE: ENHANCING CONFIDENCE IN CARDIAC MR QUANTIFICATION OF VALVE REGURGITATION

Swati S. Mody, MD,MBBS (*Presenter*)
Aparna Joshi, MD (*Abstract Co-Author*)
Michael Dimaria (*Abstract Co-Author*)
Jimmy C. Lu, MD (*Abstract Co-Author*)
Adam L. Dorfman, MD (*Abstract Co-Author*)
Sowmya Balasubramanian, MD,MSc (*Abstract Co-Author*)
Prabhakar Rajiah, MD, FRCR (*Abstract Co-Author*)
Prachi P. Agarwal, MD (*Abstract Co-Author*)

TEACHING POINTS

• Understand fundamentals of phase contrast (PC) flow quantification in cardiac MR (CMR), recognize limitations and pitfalls • Learn strategies to assess internal consistency and reliability of flow data • Learn methods to calculate valvular regurgitation in different scenarios such as coexistent shunt, flow turbulence, prolapse • Detect previously unsuspected abnormalities such as shunts based on incongruous flow data

TABLE OF CONTENTS/OUTLINE

Basics principles of PC CMR Check internal consistency and reliability of data by using various flow data such as SVC, descending aorta, pulmonary arteries, atrioventricular valves 3. Pitfalls: Flow turbulence, vessel dilation, short vessel course, arrhythmia Utility of PC CMR to assess valvular regurgitation with illustrative cases a. Aortic and Pulmonic regurgitation i. Quantify regurgitant fraction by direct measurements and improve confidence by using internal data ii. Workaround for flow turbulence from stenosis: measure above or below the jet iii. Qualitative assessment: Holodiastolic flow reversal in the descending aorta supports severe aortic regurgitation b. Atrioventricular valve (AVV): Mitral and tricuspid regurgitation i. Various methods to calculate AVV regurgitation ii. Special scenarios: Mitral regurgitation in mitral valve prolapse, coexistent shunt iii. Direct assessment of AVV regurgitation with 4D flow and valve tracking c. Detecting unsuspected lesions such as shunts due to incongruous data Conclusion: PC imaging is an important part of CMR which, when carefully prescribed, measured, and validated, yields data that informs patient management in valvular regurgitation and may reveal unsuspected abnormalities.

CAEE-34 GADOLINIUM AND GLUCOSE: A PICTORIAL GUIDE TO MULTIMODALITY IMAGING OF CARDIAC SARCOID DISEASE

Harout Kolanjian, MD (*Presenter*)
Matthew Morgan (*Abstract Co-Author*)
Vaishnavi Gnanananthan, MBBS (*Abstract Co-Author*)
James S. Shambrook, BMBS, FRCR (*Abstract Co-Author*)
Charles Peebles (*Abstract Co-Author*)
Ausami Abbas, MBBS (*Abstract Co-Author*)

TEACHING POINTS

This presentation aims to educate the reader on: 1. The role of MRI and F-18 FDG PET/CT in the diagnosis and therapeutic monitoring of cardiac sarcoidosis 2. Typical patterns of myocardial enhancement which correspond with established scar 3. Patterns of F-18 FDG uptake that correlates with active inflammation 4. Extracardiac findings seen on cardiac imaging

TABLE OF CONTENTS/OUTLINE

The role of MRI: MRI provides valuable information on global and longitudinal myocardial function. Typical late Gadolinium enhancement (LGE) patterns for cardiac sarcoidosis involve the mid-myocardium or sub-epicardium, sparing the sub-endocardium, in a non-coronary distribution. In this pictorial review, we demonstrate the classic patterns including nodular, flame shaped, basal anteroseptal involvement and the RV hook sign. The role of PET/CT: F-18 FDG PET/CT complements MRI by detecting active myocardial inflammation and systemic involvement, particularly during the acute disease stages, and can guide diagnosis when MRI findings are inconclusive. It is crucial to understand the extent of active myocardial disease, which potentially is beyond the extent of scarring seen on MRI. Suppressed myocardial F-18 FDG uptake protocols will be discussed, which are vital to enhance PET/CT specificity for active sarcoid lesions. Extracardiac features: Detection of extracardiac sarcoidosis improves diagnostic confidence and provides more accessible biopsy sites (lymph nodes, lungs) for histological confirmation.

CAEE-35 CT IDENTIFICATION OF FIBROSING MEDIASTINITIS AND PULMONARY VEIN STENOSIS FOLLOWING ATRIAL FIBRILLATION ABLATION

Luis Ramirez, MD (*Presenter*)
Uriel A. Tarin, MD (*Abstract Co-Author*)

TEACHING POINTS

Fibrosing mediastinitis and pulmonary vein stenosis are rare but clinically significant complications after atrial fibrillation ablation. Symptoms can be subtle and nonspecific, often delaying diagnosis. ECG-gated CT angiography with multiplanar and volume-rendered reconstructions is essential for early detection. Knowledge of anatomical risk factors can help radiologists recognize early signs and guide timely management.

TABLE OF CONTENTS/OUTLINE

Introduction - Overview of atrial fibrillation ablation and its potential complications. Pathophysiology and Risk Factors - Mechanisms of post-ablation fibrosis; predictors such as PV enlargement and anatomical variants. Imaging Approach - Description of ECG-gated CT acquisition and reconstruction techniques. Key Imaging Features -

Soft-tissue encasement of mediastinal structures, PV narrowing or occlusion, venous congestion. Case Examples - Axial, multiplanar, and volume-rendered CT images illustrating typical findings. Differential Diagnosis - Distinguishing these findings from malignancy, lymphadenopathy, or thrombus. Clinical Relevance - Importance of early recognition to prevent irreversible complications such as pulmonary hypertension. Conclusion - Radiologists play a key role in detecting post-ablation complications and improving patient outcomes.

CAEE-37 CT MYOCARDIAL FIRST PASS PERFUSION - IS IT A PROBLEM SOLVING TOOL IN CADRADS 3 DISEASE? CORRELATIVE STUDY WITH CT AND CATHETER ANGIOGRAPHY

Anandamoyee Dhar (*Presenter*)
Bharat Aggarwal, MD (*Abstract Co-Author*)

TEACHING POINTS

1. CT coronary angiography is mainstay in assessment of coronary artery diseases noninvasively2. Disease burden in CADRADS 3 stenosis and need for invasive management is a dilemma- role of CT first pass perfusion3. Significance of stenosis detected in CT coronary angiography4. Correlation of 100 cases of CT first pass perfusion with CT coronary and catheter angiography findings. 5. False positive cases and technical causes

TABLE OF CONTENTS/OUTLINE

1. Technique of CT coronary and CT first pass perfusion2. Spectrum and findings in 100 cases of CT first pass perfusion and correlative CT coronary and catheter angiography .3. Correlation with stress perfusion and clinicla follow up 4. Challenges in CT perfusion studies and causes of error5. summary and way forward

CAEE-38 REVISITING HEMODYNAMICALLY SIGNIFICANT CORONARY ARTERY ANOMALIES: A PICTORIAL REVIEW

Smily Sharma, MD, FRCR (*Presenter*)
Venkata Subbaih Arunachalam, MD (*Abstract Co-Author*)
jineesh valakkada, MD (*Abstract Co-Author*)
Anoop Ayyappan, MD (*Abstract Co-Author*)
Ajay Alex (*Abstract Co-Author*)

TEACHING POINTS

1. To discuss briefly the relevant anatomy and embryology of coronary arteries 2. To discuss the imaging features and associations of hemodynamically significant coronary artery anomalies, using illustrative cases 3. To discuss the association of hemodynamically significant coronary artery anomalies with congenital heart diseases, such as coronary artery fistulas with pulmonary atresia with an intact ventricular septum 4. To discuss imaging approach to dilated coronary arteries 4. To provide a reporting checklist and elaborate on the detailed imaging evaluation that is relevant to the management of these coronary artery anomalies

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Anatomy and Embryology of coronary arteries 3. Classification of coronary anomalies 4. Imaging Protocol 5. Anomalous origin of the coronary artery from the pulmonary artery: 5A. (ALCAPA)- Adult and Infantile types 5B. ARCAPA 5C. Rare varieties like ALADCAPA 6. Anomalous origin of coronary artery with interarterial course 6A. Imaging features and pathophysiology 6B. Imaging features affecting management 6C. Differentials: Trans-septal course 7. Coronary Artery Fistulas 7A. Embryological basis and pathophysiology 7 B. Classification 7C. Coronary Cameral Fistulas 7D. Coronary arterio-venous fistulas 7E. Imaging guide to the management of coronary artery fistulas 8. Imaging approach to dilated coronary arteries: differentiating ALCAPA, coronary artery aneurysms, Kawasaki disease, and coronary artery fistulas 9. Association of hemodynamically significant coronary artery anomalies with congenital heart disease 9. Reporting Checklist 10. Take home points

CAEE-39 TRIPLE RULE OUT PROTOCOL: HOW MANY STRIKES DOES IT TAKE TO ELIMINATE A CHEST PAIN?

JOAO COSTA (*Presenter*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Lucas d. Gomes de Farias, MD, PhD (*Abstract Co-Author*)
Maisa B. Moroz, MD (*Abstract Co-Author*)
Roberto V. Torres, MD (*Abstract Co-Author*)
Patricia Terasaca (*Abstract Co-Author*)
Henrique Andreucci (*Abstract Co-Author*)
Mariana Costa, MD (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The triple rule-out (TRO) protocol is a computed tomographic (CT) angiography technique designed to evaluate patients with acute chest pain for three critical conditions: acute coronary syndrome (ACS), acute aortic syndrome (AAS), and pulmonary embolism (PE). Chest pain is one of the main causes of emergency room visits, being responsible for delayed diagnosis, excessive exposure to radiation, unnecessary invasive procedures and even more radical outcomes. Improvement and diagnostic speed in this context have become indispensable items in any medical center. The development and upgrade of these protocol has tremendous potential to further the role of chest imaging. There are few studies addressing the topic in question, so encouraging research and analysis of this protocol can bring benefits to the theoretical and practical field of radiology.

TABLE OF CONTENTS/OUTLINE

Chest pain and its main differential diagnoses. Introduction and clinical applications of the Triple Rule Out (TRO) protocol. Methodology of the Triple Rule Out in our imaging diagnostic center. Qualitative comparison between different high end CT scans High number of patients analysed. Medicamentous and intravenous contrast doses. Sequence acquisition. Imaging interpretation. Our experience utilizing these methods. Limitations and challenges. Future directions.

CAEE-40 EBSTEIN ANOMALY

Shaimaa A. Fadl, MD (*Presenter*)
Jonathan Revels, DO (*Abstract Co-Author*)

TEACHING POINTS

To understand the role of cardiac MRI in the anatomical and functional assessment of Ebstein anomaly.To recognize the key CMR imaging features that distinguish Ebstein anomaly and its variants.To review the clinical implications of CMR findings in surgical planning, risk stratification, and follow-up.

TABLE OF CONTENTS/OUTLINE

I. BackgroundII. Role of Cardiac MRI in Ebstein’s AnomalyIII. Key Imaging FeaturesIV. Overview of Carpentier classificationV. Quantitative CMR Parameters and advances.VI. Role of CMR in preoperative planningVII. Management options (including cone repair)VIII. Imaging considerations in neonates, children, pregnancy, and in patients with associated congenital anomalies.

CAEE-41 CRACKING THE CODE OF CARDIAC CALCIFICATION: A MULTIMODALITY RADIOLOGIC ATLAS OF INTRACARDIAC AND PERICARDIAL MINERALIZATION

Furkan Ufuk, MD (*Presenter*)
Iclal Ocak, MD, MD (*Abstract Co-Author*)

Lydia Chelala, MD (*Abstract Co-Author*)
Luis A. Landeras, MD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize the imaging spectrum of intracardiac and pericardial calcifications across radiography, CT, and MRI, and differentiate their locations for accurate diagnosis. • Understand clinical implications: intracardiac calcifications (e.g., valvular, myocardial, coronary) often indicate underlying disease; pericardial calcifications suggest prior pericarditis and possible constrictive physiology. • Highlight how advanced techniques—3D post-processing, dual-energy CT, and AI-driven quantification—enhance detection, characterization, and risk assessment.

TABLE OF CONTENTS/OUTLINE

• Background and pathology of cardiac calcifications. • Imaging approach by modality: radiography (initial clues), CT (detection, localization, quantification), MRI (functional assessment). • Detailed pictorial review: valvular, coronary, myocardial, and intracavitary calcifications. • Pericardial calcifications: classic imaging signs and functional impact. • Emerging techniques: DECT, cinematic rendering, AI quantification. • Clinical implications and management: imaging-guided decision-making for valve interventions and pericardiectomy. • Conclusion: A practical, image-rich atlas to improve diagnostic confidence, avoid pitfalls, and advance clinical care through multimodality integration.

CAEE-42 WHAT ABOUT THE HEART IN NON-GATED CT ANGIOGRAPHY? NO GATING, NO PROBLEM: THE BIG PICTURE FOR RADIOLOGY TRAINEES

Genier Fabian Castano Lizarazo, MD (*Presenter*)
Moises Jimenez (*Abstract Co-Author*)
Samuel Castillo, MD (*Abstract Co-Author*)
Luis Ramirez, MD (*Abstract Co-Author*)
Guadalupe Castro Nolasco, MD (*Abstract Co-Author*)
Maria Carolina Penaranda Lewis, MD (*Abstract Co-Author*)
Mariana Madrid, MD (*Abstract Co-Author*)

TEACHING POINTS

To correlate cardiac findings in non-gated chest CT angiography with electrocardiographically synchronized studies for accurate clinical interpretation. To outline a systematic approach for evaluating cardiac anatomy and pathology in non-gated chest CT studies. To highlight key cardiac and pericardial pathologies detectable in non-gated CT and their clinical implications. To emphasize pitfalls, mimics, and complementary imaging techniques for ambiguous findings. To demonstrate real-world cases of incidental cardiac diagnoses in non-gated chest CT and their impact on patient management.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Cardiac Evaluation in Non-Gated Chest CT. 2. Systematic Cardiac Assessment in Non-Gated Chest CT: A Step-by-Step Guide. 3. Key Cardiac Pathologies Detectable in Non-Gated CT: Pearls and Pitfalls. 4. Presentation of Five Compelling Cases of Cardiac Pathology Identified on Non-Gated CT Diagnosed at National Institute of Cardiology with ECG-Gated CTA Follow-up. 5. Bridging the Gap: When to Escalate to ECG-Gated CT or MRI. 6. Conclusions.

CAEE-43 THE VALUE OF "DOUBLE DETECTION" METHOD IN CORONARY COMPUTED TOMOGRAPHY ANGIOGRAPHY (CCTA) SCANNING

Ruixue Cao (*Presenter*)

TEACHING POINTS

Using a new method to optimize coronary CTA scanning

TABLE OF CONTENTS/OUTLINE

1) The clinical value of CCTA Coronary computed tomography angiography (CCTA) is the main non-invasive method for detecting coronary artery lesions, playing an important role in clinical practice due to its high diagnostic accuracy, good negative predictive value and wide clinical applicability 2) The deficiencies in conventional scanning Contrast agent dosage and flow rate are the key factors for a high-quality CCTA examination. Due to individual differences between patients, we often do not control the dosage accurately. And for patients with large body weight or poor cardiac function, there may be contrast agent residues in the right atrium due to excessive dosage of contrast agent, which affects the display of coronary artery. 3) How to achieve 'double detection' The level where the pulmonary artery and aorta appeared simultaneously was selected as the real-time monitoring. The two ROIs were placed at the descending aorta (ROI1) and the pulmonary artery (ROI2) respectively. The CT values of the two ROIs were monitored in real time after injection of contrast agent. When its intersected, the scan was manually triggered. 4) Advantages of 'double detection' a. Coronary artery showed clearly b. No artifact caused by contrast agent residue in the right atrium. C. High image quality

CAEE-44 STEP-BY-STEP CARDIAC AND PERICARDIAL EVALUATION ON NON-GATED CHEST CT

Francisco Calle Bernal, MD (*Presenter*)
Paula N. Patino, MD (*Abstract Co-Author*)

TEACHING POINTS

Provide general radiologists with a structured approach to evaluate cardiopericardial findings on non-gated chest CT. Introduce a five-step approach for assessing key anatomical segments: chambers, valves, septa, coronaries, and pericardium. Review normal anatomy and imaging features of each segment to establish diagnostic baselines. Identify common cardiopericardial pathologies using real examples from non-gated CT scans. Highlight imaging pitfalls and how to recognize them in routine chest imaging. Offer guidance on when and why to recommend further evaluation with dedicated cardiac imaging modalities (e.g., ECG-gated CT, MRI, or echocardiography).

TABLE OF CONTENTS/OUTLINE

Step 1: Atria and Ventricles Anatomy of right and left atria and ventricles Cardiac chamber size assessment Common cardiac masses (thrombus, tumors, etc.) Step 2: Valves Tricuspid valve anatomy and abnormalities Mitral valve anatomy and mitral annular calcification (MAC) Aortic and pulmonic valve anatomy and aortic valve calcification (AVC) Step 3: Interatrial Septum and Myocardial Wall Interatrial and interventricular septum anatomy Common findings (PFO, lipomatous hypertrophy) Myocardial infarction imaging Step 4: Coronaries Coronary artery anatomy and calcification scoring Coronary anomalies and fistulas Coronary venous system and its clinical relevance Step 5: Pericardium Normal anatomy and sinuses/recesses Congenital absence Pericardial effusion, pericarditis, tamponade Pericardial constriction and calcification

CAEE-45 PERICARDIUM - NOT JUST A FLIMSY LAYER

Aprateem Mukherjee, MD, FRCR (*Presenter*)

TEACHING POINTS

After going through the exhibit, the reader will be able to: • Describe the CT and MR appearances of normal pericardial anatomy and pericardial recesses. • Apply cross sectional techniques to the diagnosis of different pericardial anomalous including congenital pericardial anomalies, pericardial effusions, constrictive pericarditis, and neoplasms • Understand contribution of pericardial anatomy and physiology in ventricular interdependence and its importance in constrictive pericarditis and the role of cardiac MRI in understanding pericardial physiology. • Identify selected mimics of pericardial neoplasms.

TABLE OF CONTENTS/OUTLINE

• Introduction • Normal pericardial anatomy and pericardial recesses and reflections • Pericardium appearance in different imaging modalities - Conventional, CT, MRI • Comparison of imaging techniques - CT and MRI with respect to their advantages/disadvantages • Standardised protocol for imaging of pericardium with MRI • Congenital pericardial conditions - pericardial defects/cysts • Pericardial collections - effusions, tamponade • Pericarditis - Constrictive, effusioconstrictive, calcific pericarditis and role of MR imaging • Differentiating restrictive cardiomyopathy from constrictive pericarditis • Pericardial neoplasm - benign, malignant • Mimickers of pericardial masses Take home points

CAEE-46 CARDIAC MAGNETIC RESONANCE IN THE ERA OF PARAMETRIC MAPPING: TRANSFORMING MYOCARDIAL INFARCTION DIAGNOSIS

Karen De Icaza Benet (*Presenter*)
Omar A. Gamboa Abundis, MD (*Abstract Co-Author*)
Pablo Andres Hernandez Soto (*Abstract Co-Author*)
Rafael Sanez (*Abstract Co-Author*)
Miguel A. Cruz, MD (*Abstract Co-Author*)
Aloha Meave, MD (*Abstract Co-Author*)
Gabriela Melendez, MD (*Abstract Co-Author*)
Daniel Campuzano (*Abstract Co-Author*)

TEACHING POINTS

- Cardiac MRI Mapping in Myocardial InfarctionMapping techniques (T1, T2, T2*) allow distinction between acute and chronic myocardial infarction.Acute infarction shows elevated native T1 and T2 values due to edema and inflammation, while chronic infarction presents normalized T2 but increased ECV from fibrosis.They enhance detection of intramyocardial hemorrhage and microvascular obstruction, both markers of worse prognosis.T2* mapping is sensitive to hemorrhage, and mapping sequences can better delineate MVO than conventional imaging.Mapping aids in assessing post-infarction complications and myocardial remodeling.It provides contrast-free evaluation of tissue viability, risk of arrhythmia, and structural changes, even in patients with contraindications to gadolinium.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Relevance of myocardial infarction as a leading cause of morbidity and mortality.Advances in imaging diagnostics: the growing role of cardiac magnetic resonance (CMR). 2. Myocardial Infarction: General Concepts: Pathophysiology: ischemia, necrosis, and myocardial remodeling.Clinical manifestations and conventional diagnosis. 3. Cardiac Magnetic Resonance: Fundamentals: Advantages over other imaging modalities. 4. Myocardial Parametric Mapping: What T1, T2, and extracellular volume (ECV) mapping are.Information they provide about myocardial tissue. 5. Applications of CMR Mapping in Myocardial Infarction: Tissue characterization: detection of edema, fibrosis, and viability.Prognostic value and support in clinical decision-making.Complications. 6. Limitations and Challenges 7. Future Perspectives 8. Conclusions

CAEE-47 ECG-LESS CARDIAC CT: A FEASIBLE ALTERNATIVE FOR CARDIAC AND CORONARY IMAGING - WHAT IT IS AND HOW TO IMPLEMENT IT

Luis A. Landeras, MD (*Presenter*)
Lydia Chelala, MD (*Abstract Co-Author*)
Iclal Ocak, MD, MD (*Abstract Co-Author*)
Furkan Ufuk, MD (*Abstract Co-Author*)

TEACHING POINTS

• Introduce ECG-less cardiac CT as a viable alternative for imaging the heart and coronary arteries.• Highlight key technological enablers—such as wide detector coverage, fast gantry rotation, motion correction, and deep learning image reconstruction (DLIR)—that enable high-quality, single-heartbeat coronary CT imaging without ECG leads.• Demonstrate how this protocol reduces examination time while maintaining comparable radiation dose, contrast use, and image quality to conventional CCTA.• Address challenges such as motion artifacts in patients with high or irregular heart rates and emphasize the need for optimal protocol selection and software-assisted phase reconstruction.

TABLE OF CONTENTS/OUTLINE

1. Introduction: The rationale for eliminating ECG dependency in cardiac CT2. Technological Foundation and Protocol Design: Patient preparation, basic principles of ECG-less cardiovascular imaging, and AI-based phase selection (SmartPhase), motion correction (SnapShot Freeze), and image reconstruction (DLIR)3. Efficiency & Diagnostic Performance: Reduced scan times, equivalent SNR/CNR, radiation, and contrast usage4. Limitations & Pitfalls5. Case Illustrations6. Summary & Future Directions

CAEE-48 DEATH IN THE BLOOD: IMAGING OF CARDIOVASCULAR INFECTIONS

Stacy J. Kim, MD (*Presenter*)
Caroline Robb, MD (*Abstract Co-Author*)
Cody Thornburgh, MD (*Abstract Co-Author*)
Adam Naylor, MD (*Abstract Co-Author*)
Sanjeev Bhalla, MD (*Abstract Co-Author*)

TEACHING POINTS

Cardiovascular infections have a high morbidity and mortality. They can result in the spread of infection by blood to other parts of the body and result in serious complications such as aneurysms/pseudoaneurysms, surgical site dehiscence, septic emboli, multi-organ infarction, and heart failure. Cardiovascular infections can occur in the setting of native tissues or in the setting of surgery, endovascular procedures, or device placement. Unfortunately, cardiovascular infections are often challenging to assess by imaging - chest radiography has limited utility and computed tomography (CT) and magnetic resonance imaging (MRI) can be limited in the absence of intravenous contrast or cardiac gating. Despite the limitations of imaging, radiologists may be the first to suggest infection. The purpose of this educational exhibit is to review the imaging manifestations and mimics of cardiovascular infections.

TABLE OF CONTENTS/OUTLINE

I. Heart A) Endocarditis (native) B) Myocarditis C) Pericarditis II. Aorta A) Infectious aortitis B) Infectious pseudoaneurysm III. Pulmonary arteries A) Infectious pseudoaneurysm B) Infected patent ductus arteriosum IV. Veins V. After surgery/endovascular procedures A) Valve replacement B) Aortic repair VI. After device placement A) Left ventricular assist device B) Left atrial appendage occlusion device C) Septal occluder device D) Pacemaker-defibrillator VII. Mimics A) Non-infectious endocarditis, myocarditis, pericarditis B) Aortic penetrating atherosclerotic ulcer, traumatic pseudoaneurysm, aneurysm rupture C) Iatrogenic pulmonary artery pseudoaneurysm D) Bland venous thrombus E) Tumors F) Expected post-surgical/procedural changes

CAEE-49 MULTIMODAL PERSPECTIVES IN NEONATOLOGY: AN INTEGRATED APPROACH TO DIAGNOSIS

Claudia Mendoza, MD (*Presenter*)

TEACHING POINTS

Congenital heart disease affects 1-2% of neonates, with many cases requiring urgent imaging evaluation for life-saving interventions. Advanced multimodal imaging approaches, including echocardiography, cardiac CT, and MRI, play pivotal roles in diagnosing and managing critical neonatal conditions such as duct-dependent lesions, vascular rings (double aortic arch), coronary artery fistulas, and aortopulmonary windows. Echocardiography provides non-invasive hemodynamic assessment, while CT angiography offers rapid, detailed anatomical definition of complex cardiovascular structures. Cardiac MRI excels in tissue characterization and functional evaluation

without radiation exposure. These complementary imaging modalities enable precise preoperative planning, particularly for surgical correction of vascular rings and coronary fistulas, while tailored protocols minimize risks in this vulnerable population. Early recognition of characteristic findings - such as the complete vascular ring in double aortic arch or the aneurysmal dilation at fistula drainage sites - guides timely intervention to prevent complications like myocardial ischemia or pulmonary hypertension. Multidisciplinary collaboration between radiologists, cardiologists, and surgeons ensures optimal translation of imaging findings into clinical decisions, significantly improving outcomes for neonates with congenital heart disease.

TABLE OF CONTENTS/OUTLINE

IntroductionImaging Modalities in Neonatal CHDPrincipal Congenital Cardiac Pathologies in NeonatesKey Imaging Findings by PathologyConclusions

CAEE-50 REPAIRED TETRALOGY OF FALLOT SPECTRUM: IMAGING PERSPECTIVES IN FOLLOW-UP

Harold Goerne, MD (*Presenter*)
Prabhakar Rajiah, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. To review the spectrum of Tetralogy of Fallot (TOF)2. To discuss the surgical options for Tetralogy of Fallot3. To illustrate normal and abnormal imaging appearances after surgery4. To review the critical functional parameters in follow-up

TABLE OF CONTENTS/OUTLINE

• Introduction• Spectrum of TOF- Classical, absent/rudimentary pulmonary valve, pulmonary valve atresia• Clinical features• Associated anomalies- pulmonary atresia, absent pulmonary valve, common CAV canal, DORV, coronary anomalies• Role of Imaging- Echo, MRI, CT, catheterization• CT and MRI protocols- Pre- and post-surgery• Pre-surgical evaluation of TOF- Morphological evaluation- Major aortopulmonary collaterals (MAPCAs)- Coronary artery anatomy and anomalies- Right arch- ASD- Left SVC- Common AV canal• Surgeries for TGA- BT shunt, definitive repair, unifocalization, RV-PA conduit• Post-surgical evaluation- Normal appearances . MRI RVEF, volumes, pulmonic regurgitation parameters.• Post-surgical complications - Pulmonary regurgitation, RVOT aneurysm, Pulmonary stenosis, RV dilation, RV dysfunction, RV fibrosis• Indications for Pulmonary valve replacement- Surgical/Transcathet

CAEE-51 NOTHING BREAKS LIKE A HEART: REVISITING ACUTE CARDIAC-ORIGIN CHEST PAIN

Lucas d. Gomes de Farias, MD, PhD (*Presenter*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Roberto V. Torres, MD (*Abstract Co-Author*)
Daniel Giunchetti Strabelli, MD (*Abstract Co-Author*)
Thamara C. Morais, MD (*Abstract Co-Author*)
Roberto N. Dantas JR, MD (*Abstract Co-Author*)
Cesar H. Nomura, MD, PhD (*Abstract Co-Author*)
Ricardo D. Sartim, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Acute chest pain is one of the most frequent complaints in emergency departments and represents a diagnostic challenge due to its wide range of potential etiologies. 2. Early and accurate identification of cardiac-origin elated causes is crucial, as they frequently involve life-threatening conditions. This underscores the radiologist's vital role in timely diagnosis and in guiding clinical decision-making, which directly impacts patient outcomes. 3. Multimodal imaging plays a pivotal role in the evaluation and management of these patients. 4. The purpose of this exhibit is: (a) To review usual and unusual cases related to causes of acute cardiac-origin chest pain. (b) To correlate important findings with the anatomy, embryology, and pathophysiology, focusing on their clinical-radiological correlations. (c) To highlight their characteristics in order to familiarize radiologists, preventing unfavorable patient outcome. (d) To review CT and MRI protocols in the evaluation of patients with suspected acute cardiac-origin chest pain.

TABLE OF CONTENTS/OUTLINE

1. Applied diagnostic techniques in the evaluation of heart. 2. Milestones in the evolution of acute cardiac-origin chest pain over the years. 3. Techniques: CT angiography, conventional angiography, intravascular ultrasound, and optical coherence tomography - pros e cons. 4. CT and MRI angiography protocols 5. Acute cardiac-origin chest pain - possible factors: (a) Valves (b) Myocardium (c) Pericardium (d) Epipericardial fat (e) Coronary arteries 7. Miscellaneous and other findings 8. Sample cases of pearls, pitfalls, diagnostic difficulties, and mimics. 9. Future directions: artificial intelligence 10. Summary and take-home messages.

CAEE-53 IMAGING THE BREAKING POINT: RADIOLOGIC SIGNS OF MYOCARDIAL RUPTURE

Anisha Gechuki Onchonga, MD (*Presenter*)
Sukumaran R. Binukrishnan, FRCR, MRCP (*Abstract Co-Author*)
Monika Radike, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Define myocardial rupture and understand the common causes.Highlight the clinical presentation of myocardial rupture. Identify the spectrum of imaging findings of myocardial rupture.

TABLE OF CONTENTS/OUTLINE

1. Definition and risk factors2. Case-based imaging features in different clinical settings.Myocardial rupture is the disruption of cardiac tissue leading to a defect in the left ventricular (LV) free wall, or septum, papillary muscle rupture, or pseudo-aneurysm formation.Main causes include acute myocardial infarction, trauma, infection, and iatrogenic injury.Risk factors for myocardial rupture in the setting of AMI include delays in presentation, hypertension, diabetes, and smoking. Rupture most commonly involves the inferolateral wall, usually at the junction of normal and infarcted myocardium. Post-infectious myocardial rupture occurs following infective endocarditis, formation of a paravalvular abscess and fistulation into cardiac chambers. Sepsis can also culminate in infarction. Iatrogenic myocardial rupture occurs following minimally invasive or open cardiovascular procedures.Symptoms of myocardial rupture varies widely. Timely diagnosis requires a high index of clinical suspicion supported by imaging findings.Gated and non-gated cardiac computer tomography are the imaging workhorse. MRI is excellent for tissue characterisation and quantifying ventricular function. Echocardiogram is adjunctive, mostly used for point-of-care imaging or follow-up. Features of myocardial rupture on CT include LV wall defect, perfusion defects and pseudo-aneurysms. Features of contained rupture include adjacent epicardial fat stranding, and adherent pericardium.

CAEE-54 MODERN HEART TRANSPLANT REJECTION SCREENING AND SURVEILLANCE: INTEGRATED ROLE OF CARDIAC IMAGING

Kate Hanneman, MD, MPH (*Presenter*)
Felipe Castillo Aravena, MD (*Abstract Co-Author*)
Yas Moayedi (*Abstract Co-Author*)
Juan Dueroposada (*Abstract Co-Author*)

TEACHING POINTS

• Historically surveillance for allograft rejection relied on endomyocardial biopsy which is invasive and subject to sampling limitations • Contemporary allograft rejection surveillance protocols integrate cardiac MRI with molecular diagnostics such as donor-specific antibody testing, gene expression profiling (GEP), and donor-derived cell-free DNA (dd-cfDNA) to enhance early rejection detection and improve patient outcomes • Understanding the imaging features of different rejection types, including acute cellular rejection (ACR), antibody-mediated rejection (AMR), and cardiac allograft vasculopathy (CAV), is essential

TABLE OF CONTENTS/OUTLINE

1. Introduction Epidemiology and survival trends in heart transplantation Importance of rejection surveillance due to non-specific symptoms 2. Types of Rejection Overview of ACR, AMR, and CAV Pathophysiology and clinical implications 3. Traditional vs. Emerging Surveillance Strategies Limitations of endomyocardial biopsy Advances in non-invasive testing and their role in modern protocols 4. Cardiac MRI in Transplant Rejection Imaging protocols and sequences Characteristic findings for each type of rejection Role in differentiating rejection from other pathologies 5. Case-Based Review Illustrative cases demonstrating MRI findings and correlation with clinical, non-invasive molecular tests, and biopsy data 6. Integration into Clinical Practice Contemporary algorithms for rejection surveillance Multimodal approach incorporating imaging and molecular diagnostics 7. Conclusion and Future Directions Cardiac MRI as a cornerstone of non-invasive transplant rejection monitoring

CAEE-55 FROM FLOW TO FUNCTION: THE ROLE OF 4D FLOW MRI IN CONGENITAL HEART DISEASE IMAGING

Anh Luu (*Presenter*)
Erin Opfer (*Abstract Co-Author*)

TEACHING POINTS

4D Flow MRI is an advanced imaging technique that allows comprehensive, dynamic visualization of blood flow in three dimensions. It is particularly useful in evaluating complex congenital heart disease (CHD), where traditional imaging may not adequately capture abnormal hemodynamics. This exhibit highlights how 4D Flow MRI contributes to improved understanding of conditions such as Fontan circulation, Tetralogy of Fallot (TOF), Transposition of the Great Arteries (TGA), and valvular disorders. Learners will explore the principles of 4D Flow MRI, its clinical applications in CHD, and the added value it brings in assessing flow direction, volume, and wall shear stress. The exhibit also discusses recent advances in acquisition and analysis techniques tailored for pediatric patients, including faster imaging protocols and improved post-processing. Emphasis will be placed on its emerging role in risk stratification, surgical planning, and long-term follow-up in CHD patients, as well as future opportunities for integrating this technology more broadly in clinical care.

TABLE OF CONTENTS/OUTLINE

Introduction to 4D Flow MRI in Congenital Heart Disease (CHD) Clinical Applications in CHD Recent Technological Advances and Pediatric Adaptations Challenges in Pediatric Implementation and Interpretation Future Directions and Ongoing Research

CAEE-56 NON INVASIVE DETECTION OF MYOCARDIAL INFLAMMATION: THE ROLE OF MULTIPARAMETRIC CARDIAC MRI IN THE EVALUATION OF MYOCARDITIS

Diego Leonardo Meza Neri (*Presenter*)
Claudia Isabel Hernandez, MD (*Abstract Co-Author*)
Doris Licely Canche Aguilar, MD (*Abstract Co-Author*)
Elsa Rojas Hernandez, MD (*Abstract Co-Author*)
Sandra Rosales, MD (*Abstract Co-Author*)

TEACHING POINTS

Importance of early detection of myocarditis : Discuss why identifying myocardial inflammation early is crucial for patient management and outcomes. Role of multiparametric cardiac MRI : Explain how advanced MRI techniques (T1, T2 mapping, late gadolinium enhancement, etc.) contribute to the accurate assessment of myocarditis. Diagnostic accuracy of MRI : Highlight the sensitivity and specificity of MRI in comparison to other diagnostic methods like endomyocardial biopsy or echocardiography. Implicaciones clínicas de los hallazgos de la resonancia magnética : detalle cómo los hallazgos de la resonancia magnética ayudan a orientar las decisiones de tratamiento y el pronóstico en pacientes con sospecha de miocarditis. Challenges and limitations : Address the challenges of MRI interpretation and the potential pitfalls in diagnosing myocarditis.

TABLE OF CONTENTS/OUTLINE

Introduction Definition and clinical significance of myocarditis Overview of traditional diagnostic methods Pathophysiology of Myocarditis Inflammatory processes in myocarditis Causes and risk factors Role of Cardiac MRI in Myocarditis Overview of cardiac MRI technology Key MRI techniques used in the assessment of myocarditis (e.g., T1 and T2 mapping, late gadolinium enhancement) Multiparametric Approach to Myocardial Inflammation How multiparametric MRI enhances diagnostic accuracy Case examples demonstrating different MRI findings in myocarditis Clinical Applications and Case Studies Real-world examples of MRI in the diagnosis and management of myocarditis Correlation of MRI findings with clinical outcomes. Conclusion Summary of key findings Future directions in the use of cardiac MRI for myocarditis detection

CAEE-57 LV HYPERTROPHY DECODED: SOLVING THE PUZZLE WITH PARAMETRIC MAPPING AND ECV

Sadia Sultana, MRCP,FRCR (*Presenter*)
Shravya Srinivas Rao, MD (*Abstract Co-Author*)
Jennifer S. Tang, FRANZCR, MBBS (*Abstract Co-Author*)
Sean Murphy, MBBCh (*Abstract Co-Author*)
Nandini M. Meyersohn, MD (*Abstract Co-Author*)
Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*)
Sandeep S. Hedgire, MD (*Abstract Co-Author*)
Vinit Baliyan, MD,MBBS (*Abstract Co-Author*)
Albree Tower-Rader (*Abstract Co-Author*)
Godtfred Holmvang (*Abstract Co-Author*)

TEACHING POINTS

Left ventricular (LV) hypertrophy can arise from diverse etiologies, including hypertensive heart disease, aortic stenosis, hypertrophic cardiomyopathy, and infiltrative disorders such as amyloidosis. Conventional imaging techniques often fall short in differentiating these conditions. Cardiac MRI with T1 mapping and extracellular volume (ECV) quantification offers a powerful non-invasive tool to assess myocardial composition and detect diffuse fibrosis or infiltration. To understand role of T1 mapping and ECV in quantification myocardial tissue composition To discuss diagnosis of different pathologies of LV hypertrophy with help of T1 mapping and ECV To learn role of the quantitative metrics in early diagnosis and monitoring disease progression or therapeutic response

TABLE OF CONTENTS/OUTLINE

1. Introduction o Clinical significance of LV hypertrophy o Limitations of conventional imaging 2. Pathophysiology of LV Hypertrophy o Common etiologies o Role of myocardial fibrosis and infiltration 3. Cardiac MRI Techniques o Overview of native T1 mapping o ECV quantification principles and protocols 4. T1/ECV in Different Pathologies o Hypertensive heart disease o Hypertrophic cardiomyopathy o Aortic stenosis o Cardiac amyloidosis o Fabry disease 5. Case-Based Review o Comparative imaging and diagnostic insights o Diagnostic algorithms o Prognostic value and therapy monitoring 6. Challenges and Limitations o Technical considerations o Overlap of values across diseases 7. Conclusion o Summary of clinical utility o Future directions in quantitative CMR

CAEE-58 GRAND PRIX OF THE HEART: SET THE HEART RACING THROUGH A SYSTEMATIC APPROACH TO NON CORONARY CARDIAC ANATOMY THROUGH THE EMBRYOLOGIC LENS

Heli D. Rueda, MD (*Presenter*)
Daniel A. Rojas Padilla, MD (*Abstract Co-Author*)
Liliana Arias (*Abstract Co-Author*)
Mini V. Pakkal, FRCR, MBBS (*Abstract Co-Author*)

TEACHING POINTS

To understand normal cardiac anatomy on CT based on embryological development. To promote a step-by-step systematic checklist for Cardiac CT interpretation in order to identify anatomical variants, common pitfalls and avoid missing important imaging findings. To demonstrate the utility of a mental checklist assessment in educational and clinical practice, in routine cardiac CT imaging evaluations through examples.

TABLE OF CONTENTS/OUTLINE

Grand Prix of the Heart Prepare Your Car: Study and Protocol Considerations Was the study and protocol appropriate for optimal cardiac CT imaging? The Race Begins: Cardiac CT Analysis Right Atrium (RA) Review systemic venous connections, coronary sinus, and interatrial septum. Explain developmental anatomy and present a RA checklist, including common variations such as atrial septal defects. Right Ventricle (RV) Focus on recognizing RV anatomy, including the tricuspid valve and pulmonary artery system. The checklist addresses RV evaluation and highlights variations of the right ventricle. Left Atrium (LA) Examine pulmonary venous connections, the LA chamber, and appendage. Provide developmental context, a checklist for assessment, and discuss variations like anomalous pulmonary venous return. Left Ventricle (LV) Review the LV anatomy, mitral valve, and aortic root. The section includes a checklist for evaluating the LV and variations from the aortic root and mitral valve (For example prolapse). The Podium: Key Conclusions Summarize the importance of a checklist approach for accurate cardiac CT interpretation. Post Grand Prix Conference: Interactive Q&A Engage participants with an interactive quiz to reinforce key learning points.

CAEE-59 THE EASIEST WAY TO REDUCE RADIATION DOSE IN CORONARY CT ANGIOGRAPHY: STANDARDIZING TWO OFTEN-OVERLOOKED SCAN PARAMETERS

Hiroki Komesu (*Presenter*)

TEACHING POINTS

Coronary CT angiography is a crucial diagnostic tool for ischemic heart disease. However, radiation exposure remains a concern. This exhibit explains that often-overlooked scan parameters, particularly acquisition window and number of acquisition beats, significantly contribute to increased radiation dose. Furthermore, it describes the standardization of these parameters. The main teaching points are as follows:1. Learn the optimal cardiac phase trends for each heart rate. 2. Learn the appropriate reconstruction methods for each heart rate. 3. Learn the appropriate scan parameter settings (acquisition window and number of acquisition beats) for each heart rate. 4. Understand the radiation dose reduction effects and the improvement in inter-technologist variability in radiation dose achieved through the standardization of scan parameters. Standardizing acquisition window and number of acquisition beats is a valuable strategy for significant radiation dose reduction without compromising diagnostic image quality. By focusing data acquisition on diagnostically relevant cardiac phases, a 32% reduction in median CTDIvol was achieved ($p < 0.01$).

TABLE OF CONTENTS/OUTLINE

1. Importance of radiation dose reduction in coronary CT angiography 2. Variability in CT scan parameters among radiologic technologists 3. Standardization of scan parameters 4. Effects of standardization on radiation dose reduction 5. Impact on clinical effectiveness 6. Workflow applicable to other facilities

CAEE-60 OPTIMIZING AND MANIPULATING BLOOD-TISSUE CONTRAST IN CARDIAC MRI

Zhongwei Zhang, MD, PhD (*Presenter*)
Jie Zheng, PhD (*Abstract Co-Author*)
Scott M. Bugenhagen, MD, PhD (*Abstract Co-Author*)
Manish Aggarwal (*Abstract Co-Author*)
Pamela K. Woodard, MD (*Abstract Co-Author*)

TEACHING POINTS

Cardiac MRI (CMR) excels in distinguishing blood from surrounding tissues, offering critical insights into various cardiac and vascular conditions. This Education Exhibit will offer a comprehensive overview of blood-tissue contrast mechanisms, focusing on advanced MRI techniques that optimize and manipulate this contrast in cardiac imaging.

TABLE OF CONTENTS/OUTLINE

1) Cardiac Cycle, Synchronization and MRI Data Acquisition; 2) Motion Correction and Navigation approaches - Reviews techniques to mitigate motion artifacts. 3) Overview of blood and tissue MR properties and contrast mechanisms - the intrinsic properties of blood and myocardium, including flow effects, will be reviewed, and their impact on resulting MRI contrast will be explained. 4) Black-blood, gray-blood, bright-Blood, and simultaneous black and bright blood imaging techniques - The principles behind black-blood (blood suppression), gray blood (partial blood suppression) and bright-blood (blood signal enhancement or contrast enhancement) imaging will be discussed, with an emphasis on their clinical applications in CMR. 5) Data acquisition strategies - Covers Cartesian and non-Cartesian k-space sampling (radial, spiral, hybrid) and physiological controls (ECG, iNAV, PACE, Multitasking), emphasizing blood contrast enhancement. 6) MRI acceleration techniques - Discusses GRAPPA, CAIPIRINHA, and compressed sensing (CS), and AI-driven methods for faster imaging. 7) Recent advances in CMR studies: introduces "one-stop shopping" in cardiac MRI with push-button approaches in CMR applications.

CAEE-61 HOW TO USE ARTIFICIAL INTELLIGENCE IN CARDIAC MAGNETIC RESONANCE IMAGING AND DIAGNOSIS

Toshimichi Takeda (*Presenter*)
Ryo Ogawa, PhD, MD (*Abstract Co-Author*)
Kohei Tabo (*Abstract Co-Author*)
Takanori Kouchi (*Abstract Co-Author*)
Teruhito Kido, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Various information related to medical data can be obtained by machine learning. We explain how artificial intelligence is used during cardiac MRI scanning, reconstruction/post-processing, and diagnosis. 1. To review the role of artificial intelligence.2. To explain the application of artificial intelligence in cardiovascular magnetic resonance.3. To explain the principle of artificial intelligence.

TABLE OF CONTENTS/OUTLINE

1. Image reconstructed by deep learning algorithm; overview, algorithm, example (Black-Blood T2 weighted Image, Whole heart coronary magnetic resonance angiography, cine MRI)2. landmark mark detection; overview, algorithm,example (resting-phase detection by right coronary artery)3. Segmentation; overview, algorithm,example (Automated inversion time selection for late gadolinium)4. Classification by Neural network; overview, algorithm,example (Classification of myocardial infarction by convolutional neural network)6. Explainable AI about convolutional neural network; overview, algorithm, example (Gradient-weighted class activation mapping, Guided gradient-weighted class activation mapping)7. Classification by Vison transformer; overview, algorithm,example (Classification of myocardial infarction by vison transformer)8. Explainable AI about vison transformer; overview, algorithm,example (Attention map)

CAEE-62 PET-MRI FUSION IMAGING IN CARDIAC SARCOIDOSIS: A NEW PARADIGM FOR DIAGNOSIS AND PROGNOSIS

Paula Escobosa Garcia, MD (*Presenter*)
Santiago A. Bolivar Cuevas, MD (*Abstract Co-Author*)
Belen del Rio Carrero, MD (*Abstract Co-Author*)
Hector I. Jofre Grimaldo (*Abstract Co-Author*)
Angela M. Diaz Cardenas, MD (*Abstract Co-Author*)
Antonio Medina, MD (*Abstract Co-Author*)

Gemma Burcet Rodriguez, MD (*Abstract Co-Author*)
Paula C. Notta (*Abstract Co-Author*)

TEACHING POINTS

To outline the clinical features and diagnostic criteria of cardiac sarcoidosis (CS).To examine the MRI characteristics of CS, with an emphasis on late gadolinium enhancement (LGE), and evaluate how early detection enhances diagnostic precision and clinical outcomes.To discuss recent innovations in hybrid PET/MRI imaging and how this integrated approach improves the diagnosis and assessment of CS.

TABLE OF CONTENTS/OUTLINE

Introduction and challenges in the diagnosis of CS: definition and clinical characteristics of cardiac sarcoidosis, key diagnostic challenges, including the limitations of endomyocardial biopsy, and the widely recognized diagnostic criteria established by the Japanese Circulation Society. Advances in imaging for the evaluation of CS overview of advanced imaging techniques, such as cardiac MRI with LGE and hybrid PET/MRI, emphasizing the simultaneous detection of both inflammation and myocardial fibrosis provided by the PET/MRI approach.Impact of the multimodal approach in the diagnosis and management of CS the integration of advanced imaging techniques for accurate diagnosis, monitoring, and predicting adverse events in cardiac sarcoidosis.

CAEE-63 UTILITY OF CT IN PLANNING OF TRANSCATHETER AORTIC VALVE REPLACEMENT: A TO Z

Prabhakar Rajiah, MD, FRCR (*Presenter*)

TEACHING POINTS

1. To review the role of CT in the pre-procedural evaluation for TAVR. 2. To illustrate the key CT parameters for TAVR planning 3. To provide answers to the common questions that are required from a CT interpreter

TABLE OF CONTENTS/OUTLINE

A. Introduction B. Measurements for typical TAVR i. Annular sizing ii. LVOT sizing iii. Height of coronary ostia iv. Dimensions of sinus of valsalva v. Sinotubular junction vi. Optimal fluoroscopic angles vii. Membranous septal height C. Low-flow, low-gradient aortic stenosis Aortic valve calcium score (> 2000 in men, > 1200 in women) D. Valve-in-valve TAVR i. Bioprosthetic valve evaluation ii. Surgical valve sizing iii. Virtual valve to coronary ostial distance iv. Coronary ostial height v. Sinus of Valsalva diameter vi. Measurements for BASILICA procedure-Eccentricity index E. Bicuspid aortic valve i. Morphological classification- ii. Sizing of annulus- 2 nd orthogonal plane parallel to device landing zone iii. Concomitant aortopathy iv. Horizonal aorta- < 30 degrees v. Coronary artery anomalies vi. Coronary ostial height F. Native aortic regurgitation i. Large annulus ii. Poor visualization at fluoroscopy iii. Absent calcification- Impaired fixation in annulus iv. Aortopathy G. Concomitant valvular disease i. Mitral regurgitation (30 %) ii. Tricuspid regurgitation (24 %) iii. Planning for other transcatheter interventions H. Access vessel evaluation i. Aorta- aneurysm, stenosis, dissection, ulceration ii. Iliofemoral vessels-narrowest diameter, tortuosity, calcifications iii. Alternate access- transsubclavian/axillary, transcarotid, transcaval, transaortic, transapical.

CAEE-64 LEFT VENTRICULAR HYPERTROPHY (LVH): DIAGNOSTIC APPROACH WITH CARDIAC MRI

Maria M. De Avila Gomez, MD (*Presenter*)
Miguel A. Cruz, MD (*Abstract Co-Author*)
Omar A. Gamboa Abundis, MD (*Abstract Co-Author*)
Pablo Andres Hernandez Soto (*Abstract Co-Author*)
Maria D. Egas Bejar, MD (*Abstract Co-Author*)
Gabriela Melendez, MD (*Abstract Co-Author*)
Aloha Meave, MD (*Abstract Co-Author*)

TEACHING POINTS

Set out the mainstays of cardiac MRI protocol for the approach of left ventricular hypertrophy. Define and represent MRI findings of the different phenotypes of left ventricular hypertrophy. Propose a diagnostic algorithm for suspected left ventricular hypertrophy.

TABLE OF CONTENTS/OUTLINE

Overview. Cardiac MRI protocol for the approach of LVH (Left ventricular hypertrophy). Hypertrophic cardiomiopathy. Aortic stenosis and hypertensive induced LVH. Athlete's heart. Cardiac amyloidosis. Anderson Fabry disease. Phenotypic differences in anatomical and tissue characterization in cardiac magnetic resonance (CMR). Proposed diagnostic algorithm for LVH. Take home messages.

CAEE-65 SCENARIO-BASED APPROACH TO DIAGNOSING COMPLICATIONS OF 3-STAGE PALLIATION SURGERY

Shravan Sridhar, MD, MS (*Presenter*)
Jonathan A. Liu, MD (*Abstract Co-Author*)
Noah M. Seymore, MD (*Abstract Co-Author*)
Kimberly G. Kallianos, MD (*Abstract Co-Author*)
Joseph Mansour, MD (*Abstract Co-Author*)
Muhammad Naeem, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Single ventricle congenital heart disease is often managed with 3-stage palliation surgery. Post-operative imaging is instrumental in detecting short- and long-term complications and ensuring patient longevity. This exhibit focuses general post-operative complications, complications specific to 3-stage palliation, and imaging pitfalls. Learning objectives include: 1) Review complications specific to 3-stage palliation surgery 2) Recognize clinical scenarios in which to suspect a certain complication or recommend specific imaging workup to the clinical team 3) Learn which clinical tests can inform radiologic diagnosis of a particular complication.

TABLE OF CONTENTS/OUTLINE

1. Title2. Objectives3. Fontan overview4. Complication categories5. General complications overview6. General complications - helpful labs7. Post-Fontan complications overview8. Fontan failure9. Post-Fontan complications - helpful labs10. Scenario overview11. Scenario: Prior surgery + acute symptoms12. Hematoma/bleed13. Endocarditis14. Pitfall: Anastomotic breakdown15. Acute conduit thrombosis16. Pitfall: Pseudothrombosis17. Myocarditis and infarct18. Pitfall: Omission of LGE imaging19. Scenario: Remote surgery + chronic symptoms20. Collaterals21. Pitfall: Lack of delayed imaging22. Plastic bronchitis23. Pitfall: Mistake for aspiration24. Chylous effusion25. Pitfall: Mistake for simple effusion26. FALD27. Pitfall: Hepatic congestion28. HCC29. Protein-losing enteropathy30. Summary: Tables + scenarios31. References

CAEE-66 CARDIAC AND MEDIASTINAL FAT CONTAINING LESIONS: A PICTORIAL REVIEW

Joshua Charkin, MBChB, BSc (*Presenter*)
Ben Ariff, MBBS (*Abstract Co-Author*)
Deepa Gopalan, MRCP, FRCR (*Abstract Co-Author*)
Samir Mahboobani, MBBS (*Abstract Co-Author*)
Punam Pabari (*Abstract Co-Author*)
Mohsen Hajhosseiny, MD (*Abstract Co-Author*)
Ayo Oluboyede, MBBS, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Fat-containing lesions in the heart and mediastinum, though rare, are increasingly identified due to advancements in imaging technology, posing new diagnostic challenges. These lesions encompass both benign and potentially harmful conditions that require precise differentiation for effective management. This review aims to familiarize radiologists with common fat-containing lesions, including Lipomatous Hypertrophy of the Interatrial Septum, age-related fatty infiltration of the heart, arrhythmogenic cardiomyopathy, fatty metaplasia post myocardial infarction, intracardiac lipomas, pericardial lipomas, and mediastinal teratomas. By emphasizing the significance of these lesions and understanding their imaging characteristics, the review underscores how accurate diagnosis can minimize unnecessary investigations and improve patient outcomes.

TABLE OF CONTENTS/OUTLINE

1. Introduction Overview of Fat-Containing Lesions Normal Fat Distribution Importance of Accurate Diagnosis 2. Lipomatous Hypertrophy of the Interatrial Septum & Degenerative Fatty Changes in the Ventricles Fatty Infiltration in the Heart Imaging Features of LHIS FDG PET-CT in Diagnosis 3. Arrhythmogenic Cardiomyopathy Overview and Diagnosis of ARVC Imaging characterisitics 4. Fatty Metaplasia Post-Infarct Pathophysiology and Imaging Features Role of MRI and CT in Diagnosis 5. Intra-cardiac Lipoma Characteristics and Imaging Features (Echocardiography, CT, MRI) 6. Pericardial Lipoma Overview and Imaging Features (TTE, CT, MRI) 7. Mediastinal Teratoma Overview and Imaging Features (CT, MRI) 8. Tuberous Sclerosis Overview and Imaging of Cardiac Manifestations 9. Conclusion Summary of Fat-Containing Lesions

CAEE-67 DEMYSTIFYING EBSTEIN'S ANOMALY: KEY STEPS FOR A STRUCTURED MRI REPORT

Francisco Javier Vazquez Castro, MD (*Presenter*)
Miguel A. Cruz, MD (*Abstract Co-Author*)
Aloha Meave, MD (*Abstract Co-Author*)
Omar A. Gamboa Abundis, MD (*Abstract Co-Author*)
Maria M. De Avila Gomez, MD (*Abstract Co-Author*)
Karen De Icaza Benet (*Abstract Co-Author*)
Pablo Andres Hernandez Soto (*Abstract Co-Author*)

TEACHING POINTS

Standardize the cardiac magnetic resonance (CMR) technique by using a systematic and homogeneous protocol that includes cine-SSFP sequences, 4D Flow (if available), and late gadolinium enhancement. Understand and describe the Carpentier classification (A-D) according to the degree of apical displacement of the septal leaflet and the size of the "atrialized" ventricle, which helps guide the assessment of anatomical severity. Utilize quantitative severity indices such as the Celermajer Index, the total right/left volumetric index, and the valve rotation angle; these parameters complement the overall evaluation. Calculate tricuspid regurgitation (TR) using CMR by directly quantifying the regurgitant volume (e.g., with 4D Flow) or by indirect methods (flow planimetry with phase contrast). Highlight relevant preoperative findings: localization of the anterior leaflet, septal displacement, measurement of the functional right ventricle (RV) and "atrialized" ventricle volumes, as well as the RV ejection fraction, as these are key determinants for surgical planning and prognosis.

TABLE OF CONTENTS/OUTLINE

Introduction and Objectives CMR Protocol Equipment characteristics, main parameters, and recommended sequences Anatomical and Physiopathological Fundamentals Definition Key anatomical changes Carpentier Classification Celermajer Index Valve rotation (tricuspid valve angle) Tricuspid regurgitation Surgical indications Report template Conclusions References

CAEE-68 MYOCARDIAL CT PERFUSION: TECHNIQUES, EVIDENCE, IMAGE INTERPRETATION, AND CLINICAL APPLICATIONS IN STABLE ANGINA AND INOCA

Kazuki Yoshida, MD, PhD (*Presenter*)
Yuki Tanabe (*Abstract Co-Author*)
Takaaki Hosokawa (*Abstract Co-Author*)
Tomoro Morikawa, MD (*Abstract Co-Author*)
Yusuke Kobayashi, MD (*Abstract Co-Author*)
Kentaro Ohara (*Abstract Co-Author*)
Teruhito Kido, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Myocardial CT perfusion (CTP) is a valuable imaging technique for the diagnosis of myocardial ischemia and has been incorporated into CAD-RADS 2. From the early days of the CORE320 study to recent multicenter prospective trials and meta-analyses, its diagnostic utility in stable angina has become well established. In recent years, growing attention has been paid not only to stable angina but also to ischemia with non-obstructive coronary arteries (INOCA), a condition gaining recognition as a cause of anginal symptoms and myocardial ischemia. In this context, CT perfusion is expected to play an increasing role alongside conventional gold-standard modalities such as MR perfusion and PET.In this presentation, we will provide an overview of myocardial CT perfusion techniques (static CTP and dynamic CTP), supporting evidence, image interpretation methods and pitfalls. We will also present representative cases highlighting its clinical utility in patients with stable angina and INOCA, as well as cases of microvascular dysfunction associated with other cardiac diseases.

TABLE OF CONTENTS/OUTLINE

• Overview of CT perfusion in the context of CAD-RADS 2• Imaging techniques: Static CTP and Dynamic CTP• Clinical evidence:o Diagnostic valueo Prognostic valueo Studies focused on INOCA• Image interpretation methods and common pitfalls• Case presentations in stable angina:o Evaluation of single-vessel disease (1VD)o In-stent restenosis (ISR)o Triple-vessel disease (3VD)• Case presentations in INOCA:o Vasospastic anginao Microvascular angina• Other relevant cases with microvascular dysfunction:o Coronary-pulmonary artery fistulao Aortic stenosiso Hypertrophic cardiomyopathyo Cardiac amyloidosis

CAEE-69 FROM BENIGN TO DEADLY: A CTA-BASED ATLAS OF CORONARY ARTERY ANOMALIES

Matthew Whalen (*Presenter*)
Asad U. Malik, MD (*Abstract Co-Author*)
Ramy Shoela, MD (*Abstract Co-Author*)

TEACHING POINTS

Coronary artery anomalies are increasingly identified due to advancements in coronary CT angiography (CTA) and 3D image reconstruction techniques. Accurate recognition of these anomalies is vital for interpreting cardiovascular symptoms and pathologies. Pre-procedural awareness of coronary anomalies is critical for planning and safely performing coronary catheterization. Anomalies with an interarterial course carry a heightened risk of sudden cardiac death. Certain anomalies may result in coronary "steal" phenomena, where abnormal shunting diverts blood away from the myocardium, leading to ischemia.

TABLE OF CONTENTS/OUTLINE

1. Overview of normal coronary artery anatomy: a. High resolution CTA imaging, multiplanar reconstruction and cinematic 3D rendering of coronary vasculature. b. Role of 3D imaging in anatomical assessment 2. Coronary Artery Variants with minimal or no clinical impact: a. Accessory origin of the conus branch directly from the aorta. b. Accessory origin of the circumflex artery from the aorta. 3. Potentially Clinically Significant Coronary Artery Variants: a. Anomalous Right Coronary Artery from Left Cusp, with various benign and malignant courses i. Clinical manifestations, imaging features, and therapeutic options b. Tubular Origin of Right Coronary Artery i. Diagnostic challenges and management strategies c. Myocardial Bridging i. Diagnosis and management strategies 4. High risk Coronary Artery Variants with established clinical significance: a. Anomalous Right Coronary Artery from the Pulmonary Artery i. Diagnosis, clinical picture and management b. Anomalous Left Coronary Artery from Pulmonary Artery i. Clinical presentation

CAEE-70 OVERVIEW OF THE FONTAN CIRCULATION: INDICATIONS, METHODS AND COMPLICATIONS

Akihiro Inoue, MD (*Presenter*)
Michinobu Nagao, MD, PhD (*Abstract Co-Author*)
Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*)
Masaki Watanabe, MD (*Abstract Co-Author*)
Shuji Sakai, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Fontan procedure is a method of connecting the vena cava and pulmonary artery bypassing the right ventricle. The Fontan procedure improves the prognosis in childhood, but it is not a curative surgery; rather, it is a palliative surgery. The systemic venous pressure is always high because the systemic circulation and pulmonary circulation run in series. The long-term mortality rates in adult patients with congenital heart disease after the Fontan procedure have remained high compared to those with other congenital heart diseases. Complications of the Fontan circulation include failure of the Fontan circulation, vessel lesions, Fontan-associated liver disease (FALD), etc. Radiologists must be well versed in the physiology and complications of the Fontan circulation. This educational exhibit will focus on indication and surgical methods for Fontan procedure and postoperative complications after Fontan procedure.

TABLE OF CONTENTS/OUTLINE

1) Indications and postoperative pathophysiology of Fontan procedure. 2)Surgical methods for Fontan procedure. 3)Normal images in Fontan circulation and points to note during examination. 4) Complications after Fontan procedure (?Failure of the Fontan circulation, atrioventricular valve regurgitation, aortic valve regurgitation ? Vessel lesion such as conduit stenosis/dilation, pulmonary artery stenosis, pulmonary hypertension ?FALD ?Thrombosis ?Pulmonary arteriovenous fistula ?Lymphatic disorders such as protein-losing enteropathy and plastic bronchitis ?others). 5)Summary.

CAEE-71 THE FORGOTTEN VALVE: A CLOSER LOOK AT CONGENITAL AND ACQUIRED DEFECTS OF THE TRICUSPID VALVE

Kristina Ramirez Garcia, MD (*Presenter*)
Catalina Jaramillo, MD (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)

TEACHING POINTS

Tricuspid valve disease is often overlooked, yet it can lead to right heart failure and pulmonary hypertension. CT and MRI play key roles in identifying anatomical and functional abnormalities Ebstein’s anomaly is associated with maternal lithium use and is characterized by adherence of the septal and posterior tricuspid valve leaflets to the myocardium, apical displacement of the functional annulus, and dilatation of the "atrialized" portion of the right ventricle with wall thinning. Carcinoid syndrome occurs in 5% of carcinoid tumors, caused by serotonin release into the systemic circulation. Serotonin-induced fibrosis leads to restrictive cardiomyopathy and TV regurgitation. Libman-Sacks endocarditis is characterized by bacterial-free verrucous vegetations on the valves in patients with systemic lupus erythematosus, due to fibrin and platelet deposition. When affecting the TV it may result in valvular insufficiency or stenosis with leaflet thickening and vegetations. In patients with Marfan syndrome, pectus excavatum deformity can cause mass effect upon the right atrium, potentially leading to tricuspid stenosis.

TABLE OF CONTENTS/OUTLINE

Embryology and Anatomy Role of CT and MRI in the evaluation Congenital conditions: Tricuspid atresia Ebstein’s anomaly Acquired conditions: Functional valvular disease Infectious and non-infectious endocarditis Carcinoid syndrome Iatrogenic and traumatic injuries Neoplasms

CAEE-72 CARDIAC MAGNETIC RESONANCE IMAGING FINDINGS OF STRESS CARDIOMYOPATHIES

Mecit Kantarci, MD, PhD (*Presenter*)
Cihan Duran, MD (*Abstract Co-Author*)
Volkan Kizilgoz (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)
Laura A. Ocasio, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

Stress cardiomyopathies (SCs) are reversable morphological and functional alterations of the heart muscle. The apical form of this disease have been known as Takotsubo Cardiomyopathy (TCM) in the literature. TCM was described by Dote et. al in 1990 and the name was given because of the specific morphology of the left ventricle which resembles Tako-Tsubo, an octopus trap that Japanese fishermen use. There are mid-ventricular, apical, basal and focal types of SCs. No late gadolinium enhancement is observed in SCs in cardiac MR images. Typical radiological findings along with related patient history should always be indicative of SCs. The radiology report should underline the specific myocardial morphology and classify the type of disease. SCs are known to bring non-negligible risks such as acute heart failure, cardiac arrhythmias or even death. Clinicians and radiologists should be aware of the diagnostic clues and radiological findings of this unique condition.

TABLE OF CONTENTS/OUTLINE

-What is Takotsubo disease? -Morphological and functional alterations -Types of stress cardiomyopathies -Cardiac MR images - What needs to be indicated? -Examples of different types of stress cardiomyopathies -How to report cardiac MR imaging of stress cardiomyopathies?

CAEE-73 CINE CARDIAC COMPUTED TOMOGRAPHY FOR PRE- AND POST-TREATMENT EVALUATION OF HEART VALVE DISEASES

Nobuko Tanitame, MD (*Presenter*)
Keizo Tanitame, MD (*Abstract Co-Author*)

TEACHING POINTS

Heart valve failure or dysfunction can lead to reduced cardiac function, and untreated heart valve disease may become life-threatening. Echocardiography and cardiac magnetic resonance imaging (MRI) are first-line imaging modalities for assessing heart valves. However, electrocardiogram (ECG)-gated contrast-enhanced cardiac computed tomography (CT) enables retrospective reconstruction of cross-sectional images in any desired plane, making it a valuable tool for pre- and post-treatment evaluation of heart valve disease. Compared to echocardiography and MRI, cardiac CT provides superior visualization of heavily calcified or mechanical prosthetic valves. For functional valve assessment, 10 to 20 data sets are typically reconstructed throughout the R-R interval, allowing the generation of cine loops in planes parallel and perpendicular to the target valve. This presentation highlights the clinical utility of cine cardiac CT in evaluating valvular leaflet morphology and function.

TABLE OF CONTENTS/OUTLINE

1. 256-Multidetector CT protocol for heart valve evaluation *Contrast material injection, ECG-gated acquisition, Image reconstruction using motion correction software, and cine loop generation on a workstation 2. Mitral valve * Valve prolapse *Vegetation on MitraClip *Mitral annulus calcification *Impaired motion of the anterior mitral leaflet due to a left atrial myxoma 3. Aortic valve *Bicuspid valve *Valve prolapse *Stenosis with extensive valvular calcification *Coronary cusp thrombus following TAVI 4. Tricuspid valve *Dysplastic valve *Stuck mechanical valve *Tricuspid pouch 5. Pulmonary valve *Regurgitation *Restricted motion after valvuloplasty *Hypoplastic valve

CAEE-74 BEYOND THE INFARCT: CARDIAC MRI PATTERNS ACROSS THE ISCHEMIC HEART DISEASE SPECTRUM AND PITFALLS

Andita D. Hidayati, MD (*Presenter*)
Janardhana Ponnatapura, MD (*Abstract Co-Author*)

Silanath Terpenning, MD (*Abstract Co-Author*)

TEACHING POINTS

·Review the pathophysiology of ischemic heart disease and cardiac MR role to assess the disease ·To demonstrate Cardiac MR features in the entire spectrum of ischemic heart disease, from acute ischemia to chronic infarct and complications that providing vital information that influences treatment decisions including: ·Stress perfusion imaging detects physiologically significant ischemia beyond anatomical stenosis, while late gadolinium enhancement (LGE) identifies infarcted and viable myocardium. ·Advanced techniques like T1/T2 mapping provide tissue characterization and allow for more precise assessment, even in subtle pathology. Review the mimics of ischemic heart disease cardiac MR pattern

TABLE OF CONTENTS/OUTLINE

•Introduction, Why CMR in Ischemic Heart Disease? •Pathophysiology of ischemia •Inducible ischemia •Transmural enhancement of Ischemic Herat Disease and its mimics •Subendocardial enhancement of Ischemic Herat Disease and its mimics •Complication of ischemic heart disease •Role of multidisciplinary conference •The role of supplementary imaging such as echocardiogram, nuclear medicine stress test, and PET CT •Management algorithm for ischemic heart disease

CAEE-75 IMAGING TETRALOGY OF FALLOT ACROSS TIME AND MODALITY

Spencer Glancy, MD (*Presenter*)
Robert J. Smalley, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Know TOF Anatomy: Recognize the four core defects on fetal ultrasound, cardiac MRI and CT. 2. Understand Surgical Repairs: Be familiar with common repair techniques and resulting anatomy. 3. Identify Post-Op Complications: Learn common issues needing follow-up (Pulmonary regurgitation, right ventricular dysfunction, residual lesions, aortic dilatation). 4. Cardiac MRI indications and key data reporting elements. 5. Cardiac CT indications and key data reporting elements.

TABLE OF CONTENTS/OUTLINE

1. Introduction a. Definition of Tetralogy of Fallot b. Common associated anomalies c. Goals of repair d. Common surgical techniques 2. Prenatal diagnosis a. Normal fetal outflow tracts b. TOF outflow tracts on standard screening US views 3. Post-op appearance, near term a. Postoperative radiographs i. Common support devices ii. Uses of post-operative imaging to guide diuresis b. Postoperative lung scintigraphy 4. Post-operative complications a. Pulmonary regurgitation b. Branch pulmonary artery stenosis c. RV dysfunction d. Residual lesions e. Aortic dilation f. Conduit stenosis 5. Cardiac MRI a. Indications b. Standard and advanced sequences c. Key data reporting elements 6. Cardiac CT a. Indications b. Indication-specific techniques c. Key data reporting elements

CAEE-77 HARD HEART: DECODING THE HIDDEN LANGUAGE OF CARDIAC CALCIFICATIONS

Danilo O. Ramos, MD (*Presenter*)
Vinicius C. Serra, MD (*Abstract Co-Author*)
Andre Vaz (*Abstract Co-Author*)

TEACHING POINTS

(1) understand the pathophysiology and mechanisms behind cardiac calcifications detectable on CT; (2) recognize the imaging patterns and etiologies of dystrophic and metastatic cardiac calcifications; (3) differentiate true cardiac calcifications from imaging artifacts and mimickers; (4) identify clinically relevant calcifications that may require further evaluation or intervention; and (5) highlight best practices for evaluating and reporting incidental cardiac calcifications in CT exams.

TABLE OF CONTENTS/OUTLINE

(1) introduction, providing an overview of cardiac calcifications and their clinical importance; (2) pathophysiology, discussing the mechanisms of dystrophic and metastatic calcifications; (3) etiologies, addressing infectious, ischemic, metabolic, neoplastic, inflammatory, and traumatic causes; (4) imaging evaluation, covering CT protocols, technical considerations, and the role of ECG gating; (5) imaging patterns on CT, distinguishing dystrophic, metastatic, valvular, myocardial, pericardial, and vascular calcifications; (6) pitfalls and mimickers, recognizing diagnostic traps and artifacts; (7) reporting recommendations, detailing how to describe, classify, and suggest appropriate clinical management; and (8) case-based illustrations, providing key examples demonstrating imaging features and interpretation challenges.

CAEE-78 WHISPERS BEHIND THE BEAT: DETECTING CARDIAC METASTASES - A PICTORIAL ESSAY

Danilo O. Ramos, MD (*Presenter*)

TEACHING POINTS

Review the main imaging features that differentiate primary and secondary cardiac masses, and discuss the role of advanced multimodality imaging in their evaluation. Describe the anatomical landmarks involved in metastatic spread to the heart (pericardium, epicardium, myocardium, valves, and chambers). Understand the epidemiology of cardiac metastases, including prevalence, most common primary origins, and histologic types. Propose a diagnostic workflow based on tumor features (size, borders, tissue invasion, location, pericardial involvement, solitary vs. multiple lesions) and tissue characteristics (contrast enhancement, T1- and T2-weighted imaging signal intensities). Identify key "red flags" in imaging findings suggestive of cardiac metastatic involvement.

TABLE OF CONTENTS/OUTLINE

Major Secondary Cardiac Tumors: Epidemiology, pathophysiology, and imaging findings (melanoma, renal cell carcinoma, hepatocellular carcinoma, sarcomas, colorectal cancer [Lynch syndrome], leukemia, bronchogenic carcinoma, breast cancer). Role of Multimodality Imaging: Advantages and limitations of echocardiography, computed tomography (CT), magnetic resonance imaging (MRI), and PET/CT in diagnosis and surgical planning. Differential Diagnosis and Pitfalls: Common mimickers, artifacts, and potential errors in the evaluation of cardiac masses.

CAEE-79 UNPLUGGING THE HEART: CARDIOVASCULAR CT INSIGHTS FOR PRE-EXTRACTION EVALUATION OF CARDIAC DEVICES - A PRIMER FOR RADIOLOGISTS

Danilo O. Ramos, MD (*Presenter*)

TEACHING POINTS

Understand the role of cardiovascular CT in the pre-extraction evaluation of cardiac implantable electronic devices (CIEDs). Recognize major imaging findings suggestive of device-related complications, such as lead adherence, fractures, perforation, and infection. Review CT acquisition protocols optimized for detailed evaluation of leads, vascular structures, and cardiac chambers. Propose a structured imaging approach for risk stratification and procedural planning. Highlight imaging findings that impact extraction strategy and predict procedural complexity.

TABLE OF CONTENTS/OUTLINE

Introduction: Clinical importance of pre-extraction cardiac device imaging. CT Protocols for Device Evaluation: Acquisition parameters and optimization strategies. Imaging Findings Suggestive of Complications: Lead fracture, adherence, perforation, infection, and venous occlusion. Structured CT Evaluation Prior to Extraction: Systematic assessment and risk stratification. Pitfalls and Artifacts: Recognition of imaging pitfalls and differentiation from true pathology. Conclusion: Radiologist's role in improving safety and outcomes of device extraction procedures.

CAEE-80 PROSTHETIC HEART VALVES - IMAGING OF POSTOP COMPLICATIONS

Junwoo Kim, MD (*Presenter*)
Zehavit Kirshenboim (*Abstract Co-Author*)

Emrah Duman, MD (*Abstract Co-Author*)
Azza A. Elgendy, MD, PhD (*Abstract Co-Author*)
Omer Onder, MD (*Abstract Co-Author*)
Joan M. Lacomis, MD (*Abstract Co-Author*)

TEACHING POINTS

Heart valve pathologies are critical to identify and characterize due to their significant impact on cardiac function and patient outcomes. Accurate diagnosis enables timely medical or surgical intervention, reducing morbidity and mortality. Following valve repair or replacement, radiologists play a pivotal role in detecting postsurgical complications, which may include prosthetic valve dysfunction, pseudoaneurysm, infection, paravalvular leaks and dehiscence. Each complication exhibits distinct imaging features across modalities such as echocardiography, cardiac CT, and MRI. Echocardiography is typically the initial tool for detecting these abnormalities; however, the importance of cardiac CT has grown significantly in recent years. CT offers outstanding spatial and temporal resolution, making it a vital tool for evaluating tissue planes and the spatial alignment between the prosthetic valve and the annulus. Additionally, gated cine images are highly valuable for identifying functional abnormalities. This presentation highlights the CT appearance of heart valve pathologies, reviews common postsurgical complications, and provides a comprehensive guide to their imaging appearances for optimized patient care.

TABLE OF CONTENTS/OUTLINE

Purpose Postsurgical complications 1)Prosthetic valve dysfunction 2)Pseudoaneurysm 3)Infection 4)Paravalvular leaks 5)Dehiscence Conclusion

CAEE-81 "CARDIAC CURVEBALLS": IMAGING THE OUTLIERS IN CARDIAC ANEURYSMS

Suman T. Prabhakar, MD, FRCR (*Presenter*)
Ashish Gupta, MBBS (*Abstract Co-Author*)
Srikanth Sola, MD (*Abstract Co-Author*)
Carole J. Dennie, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

1. To illustrate various aneurysms of ventricles and atria including coronaries. 2. To describe MRI/CT techniques and key imaging findings, emphasizing on rare cases and management strategies.

TABLE OF CONTENTS/OUTLINE

Cardiac aneurysms can be caused potentially by wide varieties of aetiologies. Cardiac CT and MR aid in non-invasive diagnosis. We emphasize on unusual cardiac aneurysms and therapeutic procedures performed. The cases were classified as follows- A) CONGENITAL ANEURYSMS: • LEFT VENTRICLE: Crypts, diverticulum, submitral aneurysms, double chamber. • ATRIAL: Congenital anomalous communication between right pulmonary artery to left atrium, Congenital aneurysm of right atrial appendage, Ruptured sinus of Valsalva. B) ACQUIRED ANEURYSMS: • Aneurysms due to myocardial infarction, Aneurysms due to vasculitis, Aneurysm due to infectious endocarditis, Mycotic aneurysms. C) ANEURYSMS DUE TO HERITABLE GENETIC DISORDERS • Arrhythmogenic Right Ventricular Dysplasia • Brugada syndrome D) MISCELLANEOUS • Takotsubo Cardiomyopathy • Apical Aneurysm in Hypertrophic Cardiomyopathy. This educational exhibit is primarily focussed to describe key imaging points of unusual cardiac aneurysms to aid in diagnosis, which is important due to their differential complications and treatment strategies.

CAEE-82 SOMETHING OLD, SOMETHING NEW, SOMETHING BORROWED, SOMETHING BLUE: A COMPREHENSIVE REVIEW OF APICAL HYPERTROPHIC CARDIOMYOPATHY WITH AN EMPHASIS ON CARDIAC MRI AND CURRENT EVIDENCE-BASED INSIGHTS

Omer Onder, MD (*Presenter*)
Emrah Duman, MD (*Abstract Co-Author*)
Emilee Kurtz (*Abstract Co-Author*)
Zehavit Kirshenboim (*Abstract Co-Author*)
Kyung Hee Lee (*Abstract Co-Author*)
Timothy Wong (*Abstract Co-Author*)

TEACHING POINTS

1- First described in 1976, apical hypertrophic cardiomyopathy (HCM) is now recognized as a dynamic and evolving entity. Recent studies emphasize its unique epidemiologic, clinical, and imaging features, with particular focus on updating hypertrophy thresholds to improve diagnostic accuracy, enable early identification of "relative apical HCM" subgroup, and further optimize risk stratification. 2- Although traditionally considered a benign subtype, apical HCM is now recognized to carry a risk of sudden cardiac death comparable to other HCM forms in selected high-risk patients, particularly those with apical aneurysms or extensive late gadolinium enhancement (LGE). Accurate differentiation from phenocopies and guideline-driven management are critical to optimize patient outcomes. 3- Cardiac MRI plays a key role in diagnosing and monitoring apical HCM, allowing assessment of high-risk imaging features and guiding personalized risk stratification and implantable cardioverter-defibrillator (ICD) placement decisions. This exhibit presents a comprehensive overview of apical HCM, particularly focusing on MRI findings and current evidence-based insights.

TABLE OF CONTENTS/OUTLINE

A. Introduction & Objectives B. Hypertrophic cardiomyopathy (HCM) subtypes C. Apical HCM - Epidemiology - Clinical presentation - Potential complications D. Imaging in apical HCM - Various imaging modalities - Added value of cardiac MRI - MRI features of apical HCM - Wall thickness measurement - Imaging-based diagnostic criteria - Relative versus absolute apical HCM E. Phenocopies of apical HCM & differential diagnoses F. Follow-up, risk stratification & management G. Summary H. Conclusion

CAEE-83 WHEN AND HOW TO PERFORM CORONARY CTANGIOGRAPHY (CCTA) WITHOUT ELECTROCARDIOGRAPHIC TRIGGERING (ECG-LESS) APPROPRIATELY

Tingting Qu (*Presenter*)

TEACHING POINTS

1) Point out the limitations of conventional ECG-gated CCTA in certain situations.2) Demonstrate the necessary imaging techniques for performing ECG-less CCTA.3) Demonstrate the appropriate protocols for successful CCTA using ECG-less mode.

TABLE OF CONTENTS/OUTLINE

1) Limitations of conventional ECG-gated CCTA• Patients with arrhythmia (atrial fibrillation, frequent premature beats) or pacemaker may have trouble synchronizing gating information• Patients unable or have no time for placing chest ECG electrodes (with skin burns, severe dermatitis, trauma)• Some privacy conscious patients2) Necessary techniques for ECG-less CCTA• Perform CCTA in 1 heartbeat with fast rotation speed.• Able to select the data sequence with the least motion for reconstruction• Have robust cardiac motion correction algorithms 3) Strategies for ECG-less CCTA• Select wide detector or ultra-high helical pitch to cover heart in 1 heartbeat to avoid beat-to-beat variation• Use fast rotation speed for excellent temporal resolution• Ensure adequate scan duration (about 500ms) for adaptive reconstruction• Compensate motion artifacts using motion correction algorithms• Use advanced reconstruction algorithms to reduce noise and other artifacts

CAEE-84 ISOLATING THE DANGER: MULTIMODALITY IMAGING OF THE LEFT ATRIAL APPENDAGE BEFORE AND AFTER OCCLUSION

Nisha Korakavi, MD (*Presenter*)
Robert C. Gilkeson, MD (*Abstract Co-Author*)
Amit Gupta, MD, MBBS (*Abstract Co-Author*)
Cody R. Johnson, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To understand the role of CTA and CMR in excluding LAA thrombus, assessing morphology, and guiding device selection for LAA occlusion. 2. To recognize the utility of dual-phase CTA and the "Reverse Thrombus Sign" in distinguishing thrombus from slow contrast flow. 3. To identify key post-procedural imaging findings, including normal device placement, peridevice leaks, and complications like thrombus formation or embolization.

TABLE OF CONTENTS/OUTLINE

Introduction Atrial Fibrillation and risk for thrombus Need for Left atrial appendage (LAA) occlusion Methods of LAA occlusion: Device placement or surgical management LAA Occluder Devices Watchman and Watchman FLX Amulet Other devices Pre-Procedural Imaging Key Imaging Considerations Thrombus exclusion Precise LAA measurements (critical for correct device sizing.) The "Reverse Thrombus Sign" (suggestive of slow LAA flow.) b. Imaging with CTA 1. Scanning: Single energy versus dual/multi-energy CT . 2. Dual-phase contrast (Thrombus versus slow flow). 3. Assessment of adjacent structures and fluoroscopic angle simulation. Cardiac MRI as an alternative Scanning protocol : No contrast required Assessment of LAA function. Post-Procedural Imaging and Follow-Up Post-implantation evaluation of device positioning and function Assessment of Procedural Complications Device-related thrombus Peridevice leak Device embolization and structural complications Pericardial effusion and adjacent structure injury

CAEE-85 A NOVEL APPROACH FOR OPTIMAL CARDIAC PHASE SELECTION IN CORONARY CTA: CAN QUANTITATIVE ASSESSMENT AND VISUALIZATION OF CARDIAC MOTION BE ACHIEVED USING VELOCITY ANALYSIS?

Hiroki Komesu (*Presenter*)
Tatsuya Maruno (*Abstract Co-Author*)

TEACHING POINTS

In coronary CT angiography, motion artifacts are prominent in patients with a heart rate around 70 bpm. This is attributed to the complex timing of cardiac contraction and relaxation, as well as the increased influence of the atrium. This exhibit proposes a method to quantitatively determine the optimal cardiac phase (cardiac phase images with minimal motion artifacts and facilitating diagnosis) using velocity analysis of image analysis software on the acquired data. The main educational points are as follows: 1. To demonstrate the difference in contraction timing between ventricles and atria. 2. To approximate overall cardiac velocity and quantitatively select cardiac phases with fewer motion artifacts by using velocity graphs of both ventricles and atria. 3. To show that images calculated using velocity graphs are superior to the conventional visual selection method. 4. Principles of velocity analysis and tips for improving analysis accuracy. By using the velocity analysis function, it is possible to quantitatively and efficiently calculate coronary CTA images with fewer motion artifacts.

TABLE OF CONTENTS/OUTLINE

1. Introduction; 2. Incidence of Motion Artifacts Based on Heart Rate During Imaging; 3. Characteristics of Cardiac Motion Around 70 bpm and Challenges in Optimal Phase Selection; 4. Procedure for Optimal Cardiac Phase Selection Using Velocity Graph; 5. Relationship Between Velocity Graph and Motion Artifact Score; 6. Accuracy of Optimal Cardiac Phase Determined from Velocity Graph; 7. Algorithm of Velocity Analysis; 8. Tendencies and Potential Causes of Optimal Cardiac Phase in Left and Right Coronary Arteries; 9. Clinical Applications of Velocity Mapping in VR

CAEE-86 EFFECTIVENESS OF DEEP LEARNING-BASED IMAGE RECONSTRUCTION INCLUDING MOTION CORRECTION AND ITS POTENTIAL FOR RADIATION DOSE REDUCTION

Takayoshi Yamaguchi (*Presenter*)
Yuichi Kondoh (*Abstract Co-Author*)
Yuji Miura (*Abstract Co-Author*)
Keiichi Hanaoka, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Explaining the current status of factors that deteriorate coronary CT images and countermeasures2. Summarize of the relationship between heart rate during scan and motion artifacts, and the distribution of heart rate phases used for image reconstruction3. Overview of new coronary artery motion correction technology using deep learning4. The effectiveness of the motion correction technique at each heart rate will be verified using clinical cases by comparing it with conventional image reconstruction methods.5. Proposal of an optimal scan protocol based on the relationship between image quality at each heart rates and selected cardiac phases6. The effectiveness of the proposed new imaging protocol in reducing radiation dose and improving image quality will be clarified through comparison with conventional imaging methods.

TABLE OF CONTENTS/OUTLINE

1.Introduction2.Summarize the various factors that cause unclear coronary CT images3.Explains the effect of heart rate during imaging on image quality in previous image reconstruction methods4.Explanation of the features of a new coronary artery motion correction technology developed using deep learning5.Comparison of the relationship between heart rate and image quality in clinical cases using conventional image reconstruction and a new motion correction method6.Analysis of optimal cardiac phase selected by various image reconstruction methods at each cardiac rate during CT scanning7.Proposal of a new scanning protocol using an image reconstruction method including motion correction8.Revealing the effect of new scanning protocols in improving image quality and reducing radiation exposure

CAEE-87 OPTIMIZING TRIGGER POINTS IN TEST BOLUS TRACKING: AN EDUCATIONAL INSIGHT INTO CONTRAST DYNAMICS IN VALVULAR HEART DISEASE

Tetsuo Hironaga (*Presenter*)
Shinobu Mano (*Abstract Co-Author*)
HIROYUKI KOBAYASHI (*Abstract Co-Author*)
Masahisa Tokunaga (*Abstract Co-Author*)
Asuka Goto (*Abstract Co-Author*)
Atsushi Watanabe, MD,PhD (*Abstract Co-Author*)
Aoi Hayashi (*Abstract Co-Author*)

TEACHING POINTS

•Understand how different valvular diseases alter time-enhancement curves (TECs). •Learn visual strategies for assessing scan timing in the absence of a distinct peak. •Recognize the potential utility of the AAo > LA CT attenuation difference as a supplementary indicator. •Encourage technologist-led optimization of cardiac CT scan protocols based on physiological indicators.

TABLE OF CONTENTS/OUTLINE

Overview of the physiological impact of valvular diseases on contrast circulation Visual examples of TEC changes in tricuspid, mitral, and aortic regurgitation Handling ambiguous peaks: using the AAo > LA CT attenuation difference as a supplementary visual marker Enhancing visualization by monitoring at the level of the left atrium Educational flowchart for determining the appropriate trigger point Conclusion: In patients with valvular heart disease, conventional peak-based triggering may not yield optimal scan timing due to irregular contrast dynamics. This exhibit introduces a physiology-informed, visually guided approach that leverages the AAo > LA CT attenuation difference as a supplementary indicator, aiming to enhance consistency in trigger point selection during cardiac CT. While further quantitative validation is warranted, this method offers practical educational value , particularly for technologists involved in contrast protocol optimization.

CAEE-88 OPTIMIZING CORONARY CT ANGIOGRAPHY: MOTION CORRECTION ALGORITHMS AS A COST-EFFECTIVE ALTERNATIVE TO HIGH-COVERAGE SCANNERS

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)

TEACHING POINTS

Motion artifacts significantly impact CTCA interpretation, especially at high heart rates. Motion Correction Algorithm (MCA) enhances image quality by compensating for motion within a single cardiac cycle. MCA enables the use of less expensive CT scanners without compromising diagnostic performance .Clinical studies support MCA as an effective alternative to high-coverage scanners, improving diagnostic accuracy and image interpretability. Tailoring imaging strategies with MCA allows for optimized resource allocation in different clinical settings.

TABLE OF CONTENTS/OUTLINE

Describe the limitations of coronary motion artifacts in CTCA. • Explain the principles of motion correction algorithms (MCA). • Demonstrate how MCA can serve as an alternative to high-coverage CT scanners. • Provide clinical examples showcasing MCA in different CT scanner configurations. MCA analyzes adjacent cardiac phases to detect vessel movement. The algorithm determines motion severity and spatial displacement. The motion is compensated on a per-segment basis, enhancing vessel sharpness and diagnostic accuracy. MCA is applicable to both single-energy CT (SECT) and dual-energy CT (DECT), allowing flexible integration into different imaging workflows.Clinical studies have demonstrated that MCA improves image quality and diagnostic accuracy. Research has shown that MCA enhances the assessment of calcified plaques, reduces artifacts, and improves stenosis quantification. SECT with MCA: Ideal for high-definition imaging, especially in patients with coronary stents. DECT with MCA: Reduces blooming artifacts, making it suitable for patients with heavy calcifications and borderline renal function.

CAEE-89 EVOLUTION OF DEEP LEARNING-BASED MOTION CORRECTION ALGORITHMS FOR NON-ECG-GATED CT : APPLICATION TO CARDIAC IMAGING

Yoshihiro Haga, PhD, RT (*Presenter*)
Koichi Chida, PhD (*Abstract Co-Author*)
Masahiro Sota, MSc, RT (*Abstract Co-Author*)
Yuji Kaga, RT (*Abstract Co-Author*)
TOSHIKI KATO (*Abstract Co-Author*)

TEACHING POINTS

CT scans have become faster over time, making it possible to take images in a short time. However, the presence of motion artifacts (e.g., heart rate, gastrointestinal, breath-hold stoppage failure, etc.) may induce image quality degradation. Although there have been developments such as faster rotation speeds, Dual Source CT, multi-row detectors CT, and high pitch imaging, there have been limitations. Recently, deep learning techniques were also introduced to the development of motion correction algorithm (MCA). This study examines the clinical application of Clear Motion Lung , a motion correction algorithm developed by Canon Medical Systems Inc. We have extended this lung-specific algorithm to the field of cardiology.

TABLE OF CONTENTS/OUTLINE

1. To understand motion artifact characteristic2. To understand the principles of the Motion Compensation Algorithm (CLEAR Motion Lung: CML) in non-ECG synchronized CT developed by Canon3. To understand the optimal scanning protocol using CML for non-ECG-gated CT4. To understand the advantages and disadvantages of clinical imaging with CML 5. To understand the clinical application of CML in non-ECG-gated CT

CAEE-90 THE IMITATION GAME: DIAGNOSING HCM LOOK-ALIKES

Catalina Jaramillo, MD (*Presenter*)
Kristina Ramirez Garcia, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)
Monica D. Ocampo, MD (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)

TEACHING POINTS

Not all apparent HCM is true HCM. MRI helps distinguish mimics through key tissue and functional features. This presentation highlights key MRI features for accurate differentiation.• In patients over 65, cardiac amyloidosis should be considered when cardiac MRI reveals left ventricular hypertrophy, global systolic dysfunction, biatrial enlargement, and diffuse subendocardial late gadolinium enhancement.• Fabry's disease, an X-linked lysosomal storage disorder, often presents on cardiac MRI with left ventricular hypertrophy and characteristically low native T1 values due to glycosphingolipid accumulation.• Chronic use of chloroquine can lead to a cardiomyopathy that mimics HCM, with biventricular hypertrophy, diffuse myocardial fibrosis on LGE, low native T1, vacuolization, and false-positive PYP scans.• Friedreich's Ataxia Cardiomyopathy resembles HCM on cardiac MRI, with extracellular volume expansion and cardiomyocyte hypertrophy contributing to the observed myocardial thickening and fibrosis. • Hypertensive cardiomyopathy has a characteristic pattern of left ventricular hypertrophy, typically presenting with concentric hypertrophy, while hypertrophic cardiomyopathy often shows asymmetric hypertrophy, particularly involving the septum. • Danon disease is an X-linked storage disorder causing cardiomyopathy, most often symmetric HCM (56%), then asymmetric (38%), and rarely dilated (6%).

TABLE OF CONTENTS/OUTLINE

1. Introduction2. HCM: Characteristics and Brief Overview3. Conditions that can mimic HCM• Amyloidosis• Athletes heart• Hypertensive Heart Disease• Fabry's Disease• Danon disease• Chloroquine induced• Friedreich's Ataxia4. Conclusion

CAEE-91 NOT JUST A PDA: MULTIMODAL IMAGING OF THE AORTOPULMONARY WINDOW FROM FETAL LIFE TO ADULTHOOD

Jochen Gerstner, MD (*Presenter*)
Laura Acosta, MD (*Abstract Co-Author*)
Lorna Browne, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Aortopulmonary window (APW) is a rare congenital defect often mistaken for patent ductus arteriosus (PDA), with important clinical and surgical implications. Multimodal imaging—particularly CT angiography and cardiac MRI—is key to accurate diagnosis and classification. Timely identification is critical to prevent progressive complications such as pulmonary overcirculation and pulmonary hypertension. APW can be missed on echocardiography, resulting in severe pulmonary hypertension and potentially leading to Eisenmengers syndrome. This exhibit will: a. Illustrate the embryology and classification of APW. b. Provide a multimodality case-based review using CT and MR imaging. c. Highlight key diagnostic features across a spectrum of presentations, including late-presenting cases. d. Discuss surgical repairs and implications of APW variants with PDA or interrupted aortic arch.

TABLE OF CONTENTS/OUTLINE

Background : Embryology and developmental anatomy of the aorticopulmonary septum Classification : Overview of APW types I-III Imaging Methods : a. CT angiography protocols and key reconstructions b. MRI protocols including 4D flow MR Case Series : a. Multimodal review of preoperative and postoperative cases b. Late presentation with pulmonary hypertension missed on multiple echocardiograms Differential Diagnosis : PDA, truncus arteriosus, MAPCAs Diagnostic Pearls and Pitfalls : Practical guidance for radiologists Conclusion : APW spans a diverse clinical spectrum. Recognizing its variants and associations is vital when evaluating neonates with suspected shunt lesions and in older patients with unexplained pulmonary hypertension.

CAEE-92 THROUGH THE DOOR TO DORV: THE ROLE OF IMAGING IN OPERATIVE DECISION-MAKING FOR DOUBLE OUTLET RIGHT VENTRICLE

Shravan Sridhar, MD, MS (*Presenter*)
Muthu Kumar Sakthivel, MBBS, MD (*Abstract Co-Author*)
Prabhakar Rajiah, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

Double outlet right ventricle (DORV) is a rare congenital heart disease and is typically repaired in the perinatal period. The surgical management strategy depends on alignment between the ventricular septal defect and arteries, degree of ventricular outflow obstruction, ventricular development, and presence of other defects. Here, we examine malformations, preoperative imaging parameters, and operations for DORV. Learning objectives include 1) Differentiate the different types of DORV based on morphologic features, 2) Understand utility of CT and MRI in the assessment of unrepaired DORV, 3) Become familiar with interventions and image-based decision points.

TABLE OF CONTENTS/OUTLINE

1. Title, disclosure2. Abbreviations3. Overview4. Embryology and anatomy a. Conotruncal rotationb. DORV mechanism5. Malformations a. Ventriculoarterial malalignmentb. CAEE-93 EMERGING POTENTIAL OF NON-ECG-GATED CARDIAC CT: CURRENT ACHIEVEMENTS AND FUTURE PERSPECTIVES

Junji Mochizuki, MSc, RT (*Presenter*)
Noriko Oyama-Manabe, MD, PhD (*Abstract Co-Author*)
Yoshiki Hata (*Abstract Co-Author*)

TEACHING POINTS

A. To understand the technological advancements enabling non-ECG-gated cardiac CT B. To recognize clinical scenarios where non-ECG-gated imaging is effective C. To compare ECG-gated and non-ECG-gated techniques to guide appropriate imaging selection

TABLE OF CONTENTS/OUTLINE

A. Overview of ECG-Gated Cardiac CT and Its Limitations ECG-gated cardiac CT has been central to coronary artery assessment and cardiac function evaluation. However, its clinical use can be limited by heart rate dependency, the need for ECG lead placement, and patient preparation. B. Technological Innovations Enabling Non-ECG-Gated Imaging Recent advancements in CT hardware and software—including wide detector coverage, improved temporal resolution, and advanced motion correction algorithms—have enabled non-ECG-gated cardiac imaging with clinically acceptable image quality. C. Clinical Applications of Non-ECG-Gated Cardiac CT Coronary Artery Disease: Morphologic assessment of coronary arteries and plaque characterization Myocardial Disease: Evaluation of myocardial perfusion abnormalities and delayed enhancement Aortic Disease: Rapid evaluation of aortic dissection and aneurysm, particularly in emergency settings D. Advantages and Limitations Non-ECG-gated imaging offers simplified scanning protocols and reduced scan times. However, because it is not synchronized with the cardiac cycle, selective exposure based on the heartbeat is not possible, which may lead to increased radiation dose. Additionally, narrowing the exposure range makes the scan more susceptible to motion artifacts. Furthermore, due to the absence of ECG information, functional cardiac assessment is difficult.

CAEE-94 WILL MACHINE LEARNING REPLACE TRADITIONAL CARDIAC IMAGING?

Mehrad Rokni, MD (*Presenter*)
Linh Vo (*Abstract Co-Author*)
Kamhung Lam (*Abstract Co-Author*)
Sofiya Ghazaryan (*Abstract Co-Author*)
Michelle Wang (*Abstract Co-Author*)
Nicholas Fong (*Abstract Co-Author*)
Majid Hassan, MD (*Abstract Co-Author*)
Ahmadreza Ghasemiesfe, MD (*Abstract Co-Author*)
Misagh Piran, MD (*Abstract Co-Author*)

TEACHING POINTS

Artificial intelligence (AI) transforms cardiac imaging by enhancing segmentation, diagnosis, and risk stratification in coronary CT, cardiac MRI, echocardiography, and nuclear cardiology. AI achieves high diagnostic accuracy (e.g., 95% sensitivity in CT plaque detection) and speeds analysis (30-50% faster MRI processing), improving workflow efficiency. Limitations include training data biases, model transparency issues, and regulatory hurdles (~10% of tools FDA-cleared in 2025). AI is not a replacement but a collaborative tool, amplifying radiologist precision and expanding access in underserved areas. Responsible integration ensures ethical deployment and improved patient outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction Definition of AI and machine learning Historical context in cardiac imaging Key Applications Automated segmentation in CT and MRI Diagnostic support in echocardiography Prognostic modeling in nuclear cardiology Advantages Enhanced precision, consistency, speed Reduced workload, better rural access Challenges Algorithmic bias, data limitations Regulatory and interpretability issues Future Directions Radiologist-AI collaboration Ethical and oversight frameworks

CAEE-95 EVOLUTION OF MYOCARDIAL INFARCT: CHALLENGES FOR CMR IMAGING

Nicole Bodnariuc (*Presenter*)
Felipe S. Torres, MD, PhD (*Abstract Co-Author*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)
Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Myocardial infarcts (MI) are commonly seen on CMR and yet their evolution over time is not well captured, because repeated imaging follow-up is not standard of care. Various stages of a myocardial infarct can lead to both over and under-estimation of viable myocardium versus replacement fibrosis in MI.

TABLE OF CONTENTS/OUTLINE

Viability assessment in acute MI can result in over-estimation of infarct size in the presence of acute myocardial edema from ischemic injury. Imaging findings of acute MI include elevated native T1 and T2 values, and late gadolinium enhancement (LGE) Fatty (lipomatous) metaplasia can develop within chronic MI and cause over-estimation of viability (also by nuclear perfusion imaging). Fatty metaplasia can also mimic MI on late gadolinium enhancement imaging requiring other clues that fatty metaplasia is present (chemical shift artifact on steady state free precession imaging, hyperintensity on spin echo imaging, fat saturation techniques, computed tomography) Native T1 values are elevated in the presence of fibrosis and can be used to identify scar in MI, without the use of LGE imaging. However, this can be confusing in the presence of fatty metaplasia, which decreases native T1 values. Multi-sequence protocols are key to recognizing fatty metaplasia. Microvascular obstruction (MVO), intramyocardial hemorrhage (IMH) are associated with larger MI and confer worse prognosis. However, the long term- prognostic implications of fatty metaplasia are not clear and whether there is higher risk of fatty metaplasia in areas of MVO and IMH. Differentiation of MVO versus IMH is challenging without the use of T2* imaging.

CAEE-96 RIGHTS AND LEFTS OF VENTRICULAR NONCOMPACTION

Gregory Jew, MD (*Presenter*)
Abhishek Chaturvedi, MD (*Abstract Co-Author*)

TEACHING POINTS

1. What is ventricular non compaction 2. What is the clinical significance of non compaction (NC) 3. How to diagnose noncompaction using cardiac MRI. 4. Complications of LVNC and RVNC. 5. Differential Diagnosis for noncompation

TABLE OF CONTENTS/OUTLINE

1. What is ventricular non compaction? 2. Background and History. 3. Clinical impacts of noncompaction. 4. Diagnostic criteria for LVNC5. Background for RVNC. 6. Clinical impact of RVNC. 7. Diagnostic criteria for RVNC. 8. Complications of LVNC and RVNC. 9. Differential diagnoses and common pitfalls when encountering noncompaction

CAEE-97 CARDIAC CT MANIFESTATIONS OF IMMUNE CHECKPOINT INHIBITORS TREATMENT

Vincenzo Scialo (*Presenter*)
Vanessa Stubbs (*Abstract Co-Author*)
Joerg Herrmann (*Abstract Co-Author*)
Melanie Bois (*Abstract Co-Author*)
Esther Lutgens (*Abstract Co-Author*)
Tim Leiner, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Immune checkpoint inhibitors (ICI), while revolutionizing cancer therapy, can disrupt cardiac immunotolerance and trigger immune-related adverse events such as myocarditis, vasculitis and coronary artery inflammation. Understanding the cardiac immunological architecture is essential to insight the pathogenesis of ICI-induced toxicity. ICI-related cardiac complications show radiological correlates on cardiac CT imaging, for instance accelerated atherosclerosis and peri - coronary inflammation. Cardiac CT offers a non-invasive tool to recognize imaging features of immune-mediated cardiovascular toxicity. Imaging biomarkers such as increased Hounsfield unit values in peri-coronary adipose tissue (PCAT) and phenotypic analysis of coronary plaques may serve as non-invasive hallmarks for vascular immune dysregulation. Cardiac CT is an essential tool in multidisciplinary cardio-oncological care.

TABLE OF CONTENTS/OUTLINE

Introduction to cardio-immunology: definition and physiology of the immune system in cardiac physiology.Immuno-Anatomy of the Heart: Immune composition inside the cardiac layers. ICI and Immune Dysregulation: signs of reduced immunotolerance (from histology to imaging).Imaging findings of accelerated atherosclerosis on CCTA: Plaque phenotype, remodeling, and PCAT changes.

CAEE-98 "UNMASKING MINOCA: THE DIAGNOSTIC POWER OF CARDIAC MRI" HIGHLIGHTING THE PIVOTAL ROLE OF CMR IN UNCOVERING THE HIDDEN CAUSES OF MYOCARDIAL INFARCTION WITH NON-OBSTRUCTIVE CORONARY ARTERIES

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)

TEACHING POINTS

MINOCA is a working diagnosis, not a final one; it requires thorough investigation to determine the underlying cause. Cardiac MRI (CMR) is a crucial non-invasive tool in differentiating the etiology of MINOCA—whether ischemic, inflammatory, or cardiomyopathic. CMR provides tissue characterization, which guides patient management and prognosis beyond what angiography alone can offer. The absence of obstructive coronary disease does not rule out myocardial infarction, which can be confirmed by late gadolinium enhancement patterns. Early use of CMR (ideally within 7 days of presentation) increases diagnostic yield significantly.

TABLE OF CONTENTS/OUTLINE

1. Definition & Clinical Context 2. Diagnostic Approach Initial evaluation includes: ECG Troponin levels Coronary angiography Exclusion of mimics (e.g., myocarditis, pulmonary embolism, Takotsubo). 3. Role of Cardiac MRI Protocol: Cine SSFP, T2-weighted imaging, T1/T2 mapping, early/late gadolinium enhancement. Detects: Infarction: subendocardial or transmural LGE in a coronary territory. Myocarditis: mid-wall or subepicardial LGE, often in inferolateral wall. Takotsubo cardiomyopathy: apical ballooning with myocardial edema, typically no LGE. Other: microvascular dysfunction, embolic events, vasospasm, spontaneous coronary dissection. 4. Clinical Implications CMR provides a definitive diagnosis in ~75-90% of MINOCA cases. Identifying the etiology influences: Antiplatelet or anticoagulation decisions. Need for immunosuppressive therapy (e.g., myocarditis). Long-term prognosis and follow-up planning. 5. Case Examples

Abstract Archives of the RSNA, 2025

CHEE

Chest Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

CHEE-1 BLIND SPOTS - OCCULT CANCER ON CHEST PLAIN RADIOGRAPH

Junwoo Kim, MD (*Presenter*)
Azza A. Elgendy, MD, PhD (*Abstract Co-Author*)
Emrah Duman, MD (*Abstract Co-Author*)
Zehavit Kirshenboim (*Abstract Co-Author*)
Rodolfo Calderon (*Abstract Co-Author*)
Chinwike T. Agbo, MD (*Abstract Co-Author*)

TEACHING POINTS

Chest radiograph interpretation is a demanding task, requiring a delicate balance between speed and accuracy. Proper interpretation of chest radiographs requires reasonable clinical knowledge, anatomical knowledge, and a comprehensive systematic approach. Despite its high spatial resolution, surpassing that of computed tomography (CT), the presence of inherently dense regions such as at the scapula tip, hilum, and costochondral junction with superimposition of structures can pose challenges to lesion detection as part of the interpretation of chest radiographs. Although aberrations in mediastinal lines and stripes can help with lesion detection and differential diagnosis, acknowledging specific blind spots within the lung could significantly enhance chest radiograph interpretation and potentially reduce the likelihood of missing concerning nodules. We propose a comprehensive approach to chest radiograph interpretation with a focus on division of the lung into zones with identification of key areas of focus within the lung in addition to mediastinal lines and stripes identification that will serve as a guide for radiologists to address these blind spots and enhance accuracy in nodule and potentially malignancy detection. We will highlight the practical impact of highlighting these key lung blind spots by analyzing various chest radiographs with pertinent findings along with their CT/PET-CT correlates that were initially overlooked.

TABLE OF CONTENTS/OUTLINE

Purpose / A case series on blind spots / Conclusion

CHEE-2 CHEST RADIOGRAPHIC PATTERNS OF DIFFUSE LUNG DISEASE: A SYSTEMATIC APPROACH

Kristopher W. Cummings, MD (*Presenter*)
Sarah Anderson, MD (*Abstract Co-Author*)
Carlos Andres Rojas, MD (*Abstract Co-Author*)
Clinton E. Jokerst, MD (*Abstract Co-Author*)
Prasad M. Panse, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Identify and describe characteristic radiographic patterns associated with diffuse lung diseases. 2. Present a structured and systematic approach to refining the differential diagnosis of diffuse lung disease when interpreting a chest radiograph. 3. Illustrate key concepts through case-based radiographic examples with computed tomography (CT) correlates.

TABLE OF CONTENTS/OUTLINE

I. Introduction a. Overview of diffuse lung disease b. Importance of chest radiography in initial evaluation c. Limitations of chest radiography and role of CT correlation II. Systematic approach to diffuse lung disease on chest radiographs a. What is the predominant pattern? i. Linear ii. Nodular iii. Alveolar b. Is architectural change present to indicate chronicity? i. Distortion ii. Volume Increase / Decrease c. What is the distribution? i. Diffuse ii. Upper/middle/lower lung predominant iii. Central or peripheral d. Are there other associated findings? III. Case-based examples a. Several radiographic case-based examples with CT correlates for common diffuse lung diseases with emphasis on high-yield differential diagnoses IV. Summary a. Review framework for a diagnostic approach to diffuse lung disease on a chest radiograph b. Emphasize the importance of diffuse lung disease imaging patterns and pertinent clinical history V. References

CHEE-3 A FINE LINE BETWEEN SAFE AND SORRY: RADIOGRAPHIC EVALUATION OF THORACIC DEVICES

Rudinei Carlos Mezacasa Junior, MD (*Presenter*)

TEACHING POINTS

Chest radiography in intensive care and emergency settings plays a crucial role in monitoring critically ill patients, especially in the evaluation of invasive medical devices. Anatomical recognition and a solid understanding of proper positioning criteria are essential skills for radiologists and attending physicians, contributing significantly to the prevention of serious complications arising from device misplacement. The objective of this work is to provide an educational and systematic approach to the most commonly assessed devices on chest radiographs: endotracheal tubes, gastrointestinal tubes, and short and long term central venous catheters. Through illustrative examples, anatomical diagrams, and real radiographic images, we will discuss objective criteria for ideal positioning, relevant anatomical landmarks, and acceptable variations. Cases of malpositioning and associated complications will also be analyzed, highlighting the importance of early intervention. As a final product, a visual interpretation algorithm and a practical checklist will be proposed, focusing on patient safety and the reduction of diagnostic errors.

TABLE OF CONTENTS/OUTLINE

Case-based didactic review of the correct positioning of the main devices seen on chest radiographs, based on our service's digital archive and correlated with a comprehensive literature review.

CHEE-4 CHEST X-RAY PITFALLS IN THE EMERGENCY DEPARTMENT AND EMERGING AI

Oscar Jesus Perez Gonzalez, MD (*Presenter*)

TEACHING POINTS

Identify common interpretation errors on emergency chest radiographs: apical pneumothorax, subtle pulmonary consolidations, rib fractures, and catheter malposition.Understand key radiographic signs that are often missed and strategies to avoid these errors.Recognize the potential role of artificial intelligence as a complementary tool, especially in resource-limited environments.

TABLE OF CONTENTS/OUTLINE

Introduction: Importance of chest radiographs in emergency settings. Case 1: Missed apical pneumothorax. Case 2: Misinterpreted pulmonary consolidation. Case 3: Undetected rib fractures. Case 4: Malpositioned central venous catheter. Case 5: AI-assisted detection of rib fractures. Conclusion: Educational reinforcement of systematic reading and critical adoption of emerging AI.

CHEE-5 AN OLD DIAGNOSIS, NEW INSIGHTS: REVISITING PULMONARY EDEMA THROUGH MULTIMODALITY IMAGING

Helena Puigderrajols Vehils, MD (*Presenter*)
Alejandra Alvarado, MD (*Abstract Co-Author*)
Marcos A. Mestas Nunez SR, MD (*Abstract Co-Author*)
Alejandra Micolich Vergara, MD (*Abstract Co-Author*)
Jose Maria Maiques Llacer, MD (*Abstract Co-Author*)
Flavio Zuccarino (*Abstract Co-Author*)

TEACHING POINTS

• To present an updated classification of pulmonary edema, integrating current pathophysiological concepts, clinical presentation, and imaging evolution after therapy. • To illustrate characteristic imaging features using chest radiography and CT, with complementary roles of thoracic ultrasound and MRI. • To enhance diagnostic accuracy via pattern recognition, improving radiologic interpretation and clinical decision-making.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Definition and classification of pulmonary edema. - Relevance of underlying pathophysiology. 2. Imaging Modalities - CXR and CT: cornerstone tools. - Ultrasound: bedside detection and monitoring. - MRI: additional tool in specific clinical scenario. 3. Types and Patterns Hydrostatic Edema : - Bilateral: cardiogenic (LHF, LA obstruction), PVOD, fluid overload. - Unilateral: mitral regurgitation, decubitus, re-expansion, vascular obstruction. Permeability Edem a: - With DAD: ARDS - Without DAD: drug-induced, medication-related. Mixed Edema : - HAPE, neurogenic, post-surgical (LVRS, transplant, pneumonectomy).

CHEE-6 AND BREATHE NORMALLY: A BACK-TO-BASICS APPROACH TO MOSAIC ATTENUATION

Delfina Linares, MD (*Presenter*)
Maria C. Ferrario, MD (*Abstract Co-Author*)
Maria S. Fernandez Castillo Odena, MD (*Abstract Co-Author*)
Sofia D. Gambetta I, MD (*Abstract Co-Author*)
Joaquin Martinez Pereira, MD (*Abstract Co-Author*)
Federico G. Diaz Telli, MD (*Abstract Co-Author*)
Antonella Pierina Ruiz, MD (*Abstract Co-Author*)
JOSEFINA MEDINA (*Abstract Co-Author*)
Juan P. Perotti, MD (*Abstract Co-Author*)

TEACHING POINTS

To differentiate and classify the causes of mosaic attenuation. - To review the pathophysiologic mechanisms underlying mosaic attenuation on chest CT. - To identify ancillary findings associated with mosaic attenuation that help guide the differential diagnosis. - To emphasize the importance of expiratory CT in the assessment of mosaic attenuation. - To integrate clinical history and contextual imaging findings to narrow the diagnostic possibilities.

TABLE OF CONTENTS/OUTLINE

Introduction Definition of mosaic attenuation Clinical relevance and diagnostic challenges Pathophysiologic Mechanisms Imaging Approach to Mosaic Attenuation Role of inspiratory and expiratory CT Distribution patterns Ancillary imaging findings Diagnostic Classification Vascular-type pattern Airway-type pattern Parenchymal-type pattern Mixed-pattern considerations Common Pitfalls and Mimickers Artifacts Misinterpretation of normal variants Overlapping features Clinical Integration and Diagnostic Strategy Role of clinical history and pulmonary function tests Diagnostic algorithm Conclusion

CHEE-7 SIFTING THROUGH THE LAYERS: USING AVERAGE INTENSITY PROJECTION ON CT TO BETTER UNDERSTAND CXR ANATOMY/PATHOLOGY

Om Evani, MD (*Presenter*)
Emile B. Gordon, MD (*Abstract Co-Author*)
Katherine A. Cheng, MD (*Abstract Co-Author*)
Holly L. Nichols, MD (*Abstract Co-Author*)
H. Page McAdams, MD (*Abstract Co-Author*)
Michael R. Harowicz, MD (*Abstract Co-Author*)

TEACHING POINTS

Chest radiograph (CXR) can be a challenging modality to interpret given the superimposition of multiple structures in the body wall, mediastinum, and lung parenchyma. Computed tomography (CT) correlates have long been helpful for teaching CXR anatomy and pathology; however, the Average Intensity Projection (AIP) CT technique is a lesser known and under-utilized tool that can help educate learners at the workstation and serve as a problem-solving tool when comparing CXR to a prior CT. AIP technique shows the average attenuation value of CT voxels over a set slice thickness. This can create a scrollable CXR using coronal and sagittal CT images, which mimics both frontal and lateral CXRs, respectively. Reviewing these simulated CXRs at different coronal and sagittal CT depths can better enable learners to comprehend CXR normal anatomy and distinguish from abnormalities.

TABLE OF CONTENTS/OUTLINE

1) Review normal CXR anatomy using AIP: Normal lines/stripes, Anterior, middle, and posterior mediastinal structures, Lateral CXR anatomy. 2) Understanding normal/abnormal courses of lines/tubes: Normal left internal jugular vein line crossing midline at/just below the clavicle in the left brachiocephalic vein, Arterially placed lines, Anatomic variants (duplicated SVC). 3) Highlight CXR pathology and potential fake-outs: Partial anomalous pulmonary venous return, Subcarinal nodal metastasis mimicking ascending aorta, Dilated left superior intercostal vein mimicking mediastinal mass, Left upper lobe collapse.

CHEE-8 NON-ACUTE LUNG TRANSPLANT COMPLICATIONS: PEARLS AND PITFALLS

Noelani Gonzales, DO (*Presenter*)
Catherine C. Bullock, MD (*Abstract Co-Author*)
Isabel Oliva Cortopassi, MD (*Abstract Co-Author*)
Prabhakar Rajiah, MD, FRCR (*Abstract Co-Author*)
Satinder P. Singh, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Non-acute complications of lung transplant fall into five main categories: 1) rejection, 2) infection, 3) malignancy, 4) primary disease recurrence, and 5) late post-surgical anastomotic complications. 2. Protocol selection is key in identifying diagnoses. 3. Diagnosing post lung transplant complications on chest imaging can help clinicians prevent allograft failure.

TABLE OF CONTENTS/OUTLINE

Timing of lung transplant complications Infection - Aspergillus Most common infection to cause bronchial narrowing/stenosis - Infected pneumatocele Allograft dysfunction - Bronchiolitis obliterans syndrome (BOS) Most common form of chronic lung allograft dysfunction (CLAD) Pearl: Check expiratory views for air trapping Pitfall: BOS and RAS can occur at the same time - Restrictive allograft syndrome (RAS) Less common form of CLAD - Organizing pneumonia Malignancy - Bronchogenic carcinoma Pearl: Hounsfield units can help differentiate a mass from mucus - Post transplant lymphoproliferative disorders (PTLD) Pitfall: Rare presentations of chronic vascular rejection include a mass-like pattern that may appear indistinguishable to PTLD on CT Primary disease recurrence - Sarcoidosis 47% recurrence post-transplant Pearl: Could manifest as a single nodule as soon as 2 months post-transplant - Alveolar proteinosis Pitfall: Can be indistinguishable to pulmonary edema on CT Anastomotic complications - Venous aneurysms Pearl: A radiographic "double density" should prompt a CT to rule out anastomotic complications such as venous aneurysm - Vascular anastomotic narrowing - Bronchial stenosis May present as "vanishing bronchus intermedius syndrome"

CHEE-9 THE NODULAR PATTERN IN CHEST CT: A STEP-BY-STEP DIFFERENTIAL DIAGNOSIS

Inigo Deba Ayarza, MD (*Presenter*)
Manex Lasa, MD (*Abstract Co-Author*)
Mikel Merino Aboitiz, MD (*Abstract Co-Author*)
Paula Blanco Hernandez, MD (*Abstract Co-Author*)
Andres Riano Garcia, MD (*Abstract Co-Author*)
Udane Oiartzabal, MD (*Abstract Co-Author*)
Javier Castillo de Juan (*Abstract Co-Author*)
Silvia Cisneros Carpio, MD (*Abstract Co-Author*)

TEACHING POINTS

The secondary pulmonary lobule is the key structural unit for interpreting micronodular patterns on chest CT. Pulmonary micronodules (<6 mm) are classified by distribution: centrilobular, perilymphatic, or random. Centrilobular nodules often reflect infectious, inflammatory, or vascular processes and may display a "tree-in-bud" pattern. Perilymphatic nodules follow lymphatic routes and are characteristic of sarcoidosis, lymphangitic carcinomatosis, and pneumoconioses. Randomly distributed nodules suggest hematogenous spread, seen in miliary infections and metastatic disease.Accurate classification of distribution patterns, combined with clinical and ancillary imaging findings, is essential for differential diagnosis and optimized patient management.

TABLE OF CONTENTS/OUTLINE

1. Introduction to the Secondary Pulmonary Lobule: 1a. Anatomy and imaging relevance 1b. Dimensions and visibility on HRCT 2. Micronodular Pattern: Definition and Importance 2a. Subtype of nodular pattern 2b. Criteria: nodules <3 mm in diameter 3. Classification by Distribution 3a. Centrilobular: common etiologies and imaging clues 3b. Perilymphatic: typical diseases and path of spread 3c. Random: implications of hematogenous dissemination 4. Diagnostic Algorithm and Case-Based Approach 4a. Stepwise identification of distribution patterns 4b. Illustrated cases highlighting typical appearances 5. Clinical Integration and Conclusion 5a. Correlation with clinical data and ancillary CT signs 5b. Role of the radiologist in guiding diagnosis and management

CHEE-10 STRANGER THINGS: UNUSUAL LUNG INFECTIONS IN PULMONARY IMAGING

Catalina Jaramillo, MD (*Presenter*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)
Emma C. Ferguson, MD (*Abstract Co-Author*)
Erika G. Odisio, MD (*Abstract Co-Author*)
Liliana Arias (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)

TEACHING POINTS

• Legionella pneumophila infection often begins as a unilateral, unilobar alveolar infiltrate that may progress to consolidation or spread to new areas. Lower lobe involvement and pleural effusion are common findings on imaging. • HHV-8 pulmonary infection, often seen in immunocompromised patients like those with HIV, is primarily associated with Kaposi's sarcoma. Imaging shows asymptomatic nodular opacities, peribronchovascular thickening, pleural effusions, and possible endobronchial lesions. • Mucormycosis, common in immunocompromised individuals, especially diabetics, is characterized by the reverse halo sign, where ground-glass opacity is surrounded by consolidation. • Pulmonary Strongyloides stercoralis infection, seen in hyperinfection or disseminated disease, often shows ground-glass opacities with interlobular septal thickening on CT, suggestive of alveolar hemorrhage. • Human pulmonary dirofilariasis is a rare zoonotic infection from Dirofilaria immitis (dog heartworm), presenting as a solitary, well-circumscribed, noncalcified subpleural nodule—often in the lower lobes—due to infarction from embolized dead worms.• Pulmonary paragonimiasis, caused by lung flukes, is acquired by eating undercooked freshwater crustaceans and presents with peripheral nodules, cystic lesions, pleural effusion, consolidation, lymphadenopathy, or pericardial involvement.

TABLE OF CONTENTS/OUTLINE

• Bacteriao Legionella pneumophila o Francisella tularensis o Nocardia species• Viruso Human Herpesvirus • Fungio Paracoccidioides specieso Mucormycosis • Parasiteso Strongyloides stercoralis o Echinococcus specieso Pulmonary Dirofilariasiso Loa loa o Paragonimiasis

CHEE-11 QUANTITATIVE IMAGING BIOMARKERS IN LUNG CANCER: CURRENT TRENDS AND FUTURE DIRECTIONS

Amanda Acevedo (*Presenter*)
Ronak Kundalia, MSc, BS (*Abstract Co-Author*)
Jean Bontemps (*Abstract Co-Author*)
C. David Pfaehler (*Abstract Co-Author*)
Joice C. Prodigios, MD (*Abstract Co-Author*)
Jessica Gemmell (*Abstract Co-Author*)
Henry Okonkwo (*Abstract Co-Author*)
Brianna A. Karim, BS (*Abstract Co-Author*)
Maysa R. de Oliveira, MD (*Abstract Co-Author*)
Jennifer Wen (*Abstract Co-Author*)
Pavan Iyengar (*Abstract Co-Author*)
Joao Fonseca, MD (*Abstract Co-Author*)
Bruno Hochhegger, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Describe the standardized workflow for creating quantitative imaging biomarkers (QIBs). Interpret key CT, PET, and MRI metrics (e.g. volumetry, SUV-based indices, etc.) and explain how each informs lung-cancer detection, staging, and therapeutic response assessment. Identify how AI-driven radiomics and radiogenomics uncover imaging phenotypes linked to molecular pathways and evaluate their added prognostic value beyond conventional staging. Recognize the advantages, limitations, and future potential of emerging technologies—dual-energy & photon-counting CT, PET/MRI, federated learning, and multi-omics integration—in advancing precision oncology. Apply QIB knowledge to clinical decision-making and research design, appreciating current implementation barriers and strategies to overcome them.

TABLE OF CONTENTS/OUTLINE

Introduction: Role of imaging in lung cancer screening and diagnosis Core Concepts: QIB definitions, radiomics workflow, and standardization efforts Established QIBs: RECIST 1.1, tumor volume, SUVmax, ADC, MTV, and TLG Emerging Technologies: AI-assisted segmentation, radiogenomics, DECT, PET/MRI, photon-counting CT Clinical Applications: QIBs in early detection, therapeutic response, and risk stratification Challenges: Reproducibility, feature variability, data-sharing barriers, and ethical issues Future Directions: Multi-omics integration, federated learning, and precision oncology Conclusion: QIBs hold promise to personalize lung cancer care and improve outcomes

CHEE-12 TNM-9: TRACKING, NAVIGATING, AND MAPPING THE NEW LUNG CANCER STAGING SEA

Pedro Mecate Prada, MD (*Presenter*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Caio Nunes, MD (*Abstract Co-Author*)
Hamilton Shoji, MD (*Abstract Co-Author*)
Pedro Paulo T. Torres, MD (*Abstract Co-Author*)
Gustavo B. Teles, MD (*Abstract Co-Author*)
Ana Carolina Macedo, MD (*Abstract Co-Author*)
Patricia Yokoo, MD, PhD (*Abstract Co-Author*)
Danilo P. Bianco, MD (*Abstract Co-Author*)
Murilo M. Silva, MD (*Abstract Co-Author*)
Marcelo B. Funari, MD, PhD (*Abstract Co-Author*)
Rodrigo C. Chate, MD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the clinical relevance of early detection and accurate diagnosis of lung cancer using the updated TNM-9 classification. Emphasize the role of imaging modalities, including 18-FDG-PET/CT, in the precise staging and therapeutic planning of lung cancer. Review the changes in lymph node involvement criteria and the introduction of new subgroups in metastasis classification. Present illustrative cases to demonstrate diagnostic challenges, typical imaging features, and treatment strategies.

TABLE OF CONTENTS/OUTLINE

Introduction - Overview of epidemiology, anatomy, and clinical impact of lung cancer. Imaging Modalities 18-FDG-PET/CT: Essential for accurate staging and evaluation of lymph node involvement. CT/MRI: Define lesion extent, guide biopsy, and surgical planning. TNM-9 Classification Updates Tumor (T): No significant changes from TNM-8. Lymph Nodes (N): Introduction of N2a and N2b categories for better prognostic differentiation. Metastasis (M): New subgroups M1c1 and M1c2 to distinguish between single and multiple organ involvement. Case-Based Review Show various cases of different classifications, including examples of the changes in TNM-9. Treatment and Follow-Up: Imaging role in staging, planning, and monitoring. Diagnostic Flowchart: Structured algorithm to support accurate reporting.

CHEE-13 ULTRASOUND ASSESSMENT OF DIAPHRAGMATIC FUNCTION: REDEFINING AND EXPANDING THE RADIOLOGIST'S ROLE

Lluria Cornellas Escayola, MD (*Presenter*)
Laura B. Cabanzo Campos, MD, PhD (*Abstract Co-Author*)
Luis A. del Carpio Bellido Vargas, MD (*Abstract Co-Author*)
Oscar Persiva, MD (*Abstract Co-Author*)
Ana L. Sanchez Martinez (*Abstract Co-Author*)
Ivan Vollmer, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to review the anatomical and physiological fundamentals of diaphragmatic function with an emphasis on its relevance in clinical practice, to present a standardized ultrasound protocol for diaphragmatic function assessment, including key sonographic findings and their most relevant clinical applications, and to explore emerging techniques and future perspectives of ultrasound in the evaluation of the diaphragm, highlighting its expanding utility in diverse clinical settings.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Diaphragmatic Anatomy and Function 2. Diaphragmatic Dysfunction: Clinical Aspects and Diagnosis 3. Ultrasound Assessment of Diaphragmatic Function a. Technique: Assessment of Diaphragmatic Excursion Assessment of Diaphragmatic Thickness and Thickening Fraction b. Limitations and Recommendations c. Clinical Applications d. Clinical Cases 4. Ultrasound-Guided Diaphragmatic Electromyography 5. What Lies Ahead: Emerging Techniques in Diaphragmatic Ultrasound

CHEE-14 TNM 9 IN ACTION: A RADIOLOGIST'S TOOLKIT FOR LUNG CANCER STAGING AND REPORTING TO GUIDE TREATMENT DECISIONS

Francisco Calle Bernal, MD (*Presenter*)
Paula N. Patino, MD (*Abstract Co-Author*)

TEACHING POINTS

Provide radiologists with a comprehensive framework for staging lung cancer using CT imaging, aligned with the TNM-9 classification. Emphasize the impact of imaging findings on surgical decision-making, with examples drawn from current thoracic surgical practices. Apply a systematic approach to evaluating the tumor, lymph nodes, and metastasis for accurate staging. Highlight the value of structured reporting to ensure clarity and completeness in communication. Offer practical guidance for integrating imaging findings into multidisciplinary rounds (MDR) to support collaborative treatment planning.

TABLE OF CONTENTS/OUTLINE

Overview of the Lung Cancer TNM 9 System T: Tumor Component Tumor Size Local Invasion Separate Tumor Nodules Measurement Pitfalls (Multiplanar Reconstructions & Atelectasis) N: Regional Lymph Nodes Nodal Stations and Staging Imaging Modalities and Pitfalls M: Distant Metastasis Intrathoracic and Extrathoracic Sites Metastasis Subcategories Special Tumor Patterns Second Primary vs. Multifocal Disease Pneumonic-Type Adenocarcinoma and GGOs Lymphangitic Carcinomatosis Staging Groups and Tables Clinical vs. Pathological Staging Summary Table by TNM Surgical Treatment Tumor-Related Factors Patient-Related Factors Surgical Approach Considerations Operating on T4 Tumors Systematic Approach to Lung Cancer Reporting Multidisciplinary Rounds (MDR) Participation

CHEE-15 RADIOLOGY ON THE ONCOLOGIC FRONTLINE: ASSESSING TUMOR RESPONSE IN THORACIC CANCERS

Juan Bosco Nieto Jimenez, MD (*Presenter*)
Roger Cortada, MD (*Abstract Co-Author*)
Laura B. Cabanzo Campos, MD, PhD (*Abstract Co-Author*)
Luis A. del Carpio Bellido Vargas, MD (*Abstract Co-Author*)
Ana L. Sanchez Martinez (*Abstract Co-Author*)
Ivan Vollmer, MD (*Abstract Co-Author*)

TEACHING POINTS

To understand the current criteria for Tumor Response assessment in thoracic malignancies To review the use of RECIST 1.1 in thoracic tumors To introduce new strategies such as iRECIST, PERCIST, response assessment in tumors treated with tyrosine kinase inhibitors(TKI), and modified RECIST for malignant pleural mesothelioma (MPM) To discuss challenges, pitfalls and new arising techniques (AI, radiomics?)

TABLE OF CONTENTS/OUTLINE

1. Introduction: Importance of Imaging in Thoracic Oncology 2. Overview of Thoracic Cancers 2.1. Lung Cancer (NSCLC and SCLC) 2.2. Malignant Pleural Mesothelioma 2.3 Pulmonary metastases 3.Imaging Principles in Thoracic Oncology 3.1. Imaging Techniques: 3.1.2. Computed Tomography (CT) 3.1.3. Positron Emission Tomography (PET-CT) 3.1.4. Magnetic Resonance Imaging (MRI) 3.2. Role of Each Modality in Diagnosis, Staging, and Follow-Up 3.3. Advantages and Limitations 4. Radiologic Assessment of Tumor Response 4.1. RECIST 1.1 Criteria: Principles and Application 4.2. iRECIST Criteria: Immune Response Patterns 4.3. Other Criteria: PERCIST, modified RECIST for MPM, TKI treated turnors 4.4. Morphological vs. Metabolic Response 4.5. Complex Imaging Findings: Pseudoprogression, Necrosis, Fibrosis, Cavitation 5. Imaging in Clinical Practice 5.1. Imaging Patterns in Immunotherapy 5.2. Radiological Follow-Up: Protocols and Timing 6. Emerging Trends and New Technologies 6.1. Radiomics and Quantitative Imaging 6.2. Artificial Intelligence in Thoracic Imaging 6.3. Image Fusion and Hybrid Techniques 7. Discussion 8. Conclusion

CHEE-16 BEYOND THE NODULES: MANAGING INCIDENTAL FINDINGS IN LOW-DOSE CT FOR LUNG CANCER SCREENING

Chiara Pozzessere, MD (*Presenter*)
Cedric Bongard (*Abstract Co-Author*)
Cynthia Schneider (*Abstract Co-Author*)
Kevin Selby (*Abstract Co-Author*)
David Rotzinger, MD,PhD (*Abstract Co-Author*)
Christophe Von Garnier (*Abstract Co-Author*)

TEACHING POINTS

• To describe incidental findings detected on low-dose CT (LDCT) for LCS and to define which require reporting and recommendations for further management according to the ACR reference guidelines and the ERS/ESTS/ESTRO/ESR/ESTI/EFOMP statement. • To offer practical tips and strategies for identifying which findings to report and for communicating their management effectively, thereby supporting referring physicians, reducing patient anxiety, and optimizing resource use.

TABLE OF CONTENTS/OUTLINE

The burden of incidental findings in lung cancer screening (LCS) and their impact on participants, referral physicians, radiologists' workload and healthcare costs will be presented. Ethical and medico-legal implications will also be addressed.A systematic overview of common and uncommon pulmonary (e.g. emphysema, interstitial lung abnormalities, diffuse cystic lung disease,..) and extra-pulmonary (e.g. coronary artery calcifications, aortic aneurysm, mediastinal mass, breast and other extra-thoracic lesions, bone demineralization..) incidental findings will be illustrated with guidance based on ACR and ERS/ESTS/ESTRO/ESR/ESTI/EFOMP recommendations. Strategies for effective, balanced reporting and well-framed recommendations will be provided to support decision-making, ensure appropriate referrals and reduce unnecessary investigations.

CHEE-17 PEELING BACK THE LAYERS: A LAYERED APPROACH TO RESOLVING PLEURAL AND EXTRAPLEURAL MIMICRY ON IMAGING

Caio Nunes, MD (*Presenter*)
Margrit E. Muller, MD (*Abstract Co-Author*)
Lara Quiche, MD (*Abstract Co-Author*)
Lucas Da Silva Costa, MD (*Abstract Co-Author*)
Guilherme Swerts Pereira (*Abstract Co-Author*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Marcelo B. Funari, MD, PhD (*Abstract Co-Author*)
Patricia Yokoo, MD, PhD (*Abstract Co-Author*)
Rodrigo C. Chate, MD (*Abstract Co-Author*)
Pedro Paulo T. Torres, MD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)

TEACHING POINTS

- Highlight imaging features across modalities: explore how radiography, ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI) contribute to differentiate pleural from extrapleural lesions. - Demonstrate complexities in lesion localization: illustrate how lesion morphology, the presence of pleural effusion, rib involvement, and fat plane displacement can complicate the accurate localization of pleural and extrapleural lesions, using case examples. - Address diagnostic challenges in distinguishing benign from malignant solid pleural lesions, emphasizing critical factors like size, growth patterns, enhancement characteristics, and advanced imaging features (PET-CT, DWI-MRI). - Elucidate tumor-like pleural conditions: recognize conditions such as pleural plaques, organizing hematomas, and benign fibrous tumors to avoid the overdiagnosis of malignancy. - Evaluate diagnostic pitfalls in assessing extrapleural masses: focus on extrapleural lesions involving the pleura, originating from the chest wall, diaphragm, or mediastinum. - Discuss strategies to improve diagnostic accuracy in complex cases.

TABLE OF CONTENTS/OUTLINE

- Normal pleural anatomy and imaging - Imaging Modalities: radiography, ultrasound, CT, MRI - Pleural vs. extrapleural lesions: morphological features, associated findings, case-based challenges - Solid Pleural Lesions: benign vs. malignant - Tumor-like pleural conditions mimicking malignancy: pleural plaques, organizing hematoma, benign fibrous tumors - Extrapleural lesions impinging on the pleura: chest wall, diaphragmatic, and mediastinal masses - identification of extrapleural origin - Conclusion and take-home messages

CHEE-18 ETHICAL, REGULATORY, AND PRACTICAL CHALLENGES IN AI-DRIVEN CHEST IMAGING

Juliana Barreto Caldas De Lima (*Presenter*)
Maysa R. de Oliveira, MD (*Abstract Co-Author*)
Joao Fonseca, MD (*Abstract Co-Author*)
Jessica Gemmell (*Abstract Co-Author*)
Brianna A. Karim, BS (*Abstract Co-Author*)
Henry Okonkwo (*Abstract Co-Author*)
Jennifer Wen (*Abstract Co-Author*)
Pavan Iyengar (*Abstract Co-Author*)
Amanda Acevedo (*Abstract Co-Author*)
Kayla Davis (*Abstract Co-Author*)
Kenneth Davis (*Abstract Co-Author*)
Joice C. Prodigios, MD (*Abstract Co-Author*)
Bruno Hochhegger, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Highlight AI's benefits in diagnostic accuracy, workflow efficiency, and personalized patient care in chest imaging. Understand how challenges such as bias, transparency limitations, and validation difficulties impact AI-driven chest imaging. Discuss strategies to enhance fairness, explainability, and trust in AI models. Review regulatory and validation pathways for safe, accountable AI. Recognize the radiologist's role in AI adoption, including continuous education and collaboration.

TABLE OF CONTENTS/OUTLINE

1. Transformative Benefits of Chest AI Summary of AI's advantages in improving diagnostic accuracy, workflow efficiency, and personalized patient care. 2. Why Chest Imaging Needs Ethical AI Overview of ethical, regulatory, and practical challenges arising from AI implementation. 3. Identifying and Correcting Chest AI Bias Key sources of bias and practical steps to improve model fairness. 4. Navigating AI Regulatory Pathways Comparative view of FDA, EU AI Act, and NMPA frameworks and approval considerations. 5. Overcoming Integration Barriers Best practices for workflow integration, achieving generalization, and fostering radiologist engagement and trust. 6. Building the Future: Safe, Transparent, and Inclusive AI Guidelines for sustainable, ethical AI deployment.

CHEE-19 OVERVIEW OF ESOPHAGEAL SURGERY FOR RADIOLOGISTS

Daniel B. Green, MD (*Presenter*)
Sharon Steinberger, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit is designed to provide radiologists with an overview of esophageal surgeries. With a better understanding of what the surgeon needs to know, radiologists will be more likely to know what to look for and provide helpful information in their reports. Teaching topics will include:1) Imaging features of esophageal perforation and how to distinguish them from other non-surgical causes of pneumomediastinum. 2) Suggested imaging protocol for CT esophagography with examples of pre-contrast images and prone images as helpful additional series. 3) Brief overview of different surgical techniques for esophagectomy and some pre-operative anatomic considerations. 4) Expected post-surgical findings and post-surgical complications including esophageal stent complications. 5) Long-term surveillance to include cancer recurrence and later post-surgical complications.

TABLE OF CONTENTS/OUTLINE

Scenarios will include:1) Suspected esophageal perforation2) Known esophageal cancer3) Acute complication from esophagectomy4) Esophageal stent5) Long-term surveillance following esophagectomy6) Achalasia7) Esophageal diverticulum

CHEE-20 DON´T LOSE YOUR WAY. "RIBS CAN ALSO BE BAD"

Alexandra Roxana Flores Calles, MD (*Presenter*)

TEACHING POINTS

DONT LOSE YOUR WAY. RIBS CAN ALSO BE BADComputed tomography (CT) plays a crucial role in the diagnosis and evaluation of costal masses, offering detailed imaging that aids in the identification and characterization of lesions. CT scans provide high-resolution cross-sectional images, which are particularly useful in assessing the anatomical location, size, and extent of rib masses. This imaging modality allows clinicians to distinguish between benign and malignant lesions, guide biopsies, and plan surgical interventions. One of the primary advantages of CT in diagnosing rib masses is its ability to detect subtle bony changes and soft tissue involvement. Malignant tumors often show evidence of aggressive bone destruction, cortical disruption, and irregular mass borders, which are typically suggestive of malignancy. Additionally, CT can reveal the presence of adjacent soft tissue infiltration, which may be indicative of malignancy extending beyond the ribs. These features are critical in staging tumors, especially in cases of primary bone malignancies like osteosarcoma or metastatic disease. Certain characteristics are highly suggestive of malignancy in costal masses on CT. These include large, ill-defined masses with irregular margins, evidence of rib erosion or destruction, and heterogeneous enhancement after contrast administration.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Presentation of four cases of costal masses with radiological findings on computed tomography highly suggestive of malignancy in patients admitted to the Instituto Salvadoreño del Seguro Social Hospital, accompanied by pathological correlation.3. Literature Review 4. Conclusions

CHEE-21 WATCH OUT FOR THE CHEST! SYSTEMIC INFECTIOUS DISEASES WITH TYPICAL THORACIC MANIFESTATIONS

Pyetra Oliveira, MD (*Presenter*)
Caroline B. Nunes, MD (*Abstract Co-Author*)
Fabiana Campos, MD (*Abstract Co-Author*)
JOAO COSTA (*Abstract Co-Author*)
Maisa B. Moroz, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)
Guilherme Hipolito Bachion (*Abstract Co-Author*)
Camila S. Franco, BMedSc (*Abstract Co-Author*)
Tassia R. Yamanari, MD (*Abstract Co-Author*)
Hye J. Lee, MD (*Abstract Co-Author*)

TEACHING POINTS

Systemic infections are often a severe condition with rapid progression and nonspecific manifestations, factors that might delay the diagnosis and hinder an appropriate management. A wide spectrum of systemic infections present thoracic manifestations, which may narrow the differential diagnosis and guide the clinical investigation. Teaching Points: • Review the most common pathways of thoracic involvement in systemic infections • Illustrate the thoracic manifestations of the systemic infections, focusing on the main pathways of the disease and the different ethiologies • Propose a systematic approach based on the main chest imaging findings and clinical features

TABLE OF CONTENTS/OUTLINE

• Introduction • Physiopathology of thoracic involvement in systemic infections • Case-based illustration of the most common and uncommon systemic infections with thoracic manifestations and associated findings, including viral (e.g. dengue fever), bacterial (e.g. mycobacterial, leptospirosis, septic emboli), fungal (e.g., histoplasmosis, paracoccidioidomycosis, cryptococcosis) and parasitic agents (e.g., malaria, toxoplasmosis, Chagas disease). • Differential diagnosis with multimodality imaging: a systematic approach • Take home messages

CHEE-22 INTERPRETING THE SPINE ON CHEST CT: A SYSTEMATIC APPROACH FOR RADIOLOGISTS

Francisco Calle Bernal, MD (*Presenter*)
Maria Lucia Brun, MD (*Abstract Co-Author*)
Paula N. Patino, MD (*Abstract Co-Author*)

TEACHING POINTS

Provide a comprehensive and systematic approach to identifying and evaluating spinal pathologies on routine chest CT scans. Describe common incidental findings, as well as relevant congenital and structural disorders. Review traumatic injuries and degenerative changes, with emphasis on findings that help differentiate acute vs. chronic pathology. Explore primary and secondary neoplastic conditions, focusing on distinguishing imaging characteristics. Address infectious processes including spondylodiscitis, paraspinal abscesses, and Pott's disease. Propose an algorithm for the systematic evaluation of spinal abnormalities on chest CT.

TABLE OF CONTENTS/OUTLINE

Step 1: Alignment Normal alignment Scoliosis Scheuermann's Disease Age-related hyperkyphosis Step 2: Vertebral Bodies Normal anatomy Congenital anomalies Traumatic fractures Insufficiency fractures and osteoporosis Sickle cell disease Benign density findings (Bone island, Osteopoikilosis) Malignant findings (Metastasis, Myeloma) Diffuse abnormalities (Osteopetrosis, Renal osteodystrophy) Step 3: Intervertebral Discs Normal disc features Spondylodiscitis Degenerative changes Step 4:

Spinal Canal Benign findings: Dural and ligamentum flavum calcifications Hemorrhage Congenital anomalies Tumors Pneumorrhachis and epidural lipomatosis Step 5: Neural Foramina & Paraspinal Soft Tissues Tumors: Schwannoma, Plasmacytoma, Lymphoma Cysts: Neurenteric, Extradural arachnoid Hematopoiesis Sarcomas: Chondrosarcoma, Osteosarcoma

CHEE-23 WHEN IMMUNITY FAILS: IMAGING INFECTIOUS AND NON-INFECTIOUS CHEST DISEASE IN PRIMARY IMMUNODEFICIENCY DISORDERS

Luiza A. Oliveira Gatto, MD (*Presenter*)
Caroline Novis, MD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)
Camila S. Franco, BMedSc (*Abstract Co-Author*)
Israel Missrie, MD (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- To review the spectrum of thoracic manifestations in Primary Immunodeficiency Disorders (PIDs), highlighting the key infectious pulmonary patterns and how these contribute to long-term structural changes in the lungs. - To highlight the growing recognition of non-infectious thoracic complications in PIDs, including interstitial lung disease (ILD), lymphoproliferative disorders, and thoracic neoplasms.- To emphasize that imaging findings in PIDs —such as ground-glass opacities, pulmonary nodules, bronchiectasis, and lymphadenopathy— are often non-specific and require careful clinical and laboratory correlation. - To illustrate that, while many PIDs share overlapping imaging features, certain disorders exhibit relatively specific patterns that aid in differential diagnosis

TABLE OF CONTENTS/OUTLINE

1. Introduction An overview of Primary Immunodeficiency Disorders (PIDs), including their epidemiology, pathophysiology, and clinical aspects. 2. Thoracic Imaging Features of PIDs a) Most common infectious and non-infectious findings b) Specific findings in CVID, Job Syndrome, Ataxia Telangiectasia Syndrome, Hyper-IgM Syndrome, Chronic Granulomatous Disease (CGD), and other primary immunodeficiency syndromes, correlating with pathology. 3. Diagnostic Challenges and Mimics a) Findings that help differentiate between infectious, neoplastic, and lymphoproliferative causes, and when nuclear medicine can assist. b) Demonstrating the multiple imaging patterns of interstitial lung disease in the context of PIDs. 4. Conclusion and Take-Home Messages

CHEE-24 WHOSE LINE IS IT ANYWAY: A RADIOLOGIST'S GUIDE TO WHAT GOES WHERE AND WHY

Shaun H. Johnson, MD (*Presenter*)
Nathan M. Amann, MD (*Abstract Co-Author*)
Zac Ohs (*Abstract Co-Author*)
Navid Faraji, MD (*Abstract Co-Author*)

TEACHING POINTS

Review both common and uncommon lines that new radiologists will encounter on chest X-Ray Recognize ideal vs. malpositioned placement of medical devices Understand which medical specialties utilize these various lines and devices and for what purpose Review possible complications of these lines

TABLE OF CONTENTS/OUTLINE

A case-based project to help radiology residents identify lines and devices on chest X-Ray, understand their clinical purpose, and assess proper placement.Each slide answers three questions: Whose line is it? Which medical services utilize this line What does it do? What type of medical intervention is it used for Is it in the right spot? Review the correct path and location of the line, common malposition, and complications Such devices that will be included: Mediport, Subclavian CVC, Venous Pacer, IJ CVC, PICC line, Dual-chamber pacemaker, ECMO, ICD, Biventricular Pacemaker.

CHEE-25 NOT ALL ABOUT THE HEART: UNDERSTANDING NON CARDIOGENIC PULMONARY EDEMA

Adriana Campmany, MD (*Presenter*)
Carme Lozano, MD (*Abstract Co-Author*)
Marta Cufi Quintana (*Abstract Co-Author*)
Marta Andreu, MD (*Abstract Co-Author*)
Eva Castaner, MD (*Abstract Co-Author*)
Xavier Gallardo, MD (*Abstract Co-Author*)
Albert Calvo Porcel, MD (*Abstract Co-Author*)
Fiona Pallares Quinn, MD (*Abstract Co-Author*)

TEACHING POINTS

- Describe the pathophysiology of non-cardiogenic pulmonary edema.- Describe the radiological characteristics of non-cardiogenic pulmonary edema and expose the main differences with cardiogenic pulmonary edema.- Identify the most representative etiologies of non-cardiogenic pulmonary edema and their radiological findings.

TABLE OF CONTENTS/OUTLINE

Pulmonary edema is one of the most frequent entities seen on chest radiological images. It has a variety of imaging manifestations that can be identified by chest X-ray and/or CT. Non-cardiogenic pulmonary edema is a pathophysiological entity characterized by an alteration of the pulmonary capillaries that causes an increase in permeability to liquids and proteins. Although non-cardiogenic pulmonary edema is less common than cardiogenic edema, there is a wide range of etiologies including ARDS, neurogenic pulmonary edema, re-expansion pulmonary edema, negative pressure pulmonary edema, near drowning pulmonary edema, systemic capillary leak syndrome, pulmonary veno-occlusive disease, transfusion-related acute lung injury, pulmonary embolism, high-altitude pulmonary edema, opioid or drug overdose, etc. We propose a review of the most frequent etiologies and the most characteristic radiological image through clinical cases. Through careful analysis of the radiological findings and their integration with the context and clinical history, the radiologist can diagnose non-cardiogenic pulmonary edema and guide its etiology, facilitating the early establishment of the appropriate treatment.

CHEE-26 AORTIC THROMBUS: IMAGING PATTERNS AND DIAGNOSTIC CONSIDERATIONS

Amanda Lee, MD (*Presenter*)
Robert J. Optican, MD, MBA (*Abstract Co-Author*)
Brendan C. Cline, MD (*Abstract Co-Author*)
Travis S. Henry, MD (*Abstract Co-Author*)

TEACHING POINTS

- Aortic thrombus is an uncommon but high-stakes imaging finding with potential to cause stroke, visceral infarction, or death. - Presentations vary by location: root, arch, or descending thoracic aorta, each with distinct clinical and management implications. - Accurate differentiation between thrombus and mimics such as intramural hematoma (IMH) or rare aortic intimal sarcoma is essential. - CT angiography, including noncontrast and contrast phases, plays a pivotal role in diagnosis and treatment planning. - Management may include systemic anticoagulation, surgical thrombectomy, or endovascular intervention, depending on thrombus extent, location, and patient stability.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Importance of early recognition and potential complications 2. Background: Etiologies including hypercoagulability, post-surgical changes, and idiopathic cases 3. Clinical Presentation: Symptomatic (embolism, ischemia) or incidental findings 4. Imaging Appearances: Case-based review of aortic root, arch, and descending

thrombus; distinguishing features of IMH and sarcoma 5. Management Strategies: Anticoagulation, surgery, IR 6. Outcomes: Variable based on location and response; root involvement carries highest risk 7. Summary of Teaching Points

CHEE-27 BEYOND BEAUTY: CHEST CT IN THE ERA OF COSMETIC PROCEDURES

Maisa B. Moroz, MD (*Presenter*)
Tassia R. Yamanari, MD (*Abstract Co-Author*)

TEACHING POINTS

To review common thoracic aesthetic procedures and their expected post-procedural imaging features. To recognize potential complications on CT and PET-CT imaging that may mimic pathology. To guide radiologists in differentiating normal post-procedure changes from true thoracic disease.

TABLE OF CONTENTS/OUTLINE

This educational exhibit presents a series of CT images illustrating expected post-procedural changes, such as subcutaneous emphysema after Renuvion, fat interposition in pectoral muscles after lipofilling, costal cartilage defects post-rhinoplasty, and peri-implant collections.Beyond the typical postoperative imaging findings, radiologists must be vigilant for local and systemic complications. These include fluid collections such as hematomas, seromas and abscesses, migration of filler substances or silicone, which may cause inflammatory reactions or granuloma formation. In more severe cases, complications like pneumomediastinum, breast implant-associated anaplastic large cell lymphoma (BIA-ALCL), or even autoimmune syndromes, such as Autoimmune Syndrome Induced by Adjuvants (ASIA), may occur.The exhibit emphasizes the importance of correlating clinical history and procedural details with imaging appearances.

CHEE-28 STORAGE WARS: CARDIOTHORACIC MANIFESTATIONS OF LYSOSOMAL STORAGE DISEASES

Emily A. Soeder-Suarez, MD (*Presenter*)
Camila Urzua Fresno, MD, MSc (*Abstract Co-Author*)
Felipe A. Sanchez, MD (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)

TEACHING POINTS

Lysosomal storage diseases (LSDs) are a group of rare inherited disorders characterized by defective lysosomal enzyme activity, leading to the progressive accumulation of macromolecules and resultant cellular dysfunction. Although these diseases can impact multiple organ systems, cardiothoracic manifestations are a common yet under-recognized feature, contributing significantly to morbidity and mortality. Pulmonary involvement typically presents as interstitial lung disease, such as in Niemann-Pick and Gaucher diseases, whereas certain LSDs, such as Danon and Fabry diseases, primarily affect the cardiovascular system with manifestations that include hypertrophic cardiomyopathy, myocardial fibrosis and valvular dysfunction. Early identification allows for timely interventions, including enzyme replacement therapy, which can significantly alter disease progression and improve patient outcomes. The goals of this exhibit are to: Review the epidemiology, classification and pathophysiology of LSDs.Discuss the clinical and imaging findings of the most common LSDs that affect the cardiopulmonary system and other thoracic organsReview complications and differential diagnoses

TABLE OF CONTENTS/OUTLINE

(1) Lysosomal Storage Disease background, classification and epidemiology (2) Gaucher Disease (2) Nieman-Pick Disease (3) Pompe Disease (4) Fabry Disease (5) Danon Disease (6) Mucopolysaccharidoses (eg. Hurler and Hunter syndromes). (7) Other LSDs (8) Role of Imaging in LSDs

CHEE-29 PULMONARY DENSITOMETRY IN THE EVALUATION OF THE ATTENUATION PATTERN IN MOSAIC: A PIECE OF CAKE ?

Laura M. Garcia Ramirez, BMedSc, BMedSc (*Presenter*)
Andres Guillermo Tarra Romero, MD (*Abstract Co-Author*)
Omar A. Gamboa Abundis, MD (*Abstract Co-Author*)

TEACHING POINTS

• Mosaic attenuation is an imaging pattern on CT of the chest that is defined as variable lung attenuation that results in a heterogeneous appearance of the parenchyma. • In some instances, the areas of lower attenuation are abnormal, while in other instances the areas of higher attenuation are abnormal.• Airtrapping involving an entire pulmonary segment can occasionally be seen in a small percentage of normal individuals, and the presence of airtrapping increases with age and is more pronounced in smokers Therefore, various degrees of mosaicism and airtrapping may be an incidental finding and not related to the underlying symptoms of the patient.• The attenuation pattern in mosaic, most commonly occurs in diseases that affect the: Small airways Alveoli Pulmonary Vasculature Interstitium• For the assessment of lung densitometry, an adequate inspiration and expiration phase must be present.• AIR TRAPPING: defined as the percentage of low-attenuation areas = -856 HU on expiratory CT, which we refer to as "LAA-856E" as measures of small airways disease.• Defined as the percentage of low-attenuation areas = -950 HU on inspiratory CT, which we refer to as "LAA-950I".

TABLE OF CONTENTS/OUTLINE

1. Introduction2. High-Resolution CT3. Etiology• Small airways• Alveoli Pulmonary• Vasculature Interstitium4. Pulmonary densitometry: interpretation and systematic reporting of results.5. Take - Home Messages.6. Conclusions.7. Bibioglaphry

CHEE-30 LOOK BEYOND THE LUMEN: SYSTEMATIC DIAGNOSIS OF INTRA-BRONCHIAL MASSES

Katsuhiko Taira (*Presenter*)
Ryosuke Taiji, MD (*Abstract Co-Author*)
Aya Yamada, MD (*Abstract Co-Author*)
Shoko Nakanishi (*Abstract Co-Author*)
Mako Iwata (*Abstract Co-Author*)
Kiyoyuki Minamiguchi (*Abstract Co-Author*)
Toshihiro Tanaka, MD (*Abstract Co-Author*)

TEACHING POINTS

Central airway lesions often mimic asthma, presenting with wheezing and chronic cough; careful evaluation of the trachea and main bronchi is crucial in such cases.Imaging plays a key role in detecting tumorous lesions and assessing their extent; for example, adenoid cystic carcinoma typically shows submucosal spread along the bronchial wall.Diffuse central airway narrowing may appear similar across diseases, but preservation of the membranous portion can suggest cartilaginous disorders such as relapsing polychondritis.

TABLE OF CONTENTS/OUTLINE

Introduction: Diagnostic challenges in intra-bronchial lesionsCongenital lesions: Bronchial atresia, CPAM Inflammatory diseases: ABPA, endobronchial TB, relapsing polychondritis Benign tumors: Bronchiolar adenoma Low-grade malignancies: Carcinoid tumors, adenoid cystic carcinoma, mucoepidermoid carcinoma High-grade malignancies: Squamous cell carcinoma, adenocarcinoma, small cell carcinoma Endobronchial metastases: RCC, breast, colon, melanoma Summary and take-home points

CHEE-31 INHALE, EXHALE: A REVIEW OF PNEUMOCONIOSIS IN THE MODERN DAY

Caroline Robb, MD (*Presenter*)
Stacy J. Kim, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)
Sanjeev Bhalla, MD (*Abstract Co-Author*)

TEACHING POINTS

Although the number of deaths attributable to pneumoconiosis has declined over the last 25 years, the incidence and prevalence continues to rise in the United States. The increasing prevalence and incidence of pneumoconiosis necessitates that radiologists continue to remain vigilant and capable of diagnosing these conditions promptly and accurately. Pneumoconiosis is a lung condition caused by the inhalation of inorganic dust particulates. Exposure to these particulates depends on occupation and geographic environment. On imaging exams, many pneumoconioses have overlapping features that may make it difficult to determine the specific offending particulate. However, complications associated with pneumoconioses, such as pulmonary fibrosis and lung malignancy, are just as important for the radiologist to recognize.

TABLE OF CONTENTS/OUTLINE

Review the causes of different types of pneumoconioses and the role of occupation and geographic location in the development of pneumoconiosis. Analyze common and rare forms of pneumoconiosis in a case-based format. Evaluate pneumoconiosis-associated complications in a case-based format. Assess the utility of different imaging modalities in the diagnosis of pneumoconioses and their associated complications. Examine common interpretative and diagnostic pitfalls and how to avoid these; for example, how to distinguish between benign and malignant complications such as progressive massive pulmonary fibrosis and a lung malignancy.

CHEE-32 BARIUM ASPIRATION: A PRACTICAL GUIDE FOR RADIOLOGISTS FACING AN UNEXPECTED COMPLICATION

Abraham Jesus Sansores Gongora, MD (*Presenter*)
Luis Enrique Nunez Castellanos, MD (*Abstract Co-Author*)
Juan Jose Duran Rosas, MD (*Abstract Co-Author*)
Lourdes M. Avila, MD (*Abstract Co-Author*)

TEACHING POINTS

Barium Aspiration: A Practical Guide for Radiologists Facing an Unexpected Complication Barium aspiration is a rare but potentially life-threatening complication encountered during gastrointestinal contrast studies. This educational presentation aims to equip radiologists with essential knowledge for identifying, classifying, and managing this event. The objectives include understanding the normal physiology of swallowing, recognizing the pathophysiological mechanisms of bronchoaspiration, and establishing key risk factors such as neurologic impairment, esophageal motility disorders, and altered levels of consciousness. Through clinical case reviews, the distinction between contrast penetration and aspiration is highlighted, along with imaging findings before and after bronchoaspiration. Management strategies are presented in a stepwise approach, including promoting an effective cough, Trendelenburg positioning, and suctioning. In cases where initial measures fail, bronchoalveolar lavage is recommended to evacuate retained contrast material from the airways. This practical guide underscores the importance of timely recognition and intervention to prevent serious respiratory compromise and improve patient outcomes in the radiologic setting.

TABLE OF CONTENTS/OUTLINE

Physiology of swallowing and protective mechanisms Pathophysiology of aspiration and V/Q mismatch Risk factors (neurologic, esophageal, systemic) Classification: penetration vs. aspiration Imaging findings before and after aspiration Management protocol and lavage indications Clinical case examples with imaging Final recommendations for radiologists

CHEE-33 ROLE OF CT IN SEVERE ASTHMA

Javier Saez, MD (*Presenter*)

TEACHING POINTS

Chest CT is the imaging modality of choice in the assessment of asthma. Inspiratory and expiratory acquisitions are essential. Bronchial wall thickening is a hallmark of airway remodeling Visual assessment of bronchial wall thickening requires special focus on segmental branches of the upper and lower lobes. Mucus plugs are highly prevalent in severe asthma. There are two main phenotypes of mucus plugs based on their length: stringy and stubby . Quantification of mucus plugs is based on the Dunican score . Air trapping appears as areas of reduced density or limited volume loss on expiratory CT and reflects small airway disease. Use of quantitative imaging software enhances objectivity and reproducibility

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology and role of imaging in severe asthma CT Protocol and Technical Considerations Preferred acquisition technique (high-resolution CT) Normal Thoracic Anatomy Review of bronchopulmonary segments Key Imaging Findings in Severe Asthma Bronchial wall thickening Qualitative and quantitative assessment Manual vs. automated measurement Mucus plugs Imaging features and clinical relevance Identification, quantification and phenotyping Air trapping Visual and quantitative evaluation Mosaic attenuation pattern Associated Imaging Findings Bronchiectasis Tracheobronchomalacia Chronic obstructive pulmonary disease overlap Allergic bronchopulmonary aspergillosis Eosinophilic granulomatosis with polyangiitis Infectious complications Future Directions Role of quantitative imaging software Conclusion Summary of imaging's role in the evaluation of severe asthma Importance of integration into clinical guidelines and structured reporting

CHEE-34 CUT, CLIPPED, AND STAPLED: LUNG CANCER POST-OPERATIVE IMAGING - WHAT THE THORACIC SURGEON WANTS TO KNOW

Shravan Sridhar, MD, MS (*Presenter*)
Tician Schnitzler, MD, MSc (*Abstract Co-Author*)
Devan Diwanji, MD (*Abstract Co-Author*)
Daniel B. Green, MD (*Abstract Co-Author*)

TEACHING POINTS

Surgical management of lung cancer is limited to low clinical stage malignancy. Surgeries range from non-anatomic wedge resection to pneumonectomy and escalation depends on disease extent. Post-operative imaging is instrumental in detecting early and late complications and ensuring patient longevity. This exhibit focuses on imaging findings that directly impact management in the early and late postoperative period. Learning objectives include: 1) Review surgical management strategy for low stage lung cancer 2) Recognize early and late postoperative complications 3) Understand importance of time course to assess treatment success.

TABLE OF CONTENTS/OUTLINE

1. Title2. Objectives3. Surgical approach + escalation4. Wedge resection5. Segmentectomy6. Lobectomy7. Sleeve lobectomy8. Pneumonectomy9. Peri-operative management10. Pleural management (persistent air leak/effusion)11. Pulmonary hygiene (atelectasis, diaphragm paralysis)12. Reintubation13. Postop fever14. Postop pain 15. Complications of surgical dissection (hernias, torsion)16. Hilar complications (accidental bronchial ligation, stenosis, dehiscence, stump thrombus)17. Assessing treatment success (residual/recurrent tumor, metastasis)18. Summary: Scenarios and complications19. References

CHEE-35 WHEN IS A CTPA TRULY NONDIAGNOSTIC? A PRACTICAL FRAMEWORK FOR EVALUATING CONTRAST QUALITY AND PULMONARY EMBOLISM DETECTABILITY

Anish Pundyavana, BS (*Presenter*)
Daniel Giraldo Herrera, MD (*Abstract Co-Author*)

Omar Jamil, MD (*Abstract Co-Author*)
Joshua Ewell, DO (*Abstract Co-Author*)

TEACHING POINTS

Pulmonary artery (PA) attenuation on CTPA is an objective, yet underutilized, marker of contrast bolus quality. In borderline or equivocal CTPAs, PA attenuation measurement offers an evidence-based approach to assess study adequacy. Main PA attenuation <200 HU often correlates with reduced confidence for PE exclusion, warranting caution in reporting. Utilizing attenuation thresholds can standardize recommendations for repeat or alternative imaging, particularly for high-risk patients. This exhibit provides a practical framework for applying PA attenuation measurements, with reporting strategies and illustrative cases.

TABLE OF CONTENTS/OUTLINE

1. Rationale for Pulmonary Artery Attenuation Measurement (Workflow algorithm, chart for attenuation at different levels) 2. Practical Application of Attenuation Thresholds (Figures for interpreting HU Values: a. <150 HU: Likely non-diagnostic. b. 150-200 HU: Equivocal study quality. c. >200 HU: Generally diagnostic quality, Table: Suggested Interpretation and Recommended Actions) 3. Case Illustration 1: Diagnostic Study 4. Case Illustration 2: An Equivocal Study (Clarifying diagnostic uncertainty with attenuation data) 5. Case Illustration 3: The Danger of Poor Opacification a. Educational Takeaway: Caution with "negative" studies if opacification is poor. 6. Case Illustration 4: Poor opacification due to patient factors 7. Reporting Language and Clinical Integration (Guide: Side-by-side reporting examples (with and without HU context))

CHEE-36 RESIDENT SURVIVAL GUIDE: A COMPARTMENT-BASED REVIEW OF THORACIC CT PITFALLS, ANATOMIC VARIANTS, AND PSEUDO-LESIONS MIMICKING PATHOLOGIES

Camila P. Reifegerste, MD (*Presenter*)
Felipe Cintra Valentin (*Abstract Co-Author*)
Bruno L. Moreira, MD (*Abstract Co-Author*)
Bruna B. Libanio, MD (*Abstract Co-Author*)
Augusto K. Medeiros, MD (*Abstract Co-Author*)
Camila V. Machado, MD (*Abstract Co-Author*)
Pablo Rydz P. Santana, MD (*Abstract Co-Author*)
Murilo d. Peixoto, MD (*Abstract Co-Author*)

TEACHING POINTS

Chest computed tomography (CT) interpretation can be particularly challenging for radiology residents due to the wide range of normal variants, benign findings, and technical pitfalls that can mimic significant pathology. Misinterpretation of these mimics may lead to unnecessary follow-up imaging, invasive procedures, or even mismanagement. This educational exhibit presents a compartment-based review—covering the mediastinum and cervicothoracic junction, thoracic wall and musculoskeletal structures, and the pleuropulmonary compartment. Real-life cases are used to illustrate key pitfalls, such as dependent atelectasis simulating micronodules, cranial thymic extension mimicking lymphadenopathy, and delayed vascular opacification in fibrotic lungs mimicking pulmonary embolism. Anatomical variants are also discussed as common diagnostic traps.Each case includes concise teaching points that highlight the diagnostic challenge and provide practical tips to avoid error.This exhibit is intended to serve as a practical manual for radiology residents, to be read at the beginning of their training, helping them avoid common interpretive errors on chest CT.

TABLE OF CONTENTS/OUTLINE

(1)Introduction: Importance of recognizing anatomical variants and benign findings that mimic clinically significant thoracic pathology (2) Evaluation of findings by anatomical compartment: (a) Mediastinal / Cervicothoracic region (b) Musculoskeletal structures / Thoracic wall (c) Pleuroparenchymal compartment (3)Practical Recommendations (4) Summary

CHEE-37 PLEURAL MESOTHELIOMA: CURRENT KNOWLEDGE, DIAGNOSIS, AND IMAGING REVIEW

Furkan Ufuk, MD (*Presenter*)
Iclal Ocak, MD, MD (*Abstract Co-Author*)
Lydia Chelala, MD (*Abstract Co-Author*)
Sachin Seetharam, MD, BS (*Abstract Co-Author*)
Emily Miller, MD (*Abstract Co-Author*)
Luis A. Landeras, MD (*Abstract Co-Author*)
Christopher M. Straus, MD (*Abstract Co-Author*)

TEACHING POINTS

• Understand the pathophysiology, histologic subtypes (epithelioid, sarcomatoid, biphasic), and prognostic implications of malignant pleural mesothelioma (MPM). • Review the multimodality imaging approach to MPM—including chest X-ray, CT, MRI, and PET-CT—with emphasis on diagnostic signs, staging features, and treatment planning. • Familiarize with updated TNM 9 staging criteria and modified RECIST 1.1 response assessment guidelines specific to mesothelioma. • Recognize imaging pitfalls and mimics (e.g., prior pleurodesis, empyema, metastatic pleural disease) and differentiate post-treatment changes from recurrence. • Explore advanced imaging innovations such as radiomics, AI-based segmentation, PET/MRI, and emerging molecular tracers for improved diagnostic precision.

TABLE OF CONTENTS/OUTLINE

1. Epidemiology, pathophysiology, and histology of MPM 2. Imaging overview: CT as the cornerstone, MRI for local invasion, PET-CT for staging 3. Radiologic hallmarks and staging (TNM 9) with sample cases 4. Modified RECIST criteria for treatment response assessment 5. Post-treatment imaging: surgical, chemotherapeutic, radiation-related findings 6. Imaging pitfalls and differential diagnosis 7. Future directions: AI, radiomics, PET tracers, volumetric staging

CHEE-38 RADIOLOGICAL INSIGHTS INTO RARE INTERSTITIAL LUNG DISEASES

Furkan Ufuk, MD (*Presenter*)
Iclal Ocak, MD, MD (*Abstract Co-Author*)
Lydia Chelala, MD (*Abstract Co-Author*)
Vanessa Peters, MD (*Abstract Co-Author*)
Luis A. Landeras, MD (*Abstract Co-Author*)

TEACHING POINTS

Illustrate hallmark HRCT and advanced-imaging patterns of selected rare interstitial lung diseases (ILDs). Correlate imaging features with genetic, pathologic, and broncho-alveolar findings to build a confident, multidisciplinary diagnosis. Review evidence-based and emerging therapies and demonstrate how imaging guides management and longitudinal follow-up.

TABLE OF CONTENTS/OUTLINE

Background - Epidemiology, diagnostic delay, and clinical impact of rare ILDs; need for pattern-based radiologic triage. Spectrum of Disease Pulmonary Alveolar Proteinosis - crazy-paving and “sedimentation” sign. Pulmonary Alveolar Microlithiasis - sand-storm lungs, black-pleura sign. Pleuroparenchymal Fibroelastosis - apical pleural caps and platythorax. Genetic / Congenital ILDs (e.g., Hermansky-Pudlak, Birt-Hogg-Dubé). Multiple Cystic Lung Diseases - algorithmic approach to LAM, PLCH, BHD. Diagnostic Toolbox - HRCT pattern recognition, quantitative CT, dual-energy CT, ultra-short-TE MRI; integration of bronchoscopy, cryo-biopsy, and next-generation sequencing. Therapeutic Strategies - Whole-lung lavage, mTOR inhibitors, antifibrotics, GM-CSF therapy, and timing of lung transplantation. Pearls, Pitfalls, and Mimickers - Avoiding misdiagnosis and unnecessary surgery; imaging red flags for acute complications. Future Directions - AI-driven radiomics, liquid-biopsy correlations, gene-editing trials, and international ILD registries.

CHEE-39 THE IRRADIATED CHEST: WHEN HEALING IMITATES HARM

Rhillary S. Sa, MD (*Presenter*)
Lhuanna Maria Barbosa Teixeira, MD (*Abstract Co-Author*)
Evandro J. Bonetti, MD (*Abstract Co-Author*)
Camila P. Reifegerste, MD (*Abstract Co-Author*)
Augusto K. Medeiros, MD (*Abstract Co-Author*)
Bruna B. Libanio, MD (*Abstract Co-Author*)

TEACHING POINTS

-Radiation-induced changes may affect lungs, pleura, lymph nodes, thymus, bones, and chest wall. -Imaging findings are dose-dependent and often respect the radiation field, rather than anatomic boundaries -Modern techniques like SBRT and IMRT produce atypical radiation-induced lung injuries patterns (e.g., mass-like, scar-like) that may mimic recurrence. -Recognition of these patterns helps avoid misdiagnosis and unnecessary biopsies. -Time from radiotherapy, review of dose maps, and correlation with clinical context are essential for accurate interpretation.

TABLE OF CONTENTS/OUTLINE

Introduction: -Rationale and clinical impact of recognizing radiation-induced lung injury (RILI) -Overview of thoracic RT modalities (3D-CRT, IMRT, SBRT) Pathophysiology and Phases of RILI: -Acute inflammatory phase (2-12 weeks) -Proliferative/subacute phase (3-9 months) -Fibrotic phase (>9 months) Imaging Patterns According to Technique: -Typical vs. atypical findings -Modified conventional, scar-like, mass-like patterns -Pneumonia in organization (OP-like) -Extra-pulmonary manifestations (pleura, muscle, thymus) Differential Diagnosis: -Tumor recurrence -Infection -Drug-induced toxicity -Organizing pneumonia Clinical Tips and Pitfalls: -Importance of time interval post-RT -When to suspect recurrence -Role of PET/CT and when to avoid it Conclusion and Summary of Key Messages

CHEE-40 BREAKING THE WALL: UNCOVERING PEDIATRIC THORACIC WALL LESIONS

Maria Tamyres De Carvalho Freitas, MD (*Presenter*)
GABRIELE SPERANDIO (*Abstract Co-Author*)
Natasha Manzoli Elias, MD (*Abstract Co-Author*)
Paulo Henrique Takanashi Murakawa (*Abstract Co-Author*)
Camila V. Machado, MD (*Abstract Co-Author*)
TAIS COSTA (*Abstract Co-Author*)
Mariana Rodrigues, MD (*Abstract Co-Author*)
Danilo T. Wada, MD (*Abstract Co-Author*)

TEACHING POINTS

After attending to this exhibit, the learner should be able to: Understand the most common thoracic wall injuries in the pediatric age group. Distinguish the specific imaging patterns for each pathology. Identify possible differential diagnoses. Recognize typical imaging patterns to prevent unnecessary interventions.

TABLE OF CONTENTS/OUTLINE

Introduction to Chest Wall Tumors in Children Focus on imaging characteristics of chest wall tumors and how to differentiate them. Benign: Soft tissue origin: Hemangioma/vascular malformation Lymphangioma Lipoma/lipoblastoma Hamartoma Neurofibroma and ganglion cell tumor Fibroma/fibromatosis/desmoid Bone origin: Osteochondroma, osteoid osteoma and aneurysmal bone cyst. Fibrous dysplasia Langerhans cell histiocytosis Malignant: Ewing sarcoma/PNET Sarcomas. Lymphoma/leukemia. Malignant peripheral nerve cell tumor. Bone and soft tissue metastases.

CHEE-41 DENDRIFORM PULMONARY OSSIFICATION: A NOT SO RARE CAUSE OF LUNG CALCIFICATION

Ainhoa Clemente Idoate, MD (*Presenter*)
Cristina Sanchez, MD (*Abstract Co-Author*)
Elia Lecumberri, MD (*Abstract Co-Author*)
Pablo Bartolome, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review and illustrate the chest CT findings in dendriform pulmonary ossification. 2. To discuss the physiopathology of this process. 3. To highlight the commonality DPO in routine chest CT, despite the overall conception of it being a rare disease. 4. To display the most common differential diagnosis and how to avoid misdiagnosis. 5. To analyze the relationship of DPO with ILD (interstitial lung disease) and GERD (gastroesophageal reflux disease).

TABLE OF CONTENTS/OUTLINE

1. Introduction: The importance of a precise diagnosis of pulmonary ossification to avoid over diagnosis and overtreatment. 2. Bone in the lungs: discussion of a physiopathology oddity. 3. Pulmonary ossification: radiological imaging findings • Main HRCT findings • Distribution • Ancillary features. 4. Differential diagnosis. 5. Association with ILD and GERD. 6. Conclusions

CHEE-42 YOU CAN DO IT: CREATING A PEER-LEARNING CONFERENCE IN YOUR THORACIC IMAGING SECTION

Neud Kiros, MD (*Presenter*)
Tannoz Norouzi (*Abstract Co-Author*)
Monisha Shetty, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Illustrate the educational and cultural value of a sectional peer learning conference and differentiate it from traditional peer review 2. Outline actionable steps to set up a peer learning conference that is both accessible and sustainable 3. Compare various formats of a peer learning conference 4. Analyze illustrative cases highlighting the utility of a peer learning conference and sources of bias

TABLE OF CONTENTS/OUTLINE

1. Background a. Peer review vs. Peer learning i. Quantitative vs. Qualitative ii. Punitive vs. Non-punitive iii. Done in isolation vs. Collaborative iv. Random sample vs. Curated 2. Instructions to create the conference infrastructure a. Secure CME b. Share the purpose of the conference c. Case curation d. Review sources of bias/error e. Encourage participation i. Inclusion of great pickups, near misses ii. Digital reminders f. Share a method to store cases g. Determine a date and time h. Invite current/future body imaging fellows i. Give them insight into their future careersii. Inspire them to continue peer learning at their future institutions i. Periodically check-in with attendees i. Invite suggestions regarding format, frequency, style 3. Discussion of various formats a. In-person or virtual b. Formality c. Presentation style d. Moderation 4. Benefits of a sectional peer learning conference a. Share newly acquired knowledge b. Increase radiologist engagement c. Understand individual practice patterns d. Improve patient care 5. Illustrative cases a. Satisfaction of search/report b. Framing bias c. Availability bias d. Confirmation bias e. Anchoring bias f. Commission/Omission bias g. Blind spots h. Automation bias

CHEE-43 MRI EVALUATION AND PREOPERATIVE STAGING OF ESOPHAGEAL CARCINOMA - DIAGNOSTIC PERFORMANCE AND CORRELATION OF MRI T AND N STAGES WITH EUS AND HISTOPATHOLOGIC T AND N STAGES

Rachna Madan, MBBS, MD (*Presenter*)
Mark M. Hammer, MD (*Abstract Co-Author*)

TEACHING POINTS

Use of MRI in the prediction of response to therapy for the treatment of esophageal cancer continues to be explored, and its early differential value remains controversial. This educational exhibit highlights the incremental value of using MRI pre and post treatment for improving preoperative staging, selecting patients for trimodality therapy and and predicting tumor response post treatment.

TABLE OF CONTENTS/OUTLINE

1. Esophageal MRI Protocol and Qualitative and Semi-Quantitative Assessment of MRI data2. MRI data correlation with CT and PET CT; MRI T and N stage Correlation with EUS and pathologic T and N stage correlation 3. Use of MR parameters (craniocaudal tumor length, vascular invasion, number of involved nodes, ADC values) to predict response to treatment and guide clinical decision making. 5. High sensitivity of MRI when used for the detection of esophageal cancer makes it a promising imaging modality for early T-stage disease and potentially for active surveillance in patients who have undergone neoadjuvant therapy.

CHEE-44 IMAGING OF PROCEDURES PERFORMED FOR COMPLEX PLEURAL FLUID COLLECTIONS: WHAT THE RADIOLOGIST NEEDS TO KNOW

Carol N. Sanchez Santana, BS (*Presenter*)
Babina Gosangi, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

• Review the etiology and characteristics of complex pleural effusions, including empyema, hemothorax, and chylothorax. • Demonstrate the role of imaging in the diagnosis and management of complex pleural fluid collections. • Discuss the procedures performed for these conditions, expected post procedural appearance and complications.

TABLE OF CONTENTS/OUTLINE

• Introduction • Complex Pleural Fluid Collections • Empyema a. Classification, staging, and quantification b. Role of Imaging i. Ultrasound ii. Chest X-Ray iii. CT iv. MRI c. Intervention i. Tube Thoracostomy ii. Thoracomyoplasty iii. Pleural decortication iv. Clagett window v. Eloesser flaps d. Complications i. Post-pyothorax pleural lymphoma ii. Empyema Necessitans iii. Fibrothorax • Hemothorax e. Etiology & Diagnosis f. Role of Imaging i. FAST Ultrasound ii. Chest X-Ray iii. CT g. Intervention i. Tube Thoracostomy ii. Open Thoracotomy iii. Video-assisted thoracoscopic surgery (VATS) with decortication h. Complications i. Empyema ii. Trapped Lung iii. Fibrothorax • Chylothorax i. Etiology & Diagnosis j. Role of Imaging i. Ultrasound ii. Lymphangiography iii. Chest X-Ray iv. CT v. MRI k. Intervention i. Thoracentesis ii. Pleurodesis iii. Thoracic Duct Ligation iv. Thoracic Duct Embolization l. Complications

CHEE-45 CASE-BASED REVIEW OF NON-CARDIOVASCULAR DEVICES IN CHEST RADIOGRAPHY

Francisco Calle Bernal, MD (*Presenter*)
Paula N. Patino, MD (*Abstract Co-Author*)

TEACHING POINTS

Present a radiographic review of common non-cardiac devices visible in chest imaging. Provide a case-based review of devices that may appear similar on radiographs but have distinct anatomical placement, clinical indications, and purposes. Highlight clinical indications, key anatomical landmarks, and potential complications for each device. Provide practical imaging tips to help radiologists accurately identify device components and recognize normal vs. abnormal placements.

TABLE OF CONTENTS/OUTLINE

Esophageal Devices Ambulatory pH Monitors. Esophageal Temperature Probe Gastric Devices Gastric Pacemaker. Sengstaken-Blakemore Tube: Intragastric Balloon, Gastric Banding Nervous System Stimulation Devices Deep Brain Stimulator, Occipital Nerve Stimulator Vagus Nerve Stimulator Diaphragmatic Pacing System Pain and Anesthesia-Related Devices Interscalene Brachial Plexus Block Serratus Anterior Block Thoracic Epidural Catheter. Spinal Cord Stimulators Cervical and Thoracic spinal electrode placements. Miscellaneous Devices Subcutaneous Contraceptive Implants Continuous Glucose Monitors.

CHEE-46 THE ABCS OF LUNG ALLOGRAFT DYSFUNCTION: ALAD, BLAD, AND CLAD DEMYSTIFIED

Dayana Davoudi, BSc (*Presenter*)
Aly Muhammad Ladak (*Abstract Co-Author*)
Micheal McInnis, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize CT imaging features of acute, baseline, and chronic lung allograft dysfunction (ALAD, BLAD, and CLAD) 2. Distinguish CT findings of CLAD subtypes: bronchiolitis obliterans syndrome (BOS), restrictive allograft syndrome (RAS), and mixed phenotypes 3. Appreciate the role of emerging imaging technologies in lung allograft dysfunction 4. Apply a structured approach to evaluating lung transplant recipients on chest CT

TABLE OF CONTENTS/OUTLINE

Lung allograft dysfunction is a major concern in the care of lung transplant recipients, but it is challenging to diagnose and classify radiologically. This exhibit outlines imaging characteristics of distinct forms of lung allograft dysfunction, including acute, baseline, and chronic lung allograft dysfunction (ALAD, BLAD, and CLAD, respectively), as well as how they relate to each other. We also outline how to differentiate between CLAD phenotypes, including bronchiolitis obliterans syndrome (BOS) and restrictive allograft syndrome (RAS), on CT imaging. Lastly, we propose a structured, radiologist-friendly approach to abnormal imaging findings in the lung transplant patient. Overview of Lung Allograft Dysfunction Definitions: ALAD, BLAD, CLAD Pathophysiology, epidemiology, and presentation Spirometric criteria CT Imaging Findings CT imaging findings and differential diagnoses CLAD Subtypes: Imaging Features BOS: mosaic attenuation, air trapping, hyperinflation RAS: pleuroparenchymal thickening, volume loss, traction bronchiectasis Mixed CLAD patterns Novel CT imaging techniques: Parametric response mapping Machine learning texture analysis Systematic Approach to Lung Tx CT Checklist for radiologists in transplant surveillance

CHEE-47 HIGH-RESOLUTION CT MANIFESTATIONS OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED LUNG DISEASE

Bethelhem B. Belachew, MD (*Presenter*)
Hallie A Carol (*Abstract Co-Author*)
Scott Canna (*Abstract Co-Author*)
Abass Noor, MD (*Abstract Co-Author*)

TEACHING POINTS

Systemic juvenile idiopathic arthritis (sJIA) comprises 10-20% of cases of JIA—the leading childhood rheumatic disease. Historically, pleuritis and pleural effusion were the primary recognized pulmonary manifestations of sJIA. However, recent reports of severe, potentially life-threatening chronic lung diseases have emerged, collectively referred to as sJIA-associated lung disease. These include pulmonary alveolar proteinosis, interstitial lung disease, and pulmonary hypertension. Lung involvement in sJIA have proposed risk factors, including onset age < 2 years and chronic, recurrent, or poorly controlled Macrophage Activation Syndrome (MAS), among others. High-resolution CT (HRCT) remains the modality of choice to assess these findings for diagnosis and follow-up. The purpose of this exhibit is to 1) review the key imaging features of lung involvement in sJIA, 2) demonstrate 4 cases from our institution and 3) discuss the importance of HRCT for timely diagnosis in these patients.

TABLE OF CONTENTS/OUTLINE

Introduction Pathophysiology and risk factors of sJIA-associated lung disease. Symptoms of sJIA-associated lung disease. Role of imaging in diagnosis of sJIA-associated lung disease.Imaging features for sJIA-associated lung disease through case seriesConclusion

CHEE-48 LUNG LESION DISTRIBUTION PATTERNS: A CASE-BASED DIAGNOSTIC FRAMEWORK

Lydia Chelala, MD (*Presenter*)
Sophie Cemaj, MD (*Abstract Co-Author*)
Luis A. Landeras, MD (*Abstract Co-Author*)
Iclal Ocak, MD, MD (*Abstract Co-Author*)
Jonathan H. Chung, MD (*Abstract Co-Author*)
Furkan Ufuk, MD (*Abstract Co-Author*)

TEACHING POINTS

• Understand the physiologic basis of lesion distribution—how ventilation-perfusion gradients, lymphatic flow, and particle deposition influence where diseases occur in the lung. • Recognize key CT distribution patterns—upper vs. lower lobe, central vs. peripheral, or diffuse—and their diagnostic implications. • Apply a case-based framework integrating lesion location with radiologic pattern (e.g., nodular, reticular, cystic) to narrow differentials in diffuse lung disease. • Emphasize diagnostic power of combining anatomic distribution with CT morphology for more confident interpretation.

TABLE OF CONTENTS/OUTLINE

• Introduction: Diagnostic value of lesion location on CT• Physiology of Distribution: V/Q mismatch, lymph flow, oxygenation• Upper- and Lower-Zone Predominance: Case-based review• Central vs. Peripheral Disease: Imaging and clinical correlates• Diffuse/Random Patterns: Miliary TB, metastases, cystic lung disease• Radiologic Pattern Integration: Ground-glass, nodular, cystic findings across zones• Summary: A structured approach to evaluating lesion distribution in diffuse lung disease

CHEE-49 ADVANCES IN THE DIAGNOSTIC CONCEPT AND IMAGING OF PULMONARY FUNGAL INFECTION IN VARIOUS IMMUNE CONDITIONS: FOCUSED ON RADIOLOGY-PATHOLOGY COMPARISONS

Semin Chong, MD (*Presenter*)
Joungho Han (*Abstract Co-Author*)
Tae Jung Kim, MD, PhD (*Abstract Co-Author*)
Yeon Joo Jeong, MD, PhD (*Abstract Co-Author*)
Yumi Wi (*Abstract Co-Author*)
Kyung S. Lee, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Fungal pneumonia is a kind of chronic granulomatous infection in immunocompetent subjects, but not typically involve granulomatous inflammation in immunocompromised patients with unchecked proliferation of organisms, absent or poorly-formed granulomas, and wide spread disease showing diverse imaging features. For early diagnosis and timely treatment, identifying the presence of pneumonic process on imaging study is the essential step for proper management. Pattern recognition and common and specific organisms in each setting of patient immune status is the recent approach for the diagnosis of fungal infection particularly in immnunocompromised patients. Despite of overlapping imaging features, the integration of pneumonic pattern, immune status, and common organisms involved in each condition helps reach the probable diagnosis the specific fungal pneumonia. Bronchoalveolar lavage with or without transbronchial lung biopsy rather than direct surgical lung biopsy is the final diagnostic procedure for specific fungal pneumonia.

TABLE OF CONTENTS/OUTLINE

1. Overview of pulmonary fungal infection 2. CT and histopathology of chronic granulomatous infection; difference from community-acquired pneumonia 3. CT findings of fungal infection in immunocompetent or mildly immunocompromised patients and pathologic comparisons 4. CT findings of fungal infection in diverse immunocompromised status and pathologic comparisons 5. Covid-19 associated pulmonary aspergillosis and mucromycosis 6. Pulmonary fungal infection in specific clinical settings 7. Summary and Conclusion

CHEE-50 IGG4-RELATED LUNG DISEASE: WHAT THE RADIOLOGISTS SHOULD KNOW

Aylen Gonzalez Gonzalez, MD (*Presenter*)
Sofia Pividori, MD (*Abstract Co-Author*)
Bruno Miguel Manzanares, MD (*Abstract Co-Author*)
Teresa A. Garcia, MD (*Abstract Co-Author*)

TEACHING POINTS

Although rare, IgG4-related disease is an emerging multi-organic syndrome that can pose a diagnostic dilemma. The radiologist must be familiar with the imaging findings and differential diagnosis. The aim of the present study is to: - Review the typical radiologic findings of the IgG4-related lung disease. - Classify them into four patterns. - Review the pearls and pitfalls of this recently discovered disease.

TABLE OF CONTENTS/OUTLINE

1) Introduction and Clinical characteristics 2) Role of different modalities 3) Findings classification Solid nodular Broncho-vascular Alveolar interstitial Ground glass opacity 4) Differential diagnosis Infections Inflammatory Neoplasms 5) Conclusions 6) Summary

CHEE-52 KEY ASPECTS RADIOLOGISTS SHOULD KNOW FOR THE DIAGNOSIS OF HYPERSENSITIVITY PNEUMONITIS ACCORDING TO THE 2020 ATS/JRS/ALAT CLINICAL PRACTICE GUIDELINE

Omar Andres Pantoja Burbano, MD (*Presenter*)
Felipe Aluja, MD, MEd (*Abstract Co-Author*)
Maria Alejandra Amaya, MD (*Abstract Co-Author*)

TEACHING POINTS

• The ATS/JRS/ALAT guideline provides a framework for the multidisciplinary approach to patients with hypersensitivity pneumonitis (HP).• Understanding the clinical context described in this guideline is essential in order to include HP in the differential diagnosis.• Characteristic radiologic findings of HP are classified in this guideline according to HRCT patterns, which aid in the suspicion and recognition of this condition.• HRCT is established as a central component in the diagnosis of HP

TABLE OF CONTENTS/OUTLINE

• Introduction to the 2020 ATS/JRS/ALAT Guideline for the Diagnosis of Hypersensitivity Pneumonitis (HP) • Key Clinical and Laboratory Points Radiologists Should Be Aware of in the Context of Suspected HP • HP Patterns and Their Imaging Characteristics • Common and Uncommon Differential Diagnoses of HP • Key Imaging Findings Radiologists Should Include in Their Report to Support Multidisciplinary Management • Conclusion

CHEE-53 AORTIC PATHOLOGIES: MUST-KNOW FOR A RADIOLOGIST

Syed Muhammad Awais Bukhari, MD (*Presenter*)
Cody R. Johnson, MD (*Abstract Co-Author*)
Nisha Korakavi, MD (*Abstract Co-Author*)
Sreyes Venkatesh (*Abstract Co-Author*)
Brian Zhang (*Abstract Co-Author*)
Robert C. Gilkeson, MD (*Abstract Co-Author*)
Amit Gupta, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Identify key imaging features and clinical implications of essential aortic pathologies, including acute aortic syndromes, aneurysms, and endoleaks. 2. Use case-based quiz questions to reinforce diagnostic reasoning and improve pattern recognition. 3. Recognize uncommon but critical aortic conditions such as vasculitis, mycotic aneurysms, and IgG4-related aortitis.

TABLE OF CONTENTS/OUTLINE

1. Introduction o Rationale for using quiz-based learning to reinforce high-yield aortic imaging diagnoses. 2. Case-Based Interactive Quiz • Case 1: Aortic dilatation and aneurysm • Case 2: Acute aortic syndromes (dissection, IMH, pseudoaneurysm) • Case 3: Penetrating atherosclerotic ulcer • Case 4: Endoleaks (Types I-V) • Case 5: Aortic arch anomalies • Case 6: Atypical pathologies (mycotic aneurysm, vasculitis, IgG4-related disease) 3. Answer Review and Teaching Pearls 4. Detailed explanation of correct answers, common pitfalls, and key imaging signs. 5. Conclusion Summary of must-know aortic entities and strategies to improve detection and accuracy.

CHEE-54 PEARLS AND PITFALLS IN LUNG CANCER SCREENING

Prabhakar Rajiah, MD, FRCR (*Presenter*)
Arzu Canan, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To review the key recommendations of Lung-RADS 2.0 2. To highlight key pitfalls in lung cancer screening 3. To illustrate practical tips to avoid pitfalls in lung cancer screening

TABLE OF CONTENTS/OUTLINE

A. INTRODUCTION B. PEARLS AND PITFALLS IN LUNG CANCER SCREENING 1.False negative diagnosis 2.False positive diagnosis 3.Image acquisition parameters 4.Image reconstruction parameters 5.Bidimensional measurements 6.Increased attenuation of subsolid nodules 7.Volume doubling time 8.Infection/inflammation 9.Nodular radiation changes 10.Endobronchial secretions vs neoplasm 11.Bubbly lesions 12.Atypical cysts 13.Temporary regression of malignant nodules 14.Low FDG avidity of lung adenocarcinomas

CHEE-55 SEEING IS BREATHING: CURRENT AND EMERGING TECHNIQUES IN EVALUATING CHRONIC DYSPNEA

Cody Thornburgh, MD (*Presenter*)
Talissa A. Altes, MD (*Abstract Co-Author*)
Gabriela Maria Garcia Delgado (*Abstract Co-Author*)
Yun Shim (*Abstract Co-Author*)
Robert P. Thomen, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Dyspnea is a symptom that results from dysregulation of the demand for breathing and the ability to meet that demand. 2. In the difficult dyspnea patient, a multi-disciplinary approach is typically necessary to determine the driving cause of a patient's dyspnea, including pulmonologists, cardiologists, radiologists, and neurologists. 3. By understanding the causes of dyspnea, the radiologist can be an integral member of the clinical team by providing meaningful interpretations of chest radiographs, high resolution CT, and advanced cardiac imaging. 4. Hyperpolarized Xenon-129 ventilation MR (HPG MRI) is a new-to-market FDA approved technique that is a powerful imaging tool in the difficult dyspnea patient. HPG MRI allows increased clinical confidence by ruling out small airway disease as a source of dyspnea.

TABLE OF CONTENTS/OUTLINE

1. Background/Objectives 2. Causes of Dyspnea --- a. Pulmonary --- b. Cardiac --- c. Central --- d. Hematological --- e. Metabolic --- f. Environmental & Mechanical 3. The Clinical Approach --- a. History and Physical examination --- b. Labs --- c. Pulmonary function testing --- d. Cardiopulmonary exercise testing 4. The Imaging Approach --- a. Chest radiography --- b. High resolution and Dynamic airway Chest CT --- c. Advance cardiac imaging ------ i. Cardiac MR ------ ii. Coronary CTA ------ iii. Echocardiography --- d. Ventilation imaging ------ i. SPECT V/Q ------ ii. Hyperpolarized Xenon-129 MRI (HPG MRI) Ventilation 5. Case Examples 6. Future frontiers --- a. HPG MRI Dissolved phase imaging --- b. HPG MRI RBC Oscillation in pulmonary hypertension

CHEE-56 INTEGRATING TNM 9 INTO RADIOLOGY PRACTICE: A PICTORIAL REVIEW

Amalia Constantinescu, MD (*Presenter*)
Emil R. Stoicescu I, MD (*Abstract Co-Author*)
Diana Manolescu (*Abstract Co-Author*)

TEACHING POINTS

1. Presenting the updates introduced by the ninth edition TNM system for lung cancers.2. Establishing the relevance of the new classification for patient management.3. Illustrating the modifications using structured reports.

TABLE OF CONTENTS/OUTLINE

Background and need for TNM revisionsUpdates in the T, N, and M descriptorsReclassification of stage groups with clinical impactImaging case examples with comparisons to TNM 8Summary: integration of TNM 9 into radiologic practice

CHEE-57 A PATIENT WITH HEMOPTYSIS: HOW RADIOLOGY CAN HELP?

Dinea Bucic, MD (*Presenter*)
Ana M. Alduk, MD,PhD (*Abstract Co-Author*)
Maja Hrabak Paar, MD (*Abstract Co-Author*)

TEACHING POINTS

Hemoptysis refers to the expectoration of blood from the lung alveoli or airways of the lower respiratory tract. Massive hemoptysis is a life-threatening condition with a high risk of asphyxiation or exsanguination. The primary role of the radiologist is to urgently identify the underlying etiology and mechanism of hemoptysis to guide appropriate management. This exhibit aims: • To outline the diagnostic algorithm for evaluating patients with hemoptysis, including the optimal CT protocol. • To discuss the spectrum of radiological findings associated with hemoptysis. • To show how endovascular interventional procedures could be used for the treatment of hemoptysis in different clinical scenarios. • To present a case-based review of common causes of hemoptysis. • To emphasize the importance of multidisciplinary collaboration in the management of patients with hemoptysis.

TABLE OF CONTENTS/OUTLINE

1. Overview of hemoptysis, including most common causes 2. Diagnostic algorithm in patients with hemoptysis 3. CT imaging protocols for patients with hemoptysis 4. Characteristic CT findings in patients with hemoptysis of different etiology, including infection, lung cancer, bronchiectasis, pulmonary arteriovenous malformation, etc. 5. An aberrant intrabronchial course of the bronchial artery - risks of bronchoscopy 6. An overview of the endovascular interventional procedures in patients with hemoptysis (bronchial, systemic, and pulmonary artery embolization) 7. Multidisciplinary approach to a patient with hemoptysis

CHEE-58 FUNGAL FINDS: IMAGING AND MANAGEMENT OF PULMONARY ASPERGILLUS

Hira Qureshi, MD (*Presenter*)
Naaemah Saleem (*Abstract Co-Author*)

Jeffrey D. Nadig, MD (*Abstract Co-Author*)

TEACHING POINTS

The exhibit reviews the diverse imaging features of pulmonary aspergillosis, ranging from non-invasive aspergilloma to semi-invasive and invasive forms. Key radiologic signs—including the air crescent and finger-in-glove appearances—are highlighted, emphasizing their diagnostic value when interpreted in the appropriate clinical and immunologic context. Case examples illustrate imaging-pathologic correlation and the critical role of immune status in disease manifestation and progression. Imaging's role in monitoring response to treatment and guiding surgical planning is also discussed.

TABLE OF CONTENTS/OUTLINE

Radiographic and CT findings of pulmonary aspergillosis across its clinical spectrum are explored. Aspergilloma often presents with the air crescent sign but must be distinguished from mimics like Rasmussen aneurysm, abscesses, malignancy, and hydatid cysts. ABPA typically shows the finger-in-glove sign due to mucus impaction in dilated bronchi, caused by both obstructive and non-obstructive conditions. Semi-invasive and invasive aspergillosis may share findings such as ground-glass opacities and the halo sign, with imaging patterns determined by the patient's immune status. The spectrum of imaging findings, including non-specific signs, is reviewed, along with clinical and laboratory clues for differentiation. Also addressed is the paradoxical worsening of imaging findings following early antifungal therapy, emphasizing the importance of understanding the expected timeline of radiologic resolution and correlating it with clinical progress. Surgical planning considerations, including imaging-based criteria for intervention, are also discussed.

CHEE-60 PULMONARY VENO-OCCLUSIVE DISEASE (PVOD) AND PULMONARY CAPILLARY HEMANGIOMATOSIS (PCH): KEY IMAGING FINDINGS

Adam Gaisinsky (*Presenter*)
Arwa K. Almutairi I, MBBS (*Abstract Co-Author*)
Prodipto Pal (*Abstract Co-Author*)
Micheal McInnis, MD (*Abstract Co-Author*)

TEACHING POINTS

Pulmonary veno-occlusive disease (PVOD) is a rare and fatal cause of pulmonary arterial hypertension (PAH) characterized by the narrowing of pulmonary venules by intimal fibrosis. Diagnosing PVOD is challenging due to the difficulty of differentiating PVOD from other causes of PAH. However, it is essential to consider PVOD in the differential of PAH because of its poor response to therapy, rapid progression, and the need for early consideration of lung transplantation, the only definitive treatment. This exhibit will review the patient presentation of PVOD and provide an overview of relevant diagnostic tools and clues. Additionally, 7 imaging findings of PVOD on high-resolution computed tomography (HRCT) will be reviewed as HRCT findings are key in confirming a diagnosis of PVOD. Lastly, pathology findings will be reviewed alongside HRCT findings to illustrate radiology-pathology correlation.

TABLE OF CONTENTS/OUTLINE

This exhibit will begin with an introduction to PVOD and its epidemiology. The risk factors and associated conditions will be reviewed, with discussion of both the hereditary form and other causes of PVOD. This will be followed by an introduction to the patient presentation and diagnostic tools/approach with focus on findings that differentiate PVOD from other causes of PAH. Next, 7 key HRCT imaging findings will be introduced in detail. Pathology findings will also be introduced, and radiology-pathology correlations will be illustrated. The exhibit will then move through complete patient cases focusing on showcasing classic imaging findings of PVOD and demonstrating radiology-pathology correlation. Lastly, the exhibit will conclude with a summary of the key take-home messages.

CHEE-61 UNLOCKING THE MYSTERIES OF PREINVASIVE LUNG LESIONS: ESSENTIAL INSIGHTS FOR RADIOLOGISTS

Janardhana Ponnatapura, MD (*Presenter*)

TEACHING POINTS

Lung cancer stands as the predominant cause of both cancer incidence and mortality on a global scale. Within the spectrum of pulmonary abnormalities, preinvasive lesions represent a critical subset. These lesions, while not yet malignant, harbor the potential for progression into full-blown cancer. Among the diverse array of preinvasive lesions are squamous dysplasia (SD), squamous cell carcinoma in situ (CIS), atypical adenomatous hyperplasia (AAH), adenocarcinoma in situ (AIS), and diffuse idiopathic pulmonary neuroendocrine cell hyperplasia (DIPNECH). The identification of these preinvasive lesions holds paramount significance for radiologists, as they often serve as the primary point of contact for such findings. A comprehensive understanding of these lesions is imperative for early detection, accurate differentiation, and effective patient management. By leveraging their expertise, radiologists play a pivotal role in enhancing patient outcomes through timely intervention and treatment strategies.

TABLE OF CONTENTS/OUTLINE

• WHO classification of preinvasive lesions in the lung-SD/CIS-AAH-AIS - non-mucinous, with mucinous, mixed-Neuroendocrine cell proliferations and DIPNECH• Imaging spectrum and its characteristics - Multimodality imaging• Role of Radiologists to identify and differentiate from mimickers like infection, post-RT• Role of pulmonologist and oncologist• Imaging surveillance• Role of cardiothoracic surgeons - What surgeons what radiologists to know• Management of these lesions• Algorithm to approach and manage these lesions

CHEE-62 COUGH, BLEED, REPEAT: A VISUAL JOURNEY THROUGH IDIOPATHIC PULMONARY HEMOSIDEROSIS

Florentino Saenz, MD (*Presenter*)
Vijay K. Aggarwal, MBBS (*Abstract Co-Author*)
Ameya J. Baxi, MBBS,DMRD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Idiopathic Pulmonary Hemosiderosis (IPH) is a rare but serious cause of diffuse alveolar hemorrhage, especially in children. 2. Diagnosis is one of exclusion and requires high clinical suspicion, imaging, bronchoscopy, and histopathologic confirmation. 3. Radiologic patterns on chest X-ray and HRCT can vary by disease phase, ranging from ground-glass opacities to chronic fibrotic changes. 4. Histopathology and imaging together help distinguish IPH from a wide differential of pulmonary hemorrhage including vasculitides or Goodpasture syndrome. 5. Management and prognosis are greatly influenced by timely recognition and immunosuppressive therapy.

TABLE OF CONTENTS/OUTLINE

1. Introduction and Epidemiology of IPH. 2. Classification of Pulmonary Hemosiderosis. 3. Clinical Presentation and Phases of Disease. 4. Imaging Features on Radiograph and HRCT. 5. Histopathologic Correlation and Diagnostic Criteria. 6. Differential Diagnosis: Vasculitis, Goodpasture, SLE. 7. Case Series: Pediatric and Adult Presentations. 8. Complications, Prognosis, and Management Considerations.

CHEE-63 THORACIC PARAGANGLIOMA: A RADIOLOGIST'S GUIDE TO IMAGING, DIFFERENTIALS, AND MANAGEMENT PITFALLS

Achala Donuru, MD (*Presenter*)
Ghanwa Khawaja, DO (*Abstract Co-Author*)
Rupali Jain, MD,MBBS (*Abstract Co-Author*)
Mariah Novy (*Abstract Co-Author*)
Vinay V. Kandula, MBBS (*Abstract Co-Author*)
Maruti K. Kumaran, MD (*Abstract Co-Author*)

TEACHING POINTS

Thoracic paragangliomas are rare neuroendocrine tumors originating from extra-adrenal chromaffin cells. While uncommon, radiologists play a crucial role in their initial detection, characterization, and guiding management, particularly in preventing life-threatening complications. Thoracic paragangliomas typically manifest as intensely enhancing, hypervascular masses on CT and MRI, often in characteristic locations like the paravertebral space or aortopulmonary window. Recognizing these features is key, but differentiating thoracic paragangliomas from mimics like neurogenic tumors, lymphadenopathy, vascular lesions, and rare cardiac masses requires careful analysis of location, morphology, and enhancement patterns. Functional imaging, especially Ga-DOTATATE PET/CT, is invaluable for confirming diagnosis, staging, and surveillance. Critically, radiologists must understand the potential for catecholamine secretion and communicate the absolute necessity of pre-procedural alpha-blockade before any intervention (biopsy or surgery) to prevent hypertensive crisis. This presentation reviews the spectrum of imaging findings, highlights key differentials with examples, discusses the utility of functional imaging, and emphasizes the radiologist's vital role in safe patient management.

TABLE OF CONTENTS/OUTLINE

Introduction: Paragangliomas significance and locations. Imaging Findings: CT & MRI hallmarks. Differential Diagnosis: Location-based approach with imaging examples. Functional Imaging: Role of Ga-DOTATATE PET/CT. Management: Radiologist's role, biopsy risks, alpha-blockade necessity. Conclusion & Key Takeaways.

CHEE-64 HRCT PATTERNS IN ILD AND THEIR MIMICKERS: A RAPID GUIDE FOR RADIOLOGY RESIDENTS

Diana Kokash, MD (*Presenter*)

TEACHING POINTS

Accurate interpretation of HRCT in ILD requires pattern-based analysis, emphasizing features such as ground-glass opacities, reticulation, honeycombing, and traction bronchiectasis. Distribution (upper vs lower lobe, peripheral vs central) and symmetry of findings provide key diagnostic clues. Differentiation of fibrotic from inflammatory changes is essential for treatment planning and prognosis. ILD mimickers such as infection, edema, drug toxicity, and neoplasms must be systematically excluded. Optimal HRCT technique (inspiratory, expiratory, and prone views when indicated) improves diagnostic accuracy. Follow-up HRCT plays a key role in monitoring disease progression, therapeutic response, and complications. Awareness of common pitfalls—such as mistaking dependent atelectasis or motion artifact for true fibrosis—enhances diagnostic reliability.

TABLE OF CONTENTS/OUTLINE

Introduction and Clinical Importance and follow up. HRCT protocol. Recognizing HRCT patterns Recognizing: UIP Pattern, NSIP Pattern, Organizing Pneumonia, Hypersensitivity Pneumonitis, acute interstitial pneumonia, Sarcoidosis Mimics of ILD Pitfalls Step-by-step approach to interstitial lung disease. Important checklist for follow up CT in ILD.

CHEE-65 PORTABLE DDR: BRINGING DYNAMIC CHEST IMAGING TO THE BEDSIDE

Michaela Cellina (*Presenter*)
Rossella Catona, MD (*Abstract Co-Author*)
Maurizio Ce, MD,BA (*Abstract Co-Author*)
Gabriele Drago, MD (*Abstract Co-Author*)
Stefano Pedrini (*Abstract Co-Author*)
Matilde Pavan, MD (*Abstract Co-Author*)
Giancarlo Oliva (*Abstract Co-Author*)

TEACHING POINTS

Portable DDR enables bedside dynamic chest imaging, offering functional insights into diaphragmatic motion, lung perfusion (contrast-free), and post-procedural complications.

TABLE OF CONTENTS/OUTLINE

DDR is a novel high-resolution imaging technique employing pulsed X-ray emission to rapidly acquire multi-frame sequential images of a targeted anatomical region, rendered as cine loops. Initially developed for orthostatic imaging, its recent integration into portable systems now enables dynamic acquisitions at the patient's bedside, unlocking the potential for new diagnostic insights. Diaphragmatic dysfunction, arising from various etiologies including vascular disorders, trauma, infections, neuromuscular diseases, and neoplasms, can be evaluated with DDR. This technique provides functional, structural, and morphological information across different breathing patterns, visually depicting diaphragmatic motion over time through color-coded curves and quantifying the range of motion to aid in diagnosis. Furthermore, DDR eases the assessment of lung motility and the identification of abnormal motion associated with adhesions, proving information in diagnosing breath abnormalities in lung cancer patients. Regional lung ventilation can be analyzed with color-coded maps, illustrating temporal changes in pixel density. This allows the identification of ventilation disparities and the evaluation of respiratory interventions, particularly in Intensive Care Units. Perfusion abnormalities, can be investigated without the need for contrast media, making it a safe alternative for patients with severe allergies or impaired renal function.

CHEE-66 MASTERING CONTRAST-ENHANCED CHEST CT: EVIDENCE AND PRACTICAL SOLUTIONS FOR OPTIMAL IMAGING

Masahiro Yanagawa, MD, PhD (*Presenter*)
Akinori Hata, MD, PhD (*Abstract Co-Author*)
Midori Ueno, MD (*Abstract Co-Author*)
Miyuki Tomiyama (*Abstract Co-Author*)
Daiki Nishigaki, PhD (*Abstract Co-Author*)
Shuhei Doi, MD (*Abstract Co-Author*)
Kazuki Yamagata, MD (*Abstract Co-Author*)
Yuka Fujita, MD (*Abstract Co-Author*)
Yukiko Tokuda, MD, PhD (*Abstract Co-Author*)
Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Recent advances in chest CT, particularly high-speed imaging and 3D reconstruction, have revolutionized diagnostic capabilities. While numerous studies have addressed CT contrast agents, evidence-based chest imaging protocols remain less detailed in the literature. This educational exhibit focuses on optimal protocols and practical considerations for thoracic neoplastic lesions, supported by illustrative clinical cases. It also provides evidence-based insights into contrast agent distribution and dynamics, state-of-the-art image reconstruction techniques, and clinical applications of dual-energy CT (DECT) and photon-counting CT (PCCT).

TABLE OF CONTENTS/OUTLINE

1. Pharmacokinetics and biodistribution of contrast agents: a) Mechanisms of distribution and excretion after intravascular administration. b) Effect of CT on organ enhancement due to patient factors (body weight, cardiac function, renal function, etc.) and technical factors (contrast agent injection speed, time, injection method) 2. Case-based CT protocols for standard thorax (excluding cardiac/major vessels), suspected pulmonary neoplasms, and suspected mediastinal tumors: Purpose & Indications, Optimized Contrast Timing including Dynamic CT, Imaging Parameters (kVp, mA, slice thickness, etc.), and Basic Reconstruction. 3. Advanced Technologies & Image Reconstruction a) DECT vs. PCCT: Principles & Material Differentiation. b) Clinical Importance of High Spatial Resolution / Spectral Imaging based on recent research. c) Image Reconstruction (including Deep Learning) for Radiation/Contrast Reduction. d) Green Radiology: Contribution to the reduction of environmental impact.

CHEE-67 LEARNING FROM IMAGING: UNDERSTANDING PULMONARY COMPLICATIONS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION

Sachiko Nakano (*Presenter*)
Kimiteru Ito (*Abstract Co-Author*)
Miyuki Sone, MD (*Abstract Co-Author*)

TEACHING POINTS

Nearly 100 hematopoietic stem cell transplantations (HSCT) are carried out per year at this institution. Given the substantial clinical experience accumulated, a collaboration on documenting comprehensive knowledge of pulmonary complications after hematopoietic stem cell transplantation is suggested. This documentation would encompass treatment strategies and post-transplant immune dynamics, with the aim of facilitating knowledge sharing. Immunity in hematopoietic stem cell transplantation will be learned about. Pulmonary diseases that can occur due to changes in immunity will be understood. Learn about the diagnostic process through case images."

TABLE OF CONTENTS/OUTLINE

: 1. Category of hematologic tumor.2. Therapy of hematologic tumor.3. Respiratory complications after HSCT.4. Image of pulmonary complications 1.5. Image of pulmonary complications 2.

CHEE-68 TUBED AND CONFUSED: A GUIDE TO CHEST TUBE MISPLACEMENTS

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Maximiliano Carrera (*Abstract Co-Author*)
Lyan Cabello Ballester (*Abstract Co-Author*)
Larry M. Alejandro Vargas, MD (*Abstract Co-Author*)
Jose Nieves-Munoz (*Abstract Co-Author*)
Hector Munoz-Miro (*Abstract Co-Author*)
Andrea M. Ruiz Mojica, MD (*Abstract Co-Author*)
Victor Guzman-Rivera, MD, MS (*Abstract Co-Author*)
Jose A. Maldonado, MD (*Abstract Co-Author*)

TEACHING POINTS

Review normal thoracic anatomy using a greenhouse analogy for engaging visual learning Discuss chest tube indications, types, and placement guidelines Identify normal imaging appearance of correctly placed tubes Highlight common malpositions (e.g., intrafissural, intraparenchymal, subcutaneous, intracardiac, kinked) with institutional case examples

TABLE OF CONTENTS/OUTLINE

Outline Introduction Objectives Anatomy relevant to chest tube placement Indications and tube types Placement guidelines Greenhouse analogy Misplaced tubes (subcutaneous, intracardiac, intrafissural, intraparenchymal, kinked) Imaging findings from institutional cases Conclusion Abstract Thoracostomy tubes are inserted into the pleural space to evacuate air, blood, or fluid. Correct placement is vital, as malpositioning can result in complications. This exhibit uses a greenhouse analogy—ribcage as greenhouse, lungs as trees, heart as fountain, and chest tubes as drainage pipes—to simplify spatial understanding. Misplacements such as intrafissural (tangled in branches), subcutaneous (outside the greenhouse), and intracardiac (piercing the fountain) are illustrated using real institutional cases. Chest tube types, placement techniques, and anatomical landmarks are reviewed, with X-ray and CT correlations. This visual guide enhances recognition of misplacement patterns, enabling timely intervention and improving patient outcomes.

CHEE-69 PULMONARY BLOOD FLOW ANALYSIS USING OBLIQUE DYNAMIC CHEST RADIOGRAPHY

Tasuku Nakajima, MPH, RT (*Presenter*)
Ryuichi USHIJIMA (*Abstract Co-Author*)
Rie Tanaka, PhD (*Abstract Co-Author*)
Aki Kido, MD, PhD (*Abstract Co-Author*)
Kyo Noguchi, MD (*Abstract Co-Author*)

TEACHING POINTS

Dynamic chest radiography (DCR) is a newly developed functional X-ray imaging technique that visualizes pulmonary blood flow without using contrast media (Fig. 1). DCR-based pulmonary blood flow findings are reportedly consistent with those in other imaging modalities, such as lung scintigraphy, pulmonary arteriography, and contrast-enhanced chest computed tomography (CT). However, DCR is usually performed in the posteroanterior (PA) direction, therefore, it cannot analyze the lung regions behind the heart in the PA direction. One solution is oblique imaging, as is done in lung scintigraphy. The purpose of this exhibit is to expose radiologists to a series of clinical cases in order to utilize oblique DCR to assess pulmonary blood flow in daily clinical settings.

TABLE OF CONTENTS/OUTLINE

Key diagnostic points will be highlighted in the discussion of each case using color-mapping images created by PA and oblique DCR, alongside corresponding clinical findings on CT, pulmonary angiography, and lung single photon emission computed tomography (SPECT). The list of cases includes: Follow-up of Chronic thromboembolic pulmonary hypertension (CTEPH), and Acute pulmonary embolism (PE) (Figs. 2,3,4) CTEPH before and after balloon pulmonary angioplasty (BPA) (Fig. 5)

CHEE-70 PULMONARY HYDATID DISEASE :RADIOLOGIC PEARLS FROM ENDEMIC REGION

Navdeep Kaur, MBBS,MD (*Presenter*)

TEACHING POINTS

Pulmonary hydatid disease is a key differential for cystic lung lesions , especially in patients from endemic regions or with a history of contact with livestock/dogs. CT thorax is the imaging modality of choice for characterizing hydatid cysts, detecting complications like rupture or infection, and identifying other organ involvement. Differentiating uncomplicated from complicated cysts is critical for guiding clinical management. Avoid needle aspiration or biopsy of suspected hydatid cysts , as rupture can lead to anaphylaxis and dissemination. Serologic testing can support diagnosis but is not always reliable , especially in isolated pulmonary cases—hence, imaging plays a central role. Radiologists play a crucial role in preoperative planning , by identifying the number, location, size, and complication status of the cysts.

TABLE OF CONTENTS/OUTLINE

Introduction - Overview of hydatid disease : etiology and epidemiology Pathophysiology and Life Cycle - Echinococcus granulosus and its pulmonary tropism- Stages of cyst development relevant to imaging Imaging Modalities and Findings- Chest radiograph: classic signs (e.g., water-lily, crescent signs) CT: identification of cyst integrity, daughter cysts, complications MRI and ultrasound (in select cases) Differential Diagnosis - Distinguishing from abscesses, neoplasms, congenital cysts, and fungal infections Key imaging pearls for differentiation Structured Imaging approach to diagnosis and management of Pulmonary Hydatid Cyst Teaching Points Take home message Case-Based Learning - Annotated case examples with step-by-step diagnostic reasoning- Interactive quiz for self-assessment

CHEE-71 CT IMAGING OF CYSTIC LUNG DISEASE

Shaun Aciu, MD (*Presenter*)
Katarina Stoffers (*Abstract Co-Author*)
Partha Hota, DO (*Abstract Co-Author*)
Chandra Dass, MD (*Abstract Co-Author*)
Yogesh S. Gupta, DO (*Abstract Co-Author*)

TEACHING POINTS

Provide a framework for understanding cystic lung diseases with a focus on the four major diffuse cystic lung diseases (DCLDs) most likely to be encountered on chest CT (i.e. lymphangioleiomyomatosis, lymphoid interstitial pneumonia, pulmonary Langerhans cell histiocytosis, Birt-Hogg-Dubé syndrome) Discuss important imaging features and key demographic variables that are critical to differentiating DCLDs and achieving an accurate diagnosis Present treatment options, which can meaningfully alter the natural history of disease progression and thereby underscore the necessity for accurate identification

TABLE OF CONTENTS/OUTLINE

: CT is the most valuable noninvasive modality in the diagnosis of DLCDs. By combining a discerning radiologic evaluation with select clinical characteristics, the radiologist can arrive at an accurate diagnosis in most instances. This allows for earlier disease intervention with reduction in morbidity and mortality. • Definition of a cyst and of cystic lung disease with differentiation from mimics (i.e. emphysema, cavity, cystic bronchiectasis, honeycombing) • Etiological classification of cystic lung diseases • CT imaging features of DCLDs with emphasis on major entities, including an algorithmic approach • Discussion of clinical variables, pathophysiology, histopathology, treatment options, and future directions of various DCLDs

CHEE-72 MUCIN-PRODUCING LESIONS OF THE LUNG: MANY FACES, ONE DIAGNOSIS

Danilo O. Ramos, MD (*Presenter*)

TEACHING POINTS

Review the types, pathophysiology, and epidemiology of mucin-producing lung lesions. Describe the diverse CT imaging appearances of invasive mucinous adenocarcinoma. Recognize tumor spread patterns and their prognostic implications. Highlight key differential diagnoses for multifocal consolidative lesions. Discuss the radiologist's role in initial diagnosis, follow-up, and management.

TABLE OF CONTENTS/OUTLINE

Imaging Modalities and Acquisition Protocols: Radiography, CT, PET/CT, Bronchoscopy imaging. Spectrum of Imaging Findings (CT Focus): Consolidation, ground-glass opacities, air-bronchograms, mucous bronchograms, centrilobular nodules ("tree-in-bud"), nodules and masses, cystic spaces, cavitations. Patterns of Tumor Spread and Case Follow-Up: Aerogenous/bronchogenic spread, hematogenous spread (rare), lymphatic dissemination (rare), pleural involvement (rare), spread through airspaces (STAS). Important Differential Diagnoses: Lymphoma, inflammatory myofibroblastic tumor, amyloidosis, vasculitis, granulomatous diseases (e.g., tuberculosis, silicosis), pulmonary hemorrhage, alveolar infiltrates (e.g., alveolar proteinosis, eosinophilic pneumonia).

CHEE-73 PULMONARY HYPERTENSION IN THE ERA OF ADVANCED CT: CLINICAL INSIGHTS FROM DUAL-ENERGY AND PHOTON-COUNTING TECHNOLOGIES

Daniel Selva, MD (*Presenter*)
Anton Aubanell, MD (*Abstract Co-Author*)
Marco Ciuffreda, MD (*Abstract Co-Author*)
Laura Maneu Bernado, MD (*Abstract Co-Author*)
Javier Saez, MD (*Abstract Co-Author*)
Lidia Canales, MD (*Abstract Co-Author*)
Ana M Gimenez Palleiro, MD (*Abstract Co-Author*)
Jose M Brenes, MD (*Abstract Co-Author*)

TEACHING POINTS

Pulmonary hypertension (PH) is a complex, multifactorial condition requiring a coordinated, multidisciplinary approach, with radiologists playing a key role in detecting and characterizing its causes. Recent studies support CT pulmonary angiography (CTPA) as the first-line imaging modality for diagnosing chronic thromboembolic pulmonary hypertension (CTEPH) (Group 4). It also enables comprehensive assessment of thoracic abnormalities linked to other PH groups, including COPD and interstitial lung disease (Group 3); systemic and metabolic conditions such as sarcoidosis and Langerhans cell histiocytosis (Group 5); fibrosing mediastinitis (Group 5); and congenital anomalies like intracardiac shunts, patent ductus arteriosus, and anomalous pulmonary venous return, which may be missed on transthoracic echocardiography (Group 1). Emerging technologies such as dual-energy and photon-counting CT offer enhanced anatomical and functional imaging, improving diagnostic accuracy and long-term management of PH.

TABLE OF CONTENTS/OUTLINE

Review the definition of pulmonary hypertension and the current etiological classification into clinically distinct groups. Provide a structured overview of specific radiologic findings, illustrated with clinical and pathological correlation. Emphasize the diagnostic utility of dual-energy CT and photon-counting CT in the evaluation of patients with pulmonary hypertension, particularly through the use of iodine perfusion maps and lung parenchymal density assessment, and compare these modalities with other functional imaging techniques, including SPECT.

CHEE-74 SEALED, BUT NOT HEALED: POSTOPERATIVE THORACIC COMPLICATIONS ON CT - A PICTORIAL ESSAY

Danilo O. Ramos, MD (*Presenter*)

TEACHING POINTS

Recognize the diversity of postoperative thoracic complications detectable on CT. Understand the importance of imaging timing and technique for early diagnosis. Identify critical CT patterns that suggest infectious, vascular, traumatic, or mechanical complications. Highlight the radiologist’s role in guiding clinical management and improving outcomes. Emphasize the necessity of vigilance to avoid missing subtle yet significant postoperative findings.

TABLE OF CONTENTS/OUTLINE

Introduction: Definition and significance of postoperative thoracic complications. Imaging Evaluation: Role of radiography and CT in postoperative assessment. Spectrum of Complications: Infectious (empyema, pneumonia), vascular (bleeding), traumatic (lung torsion, hilar hematoma), mechanical (bronchopleural fistula, pulmonary hernia, bronchial stenosis), and foreign body (gossypiboma). Key Imaging Findings: Typical CT appearances and differential considerations. Clinical Relevance: Importance of early recognition and multidisciplinary management. Conclusion: The radiologist’s essential contribution to optimizing postoperative outcomes.

CHEE-75 A FUNDAMENTAL APPROACH TO SMOKING RELATED INTERSTITIAL LUNG DISEASE

Andrew Moore, MD (*Presenter*)
Daffolyn Rachael Fels Elliott (*Abstract Co-Author*)
Gregory M. Lee, MD (*Abstract Co-Author*)
Jeffrey P. Kanne, MD (*Abstract Co-Author*)
Christopher Walker, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Smoking related interstitial lung disease (SR-ILD) is a common and likely underrecognized entity that lacks consensus in clinical, pathological, and radiological diagnosis. 2. A pattern-based approach to imaging can improve the radiologist’s accuracy. 3. Cessation of smoking can result in resolution, reversal, or stabilization of imaging and clinical findings of lung disease. 4. SR-ILD is broad and ranges from benign and potentially reversible clinical and radiological findings such as respiratory bronchiolitis, which occurs in nearly all smokers, to more chronic and severe diseases such as idiopathic pulmonary fibrosis. 5. Acute onset lung disease related to smoking may represent acute eosinophilic pneumonia and can be life-threatening.

TABLE OF CONTENTS/OUTLINE

Background/Epidemiology Cigarette smoking remains a significant contributor to morbidity/mortality worldwide SR-ILD is associated with cigarette use Pattern-based approach to radiologic diagnosis Review of pulmonary function tests (PFT) Clinical, pathological, and radiological manifestations of SR-ILD: Respiratory bronchiolitis (RB) Desquamative interstitial pneumonia (DIP) Pulmonary Langerhans cell histiocytosis (PLCH) Smoking related interstitial fibrosis (SRIF)/air space enlargement with fibrosis (AEF) Combined pulmonary fibrosis and emphysema (CPFE) Idiopathic pulmonary fibrosis (IPF) Acute eosinophilic pneumonia (AEP) E-cigarette and vaping associated acute lung injury (EVALI) Diagnostic controversies and consensus recommendations Conclusion

CHEE-76 UNRAVELING CYSTIC LUNG DISEASES: WHAT RADIOLOGISTS NEED TO KNOW

Ziyu Xian, MD (*Presenter*)
Daniel Kowal, MD (*Abstract Co-Author*)

TEACHING POINTS

Cystic lung diseases encompass a diverse and diagnostically challenging group of disorders, often presenting with overlapping clinical and imaging features. Unlike emphysema, pulmonary cysts typically have well-defined, perceptible walls and are frequently secondary to an underlying disease process. Early and accurate identification is crucial to guide appropriate patient management, prevent progressive pulmonary decline, and reduce the risk of associated complications. This educational exhibit will showcase the radiographic and computed tomography findings of both common and uncommon cystic lung diseases, including lymphangioleiomyomatosis, pulmonary Langerhans cell histiocytosis, lymphoid interstitial pneumonia, Birt-Hogg-Dubé syndrome, and Pneumocystis jirovecii pneumonia. We will emphasize key imaging characteristics such as cyst morphology, distribution patterns, and other associated pulmonary findings including ground-glass opacities and pulmonary nodules. Lastly, we will address common diagnostic mimickers such as emphysema, honeycombing, cystic bronchiectasis, cavities, bullae and pneumatoceles, highlighting distinguishing features to avoid potential pitfalls.

TABLE OF CONTENTS/OUTLINE

• Introduction• Cystic lung diseases. For each disease, will discuss pathophysiology, epidemiology, radiographic and HRCT features, and management• Cyst mimics• Summary comparison table/diagram • References

CHEE-77 THE RADIOLOGY HALL OF FAME: CHEST EDITION

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Carlos Perez Morales (*Abstract Co-Author*)
Ariana Salgueiro Estela (*Abstract Co-Author*)
Antonio De La Cruz, MD (*Abstract Co-Author*)
Amanda P. Marrero-Gonzalez, MD, BS (*Abstract Co-Author*)

TEACHING POINTS

Review commonly encountered chest eponyms with emphasis on clinical presentation, historical relevance, and key imaging features. Use a “Hall of Fame” format to aid recognition and learning of eponyms in thoracic and cardiac radiology. Illustrate imaging findings using radiographs and CTs from our institution to highlight diagnostic clues and clinical impact.

TABLE OF CONTENTS/OUTLINE

Introduction Objectives Subjects The Pulmonary Pavilion: Birt-Hogg-Dubé, Hampton’s Hump, Kerley B Lines, Chilaiditi Sign, Golden S Sign The Bronchial Boulevard: Kartagener Syndrome, Lady Windermere Syndrome The Cardiac Gallery: Tetralogy of Fallot, Ebstein Anomaly, Yamaguchi Syndrome, Marfan Syndrome, Takayasu Arteritis The Mediastinal Memorial: Pancoast Tumor, Kommerell Diverticulum The Thoracic Tapestry: Wegener’s Granulomatosis, Debakey Classification The Skeleton Atrium: Roesler’s Sign Imaging Findings Conclusion Abstract: Chest eponyms are imaging findings named after individuals who first described them. These often offer key diagnostic clues. This exhibit reviews over 15 thoracic and cardiac eponyms, highlighting historical background and characteristic imaging. Using themed sections and a “Hall of Fame” visual format, we incorporate institutional cases on radiographs, CTs, and MRIs. This exhibit serves as a useful educational tool for students, residents, and radiologists.

CHEE-78 THORACIC RADIOLOGY MEETS SPECTRAL CT: APPLICATIONS AND CLINICAL INSIGHTS

Rodrigo Sutil, MD (*Presenter*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Alejandra Somoano Marfull (*Abstract Co-Author*)
Silvia Revuelta Gomez, MD (*Abstract Co-Author*)
Cesar Antonio Lopez Lopez, MD (*Abstract Co-Author*)
Teresa Cobo Ruiz, MD (*Abstract Co-Author*)
Victor Fernandez Lobo (*Abstract Co-Author*)
Maria Elena Pena Gomez, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review the physical fundamentals and technical aspects of spectral imaging, as well as the advantages and limitations of its application in radiology. - Describe the applications of spectral imaging in thoracic radiology.

TABLE OF CONTENTS/OUTLINE

Spectral computed tomography is an advanced imaging technique known for its ability to decompose and characterise materials. The radiologist's knowledge of the physical fundamentals can be useful in understanding the different tools offered by this technique, its semiology, as well as its artifacts and limitations. In the field of thoracic radiology, it has made important contributions in the diagnosis of vascular diseases such as acute and chronic pulmonary thromboembolism, in the control of malignant lung masses treated with percutaneous ablation and has an emerging role in the characterisation of lung tumors.

CHEE-79 THORACIC PSEUDOANEURYSMS: A MULTI-VESSEL IMAGING REVIEW, ETIOLOGIES, DIAGNOSTIC MIMICS, AND MANAGEMENT STRATEGIES

Achala Donuru, MD (*Presenter*)
Rupali Jain, MD,MBBS (*Abstract Co-Author*)
Julia Jacob, MD (*Abstract Co-Author*)
Narainder Gupta, MD, FRCR (*Abstract Co-Author*)
Arun C. Nachiappan, MD (*Abstract Co-Author*)
Dongming Xu, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Pathophysiology Understand the mechanism of pseudoaneurysm formation vs. true aneurysms. Etiologies Recognize diverse etiologies (traumatic, infectious, iatrogenic, post-MI). Imaging Identify key imaging features on CT, MR, and Echo (neck, hematoma, communication). Modalities Appreciate strengths/weaknesses of CT, MR, and Echo for specific scenarios. Location Recognize imaging patterns based on vessel location (aorta, pulmonary, etc.). Mimics Differentiate pseudoaneurysms from true aneurysms, dissections, masses, cysts. Management Review endovascular, surgical, percutaneous, and conservative options. Pearls Implement a systematic approach for accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

I. Introduction: Definition and Significance of Thoracic Pseudoaneurysms II. Pathophysiology and Etiology: Mechanisms of Formation, Etiologic Classification (Traumatic, Infectious, Iatrogenic, etc.) III. Imaging Modalities: CT Angiography (CTA), MR Angiography (MRA), Echocardiography (TTE/TEE), Conventional Angiography IV. Pseudoaneurysms by Location V. Complications: Rupture, Thrombosis, Embolization, Cardiac Tamponade VI. Differential Diagnosis: True Aneurysms, Aortic Dissections, Mediastinal Masses, Hematomas, Pericardial Cysts, Ventricular Diverticula VII. Management: Endovascular Repair, Surgical Repair, Percutaneous Thrombin Injection, Conservative Management VIII. Diagnostic Approach Flowchart Summarize the systematic approach to evaluating a patient with suspected pseudoaneurysm with a flow chart. IX. Conclusion: Key Takeaways and Importance of Multidisciplinary Approach

CHEE-80 HIDDEN IN PLAIN SIGHT: THORACIC TUMORS MASQUERADING AS NON-THORACIC CONDITIONS

Makiko Murota, MD (*Presenter*)
Yuka Yamamoto, PhD (*Abstract Co-Author*)
Yoshihiro Nishiyama, MD (*Abstract Co-Author*)

TEACHING POINTS

Thoracic tumors, including lung cancer, may be associated with chief complaints in other parts of the body or other disease. However, in such cases, the possibility of thoracic tumors may not be recognized or overlooked. The purpose of this presentation is to expose radiologists to such challenging cases, enabling them to recognize the association with thoracic tumors and their imaging findings.

TABLE OF CONTENTS/OUTLINE

Explanations of the pitfall and how it is associated with thoracic tumors, clinical considerations and relevance, and imaging findings will be provided. 1. neurological complaint, 2. otolaryngological complaint, 3. orthopaedical complaint, 4. disorders of the endocrine system, and 5. Others.

CHEE-81 RADIOLOGICAL SPECTRUM OF CLAD: INSIGHTS FROM THE UPDATED ISHLT DIAGNOSTIC CRITERIA

Taiki Fukuda, MD, PhD (*Presenter*)
Yusei Nakamura, MD (*Abstract Co-Author*)
Shu Chi Tseng, MD (*Abstract Co-Author*)
Yuki Ko (*Abstract Co-Author*)
Staci Gagne, MD (*Abstract Co-Author*)
Takeshi Johkoh, MD, PhD (*Abstract Co-Author*)
Yi Li (*Abstract Co-Author*)
David Christiani, MD (*Abstract Co-Author*)
Hiroya Ojiri, MD (*Abstract Co-Author*)
Lynette M. Sholl (*Abstract Co-Author*)
Mizuki Nishino, MD, MPH (*Abstract Co-Author*)
Hiroto Hatabu, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand updated ISHLT criteria for chronic lung allograft dysfunction (CLAD) and its radiological classifications into distinct phenotypes. 2. Recognize characteristic imaging findings of restrictive allograft syndrome (RAS)-like opacities (RLOs), bronchiolitis obliterans syndrome (BOS), and their mixed presentations. 3. Identify the temporal evolution of radiological patterns in CLAD, including COVID-19-associated manifestations. 4. Recognize the limitations in radiological differentiation between undefined and unclassifiable CLAD phenotypes and the association with diaphragmatic elevation and pleural effusion. 5. Understand the role of radiological findings in clinical decision-making and long-term monitoring of CLAD progression in lung transplant recipients.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Outline the new ISHLT diagnostic criteria; Impact of radiological phenotyping on treatment and outcomes in lung transplant patients. 2. Radiological manifestations of CLAD phenotypes: Demonstrate the characteristic CT findings of RLOs, BOS, and mixed pattern presentations. 3. Temporal evolution of radiological findings: Sequential imaging changes in CLAD progression, with focus on RLOs. 4. COVID-19 and CLAD: COVID-19 as a potential trigger for RLOs development. 5. Undefined and unclassified phenotypes: Radiological overlap between phenotypes, particular attention to the significance of diaphragmatic elevation and pleural effusion. 6. Clinical applications and management strategies: Clinical applications of various radiological evaluations in CLAD management; Emphasize the value of imaging assessment in predicting outcomes and guiding treatment decisions.

CHEE-82 STEPWISE APPROACH TO TRACHEAL ABNORMALITIES ON CT

Melisa Prieto Peralta, MD (*Presenter*)
Kiran Batra, MD (*Abstract Co-Author*)
Asha Kandathil, MD (*Abstract Co-Author*)
Arzu Canan, MD (*Abstract Co-Author*)

TEACHING POINTS

Tracheal abnormalities cover a broad spectrum, including congenital defects, infections, inflammation, and neoplastic conditions. These abnormalities can be focal or diffuse and are often linked with systemic diseases. CT offers an effective tool for identifying and diagnosing these conditions. This presentation aims to provide a clear, stepwise approach to evaluating tracheal abnormalities on CT, helping radiologists improve their ability to confidently recognize and differentiate various pathologies.

TABLE OF CONTENTS/OUTLINE

A.Introduction B.Stepwise approach:1-Identify Structural Variations a.Tracheal bronchus b.Cardiac bronchus c.Diverticula 2-Evaluate for tracheal nodules a.Assess number of nodules b.Single nodule i.Benign:Mucus plug, hamartoma, chondroma,papilloma,amyloidoma ii.Malignant:Squamous cell carcinoma,carcinoid,adenoid cystic carcinoma, mucoepidermoid carcinoma,sarcoma, IMT c.Multiple nodules-Consider diffuse processes: Mucus, papillomatosis, TB/BOCP, metastases.3-Assess tracheal diameter a.Increased diameter i.Tracheobronchomegaly ii.Tracheomalacia iii.Saber sheath trachea b.Decreased diameter i.Evaluate for extrinsic compression:Goiter, LAP, fibrosing mediastinitis ii.Assess extension of tracheal involvement 1.Focal:Post-intubation stenosis,Post-RT stenosis, Congenital tracheal stenosis 2.Diffuse:Associated with wall thickening: a.Horse-show type thickening: Relapsing polychondritis,TB/BOCP b.Circumferential thickening: Infectious,amyloidosis,GPA,sarcoidosis,IBD 4-Additional imaging techniques a.Expiratory CT b.Dynamic airway CT 5-Clinical Correlation and Associated abnormalities.Conclusion

CHEE-83 MULTIMODALITY SNIFF TESTING FOR DIAPHRAGM DYSFUNCTION: COMPREHENSIVE EVALUATION WITH FLUOROSCOPY AND ULTRASOUND

Albert Chiu, DO (*Presenter*)
Kristina Yancey, MD (*Abstract Co-Author*)
Amar Shah, MD (*Abstract Co-Author*)
Mark D. Sugi, MD (*Abstract Co-Author*)
Maria Zulfiqar, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Review the anatomical and physiological underpinnings of the diaphragm relevant to dynamic evaluation (sniff testing). Master fluoroscopic and ultrasonographic techniques for accurate, real-time evaluation of diaphragmatic function. Identify critical imaging findings that guide management, including those that indicate further testing, surgical referral, or supportive therapy.

TABLE OF CONTENTS/OUTLINE

Anatomy and Physiology Overview Clinical anatomy of the diaphragm Mechanics of diaphragmatic motion during normal breathing and sniff testing. Innervation and implications of phrenic nerve dysfunction Fluoroscopic Sniff Test Equipment setup and patient positioning Technique for dynamic assessment Normal, diminished, and paradoxical motion examples Limitations and radiation considerations Ultrasound Sniff Test (M-mode) Probe positioning and image optimization M-mode waveforms: normal, reduced, and paradoxical motion patterns Advantages in pediatric, intensive care, and radiation-sensitive populations Comparative Analysis of Modalities Strengths and limitations of fluoroscopy vs ultrasound Situational recommendations based on patient factors and institutional resources Case-Based Review Annotated examples of normal and abnormal findings Paradoxical elevation due to paralysis or phrenic nerve palsy. Decreased or absent movement due to partial paralysis, weakness, chronic eventration Delayed motion due to early or partial phrenic nerve injury Fixed elevation due to chronic eventration, massive pleural effusion, or prior surgery/scarring Tips for accurate interpretation and reporting Correlation with clinical outcomes

CHEE-84 THE "SHORT" END OF THE STICK: A COMPREHENSIVE REVIEW OF TELOMERE-RELATED INTERSTITIAL LUNG DISEASE WITH SYSTEMATIC AND CASE-BASED APPROACH

Omer Onder, MD (*Presenter*)
Brittany Cody (*Abstract Co-Author*)
Zehavit Kirshenboim (*Abstract Co-Author*)
Kyung Hee Lee (*Abstract Co-Author*)
Emrah Duman, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Telomeres are repetitive DNA-protein complexes at chromosome ends that maintain genomic integrity and regulate cellular aging. Short telomeres cause premature senescence and impaired tissue repair. Multisystem clues such as premature graying, hematologic abnormalities, or cryptogenic cirrhosis should raise suspicion for short telomere syndromes in patients with interstitial lung disease (ILD). 2. Telomere-related ILD most commonly shows a UIP pattern on CT but may also present with atypical features or emphysema, complicating radiologic-pathologic correlation. Histopathology often reveals overlapping fibrotic patterns without a pathognomonic marker, requiring clinical and genetic data for accurate diagnosis. Post-transplant, these patients face increased risks of airway complications, marrow failure, and viral infections, requiring tailored immunosuppression and close monitoring. 3. This exhibit provides a comprehensive review of telomere-related ILDs through case examples, summarizing key literature insights and providing practical clues for clinical care. Recognizing these distinct features and ensuring multidisciplinary coordination are vital for timely transplant evaluation, personalized management, and anticipation of post-transplant complications.

TABLE OF CONTENTS/OUTLINE

A. Introduction: Telomeres B. Telomere length testing C. Short telomere syndromes D. Telomere-related ILDs - Clinical findings - Radiological patterns - Histopathological features - Important considerations - Case examples F. Post-transplant complications - Airway complications - Hematological complications - Infectious complications - Other complications G. Summary H. Conclusion

CHEE-85 BEYOND INVASIVE ADENOCARCINOMA: A VISUAL GUIDE TO PERSISTENT SUBSOLID PULMONARY NODULES ON CT

Yanyan Xu, MD, PhD (*Presenter*)
He Chen (*Abstract Co-Author*)
Sheng Xie (*Abstract Co-Author*)
Min Xu, PhD (*Abstract Co-Author*)

TEACHING POINTS

1.Classify the spectrum of persistent SSNs into neoplastic (adenocarcinoma spectrum) and non-neoplastic (infectious/inflammatory) etiologies.2.Identify key CT features to differentiate benign vs. malignant SSNs3.Propose evidence-based management pathways based on Fleischner Society guidelines

TABLE OF CONTENTS/OUTLINE

I. Introduction A. Clinical Significance, Diagnostic challenge; B. Objectives of the Exhibit; 3. Provide evidence-based management algorithms to guide biopsy/follow-up decisions. II. Spectrum of Persistent Subsolid Nodules A. Neoplastic Etiologies (80% of cases) 1. Preinvasive lesions - Atypical adenomatous hyperplasia (AAH); Adenocarcinoma in situ (AIS). 2. Invasive adenocarcinoma: - Minimally invasive (MIA); Invasive adenocarcinoma. B. Non-Neoplastic Etiologies (20% of cases) 1. Infectious - Fungal (e.g., cryptococcosis; mucormycosis; Tuberculosis. 2. Inflammatory: - Organizing pneumonia (OP); Pulmonary capillary hemangiomatosis (PCH). III. Key Differentiating Features on CT A. Malignant Clues - Morphology, Kinetics, Quantitative metrics. B. Benign Mimics. C. Case Examples IV. Diagnostic Algorithm & Management A. Flowchart: "When to Biopsy?" . B. Pitfalls to Avoid V. Teaching Tools & Visual Strategy A. Interactive Elements - Quiz: "Malignant or Benign?". B. Take-Home Infographic VI. Conclusion & Future Directions - Persistent SSNs require integration of “morphology + kinetics + clinical context” - Emerging tools: AI-based risk stratification (e.g., radiomics). - Call to action: Standardize follow-up protocols to reduce unnecessary procedures.

CHEE-86 MANUAL FOR PECTORAL MUSCLE EVALUATION: KEY INSIGHTS FOR THE THORACIC RADIOLOGIST

Enzo Calheiros, MD (*Presenter*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Bruno Ramos, MD (*Abstract Co-Author*)
Maria Vitoria Ludwig, MD (*Abstract Co-Author*)
Daniel Giunchetti Strabelli, MD (*Abstract Co-Author*)
Renata F. Batista Pereira, MD (*Abstract Co-Author*)
Marcos Felippe D. Correa, MD (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)
Cesar H. Nomura, MD, PhD (*Abstract Co-Author*)
Lucas d. Gomes de Farias, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Imaging exams like CT and MRI are key in diagnosing issues with the pectoral muscles, such as trauma, tumors, or postoperative changes, with the thoracic radiologist playing a crucial role in detecting abnormalities.- Knowledge of normal and pathological variations in the pectoral muscles is essential for accurate radiological evaluation, which impacts clinical management and patient prognosis.- While CT is effective for assessing bone injuries, MRI is the preferred modality for evaluating pectoral muscles due to its superior ability to differentiate soft tissues, identify muscle injuries, and detect conditions like edema, hematomas, and fibrosis.- MRI excels at distinguishing benign from malignant lesions and provides information for accurate lesion localization, guiding treatment decisions. It is essential for assessing the relationship between pectoral muscles and surrounding structures, especially in surgical planning for breast reconstruction or aesthetic procedures.- The thoracic radiologist must have proficiency in differentiating normal anatomical variants from pathological findings is fundamental to avoid misinterpretation and unnecessary interventions.

TABLE OF CONTENTS/OUTLINE

1. Background:- Anatomy2. Normal variants- Pectoralis quartis muscle- Sternalis muscle3. Post-mastectomy changes4. Trauma - CT vs. MRI - Tendon rupture5. Aesthetic modifications6. Tumors7. Summary and take-home messages

CHEE-87 UNUSUAL DISEASE-SPECIFIC THORACIC MANIFESTATIONS IN CONNECTIVE TISSUE DISEASE

Ryan Walsh, MBBCh, BSc (*Presenter*)
Laura Marsland, MBChB (*Abstract Co-Author*)
Hasti Robbie, MD (*Abstract Co-Author*)

TEACHING POINTS

Connective tissue disease (CTD)-associated interstitial lung disease (ILD) presents with a range of distinct imaging features that can help refine the differential diagnosis. Recognising these patterns is crucial for accurate assessment. For example, Shrinking Lung Syndrome (SLS) in systemic lupus erythematosus (SLE) manifests as progressive lung volume loss and restrictive function without evidence of ILD or pleural disease. Rheumatoid usual interstitial pneumonitis (RA-UIP) can be differentiated from idiopathic UIP by signs such as anterior upper lobe involvement, a straight edge appearance, and exuberant honeycombing. Melanoma differentiation-associated protein 5 (MDA5) anti-synthetase syndrome, part of the idiopathic inflammatory myopathy spectrum, is notable for rapidly progressive ILD with high early mortality; high-resolution CT may reveal a "reverse oedema" pattern and diaphragmatic "hugging." In Sjögren's syndrome, lymphocytic interstitial pneumonia (LIP) is characterised by perivascular cysts and ground glass opacities, while diffuse alveolar haemorrhage (DAH) in SLE typically shows a crazy-paving pattern on CT and carries high mortality without plasmapheresis.

TABLE OF CONTENTS/OUTLINE

This exhibit will review the diagnostic value of unusual CTD thoracic findings on CT, illustrated through a case series covering SLS in SLE, rapidly progressive ILD in MDA5+ syndrome, LIP in Sjögren's, acute SLE manifestations, rheumatoid-ILD, hypersensitivity pneumonitis in RA, emphysema in never-smokers with RA or scleroderma, and the distinction between reversible and irreversible CTD-ILD. Key reporting points and take-home messages will be summarised.

CHEE-88 RADIOLOGICAL-PATHOLOGICAL CORRELATION IN CONNECTIVE TISSUE DISEASE-ASSOCIATED LUNG DISEASES

Tae Iwasawa, MD, PhD (*Presenter*)
Tomoe Sawazumi (*Abstract Co-Author*)
MAI MATSUMURA (*Abstract Co-Author*)
Tamiko Takemura, MD, PhD (*Abstract Co-Author*)
Tomohisa Baba (*Abstract Co-Author*)
Takashi Ogura (*Abstract Co-Author*)
Akira Haga, MD, PhD (*Abstract Co-Author*)
NAOFUMI YASUDA (*Abstract Co-Author*)
Shoichiro Matsushita, MD (*Abstract Co-Author*)

TEACHING POINTS

Computed tomography (CT) findings in connective tissue disease-associated interstitial lung disease (CTD-ILD) are often complex due to overlapping pathological features such as bronchiolitis, usual interstitial pneumonia (UIP), and nonspecific interstitial pneumonia (NSIP). As ILD classification is primarily histopathological, radiologists must understand the pathological correlates of these imaging patterns. However, according to the 2023 ILD guidelines of the American College of Rheumatology, surgical lung biopsy is not recommended for suspected CTD unless malignancy is suspected. This study describes CT images with corresponding histological findings in patients not initially diagnosed with CTD to help radiologists understand CTD-associated lung disease.

TABLE OF CONTENTS/OUTLINE

1) Dermatomyositis: Loss of lung volume suggests diffuse alveolar damage (Fig. 1). 2) Systemic sclerosis: NSIP is the most common disease; however, UIP may occur. Discordant patterns were frequently observed (Figs. 2, 3). 3) Rheumatoid arthritis: Cellular and destructive bronchiolitis are the key histological features (Figs. 4, 5). 4) Sjögren's syndrome: airway disease, ILD, and lymphoproliferative disorders coexist and produce diverse CT patterns (Figs. 6,7). 5) Pulmonary hypertension (PH): Enlargement of the main pulmonary artery and right ventricular hypertrophy suggest PH, and interlobular septal thickening and ground-glass opacities may indicate pulmonary veno-occlusive disease (Fig. 8).

CHEE-89 LOOKING UP FOR A DIAGNOSIS: IMAGING AND DIFFERENTIAL DIAGNOSIS OF UPPER-ZONE PREDOMINANT LUNG DISEASES

Felipe Castillo Aravena, MD (*Presenter*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)
Felipe S. Torres, MD, PhD (*Abstract Co-Author*)
Micheal McInnis, MD (*Abstract Co-Author*)
Felipe A. Sanchez, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

1. Awareness of normal anatomic and physiologic differences between the upper and lower lobes is essential for accurate interpretation of lung diseases. 2. Differences in V/Q ratio, lymphatic flow, mechanical stress, and an alkaline environment explain the upper-zone predominance of lung diseases. 3. Several diseases—including sarcoidosis, tuberculosis, hypersensitivity pneumonitis, and pulmonary Langerhans cell histiocytosis—share an upper-zone predominance, but can be differentiated by their hallmark imaging findings and associated clinical scenarios. 4. Characteristic imaging features combined with their zonal distribution are key to narrowing the differential diagnosis and avoiding pitfalls.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Zonal anatomy and physiology of the lungs 2. Pathophysiology of upper-zone predominant diseases: Ventilation/perfusion ratio. Lymphatic drainage and clearance. Mechanical forces and stress points. Alkaline regional environment. 3. Granulomatous diseases: Sarcoidosis. Pneumoconiosis. Tuberculosis 4. Hypersensitivity-related diseases: Hypersensitivity pneumonitis (HP). Allergic bronchopulmonary aspergillosis (ABPA) 5. Smoking-related diseases: Emphysema. Respiratory bronchiolitis. Pulmonary Langerhans cell histiocytosis (PLCH) 6. Mechanical/structural stress-related diseases: Pleuroparenchymal fibroelastosis (PPFE). Marfan syndrome 7. Alkaline regional environment diseases: Metastatic pulmonary calcification (MPC) 8. Pearls and pitfalls 9. Summary table

CHEE-90 UNMASKING THE GENTLE GIANT : A RADIOLOGIST'S GUIDE OF SOLITARY FIBROUS TUMOR OF THE PLEURA

Andita D. Hidayati, MD (*Presenter*)
Daniel Vargas, MD (*Abstract Co-Author*)
Daniel Ocazionez-Trujillo, MD (*Abstract Co-Author*)
Ameya J. Baxi, MBBS,DMRD (*Abstract Co-Author*)
Vijay K. Aggarwal, MBBS (*Abstract Co-Author*)
Carlos S. Restrepo, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the etiology, histology, and epidemiology of solitary fibrous tumors (SFT) of the pleura as well as understand the mesenchymal origin and variable behavior (benign vs malignant) of SFTs 2. Structured approach to recognizing key imaging characteristics of solitary fibrous tumor across modalities, including features that suggest malignant transformation and differentiating them from other mimics 3. Review paraneoplastic manifestations associated with SFTs 4. Apply imaging clues to predict tumor aggressiveness and guide clinical management

TABLE OF CONTENTS/OUTLINE

- Learning objectives- Introduction- Embryology and anatomy- Case series with imaging hallmarks of SFT of the pleura with conventional and advanced imaging- Benign vs malignant transformation: Imaging Differentiators- SFT Mimics and Differential Diagnosis- Management- Summary

CHEE-91 PULMONARY INFECTIONS IN IMMUNOCOMPROMISED PATIENTS: A RADIOLOGIC REVIEW

Rodolfo de Jesus Martinez Marquez, MD (*Presenter*)
Luis A. Sosa, MD (*Abstract Co-Author*)
Maria G. Gracia Munoz, MD (*Abstract Co-Author*)

TEACHING POINTS

To review radiologic manifestations of pulmonary infections in immunocompromised patients and correlate imaging features with specific pathogens. | To highlight key imaging signs that can guide differential diagnosis based on the immune defect and clinical setting. | To emphasize the importance of recognizing infection patterns linked to community acquired, nosocomial, reactivation, and environmental exposures.

TABLE OF CONTENTS/OUTLINE

Brief overview of immunodeficiencies and associated risk factors. | Classification of infections by source and mechanism (community-acquired, nosocomial, reactivation, environmental). | Review of common pathogens: bacteria (e.g., Mycobacteria), viruses (e.g., CMV, HSV, VZV), and fungi (e.g., Pneumocystis , Aspergillus , Cryptococcus). | Imaging hallmarks of each pathogen group. | Diagnostic strategies and interpretive tips for radiologists.

CHEE-92 THERE'S SOMETHING GLEAMING INSIDE! IMAGING OF PRIMITIVE AND SECONDARY HYPER-ENHANCING LESIONS OF THE MEDIASTINUM

Chiara Moroni, MD (*Presenter*)
Diletta Cozzi, MD (*Abstract Co-Author*)
Edoardo Cavigli, MD (*Abstract Co-Author*)
Vittorio Miele, MD (*Abstract Co-Author*)

TEACHING POINTS

Mediastinal lesions are rare entities with heterogeneous imaging characteristics. In few cases they may show intense contrast enhancement representing pathological growing of specific tissues or hypervascular metastases from other districts. In this pictorial review we report primitive and secondary hyper-enhancing mediastinal lesions (HEML) from a single tertiary center focusing on tissue origin, site of onset and imaging presentation, to help the radiologist in the differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Primitive HEMLs generally originate from specific structures (Table 1): - Nervous system: Antoni A Swannomas and malignant peripheral nerve sheath tumors may be hyper-enhancing and are preferably (though not-exclusively) found in the posterior mediastinum (PM) (fig 1). - Vasculature: angiosarcomas may show hyper-enhancing foci and are generally described in the anterior mediastinum (AM) (fig 2). - Lymphatics: unicentric Castleman's disease is a rare, non-clonal lymphoproliferative disorder commonly described as a hyperenhancing mediastinal mass. -Neuroendocrine tissue: paragangliomas derive from paraganglia and can be located in the posterior or middle mediastinum; thymic neuroendocrine tumors (NETs) show generally high heterogenous enhancement in the AM; esophageal NETs, besides, arise in PM (fig 3). - Soft tissues: synovial sarcoma is a spindle-cell sarcoma and is the most frequently found in the mediastinum. -Thyroid and parathyroid: ectopic thyroid and parahtyroid, thyroid and parathyroid tumors or goitre may be HEMLs (fig 4). Secondary HEMLs derive mostly from neuroendocrine, renal and thyroid tumors or from melanoma and hepatocellular carcinoma.

CHEE-93 CHEST CT USING SILVER BEAM FILTER: LUNG NODULE DETECTION WITH ULTRA-LOW RADIATION DOSE

Hiroshi Moriya, MD, PhD (*Presenter*)
Motoharu Hakozaki (*Abstract Co-Author*)
Masahiro Suzuki (*Abstract Co-Author*)
Kenji Fujii (*Abstract Co-Author*)

TEACHING POINTS

1.Reduction of radiation exposure with Silver Beam Filter 2.Image quality evaluation of CT equipped with Silver Beam Filter: Phantom-based evaluation 3.Pulmonary nodule detection capability of ultra-low-dose CT equipped with Silver Beam Filter

TABLE OF CONTENTS/OUTLINE

1. Reduction of radiation exposure with Silver Beam Filter The Silver Beam Filter (Ag) absorbs low-energy X-rays and shifts them to higher energies, significantly reducing radiation exposure. Deep Learning-based image reconstruction enables ultra-low dose CT scans with low noise. 2. Image quality evaluation of CT equipped with Silver Beam Filter Phantom used: patient-specific lung phantom created with a 3D printer (created from clinical lung images of ultra-high resolution CT). Reference: Three-dimensional printing of patient-specific lung phantoms for CT imaging: Emulating lung tissue with accurate attenuation profiles and textures. Med Phys. 2022) Equipment: 320-row area detector CT (Aquilion ONE / INSIGHT Edition) Scanning conditions: 3D Landmark Scan, 120kV(Ag), tube current 40, 20, 10 mA, 0,5sec rotation, CTDI 0.04, 0.14, 0.36, Image reconstruction: FBP, iterative reconstruction (AIDR3D), Deep Learning Reconstruction (AiCE LUNG), ultra-high-resolution reconstruction (PIQE). 3.Pulmonary nodule detection capability of ultra-low-dose CT equipped with Silver Beam Filter Using Silver Beam Filter, ultra-low dose helical scan (3D Landmark Scan, 120kV(Ag), 40mA, CTDI 0.2) data was reconstructed with PIQE image reconstruction. The nodule detection capabilities of conventional CT and ultra-low-dose CT were compared in 200 consecutive cases.

CHEE-94 CLINICAL APPLICATIONS OF ELECTRON DENSITY IMAGING DERIVED FROM DUAL-ENERGY CT IN THORACIC RADIOLOGY

Hiroaki Nagano, MD, PhD (*Presenter*)
Koji Takumi, MD, PhD (*Abstract Co-Author*)
Ryota Nakanosono, MD (*Abstract Co-Author*)
Fumitaka Ejima (*Abstract Co-Author*)
Tsubasa Nakano (*Abstract Co-Author*)
Masanori Nakajo, MD (*Abstract Co-Author*)
Kiyohisa Kamimura, MD, PhD (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Recent technical advancements in dual-energy CT (DECT) allow measurement of electron density (ED) in tissues. ED, which reflects the probability of an electron occurring at a specific location, shows a linear correlation with mass density and Hounsfield units. ED imaging allows visualization and quantification of mass density and has been reported to enhance disease detection, diagnosis, and prognostication in thoracic imaging. The purposes of this exhibit are: 1. To illustrate the basic principles of ED derived from DECT 2. To illustrate clinical cases and data with ED in the field of thoracic radiology 3. To discuss pitfalls and limitations of ED

TABLE OF CONTENTS/OUTLINE

1. Basic principles of ED derived from DECT 2. Overview of ED in the field of thoracic radiology 3. Clinical applications of ED in thoracic imaging: Lung cancer (lesion detection, accurate tumor staging, prediction of pathological aggressiveness, PD-L1 expression, and treatment response) Pneumonia lesion detection Pulmonary embolism (lesion detection, differentiation between chronic thromboembolic pulmonary hypertension and acute pulmonary embolism, and prediction of treatment response) Cardiovascular disease (diagnosis of acute myocardial infarction, characterization of coronary artery plaque, detection of thrombus) 4. Pitfalls and limitations in ED

CHEE-95 MULTI-FOCAL PULMONARY CONSOLIDATION ON CHEST CT: A SYSTEMATIC IMAGING-BASED APPROACH TO DIFFERENTIAL DIAGNOSIS

Makiko Murota, MD (*Presenter*)
Yuka Yamamoto, PhD (*Abstract Co-Author*)
Yoshihiro Nishiyama, MD (*Abstract Co-Author*)

TEACHING POINTS

Consolidation on chest CT is frequently assumed to represent bacterial pneumonia, particularly in clinical practice. However, multi-focal consolidation can be caused by a wide variety of diseases, including interstitial lung disease and malignancies, making careful differential diagnosis essential. This exhibit will 1) review the high-resolution CT (HRCT) findings of pulmonary multi-focal consolidation, and 2) present a systematic approach to its differential diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Definition of consolidation Based on Fleischner society's glossary of terms for thoracic imaging 2. Approach to differential diagnosis A) Acute vs. subacute/chronic clinical course B) Distribution pattern (e.g., segmental or non-segmental; upper or lower lung predominance; central vs. peripheral predominance) C) Morphologic characteristics of the opacities D) Integration of clinical information (e.g., medical history, laboratory data) 3. Key imaging features for differential diagnosis A) Centrilobular nodules B) Cavitation C) Interlobular septal thickening D) Bulging fissure E) High- or low-attenuation areas on mediastinal window settings 4. Summary

CHEE-96 CYSTS, CAVITIES, AND CONFUSION: A RADIOLOGY TRAINEE'S GUIDE TO DIAGNOSING AND MANAGING CYSTIC LUNG DISEASE

Ronald Gathagan, MD (*Presenter*)
Caroline Merriam, DO (*Abstract Co-Author*)
Manroop Kaur, MD (*Abstract Co-Author*)
Cristina Fuss, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Cystic lung diseases present a diagnostic challenge requiring careful assessment of imaging features and clinical context. High-resolution CT is essential for evaluation, but distinguishing between benign and more serious causes demands a structured approach. Early recognition is critical for appropriate management and avoidance of complications. This presentation aims to equip radiology trainees with a framework for interpreting cystic lung diseases. Key entities include pulmonary Langerhans cell histiocytosis, lymphangioleiomyomatosis, lymphocytic interstitial pneumonia, Pneumocystis jirovecii pneumonia, and congenital anomalies such as CPAM and pulmonary sequestration. Emphasis will be placed on characteristic imaging patterns, distribution clues, and common pitfalls to improve diagnostic confidence.

TABLE OF CONTENTS/OUTLINE

Basic Principles Definition, importance of HRCT Major Cystic Lung Diseases Pulmonary Langerhans cell histiocytosis (PLCH) Lymphangioleiomyomatosis (LAM) Lymphocytic interstitial pneumonia (LIP) Pneumocystis jirovecii pneumonia (PJP) Congenital anomalies (CPAM, sequestration) Associated Causes Infectious Autoimmune: SLE, JIA, Kawasaki, IBD Malignancy: Leukemia, lymphoma, neuroblastoma, metastases Post-surgical/Trauma: Post-pericardiotomy, chest trauma Complications and common pitfalls Pneumothorax, superimposed infection Misidentifying emphysema/cavities Missing systemic clues (e.g., TSC, autoimmune)

CHEE-97 BEYOND THE GUT: PATTERNS, PITFALLS AND TREATMENT-RELATED COMPLICATIONS IN INFLAMMATORY BOWEL DISEASE

Caroline Novis, MD (*Presenter*)
Gabriel Belizario Amorim Silva, MD (*Abstract Co-Author*)
Renata Nabeiro Dias Angelo, MD (*Abstract Co-Author*)
Luiza A. Oliveira Gatto, MD (*Abstract Co-Author*)
Tassia R. Yamanari, MD (*Abstract Co-Author*)
Eduardo Kaiser Ururahy Nunes Fonseca, MD (*Abstract Co-Author*)
Camila S. Franco, BMedSc (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

To review thoracic manifestations of inflammatory bowel disease (IBD), focusing on complications arising from systemic disease and immunosuppressive therapy. To illustrate a spectrum of infectious and non-infectious pulmonary findings associated with IBD through real-case examples. To discuss imaging clues that aid in distinguishing overlapping patterns in immunocompromised patients, supporting timely diagnosis and treatment.

TABLE OF CONTENTS/OUTLINE

Introduction : Overview of IBD as a systemic disease and its impact on the thorax, particularly under immunosuppression. Pathophysiology and Mechanisms : Pulmonary involvement through immune-mediated mechanisms vs. therapy-related complications. Non-infectious Manifestations : Imaging features of organizing pneumonia, granulomatous inflammation, and drug-induced lung disease. Infectious Complications : Case-based review of opportunistic infections (e.g., TB, histoplasmosis, nocardiosis, aspergillosis). Imaging Patterns and Diagnostic Pitfalls : Overlapping features between infection and inflammation, with emphasis on CT findings and clinical correlation. Differential Diagnosis and Management Impact : Role of imaging in guiding further testing, biopsy decisions, and treatment adjustment. Conclusion : Thoracic involvement in IBD is diverse; radiologists must recognize key imaging patterns to contribute to timely, accurate care.

CHEE-98 DIAGNOSING NON-ONCOLOGIC CARDIOVASCULAR CONDITIONS WITH PET-CT: IT'S NOT ALL ABOUT CANCER

Tatiana Lopez Sandoval, MD (*Presenter*)
Pedro Dib Hoyos, MD (*Abstract Co-Author*)
Tatiana Arroyave, MEd (*Abstract Co-Author*)
David Jimenez Marin, MD (*Abstract Co-Author*)
Sebastian Pelaez SR, MD (*Abstract Co-Author*)

TEACHING POINTS

Positron emission tomography (PET) plays a significant role in the evaluation of non-oncology cardiac diseases, offering unique insights into myocardial perfusion, viability, inflammation, and infection. It is instrumental in detecting myocardial inflammation, such as in cardiac sarcoidosis, and review evaluation of cardiac infections, such as prosthetic valve endocarditis and device infections.The most sensitive technique for assessing myocardial viability is PET/CT with 18F-FDG, especially in patients with ischemic heart disease and ventricular dysfunction.PET/CT plays a complementary role in the diagnosis of infective endocarditis, especially in patients with prosthetic valves or implantable cardiac devices. It detects hypermetabolism associated with infection.Prosthetic valves may show increased metabolic activity, especially during the postoperative period. The uptake typically appears homogeneous, diffuse, and of low intensity. The evaluation of inflammatory or infectious processes in valves is characterized by intense metabolic activity.PET/CT with 18-FDG in sarcoidosis, has the ability to detect hidden systemic involvement and correlate with inflammatory activity positions, particularly in atypical clinical presentations.PET/CT with 18-FDG has becoming established as a fundamental diagnostic tool in the study and follow-up of large vessel vasculitis. Its combination of whole-body coverage and metabolic sensitivity allows for early detection and individualized treatment planning.

TABLE OF CONTENTS/OUTLINE

Learning objectives - Introduction - Myocardial viability - Endocarditis - Prosthetic valves - Sarcoidosis - Vasculitis - Conclusions

CHEE-99 UNDERSTANDING MOLECULAR UPDATES IN NON-SMALL CELL LUNG CANCER: A PRACTICAL APPROACH FOR RADIOLOGISTS

Dario Nascimento Ferreira Alves, MD (*Presenter*)
Bruno Ramos, MD (*Abstract Co-Author*)

Alex Dias, MD (*Abstract Co-Author*)
Roddie Moraes Neto, MD (*Abstract Co-Author*)
Maria Vitoria Ludwig, MD (*Abstract Co-Author*)
Debora Mayumi Takamune, MD (*Abstract Co-Author*)
Leonardo Rosolen Iunes, MD (*Abstract Co-Author*)
Hye J. Lee, MD (*Abstract Co-Author*)
Thais C. Lima (*Abstract Co-Author*)
Tassia R. Yamanari, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the Role of Molecular Profiling : Recognize the critical importance of molecular profiling in non-small cell lung cancer (NSCLC) for identifying oncogenic driver mutations (e.g., EGFR, KRAS, ALK) and guiding personalized treatment strategies. Identify Imaging Characteristics : Learn the distinct radiological features on chest CT scans associated with specific gene mutations to improve diagnostic accuracy. Correlate Mutations with Epidemiology Monitor Treatment Response and Resistance Recognize Therapy-Related Toxicities Integrate Genomic and Imaging Data

TABLE OF CONTENTS/OUTLINE

Introduction Overview of lung cancer as a leading cause of cancer-related deaths. Importance of molecular profiling in NSCLC. Background: Genomic Abnormalities in NSCLC Key mutations: EGFR, KRAS, ALK, MET, HER2, BRAF, ROS1, RET. Distribution of Oncogenic Driver Mutations Prevalence of mutations in lung adenocarcinoma (e.g., KRAS: 26%, EGFR: 15%, ALK: 7%). Imaging Characteristics, Clinical Features, Epidemiological profile and Subtype associations for each mutation (with case studies) EGFR Mutations Subtype associations: Exon 19 deletion (miliary pattern), Exon 21 (subsolid components). ALK Mutations KRAS Mutations Aggressive subtypes (G12C, G12V). RET Mutations MET Mutations HER2 Mutations BRAF Mutations Subtypes: Class I (V600) and Classes II/III (non-V600) ROS1 Mutations Therapeutic Approaches and Follow-Up Conclusion References

CHEE-100 CLIMATE CHANGE AND CARDIOTHORACIC IMAGING: A PRIMER FOR RADIOLOGISTS

Heytor Jose De Oliveira Cabral, MD (*Presenter*)
Eduarda Bezerra Cirne, MD (*Abstract Co-Author*)
Felipe L. Costa, MD (*Abstract Co-Author*)
Israel Missrie, MD (*Abstract Co-Author*)
Cassio G. Reis JR (*Abstract Co-Author*)
Alexandre M. Silva, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

• Climate change is already impacting human health, with its effects disproportionately affecting vulnerable populations.• Recent studies have shown that climate-driven factors can exacerbate the burden of cardiac and respiratory diseases, leading to an increase in adverse outcomes.• Understanding the impact of climate change on these organ systems helps radiologists better assess the underlying causes and implications of related imaging findings, and proactively identify environmental factors that may affect patient outcomes.• Cardiothoracic radiologists should recognize opportunities to improve environmental sustainability in cardiovascular imaging and actively adopt practices to reduce the carbon footprint of their imaging processes.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Health effects of climate change. 2. Basic concepts of climate science for radiologists. 3. Climate change and respiratory disease: What to know and look for. 4. Climate change and cardiac disease: What to know and look for. 5. Contribution of healthcare and radiology to climate change: Challenges and opportunities. 6. Ongoing and future research: Microplastics and beyond. 7. Take-home messages

CHEE-101 THORACIC AMYLOIDOSIS UPDATED: A STEPWISE APPROACH TO TYPICAL AND ATYPICAL IMAGING FINDINGS

Heytor Jose De Oliveira Cabral, MD (*Presenter*)
Ana Madeira, MD (*Abstract Co-Author*)
Roberto V. Torres, MD (*Abstract Co-Author*)
Pablo Rydz P. Santana, MD (*Abstract Co-Author*)
Igor R. Oliveira, MD (*Abstract Co-Author*)
Israel Missrie, MD (*Abstract Co-Author*)
Cassio G. Reis JR (*Abstract Co-Author*)
Alexandre M. Silva, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

• Thoracic amyloidosis presents with a heterogeneous spectrum of imaging manifestations. • Typical findings include pulmonary nodules, interstitial thickening, tracheobronchial wall calcification, and pleural thickening. These features may often mimic more common conditions such as sarcoidosis or chronic infections. • Atypical or less common manifestations include cavitary lesions, soft tissue masses, lymphadenopathy, and involvement of vascular or esophageal structures. •The development of new imaging biomarkers with radiomics and artificial intelligence are needed to advance early detection and guide management in clinical practice. •This work proposes a stepwise approach using multimodality imaging for thoracic amyloidosis, outlining pearls and pitfalls to enhance recognition and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

• Introduction: Definitions, classification, and overview of thoracic involvement. • Understanding Amyloidosis: Radiologic-Pathologic Correlations: imaging in systemic and localized forms. Congo red staining and histopathological diagnosis. • Multimodality Imaging in Thoracic Amyloidosis: An Update - Lung parenchyma; Airways; Mediastinum; Pleura; Chest wall; Heart and vessels. •Optimizing Diagnosis: Pearls and Pitfalls - The role of CT, MRI, PET-CT, and Tc-PYP SPECT. Differential diagnosis • Summary: A 6-Step Systematic Approach. • Future Directions - Radiomics and artificial intelligence. •Take-Home Messages

CHEE-102 BEYOND THE USUAL SUSPECT: A RADIOLOGIST GUIDE INTO DIAGNOSING THORACIC ENDOMETRIOSIS

Rowaa H. Mohamed Ahmed, MBBS (*Presenter*)
Ines Mata, MD (*Abstract Co-Author*)
Ikenna R. Okam, MBBS, FRCR (*Abstract Co-Author*)
Monika Radike, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Thoracic endometriosis is often under-diagnosed, despite its significant implications on patient’s health.Thoracic endometriosis syndrome (TES) can present with a constellation of clinical manifestations, including catamenial pneumothorax , catamenial hemothorax , catamenial hemoptysis , and pulmonary nodules . Diagnosis requires a high degree of clinical suspicion due to the nonspecific nature of symptoms.TES might be seen in women with concomitant pelvic endometriosis and may reflect the progression of the disease. However, it is important to note that thoracic endometriosis can also occur in isolation . CT is the preferred imaging modality for assessing the differential diagnosis of TES. It is highly sensitive for detecting pneumothorax , hemothorax , and pleural effusions . Additionally, CT can identify nodular lesions or bullae in the lung parenchyma. CXR may show pneumothorax but has lower sensitivity compared to CT for other features of TES. MRI is particularly useful for diagnosing diaphragmatic endometriosis and detecting lesions in the pleura. Video-assisted thoracoscopic surgery (VATS) is considered the gold standard for the diagnosis and treatment of pleural endometriosis. Allowing for direct visualization and resection of endometrial implants.The temporal association of symptoms with menstruation and imaging findings provide key diagnostic clues.A high index of suspicion is crucial to provide a timely and accurate diagnosis leading to improved outcome for patients.

TABLE OF CONTENTS/OUTLINE

Background information and epidemiology. Types of thoracic endometriosis. Clinical presentation. Imaging modalities and suggested protocols. Case examples. Take home messages. References

CHEE-103 NEXT-GENERATION CARDIAC DEVICES: AN IMAGING-BASED REVIEW

Joey Gu, MD (*Presenter*)
Saurabh Agarwal, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review common types of non-valvular cardiac devices, clinical indications, and next-generation variants. 2. Recognize both normal and abnormal radiographic appearances of next-generation cardiac devices. 3. Recognize common cardiac device mimics.

TABLE OF CONTENTS/OUTLINE

Common types of cardiac devices, clinical indications, and next-generation variants - Pacemakers: leadless pacemakers, cardiac resynchronization therapy (CRT) devices - Implantable cardioverter defibrillators (ICDs): subcutaneous ICDs - Circulatory assist devices: left ventricular assist devices (LVADs), intra-aortic balloon pumps (IABPs) - Closure devices: left atrial appendage (LAA) closure devices, atrial septal occlusion devices - Cardiac event recorders: implantable loop recorders, external loop recorders, patch recorders - Implantable pulmonary artery pressure monitors Normal and abnormal radiographic appearances - Leadless pacemakers, CRT devices - Subcutaneous ICDs - LVADs, IABPs - LAA closure devices, atrial septal occlusion devices - Implantable loop recorders, external loop recorders, patch recorders - Implantable pulmonary artery pressure monitors Common cardiac device mimics - Deep brain/cranial nerve stimulators - Gastric/diaphragmatic pacemakers - Bone implants (kyphoplasty devices, antibiotic spacers, etc.) - Endobronchial valves - External objects (wireless earbuds, electric vapes, etc.)

EREE-1 PEARLS AND PITFALLS IN IMAGING BLUNT TRAUMA OF THE BOWEL AND MESENTERY

Kazi A. Irfan, MD, FRCR (*Presenter*)
Mohamed G. Elbanan, MD (*Abstract Co-Author*)
Amr S. Abdelaziz, MD (*Abstract Co-Author*)
David L. Raj, MD (*Abstract Co-Author*)
Ayman H. Gaballah, MD, FRCR (*Abstract Co-Author*)
Sadia Sajid, MBBS (*Abstract Co-Author*)
Joe Jose, MD (*Abstract Co-Author*)
Andrew Sun, MD (*Abstract Co-Author*)
Alex Lee, BS (*Abstract Co-Author*)
Azfar Siddiqui, MD (*Abstract Co-Author*)

TEACHING POINTS

*Mechanisms of bowel and mesenteric trauma *Important clinical signs *CT Protocol *Imaging features of bowel and mesenteric trauma *Pitfalls in diagnosis and overcoming them

TABLE OF CONTENTS/OUTLINE

*Epidemiology *Mechanisms of bowel injury : A. Crush injury B. Shear injury C. Burst injury *Clinical signs *CT Protocol *CT signs of bowel trauma: A. Hard signs: ***Extraluminal air in the abdominal cavity ***Leakage of bowel contents ***Bowel wall discontinuity B. Soft signs ***Free fluid ***Bowel wall thickening ***Bowel wall hematoma ***Abnormal bowel enhancement *CT signs of mesenteric trauma A. Mesenteric contrast extravasation B. Mesenteric stranding C. Mesenteric hematoma D. Beading/termination of mesenteric vessels *Ancillary imaging features associated with bowel injuries A. Traumatic abdominal wall hernia B. Seat belt sign *Bucket-handle tear of the mesentery *Accuracy of CT in diagnosis of bowel and mesenteric injuries *Approach to diagnostic pitfalls

EREE-2 MESENTERIC AND BOWEL TRAUMA: RADIOLOGIC CLUES TO AVOID MISSED DIAGNOSES

Eva Gimenez Comet, MD (*Presenter*)
Aram Ehsan (*Abstract Co-Author*)
Marta Bonfill Garcin (*Abstract Co-Author*)
Adria Roset Altadill, MD (*Abstract Co-Author*)
Marta Mazuque Mancilla (*Abstract Co-Author*)
VICTOR PINEDA SANCHEZ, PhD, MD (*Abstract Co-Author*)

TEACHING POINTS

- Mesenteric and bowel injuries are among the most commonly missed injuries on abdominal trauma CT. - Identify “hard” CT signs (specific, requiring urgent surgery) and “soft” CT signs (more common, less definitive), with the presence of multiple soft signs suggesting the need for follow-up imaging , especially in cases of clinical deterioration. - Associated findings (e.g., seatbelt signs, vertebral fractures, abdominal wall hernias) should raise suspicion for underlying mesenteric or bowel injuries.

TABLE OF CONTENTS/OUTLINE

Mesenteric and bowel injuries are frequently underdiagnosed in blunt abdominal trauma. Their low incidence, subtle and non-specific appearance, and limited radiologic awareness contribute to diagnostic challenges, particularly in polytrauma settings, where multiple concurrent injuries may lead to misinterpretation or oversight. Although most of these injuries are managed conservatively, early identification of those requiring surgical intervention is crucial to prevent life-threatening complications such as hemorrhage, peritonitis, and abdominal sepsis, which significantly increase morbidity and mortality. Radiologists must be able to recognize both “hard” CT signs, which are specific but infrequent and require urgent surgical intervention, and “soft” CT signs, which are more common but less definitive. The presence of multiple soft signs, particularly in cases of clinical deterioration, should prompt follow-up imaging to enhance diagnostic accuracy. Associated findings, such as seatbelt signs, vertebral fractures, and traumatic abdominal wall hernias, should raise suspicion for underlying mesenteric or bowel injury.

EREE-3 ABERRANT GAS: URGENT AND BENIGN EMPHYSEMATOUS FINDINGS IN EMERGENCY RADIOLOGY AND HOW TO COMMUNICATE THEM TO CLINICIANS

Nathan Barber (*Presenter*)
William Auffermann, MD, PhD (*Abstract Co-Author*)
Soham Banerjee, MD (*Abstract Co-Author*)

TEACHING POINTS

Ectopic gas, or gas in tissues that normally do not contain gas, is a frequent cause for alarm for radiologists and clinicians alike. This exhibit systematically reviews examples of emergency imaging with both urgent and benign gaseous findings. After this session, participants will be able to: (1) understand the perceptual tools used to perceive aberrant gas, (2) distinguish benign from more urgent pathologies among multiple body systems, and (3) relay these findings to clinicians and discuss the role natural language processing and artificial intelligence may play in ensuring the best patient outcomes.

TABLE OF CONTENTS/OUTLINE

1. Introduction and background: (1a) Basic Perception Tips (1b) Basic Interpretive Tips (1c) Report Language Choice (1d) Natural Language Processing in Clinical Care; 2. Brain, Head, and Neck: (2a) Chest (2b) Abdomen and Pelvis (2b-1) Gastrointestinal (2b-2) Genitourinary; 3. Spine 4. Musculoskeletal 5. Conclusion and Summary

EREE-4 HIGH-VELOCITY IMPACT: PELVIC FRACTURES IN THE FAST LANE

Antonio De La Cruz, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Juan Gonzalez, MD (*Abstract Co-Author*)
Ariana Salgueiro Estela (*Abstract Co-Author*)
Jose A. Lara, MD (*Abstract Co-Author*)
Manolin Gomez Rivadeneira (*Abstract Co-Author*)

TEACHING POINTS

Use imaging patterns to distinguish pelvic fracture types and predict associated injuriesIdentify key CT signs of vascular and urogenital traumaCorrelate injury mechanisms with imaging to guide management

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Pelvic Anatomy Overview IV. Fracture Patterns a. Lateral compression, AP compression, Vertical Shear b. Acetabular, Sacral, Avulsion V. Vascular Injury a. Contrast Leak, Hematoma, Embolization? VI. Urogenital and Bowel Injury a. Bladder, Urethra, Vaginal/Rectal VII. Imaging Modalities a. CT, CT Cystogram, Angiography VIII. Management Implications IX. Conclusion Abstract: Pelvic trauma encompasses a complex spectrum of injuries involving bone, vessels, and pelvic organs. This exhibit highlights key fracture patterns and associated complications through CT cases from our institution. Fracture types include lateral compression, anteroposterior (open book) fractures, vertical shear, acetabular, sacral, and avulsion injuries. Vascular injuries including active bleeds, retroperitoneal hematomas, and angiographic findings requiring embolization are also demonstrated. Urogenital and bowel traumas—ranging from bladder rupture and urethral injury to vaginal involvement—are explored with a focus on CT cystography and dedicated pelvic imaging.

EREE-5 TESTICULAR TUMORS: EVERYTHING AN IMAGING SPECIALIST SHOULD RECOGNIZE

Marcio Gulinelli, MD (*Presenter*)
Victor Arthur Ohannesian (*Abstract Co-Author*)
Marcela Soveral, MD (*Abstract Co-Author*)
Pedro Carani (*Abstract Co-Author*)

TEACHING POINTS

The purposes of this exhibit are: 1. Importance of learning the testicular anatomy. 2. Understand the ultrasound technique to better perform the exam. 3. Know the ultrasound manifestation of the main testicular tumors and their anatomopathological correlations.

TABLE OF CONTENTS/OUTLINE

• Anatomy of testicles. • Ultrasound technique used to evaluate the plantar artery, the main adjustments, parameters and what should be analyzed. • Illustrate with cases from our department the main testicular tumors and their anatomopathological correlations.

EREE-6 KNEE AVULSION FRACTURES: A CASE-BASED SURVIVAL GUIDE FOR THE ON-CALL RESIDENTS

Aaron Mahajan, md (*Presenter*)
Kaushal Mehta, MD (*Abstract Co-Author*)
Kalpesh K. Panchal, MD (*Abstract Co-Author*)
Carl C. Flink, MD (*Abstract Co-Author*)

TEACHING POINTS

- Discuss various types of knee avulsion fractures- Discuss the innocuous appearance of these fractures on radiography and that they are often associated with occult soft tissue (ligamentous, tendon, meniscal) injuries and the clinical significance of the failure to promptly recognize and treat them

TABLE OF CONTENTS/OUTLINE

- Anatomy - Case-Based Review focusing on the radiographic appearance, MRI imaging features, biomechanics, patterns and what the Resident needs to know - Ligamentous Avulsion Injuries1. Segond2. Reverse Segond3. ACL avulsion4. PCL avulsion5. Arcuate Sign6. Pellgrini-Steida Lesion7. Iliotibial band - Musculotendinous Avulsion Injuries1. Quadriceps tendon 2. Patellar tendon3. Semimembranous tendon 4. Biceps Femoris tendon5. Sinding-Larsen-Johansson Syndrome6. Osgood-Schlatter Disease

EREE-7 AORTA BE KIDDING ME: LATEST IMAGING UPDATES OF TEAR-ABLE EMERGENCIES

Sandra Victoria Servin Baltierra, MD (*Presenter*)
Omar A. Gamboa Abundis, MD (*Abstract Co-Author*)
Shahin Soltani Darani, MD (*Abstract Co-Author*)

TEACHING POINTS

1.Aortic emergencies are a common reason for emergency department visits; 2.Chest pain is extensive and primarily involves three vascular beds, approximately 30% of which are of aortic origin; 3.The primary mechanism is medial weakening due to systemic arterial hypertension; 4.Computed tomography is the modality of choice, being fast and versatile, allowing for its exclusion or confirmation, as well as for appropriate procedure planning; 5.There have recently been updates to the European and American guidelines that better specify the reporting of these aortic emergencies.

TABLE OF CONTENTS/OUTLINE

1.Classification of cardiovascular emergencies; 2.Recognizing the imaging findings of an acute aorta and how to report them based on a checklist; 3.Most recent updates (2024) regarding international guidelines (American and European) on aortic emergencies.

EREE-8 AO SPINE CLASSIFICATION OF THORACOLUMBAR INJURIES: A GUIDE FOR RADIOLOGISTS

Rinald Paloka, MD (*Presenter*)
Giuseppe Cruciata, MD (*Abstract Co-Author*)
Anton O. Beitia, MD (*Abstract Co-Author*)
Vishal Patel, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review key thoracolumbar spinal anatomy. 2. Understand the structure and rationale of the AO Spine Thoracolumbar Classification system, including its hierarchical organization and clinical applicability. 3. Identify and distinguish fracture morphologies by mechanism of injury: compression (Type A), distraction (Type B), and axial translation or rotation (Type C). 4. Learn how neurologic status (N0-N4, NX) and case specific modifiers (M1, M2) influence urgency and surgical decision-making. 5. Integrate classification into radiology workflow to improve communication with clinical teams.

TABLE OF CONTENTS/OUTLINE

1. Introduction and Epidemiology : Incidence, clinical impact, and relevance of thoracolumbar trauma in polytrauma setting. 2. Anatomy and Biomechanics of Injury : Review spinal anatomy and understanding how mechanical forces translate into injury morphology. 3. Evolution of the classification system : Progression through historical systems such as Bohler (1935), Holdsworth (1970), Denis (1983), AO MAGERL spine (1994), TLICS (2005), and rationale for new system AO Spine (2013). 4. Detailed breakdown of the AO Spine system : including fracture morphology, neurologic status grading, and clinical modifiers. 5. Case-Based Applications : Annotated

examples of cases across all types and subtypes. 6. Structured Reporting Framework : Examples on how to incorporate AO elements into radiology reports. 7. Common Pitfalls and Interobserver Variability : Diagnostic traps, ambiguous cases, and strategies to improve reliability.

EREE-9 PELVIC FRACTURES AND PENILE INJURY

Jake Barrett, MD,MS (*Presenter*)
Christina A. LeBedis, MD, MS (*Abstract Co-Author*)
Carl C. Flink, MD (*Abstract Co-Author*)
Christian J. Ashby, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Pelvic trauma commonly results in perineal and penile injury, which can manifest in distinct ways based on the mechanism of injury. 2. Identification of imaging findings related to pelvic floor injury during the initial trauma scan including injury of the bulbospongiosus and ischiocavernosus. 3. Understanding patient outcomes related to penile injury after pelvic trauma, such as the development of erectile dysfunction.

TABLE OF CONTENTS/OUTLINE

1. Introduction and classification of pelvic trauma. 2. Review of normal pelvic floor anatomy. 3. Relationships and imaging classifications of penile injury; review of current literature and distinct imaging findings. 4. Exploration of poor outcomes related to penile injury after pelvic trauma. 5. Sample cases and discussion.

EREE-10 A PRIMER ON IMAGING APPROACH TO ACUTE GASTROINTESTINAL BLEED

Sadia Sajid, MBBS (*Presenter*)
Mohamed G. Elbanan, MD (*Abstract Co-Author*)
Amr S. Abdelaziz, MD (*Abstract Co-Author*)
Ayesha Nasrullah, MD,FRCR (*Abstract Co-Author*)
Azfar Siddiqui, MD (*Abstract Co-Author*)
Nanda Deepa Thimmappa, MD (*Abstract Co-Author*)
David L. Raj, MD (*Abstract Co-Author*)
Ryan M. Davis, MD (*Abstract Co-Author*)
Emre Demirci, MD (*Abstract Co-Author*)
Kazi A. Irfan, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

-Review of causes of upper and lower gastrointestinal bleed (GIB) -Discuss the multimodality imaging approach for the diagnosis of upper and lower GIB -Optimal Imaging techniques with emphasis on CT angiography (CTA) -Practical guideline for the residents for accurate case interpretation and avoiding the pitfalls with case-based illustration -Radiologic advances in the diagnostic and therapeutic approach to GIB. -Highlight the crucial role of radiologists in making accurate diagnosis and management of the life-threatening condition

TABLE OF CONTENTS/OUTLINE

-Introduction -Diagnostic imaging approach with review of different imaging modalities Computed tomography angiography (CTA), Nuclear Medicine - Technetium 99m scintigraphy Multiphase computed tomography enterography (CTE) Catheter angiography (CA). -Imaging features with case-based illustration of upper and lower GIB with underlying causes as below: Inflammatory - Gastritis, Gastric and Duodenal ulcers, diverticulitis, Inflammatory bowel disease Vascular - Dieulafoy's lesion, Angiodysplasia, esophageal and rectal varices, Aortoenteric fistula Congenital - Meckel Diverticulum Benign and Malignant tumors Post surgical - Post gastric bypass vascular leak, post pancreatic transplant jejunal varices Post traumatic - Motor vehicle accidents, foreign body Localized: Endometrial implants Idiopathic - Unidentifiable cause Coagulopathy- Anticoagulation, Hemophilia -Key learning points -Conclusion

EREE-11 DEVELOPING A GUT FEEL: SPECTRUM OF BOWEL AND MESENTERIC INJURIES

Nandakumar Patnam Gopal Chetty, MD (*Presenter*)
Tushar Kumar, MBBS, MD (*Abstract Co-Author*)
Gopal V. Punjabi, MD (*Abstract Co-Author*)
Manish Dhyani, MD (*Abstract Co-Author*)
Claire K. Sandstrom, MD (*Abstract Co-Author*)
Rajat Bhargava, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Reviewed trauma mechanisms with emphasis on anatomically vulnerable sites. 2. Highlighted both highly predictive and subtle imaging signs using a finding-based approach to distinguish surgical from non-surgical candidates. 3. Demonstrated incremental diagnostic value of spectral CT in the acute trauma setting. 4. Identified common pitfalls in imaging evaluation of bowel and mesenteric trauma.

TABLE OF CONTENTS/OUTLINE

1. Mechanisms and Common Sites of Bowel and Mesenteric Injury. 2. Key facts regarding incidence and error-reduction strategies. 3. Imaging signs of Bowel and Mesenteric Trauma. 4. Case-Based Review of Key Bowel and Mesenteric Injury Patterns.

EREE-12 SAVING SKIN: ACUTE DERMATOLOGIC LESIONS RADIOLOGISTS CAN'T MISS

Matheus Fritzen, MD (*Presenter*)
Julia D. Zavariz, MD (*Abstract Co-Author*)
Rosa Maria Silveira Sigrist, MD (*Abstract Co-Author*)
Mateus Esmeraldo, MD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: To demonstrate normal skin anatomy as visualized on high-frequency ultrasound (=18 MHz). To describe key ultrasound findings of urgent dermatologic lesions such as epidermal inclusion cysts, hidradenitis suppurativa, panniculitis, myiasis, and foreign bodies. To discuss how Doppler imaging and B-mode complement each other in characterizing inflammation, infection, and complications. To highlight "can't miss" imaging clues that alter clinical management in the emergency setting.

TABLE OF CONTENTS/OUTLINE

A. Imaging Technique and Anatomy Overview Layer-by-layer evaluation: epidermis, dermis, hypodermis Use of 18-24 MHz transducers for optimal resolution Role of Doppler (color and power) in detecting inflammation and vascularity B. Cystic Lesions and Their Complications Epidermal Inclusion Cysts : Well-defined, hypoechoic masses with posterior enhancement Infected or Ruptured Cysts : Ill-defined margins, hypervascular rim, internal debris and edema C. Inflammatory Dermatoses Hidradenitis Suppurativa (HS) : Hypoechoic tracts and pseudocysts with increased vascularity Panniculitis : Septal: "Cobblestone" edema between echogenic septa Lobular: Hyperechoic stranding with thickened septa D. Infective and Infestative Lesions Myiasis : Mobile echogenic larvae within hypoechoic pocket Abscesses : Anechoic or complex collections with peripheral Doppler activity E. Foreign Bodies and Artifacts Retained Foreign Material : Linear hyperechoic structures with posterior shadowing Twinkling Artifact : Useful in detecting crystalline/glass fragments Case example: Facial trauma with embedded glass missed on clinical exam

EREE-13 IS MRI THE MAINSTAY OR STILL AN ALTERNATIVE? - ROLE OF MRI IN ACUTE ABDOMINOPELVIC EMERGENCIES

Usha Jayagurunathan, MD, FRCR (*Presenter*)
Harish Gudi, MD, MBBS (*Abstract Co-Author*)
Sriram Jaganathan, MD (*Abstract Co-Author*)
Eswaramoorthy Sellamuthu, DNB,DMRD,MBBS (*Abstract Co-Author*)

TEACHING POINTS

· Review various common acute abdominopelvic emergencies and the imaging modalities being utilized. · Disadvantages of the other imaging modalities in specific settings and Why MRI scores over the other modalities in specific scenarios? · Limitations of MRI in those situations and the way forward.

TABLE OF CONTENTS/OUTLINE

1. Introduction to various common acute abdominopelvic emergency pathologies. 2. Different imaging modalities utilized for the diagnosis of acute emergencies. 3. Disadvantages and limitations of the different investigations in this specific scenario 4. Role of MRI and the advantages. 5. Various MR imaging findings and classic images of few of the common acute abdominopelvic emergencies. a. Acute cholecystitis including emphysematous and gangrenous b. Choledocholithiasis c. Acute pancreatitis d. Appendicitis, Colitis and terminal ileitis e. Acute pyelonephritis and renal abscesses f. Prostatic and seminal vesicle abscesses g. Acute torsion of ovary/dermoid in pregnancy h. Ruptured ectopic pregnancy 6. Is MRI the mainstay or the alternate in these scenarios? 7. Limitations and pitfalls of MRI.Conclusion MRI helps in diagnosing certain acute abdominopelvic emergencies where CT may be harmful or less informative, and the US has its limitations. However, MRI is not without pitfalls and CT may have to be utilized if MRI is not of diagnostic quality or MRI results are not convincing. It is imperative for radiologists to understand the specific role of MRI, the pitfalls and the appropriate findings in these clinical scenarios.

EREE-14 MIND THE MISS: FREQUENT ERRORS IN EMERGENCY HEAD CT AND HOW TO PREVENT THEM

Alejandra Somoano Marfull (*Presenter*)
Silvia Revuelta Gomez, MD (*Abstract Co-Author*)
Aranzazu Sanchez Gabin, MD (*Abstract Co-Author*)
Rodrigo Sutil, MD (*Abstract Co-Author*)
Marta Drake Perez, MD (*Abstract Co-Author*)
David Castanedo SR, MD (*Abstract Co-Author*)

TEACHING POINTS

To recognize the most common perceptual and cognitive errors in radiology. To identify key anatomical blind spots prone to diagnostic oversight. To apply targeted strategies in high-stakes emergency scenarios such as trauma, stroke, and headache. To utilize a practical checklist to minimize interpretive errors in emergent cranial CT.

TABLE OF CONTENTS/OUTLINE

Diagnostic errors remain a leading cause of medical harm, being radiology particularly vulnerable due to reliance on image perception and interpretation. In this educational exhibit, we explore the root causes and practical solutions to errors in cranial CT. Error Typology: We review perception errors and cognitive biases—such as anchoring, confirmation, availability, framing, attribution, satisfaction of search, premature closure, inattentional blindness, and hindsight bias—that compromise diagnostic accuracy. Anatomical Blind Spots: With examples from our institution, we highlight regions frequently missed in cranial CT interpretation, including cerebral sulci, brainstem, dural and cavernous sinuses, sellar/suprasellar region, skull base foramina, cavum, orbits, nasal cavity, paranasal sinuses, and deep head and neck compartments Emergency-Specific Strategies: We propose actionable techniques to avoid errors in the context of traumatic brain injury, acute headache, and stroke code evaluations. Cranial CT Checklist: We conclude with a ten-point checklist designed to serve as a rapid, systematic guide during emergency cranial CT reporting.

EREE-15 TISSUE ISSUES: FAST-TRACKING MSK EMERGENCIES WITH ULTRASOUND

Jose Flavio De Oliveira Neto (*Presenter*)
Antonio Neto (*Abstract Co-Author*)
Davi Sossai (*Abstract Co-Author*)
Karina Hayama, MD (*Abstract Co-Author*)
Thaina d. Rodrigues, MD (*Abstract Co-Author*)
Myrian Linhares, MD (*Abstract Co-Author*)
Leticia dos Reis Morimoto, MD (*Abstract Co-Author*)
Julio B. Guimaraes, MD, PhD (*Abstract Co-Author*)
Andre Y. Aihara, MD, PhD (*Abstract Co-Author*)
Adham A. Castro, MD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is to: Highlight the pivotal role of musculoskeletal ultrasound (MSK-US) in diagnosing and managing acute MSK emergencies, including tendon injuries, joint effusions, fractures, and foreign bodies.Demonstrate how MSK-US enables real-time, dynamic evaluation of soft tissues and joints, offering a radiation-free alternative for pediatric and urgent care populations.Emphasize the importance of standardized scanning protocols, anatomical proficiency, and integration with clinical findings to improve diagnostic precision and patient outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of MSK emergencies and the advantages of ultrasound in urgent settings.Essential Techniques: Step-by-step guidance for focused emergency exams (e.g., hip, knee, ankle) and dynamic maneuvers.Pathology Spotlight: Tendon Injuries: Ultrasound findings of tears (fiber discontinuity, retraction, hypervascularity).Joint Effusions/Synovitis: Differentiation from unossified epiphysis and septic arthritis.Fractures/Hematomas: Cortical disruption detection and occult fracture identification.Foreign Bodies: Material-specific echogenicity and multimodal imaging correlation. Clinical Integration: Case-based examples underscoring ultrasound's impact on triage and treatment decisions.Future Directions: Create an algorithm to help radiologists and trainees master essential musculoskeletal ultrasound principles.

EREE-16 NOT ALWAYS A CLOT: CONSIDER MUSCULOSKELETAL CAUSES IN LOWER LIMB ASYMMETRY

Renato Fujiki, MD (*Presenter*)
Rafael Viana Dos Santos, MD (*Abstract Co-Author*)
Pedro Bernis, MD (*Abstract Co-Author*)
Lucas O. Madeira, MD (*Abstract Co-Author*)
Paulo Ferreira, MD (*Abstract Co-Author*)
Livia Vasconcelos, MD (*Abstract Co-Author*)
Raul N. Pigatto, MD, MBA (*Abstract Co-Author*)
Paulo R. Moreira, MD (*Abstract Co-Author*)
Ricardo Caracante, MD (*Abstract Co-Author*)
Andre S. Kamogari Nakamura, MD (*Abstract Co-Author*)
Alberto P. Bambirra, MD (*Abstract Co-Author*)
Irline Cordeiro de Macedo Pontes, MD (*Abstract Co-Author*)
Henrique A. Lino, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)

TEACHING POINTS

Lower limb asymmetry is a common reason for medical evaluation, particularly when it presents acutely and with pain. Deep vein thrombosis (DVT) is often the initial concern and must be ruled out. However, when DVT is excluded, the underlying cause can remain unclear, potentially leading to patient anxiety and inappropriate treatment. In such cases, considering musculoskeletal disorders as a possible explanation can help clarify the diagnosis and guide more effective care. The purpose of this exhibition is to: - Review the clinical presentation of lower limb asymmetry, encompassing both acute conditions (such as DVT) and chronic manifestations. - Emphasize the role of radiology in identifying the underlying causes of lower limb asymmetry. - Discuss common musculoskeletal differential diagnoses, with a focus on their imaging characteristics.

TABLE OF CONTENTS/OUTLINE

1. Introduction a. Epidemiology and clinical presentation of acute and chronic lower limb asymmetry b. Recommended radiological approach, with emphasis on DVT evaluation 2. Imaging Modalities: Diagnostic Roles and Comparative Analysis a. Radiography (X-ray) b. Ultrasonography c. Computed Tomography (CT) d. Magnetic Resonance Imaging (MRI) 3. Musculoskeletal Differential Diagnoses: Case-Based Review a. Infectious etiologies b. Traumatic injuries c. Degenerative conditions d. Neoplastic processes e. Miscellaneous causes 4. Conclusion Key points and take-home messages

EREE-17 PROMPT ENGINEERING IN EMERGENCY RADIOLOGY: A PRACTICAL GUIDE FOR RADIOLOGISTS AND TRAINEES

Nicholas Dietrich (*Presenter*)
Jack Lott (*Abstract Co-Author*)
Joseph Bellissimo (*Abstract Co-Author*)
Dhruv Patel (*Abstract Co-Author*)

TEACHING POINTS

1.) Define prompt engineering and its role in leveraging large language models (LLMs) for emergency radiology decision support. 2.) Demonstrate prompting strategies using real-world, context-specific examples. 3.) Identify common prompting errors and provide actionable mitigation strategies. 4.) Highlight best practices for integrating prompt engineering into clinical workflows, tools, and radiology education.

TABLE OF CONTENTS/OUTLINE

1.) Introduction and Scope: Define prompt engineering; explain its relevance to LLM-powered tools for triage, protocoling, and communication in emergency settings. 2.) Core Prompting Techniques: Overview of strategies: zero-shot, few shot, chain-of-thought, domain/role prompting, and retrieval-augmented generation. Describe their benefits and limitations in emergency radiology tasks. 3.) Clinical and Workflow Application: Provide examples of prompts supporting tasks such as guideline recommendation, protocol selection, report summarization, and urgency triage. Demonstrate representative model outputs from current LLMs to illustrate how prompt structure may impact response quality. 4.) Common Pitfalls and Mitigatio n: Highlight errors such as vague inputs, over-complex prompts, unrealistic expectations, and misalignment with model capabilities. Emphasize iterative prompt refinement, radiologist oversight, and clinical fact-checking. 5.) Practical Integration and Future Directions: Discuss embedding prompts in structured report templates, PACS, and decision support tools. Address regulatory, ethical, and training considerations for future implementation.

EREE-18 THE EVOLVING ROLE OF INTERVENTIONAL RADIOLOGY IN THE DIAGNOSIS AND MANAGEMENT OF TRAUMA: A COMPLEMENT TO CT IMAGING

Sophia Li (*Presenter*)
Devang Butani, MD (*Abstract Co-Author*)
Ashwani K. Sharma, MD (*Abstract Co-Author*)
Andrew J. Cantos, MD (*Abstract Co-Author*)

TEACHING POINTS

Trauma is the leading cause of death in people under age 35 while hemorrhage remains the 2nd leading cause of mortality in post-traumatic patients. Interventional Radiology (IR) plays a vital role in both the management of acute traumatic injuries as well as provides clarity for unclear imaging findings. While CT has largely replaced conventional angiography in the diagnosis of traumatic injuries, IR remains an indispensable for difficult to diagnose or ambiguous cases. For example, conventional angiography can visualize small vessel bleeding more accurately compared to diagnostic CT. This exhibit will review various solid organ traumatic injuries, both correlating diagnostic and interventional imaging, as well as provide an overview of endovascular intervention options for each case. We will also examine comparative cases demonstrating how conventional angiography can resolve ambiguities seen on diagnostic imaging.

TABLE OF CONTENTS/OUTLINE

1. Background of acute abdominal traumatic injuries 2. Review of multimodality imaging findings 3. Angiographic correlation of diagnostic imaging finding 4. Review of endovascular treatment options 5. Summary of educational points

EREE-19 BRAIN DRAINS AND PAINFUL STRAINS: THE PRESSURE IS REAL!

Mariana R. Defreitas, MD (*Presenter*)
Ana Bucci, MD (*Abstract Co-Author*)
Stephanie Ntim (*Abstract Co-Author*)
John P. Nazarian, MD (*Abstract Co-Author*)
Hunter McLellan (*Abstract Co-Author*)
Robert M. Morgan JR, MD (*Abstract Co-Author*)

TEACHING POINTS

1)Both spontaneous intracranial hypotension (SIH) and idiopathic intracranial hypertension (IIH) can present to the ED with acute symptoms 2)Nonfocal neurological exam can delay accurate diagnosis 3)Recognizing imaging findings of abnormal intracranial pressure can optimize prompt diagnosis and management

TABLE OF CONTENTS/OUTLINE

A. Introduction i)Headache-2-4% ED visits ii)SIH and IIH in differential iii) nonfocal neurological symptoms common iv) diagnosis is challenging and often missed in ED iv)head imaging may provide clues B. Spontaneous intracranial hypotension i) 4-5/100,000 prevalence ii) CT head findings (subdural fluid/blood and sag of midbrain/pons) iii) MRI head findings (engorged venous sinus and pituitary, meningeal enhancement, decreased mamillopontine distance, effacement of basal cisterns, brain sag) iv) Next steps-LP, MRI spine, CT myelography v) overview of types/causes C. Idiopathic Intracranial hypertension i)prevalence 3/100,000 ii) risk factors-obesity, female sex, reproductive age iii) CT head findings in orbits and sella iv) MRI head findings (optic nerves, Meckel's caves, and venous sinuses) iv)Next steps-fundoscopic exam, LP w/ opening pressure) D. Mimics and Differential i) Low-lying tonsils ddx, including Chiari I ii) Pituitary ddx iii) primary venous sinus pathology iv) secondary causes a)IIH - increased ICP (trauma, parenchymal swelling, and neoplasms) b)low CNS from post-LP or CNS surgery) E. Summary: Approach by ED interpreting radiologist should include i)Looking for clues on head CT ii) Considering mimics and ddx iii) Providing guidance for ancillary imaging and next steps

EREE-20 SEEING THE UNSEEN: ULTRASOUND ESSENTIALS IN UROLOGIC EMERGENCIES

Antonio Neto (*Presenter*)
Jose Flavio De Oliveira Neto (*Abstract Co-Author*)
Jose Eduardo Mourao Santos, MD, PhD (*Abstract Co-Author*)
Eduardo Sales Loureiro (*Abstract Co-Author*)
Juliana Fraga Soares, MD (*Abstract Co-Author*)
Bruna De Lima (*Abstract Co-Author*)

Aline Chan, MD (*Abstract Co-Author*)
Enzo Fatuch (*Abstract Co-Author*)

TEACHING POINTS

To demonstrate the essential role of ultrasound in diagnosing genitourinary emergencies with speed and precision. To outline a structured sonographic approach to the penis, scrotum, and urinary tract in acute settings. To recognize key ultrasound findings that differentiate between urgent and non-urgent conditions. To reinforce knowledge of normal sonographic anatomy as a foundation for identifying critical pathology.

TABLE OF CONTENTS/OUTLINE

Genitourinary emergencies require swift and accurate diagnosis to prevent irreversible tissue damage. Ultrasound, as a rapid, real-time, non-invasive modality, is vital in such scenarios. This exhibit offers a comprehensive review of high-yield sonographic techniques and findings in emergency urologic imaging, structured by anatomical compartments: penis, scrotum, and urinary tract. It emphasizes the importance of normal anatomy as a baseline, and presents classic pathological patterns associated with emergent conditions such as testicular torsion, penile fracture, priapism, epididymo-orchitis, testicular trauma, pyelonephritis, renal infarction, and bladder rupture. Through illustrated cases, it discusses B-mode and Doppler findings, comparative anatomy, and decision-making algorithms to guide radiologists in acute care. This exhibit aims to enhance diagnostic accuracy and expedite intervention in high-stakes scenarios.

EREE-21 RED HERRINGS: IMAGING MIMICS OF HEMORRHAGE THROUGHOUT THE BODY

Ahmad Amer, MD (*Presenter*)
Daniel Giraldo Herrera, MD (*Abstract Co-Author*)
Omar Jamil, MD (*Abstract Co-Author*)
Hugo F. Bueno, MD (*Abstract Co-Author*)
Meir H. Scheinfeld, MD, PhD (*Abstract Co-Author*)
Humaira Chaudhry, MD (*Abstract Co-Author*)
Robert J. Dym, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the typical imaging appearance of hemorrhage on CT across various anatomical regions. Identify common mimics of hemorrhage, including artifacts, anatomical variants, contrast-related phenomena, and non-hemorrhagic pathology. Differentiate true hemorrhage from its mimics using imaging clues, including Hounsfield units, enhancement patterns, temporal evolution, and multimodality correlation. Understand the clinical implications of misinterpreting mimics as hemorrhage, including the potential impact on patient management and treatment. Apply a systematic approach to evaluating high-attenuation or hemorrhage-like findings to improve diagnostic accuracy and reduce interpretive errors.

TABLE OF CONTENTS/OUTLINE

Introduction: Overview of clinical relevance of hemorrhage on CT and diagnostic challenges posed by its mimics. Vicarious Excretion and Enhancing Fluid Collections: Discussion of contrast accumulation and how this may simulate hemorrhage on CT. Imaging Artifacts: Review of artifacts from metallic hardware or dense contrast that may obscure or mimic hemorrhage. Physiological Calcifications: Analysis of benign calcifications that may appear hyperdense on non-contrast CT and simulate hemorrhage. Soft Tissue Mimics: Case-based discussion of soft tissue processes that may present as high-attenuation lesions resembling hematoma. Vascular Lesions: Overview of AVMs, hemangiomas, and cavernomas that may appear hyperdense or enhance on imaging, with focus on distinguishing features and risk of true hemorrhage. Conclusion: Summary of diagnostic strategies and approaches to avoid interpretive errors in hemorrhage-like presentations on CT.

EREE-22 SKIN ULTRASOUND IN THE EMERGENCY DEPARTMENT: WHEN THE SKIN HURTS

Francisco J. Garrido Cisterna, MD (*Presenter*)
Carlos R. Riquelme, MD (*Abstract Co-Author*)
Miguel Villaseca (*Abstract Co-Author*)
Francisco Reyes-Baraona (*Abstract Co-Author*)
Paulina Cofre, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Cutaneous ultrasound with high-frequency transducers allows optimal evaluation of the different layers of the skin, being a fundamental support for the differential diagnosis of skin lesions. 2. Ultrasound is useful for the diagnosis of patients presenting with skin lesions in the emergency department. 3. Proper recognition of these skin lesions is key to guide management by the emergency physician.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Basic skin anatomy 3. Equipment and technical requirements 4. Skin ultrasound technique 5.Common skin lesions evaluated in emergency setting: Uncomplicated and complicated epidermal cyst, Furuncle and skin abscess, Folliculitis, Panniculitis: cellulitis and erythema nodosum, Hematoma, Foreign body, Plantar wart, Pilonidal cyst, Superficial venous thrombosis, Necrotizing fasciitis 6. Conclusions

EREE-23 ON-CALL MODE: KEEP ABREAST OF BREAST FINDINGS

Sravani Mannuru, MD (*Presenter*)
Otavio Augusto Ferreira Dalla Pria, MD (*Abstract Co-Author*)
Reine Fahed, MD (*Abstract Co-Author*)
Bruna M. Thompson, MD, PhD (*Abstract Co-Author*)
Fabiana C. Policeni, MD (*Abstract Co-Author*)
Fabiola P. Kestelman, MD (*Abstract Co-Author*)
Su Kim Hsieh, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-Identifying true breast emergencies, next steps (abscesses, ulcers: do we need MR, US, aspirations, ABx, etc?) - When incidental breast findings are suspicious (men vs women) - implants complications and next steps - pain, skin changes (infection, paget, etc) - breast trauma (do we need to do extra imaging? CT? Just US? MRI?) do we need to treat breast hematomas?

TABLE OF CONTENTS/OUTLINE

Incidental breast findings are not uncommon during imaging studies performed for non-breast-related indications, particularly in the on-call setting where urgent priorities may overshadow subtle but significant abnormalities. Additionally, patients may present to urgent care with acute breast symptoms requiring immediate evaluation.This educational exhibit presents a multimodality review of incidental breast findings encountered on ultrasound, CT, MRI, and chest X-rays. Key entities include abscesses, mastitis, hematomas, suspicious masses, architectural distortion, and calcifications. We outline imaging features that differentiate emergent conditions—such as abscesses or infected hematomas—from non-emergent but suspicious findings that require structured reporting, BI-RADS categorization, and timely diagnostic follow-up. Designed for radiology trainees and practicing radiologists, this exhibit offers a pattern-based approach to triaging breast findings in the acute setting, emphasizing clinical integration, appropriate escalation, and interdisciplinary communication.

EREE-24 PRACTICAL ASSESSMENT OF CEREBRAL EDEMA AND HERNIATIONS: A RESIDENT'S GUIDE

Juan De Dios Del Toro Arellano, MD, MD (*Presenter*)
Laura M. Sanchez, MD (*Abstract Co-Author*)
Gustavo Alonzo Correa I, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the basic pathophysiological mechanisms of cerebral edema (vasogenic, cytotoxic, interstitial) and their characteristic appearance on neuroimaging. Identify the main types of cerebral herniation (subfalcine, transtentorial, tonsillar) and understand their sequence of development. Describe the key findings on neuroimaging modalities (CT and MRI) that allow for the identification and differentiation of the various types of cerebral edema and herniation. Distinguish the subtle and advanced imaging signs of cerebral herniation, recognizing key anatomical structures and displacement changes. Apply a systematic approach to the review of neuroimaging studies in patients with suspected cerebral edema or herniation, optimizing time and diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

Physiology of the blood-brain barrier, Cytotoxic cerebral edema, Vasogenic cerebral edema, Interstitial cerebral edema, Key levels in the assessment of cerebral herniations, Subfalcine herniation, Upward transtentorial herniation, Downward transtentorial herniation, Tonsillar herniation, Extracranial herniations

EREE-25 FROM SNIFFLES TO SEPSIS: PEDIATRIC RADIOLOGY EMERGENCIES SURVIVAL GUIDE FOR THE ON-CALL RESIDENT

Sammar Ghannam, MD, MPH (*Presenter*)
Cory Pfeifer, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

This will serve as a review for trainees, early career attendings, and general radiologists to complete prior to taking pediatric call.Review the most common and "do not miss" multisystem pediatric radiology pathologies that present to the emergency center. Review how to perform an intussusception reduction and upper gastrointestinal fluoroscopy study to emergently assess for midgut volvulus.

TABLE OF CONTENTS/OUTLINE

Introduction. Most common/important pathologies- Musculoskeletal (e.g. signs of child abuse, buckle fracture, elbow ossification, hip effusion, etc.). Most common/important pathologies- Neuroradiology (e.g. ping pong ball fracture, tonsillar abscess, atlantooccipital separation, hypoxic ischemia, etc.). Most common/important pathologies- Chest (e.g. round pneumonia, aspirated foreign bodies, lobar pneumonia, etc.). Most common/important pathologies- Gastrointestinal (e.g. pneumoperitoneum, necrotizing enterocolitis, bowel dilation, pyloric stenosis, appendicitis, etc.). Technique for most common/important procedures including intussusception reduction and upper gastrointestinal fluoroscopy study for midgut volvulus. Conclusion/ take home points.

EREE-26 EMERGENCY IMAGING OF ADULTS WITH CONGENITAL HEART DISEASE

Caroline Robb, MD (*Presenter*)
Demetrios A. Raptis, MD (*Abstract Co-Author*)
Constantine A. Raptis, MD (*Abstract Co-Author*)
Daniel Vargas, MD (*Abstract Co-Author*)
Sanjeev Bhalla, MD (*Abstract Co-Author*)

TEACHING POINTS

With advancements in medical and surgical care, adults with congenital heart disease (CHD) now outnumber children with CHD, and the adult population continues to grow each year. As the number of adults with CHD has increased, more non-cardiac radiologists are encountering imaging studies from these patients, particularly in the emergency department. Emergency radiologists must now be able to identify untreated and undiagnosed CHD in adults, and recognize expected post-surgical appearances and complications. Emergency radiologists need to be confident in diagnosing acute, critical, and noncritical findings that are seen in adults with CHD, findings that can involve multiple organ systems including the cardiovascular, pulmonary, hepatic, and neurologic systems. Radiologists must also be careful to avoid interpretative pitfalls when managing these patients by optimizing imaging protocols and distinguishing expected post-surgical anatomy from abnormal post-surgical appearances.

TABLE OF CONTENTS/OUTLINE

Recognize the need for emergency radiologists to become familiar and comfortable with the imaging of adults with treated and untreated CHD. Review the most common causes of CHD in adults and common post-surgical appearances. Understand the critical and noncritical presentations of adults with CHD using a multisystemic approach, including cardiovascular findings such as dissection and thromboembolic events, hepatic findings such as liver failure, pulmonary findings, and central nervous system findings such as paradoxical embolism. Examine common interpretative pitfalls and how to avoid these, such as by optimizing imaging protocols and recognizing normal and abnormal post-surgical anatomy.

EREE-27 THE FUTURE OF EMERGENCY RADIOLOGY PRACTICE: INNOVATIVE FORWARD-LOOKING

Ahmed O. Hamouda, MD, MSc (*Presenter*)
Waleed Abdellatif, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

Evaluate emerging technologies transforming emergency radiology (ER) and their clinical integration. Explore future directions in ER education and training. Propose strategies to address challenges and promote sustainable subspecialty growth.

TABLE OF CONTENTS/OUTLINE

ER has rapidly evolved into a vital subspecialty, driven by rising patient volumes, the need for timely diagnoses, and major imaging advancements. This review provides a forward-looking perspective on ER by evaluating transformative technologies—particularly artificial intelligence (AI) and advanced imaging—and their integration into clinical workflows. It also examines current diagnostic practices and existing limitations. The review emphasizes the need for emergency radiologists to lead, not just adapt to, innovation. Societies such as ASER and ESER have played a key role in advancing the field. Key innovations include standardized ER fellowship models, FDA-approved AI tools for triage and diagnosis, virtual reality training, and AI validation frameworks with radiologist oversight. Workforce solutions discussed include fair compensation, shift limits to reduce burnout, and strengthening the pipeline of specialty-trained radiologists through expanded teleradiology. Emerging trends such as point-of-care ultrasound, ambulance-based CT, contrast-enhanced ultrasound for bleeding detection, radiogenomics, and hybrid ERs are reviewed for their transformative potential. The roadmap for sustainable growth emphasizes global collaboration via shared case databases, advocacy for AI/teleradiology reimbursement, and establishing competency benchmarks in ER fellowships.

EREE-29 MESENTERIC ISCHEMIA: TO BE OR NOT TO BE, THAT IS THE QUESTION

Daniel L. Cardoso, MD (*Presenter*)
Mariana Costa, MD (*Abstract Co-Author*)
Beatriz A. Macedo (*Abstract Co-Author*)
Larissa Marciano (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Alexandre M. Pereira, MD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Ralph R. Tavares, MD (*Abstract Co-Author*)
Alexandre Pasquali (*Abstract Co-Author*)
Fabio P. Pereira (*Abstract Co-Author*)

TEACHING POINTS

Recognize the anatomy of the mesenteric vasculature on computed tomography (CT). Understand aspects related to mesenteric ischemia (MI). Detailed knowledge on identifying and characterizing potential causes of MI. Comprehend the pathophysiology of MI and correlate with the imaging findings. Insight into the decision-making process for managing MI.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION: Overview of mesenteric vasculature anatomy and CT anatomical landmarks. Pathophysiology of MI. Potential causes of MI (occlusive versus non-occlusive). DIAGNOSIS AND IMAGING FINDINGS: Criteria for MI characterization on CT and protocol optimization. The process of identifying each stage of MI. Prognostic implications of MI imaging findings. Treatment strategies: occlusive and non-occlusive causes. SUMMARY AND SYSTEMATIC APPROACH: A streamlined approach to integrating imaging findings with clinical decision-making. TAKE HOME MESSAGES.

EREE-30 THE SPECTRUM OF PNEUMATOSIS INTESTINALIS: A CHALLENGE FOR THE RADIOLOGIST AND A DILEMMA FOR THE SURGEON

Ana Claudia Vincenzi Raduan Uski (*Presenter*)
Carolina P. Abud, MD (*Abstract Co-Author*)
Camila P. Reifegerste, MD (*Abstract Co-Author*)
Marilia P. Ferreira, MD (*Abstract Co-Author*)
Maria Helena N. Pedroso (*Abstract Co-Author*)

TEACHING POINTS

Pneumatosis intestinalis (PI) is an uncommon radiologic finding characterized by the presence of gas within the bowel wall. Although often associated with intestinal ischemia and other abdominal emergencies, it may also be related to benign conditions. PI is classified into two main forms: primary, represented by Pneumatosis Cystoides Intestinalis (PCI), and secondary, which carries a higher risk of severity. Computed tomography (CT) is the diagnostic method of choice, allowing detailed characterization of gas patterns (linear, bubbly, or band-like) and identification of associated signs such as bowel wall thickening or thinning, lack of mucosal enhancement, ascites, porto-mesenteric venous gas (PMVG), and mesenteric thrombosis. Radiologists must be familiar with the imaging features suggestive of PI, as this plays a key role in risk stratification. Accurate interpretation helps avoid unnecessary interventions in benign cases and supports prompt management in potentially life-threatening situations.

TABLE OF CONTENTS/OUTLINE

• Introduction;• Objectives;• Pathogenesis;• Imaging Methodos and findings;• Radiologic cases with clinical and/or surgical correlation;• Recognize the score available to predict mortality in patients with intestinal pneumatosis.• Conclusion / take home message• References

EREE-31 IMAGING THE UNSPEAKABLE EMDASH CASE-BASED JOURNEY INTO CHILDHOOD TRAUMA

Hiba Sawliha Syed, MBBS (*Presenter*)
Zohaib Mallick, MBBS (*Abstract Co-Author*)
Uffan Zafar, MD (*Abstract Co-Author*)

TEACHING POINTS

1. What counts as non-accidental injury in children. 2. Epidemiology and outcomes. 3. Understanding mechanisms of injury and the resulting injury patterns. 4. Pitfalls and mimickers. 5. Collaborating with clinicians. 6. Guidelines for the radiologist’s reporting

TABLE OF CONTENTS/OUTLINE

1. Introduction to Non-accidental Injury (NAI) in Children a. Definitions b. Categories of abuse c. Legal and ethical responsibilities of the radiologist 2. Epidemiology and Outcomes a. Global Statistics b. Risk factors c. Long-term medical, developmental, and legal outcomes 3. Mechanisms of Injury and Classic Injury Patterns a. Mechanics of Injury: shaking, impact, compression b. Radiologically detectable injuries i. Skeletal ii. Cranial/Intracranial iii. Thoracoabdominal iv. Spinal and soft tissue injuries c. Case-based examples and imaging walkthroughs 4. Pitfalls, Mimickers, and Diagnostic Challenges a. Osteogenesis Imperfecta, Rickets, Scurvy b. Birth trauma c. Normal variants d. Limitations in injury dating and subtle signs e. Overlap with accidental injuries and documentation bias 5. Interdisciplinary Collaboration in Suspected NAI a. How and what to communicate b. Working in the presence and absence of a child protection support system 6. Guidelines and Best Practices a. Imaging Protocols (skeletal survey, head CT/MR, ultrasound) b. Structured reporting. c. Reporting timelines and corroboration d. Legal implications and documentation standards 7. Learning Takeaways for Residents a. Checklist approach for NAI suspicion and imaging work-up b. Reinforcement of the radiologist’s proactive role c. Final call to action

EREE-32 DONT BE RASH,GET AN ULTRASOUND-A CASE COLLECTION OF RADIOLOGIST´S JOURNEY THROUGH SKIN CONDITIONS AT HOSPITAL

Juliana Lie Taya (*Presenter*)
Felipe Correa Brito, MD (*Abstract Co-Author*)
Priscilla T. Forster, MD (*Abstract Co-Author*)

TEACHING POINTS

• Showcase techniques for enhancing your skills in dermatologic ultrasound.• Establish the essential aspects that must be included in your report for more precise diagnostics and establishment of relevant differentials.• Highlight the key ultrasound imaging features of prevalent diseases you may encounter in a hospital setting.• Demonstrate the positive impact of a trained radiologist in the field.

TABLE OF CONTENTS/OUTLINE

•Introduction- Basics of Ultrasonography - Review of the ultrasounds’ physics applied in dermatology.•Dermatologic Tutorial:- A structured approach to performing dermatological ultrasound -Fundamental components that should be in the report. •CASE 1: Thumbs Up -Clinical history and examination -Ultrasound and correlation -Diagnosis •CASE 2: Shades of purple -Clinical history and examination -Ultrasound and correlation -Diagnosis •CASE 3: More than just an abcess -Clinical history and examination -Ultrasound and correlation -Diagnosis •CASE 4: It's not a pimple -Clinical history and examination -Ultrasound and correlation -Diagnosis •Conclusion: Dermatological ultrasound is crucial for improving diagnostic precision in skin lesions, clarifying differential diagnoses, guiding treatment approaches and evaluating therapeutic success. Achieving such outcomes requires the technique to be performed correctly and necessitates a strong collaboration between the radiologist and the support team, not only through the report it self but also via direct and clear communication.

EREE-33 CT OF SPONTANEOUS RUPTURE OF THE SPLEEN: SPECTRUM OF CAUSES AND FINDINGS BEYOND TRAUMA

Mohammad Yasrab (*Presenter*)
Zahra Rahmatullah, MD (*Abstract Co-Author*)
Linda C. Chu, MD (*Abstract Co-Author*)
Satomi Kawamoto, MD (*Abstract Co-Author*)
Elliot K. Fishman, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Atraumatic splenic rupture is a rare but potentially fatal emergency that can be spontaneous or secondary to range of underlying etiological factors 2. Accurate detection of atraumatic splenic hemorrhages and ruptures is dependent on proper scan protocols as well as scan display (MPR, MIP, VRT) 3. Depending on the underlying cause, splenic ruptures and bleeds have a range of CT appearances, including associated splenic infarcts, hypersplenism, infiltration, vascular malformations, primary

and secondary masses, and even associated pathology of other abdominal structures such as the pancreas 4. Early detection is critical for outcome and attention to complications including massive bleeds, multifocal disease will be addressed

TABLE OF CONTENTS/OUTLINE

1. Patient demographics, clinical presentation, risk factors, incidence/prevalence of spontaneous splenic hemorrhages and ruptures 2. CT scan protocols and display protocols for the detection of spontaneous and pathologic atraumatic splenic hemorrhages and ruptures3. Case studies showing the various appearances of splenic hemorrhages and ruptures including infectious etiologies, autoimmune processes, vascular malformations, systemic phenomenon such as thromboembolism and hematologic pathologies, medication adverse effects, and both benign and malignant masses4. Pearls and pitfalls in the diagnosis of spontaneous splenic ruptures and hemorrhages will be discussed with studies5. Future direction, conclusion, and references

EREE-34 CLOSED FOR CONSTRUCTION: UNVEILING POSTPARTUM COMPLICATIONS

Mariana R. Defreitas, MD (*Presenter*)
Rachel Bright, MD (*Abstract Co-Author*)
Ana Bucci, MD (*Abstract Co-Author*)
Erin Inman (*Abstract Co-Author*)
Jason A. Pietryga, MD (*Abstract Co-Author*)
Kristen Olinger, MD (*Abstract Co-Author*)

TEACHING POINTS

(I) Recognize imaging findings of postpartum complications in abdomen and pelvis (II) Recognize pathologies specific to C-section and vaginal birth (III) Distinguish normal postpartum imaging findings from complications

TABLE OF CONTENTS/OUTLINE

I. Introduction a . Prevalence and morbidity of postpartum complications b. Role of imaging c. Modalities and approach II. Spectrum of Pathologies a. General postpartum complications i. Active hemorrhage ii. Thrombophlebitis iii. Endometritis iv. Retained products of conception b. Post-partum complications more specific to c-section i. Hematomas 1. Bladder flap 2. Subfascial 3. Rectus sheath 4. Abdominal wall ii. Structural 1. Review of normal post-op appearance 2. Uterine dehiscence 3. Uterine rupture 4. Uterine arteriovenous fistula iii. Infections/abscesses 1. Intrabdominal/intrapelvic 2. Rectus sheath 3. Subcutaneous iv. Iatrogenic 1. Ureteral injury 2. Bladder injury c. Post-partum complications more specific to vaginal birth i. Hematomas 1. Vaginal, vulvar, rectovaginal ii. Structural 1. Review of normal post-partum pelvis 2. Rectal lacerations 3. Urethral injury 4. Rectovaginal fistula 5. Uterine inversion iii. Musculoskeletal 1. Pubic diastasis 2. Sacral stress fracture III. Conclusion there is a wide range of postpartum complications that can be recognized by interpreting radiologist on abdominal and pelvic imaging. Recognizing these pathologies and distinguishing these findings from normal postpartum appearance of pelvic organs is essential for fulfilling the role of radiology in postpartum care.

EREE-35 "BEYOND APPENDICITIS": UNCOMMON PEDIATRIC EMERGENCIES UNVEILED BY ULTRASOUND

Mario Ruben Paz Campos, MD (*Presenter*)
Cristina Delange Izurrategui, MD (*Abstract Co-Author*)
Diego Suarez Sanchez-Infante (*Abstract Co-Author*)
Arturo Gross, MD (*Abstract Co-Author*)
Teresa Canas Macias, MD (*Abstract Co-Author*)

TEACHING POINTS

To highlight ultrasound as a first-line modality in pediatric emergencies, emphasizing its role in identifying rare but prognostically significant conditions, while reinforcing its safety and real-time diagnostic advantages. To promote a systematic, station-based approach to pediatric ultrasound—head/neck, thorax, abdomen, and musculoskeletal—to enhance diagnostic accuracy and broaden the clinical perspective beyond common pathologies.

TABLE OF CONTENTS/OUTLINE

Ultrasound plays a pivotal role in pediatric emergency imaging, offering a radiation-free, bedside modality aligned with the ALARA principle. Pediatric pathology can be efficiently approached through five anatomical stations: head, neck, thorax, abdomen, and musculoskeletal system. In the head and neck, ultrasound allows rapid assessment of hydrocephalus, deep neck infections, and ocular pathologies such as vitreous hemorrhage—a potential cause of sudden blindness. Thoracic ultrasound outperforms radiography in detecting pneumonia, pleural effusions, and pneumothorax. Abdominal ultrasound should not be limited to appendicitis; rarer yet critical diagnoses include Wilkie's syndrome, omental infarction, and mesenteric adenitis. Musculoskeletal ultrasound enables real-time evaluation of fractures, tendon ruptures, muscle fiber tears, and soft tissue infections. Radiologists possess a deeper understanding of anatomy, pathology, and scanning technique, often surpassing clinical operators in diagnostic accuracy. In pediatric emergencies, thinking beyond appendicitis and empowering radiologists to lead sonographic evaluation ensures faster, safer, and more comprehensive care.

EREE-36 THE USUAL SUSPECTS: IMAGING OF CRIME AND INCARCERATION

Armand Garewal (*Presenter*)
Ahmad Amer, MD (*Abstract Co-Author*)
Daniel Giraldo Herrera, MD (*Abstract Co-Author*)
Robert J. Dym, MD (*Abstract Co-Author*)
Omar Jamil, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Identify illicit foreign objects on imaging and assess their potential to harm the patient. 2. Distinguish the radiologic features of commonly concealed items across various imaging modalities. 3. Evaluate when additional imaging is necessary to determine object location, related complications, or surgical indications. 4. Recognize concealment methods and injury patterns commonly associated with specific populations. 5. Detect secondary complications related to drug concealment. 6. Understand how foreign objects may contribute to or result from traumatic injuries.

TABLE OF CONTENTS/OUTLINE

Introduction: Radiologists serving incarcerated patients need to recognize illicit objects on imaging. Prompt recognition will determine need for further imaging or consultation with other services. ?Deliberate Foreign Body Ingestion : Radiologic follow up and surgical implications. Drug Ingestion for Trafficking : Imaging appearance and consequences of absorption. ?Patterns of Drug Concealment : Packing, Pushing, Stuffing, and External.? Foreign Bodies in Trauma : Imaging features of unconventional weaponry.

EREE-37 TRAUMATIC INJURIES OF THE CRANIOCERVICAL JUNCTION IN ADULTS: WHAT CT MISSES, MRI REVEALS

Roy Riascos, MD, MBA (*Presenter*)
Juan Ricardo, MD (*Abstract Co-Author*)
Andres F. Mejia Leon, MD (*Abstract Co-Author*)
Kamand Khalaj, MD, MPH (*Abstract Co-Author*)
David E. Timaran Montenegro, MD (*Abstract Co-Author*)
Shekhar D. Khanpara, MD,MBBS (*Abstract Co-Author*)
Eliana E. Bonfante, MD (*Abstract Co-Author*)
Jennifer L. McCarty, MD (*Abstract Co-Author*)

TEACHING POINTS

The craniocervical junction (CCJ) is a complex anatomical region where high-energy trauma can result in life-threatening injuries. While CT is the first-line modality for trauma, it primarily detects osseous injuries and may miss critical soft tissue damage. This educational exhibit aims to expand the viewer's understanding of adult CCJ trauma by integrating a multimodality imaging approach.

TABLE OF CONTENTS/OUTLINE

Reviewing the detailed anatomy of the CCJ—including bony, ligamentous, and vascular structures—using cross-sectional imaging and 3D models. Presenting a comprehensive overview of traumatic injuries affecting the occipital condyles, atlas, axis, and associated ligaments. Demonstrating the complementary roles of CT, MRI, and CTA in diagnosing craniocervical injuries. Attendees will gain insight into CT findings such as craniovertebral dissociation and fractures of C1-C2; MRI evaluation of ligamentous disruption, spinal cord injury, and prevertebral hematoma; and CTA detection of associated vascular injuries. A structured review table will summarize key injuries and imaging pearls, equipping radiologists with the tools to recognize subtle but critical findings beyond bone windows.

EREE-38 BLOOD, SWEAT, AND SPINES: CRACKING THE CODE OF VASCULAR LESIONS IN THE CORD

David E. Timaran Montenegro, MD (*Presenter*)
Roy Riascos, MD, MBA (*Abstract Co-Author*)
Kamand Khalaj, MD, MPH (*Abstract Co-Author*)
Jennifer L. McCarty, MD (*Abstract Co-Author*)
Andres F. Mejia Leon, MD (*Abstract Co-Author*)
Mario Mahecha, MD (*Abstract Co-Author*)
Eliana E. Bonfante, MD (*Abstract Co-Author*)

TEACHING POINTS

Understanding the vascular roadmap of the spine is key to diagnosing ischemic and hemorrhagic spinal lesions with precision. This educational exhibit walks you through the intricate arterial and venous anatomy of the spinal canal and showcases the imaging signatures of vascular pathology, one compartment at a time. Through a series of high-yield MR cases and a focus on localization, viewers will gain an intuitive grasp of how vascular territories shape the clinical and imaging landscape of spinal disease.Teaching Points: -Review the vascular compartments of the spine, including key arterial and venous players. -Learn how to tailor MR imaging to detect ischemic and hemorrhagic spinal cord lesions. -Recognize characteristic patterns based on vascular territory, using cervical, thoracic, and conus medullaris cases.

TABLE OF CONTENTS/OUTLINE

-Vascular anatomy: anterior/posterior spinal arteries and venous plexuses -MR sequences best suited for vascular lesion detection -Pattern-based review of Ischemia: -Cervical spine - anterior vs. posterior spinal artery involvement -Thoracic spine - regional vascular nuances -Conus medullaris - terminal cord vulnerabilities -Spinal hematomas -Intramedullary -Extramedullary -Summary table for quick-reference pattern recognition

EREE-39 ACUTE ABDOMINAL PAIN IN ONCOLOGY PATIENTS: DIAGNOSTIC CHALLENGES AND IMAGING INSIGHTS

Jia Cheng Yao, MD (*Presenter*)
Iain D. Kirkpatrick, MD, FRCPC (*Abstract Co-Author*)
Vincent M. Mellnick, MD (*Abstract Co-Author*)
Philippe A. Soyer, MD, PhD (*Abstract Co-Author*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)
Michael N. Patlas, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Recognize key imaging features of acute abdominal emergencies in cancer patients, including thrombotic, hemorrhagic, obstructive and iatrogenic complications. Understand how acute abdominal emergencies may vary across different cancer types, such as hematologic, gastrointestinal and hepatobiliary. Understand the underlying mechanisms of abdominal pain in oncology patients, including effects of malignancy, chemotherapy, surgery, and immunosuppression. Identify high-risk scenarios such as treatment/chemotherapy-associated complications that require urgent intervention. Review appropriate imaging protocols and the radiologist's role in early diagnosis and communication in oncologic emergencies.

TABLE OF CONTENTS/OUTLINE

This case-based presentation highlights acute abdominal emergencies in cancer patients, including thromboembolism, hemorrhage, and treatment-related complications. It emphasizes key imaging findings, varying complications associated with different malignancy types, and the radiologist's role in timely diagnosis and management. 1. Introduction 2. Case Base Review a) Thrombotic: mesenteric thrombus (arterial/venous), tumor thrombus/Budd-Chiari syndrome; b) Hemorrhagic: hemorrhagic/ruptured malignancy, hemorrhagic cholecystitis; c) Obstructive: bowel obstruction, urinary obstruction; d) Treatment-related: chemotherapy-related complication (perforation, colitis/enteritis), stent migration (pancreatic, biliary); 3. Conclusion: importance of prompt imaging in optimizing outcomes

EREE-40 CT FINDINGS OF ABDOMINAL BICYCLE HANDLEBAR INJURIES IN CHILDREN AND YOUNG ADULTS: PICTORIAL REVIEW

Irune Perez Arroyuelos (*Presenter*)
Nerea Insausti Jaca (*Abstract Co-Author*)
Silvia Lopez (*Abstract Co-Author*)
Maria Berastegui (*Abstract Co-Author*)
Paula Garcia Barquin, MD (*Abstract Co-Author*)
Maria Begona Guantes Del Vigo (*Abstract Co-Author*)
Alex Esnaola Braceras (*Abstract Co-Author*)

TEACHING POINTS

The bicycle handlebar (or handlebar of scooter or electric scooter) is a unique mechanism of injury. Handlebar injuries are more likely to cause abdominal and soft tissue injuries. In the abdomen, injuries to the pancreas, small bowel, mesentery, liver and spleen are the most common injuries attributed to direct handlebar trauma. The objectives of this study are:-Explain the mechanism of handlebar abdominal injuries.-Evaluate the presentation, location , severity and illustrate some representative cases of different abdominal trauma related to this mechanism.

TABLE OF CONTENTS/OUTLINE

In this exhibit we show and discuss different cases of handlebar abdominal injuries in children and young adults recorded in our institution: 1) Pancreatic injuries2)Splenic injuries3)Renal injuries4)Hepatic injuries5)Adrenal injuries Take home points.

EREE-41 BRICKING BAD: REVIEW OF LUMBAR FRACTURES

Claudia M. Muns, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Larry M. Alejandro Vargas, MD (*Abstract Co-Author*)
Paola Berrios Jimenez (*Abstract Co-Author*)
Noralys E. Pagan (*Abstract Co-Author*)
Joaquin R. Ortiz-Cruz, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review lumbar spine anatomy using a construction analogy. - Identify lumbar spine fractures: compression, burst, wedge, chance, and retrolisthesis. - Analyze real trauma cases from our institution using CT imaging. - Use visual aids for diagnosis, classification, and treatment.

TABLE OF CONTENTS/OUTLINE

1. Introduction and Objectives 2. Anatomy Review (Vertebrae, Discs, Ligaments, Nerve Roots) 3. AO Spine Classification: C: Dislocation, Displacement B: Chance, Posterior Tension Band Disruption, Hyperextension A: Wedge, Split, Incomplete Burst, Complete Burst 4. Cases and Conclusion Abstract: Lumbar spine fractures account for 5-10% of trauma fractures, often from motor vehicle accidents or falls. These injuries may cause instability or neurological deficits, requiring precise classification. Using the AO Spine Classification, fractures are categorized into compression (A), distraction (B), and translation (C). A construction analogy aids understanding: vertebrae as bricks, discs as cement, and spinous processes as metal beams. Fractures are depicted as construction accidents—e.g., a Chance fracture as a TNT explosion and an A3 incomplete burst fracture as a wrecking ball hitting a brick wall. This exhibit features real CT cases from our trauma center, highlighting anatomy, classification, and management to enhance education for medical students, residents, and imaging specialists.

EREE-42 MEMBERS ONLY: IMAGING PENILE EMERGENCIES

Meghan G. Lubner, MD (*Presenter*)
Jason A. Pietryga, MD (*Abstract Co-Author*)
Nicholas G. Rhodes, MD (*Abstract Co-Author*)
Jamie Marko, MD (*Abstract Co-Author*)
Benjamin L. Triche, MD (*Abstract Co-Author*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)
Daniel Shapiro (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Ultrasound and MRI are the mainstays of penile imaging. Fluoroscopy (retrograde urethrogram, voiding cystourethrogram) can be added when evaluating the urethra. 2. Technique and positioning as well as knowledge of normal anatomy is important when imaging the penis. 3. The tunica albuginea is an important landmark in trauma and in tumors and is well seen as a low T2 signal intensity fascial plane on MRI or a slightly echogenic fascial plane on US. 4. Penile fracture is defined as a disruption of the tunica with corporal rupture and requires surgical repair. This can be associated with penile hematoma and urethral injury. 5. High flow priapism is often post traumatic and due to arteriocavernosal fistula related to straddle injury. Low flow or ischemic priapism is most commonly associated with sickle cell anemia. 6. Penile infection can be due to retrograde urinary infection, abdominal or subcutaneous sources, fistula formation or foreign bodies. Gas-forming infections are a surgical emergency. 7. It is important to include the penis and urethra in your imaging search pattern if they are included in the field of view.

TABLE OF CONTENTS/OUTLINE

I. Normal Anatomy a. MRI b. US c. Schematic II. Penile hematoma/fracture a. Injury during intercourse b. Other blunt trauma c. Penetrating injury d. Associated urethral injury III. Priapism a. High flow/traumatic b. Low flow/ischemia c. Malignant IV. Infection a. Penile scrotal abscess b. Gas forming infection c. Foreign body/instrumentation/complications of prosthesis or augmentation/cosmetic procedures d. Fistula V. Tumor related emergencies a. Obstruction b. Hemorrhage c. Hormonally active tumor d. Complications of therapy

EREE-43 HOLD YOUR HORSES: HORSE-RELATED INJURIES AT A LEVEL 1 TRAUMA CENTER

Alejandra Cardona Del Valle, MD (*Presenter*)
Claudia M. Muns, MD (*Abstract Co-Author*)
Maximiliano Carrera (*Abstract Co-Author*)
Larry M. Alejandro Vargas, MD (*Abstract Co-Author*)
Jose A. Lara, MD (*Abstract Co-Author*)

TEACHING POINTS

Review incidence and types of injuries from horseback falls, including head, spine, thoracic, abdominal, pelvic, and extremity trauma.Identify characteristic imaging findings across modalities (X-ray and CT).Discuss safety precautions to prevent injury and important things to report in each pathology.

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Retrospective Study: Demographics and Injury Statistics IV. Imaging Findings by Region: • Head • Spine • Thoracic • Pelvic/Abdominal • Upper and Lower Extremities V. Diagrams and Anatomy Review VI. Safety Precautions and Important thing to Report VII. Conclusion Horse-related trauma involves high-energy injuries with a wide anatomical range, posing challenges in trauma care. This retrospective study from our Level 1 trauma center reviews horse-related injuries treated in 2024, analyzing demographics, injury types, and imaging findings. Using CT and X-ray examples from real cases, we demonstrate key patterns and the role of imaging in assessing severity, guiding management, and predicting outcomes. The exhibit presents classic imaging findings by injury location and discusses their clinical implications. It aims to enhance understanding of equestrian trauma and the importance of radiology in diagnosis, treatment, and prevention.

EREE-44 RENAL GRAFTS UNDER THE ULTRASOUND: EMERGENCY SETTING CHALLENGES

Paula E. Hernandez Quiroz, MD (*Presenter*)
Veronica Espinosa Cruz, MD (*Abstract Co-Author*)
Eunice L. Urbina Marure, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Gain knowledge of the anatomy and physiology of renal grafts and their types.2. Develop skills to perform and interpret ultrasound evaluations of renal grafts, including Doppler assessments.3. Learn to recognize complications associated with renal grafts through ultrasound imaging.4. Differentiate normal from pathological ultrasound findings using clinical cases.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Overview of Renal Transplantation (Types of Renal Grafts, Vascular Supply and Drainage) 2. Ultrasound Imaging Techniques - Ultrasound Protocols and Doppler Ultrasound Applications 3. Review of complications in kidney grafts with ultrasound findings based on Case-Based Problems.- Perinephric fluid - Renal collecting system abnormalities - Vascular complications - Focal parenchymal abnormalities - Diffuse parenchymal abnormalities. 4. Conclusion - Summary of Key Takeaways - Teaching points 5.References

EREE-45 NONACCIDENTAL TRAUMA AND ITS "MIMICS": A MULTIMODALITY IMAGING REVIEW WITH INTERDISCIPLINARY INTEGRATION

Nadia Solomon, MD,MA,MSc (*Presenter*)
Jamie M. Elifritz, BS, MD (*Abstract Co-Author*)
Stacy K. Goergen, MBBS (*Abstract Co-Author*)
Khalid Al-Dasuqi, MD (*Abstract Co-Author*)
Megan B. Marine, MD (*Abstract Co-Author*)
Anne Sailer, MD (*Abstract Co-Author*)
Jannatun Sikder, MD (*Abstract Co-Author*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)

Richard A. Bronen, MD (*Abstract Co-Author*)
Ting Y. Tao, MD, PhD (*Abstract Co-Author*)
Cinthia Cruz Romero, MD (*Abstract Co-Author*)
Sean A. Lisse, MD (*Abstract Co-Author*)

TEACHING POINTS

Radiologists play a critical role in identifying non-accidental trauma (NAT) while also recognizing imaging "mimics." Distinguishing these mimics is essential to: diagnose significant medical conditions requiring specific tests and treatment; prevent unjust family separation; and ensure alternative diagnoses are appropriately considered before legal proceedings. Radiologists must be vigilant in identifying potential NAT mimics and collaborate with the multidisciplinary team to ensure accurate diagnosis and appropriate patient care. This presentation will demonstrate that many alleged NAT mimics can be definitively distinguished from true NAT through a comprehensive approach that integrates imaging expertise, clinical evaluation, and targeted non-imaging investigations.

TABLE OF CONTENTS/OUTLINE

This presentation aims to a) review imaging findings suggestive of NAT, b) describe both clinical and imaging best practices for diagnosis, and c) discuss pathology that can mimic imaging findings of NAT. This multimodality approach will demonstrate potential mimics for NAT including: accidental injury; congenital and developmental variants; birth trauma; infections and postinfectious conditions; primary bone diseases; vitamin deficiencies and toxins; connective tissue disorders; skeletal dysplasias; metabolic, hematologic, and coagulation disorders; and hypoxic and ischemic conditions.

EREE-46 WHAT THE RADIOLOGIST NEEDS TO KNOW ABOUT COSMETIC PROCEDURES IN THE ABDOMEN AND PELVIS

Nadia Solomon, MD,MA,MSc (*Presenter*)
Mohamed Badawy, MD (*Abstract Co-Author*)
Francisco Calle Bernal, MD (*Abstract Co-Author*)
Mine Sorkun, MD (*Abstract Co-Author*)
Jonathan S. Luchs, MD (*Abstract Co-Author*)
Alberto Gallerani (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Douglas S. Katz, MD (*Abstract Co-Author*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)

TEACHING POINTS

Introduce the radiologist to the wide range of cosmetic procedures performed on the abdomen and pelvis. Describe the expected post-procedural appearances of these procedures on imaging, with a focus on cross-sectional imaging modalities. Describe potential acute and chronic complications of cosmetic procedures performed on the abdomen and pelvis, using case examples to illustrate imaging findings. Discuss management of complications, where applicable.

TABLE OF CONTENTS/OUTLINE

This exhibit will introduce the radiologist to the wide range of cosmetic procedures performed on the abdomen and pelvis, including abdominoplasty, implant procedures (e.g., buttock implants, six-pack creation), liposuction, fat transfer (most commonly, the "Brazilian butt lift"), cosmetic injections (e.g., buttock injections, penile injections, "labial puffing"), etc. It will describe the expected post-procedural appearances of these procedures on imaging, with a focus on computed tomographic and magnetic resonance imaging modalities. The exhibit will also describe potential complications of cosmetic procedures performed on the abdomen and pelvis (e.g., infection, hematoma, visceral laceration/hemorrhage, wound dehiscence, implant malposition or rupture, injection granuloma or material migration), using case examples to illustrate imaging findings. Finally, the exhibit will briefly discuss the management of complicated cosmetic procedures, where applicable.

EREE-47 MRI FOR ABDOMINAL PAIN IN PREGNANCY: APPENDICITIS AND BEYOND

Jonathan Levine, MD (*Presenter*)
Michio Taya, MD, MSc (*Abstract Co-Author*)

TEACHING POINTS

Often obtained in pregnancy to assess for acute appendicitis, MRI may uncover unexpected diagnoses beyond appendicitis. The MRI diagnosis of pathologies more commonly seen by CT may be a challenge for the radiologist given physiologic and anatomic changes in pregnancy. Through the presentation of over 12 MRI cases from multiple organ systems and a highlight of pertinent literature, this exhibit will prepare the audience to recognize common and atypical causes of abdominal pain in pregnancy. Considerations unique to antepartum patients will be emphasized, including pathologies more likely to occur in pregnancy and interpretation of findings in the absence of IV contrast.

TABLE OF CONTENTS/OUTLINE

1. Goals and objectives 2. Clinical challenges associated with assessment of patients with abdominal pain during pregnancy 3. Safety considerations for MRI during pregnancy, including heating, acoustic effects, and contrast safety 4. Suggested MRI protocol for abdominal pain in pregnancy 5. Case-based overview of pathologies that may be expectedly or incidentally encountered by MRI. The exhibit will highlight how pregnancy may affect the incidence and presentation of each pathology: Gynecologic (ovarian torsion, adnexal masses, leiomyoma-related pathologies), Urinary tract (nephrolithiasis, pyelonephritis), Hepatobiliary (cholelithiasis, cholecystitis, pancreatitis, HELLP syndrome), Gastrointestinal (appendicitis, diverticulitis, Crohn's, bowel obstruction), Vascular (hemorrhage, venous thrombosis)

EREE-48 LOOK AGAIN: CASE-BASED REVIEW OF SUBTLE BUT IMPORTANT FINDINGS DURING EMERGENCY ON-CALL SHIFTS

Cisel Yazgan, MD, MD (*Presenter*)
Oguzhan Can, MD (*Abstract Co-Author*)
Isin Seda Sahin, MD (*Abstract Co-Author*)

TEACHING POINTS

• To recognize subtle but clinically significant imaging findings that can be overlooked under on-call conditions such as time pressure, high image load, and lack of detailed clinical information• To highlight diagnostic challenges caused by anatomical variations, atypical presentations, anatomic blind spots• To enhance learning by emphasizing high-yield teaching points relevant to radiology residents

TABLE OF CONTENTS/OUTLINE

1. Introduction During on call shifts radiologists interpret images under pressure turn around time, high workload and limited clinical information. These conditions can increase the likelihood of misdiagnosis particularly when CT findings subtle or requiring clinical correlation.2. Case Based Review Selected emergency CT cases from our institution demonstrating overlooked but clinically important findings. Recognizing Regions Prone to Missed Hemorrhage Subtle hemorrhages in anatomically challenging blind spots Subtle Signs of Spinal Instability Indirect CT findings suggestive of PLC injury Hidden Clues of Aortic Dissection on NCCT Recognizing secondary signs in the absence of contrast Subtle Retroperitoneal Perforation Indolent clinical course with minimal localized gas Early Ischemic Signs on NCCT Importance of window settings Fractures Extending Toward Critical Structures Overlooked maxillofacial injuries with potential complications Indirect Radiologic Clues: When Primary Signs Are Absent Fat stranding, soft tissue changes, and subtle asymmetry

EREE-49 ULTRASOUND & SURGICAL CORRELATION IN ACUTE PENILE TRAUMA: RECOGNIZING TRUE FRACTURES AND AVOIDING PITFALLS

Ignacio Cavaller, MD (*Presenter*)
Angel Sanchez Guerrero (*Abstract Co-Author*)

Elena Martinez Chamorro (*Abstract Co-Author*)
Miguel Diez, MD (*Abstract Co-Author*)
Hugo Gonzalez, MD (*Abstract Co-Author*)

TEACHING POINTS

To describe the anatomy of the penis relevant to imaging (ultrasound). To review the ultrasound features of penile fracture and its mimics in 9 cases of our institution To correlate sonographic findings with intraoperative results in 4 cases. To highlight the differences between true and false penile fractures and its importance of early diagnosis in preventing complications.

TABLE OF CONTENTS/OUTLINE

Penile anatomy and mechanisms of injury. Sonographic findings of true penile fractures. Differentiation from false penile fractures: common mimics. Correlation with surgical findings and treatment strategies. Complications and long-term outcomes.

EREE-50 EMERGENCY NEURORADIOLOGY: EASY THINGS MISSED IN THE DARKNESS

Babajide Owosela, BS (*Presenter*)
Timothy Arleo, MD (*Abstract Co-Author*)
Taejin Min, MD,PhD (*Abstract Co-Author*)
Siddhartha Kosaraju, MD (*Abstract Co-Author*)
Ling Chen Chien, MD (*Abstract Co-Author*)
Ryan B. Peterson, MD (*Abstract Co-Author*)

TEACHING POINTS

Interpretive error rates in neuroradiology significantly increase during overnight and weekend shifts. Performance changes related to fatigue include delayed fixation, altered search patterns, and reduced confidence may provide compounded risk, especially in subtle or atypical presentations. This exhibit highlights missed findings in emergency neuroradiology cases interpreted after-hours. Through a case-based review, we will: Examine the evidence linking fatigue and after-hours interpretation with increased error rates. Identify common neuroradiologic entities prone to overnight misses, emphasizing subtle imaging clues. Discuss strategies to reduce diagnostic error, including structural workflow changes and fatigue mitigating techniques.

TABLE OF CONTENTS/OUTLINE

Introduction Burden of mistakes made after-hours compared to weekday interpretations Brief literature review on radiologist fatigue and performance decline Review of Missed Emergency Cases Right internal jugular (IJ) thrombus Carotid-cavernous fistula Cerebellopontine angle mass Intracranial pseudoaneurysm Cervical spine extruded disc Thoracic pneumothorax Fat embolism syndrome Mechanisms of Diagnostic Failure Eye-tracking and cognitive fatigue studies Systemic factors: staffing models, burnout Solutions and Future Directions Structured reporting, checklists, AI triage tools Environmental modifications (light, breaks, ambient stimuli) Institutional support for overnight readers

EREE-51 TRAUMA AT THE SURFACE, DANGER BENEATH: IMAGING THE ABDOMINAL WALL

Nandakumar Patnam Gopal Chetty, MD (*Presenter*)
Ranjana Ramesh (*Abstract Co-Author*)
Navin Ramesh (*Abstract Co-Author*)
Rajat Bhargava, MD, MBBS (*Abstract Co-Author*)
Claire K. Sandstrom, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Seatbelt Sign as a Sentinel Indicator : In the absence of solid organ trauma, a positive seatbelt sign may be the sole clue to underlying bowel and vascular injuries. 2. Morel-Lavallee Lesion Demands a Strategic Shift : Its presence calls for a modified approach to fracture fixation, given the elevated risk of postoperative infection. 3. Traumatic Hernias as Markers of Multisystem Injury : Often accompanied by bowel and mesenteric trauma, these hernias necessitate surgical repair to forestall future complications. 4. Rectus Sheath Hematomas Require Timely Intervention : Resulting from epigastric artery damage, rapidly expanding hematomas can mandate invasive management such as angioembolization.

TABLE OF CONTENTS/OUTLINE

1. Overview and anatomic considerations. 2. Seatbelt sign-related injuries. 3. Moral-Lavallee lesion. 4. Body wall muscular and juxtamuscular injuries. 5. Traumatic body wall hernia spectrum.

EREE-52 AORTA EMERGENCY: A RESIDENT'S CRASH COURSE IN ACUTE AORTIC SYNDROMES

Arianne Idaly Ramos Galvan, MD (*Presenter*)

TEACHING POINTS

Review the definition and classification of Acute Aortic Syndromes (AAS), including aortic dissection, intramural hematoma (IMH), and penetrating atherosclerotic ulcer (PAU).Understand the normal anatomy and histology of the aortic wall, to establish the foundation for interpreting disease mechanisms and imaging findings.Recognize the key pathophysiological mechanisms underlying each AAS subtype. Review optimal CT imaging protocols for AAS detection. Differentiate between the key imaging features of each AAS. Recognize imaging mimics and analyze differential diagnoses, tips and tricks. Apply guideline based knowledge to support urgent triage and treatment planning.

TABLE OF CONTENTS/OUTLINE

Introduction: Definition of Acute Aortic Syndrome (AAS), epidemiology and clinical importance.Anatomy and histology of the aorta: gross anatomical divisions, aortic wall layers and vascular histology.Classification of Acute Aortic Syndromes: Pathophysiology and histopathological correlates. Protocol for multiphasic CT angiography. Key radiological findings.Differential diagnosis and mimics (tips and tricks).Management and prognosis (brief overview).Conclusions and key takeaways.

EREE-53 AAST GRADING OF RENAL TRAUMA - AN OVERVIEW FROM A RESIDENT'S APPROACH WHILE WORKING IN THE ED

Jordan K. Gonia, MD (*Presenter*)
Olivia A. Thoroughman, DO (*Abstract Co-Author*)
James T. Lee, MD (*Abstract Co-Author*)
Andres R. Ayoob, MD (*Abstract Co-Author*)
Amanda C. Gibson, DO (*Abstract Co-Author*)
Joseph W. Owen, MD (*Abstract Co-Author*)

TEACHING POINTS

This exhibit aims to provide a clear understanding of the changes in the 2018 update to the AAST renal trauma grading system. Learners will review key aspects of retroperitoneal and renal anatomy relevant to trauma assessment, recognize characteristic imaging findings across Grades I to V, and focus on the distinguishing features of high-grade injuries. The role of multiphasic contrast enhanced CT will be highlighted. Additionally, we will explore utilizing imaging findings to help guide clinical management in renal trauma.

TABLE OF CONTENTS/OUTLINE

The exhibit begins with an introduction to the relevance of renal trauma in emergency care, followed by a brief review of pertinent renal and retroperitoneal anatomy. We will then examine the key changes introduced in the 2018 AAST renal injury grading update and outline the current criteria used to classify renal injuries. Next, the role of multiphasic CT imaging protocols will be discussed, leading to a case based review of renal injuries of differing grades. The exhibit will conclude with a discussion on clinical management considerations.

EREE-54 DECIPHERING ACUTE PELVIC PAIN: GYNECOLOGIC EMERGENCIES

Mariana Costa, MD (*Presenter*)
Daniel L. Cardoso, MD (*Abstract Co-Author*)
Alexandre M. Pereira, MD (*Abstract Co-Author*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Thiago Vieira, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the key anatomical structures of the pelvic cavity; Understand the different causes of acute gynecological pelvic pain and related imaging features; Comprehend the presentations of ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MRI) of the most common causes of acute pelvic pain; Recognize the potential pitfalls in diagnosing pelvic lesions

TABLE OF CONTENTS/OUTLINE

INTRODUCTION Flowchart of causes of acute pelvic pain Causes of acute pelvic pain in women: gastrointestinal, obstetric and gynecological Overview of the main gynecological causes DIAGNOSIS AND IDENTIFICATION OF ACUTE PELVIC PAIN CAUSES UTERINE Leiomyoma degeneration; Torsion of a uterine leiomyoma; Uterine torsion; OVARIAN Corpus luteum; Ruptured ovarian cyst; Hemorrhagic cyst; Ovarian hyperstimulation; Ovarian torsion; ADNEXAL Fallopian tube torsion; OTHERS Pelvic Inflammatory Disease (PID) and complications; Ovarian vein thrombosis; SYSTEMATIC APPROACH: A ROADMAP SUMMARY AND TAKE-HOME MESSAGES

EREE-55 ESSENTIALS OF HEAD AND NECK GUNSHOT WOUND NEUROIMAGING

Alexander McClanahan, MD, MS (*Presenter*)
Anna Eshghi, DO (*Abstract Co-Author*)
Satya N. Patro, MD (*Abstract Co-Author*)
Rudy L. van Hemert JR, MD (*Abstract Co-Author*)
Naghmeh Eshghi, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Gunshot wound patterns are shaped by the firearm, projectile design, velocity, and the biomechanical properties of the affected tissue. Low-elasticity tissues such as brain parenchyma are more susceptible to cavitation injury than relatively high-elasticity tissues such as the muscle, fascia and osseous structures, which are better able to withstand temporary ballistic cavitation. 2. CT and CT angiography (CTA) are the first-line tools for evaluating gunshot and vascular injuries in the head and neck. In cases where CTA is equivocal for vascular injury, digital subtraction angiography is helpful as the gold standard for defining the extent of vascular injury. 3. Given the anatomical complexity and high concentration of vital structures in the small area of the head and neck, a systematic approach to reviewing head and neck gunshot wound imaging is essential. 4. A systematic framework begins with the topogram and then evaluates tissues from superficial (entry/exit sites, superficial soft tissues) to deep (aerodigestive and facial bone/skull, followed by brain/spine parenchymal, and finally vascular structures).

TABLE OF CONTENTS/OUTLINE

• Laceration injury o Scalp laceration o Neck laceration • Penetration injury o Parenchymal Brain & Spinal Cord Injury § Contusion, infarct, bullet track effects § Role of MRI in delayed complications o Osseous Injury § Calvarial, facial, vertebral fractures § Secondary bone projectiles o Arterial Injuries § Dissection, pseudoaneurysm, occlusion § Predictors of need for angiography o Venous Injuries § Jugular and dural sinus thrombosis § MRV/CTV indications o Neck Soft Tissue Injury § Oropharyngeal, esophagus § Contrast extravasation, fistula

EREE-56 PEDIATRIC KNEE MSK MRI IN THE EMERGENCY DEPARTMENT: PEARLS AND PITFALLS

Catherina Zadeh, MD, FRCR (*Presenter*)
Krishnakumari A. Modi, MBBS (*Abstract Co-Author*)
Renata Correa Osorio, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)

TEACHING POINTS

• Pediatric knee MRIs in the ED pose interpretive challenges due to normal variants and subtle pathology. • Prompt diagnosis of ligamentous, meniscal, osteochondral, and infectious conditions impacts management. • A structured, systematic approach reduces misinterpretation and improves clinical decision-making.

TABLE OF CONTENTS/OUTLINE

1. Normal MRI Anatomy and Growth Variants Review of physeal development, ossification centers, and common mimics (e.g., bipartite patella, tubercle fragmentation). Emphasis on age-based comparison and avoiding overdiagnosis. 2. Acute Ligamentous and Meniscal Injuries MRI appearance of partial/complete ACL tears, tibial spine avulsions, and meniscal root and bucket-handle tears. Stress on secondary signs and patterns of bone contusion. 3. Osteochondral Injuries Differentiation of stable versus unstable osteochondritis dissecans using key MRI features such as fluid clefts and displacement. Includes management implications. 4. Knee Joint Effusions in the ED MRI patterns of septic arthritis, juvenile idiopathic arthritis, and lipohemarthrosis. Visual comparison of effusion characteristics and marrow involvement. 5. Stepwise MRI Interpretation Strategy A diagnostic flowchart outlining a practical 5-step approach: growth plate ? bone injury ? ligaments ? cartilage ? effusion. Designed to streamline urgent reads.

EREE-57 BREAST ER: "CAN'T MISS" PATHOLOGIES

Nisha Pradhan, MD (*Presenter*)
Ana Bucci, MD (*Abstract Co-Author*)
Mariana R. Defreitas, MD (*Abstract Co-Author*)
Cherie M. Kuzmiak, DO (*Abstract Co-Author*)

TEACHING POINTS

(1) To gain a better understanding of breast pathologies that may initially present in the ER setting. (2) Overview of “can’t miss” infectious and non-infectious breast pathologies.

TABLE OF CONTENTS/OUTLINE

I. Introduction a. The emergency setting can be a vital part of the detection and characterization of breast lesions in women. b. While the most common breast pathology seen in the ER is likely of infectious etiology, there are also other key pathologies that if diagnosed in a timely fashion can expedite the patient’s access to pertinent care and improve their outcomes. II. Content a. Breast pathologies that present in the emergency room encompass a wide range of abnormalities, ranging from noninfectious to infectious and benign to malignant findings. b. Cases will showcase breast pathologies diagnosed on imaging in the emergency setting, and will range from breast tenderness and postoperative breast pathologies to reconstruction complications and blunt trauma. c. Timely and accurate diagnosis expedited the patient’s time to workup and treatment. III. Summary a. While the most common presentation of breast pathology in the emergency setting is often infectious, the less

common presentations are equally important for radiologists to recognize to optimize patient care and outcomes. b. Appreciating the clinical significance of these findings is crucial, as they may directly impact patient management and follow-up recommendations.

Nov. 30 – Dec. 4
RSNA® 2025
Imaging the Individual

Abstract Archives of the RSNA, 2025

GIEE

Gastrointestinal Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

GIEE-1 ALPHA-PHETOPROTEIN RISING, GO CHECK THE LIVER, BUT... WHERE TO LOOK NEXT? A REVIEW OF HEPATOCELLULAR CARCINOMA METASTATIC DISEASE

Isabel Fonseca Buelga, MD (*Presenter*)
Elena Canales Lachen (*Abstract Co-Author*)
Claudia Viescas Huerta, MD (*Abstract Co-Author*)
Diego Alejandro Garcia Paredes, MD (*Abstract Co-Author*)
Sergio Sintes (*Abstract Co-Author*)
Alba Salgado Parente, MD (*Abstract Co-Author*)
Luis Gonzalez Campo, MD (*Abstract Co-Author*)
Ana Villanueva, MD (*Abstract Co-Author*)
Carlos Tramblin De La Moneda, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Brief review of epidemiology of metastatic hepatocellular carcinoma and principal imaging features 2. To describe the pathways of dissemination of hepatocellular carcinoma 3. To illustrate the different sites of metastases by sample cases. 4. To discuss the recurrence after liver transplant, both locally and at distance. 5. To talk about the risks of diagnostic and therapeutic procedures in recurrence.

TABLE OF CONTENTS/OUTLINE

1. Introduction and epidemiology of metastasic hepatocellular carcinoma (CHC). 1.1 Principal Imaging Characteristics 2. Dissemination pathways 2.1 Hematogenous Spread 2.1.1 Bone 2.1.2 Lung 2.1.3 Less frequent metastases 2.2 Lymphatic Spread 2.3 Peritoneal Implants 2.4 Local Invasion 3. Liver transplant and recurrence 3.1 Epidemiology of recurrence after liver transplant 3.2 Etiopathogenesis 3.3 Imaging Features 3.4 Diagnostic/Therapeutic procedures and the risk of recurrence

GIEE-2 FROM LEGACY TO INNOVATION: RADIOLOGICAL ASSESSMENT OF GASTROINTESTINAL MEDICAL DEVICES AND THEIR ASSOCIATED COMPLICATIONS

Jose Carlos Garcia-Gil Garcia, MBBCh (*Presenter*)

TEACHING POINTS

1. To review the classical intra-abdominal medical devices and delve into their less common complications. 2. To present the latest-generation medical devices, highlighting the radiological features that enable accurate identification and discussing potential complications related to their placement.

TABLE OF CONTENTS/OUTLINE

The continuous advancement of technology not only leads to the development of new tools that radiologists must become familiar with, but also to the evolution of established devices in terms of design and functionality. This presentation aims to revisit the most commonly used intra-abdominal devices over recent decades and explore their less frequently observed complications. Given the large number of devices currently in use, this work has been divided into two parts. The first part focuses on devices placed within the gastrointestinal tract and the biliopancreatic system—ranging from well-established bariatric tools and endoclips to more recent innovations such as lumen-apposing metal stents (LAMS). It should be emphasised that a thorough count of all such devices is essential, with careful correlation between imaging findings and the patient's surgical and endoscopic reports. It is strongly recommended to list these devices at the beginning of the radiological report, including a brief description of their location and any complications arising from their placement.

GIEE-3 "UNVEILING THE UNREAL": COMPREHENSIVE IMAGING REVIEW OF ABDOMINAL PSEUDOLESIONS

Firat Atak, MD (*Presenter*)
Asli Ceren Akbiyik (*Abstract Co-Author*)
Deniz Berkay Sonu, MD (*Abstract Co-Author*)
Onat Guner, MD (*Abstract Co-Author*)
Sevtap Arslan (*Abstract Co-Author*)
Ilkay Idilman, MD (*Abstract Co-Author*)
Ali Devrim D. Karaosmanoglu, MD (*Abstract Co-Author*)
Deniz Akata, MD (*Abstract Co-Author*)
Mustafa Nasuh Ozmen, MD (*Abstract Co-Author*)
Musturay Karcaaltincaba, MD (*Abstract Co-Author*)

TEACHING POINTS

1) Recognize common abdominal CT/MRI pseudolesions using multiple illustrative cases and imaging examples. 2) Understand main causes-anatomical variants, artifacts, iatrogenic and benign changes. 3) Apply practical tips to distinguish pseudolesions from true lesions.

TABLE OF CONTENTS/OUTLINE

A. Definition and causes of pseudolesions. B. Practical differentiation strategies from true lesions, C. Location-specific pseudolesions in: diaphragm (slip, crus mimicking adenopathy, peridiaphragmatic pseudofluid); liver (perfusion anomaly, fat-related, post-treatment, others); spleen (wandering spleen, splenosis, zebra-pattern); pancreas (intrapancreatic accessory spleen, lobulation anomalies, clefts); gastrointestinal tract (intraluminal content, ectopic pancreatic tissue, gastric diverticula); genitourinary tract (hypertrophied renal parenchyma in atrophy, microcysts, hypertrophied column of Bertin, ureteral-jet artifacts and bulking agents, cryptorchidism, ovarian transposition, differential cervical enhancement, pessaries); vascular and miscellaneous entities such as venous pseudothrombosis, prominent cisterna chyli, accessory breast tissue, fallen gallstones, epiploic appendagitis, hemostatic sponges, gossypiboma, fat injections, out-of-field artifacts, hernia repair changes, extramedullary hematopoiesis, abdominal wall endometriosis, rectus sheath hematoma, and omental edema. D. Conclusion.

GIEE-4 QUANTIFICATION BEYOND THE LIVER: PANCREATIC DEPOSITION DISEASES - WHAT ARE THE BENEFITS?

Sthefane Nunes, MD, MD (*Presenter*)
Eleonora Silva (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)
Caroline L. Ghezzi (*Abstract Co-Author*)
Clara Fiorot, MD (*Abstract Co-Author*)
BRUNA RAMOS ALENCAR MARIANO (*Abstract Co-Author*)
Nara Vedoveli (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Viviane B. Amorim, MD (*Abstract Co-Author*)

TEACHING POINTS

Review the mechanisms and metabolic consequences of pancreatic iron and fat deposition, along with associated conditions. Detail key multiparametric MRI and CT methods for quantifying pancreatic iron and fat overload. Propose a practical approach to simplify imaging evaluation and enhance interpretation accuracy.Discuss indirect benefits beyond the abdominal focus, such as predicting cardiac iron deposition.

TABLE OF CONTENTS/OUTLINE

This presentation provides an overview of pancreatic iron and fat deposition. We will explore the pathological mechanisms and associated conditions (e.g., hemochromatosis for iron; MASLD and obesity for fat overload). Emphasis will be placed on the importance of identifying these patients due to potential clinical sequelae, including decreased pancreatic enzyme production, pancreatitis, and diabetes mellitus.MRI techniques for iron quantification—including signal intensity ratio, pancreatic signal index, and relaxometry—will be discussed. Methods for assessing fat infiltration on both unenhanced CT (average density, pancreas/spleen density ratio, pancreas/spleen density subtraction) and MRI (chemical shift imaging and proton density fat fraction [PDFF]) will also be presented.Through case-based examples, we will review parameter analysis and offer a practical approach to facilitate the diagnosis.

GIEE-5 RETROPERITONEAL TUMORS: A RADIOLOGIC JOURNEY FROM COMMON PRESENTATIONS TO UNUSUAL ENTITIES

Fatima Quispe Villca, MD,MMed (*Presenter*)
Silvia E. Gimenez, MS (*Abstract Co-Author*)
Teresa A. Garcia, MD (*Abstract Co-Author*)
Julieta Arellano (*Abstract Co-Author*)
Nicolas Roccatagliata, MD (*Abstract Co-Author*)
Ana Maria Javadi Nia (*Abstract Co-Author*)
Marco Bonilha Zocatelli, MD (*Abstract Co-Author*)

TEACHING POINTS

Retroperitoneal tumors are uncommon and often diagnosed late due to their silent growth within a deep anatomical compartment.Most are of mesenchymal origin, with liposarcoma being the most common type.Computed tomography and magnetic resonance imaging are essential toolsIt is crucial to distinguish primary retroperitoneal tumors from secondary involvement due to adjacent organ invasion or metastases.

TABLE OF CONTENTS/OUTLINE

Retroperitoneal tumors are rare neoplasms that account for a very small proportion of all cancers diagnosed each year. They originate in the retroperitoneal space, a deep and complex cavity located between the diaphragm and the pelvis, which contains vital organs and structures such as the kidneys, adrenal glands, pancreas, major blood vessels, and ureters. Due to their location and asymptomatic growth, they are often detected at advanced stages, when they have already reached a considerable size. This late detection increases the risk of invasion or compression of neighboring organs, with potential complications such as ischemia, tissue necrosis, and frequent recurrence, especially in malignant tumors like sarcomas. Therefore, early diagnosis is essential, and imaging techniques such as computed tomography and magnetic resonance imaging are key to their identification.

GIEE-6 THE GREAT DIVIDE: A RADIOLOGICAL JOURNEY ACROSS THE DIAPHRAGM

Marilia A. Tavares, MD (*Presenter*)
Renan Arakaki, MD (*Abstract Co-Author*)
Aley Talans, MD (*Abstract Co-Author*)
Lucas R. Torres, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Eduardo O. Pacheco, MSc, MD (*Abstract Co-Author*)
Ulysses S. Torres, MD, PhD (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Review the anatomy of the diaphragm, including its attachments, openings, and main anatomical variants.Present the different types of diaphragmatic lesions, classified by their relationship with thoracic and abdominal structures.Discuss the main imaging findings and their relevance in diagnosis and clinical management.

TABLE OF CONTENTS/OUTLINE

The diaphragm is a musculotendinous structure that separates thoracic and abdominal cavities and can be affected by a wide variety of diseases. Given its strategic location and close relationship with surrounding structures, diaphragmatic involvement may arise from adjacent thoracic or abdominal processes, occur intrinsically, or result from transdiaphragmatic spread.This educational exhibit presents a structured pictorial review, beginning with a targeted anatomical overview with original didactic drawings to enhance comprehension. Lesions are classified according to their spatial relationship to the diaphragm to facilitate understanding and pattern recognition:- Above the diaphragm: asbestosis, pleural mesothelioma, metastases.- Within the diaphragm: endometriosis, congenital or acquired hernias.- Below the diaphragm: endometriosis, peritoneal carcinomatosis.- Crossing the diaphragm: biliobronchial fistulas, transdiaphragmatic abscess, transdiaphragmatic tumor extension.Each category is illustrated by clinical cases, followed by image-focused discussion emphasizing the importance of diaphragmatic anatomy in radiologic interpretation. Key teaching points are summarized throughout the presentation in a take-home message format to reinforce diagnostic awareness and support practical application.

GIEE-7 INTERNAL HERNIAS: WHEN TO SUSPECT, WHAT TO LOOK FOR

Teresa A. Garcia, MD (*Presenter*)
Fatima Quispe Villca, MD,MMed (*Abstract Co-Author*)
Julieta Arellano (*Abstract Co-Author*)
Ana Maria Javadi Nia (*Abstract Co-Author*)

Nicolas Roccatagliata, MD (*Abstract Co-Author*)
Ana E. Sanchez Sierra I, MD,MD (*Abstract Co-Author*)
Marco Bonilha Zocatelli, MD (*Abstract Co-Author*)

TEACHING POINTS

They are defined as the protrusion of abdominal viscera through defects in the peritoneum or mesentery, which may be congenital or acquired. Although rare, internal hernias have high morbidity and mortality when not diagnosed promptly, especially due to complications such as bowel ischemia. Contrast enhanced computed tomography is key for early diagnosis, allowing identification of findings such as clustered bowel loops in atypical locations and signs of ischemic compromise. Familiarity with the common locations and typical radiologic features of internal hernias is essential for radiologists, as timely diagnosis can prevent life-threatening surgical emergencies.

TABLE OF CONTENTS/OUTLINE

Internal hernias present a diagnostic challenge due to their low frequency and nonspecific clinical and imaging features, which can mimic other acute abdominal conditions. They are defined as the protrusion of abdominal viscera, typically small bowel loops, through congenital or acquired defects in the peritoneum or mesentery. Although uncommon, they carry a high risk of morbidity and mortality if not diagnosed early, mainly due to the potential for intestinal ischemia. Contrast-enhanced computed tomography is essential for early detection, as it can reveal signs such as clustered bowel loops in atypical locations, obstruction, and in advanced cases, ischemic changes. Paraduodenal hernias are the most frequent type, while postoperative hernias have increased due to the rise in bariatric surgeries. Because symptoms are often vague and intermittent, familiarity with anatomical landmarks and characteristic imaging patterns is crucial for radiologists to ensure timely diagnosis and prevent serious complications.

GIEE-8 THE POWER OF ATTRACTION: IMAGING IN MAGNETIC GASTROINTESTINAL SURGERY

Kathy Truong (*Presenter*)
Cibele Luna, MD (*Abstract Co-Author*)
Eduardo A. Moya, MD (*Abstract Co-Author*)
Yamile Blain, MD (*Abstract Co-Author*)

TEACHING POINTS

-Review the core technical principles of magnetic surgery. -Describe gastrointestinal (GI) applications of magnetic surgery. -Highlight the role of imaging in magnetic-assisted GI procedures.

TABLE OF CONTENTS/OUTLINE

1. Introduction to magnetic surgery and its evolving role in minimally invasive procedures. 2. Overview of magnetic device technology and foundational principles. 3. Applications of magnetic devices in GI procedures. 4. Role of imaging in magnetic GI surgery: a. Identify eligible patients b. Verify magnet placement and localization c. Monitor magnet adhesion and passage d. Identify complications (device failure, leak detection, restenosis/restricture, etc.)

GIEE-9 LIGHTING UP THE LIVER: CEUS IN FOCAL LESIONS

Jonahi S. Serrano Heredia, MD (*Presenter*)
Veronica Espinoza Cruz (*Abstract Co-Author*)
Ana C. Gandara, MD (*Abstract Co-Author*)
Jose A. Cienfuegos Alvear, MD (*Abstract Co-Author*)
Sofia Arizaga, MD (*Abstract Co-Author*)
Monica Chapa-Ibarguengoitia, MD (*Abstract Co-Author*)
Juan Jose Duran Rosas, MD (*Abstract Co-Author*)

TEACHING POINTS

CEUS enables real-time liver lesion characterization without nephrotoxicity or radiation. Hemangiomas : peripheral nodular enhancement with centripetal fill-in. FNH : fast homogeneous arterial enhancement, no washout, ± central scar. Adenomas may mimic HCC—look for arterial enhancement and late washout. HCC : arterial hyperenhancement + mild, late washout (LI-RADS). CCC and hypovascular mets : rim/heterogeneous enhancement, early washout. Hypervascular mets (e.g., NETs): strong arterial uptake, earlier/more marked washout.

TABLE OF CONTENTS/OUTLINE

I. Introduction Role of CEUS in liver lesion evaluation Comparison with CT/MRI CEUS contrast agents and phases II. CEUS Enhancement Patterns: Overview Arterial, portal, and late phase behavior Definition of washout and diagnostic implications III. Benign Lesions Hemangioma Peripheral nodular enhancement Centripetal fill-in, sustained enhancement Focal Nodular Hyperplasia (FNH) Rapid homogeneous arterial enhancement Central scar, no washout Hepatocellular Adenoma Variable enhancement Possible mild late washout Subtype considerations IV. Malignant Lesions Hepatocellular Carcinoma (HCC) Arterial hyperenhancement Mild, late washout CEUS LI-RADS correlation C holangiocarcinoma (CCC) Peripheral arterial enhancement Progressive centripetal fill-in Marked, early washout Metastases Hypervascular (e.g., NETs, RCC): strong arterial enhancement, early washout Hypovascular (e.g., colon, breast): poor arterial enhancement, early marked washout V. Conclusion CEUS interpretation tipsKey features to differentiate benign vs malignant lesions

GIEE-10 PATH BEYOND THE BLIND-END: UNRAVEL THE IMAGING SPECTRUM OF APPENDICEAL PATHOLOGIES

Siva K. Konduru, MBBS (*Presenter*)
Sriram Jaganathan, MD (*Abstract Co-Author*)
Aastha S. Bhatt, MD,MBBS (*Abstract Co-Author*)
Anil K. Dasyam, MD (*Abstract Co-Author*)
Venkata S. Katabathina, MD (*Abstract Co-Author*)

TEACHING POINTS

Discuss a wide spectrum of entities from incidental appendicoliths, and acute appendicitis to neoplasms.Recognizing diverse imaging patterns across ultrasound, CT, and MRI for diagnosis and appropriate clinical management.Discuss different imaging pearls of epithelial and neuroendocrine appendiceal neoplasms with histopathological correlation.Evolving role of imaging in the management of the common and uncommon appendiceal neoplasms.

TABLE OF CONTENTS/OUTLINE

Introduction and anatomy of the appendix including various positional variations of appendix on cross sectional imaging. Various modalities and techniques used for imaging the appendix including their pitfalls and limitations. Imaging features, pathophysiology and management of appendiceal diseases including: • Appendicoliths and foreign bodies.• Acute appendicitis.• Inflammatory bowel diseases involving the appendix.• Primary epithelial neoplasms including Mucinous and Non-mucinous types.• Neuroendocrine Neoplasms.• Miscellaneous and mimics. Evolving role of imaging in the management of appendiceal neoplasms. Conclusion: Appendiceal pathology is diverse, extending beyond classic appendicitis to include chronic inflammatory, neoplastic, and mimicking entities. Advances in CT, ultrasound, and MRI have significantly enhanced the diagnostic confidence and the ability to differentiate various appendiceal diseases. A pattern-based radiologic approach enables precise diagnosis, optimizes patient outcomes, and underscores the radiologist's key role in appendiceal disease evaluation and multidisciplinary care.

GIEE-11 DECODING GASTROINTESTINAL DISEASES THROUGH IMAGING: RADIOLOGIC-PATHOLOGIC CORRELATION AND THE EXPANDING ROLE OF ADVANCED CT TECHNOLOGIES

Kota Yokoyama, MD, PhD (*Presenter*)
Junichi Tsuchiya, MD, PhD (*Abstract Co-Author*)

Hirofumi Yamada (*Abstract Co-Author*)
Yusuke Kawasaki, MD (*Abstract Co-Author*)
Akane Ozawa (*Abstract Co-Author*)
Yoshio Kitazume (*Abstract Co-Author*)
Jun Isogai, MD (*Abstract Co-Author*)
Ukihide Tateishi, PhD (*Abstract Co-Author*)

TEACHING POINTS

- GI diseases encompass a broad spectrum including tumors and inflammatory conditions, each with distinct imaging-pathology signatures. - Radiologic-pathologic correlation deepens understanding of disease processes and clarifies key imaging features essential for accurate diagnosis. - Emerging technologies such as PCD-CT, MRI, and nuclear medicine improve visualization of lesion composition, vascularity, and metabolic activity. - Recognizing disease-specific imaging features aids in differentiating rare entities from more common conditions.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Diagnostic challenges in GI disease and the need for imaging-pathology integration - Benefits of advanced modalities (PCD-CT, MRI, nuclear medicine) 2. Imaging-Pathology Correlation by Disease Category - Epithelial tumors gastric cancer, colorectal adenomas, neuroendocrine tumors (NETs), melanomas, LAMN and pseudomyxoma peritonei (PMP) - Mesenchymal tumors sarcomas, lymphoma - Polyposis syndromes familial adenomatous polyposis (FAP), Cowden syndrome, Cronkhite-Canada syndrome - Inflammatory diseases Crohn's disease, irAE colitis, Satoyoshi syndrome - Metastases and atypical entities 3. Role of Emerging Imaging Modalities - PCD-CT Enhanced spatial/spectral resolution, iodine quantification, lesion conspicuity - MRI Diffusion-weighted and contrast-enhanced MRI for lesion evaluation. - Nuclear medicine Functional imaging of metabolic activity and inflammation 4. Conclusion Integration of advanced imaging with pathology enables accurate diagnosis, subtyping, and disease monitoring in GI conditions, ultimately enhancing patient care.

GIEE-12 HEPATIC INFLAMMATORY PSEUDOTUMOR: CHAMELEON OF THE LIVER

Tushar Kumar, MBBS, MD (*Presenter*)
Bahar Mansoori, MD (*Abstract Co-Author*)
Yongjun Liu (*Abstract Co-Author*)
Orpheus Kolokythas, MD (*Abstract Co-Author*)

TEACHING POINTS

1.Provide an overview of hepatic inflammatory pseudotumor - definition, epidemiology, and pathophysiology.2.Discuss the current diagnostic criteria of hepatic inflammatory pseudotumor - historic and current standards.3.Provide detailed radiological features of hepatic inflammatory pseudotumor across various imaging modalities.4.Provide a brief note on histopathological findings, inflammatory myofibroblastic tumor and relation to IgG4 related disease.

TABLE OF CONTENTS/OUTLINE

Hepatic inflammatory pseudotumor 1.Definition 2.Epidemiology 3.Pathophysiology 4.Clinical features 5.Differential diagnosis -abscess, hepatocellular carcinoma, hepatic adenoma, focal nodular hyperplasia, metastases. Imaging findings of hepatic inflammatory pseudotumor 1. Ultrasound a) Role of sonography b) Conventional high-resolution B mode US findings c) Color doppler US findings d) Contrast-enhanced ultrasound 2. Contrast-enhanced CT (CECT) a) CECT findings associated with hepatic inflammatory pseudotumor b) Role of CT in problem solving of clinically difficult cases 3. MRI a) MRI findings associated with hepatic inflammatory pseudotumor b) Role of MRI in problem solving of clinically difficult cases 4.PET/CT a) PET/CT findings associated with hepatic inflammatory pseudotumor b) Role of PET/CT in problem solving of clinically difficult cases Histopathological findings of hepatic inflammatory pseudotumor Relation to IgG4 related disease. Inflammatory myofibroblastic tumor, ALK-1, IgG4 positive plasma cells.

GIEE-13 DIVERTICULITIS UNPLUGGED: HOW CT SCANS REVEAL MORE THAN JUST GUT FEELINGS

Guilherme Swerts Pereira (*Presenter*)
Pedro Mecate Prada, MD (*Abstract Co-Author*)
Thais Mussi, MD, PhD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)
Thiago M. Baraviera, MD (*Abstract Co-Author*)

TEACHING POINTS

- Highlight the clinical importance of CT in the diagnosis and management of acute diverticulitis, a leading cause of emergency visits and hospital admissions. - Emphasize the central role of CT in identifying complications that guide decisions between conservative treatment, percutaneous drainage, or surgery. - Review key CT findings such as contained vs. frank perforation, fistulas, adhesions, and the pseudotumoral form of diverticulitis. - Reinforce the essential role of radiologists in interpreting acute and late complications and effectively communicating findings to optimize patient outcomes.

TABLE OF CONTENTS/OUTLINE

1. Initial Concepts: definition of diverticulosis, acute diverticulitis and complicated diverticulitis 2. Flowchart for diagnosis and management of diverticulitis 3. Complications: - Complications due to abscess: pericolic abscess, pelvic abscess, retroperitoneal abscess, tubo-ovarian abscess and possible colo-adnexial fistula. - Complications that may require surgical intervention: intestinal subocclusion, microperforation / locked perforation, unblocked perforation. - Other complications: Septic thrombophlebitis, pseudotumoral diverticulitis, digestive hemorrhage. 4. Differential diagnoses: - Epiploic appendagitis. - Colitis. - Colorectal carcinoma with inflammatory changes. 5. Take home messages 6. References

GIEE-14 LIVER METASTASES BEYOND CLASSICAL IMAGING FINDINGS

Sandra Baleato Gonzalez, MD, PhD (*Presenter*)
Roberto Garcia Figueiras, MD, PhD (*Abstract Co-Author*)
Joan C. Vilanova, MD, PhD (*Abstract Co-Author*)
Cecilia Vieira-Leite (*Abstract Co-Author*)
Antonio Luna, MD, PhD (*Abstract Co-Author*)
Cristina Asensio (*Abstract Co-Author*)
Enrique Flores, MD (*Abstract Co-Author*)

TEACHING POINTS

Liver metastases are more common than primary lesions and their presence impact in patients´ prognosis. Metastases treatment depends on the type of primary tumor and include chemotherapy, immunotherapy, surgery, or ablative techniques. Imaging is mandatory in the evaluation of metastatic liver for diagnosis, therapy planning, follow up. Besides, imaging features and advanced imaging techniques can have clinical value for response prediction and prognosis of patient´s outcome. Radiomics have an emerging role in the identification of the growth patterns of liver metastases.The objectives of this exhibit are: To illustrate the role of imaging in the detection and characterization of metastases. To evaluate advantages and disadvantages of every imaging technique. To recognize imaging findings with prognostic and predictive value. To discuss the role of advanced imaging techniques and radiomics. To review key points of imaging-based planning of surgery and locoregional therapies.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Imaging findings of liver metastases. 2.1. Contrast-enhanced US and elastography. 2.2. Conventional CT and multi-energy CT (DECT and photon-counting CT), perfusion CT 2.3 .MRI-based imaging techniques (diffusion-weighted imaging, perfusion, liver-specific contrast agents) 2.4. PET with different radiotracers 3. Technical features that Improve metastases detection 4. Clinical challenges. 5. Prognostic factors 5.1. Morphology 5.2. Iodine quantification 5.3. MR signal on gadoxetic-enhanced hepatobiliary phase. 5..4. Molecular radiotracers. 6. Radiomics. 7. Imaging-based therapy planning 8. Conclusions

GIEE-15 WHAT HIDES BEHIND PERSISTENT JAUNDICE? BILIARY ATRESIA: DECODING RADIOLOGICALDIAGNOSIS WITH ULTRASOUND, MRI, ANDCLINICAL MANAGEMENT

David Melara, MD (*Presenter*)

TEACHING POINTS

Biliary atresia is a critical cause of neonatal cholestasis, and early detection significantly improves prognosis. Ultrasound is the most important initial imaging modality. The most specific findings include the triangular cord (TC) sign , observed as an echogenic fibrous remnant anterior to the right portal vein branch; a small (<1.5 cm), absent, or morphologically abnormal gallbladder (lobulated shape, irregular wall, or absence of postprandial contraction); absence of the common bile duct ; periportal echogenic thickening ; and increased subcapsular hepatic arterial flow . The combination of the TC sign and gallbladder abnormalities yields a sensitivity of 96.9% and specificity of 94.4% . However, in early stages or atypical cases, these features may not be evident, requiring correlation with other imaging modalities.

TABLE OF CONTENTS/OUTLINE

Introduction Ultrasound Findings Magnetic Resonance Imaging (MRI) Findings Classification and Management Key Points to Remember

GIEE-16 ILIAC FOSSA PAIN: MAIN DIFFERENTIAL DIAGNOSES AND THE ROLE OF ULTRASONOGRAPHY

Jose Lucas S. Galvao I, MD (*Presenter*)
Gabriela Lauar, MD (*Abstract Co-Author*)
Maristela Andreozzi (*Abstract Co-Author*)
Cinthia C. Barbisan, MD (*Abstract Co-Author*)
Caio P. Martinel, MD (*Abstract Co-Author*)
Ana Carolina Gaetan Afonso, MD (*Abstract Co-Author*)
Arthur H. Godeiro, MD (*Abstract Co-Author*)
ISABELA NASCIMENTO (*Abstract Co-Author*)
Leonardo Lima (*Abstract Co-Author*)
Bruna Maria Lobato Vaughan, MD (*Abstract Co-Author*)

TEACHING POINTS

Pain in the iliac fossa requires detailed investigation to identify the underlying cause and guide appropriate treatment. These causes are commonly divided into gynecological and intestinal pathologies, often influenced by factors such as age, sex, and pain location (right vs. left). Because pelvic and lower abdominal pain can overlap, a structured approach to imaging is essential to narrow the differential diagnosis. Ultrasound and CT play a key role in distinguishing gynecological from non-gynecological causes. Ultrasound, though operator-dependent, is often the first-line tool due to its accessibility and non-invasive nature. High-frequency linear transducers are preferred for intestinal assessment, while intracavitary probes are ideal for evaluating female pelvic structures.

TABLE OF CONTENTS/OUTLINE

The aim of this study is to demonstrate, through clinical cases from our hospital, the importance of ultrasound in the investigation of iliac fossa pain complaints. We review the main associated pathologies, expected ultrasound findings, and situations where complementary methods may be required for a more accurate diagnosis.

GIEE-17 RADIOLOGICAL APPROACH TO COMPLICATIONS OF ROUX-EN-Y GASTRIC BYPASS

Kazi A. Irfan, MD, FRCR (*Presenter*)
Nanda Deepa Thimmappa, MD (*Abstract Co-Author*)
Azfar Siddiqui, MD (*Abstract Co-Author*)
Ayesha Nasrullah, MD,FRCR (*Abstract Co-Author*)
Ayman H. Gaballah, MD, FRCR (*Abstract Co-Author*)
Mohamed G. Elbanan, MD (*Abstract Co-Author*)
David L. Raj, MD (*Abstract Co-Author*)
Maged Algazzar, MD (*Abstract Co-Author*)
Sadia Sajid, MBBS (*Abstract Co-Author*)
Amr S. Abdelaziz, MD (*Abstract Co-Author*)

TEACHING POINTS

Explain the surgical procedure of Roux-en-Y gastric bypass Outline the imaging modalities used post surgery Describe the expected postsurgical changes Discuss the spectrum of postsurgical complications Illustrate the mechanisms of internal hernia post Roux-en-Y gastric bypass Highlight the imaging approach to the diagnosis of internal hernia

TABLE OF CONTENTS/OUTLINE

*Surgical procedure of Roux-en-Y gastric bypass *Imaging modalities in postsurgical evaluation A. Fluoroscopy B. Computed tomography *Normal postsurgical imaging anatomy and expected postsurgical changes *Specific complications of Roux-en-Y gastric bypass A. Complications at the gastrojejunal anastomosis: **Marginal ulcer **Stricture **Gastrogastric fistula **Perforation B. Complications at the jejunojejunal anastomosis: **Intussusception C. Small bowel obstruction **Roux limb **Biliopancreatic limb **Common channel D. Internal hernias secondary to altered anatomy * Signs of internal hernia post Roux-en-Y gastric bypass *Systemic approach to the diagnosis of internal hernia *Imaging spectrum of post-surgical complications

GIEE-18 TINY BUT TROUBLESOME: THE DUODENUM'S MANY FACES

Amanda Guimaraes, MD (*Presenter*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Daniel L. Cardoso, MD (*Abstract Co-Author*)
Lais Oliveira, MD (*Abstract Co-Author*)
Igor J N Leite, MD (*Abstract Co-Author*)
Luiz Lima, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Vinicius Borges, MD (*Abstract Co-Author*)

TEACHING POINTS

Most gastrointestinal radiology literature has focused on the colon, stomach, and distal small bowel, often overlooking the duodenum—particularly on CT imaging. However, due to its complex anatomy, spanning both intra and retroperitoneal spaces, and its close proximity to surrounding organs, the duodenum is susceptible to a wide range of primary and secondary pathologic processes, some of which are unique to this segment of the bowel. This imaging review aims to highlight the wide spectrum of duodenal lesions, with a focus on their CT and MRI features. It also revisits the radiologic anatomy of the duodenum and explores the clinical and epidemiological aspects of both benign and malignant lesions. By shedding light on this often-overlooked segment, we hope to enrich the radiologic community’s knowledge and promote greater diagnostic awareness of duodenal conditions.

TABLE OF CONTENTS/OUTLINE

Teaching Points, Anatomy Review, Duodenal Primary tumors and Not tumor findings, Imaging findings and key points about deseases, Take home message and references.

GIEE-19 WHEN ORGANS BURST: IMAGING CLUES TO SPONTANEOUS INTRA-ABDOMINAL VISCERAL RUPTURE

Mohammad Mohsin Arshad, MD (*Presenter*)
Syeda Shabistan Intekhab, MBBS (*Abstract Co-Author*)
Devendra Kumar, MBBS, MD (*Abstract Co-Author*)
Abdulla Al-Hashemi, MD (*Abstract Co-Author*)
Mahmoud Al Raheem Heidous, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To explore the major etiologies of spontaneous intra-abdominal organ rupture.2. To review the key radiological findings encountered in spontaneous intra-abdominal organ rupture. 3. To underline the importance of intra-abdominal visceral rupture as a rare but potentially catastrophic differential diagnosis in cases of spontaneous hemo-peritoneum.

TABLE OF CONTENTS/OUTLINE

1. Overview 2. Common etiologies by organs A). Hepatic - benign and malignant tumors, HELLP syndrome, parasitic infections, infiltrative and inflammatory disorders. coagulation abnormalities B). Splenic - Hematological malignancies, infectious diseases, metabolic diseases, autoimmune disorders, non hematological malignancies. C). Stomach - acute gastric distention, sodium bicarbonate ingestion, E coli sepsis in neonates D). GI - Neoplastic causes, immune mediated such as crohns, infectious, medication related injury, sterocoral perforation. E). Renal - Neoplasms, vascular abnormalities, cystic renal diseases, renal infections F). Adrenal - severe physiological stress and sepsis G). Gynecological - ectopic pregnancy, ruptured ovarian cyst, HELLP syndrome 3. Key Radiological findings seen in different organs A). Hemoperitoneum/Pneumoperitonuem B). Tumor/Organ rupture C).Peri-hepatic/Peri-splenic/Peri-nephric hematoma D). Intra-peritoneal free fluid 4. Clinical relevance

GIEE-20 WILL 4D FLOW MRI CHANGE INTERVENTIONAL RADIOLOGY?

Ryota Hyodo, MD, PhD (*Presenter*)

TEACHING POINTS

4D Flow MRI acquires comprehensive hemodynamic data over the entire field of view in one scan, enabling objective, retrospective blood flow assessment. Its value in evaluating flow in the heart and large vessels has already been demonstrated. In Interventional Radiology, treatment planning has traditionally relied on 3D anatomical images (from CT or MRI) and 2D flow imaging (such as ultrasound) to infer overall hemodynamics from these limited data. In contrast, 4D Flow MRI can delineate the direction, velocity, and volume of blood in each vessel, thereby improving understanding of disease status, refining treatment indications and efficacy evaluations, and even aiding in prognosis prediction. Moreover, the 3D vector maps and streamline images generated by 4D Flow MRI are intuitive for both clinical staff and patients, promoting better team communication and facilitating informed consent. Overall, 4D Flow MRI holds substantial promise for advancing the field of Interventional Radiology.

TABLE OF CONTENTS/OUTLINE

This educational exhibit is divided into three sections. The first section explains what 4D Flow MRI can offer to clinicians, highlighting its unique ability to capture multidirectional flow dynamics that conventional modalities cannot. The second section presents actual clinical case reports where 4D Flow MRI has influenced interventions, including stent graft treatments for abdominal aortic aneurysms and aortic dissections, stenting for portal vein stenosis and embolization for hepatic encephalopathy, and preoperative portal branch embolization. The third section discusses the current challenges and future prospects in the clinical application of 4D Flow MRI.

GIEE-21 IMAGING OF SEGMENTAL COLITIS ASSOCIATED WITH DIVERTICULOSIS

Liang Yen Liu, MD (*Presenter*)
Stephen G. Wahlig, MD (*Abstract Co-Author*)
Cheng Hong (*Abstract Co-Author*)
Sina Houshmand, MD (*Abstract Co-Author*)
Joseph R. Leach, MD, PhD (*Abstract Co-Author*)
Spencer C. Behr, MD (*Abstract Co-Author*)
Derek Sun, MD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize segmental colitis associated with diverticulosis (SCAD) as a distinct and emerging entity from diverticulitis and inflammatory bowel disease (IBD). • Sigmoid and descending colonic inflammation sparing diverticula, rectum, and proximal colon is a key feature of SCAD. • While diagnosis is confirmed with endoscopy and pathology, imaging helps exclude SCAD from mimics, including diverticulitis, IBD, ischemia, and malignancy.

TABLE OF CONTENTS/OUTLINE

1) Segmental Colitis Associated with Diverticulosis (SCAD) Overview a) Chronic sigmoid/descending colon inflammation, sparing rectum/proximal colon and diverticula; more common in men >50 with diverticulosis. b) Pathogenesis unclear, likely multifactorial. c) Symptoms: diarrhea, pain, hematochezia. d) Most resolve spontaneously or with antibiotics/5-ASA; severe cases: steroids, biologics, surgery. 2) Diagnosis a) Endoscopy: segmental inflammation, spares diverticula/rectum/proximal colon. b) Biopsy: chronic inflammation, cryptitis, goblet cell depletion, no granulomas. 3) Imaging a) Overlap with diverticulitis/IBD: i) Circumferential bowel wall thickening, free fluid, mainly spares diverticula. ii) Involves longer sigmoid segments, minimal fat stranding, fewer inflamed diverticula iii) Engorged vasa recta, muscular hypertrophy. 4) Complications a) Strictures, fistula, perforation, bleeding, abscess. 5) Mimics a) Diverticulitis, IBD, ischemic colitis, colon cancer. b) Review key features to distinguish SCAD from mimics 6) Summary a) While diagnosis requires endoscopy & biopsy, imaging aids diagnosis & excludes other causes. b) SCAD has milder course, good treatment response.

GIEE-22 ALL THAT GLITTERS IS NOT GOLD: NOT EVERY INJURY IN THE COMMON BILE DUCT IS CHOLANGIOCARCINOMA

Lais Oliveira, MD (*Presenter*)
Amanda Guimaraes, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Igor J N Leite, MD (*Abstract Co-Author*)
Luiz Lima, MD (*Abstract Co-Author*)

TEACHING POINTS

Cholangiocarcinoma of the common bile duct is a rare and aggressive malignant neoplasm of the extrahepatic bile ducts, for which early diagnosis is crucial to guide therapeutic management and avoid unnecessary procedures. This imagining study reviews the radiological anatomy of the common bile duct and associated structures, and also addresses the main benign and malignant conditions that mimic its clinical and imaging presentation. The challenges of differential diagnosis using methods such as magnetic resonance cholangiopancreatography (MRCP), and contrast-enhanced computed tomography are discussed, highlighting their contributions in assessing lesion extent, enhancement pattern, and vascular involvement. This review aims to contribute to the updating and improvement of radiologists' knowledge, emphasizing the central role of radiology in diagnostic definition and in the early and effective direction of treatment.

TABLE OF CONTENTS/OUTLINE

anatomical review - importance of evaluating the differential diagnoses of cholangiocarcinoma - broad examples of mimicking pathologies - diagnostic challenge for radiology and opportunity for learning improvement

GIEE-23 IS IT STILL ALIVE? A PRACTICAL GUIDE TO LI-RADS 2024 POST-TREATMENT CATEGORIES HELPING GENERAL RADIOLOGISTS REPORT WITH CONFIDENCE

Rodrigo Borrero, MD (*Presenter*)
Camilo A. Barragan Leal, MD (*Abstract Co-Author*)
John Robert D. Beecroft, MD (*Abstract Co-Author*)
Jorge A. Abreu Gomez, MD (*Abstract Co-Author*)
Vanessa Murad, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the rationale behind the 2024 LIRADS posttreatment response updates, including key distinctions between radiation and nonradiation therapies. Recognize normal and abnormal posttreatment imaging findings to confidently differentiate expected changes from residual or recurrent disease. Apply LIRADS 2024 treatment response categories to improve clarity in reporting and facilitate multidisciplinary management of hepatocellular carcinoma.

TABLE OF CONTENTS/OUTLINE

Background Overview of HCC as the most common hepatic malignancy. Spectrum of therapies: ablation, resection, transplantation, embolization, systemic treatment. Importance of understanding therapy mechanisms, imaging appearances and response patterns. Introduction to the 2024 LIRADS Treatment Response Algorithm updates. Imaging Findings or Procedure Details Overview of posttreatment imaging features of HCC following radiation and nonradiation therapies. Review of mechanisms of action, expected temporal changes, and interpretation challenges. Differentiation between viable tumor, posttreatment changes, and complications such as nontarget embolization or radiation-induced liver disease. Emphasis on using contrast-enhanced CT/MRI with LIRADS 2024 criteria. Visual examples and key interpretive tips. Conclusion Role of radiologists in assessing HCC treatment response. Structured framework provided by the updated 2024 LIRADS algorithm. Importance of distinguishing between viable and nonviable disease, and expected changes vs complications. Contribution of radiologists to multidisciplinary HCC care through understanding therapy selection, mechanisms of tumor lysis, and expected imaging findings.

GIEE-24 THE FLOW MUST GO ON: IMAGING PORTOSYSTEMIC PATHWAYS

Thais Barreiro, MD (*Presenter*)
Joap Golfi, MD (*Abstract Co-Author*)
Thiago J. Penachim, MD (*Abstract Co-Author*)
Pedro Henrique Silva Pacetti (*Abstract Co-Author*)
Simone Perales (*Abstract Co-Author*)
Ilka Boin (*Abstract Co-Author*)
Daniel Lahan-Martins, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-In cirrhosis, elevated portal pressure leads to the formation of spontaneous portosystemic shunts (SPSS), which bypass hepatic circulation. -The morphological and hemodynamic features of SPSS — such as size, number, anatomical distribution, and blood flow — are key determinants of clinical complications associated with portal hypertension. -Despite their clinical significance, detection and characterization of SPSS remain challenging.-There is a critical need for noninvasive imaging modalities with high sensitivity and specificity to accurately identify and quantify SPSS. -Imaging-based surveillance of SPSS is essential for prognostication and for guiding therapeutic strategies in the management of patients with cirrhosis.

TABLE OF CONTENTS/OUTLINE

-Blood flow pathways in patients with portal hypertension; -Major portosystemic shunts exemplified through clinical cases and schematic illustrations; -Key aspects that radiologists should assess in imaging studies of patients with portal hypertension; -The role of imaging in predicting major complications (encephalopathy, gastroesophageal variceal bleeding, and portal vein thrombosis).

GIEE-25 NOT SO TARGETED: WHEN ONCOLOGIC TARGETED THERAPIES TAKE A WRONG TURN IN THE ABDOMEN

Nandakumar Patnam Gopal Chetty, MD (*Presenter*)
Nikhil H. Ramaiya, MD (*Abstract Co-Author*)
Sreeharsha Tirumani, MD (*Abstract Co-Author*)
Jennifer Huang (*Abstract Co-Author*)
Petros Grivas (*Abstract Co-Author*)
Rajat Bhargava, MD, MBBS (*Abstract Co-Author*)
Puneet Bhargava, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize imaging findings of therapy-related adverse events that may mimic progression or infection. 2. Organ system-based approach incorporating American Society of Clinical Oncology (ASCO) and European Society of Medical Oncology (ESMO) guidelines. 3. Role of AI chatbots in supporting further management.

TABLE OF CONTENTS/OUTLINE

1. Targeted therapy: Brief Classification and mechanism of action of Targeted Therapeutics. 2. Organ-Based Framework: Red flags in the right upper quadrant : i) Drug associated Hepatitis: ipilimumab, atezolizumab ii) Cholecystitis: pazopanib, everolimus iii) Pancreatitis: sunitinib, lenvatinib, everolimus, ipilimumab, atezolizumab iv) Hepatic Steatosis: cabozantinib. Bowel danger signs : i) Intestinal Perforation: bevacizumab, sorafenib, sunitinib, rituximab ii) Pneumatosis Intestinalis: bevacizumab, sunitinib, sorafenib iii) Intestinal Lymphangiectasia: pazopanib, sunitinib, cabozantinib iv) Tumor-Bowel Fistula (e.g., GIST): imatinib, bevacizumab. 3. Explore the role of ChatGPT and Microsoft Co-pilot in the Management Workflow. 4. Propose diagnostic and management algorithm for oncological treatment related toxicities.

GIEE-26 WHERE ARE WE WITH COLORECTAL CANCER (CRC) SCREENING: CT COLONOGRAPHY

Michio Taya, MD, MSc (*Presenter*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)
Matthew H. Lee, MD (*Abstract Co-Author*)
David H. Kim, MD (*Abstract Co-Author*)

TEACHING POINTS

1. CT colonography is equivalent to colonoscopy in the detection of polyps = 6 mm supported by the most recent USPSTF systematic literature review. 2. Detection and removal of polyp precursor lesions (ie, advanced adenomas and sessile serrated lesions) enable true prevention of colorectal cancer where selective polypectomy practices at CTC can minimize unnecessary polypectomies. 3. Oral contrast tagging of the polyp mucosal surface is a key to detect flat sessile serrated lesions. Quality bowel preparation with cathartic and dual barium and iodine-based tagging agents are needed. 4. Despite the effectiveness of CTC for CRC prevention and screening, screening adherence is low, and radiologist engagement will be a key for widespread implementation. 5. Opportunistic screening and AI will further enhance the value of CTC.

TABLE OF CONTENTS/OUTLINE

1. History of CTC including the extended path to Medicare coverage and current usage among CRC screening options 2. Review of the literature regarding CTC performance, outcomes of CTC surveillance for sub-centimeter polyps, and programmatic long-term observations 3. Components of optimized technique at CT colonography 4. Current concepts in colorectal cancer screening including the pathogenesis of precancerous lesions and tenets to the size-based selective polypectomy

strategy utilized at CTC. 5. Barriers to widespread implementation - historical barriers (e.g. insurance coverage), reliance on GI for same day optical colonoscopy, radiologist and referring provider "buy-in." 6. Future directions

GIEE-27 FROM SWALLOW TO SIGMOID: A JOURNEY THROUGH BARIUM IMAGING

Aishwarya Dahake, MBBS (*Presenter*)
Padma V. Badhe, MD,MBBS (*Abstract Co-Author*)
Aishwarya Bagade, MBBS (*Abstract Co-Author*)
Siva Kumar, MD,MBBS (*Abstract Co-Author*)
OMKAR METTAN (*Abstract Co-Author*)

TEACHING POINTS

To understand the standard procedures, types of barium studies, radio anatomy and to identify image pattern of various pathologies on barium studies .

TABLE OF CONTENTS/OUTLINE

Barium study is a specialized imaging technique using barium, a positive radiographic contrast, and X-rays to visualize the gastrointestinal (GI) tract. Since the early 20th century, it has evolved from a basic swallowing test to a dynamic tool for real-time imaging of GI anatomy and function. Despite newer diagnostic tools like ultrasound, capsule endoscopy, CT, and MRI, barium studies remain relevant due to their ability to assess swallowing, motility, and morphological abnormalities in a single, global exam. They are non-invasive, cost-effective, and widely available, aiding in diagnosis and guiding further medical, endoscopic, or surgical management. This article presents a systematic approach to the procedure, types of conventional studies, and imaging findings in GI diseases. Barium sulphate, the contrast of choice, is highly radio-opaque, non-toxic, inert, and suitable for double-contrast studies. Barium studies include oesophagogram, modified oesophagogram, upper GI series, small bowel series, enteroclysis, distal cologram, and barium enema. Preparation involves overnight fasting and avoiding activities that stimulate salivation. The primary contraindication is suspected GI perforation due to the risk of fatal barium peritonitis. Indications include dysphagia, GERD, strictures, Crohn's disease, ulcers, masses, and Hirschsprung disease. Distal cologram remains essential for evaluating stoma reversal.

GIEE-29 ROLE OF IMAGING IN PANCREATIC CANCER SCREENING FOR HIGH-RISK POPULATION WITH GENETIC AND HEREDITARY CAUSES LINKED TO SPECIFIC GENETIC SYNDROMES OR MUTATIONS

Pardeep K. Mittal, MD (*Presenter*)
Srinivasa R. Prasad, MD (*Abstract Co-Author*)
Anil K. Dasyam, MD (*Abstract Co-Author*)
Venkata S. Katabathina, MD (*Abstract Co-Author*)
Courtney C. Moreno, MD (*Abstract Co-Author*)
Camila Lopes Vendrami, MD (*Abstract Co-Author*)
Ulas Bagci, MSc, PhD (*Abstract Co-Author*)
Frank H. Miller, MD (*Abstract Co-Author*)

TEACHING POINTS

Teaching points:-Discuss NCCN guidelines recommend pancreatic cancer screening for high-risk individuals, primarily those with familial or genetic predispositions.-Discuss Genetic Mutations and Syndromes Associated with Increased Risk for Pancreatic Cancer-Discuss preferred imaging modalities for pancreatic cancer screening and strategies for follow up.-Discuss AI for screening and classifying pancreatic risk.

TABLE OF CONTENTS/OUTLINE

Pancreatic ductal adenocarcinoma has a high mortality rate. The risk for PDA is multifactorial, as both environmental and inherited causes. Heredity factors play a key role in the development of pancreatic cancer in 5% to 10% of all cases, including in individuals with an underlying germline gene mutation and those with a strong family history of PDA. It is important to identify the target population that would benefit from screening and follow specific recommendations and considerations.· High-Riskfamily history of pancreatic cancer or who carry specific genetic mutations (CDKN2A, PRSS1, STK11).· Screening Modalities:MRI and EUSScreening Intervals:· Genetic Testing:· Indeterminate Lesions:Follow up 3-6 months.· High-Risk Lesions:imaging within 3 months if surgical resection is not planned.· Follow-up:After diagnosis and treatment, regular follow up scans to monitor recurrence. · Familial Risk:· Screening at age 50 with strong family history of pancreatic cancer, even without a known genetic mutation:

GIEE-30 BEYOND CROHN'S DISEASE: PATHOLOGICAL INSIGHTS FROM CT AND MR ENTEROGRAPHY

Caroline L. Ghezzi (*Presenter*)
Henrique M. Guerra, MD (*Abstract Co-Author*)
Debora Koltermann Da Silva (*Abstract Co-Author*)
Meiri Silva (*Abstract Co-Author*)
Barbara Luiza Bernardi (*Abstract Co-Author*)
Karina Zinn, MD (*Abstract Co-Author*)
Mateus Schenato, MD (*Abstract Co-Author*)
Camila B. Visconti, MEd (*Abstract Co-Author*)
Ariane Giovanaz (*Abstract Co-Author*)
Natalia H. Concatto, MD (*Abstract Co-Author*)
Rubia Vanceta (*Abstract Co-Author*)
Alice Schuch, MD (*Abstract Co-Author*)

TEACHING POINTS

To demonstrate that Enterotomography (CTE) and EnteroMRI (MRE) are essential tools for diagnosing a wide range of intestinal pathologies beyond Crohn's disease, including both neoplastic and non-neoplastic conditions. To highlight how mastering the imaging features of these conditions can enhance the radiologist's performance, directly influencing the quality of patient care.

TABLE OF CONTENTS/OUTLINE

Introduction Objective and relevance of CT enterography (CTE) and MR enterography (MRE) in diagnosing intestinal pathologies beyond Crohn's disease. Technique Explanation of how CTE and MRE are performed, their advantages, indications, and benefits for diagnosing intestinal diseases. Pathologies Neoplastic Lesions: - GIST (Gastrointestinal Stromal Tumors) - Adenocarcinoma - Neuroendocrine Tumors - Metastasis Non-Neoplastic Lesions - Celiac Disease - Meckel's Diverticulum - Ulcerative Colitis - Pseudomembranous Colitis Vascular Pathologies - Angioectasias - Arterial lesions - Venous abnormalities Miscellaneous - Intestinal malrotation - Familial adenomatous polyposis syndrome Conclusion Summary of the importance of CTE and MRE for diagnosing a wide range of intestinal pathologies and their impact on clinical practice.

GIEE-31 SOFT TISSUE SARCOMAS IN THE DIFFERENTIAL DIAGNOSIS OF ABDOMINOPELVIC MASSES: A PICTORIAL ESSAY

Luana Alves, MD (*Presenter*)
Andre Ferreira, MD (*Abstract Co-Author*)
Paula Castro, MD (*Abstract Co-Author*)
Clara Fiorot, MD (*Abstract Co-Author*)
Luiza Ambrozino, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Identify characteristic CT and MRI features of common abdominopelvic sarcomas, including liposarcomas, leiomyosarcomas, and GISTs. - Recognize less frequent sarcoma subtypes such as undifferentiated pleomorphic sarcoma, malignant peripheral nerve sheath tumor, solitary fibrous tumor, and desmoid-type fibromatosis. - Understand key imaging clues that differentiate sarcomas from more prevalent abdominopelvic masses, aiding biopsy planning and treatment.

TABLE OF CONTENTS/OUTLINE

I. Introduction Importance of considering sarcomas in the differential of abdominal/pelvic masses. II. Common Sarcomas - Liposarcoma: fat-containing lesions with varying dedifferentiation. - Leiomyosarcoma: heterogeneous solid masses, often retroperitoneal. - GIST: well-circumscribed GI-related tumors with variable enhancement. III. Less Common Sarcomas - Undifferentiated pleomorphic sarcoma: large, necrotic, aggressive masses. - Malignant peripheral nerve sheath tumor: fusiform, nerve-related. - Solitary fibrous tumor: well-defined, variable vascularity. - Desmoid tumor: infiltrative masses, often abdominal wall or mesentery. IV. Differential Diagnosis Lipoma variants, angiomyolipoma, fibroids, carcinoma, hemangioma. V. Conclusion Recognizing imaging patterns improves diagnostic accuracy and guides management.

GIEE-32 IMAGING SPECTRUM OF CHOLANGIOCARCINOMA: FROM DIAGNOSIS TO POST-TREATMENT ASSESSMENT

Guilherme Naves, MD (*Presenter*)
Antonio E. Silva JR, BDS (*Abstract Co-Author*)
Matheus M. Gomes SR, MD (*Abstract Co-Author*)
Joao Manoel M. Santos, PhD (*Abstract Co-Author*)
Yuri C. Neves, PhD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)
Rodrigo P. Polizio, MD (*Abstract Co-Author*)
Victoria Chernyak, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

1. Review the imaging characteristics of intrahepatic and extrahepatic cholangiocarcinoma. 2. Discuss differential diagnosis and pitfalls in imaging interpretation, with emphasis on clinically relevant mimics. 3. Introduce standardized terminology and structured radiological reporting. 4. Describe post-treatment imaging patterns, including typical responses and diagnostic criteria for assessing tumor viability.

TABLE OF CONTENTS/OUTLINE

1) Introduction • Overview and clinical context of cholangiocarcinoma • Anatomical classification 2) Precursor Lesions and Early Detection • Screening on higher-risk population • Early and atypical imaging features of cholangiocarcinoma • Precursor lesions 3) Radiological Features and Lexicon • Multimodality imaging characteristics of each subtype • Bismuth-Corlette classification 4) Differential Diagnosis and Common Pitfalls Intrahepatic cholangiocarcinoma DDx: • Metastases • Epithelioid hemangioendothelioma • Hepatocellular carcinoma • Biliary inflammatory diseases (e.g., IgG4 cholangiopathy) Hilar and extrahepatic cholangiocarcinoma DDx: • Biliary inflammatory diseases • Differentiation between malignant and benign strictures 5) Prognostic Imaging Features and Clinical Implications • Features associated with worse prognosis 6) Structured Reporting • Review of recent clinical guidelines • Surgical planning considerations • Required reporting elements 7) Post-Treatment Imaging and Assessment of Tumor Viability • Expected imaging patterns post-treatment • Diagnostic criteria for assessing tumor viability. 8) Future directions and emerging technologies.

GIEE-33 WEIGHT OF THE NATION: UNVEILING BARIATRIC SURGERY COMPLICATIONS THROUGH IMAGING

Nandakumar Patnam Gopal Chetty, MD (*Presenter*)
Rajat Bhargava, MD, MBBS (*Abstract Co-Author*)
Puneet Bhargava, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review post-operative anatomy with surgical rationale. 2. Imaging review and algorithmic management in post-bariatric surgeries.

TABLE OF CONTENTS/OUTLINE

1. Roux-en-Y Gastric Bypass Complications (RYGB): Leak/abscess, gastrojejunostomy and jejunojejunostomy strictures, gastrogastric fistula, marginal ulceration, Blind pouch syndrome, small bowel obstruction, Peterson-type internal hernia. 2. Sleeve Gastrectomy: Leak/abscess, hemorrhage, mid-gastric sleeve stricture, splenic infarct, portomesenteric thrombosis. 3. Gastric Banding: Normal phi angle- 4 to 58 degrees, stomal diameter- <4mm, pouch diameter- <4cm. O-sign due to en-face O appearance of slipped gastric band. Band prolapse (cranial > caudal), gastric erosion, mechanical failure.

GIEE-34 LEARNING FROM MISTAKES: DIAGNOSTIC PITFALLS AND MIMICKERS IN 101 SUSPECTED CASES OF CHOLANGIOCARCINOMA- A 10-YEAR INSTITUTIONAL REVIEW

Diego Jose Torres Duque, MBBS (*Presenter*)
Nicolas Ruiz Diaz, MD (*Abstract Co-Author*)

TEACHING POINTS

Over a 10-year period, we reviewed 101 cases initially suspected of cholangiocarcinoma, of which 36 (35.6%) were diagnostic mimickers. The most frequent mimicker was choledocholithiasis, followed by metastatic disease, both capable of closely simulating malignancy. Diagnostic errors commonly stemmed from misinterpreting enhancement patterns, underestimating the clinical or biochemical context, or overrelying on isolated findings. Real-world errors offer valuable opportunities for growth and reflection, especially when accompanied by imaging-pathology correlation. We propose a classification of common diagnostic pitfalls and a structured checklist for a more systematic approach to biliary lesion evaluation.

TABLE OF CONTENTS/OUTLINE

1. Introduction. 2. Case-Based Analysis : 36 Diagnostic Mimickers Identified From a cohort of 101 suspected cases: False positives: benign conditions simulating CCA Choledocholithiasis (n=11) Inflammatory strictures PSC, IgG4 disease, biliary actinomycosis, adenomas False negatives: malignancies misclassified or diagnosed late Pancreatic adenocarcinoma, gallbladder cancer, ductal carcinoma Overcalls: overstaging indeterminate or treated lesions 3. Classification of Error Types 4. What We Learned Key takeaways illustrated through individual case vignettes.5. Diagnostic Checklist Structured evaluation guide for biliary lesions—including location, morphology, enhancement, secondary signs, and clinical correlation.6. Summary and Take-Home Messages: A practical roadmap to reduce error and improve confidence in cholangiocarcinoma assessment.

GIEE-35 EVALUATION OF RECTAL CANCER POST-TREATMENT: PITFALLS AND RESPONSE ASSESSMENT SCALES

Patricia Garcia, MD, PhD (*Presenter*)
Isabel Salmeron (*Abstract Co-Author*)
Lourdes del Campo, PhD (*Abstract Co-Author*)

TEACHING POINTS

-To illustrate MRI interpretation with histological correlation -To discuss treatment response classification systems

TABLE OF CONTENTS/OUTLINE

Magnetic Resonance Imaging (MRI) plays a crucial role in assessing treatment response in rectal cancer after neoadjuvant therapy, aiding in clinical decision-making for surgical or watch-and wait strategies. However, several pitfalls can affect accuracy, leading to misinterpretations that impact patient outcomes; these include fibrosis mimicking residual disease, difficulty distinguishing viable tumor cells from treatment related changes and limitations in assessing mucinous tumors. Recognizing these pitfalls is essential to optimize MRI -based evaluations.We reviewed patients with rectal cancer diagnosed at our center over the last two years, correlating MRI images with pathological anatomy results.Focusing on specific morphologic T2-weighted MRI, the five-category scale offers a more detailed classification, ranging from complete response (mrTRG 1) to no response (mrTRG 5), incorporating distinctions in fibrosis and tumor viability. Meanwhile, the three-category response scale classifies outcomes as complete response, near complete response or residual mass. The inclusion of DWI enhances sensitivity by differentiating between treated tissue and residual tumor.

GIEE-36 PANCREATITIS - NOT JUST A GUT FEELING

Adam Misseldine, MD (*Presenter*)
Andrew Ko, MD (*Abstract Co-Author*)
Lyndon Luk, MD (*Abstract Co-Author*)
Hanisha Patel, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Discuss pancreatic anatomy and pathophysiology of acute and chronic pancreatitis. 2. Recognize key imaging features of acute and chronic pancreatitis across various modalities including CT, MRI, and ultrasound. 3. Review complications of pancreatitis, including necrosis, pancreatic fluid collections, and vascular abnormalities. 4. Discuss the role of radiology within the multildisciplinary treatment of pancreatitis, including pre- and post- intervention imaging for GI and IR procedures.

TABLE OF CONTENTS/OUTLINE

1. Goals and objectives. 2. Pancreatic anatomy. 3. Pathophysiology of acute and chronic pancreatitis. 4. Cases of pancreatitis. 5. Cases of related complications. 6. Cases of pre- and post- intervention imaging. 7. Final take-home points.

GIEE-37 "ONE SIZE DOESN'T FIT ALL": APPLYING LI-RADS TR 2024 TO A VARIETY OF HEPATIC INTERVENTIONS

Luiz Lima, MD (*Presenter*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Igor J N Leite, MD (*Abstract Co-Author*)
Lais Oliveira, MD (*Abstract Co-Author*)
Amanda Guimaraes, MD (*Abstract Co-Author*)
Luiz Rodrigues Santos, MD (*Abstract Co-Author*)
Jose Marinho (*Abstract Co-Author*)

TEACHING POINTS

This educational exhibit showcases the application of LI-RADS Treatment Response (TR) 2024 in the evaluation of hepatocellular carcinoma (HCC) following locoregional therapy. Although LI-RADS TR 2024 provides a standardized framework for assessing treatment response, post-treatment imaging appearances vary according to the type of therapy—such as transarterial chemoembolization (TACE), radiofrequency or microwave ablation (RFA/MWA), and transarterial radioembolization (TARE). This exhibit displays a wide range of imaging examples from various treatment modalities, demonstrating the characteristic post-treatment appearances and their corresponding LI-RADS TR 2024 classifications. Recognizing these therapy-specific imaging patterns and integrating multidisciplinary insights enhances diagnostic accuracy and supports optimal patient management.

TABLE OF CONTENTS/OUTLINE

* Teaching Points: Rationale for adapting LI-RADS TR 2024 to various therapeutic contexts. * Therapy-Specific Imaging Features: Description of the distinct imaging findings observed on follow-up after different types of locoregional therapies, along with their classification according to the LI-RADS TR 2024 criteria. * Case-Based Learning: Illustrated cases demonstrating key imaging findings for each therapy and its cattegory. * Conclusion and Educational Value: Emphasis on the importance of contextual interpretation and multidisciplinary collaboration.

GIEE-38 BARIATRIC SURGERY-BEYOND THE BYPASS

Vedang Patel, MD (*Presenter*)
Bahram Kiani, MD (*Abstract Co-Author*)
Nicholas G. Rhodes, MD (*Abstract Co-Author*)
Samuel J. Galgano, MD (*Abstract Co-Author*)
Jason A. Pietryga, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Obesity is a growing epidemic affecting nearly 42% of adults and 20% of children/adolescents in America. 2. Bariatric surgery is the most effective and durable treatment for obesity. 3. While sleeve gastrectomy (SG) and Roux-en-Y gastric bypass (RYGB) are the most commonly performed bariatric procedures in the US, newer surgeries including the one-anastomosis gastric bypass (OAGB), biliopancreatic diversion with duodenal switch (BPD-DS), and single-anastomosis duodeno-ileal bypass with sleeve gastrectomy (SADI-S) are being performed. 4. Radiologists need to be familiar with the anatomy of these various bariatric surgeries to determine if the postoperative anatomy is normal or if there is a complication. 5. Imaging (particularly CT) plays a major role in the diagnosis of complications of bariatric surgery.

TABLE OF CONTENTS/OUTLINE

1. Review background information regarding obesity and indications for bariatric surgery. 2. Review statistics regarding trends in bariatric surgeries both within and outside of the US. 3. Review the normal postoperative anatomy of common and newer bariatric surgeries including SG, RYGB, OAGB, BPD-DS, and SADI-S. 4. Present a simple strategy to identify the bariatric surgery based on gastric anatomy and anastomoses. 5. Present imaging examples of complications of bariatric surgeries including hemorrhage, leak, infection, marginal ulcer, gastric ulcer, gastro-gastric fistula, small bowel obstruction, internal hernia, intussusception and protein malnutrition.

GIEE-39 IMAGES THAT SPEAK: A VISUAL JOURNEY THROUGH SMALL BOWEL LYMPHOMA

Nara Vedoveli (*Presenter*)
Sthefane Nunes, MD, MD (*Abstract Co-Author*)
Eleonora Silva (*Abstract Co-Author*)
Igor J N Leite, MD (*Abstract Co-Author*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Review the imaging patterns of small bowel lymphoma and their incidence rates. - Identifique esses padrões em exames de tomografia computadorizada e ressonância magnética. - Understand the structural and imaging characteristics of lesions and their association with complications. - Emphasize the essential role of radiologists in assessing both local and systemic disease, guiding diagnosis, and contributing to improved therapeutic management and prognosis.

TABLE OF CONTENTS/OUTLINE

Small bowel lymphoma is predominantly of the Non-Hodgkin type, with the highest incidence occurring in the ileum (60-65%), followed by the jejunum and duodenum. It can manifest in various forms on computed tomography (CT) and magnetic resonance imaging (MRI). The most prevalent imaging patterns include pronounced mass-like wall thickening with luminal dilation (pseudoaneurysmal), along with polypoid and stenotic presentations. Complications primarily involve ulceration, hemorrhage, and perforation. This presentation showcases cases of small bowel lymphoma across different subtypes, with the following objectives: 1. To identify key imaging features. 2. To review the most common patterns. 3. To understand the correlation between imaging characteristics and major complications. 4. To highlight the critical role of the radiologist in diagnosis, staging, treatment, and prognosis.

GIEE-40 THE FORGOTTEN SEGMENT: A COMPREHENSIVE LOOK AT JEJUNAL PATHOLOGIES

Irma Uliano Effting Zoch De Moura, MD (*Presenter*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Caroline Lorenzoni Almeida Ghezzi, MD,PhD (*Abstract Co-Author*)

TEACHING POINTS

? Brief summary of imaging techniques for small bowel ? Offer a brief overview on small bowel and especially, jejunum anatomy ? Highlight the main aspects to detect lesions in the small intestine ? Expose different diagnoses of jejunal pathologies and their respective imaging characteristics on CT and MRI

TABLE OF CONTENTS/OUTLINE

Introduction: In the interpretation of abdominal imaging, the small bowel—particularly the jejunum—is often underappreciated. This presentation aims to highlight the differential diagnoses associated with jejunal findings, supported by illustrative case examples.Neoplastic lesions: ? Neoplasms of the jejunum ? leiomioma ? lipoma ? polyps ? GIST ? lymphoma ? adenocarcinoma ? neuroendocrine tumor ? metastasis Non-neoplastic lesions: ? Inflammatory/infectious diseases of the jejunum ? diverticulum and diverticulitis ? celiac disease ? Crohn's disease ? enteritis ? graft-versus-host disease ? Vasculars pathologies of the jejunum ? angiodysplasia ? angioedema ? vasculitis ? arteriovenous malformations? Miscellaneous ? ectopic pancreatic tissue ? abdominal hernia ? invagination ? intestinal malformation Conclusion: This presentation exposes a range of small bowel diseases with a focus on their distinguishing features on CT and MRI, emphasizing how these pathologies involve the jejunum and outlining key imaging findings to aid in accurate diagnosis.

GIEE-41 PERIANAL IMAGING FINDINGS: OH, IT MUST BE JUST ANOTHER FISTULA... (SPOILER ALERT: IT'S NOT)

Roberto Fornell-Perez, MD, PhD (*Presenter*)
Ane Ibanez-Zubiarrain (*Abstract Co-Author*)
Almudena Quilez-Larragan (*Abstract Co-Author*)
Gonzalo Lecumberri-Cortes (*Abstract Co-Author*)
Ines Alonso Sanchez, MD (*Abstract Co-Author*)
Maria Victoria Barcena-Robredo (*Abstract Co-Author*)
Maite Urizar Gorosarri, MD (*Abstract Co-Author*)

TEACHING POINTS

Perianal pathology extends significantly beyond fistulizing disease, encompassing vascular anomalies (hemorrhoids, varices), cystic lesions, inflammatory-infectious conditions (abscesses, hidradenitis, Fournier's gangrene, condylomas), neoplastic processes, and post-surgical alterations. MRI provides exceptional soft tissue contrast for evaluating perianal pathologies; specific imaging characteristics can differentiate various conditions that may present with similar clinical symptoms. Familiarity with the complete spectrum of perianal pathologies is crucial for radiologists to avoid misinterpretation that might lead to unnecessary procedures or delayed treatment. Recognition of normal anatomical variants and post-surgical changes in the perianal region prevents diagnostic errors and improves patient management.

TABLE OF CONTENTS/OUTLINE

Introduction Prevalence and significance of non-fistulizing perianal pathologies Overview of imaging modalities with emphasis on MRI advantages Vascular Pathologies Hemorrhoids: internal / external, imaging features Perianal varices: associations and MRI characteristics Cystic Lesions Epidermoid and pilonidal cysts Tailgut cysts and developmental anomalies Inflammatory-Infectious Conditions Abscesses Hidradenitis suppurativa Fournier's gangrene: rapid recognition Condylomas and infectious lesions Neoplastic Processes Benign tumors Malignant lesions: primary anal canal tumors, subtypes Anatomical and Post-surgical Considerations Prolapse and anatomical variants Post-surgical alterations and potential pitfalls Conclusion: Importance of comprehensive knowledge in accurate diagnosis and patient management

GIEE-42 WHEN THE APPENDIX HIDES: THE RADIOLOGIST'S GUIDE TO APPENDIX VARIANTS AND MIMICS

Ana Helena Pavan Amaral, MD (*Presenter*)
Carolinna Nicolau, MD (*Abstract Co-Author*)
Mariana Campos, MD (*Abstract Co-Author*)
Guilherme B. De Napoli, MD (*Abstract Co-Author*)
Eduardo Martins, MD (*Abstract Co-Author*)
Marco A. Rodstein, MD (*Abstract Co-Author*)
Daniel Lahan-Martins, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The most commonly described variations of the vermiform appendix include retrocecal, pelvic, subcecal, pre-ileal, and post-ileal, with varying percentages depending on the study methodology. These anatomical differences influence the clinical presentation of acute appendicitis and can be challenging when associated with atypical locations. Additionally, several conditions can mimic the clinical presentations of appendicitis. However, on CT, we are able to make the right diagnosis, that may include epiploic appendagitis, appendiceal diverticulitis, appendiceal endometriosis, mucocele, and primary appendiceal neoplasms. Recognizing these anatomical variations and differential diagnoses is crucial for accurate image interpretation and appropriate clinical management.

TABLE OF CONTENTS/OUTLINE

1.Introduction. 2. Anatomy of vermiform appendix and its variability. 3. Acute appendicitis and its complications. 3. Beyond acute appendicitis: pitfalls and mimics to be aware and how to make the right diagnosis. 4. Conclusion.

GIEE-43 DIAGNOSTIC ALGORITHM FOR THE MANAGEMENT OF A PANCREATIC MASS. IS IT MALIGNANT?

Juan C. Spina JR, MD (*Presenter*)

TEACHING POINTS

1-Pancreatic adenocarcinoma, neuroendocrine tumors and different types of mass-forming chronic pancreatitis have different prognoses and require different treatment. Unfortunately, many times the overlap in their imaging and clinical features hinders a preoperative differential diagnosis. 2- Type 1 autoimmune pancreatitis (AIP) is the pancreatic manifestation of a multiorgan disease (IgG4-related disease) while type 2 AIP is a pancreas specific disorder not associated with IgG4. Surgery must be avoided in these patients. 3- If a pancreatic mass is resectable, and AIP has been ruled out, patients should undergo surgery to determine the true etiology of the pancreatic mass if preoperative diagnosis was not possible.

TABLE OF CONTENTS/OUTLINE

1) Introduction 2) Review and clinical presentation of most frequent types of mass-forming chronic pancreatitis (chronic pancreatitis, type 1 and type 2 autoimmune pancreatitis, groove pancreatitis, eosinophilic pancreatitis, follicular pancreatitis) 3) Typical and atypical presentation of malignant tumors: Adenocarcinoma, neuroendocrine tumors, solid pseudopapillary tumors, metastatic pancreatic disease, other. 4) MDCT and MRI findings. Tips for differential diagnosis between malignancy and inflammatory diseases with pathologic correlation. 5) Role of endoscopic ultrasoundPharmacologic treatment or surgery. 6) A multidisciplinary decision with example cases. 7) Suggestion of an algorithm for management of these patients.

GIEE-44 FROM LABS TO IMAGING: TUMOR MARKER INSIGHTS FOR ABDOMINAL RADIOLOGISTS TO IMPROVE INTERPRETATION AND RECOMMENDATION

Connie Ge, MD (*Presenter*)
Krista E. Suarez-Weiss, MD (*Abstract Co-Author*)
Ankur Pandey, MD (*Abstract Co-Author*)

TEACHING POINTS

- Highlight individual tumor markers' roles in the diagnosis, response, & recurrence of GU/GI malignancies in the context of image interpretation. - Illustrate specific cases of tumor markers to aid in accurate decision-making through a case based approach - Emphasize current limitations, including marker overlap with benign entities & variable sensitivity/specificity

TABLE OF CONTENTS/OUTLINE

HCC LI-RADS US Surveillance v2024: defining positive AFP/markedly elevated AFP, with recommendations. AFP: Recurrence, making recommendations, & pitfalls. Pancreatic cancer CA 19-9: local recurrence & metastasis. Characterization with pancreatic cyst fluid analysis: 2024 Kyoto guidelines - differentiating IPMN/MCN from others, distinguishing IPMN/MCN with LGD from HGD/IC. Colorectal Ca CEA: Recurrence & metastasis. Gallbladder cancer Utility of CA 19-9 & CEA in progression, response, or recurrence, rather than for initial diagnosis. Neuroendocrine tumor Chromogranin, 5-HIAA Prostate cancer Utility/drawbacks of PSA, PSA density, PSA velocity, free-PSA. Aid in visceral and bone metastases. Biochemical recurrence in post-treatment imaging: prostatectomy vs. radiotherapy. Ovarian Ca CA-125 in initial diagnosis in conjunction with US, & in monitoring treatment. Other markers: HE4, CEA & CA19-9. Testicular cancer AFP & HCG. Future developments Liquid biopsy: emerging role of Circulating tumor DNA New indices combining tumor markers, possibly aided by AI: personalized care. Emerging markers, ex. AFP-L3%, & DCP for HCC.

GIEE-45 COMPLEX BILIARY RECONSTRUCTION - PRE- AND POST-OPERATIVE APPEARANCE

Ann T. Foran, MBBCh (*Presenter*)
Rachita Khot, MD (*Abstract Co-Author*)
Manoj C. Mathew, MD (*Abstract Co-Author*)
Karthik M. Sundaram, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. As surgical techniques evolve, deviations from traditional biliary reconstructions (end-to-end and end-to-side hepaticojejunal anastomoses) are increasingly encountered in academic & general radiology settings. Radiologists must be prepared to recognize these complex reconstructions in routine & emergent imaging. 2. Deviations include a) ductoplasties, which combine two or more ducts into a single end-to-end or end-to-side anastomosis, and b) creation of two or more end-to-end anastomoses. 3. Complex reconstructions are more commonly seen in living donor liver transplants (LDLTs) but also occur in segmentectomies and lobectomies, requiring accurate imaging recognition. 4. The presence of multiple anastomoses increases the risk of complications such as anastomotic strictures, biliary leaks, and cholangitis. Understanding these potential issues aids in effective monitoring and management. 5. Our exhibit emphasizes the need for high-resolution MRCP and advocates for the use of Eovist™ in MR imaging for complex reconstructions.

TABLE OF CONTENTS/OUTLINE

1. Overview of biliary surgery and evolution toward complex anastomoses. 2. Role of imaging in complex biliary reconstruction, with a focus on MRI protocols, MRCP, and hepatobiliary phase imaging with Eovist™. 3. Discussion of common biliary anatomic variants (e.g. duct length, accessory ducts, aberrant drainage) and their impact on surgical planning. 4. Expected anatomy and imaging appearances after surgical reconstruction, particularly post-LDLT. 5. Brief review of potential complications and management strategies following complex biliary reconstructions

GIEE-46 DECIPHERING FAT IN THE LIVER: MIMICS, MASQUERADES, AND MISINTERPRETATIONS

Pravalya Chaparala, MD (*Presenter*)
Dinesh Rongali, MBBS (*Abstract Co-Author*)
Gopal Kodali, MD,MBBS (*Abstract Co-Author*)
Pooja Atkuri (*Abstract Co-Author*)
Rajesh Yalamanchi, MBBS, MD (*Abstract Co-Author*)
Ravi K. Kaza, MD (*Abstract Co-Author*)

TEACHING POINTS

1.Fat within the liver may be focal, diffuse, microscopic, or macroscopic and can occur in both benign and malignant lesions. 2.Atypical appearances of hepatic steatosis, such as focal nodular steatosis , focal fatty sparing , and diffuse perivascular or subcapsular steatosis , can be difficult to distinguish from other malignant processes. 3.Contrast-enhanced ultrasound can be used to exclude a mass in cases of focal nodular steatosis or sparing, as those areas will show enhancement similar to the rest of the hepatic parenchyma. 4.Chemical shift MRI sequences are essential for the identification of fat in liver lesions, enabling accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

1) Review of Imaging Techniques for Hepatic Lesion Characterization: Multiphase CT , including material characterization with Dual-energy CT Contrast-enhanced ultrasound Chemical shift MRI 2) Fat-Containing Liver Lesions: Macroscopic Fat: Benign Lesions Angiomyolipomas and lipomas Malignant Lesions Liposarcomas and fat-containing metastases Others Pseudolipomas of Glisson's capsule and pericaval fat Microscopic Fat: Benign Lesions Hepatic adenoma Atypical Lesions Focal nodular hyperplasia, hydatid cyst Malignant Lesions Hepatocellular carcinoma Other Conditions Focal hepatic steatosis 3) Focal Steatosis/Sparing: Typical Locations Gallbladder fossa, anterior to porta hepatis, adjacent to fissure for ligamentum teres Identification of Characteristic Features Geographic margins without mass effect 4) Atypical Patterns of Diffuse Steatosis: Locations Periportal, around hepatic veins, subcapsular Can Mimic Infiltrative neoplasm or inflammation

GIEE-47 FUNDAMENTALS OF PERCUTANEOUS SAMPLING: A GUIDE FOR ABDOMINAL IMAGING PROCEDURES

Mark J. Hoegger, MD, PhD (*Presenter*)
David H. Ballard, MD (*Abstract Co-Author*)
Malak Itani, MD (*Abstract Co-Author*)
Daniel R. Ludwig, MD (*Abstract Co-Author*)
Anup S. Shetty, MD (*Abstract Co-Author*)
Benjamin S. Strnad, MD (*Abstract Co-Author*)
Jia Chu, MD (*Abstract Co-Author*)
Michael H. Lanier, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Many image-guided procedures are rooted in abdominal radiology and require fundamental skill sets taught during training. However, the combination of clinical factors and barriers to acquiring technical skills may present challenges. Further, the lack of a formal curriculum may compound challenges in learning image-guided procedures. The purpose of this exhibit is to: 1. Provide a formulaic workup for image-guided sampling procedures. 2. Describe the various procedural imaging equipment and sampling tools. 3. Explain the fundamentals of various abdominal imaging-based sampling studies. 4. Guide intraprocedural troubleshooting and the detection and management of post-biopsy complications.

TABLE OF CONTENTS/OUTLINE

1. Procedural workup: procedure timeline, consent, and biopsy planning/target selection. 2. Equipment: US, CEUS, CT, sampling devices 3. General technical considerations: needle finding, fine needle aspiration (FNA), and core needle biopsy. 4. Procedure-specific principles: thyroid sampling, lymph node biopsy, paracentesis, thoracentesis, liver biopsy, kidney biopsy, retroperitoneal, and mesenteric biopsy. 5. Troubleshooting: intraprocedural and post-procedural.

GIEE-48 CHANGES OF MRI FEATURES IN VIABLE HEPATOCELLULAR CARCINOMA AFTER TRANSARTERIAL CHEMOEMBOLIZATION

Yuan-Cheng Wang, MD, PhD (*Presenter*)
Weilang Wang (*Abstract Co-Author*)

TEACHING POINTS

Provide a concise overview of post-TACE treatment response evaluation protocols. Emphasize a frequently overlooked clinical issue: the imaging characteristics of viable tumor following TACE differ markedly from those of pre-treatment HCC.Summary of the variability in the morphology and distribution of viable tumors.

TABLE OF CONTENTS/OUTLINE

Introduction to the LI-RADS Treatment Response Algorithm (LR-TRA) v2024.Case-based illustration of pre- and post-treatment signal alterations and enhancement pattern changes in viable tumors. Clinical insights into viable tumors presenting with diverse morphologies and locations.

GIEE-49 CHOLEDOCHAL CYSTS: CLASSIFICATION, IMAGING, AND ANATOMICAL VARIANTS OF THE PANCREATICOBILIARY TRACT — A PICTORIAL REVIEW

Agustin Z. Guzman Mercado, MD (*Presenter*)

TEACHING POINTS

1. Choledochal cysts are rare malformations of the bile ducts, most commonly classified using the Todani system (Types I-V), with important implications for management and prognosis.2. MRCP is the gold standard for noninvasive evaluation of the biliary and pancreatic ducts3. Imaging plays a key role in diagnosis providing complementary information on cyst type, extent, and associated complications (e.g., cholangitis, stone formation, malignancy).4. Pancreaticobiliary junction anomalies are frequently associated with choledochal cysts and may increase the risk of malignancy.5. Key imaging pearls: Always assess the entire biliary tree and pancreatic duct, look for signs of malignant transformation (wall thickening, mural nodules), and correlate with clinical history to guide management.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Definition and clinical relevance of choledochal cysts - Epidemiology and pathophysiology 2. Pancreaticobiliary Anatomy - Normal anatomy of the bile ducts and pancreatic duct - Common anatomical variants 3. Classification of Choledochal Cysts - Todani classification (Types I-V) - Associated pancreaticobiliary anomalies 4. Imaging Modalities and Findings (Cases) - Ultrasound, CT, MRI, MRCP - Characteristic imaging features by modality 5. Complications and Malignant Transformation - Stone formation, cholangitis, pancreatitis, cancer 6. Management and Surgical Considerations - Treatment strategies by cyst type - Importance of anatomical knowledge for surgery 7. Teaching Points - Summary of key learning points 8. Take-Home Messages - Final pearls and clinical reminders

GIEE-50 GETTING STIFF: A PRACTICAL LIVER MR ELASTOGRAPHY GUIDE FOR RADIOLOGY RESIDENTS

Leivanio Ponte Teixeira, MD (*Presenter*)
Anna Beatriz Ferreira Obara, MD (*Abstract Co-Author*)
Yuri Inoue (*Abstract Co-Author*)
Barbara Pereira, MD (*Abstract Co-Author*)
Andre L. Bordini, MD (*Abstract Co-Author*)
Fernando D. Tamamoto SR, MD (*Abstract Co-Author*)
Rodrigo P. Polizio, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Understanding what is Liver fibrosis and why it's necessary to stage it.2. Recognizing Liver MRE key clinical indications, primarily indicated for noninvasive staging of liver fibrosis in patients with chronic liver diseases.3. Understanding the physical principles of Liver MR Elastography.4. Dominating the patient preparation and technical considerations, extremely necessary to begin image interpretation and to easily identify image acquisition errors and non-diagnostic exams.5. Interpreting the images and doing the accurate Liver Stiffness Measurement in kilopascals (kPa), understanding that higher values suggest increasing stages of fibrosis.

TABLE OF CONTENTS/OUTLINE

Introduction What is Liver Fibrosis? What are the Causes of Increased Liver Stiffness? Why Do We Have to Evaluate Liver Fibrosis? What’s the Importance of Liver MRE? First Step: Understand The Liver MRE How It Physically Works Liver MRE? How to Prepare the patient? What MRI Sequences Do We Need to Recognize? Second Step: Check The Quality of Exam Is This a High-Quality Exam? Is This a Low-Quality Exam? Is This a Non-Diagnostic Exam? What Can We Do to Correct and Reduce Errors? Third Step: Interpret the Liver MRE How Do We Do the Liver Stiffness Measurement? Which Areas Do We Have to Avoid? How Do We Interpret the Values of LSM? How Can We Report?

GIEE-51 SPLENIC ELASTOGRAPHY: WHAT IT IS, HOW IT IS PERFORMED, AND HOW IT IS INTERPRETED

Elisa De Jesus Ramos, MD (*Presenter*)
Veronica Espinoza Cruz (*Abstract Co-Author*)
Adan Elizalde, MD, MD (*Abstract Co-Author*)
Tania D. Grimaldo Galeana, MD (*Abstract Co-Author*)
Alejandro Garcia Pena, MD (*Abstract Co-Author*)

TEACHING POINTS

To describe the anatomy and physiology of the spleen. To explain the pathophysiology of portal hypertension. To describe the use of splenic elastography in the diagnosis of portal hypertension. To list the indications for splenic elastography. To detail what splenic shear wave elastography consists of. To explain the protocol for performing splenic elastography using shear wave ultrasound. To describe the process of interpreting the results of splenic elastography.To analyze the limitations and effectiveness of splenic elastography as a non-invasive imaging method for detecting portal hypertension.

TABLE OF CONTENTS/OUTLINE

Anatomy and physiology of the spleen. Pathophysiology of portal hypertension. Splenic elastography and portal hypertension. Splenic elastography: What it is and how it works. Indications for splenic elastography. Protocol for performing splenic elastography using shear wave ultrasound. Interpretation of results. Limitations and effectiveness of splenic elastography as a non-invasive imaging method for detecting portal hypertension. Review of representative cases of splenic elastography in patients with portal hypertension. Conclusions

GIEE-52 ULTRASOUND-BASED LIVER FAT QUANTIFICATION: PROTOCOL FOR OPTIMIZING MEASUREMENT ACQUISITION AND INTERPRETATION OF RESULTS

Reinhard I. Kubale, MD (*Presenter*)
Andrew T. Trout, MD (*Abstract Co-Author*)
Jonathan R. Dillman, MD, MSc (*Abstract Co-Author*)
Erika Rubesova, MD (*Abstract Co-Author*)
Yassin Labyed (*Abstract Co-Author*)
Arati Gurung (*Abstract Co-Author*)
Jean-Michel Correas, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Understand the role of ultrasound-derived fat fraction (UDFF) in quantifying liver fat. • Learn standardized protocols for acquiring UDFF measurements to ensure reproducibility. • Interpret UDFF results in the context of steatosis, correlating with MRI and clinical findings. • Recognize pitfalls in ultrasound measurements and strategies to reduce artifacts. • Suggested guidance for interpretation of UDFF measurements.

TABLE OF CONTENTS/OUTLINE

• Introduction: Importance of liver fat quantification in MASLD. • Quantitative Ultrasound Techniques: Overview of UDFF principles. • Measurement Protocol: Step-by-step guide for acquiring reliable UDFF data. • Pitfalls: Common challenges and how to address them. • Case Examples: Illustrative cases demonstrating measurement and interpretation. • Interpretation Guidance: Detecting and quantifying hepatic steatosis • Conclusion: Role of ultrasound in liver disease management.

GIEE-53 INFLAMMATORY BOWEL DISEASE AND CANCER: REVEALING THE UNSEEN - A RADIOLOGIST'S GUIDE

Rodrigo Borrero, MD (*Presenter*)
Tanya P. Chawla, MBBS (*Abstract Co-Author*)

TEACHING POINTS

Be aware of the risk factors in patients with IBD that increase the risk of malignancy within the GI tract Understand pathological associations and provide an update on histopathological features of GI cancers in this subpopulation Demonstrate the spectrum of findings seen in cancers associated with IBD

TABLE OF CONTENTS/OUTLINE

IBD, including Crohn's disease and ulcerative colitis, increases the risk of GI cancers due to chronic inflammation. Persistent inflammation leads to cycles of damage and repair in the intestinal mucosa, increasing the likelihood of DNA damage, mutations, and cancer development. Key risk factors include disease duration and extent, inflammation severity, genetic susceptibility, and coexisting conditions like PSC. Regular surveillance through colonoscopy and biopsies is essential for early detection. Imaging techniques such as contrastenhanced CT and MRI are crucial for management and assessing complications. Imaging findings in IBD patients concerning for malignancy include asymmetric bowel wall thickening, loss of mural stratification, and a soft tissue mass. CT and MRI play a significant role in depicting these features, which may indicate colorectal cancer, small bowel adenocarcinoma, or other GI neoplasms. Techniques to improve diagnostic confidence will also be discussed. Radiology is essential in detecting atypical imaging findings that may indicate cancer. The integration of surveillance guidelines and advanced imaging techniques ensures accurate assessment of treatment response and early detection of complications. By recognizing normal and abnormal imaging findings, clinicians can effectively manage IBDrelated cancers, improving prognosis and patient care

GIEE-54 MESS IN THE MESENTERY: A MULTIMODALITY APPROACH TO MASSES AND MIMICS

Namita Sharma, MD (*Presenter*)
Kelly Harper, MD,FRCPC (*Abstract Co-Author*)
Mary B. Bissell, Md, MSc (*Abstract Co-Author*)

TEACHING POINTS

By the end of this exhibit, the reader will be able to: Describe mesenteric anatomy, its relationship to adjacent organs, and its relevance to tumor spread. Review major categories of mesenteric pathologies, including congenital, neoplastic, vascular, infectious, and inflammatory. Develop a differential diagnosis on US, CT, and MRI using a morphology-based approach to categorize lesions as cystic, solid, or inflammatory/infectious. Safely perform percutaneous biopsy of mesenteric lesions using advanced techniques for challenging targets.

TABLE OF CONTENTS/OUTLINE

Introduction & Anatomy Mesenteric masses span a broad differential and pose a diagnostic challenge. Understanding abdominal anatomy and disease patterns, along with a multimodality imaging strategy, is essential for accurate assessment. Imaging Assessment: Through a case-based review, we explore common and rare cystic, solid, and diffuse/infiltrative lesions, highlighting key imaging features and diagnostic pearls. Diagnostic Pitfalls: Interpretive pitfalls and mimics are reviewed are reviewed in context with clinical and imaging correlation. Percutaneous Biopsy: Indications, considerations, and techniques for safe image-guided sampling, including of mobile or bowel-covered mesenteric lesions, are discussed. Conclusion: While biopsy remains the gold standard, imaging helps narrow differentials, guide intervention, and may obviate invasive procedures. A systematic and comprehensive approach enhances diagnostic confidence and management.

GIEE-55 OVARIAN IMAGING WITH CONTRAST-ENHANCED ULTRASOUND: UNLOCKING THE POTENTIAL

Meaghan Reid, MD (*Presenter*)
Kelsey Brisebois (*Abstract Co-Author*)
Christine Merrill, BSc (*Abstract Co-Author*)
Stephanie R. Wilson, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Greyscale ultrasound is firmly established as the preferred first-line imaging modality in the assessment of ovarian masses.2. Morphologic features of ovarian tumors frequently overlap between benign and malignant disease.3. Complex cystic morphology is most common and all solid components, papillary projections, and septa are evaluated to determine their blood flow which varies directly with malignancy. 4. Contrast-Enhanced Ultrasound (CEUS) is safe and repeatable, providing superior information to high-quality greyscale ultrasound about microvascular flow in ovarian lesions, aiding in differentiation of benign from malignant pathology. 5. CEUS Quantification of blood flow performed with region of interest (ROI) time intensity curve (TIC) methodology provides objective information about blood flow. 5. Malignant ovarian masses often demonstrate higher peak enhancement, shorter rise time, larger area under the curve, rapid time to peak and faster washout in comparison with benign lesions

TABLE OF CONTENTS/OUTLINE

1. Ovarian Cancer: its incidence, significance and challenges for diagnosis.2. Greyscale and Doppler -3. The contribution of CEUS in imaging of ovarian masses.. 4. The differentiation of benign vs malignant ovarian lesions with CEUS. 5 The applications of CEUS quantification in imaging of pelvic masses.

GIEE-56 FAST AND FOCUSED: IMPLEMENTING ABBREVIATED MRI FOR LIVER CANCER SURVEILLANCE

Hosseini Shabanan, MD, MPH (*Presenter*)
Pouria Yazdian, MD (*Abstract Co-Author*)
Mustafa R. Bashir, MD (*Abstract Co-Author*)
Bachir Taouli, MD (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)
Takeshi Yokoo, MD, PhD (*Abstract Co-Author*)
Kathryn J. Fowler, MD (*Abstract Co-Author*)
Claude B. Sirlin, MD (*Abstract Co-Author*)

TEACHING POINTS

Abbreviated MRI (AMRI) is a promising alternative to liver ultrasound for hepatocellular carcinoma (HCC) surveillance, offering reduced scan time and cost compared to full-sequence liver MRI, the reference standard. This educational exhibit reviews the clinical rationale, imaging workflow, and interpretation strategies for various AMRI protocols (i.e., non-contrast, dynamic, and hepatobiliary phase [HBP] AMRI). We outline protocol design considerations, describe the typical imaging appearances of HCC across AMRI sequences, and highlight the practical advantages and limitations of each AMRI protocol relative to one another. Additionally, we examine AMRI's role in both screening and surveillance settings, emphasizing differences in performance and application.

TABLE OF CONTENTS/OUTLINE

? Introduction Importance of HCC surveillance in high-risk patients; potential of AMRI to enhance surveillance, particularly in patients with suboptimal ultrasound ? What Is Abbreviated MRI? Concept, AMRI protocols, and comparison with full MRI ? Design of AMRI Protocols Key sequences, workflow, and contrast timing ? Image Interpretation Essentials HCC features on each AMRI protocol; strengths and limitations of each protocol; reporting guidelines; and follow-up recommendations ? Case-Based Applications Examples of true and false diagnoses on AMRI compared to reference standard full MRI exams (real-world cases); comparison with ultrasound ? Practical Implementation Patient selection, workflow integration, and logistical considerations ? Current Evidence Overview of literature and AMRI's role in surveillance pathways ? AMRI in Daily Practice Key takeaways and future opportunities

GIEE-57 CYSTIC PANCREATIC LESIONS: IMAGING DIFFERENTIATION, MALIGNANCY RISK, AND UPDATED SURVEILLANCE STRATEGIES

Alexandra Panyukova, MD (*Presenter*)
Mishal Shahab, MBBS (*Abstract Co-Author*)
Arwa Elsamny, MBBCh (*Abstract Co-Author*)
Shadi Daghighi, MD (*Abstract Co-Author*)
Michele Lisi, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Cystic pancreatic lesions encompass both nonneoplastic and neoplastic entities , the latter of which includes a spectrum of histologic subtypes with distinct imaging characteristics and variable malignant potential. 2. Imaging evaluation should be systematic , assessing morphology, main pancreatic duct dilatation, presence of capsule, mural nodules, and cyst growth rate—features critical for diagnosis and risk stratification. 3. Multiple management guidelines exist with differing recommendations , including Fukuoka 2017, ACG 2018, ACR 2017, European 2018, AGA 2015, updated Kyoto 2024 guidelines, contributing to variation in clinical practice. 4. The 2024 Kyoto guidelines offer updated criteria , refining definitions of high-risk stigmata and worrisome features, and providing more precise recommendations for surveillance and surgical referral.

TABLE OF CONTENTS/OUTLINE

1.Introduction 2.Learning 3.Overview of the pancreatic cystic lesions 4.Nonneoplastic Cysts (Pseudocysts: Typical clinical scenario, CT/MRI features, complications; Differentiation from neoplastic cysts) 5.Cystic Pancreatic Neoplasms (Demographics and clinical presentations, typical imaging characteristics, association with malignancy, case-based review) 5.1 Serous Cystadenoma 5.2 Mucinous Cystic Neoplasm 5.3 Solid Pseudopapillary Neoplasm 5.4 Intraductal Papillary Mucinous Neoplasm (Main duct IPMN, side brunch IPMN, mixed type, field defect) 5.5 Cystic pancreatic neuroendocrine tumors 6.Follow-Up and Management Guidelines 6.1 Comparison of the existing guidelines 6.2 ACR Guidelines 6.3 Fukuoka Guidelines, 2017 6.4 Kyoto Guidelines, 2024: What's New? 7.Take Home Points 8.References

GIEE-58 BEYOND THE BOWEL: BEHIND THE COMPLICATIONS OF CROHN'S DISEASE

Levi B. Oliveira, MD (*Presenter*)
Nathalia O. Menezes, MD (*Abstract Co-Author*)
Martin Horwarth, MD (*Abstract Co-Author*)
Fernanda G. Velloni, MD (*Abstract Co-Author*)
Cassia T. Guimaraes, MD (*Abstract Co-Author*)
Daniel Lahan-Martins, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Provide an overview of complications of Crohn's disease. - Discuss typical and atypical cases of complications of Crohn's disease. - Review the main differential diagnoses of complications of Crohn's disease. - Offer useful tips for challenging cases to enhance accurate diagnosis. - Create a radiological guide to help interpret the complications of Crohn's disease.

TABLE OF CONTENTS/OUTLINE

- Crohn's disease is a chronic multifactorial transmural inflammatory disease affecting the gastrointestinal tract, mainly in young white women. - Complications affect one-third of patients at diagnosis. - We will explore both classical and uncommon imaging manifestations of complications of Crohn's disease, including potential malignant behavior. - Provide tips for challenging cases where the diagnosis may not be apparent from imaging alone.

GIEE-59 PANCREATIC MALIGNANCY IN DISGUISE: A TALE OF MISSED DIAGNOSES AND MIMICKING PATHOLOGIES

Mandeep S. Virk, MBBS, MD (*Presenter*)
Ravi K. Kaza, MD (*Abstract Co-Author*)
Naveen Rajamohan, MD,MBBS (*Abstract Co-Author*)
Venkata Gopala Rao Kodali (*Abstract Co-Author*)
Hala A. Khasawneh, MBBS (*Abstract Co-Author*)
Gaurav Khatri, MD (*Abstract Co-Author*)

TEACHING POINTS

• Pancreatic cancer remains one of the most lethal malignancies, often diagnosed late due to vague symptoms and overlapping features with benign or less aggressive conditions. • Understanding its typical and atypical imaging features and mimics is key to improving diagnostic accuracy. • Identifying important pitfalls in pancreatic imaging is important for optimal patient care.

TABLE OF CONTENTS/OUTLINE

• Background. • Typical and atypical imaging findings of pancreatic ductal adenocarcinoma (PDA). • Comon and uncommon mimickers of PDA. • Imaging findings of mimickers - Case examples with pathological proven diagnosis. a) Focal Acute Pancreatitis. b) Mass-forming Chronic Pancreatitis. c) Autoimmune Pancreatitis. d) Groove Pancreatitis. e) Neuroendocrine Tumor. f) Metastases. g) Lymphoma. h) Solid Pseudopapillary Neoplasm. • Pitfalls in diagnosis of pancreatic neuroendocrine tumors. • How to arrive at a diagnosis and overcome pitfalls. • Discuss role of advanced imaging techniques and recent advances in improving detection - a) Endoscopic Ultrasound (EUS) b) Contrast Enhanced Ultrasound (CEUS) c) Elastography d) Radiomics e) Artificial Intelligence (AI). Summary.

GIEE-60 SOUND DECISIONS: ULTRASOUND IN CHRONIC LIVER DISEASE ASSESSMENT AND SURVEILLANCE

David T. Fetzer, MD (*Presenter*)
Aya Kamaya, MD (*Abstract Co-Author*)
Shuchi K. Rodgers, MD (*Abstract Co-Author*)
Theodore T. Pierce, MD, MPH (*Abstract Co-Author*)

TEACHING POINTS

1) Ultrasound is central to chronic liver disease (CLD) care continuum, from detection (eg. steatosis) to fibrosis staging, to HCC surveillance. 2) Best used in combination with clinical and biochemical tools. 3) Technological advances (elastography, fat quantification) enhance diagnostic utility. 4) Ensures appropriate patient selection for referral, therapeutic interventions, and enrollment in surveillance.

TABLE OF CONTENTS/OUTLINE

INTRO: • Overview of CLD • US integrates with clinical tools to assess liver disease progression and guide management decisions. EARLY DETECTION: A. Clinical Evaluation: • Potential risk factors and etiologies • Consider less common diseases • Lab test correlation • Risk assessment scores (eg. FIB-4) • Serum fibrosis panels. B. Role of basic B-mode US: Liver size, morphology, parenchyma, contour. Doppler: Assess inflow; outflow. GRADING & SURVEILLANCE OF STEATOSIS. A. Liver fat quantification (LFQ) o Confirms and quantifies. o Correlates with metabolic risk and fibrosis progression. o Baseline for monitoring response to therapy. B. Combing with Clinical Scores: o FIB-4 + LFQ or LFQ + Elastography to risk-stratify. o Decision-making: who needs referral and treatment vs. monitoring. STAGING AND SURVEILLANCE OF FIBROSIS/CIRRHOSIS. A. Elastography • Interpretation (cutoffs for significant fibrosis, cirrhosis). B. Combining with Clinical Scores • FIB-4 + elastography to further risk-stratify • Decision-making (Referral for portal hypertension monitoring; Enrollment in HCC surveillance). HCC SURVEILLANCE. A. Eligibility. B. Modalities (US every 6 months ± AFP). C. Standardized reporting (US LI-RADS). D. Patient-specific surveillance, management.

GIEE-61 MORE THAN JUST FAT: MULTIPARAMETRIC MRI AS KEY RADIOLOGICAL TOOL IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Clara Fiorot, MD (*Presenter*)
Luiza Ambrozino, MD (*Abstract Co-Author*)
Sthefane Nunes, MD, MD (*Abstract Co-Author*)
Eleonora Silva (*Abstract Co-Author*)
Juliana Da Trindade (*Abstract Co-Author*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Understand the pivotal role of multiparametric MRI (mp-MRI) in evaluating key features of MASLD, including steatosis, iron overload, inflammation, and fibrosis. Learn how to integrate imaging findings with clinical and laboratory data to enhance diagnostic accuracy and assess disease severity. Review the application of mp-MRI through illustrative clinical case studies. Explore the utility of mp-MRI for monitoring disease progression and response to therapy in MASLD.

TABLE OF CONTENTS/OUTLINE

1. Introduction - Overview of MASLD diagnosis and its growing global prevalence.- The evolving role of imaging in the diagnosis, characterization, and longitudinal monitoring of MASLD.- Introduction to multiparametric MRI as a comprehensive and non-invasive modality for liver assessment. 2. Imaging Techniques and Interpretation - Comparative review of conventional imaging modalities for liver steatosis assessment: Conventional ultrasound (US), Quantitative US, FibroScan®, 2D shear wave elastography (2D-SWE), Computed tomography, Magnetic resonance imaging (MRI) - Multiparametric MRI, - Magnetic resonance elastography.-Discussion of clinical guidelines (EASL, AASLD) and the placement of each imaging modality within these frameworks.-Evaluation of the strengths, limitations, and diagnostic performance of each technique.- MRI protocol overview: including T1 mapping, R2* mapping, and MR elastography.- Common pitfalls and challenges in MRI and MRE interpretation.

GIEE-62 FROM STANDARDIZATION TO PREVENTION: TRACING LI-RADS' IMPACT ON SCREENING AND CLINICAL PRACTICE

Pouria Yazdian, MD (*Presenter*)
Sedighe Hosseini Shabanan, MD, MPH (*Abstract Co-Author*)
Robert M. Marks, MD (*Abstract Co-Author*)
Victoria Chernyak, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

The Liver Imaging Reporting and Data System (LI-RADS) was developed to reduce inconsistencies in interpreting and reporting liver observations by providing a standardized framework essential for consistent follow-up and treatment planning. This exhibit highlights the evolution of LI-RADS from a reporting lexicon to a comprehensive framework supporting liver cancer management—from initial screening ultrasound, through accurate diagnosis often eliminating biopsy, to post-treatment response assessment in patients undergoing locoregional therapy or being evaluated for liver transplant at tertiary care centers. Through case-based examples—including ultrasound surveillance, CT/MRI findings across LI-RADS categories with major and ancillary features, and post-treatment assessments using updated LR-TR criteria—this exhibit demonstrates LI-RADS as a practical tool in daily radiologic practice LI-RADS is now a multi-modality system: CT, MRI, US, CEUS, and treatment response Integrated into guidelines, unifying HCC imaging criteria High diagnostic accuracy and precision US LI-RADS enhances surveillance; abbreviated MRI and CEUS improve early detection LR-TR criteria further refine post-treatment evaluation Future directions: AI, radiomics, and probabilistic malignancy prediction

TABLE OF CONTENTS/OUTLINE

Introduction: Standardization in liver imaging LI-RADS Evolution (2011-2024) Diagnostic Algorithm: Features and categories Ancillary Features in Diagnosis Ultrasound LI-RADS in HCC Surveillance Abbreviated MRI and CEUS in Screening LI-RADS treatment response (LR-TR) criteria Clinical Impact on Diagnosis and Outcomes Future Directions: AI, radiomics, and LI-RADS enhancements

GIEE-63 RADIOLOGICAL ASSESSMENT IN GASTRIC CANCER, ESSENTIAL CRITERIA FOR ACCURATE STAGING

Valentina Garralda (*Presenter*)
Manuela Jubete, MD (*Abstract Co-Author*)
Daniela Soloaga (*Abstract Co-Author*)
Mariano Lorea (*Abstract Co-Author*)
Roy Lopez Grove, MD (*Abstract Co-Author*)

TEACHING POINTS

TNM staging by computed tomography is critical in determining optimal treatment and prognosis, making the difference between curative and palliative surgical management. Multiphasic contrast-enhanced CT and PET/CT play a central role in assessing the extent of gastric cancer, guiding treatment decisions through detailed assessment of local invasion and metastatic spread. Prognosis correlates with stage at diagnosis: early (mucosal/submucosal) or advanced (deeper layers). Systematic

radiological assessment optimises treatment and improves survival. Identification of dissemination routes (lymphatic, peritoneal and haematogenous) allows anticipation of tumor progression and planning more effective interventions.

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology Imaging techniques Upper endoscopy Endoscopic ultrasound (EUS) CT/Pneumo-CT PET-CT/Pneumo PET-CT Describe which method is best for assessing tumour invasion, lymphatic spread and distant metastasis. T classification N classification Perigastric and extra perigastric nodes. M classification The most common dissemination routes. Pitfalls Conclusions

GIEE-64 ATYPICAL SPREAD AND RECURRENCE PATTERNS IN PANCREATIC CANCER: IMAGING FEATURES AND COMMON MIMICKERS

Masashi Asano, MD (*Presenter*)
Yoshifumi Noda, MD, PhD (*Abstract Co-Author*)
Nobuyuki Kawai, MD, PhD (*Abstract Co-Author*)
Shingo Omata, MD (*Abstract Co-Author*)
Tetsuro Kaga, MD, PhD (*Abstract Co-Author*)
Yukiko Takai (*Abstract Co-Author*)
Hiroki Kato (*Abstract Co-Author*)
Masayuki Matsuo, MD (*Abstract Co-Author*)

TEACHING POINTS

•To review critical anatomical structures and imaging features that radiologists must assess in pancreatic cancer, with an emphasis on findings that influence staging and treatment strategy.•To present case-based examples of atypical patterns of tumor progression and recurrence, highlighting their clinical significance and potential diagnostic pitfalls.•To recognize common imaging mimickers of atypical pancreatic cancer spread in order to avoid misinterpretation and suboptimal clinical decision-making.

TABLE OF CONTENTS/OUTLINE

1. Evaluation of Local Invasion - Case-based review of key anatomical landmarks and tumor-vessel interface assessment in relation to resectability criteria2. Case-Based Review of Uncommon Patterns of Tumor Spread and Recurrence - Tumor thrombus in the portal vein- Intraductal tumor extension- Diffuse tumor infiltration of the pancreas- Needle-tract seeding following EUS-FNA- Peritoneal dissemination, including port-site seeding- Pulmonary metastasis mimicking consolidation- Hepatic metastasis mimicking arterioportal shunting3. Imaging Mimickers of Atypical Spread of Pancreatic Cancer: Differentiating Features and Management - Tumor thrombus vs. bland thrombus; Anticoagulant therapy, iodine quantification- Diffuse pancreatic infiltration vs. autoimmune pancreatitis; Serum IgG4, MRI, biopsy- Needle-tract seeding vs. subepithelial gastric tumor; PET-CT, biopsy/partial gastrectomy- Peritoneal dissemination vs. abdominal wall desmoid tumor; PET-CT, MRI, biopsy

GIEE-65 MASTERING TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT (TIPS): FROM INTERVENTIONAL PROCEDURE TO IMAGING SURVEILLANCE

Jorge O. Ibarra Chairez, MD (*Presenter*)

TEACHING POINTS

Review the key technical aspects of Transjugular Intrahepatic Portosystemic Shunt (TIPS) placement and post procedural changes. Understand the normal and abnormal imaging findings on post-procedural evaluation. Provide a practical ultrasound-based approach to the Doppler evaluation of TIPS during follow-up.

TABLE OF CONTENTS/OUTLINE

Background, indications and contraindications for TIPS placement. TIPS placement technique overview and angiographic findings. Hemodynamic changes after TIPS. Post-procedural imaging: CT and US surveillance. Doppler ultrasound evaluation: Expected flow patterns and velocity criteria Common pitfalls and limitations Suggested acoustic windows to improve spectral Doppler evaluation Case-based review of TIPS dysfunction and complications. Summary and key take-home points.

GIEE-66 VALUE OF PHOTON COUNTING CT IN ABDOMINAL ONCOLOGIC IMAGING

Seyedeh Niloufar Rafiei Alavi, MD (*Presenter*)
Akash C. Joshi, MD (*Abstract Co-Author*)
Arti Gupta, MD (*Abstract Co-Author*)
Maryam Rahmani, MD (*Abstract Co-Author*)
Vahid Yaghmai, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

Photon-counting CT (PCCT) offers improved spatial resolution with reduced radiation dose, making it ideal for screening and diagnosis of abdominal malignancies, including better detection of pancreatic and renal cysts. PCCT improves lesion characterization and assessment of treatment response, with studies demonstrating improved visualization of hypervascular liver lesions and perineural invasion in pancreatic adenocarcinoma. Spectral flexibility in PCCT allows selection of high or low keV images. High keV reduces beam-hardening artifacts, while low keV increases contrast-to-noise ratio and conspicuity of liver metastases and pancreatic tumors. PCCT enables advanced spectral reconstructions including virtual non-contrast (VNC) and iodine maps, supporting quantitative iodine analysis that may aid in cancer diagnosis and prognosis. Iodine quantification can be useful for cancer diagnosis and prognosis of cancers

TABLE OF CONTENTS/OUTLINE

1. Basic technical principles of PCCT2. Benefits of high spatial resolution with dose saving on cancer screening and tumor detection3. Enhanced tumor visualization and treatment response monitoring4. Spectral Imaging Capabilities: keV Tuning for Optimal Image Quality5. Advanced Quantitative Tools: Virtual Non-Contrast and Iodine Mapping

GIEE-67 IMAGING OF COMPLICATIONS AFTER ANORECTAL SURGERY: A STRUCTURED PICTORIAL REVIEW

Murilo d. Peixoto, MD (*Presenter*)
Victor Martinelli Preto, MD (*Abstract Co-Author*)
Joao Manoel M. Santos, PhD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Review common anorectal surgical procedures (e.g., LAR, APR, ELAPE, coloanal anastomosis). Recognize normal post-operative imaging appearances and post-neoadjuvant chemoradiation features that may support a non-operative watch-and-wait approach or indicate technical challenges for surgery. Identify key complications following anorectal surgery and correlate them with expected timing and imaging findings.

TABLE OF CONTENTS/OUTLINE

Postoperative imaging plays a pivotal role in the assessment of complications after anorectal cancer surgery, particularly considering the technical challenges posed by the need to preserve sphincteric function and quality of life while achieving adequate resection margins. This exhibit presents a structured framework that classifies complications by timing—distinguishing early (=30 days) from late (>30 days)—and by anatomical and etiological patterns. Complications are explored across the surgical site and abdominal wall, including infectious processes (abscesses, collections, fistulas), ischemic changes, obstructive or stricturing complications, locoregional recurrence, and other entities encountered in clinical practice. CT and MRI cases illustrate these findings with an emphasis on distinguishing expected postoperative appearances from true pathology, aiming to improve diagnostic accuracy and multidisciplinary communication.

GIEE-68 THE HIDDEN THREAT: ESOPHAGEAL EMERGENCIES

Paula Munoz Carrasco, MD (*Presenter*)
Juan Jimenez Ruiz, MD (*Abstract Co-Author*)
Patricia Garcia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

-To review esophageal emergencies.-To illustrate them with different imaging techniques.

TABLE OF CONTENTS/OUTLINE

The aim of this review is to examine the spectrum of acute esophageal pathologies that may present as medical emergencies. These conditions often present with nonspecific manifestations, are frequently underdiagnosed, and are associated with significant morbidity and mortality. Increasing awareness is essential for early recognition and is crucial for proper management and improved patient outcomes.We focus on the presentation and imaging findings of a broad spectrum of acute esophageal conditions—including esophagitis, esophageal necrosis, foreign body impaction, and multiple fistulas—and emphasize the value of CT as a diagnostic tool for guiding clinical decision-making and evaluating potential complications such as perforation.

GIEE-69 MRI OF CROHN'S PERIANAL FISTULA : WHAT THE SURGEON NEEDS TO KNOW AND WHY

Meddeb Dorra, MD (*Presenter*)
Mohamed A. Haouari I, MD (*Abstract Co-Author*)
Caroline Touloupas (*Abstract Co-Author*)
Alexandre Delpla (*Abstract Co-Author*)
Boulay-Coletta Isabelle, MD (*Abstract Co-Author*)
Marc Zins, MD (*Abstract Co-Author*)

TEACHING POINTS

- Crohn's disease (CD) is a common cause of perianal suppurations. - Perineal involvement can occur in patients with known luminal CD but may also present as the initial or sole manifestation. - A detailed understanding of ano-perineal anatomy is crucial for accurate diagnosis and optimal management. - MRI plays a central role in the diagnosis, treatment planning, and follow-up of perianal fistulas enabling gastroenterologists and surgeons to select the optimal therapeutic approach and to evaluate treatment efficacy. - MRI protocole should be optimal to be able to answer to the surgeon questions. - Precise assessement of fistulous tracts and their extensions, particularly toward the supra levatoric space, within puborectalis muscle or to ischioanal fossa, is essential for guiding surgical drainage. - Differentiating between tracts with inflammatory masses made of granulation tissue and purulent tracts and abscesses is essential, as each requires distinct management approaches. - The ultimate stage in the treatment of crohn's fistulas is closure of the tract using one of several sphincter-sparing techniques. Each technique is adapted to a particular type of fistula, depending on the width and height of the internal opening, the length and the degree of inflammation of the tract.

TABLE OF CONTENTS/OUTLINE

* MRI Protocol : utility of every sequence.* Place of ano-perineal MRI in the management strategy of perianal CD* MRI report : Essential details required by the surgeon.

GIEE-70 HIDDEN IN PLAIN SIGHT: WHEN TUBERCULOSIS STRIKES THE ABDOMEN

Pedro Berriel, MD (*Presenter*)
Renata Sande Paiva, MD (*Abstract Co-Author*)
Andrey Ribeiro, MD (*Abstract Co-Author*)
Bruna Mendes, MD (*Abstract Co-Author*)
Vitor Soares, MD (*Abstract Co-Author*)
Mateus Pereira Dos Santos Gomes, MD (*Abstract Co-Author*)
Miriam M. Barreto, MD, PhD (*Abstract Co-Author*)
Rosana S. Rodrigues, MD, PhD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Explain the pathways of Mycobacterium tuberculosis dissemination Demonstrate the most common abdominal and pelvic manifestations and how they appear on CT and MRI Understand the role of imaging in promptly identifying complications and diagnosing an underlying cause of acute abdomen.

TABLE OF CONTENTS/OUTLINE

I. Introduction Understand the dissemination routes of the bacillus: hematogenous and lymphatic dissemination Highlight the importance of imaging studies in detecting early complications and raising the possibility of a granulomatous infectious process as a differential diagnosis II. Abdominal and Pelvic Manifestations of Disseminated Tuberculosis with Abdominal Involvement Recognize the manifestations of tuberculosis in various pelvic and abdominal organs:a) Discuss potential complications, such as abscess formation and recurrent urinary tract infections b) Lymph node conglomerates causing mass effect c) Dysmenorrhea and dyspareunia d) Peritonitis e) Altered bowel habits, such as diarrhea and constipation III. Imaging Findings of Disseminated Tuberculosis in the Abdomen and Pelvis a) Peritonitis b) Organ-specific findings based on imaging: Liver Spleen Kidneys Gastrointestinal tract Male and female reproductive organs IV. Conclusion Recognizing the disseminated form and the most common complications of this high-prevalence disease enables rapid clinical management and reduces morbidity.

GIEE-71 SCREENING AND SURVEILLANCE IN MASLD USING MRI-BASED BIOMARKERS: FROM FIBROSIS TO FOCAL LESIONS

Gabriela Carboni, MD (*Presenter*)
Gabriela Furlin, MD (*Abstract Co-Author*)
Gabriela Sequeira De Campos Morais (*Abstract Co-Author*)
Henrique M. Guerra, MD (*Abstract Co-Author*)
Ivan M. Pedrollo, MD (*Abstract Co-Author*)
Alice Schuch, MD (*Abstract Co-Author*)

TEACHING POINTS

Fibrosis is the main prognostic factor in MASLD, independently associated with liver-related events and overall mortality. MR elastography is the most accurate noninvasive technique for liver stiffness assessment and should be integrated into longitudinal monitoring protocols. PDFF and R2* mapping by MRI are reliable imaging biomarkers for quantifying hepatic steatosis and iron overload, respectively - two key components of MASLD that may influence disease progression, affect imaging interpretation, and provide an important basis for monitoring therapeutic response. Hepatocellular carcinoma (HCC) may develop in MASLD even without cirrhosis, particularly with other risk factors like precirrhotic MASH, diabetes, obesity, alcohol use, older age, male sex, smoking, or family history of HCC. Gadoxetic acid-enhanced MRI improves the detection and characterization of focal liver lesions, particularly in steatotic and iron-overloaded livers, especially when conventional MRI or other modalities are inconclusive.

TABLE OF CONTENTS/OUTLINE

MASLD: epidemiology and screening. Imaging-based screening: importance of detecting early fibrosis and HCC risk in non-cirrhotic patients. MR elastography for fibrosis assessment: role as a noninvasive biomarker; clinical indications and integration with PDFF and R2*. Gadoxetic acid-enhanced MRI: improved lesion detection and characterization in challenging livers. Case-based review: multiparametric MRI in clinical practice. Future directions: hepatobiliary contrast uptake as a biomarker.

GIEE-72 LOW-PHOSPHOLIPID ASSOCIATED CHOLELITHIASIS (LPAC) SYNDROME: LEAVE NO STONE UNTURNED

Daniel L. Cardoso, MD (*Presenter*)
Giovanni G. Cerri, PhD (*Abstract Co-Author*)
Sabrina M. Ando, MD (*Abstract Co-Author*)
Ralph R. Tavares, MD (*Abstract Co-Author*)

TEACHING POINTS

Recognize the anatomy of the biliary tract and its variants. Understand biliary tract lithiasis. Detailed knowledge on identifying and characterizing primary and secondary causes of hepatolithiasis and their imaging findings. Comprehend LPAC syndrome and its impact on the diagnostic approach to biliary lithiasic diseases. Insight into the decision-making process for managing hepatolithiasis.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION: Overview of biliary tract anatomy and anatomical landmarks. Anatomical variants of the biliary tract and their impact on clinical practice. The pathophysiology of the biliary tract lithiasis. DIAGNOSIS AND IMAGING FINDINGS: Differential diagnosis of biliary tract lithiasis. Primary and secondary hepatolithiasis. LPAC Syndrome. Treatment strategies: conservative x interventional x surgical approaches. SUMMARY AND SYSTEMATIC APPROACH: A streamlined approach to integrating imaging findings with clinical decision-making. TAKE HOME MESSAGES.

GIEE-73 LOCAL RECURRENCE IN RECTAL CANCER: FROM DETECTION TO STRUCTURED REPORTING

Valesca B. Monteiro, MD (*Presenter*)
Brunna C. Oliveira, MD, MSc (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)
Rodrigo Sanford Damasceno, MD (*Abstract Co-Author*)
Bernardo Salvajoli (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

*Understand current concepts and management strategies for rectal cancer recurrence. *Recognize key imaging features of local recurrence and expected post-treatment changes. *Evaluate the strengths and limitations of CT, MRI, and PET in the restaging process. *Apply a structured, compartment-based approach to interpretation and reporting. *Identify post-operative anatomical modifications and complications related to treatment. *Discuss surgical re-approaches, re-irradiation, and considerations for palliative care.

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology and clinical impact of local recurrence Management of Recurrence Treatment guidelines and decision-making algorithms Surgical Techniques Exenterative approaches organized by pelvic compartments Anatomical Considerations Key pelvic landmarks and altered anatomy after treatment, with MRI correlation Imaging Modalities Comparative role of CT, MRI, and PET in detecting recurrence Imaging Evaluation: Recurrence vs. Post-Treatment Changes Systematic approach to differentiate recurrence from surgical or radiation-related changesCommon imaging patterns and treatment-related complicationsReporting templates, challenges, and diagnostic pitfalls Interactive Case-Based Learning Real-life examples reinforcing critical imaging and clinical decision points

GIEE-74 A CASE-BASED SANITY CHECK OF LEADING AI MODELS FOR PANCREATIC TUMOR DETECTION: REAL-WORLD CHALLENGES

Felipe Lopez-Ramirez, MD (*Presenter*)
Emir Syailendra, MD (*Abstract Co-Author*)
Satomi Kawamoto, MD (*Abstract Co-Author*)
Elliot K. Fishman, MD (*Abstract Co-Author*)
Linda C. Chu, MD (*Abstract Co-Author*)

TEACHING POINTS

Real-world evaluations are essential for understanding the clinical capabilities and limitations of state-of-the-art AI for pancreatic tumor detection. Case-based analysis can reveal context-specific weaknesses, not captured by standard test sets and aggregated metrics. Anatomical variations (e.g. unusual pancreatic morphology or adjacent lesions) can impact AI performance. Visual comparison with radiologist interpretations highlights pitfalls requiring specific attention, underscoring the need for human-AI collaboration. Understanding the strengths and limitations of AI enables informed deployment, improves trust in real-world applications and supports regulatory decisions.

TABLE OF CONTENTS/OUTLINE

Introduction: • Early detection in pancreatic cancer and potential role of AI in screening. Rationale for case-based "sanity checks" beyond conventional aggregated benchmarks. Current Landscape: •Overview of deep learning models for pancreatic tumor detection. • Review of top-performing, public algorithms. Training data, evaluation metrics, and known limitations. Case-Based Evaluation: • Real-world cases including cystic lesions, neuroendocrine tumors, and ductal adenocarcinoma. • Impact of challenging anatomy and clinical scenarios on performance. Clinical Implications: • AI models assist vs. mislead diagnosis. • Uncertainty quantification and interpretability (probability outputs). Clinical Deployment: •Guidance for AI integration into radiology workflows. •Considerations for user education, model explainability and trust calibration. Conclusion: • Key findings from the case-based evaluation, and recommendations for clinicians and researchers.

GIEE-75 BEYOND B1000: EVALUATING B1500 DIFFUSION-WEIGHTED MRI FOR ACCURATE RESTAGING OF RECTAL CANCER

Mariam Vargas Gonzalez, MD (*Presenter*)

TEACHING POINTS

Enhanced Tumor Detection High b-value DWI (b1500) significantly improves residual tumor conspicuity post-neoadjuvant therapy, reducing T2 shine-through and providing clearer lesion margins. Precision in Restaging Incorporating b1500 allows for more accurate differentiation between fibrosis, necrosis, and viable tumor, enhancing restaging accuracy and optimizing treatment planning. Clinical Relevance High b-value protocols can be seamlessly integrated into existing workflows, offering impactful diagnostic insights without extending scan times, making them practical for routine clinical use. Patient-Centered Outcomes By improving residual tumor detection, b1500 DWI can reduce unnecessary surgeries and overtreatment, supporting personalized oncologic care and better long-term outcomes.

TABLE OF CONTENTS/OUTLINE

Introduction Importance of accurate rectal cancer restaging Role of DWI in post-therapy evaluation Rationale for High b-value DWI (b1500) Limitations of conventional b 800 -1000 DWI Advantages of b1500 in detecting residual tumor Technical Considerations MRI protocol optimization Imaging parameters and artifact management Clinical Applications Differentiation of fibrosis vs. residual tumor Case examples and comparative imaging Impact on Patient Management Personalized treatment planning Potential to reduce overtreatment Conclusion and Future Directions Emerging research and ongoing studies Integration into routine clinical practice

GIEE-76 TROUBLE IN THE GRAFT: SPOTTING LIVER TRANSPLANT COMPLICATIONS BEFORE IT'S TOO LATE

Gretel Pibernus, MD (*Presenter*)
Federico G. Diaz Telli, MD (*Abstract Co-Author*)
Juan P. Perotti, MD (*Abstract Co-Author*)
Joaquin Martinez Pereira, MD (*Abstract Co-Author*)

Maria S. Fernandez Castillo Odena, MD (*Abstract Co-Author*)
Carlos J. Padin, MD (*Abstract Co-Author*)
Martin G. Vargas, MD (*Abstract Co-Author*)
Matias Greca, MD (*Abstract Co-Author*)

TEACHING POINTS

-To illustrate the most frequent vascular and biliary complications following liver transplantation through real clinical cases and multimodality imaging. -To highlight the value of grayscale ultrasound, color Doppler, spectral Doppler, and CT in the early detection and characterization of post-transplant complications. -To compare abnormal imaging findings with normal ultrasound appearances of each vascular structure and the biliary tract, in order to improve diagnostic accuracy. -To provide practical teaching points for identifying key features of hepatic artery thrombosis, portal vein thrombosis, hepatic vein thrombosis, and biloma. -To reinforce a pattern-based, case-driven approach for distinguishing true complications from normal post-operative findings

TABLE OF CONTENTS/OUTLINE

Introduction - Common complications after liver transplantation - Overview: Hepatic artery, portal vein, hepatic veins, and biliary tract Hepatic Artery Complications - Normal ultrasound appearance of the hepatic artery - Multimodality imaging: Grayscale US, color Doppler, spectral Doppler, CT - Teaching point Portal Vein Complications - Normal ultrasound appearance of the portal vein - Multimodality imaging: Grayscale US, color Doppler, spectral Doppler, CT - Teaching pointHepatic Vein Complications - Normal ultrasound appearance of the hepatic veins - Multimodality imaging: Grayscale US, color Doppler, spectral Doppler, CT - Teaching point Biliary Tract Complications - Normal ultrasound appearance of the biliary tract - Imaging findings: Grayscale US and CT - Teaching point Summary of Teaching Points - Key concepts and diagnostic pearls

GIEE-77 MCRP PATTERNS OF BILIARY AND PANCREATIC DILATATION: A PRIMER FOR RESIDENTS

Frederico Macedo, MD (*Presenter*)
Carolinna Nicolau, MD (*Abstract Co-Author*)
Ana Helena Pavan Amaral, MD (*Abstract Co-Author*)
Rebeca Fraga, MD (*Abstract Co-Author*)
Laila Motizuki (*Abstract Co-Author*)
Marco A. Rodstein, MD (*Abstract Co-Author*)
Daniel Lahan-Martins, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Magnetic resonance (MR) cholangiopancreatography (MRCP) is a widely used noninvasive method in the evaluation of pancreatobiliary disorders. As opposed to endoscopic retrograde cholangiopancreatography (ERCP) it allows evaluation of biliary ducts proximal and distal to injury, as well as extra ductal lesions.Biliary duct dilation is a common finding and is often incidental. There are numerous etiologies, benign and malignant, including obstructive causes such as choledocholithiasis, periampullary tumors, Klatskin tumor, and pancreatic neoplasms, as well as non-obstructive causes such as sclerosing cholangitis and Caroli disease. The main points for evaluation in cases of biliar duct dilation are the presence of gallstones or sites of obstruction, the location of the dilatation, communication with the bile ducts, and the characteristics of the pathology (neoplasia or inflammatory, for example).

TABLE OF CONTENTS/OUTLINE

1.Introduction 2.Causes of biliary duct dilation and differential diagnoses. 3.Key aspects to evaluate in biliary duct dilation. 4.Conclusion

GIEE-78 THE EVOLVING ROLE OF ULTRASOUND IN DETECTING HIGH-RISK MASH AMONG MASLD PATIENTS

ISABELA NASCIMENTO (*Presenter*)
Carla C. Branco, MD, PhD (*Abstract Co-Author*)
Gabriela Lauar, MD (*Abstract Co-Author*)

TEACHING POINTS

Metabolic dysfunction-associated steatotic liver disease (MASLD), the predominant chronic liver disease globally (~30% prevalence), is strongly associated with obesity and metabolic syndrome. Its progressive form metabolic dysfunction-associated steatohepatitis (MASH) leads to portal hypertension, cirrhosis, hepatocellular carcinoma, and liver failure. Early identification of high-risk patients (BMI=30, insulin resistance, elevated LFTs) enables timely intervention. While B-mode ultrasound has limited early fibrosis detection, optimized protocols (echotexture grading + composite morphology) improve accuracy. Elastography (Baveno VI criteria) remains gold-standard for non-invasive staging (=F2/F3-F4) and complication prediction, though confounded by acute injury, comorbidities, or severe steatosis. A multimodal approach combining clinical scores (FIB-4) and advanced imaging (US + elastography) optimizes early detection and management, improving outcomes through accessible risk stratification.

TABLE OF CONTENTS/OUTLINE

1. MASLD Epidemiology Global burden & metabolic links 2. Disease Progression Steatosis ? MASH ? Cirrhosis 3. Risk Stratification High-risk MASH criteria & mortality predictors 4. Diagnostics Ultrasound: Optimized protocols (echotexture/composite scoring) Elastography: ARFI thresholds (5/9/13/17 kPa) & confounders 5. Multimodal assessment Imaging pathways, clinical scores and referral triggers

GIEE-79 MULTIMODALITY IMAGING REVIEW OF ABDOMINAL WALL HERNIAS: MULTIDISCIPLINARY IMAGING REVIEW WITH PEARLS FROM THE SURGEON

Colin McQuade, MBBCh, FFR(RCSI) (*Presenter*)
Ciara O'Brien, FRCPC, MBBCh (*Abstract Co-Author*)

TEACHING POINTS

• Abdominal wall hernias are common yet diverse • Accurate imaging is essential for diagnosis, surgical planning, and assessing post-operative complications.• Radiologists must use precise terminology & report key anatomic details to aid surgeons in determining surgical approach & technique.• Multimodality imaging—particularly US, CT and MRI—enhances evaluation in complex or recurrent cases.• Surgeons seek specific imaging information including hernia size, content, location relative to landmarks, mesh integrity & signs of recurrence.• Post-operative complications such as mesh infection, failure, or chronic pain require structured, stepwise radiologic assessment.• Incorporating pearls from general surgeons ensures imaging aligns with surgical decision-making & improves patient outcomes.

TABLE OF CONTENTS/OUTLINE

1. Introduction : Clinical significance and imaging role 2. Anatomy Review : Layers of the abdominal wall 3. Hernia Classification : By location & etiology 4. Imaging Modalities : Plain film, US, CT, and MRI 5. Common and Uncommon Hernias : Including inguinal, femoral, umbilical, Spigelian, lumbar & obturator 6. Complicated Presentations : Incarceration, strangulation, obstruction 7. What the Surgeon Wants to Know : Key descriptors & planning pearls 8. Post-Surgical Imaging : Normal findings, timelines, red flags 9. Complications : Mesh failure, chronic pain, seroma, recurrence 10. Pitfalls in Imaging Recognising appearance across all imaging, including radiotracer uptake on PET/CT 11. Conclusion : Accurate, structured imaging of abdominal wall hernias—guided by surgical needs and interdisciplinary collaboration optimizes surgical planning, and improves patient outcomes.

GIEE-80 MRI COMPATIBILITY OF COMMON MEDICAL DEVICES IN THE ABDOMEN AND PELVIS

Caleb Iness (*Presenter*)
Senglee Loa (*Abstract Co-Author*)
Alex D. Lee (*Abstract Co-Author*)

David S. Sarkany, MD (*Abstract Co-Author*)
Nassier T. Harfouch, MD (*Abstract Co-Author*)

TEACHING POINTS

Review MRI safety terminology: Safe, Conditional, UnsafeFor MR conditional devices, provide parameters such as field strength limitationsProvide imaging correlates of common medical devicesIntroduce management and follow-up guidelines for safe imaging practices when applicable.

TABLE OF CONTENTS/OUTLINE

MRI is a vital diagnostic tool in modern medicine, but the strong magnetic fields and radiofrequency pulses it utilizes can interfere with quality image or impose risks on patients with medical devices. It is important to understand the MRI compatibility of common medical devices to ensure patient safety and optimal diagnostic outcomes. This exhibit evaluates common medical devices in the abdomen and pelvis across different modalities and provides guidance for safe MRI imaging practices. Introduction, MR Safety Classification, MR Compatibility of Common Feeding Tubes, MR Compatibility of Common Gastrointestinal/Biliary Stents, MR Compatibility of Common VP Shunts, MR Compatibility of Common Spinal Cord Stimulators

GIEE-81 PAUSE BEFORE YOU PLAN: MRI AS A STRATEGIC TOOL IN PERITONEAL CARCINOMATOSIS

Mariana C. Kucharczyk, MD (*Presenter*)
Anna F. Garcia Herrmann, MD (*Abstract Co-Author*)
Analia S. Varela JR, MD (*Abstract Co-Author*)
Fernando D. Losada Lopez, MD (*Abstract Co-Author*)
Fernando Sanchez Loria, MD (*Abstract Co-Author*)
Lisandro Paganini, MD (*Abstract Co-Author*)

TEACHING POINTS

- Understand the clinical significance of peritoneal carcinomatosis and the limitations of conventional imaging. - Recognize the technical parameters and acquisition strategy of a dedicated MRI protocol for peritoneal disease. - Learn the PAUSE structured reporting system for interpretation of MRI findings and its clinical value. - Identify key MRI features and its surgical correlation, highlighting critical imaging findings that impact surgical decision-making.

TABLE OF CONTENTS/OUTLINE

Technical Overview: - Patient preparation and MRI acquisition protocol - Practical considerations to optimize image quality and reduce artifacts PAUSE Reporting Framework: - Definition and examples of each reporting domain. - Step-by-step guide to structured region-by-region scoring. - Common imaging pitfalls and how to address them. Surgical Correlation and Validation: - Illustration of MRI-based PCI (rPCI) versus surgical PCI (CxPCI). - Highlight of clinical scenarios where MRI findings altered surgical management. - Institutional experience and statistical data of high radiographic-surgical correlation (Spearman ? = 0.98, Kappa > 0.85 in key domains). Case-Based Learning: - Annotated examples of high-grade serous carcinoma, mucinous tumors, and mesenteric involvement. - Emphasis on detection of unfavorable sites and extra-peritoneal disease. - TIPs and interpretation strategies tailored to histologic subtypes.

GIEE-82 SPOTLIGHT ON THE SPLEEN: WHAT EVERY RADIOLOGIST SHOULD KNOW, FROM INCIDENTALOMA TO EMERGENCY FINDINGS

Colin McQuade, MBBCh, FFR(RCSI) (*Presenter*)
Ciara O'Brien, FRCPC, MBBCh (*Abstract Co-Author*)

TEACHING POINTS

• The spleen is often under-appreciated in abdominal imaging, yet its appearance can offer critical insights into both localized & systemic disease processes.• A structured, multimodality approach aids in confidently distinguishing benign incidental findings from urgent or malignant pathology.• Radiologists should recognize common "incidentalomas" such as cysts, hemangiomas, & granulomatous calcifications to avoid unnecessary alarm.• Emergency splenic conditions—such as infarction, rupture, or vascular injury—require prompt recognition & clear communication.• Heterotopic and ectopic splenic tissue, including accessory spleens & splenosis, is frequently misinterpreted as pathology; correct identification prevents unnecessary workup.• The spleen is a barometer for systemic disease; patterns of splenic involvement can suggest hematologic, infectious, or infiltrative disorders.

TABLE OF CONTENTS/OUTLINE

1. Introduction : Why the spleen matters 2. Benign Incidental Findings : Cysts, infarcts, granulomatous calcifications 3. Focal Lesions : Benign vs malignant, primary vs secondary 4. Heterotopic and Ectopic Splenic Tissue : Accessory spleens, splenosis & common mimics 5. Vascular & Traumatic Emergencies : Rupture, infarction, torsion 6. Systemic Disease Clues : Lymphoma, infection, infiltrative disease 7. Pearls & Pitfalls : Mimickers, when to worry 8. Conclusion : The spleen, though often overlooked, serves as a diagnostic window into both acute and chronic pathology. Familiarity with its full imaging spectrum allows radiologists to add significant value, guiding appropriate follow-up, intervention, or reassurance.

GIEE-83 BEYOND THE MORPHOLOGY: FUNCTIONAL IMAGING OF THE LIVER WITH GADOXETIC ACID

Eleonora Silva (*Presenter*)
Sthefane Nunes, MD, MD (*Abstract Co-Author*)
Caroline L. Ghezzi (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)
Nara Vedoveli (*Abstract Co-Author*)
Viviane B. Amorim, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Explain the mechanism of action of gadoxetic acid in Magnetic Resonance Imaging (MRI). Highlight the clinical indications and benefits of the gadoxetic acid on MRI in the liver function assessment. Describe key MRI parameters and formulas that are used to evaluate liver function with gadoxetic acid administration. Demonstrate the application of liver function assessment through case-based examples.

TABLE OF CONTENTS/OUTLINE

This presentation explores the role of gadoxetic acid-enhanced MRI in the evaluation of hepatic function. First, we will review the molecular mechanism of gadoxetic acid uptake and excretion. Further, the clinical advantages of this contrast agent will be discussed, including its utility in prognostic evaluation of liver disease, pre-hepatectomy planning and predicting liver function after major resections or transplantation. Additionally, we will thoroughly detail the main MRI parameters and quantitative methods used for hepatic function assessment, supported by illustrative case-based examples.

GIEE-84 MULTIVISCERAL TRANSPLANT SIMPLIFIED: EXPECTED APPEARANCE AND COMPLICATIONS

Yamile Blain, MD (*Presenter*)
Cibele Luna, MD (*Abstract Co-Author*)
Patricia Balcacer, MD (*Abstract Co-Author*)

TEACHING POINTS

• To define and differentiate multiorgan, multivisceral, and composite visceral transplantation. • To review the role of imaging in preoperative assessment and postoperative evaluation of multivisceral transplant patients. • To illustrate normal postoperative anatomy and expected imaging findings. • To recognize key imaging features of common postoperative complications

TABLE OF CONTENTS/OUTLINE

1. Definitions and Nomenclature ? Multiorgan ? Multivisceral ? Composite Visceral Transplantation* 2. Indications for MVT Short bowel syndrome, intestinal failure, dysmotility syndromes, diffuse portomesenteric thrombosis, and mesenteric tumors 3. Preoperative Workup Imaging assessment: CT and MRI angiography, fluoroscopic studies 4. Surgical Technique Highlights ? Arterial supply ? Venous drainage ? Foregut, midgut, and hindgut reconstruction 5. Postoperative Anatomy Expected imaging findings and variations 6. Complications** ? Bowel-related issues: Obstruction, leak, fistula ? Pancreaticobiliary complications ? Vascular complications: Thrombosis, pseudoaneurysms ? Immune-mediated and infectious complications ? Neoplastic developments: Post-transplant lymphoproliferative disorder * For each type, a representative illustration will be provided **Representative cases for each type of complication will be provided

GIEE-85 BURNS BENEATH THE SURFACE: DECODING THE RADIOLOGIC SIGNATURE OF ABDOMINAL RADIATION INJURY

Flavia N. Maruyama I, MD (*Presenter*)
Brenda Oliveira, MD (*Abstract Co-Author*)
Vinicius C. Fiorot, MD (*Abstract Co-Author*)
Luan Luis Xavier de Andrade Luan, MD (*Abstract Co-Author*)

TEACHING POINTS

To review the pathogenic mechanism caused by radiation in oncological treatment; To list the most common abdominal complications after therapeutic radiation; To describe the main radiological (imaging) findings of abdominal complications (side effects) related to radiation in the treatment of malignant tumors.

TABLE OF CONTENTS/OUTLINE

Introduction; Pathophysiology of radiotherapy; Findings in multiple imaging modalities of patients undergoing abdominal oncological follow-up; Conclusion.

GIEE-86 A STRANGER IN A STRANGE LAND: MULTIMODAL IMAGING EVALUATION OF THE ESOPHAGUS

Lucas d. Gomes de Farias, MD, PhD (*Presenter*)
Enzo Calheiros, MD (*Abstract Co-Author*)
Daniel Giunchetti Strabelli, MD (*Abstract Co-Author*)
Felipe D. Barbosa, MD (*Abstract Co-Author*)
Jose D. Fernandes SR (*Abstract Co-Author*)
Elisa A. Bretas, MD (*Abstract Co-Author*)
Jose de Arimateia B. Araujo Filho, MD,PhD (*Abstract Co-Author*)
Marcio V. Sawamura, MD, PhD (*Abstract Co-Author*)
Cesar H. Nomura, MD, PhD (*Abstract Co-Author*)
Ricardo D. Sartim, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Evaluation of the esophagus reveals diagnostic difficulties for both the clinician and the radiologist. 2. Due to non-specific and sometimes confusing symptoms, analysis of the esophagus can be particularly difficult and is often neglected in the radiologist's daily practice. The purpose of this exhibit is: 3. To review usual and unusual cases related to esophagus. (a) To correlate important findings with the anatomy, embryology, and pathophysiology, focusing on their clinical-radiological correlations. (b) To understand how radiological images are correlated to upper gastrointestinal endoscopy and endoscopic ultrasound images. (c) To highlight their characteristics in order to familiarize radiologists, preventing unfavorable patient outcome. (d) To review radiological protocols in the evaluation of patients with esophageal involvement.

TABLE OF CONTENTS/OUTLINE

1. Applied embryology, anatomy, and physiology of the esophagus 2. Techniques: X-ray, CT and MRI - pros and cons 3. Applications: a case-based review (a) Congenital and anatomical variants (b) Motility disorders (c) Diverticula (d) Hernia (e) Inflammatory and infectious diseases (f) Esophagogastric hernias (g) Fistula (h) Vascular (i) Neoplasm (j) Intervention and postoperative changes (k) Foreign body (l) Miscellaneous and other findings 4. Sample cases of pearls, pitfalls, diagnostic difficulties, and mimics. 5. Future directions 6. Summary and take-home messages.

GIEE-87 ADVANCED TECHNIQUES OF VASCULAR ANASTOMOSIS IN LIVER TRANSPLANTATION. WHAT THE RADIOLOGIST SHOULD KNOW

Joao Pedro C. Lino, MD (*Presenter*)
Tomas M. Lacerda, MD (*Abstract Co-Author*)
Laura M. Coura, MD (*Abstract Co-Author*)
Fernando M. Coelho, MD, PhD (*Abstract Co-Author*)
Thiago M. Baraviera, MD (*Abstract Co-Author*)

TEACHING POINTS

- Review previous technical limitations regarding vascular anastomosis in liver transplant.Understand how advances in vascular anastomosis and grafts have changed the way radiologist evaluate pre and post liver transplant imaging examsDescribe anatomy of the usual vascular anastomosis and new techniques. - Discuss what radiologists need to report to provide essential information in cases advanced vascular techniques may be needed. - Show normal aspects, pitfalls and complications in advanced vascular techniques.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION - Brief discussion about previous limitations in liver transplant. - Review pre transplant planning of vascular anastomosis, such as arterial occlusion and dissection, portomesenteric venous thrombosis. - Defend the importance of multidisciplinary board of pre transplant evaluation patients to determine technical viability of the surgery, based on surgical expertise team and imaging findings TYPES OF ADVANCED VASCULAR ANASTOMOSIS - Describe the advanced vascular anastomosis techniques including: arterial patches and grafts and portal vein anastomosis to other veins COMPLICATIONS - Show didactic cases of advanced vascular anastomosis techniques, describing normal aspects, complications and pitfalls.

GIEE-88 STOMACH AND BEYOND: IMAGING FEATURES OF LINITIS PLASTICA IN THE ABDOMEN AND PELVIS

Khaled Y. Elbanna, FRCR (*Presenter*)

TEACHING POINTS

Demonstrate characteristic multimodality imaging findings of the infiltrative and non-polypoid linitis plastica tumor pattern commonly seen in primary and metastatic signet ring cell carcinoma (SRCC) involving stomach, colon, rectum, gallbladder, and urinary bladder. Highlight essential imaging hallmarks of linitis plastica on CT and complementary modalities such as MRI and PET-CT. Provide practical imaging strategies enabling radiologists to proactively suggest biopsy or repeat endoscopic sampling in cases with subtle or ambiguous imaging findings suggestive of SRCC.

TABLE OF CONTENTS/OUTLINE

1. Clinical Relevance Overview and diagnostic challenges of SRCC and linitis plastica. 2. Multimodality Imaging Features Key imaging characteristics on CT, MRI, and PET-CT. Case-based examples across hollow viscera. 3. Diagnostic Pitfalls and Clinical Pearls Common pitfalls in biopsy and imaging interpretation. Checklist for comprehensive reporting.

GIEE-89 THE DARK SIDE OF LI-RADS: EXPLORING ITS LIMITATIONS

Amit J. Choudhari, FRCR,MBBS (*Presenter*)
Akshay D. Baheti, MD, MD (*Abstract Co-Author*)
Purvi Haria, DMRD, MD (*Abstract Co-Author*)
Aparna Katdare (*Abstract Co-Author*)
Amrita Guha, MD,MBBS (*Abstract Co-Author*)

TEACHING POINTS

Introduction The Liver Imaging Reporting and Data System (LI-RADS) aims to standardize liver imaging interpretation for hepatocellular carcinoma (HCC) diagnosis. Despite its widespread adoption, LI-RADS faces significant challenges that impact its clinical utility. This exhibit will delve into the limitations of LI-RADS, focusing on diagnostic performance, inter-observer variability, implementation barriers, and geographic disparities. Teaching Points Understand the diagnostic performance limitations of LI-RADS across different imaging modalities. Recognize the impact of inter-observer variability on LI-RADS application. Identify barriers to LI-RADS implementation in various clinical settings. Explore geographic and population-based disparities in LI-RADS performance. We attempt to simplify the approach by offering a free app

TABLE OF CONTENTS/OUTLINE

Introduction and Background Evolution and adoption of LI-RADS Diagnostic Performance Limitations Imaging modality challenges Sensitivity vs. specificity trade-offs Inter-Observer Variability Reproducibility issues Factors influencing variability Implementation and Adoption Barriers Complexity and workload Institutional inconsistencies Geographic and Population Variations Regional differences in HCC presentation Impact of local treatment protocols Future Directions and Research Needs Refining categorization and algorithms Enhancing global applicability

GIEE-90 FROM ROOT TO BRANCH: AN ILLUSTRATED GUIDE TO BILIARY TREE DISORDERS

Anna Beatriz Ferreira Obara, MD (*Presenter*)
Rodrigo P. Polizio, MD (*Abstract Co-Author*)
Barbara Pereira, MD (*Abstract Co-Author*)
Leivanio Ponte Teixeira, MD (*Abstract Co-Author*)
Yuri Inoue (*Abstract Co-Author*)
Fernando D. Tamamoto SR, MD (*Abstract Co-Author*)
Yuri C. Neves, PhD (*Abstract Co-Author*)

TEACHING POINTS

Know the anatomy of the bile ducts, as well as the main pathophysiological mechanisms involved.Revisit the diagnostic parameters for the etiologies of cholangiopathies.Demonstrate the imaging characteristics of benign and malignant conditions affecting the biliary tree.

TABLE OF CONTENTS/OUTLINE

Cholangiopathies are a diverse group of diseases categorized into congenital, immune-mediated, infectious, neoplastic, idiopathic, and other causes, like vascular-related conditions. Diagnosing these remains challenging for radiologists, as clinical, laboratory, and imaging findings often overlap. Identifying the underlying etiology is crucial for treatment, impacting prognosis. Caroli's disease is a congenital condition with cystic dilatation of intrahepatic ducts, potentially linked to hepatic fibrosis. Polycystic liver disease, often associated with polycystic kidney disease, shows multiple hepatic cysts without biliary involvement. In cystic fibrosis, thick bile causes ductal obstruction and cirrhosis. Primary sclerosing cholangitis leads to progressive bile duct stenosis, often linked with ulcerative colitis. IgG4 cholangiopathy mimics sclerosing cholangitis but responds well to corticosteroids. Primary biliary cholangitis involves small duct autoimmune damage. Recurrent pyogenic cholangitis, common in endemic areas, causes infections and intrahepatic stones. Paracoccidioidomycosis cholangiopathy results from fungal infection. In AIDS, cholangiopathy arises from opportunistic infections. Ischemic, portal, and iatrogenic forms result from vascular damage or biliary trauma. Neoplasms like cholangiocarcinoma and IPMN-B carry malignant potentia.

GIEE-91 NATURAL COURSE AND EVOLUTION OF RESPONSE OF HEPATOCELLULAR CARCINOMA (HCC) TO TRANS-ARTERIAL RADIO-EMBOLIZATION: ASSESSMENT WITH MRI USING EXTRACELLULAR AND HEPATOBILIARY MRI CONTRAST AGENTS

Maryam Haghshomar, MD (*Presenter*)
Frank H. Miller, MD (*Abstract Co-Author*)
Amir Borhani, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Unlike the response to thermoablative locoregional therapies, response to trans-arterial radioembolization (TARE) is time dependent and evolves over the time. Post-treatment findings are highly affected by the technique, dose, and size/biology of the tumor. 2. Persistent enhancement within the treated lesion after radiation-based treatments is not uncommon and can be seen in cases who had eventual complete response. 3. A new LIRADS treatment response algorithm has been designed specifically for assessment of response after radiation-based treatments.

TABLE OF CONTENTS/OUTLINE

1. Overview of Trans-arterial Radioembolization a. Techniques b. Indications 2. Mechanism of Action a. Pathways of ischemia and cell death b. Flow-dependency of TARE 3. Natural Course of Response to TARE and Rad-Path Correlation 4. Assessment of Treatment Response with MRI a. Extracellular versus Hepatobiliary Agent b. Findings on dynamic post-contrast sequence c. Role of Ancillary Features 5. Overview of new LIRADS Treatment Response Algorithm for Radiation-based Treatments a. Why? b. What’s new? c. Algorithm 6. Pitfalls and Challenges 7. Future Directions 8. Conclusion

GIEE-93 ANATOMIC-ULTRASONOGRAPHIC CORRELATION OF THE ANORECTAL REGION: WHAT EVERY RADIOLOGIST SHOULD KNOW

Lucas Perussi De Souza, MD (*Presenter*)
Maria Gabriela Vargas Rezende (*Abstract Co-Author*)
Ana Luiza Rodrigues Pereira, MD (*Abstract Co-Author*)
Pedro Henrique Menezes, MD (*Abstract Co-Author*)
Hugo Franco, MD (*Abstract Co-Author*)
Humberto Pinto Wanderley Neto (*Abstract Co-Author*)
Patricia de Paula Silva Wanderley Calestini, MD (*Abstract Co-Author*)
Bruno Chui (*Abstract Co-Author*)
Sandro Valle (*Abstract Co-Author*)
Luiza Godoy (*Abstract Co-Author*)
Isabella Oliveira (*Abstract Co-Author*)
Gabriela Giaretta (*Abstract Co-Author*)
Miguel J. Neto (*Abstract Co-Author*)

TEACHING POINTS

Mastery of anorectal anatomy is essential for accurate interpretation of imaging studies in patients with suspected anorectal fistulas. Endocavitary and transperineal ultrasound are highly effective tools for evaluating fistulous tracts, internal openings, and sphincteric involvement. The diagnostic accuracy of ultrasound can be comparable to magnetic resonance imaging (MRI), particularly in non-complex cases. Correlation between anatomical planes and ultrasonographic findings enables radiologists to provide safe and informed diagnostic guidance. Radiologists must be able to recognize both normal and pathological anorectal patterns on imaging

TABLE OF CONTENTS/OUTLINE

Accurate identification of the fistulous tract, internal opening, and involved structures is essential for guiding surgical treatment, preventing recurrence, and preserving sphincter function. Anatomic-ultrasonographic review of the anorectal region, correlating the main anatomical planes with findings obtained through high-resolution ultrasound.Ultrasonography has become an essential tool in the evaluation of anorectal fistulas, allowing detailed visualization of the sphincter complex and fistulous pathways. Anatomic-imaging correlation is key for precise fistula classification. Comparative studies have demonstrated high concordance between anorectal ultrasound and MRI, with ultrasonography offering advantages in terms of cost, accessibility, and real-time dynamic evaluation. This study provides an integrated review of anal canal anatomy through the lens of ultrasonography, emphasizing the importance of anatomical expertise in the accurate interpretation of sonographic findings by the radiologist.

GIEE-94 US PRESIDENT OBAMA GOT A VIRTUAL COLONOSCOPY, SHOULD YOU?

Uffan Zafar, MD (*Presenter*)
Zohaib Mallick, MBBS (*Abstract Co-Author*)
Muhammad Abdullah (*Abstract Co-Author*)

TEACHING POINTS

? Review major guideline endorsements (USPSTF, ESGE, ESGAR, ACS, MSTF) for CTC screening. ? Understand when CTC is preferred over colonoscopy in clinical practice. ? Interpret key trial evidence validating CTC's diagnostic performance. ? Explore CTC's role in population-based screening, particularly in LMICs. ? Recognize technical challenges, extracolonic findings, and risk stratification.

TABLE OF CONTENTS/OUTLINE

Introduction to Colorectal Cancer Screening ? Global burden and screening impact ? Role of early detection CT Colonography Overview ? History and technical basics ? Comparison with other modalities International Guidelines: Who Recommends What? ? USPSTF (2021) : CTC every 5 years, ages 45-75 (Grade A) ? American Cancer Society (ACS) : CTC among acceptable screening tests ? ESGE/ESGAR : CTC as first-line imaging when colonoscopy fails or is refused ? US Multi-Society Task Force (MSTF) : CTC as second-tier screening ? EUREF/ESGAR (Europe) : Strong support where no organized FIT screening exists When to Choose CTC Diagnostic Performance: Trials & Meta-analyses Case Examples: Adenomas & Flat Lesions C-RADS & Extracolonic Findings ? Classification system for colonic and extracolonic lesions ? Management protocols Technical Considerations & Pitfalls ? Prep protocols, tagging, insufflation ? Flat lesions and motion artifacts Challenges in Implementation Future Directions

GIEE-95 UNEXPECTED VESSELS: CLINICALLY RELEVANT ABDOMINAL VASCULAR VARIANTS ON CTA WITH 3DRECONSTRUCTION, INTERACTIVE CASE-BASED QUIZ

Luis Enrique Nunez Castellanos, MD (*Presenter*)
Abraham Jesus Sansores Gongora, MD (*Abstract Co-Author*)
Juan Jose Duran Rosas, MD (*Abstract Co-Author*)

TEACHING POINTS

• Abdominal vascular variants are frequent and clinically relevant, particularly in surgical oncology and endovascular procedures.• CT angiography with 3D reconstruction is crucial for accurate vascular mapping and pre-procedural planning.• Failure to recognize these anomalies can increase surgical risks, prolong operative time, and lead to severe complications.• Collateral pathways, such as the Arc of Riolan, play a critical compensatory role in chronic vascular diseases.• Interactive quizzes are an effective educational tool to reinforce anatomical and clinical knowledge in cross-sectional imaging.

TABLE OF CONTENTS/OUTLINE

IntroductionBrief overview of normal abdominal vascular anatomy.Frequency and significance of vascular anomalies.Importance of pre-procedural detection to avoid complications.Group 1: Vascular anomalies relevant in surgical context Celiac trunk stenosis with collateral formation via the Arc of Riolan.Absence of celiac trunk with direct aortic origin of the splenic and common hepatic arteries (pre- and post-pancreatectomy images).Group 2: Incidental vascular variants with oncologic or interventional implications Right hepatic artery arising from the superior mesenteric artery in a patient with pelvic oncologic history.Left gastric artery arising directly from the abdominal aorta, with left hepatic artery as a branch.Additional Cases (if space allows)Triple or double renal arteries detected incidentally or during pre-surgical staging.Interactive QuizPresentation of anonymized cases with CTA and 3D images.Audience will answer multiple-choice questions on diagnosis, clinical relevance, and management implications.

GIEE-96 LIVER ON FIRE:THE RADIOLOGICAL SPECTRUM OF INFECTIOUSAND INFLAMMATORY PROCESSES IN THE LIVERPARENCHYMA

Tabata X. Silva, MD (*Presenter*)
Kamila S. Albuquerque, MD (*Abstract Co-Author*)
Italo R. Cruz SR, MD (*Abstract Co-Author*)
Eduardo M. Araujo, MD (*Abstract Co-Author*)
Julia A. Miranda, MD (*Abstract Co-Author*)

TEACHING POINTS

Liver infectious and inflammatory processes represent a diagnostic challenge due to clinical and radiological findings that vary according to the etiology and the patient's immunological status.This study aims to demonstrate and review the main findings in computed tomography (CT) and magnetic resonance imaging (MRI) of liver infectious and inflammatory processes, with emphasis on the differentiation between the main etiological agents.A literature review was carried out, combined with a retrospective analysis of cases documented in the radiology archives of a tertiary institution, involving patients diagnosed with liver infections or inflammatory hepatitis. The examinations included ultrasound, CT and MRI, with evaluation of the morphological characteristics, enhancement pattern and distribution of the lesions. Abscesses presented as hypodense collections with peripheral enhancement and, occasionally, the presence of gas on CT, and may be pyogenic or fungal, making it difficult to distinguish from metastases. Viral and autoimmune hepatitis present nonspecific signs, therefore MRI with its functional sequences (diffusion, hepatospecific phase) can provide more sensitive information about inflammation and the extent of involvement. Granulomatous diseases may manifest with calcified nodules or periportal fibrosis, which are better visualized on CT.

TABLE OF CONTENTS/OUTLINE

Knowledge of imaging patterns, combined with clinical and laboratory integration, is essential for an accurate diagnosis of infectious and inflammatory processes in the liver.CT and MRI play a key role in etiological differentiation and in the therapeutic management of these patients.

GIEE-97 EMVI: THE ENEMY AT THE TUMOR'S EDGESILENT VENOUS INVASION IN RECTAL CANCER - RADIOLOGICAL ASPECTS AND PROGNOSTIC IMPLICATIONS

Kamila S. Albuquerque, MD (*Presenter*)
Tabata X. Silva, MD (*Abstract Co-Author*)
Italo R. Cruz SR, MD (*Abstract Co-Author*)
Eduardo M. Araujo, MD (*Abstract Co-Author*)
Julia A. Miranda, MD (*Abstract Co-Author*)

TEACHING POINTS

Extramural venous invasion (EVI) is an important prognostic marker in rectal cancer, associated with a higher risk of hematogenous metastases and local recurrence. High-resolution magnetic resonance imaging is the most effective imaging method for detecting EVI, especially in T2 and DWI sequences.A literature review was

performed, together with a retrospective analysis of cases of rectal câncer, covering both positive and negative cases for EMVI, as well as their differential diagnoses. In addition, the patients were evaluated in the post-treatment period.In the positive cases, the presence of EMVI was associated with worse prognostic features, such as early liver metastasis and advanced staging. In the negative cases, diagnostic pitfalls such as dilated veins and imaging artifacts stood out. Post-treatment cases demonstrated both complete response and the limitations of imaging to differentiate fibrosis from residual tumor.

TABLE OF CONTENTS/OUTLINE

This paper aims to present the typical radiological findings and diagnostic difficulties of EVI in real cases, in addition to discussing the prognostic and therapeutic implications. Recognition of its radiological patterns, limitations and differential diagnoses is essential for an effective oncological approach.

GIEE-98 A RADIOLOGIST'S GUIDE TO CHOLANGIOPATHIES: DIAGNOSTIC PATTERNS, PITFALLS AND PEARLS

Raeesa Patel, MBBS (*Presenter*)

TEACHING POINTS

Cholangiopathies encompass a diverse group of biliary disorders, ranging from autoimmune and infectious to drug-induced and ischemic aetiologies. These conditions often present with overlapping clinical features and biochemical profiles, making imaging a pivotal tool in the diagnostic algorithm. Magnetic Resonance Cholangiopancreatography (MRCP) is the gold standard non-invasive imaging modality for diagnosing and monitoring these pathologies. Accurate interpretation requires a systematic approach and familiarity with the differing morphological patterns. This pictorial review highlights the key imaging findings in a range of cholangiopathies, both common and rare entities, including Primary Sclerosing Cholangitis (PSC), Primary Biliary Cholangitis (PBC), IgG4-related Sclerosing Cholangitis (ISC) and ketamine cholangiopathy. Important diagnostic clues include the anatomical distribution of ductal abnormalities, the length and morphology of strictures, the presence or absence of upstream biliary dilatation, and associated changes in the liver parenchyma. Ancillary findings involving the pancreas, kidneys, and vascular structures may provide additional evidence supporting a particular diagnosis. Through a case-based visual guide, this exhibit aims to enhance familiarity with classical imaging appearances, promote a structured approach, and highlight key discriminators that aid in differentiating among the various cholangiopathies and its mimics.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Autoimmune 3. Infective 4. Ischemic 5. Drug-Induced 6. Mimics 7. Comparison of Cholangiopathies

GIEE-99 WHEN THE CYST PERSISTS: UNDERSTANDING THE VARIOUS PANCREATIC CYST FOLLOW-UP GUIDELINES

Thomas Seykora, MD (*Presenter*)
Melkamu D. Adeb, MD (*Abstract Co-Author*)

TEACHING POINTS

Incidental pancreatic cystic lesions are commonly encountered by the radiologist. Although there are several society guidelines regarding the follow up of pancreatic cysts, there is heterogeneity when providing follow up recommendations in clinical practice. After viewing this exhibit, the reader will (1) become familiar with commonly used pancreatic cyst follow-up guidelines, (2) understand differences among the guidelines, and (3) be equipped to engage in multidisciplinary care of patients with pancreatic cysts.

TABLE OF CONTENTS/OUTLINE

I. Introduction: types of pancreatic cystic lesions including intraductal papillary mucinous neoplasm (IPMN), serous cystadenoma, and mucinous cystic neoplasm. II. Pancreatic cyst follow-up guidelines: 2024 Kyoto guidelines, 2018 American College of Gastroenterology (ACG) guidelines, 2017 ACR Incidental Findings Committee White Paper, 2017 Fukuoka guidelines, 2015 American Gastroenterological Association (AGA) guidelines. III. Differences among guidelines.

GIEE-100 BRIDGING THE GAP: IMAGING FINDINGS OF LUMEN-APPOSING METAL STENTS

Thomas Seykora, MD (*Presenter*)
Melkamu D. Adeb, MD (*Abstract Co-Author*)

TEACHING POINTS

Lumen-apposing metal stents (LAMS) are being increasingly utilized in interventional gastroenterology. Radiologists should understand common indications for LAMS and recognize their imaging appearance and complications. After viewing this exhibit, the reader will (1) understand various applications of LAMS, (2) recognize the expected imaging appearance of LAMS, and (3) be able to identify complications of LAMS.

TABLE OF CONTENTS/OUTLINE

I. Introduction: common types of LAMS, indications for LAMS placement such as drainage of pancreatic or peripancreatic collections, biliary drainage, managing strictures, creating anastomoses, creating enteric bypass, and addressing obstructions. II. Imaging appearance of LAMS: plain film, fluoroscopy, ultrasound, CT, MRI, and endoscopic ultrasound (EUS). III. Imaging protocols to assess for complications, such as CT GI bleed. IV. Complications of LAMS: stent migration stent occlusion, bleeding, perforation, infection, luminal or biliary obstruction, and buried stent syndrome. V. Summary and clinical pearls.

GIEE-101 IMAGING MYRIAD OF PORTOCAVAL SPACE PATHOLOGIES - A DEEP DIVE

Aruna R. Patil, MD, FRCR (*Presenter*)
Yashant Aswani, MD (*Abstract Co-Author*)
Jayanth Reddy (*Abstract Co-Author*)

TEACHING POINTS

Porto caval space is a narrow space between the portal vein anteriorly and Inferior vena cava posteriorly. There are specific variants , pathologies and surgical implications localized to this space . Variant arteries, veins can traverse this space unawareness of which might result in inadvertent bleeding. Certain neoplasms are classically located in this space . Portocaval space serves as a pathway for spread of certain infective / inflammatory processes Portocaval space is the landmark for epiploic foramen that connects greater and lesser sac.

TABLE OF CONTENTS/OUTLINE

1.Anatomy of portocaval space- imaging and surgical with illustrations 2. Normal contents and variants - caudate lobe of liver , vascular structures , lymphnodes (12p, 12b) , pancreas, epiploic foramen, fat. 3. Surgical implications: arterial variants , lymphadenectomy in HPB malignancies Portocaval shunts - Temporary portocaval shunt in LT, Porto caval shunt for EHPVO, Inflow modulation for SFSS in live donor liver transplant Pancreaticoduodenectomy- separating uncinate margin of pancreas from SMA Pringle maneuver. 4. Presentation of lesions arising in this space - biliary compression / vascular compression. 5. Pathologies: Vascular: variants -Replaced RHA or accessory RHA from SMA, Early bifurcation of RHA from CA, Pancreaticoduodenal vein, Cavernomatous transformation of portal vein, Reconstruction in LT 6. Pancreas related -circumportal pancreas, pancreatitis. 7. Lymph nodal: metastases, lymphoma, lymphatic malformation. 8.Caudate lobe lesions: solid mass / cysts. 9.Epiploic foramen: hernia, disease spread , extension of collection / hematoma. 10.Primary tumors: lipoma, paraganglioma, sarcoma

GIEE-102 UNMASKING COMPLICATIONS AFTER PANCREATIC CANCER SURGERY: KEY IMAGING CLUES FOR DIAGNOSIS AND MANAGEMENT

Khoschy Schawkat, MD, PhD (*Presenter*)
Daniel A. Souza, MD, MSc (*Abstract Co-Author*)
Ravi V. Gottumukkala, MD (*Abstract Co-Author*)

Avinash R. Kambadakone, MD, FRCR (*Abstract Co-Author*)
Michael H. Rosenthal, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

• Recognize the spectrum of post-pancreatectomy complications and their imaging features. • Differentiate between expected postoperative findings and complications. • Understand the role of various imaging modalities (CT, MRI, PET/CT) in identifying complications. • Apply a systematic approach to interpreting post-surgical imaging, guiding clinical decision-making and intervention.

TABLE OF CONTENTS/OUTLINE

1. Introduction • Importance of imaging in post-pancreatectomy patient management • Common surgical procedures • Normal postoperative anatomy 2. Vascular Complications (CT angiography, DSA findings) • Pseudoaneurysms and hemorrhage • Arterial stenosis/occlusion & implications for management 3. Anastomotic & Biliary Complications (MRI/MRCP pearls) • Pancreatojejunostomy leaks • Biliary strictures and leaks 4. Infectious & Inflammatory Complications • Differentiating abscesses from normal post-op collections • Delayed pancreatitis & fat necrosis • Percutaneous vs. surgical drainage strategies 5. Gastrointestinal & Functional Complications • Delayed gastric emptying. • Bowel ischemia, obstruction, and malabsorption 6. Imaging Pearls & Pitfalls • Avoiding common misdiagnoses in postsurgical imaging • Key differentiators between normal healing and pathology 7. Clinical Implications & Multidisciplinary Management • Role of radiologists in guiding surgical and interventional decisions • Conservative vs. IR vs. surgical approaches 8. Conclusion & Take-Home Points • Summary of key imaging findings and management strategies • Interactive learning case

GIEE-103 IMAGING FEATURES IN THE LIVER AFTER RADIOEMBOLIZATION FOR LIVER CANCER

Hyo-Cheol Kim, MD (*Presenter*)

TEACHING POINTS

Transarterial radioembolization (TARE), also referred to as radioembolization or selective internal radiation therapy, is an interventional radiological modality employed for the management of primary liver neoplasms and hepatic metastases. This therapeutic intervention inevitably subjects normal hepatic parenchyma to varying degrees of irradiation, resulting in diverse radiological manifestations that can influence the interpretation of subsequent imaging studies. Throughout the post-procedural surveillance period, numerous imaging findings associated with the intervention itself (e.g., peritumoral edema, ring enhancement, hepatic fibrosis, parenchymal radiation necrosis, and enhancement of the treated area) may present challenges in image interpretation and assessment of treatment response. The objectives of this presentation are threefold: 1. To elucidate the fundamental principles underlying radioembolization. 2. To acquaint oneself with the imaging characteristics observed in liver tumors and the surrounding parenchyma following radioembolization, emphasizing potential diagnostic pitfalls. 3. To interpret the tumor response by LI-RADS.

TABLE OF CONTENTS/OUTLINE

1. Overview of radioembolization. 2. Evaluation of tumor response: delayed response, ring enhancement, and dystrophic calcification. 3. Non-tumoral imaging findings: peritumoral edema, hepatic fibrosis, parenchymal necrosis, and enhancement of the treated area. 4. Imaging features during and/or following subsequent therapeutic interventions. 5. LI_RADS classification and its interpretation of treated tumor by radioembolization

GIEE-104 BURNING HOLES: A RADIOLOGIST'S GUIDE TO PEPTIC ULCER DISEASE

Leonel Camejo (*Presenter*)
Shalom Mammen (*Abstract Co-Author*)
George A. Souflis, DO (*Abstract Co-Author*)
Daniel Gonzalez, DO (*Abstract Co-Author*)
Ashley Woodford, MD (*Abstract Co-Author*)
Bhishak H. Kamat, MD (*Abstract Co-Author*)
Blachy R. Davila, MD (*Abstract Co-Author*)
Omar Agosto, MD (*Abstract Co-Author*)

TEACHING POINTS

In the United States, peptic ulcer disease (PUD) affects approximately one out of 12 people. One in five peptic ulcers is associated with Helicobacter pylori infection, while most others result from NSAID overuse. Complications include bleeding, obstruction, fistulization, and perforation, the most serious complication, with a reported mortality rate as high as 20%. PUD arises from an imbalance in the protective and aggravating factors of the gastric mucosa. H. pylori and NSAIDs disrupt mucosal integrity through inflammation and inhibition of prostaglandin synthesis, respectively. Computed tomography (CT) aids in diagnosing PUD by highlighting direct and indirect signs. It also detects the aforementioned PUD-related complications, helping gauge prognosis and guide management.

TABLE OF CONTENTS/OUTLINE

This educational exhibit aims to review the imaging findings associated with PUD and discuss the clinical use of CT in diagnosing PUD and its complications. PUD is characterized by sores that extend into the muscularis propria of the gastric epithelium of the duodenum or stomach. It arises primarily from H. pylori infection and NSAID overuse. CT can evaluate direct and indirect signs of PUD and help classify them as uncomplicated or complicated (e.g., bleeding, perforation, obstruction). This exhibit will review the spectrum of PUD cases radiologists may encounter and propose a diagnostic imaging algorithm for PUD diagnosis to help guide treatment.

GIEE-105 CIRQUE DU RADIOLOGY: WITNESS THE ASTONISHING ABDOMINAL EPONYMS!

Claudia M. Muns, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Carlos Perez Morales (*Abstract Co-Author*)
Ariana Salgueiro Estela (*Abstract Co-Author*)
Marcos Martinez (*Abstract Co-Author*)
Jose A. Lara, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review key abdominopelvic pathologies, emphasizing clinical presentation, history, and imaging features. 2. Present abdominopelvic eponyms as circus acts for engaging visual learning. 3. Illustrate imaging findings across multiple modalities to enhance diagnosis and management.

TABLE OF CONTENTS/OUTLINE

1. Introduction and Objectives 2. Categories: - The Vascular Daredevils - The GI Contortionists - The Great Liver and Gallbladder Mysteries - The Freak Show of Renal and Urinary Oddities - The Gynecologic Wonders - The Mysterious Skin and Soft Tissue Oddities 3. Imaging Findings and Conclusion Abstract: Abdominal eponyms in radiology provide key diagnostic clues with historical significance. These terms enhance retention, convey complex concepts, and promote interest in medical history. This exhibit explores over 15 abdomen-related eponyms using a circus theme, grouping them into acts for engaging learning. Each act reviews historical context, anatomical basis, and characteristic imaging findings through radiographs, CT, MRI, and ultrasound. This unique approach aids medical students, residents, and imaging specialists in recognizing and applying these eponyms in clinical practice.

GIEE-106 REVOLUTIONARY ULTRASOUND TECHNIQUES IN IBD FOLLOW-UP: A NEW ERA IN PATIENT CARE

Claudia M. Muns, MD (*Presenter*)
Alejandra Cardona Del Valle, MD (*Abstract Co-Author*)
Zofia Marrero (*Abstract Co-Author*)
Jesus G. Rivera Roman (*Abstract Co-Author*)
Wilma Rodriguez-Mojica, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Overview of Inflammatory Bowel Disease (IBD) and comparison of different follow-up imaging modalities. Discuss the approach of IBD evaluation with a routine Intestinal Ultrasound (IUS) with a checklist of the pertinent findings. 2. Review normal findings and IBD changes, with a radiology report template to properly report pertinent findings

TABLE OF CONTENTS/OUTLINE

I. Introduction II. Objectives III. Anatomy Review IV. Normal findings in IUS and outline of key features to assess V. Gastrointestinal Features of IBD with Respective Imaging Findings on IUS, CT, and MRI VI. Common Findings and Complications: 1. Active vs. Non-active Disease 2. Penetrating vs. Stricturing Disease 3. Disease Activity Scoring VI. Template for structured reporting VII. Conclusion Abstract: The global incidence of IBD has risen in the last decade, making accurate diagnostics and disease tracking more critical. Imaging tools, particularly IUS, have proven to be non-invasive, cost-effective, and accurate for diagnosing and monitoring IBD. Radiologists and gastroenterologists must be trained in IUS and follow a standardized protocol to enhance interdisciplinary communication. Considering the seriousness of IBD complications, differentiating between structuring and penetrating disease using IUS and comparing disease progression is vital. We aim to equip radiologists to detect early and chronic IBD, enabling better patient management and preventing long-term complications.

GIEE-107 LIVER CYSTS WITH MUCIN SECRETION. RADIOLOGICAL - PATHOLOGICAL CORRELATION

Diego M. Haberman, MD (*Presenter*)
Ignacio Perez Fernandez, MD (*Abstract Co-Author*)
Oscar Andriani, MD (*Abstract Co-Author*)
Mariano Volpacchio, MD (*Abstract Co-Author*)
Miriam Galich (*Abstract Co-Author*)
Augusto Centellas Vargas, MD (*Abstract Co-Author*)
Karen Garcia Dumeth (*Abstract Co-Author*)

TEACHING POINTS

Liver cysts include a wide spectrum of pathological entities with different etiology. They have various clinical implications, radiological features, as well as different prognosis and treatment. Some liver cysts have a mucin producing epithelium, and regarding its biology, are considered premalignant lesions, with a well known invasive capability. These cysts include Mucinous Cystic Neoplasm (MCN), formerly known as Biliary cistoadenoma/carcinoma, Intraductally papillary neoplasm of the bile duct (B-IPMN) and Ciliated foregut cyst. The purpose of these presentation is to review and analize radiological features of each one of these lesions. We emphasize in radiological - pathological comparation in parh proven cases.

TABLE OF CONTENTS/OUTLINE

a) Recognize imaging features of MCN, B-IPMN and Ciliated foregut cyst b) Compare radiology with pathology including macro and micrscopy, for a better understanding of mucin producing liver cysts. c) Emphasize the impact of appropriate diagnosis and the role of imaging in surgical planification for therapeutic decisión making.

GIEE-108 NOT YOUR AVERAGE ADENO: A LOOK AT RARE RECTAL LESIONS

Anas Hasson Alnajjar, MBBS (*Presenter*)
Zainab Salman, MD (*Abstract Co-Author*)
Heba Hamad, MD (*Abstract Co-Author*)
Ahmed Al Kindi, MD (*Abstract Co-Author*)

TEACHING POINTS

• To familiarize radiologists with rectal lesions that mimic adenocarcinoma but represent distinct, often benign or rare tumor types.• To explain the key CT and MRI imaging features that help differentiate uncommon rectal lesions such as GIST, NET, schwannoma, and others.• To highlight the characteristic histologic findings associated with each lesion and their relevance to imaging interpretation.• To demonstrate the role of imaging in guiding clinical management, including biopsy decisions, surgical planning, or other oncologic treatment options.• To promote a pattern-based, systematic approach for evaluating rectal lesions, reducing the risk of mislabeling benign or rare tumors as adenocarcinoma.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Case-Based Review: • Gastrointestinal Stromal Tumor (GIST) • Neuroendocrine Tumor (NET) • Lymphoma • Schwannoma • Hemangioma • Leiomyoma • Villous Adenoma • Tailgut Cyst • Rectal Endometriosis 3. Comparison with Adenocarcinoma 4. Pearls, Pitfalls, and Management Tips 5. Conclusion

GIEE-109 IMAGING FINDINGS AND COMPLICATIONS OF WEIGHT LOSS INTERVENTIONS

Billy S. Chien, MD (*Presenter*)
Robert T. Kleven, MD, PhD (*Abstract Co-Author*)
Preethi Hyndhavi Kanumuri (*Abstract Co-Author*)
William Baker (*Abstract Co-Author*)
Emily June Zolfaghari (*Abstract Co-Author*)
Anne Sailer, MD (*Abstract Co-Author*)
Joseph J. Cavallo, MD,MBA (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)
Vincent M. Mellnick, MD (*Abstract Co-Author*)
Douglas S. Katz, MD (*Abstract Co-Author*)
Khaled M. Elsayes, MD, PhD (*Abstract Co-Author*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)
Nadia Solomon, MD,MA,MSc (*Abstract Co-Author*)

TEACHING POINTS

• Introduce the radiologist to common types of bariatric surgery, including normal post-surgical anatomy. • Discuss imaging examinations best suited to interrogate post bariatric anatomy and potential complications. • Discuss common and uncommon potential complications associated with each type of bariatric surgery. • Briefly introduce weight loss medications, including expected imaging findings and imaging of potential side effects/complications.

TABLE OF CONTENTS/OUTLINE

• Introduction to the prevalence of bariatric surgery, including Roux-en-Y gastric bypass, sleeve gastrectomy, gastric banding, biliopancreatic division with duodenal switch, etc. • Descriptions and illustrations of the intended post-surgical anatomy of various types of bariatric surgery and the mechanisms by which they promote weight loss. • Early post-surgical potential complications seen with all types of bariatric surgery: leaks, bleeds, marginal ulcers, venous thromboembolism. • Specific potential complications seen with Roux-en-Y Gastric Bypass: gastrogastric fistula, gallstone disease, internal hernias, afferent loop syndrome. • Specific potential complications seen with Gastric Banding: slipped band, band erosion, pseudoachalasia. • Specific potential complications seen with Sleeve Gastrectomy: gastric stenosis, reflux, bleeding.

GIEE-110 PEARLS AND PITFALLS OF CONTRAST-ENHANCED ULTRASOUND LI-RADS: OPTIMIZING ACCURACY IN HEPATOCELLULAR CARCINOMA DIAGNOSIS

Fangshi Lu, MD,FRCPC (*Presenter*)
Hyun-Jung Jang, MD (*Abstract Co-Author*)
Tae Kyoung Kim, MD, PhD (*Abstract Co-Author*)
Korosh Khalili, MD (*Abstract Co-Author*)
Khaled Y. Elbanna, FRCR (*Abstract Co-Author*)
Dilkash Kajal (*Abstract Co-Author*)
Vaibhav Jain, MD,MBBS (*Abstract Co-Author*)
Ahmed M. Gabr, MD, MSc (*Abstract Co-Author*)
Xiaoyang Liu, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. CEUS Liver Imaging Reporting and Data System (CEUS LI-RADS) provides standardized frame work for lesion categorization, but unique technical and interpretive challenges can impact diagnostic confidence and accuracy. 2. Accurate timing and dynamic assessment of lesions on arterial phase is key in correct LI-RADS categorization and diagnosis. 3. Washout can be subtle, and intermittent scanning is important to prevent bubble destruction. 4. Common pitfalls in CEUS interpretation include misinterpreting early washout in cholangiocarcinoma and non-hepatocellular malignancy as HCC and misclassification due to suboptimal contrast injection technique. 5. Near field lesions are prone to bubble destruction resulting in pseudowashout. 6. Fine adjustments to compensate for excessive attenuation such as amplifying the signal from far field can increase risk of pseudoenhancement.

TABLE OF CONTENTS/OUTLINE

1. Review on essential CEUS features for each LI-RADS category, with illustrative cases that underscore best practices and potential diagnostic traps. 2. Tips on optimizing timing of arterial imaging, recognizing the subtlety of late and mild washout. 3. Discuss how to solve discrepancies between CEUS and CT/MRI. 4. Review Common Pitfalls: misinterpreting early washout as HCC, misclassification due to suboptimal contrast injection technique, pseudo enhancement and pseudo washout.

GIEE-111 MR APPEARANCE OF ADVANCED BENIGN PANCREAS CONDITIONS: A SPECTRUM OF POST-INFLAMMATORY DISEASES THAT MAY NEED INTERVENTION

Nikita Consul, MD (*Presenter*)
Jorge Machicado Rivero (*Abstract Co-Author*)
George Zacur (*Abstract Co-Author*)
Reve Chahine, MD, FRCR (*Abstract Co-Author*)
Richard Kwon (*Abstract Co-Author*)
Hero K. Hussain, MD, FRCR (*Abstract Co-Author*)

TEACHING POINTS

1. Pancreas anatomy and associated benign conditions can contribute to recurrent/chronic pancreatitis, but are manageable with interventions if detected. 2. Clear understanding of the advanced interventions used to treat pancreatitis and its sequelae can inform how we read MRI/MRCP of the pancreas.

TABLE OF CONTENTS/OUTLINE

1. Imaging the Pancreas a. MRI/MRCP protocol and quality assurance b. MR signal characteristics with imaging examples of chronic pancreatitis on: i. T2-weighted (T2w) and T2w fat-sat ii. In-phase and out-of-phase iii. Dynamic contrast-enhanced T1-weighted (T1w) sequences c. Ductal anatomy on 2D-MRCP versus 3-D MRCP d. Procedural intervention overview with ERCP/EUS 2. Pancreas anatomic variants that predispose to inflammation and how this impacts intervention a. Parenchymal variants i. Annular pancreas ii. Pancreas bifidum b. Ductal variants i. Complete/incomplete divisum ii. Ansa pancreatica iii. Common channel 3. Other features of pancreatitis and intervenable sequelae a. Parenchymal/Vascular i. Pseudocyst and walled-off-necrosis (WON) ii. Thrombosis b. Ductal i. Stricture/stone ii. Disconnected pancreatic duct syndrome 4. Post-interventional appearances of the pancreas and cases of repeat interventions a. Duct stent placement and follow-up sequelae b. Hepaticojejunostomy c. Cystgastrostomy d. Pseudoaneurysm embolization 5. Summary of what not-to-miss in recurrent/chronic pancreatitis, ranked by severity and extent of surgical management required.

GIEE-112 RADIOLOGIC FINDINGS IN COMPLICATIONS OF OBESITY TREATMENTS

Ester Carballo, MD (*Presenter*)
Elena Luque, MD (*Abstract Co-Author*)
Alejandro Vera Gonzalez, MD (*Abstract Co-Author*)
Laura Galvan Herraez (*Abstract Co-Author*)

TEACHING POINTS

- Radiologic imaging is essential for identifying complications related to obesity treatments, both surgical and non-surgical. - Radiologists must be familiar with various bariatric procedures and their potential complications to ensure prompt and accurate diagnosis. - CT is the preferred modality for assessing post-treatment complications due to its high sensitivity and ability to evaluate complex anatomy. - Non-surgical options like intragastric balloons may cause serious issues such as migration, obstruction, or perforation. - A structured, case-based approach improves diagnostic accuracy and guides timely clinical management.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Obesity trends and the role of bariatric treatments 2. Imaging Modalities: Radiography, contrast fluoroscopy, and CT 3. Non-Surgical Complications: Gastric balloon and gastric banding issues 4. Surgical Complications: Leaks, hernias, collections, ileus, bleeding 5. Diagnostic Strategy: Imaging red flags and clinical correlation 6. Conclusion: Key radiologic findings and their clinical impact

GIEE-113 PRECONTRAST LIVER: WHAT IS IT GOOD FOR ANYWAY?

Ann A. Shi, MD (*Presenter*)
Evelyne M. Loyer, MD (*Abstract Co-Author*)
Sireesha Yedururi, MBBS (*Abstract Co-Author*)
Veronica L. Cox, MD (*Abstract Co-Author*)
Sergio Klimkowski, MD (*Abstract Co-Author*)
Peter Young, MD, MD (*Abstract Co-Author*)
Hyunseon C. Kang, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

· Understand the limitations of single portal venous phase for liver oncologic imaging.· Discuss the value of the precontrast phase for detection and accurate size measurement of liver metastases, essential for staging and tumor response assessment.· Learn how detection of calcifications may allow definitive diagnosis of hepatic metastases.· Review the utility of the precontrast phase in the setting of post-treatment changes, metallic artifact and hemorrhage.

TABLE OF CONTENTS/OUTLINE

· Introduction to the key role of the precontrast phase in liver oncologic imaging.· Characterization of liver lesions.o Precontrast phase differentiates hypervascular metastases from perfusional phenomena in the liver.o Change in size between precontrast and portal venous phase allows small nonspecific hypodense nodules to be characterized as metastases.· Detection of metastases.o Isoenhancing metastases are best seen on precontrast.o Punctiform calcifications on precontrast may be diagnostic of metastases.· Precontrast phase allows for more accurate assessment of tumor response.· The value of precontrast images for evaluating post-treatment changes, metallic artifact, and hemorrhage.

GIEE-114 TRAGEDY OF THE COMMONS: DISORDERS OF THE COMMON BILE DUCT

Timothy M. McMahon, MD, MS (*Presenter*)
Atif Zaheer, MD (*Abstract Co-Author*)

TEACHING POINTS

-Disorders of the common bile duct encompass a wide range of conditions, from the more common choledocholithiasis to rare, complex disorders like cholangiocarcinoma, portal cholangiopathy, and hyper-IgG4-related disease. While clinical and radiological features can be similar, this exhibit examines characteristics of both common and uncommon CBD disorders evident on advanced imaging techniques including ultrasound, CT, MRCP, and ERCP which can help with diagnosis. -Diagnostic pitfalls and mimics can lead to misdiagnosis or missed diagnoses if not carefully evaluated. Common imaging artifacts, such as a crossing vessel or flow void artifact on MRCP, are highlighted to illustrate features that help distinguish them from obstructive pathologies. -Varying management approaches for each condition—ranging from conservative management and medical therapy for benign disorders to surgical or oncological interventions for malignancies—are covered and important imaging features that can alter management are highlighted.

TABLE OF CONTENTS/OUTLINE

Introduction Anatomy Benign Conditions -Clinical Background -Imaging Features -Management Malignant Conditions -Clinical Background -Imaging Features -Management Pitfalls and Mimics

GIEE-115 CONTRAST ENHANCED ULTRASOUND OF THE SPLEEN. EASY, USEFUL AND VERY EFFECTIVE

Demosthenes D. Cokkinos, MD, PhD (*Presenter*)
Stefanou Danai-Eleni, MD,MSc (*Abstract Co-Author*)
Panagiotis Koutsogeorgas (*Abstract Co-Author*)

TEACHING POINTS

To review indications of Contrast enhanced ultrasound (CEUS) in the spleen. To show cases in which CEUS improves baseline US findings, answering clinical questions. To explain the added value of CEUS.

TABLE OF CONTENTS/OUTLINE

The commonest pathologic conditions of the spleen are reviewed with imaging examples on B mode, Colour Doppler and CEUS, correlated with CT or MR when these were performed. Presented cases include lymphoma, cysts, sarcoidosis, infarcts, splenunculus in differentiation to a splenic hilum lymph node, metastases, trauma (rupture, haematoma, extravasation), inflammatory pseudotumour, abscess, Littoral cell angioma, Carney complex etc. CEUS overcomes non-enhanced US limitations, as it is more sensitive for microvascculature detection, aiding lesion detection and characterization. CEUS indications, contraindications, limitations and pitfalls are also mentioned.

GIEE-116 HEPATOBILIARY-ENHANCED MRI: A COMPREHENSIVE GUIDE TO ENHANCE THE RADIOLOGIST'S KNOWLEDGE

Saubhagya Srivastava, MD (*Presenter*)
Otavio Augusto Ferreira Dalla Pria, MD (*Abstract Co-Author*)
Camila Gadens Zamboni, MD (*Abstract Co-Author*)
Caroline Lorenzoni Almeida Ghezzi, MD,PhD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Eleonora Silva (*Abstract Co-Author*)
Carolina A. Heming, MD (*Abstract Co-Author*)

TEACHING POINTS

MRI enhanced with gadoxetic acid (gadolinium ethoxybenzyl diethylenetriaminepentaacetic acid - Gd-EOB-DTPA) is pivotal in evaluating hepatocytes and biliary ducts due to its characteristic hepatic metabolism. This presentation aims to depict a comprehensive guide to protocoling and interpreting this technique daily, demonstrate pitfalls/limitations, and provide various useful cases where gadoxetic acid is applicable. For Part I, we will show basic concepts of gadoxetic acid and other gadolinium-based agents, as well as their metabolism and a guide to protocoling a gadoxetic MRI. For Part 2, we will depict a basic interpretation and important pitfalls of this modality; for Part 3, we will demonstrate a diversity of cases where gadoxetic acid plays a pivotal role; For Part 4, we will summarize gadoxetic acid applicability and limitations, as well as suggest a protocol guide and conclude with important take-home messages.

TABLE OF CONTENTS/OUTLINE

1- Brief review of gadoxetic acid metabolism comparing it to other gadolinium-based agents; 2- Suggestion of a protocol guide for MRI-enhanced gadoxetic acid; 3- Basic interpretation of normal imaging findings and pitfalls when applying gadoxetic acid-enhanced MRI; 4- Diversity of cases, including benign and malignant neoplasms of the liver/biliary ducts, cystic lesions, trauma/iatrogenic bile leaks, infections, and congestive liver syndromes, among others; 5- Conclusion and take-home messages.

GIEE-117 FROM PLEXUS TO PATHOLOGY: UNDERSTANDING ABDOMINAL NEUROGENIC TUMORS

Sean O'Rourke, MD (*Presenter*)
Alex Lin, MD (*Abstract Co-Author*)
Lyndon Luk, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the normal anatomy of the peripheral nervous system and adrenal glands. 2. Illustrate typical and atypical CT, MRI, and nuclear medicine/PET imaging findings of benign and malignant neurogenic tumors in the abdomen and pelvis. 3. Correlate imaging findings with surgical pathology specimens of neurogenic tumors.

TABLE OF CONTENTS/OUTLINE

A. Anatomy of the peripheral nervous system, including the adrenal glands. B. Case-based review of abdominal neurogenic tumors utilizing imaging findings from CT, MRI and PET/CT. 1. Tumors of Ganglion Cell Origin: ganglioneuroma, ganglioneuroblastoma, neuroblastoma. 2. Tumors of the Paraganglionic System: pheochromocytoma, paraganglioma. 3. Tumors of Nerve Sheath Origin: schwannoma, neurofibroma, neurofibromatosis, malignant nerve sheath tumor. C. Review of management and correlation of imaging with surgical pathology specimens.

GIEE-118 THE USUAL, THE UNUSUAL, AND THE UNEXPECTED: A DIAGNOSTIC JOURNEY THROUGH PANCREATOBILIARY LESIONS

Mayu Uka, MD (*Presenter*)
Yoko Shinno (*Abstract Co-Author*)
Takehiro Tanaka (*Abstract Co-Author*)
Maiko Tamura (*Abstract Co-Author*)
Shinichi Shimizu (*Abstract Co-Author*)
Tomohiko Mannami (*Abstract Co-Author*)
Takafumi Kubo (*Abstract Co-Author*)
Takashi Mukai (*Abstract Co-Author*)
Takao Hiraki, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

The purpose of this exhibit is: 1)To review imaging features on contrast enhanced CT, MRI of pancreatobiliary lesions that can be diagnostically misleading, comparing them with common differential diagnoses and correlating them with histopathology.2)To review various cases from typical to atypical imagings.3) To discuss the point of differential diagnosis.

TABLE OF CONTENTS/OUTLINE

The pancreatobiliary region presents a unique diagnostic challenge due to the wide spectrum of lesions that may arise-from benign mimickers and inflammatory conditions to rare or aggressive neoplasms. While some cases follow expected patterns, others surprise us with atypical presentations, overlapping features, or deceptive appearances on imaging and histopathology.This educational exhibit highlights key diagnostic pitfalls in imaging through a curated selection of real cases-ranging from common to diagnostically challenging lesions-by correlating imaging findings with histopathology. The cases include both tumors and tumor-mimicking conditions.

GIEE-119 MRI ASSESSMENT OF ANAL CANCER: A COMPREHENSIVE REVIEW OF INITIAL STAGING, TREATMENT RESPONSE EVALUATION, AND POST-THERAPY SURVEILLANCE

Marta Alaia Montes Zubia, MD (*Presenter*)
Jennifer Barredo Parra (*Abstract Co-Author*)
Ander Garcia Etxebarria (*Abstract Co-Author*)
Udane Perez Ibarrondo, MD (*Abstract Co-Author*)
Ibai Estibez Olea (*Abstract Co-Author*)
Inigo Alcaraz Hernando, MD (*Abstract Co-Author*)
Mikel Isla-Jover, MD (*Abstract Co-Author*)
Martin Santamaria Boado, MD (*Abstract Co-Author*)

TEACHING POINTS

MRI is the modality of choice for evaluating local disease in anal cancer, both early and advanced. High-resolution MRI protocol is essential , with axial and coronal T2W sequences aligned to the anal canal. Anal cancer is not rectal cancer ; staging criteria and imaging approach differ. T stage is based on tumor size , not invasion depth; measure in all planes. Nodal staging depends on node location , not number; complement MRI with PET-CT or FNA if needed. Post-treatment MRI should be done 6 months after CRT , when response peaks; earlier imaging may mislead. Local recurrence occurs in 30% of patients , often within 2 years; biopsy and salvage APR may be needed.

TABLE OF CONTENTS/OUTLINE

Background Epidemiology and imaging role in anal cancer diagnosis, staging, and follow-up. Anal Canal Anatomy Anatomical vs surgical canal: relevance in staging. Key MRI landmarks including the puborectalis and sphincter complex. MRI Technique Recommended sequences and proper orientation relative to the anal canal axis. Staging Overview (TNM) T: tumor size. N: lymph node location. M: distant metastases (CT/PET-CT). Imaging Features Tumor signal characteristics on T2, DWI and contrast. Evaluation of sphincter and adjacent structure involvement. Post-Treatment Assessment Optimal timing (6 months post-CRT). Fibrosis vs residual tumor based on signal and diffusion restriction. Recurrence and Management Local recurrence in 30% of patients, often within 2 years. Early detection, histological confirmation and possible APR. Conclusion MRI plays a central role throughout the management of anal cancer: from initial diagnosis and staging to post-treatment assessment, surveillance and guiding further interventions.

GIEE-120 PORTRAIT OF AN INTRUDER: IMAGING FEATURES OF CHOLANGIOCARCINOMA

Claudia Viescas Huerta, MD (*Presenter*)
Isabel Fonseca Buelga, MD (*Abstract Co-Author*)
Diego Alejandro Garcia Paredes, MD (*Abstract Co-Author*)
Sergio Sintes (*Abstract Co-Author*)
Elena Canales Lachen (*Abstract Co-Author*)
Luis Gonzalez Campo, MD (*Abstract Co-Author*)
Antonio Michael-Fernandez, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Brief description of epidemiology, risk factors and therapeutic options for cholangiocarcinoma.2. To review cholangiocarcinoma subtypes based on their morphologic growth pattern and their imaging features.3. To explain cholangiocarcinoma subtypes based on their location on the biliary tree and their imaging findings.4. To discuss their differential diagnosis by using illustrative cases.

TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Cholangiocarcinoma subtypes based on their morphologic growth pattern: Mass forming, Periductal infiltrating and Intraductal subtypes.3. Cholangiocarcinoma subtypes based on their location on the biliary tree: intrahepatic, perihiliar and distal cholangiocarcinoma.4. Differential diagnosis: mass forming (sclerosed hemangioma, hepatic hydatid infection, intrahepatic lymphoma, hepatocellular carcinoma, adenocarcinoma metastases), periductal infiltrating (IgG4- related disease, benign fibrosis, primary sclerosis cholangitis), intraductal (calculi, ampullary tumor).5. Summary.

GIEE-121 IMAGING INSIGHTS INTO ADVERSE EFFECTS ON THE HEPATOBILIARY SYSTEM AND PANCREAS FROM SYSTEMIC ANTI-CANCER TREATMENTS

Sudhakar K. Venkatesh, MD, FRCR (*Presenter*)
Christopher L. Welle, MD (*Abstract Co-Author*)
Natally Horvat, MD, PhD (*Abstract Co-Author*)
Nguyen H. Tran, MD (*Abstract Co-Author*)
Ilkay Idilman, MD (*Abstract Co-Author*)
Patrick Navin, MBBCh, FFR(RCSI) (*Abstract Co-Author*)
Chandramohan Anuradha, MD,FRCR (*Abstract Co-Author*)
Tiffany Hennedige, MBBS, FRCR (*Abstract Co-Author*)
Mark A. Anderson, MD (*Abstract Co-Author*)
Musturay Karcaaltincaba, MD (*Abstract Co-Author*)
Zongming Eric Chen (*Abstract Co-Author*)

TEACHING POINTS

1. Systemic anticancer treatments, including chemotherapy, immunotherapy, and their combinations, can result in various hepatobiliary and pancreatic adverse effects. 2. These adverse effects can occur in asymptomatic patients, making early detection crucial for preventing progression by stopping or reducing the dose, or change to alternative drugs. 3. Imaging plays a vital role in differentiating treatment-related adverse effects from disease progression, ensuring accurate diagnosis and appropriate management.

TABLE OF CONTENTS/OUTLINE

Hepatic adverse effects Hepatitis- ICI hepatitis Hepatic steatosis Chemotherapy associated steatohepatitis (CASH) Sinusoidal obstruction syndrome Nodular regenerative hyperplasia (NRH) Chemotherapy Associated Liver Morphology Changes in Hepatic Metastases (CALMCHeM) or Pseudocirrhosis Portal vein thrombosis Eosinophilic abscess/infiltration/granuloma ICI-induced hepatopathy- hepatocellular injury Reactivation of hepatitis B and C Autoimmune hepatitis Biliary adverse effects: Biliary stasis with sludge and stones- altered bile composition Biliary inflammation Sclerosing cholangitis Ischemic cholangitis Acute acalculous cholecystitis Pancreas adverse

effects: Pancreatitis Pancreatic fibrosis Pancreatic atrophy Impact on Imaging Interpretation Focal SOS and focal steatosis may mimic metastases Poor/missed detection of metastases Pseudo progression vs. true progression Take Home Points Severe hepatitis may result in cessation of immunotherapy ICI therapy may cause pseudo progression Infectious complications are common in marrow suppressionDiffuse change and focal change in liver may obscure or mimic metastases respectively

GIEE-122 ELUSIVE SPLENIC PATHOLOGY AND THE ROLE OF MR IMAGING

Nikolas Brozovich, MD (*Presenter*)
Manohar Roda, MD, MBBS (*Abstract Co-Author*)
Courtney C. Moreno, MD (*Abstract Co-Author*)
Frank H. Miller, MD (*Abstract Co-Author*)
Pardeep K. Mittal, MD (*Abstract Co-Author*)

TEACHING POINTS

Splenic pathology is often encountered in clinical practice with the majority of pathology being benign. Due to the overwhelmingly benignity of splenic lesions, familiarity with both benign and malignant pathology is often overlooked. However, accurate classification of splenic abnormalities is often imperative for patient management. Hemangiomas are most commonly encountered, while lymphoma is the most common malignant neoplasm encountered, and angiosarcoma the most common primary neoplasm encountered. An algorithmic approach will be presented to ensure accurate classification of cystic and solid splenic pathology with an emphasis on MR imaging as an essential problem solving tool for accurate diagnosis. Atypical presentation and signal characteristics of splenic lesions will also be presented.

TABLE OF CONTENTS/OUTLINE

Diagnostic algorithm and Classification of Splenic Lesions- Cystic Lesions- Infectious and Non-infectious Solid Lesions- Hypervascular and Non-hypervascular Miscellaneous lesions including congenital anomalies

GIEE-123 BEYOND THE USUAL: MRI SPECTRUM OF SMALL BOWEL OBSTRUCTION

Martin Dufwenberg, MD (*Presenter*)
Bekir Sanal, MD (*Abstract Co-Author*)
Hina Arif Tiwari, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Recognize the key features of small bowel obstruction on MRI. 2. Differentiate between common and uncommon causes of small bowel obstruction on MRI. 3. Understand the advantages and limitations of MRI in imaging small bowel obstruction when compared to CT. 4. Understand MRI protocols used when imaging small bowel obstruction.

TABLE OF CONTENTS/OUTLINE

Introduction 1. Why should we use MRI for small bowel obstruction? 2. Techniques: MR enterography vs standard MRI 3. Sequences: T2, DWI, pre- and post-contrast sequences in dynamic contrast-enhanced imaging Recognizing small bowel obstruction Key imaging findings on MRI Differential diagnosis of small bowel obstruction Case-based review of small bowel obstruction on MRI Intraluminal obstruction 1. Gallstone ileus (case showcased in pdf upload) Intrinsic to bowel wall 1. Ileo-colonic intussusception (case showcased in pdf upload) 2. Post traumatic - infected cecal hematoma (case showcased in pdf upload) 3. Colonic mass - sigmoid colon adenocarcinoma (case showcased in pdf upload) 4. Small bowel mass - duodenal adenocarcinoma 5. Inflammatory bowel disease - Crohn's stricture 6. Reactive mural edema from abscess - perforated appendicitis 7. Post-surgical stricture Extrinsic to bowel wall 1. Spigelian hernia (case showcased in pdf upload) 2. Femoral hernia 3. Umbilical hernia in pregnancy 4. Paraumbilical hernia 5. Peritoneal carcinomatosis 6. Adhesive disease - post-surgical 7. Fibrovascular band - Meckel diverticulum 8. Mass effect - metastatic mesenteric adenocarcinoma Ischemic features of small bowel obstruction 1. Bowel wall thickening 2. Hypoenhancement Pitfalls of MR in imaging small bowel obstruction Comparison to CT Conclusion References

GIEE-124 EVALUATION OF THE POST-OPERATIVE ESOPHAGUS: WHAT THE RADIOLOGIST NEEDS TO KNOW

Laura R. Carucci, MD (*Presenter*)
Mary A. Turner, MD (*Abstract Co-Author*)

TEACHING POINTS

• Esophageal surgery is not uncommon and several procedures may be encountered by radiologists • Surgery may be performed for neoplasm, reflux, hiatal hernia, stricture, diverticula, fistula, perforation, achalasia and other motility disorders • Imaging is used to define anatomy, evaluate the success of the procedure and assess for complications • Radiologists must be familiar with procedures, expected findings & potential complications for accurate diagnosis • We will explore a spectrum of post-surgical and post-treatment changes involving the esophagus

TABLE OF CONTENTS/OUTLINE

• Describe esophageal surgical procedures, review expected findings and complications following: Esophagectomy and conduits (gastric, colon, jejunum), Distal esophagectomy & gastrectomy, LINX anti-reflux procedure, Myotomy (Heller and POEM), Fundoplication and hiatal hernia repair • Review postoperative complications: Leak, dissection, fistula, stricture, hernias (including paraconduit, paraesophageal), recurrent tumor, recurrent symptoms / surgical failure • Provide technique tricks and tips and diagnostic pitfalls

GIEE-125 THE POST-OPERATIVE COLON: RECOGNIZING THE ALTERED ANATOMY, COMPLICATIONS AND PITFALLS

Laura R. Carucci, MD (*Presenter*)
Mary A. Turner, MD (*Abstract Co-Author*)

TEACHING POINTS

• Numerous articles and presentations regarding postop UGI imaging, with a relative paucity of information on postop colon imaging. Yet, colorectal surgery constitutes approximately 28% of abdominal surgeries • Radiologists must be familiar with various surgical procedures and expected postoperative findings to recognize complications • We plan to describe a variety of colonic surgical procedures and discuss the expected postoperative anatomy and imaging findings • We will review a spectrum of imaging findings of complications following colon surgery

TABLE OF CONTENTS/OUTLINE

• Indications for colon surgery: Primary colorectal cancer, malignancy secondarily involving colon, IBD, diverticular disease, fistula, volvulus, trauma • Procedures: Segmental colectomy, Right or left hemicolectomy, Subtotal colectomy, Low anterior resection, Abdominoperineal resection, Total colectomy, Ileal pouch anal anastomosis, Colostomies, mucus fistulas, reconstructions • Imaging Indications: Diagnosis of complications, Healing prior to ostomy take down, providing a GI "Roadmap" (prior surgery, trauma) • Imaging Techniques: Single contrast enema, Ostomy enema, CT, MRI. • Expected postop findings and pitfalls. Postop anatomy often difficult to accurately identify on cross-sectional imaging. • Complications: Leak, abscess, fistula, stricture, obstruction, hernia, bleeding / vascular abnormalities, rectal stump breakdown, GU injury, recurrent tumor, colostomy complications (necrosis, ulceration, stenosis, prolapse, hernia) • Thorough radiologic assessment and knowledge of expected postop anatomy and potential complications following colon surgery will help avoid misdiagnosis

GIEE-126 MORE THAN MEETS THE EYE: RADIOLOGIC INSIGHTS INTO NON-NEOPLASTIC ESOPHAGEAL DISEASE

Lucia Ortega Uribe, MD (*Presenter*)
Laura Ruiz, MD (*Abstract Co-Author*)

Daniela A. Patarroyo, MD (*Abstract Co-Author*)
Victor A. Ortega, MD (*Abstract Co-Author*)

TEACHING POINTS

Establish a basic understanding of esophageal anatomy to effectively detect and characterize abnormalities, primarily using CT imagingSeveral non-neoplastic esophageal pathologies can present as clinical emergencies, often leading to complications such as abscess formation in adjacent critical anatomic spaces. Prompt recognition and management are crucial to prevent severe outcomesReview the spectrum of imaging findings for this group of non-neoplastic esophageal diseases across multiple modalities and identify key imaging features crucial for accurate diagnosisThis presentation focused on non-neoplastic esophageal conditions commonly seen in CT imaging, recognizing their imaging features is essential to avoid confusion with other types of pathology and to ensure appropriate treatment

TABLE OF CONTENTS/OUTLINE

Anatomy : Histology, Gross anatomy.Imaging techniques : Fluoroscopy, X ray, Computed TomographyDiseases : Esophageal perforation, Foreign body, Esophagitis, Spontaneous esophageal hematoma, Killian´s diverticulum, Other diseasesConclusions : Recognition of esophageal anatomy and non-neoplastic pathology through various diagnostic imaging modalities primarily computed tomography is essential for distinguishing between different clinical contexts and ensuring appropriate treatment, particularly in potentially life-threatening conditions such as perforation, prolonged foreign body impaction, and esophageal hematomas

GIEE-127 NAVIGATING LI-RADS ULTRASOUND VISUALIZATION SCORE: HOW TO APPROACH & APPLY

Amanda C. Gibson, DO (*Presenter*)
Ahmed M. Gabr, MD, MSc (*Abstract Co-Author*)
Shuchi K. Rodgers, MD (*Abstract Co-Author*)
Mohammed A. Ismail, DO (*Abstract Co-Author*)
Cheng W. Hong, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

According to the American Association for the Study of Liver Disease (AASLD), patients with risk factors for developing hepatocellular carcinoma (HCC), chronic hepatitis B infection or cirrhosis of any cause, should undergo biannual screening with serum alpha fetoprotein and ultrasound (US) to detect HCC at an early, treatable stage. US is considered the first-line imaging modality for these at-risk patients due to its proven efficacy, accessibility, and cost effectiveness. An important facet of US surveillance is application of the Liver Imaging Reporting and Data System (LI-RADS) in order to designate a category (US-1 Negative, US-2 Subthreshold, or US-3 Positive) and a visualization score (VIS-A No or minimal limitations, VIS-B Moderate limitations, or VIS-C Severe limitations), which have important management implications. LI-RADS US Surveillance version 2024 utilizes updated terminology and management recommendations as well as tips on assigning an appropriate visualization score. Accurate utilization of LI-RADS ensures consistent communication among healthcare providers and directly influences patient management, follow-up intervals, and potential referral for advanced imaging or biopsy.

TABLE OF CONTENTS/OUTLINE

1. Explain updated terminology for LI-RADS US visualization score and management recommendations 2. Provide the rationale for assigning an appropriate US visualization score 3. List factors that affect the US visualization score 4. Review examples of VIS-A: No or minimal limitations, VIS-B: Moderate limitations, and VIS-C: Severe limitations along with correlative contrast enhanced US, CT, and MR imaging

GIEE-128 IT´S A WORMY SITUATION - RADIOLOGIC IMAGING IN ECHINOCOCCOSIS

Caroline Bestler, MD (*Presenter*)

TEACHING POINTS

Hydatid disease is a unique parasitic disease that is endemic in many parts of the world. The most common types are E. granulosus and E. mulitlocularis. Both can occur almost anywhere in the body and demonstrate a variety of imaging features that vary according to growth stage, associated complications, and affected tissue. Radiologic findings range from purely cystic lesions to a completely solid, tumor-like appearance. Ultrasound, standard X-Ray, computed tomography (CT) and magnetic resonance imaging (MRI) are the common imaging modalities in hydatid disease. Which imaging method used depends on the involved organ and the growth stage of the cyst. For both types exist Ultrasound- and CT-classification systems. Medical therapy is performed using albendazole. In the case of E. granulosus, the indication for surgery depends on the CE stage, the size, and the location of the lesion. In the case of E. multilocularis, a radical resection should always be performed whenever still possible.

TABLE OF CONTENTS/OUTLINE

1. Global distribution of echinococcosis 2. Importance of radiology in diagnosis of echinococcosis 3. Cystic echinococcosis (E. granulosus) in imaging 3.1. Cyst classification 3.2. WHO - IWGE ultrasound classification 4. Alveolar echinococcosis (E. multilocularis) in imaging 4.1. Overview 4.2. Imaging techniques 4.1.1 Ultrasound 4.1.2. CT 4.1.3. MRI 5. Complications in the context of echinococcosis 6. Case reports 7. Interdisciplinary treatment of echinococcosis at the university hospital of Würzburg 8. Discussion

GIEE-129 FLOW DISRUPTED: A REVIEW OF COMMON AND UNCOMMON HEPATIC VASCULAR DISORDERS

Wendy Qiu, MD (*Presenter*)
Mehri Manouchehr-Pour (*Abstract Co-Author*)
Shawdi Manouchehr-Pour, MD (*Abstract Co-Author*)
Evan A. Raff, MD (*Abstract Co-Author*)
Karoly Viragh, MD (*Abstract Co-Author*)
Priyanka Dube, DO (*Abstract Co-Author*)

TEACHING POINTS

Hepatic vascular diseases include a range of congenital and acquired conditions involving the liver’s vascular supply. This multiple-choice question (MCQ) based exhibit will review normal hepatic vascular anatomy, its variants, and provide a comprehensive imaging review of the spectrum of congenital and acquired hepatic vascular pathologies, associated complications, and mimics. Through clinically relevant scenarios and illustrative examples, this exhibit aims to enhance diagnostic accuracy and confidence among radiologists and health care professionals involved in the assessment and management of hepatic vascular disorders.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Anatomy: normal, variant & aberrant anatomy 3. Congenital Vascular Pathology cases: hepatic hemangioma (venous malformation), focal nodular hyperplasia, hereditary hemorrhagic telangiectasia 4. Acquired Vascular Pathology cases: cirrhosis and sequela of portal hypertension (cavernous transformation of the portal vein, porto-systemic shunts), Budd-Chiari syndrome, passive hepatic congestion, SVC obstruction 6. Complications: infection/inflammation related complication cases - thrombophlebitis (falciform ligament, pylephlebitis); transplant-related complication cases - hepatic artery stenosis/thrombosis/IVC thrombosis 7. Mimics: transient hepatic attenuation and intensity differences (THAD/THID), third inflow hepatic pseudolesions 8. Summary and conclusion

GIEE-130 WHEN ABDOMINAL IMAGING TELLS A DIFFERENT STORY: THAT SHOULDN'T BE THERE

Rodrigo S. Loto, MD (*Presenter*)
Martin M. Pesce, MD (*Abstract Co-Author*)
Victorio Del Casale, MD (*Abstract Co-Author*)
Luciano B. Lovotti, MD (*Abstract Co-Author*)
Roberto E. Elias, MD (*Abstract Co-Author*)

TEACHING POINTS

- Explain the scenarios in which the abdominal organs are not in their usual place. - Anatomical review. - Demonstrate those alterations that share the atypical location. - Key radiological points.

TABLE OF CONTENTS/OUTLINE

An organ's abnormal positioning within the abdominal and pelvic cavities can occur due to a few key mechanisms. We propose that these mechanisms include: 1. Loss of Fixation Elements : Organs are normally held in place by various anatomical structures, such as ligaments and connective tissues. If these fixation elements are damaged or lost due to factors like surgery, injury, or congenital issues, the organ may shift from its original location. For example, trauma can lead to the tearing of ligaments, causing an organ to become mobile and susceptible to displacement. 2. Displacement : This mechanism refers to an organ moving away from its usual location. Displacement can result from increased pressure within the abdominal cavity, abnormal growth or conditions that cause organ enlargement. Extrusion of the viscera refers to the displacement or prolapse of internal organs from their normal position within the abdominal or pelvic cavity. Hernias are the most common cause of extrusion. 3. Retraction : Retraction occurs when an organ is pulled toward a certain area, often due to scar tissue or adhesions that develop from previous surgeries or chronic inflammation. The goal of this investigative review is to showcase these mechanisms through illustrative case studies that examine how various processes affect the typical positioning of abdominal and pelvic organs.Special attention will be given to the importance of early detection in cases that require urgent intervention.

GIEE-131 BUDD-CHIARI SYNDROME: IMAGING TIMELINE FOR UNRAVELLING ITS STAGES

Ashima Muttreja, MD (*Presenter*)
Donald G. Mitchell, MD (*Abstract Co-Author*)
Ashlesha S. Udare, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

To understand the pathophysiology and clinical stages of Budd Chiari Syndrome (BCS) To identify key US, CT, MR and venographic features in the different stages of BCS

TABLE OF CONTENTS/OUTLINE

Background: BCS results from primary intrinsic obstruction of the hepatic veins or suprahepatic IVC from thrombus or webs, or secondary to extrinsic compression. Symptom severity is related to the extent of hepatic vein obstruction and hepatic functional reserve. Increased hepatic sinuosoidal pressure leads to liver congestion and impaired portal venous perfusion. BCS stages and their imaging manifestations: Fulminant/Acute (<1 month): Rare fulminant presentation <1week with encephalopathy, jaundice, ascites and rapid liver failure Acute hepatic vein or IVC thrombus Heterogenous hypoenhancement +/- caudate lobe hypertrophy Subacute (1-6months) Abdominal pain and ascites Absent hepatic veins and enlargement of accessory hepatic veins Peripheral abnormal liver signal and enhancement Caudate lobe hypertrophy compressing the IVC Intrahepatic comma shaped collaterals Portal hypertension with portosystemic collaterals Spiderweb collateral veins on catheter venography Chronic(>6months) Peripheral hepatic atrophy increased in early and late enhancement Development of FNH-like nodules (no malignant potential) Increased risk of HCC Possible portal vein thrombus +/- findings in subacute stage Management implications: Fulminant and Acute: anticoagulation, thrombectomy Subacute: Venoplasty, stents Chronic: Shunts, TIPS, liver transplantation Conclusion: The imaging features of BCS depend on the stage of disease and affect management.

GIEE-132 ACUTE GALLBLADDER PATHOLOGIES BEYOND UNCOMPLICATED CHOLECYSTITIS

William Wei, MD (*Presenter*)
Gavin M. Sugrue, MBBCh (*Abstract Co-Author*)
Shamir Rai, MD (*Abstract Co-Author*)
Nicolas Murray, MD, FRCPC (*Abstract Co-Author*)

TEACHING POINTS

Radiologists must recognise acute gallbladder entities beyond uncomplicated cholecystitis. Imaging dictates timely management. Ultrasound is first-line. CT and MRI/MRCP refine calculus detection, mural perfusion and complication staging. Red-flag complications demand urgent surgical or percutaneous intervention. These include gangrenous/emphysematous cholecystitis, hemorrhage, perforation, fistula formation, and volvulus. Cross-sectional imaging distinguishes mimickers masquerading as inflammation, including gallbladder carcinoma and cystic artery pseudoaneurysm. A structured checklist, such as stone, wall, lumen, pericholecystic fat, vascularity, ducts/bowel, can boost diagnostic accuracy and outcomes.

TABLE OF CONTENTS/OUTLINE

1 Introduction & Epidemiology 2 Calculous Disease - Cholelithiasis - Acute uncomplicated cholecystitis 3 Inflammatory Complications - Gangrenous - Emphysematous - Hemorrhagic 4 Structural Complications - Perforation - Mirizzi syndrome - Fistulas - Gallstone ileus & Bouveret syndrome 5 Anatomic Displacements - Gallbladder herniation - Gallbladder volvulus 6 Vascular Complications - Cystic artery pseudoaneurysm - Ischemia & portal venous thrombosis 7 Neoplastic Mimic - Gallbladder carcinoma 8 Traumatic Injuries 9 Management Pearls & Future Directions

GIEE-133 GASTRIC ADENOCARCINOMA: THE RADIOLOGIST'S PERSPECTIVE

Abel Gonzalez Huete, MD (*Presenter*)

TEACHING POINTS

To understand the pathological basis and imaging characteristics of gastric adenocarcinoma. To review current imaging protocols and techniques for the detection and staging of gastric cancer. To illustrate key imaging features relevant to tumor characterization and accurate staging. To highlight the radiologist's role in assessing locoregional and distant disease spread.

TABLE OF CONTENTS/OUTLINE

Introduction : Pathologic classification, epidemiology, and risk factors Imaging modalities : Endoscopy, Endoscopic Ultrasound (EUS), CT, MRI, and PET-CT. Strengths and limitations of each modality. CT technique and gastric distension protocol. Detection : Typical imaging patterns and potential complications. Staging : Application of the TNM classification with emphasis on imaging criteria and correlation with histopathology. T stage : T1a, T1b, T2, T3, T4a, T4b. N stage Regional lymph nodes (perigastric and extraperigastric) M stage : Non-regional lymph nodes, hematogenous spread, and transperitoneal dissemination Extramural venous invasion (EVI) : Definition, imaging signs, classification types, and prognostic implications. Conclusion References

GIEE-134 PATTERNS OF LYMPHATIC SPREAD OF MALIGNANCIES IN THE ABDOMEN AND PELVIS

Michael H. Lanier, MD, PhD (*Presenter*)
Tyler J. Fraum, MD (*Abstract Co-Author*)
Mark J. Hoegger, MD, PhD (*Abstract Co-Author*)
Malak Itani, MD (*Abstract Co-Author*)
Katerina Konstantinoff, MD (*Abstract Co-Author*)
Daniel R. Ludwig, MD (*Abstract Co-Author*)
Amanda L. Mehrsheikh, MD (*Abstract Co-Author*)
Vincent M. Mellnick, MD (*Abstract Co-Author*)
Nathan P. Skinner, MD, PhD (*Abstract Co-Author*)
Grant Yoneoka, MD (*Abstract Co-Author*)
Anup S. Shetty, MD (*Abstract Co-Author*)

TEACHING POINTS

Lymphadenopathy has important staging implications for patients with cancer. Additionally, identification of lymphadenopathy on imaging may be the first finding of malignancy. Lymphatic spread of disease typically follows a predictable pattern based on drainage anatomy. Radiologists can use these patterns not only to provide important staging information but also to help identify the primary neoplasm when lymphadenopathy is the initial imaging finding. This exhibit will: 1) Illustrate normal lymphatic drainage anatomy and normal lymph node morphology. 2) Describe typical pathways of lymphatic spread of gastrointestinal and genitourinary cancers to help develop tailored search patterns for specific malignancies. 3) Discuss staging importance of identifying regional versus non-regional lymph nodes. 4) Cover common pitfalls and overcalls.

TABLE OF CONTENTS/OUTLINE

1) The role of diagnostic imaging in cancer nodal staging. 2) Normal lymphatic drainage anatomy and lymph node morphology. 3) Disease-specific patterns of lymphadenopathy for genitourinary and gastrointestinal, including hepatobiliary, malignancies. 4) Working backward: identifying the primary location of disease when lymphadenopathy is the initial imaging finding. 5) Common pitfalls and overcalls: periportal, foramen of Winslow, celiac ganglion, inguinal lymph nodes.

GIEE-135 CONTRAST ENHANCED ULTRASOUND IS EXCELLENT FOR IMAGING GALLBLADDER AND BILE DUCTS PATHOLOGY

Demosthenes D. Cokkinos, MD, PhD (*Presenter*)
Stefanou Danai-Eleni, MD,MSc (*Abstract Co-Author*)
Panagiotis Koutsogeorgas (*Abstract Co-Author*)

TEACHING POINTS

To explain the use of Contrast Enhanced Ultrasound (CEUS) in imaging gallbladder and bile ducts pathology. To review indications, imaging findings, limitation and pitfalls. To study the way in which CEUS increases the diagnostic value of baseline, unenhanced US.

TABLE OF CONTENTS/OUTLINE

Basic knowledge of US contrast agents is refreshed. Pathology in the gallbladder and bile ducts with indication for CEUS is outlined. Various indications for CEUS of the gallbladder include elucidating normal variants, differentiating dense biliary sludge from polyps and cancer, assessment of cholecystitis, hepatitis, abscess and wall rupture. Benign lesions as adenomyomatosis are also imaged. CEUS of the biliary tree is useful for distinguishing sludge from intraluminal masses, as well as detecting and characterising cholangiocarcinoma and intrahepatic metastases. All pathological entities are explained with imaging findings on CEUS, correlated with CT or MR when these were performed. CEUS findings are compared to those of baseline, unenhanced US to assess the increase in US diagnostic value post contrast injection.

GIEE-136 JUST ANOTHER CYST OR A HIDDEN PDAC? A PRIMER ON DETECTING MALIGNANCY IN FOLLOW UP OF PANCREATIC CYSTS

Praveen V. Polamraju, MD (*Presenter*)
Naveen Rajamohan, MD,MBBS (*Abstract Co-Author*)
Hala A. Khasawneh, MBBS (*Abstract Co-Author*)
Venkata Gopala Rao Kodali (*Abstract Co-Author*)
Gaurav Khatri, MD (*Abstract Co-Author*)
Ravi K. Kaza, MD (*Abstract Co-Author*)

TEACHING POINTS

• While the majority of pancreatic cystic lesions are benign, it is crucial to identify suspicious features given high mortality rates of pancreatic malignancy, especially adenocarcinoma (PDAC).• Pancreatic cystic lesions with malignant risk include intraductal papillary mucinous neoplasms, mucinous neoplasm, cystic metastases, and cystic pancreatic neuroendocrine tumors.• Identifying “worrisome features” and “high-risk stigmata” with Kyoto guidelines can lead to earlier detection of pancreatic adenocarcinoma.• Patients with intraductal papillary mucinous neoplasms are at higher risk for developing malignancy within the cyst and distant from the cyst in normal appearing pancreas.

TABLE OF CONTENTS/OUTLINE

• Introduction a. Imaging features of various types of pancreatic cystic lesions b. Highlights and pitfalls of Kyoto guidelines with highlights of key differences from prior guidelines • Cases highlighting pancreatic malignancy on follow up of pancreatic cystic lesions a. New “worrisome features” or “high-risk stigmata” b. New synchronous pancreatic adenocarcinoma c. Pitfalls in detecting occult pancreatic malignancy in high-risk patients, including atypical pancreatitis cases • Management of suspicious pancreatic cystic lesions with multidisciplinary approach a. Correlation of high-risk pancreatic cystic lesions with endoscopic ultrasound, operative findings, and pathology • Conclusions a. Vigilance on surveillance exams can lead prompt management and improved patient outcomes

GIEE-137 CYSTIC DUCT ESSENTIALS: WHAT RADIOLOGISTS NEED TO KNOW

Nanjiba Nawaz, MD (*Presenter*)
Ali Agely, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Identify the normal anatomy and common variants of the cystic duct with their surgical and diagnostic implications. 2. Describe the imaging features of key cystic duct pathologies across multiple modalities. 3. Explain the role of interventions in managing cystic duct disorders to guide radiologic reporting for optimal treatment planning. 4. Recognize postoperative appearances and complications of the cystic duct to differentiate normal from abnormal findings. 5. Apply strategies to avoid diagnostic pitfalls for enhanced diagnostic accuracy.

TABLE OF CONTENTS/OUTLINE

Introduction Normal Cystic Duct Anatomy Anatomic Variants Clinical Significance of Variants Calculus disease pre-cholecystctomy, Mirizzi syndrome Calculus disease post-cholecystectomy, complications Malignancy Inflammatory conditions

GIEE-138 ABDOMINAL FIBROMATOSIS: MULTIMODALITY IMAGING INSIGHTS INTO A CHALLENGING ABDOMINAL MIMICKER

Max Andresen III, MD (*Presenter*)
Cristian Varela, MD (*Abstract Co-Author*)
Maria J. Baladron, MD (*Abstract Co-Author*)
Ignacio Maldonado, MD (*Abstract Co-Author*)
Rocio Macarena Castro Venegas, MD (*Abstract Co-Author*)

TEACHING POINTS

• Review the imaging features of abdominal fibromatosis in multimodality imaging, including US, CT, MRI, and PET-CT.• Provide a case-based review of the typical and atypical abdominal fibromatosis presentations.• Highlight the fundamental role of imaging in diagnosis and assessing the disease's extent.• Emphasize the importance of recognizing abdominal fibromatosis and its potential to mimic other abdominal pathologies.• Outline the main risk factors associated with the development of abdominal fibromatosis.

TABLE OF CONTENTS/OUTLINE

• Overview of abdominal fibromatosis: clinical presentation, types, pathophysiology, epidemiology, and risk factors.• Multimodality imaging presentation of abdominal fibromatosis: case-based review of imaging features in US, CT, MRI, and PET-CT, highlighting typical and atypical manifestations.• Key differential diagnoses and significant diagnostic challenges in abdominal fibromatosis.• The role of imaging in the management and treatment assessment of abdominal fibromatosis.

GIEE-139 INFLAMED AND MISNAMED: A REVIEW OF APPENDICEAL PATHOLOGY OFF THE BEATEN PATH

Newton V. Nagirimadugu, MD (*Presenter*)
Yayone Rivaud, MD (*Abstract Co-Author*)
Melkamu D. Adeb, MD (*Abstract Co-Author*)

TEACHING POINTS

Appendiceal pathologies can be neoplastic or non-neoplastic. Neoplastic pathologies include LAMN, HAMN, appendiceal adenocarcinoma, neuroendocrine tumor (NET), lymphoma, and stromal tumors. Non-neoplastic pathologies include inflammation (e.g., acute appendicitis, stump appendicitis), inverted appendix, diverticulosis, endometriosis, IBD, and distal intestinal obstruction syndrome (DIOS). LAMN and HAMN often present with a thin-walled appendix containing low-attenuation mucin and may have calcifications or pseudomyxoma peritonei. Appendiceal NETs are typically incidental, mildly enhancing, and usually do not cause dilation; Ga-68 Dotatate PET can assist in diagnosis. Inverted appendix and endometriosis may mimic neoplasms or inflammation. DIOS in cystic fibrosis may cause an enlarged appendix with thick mucinous fecal material mimicking appendicitis. Non-appendiceal conditions like Crohn's disease, ovarian pathology, and hydrosalpinx may mimic appendiceal disease. Radiologists should understand the imaging workup of appendiceal pathologies, provide appropriate differentials, and distinguish mimics.

TABLE OF CONTENTS/OUTLINE

1. Overview of appendiceal pathology 2. Imaging (US, CT, MRI) strengths and limitations 3. Appendiceal pathologies Inflammation Acute appendicitis (uncomplicated, perforated, with abscess) Chronic/recurrent appendicitis Stump appendicitis Special considerations: pregnancy, pediatrics Neoplasms (with rad-path correlation) LAMN HAMN Adenocarcinoma Goblet cell carcinoma Neuroendocrine tumor Lymphoma Stromal tumors Other pathologies Endometriosis Inverted appendix DIOS Mimics Crohn’s disease Ovarian pathology Hydrosalpinx

GIEE-140 MASTERING FLUOROSCOPIC DEFECOGRAPHY: ANATOMY, TECHNIQUE AND DIAGNOSIS

Maria Isabel Leon Garcia, MD (*Presenter*)
Lourdes M. Avila, MD (*Abstract Co-Author*)

TEACHING POINTS

To review pelvic floor anatomy and illustrate the step-by-step fluoroscopic defecography protocol, including contrast materials, patient preparation, and positioning. To identify and analyze key radiographic landmarks, lines, angles, and measurements essential for diagnosing defecatory disorders such as incontinence, rectocele, intussusception and proctocele.

TABLE OF CONTENTS/OUTLINE

Overview of pelvic floor anatomy relevant to defecography Detailed protocol for fluoroscopic defecography: contrast agents, technique and patient instructions Anatomical findings and dynamic sequences during defecation Radiologic criteria and measurements for common pelvic floor disorders such as: Incontinence, Rectocele, Intussusception and Proctocele Case-based examples with annotated fluoroscopic images Practical tips and pitfalls in image interpretation

GIEE-141 BEYOND THE BASICS: ATYPICAL PRESENTATIONS AND PITFALLS IN PANCREATIC TUMOR IMAGING

Eisuke Mukaida, MD (*Presenter*)
Akio Tamura, MD (*Abstract Co-Author*)
Jun Obara, MD (*Abstract Co-Author*)
Kunihiro Yoshioka, MD (*Abstract Co-Author*)

TEACHING POINTS

Imaging diagnosis of pancreatic tumors requires an integrated evaluation of multiple factors, including patient age, sex, tumor location, vascular characteristics, internal structure, and the clinical course.This study reviews the imaging characteristics of major pancreatic neoplasms, including pancreatic cancer, IPMN, and SPN with particular emphasis on the following three aspects:

TABLE OF CONTENTS/OUTLINE

Table of Contents: 1. Reaffirming typical imaging findings: Enhancing the ability to accurately recognize characteristic tumor features. 2. Introducing atypical presentations: Showcasing cases that are commonly misdiagnosed in clinical practice. 3. Strategies to avoid diagnostic pitfalls: Highlighting key points to reduce misinterpretation, especially in distinguishing uncinate process tumors from extrapancreatic lesions. Outline: Pancreatic tumors encompass a range of histological types and origins, each with varied imaging findings. Accurate diagnosis is critical for determining treatment strategies. However, the risk of misdiagnosis depends on the tumor location, blood flow, and relationships with the surrounding organs, underscoring the importance of understanding the pitfalls and atypical presentations.This exhibition aims to reaffirm the typical features of various pancreatic tumors, present atypical cases encountered in clinical practice, and share perspectives to avoid misdiagnoses. Additionally, it references the 2019 WHO classification, which has renewed focus on PanIN, and the updated 2023 clinical guidelines for IPMN, to help organize and convey the latest knowledge.

GIEE-142 FLUOROSCOPY REVISITED: PICTORIAL INSIGHTS AND ITS ROLE IN POST-OPERATIVE ONCOLOGIC IMAGING

Sunil Kumar Puri, MD (*Presenter*)
Jitin Goyal, MBBS (*Abstract Co-Author*)
Prerna Garg, MD, MBBS (*Abstract Co-Author*)

TEACHING POINTS

1. Management of neck and gastro-oesophageal cancer involves surgery, in resectable cases and radiation either as primary or in adjuvant settings. Both can cause post treatment complications causing distress in the patient upsetting aftercare. 2. Interpretation of these complications needs adequate insight to the surgical steps on part of the reading radiologist, especially the site of anastomosis, which in majority is the culprit zone of leak. 3. Anastomotic leak causing respiratory distress, pulmonary complications and superadded infections in neck collection are factors responsible for post-surgical morbidity and mortality. 4. Barium is more sensitive than water soluble contrast for depiction of GI fistula due to inherent hyperosmolarity in later causing osmotic flux and dilution in bowel tract. 5. Instances when extraintestinal or possible vascular communication (life threatening embolization with barium) is suspected on clinical grounds, use of water-soluble contrast is advocated. 6. With regards to mediastinal aero-digestive tract this consensus is reversed due to adverse risk of pulmonary edema by ionic water-soluble contrast. 7. Cross-sectional imaging with computed tomography (CT) is less sensitive for direct visualization and assessment of fistulas in neck and upper gastro-intestinal tract, though extraluminal information conveyed by CT is unmatched.

TABLE OF CONTENTS/OUTLINE

Clinical cases with combined fluoroscopy and cross-sectional imaging in post treated cases of carcinoma of: Supra-glottis Glottis Hypo-pharynx Oesophagus Stomach

GIEE-143 BETTER TOGETHER: IMPROVING CLINICAL CARE THROUGH DIRECT GASTROENTEROLOGY AND RADIOLOGY COLLABORATION

Anup S. Shetty, MD (*Presenter*)
Vincent M. Mellnick, MD (*Abstract Co-Author*)
Richard Tsai, MD (*Abstract Co-Author*)

Tyler J. Fraum, MD (*Abstract Co-Author*)
Daniel R. Ludwig, MD (*Abstract Co-Author*)

TEACHING POINTS

Fragmentation of care and rising clinical volumes have reduced direct consultation between radiologists and gastroenterologists. Image evaluation without appropriate clinical context can result in less targeted and useful interpretations that do not address the "real" clinical question or lead to clinically unnecessary or even harmful invasive investigations. Through a series of case discussions, this exhibit illustrates how bi-directional collaboration between gastroenterologists and radiologists helps the radiologist provide more specific and accurate diagnoses and expand the differential diagnosis when appropriate. It will also highlight how interpretations can be tailored to the clinical scenario, particularly as patients may now routinely read their own reports. This exhibit will: 1) Describe the benefits of GI-radiology collaboration from the perspectives of both the gastroenterologist and the radiologist 2) Highlight instances in which this collaboration is essential for accurate imaging interpretation and appropriate clinical management 3) Illustrate this collaborative process for evaluating and managing complex patients through a series of cases

TABLE OF CONTENTS/OUTLINE

- GI/radiology collaboration: how we are better together? - Settings and circumstances: informal consultation, multidisciplinary conferences, intraprocedural consultation - A wish list: GI recommendations for more useful radiologic interpretations - Case illustrations: inflammatory pancreaticobiliary disease, bile leaks, indeterminate liver lesions, GI malignancies, active bleeding, outside imaging second opinion consultations, brokering differing opinions among consulting services

GIEE-144 PEARLS AND PITFALLS OF THE LI-RADS V2024 CT/MRI RADIATION TREATMENT RESPONSE ALGORITHM

Ava Mirtsching, MD (*Presenter*)
Kethan Lala (*Abstract Co-Author*)
Hala A. Khasawneh, MBBS (*Abstract Co-Author*)
Takeshi Yokoo, MD, PhD (*Abstract Co-Author*)
Gaurav Khatri, MD (*Abstract Co-Author*)
Mishal Mendiratta-Lala, MD (*Abstract Co-Author*)

TEACHING POINTS

• Updated LI-RADS 2024 CT/MRI Radiation Treatment Response Algorithm (TRA) provides succinct criteria for determining tumor viability and emphasizes interval change assessment. • Accounts for expected post radiation changes: persistent arterial phase masslike hyperenhancement, peri-tumoral perfusion.• Introducing LR-TR nonprogressing replacing LR-TR equivocal for radiation-based locoregional therapies (LRTs).• Viability defined by masslike enhancement on any postcontrast phase.• Use of ancillary features to identify LR-TR viable observations that would not have been captured using the 2017 criteria.• TRA is applicable for HCC and LR-M observations after radiation-based LRTs.

TABLE OF CONTENTS/OUTLINE

1. LI-RADS 2024 Radiation TRA Criteria.- LR-TR nonprogressing vs LR-TR equivocal.- Presence vs absence of masslike enhancement.- Optional ancillary features for tumor viability: DWI, T2w-signal intensity.2. Pearls/Pitfalls in application of the 2024 Radiation TRA.- Measurement of masslike enhancement: single dimension.- Categorizing cases where unable to delineate treated observations from surrounding parenchymal changes.- Cases when unsure of posttreatment change or tumor viability.- Must exclude increase in size of masslike enhancement prior to categorizing as LR-TR nonprogressing.- Utility of DWI images for detecting early LR-TR viable.- Utility of peri-procedural images to assess response.- Combination of both radiation based and non-radiation based LRTs.

GIEE-145 BRIDGING THE GAP: IMAGING OF LUMEN APPOSING METALLIC STENTS

Ananya Panda, MD, MBBS (*Presenter*)
Maheen Rajput, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Gilles Hoilat, MD (*Abstract Co-Author*)
Munish Ashat (*Abstract Co-Author*)
Rami El Abiad (*Abstract Co-Author*)

TEACHING POINTS

1. To describe technique and imaging of lumen apposing metallic stents (LAMS) in management of pancreatitis 2. To discuss techniques and imaging appearances of LAMS in other novel indications 3. To review imaging of complications of LAMS

TABLE OF CONTENTS/OUTLINE

Lumen Apposing Metallic Stent (LAMS) acts as a bridge between two body cavities. It was initially devised for pancreatic fluid collections and walled off necrosis. Now, the uses have become diverse and innovative. The exhibit will: 1) Describe endoscopic techniques and imaging appearances of LAMS for the following established and emerging indications: (A) Management of peripancreatic fluid collections: Cyst-gastrostomy , Cyst-duodenostomy, Cyst-esophagostomy (B) Endoscopic Ultrasound Directed transGastric ERCP (EDGE) procedure for Roux-en-Y gastric bypass reversal prior to ERCP and other endoscopic procedures (C) Reversal of vertical banded gastroplasty for obstructive symptoms (D) Gastro-enterostomy (E) Choledocho-duodenostomy (F) Trans-gallbladder drainage: Cholecysto-duodenostomy, Cholecysto-gastrostomy (G) Trans-gastric hepatic drainage (H) Drainage of other post-operative collections (I) Treatment of benign enteric strictures 2) Review imaging appearances of complications of LAMS: (A) Misdeployment (B) Perforation (C) Bleeding (D) Migration (E) Buried LAMS (F) Occlusion (G) Infection (H) Bowel Obstruction (I): Fistula

GIEE-146 INFILTRATIVE HEPATOCELLULAR CARCINOMA: THE HIDDEN GIANT

Margrit E. Muller, MD (*Presenter*)
Lara Quiche, MD (*Abstract Co-Author*)
Thiago M. Baraviera, MD (*Abstract Co-Author*)
Cassia F. Tridente, MD (*Abstract Co-Author*)
Thais Mussi, MD, PhD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

- Infiltrative hepatocellular carcinoma (HCC) often lacks a defined mass and classic enhancement patterns, which makes its diagnosis particularly challenging. - Tumor thrombus in the portal vein is a critical imaging finding that should raise suspicion of infiltrative HCC. - MRI, particularly with diffusion-weighted imaging (DWI) and T2-weighted sequences, significantly improves diagnostic accuracy. - Infiltrative liver lesions that do not meet the criteria for LR-5 or LR-TIV are classified as LR-M under the LI-RADS system. - Although LR-M includes metastases and cholangiocarcinoma in the differential diagnosis, many of these cases may represent infiltrative HCC. - Recognizing the infiltrative pattern is crucial for avoiding unnecessary biopsies and ensuring appropriate management. - Differential diagnosis includes hepatic metastases, confluent fibrosis, intrahepatic and cholangiocarcinoma.

TABLE OF CONTENTS/OUTLINE

Background and Epidemiology. Pathophysiology and Imaging Challenges. CT and MRI Findings: - Absence of mass formation; - Vascular patterns and tumor thrombus; - Role of Diffusion-Weighted and T2-Weighted sequences. LI-RADS Classification. - Case-Based Review: Disease Extent; Common Complications. Differential Diagnosis Take-Home Messages

GIEE-147 COLORECTAL LIVER METASTASES: IMAGING STRATEGIES FOR DIAGNOSIS, LOCAL TREATMENT PLANNING AND SYSTEMIC TREATMENT RESPONSE

Arya Kermanshah (*Presenter*)
Arinc Ozturk, MD (*Abstract Co-Author*)
Jacobo Alvo, MD (*Abstract Co-Author*)
Francesco Alessandrino, MD (*Abstract Co-Author*)

TEACHING POINTS

? Review current imaging guidelines for colorectal liver metastasis (CRLM) ? Describe the imaging features of CRLM before and after systemic and locoregional treatment ? Recognize essentials for treatment planning ? Outline optimal imaging strategies and highlight emerging technologies

TABLE OF CONTENTS/OUTLINE

Representative imaging examples will be provided for each section. 1. Imaging Guidelines ? Role of: CT; MRI with hepatobiliary vs extracellular agent; PET/CT (NCCN, ACR, ESGAR guidelines) 2. Primary CRLM ? Adenocarcinoma not otherwise specified: central necrosis, rim enhancement, desmoplasia, DWI positivity ? Mucinous adenocarcinoma: cystic-like morphology, peripheral rim enhancement, DWI negativity ? Growth patterns: capsulated, pushing, infiltrative 3. CRLM after systemic treatment ? Expected morphologic changes and how to interpret them? Tumor response criteria: - i. Chun criteria: attenuation, lesion-liver interface, rim enhancement - ii. RECIST 1.1 - iii. mRECIST ? Role of DWI-ADC values and correlation with tumor regression grade 4. Considerations for surgery and locoregional therapies ? Chemotherapy-related liver changes (e.g., steatosis, sinusoidal obstruction syndrome), vascular hepatic anatomy assessment, how to identify CRLM in a treated liver ? Relevant tips to identify recurrence after surgery and locoregional therapies 5. Optimal Imaging Strategies and Emerging Technologies ? From the PROMETEO-01 study to the CAMINO trial: evidence from the literature ? MRI ECA vs MRI HBP + DWI vs CT vs FDG PET/CT: which clinical scenario for each modality (with case examples) ? Emerging Technologies: when/how ctDNA aids in imaging interpretation, radiomics; artificial intelligence

GIEE-148 THE DARK SIDE OF PERIANAL MRI: MIMICS THAT CHALLENGE DIAGNOSIS

Michelle Estefania Gonzalez Cordova, MD (*Presenter*)
Rocio Gutierrez Rodriguez, MD (*Abstract Co-Author*)
Pablo V. Gil-Nagel Rodriguez, MD (*Abstract Co-Author*)
Donna Zhan Chen, MD (*Abstract Co-Author*)
Jose Carlos Garcia-Gil Garcia, MBBCh (*Abstract Co-Author*)
Lourdes del Campo, PhD (*Abstract Co-Author*)

TEACHING POINTS

To review the anatomy of the anal canal, perianal region, and pelvis for accurate disease localization.To identify imaging features that suggest mimickers of fistulizing disease or associated underlying pathology.

TABLE OF CONTENTS/OUTLINE

There is a wide range of entities that could affect perianal regions, including benign and malignant processes. Although medical history and physical examination remain fundamental in guiding the diagnosis, imaging studies play a crucial role to provide a reliable differential diagnosis and accurate localization of the disease, for which a comprehensive knowledge of anatomy is essential. Magnetic resonance imaging (MRI) may also demonstrate pathological findings that mimic true fistulous tracts, which represents a diagnostic challenge with significant clinical implications. Common fistula mimickers include pilonidal and retrorectal cyst, perianal hidradenitis suppurativa, hemorrhoids, postsurgical scars, as well as iatrogenic or traumatic lesions, and perianal neoplastic masses. Fistula MRIs from the past three years were reviewed, compiling the cases and analyzing the pathological anatomy of the identified lesions.

GIEE-149 MRI FEATURES OF FONTAN-ASSOCIATED LIVER DISEASE

Michinobu Nagao, MD, PhD (*Presenter*)
Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*)
Akihiro Inoue, MD (*Abstract Co-Author*)
Reiko Sakai (*Abstract Co-Author*)
Satoru Morita, MD, PhD (*Abstract Co-Author*)
Kei Inai (*Abstract Co-Author*)
Masami Yoneyama (*Abstract Co-Author*)
Shuji Sakai, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Although the results of Fontan procedure have been improving, it is known that arrhythmia, thromboembolism, heart failure, liver cirrhosis, and other systemic organ failure may occur over the long-term course. In particular, liver complications are called Fontan-associated liver disease (FALD), which not infrequently progresses to cirrhosis and hepatocellular carcinoma (HCC), and is reported to be associated with high mortality. Gd-EOB-DTPA MRI has the advantage of simultaneously screening for HCC and evaluating liver damage, and is suitable for follow-up of young patients because of the lack of X-ray exposure. In the Gd-EOB-DTPA hepatocyte phase, reticular low intensity mainly in the peripheral regions of the liver and decreased signal ratio of liver to spleen are characteristic findings reflecting FALD pathologies. HCC on FALD often shows high signal in the hepatocyte phase with no washout in the venous phase and no significant contrast effect in the arterial phase. FALD-occurring HCCs have a tendency toward slow enlargement, the development of partial low-signal areas in the hepatocyte phase, and diffusion restriction, which distinguish them from focal nodular hyperplasia (FNH)-like lesions. Recently, MR lymphangiography to noninvasively delineate lymphatic congestion occurring in FALD and cardiac MRI to analyze hepatic T1 map and hepatic strain for the assessment of liver fibrosis have been reported. We discuss upcoming MRI imaging and analytic technology, and introduces their clinical applications.

TABLE OF CONTENTS/OUTLINE

1) Gd-EOB-DTPA MRI features of FALD. 2) Differentiation between HCC and FNH-like lesion. 3) MR lymphagiography. 4) Cardiac MRI applications

GIEE-150 PROBING THE PERIPORTAL SPACE

Galib Mirza Nasirul Islam, MBBS (*Presenter*)
Ananya Panda, MD, MBBS (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Maria Zulfiqar, MD, MBBS (*Abstract Co-Author*)
Victoria Chernyak, MD, MS (*Abstract Co-Author*)
Leonardo G. Marcelino, MD (*Abstract Co-Author*)
Mahan Mathur, MD (*Abstract Co-Author*)

TEACHING POINTS

1. To discuss the anatomy of periportal space (PPS) 2. To describe role of imaging in evaluation of PPS and its pathologies 3. To review imaging findings in pathologies affecting PPS

TABLE OF CONTENTS/OUTLINE

The PPS is a potential space surrounding the intrahepatic portal vein and its intrahepatic branches. It extends from the porta hepatis throughout both hepatic lobes, The exhibit includes conditions which are affect the periportal space.Vascular • Portal vein: Periportal venous collaterals • Hepatic artery: Hereditary hemorrhagic, telangiectasia, pseudoaneurysm, segmental arterial mediolysis Infectious/Inflammatory • IgG4?• Sarcoidosis• Schistosomiasis • Hemophagocytic lymphohistiocystosis Biliary •Peribiliary cysts • Primary biliary cirrhosis Tumors Primary •Cholangiocarcinoma ?•Chloroma? •Lymphoma & Post-transplant lymphoproliferative disorder •Langerhans cell histiocytosis •Erdheim-Chester disease ?•Multiple myeloma •Neurofibromatosis •Schwannoma? •Kaposi? sarcoma •Inflammatory pseudotumor? Secondary •Hepatocellular carcinoma? •Hepatoblastoma? •Gall bladder cancer?•Peritoneal carcinomatosis? •Pseudomyxoma? peritonei •Contiguous spread? from other

malignancies •Metastatic calcification Miscellaneous •Extramedullary hematopoiesis? •Periportal fibrosis in cystic fibrosis? Mimics of PPS pathologies •Periportal edema? •Enlarged periportal space •Periportal steatosis •Periportal iron deposition

GIEE-151 BENIGN LIVER TUMORS AND TUMOR-LIKE LESIONS: CROSS-SECTIONAL IMAGING SPECTRUM

Nariman Khan, MD (*Presenter*)
Nathaniel Gill (*Abstract Co-Author*)
Arun Parameswaran (*Abstract Co-Author*)
Anil K. Dasyam, MD (*Abstract Co-Author*)
Amir Borhani, MD (*Abstract Co-Author*)
Narayan Lath, MBBS, FRCR (*Abstract Co-Author*)
Alia Nazarullah (*Abstract Co-Author*)
Venkata S. Katabathina, MD (*Abstract Co-Author*)

TEACHING POINTS

List benign liver tumors and tumor-like lesions in normal, steatotic, and cirrhotic livers Describe imaging spectrum of typical and atypical hemangiomas, focal nodular hyperplasia (FNH), and hepatocellular adenomas (HCAs) Discuss imaging findings of tumor-like lesions in steatotic liver benign lesions & pseudo lesions in cirrhotic liver Discuss role of imaging in detection & management of benign liver lesions

TABLE OF CONTENTS/OUTLINE

Introduction Classification: Hepatocellular, cholangiocellular, mesenchymal, mesenchymal tumors & tumor-like lesions Imaging techniques & role of Eovist contrast HCAs: Inflammatory, steatotic, beta-catenin mutated, unclassified & novel types FNH: typical & atypical findings Hemangiomas: Classic, atypical & rare Hepatic cysts Biliary hamartomas Peribiliary cyst/Caroli's disease Focal fat deposition/focal fat sparing Angiomyolipoma & Lipoma Peliosis hepatis Inflammatory pseudotumors Iatrogenic pseudotumors: treatment-related effects, retractor injury & surgical defects Benign Lesions in Cirrhosis: peribiliary cysts/hepatic cysts, hemangiomas, regenerating/dysplastic nodules, FNH-Like lesions, third inflow causing perfusion defects, THIDs/THADs, AV shunts, confluent hepatic fibrosis, focal fat sparing, nodular regenerating hyperplasia (NRH)Imaging plays a pivotal role in differentials benign liver lesions & pseudo lesions from malignancy; this helps to avoid unnecessary aggressive therapies. MRI with Eovist contrast is very helpful in characterizing benign liver masses and pseudo masses.

GIEE-152 RARE EPITHELIAL PANCREATIC TUMORS

Kumaresan Sandrasegaran, MD (*Presenter*)
Camila Lopes Vendrami, MD (*Abstract Co-Author*)
Komal A. Chughtai, MD (*Abstract Co-Author*)
Kelsey McHugh (*Abstract Co-Author*)
Motoyo Yano, MD, PhD (*Abstract Co-Author*)
Pardeep K. Mittal, MD (*Abstract Co-Author*)
David Escobar, MD,PhD (*Abstract Co-Author*)
Nancy A. Hammond, MD (*Abstract Co-Author*)
Frank H. Miller, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Provide a broad overview of the rare epithelial pancreatic tumors 2. Review the radiology-pathology classification of these tumors 3. Knowledge of some of the unique imaging and clinical features of these tumors that assist in their diagnosis

TABLE OF CONTENTS/OUTLINE

This focus of this exhibit will be the uncommon epithelial pancreatic tumors that together account for less than 10% of all pancreatic neoplasms. We will not discuss the common tumors such as pancreatic ductal adenocarcinoma (PDAC), pancreatic neuroendocrine tumor (PNET) or intraductal pancreatic mucous tumor. 1. Introduction 2. Pathological classification of rare epithelial tumors a. Benign epithelial tumors: including mixed serous-neuroendocrine tumor, intraductal oncocytic neoplasm tumors. b. Variants of PDAC: including colloid, adenosquamous, signet ring cell, medullary, hepatoid carcinomas c. Variants of PNET: including oncocytic PNET, mixed acinar-neuroendocrine carcinoma d. Other malignant epithelial tumors: including acinar cell cancer, pancreatoblastoma 3. Radiology-pathology correlation of these tumors 4. Unique imaging appearances and clinical features that help in the diagnosis of some of these cases 5. Conclusion/Take home points

GIEE-153 RARE NONEPITHELIAL PANCREATIC TUMORS

Kumaresan Sandrasegaran, MD (*Presenter*)
Komal A. Chughtai, MD (*Abstract Co-Author*)
Camila Lopes Vendrami, MD (*Abstract Co-Author*)
Kelsey McHugh (*Abstract Co-Author*)
Motoyo Yano, MD, PhD (*Abstract Co-Author*)
Pardeep K. Mittal, MD (*Abstract Co-Author*)
Nancy A. Hammond, MD (*Abstract Co-Author*)
David Escobar, MD,PhD (*Abstract Co-Author*)
Frank H. Miller, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Provide a broad overview of the nonepithelial pancreatic tumors 2. Review the radiology-pathology classification of these tumors 3. Knowledge of some of the unique imaging and clinical features of these tumors that help to identify them

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Pathological classification of nonepithelial tumors a. Benign / borderline nonepithelial tumors: including neurogenic tumors, pancreatic dermoid, inflammatory myofibroblastic tumor, solitary fibrous tumor, PEComa b. Malignant nonepithelial tumors: including Ewing sarcoma, pancreatic GI stromal tumor c. Hematologic malignancies: including lymphoma, granulocytic sarcoma, plasmacytoma 3. Radiology-pathology correlation of these tumors 4. Unique imaging appearances and clinical features that help in the diagnosis of some of these cases 5. Conclusion/Take home points

GIEE-154 ASSESSING HEPATO-BILIARY MORPHOLOGY AND FUNCTION IN PRIMARY SCLEROSING CHOLANGITIS (PSC)

Kumaresan Sandrasegaran, MD (*Presenter*)
Amar Shah, MD (*Abstract Co-Author*)
Elizabeth Carey, MD (*Abstract Co-Author*)
Aubrienne Silva (*Abstract Co-Author*)
Anshuman Panda, PhD (*Abstract Co-Author*)
Sudhakar K. Venkatesh, MD, FRCR (*Abstract Co-Author*)
Alvin C. Silva, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Review the diagnosis, clinical features and natural history of PSC 2. Understand the newer MRI scoring systems for PSC and how these correlate with clinical scoring systems 3. Learn the newer MRI techniques in PSC and how they may help determine treatment and prognosis treatment

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Clinical Features of PSC a. PSC variants 3. Natural History of PSC 4. MRI Standardized Reporting Template for PSC 5. Clinical Scoring Models used in PSC a. Mayo Risk Score b. Oxford-Amsterdam Model c. United Kingdom PSC Score 6. ANALI Score and Functional Liver Imaging Score (FLIS) 7. Useful MRI techniques in PSC a. MR elastography b. T1 mapping c. Functional parameters from gadoxetate-enhanced MRI i. Relative enhancement of liver ii. Relative enhancement of bile ducts iii. Bile flow velocity 8. Standard treatment of PSC 9. Newer treatment paradigm in PSC a. MRI biomarkers that may help determine treatment efficacy 10. Conclusions

GIEE-155 GASTRIC IMAGING - COMPREHENSIVE APPROACH AND HOW TO AVOID MISDIAGNOSIS

Yudel Tamayo, MD, RDMS (*Presenter*)

TEACHING POINTS

The normal gastric wall, rugae and lumen should be analyzed for normal enhancement and preservation of luminal capacity. Sites of edema, ulceration with or without gastric perforation must be recognized. The peritoneal spread of gastric cancer with Krukenberg tumours will be illustrated. The contrast retention by fibrosis in Signet Ring adenocarcinoma (Linitis Plastica) will be emphasized. Correlative angiographic and endoscopic studies add greater comprehension to imaging studies.

TABLE OF CONTENTS/OUTLINE

Gastric conditions prevail in critically ill, environmental exposure and genetic predispose patients requiring a comprehensive approach to gastric imaging. We will illustrate gastric and duodenal ulcers (with and without perforation), GI bleeding (PUD, Dieulafoy lesion) with CT Angiography, H. pylori and other causes of gastritis, Menetriers disease, benign and malignant neoplasms, Linitis Plastica associated to luminal deformity and contrast retention, peritoneal carcinomatosis and Krukenberg tumours, Genetic associated gastric neoplasms (Lynch and FGFR2 carriers) and postop changes and complications sling, gastric band, and Nissan fundoplication. Correlative fluoroscopic, CT and MRI and angiographic studies will be included. Endoscopic correlation will be included when available. We will provide clues to avoid misdiagnosis such as ingested high density material, peristaltic wave and absence of distention.

GIEE-156 OFF THE BEATEN POUCH: UNCOMMON ROUTES OF DIVERTICULITIS

James Hwang, MD (*Presenter*)
Billy S. Chien, MD (*Abstract Co-Author*)
Satheesh Krishna, MD (*Abstract Co-Author*)
Yashant Aswani, MD (*Abstract Co-Author*)
Helena Gabriel, MD (*Abstract Co-Author*)
Paul Nikolaidis, MD (*Abstract Co-Author*)
Meghan G. Lubner, MD (*Abstract Co-Author*)
Perry J. Pickhardt, MD (*Abstract Co-Author*)
Mark D. Sugi, MD (*Abstract Co-Author*)
Rachita Khot, MD (*Abstract Co-Author*)
Margarita V. Revzin, MD, MS (*Abstract Co-Author*)

TEACHING POINTS

- Diverticulitis can present in ways other than the typical left lower quadrant pain commonly seen with sigmoid diverticulitis. - Smoldering diverticulitis is an underrecognized chronic form of diverticulitis. - Rare complications of diverticulitis include pylephlebitis and mycotic aneurysm. - Non-classic diverticulitis has numerous more common mimics (e.g., appendicitis, cholecystitis, tubo-ovarian abscess, malignancy), and a comprehensive understanding of the unique imaging features of these similar diagnoses is crucial to making an accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

- Background information about the prevalence of diverticulosis and diverticulitis. - Diagram and description of the gastrointestinal tract, where diverticula are found, and their frequency. - Brief overview of the typical findings of uncomplicated diverticulitis. - In-depth review of the rarer, non-classic presentations of diverticulitis. - Mention of smoldering diverticulitis as an under-recognized form of diverticulitis. - Overview of the common complications of diverticulitis, including abscess, perforation, and fistulation. - Discussion of rare complications of diverticulitis, including pylephlebitis and vascular involvement (mycotic aneurysm). - Discussion of how these non-classic presentations can mimic other diagnoses. - Case-based figures of rare presentations of diverticulitis, including appendiceal diverticulitis, smoldering diverticulitis and pylephlebitis.

GIEE-157 STRATEGIC MAPPING OF GASTRIC CANCER: THE RADIOLOGIST'S ROLE IN MULTIMODAL STAGING AND THERAPEUTIC PLANNING

Renan Arakaki, MD (*Presenter*)
Thais Ribeiro, MD (*Abstract Co-Author*)
Aley Talans, MD (*Abstract Co-Author*)
Frank Shigueo Nakao (*Abstract Co-Author*)
Eduardo O. Pacheco, MSc, MD (*Abstract Co-Author*)
Ulysses S. Torres, MD, PhD (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the imaging anatomy and histological correlation of the stomach across CT, MRI, and endoscopic ultrasound. 2. Recognize the strengths and limitations of different imaging modalities in the staging of gastric cancer (T, N, and M). 3. Identify key imaging features that directly impact oncologic and surgical decision-making. 4. Be prepared to detect acute complications related to gastric tumors, including obstruction, perforation, and bleeding. 5. Familiarize with imaging characteristics of less common gastric tumors beyond adenocarcinoma.

TABLE OF CONTENTS/OUTLINE

1. Review the anatomy and histology of the stomach with correlation to imaging methods: computed tomography, magnetic resonance imaging, and endoscopic ultrasound. 2. Detail the staging of gastric cancer with a focus on practical tips regarding what oncologists and surgeons need to know. 3. Highlight the strengths and weaknesses of imaging methods (CT, MRI, PET-CT, endoscopic ultrasound) in T, N, and M staging. 4. Demonstrate practical cases from diagnosis, staging to management decisions of gastric neoplasms. 5. Present acute complications that the patient may experience as a result of a gastric tumor. 6. Review other types of tumors beyond gastric adenocarcinoma and their presentation in imaging methods (GIST, lymphoma and lipoma).

GIEE-158 ACQUIRED ABDOMINAL FISTULAS: IMAGING APPROACH AND PROTOCOL OPTIMIZATION - HOW WE DO IT

Camila P. Reifegerste, MD (*Presenter*)
Catarina Caldas (*Abstract Co-Author*)
Carolina P. Abud, MD (*Abstract Co-Author*)
Ana Claudia Vincenzi Raduan Uski (*Abstract Co-Author*)
Maria Helena N. Pedroso (*Abstract Co-Author*)
Sofia B. Maksoud, MD (*Abstract Co-Author*)

TEACHING POINTS

Fistulas in the abdominal cavity represent a diagnostic challenge and often require tailored imaging strategies for accurate detection. This Education Exhibit proposes standardized computed tomography (CT) and magnetic ressonance imaging (MRI) protocols for the evaluation of abdominal fistulas, based on our institution's clinical

experience.We have observed that certain protocols described in the literature may be suboptimal for detecting specific fistula types. For example, abdominal CT for gastrointestinal fistulas may be limited by the use of overly diluted oral iodinated contrast. Likewise, protocols evaluating vesicourethral anastomotic fistulas after prostatectomy may fail to demonstrate the fistulous tract if the excretory phase is performed too early.From these observations, we were motivated to share our experience in fistula detection and the imaging protocols currently employed at our institution, aiming to improve diagnostic accuracy and support timely and effective patient management.

TABLE OF CONTENTS/OUTLINE

1.Introduction 2.Abdominal acquired fistula cases, teaching points and practical considerations: (a) Esophageal, gastric, and proximal small bowel fistulas (b) Distal small bowel fistulas (c) Colonic and rectal fistulas (d)Urinary tract fistulas (e) Biliary fistulas (f) Pancreatic fistulas 3.Protocol pearls and practical tips 4.Summary

GIEE-159 THE BULGING PANCREAS: UNMASKING CAUSES BEYOND AUTOIMMUNITY

Julia Espindola Guimaraes (*Presenter*)
Thiago Fachini Nogueira, MD (*Abstract Co-Author*)
Aley Talans, MD (*Abstract Co-Author*)
Daniel Bekhor, MD (*Abstract Co-Author*)
Larissa R. Favaro (*Abstract Co-Author*)
Matheus M. Gomes SR, MD (*Abstract Co-Author*)
Daniella B. Parente, MD, PhD (*Abstract Co-Author*)
Eduardo O. Pacheco, MSc, MD (*Abstract Co-Author*)
Ulysses S. Torres, MD, PhD (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Recognize diffuse pancreatic enlargement, normal size thresholds and associated conditions. Review differential diagnoses associated with pancreatic enlargement: lymphoma, metastases, neuroendocrine tumors, diffuse adenocarcinoma, lipomatosis, Von Hippel-Lindau syndrome, and Mavash syndrome. Deepen knowledge of autoimmune pancreatitis, imaging findings and diagnostic criteria. Understand the clinical context and the radiologist’s role in managing autoimmune pancreatitis. Differentiate between benign and malignant causes of pancreatic enlargement.

TABLE OF CONTENTS/OUTLINE

Measurement Criteria for Pancreatic Enlargement : Review of normal pancreatic size parameters and thresholds defining diffuse enlargement with imaging examples; Differential Diagnoses and Case-Based Learning : Review of benign and malignant causes of pancreatic enlargement, illustrated with clinical cases (lymphoma, metastases, neuroendocrine tumors, diffuse adenocarcinoma, lipomatosis, Von Hippel-Lindau syndrome, Mavash syndrome), emphasizing imaging patterns and key diagnostic clues; Autoimmune Pancreatitis Review of imaging features across ultrasound, CT, and MRI; presentation of the International Consensus Diagnostic Criteria, key serologic and laboratory findings; Diagnostic Approach and Workflow: Flowchart integrating clinical and imaging findings to differentiate autoimmune pancreatitis from other diseases; Red Flags for Malignancy: Key imaging features that suggest malignant causes of pancreatic enlargement with representative cases; Summary and Take-Home Messages: Consolidation of the main diagnostic strategies, imaging pearls, and practical tips for clinical practice.

GIEE-160 POSTOPERATIVE IMAGING OF ESOPHAGECTOMY A TEACHING CASE SERIES FOR RADIOLOGY RESIDENTS

Sofia Renee Acuna Barrera, MD, MD (*Presenter*)
Bethsabel Rodriguez Encinas, MD (*Abstract Co-Author*)
Lourdes M. Avila, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the surgical management of esophagectomy.Recognize the anatomy of the esophagectomy on barium swallow studies.Identify the main characteristics of different types of conduit and route adaptations through barium swallow studies. Explain the complications associated with post-surgical changes in esophagectomy.

TABLE OF CONTENTS/OUTLINE

Introduction: Types of esophagectomy management surgerys. Fluroscopy protocol: What to look for?Anatomical Changes:Cervical approach.Thoracic aproach.Esophageal Replacement Routes:Posterior mediastinal route.Retroesternal route.Subcutaneous route.Conduit Types & Route Adaptation:Gastric conduit.Colon Conduit. Yeyunal or Ileal Conduit.Post-Surgical Complications of esophagectomy:Types of complications of esophagectomy according to evolution.Clinical cases Description on fluoroscopic images of post-surgical complications and what to look for Summary:Key points.

GIEE-161 CRITICAL INSIGHTS INTO PANCREATIC ADENOCARCINOMA: PERINEURAL SPREAD, MESOPANCREAS, AND HEPATIC METASTASIS

Salie Oliveira, MD (*Presenter*)
Thiago De Sousa (*Abstract Co-Author*)
Paulo Falcao, MD (*Abstract Co-Author*)
Tiara Vitalino Galvao, MD (*Abstract Co-Author*)
Eduardo M. Araujo, MD (*Abstract Co-Author*)

TEACHING POINTS

Perineural spread in pancreatic adenocarcinoma is associated with poorer prognosis and imaging challenges. The mesopancreas is a key surgical and anatomical structure affecting tumor spread and resection completeness. Hepatic metastasis distribution varies according to tumor location, likely influenced by venous streamline patterns. Multimodal imaging improves detection and guides therapeutic planning in pancreatic cancer. Radiologists play a key role in assessing these features to support curative strategies.

TABLE OF CONTENTS/OUTLINE

Introduction Imaging is essential in the detection, staging, and surgical planning of pancreatic adenocarcinoma. Perineural Spread Tumor infiltration along nerve fascicles is common and clinically significant. Recognition of imaging signs is crucial for prognosis and therapy decisions. Mesopancreas The main site of locoregional spread. Understanding its anatomy improves surgical planning and R0 resection rates. Hepatic Metastasis Distribution Portal venous drainage anatomy influences the lobar distribution of liver metastases. Tumors in the pancreatic head tend to metastasize to the right lobe; body/tail to both lobes. Conclusion Awareness of these three imaging aspects enhances diagnostic accuracy and informs treatment strategies in pancreatic cancer.

Abstract Archives of the RSNA, 2025

GUEE

Genitourinary Imaging Education Exhibits

Thursday, Dec. 4 9:00AM - 6:00PM Room: LEARNING CENTER

Sub-Events

GUEE-1 RADIOLOGIC ASSESSMENT OF URETEROPELVIC JUNCTION OBSTRUCTION IN ADULTS: A PICTORIAL REVIEW

Sarah Anderson, MD (*Presenter*)
Mark D. Sugi, MD (*Abstract Co-Author*)
Hiroaki Takahashi, MD, PhD (*Abstract Co-Author*)
Naoki Takahashi, MD (*Abstract Co-Author*)
Akira Kawashima, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Identify key diagnostic findings in the workup of ureteropelvic junction (UPJ) obstruction in adults to help guide management and intervention. 2. Illustrate intrinsic and extrinsic causes of UPJ obstruction in adults and common imaging appearances on multiple modalities including CT, MR, diuretic renography, ultrasound and radiography. 3. Recognize mimics and systemic processes that may cause UPJ obstruction as well as expected imaging findings after surgical intervention.

TABLE OF CONTENTS/OUTLINE

I. Background II. Adult causes of UPJ obstruction a. Congenital UPJ obstruction b. UPJ obstruction associated with aberrant crossing vessel c. Renal stones d. Neoplasms i. Urothelial cell carcinoma ii. Lymphoma iii. Metastases e. Anatomic obstruction i. Infectious/inflammatory stricture ii. Postsurgical fibrosis iii. Horseshoe and duplex kidneys iv. Crossing vessels f. Mimics i. Chronic atrophic pyelonephritis ii. Peripelvic cysts iii. Megacalycosis g. Miscellaneous i. Retroperitoneal fibrosis ii. Systemic conditions (amyloidosis, Erdheim-Chester disease) iii. Traumatic injury iv. Spontaneous hemorrhage III. Renal transplant UPJ obstruction IV. Functional imaging a. Diuretic renography V. Intervention a. Postoperative appearances of the UPJ after pyeloplasty and endopyelotomy

GUEE-2 PLOT TWISTS IN PROSTATE MRI: IT IS NOT ALWAYS ADENOCARCINOMA! UNCOMMON LESIONS AND THEIR MIMICKERS

Eduarda Bezerra Cirne, MD (*Presenter*)
Carlos A. Matsumoto, MD (*Abstract Co-Author*)
Marilia A. Tavares, MD (*Abstract Co-Author*)
Ruy R. Galves JR, MD, PhD (*Abstract Co-Author*)
Bruno A. Rocha, MD, PhD (*Abstract Co-Author*)
Eduardo O. Pacheco, MSc, MD (*Abstract Co-Author*)
Ulysses S. Torres, MD, PhD (*Abstract Co-Author*)
Giuseppe D'Ippolito, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Review the normal anatomy of the prostate and periprostatic tissues; Review and illustrate rare histological subtypes of non-acinar adenocarcinoma prostate neoplasms; Review benign prostate conditions that may mimic neoplasms; Propose a quick-reference guide for radiologists with the most representative imaging findings of these diagnoses, to support them when facing such challenging cases.

TABLE OF CONTENTS/OUTLINE

This exhibit offers a concise anatomical review of the prostate and periprostatic structures, emphasizing the histological elements involved in non-acinar prostate tumors. Through a case-based format, we explore rare neoplasms—including neuroendocrine tumors, sarcomas, lymphomas, STUMP, transitional cell, squamous cell, mucinous carcinoma, and metastases—alongside benign mimickers such as prostatitis, abscesses, atrophy, hyperplastic nodules, leiomyoma, and Cowper's gland nodules. Key clinical, epidemiological, and imaging features will be summarized, with practical MRI tips provided as a diagnostic guide for radiologists facing challenging prostate lesions.

GUEE-3 RENAL ARTERY MAPPING IN RCC SURGERY: THE UTILITY OF NITROGLYCERIN-ENHANCED CTA FOR PREOPERATIVE ASSESSMENT

Junichi Nakagawa (*Presenter*)
Norimi Nishiyama (*Abstract Co-Author*)
Takanori Masuda, PhD (*Abstract Co-Author*)
Shota Watanabe, PhD,RT (*Abstract Co-Author*)

TEACHING POINTS

Abdominal CTA is widely used for RCC surgery planning, but small vessels and anatomical variations often limit renal artery visualization, even with high-concentration contrast agents. This requires additional angiography, increasing radiation and contrast risks.Nitroglycerin-enhanced CTA improves vascular visibility by dilating renal arteries. This non-invasive, simple technique is independent of CT system specifications and can be implemented with institutional approval. This exhibit presents the protocol and workflow of nitroglycerin-enhanced CTA, includes quantitative and qualitative assessments with and without nitroglycerin, and showcases high-resolution 3D images demonstrating its value in RCC preoperative planning.

TABLE OF CONTENTS/OUTLINE

1. Introduction •Importance of vascular assessment in RCC surgery planning •Limitations of standard CTA 2. Clinical Problem •Suboptimal visualization of renal arteries •Risks of additional angiography (radiation, contrast) 3. Proposed Solution •Nitroglycerin-induced vasodilation •Advantages: non-invasive, widely applicable 4. Imaging Protocol •Nitroglycerin administration method and timing •CT acquisition parameters and reconstruction 5. Quantitative & Qualitative Assessment •Comparison of vessel visualization with and without nitroglycerin •Image quality and diagnostic confidence 6. Clinical Cases •Case examples before and after nitroglycerin •Impact on surgical planning 7. Key Teaching Points •Practical technique for routine use •Potential to reduce invasive procedures 8. Conclusion •Clinical utility in preoperative RCC evaluation •Feasibility across institutions

GUEE-4 A FIRM UNDERSTANDING: IMAGING OF PENILE PROSTHESES AND THEIR COMPLICATIONS

Cole J. Miller, MD, BS (*Presenter*)
Jena Depetris, BA, MD (*Abstract Co-Author*)
Anokh Pahwa, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Define erectile dysfunction (ED) and review its epidemiology. 2. Discuss the treatment options for ED. 3. Review penile anatomy. 4. Explain different types of penile prosthesis, their components, and imaging characteristics. 5. Describe the common and uncommon complications of PP. 6. Elucidate the pitfalls of penile prosthesis imaging interpretation.

TABLE OF CONTENTS/OUTLINE

We present a review of the imaging characteristics of penile prostheses and their complications. The explanation is accompanied by relevant cases from our hospital system. Discussion points include: Penile anatomy -Anatomical review -Appearance on CT/MRI Erectile dysfunction -Definition -Epidemiology -Overview of available treatments Penile Prosthetics -Types of PP -Components of various PP -Surgical placement & techniques -PP imaging characteristics & protocols Complications -Mechanical failure: leak, fracture, aneurysm -Malpositioning & Migration: rear tip extenders, reservoir herniation -Cylinder sizing error: Buckling, Concorde / supersonic transport deformity -Floppy glans -Erosion -Crossover -Infection Imaging pitfalls -Imaging exclusively in the deflated state -Asymmetric appearance of the penile cylinders

GUEE-5 REVIEW OF PI-RADS 3 - NAVIGATING THE AMBIGUITY OF DIAGNOSIS AND MANAGEMENT OF THIS EQUIVOCAL ENTITY

Sadina Shrestha, MD, MBBS (*Presenter*)
Mandeep S. Virk, MBBS, MD (*Abstract Co-Author*)
Swathi Kisara, MD (*Abstract Co-Author*)
Chakradhar R. Thupili, MD (*Abstract Co-Author*)
Varaha Tammisetti, MBBS, MD (*Abstract Co-Author*)

TEACHING POINTS

Understand the definition and prevalence of PI-RADS 3 category on biparametric and multiparametric prostate MRI and incidence of clinically significant prostate cancer. Definitions of PI-RADS 3 subcategories including 3a, 3b, upgraded and dominant lesions.Illustrate impact of MR imaging factors such as image quality, interobserver variability of prostate MR interpretations, overlap with benign entities such as stromal nodules, inflammation/prostatitis, lesion location and pre-existing diagnosis of non clinically significant prostate cancer.Understand and illustrate strategies to further risk-stratify PI-RADS 3 lesions using clinical biomarkers and morphologic risk factors such as patient's age, family history, PSA metrics kinetics, PSA density (>0.15 ng/mL/cc), tumor volume (<0.5 mL), MRI derived prostate gland volume (<36 mL), lesion shape (higher surface to volume ratio) to decrease the incidence of biopsies, especially in the setting of biparametric MRI.Discuss role of follow-up with PSMA PET using PRIMARY score to further risk stratify PI-RADS 3 lesions. Discuss MR-focused pathway and Risk-based pathway in making biopsy decisions and further surveillance with prostate MR.

TABLE OF CONTENTS/OUTLINE

Definition, prevalence, significance, and MR imaging findings of PI-RADS 3 category and subcategories.Imaging factors that cause PI-RADS mis-categorization.Bopsy vs. monitor approach.Risk stratification of PI-RADS 3 lesions with clinical biomarkers and MR imaging morphologic features.Risk stratification of PI-RADS 3 lesions with PSMA PET and PRIMARY score.Surveillance and biopsy strategies of PI-RADS 3 lesions.Future Considerations and Conclusions.

GUEE-6 THE PRESACRAL CONUNDRUM: IMAGING INSIGHTS INTO A COMPLEX SPACE

Kriti Kundu, MD,MBBS (*Presenter*)
Taruna Yadav, MD (*Abstract Co-Author*)
Binit Sureka, MBBS, MD (*Abstract Co-Author*)
Sarbesh Tiwari (*Abstract Co-Author*)
Ayushi Agarwal JR, MBBS (*Abstract Co-Author*)
Pushpinder S. Khera (*Abstract Co-Author*)

TEACHING POINTS

1. To review the embryologic origin and classification of presacral (retrorectal) masses. 2. To highlight imaging features and pattern approach using state of the art cases with multiple imaging modalities aiding in accurate diagnosis and effective clinical management.3. To learn about the syndromic associations with presacral masses.

TABLE OF CONTENTS/OUTLINE

Anatomy & Embryology Overview of the presacral space and its embryological derivations to explain the diverse origins of these masses. Classification of Lesions Systematic grouping into congenital, neoplastic, inflammatory, and miscellaneous lesions. Imaging Modalities Role of USG, MRI and CT in evaluating lesion location, tissue characteristics, and extent. Case-Based Review Illustrative examples of all entities including epidermoid/dermoid cysts, anterior meningoceles, teratomas, chordomas, tail gut cyst, all types of neurogenic and round cell tumors. Red Flags & Mimics Identification of features suggestive of malignancy or infection, and tips for avoiding diagnostic pitfalls. Management Pearls and conclusion How imaging findings guide biopsy decisions, surgical planning, and follow-up.

GUEE-8 PRECISE SCORING FOR MRI IN ACTIVE SURVEILLANCE: WHAT RADIOLOGISTS SHOULD KNOW

Negar Firoozeh, MD (*Presenter*)
Andrei S. Purysko, MD (*Abstract Co-Author*)
Nicola Schieda, MD (*Abstract Co-Author*)
Ronaldo H. Baroni, MD, PhD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)
Antonio C. Westphalen, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

1. Understand the clinical role of active surveillance (AS) and the limitations of PI-RADS in longitudinal follow-up.2. Learn the structure and application of PRECISE v2 for interpreting serial prostate MRIs.3. Review annotated case examples for PRECISE scores 1-5, including 3-visible vs. 3-nonvisible.4. Explore how PRECISE informs biopsy decisions and multidisciplinary care.5. Identify challenges and future directions, including standardization, AI integration, and abbreviated MRI protocols.

TABLE OF CONTENTS/OUTLINE

Active surveillance is a preferred strategy for managing favorable-risk prostate cancer, but MRI interpretation over time lacks standardization. PRECISE addresses this gap, offering a 5-point scale to categorize stability and progression on serial MRI. This exhibit introduces the updated PRECISE v2 system with high-yield case examples and practical guidance.Can PRECISE be reliably applied across 1.5T vs. 3T scanners? What about variability in multiparametric vs. biparametric protocols? How should radiologists handle MRI-invisible lesions or multifocal disease? How do we score patients undergoing androgen deprivation therapy?We discuss real-world benefits (e.g., biopsy deferral, reduced overtreatment, consistent communication), practical pitfalls (e.g., lesion size measurement, reader variability), and future opportunities. Can ADC histogram analysis or AI lesion tracking enhance reproducibility? Will abbreviated dual-sequence MRI protocols be validated for AS? This exhibit offers a roadmap for how PRECISE may evolve through standardization, quantitative metrics, and integration into clinical workflows.

GUEE-9 MICRO-ULTRASOUND PRI-MUS SCORING IN PROSTATE CANCER: CORRELATION WITH MRI AND HISTOPATHOLOGY

Kelly Greenwall (*Presenter*)
Vina Fan, MD (*Abstract Co-Author*)
Benjamin Adam (*Abstract Co-Author*)
Adam Kinnaird, MD,PhD (*Abstract Co-Author*)
Christopher I. Fung, MD (*Abstract Co-Author*)

TEACHING POINTS

Discover micro-ultrasound equipment and corresponding high-resolution prostate imaging capability. Review the PRI-MUS scoring system for prostate cancer risk stratification. Differentiate typical imaging features of PRI-MUS (MicroUS) and concordant PIRADS (MRI) scoring with histopathology examples. Contrast and analyze discordant PRI-MUS (MicroUS) and PIRADS (MRI) scoring with radiology-pathology correlation.

TABLE OF CONTENTS/OUTLINE

Introduction to prostate micro-ultrasound. Prostate risk identification using micro-ultrasound (PRI-MUS) scoring. Case-based review with radiology-pathology correlation from our institution: Cases representing each PRI-MUS score and corresponding PI-RADS and histopathology results. Cases representing discordance between PRI-MUS and PI-RADS scores. Summary of diagnostic strengths and clinical implications. Key teaching points reinforcing microUS utility in prostate cancer assessment.

GUEE-10 RADIOTHERAPY OF PRIMARY RENAL CELL CARCINOMA AND UPPER TRACK UROTHELIAL CARCINOMA: IMAGING CONSIDERATIONS BEFORE AND AFTER THERAPY

Christopher Lim, MD (*Presenter*)
Satheesh Krishna, MD (*Abstract Co-Author*)
Nicola Schieda, MD (*Abstract Co-Author*)

TEACHING POINTS

1. Stereotactic body radiotherapy (SBRT) has emerged as a treatment option for localized RCC and upper urinary tract urothelial carcinoma (UTUC). 2. Pre-treatment imaging is crucial for identifying patients who may benefit from treatment of primary RCC and UTUC with SBRT. 3. Imaging appearance of local control and recurrence of primary RCC after SBRT differs considerably compared to the appearance after surgery and thermal ablation.

TABLE OF CONTENTS/OUTLINE

1. Why is the historical concept of RCC being "radioresistant" false? What has changed leading to the rise of SBRT? 2. How does SBRT work? What is the role of the radiologist in delineating the renal mass for optimal beam shaping? 3. What are the current indications for SBRT in treatment of primary RCC and UTUC? Does the recent literature show that it is safe? 4. When can we consider management with SBRT over thermal ablation or surgery for primary RCC? Where does SBRT fit in the management paradigm? 5. How can imaging be used in identifying the optimal patients treated with SBRT? Are there any tumor size cutoffs? 6. What is the normal expected post-SBRT imaging appearance of primary RCC and UTUC? 7. Imaging findings of residual and local failure after SBRT for treatment of primary RCC and UTUC - what are the challenges compared to other forms of ablation and surgery? 8. Why is imaging the optimal way to diagnose residual/recurrent tumor after SBRT? 9. What is pseudoprogression and how to differentiate it from tumor recurrence? 10. Is pathology/biopsy limited at diagnosing recurrent tumor after SBRT? Answer: yes 11. How can radiologists identify complications after SBRT? How to prevent complications in pre-procedural imaging? 12. What is the effect of SBRT on renal function?

GUEE-11 ASSESSMENT OF THERAPEUTIC RESPONSE IN BLADDER CANCER: CAN MRI BE USED AS A SURROGATE OF COMPLETE PATHOLOGICAL RESPONSE?

Ana Luiza Calado Novaes, MD (*Presenter*)
Cecilia V. Torres, MD (*Abstract Co-Author*)
Gabriel L. Gouvea, MD (*Abstract Co-Author*)
Arthur Ogata, MD (*Abstract Co-Author*)
Ana Lemos (*Abstract Co-Author*)
Thalyne Lima (*Abstract Co-Author*)
Isadora Balderama Canedo, MD (*Abstract Co-Author*)
Fernando Taliberti Pereira de Souza SR, MD (*Abstract Co-Author*)
Jorge Elias JR, MD, PhD (*Abstract Co-Author*)
Valdair F. Muglia, MD, PhD (*Abstract Co-Author*)

TEACHING POINTS

Pathological response to neoadjuvant therapy (NAT) in muscle invasive bladder cancer (MIBC) is associated with improved clinical outcomes. T2WI, DWI and DCE sequences are essential for evaluating pathological complete response (pCR) of bladder cancer (BCa). MpMRI should be performed in all patients with MIBC after NAT, ideally between 3 and 4 weeks after the end of therapy.

TABLE OF CONTENTS/OUTLINE

Introduction: the management of BCa has evolved with the advent of systemic therapies and immunotherapies. mpMRI has emerged as a promising non-invasive tool improving treatment assessment. Objective: to discuss the basis for systemic therapy and the expanding role of mpMRI in assessing therapeutic response to NAT in MIBC. Imaging findings: mpMRI enables comprehensive anatomical and functional assessment of bladder tumors by integrating T2-weighted imaging (T2WI), diffusion-weighted imaging (DWI), and dynamic contrast-enhanced imaging (DCE). T2WI provides excellent anatomical resolution and aids in distinguishing post-treatment fibrosis from residual tumor tissue. DWI is highly sensitive in detecting small lesions; however, there is often signal overlap between viable tumor and fibrotic tissue following NAT. DCE assesses tumor vascularity and is routinely used in detecting residual or recurrent malignancy, although its interpretation remains debated due to post-treatment changes. Discussion: Although there is no consensus on the optimal protocol for evaluating response to systemic therapy, MRI has emerged as an important tool for advancing personalized treatment strategies and facilitating bladder-sparing therapies.

GUEE-12 IMAGING THE INVISIBLE: DIAGNOSIS, MANAGEMENT AND PERCUTANEOUS BIOPSY STRATEGIES IN NON-FOCAL RENAL DISEASE

Bahareh Moazen, MD, MPH (*Presenter*)
Kelly Harper, MD,FRCPC (*Abstract Co-Author*)
Mary B. Bissell, Md, MSc (*Abstract Co-Author*)

TEACHING POINTS

By the end of this exhibit, readers will be able to: 1. Identify imaging appearances of non-focal renal diseases including those causing echogenic renal cortex, medulla and renal pyramids, cortical necrosis and diseases resulting in size discrepancy. 2. Provide a meaningful differential to consultants in the context of non-focal renal diseases with appropriate next steps in management. 3. Describe a safe approach to percutaneous biopsy of the native kidney and problem solving in challenging cases.

TABLE OF CONTENTS/OUTLINE

Introduction 1. Basic structural components and key anatomy of the native kidney. 2. Overview of non-focal renal diseases, its importance in early diagnosis, and avoiding misdiagnosis. Medical renal ATN, glomerulonephritis, CKD, AIN Depositional Amyloidosis, hyperoxaluria, medullary nephrocalcinosis Ischemic Cortical necrosis, thrombotic microangiopathy, renal vein thrombosis Infection : Pyelonephritis and complications, XGP Additional categories Systemic (e.g., lupus, diabetes), infectious/inflammatory, congenital Imaging in non-focal renal disease: Review imaging patterns on US, CT, MRI and nuclear medicine scans with a table summarizing the common causes of each imaging finding. Common mimics, tips and tricks for narrowing the differential diagnosis including systemic imaging clues Percutaneous Biopsy Standard patient position and biopsy techniques with tips and tricks for challenging cases Case-Based Review Selected cases illustrating key imaging findings, laboratory and clinical manifestations, and use of percutaneous biopsy with histopathologic correlation Conclusion

GUEE-13 MASCULINIZING GENITAL SURGERY: A MULTIDISCIPLINARY APPROACH TO POSTOPERATIVE GENDER-AFFIRMING CARE AND COMPLICATIONS

Kelli J. Andresen, MD (*Presenter*)
Vanessa Williams, MD (*Abstract Co-Author*)
Cindy Thaung, MD (*Abstract Co-Author*)
Shelby J. Fishback, MD (*Abstract Co-Author*)

TEACHING POINTS

Approximately 70% of patients undergoing masculinizing genital surgery will have complications requiring further management. Understanding the anatomy and surgical techniques involved with phalloplasty and metoidioplasty are essential for diagnosis and appropriate treatment as well as for adequate communication with urologic and plastic surgery colleagues. We discuss the radiologic diagnosis of complications of masculinizing surgery including urethral (leak, stricture, fistula), flap (infection, ischemia), and donor site complications as well as the multidisciplinary management of these complications from a urology and plastic surgery perspective.

TABLE OF CONTENTS/OUTLINE

-Provide an overview of masculinizing genital surgery, including surgical techniques and postoperative anatomy. -Discuss the radiologic diagnosis of post phalloplasty/metoidioplasty urethral, flap, and donor site complications. -Urology and plastic surgery colleagues provide a clinical perspective to management of complications of phalloplasty and metoidioplasty.

GUEE-14 CLASSICAL AND EMERGING AGGRESSIVENESS FACTORS IN RENAL TUMORS: CT-BASED RADIOMICS ASSESSMENT

Andreu Ivars, MD (*Presenter*)
Blanca Pano Brufau, MD (*Abstract Co-Author*)
Maria Fresno Vallespir, MD (*Abstract Co-Author*)
Josep Puig, MD,PhD (*Abstract Co-Author*)
Carmen Sebastia Cerqueda, MD (*Abstract Co-Author*)
Carlos Nicolau, MD (*Abstract Co-Author*)

TEACHING POINTS

To review classical and emerging CT-based imaging predictors of aggressiveness in renal cell carcinoma (RCC). To identify key morphological, dynamic, and radiomic features associated with tumor heterogeneity and histologic grade.To illustrate how radiomic features, including shape, texture, and first-order statistics, can be extracted and analyzed using CT. To present a diagnostic workflow that integrates radiologic and radiomic data to support personalized prognostic evaluation in RCC.

TABLE OF CONTENTS/OUTLINE
