Plenary Session: System Interventions to Foster Clinician Well-Being

Monday, Dec. 1 11:00AM - 12:00PM Room: ARIE CROWN THEATER

LEARNING OBJECTIVES

1) Discuss current evidence regarding physician distress and quality of care consequences for organizations. 2) Identify modifiable practice characteristics that influence physician well-being. 3) Recognize evidence-based organizational approaches to promote clinician well-being.

COURSE DESCRIPTION

Occupational distress is common among physicians and can have substantial personal and professional implications. An extensive body of research has demonstrated a strong link between physicians' personal well-being and the quality of care they provide. Recent research has identified characteristics of the work environment organizations can modify to improve clinician well-being and mitigate the associated risks. In this keynote lecture, Dr. Shanafelt will review current state of professional fulfillment and burnout among physicians, discuss data on the personal and professional repercussions, and review the evidence on specific actions organizational can take to promote physician well-being.

Image Interpretation Session

Monday, Dec. 1 4:30PM - 5:30PM Room: ARIE CROWN THEATER

Aya Kamaya, MD (*Moderator*) Other-Book royalties; Elsevier

LEARNING OBJECTIVES

1) Identify key abnormal findings on radiologic studies that are critical to making a specific diagnosis. 2) Construct a logical list of differential diagnoses based on the radiologic findings, focusing on the most probable differential diagnoses. 3) Determine which, if any, additional radiologic studies or procedures are needed in order to make a specific final diagnosis. 4) Choose the most likely diagnosis based on the clinical and the radiologic information. 5) Have fun achieving 1-4!

COURSE DESCRIPTION

5 experts in the field of radiology will be shown unknown cases from the generous contributions by radiologists throughout the United States and Canada. These experts will provide insight regarding how they analyze the images and develop a differential diagnosis including a favored diagnosis.

S6-PL01A President's Address: Imaging the Individual

Umar Mahmood, MD, PhD (*Presenter*) Stock/Shareholder; Cytosite Bio. Consultant; Cytosite Bio. Grant/Research Support; Cytosite Bio. Consultant; Ziteo Medical. Grant/Research Support; Siemens Healthineers

LEARNING OBJECTIVES

Medical advances have been a primary factor in the expanded life expectancy we experience today, which has more than doubled since 1900 worldwide. Radiology plays a fundamental role in this progress, providing information needed to best treat patients. In his President's Address, Umar Mahmood, MD, PhD, will explore how radiology and the science of imaging have driven progress in medicine, and how radiologists can further advance patient care by focusing on imaging the individual. In recent decades, medicine has rapidly and exponentially expanded understanding and strengthened the evidence of how cells work, how organs operate, and how the human body functions. Knowledge of disease is revealed with increasingly finer resolution, offering exciting opportunities to improve outcomes for patients. Therapies are increasingly optimized for each individual patient, with a framework referred to as precision medicine. A radiologically guided precision treatment path exists in all specialties, benefiting patients, allowing new approaches to generate specific information, and creating new opportunities to improve care and outcomes.

S6-PL01B Opening Session: The All of Us Research Program: Advancing Precision Medicine for the Nation

Geoffrey S. Ginsburg, MD, PhD (*Presenter*) Nothing to Disclose

LEARNING OBJECTIVES

The NIH All of Us Research Program aims to gather data from 1 million or more people in the United States to accelerate research and improve health. 864,000+ participants so far have shared health-related data including electronic health records(EHRs), biospecimens, data from wearable technologies, and self-reported surveys. All of Us data are housed in the cloud-based Researcher Workbench, which includes tools, support resources, sample data workbooks and more. 16,000+ researchers from around the world representing 1,120+institutions, including 100+ international organizations, have produced over950 peer-reviewed publications using the data. This talk will highlight future directions including expansion of the breadth of data available, and the scientific impact of the program to demonstrate how All of Us is enabling individualized disease prevention, treatment, and care for all.

RSNA/AAPM Symposium: Together We Can Make a Difference

Tuesday, Dec. 2 9:30AM - 10:30AM Room: E450A

James M. Kofler JR, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe how teamwork between the radiologists, medical physicists and technologists can lead to a productive research environment. 2)Illustrate the different contributions that team members make to the research enterprise. 3)Demonstrate that a team with collective responsibilities of clinical support and research productivity can produce a synergistic and satisfying environment in the academic setting.

COURSE DESCRIPTION

Breast imaging research at UC Davis began with our participation in the NIH-funded Digital Mammography Imaging Screening Trial (DMIST), conducted from 2001 to 2004. Our site made a significant contribution to the trial, and in the process, the breast imaging team gained valuable experience in efficiently managing clinical research. During this same period, our laboratory pioneered the development of a dedicated breast CT scanner, culminating in the first cone-beam breast CT scan on a volunteer in late 2004. Over the next two decades, more than 450 patients were imaged in UC Davis–based clinical trials using four successive prototype scanners. This sustained effort was only possible through the close collaboration of radiologists, physicists, technologists, and graduate students who worked together over 25 years. More recently, our group has developed multi–x-ray source array technology, a promising approach for breast tomosynthesis that eliminates mechanical source motion, shortens scan time, and enhances image quality through a stationary planar 22-source array. Our long-standing culture of collaboration and mutual respect has enabled us to be academically productive while making meaningful contributions to the development of 2.0D, 2.5D, and 3.0D breast imaging technologies. Together, we have made a difference—and we are committed to continuing that progress.

Plenary Session Game Show: The PACS and the Furious: An RSNA Family Feud

Wednesday, Dec. 3 11:00AM - 12:00PM Room: ARIE CROWN THEATER

Iain D. Kirkpatrick, MD, FRCPC (*Moderator*) Nothing to Disclose
Zahra Kassam, MD, FRCPC (*Moderator*) Grant/Research Support; Bayer Pharmaceuticals

LEARNING OBJECTIVES

1) Identify radiologic patterns of common and uncommon multisystem diseases across organ systems in an engaging game-show format. 2) Practice differential diagnoses and review the manifestations (and their frequency) for a number of multisystem pathologies. 3) Encourage interactive learning and camaraderie by gamifying radiologic knowledge, promoting global teamwork, and demonstrating how fun and fast learning can be when PACS meets play.

COURSE DESCRIPTION

Fasten your seatbelts and boot up your PACS—this high-octane radiology showdown pits two teams of diagnostic dynamos against each other in a Family Feud-style format that’s equal parts imaging, intellect, and improv. With categories spanning multisystem diseases and their radiologic manifestations, our contestants will race to name the top answers on the board—some based on survey data from radiologists around the world. Laughter? Guaranteed. Learning? Buckle up—it’s coming at 120 kVp. Whether you’re a resident revving up your knowledge or a seasoned pro with torque to spare, come join the diagnostic drag race and see which team earns ultimate bragging rights. It’s time for The PACS and the Furious: An RSNA Family Feud!

Global Radiography Leaders Vision for the Future (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 1 8:00AM - 9:00AM Room: N226

Charlotte Beardmore, MBA (*Moderator*) Nothing to Disclose
Meena Amlani, PhD, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key trends and challenges shaping the future of the radiographer/technologist profession across Canada, the United States, and the United Kingdom. 2) Discuss the strategic vision and priorities of the CAMRT, ASRT, and the Society and College of Radiographers regarding workforce development, education, and professional advancement. 3) Evaluate global perspectives on how the profession can adapt to emerging technologies, evolving healthcare systems, and changing patient needs.

COURSE DESCRIPTION

This session will feature a live panel discussion with three global leaders offering international insights into the future of the radiographer/technologist profession. Representatives from the CAMRT (Canada), ASRT (USA), and the Society and College of Radiographers (UK) will each share their organization's vision. The panel discussion will explore common themes and global trends looking at the perspectives emerging within each of the countries represented.

Fundamental Screening Issues and Limitations in Under-Represented Populations

Monday, Dec. 1 8:00AM - 9:00AM Room: S406A

Anand K. Narayan, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe current disparities in breast cancer screening rates among underserved populations by race, ethnicity, rural status, and income. 2) Evaluate the effectiveness of individual, practice, and policy interventions to reduce breast cancer disparities. 3) Design proactive outreach and improvement plans to increase breast cancer screening percentages in underserved populations in your community.

COURSE DESCRIPTION

Mammography screening reduces breast cancer deaths, yet underserved populations face significant barriers to accessing these lifesaving services. This session will explore the social, economic, cultural, and systemic factors that contribute to breast cancer disparities in underserved groups. Through didactic sessions, case studies, and interactive discussions, learners will be equipped to examine and develop interventions to increase breast cancer screening percentages in underserved settings.

Cardiac CT Mentored Case Review: Imaging the Heart: Imaging Techniques, Anatomy, and Function

Monday, Dec. 1 8:00AM - 9:00AM Room: E353C

Jacobo Kirsch, MD, MBA (*Moderator*) Nothing to Disclose
Sandeep S. Hedgire, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify normal cardiac anatomy and recognize congenital coronary artery variants on cardiac CT. 2) Apply key technical principles to optimize image quality and ensure accurate coronary CT angiography. 3) Interpret non-coronary artery pathology, cardiac valve anatomy, and cardiac function, including chamber size assessment, using cardiac CT.

COURSE DESCRIPTION

This case-based educational session offers a comprehensive review of cardiac CT imaging, focusing on essential techniques, detailed cardiac anatomy, and functional assessment. Through expert-led lectures and mentored case discussions, participants will enhance their understanding and interpretation of cardiac CT studies in both routine and complex clinical scenarios. Topics include: Normal Anatomy and Congenital Coronary Artery Variants – Review the fundamentals of cardiac anatomy and recognize common and rare congenital coronary anomalies. Coronary CTA: Major Technical Aspects to Achieve a Successful Scan – Learn key protocols and optimization strategies to ensure high-quality coronary CT angiography. Non-CAD Coronary Artery Pathology – Identify a range of non-atherosclerotic coronary conditions, improving diagnostic confidence beyond traditional coronary artery disease. CT of Cardiac Valves and CT Cardiac Function – Gain insights into evaluating valvular structures and cardiac chamber function, including normal size parameters and functional metrics. This course is ideal for radiologists, cardiologists, and imaging specialists looking to refine their cardiac CT skills and apply them effectively in clinical practice.

Updates on Imaging of Pulmonary Vascular Diseases

Monday, Dec. 1 8:00AM - 9:00AM Room: E451A

Sanjeev Bhalla, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Optimize CT pulmonary angiography (CTPA) performance and recognize diagnostic pitfalls when interpreting CTPA for acute pulmonary embolism. 2) Apply the newly developed Pulmonary Embolism Reporting and Data System. 3) Utilize appropriate imaging modalities and protocols in the evaluation of pulmonary hypertension in adult patients. 4) Recognize less common vascular diseases such as pulmonary artery sarcoma and pulmonary arteriovenous malformations.

COURSE DESCRIPTION

Pearls and pitfalls related to the performance of CT pulmonary angiography (CTPA) and interpretation of scans for acute pulmonary embolism will be discussed. The application of dual energy and photon-counting CT technology in the evaluation of acute pulmonary embolism will be reviewed. The rationales and salient features of newly developed Pulmonary Embolism Reporting and Data System (PE-RADS) will be explained. The course includes discussion of the latest guideline in the imaging evaluation of pulmonary hypertension in adults. The less common pulmonary vascular abnormalitis will be illustrated in a case-based format.

LEARNING OBJECTIVES

1) Review acute aortic syndrome beyond the diagnosis of dissection in patients with acute chest pain, presenting the spectrum of imaging findings and key components for the reporting and management. 2) Organize the radiologist's approach to the opacified lungs due to non-infectious lung injury, emphasizing imaging patterns, etiologies, and relevant pathologic substrates. 3) Learn common etiologies, imaging diagnostic strategy, and essential components of accurate radiologic interpretation related to acute and infectious complications following lung transplantation.

COURSE DESCRIPTION

Acute chest pain and respiratory distress are among the most common reasons for consultation in emergency care services and are linked to the broad spectrum of vascular and lung pathology. Using the format of concise lectures and case conundrums, this session will conceptualize key imaging features, clinically relevant reporting, and strategies to overcome diagnostic challenges and assist in the management of acute aortic syndrome, acute lung injury, and complications after lung transplantation.

Improving Radiology Reporting: What Do Our Patients Want and How Do Standards and New Models Get Us There

Monday, Dec. 1 8:00AM - 9:00AM Room: E450B

Namita S. Gandhi, MD, MSc (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1)Through the lens of the patients, discuss current status or radiology reports, opportunities and challenges. 2) Discuss role of semantic standards like Radlex, common data elements, and IHE profiles to standardize radiology reports, enable interoperability, and drive downstream decision support for patient friendly reports. 3) Discuss recent advancements in generative AI and how it can be leveraged to bring more value to patients.

COURSE DESCRIPTION

Radiology reports are the primary mode of communication between a radiologist and the patients. With the 21st Century Cures act, patients have easy access to their reports. However, the radiology reports are primarily written for the ordering clinician, while the patient facing reading material should ideally be at 8th grade reading level. This session will focus on patient expectations from a radiology report and how can we can use semantic standards and generative AI to make radiology reports more understandable and valuable for the patients, in turn driving more patient engagement in their care.

LEARNING OBJECTIVES

1) Identify traumatic and chronic elbow injuries in athletes on different imaging modalities. 2) Describe the imaging findings seen in injuries to the distal biceps tendon as well as the common flexor and extensor tendons at the epicondyles. 3) Explain the imaging hallmarks of elbow instability in athletes.

COURSE DESCRIPTION

This session offers an in-depth exploration of elbow imaging in sports-related injuries, with focused lectures by expert musculoskeletal radiologists. Participants will gain insights into evaluating elbow fractures, tendon abnormalities of the humeral epicondyles and the distal biceps tendon, imaging of elbow instability as well as pediatric elbow imaging in athletes. After this session, the participants will be equipped with a comprehensive understanding of elbow sports injuries, enabling reporting of imaging studies that directly impacts clinical management.

What Modality is the Right Choice: CEUS vs MRI

Monday, Dec. 1 8:00AM - 9:00AM Room: N227B

Margarita V. Revzin, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Discuss pros and cons of CEUS versus MRI in evaluation of liver neoplasms. 2) Discuss pros and cons of CEUS versus MRI in evaluation of pediatric pathologies. 3) Discuss pros and cons of CEUS versus MRI in the evaluation of vascular and abdominal/pelvic pathological processes, including but not limited to aorta and post EVAR, kidney neoplasms, solid organ transplants, organs of reproduction and more.

COURSE DESCRIPTION

The session provides a review of various applications of CEUS vs MRI in a point counterpoint format, where the speakers have a chance to debate about the benefits and limitations of each of these modalities when applied to a specific organ assessment. Discussion will involve comparison of CEUS vs MRI in evaluation of liver and renal lesions, solid organ transplants, gastrointestinal tract, gyn, pediatrics, and vascular systems with emphasis on ease to perform these studies, skill set needed for interpretation of the findings, associated reimbursement issues, as well as sensitivity and accuracy of these modalities in making a correct diagnosis.

RSNA Hands-On Lab: Ultrasound Contrast Training for Beginners and Experts (Registration Fee Required)

Monday, Dec. 1 8:30AM - 10:30AM Room: S504CD

Richard G. Barr, MD, PhD (*Moderator*) Grant/Research Support; Philips Ultrasound. Grant/Research Support; Samsung. Other-Royalties ; Thieme Publishers. Other-Royalties; Elsever Publishers. Grant/Research Support; SuperSonic Imagine. Speaker's Bureau; Samsung. Grant/Research Support; SonoScape. Speaker's Bureau; Philips Ultrasound. Grant/Research Support; Siemens Ultrasound. Speaker's Bureau; Siemens Ultrasound. Grant/Research Support; Canon Medical Systems. Speaker's Bureau; Canon Medical Systems. Grant/Research Support; Mindray . Grant/Research Support; Hologic . Speaker's Bureau; Hologic

LEARNING OBJECTIVES

1) Learn how to develop a CEUS program. 2) Learn what patients are appropriate for CEUS. 3) Review organs where CEUS can be used. 4) Discuss how to optimize CEUS imaging. 5) Review how to interpret CEUS studies.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This course will provide information on how to develop and optimize a CEUS program. A didactic lecture will provide an overview of which patients are appropriate for CEUS, review of safety, general guidelines on performing CEUS. Live cases will be performed via zoom for discussion. Following the live cases the class will move to the hands-on room where vendors will demonstrate their features using phantoms and case studies. Experts in CEUS will be available to answer questions and discuss how to optimize your CEUS program.

International Perspectives on Impacts of Remote Radiology

Monday, Dec. 1 8:00AM - 9:00AM Room: S402

Jay R. Parikh, MD, FRCPC (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the potential impact remote radiology may have on patient care. 2) Describe the potential impact remote radiology may have on radiologists. 3) Describe the pros and cons of remote radiology from a practice leadership perspective.

COURSE DESCRIPTION

Internationally, there is increasing penetration of remote radiology. In this session, a panel of international radiologists will describe the use of remote radiology in their countries. The potential impact of remote radiology upon patients, radiologists and practices will be presented from international perspectives.

Pediatric Intracranial Emergencies

Monday, Dec. 1 8:00AM - 9:00AM Room: S406B

William T. O'Brien Sr, DO (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify distinguishing imaging features between pediatric stroke and common stroke mimics. 2) Recognize imaging findings associated with fetal and neonatal emergent injuries. 3) Understand imaging features and diagnostic work-up for non-traumatic causes of intracranial hemorrhage in children. 4) Review characteristic imaging manifestations of common acute intracranial infectious and inflammatory processes in children.

COURSE DESCRIPTION

This high-yield session will focus on distinguishing imaging features, critical imaging findings, and management of common emergent neurological conditions in children, to include pediatric stroke and its mimics, fetal and neonatal neurological emergencies, non-traumatic intracranial hemorrhage, and acute infectious and inflammatory processes. Engaging speakers with image-rich talks and countless clinical pearls make this a session you most certainly do NOT want to miss.

Acute Pelvic Pain in a Reproductive Age Female (Non-Pregnant)

Monday, Dec. 1 8:00AM - 9:00AM Room: E353A

Loretta M. Strachowski, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify the sonographic characteristics of adnexal torsion and remember them through the application of 7 easy to recall helpful alliterations. 2) Differentiate the phases of pelvic inflammatory disease to direct appropriate treatment. 3) Recognize non-adnexal etiologies of acute pelvic pain such as prolapsing and necrotic uterine myomas and misplaced intrauterine devices.

COURSE DESCRIPTION

Acute pelvic pain is a common presentation in the emergency department and often poses a diagnostic dilemma to the treating care provider due to the myriad of possible etiologies. Imaging plays an essential role, and it is the responsibility of the radiologist to become familiar with the imaging appearance of the most common diagnoses to expedite patient care. This refresher course will review the most common etiologies of acute pelvic pain in patients of reproductive age (excluding ectopic pregnancy) including adnexal torsion, pelvic inflammatory disease, ovarian hyperstimulation syndrome, prolapsing submucosal myomas, etc.

Now You Have a Photon Counting Detector CT: Best Practices for Maximizing Image Quality and Clinical Benefits

Monday, Dec. 1 8:00AM - 9:00AM Room: S404

Cynthia H. McCollough, PhD (*Moderator*) Grant/Research Support; Siemens Healthineers

LEARNING OBJECTIVES

1) Understand the current status and clinical deployment of PCD-CT. 2) Gain insights into the clinical benefits of PCD-CT. 3) Learn strategies to optimize image quality and reduce radiation dose in PCD-CT. 4) Discover best practices for streamlining workflow with PCD-CT systems.

COURSE DESCRIPTION

Photon-counting detector CT (PCD-CT) has transitioned from a research tool to a cutting-edge clinical device that is being increasingly adopted by hospitals and imaging centers. As an advanced imaging modality, its clinical benefits are maximized when radiologists, medical physicists, and technologists collaborate effectively to use the system to its fullest potential. This course will provide an overview of the current status of PCD-CT technologies and the theoretical and established clinical advantages of PCD-CT over conventional energy-integrating detector CT (EID-CT). Participants will learn essential strategies for optimizing PCD-CT performance, including methods to enhance image quality and reduce radiation dose. The course will also cover best practices for streamlining clinical workflows. A moderated discussion session will provide an opportunity for participants to have an in-depth discussion with the panel and share experiences, address challenges, and explore practical solutions to maximize the clinical value of PCD-CT across diverse applications.

Multidisciplinary Masterclass: Learn What Your Clinicians Need to Know for Their Head and Neck Cancer Patients

Monday, Dec. 1 8:00AM - 9:00AM Room: S401

Suresh K. Mukherji, MD, MBA (*Moderator*) Consultant; CARPLAI

LEARNING OBJECTIVES

1) Review a variety of head and neck tumors. 2) Describe the characteristic imaging findings. 3) Provide a list of "Key Elements" that you should include in your report that will make a difference in staging, treatment, and outcome.

COURSE DESCRIPTION

This is multidisciplinary head and neck tumor of experts who will replicate an actual head & neck tumor board. This is an interactive "Masterclass" for Head and Neck Oncologic Imaging which will provide the attendess to review common head and neck neoplasms, discuss their characteristic appearance and recommende key elements thay should include in their report that will affect staging treatment and outcome. This is an audience reponse format and audience questions will be encouraged.

Aortic Imaging: A Multi-Disciplinary Team Approach

Monday, Dec. 1 8:00AM - 9:00AM Room: E352

Cristina Fuss, MD, PhD (*Moderator*) Other-Speaker honorarium; Siemens. Other-Honorarium; Elsevier. Consultant; HeartFLow
Nicholas S. Burris, MD (*Moderator*) Other-Entitled to royalties related to licensure of intellectual property; Imbio Inc/4D Medical

LEARNING OBJECTIVES

1) Identify key imaging protocols and findings essential to guiding both surgical and endovascular management of aortic disease. 2) Describe how imaging contributes beyond measurement to risk stratification, procedural planning, and longitudinal surveillance. 3) Recognize the value of interdisciplinary collaboration in achieving high-quality, patient-centered aortic care.

COURSE DESCRIPTION

This session highlights the critical role of imaging in the multidisciplinary management of aortic disease, from diagnosis through intervention and follow-up. Experts in surgery as well as diagnostic and interventional radiology, will discuss how advanced imaging techniques inform clinical decision-making and enhance outcomes across the spectrum of aortic care.

Rapid Fire Cases for Residents: MSK, Neuro, Body (Sponsored by the RSNA Resident and Fellow Committee)

Monday, Dec. 1 8:00AM - 9:00AM Room: E350

Brandon K.K. Fields, MD (*Moderator*) Consultant; Mendaera
Megan K. Mercer, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Each case will include a multiple-choice question styled similarly to CORE exam items. 2) Audience members will have 30 seconds to submit answers via PollEV. 3) Each case will be followed by a concise, 90-second explanation with accompanying explanatory slides.

COURSE DESCRIPTION

This 60-minute session will feature three expert speakers specializing in musculoskeletal radiology, neuroradiology, and body imaging. Each speaker will present nine cases in a rapid-fire format to highlight key imaging findings and clinical concepts. This dynamic, interactive approach will help attendees hone their diagnostic skills, reinforce core imaging concepts, and prepare for high-stakes certification examinations in a stimulating and engaging environment.

Building a Brighter Future in Radiology: Collaborative Solutions for Efficiency, Patient Care, and Workforce Growth

Monday, Dec. 1 8:00AM - 9:00AM Room: S405

Zi Zhang, MD, MSc (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the unique strategies employed by academic radiology, private practice, and teleradiology to address the radiologist shortage. 2) Gain insights into retention and recruitment strategies tailored to different practice environments. 3) Understand the key components needed to build sustainable infrastructure for AI adoption and innovation in radiology practice.

COURSE DESCRIPTION

Radiologist shortage is an ongoing challenge that demands innovative solutions to ensure operational efficiency, patient safety, and workforce sustainability. This course series brings together leaders from academic radiology, private practice, and teleradiology companies to share comprehensive strategies addressing these key areas. A dedicated session on artificial intelligence (AI) will further explore strategies for validating, integrating, and monitoring AI solutions within clinical workflows. Attendees will benefit from actionable insights and collaborative learning to tackle the workforce shortage across diverse practice settings. This course comprises four lectures addressing critical challenges and opportunities in radiology, followed by a brief panel discussion on academic incentives to foster faculty engagement and innovation, private equity's impact on recruitment and retention, and the role of remote work in supporting radiologists across different career stages. Below is an outline of the topics: 1. Leading the Way: Addressing the Radiologist Shortage in Academic Medicine – Efficiency, Safety, and Workforce Strategies. This session will focus on streamlining workflows and operational efficiency in academic radiology settings. It will also address strategies for maintaining patient safety amidst increasing workloads. Additionally, attendees will explore innovations in recruitment and retention, emphasizing mentorship, career development, and institutional support tailored to the needs of academic radiologists. 2. Optimizing Private Practice: Innovative Solutions for Efficiency, Patient Safety, and Talent Retention. In this session, participants will examine operational solutions for private practices, including technology integration and practice restructuring. The discussion will highlight methods for ensuring high-quality patient care while optimizing efficiency. Creative retention and recruitment strategies, such as work-life balance initiatives and partnership opportunities, will also be explored to support sustainable growth in private practice. 3. Scalable Solutions: How Teleradiology Addresses Radiologist Shortages While Ensuring Quality Care. This session will provide insights into scalable models for workflow optimization and efficiency in teleradiology. The focus will be on maintaining high patient safety standards in remote practice environments. Strategies for retention and recruitment of radiologists at various stages of their careers will be discussed, including flexibility and diversity initiatives designed to attract and retain top talent in teleradiology. 4. AI as a Partner: Revolutionizing Radiology Efficiency and Workforce Support. AI has the potential to transform radiology workflows and support the workforce, but its success depends on strong infrastructure. This session will focus on building the systems, teams, and processes needed to support sustainable AI innovation and adoption. In addition to strategies for clinical validation, integration of external tools, and monitoring, the session will explore the value of developing institution-led AI solutions that are designed, trained, and continuously improved using local data to ensure long-term clinical relevance and scalability.

AI in the Education Space (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 1 9:30AM - 10:30AM Room: N226

Meredith Gammons, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Examine the advantages of integrating AI/ML concepts into radiologic sciences education, including enhanced training, resource development, and funding strategies. 2) Evaluate the current state of AI educational provisions and the level of knowledge among educators regarding AI and ML concepts within the radiologic sciences. 3) Identify how clinical workflows, decision-making processes, and dose optimization can be adapted to incorporate AI and ML features effectively in educational settings. 4) Analyze the findings from the 2023 ASRT Artificial Intelligence Educator Survey, highlighting perceived challenges and important factors for future advancements in AI education in the radiologic sciences.

COURSE DESCRIPTION

This presentation will focus on the 2023 ASRT Artificial Intelligence Educator Survey results, aiming to understand the transformative effects of artificial intelligence (AI) and machine learning (ML) on the radiologic sciences classroom. We will first explore the potential advantages of incorporating AI and ML into education, including insights into training and guidance, strategies for educators to develop resources, and methods for securing funding and institutional support. Next, we will examine how clinical workflows, decision-making, dose optimization, and various tasks can be adjusted to integrate AI and ML features in the classroom. We will review the current state of AI educational provisions, the knowledge base of educators regarding AI and ML concepts, and the perceived challenges surrounding AI education. Finally, we will analyze the survey results, which will provide valuable insights into the factors influencing future advancements in AI education and the opportunities available for enhancing teaching practices in the radiologic sciences.

Core Concepts in Abdominopelvic Trauma: Imaging Strategies and Advances

Monday, Dec. 1 9:30AM - 10:30AM Room: E450A

Carrie N. Hoff, MD (*Moderator*) Nothing to Disclose
Sameer B. Raniga, MD, FRCR (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Optimize MDCT protocols and interpretation techniques for abdominopelvic trauma imaging. 2) Identify key imaging features of solid organ, pelvic ring, bowel/mesentery, and urinary tract injuries. 3) Integrate imaging findings with clinical decision-making pathways, guiding non-operative, interventional, or surgical management. 4) Recognize common diagnostic pitfalls and apply strategies to avoid misinterpretation.

COURSE DESCRIPTION

This interactive, case-based session will provide a comprehensive overview of the most critical and commonly encountered abdominopelvic injuries, including solid organ trauma (liver and spleen), pelvic ring disruptions, bowel and mesenteric injuries, and urinary tract trauma. This course will emphasize current best practices in MDCT interpretation, key diagnostic pitfalls, and strategies to enhance communication with trauma teams. It will also focus on practical, case-based insights that connect radiologic findings with clinical management. This session is ideal for radiologists involved in trauma imaging who wish to boost their diagnostic confidence and reporting accuracy. Educational Format: Didactic lecture with case-based review (Interactive).

LEARNING OBJECTIVES

1) Explain new guidelines for use of contrast media by the American College of Radiology and other societies. 2) Identify opportunities to safely withhold contrast media at MRI.

COURSE DESCRIPTION

This course will summarize important and practice-changing updates to the safe use of contrast media as described by the American College of Radiology and other societies. It will include a debate designed to highlight opportunities for performing MRI for genitourinary indications without contrast material.

Sub-Events

M3-CGU08C Updates on CT Contrast

Carolyn L. Wang, MD (*Presenter*) Grant/Research Support; GE Healthcare

M3-CGU08D Updates on MRI Contrast (Current Guidelines and Novel Media)

M3-CHN03

Imaging of the Orbit and Visual System

Monday, Dec. 1 9:30AM - 10:30AM Room: E352

Karen Moeller, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand clinical symptoms that involve the orbit and visual system. 2) Identify specific imaging findings seen in the setting of diplopia, Horner's syndrome, and vision loss. 3) Recognize the imaging features of pediatric orbital lesions.

COURSE DESCRIPTION

This session includes four educational lectures that will focus on imaging of the orbit and visual pathway in adult and pediatric patients. There will be a detailed focus on specific clinical symptoms and their corresponding imaging findings. This approach will help the radiologist develop a targeted search pattern in various clinical scenarios. The imaging of pediatric orbital lesions will also be discussed, as early recognition of these lesions by the radiologist is important for treatment planning.

M3-CIR03

Interventional Oncological Approaches for Metastatic Colorectal Carcinoma: Embolization, Ablation, and Combinations

Monday, Dec. 1 9:30AM - 10:30AM Room: E351

Robert J. Lewandowski, MD (*Moderator*) Consultant; BD. Consultant; Boston Scientific. Consultant; Sirtex. Consultant; Trisalus

LEARNING OBJECTIVES

1) Describe the role and comparative effectiveness of portal and hepatic vein embolization techniques in inducing liver hypertrophy to optimize surgical candidacy in patients with CRLM. 2) Evaluate current ablation modalities for liver and pulmonary metastases, including the indications, limitations, and outcomes associated with each technique. 3) Differentiate among trans-arterial therapies such as hepatic arterial infusion chemotherapy (HAIC) and Yttrium-90 (Y90) radioembolization and identify appropriate clinical scenarios for their application. 4) Formulate combination treatment strategies that bridge patients with CRLM to curative resection, incorporating multimodality approaches to expand eligibility for surgery. 5) Apply recent consensus guidelines and interpret landmark clinical trials to inform evidence-based practice in interventional oncology for CRLM.

COURSE DESCRIPTION

This session explores cutting-edge interventional oncology strategies for the management of colorectal liver metastases (CRLM). Expert faculty will present a comprehensive overview of techniques including portal and hepatic vein embolization, ablation for liver and lung metastases, and transarterial therapies such as HAIC and Y90. Emphasis will be placed on patient selection, timing, and the integration of therapies to optimize outcomes. The course will also review current consensus guidelines and pivotal clinical trials shaping practice. Attendees will gain practical insights into multidisciplinary approaches that expand resection candidacy and improve patient care in CRLM.

Sub-Events

Knee Imaging: The Fundamentals

Monday, Dec. 1 9:30AM - 10:30AM Room: N228

Erin F. Alaia, MD (*Moderator*) Consultant; Biorez, Inc

LEARNING OBJECTIVES

1) Review fundamental anatomy and common injury patterns seen on knee MRI, with a focus on the meniscus, the cruciate and collateral ligaments, the posterolateral corner, and the extensor mechanism.

COURSE DESCRIPTION

This lecture-based course will cover topics which are considered fundamental to the interpretation of routine knee MRIs. Lectures will cover meniscal injury, injury of the cruciate and collateral ligaments, the posterolateral corner, and the extensor mechanism. Following this session, attendees will have a greater understanding of high-yield, common pathology and important injury patterns on knee MRI.

Sub-Events

Unintended Consequences of Screening and How to Mitigate Them (Sponsored by the RSNA Public Information Committee)

Monday, Dec. 1 9:30AM - 10:30AM Room: S402

Ruth C. Carlos, MD, MS (*Moderator*) Other-Salary support as JACR EIC; ACR . Other-Travel and lodging as GERRAF board chair; GERRAF. Other-Travel and lodging as Academy Board; Academy of Radiology and Biomedical Imaging Research. Other-Honorarium for moderating education session on lung screening; Canon Medical

LEARNING OBJECTIVES

1) Compare benefits and limitations of novel screening technologies. 2) Determine downstream impact of implementing novel screening technologies. 3) Develop potential practice approaches to novel imaging technologies.

COURSE DESCRIPTION

In this didactic course, we will discuss the benefits and pitfalls of novel screening technologies including whole body MRI and multi-cancer detection. We will compare these technologies to standard screening techniques and discuss downstream consequences of implementation of these technologies.

Sub-Events

M3-CNPM07B Limitations of Standardized Screening Programs -- Impacts and How to Improve

It IS up for Debate: Pros and Cons of Different Modality Choices for Common Pediatric GI/GU Conditions

Monday, Dec. 1 9:30AM - 10:30AM Room: S502

Amy R. Mehollin-Ray, MD (*Moderator*) Nothing to Disclose
Smyrna P. Tuburan, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe several imaging features found with MRI to diagnose inflammatory bowel disease (both intestinal and extra-intestinal) and identify key features of inflammatory bowel disease on ultrasound. 2) Explain the value of MR urography and review practical points in the diagnosis of urinary tract obstruction and describe the complementary roles of renal scintigraphy and ultrasound in the evaluation of urinary tract obstruction, including their indications, strengths, and limitations. 3) Discuss common pitfalls and limitations of upper GI fluoroscopy and strategies to avoid misdiagnosis and explain the role of ultrasound in diagnosing midgut volvulus and midgut malrotation.

COURSE DESCRIPTION

This session explores the diagnostic challenges in pediatric GI and GU imaging, highlighting the unique strengths of each modality. Through engaging discussion, learn how to navigate choices between MR enterography or ultrasound for inflammatory bowel disease, MR urography, scintigraphy or contrast-enhanced ultrasound for urinary tract obstruction, and fluoroscopy or ultrasound for midgut volvulus.

RSNA Deep Learning Lab: Data Extraction from Radiology Reports With LLMs (Beginner Friendly) (Registration Fee Required)

Monday, Dec. 1 9:30AM - 10:30AM Room: RADIOLOGY LEARNING LAB

Walter F. Wiggins, MD, PhD (*Moderator*) Consultant; Qure.ai

LEARNING OBJECTIVES

1) Describe how large language models process text using tokenization and embeddings, and explain how these concepts relate to prompt engineering. 2) Use prompt-based methods with a pre-trained LLM and Python library to classify chest x-ray reports by clinical findings, without training or fine-tuning a model.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This interactive course introduces participants to information extraction from radiology reports using large language models (LLMs) and prompt engineering, with minimal reliance on traditional model training or fine-tuning. Participants will work through a hands-on example using chest x-ray reports from a public dataset to classify reports as positive or negative for specific findings. The session will emphasize how to craft effective prompts for LLMs and evaluate their outputs, while also introducing key concepts like tokenization and embeddings as background knowledge. A user-friendly Python library will be used to abstract away lower-level details, allowing learners to focus on high-level reasoning and practical applications. No prior coding or machine learning experience is required.

Sub-Events

Best of Radiology: Artificial Intelligence, Cardiothoracic, Imaging Cancer, and Advances: Editor Picks From the RSNA Suite Journals

Monday, Dec. 1 9:30AM - 10:30AM Room: E451A

Charles E. Kahn JR, MD, MS (*Moderator*) Other-Travel support, Radiology Advisory Panel; Sectra USA
Gary D. Luker, MD (*Moderator*) Nothing to Disclose
Susanna I. Lee, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify the highlights of the research published in the past year in Radiology Advances, Radiology Artificial Intelligence, Radiology Imaging Cancer, and Radiology Cardiothoracic Imaging. 2) Describe the latest scanners, tracers, databases, software, and workflow innovations reported in these journals. 3) Understand the rationale for selection of these articles and why these innovations are likely to disseminate widely.

COURSE DESCRIPTION

Editors of the RSNA subspecialty journals will present a brief (~12 minute) presentation of the articles curated as most likely to impact on the practice of radiology. These will include pre-clinical, translational, cohort and prospective trials. Sample topics include photon counting CT, new PET and other molecular tracers, low- and high-field MRI scanners, and AI tools for image reconstruction, interpretation, and workflow enhancement. In addition, the panel discussion with audience Q & A will focus on the editorial process and future directions of each of the journals.

Monika Radike, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Help early career radiologists with an interest in academia continue to develop their vocation. 2) Give early career radiologists effective strategies for achieving success in career promotion. 3) Guide participants in aligning their mid-career goals with a good work-life balance.

COURSE DESCRIPTION

Small group format, each group assigned to at least one early career and one mid to late career radiologist ("small group mentoring committee") to organize 5 scenarios that an early career radiologist might encounter related to: 1) Finding the perfect job in academia 2) Discovering the ideal mentor and/or mentorship committee 3) Issues/hurdles one might encounter in the promotions process 4) Carving out an academic path in the non-academic setting 5)Balancing alignment between mid-career goals and work-life balance. Small groups will discuss the scenario, personal experiences and identify one person within the group to present the groups talking points to the larger group, with a full audience Q & A.

Futureproofing Radiology Departments: Exploring How AI and Embedded Radiology Will Influence New Designs (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 1 1:30PM - 2:30PM Room: N226

Catherine Gunn, MBA, RT (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify specific architectural and planning principles that can be applied to new construction and major renovation of imaging departments to accommodate AI and embedded radiology. 2) Understand the role of centralized and decentralized Intelligence Collaboration Centers in supporting seamless care across inpatient, outpatient, and remote environments. 3) Learn how innovative designs can enhance patient-centered care, streamline workflow, and improve integration across specialties.

COURSE DESCRIPTION

Artificial intelligence (AI) and the emergence of embedded radiology—where imaging is decentralized and seamlessly integrated across all specialties—are redefining the way radiology departments are planned, programmed, and designed. While much has been written about AI's impact on image interpretation and workflow optimization, far less attention has been given to how these forces will reshape the physical and operational form of future imaging environments. This lecture will offer a forward-looking and pragmatic view into how radiology departments must evolve in response to these paradigm shifts. From enterprise-wide imaging ecosystems to AI-enabled collaboration hubs and hybrid procedural platforms, we will explore the architectural and technological frameworks that will support the next generation of radiology practice.

Cardiac CT Mentored Case Review: Coronary Atherosclerotic Disease: From Straightforward to Most Complicated

Monday, Dec. 1 1:30PM - 2:30PM Room: E353C

Jill E. Jacobs, MD (*Moderator*) Nothing to Disclose
Jonathan Weir-McCall, FRCR (*Moderator*) Speaker's Bureau; Bayer

LEARNING OBJECTIVES

1) Develop a structured approach to the assessment and reporting of coronary stenosis and plaque. 2) Build a framework for integrating functional assessment of coronary artery disease into these clinical reports with awareness of both CT-FFR and CT perfusion assessment.

COURSE DESCRIPTION

This case based session - led by a team of world experts and past presidents of international cardiac imaging societies - will explore the many facets of coronary artery disease assessment using cardiac CT. Starting with cardiac calcifications, we will progress through the bread and butter of stenosis assessment, into the nuances of atherosclerotic plaque assessment. A structured and standardised approach to reporting cardiac CT will be explicated, before finishing with a discourse on the use of functional cardiac CT techniques including both CT-FFR and perfusion imaging.

Imaging of Pleural and Mediastinal Abnormalities: Fundamentals and Advances

Monday, Dec. 1 1:30PM - 2:30PM Room: E451A

Mylene T. Truong, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the classic imaging findings of malignant and benign pleural abnormalities including mesothelioma, pleural effusion, and pneumothorax. 2) Identify and characterize mediastinal neoplasm using multimodality imaging. 3) Recognizing PET/CT applications and pitfalls in the mediastinum.

COURSE DESCRIPTION

This course offers comprehensive exploration of imaging evaluation of pleural and mediastinal diseases. Designed for radiology trainees, practicing radiologists and well as researchers, it provides balanced information of classical imaging findings as well as the latest updates to foster proficiency in detecting and interpretating pleural and mediastinal abnormalities on imaging.

The View From Abroad: Interesting Gastrointestinal Cases From Around the World

Monday, Dec. 1 1:30PM - 2:30PM Room: E451B

Stephanie Nougaret, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize characteristic imaging findings of uncommon gastrointestinal conditions from diverse global regions. 2) Describe diagnostic strategies for infection, trauma, tumor, congenital, and hepatobiliary gastrointestinal cases using cross-sectional imaging. 3) Integrate international perspectives into clinical radiologic practice to enhance diagnostic accuracy in complex gastrointestinal presentations.

COURSE DESCRIPTION

This dynamic, case-based lecture session will showcase unique and challenging gastrointestinal imaging cases from around the world, presented by expert radiologists with international perspectives. Covering a spectrum of pathologies—including infection, trauma, tumor, congenital anomalies, and hepatobiliary disease—this session highlights regional variations in disease presentation and imaging patterns. By exploring these real-world examples, attendees will gain valuable diagnostic insights and broaden their differential diagnoses. The format includes focused lectures followed by interactive discussion, designed to enhance cross-sectional imaging interpretation skills. This session is ideal for radiologists seeking to expand their global diagnostic acumen and apply nuanced imaging strategies in daily practice.

RSNA Hands-On Lab: Prostate MRI: 2 (Registration Fee Required) (Supported by an Unrestricted Educational Grant from Bayer HealthCare Pharmaceuticals Inc.)

Monday, Dec. 1 1:30PM - 3:00PM Room: RADIOLOGY LEARNING LAB

Tharakeswara K. Bathala, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Optimize prostate MRI protocols for diverse clinical applications, including active surveillance, biopsy guidance, staging, focal therapy planning, and post-treatment evaluation. 2) Apply interpretation skills beyond standard PI-RADS assessment to evaluate active surveillance cases, distinguish post-treatment changes from recurrent disease, and assess treatment response. 3) Integrate multiparametric prostate MRI findings with clinical context to provide structured reporting that supports multidisciplinary treatment planning and patient management decisions.

COURSE DESCRIPTION

This comprehensive hands-on prostate MRI course addresses the evolving educational needs in contemporary prostate cancer care, where clinical applications have expanded far beyond traditional PI-RADS interpretation for initial diagnosis. As prostate MRI becomes increasingly integral to patient management across the entire cancer care continuum—from screening and active surveillance to treatment planning and response assessment—radiologists require specialized skills in both technical optimization and advanced interpretation. The course tackles critical knowledge gaps in technical protocol optimization for diverse clinical scenarios, specialized interpretation skills for complex cases including post-treatment imaging and active surveillance, and the integration of emerging technologies such as deep learning algorithms. These skills are essential as healthcare systems increasingly rely on prostate MRI for precision medicine approaches including focal therapy planning, targeted biopsy guidance, and personalized treatment monitoring. The program combines focused didactic presentations with extensive hands-on learning experiences. Following instructor-led lectures on core concepts, participants engage in case-review sessions using DICOM viewers on their devices. Interactive case discussions and real-time faculty guidance enhance collaborative learning, concluding with independent case interpretation and immediate performance feedback. This is a Bring Your Own Device (BYOD) session. In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

Vision Language Model for Radiology Application (Advanced)

Monday, Dec. 1 1:30PM - 2:30PM Room: E450B

Amara Tariq, PhD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Learn fundamental concepts of VLM design and development. 2) Identify potential applications for VLMs in the field of radiology.

COURSE DESCRIPTION

The course is designed to introduce the audience to the applications of vision-language models (VLM) in radiology. VLMs are large foundational models with capabilities to jointly process imaging and textual data. Radiology-focused VLMs are becoming increasingly popular to meet challenges in the field of radiology such as image/report generation, information retrieval, as well as image only tasks like detection and segmentation. With the knowledge learned from both images and text during training, VLMs tend to outperform image-only or text-only models. Domain-expert speakers will present the fundamentals of VLM development as well as their latest applications in radiology.

RSNA Hands-On Lab: Musculoskeletal Ultrasound: Approach to Ultrasound Assessment of the Elbow and Forearm (Registration Fee Required)

Monday, Dec. 1 2:00PM - 3:30PM Room: S504CD

Laxshmi Veda Avula (*Moderator*) Nothing to Disclose
Linda Probyn, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review anatomy and ultrasound imaging techniques for evaluation of the elbow and forearm. 2) Describe useful imaging techniques to enhance assessment of the elbow and forearm highlighting dynamic assessment. 3) Discuss ultrasound imaging of common pathologic musculoskeletal conditions at the elbow and forearm that are commonly encountered in daily activities.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. This session will review an approach to ultrasound of the Elbow and Forearm. Part 1 (35 minutes): There will be a hands-on demonstration by an instructor showing an approach to ultrasound examination of the elbow and forearm. This will include assessment of the anterior elbow (joint effusion, brachialis tendon, biceps tendon, median nerve), medial elbow (common flexor tendons, medial ligaments, ulnar nerve), lateral elbow (common extensor tendons, lateral ligaments, radial nerve) and posterior elbow (triceps tendon, bursa). Course of the Median, Ulnar and Radial nerves will be followed into the forearm along with their relationship with muscles and tendons to the level of the wrist. Dynamic assessment will be reviewed that will assist in diagnostic assessment. (20 minutes) This will be followed by a brief presentation highlighting common pathologic musculoskeletal conditions about the elbow and forearm seen on ultrasound. This includes but not limited to, joint effusion, tendon and ligament pathology, bursitis, neurovascular injury. Pearls and pitfalls will be discussed along with dynamic evaluation to enhance diagnostic accuracy. (15 minutes) Time will be allocated for questions and answers. Part 2 (45 minutes): The participants will be divided into small groups and will practice an approach to ultrasound of the elbow and forearm on a model with an instructor teaching the participants. Proper patient positioning will be shown. Tips on how to optimize ultrasound imaging to best evaluate the area of concern will be reviewed and discussed. Participants will have an opportunity to practice these skills and techniques.

Stroke and Neurovascular Imaging: Pearls for Practice

Monday, Dec. 1 1:30PM - 2:30PM Room: S406B

Vivek Yedavalli, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key imaging features that distinguish true strokes from stroke mimics using perfusion imaging in everyday clinical scenarios. 2) Recognize and avoid common pitfalls encountered in CT angiography when evaluating patients with suspected stroke. 3) Summarize recent advancements and clinical implications from large core trials in imaging large vessel occlusion strokes. 4) Assess the role of imaging in the detection and prognosis of medium vessel strokes, including emerging techniques and prognostic indicators. 5) Apply practical pearls and strategies to enhance confidence and accuracy in neurovascular imaging, regardless of practice environment or experience level.

COURSE DESCRIPTION

Stroke and Neurovascular Imaging: Pearls for Practice is a comprehensive session designed for radiologists and healthcare professionals involved in the diagnosis and management of stroke. This course emphasizes practical, case-based learning to address common challenges in neurovascular imaging, including stroke mimics, pitfalls in CT angiography, and the latest advances in imaging large and medium vessel occlusions. Through expert-led presentations, attendees will gain actionable insights to improve diagnostic accuracy and patient outcomes across diverse clinical settings.

Endometriosis: Get It Right the First Time

Monday, Dec. 1 1:30PM - 2:30PM Room: E353B

Myra K. Feldman, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the clinical scope of endometriosis, impact of underdiagnosis and role of the radiologist in diagnosis. 2) Recognize endometriosis on routine pelvic ultrasound for early detection. 3) Interpret MRI findings in the context of surgical outcomes. 4) Identify common imaging pitfalls and mimics to avoid diagnostic errors.

COURSE DESCRIPTION

This comprehensive session brings together leading experts to address the diagnostic imaging challenges of endometriosis with a focus on early detection and accuracy. Participants will gain insights into this underrecognized, clinically impactful disease through focused discussion on early detection with ultrasound, MRI interpretation with surgical correlation, and common diagnostic pitfalls.

MRI Acceleration Techniques to Reduce Scan Time: A Practical Course of Radiologists and Clinical Physicists

Monday, Dec. 1 1:30PM - 2:30PM Room: S404

Kazim Gumus, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Explain the principles fundamental MRI acceleration techniques, including Partial Fourier, SENSE, and GRAPPA, and identify their advantages and limitations in clinical practice. 2) Understand the principles of CAIPIRINHA, Compressed Sensing and Multi-band (Simultaneous Multi-Slice) techniques, their advantages and limitations on scan time reduction, image quality, and implementation in different MRI protocols. 3) Recognize different AI-based technologies in MRI reconstruction and acceleration, their advantages and limitations, and implementation on different MRI sequences.

COURSE DESCRIPTION

This course will consist of three lectures. It is designed to equip both radiologists and clinical physicists with fundamental knowledge of various MRI acceleration techniques, including, partial Fourier, GRAPPA, SENSE, SMS, CAIPIRINHA, and AI technologies. By understanding the underlying physics and mastering the protocols of these acceleration techniques, the course participants can optimize MRI scans, reduce scan time, and improve patient care.

AAPM/RSNA Basic Physics Lecture for the RT

Monday, Dec. 1 1:30PM - 2:30PM Room: N227B

Marthony Robins, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the core principles of AI, including machine learning, deep learning, and their applications in medical imaging. 2) Understand AI-driven technologies' capabilities, benefits, and limitations for image acquisition, interpretation, and workflow optimization. 3) Identify key challenges such as bias, validation, regulatory compliance, and ethical considerations when implementing AI in radiology.

COURSE DESCRIPTION

This lecture explores the real-world applications of Artificial Intelligence (AI) in radiology, focusing on how AI enhances image acquisition, interpretation, and workflow efficiency. Designed for radiation technologists, radiologists, and medical physicists, it covers key AI technologies, including deep learning, image segmentation, and computer-aided detection. Participants will gain insights into AI-driven tools for diagnosis, quality control, and dose optimization while addressing challenges like bias, validation, and regulatory considerations. By the end of the course, attendees will understand AI's role in improving diagnostic accuracy, efficiency, and patient care while ensuring safe and effective integration into clinical practice. Case studies and interactive discussions will provide practical insights for real-world implementation.

Monday, Dec. 1 1:30PM - 2:30PM Room: S401

Pablo Soffia, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the role of radiomics in the evaluation of abdominal tumors and its clinical relevance in oncology imaging. 2) Discuss how randomized controlled trials contribute to the evidence-based validation of AI tools in radiology. 3) Identify key challenges and opportunities for AI integration in radiology practice across Latin America.

COURSE DESCRIPTION

This session, presented in Spanish, offers a unique perspective on the integration of Artificial Intelligence (AI) and radiomics across Latin America. Through focused lectures expert speakers from Mexico, Canada, Argentina, and Venezuela will share their clinical experiences, research applications, and institutional strategies related to AI implementation. The session is particularly relevant for radiologists and imaging professionals interested in how emerging technologies. Participants will gain insight into the role of radiomics in abdominal oncology, the value of randomized controlled trials in AI validation, and real-world challenges and opportunities in Latin American radiology ecosystems. By the end of this course, attendees will better understand the current applications of AI and radiomics and will be equipped with examples that could inspire or guide local implementation.

Doctors and Litigation: Time for a New Paradigm (Sponsored by the American Association for Women in Radiology)

Monday, Dec. 1 1:30PM - 2:30PM Room: E350

Catherine J. Everett, MD, MBA (*Moderator*) Owner; Eidetico PLLC. Consultant; MSN. Employee; Radiology Partners

LEARNING OBJECTIVES

1) Identify the origins of litigation stress in the physician defendant. 2) Recognize the ways in which litigation stress and fear of litigation drive career abandonment, burnout, and suicide in physicians. 3) Explore the role of effective peer support, coaching, and education in mitigating litigation stress.

COURSE DESCRIPTION

Many doctors are completely unprepared for malpractice litigation, even though the majority will experience it during their careers. The experience is shrouded in secrecy and shame, and the individual physician often suffers in isolation, sometimes with disastrous consequences. Presenter Gita Pensa, M.D., is a legal performance and well-being coach for medical defendants. Recounting the story of her own transformative journey through twelve years of grueling litigation, she will discuss the complexities of litigation stress in doctors, its impact beyond legal outcomes, and how education and more effective support strategies for defendants can mitigate its impact.

Remote Imaging (Sponsored by the RSNA Associated Sciences Consortium)

Monday, Dec. 1 3:00PM - 4:00PM Room: N226

Brian Fox, MBA (*Moderator*) Nothing to Disclose
Charlotte Beardmore, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the current state of remote imaging in the industry through a review of recent organizational surveys and current workgroup activities designed to inform and guide healthcare organizations on key considerations. 2) Understand the structure, functionality, and integration of remote operations for CT and MR imaging within clinical workflows. 3) Evaluate the operational, clinical, and regulatory implications of implementing remote technologies, including cybersecurity, certification/accreditation, education/training and patient safety. 4) Apply best practices for remote scanner operation, communication, and quality assurance through real-world case studies and practical scenarios.

COURSE DESCRIPTION

This course introduces the concept and application of remote operations in CT and MR imaging—centralized, technology-enabled workstations that allow radiographers/radiologic technologists to operate scanners across multiple sites from a single location. As healthcare organizations seek to optimize resources, improve access for patients, and enhance workforce flexibility, remote solutions are emerging as a transformative innovation in diagnostic imaging. These evolving technologies require a thorough review and understanding of the regulatory landscape as well other key considerations around patient safety and staff education.

LEARNING OBJECTIVES

1) Identify and describe cardiac and pericardial neoplasms commonly faced in cardiac imaging. 2) Become familiar with adult congenital heart disease and develop an approach to interpreting this complex imaging. 3) Understand the role of CT imaging in endocarditis evaluation, including complications that may be encountered.

COURSE DESCRIPTION

This is a mentored case-based review of Cardiac CT imaging. In this session, we will be reviewing imaging of cardiac and pericardial neoplasms, adult congenital heart disease and the imaging of endocarditis. This educational session is targeted to diagnostic radiologists and cardiothoracic imagers and is designed to improve knowledge and competence in the field of cardiac CT imaging.

Temporal Bone Boot Camp

Monday, Dec. 1 3:00PM - 4:00PM Room: E352

Ian T. Mark, MD (*Moderator*) Grant/Research Support; GE Healthcare. Grant/Research Support; Lantheus

LEARNING OBJECTIVES

1) Identify and describe the key anatomical structures of the temporal bone. 2) Detect and characterize common and critical post-operative imaging appearances of the temporal bone. 3) Understand the unique anatomical and pathological considerations in pediatric temporal bone imaging. 4) Explore the principles and advantages of photon-counting detector CT in temporal bone imaging. 5) Review the imaging features of Meniere's disease and understand the role of delayed contrast-enhanced MRI.

COURSE DESCRIPTION

This lecture session is designed to equip radiologists with essential and advanced knowledge in temporal bone imaging. Through a series of focused, expert-led talks, attendees will gain a solid foundation in practical temporal bone anatomy, learn to confidently interpret post-operative imaging, and understand the nuances of pediatric temporal bone evaluation. The session will also explore cutting-edge developments in imaging technology, including photon counting detector-CT, and review the evolving role of MRI in diagnosing Meniere's disease. Ideal for radiologists at all levels, this boot camp blends core anatomical review with state-of-the-art imaging advances to enhance diagnostic accuracy and clinical collaboration.

Sub-Events

From Theory to Practice: GenAI Skills for Radiologists

Monday, Dec. 1 3:00PM - 4:00PM Room: E450B

Lisa C. Adams, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the foundational principles of generative AI and their specific applications in radiology. 2) Apply effective prompting techniques for large language models to support research and clinical workflows. 3) Assess practical strategies for translating diffusion models and other GenAI tools from research into routine radiological practice.

COURSE DESCRIPTION

Generative AI (GenAI) is rapidly entering radiology, yet many radiologists lack clear, practical guidance for its clinical use. This session is designed to provide a realistic overview of GenAI's applications and limitations in everyday radiology practice. Through focused lectures and live interaction using Poll Everywhere, participants will learn about the fundamentals of GenAI models, effective prompting strategies for large language models, and practical considerations for deploying diffusion models in clinical settings. By the end of the session, attendees will be better prepared to assess and incorporate GenAI tools into their research and clinical workflows.

Sub-Events

M7-CIN07B **GenAI in Radiology Explained**

Lessons Learned From My Biggest Complications

Monday, Dec. 1 3:00PM - 4:00PM Room: E351

Anne M. Covey, MD (*Moderator*) Stock/Shareholder; Amgen. Other-Royalties; Oxford University Press. Consultant; Boston Scientific. Other-Section Editor; American Journal of Roentgenology

LEARNING OBJECTIVES

1) Assess patient-specific and condition-specific risk factors that increase the likelihood of complications. 2) Formulate appropriate management plans for the prevention and treatment of complications. 3) Evaluate strategies for reducing the incidence of complications.

COURSE DESCRIPTION

This course offers a discussion of complications related to common and challenging interventional procedures. A panel of experts will provide insights into the identification, prevention, and management of complications related to Y90, biliary intervention, venous stenting and pulmonary thrombectomy.

Sub-Events

M7-CIR07B Complications of Venous Stenting

Nariman Nezami, MD (*Presenter*) Other-Advistory Borad; CAPS Medical. Owner; Nezami LLC. Owner; IRAD Graphics. Owner; Informed Medical Solutions. Consultant; Boston Scientific. Other-Safety Monitor; Microbot Medical. Consultant; Medtronic. Owner; NextSight Consulting. Grant/Research Support; Guerbet Medical

M7-CIR07C Complications of Y90 Radioembolization

Kirema I. Garcia-Reyes, MD (*Presenter*) Consultant; Boston Scientific . Consultant; Cook Medical. Consultant; Astra Zeneca . Consultant; Neuwave. Consultant; Varian

Cartilage Imaging: From Fundamentals to Treatment Strategies

Monday, Dec. 1 3:00PM - 4:00PM Room: E450A

Christine B. Chung, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the MR imaging characteristics, anatomy, and pathogenesis of chondral, osteochondral, and subchondral injuries using standardized terminology. 2) Explain the role of imaging in the diagnosis and assessment of osteoarthritis, including its impact on treatment planning and disease monitoring. 3) Evaluate postoperative imaging findings following cartilage repair procedures, with an emphasis on MR imaging of the knee, to guide clinical decision-making.

COURSE DESCRIPTION

This lecture-based session provides a comprehensive overview of cartilage imaging, spanning foundational anatomy and injury mechanisms to advanced imaging techniques and postoperative assessment. Expert faculty will explore the MR imaging features of chondral, osteochondral, and subchondral lesions, the role of imaging in diagnosing and monitoring osteoarthritis, and the evaluation of cartilage repair procedures, with a focus on the knee. The session addresses the growing clinical demand for precise, standardized imaging in cartilage injury and repair. By the end of the session, learners will be better equipped to interpret cartilage imaging across the disease spectrum and contribute meaningfully to treatment planning and patient care.

The Future of Education: Advances in Evaluation and Intervention

Monday, Dec. 1 3:00PM - 4:00PM Room: S402

Jessica G. Fried, MD (*Moderator*) Nothing to Disclose
Laura L. Avery, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe innovative approaches to radiology education, including curriculum redesign, competency-based training, and AI-supported learning tools. 2) Compare international models of medical education with an emphasis on the UK's implementation of competency-based frameworks. 3) Identify effective coaching strategies to support struggling trainees and promote sustainable professional growth. 4) Apply principles of precision education to personalize resident teaching and assessment in real-time clinical settings. 5) Reflect on current challenges in educational evaluation and intervention and consider actionable steps to implement change within their own institutions.

COURSE DESCRIPTION

The way we train and evaluate radiology residents is rapidly evolving. This session will explore bold forward-thinking approaches that are reshaping the educational landscape. From reworking the traditional curriculum to tapping into the power of AI and personalized coaching, our panel of educators bring diverse experiences and fresh insights to the table.

Planning a Greener Future in Pediatric Radiology

Monday, Dec. 1 3:00PM - 4:00PM Room: N228

John B. Amodio III, MD (*Moderator*) Nothing to Disclose
Sumit Pruthi, MBBS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Inform radiologists of the various ways to use AI to enhance sustainability in pediatric radiology. 2) Explain the basic principles of photon counting CT and how it differs from conventional CT systems. 3) Discuss advantages and limitations of non-contrast and contrast-enhanced MRA techniques. 4) Reduce contrast volume and waste through creative strategies.

COURSE DESCRIPTION

This session will take a practical look at photon counting CT (PCCT) — what makes the technology different, and why it matters in everyday clinical practice. We'll start with a quick overview of how direct photon conversion and energy discrimination with PCCT can lead to sharper images and less noise, even at lower doses. There will also be discussion of use of AI to enhance sustainability in pediatric radiology and discussion of advantages and limitations of non-contrast and contrast-enhanced MRA techniques Review of common contrast agents used in radiology and their environmental impact across the life cycle—from procurement to disposal. We'll explore practical ways to reduce contrast use, avoid unnecessary administration, and minimize environmental waste.

Total Body PET/CT Imaging: Current and Future Status of This Technology Innovation

Monday, Dec. 1 3:00PM - 4:00PM Room: S404

Osama R. Mawlawi, PhD (*Moderator*) Grant/Research Support; GE HealthCare

LEARNING OBJECTIVES

1) Learn about the various commercial TB system offerings and their performance characteristics. 2) Learn about the potential clinical and research applications of TB PET/CT systems. 3) Develop an in-depth understanding of the advantages and challenges of TB PET/CT systems.

COURSE DESCRIPTION

Total body (TB) PET/CT is one of the major recent innovations in the field of PET imaging. This is evidenced by the introduction of several TB systems from various manufacturers such as General Electric, SIEMENS, and United imaging. With total body PET there are potential advantages of reduced scan duration, decreased patient radiation dose, new clinical/research applications and quantitative outcome measures. This session will discuss the design and performance characteristics of these various systems as well as their potential clinical and research applications in oncology. A moderated debate centered around the need for TB systems in nuclear medicine is also included in this session and will cover the advantages/need for these systems versus their challenges.

Sub-Events

Best of AAPM Summer School: Chicago Fireside Chat: Best of AAPM Summer School: Workflow Optimization

Monday, Dec. 1 3:00PM - 4:00PM Room: N227B

Colleen Fox, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Learn selected operations management terms as they apply to radiation related workflows. 2) Gain exposure to individual and department-based approaches to improve productivity and reduce burnout. 3) Consider the pros and cons of the implementation and clinical-use of AI-based auto-contouring as an example workflow optimization effort. 4) Contemplate the undesirable or unintentional impact of workflow optimization on the professionals in that workflow.

COURSE DESCRIPTION

Over the last few years discussions on workforce shortages in the radiation professions have become common place. At the same time there are an increasing number of automation and AI solutions offering to improve workflow efficiency. Care needs to be taken to keep overall goals and the satisfaction of the staff in mind during improvement efforts. This session will explore some of the commonly held ideas around workflow optimization in a dynamic Q&A format with faculty from the AAPM 2024 Summer School on this topic. The course will touch on basic operations management terminology, potential impacts of workflow optimization efforts on the worker, and explore a few strategies that have been deployed in various radiation workflows.

Optimizing Radiologist Efficiency and Ergonomics: Informatics Solutions Leveraging AI/ML Workflows and Proactive Workstation Configurations (Sponsored by the RSNA Quality Improvement Committee)

Monday, Dec. 1 3:00PM - 4:00PM Room: E353A

Les R. Folio, DO, MPH (*Moderator*) Consultant; General Electric

LEARNING OBJECTIVES

1) Enhance wellbeing through time-tested basic ergonomic principles: three points of contact, 20-20-20 rule, and tailored, supportive workstation configuration adapting to high-volume imaging interpretation demands. 2) Understand structured hyponym-based dictation enhancing efficiency, clarity, consistency, and clinical relevance in radiology reports. 3) Streamline, simplify, and supercharge dictation with smart tools, AI auto-impressions, and workflow hacks.

COURSE DESCRIPTION

Our educational session is designed for all practicing radiologists, in addition to all imaging-centric clinical specialties — including pathologists, cardiologists, dermatologists and ophthalmologists — who are managing increasingly complex imaging data in dynamic work environments. We'll explore the full spectrum of the modern imaging workspace: from optimizing reading room environments and human-computer interactions to streamlining workflows with ergonomic hands-free, template-free hyponym dictation keeping our focus on the images, not a report template.We will further explore how radiology practices can leverage AI and IT solutions to enhance efficiency in ways that elevate both patient care and physician well-being. Participants will learn how to design and configure monitor workstations using evolving industry and practice standards, ergonomic best practices, and practical, affordable tools including articulating monitor arms, ergonomic dictation stands, and standard on-board memory gaming mouses.

Collaborative Translation of Theranostic Innovation From Bench to Commercialization to Clinical Practice (Sponsored by the RSNA Research Development Committee)

Monday, Dec. 1 3:00PM - 4:00PM Room: S502

David A. Mankoff, MD, PhD (*Moderator*) Consultant; GE Healthcare. Other-Scientific Advisory Board; Reflexion. Other-Scientific Advisory Board; ImaginAb. Stock/Shareholder; Trevarx. Consultant; Blue Earth Diagnostics
J. Brian Fowlkes, PhD (*Moderator*) Other-Equipment Support; Philips Healthcare. Other-Equipment Support; GE Healthcare. Consultant; Lantheus Medical Imaging
Shadi Abdar Esfahani, MD, MPH (*Moderator*) Grant/Research Support; SOFIE Biosciences . Consultant; Telix Pharmaceuticals. Grant/Research Support; Telix Pharmaceuticals. Grant/Research Support; Novartis Pharmaceuticals

LEARNING OBJECTIVES

1) Describe the translational pathway of PSMA-based theranostic agents, from discovery to commercialization. 2) Identify key scientific, clinical, and regulatory milestones in bringing radiopharmaceutical innovations to clinical practice. 3) Observe and learn how the challenges were addressed and overcome in different settings to reach a successful stage. 4) Recognize the importance of collaboration among basic scientists, clinicians, and industry in advancing cancer diagnostics and therapeutics. 5) Apply insights from case studies to facilitate translational efforts in their own research or clinical settings.

COURSE DESCRIPTION

This dynamic and interactive session focuses on the translational journey of PSMA-based theranostics—paired diagnostic and therapeutic radiopharmaceuticals—from laboratory discovery to clinical implementation and commercialization. Bringing together experts in basic science, clinical investigation, and industry, this course will provide a behind-the-scenes look at the collaborative process that enables innovative cancer management approaches to reach patients. With a special focus on prostate cancer, attendees will hear directly from leading figures involved in the development, clinical application, and commercial distribution of PSMA-targeted radiopharmaceuticals. This session is designed to appeal to radiologists, clinician-investigators, and industry professionals, and aligns with RSNA's mission to increase translational research content in its educational offerings.

Monday, Dec. 1 4:30PM - 5:30PM Room: N226

Brian Fox, MBA (*Moderator*) Nothing to Disclose
Catherine Gunn, MBA, RT (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe evolving trends, shifting sites of care, and demand for imaging modalities. 2) Identify technology trends impacting imaging equipment selection and deployment. 3) Apply strategic frameworks for imaging capital planning across care sites. 4) Understand how to align equipment planning with patient access, quality, and cost-effectiveness.

COURSE DESCRIPTION

The healthcare imaging landscape is evolving rapidly, with shifting sites of care, new therapies, and technological advancements redefining how and where care is delivered. This session explores the forecasted imaging volumes by modality and site of care—from traditional hospital-based departments to outpatient centers, ambulatory surgery facilities, and even retail clinics. Attendees will gain insights into how these shifts are influencing technology adoption and equipment planning strategies. The course will address key trends in imaging utilization, the impact on technology investments, and how emerging technologies are enabling these dynamics in patient care.

Agentic AI in Radiology: Definitions and Applications (Advanced)

Monday, Dec. 1 4:30PM - 5:30PM Room: E450B

Paulo E. Kuriki, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Define the core principles and types of agentic AI and distinguish them from traditional AI systems. 2) Describe practical applications of agentic AI in current radiology workflows. 3) Identify challenges and future directions for adopting agentic AI in multidisciplinary clinical settings.

COURSE DESCRIPTION

This session explores the use of agentic artificial intelligence (AI) in radiology, focusing on interactive, autonomous AI agents that go beyond traditional task-based algorithms. Through foundational overviews and real-world case studies, attendees will understand how agentic AI is reshaping radiology workflows, improving clinical decision-making, and enabling patient-centric innovations. The session will feature expert-led lectures followed by a panel discussion, offering practical guidance for safely integrating these systems into clinical practice.

Improving the Quality of PET/CT Interpretation and Updates in Vascular Inflammation

Monday, Dec. 1 4:30PM - 5:30PM Room: S405

David A. Mankoff, MD, PhD (*Moderator*) Consultant; GE Healthcare. Other-Scientific Advisory Board; Reflexion. Other-Scientific Advisory Board; ImaginAb. Stock/Shareholder; Trevarx. Consultant; Blue Earth Diagnostics

LEARNING OBJECTIVES

1) Describe methods to ensure consistent qualitative PET interpretation. 2) List and define quantitative measures use for PET imaging. 3) Describe how these principles can be applied to the use of PET for the diagnosis of vasculitis.

COURSE DESCRIPTION

This session will focus on approaches to improve the quality and clinical utility of PET interpretations with a focus on quantitative PET measures and how best to report them and systematic approaches to qualitative interpretation and reporting. These principles will be reviewed and demonstrated using PET imaging of vasculitis as a specific example

Sub-Events

M8-CNMMI04B Importance of Quantitative Assessment for PET/CT

Beyond the Workstation: Non-Traditional Careers in Radiology (Sponsored by the RSNA Professionalism Committee)

Monday, Dec. 1 4:30PM - 5:30PM Room: S402

Mario F. Chirinos Gambarini, MD (*Moderator*) Nothing to Disclose
Monica M. Sheth, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify nontraditional career paths--recognize various alternative career opportunities available to radiology professionals, including roles in industry, administration, coaching, and international outreach. 2.)Assess transition preparation strategies--evaluate effective strategies and resources that can aid in preparing for a transition from clinical radiology to alternative career paths. 3) Set realistic expectations--discuss the anticipated challenges and benefits associated with nontraditional career paths, including potential changes in work-life balance, job satisfaction, and professional development. 4) Learn from real-world experiences--gain insights from the personal experiences of panelists who have successfully transitioned to nontraditional roles, understanding the realities versus initial expectations.

COURSE DESCRIPTION

Radiologists may pursue roles outside of traditional private practice and academic radiology, whether to seek greater community impact, achieve stronger alignment with professional goals or as an avenue to gain career flexibility and avoid burnout. Several career paths are available, ranging from opportunities in industry, regulatory, administration, coaching, and international outreach. However, radiologists may not be aware of these potential paths or understand how to navigate these career pivots. This course aims to provide an examination of potential career paths, motives, transition processes, expectations and realities of non-traditional careers using a round table discussion format.

Sub-Events

Dose Calculation Tools for Fluoroscopic Imaging: An Overview of Their Development, Accessibility, and What Role They Play in Communicating and Managing Patient Risk

Monday, Dec. 1 4:30PM - 5:30PM Room: S404

David Borrego, PhD (*Moderator*) Nothing to Disclose
Emily Marshall, PhD (*Moderator*) Consultant; Bayer, Radimetrics. Other-I am currently currently a project manager on a master research agreement between the University of Florida and Canon Medical Systems. No direct financial benefit exists and this is outside of the scope of this work. No other authors have disclosures to report.; Canon Medical

LEARNING OBJECTIVES

1) Generalize the tools and resources available for radiation dose assessment in fluoroscopic imaging. 2) Evaluate the various dose metrics available and how these may be useful within their clinical workflow in communicating with patients and managing their risk. 3) Discuss the current state and future needs of radiation dosimetry in the context of low-dose research studies and what role attendees may play as stakeholders in the field.

COURSE DESCRIPTION

There are several tools and resources available to estimate the amount of radiation delivered to patients during fluoroscopic imaging procedures. This session, with a special emphasis on pediatric fluoroscopic imaging, will provide an overview of the current state of radiation dosimetry, the challenges in estimating patient dose, opportunities for dose optimization using coefficients, and what role these tools may play in improving communication and the management of patient risk. Attendees will leave the course with a developed understanding of appropriate applications and limitations of radiation dose estimates and tools available for their own educational use. This course will provide practitioners the background needed to confidently produce, explain, and contextualize patient dose and risk following fluoroscopic imaging procedures.

Sub-Events

Imaging of Pulmonary Infections

Thursday, Dec. 4 8:00AM - 9:00AM Room: E451A

Claudio Silva, MD, MSc (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify imaging findings of pulmonary infections in both immunocompetent and immunocompromised patients. 2) Explain and differentiate radiological patterns of various fungal pulmonary infections. 3) Present how emerging biomarkers in pneumonia integrate with imaging findings to achieve more precise diagnoses.

COURSE DESCRIPTION

This course will outline a systematic approach for characterizing imaging findings and establishing optimal diagnostic pathways for pulmonary infections in both immunocompetent and immunocompromised patients. We will explore the complexities of fungal infections, focusing on their unique radiological patterns and the implications for patient care. Additionally, the session will present the role of emerging biomarkers in pneumonia, discussing how these can be integrated with traditional imaging findings to facilitate more accurate diagnoses and guide treatment strategies, ultimately enhancing multidisciplinary patient management.

Resilience and Wellness: Tools for Emergency Radiologists

Thursday, Dec. 4 8:00AM - 9:00AM Room: N228

Hao S. Lo, MD, MBA (*Moderator*) Nothing to Disclose
Krystal Archer-Arroyo, MD (*Moderator*) Consultant; Siemens Healthineers USA

LEARNING OBJECTIVES

1) Understand the scope and impact of workplace violence and safety in the healthcare setting. 2) Define and discuss burnout and wellness for the emergency radiologist. 3) Explain the details of a medicolegal lawsuit as it pertains to the emergency radiologist.

COURSE DESCRIPTION

This course addresses physician burnout as a major challenge in emergency radiology. We will explore three critical areas: workplace violence and safety, burnout itself, and medicolegal concerns. You will identify common causes of radiologist burnout and gain practical strategies and tools to enhance your resilience and overall well-being. We will examine these crucial considerations from the individual, leadership, and system perspectives.

Advances in Focused and Abbreviated Abdominal and Pelvic MRI Protocols

Thursday, Dec. 4 8:00AM - 9:00AM Room: E451B

Hersh Chandarana, MD, MBA (*Moderator*) Speaker's Bureau; Siemens Healthineer. Other-Hardware and software research support under institutional Master Research Agreement as well as travel suport; Siemens Healthineer
Ivan Pedrosa, MD, PhD (*Moderator*) Consultant; Health Tech International

LEARNING OBJECTIVES

1) Describe and compare strengths and weaknesses of different methods for performing targeted MRI for hepatocellular carcinoma (HCC) screening. 2) Describe the current evidence for targeted protocols for pancreatic cyst surveillance. 3) Examine the latest technological advancements and innovations in Prostate MRI (such as AI-assisted image reconstruction /acquisition and intelligent scanning) that support the use of targeted and abbreviated protocols.

COURSE DESCRIPTION

With increasing healthcare costs and challenges with staffing and access to MR imaging, it is important to consider focused indication-based focused scanning and reporting MRI protocols to maximize efficiency and address the above-mentioned challenges. In this course, we will review current evidence for focused and abbreviated MRI protocol for liver cancer (hepatocellular carcinoma), pancreatic cysts, and prostate cancer as well as opportunities and challenges in implementing shortened focused protocols in busy clinical practice. Furthermore, we will have a lively panel discussion to dive deeper into opportunities and challenges and share experiences of how one can get started and measure the utility, efficacy, and cost savings with implementation of focused protocols.

Best Practices for AI Model Regulation

Thursday, Dec. 4 8:00AM - 9:00AM Room: E450B

Elizabeth O'Hare, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand how the FDA is approaching GenAI regulation within the medical device framework. 2) Explore vendor perspectives on regulatory flexibility and transparency in GenAI oversight. 3) Gain awareness of emerging AI-related policies at the federal and state level in the U.S. and international approaches to AI regulation.

COURSE DESCRIPTION

As generative AI (GenAI) technologies rapidly evolve, regulatory frameworks are under increasing pressure to keep pace—particularly in the medical device ecosystem. This session will explore how GenAI tools used in radiology and healthcare are being addressed by regulators in the United States and globally. The discussion will begin with an overview of how the U.S. Food and Drug Administration (FDA) is adapting its medical device regulatory system to address the unique challenges of GenAI. The session will then explore the broader U.S. legal and regulatory landscape, including emerging state-level AI policies and their implications for healthcare providers and vendors. Finally, the session will conclude with an international perspective, comparing how key jurisdictions outside the U.S.—including the EU, UK, and others—are approaching regulation of GenAI in medicine.

Practical Application of Photon Counting Imaging: Head to Toe

Thursday, Dec. 4 8:00AM - 9:00AM Room: E352

LEARNING OBJECTIVES

1) Describe the fundamental principles of photon-counting CT and how they differ from conventional CT technologies. 2) Identify clinical applications of photon-counting imaging across various anatomical regions, from head to toe. 3) Evaluate the practical benefits and current limitations of photon-counting CT in routine clinical workflows.

COURSE DESCRIPTION

This session will provide a practical overview of photon-counting CT (PCCT), a next-generation imaging technology poised to transform clinical radiology. Through a combination of lecture and case-based discussion, experts will explore how PCCT improves image quality, reduces radiation dose, and enables new diagnostic capabilities across a wide range of anatomical regions—from head to toe. Attendees will gain insights into real-world applications, implementation challenges, and workflow integration. By the end of the session, learners will understand how to evaluate and apply photon-counting CT in their clinical practice.

Teresa Chapman, MD, MA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Demonstrate emerging ultrasound applications in the pediatric neck, such as vocal cord motion and tonsillar pathology. 2) Update learners on pediatric thyroid nodule guidelines and provide imaging examples to differentiate benign from malignant. 3) Establish a management plan for palpable lumps and bumps based on sonographic appearance.

COURSE DESCRIPTION

This educational session with four case-based lectures focuses on the application of ultrasound to evaluate vocal cords and tonsillar pathology in children, sonographic assessment of superficial palpable lumps and bumps in children, and ultrasound evaluation for pediatric thyroid nodules with updates in management. The session will conclude with a talk describing atypical presentations of common pediatric lumps and bumps and will discuss the role of ultrasound and other imaging modalities in challenging cases of pediatric lumps and bumps. By the end of the session, audience members will have an increased confidence in their ability to diagnose these superficial abnormalities in children using ultrasound, with an improved awareness of recent innovations and current standards of care and reporting.

Imaging Response Assessment and Minimally Invasive Therapies in Breast Cancer Treatment

Thursday, Dec. 4 9:30AM - 10:30AM Room: S406A

Beatriz E. Adrada, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Learn the value of the different conventional and functional breast imaging modalities for determining response to neoadjuvant therapy in breast cancer treatment. 2) Provide a comprehensive review of the available imaging modalities for lymph node assessment in patients diagnosed with breast cancer. 3) Explore the indications, patient selection, procedural techniques, and potential limitations of cryoablation as a treatment option for breast cancer.

COURSE DESCRIPTION

This course will delve into how to breast imaging modalities can assess response to neoadjuvant therapy. It will discuss the specific advantages and limitations of each imaging modality for identifying responders versus non-responders, which is crucial for guiding further treatment decisions. It highlights the importance of lymph node assessment in a patient diagnosed with breast cancer. Finally, this course will explore novel minimally invasive techniques including cryoablation and its potential applications in breast cancer treatment.

Francesco Giganti, MD, PhD (*Moderator*) Consultant; DeepHealth. Consultant; Lucida. Consultant; Spectracure. Consultant; Procept
Sadhna Verma, MD, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand PI-RADS 3 criteria effectively in the interpretation and reporting of multiparametric prostate MRI. 2) Distinguish between expected post-treatment changes and recurrent or residual disease on prostate MRI following surgery, radiation, or focal therapy. 3) Formulate practical strategies to address common diagnostic challenges in prostate cancer imaging and reporting.

COURSE DESCRIPTION

This educational session provides a comprehensive overview of prostate cancer imaging across the disease continuum—from detection and risk stratification using PI-RADS to complex scenarios encountered in the post-treatment setting. As prostate MRI continues to evolve as a cornerstone of diagnosis and management, radiologists face increasing demands to accurately interpret pre- and post-treatment imaging while navigating pitfalls such as treatment-related changes, recurrent disease, and atypical lesion presentations.

R3-CNPM14

Should AI Autonomously Interpret Radiographs? A Debate

Thursday, Dec. 4 9:30AM - 10:30AM Room: S402

Shah Islam, FRCR (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1)Learn about challenges of deploying financially sustainable AI within value-based healthcare systems. 2) Learn about the benefits of autonomous chest x-ray reading for patients, payers and providers. 3) Learn about the risk of autonomous chest x ray reading and what must be done before responsible AI can be deployed.

COURSE DESCRIPTION

This thought-provoking educational course discusses and debates the use of AI's earliest use cases- reading of chest x-rays. The session will aim to explore current attitudes to adoption of AI in interpreting chest x-rays and where the value really lies. The session will deliver talks from front line radiologists working in different health systems, followed by a no holds barred panel discussion.

What Every Radiologist Should Know: First Trimester

Thursday, Dec. 4 9:30AM - 10:30AM Room: E351

Maitray D. Patel, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Use the new Society of Radiologists in Ultrasound (SRU) consensus lexicon to describe early pregnancy loss and ectopic pregnancy locations. 2) Understand expected and unexpected intrauterine sonographic observations following first trimester pregnancy loss or termination. 3) Recognize unusual adnexal sonographic observations that might be present in women in early pregnancy.

COURSE DESCRIPTION

Sociopolitical considerations have sharpened the need for radiologists to use precise terminology in describing normal and abnormal sonographic observations in the first trimester of pregnancy, spurring recent development of a consensus lexicon by the Society of Radiologists in Ultrasound (SRU). The SRU lexicon also addresses intrauterine and endometrial sonographic findings that can develop after cessation of a first trimester pregnancy. This educational session reviews the lexicon and highlights adnexal and intrauterine observations that radiologists might encounter to advance skills in interpretation of these sonographic studies.

Not the Usual Suspects: Vasculitis, Aortopathy and Arteriopathy

Thursday, Dec. 4 9:30AM - 10:30AM Room: S503

Ayaz Aghayev, MD (*Moderator*) Consultant; Elucid
Jacobo Kirsch, MD, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the key imaging features of inflammatory aortic disease, fibromuscular dysplasia, congenital vascular anomalies, and genetic aortopathies. 2) Differentiate between inflammatory and non-inflammatory arteriopathies using clinical context and imaging modalities such as CT, MRI, and ultrasound. 3) Apply a systematic imaging approach to diagnose uncommon large-vessel pathologies and guide clinical management.

COURSE DESCRIPTION

This lecture-based session explores a spectrum of uncommon yet clinically significant vascular diseases, including inflammatory, genetic, congenital, and non-inflammatory arteriopathies. Expert faculty will present real-world cases and current imaging strategies to identify and differentiate complex large-vessel abnormalities. Topics include vasculitis and aortic inflammation, fibromuscular dysplasia, congenital vascular anomalies in adults, and genetic aortopathies. The session is designed to enhance diagnostic confidence and accuracy among radiologists by addressing key imaging features, pathophysiologic mechanisms, and multimodality approaches. Learners will leave with a deeper understanding of how to approach challenging vascular cases that fall outside the scope of more common cardiovascular disease.

RSNA 2025 Resident Competition (Hosted by the RadioGraphics Team)

Thursday, Dec. 4 9:30AM - 10:30AM Room: S406B

Heba Albasha, MD (*Moderator*) Nothing to Disclose
Maria Lucia Brun, MD (*Moderator*) Nothing to Disclose
Otavio Augusto Ferreira Dalla Pria, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Invite residents from across the world to compete against each other in a riveting case competition. 2) Foster team-building and friendly competition.

COURSE DESCRIPTION

Please join us for a friendly case competition between programs across the world! Form a team with your co-residents and prepare for multiple rounds of fun and challenging cases! Teams can have up to 6 residents each. In-person attendance is required to participate, and the competition will be hosted through Kahoot! using a mobile device. Only twenty teams can participate, but everyone is welcome to attend the show! Please use the following form to register your team:https://forms.gle/8W6TW5ohsRtATB1x9. Limited spots will be reserved for on-site team registration - please head to the Residents Lounge on Sunday, Monday or Tuesday of the meeting to register.

Navigating High-Risk Breast Lesions: A Global Perspective

Thursday, Dec. 4 11:00AM - 12:00PM Room: N228

Vilert A. Loving, MD, MMM (*Moderator*) Speaker's Bureau; BD

LEARNING OBJECTIVES

1) Discuss the diagnosis of high-risk breast lesions. 2) Learn to weigh the risks of undertreatment versus overtreatment for high-risk breast lesions. 3) Explore management strategies for high-risk breast lesions, comparing the United States, United Kingdom, and Brazil.

COURSE DESCRIPTION

Question: When high-risk lesions are diagnosed from core needle biopsy, should radiologists recommend excision, surveillance imaging, or age-appropriate screening? Answer: It depends! The management of high-risk breast lesions remains controversial and requires a balance: the potential of undertreating associated malignancies versus overtreating benign high-risk lesions. This session seeks to shed light on this diagnostic dilemma as we discuss management strategies for high-risk breast lesions. To foster the development of best practices, lectures will include viewpoints from representatives of different countries, including the United States, United Kingdom, and Brazil. Attendees will obtain high-risk lesion management strategies to implement or further explore at their institutions.

Fundamentals of Cardiac MRI

Thursday, Dec. 4 11:00AM - 12:00PM Room: E353C

Diana Ochoa, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the standard cardiac MRI planes and the key pulse sequences used for cardiac imaging. 2) Understand the principles of tissue characterization using late gadolinium enhancement and emerging non-contrast techniques. 3) Explain the basics of MR angiography and flow imaging, and identify the top clinical applications of cardiac MRI in routine practice.

COURSE DESCRIPTION

This course provides a comprehensive overview of the fundamental principles and clinical applications of cardiac MRI. Through a series of focused lectures, attendees will gain essential knowledge on cardiac imaging planes and sequences, tissue characterization techniques including late gadolinium enhancement, basics of MR angiography and flow imaging, and the most impactful clinical uses of cardiac MRI. The session is designed for radiologists, cardiologists, and trainees seeking to build a solid foundation in cardiac MRI for effective interpretation and clinical decision-making.

Imaging of Airway Diseases

Thursday, Dec. 4 11:00AM - 12:00PM Room: E451A

Jo-Anne O. Shepard, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review the various diseases affecting the large and small airways and understand the spectrum of imaging findings.

COURSE DESCRIPTION

Imaging of Airways Diseases consists of three comprehensive lectures that will highlight imaging findings in diseases of the large and small airways. The topics will include a state-of-the-art summary of focal and diffuse non-neoplastic diseases of the central airways as well as various benign and malignant neoplasms affecting the airways. Additionally, the spectrum of imaging findings in small airways diseases will be discussed in detail.

Best Practices for Human-AI Collaboration

Thursday, Dec. 4 11:00AM - 12:00PM Room: E450B

Bonnie Armstrong, PhD, MA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Gain practical knowledge of how to anticipate common biases in AI-assisted diagnosis and apply targeted solutions such as learning through simulation, interface design changes, and training approaches. 2) Learn how to evaluate and design AI tools that align with real-world clinical workflows, cognitive limitations, and the needs of diverse users. 3) Provide guidance on how to structure, frame, and time AI outputs in ways that enhance interpretability, trust, and utility.

COURSE DESCRIPTION

This session brings together experts in human factors, cognitive science, and clinical AI to explore how we can design, communicate, and implement AI tools in ways that support clinicians and patients. The session begins with a cognitive science framework that explains how variations in thinking styles and expertise can increase susceptibility to cognitive biases and diagnostic errors in AI-assisted radiology, and presents strategies to reduce these risks through debiasing methods and thoughtful interface design. Next, the session shifts to a human-factors perspective, drawing from research in healthcare and other high-risk industries to explore how AI tools can be developed with a deep understanding of user needs, workflows, and cognitive limitations. Building on these foundations, the third talk addresses best practices for contextualizing AI-generated results - focusing on how information can be structured, framed, and timed to improve clinical utility and ensure AI outputs are actionable for both physicians and patients. Finally, the session concludes with a series of real-world case examples highlighting what effective human-AI collaboration looks like in practice, with a focus on optimizing shared decision-making, reducing cognitive burden, and building sustainable AI workflows in radiology. This session will use a lecture format and will equip participants with interdisciplinary, evidence-based strategies to improve the safety, usability, and healthy skepticism of AI in clinical care.

Addressing Imaging Disparities in American Indian and Alaska Native Communities: Opportunities and Solutions (Sponsored by the RSNA Health Equity Committee) (Advanced)

Thursday, Dec. 4 11:00AM - 12:00PM Room: N227B

Marilyn A. Roubidoux, MD (*Moderator*) Nothing to Disclose
Vaz A. Zavaletta, MD, PhD (*Moderator*) Other-Royalties; Mayo Medical Ventures licenses software to Imbio and 4D Medical

LEARNING OBJECTIVES

1) Understand the ethical principles and cultural considerations necessary for conducting health equity research in Native American communities and the role of tribal institutional role boards (IRBs). 2) Examine the role of community-driven research models that prioritize community input, trust building, and tribal sovereignty in the design, implementation, and dissemination of research findings. 3) Identify health disparities and community priorities in American Indian and Alaska Native communities, including the effects of colonization, forced relocation, and cultural erasure. 4) Analyze successful case studies of health equity research conducted with American Indian and Alaska Native communities and evaluate how these models can apply to other contexts.

COURSE DESCRIPTION

This course explores the complex and multifaceted health disparities faced by American Indian and Alaska Native communities, focusing on radiology and its intersection with health equity. The health disparities in this population are quite diverse geographically, with significant differences between urban and rural communities as well as between regions such as Alaska and Arizona. By delving into the historical and ongoing impacts of colonization, forced relocation, and cultural erasure, participants will gain a nuanced understanding of the roots of health inequities and the priorities identified by Native communities. The course analyzes successful case studies and community-driven research models to highlight the importance of tribal sovereignty, trust-building, and active community input in designing and implementing equitable healthcare solutions. Practical strategies and transferable insights will empower participants to address imaging disparities and promote health equity in diverse contexts.

Quantitative Automated Tools in Neuroimaging: A Help or Hindrance? (Advanced)

Thursday, Dec. 4 11:00AM - 12:00PM Room: S406B

Amish H. Doshi, MD (*Moderator*) Consultant; Subtle Medical. Consultant; VizAI. Consultant; BD. Consultant; Bracco. Consultant; AIRS Medical

LEARNING OBJECTIVES

1) Evaluate the clinical utility and limitations of quantitative MRI techniques in the diagnosis and management of acute stroke, neurodegenerative diseases, and multiple sclerosis. 2) Identify current challenges in implementing quantitative MRI across different neurological disorders, including technical variability, standardization issues, and integration into clinical workflows. 3) Compare the perspectives of radiologists and neurologists on the added value of quantitative MRI in multiple sclerosis, and explore its role in patient care.

COURSE DESCRIPTION

This session will explore the evolving role of quantitative MRI in the evaluation and management of neurological disorders, with a focus on stroke, neurodegeneration, and multiple sclerosis. Expert speakers will discuss whether quantification translates into clinical value, highlight the technical and practical challenges of implementing quantitative imaging, and provide interdisciplinary perspectives—including that of a clinical neurologist—on its current and future applications. Attendees will gain insight into how quantitative MRI can enhance diagnostic interpretation, inform treatment decisions, and potentially improve patient outcomes, while also recognizing the limitations and barriers to its broader adoption.

Dilachew A. Adebo, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize key imaging features of common congenital and acquired pediatric cardiovascular diseases. 2) Analyze complex congenital and acquired cardiovascular anomalies in pediatric patients using advanced imaging modalities and emerging technologies. 3) Describe common CTPA pitfalls and mimics and the role of dual-energy CT and perfusion maps for acute pulmonary embolism. 4) Discuss the complementary roles of ultrasound and MRI in the diagnosis, treatment, planning, and follow-up of vascular malformations.

COURSE DESCRIPTION

This comprehensive educational session is designed to enhance diagnostic expertise in pediatric cardiovascular imaging. With a focus on real-world clinical application, this session addresses both foundational and advanced imaging challenges that imagers face during daily routine practice. This session is ideal for radiologists of all levels seeking to strengthen their diagnostic skills and stay current with evolving technologies in pediatric cardiovascular imaging.

State-Of-The-Art and Future Advances in Breast Imaging

Thursday, Dec. 4 11:00AM - 12:00PM Room: S404

Ioannis Sechopoulos, PhD (*Moderator*) Grant/Research Support; Siemens Healthcare. Grant/Research Support; Canon Medical. Grant/Research Support; ScreenPoint Medical. Grant/Research Support; Volpara Healthcare. Grant/Research Support; Sectra Benelux. Grant/Research Support; Hologic Inc.. Grant/Research Support; iCAD. Grant/Research Support; Lunit. Other-Scientific Advisory Board member; Koning Corp.

LEARNING OBJECTIVES

1) Explore the emerging role of contrast-enhanced mammography (CEM) in breast cancer screening, diagnosis, and biopsy, and discuss considerations and hurdles to clinical implementation. 2) Discuss the latest developments in software and hardware technology in clinical and research digital breast tomosynthesis (DBT) systems and the emerging role of machine learning/AI on DBT workflow, computer-aided diagnosis, reconstruction, dose reduction, and risk prediction. 3) Describe the proven clinical utility of dedicated breast CT (bCT) for breast cancer diagnosis, the next-generation developments in bCT, and how they may further enhance clinical utility of this modality.

COURSE DESCRIPTION

Contrast-enhanced mammography (CEM) has been gaining traction as a potential screening alternative for dense breasts and high-risk patients, and many institutions are seeking to adopt this modality into their clinical practice. Design and capabilities of commercially available systems will be reviewed along with practical considerations for implementing this technology into the clinical workflow for existing and emerging indications. Digital breast tomosynthesis (DBT) is increasingly used globally as a primary screening modality for breast cancer. The technology is still changing and improving over time, including new detector technologies, faster scanning, and improved reconstruction and image processing. These developments, and the increasing use of AI and machine learning at nearly every stage of the DBT workflow, will be discussed. Numerous clinical studies demonstrating the clinical utility of dedicated breast CT (bCT) will be explained and summarized in the context of comparison to standard-of-care breast imaging techniques. Limitations of existing bCT technology will be reviewed, and next generation developments aimed at overcoming some of these challenges and expanding the utility of the modality will be presented.

LEARNING OBJECTIVES

1) Identify biomarkers of Alzheimer Disease. 2) Understand the role of Amyloid PET in diagnosing and managing Alzheimer Disease. 3) Identify the use of beta-amyloid burden quantification.

COURSE DESCRIPTION

This educational session consists of lectures highlighting Alzheimer Disease (AD), the most common cause of dementia. Attendees of this course will receive a comprehensive review of AD biomarkers, including amyloid PET and beta-amyloid burden quantification, with an emphasis on the role of radiologists in guiding diagnosis and management. Approaches to overcoming barriers to clinical implementation will be discussed.

MIDRC: Engaging the Cancer Imaging Research Community

Thursday, Dec. 4 11:00AM - 12:00PM Room: E353B

Maryellen L. Giger, PHD (*Moderator*) Stock/Shareholder; Hologic. Stock/Shareholder; Qview. Consultant; Genetech/Roche. Other Financial or Material Support; Various companies who license from the Polsky Center at the University of Chicago

LEARNING OBJECTIVES

1) Appreciate the various MIDRC tools that are open to all AI investigators. 2) Learn the potential role of large language models in routine clinical radiology practice and in benefitting patients' understanding. 3) Understand the role and need for data to advance the field of AI and enable translation to clinical use for the benefit of patient care.

COURSE DESCRIPTION

This session aims to acquaint the attendee with MIDRC, its data, and its tools. The various MIDRC tools are open to all AI investigators, whether they are developers, evaluators, or clinical users of AI. Examples will be given and related to routine clinical care. With one such example, attendees will learn the potential role of large language models in routine clinical radiology practice and in benefitting patients' understanding. The goal is to have AI benefit the radiological imaging exam as well as the patient in understanding the exam and its resulting findings. Ultimately, attendees will appreciate the role and need for data to advance the field of AI and enable translation to clinical use for the benefit of patient care.

Head and Neck After Dark: Case-Based Review of Emergency and On Call Imaging

Thursday, Dec. 4 1:30PM - 2:30PM Room: E352

Valeria Potigailo, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize critical imaging findings in head and neck emergencies: Learners will enhance their ability to identify key radiologic features across a range of urgent head and neck conditions, including facial trauma, temporal bone emergencies, non-traumatic neck emergencies, and pediatric head and neck emergencies. 2) Emphasis will be placed on high-yield and clinically relevant diagnoses frequently encountered during on-call and emergency imaging, as well as rare but critical "can't-miss" findings.

COURSE DESCRIPTION

This lecture-based session will provide a focused review of high-yield head and neck diagnoses that are essential for radiologists covering on-call and emergency imaging. Accurate and timely interpretation of these conditions can significantly impact patient care and outcomes. The session will highlight common pitfalls, critical diagnoses not to miss, and practical tips for efficient evaluation of head and neck pathology in the acute setting. Learners will improve their confidence and accuracy in identifying critical head and neck findings on emergency and after-hours imaging studies, leading to better-informed clinical decisions and patient management.

Best Practices for AI Continuous Model Evaluation

Thursday, Dec. 4 1:30PM - 2:30PM Room: E450B

Akshay Chaudhari, PhD (*Moderator*) Grant/Research Support; GE Healthcare. Grant/Research Support; Microsoft. Grant/Research Support; Stability.ai. Owner; Cognita Imaging Inc.. Grant/Research Support; Philips. Consultant; Subtle Medical. Stock/Shareholder; Brain Key. Stock/Shareholder; LVIS Corp. Other-Scientific Advisory Board; Chondrometrics GmbH. Consultant; Patient Square Capital. Consultant; Elucid Bioimaging. Grant/Research Support; Amazon

LEARNING OBJECTIVES

1) Implement Evaluation Workflows: Outline the technical steps and best practices for performing continuous AI model evaluation, from initial deployment to large-scale monitoring. 2) Manage Data Shifts: Assess the clinical impact of distributional data shifts on AI model performance and identify practical methods for their detection. 3) Leverage Automated Tools: Discuss emerging methods that use large language models and computer vision to automate the performance evaluation of other radiology AI models.

COURSE DESCRIPTION

This session will present best practices for monitoring the performance of AI models that are deployed for use in conjunction with an overseeing radiologist. Given such human-AI collaborative settings where models are not deployed autonomously, this course will cover who the responsible parties could be for ongoing evaluation and how they can perform evaluation from initial deployment to large-scale monitoring. Experts will share lessons learned from real-world attempts at deploying continuous evaluation programs, providing updates on current best practices and the evolving regulatory landscape. Topics will cover change control planning, autonomous AI implications, regulatory clearance status, impact and detection of distributional shifts, and practical lessons learned from deployment and monitoring.

Pediatric Malignancies: Multidisciplinary Masterclass

Thursday, Dec. 4 1:30PM - 2:30PM Room: S401

Camilo Jaimes Cobos, MD, MPH (*Moderator*) Nothing to Disclose
Hesham Elhalawani, MD, MSc (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Engage in a multidisciplinary discussion concerning three complex pediatric oncology cases, focusing on their clinical and imaging characteristics. 2) Present recommendations from the COG/SPR consensus papers pertaining to image acquisition and interpretation. 3) Examine the role of radiation therapy in these cases, emphasizing strategic planning and delivery considerations.

COURSE DESCRIPTION

This interactive panel discussion will delve into three complex pediatric oncology cases. The panel, composed of two pediatric radiologists, a radiation oncologist, and a medical oncologist, will guide the conversation. Suggested panel includes: - Camilo Jaimes Cobos (pediatric neuroradiology, Mass General Hospital, USA) cjaimescobos@mgb.org - Michael Gee (pediatric radiology, Mass General Hospital, USA) msgee@mgh.harvard.edu - Jessica Clymer (pediatric neuroradiology, NYU Langone Health, USA) jessica.clymer@nyulangone.org - Hesham Elhalawani (pediatric/AYA radiation oncology, Boston Children's/Brigham and Women's Hospital, USA) helhalawani@bwh.harvard.edu Each case will be introduced through its clinical presentation and initial imaging. The medical oncologist will provide insights into the biology of the tumor, its staging, and the standard medical management. Following this, the radiation oncologist will discuss treatment alternatives, intricacies of radiation planning, and crucial aspects of delivery. The discussion will emphasize key aspects of medical imaging for each case, drawing on the recent recommendations from the Children's Oncology Group (COG)/Society for Pediatric Radiology (SPR) guidelines.

AI as the New Normal In Cardiac Imaging

Thursday, Dec. 4 3:00PM - 4:00PM Room: E353C

Marly Van Assen, MSc, PhD (*Moderator*) Grant/Research Support; Siemens. Grant/Research Support; Cleerly. Grant/Research Support; Pfizer

LEARNING OBJECTIVES

1) Describe current real-life applications of AI in cardiac imaging, including workflow optimization, automated analysis and report generation. 2) Identify practical considerations for implementing AI tools in cardiac imaging. 3) Evaluate the impact of AI integration on clinical efficiency, diagnostic accuracy, and patient outcomes in cardiovascular imaging.

COURSE DESCRIPTION

This session explores practical applications of artificial intelligence across the cardiac imaging pipeline, from data acquisition to report generation. Experts will share real-world strategies for integrating AI into cardiac imaging workflows, discuss current capabilities and limitations, and demonstrate how AI tools are being used today to enhance efficiency, consistency, and diagnostic accuracy and any future perspectives. Attendees will gain actionable insights on leveraging AI in clinical practice to improve patient care.

On-Call Emergency Radiology: Cases You Can't Afford to Miss

Thursday, Dec. 4 3:00PM - 4:00PM Room: E450B

Laura L. Avery, MD (*Moderator*) Nothing to Disclose
Polina Kanj, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key imaging findings in common and high-risk trauma scenarios, including cervical spine injuries, body trauma, and ballistic wounds. 2) Recognize common pitfalls and diagnostic blind spots in trauma imaging and develop strategies to avoid them in high-pressure clinical settings. 3) Apply structured approaches to trauma imaging that improve speed and accuracy of diagnosis across a range of emergent situations. 4) Correlate clinical context with imaging features to enhance interpretation and guide timely, effective patient care decisions.

COURSE DESCRIPTION

Nothing good happens after midnight. The only things open are 7-Eleven and trouble. The whole town’s out looking for fun and finding trauma. As the night float resident, you and the CT scanner are busier than the bartender five minutes before last call. In this fast-paced case-based session, you’ll sharpen your trauma imaging skills to increase your speed to diagnosis, improve accuracy, and sidestep common pitfalls when every second counts.

Case-Based Potpourri (Liver, Spleen, Mesentery)

Thursday, Dec. 4 3:00PM - 4:00PM Room: E451B

Jeong Min Lee, MD, PhD (*Moderator*) Grant/Research Support; Bayer, Gerbet, Philips Healthcare, GE Healthcare, Samsung Medison, Clarify, Medical IP, Stardmed, RF Medical. Speaker's Bureau; Bayer, Samsung Medison, GE Healthcare, Clarify, Philps Healthcare, Starmed, Gerbet. Grant/Research Support; Central Medical Service, . Consultant; Samsung Medison

LEARNING OBJECTIVES

1) Demonstrate proficiency in identifying characteristic imaging features of hepatic, splenic, and mesenteric pathologies using multimodality approaches, including advanced MRI techniques and contrast-enhanced CT protocols. 2) Formulate comprehensive differential diagnoses for complex abdominal imaging findings and apply systematic diagnostic algorithms to challenging cases. 3) Recognize and mitigate common interpretation pitfalls in hepatic, splenic, and mesenteric imaging, implementing quality assurance strategies to reduce diagnostic errors.

COURSE DESCRIPTION

This comprehensive case-based session provides an in-depth review of hepatic, splenic, and mesenteric imaging pathology. Distinguished faculty will present challenging clinical cases encompassing both common and rare entities, emphasizing state-of-the-art imaging techniques and their clinical applications. The session will demonstrate optimal utilization of multimodality imaging (CT, MRI, ultrasound, and nuclear medicine when applicable) for accurate diagnosis and treatment planning. Interactive case discussions, real-time polling, and Q&A sessions will facilitate active learning and knowledge retention.

Best Practices for AI Education

Thursday, Dec. 4 3:00PM - 4:00PM Room: N228

Katherine P. Andriole, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Know why radiologists, whether in training or beyond, should have an understanding of Artificial Intelligence/Machine Learning (AI/ML) technologies at least at a high level. 2) Learn example curricula and ways in which radiologists and residents can be trained in AI/ML. 3) Become familiar with ways to educate care team members and patients about AI.

COURSE DESCRIPTION

Clinical Radiology will be practiced using Artificial Intelligence/Machine Learning (AI/ML) tools. Multiple steps are involved in developing and deploying machine learning models and artificial intelligence applications and clinical radiological expertise and input is required throughout the development and translation pipeline. In order to contribute to the process, Radiologists should have at a minimum, knowledge of AI/ML technology at a high level, understanding of technology limitations and recognition of error, the ability to converse and collaborate with a multidisciplinary team, capability to critically read the literature, and the ability to evaluate and properly use an AI/ML product or application. Example educational activities for residents are discussed. Other health care team members as end-users and patients as consumers must be educated as well. Methods for monitoring AI training will be discussed. This session will present best practices for educating each of these constituents.

MSK Infection: From Skin to Bone

Thursday, Dec. 4 3:00PM - 4:00PM Room: E450A

Kevin McGill, MD, MPH (*Moderator*) Consultant; Vitruvia. Grant/Research Support; Teleflex

LEARNING OBJECTIVES

1) Differentiate between the imaging characteristics of acute and chronic musculoskeletal infections, including joint infections, soft tissue infections, and osteomyelitis. 2) Interpret key imaging findings in pediatric musculoskeletal infections, understanding how they differ from adult presentations and influence diagnostic and management strategies. 3) Apply appropriate imaging modalities and protocols to effectively diagnose and monitor infections of the joints, bones, and soft tissues, with attention to clinical urgency and anatomical complexity.

COURSE DESCRIPTION

Musculoskeletal (MSK) infections are diagnostically challenging conditions that span a broad spectrum—from superficial soft tissue involvement to deep-seated osteomyelitis. This course is designed to enhance diagnostic accuracy and confidence in evaluating infectious processes across the musculoskeletal system. These high-yield lectures will cover acute and chronic joint infections, soft tissue infections, and osteomyelitis, with particular attention to pediatric-specific presentations. The course will emphasize imaging patterns, modality selection, and diagnostic pitfalls, providing tools to differentiate infection from mimics and to guide timely clinical intervention. This course is important because MSK infections can present subtly and evolve rapidly, with delays in diagnosis potentially leading to irreversible functional loss, systemic spread, or even death. Accurate image interpretation is central to early detection and treatment planning, especially in complex or atypical cases. This course addresses the clinical urgency, anatomic complexity, and age-specific considerations critical to optimal patient care. Many key issues will be addressed during the course including, differentiation of acute vs. chronic joint and bone infections, imaging strategies for evaluating soft tissue infections, including abscesses and necrotizing fasciitis, special diagnostic approaches for pediatric musculoskeletal infections, recognizing imaging findings that necessitate urgent surgical or medical management, and avoiding common diagnostic pitfalls and misinterpretations By the end of this session, participants will be able to select the most appropriate imaging modalities, recognize key diagnostic features across a spectrum of infections, and contribute effectively to multidisciplinary management.

Medicolegal Hot Topics

Thursday, Dec. 4 3:00PM - 4:00PM Room: S402

Avanti Gulhane, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Discuss how state and federal laws including supreme court decisions can influence practices of radiology and adoption of new technologies such AI. 2) Understand how medical malpractice trials are adjudicated with respect to radiology including interpretation of radiographs. 3) Understand how financial compensation is determined in a malpractice trial.

COURSE DESCRIPTION

This course is targeted towards enabling radiologists understand how the malpractice trial proceedings work in a real-world setting. The presentations listed include a diverse range of topics that will equip the audience to understand how law influences the practice of radiology. Information will be provided regarding state and federal laws on the regulation of healthcare and technologies including artificial intelligence. Focused discussion will include the change in practice of radiology following the landmark supreme court decision to overturn Roe v. Wade in 2022 and delegate legislative decisions regarding abortion to individual states.

A New Era of Dementia Imaging: State-of-The-Art

Thursday, Dec. 4 3:00PM - 4:00PM Room: S406B

Gloria C. Chiang, MD (*Moderator*) Consultant; Life Molecular Imaging. Other-Honorarium to speak at CME; Efficient CME. Consultant; Alnylam Pharmaceuticals. Consultant; Minoryx Therapeutics. Other-Honorarium to speak at CME; Peerview CME

LEARNING OBJECTIVES

1) Identify the key findings of amyloid-related imaging abnormalities (ARIA) on MRI and what action needs to be taken by the radiologist, based on ARIA severity. 2) Be familiar with how positive versus negative amyloid PET scans look qualitatively and learn about quantitative tools that may aid visual interpretation. 3) Be familiar with imaging findings that would suggest either atypical Alzheimer's or non-Alzheimer's dementia.

COURSE DESCRIPTION

Alzheimer's disease neuroimaging has changed dramatically in the last few years, as anti-amyloid therapies have become widely prescribed in the U.S. Radiologists now play a crucial role in 1) accurately diagnosing Alzheimer's disease, which may involve a combination of MRI, FDG PET, amyloid PET, and/or lumbar puncture, and 2) monitoring for amyloid-related imaging abnormalities (ARIA) while patients are on therapy. These lectures will provide the necessary tools for radiologists to appropriately diagnose and manage these patients. In addition, the speakers will walk through real-life case examples, showing how findings from MR and PET can lead the radiologist to the correct diagnosis in both typical and atypical dementia cases. Finally, speakers will discuss the future of Alzheimer's management, including the recently FDA-approved blood test.

Imaging in Cervical and Endometrial Cancer: What Referring Physicians Need to Know

Thursday, Dec. 4 3:00PM - 4:00PM Room: E351

Jeanne M. Horowitz, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review how to optimize and interpret cervical cancer MRI and PET exams for staging, with interesting case examples. 2) Explain what radiologists need to know about the 2023 Endometrial Cancer FIGO Guidelines to add value in their reports for their ordering physicians, with practical take home points. 3) Learn pearls and pitfalls of imaging endometrial and cervical cancer after treatment featuring state of the art imaging.

COURSE DESCRIPTION

"Imaging in Cervical and Endometrial Cancer: What Referring Physicians Need to Know" will feature three lecturers using interactive imaging case examples and giving practical take home points focusing on the Endometrial Cancer with FIGO 2023 Guidelines, Cervical Cancer staging with MRI and PET, and Imaging of Endometrial and Cervical Cancer after treatment.

Tracking Clues: Illuminating the Imaging Findings of Child Abuse

Thursday, Dec. 4 3:00PM - 4:00PM Room: N226

Edward J. Richer, MD (*Moderator*) Nothing to Disclose
Lynn A. Fordham, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key imaging features suggestive of Abusive Head Trauma in infants. 2) Distinguish radiographic findings of child abuse from those of common metabolic bone diseases. 3) Recognize actions to prepare for a child abuse court case that will make your testimony more efficient.

COURSE DESCRIPTION

Physical child abuse unfortunately remains all too common, and radiologists play an important role in the care of these patients through the use of imaging. Knowledge of characteristic imaging findings of child abuse, as well as potential mimics or alternatives, is essential to making an accurate diagnosis in these cases. Radiologists are also increasingly being called on to provide testimony when these cases end up in a courtroom. In this series of lectures, our experts will offer key insights into several aspects of this topic, including neuroimaging of abusive head trauma, distinguishing findings of abuse from metabolic bone disease on skeletal surveys, and how to prepare yourself when you receive a subpoena to testify.

Pre-Transcatheter Structural Heart Interventions: How to Do It

Sunday, Nov. 30 9:00AM - 10:00AM Room: E353C

Melany B. Atkins, MD (*Moderator*) Consultant; GE Heathcare. Speaker's Bureau; HeartFlow. Consultant; Arterys. Consultant; Bayer Healthcare CTEPH
Phillip M. Young, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key imaging protocols and techniques essential for planning transcatheter structural heart interventions, including TAVR, TMVR, TTVR, TPVR, and LAA closure.
2) Evaluate the imaging considerations unique to mitral, tricuspid, and pulmonary valve interventions, and apply this knowledge to support device selection, procedural planning, and complication avoidance.

COURSE DESCRIPTION

This lecture series provides a comprehensive overview of pre-procedure planning for transcatheter structural heart interventions. Experts will cover current best practices for pre-procedural assessment, with a focus on TMVR, tricuspid and pulmonary valve therapies, and LAA closure. Attendees will gain practical insights to support clinical decision-making and optimize procedural outcomes

Emergent MSK Conditions: Diagnostic Challenges and Strategies

Sunday, Nov. 30 9:00AM - 10:00AM Room: N228

Claire K. Sandstrom, MD (*Moderator*) Nothing to Disclose
Manickam Kumaravel, MD, FRCR (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify easily missed or mischaracterized hip injuries. 2) Explain the clinical significance of subtle knee findings that portend more severe soft tissue injuries. 3) Appropriately describe intraarticular calcaneal fractures, reporting what the surgeons need to know.

COURSE DESCRIPTION

From these lectures, learners will about essential lower extremity musculoskeletal trauma. Easily missed hip injuries will be reviewed, with emphasis on detection of easily missed fractures and unusual dislocation patterns. Subtle knee findings that herald more severe underlying traumatic pathology will be discussed. Fractures of the calcaneus will be reviewed, with emphasis on detection and reporting surgically relevant findings. Ultimately, the learner will better understand the importance and nuances of hip, knee, and calcaneal post-traumatic imaging.

2025 Year in Review of AI Models in Radiology

Sunday, Nov. 30 9:00AM - 10:00AM Room: E450B

Imon Banerjee, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify and discuss the most impactful AI research papers published in leading radiology journals and conferences in 2025 - Radiology: AI, European Journal of Radiology, RadioGraphics, and MICCAI. 2) Evaluate key trends, methodological innovations, and clinical implications emerging from recent AI advancements in radiology. 3) Critically appraise how top-published works address challenges such as model generalizability, data diversity, interpretability, and regulatory alignment in radiology AI.

COURSE DESCRIPTION

This session offers a curated review of the most influential AI papers in radiology published in 2025. Moderated by Dr. Imon Banerjee, the session features expert insights from leading voices in the field: Dr. Charles Kahn will highlight top papers published in Radiology: AI; Dr. Pascal Baltzer will present standout research from the European Journal of Radiology; Dr. Kenneth Wang will showcase influential work from RadioGraphics; and Dr. Kayhan Batmanghelich will discuss the best AI papers presented at MICCAI 2025. Together, the speakers will provide a comprehensive overview of emerging trends, methodological innovations, and the clinical impact of AI in radiology. This session is designed for radiologists, researchers, and informatics professionals seeking to stay current with the rapidly advancing AI landscape in medical imaging.

Hand and Wrist: Approach to Multimodality Imaging

Sunday, Nov. 30 9:00AM - 10:00AM Room: E450A

Aline Serfaty Sr, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify and characterize common and complex tendon pathologies of the hand and wrist using ultrasound and MRI. 2) Describe the imaging appearance and clinical relevance of finger pulley injuries, and recognize high-performance athlete-specific patterns. 3) Differentiate metacarpal fractures that require operative treatment from those manageable with conservative therapy based on imaging features. 4) Evaluate intrinsic and extrinsic wrist ligament injuries using advanced imaging techniques, and understand their implications for wrist instability. 5) Interpret TFCC anatomy and pathology on imaging, correlating findings with patient symptoms to support accurate diagnosis and management decisions.

COURSE DESCRIPTION

This focused and dynamic session will provide a comprehensive review of key hand and wrist pathologies, highlighting a multimodality imaging approach. Expert faculty will cover tendon injuries, pulley system trauma, metacarpal fractures, ligamentous injuries of the wrist, and triangular fibrocartilage complex (TFCC) pathology. Emphasis will be placed on the role of MRI, ultrasound, and radiographs in diagnosis, and on differentiating injuries that require surgical intervention from those that can be managed conservatively. Radiologists will gain practical tools for accurate assessment and reporting, critical for guiding optimal clinical management.

Advanced Standardization and Certification for Safe, Efficient Remote MR Scanning: Ready for Prime Time

Sunday, Nov. 30 9:00AM - 10:00AM Room: S402

Emanuel Kanal, MD (*Moderator*) Consultant; Philips Healthcare

LEARNING OBJECTIVES

1) Identify common issues associated with starting a Remote MR service at your own institution. 2) Understand the specific medicolegal liabilities/responsibilities of those participating in remote MR operations. 3) Be familiar with new standardized titles, terms, job descriptions, responsibilities, unique chain of command, and unique certification potential associated with MR personnel that are specific to remote MR environments.

COURSE DESCRIPTION

Associated with a national and, in some areas, international severe shortage of MRI technologists/radiographers, there has been a rapidly growing and notable increasing interest in remote MR scanning, where the operator of the MR scanner is in a physical location that is remote to the location of the MR scanner being operated and patient being studied. Remote MR operations have generated the potential for unique safety concerns for both the patient and healthcare practitioners. Multiple remoter MR vendors have attempted to address these concerns in their own unique methods. However, to date, no consensus standardization has yet been defined for legal liability and/or methods of patient and site safety oversight for the unique environment associated with MR imaging. This course explains some common issues one can expect to confront when initiating remote MR scanning services; introduces and defines formal legal definitions and constructs for liabilities and responsibilities ascribed to and undertaken by those participating in remote MR scanning activities; introduces a standardized safety oversight structure unique to remote MR scanning environments; and introduces the American Board of MR Safety efforts at standardizing certification of those who will participate and operate in the unique environments and safety considerations generated by remote MR scanning operations.

Advancing Knowledge in Functional Neurosurgery

Sunday, Nov. 30 9:00AM - 10:00AM Room: E351

Timothy J. Kaufmann, MD, MS (*Moderator*) Stock/Shareholder; SpineThera

LEARNING OBJECTIVES

1) Describe the basic pathophysiology of diseases treated by functional neurosurgical interventions. 2) Understand the goals and means of functional neurosurgical interventions. 3) Appreciate the importance of particular imaging which supports and enables these interventions.

COURSE DESCRIPTION

Functional Neurosurgery encompasses the surgical treatment of neurological disorders by targeting specific brain circuits or nuclei to modulate their function, such as through deep brain stimulation (DBS), lesioning including with high intensity focused ultrasound (HIFU), and the implantation of devices (e.g. vagal nerve stimulators/VNS, responsive neurostimulators/RNS, and spinal cord stimulators). Diseases treated with these interventions include epilepsy, movement disorders such as essential tremor and Parkinson disease, and chronic pain. This course will provide introductions to each of these above-mentioned interventions.

Ovarian Cancer: From Start to Finish

Sunday, Nov. 30 9:00AM - 10:00AM Room: E451B

Andrea G. Rockall, FRCR, MRCP (*Moderator*) Other-Advisory Board; RoClub

LEARNING OBJECTIVES

1) Explain the ways in which imaging adds value to the care pathway in women with suspected ovarian cancer. 2) Identify learning strategies to translate this into daily clinical practice during reporting.

COURSE DESCRIPTION

In this course, the role of imaging in the evaluation of patients with suspected or confirmed ovarian cancer will be developed, from incidental detection of adnexal masses, characterisation, staging and monitoring response to treatment. The course will focus on how imaging may add value to the diagnosis and care of patients with ovarian masses or ovarian cancer.

RSNA Hands-On Lab: Pediatric MSK Ultrasound Course (Registration Fee Required)

Sunday, Nov. 30 9:30AM - 11:30AM Room: S504CD

Andrea S. Doria, MD, PhD (*Moderator*) Grant/Research Support; Baxalta-Shire. Grant/Research Support; Novo Nordisk. Grant/Research Support; Terry Fox Foundation . Grant/Research Support; Society of Pediatric Radiology . Grant/Research Support; Radiological Society of North America

LEARNING OBJECTIVES

1) Review the anatomy and ultrasound imaging techniques used to evaluate the ankle, digits, and brachial plexus. 2) Describe dynamic imaging techniques that enhance the assessment of ankle and digit pathology. 3) Discuss common MSK pathologies involving the ankle, digits, and brachial plexus, including key ultrasound findings and potential pitfalls.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. While ultrasound of the ankle and digits is commonly requested in musculoskeletal (MSK) imaging, evaluation of the brachial plexus requires advanced imaging expertise. Nevertheless, ultrasound has emerged as a valuable diagnostic tool in pediatric centers worldwide, particularly because it can be performed without general anesthesia in young patients and offers cost-effective imaging. This 120-min pediatric musculoskeletal hands-on session is targeted to general radiologists who aim to get an overview of technical and clinical application perspectives on ultrasound scanning and interpretation of pathology of ankles and digits, and/or expand their knowledge and learn more about scanning and interpretation of abnormalities in brachial plexus nerves of children and adolescents. This session has two parts, a 60-min hands-on part where pre-assigned radiologists scan teenager models' joints in real time and a second 60-min knowledge application part where the audience has the opportunity to scan models' joints by themselves.

Madeleine Sertic, MBBCh (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the complementary roles of radiology, surgical oncology, and radiation oncology in the multidisciplinary management of gynecologic malignancies through case-based discussion. 2) Identify key imaging features that influence surgical planning, radiation therapy, and overall treatment strategy for gynecologic cancers. 3) Understand how to tailor radiology reports to highlight clinically actionable information.

COURSE DESCRIPTION

This case-based, multidisciplinary panel explores the role of imaging in the diagnosis and treatment of gynecologic malignancies. Experts in radiology, gynecologic oncology, and radiation oncology will discuss cases, highlighting how imaging guides clinical decisions. Attendees will learn how to optimize radiology reports for actionable, treatment-relevant communication.

Interesting Cases in Vascular Imaging

Sunday, Nov. 30 9:00AM - 10:00AM Room: N227B

Arzu Canan, MD (*Moderator*) Nothing to Disclose
Elsie Nguyen, MD, FRCPC (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize key imaging features of malignancies affecting large vessels. 2) Identify congenital anomalies of the great vessels and understand their clinical implications. 3) Analyze challenging aortic imaging cases and apply problem-solving strategies to interpretation. 4) Evaluate imaging findings in non-aortic vascular diseases and differentiate them from mimics.

COURSE DESCRIPTION

This case-based session will explore a range of vascular imaging findings through discussion of complex and illustrative cases. Topics will include malignancies involving large vessels, congenital abnormalities of the great vessels, challenging aortic pathology, and non-aortic vascular diseases. The session is designed to highlight diagnostic pearls, imaging pitfalls, and multidisciplinary considerations relevant to vascular imaging.

The Kids Are Alright: Gen Z Perspectives on Learning, Career, Inclusivity and Wellness (Sponsored by the RSNA Professionalism Committee and by the RSNA Resident and Fellow Committee)

Sunday, Nov. 30 9:00AM - 10:00AM Room: N226

Brandon K.K. Fields, MD (*Moderator*) Consultant; Mendaera
Nadine Bayerl, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Analyze Gen Z's distinct learning styles, communication preferences, and professional expectations. 2) Implement effective strategies for mentoring, leading, and engaging Gen Z radiologists. 3) Develop practical methods to foster inclusivity, wellness, and career satisfaction tailored to Gen Z professionals.

COURSE DESCRIPTION

Gen Z is transforming radiology — reshaping how we teach, mentor and lead. This session provides essential insights into the values, expectations and unique needs of Gen Z through expert presentations and an engaging panel discussion. Attendees will gain practical strategies to create supportive, inclusive environments that boost career satisfaction and clinical excellence for the next generation of radiologists.

QUIC Roadmap for Clinical Implementation of Breast Density Quantification (Sponsored by the RSNA Quantitative Imaging Committee)

Sunday, Nov. 30 9:00AM - 10:00AM Room: E353A

Amy M. Fowler, MD, PhD (*Moderator*) Other Financial or Material Support; Elsevier, Inc. Other-Journal Associate Editor payment; BioMed Central Limited

LEARNING OBJECTIVES

1) Recognize the clinical impact of automated mammographic breast density quantification for breast cancer risk stratification and supplemental screening. 2) Understand the technical aspects of quantitative breast density assessment, software tools available, and potential for automated integration within the electronic medical record. 3) Identify the challenges, limitations, and barriers for implementing automated quantitative breast density in clinical practice.

COURSE DESCRIPTION

Breast density on mammography reports directly impacts clinical care by determining eligibility for supplemental breast cancer screening. Breast density assessment is by visual estimation by the interpreting radiologist which can be subjective with inter- and intra-reader variability. Current commercial tools for quantifying breast density are used variably in clinical practice. There is a need for standardization and automation of mammographic breast density quantification reporting. The purpose of this lecture-based educational session is to highlight the efforts of the RSNA Quantitative Imaging Committee (QUIC) in defining a roadmap for clinical implementation of breast density quantification. Key components that will be addressed include: motivation for clinical implementation, stakeholder involvement, technical considerations, implementation barriers, and informatics integration.

Global Insights and Updates on Lung Cancer Screening (Advanced)

Sunday, Nov. 30 10:30AM - 11:30AM Room: E451A

Jared D. Christensen, MD, MBA (*Moderator*) Consultant; Riverain Inc

LEARNING OBJECTIVES

1) Compare the implementation strategies of lung cancer screening programs in the U.S., Europe, and Asia, including differences in eligibility criteria, infrastructure, and reporting models. 2) Identify regional variations in adherence and outcomes, exploring how program design and healthcare systems influence participation rates and mortality reduction. 3) Apply global insights to optimize clinical practice and policy development in lung cancer screening.

COURSE DESCRIPTION

Lung cancer screening (LCS) has emerged as a proven strategy to reduce lung cancer mortality, yet implementation and adoption vary widely across the globe. This session brings together leading experts from North America, Europe, and Asia to provide an in-depth look at the current status, unique challenges, and future directions of LCS in their respective regions. Through focused presentations and panel discussion, participants will gain comparative insights into screening eligibility criteria, reporting, infrastructure, reimbursement models, and public health outcomes.

Case-Based: Alimentary Tract

Sunday, Nov. 30 10:30AM - 11:30AM Room: E451B

Shannon P. Sheedy, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize a new fluoroscopic finding at the lower esophageal sphincter and understand how it might cause destruction of the myenteric plexus. 2) Provide select case examples that will convey the relevance of upper GI fluoroscopy skills in contemporary radiology practice. 3) Identify key imaging features of on CT, MRI, and enterography studies using case-based examples. 4) Understand cross-sectional imaging patterns in inflammatory/infectious colitis and to learn about differential diagnoses in non-neoplastic colonic diseases.

COURSE DESCRIPTION

This four-part didactic lecture series offers a focused and practical exploration of gastrointestinal (GI) radiology, designed to enhance diagnostic accuracy and clinical confidence in both fluoroscopic and cross-sectional imaging. The series begins with a deep dive into esophageal motility and idiopathic achalasia, highlighting a novel fluoroscopic finding with potential implications for understanding disease pathogenesis. The second lecture emphasizes the enduring value of upper GI fluoroscopy through case-based teaching. The third session transitions to cross-sectional imaging of the small bowel, using case examples to illustrate the appearance and assessment of various small bowel tumors. The final lecture examines colonic pathology, concentrating on imaging patterns in inflammatory and infectious colitis and approaches to non-neoplastic disease. Together, these sessions provide learners with relevant and case-driven insights to sharpen interpretive skills across the GI tract.

The Reading Room of the Future: A Prediction Based on Recent AI and Other Technological Advancements

Sunday, Nov. 30 10:30AM - 11:30AM Room: E450B

Luciano M. Prevedello, MD, MPH (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify recent AI and technology advancements shaping radiology workflows and image interpretation. 2) Describe how AI can enhance reporting, decision-making, and diagnostic efficiency in the reading room. 3) Envision the future of the radiology reading room through integration of multimodal AI and smart workflows.

COURSE DESCRIPTION

This session explores recent advancements in artificial intelligence and other emerging technologies and their potential impact on the radiology reading room. Attendees will learn how AI-driven tools may reshape workflows, enhance diagnostic accuracy, and improve efficiency. By integrating current innovations with forward-looking insights, the session presents a vision of the reading room of the future based on ongoing research and technological progress.

Nerve Imaging: Anatomy to Pathology

Sunday, Nov. 30 10:30AM - 11:30AM Room: E450A

Shivani Ahlawat, MD (*Moderator*) Speaker's Bureau; Alexion Pharmaceuticals. Grant/Research Support; Amgen Pharmaceuticals

LEARNING OBJECTIVES

1) Describe an approach to imaging peripheral nerve pathology. 2) Understand the unique anatomy and pathology of the brachial plexus and imaging features of peripheral nerve injury and entrapment in the upper and lower extremities. 3) Explain methods for performing perineural injections.

COURSE DESCRIPTION

This course is dedicated to state-of-the-art applications of MR imaging in evaluating the peripheral nervous system. Each speaker is a recognized expert in the field of peripheral nerve imaging and intervention, with abundant experience in the multidisciplinary care of patients with peripheral nerve pathology. As such, the lectures in this session provide a comprehensive framework by which MR neurography is understood as it relates to the various focal and diffuse peripheral nerve abnormalities encountered in clinical practice. In the final lecture, and approach to image-guided peripheral nerve interventions is discussed.

Imaging Paraneoplastic Syndromes: The Last Differential Diagnosis

Sunday, Nov. 30 10:30AM - 11:30AM Room: N227B

Ichiro Ikuta, MD, MMedSc (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Integrate the clinical presentation, laboratory testing, and multi-system radiologic imaging to know when paraneoplastic syndrome is appropriate to include in the differential diagnosis. 2) Recommend appropriate follow-up with multi-system imaging, laboratory testing, and clinical examinations to distinguish paraneoplastic syndrome from other mimicking pathologies. 3) Optimize multi-system imaging for paraneoplastic syndrome evaluation and monitoring.

COURSE DESCRIPTION

Cancer, chemotherapy regimens, and immunotherapies are increasingly complex. Paraneoplastic syndromes are notoriously difficult to diagnose with variable manifestations throughout the body. Knowledge of pathophysiology and multi-system imaging characteristics have evolved to make radiologists integral in the diagnosis of paraneoplastic syndromes. A combination of case-based learning and didactic teachings will provide the latest insights and sharpen your clinical wisdom.

Advances in Radiopharmaceutical Therapies: New Frontiers and Future Prospects

Sunday, Nov. 30 10:30AM - 11:30AM Room: S405

Pedram Heidari, MD (*Moderator*) Other-Advisory board; Telix pharmaceutical . Grant/Research Support; Siemens Healthineers. Grant/Research Support; Sofie. Grant/Research Support; CytoSite Biopharma

LEARNING OBJECTIVES

1) Describe the current state and future directions of theranostic strategies for neuroendocrine tumors, including clinically available agents and investigational compounds. 2) Identify emerging molecular targets for radiopharmaceutical therapy beyond PSMA and SSTR, and discuss their potential therapeutic relevance across tumor types. 3) Explain the principles and evolving methodologies of dosimetry in radiopharmaceutical therapy, and their role in personalizing treatment to improve efficacy and reduce toxicity. 4) Assess how innovations in radiopharmaceutical design, target selection, and patient-specific dosimetry are shaping the future of precision cancer care.

COURSE DESCRIPTION

This session, Advances in Radiopharmaceutical Therapies: New Frontiers and Future Prospects, will highlight the rapidly evolving landscape of targeted radiopharmaceutical therapies (RPTs) in oncology. Expert speakers will present emerging applications of theranostics in neuroendocrine tumors, the development of novel molecular targets beyond PSMA and SSTR, and cutting-edge approaches in dosimetry to enable personalized treatment planning. Attendees will gain insights into the scientific, clinical, and translational innovations driving the next generation of radiopharmaceutical therapies and their integration into precision oncology.

LEARNING OBJECTIVES

1) Learn what it is like to work with formal legal representation and the added value of enlisting formal legal services when negotiating a contract. 2) Learn common pitfalls encountered by physicians when negotiating contracts and best practices for working with formal legal representation.

COURSE DESCRIPTION

The ability to negotiate and understand contracts is one of the most challenging aspects of the job search. This session will provide participants at all career levels with tips and strategies for understanding and negotiating contracts. During this session, the various elements of a contract will be broken down and reviewed. In this process, the speakers will also explain common contract language. Additionally, the speaker(s) will describe the elements of a contract that may be negotiated and strategies for negotiation. Furthermore, options to add value to a contract with non-compensation-related benefits will be suggested.

Protocol Makeover: Neuro Edition

Sunday, Nov. 30 10:30AM - 11:30AM Room: E351

Ian T. Mark, MD (*Moderator*) Grant/Research Support; GE Healthcare. Grant/Research Support; Lantheus

LEARNING OBJECTIVES

1) Evaluate advanced MRI protocols for epilepsy to enhance lesion detection and improve diagnostic precision in pre-surgical planning. 2) Apply refined MRI techniques for spine trauma to better characterize injury patterns and guide clinical decision-making. 3) Differentiate optimized MRI protocols for orbital imaging to improve visualization of subtle pathologies and reduce diagnostic ambiguity. 4) Implement updated MRI protocols for pituitary imaging to increase diagnostic accuracy and confidence in detecting microadenomas and other sellar pathologies.

COURSE DESCRIPTION

In this dynamic and clinically focused session, neuroradiologists will explore cutting-edge MRI protocol enhancements designed to elevate diagnostic accuracy across key areas of neuroimaging. Through a series of expert-led presentations, attendees will gain practical insights into protocol optimization for epilepsy, spine trauma, orbital imaging, and pituitary evaluation. Each talk will highlight evidence-based refinements, technical considerations, and real-world applications that can be readily implemented in clinical practice. Whether you're looking to fine-tune your current protocols or adopt new strategies for challenging cases, this session offers a comprehensive makeover of essential neuro MRI techniques.

Radiation and Medical Imaging: Best Practices for Communicating Risk

Sunday, Nov. 30 10:30AM - 11:30AM Room: N228

Cynthia H. McCollough, PhD (*Moderator*) Grant/Research Support; Siemens Healthineers

LEARNING OBJECTIVES

1) Understand the difficulties in discussing radiation and identify strategies to help the audience hear the right message. 2) Describe message maps and review several examples related to the use of radiation in medical imaging. 3) Recognize best practices for communicating with the media. 4) Experience examples of effective risk communication.

COURSE DESCRIPTION

While medical imaging can provide lifesaving medical care, the transfer of energy into human tissue can be associated with some level of risk to the patient. Not only are healthcare providers responsible for balancing the benefits of medical imaging with the potential risks, but they must also be able to effectively exchange information about the benefits and risks of medical imaging with patients, their families, the public, and other health professionals. The American Association of Physicists in Medicine created a Radiation and Medical Imaging Communication Guide to assist healthcare providers with this essential task. The educational content and sample questions and answers provided in the guide are intended to provide health professionals with the tools necessary for effective risk communication about the use of ionizing radiation in medicine. This course will review the difficulties in discussing radiation and identify communication strategies that can help the audience hear the right message. Speakers will describe the use of message maps when communicating about risk and summarize best practices when communicating with the media. The session will conclude with a series of role plays to demonstrate effective communication about radiation and medical imaging.

Sunday, Nov. 30 10:30AM - 11:30AM Room: RADIOLOGY LEARNING LAB

Jae Ho Sohn, MD, MS (*Moderator*) Grant/Research Support; Siemens Healthineers. Consultant; OnTact. Grant/Research Support; Cryptolab

LEARNING OBJECTIVES

1) Learn to build basic NLP models in radiology, discussing preprocessing and model architectures, forming the foundation for more advanced NLP courses involving transformers. 2) Learn evaluation metrics and strategies for radiological NLP models. 3) Learn various potential applications of NLP in clinical radiology with hands-on coding.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This session will feature a lecture introducing the basic technical concepts and clinical applications of natural language processing (NLP), highlight potential uses for it in radiology. The goal is to introduce standard text preprocessing techniques, NLP model training approaches, and model evaluation strategies that would be widely applicable and would form the basis for studying more advanced courses that use neural network and/or transformer based methods. We will follow up the didactic portion with a hands-on Google Colab demo implementing discussed concepts for a text classification task. For best experience, we highly recommend attendees bring a laptop with a keyboard as well as have a Gmail account to access Google Colab.

Digital Twins in Medicine: Clinical Applications and the Fundamental Role of Imaging (Sponsored by the RSNA 3D Printing Special Interest Group)

Sunday, Nov. 30 10:30AM - 11:30AM Room: E352

Kenneth C. Wang, MD, PhD (*Moderator*) Nothing to Disclose
Summer J. Decker, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Define digital twin technology and its relevance to clinical medicine. 2) Discuss the importance of radiologic imaging for digital twins. 3) Describe specific clinical applications related to cardiopulmonary disease and oncology.

COURSE DESCRIPTION

Digital twin technology, consisting of highly realistic simulation which incorporates measurement data, is transforming many industries. In clinical medicine, digital twins promise to improve the monitoring of health and disease, to better predict patient-specific treatment response, and to enhance the precision of medical care. Many clinical applications will depend critically on imaging, and radiologists, imaging scientists, technologists, allied health professionals, engineers, researchers and healthcare leaders will have opportunities to impact the development and adoption of digital twin technology. In this lecture-based educational session, two leading experts in the field will illustrate the power and potential of digital twins and the role of imaging, based on their extensive experience in specific clinical areas.

Sub-Events

Screening Guidelines: Ages to Initiate and Stop and Opportunistic Screening

Sunday, Nov. 30 1:00PM - 2:00PM Room: N228

Eric L. Rosen, MD (*Moderator*) Grant/Research Support; Whiterabbit

LEARNING OBJECTIVES

1) Identify guidelines for initiating and stopping breast cancer screening and how they differ between the United States, Canada, and Europe. 2) Explain how different guidelines affect breast cancer detection as well as the metrics used to assess screening effectiveness. 3) Understand the pros and cons of different approaches to screening and their implications, both on individuals and populations.

COURSE DESCRIPTION

Three presenters representing Canada, Europe and the United States discuss perspectives on when to initiate and stop opportunistic screening for breast cancer.

Sub-Events

An Imaging Library of Cardiac Devices: What You Need to Know

Sunday, Nov. 30 1:00PM - 2:00PM Room: S402

Daniel Vargas, MD (*Moderator*) Nothing to Disclose
Sung Min Ko, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize the spectrum of cardiac devices commonly used in patients with left atrial fibrillation, ischemic or non-ischemic cardiomyopathy. 2) Understand the structural heart abnormalities that may influence device placement and lead to complications. 3) Identify imaging features of device-related complications using multimodality approaches, including chest X-ray, CT, and MRI. 4) Review safety considerations and protocol adjustments for CT and MRI in patients with implanted cardiac devices.

COURSE DESCRIPTION

Course Description: An Imaging Library of Cardiac Devices: What You Need to Know This session provides a practical overview of cardiac devices commonly encountered in patients with arrhythmia, dilated or ischemic cardiomyopathy, and infiltrative heart disease such as sarcoidosis. Through a series of focused lectures and expert-led discussions, attendees will explore how underlying structural heart disease may contribute to device-related complications. The session will highlight key imaging features of such complications using chest X-ray, CT and MRI, while also addressing safety considerations and protocol optimization of CT and MRI for imaging patients with implanted devices. Educational Format: Lecture-based session with moderated discussion. Why It Matters: As the use of cardiac devices continues to expand, radiologists must be equipped to identify device-related issues and understand their clinical context. This session aims to bridge the knowledge gap between device implantation, imaging safety, and complication recognition. Expected Outcome: Participants will gain the knowledge to confidently assess cardiac devices and associated complications, and to safely perform and interpret cardiac imaging in device-implanted patients.

RSNA Hands-On Lab: Ultrasound Liver Stiffness and Quantitative Ultrasound for Liver Fat Assessment (Registration Fee Required)

Sunday, Nov. 30 1:30PM - 3:30PM Room: S504CD

Richard G. Barr, MD, PhD (*Moderator*) Grant/Research Support; Philips Ultrasound. Grant/Research Support; Samsung. Other-Royalties ; Thieme Publishers. Other-Royalties; Elsever Publishers. Grant/Research Support; SuperSonic Imagine. Speaker's Bureau; Samsung. Grant/Research Support; SonoScape. Speaker's Bureau; Philips Ultrasound. Grant/Research Support; Siemens Ultrasound. Speaker's Bureau; Siemens Ultrasound. Grant/Research Support; Canon Medical Systems. Speaker's Bureau; Canon Medical Systems. Grant/Research Support; Mindray . Grant/Research Support; Hologic . Speaker's Bureau; Hologic

LEARNING OBJECTIVES

1) Review the appropriate technique for performing SWE for liver stiffness. 2) Review the appropriate technique for performing liver fat estimation using quantitative ultrasound. 3) Review the literature on the accuracy of SWE and quantitative ultrasound for liver fat quantification. 4) Provide an overview of the basic science of both liver SWE and liver fat using ultrasound.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This course will provide all the information needed to develop a quantitative ultrasound program for determination of liver stiffness determination and quantitative ultrasound for liver fat estimation. Didactic lecture will be presented providing how to perform the examination and interpret the examinations for both SWE and fat quantification. A review of the published guidelines will be presented. After the lecture(s) attendee will move to the hands-on room where each vendor will have models available to perform these examinations using their system. During the hands-on emphasis will be on providing instruction and demonstration how to perform the examinations accurately. Experts will be available to answer questions and discuss these technologies.

Horse or Zebra? Case-Based Review of Common and Very Rare Diagnoses in the Head and Neck

Sunday, Nov. 30 1:00PM - 2:00PM Room: N227B

Shweta Kumar, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize typical and atypical imaging features of HNSCC, skull base tumors, head and neck vascular malformations, and invasive fungal sinusitis. 2) Differentiate HNSCC, skull base tumors, head and neck vascular malformations, and invasive fungal sinusitis from mimics and rare entities.

COURSE DESCRIPTION

In this case-based Head and Neck session, attendees will be presented with common and uncommon imaging presentations of head and neck squamous cell carcinoma (HNSCC), skull base tumors, head and neck vascular malformations, and invasive fungal sinusitis. Speakers will emphasize imaging pearls that distinguish these diagnoses from the unusual and infrequent, as well as how not to get fooled by mimics and pitfalls. This session offers attendees the opportunity to refine their interpretation of complex head and neck imaging studies by incorporating tips from world experts.

Elastography: US or MRI, What is the Right Choice?

Sunday, Nov. 30 1:00PM - 2:00PM Room: S406A

John S. Pellerito, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Compare the clinical performance, strengths, and limitations of US and MRI elastography across various organ systems. 2) Identify appropriate clinical indications for the use of elastography and determine when to select US versus MRI based on diagnostic needs, patient factors, and institutional resources.

COURSE DESCRIPTION

Elastography: US or MRI, What is the Right Choice is an advanced educational session with lectures and discussion designed for radiologists and medical imaging professionals seeking to deepen their understanding of tissue stiffness evaluation using ultrasound (US) and magnetic resonance imaging (MRI)-based elastography. This course explores the principles, technical considerations and clinical applications of both modalities across organ systems including liver, breast and musculoskeletal structures. Through comparative analysis, participants will gain insights into the strengths, limitations, and appropriate indications for each technique, with emphasis on diagnostic accuracy, cost-effectiveness and workflow integration. Case-based discussions and current evidence will guide clinicians in selecting the most effective technique tailored to specific clinical scenarios.

LEARNING OBJECTIVES

1) Summarize recent advances in neuroimaging techniques used to diagnose and manage pediatric stroke. 2) Discuss imaging findings to help localize seizure foci in pediatric epilepsy. 3) Describe the key features, imaging findings, and diagnostic challenges associated with major phakomatoses.

COURSE DESCRIPTION

This course offers a focused, in-depth look at complex neurological conditions in children through four interconnected lectures. This session explores cutting-edge developments in pediatric neuroimaging, seizure localization, infectious disease of the central nervous system, and the intricate world of phakomatoses. Participants will gain insights into how brain wave patterns, vascular anomalies, inflammatory responses, and genetic syndromes shape diagnosis and management in children. With a strong clinical and diagnostic emphasis, this course brings together innovation and nuance in tackling some of the most challenging pediatric neuroconditions.

AAPM/RSNA Physics Tutorial 1

Sunday, Nov. 30 1:00PM - 2:00PM Room: N226

Frank Dong, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the basic physics of photon-counting detectors. 2) Provide an overview of available image types produced by PCCT. 3) Discuss impacts of PCCT on dose and image quality. 4) Provide a comparative overview of clinical applications and advantages of PCCT compared with conventional dual-energy spectral CT approaches. 5) Review current high-impact clinical applications of PCCT. 6) Discuss strategies and barriers to PCCT adoption in clinical practice.

COURSE DESCRIPTION

Photon counting CT (PCCT) has the potential to represent a revolutionary diagnostic imaging tool for cardiovascular, neurological, oncological as well as musculoskeletal diseases. The photon counting detector has the capability to count individual X-ray photons as compared to conventional energy-integrating detectors. The benefits of PCCT include improved spatial resolution, reduced electronic noise, and inherent spectral imaging, which enable improved iodine and soft tissue contrast and material decomposition /quantification. This course will teach the basic principles of PCCT and present the clinical applications benefiting from the technological advancements offered by PCCT.

Kate Hanneman, MD, MPH (*Moderator*) Other-Honoraria; Sanofi Genzyme. Other-Honoraria; Medscape. Other-Honoraria; MRI Online. Other-Honoraria; Bayer
Pamela K. Woodard, MD (*Moderator*) Grant/Research Support; Siemens Medical Systems

LEARNING OBJECTIVES

1) Describe recent advances in artificial intelligence research in radiology funded by the RSNA R&E Foundation. 2) Evaluate the methodological approaches and translational potential of AI applications ranging from predictive modeling to prospective deployment and clinical validation. 3) Recognize how R&E Foundation support enables early-stage, high-impact research that drives innovation in radiology and contributes to education, equity, and improved patient care.

COURSE DESCRIPTION

Explore the future of imaging in this inaugural RSNA session, featuring RSNA R&E Foundation awardees whose research is advancing the frontiers of artificial intelligence in radiology. Awardees will present their study results, highlighting innovative, impactful work supported by the Foundation. Attendees will gain insights into the diverse uses of AI in imaging research, from algorithm development to prospective clinical deployment, and learn how groundbreaking ideas funded today are shaping innovations of tomorrow.

What Every Radiologist Needs to Know: Thoracic Imaging Essentials

Sunday, Nov. 30 2:30PM - 3:30PM Room: E451A

Lydia Chelala, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify common locations for missed findings on radiographs and CTs. 2) Recognize key radiographic findings and distinctions of and between atelectasis, pneumonia, and pulmonary edema. 3) Apply correct Fleischner Society terminology to pulmonary pathology and recognize clinical helpful thoracic imaging signs.

COURSE DESCRIPTION

This session will cover fundamental concepts of thoracic imaging that are encountered daily in clinical practice in a didactic but case-rich format. Appropriate terminology, pitfalls and fundamental pathologies on radiography and computed tomography will be covered.

Sub-Events

S5-CCH03B **Blind Spots on Chest Radiograph and CT**

Emergency Radiology in Disasters: A Gamechanger in Catastrophe

Sunday, Nov. 30 2:30PM - 3:30PM Room: E450B

Koenraad H. Nieboer, MD (*Moderator*) Other-Medical Advisory Board; GE HealthCare. Speaker's Bureau; GE HealthCare
Mehmet Ruhi Onur, MD, MD (*Moderator*) Consultant; Aselsan Health System. Other-Speaker at Africa Health Excon 2023; GE Healthcare

LEARNING OBJECTIVES

1) Assess the critical steps in preparing radiology departments for effective disaster response and continuity of care. 2) Interpret key imaging findings associated with disaster-related injuries, including those from earthquakes, bomb blasts, and fire-related trauma. 3) Analyze real-world radiologic case studies from the Turkey Earthquake to identify diagnostic challenges and solutions under extreme conditions. 4) Integrate radiology into multidisciplinary emergency management plans to optimize outcomes in mass casualty incidents.

COURSE DESCRIPTION

When catastrophe strikes —be it earthquake, explosion, or fire— radiology becomes a frontline responder. Do you believe your department is prepared to respond to a disaster? This high-impact lecture session brings together experts to share life-saving insights from real-world disaster scenarios. From hospital readiness to critical imaging of trauma in mass-casualty events, you'll gain practical strategies and clinical pearls to elevate your emergency response. Whether you're preparing your department for the unthinkable or seeking to understand the radiologic signatures of disasters, this session is an essential before your institute gets involved. Disaster-related injury patterns will be discussed with critical imaging findings in the session.

Sub-Events

Where Are All the Women Informaticists (Sponsored by the RSNA Committee on Diversity, Equity and Inclusion)

Sunday, Nov. 30 2:30PM - 3:30PM Room: N228

Maureen P. Kohi, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe key barriers and enablers impacting the recruitment, retention, and advancement of women in radiology informatics. 2) Illustrate diverse career trajectories and decision-making "pivot points" that have shaped women's pathways into and through radiology informatics. 3) Develop strategies to foster a more inclusive and supportive informatics community through mentorship, visibility, and structural change.

COURSE DESCRIPTION

This session explores the persistent gender gap in radiology informatics through a dynamic series of personal narratives and thought-provoking discussions. Despite the growing influence of informatics in shaping the future of radiology, women remain underrepresented in this critical subspecialty. Four speakers will share their unique journeys—including the challenges they've faced, the pivotal moments that shaped their careers, and the strategies that helped them succeed. Through lecture and interactive panel discussion, attendees will gain insight into the structural and cultural barriers impacting women in informatics, and leave with actionable strategies to foster inclusion, mentorship, and equity in their own institutions. The expected outcome is for attendees to be better equipped to recognize barriers to equity in radiology informatics, appreciate diverse career pathways, and actively contribute to a more inclusive and supportive professional environment.

Shoulder Imaging: How I Report It

Sunday, Nov. 30 2:30PM - 3:30PM Room: E450A

Andrew J. Grainger, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Apply a structured approach to reviewing and reporting shoulder pathologies, ensuring clarity, completeness, and alignment with current radiological best practices. 2) Recognize common pitfalls and diagnostic challenges in shoulder imaging and develop strategies to improve diagnostic accuracy. 3) Where appropriate understand the advantages and disadvantages of MRI and ultrasound for imaging common shoulder complaints.

COURSE DESCRIPTION

This course offers a series of expert-led lectures addressing radiology reporting of the shoulder, tailored specifically for residents and doctors in training. Through short, focused lectures, experienced radiologists will present a "how I do it approach", highlighting their tips and tricks which will enable participants to gain practical insights into the interpretation and reporting of a wide range of shoulder pathologies. The course will focus on MRI and where applicable ultrasound, aiming to help attendees build confidence and accuracy in their reporting of the findings in common shoulder pathologies.

Go vs No-Go: Evaluating New and Advanced Technologies for Clinical Adoption (Sponsored by the RSNA Research Development Committee)

Sunday, Nov. 30 2:30PM - 3:30PM Room: S402

Janie M. Lee, MD, MSc (*Moderator*) Grant/Research Support; GE Healthcare
Premal S. Trivedi, MD, MSc (*Moderator*) Consultant; Boston Scientific. Consultant; Cook Medical. Other-Advisory Board Member; Pneumonix

LEARNING OBJECTIVES

1) Understand common strategies to critically evaluate literature supporting new technologies. 2) Identify sources of bias impacting evaluation of new technologies, particularly artificial intelligence (AI).

COURSE DESCRIPTION

Technological innovation is foundational to both diagnostic and interventional radiology. As new technologies emerge in large volume with variable amounts of supporting evidence, deciding what to adopt and what to ignore can be challenging. Further confounding evaluation is industry sourcing of the underlying data and marketing materials, which can lead to bias. This session aims to empower frontline radiologists with a practical approach to evaluation of data supporting new technologies with the central guiding question: when is it good enough for clinical adoption?

Sub-Events

Vertebral Augmentation: Cementing Your Understanding in Oncologic and Osteoporotic Disease

Sunday, Nov. 30 2:30PM - 3:30PM Room: N227B

Mehran Nasralla, MBChB, BMedSc (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand how to synthesize the key imaging findings from complex metastatic spinal imaging. 2) Learn about updates in spine augmentation which improve the health span in patients with metastatic disease. 3) Learn about the evolution of imaging and augmentation methods in the osteoporotic spine. 4) Understand patient selection and technical considerations in percutaneous sacroplasty.

COURSE DESCRIPTION

In this educational session we will explore the role of image guided spine intervention in the metastatic and osteoporotic patient cohorts. We will review the imaging findings in both patient groups and how we can successfully triage patients for intervention to improve their health span. The session will also include advances in spinal augmentation including patient selection and technical considerations.

Mariana L. Meyers, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify common pitfalls in pediatric neuroradiology and body emergency imaging, and apply practical tips to improve diagnostic accuracy during on-call situations. 2) Understand the imaging findings of gonadal torsion in pediatric patients and distinguish them from mimics to ensure timely diagnosis and intervention. 3) Recognize acute imaging findings of oncologic emergencies in pediatric cancer patients—including therapy-related complications and tumor-associated conditions—to guide urgent management.

COURSE DESCRIPTION

This case-based educational session will highlight critical imaging findings in pediatric emergency settings, with an emphasis on neuroradiology and body imaging. Talks will cover practical strategies for improving diagnostic accuracy during high-pressure on-call scenarios, including tips and tricks for interpreting complex neuro and body imaging cases. Additional presentations will explore the imaging appearance of gonadal torsion and its mimics and review acute oncologic emergencies in pediatric cancer patients, focusing on both tumor-related conditions and therapy-associated complications. This session shall equip the attendees to navigate common and high-stakes emergencies in pediatric imaging, apply decision-making strategies under pressure, and improve timely diagnosis and management in urgent care settings.

Advances in Ultrasound Imaging Through Technology and AI

Sunday, Nov. 30 2:30PM - 3:30PM Room: S404

Karen Drukker, PHD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe recent advances in ultrasound elastography for quantitative tissue characterization and relate these developments to complementary trends in MR and optical elastography. 2) Explain technical and clinical factors in developing and applying AI for quantifying pulmonary congestion using point-of-care ultrasound. 3) Summarize the principles of super-resolution ultrasound imaging and identify potential clinical applications across different organ systems.

COURSE DESCRIPTION

This lecture-based session will highlight emerging ultrasound technologies that enhance diagnostic and prognostic imaging in both acute and chronic disease. Topics include advances in ultrasound elastography for characterizing tissue viscoelasticity, point-of-care ultrasound combined with AI for quantifying pulmonary congestion in acute heart failure, and super-resolution ultrasound methods for visualizing microvascular structure and function. The session will emphasize clinically relevant applications while also addressing key technical innovations and translational considerations. Expected outcome: Attendees will be able to assess recent advances in ultrasound imaging, understand their clinical utility, and recognize opportunities for integration into practice or further investigation.

AAPM/RSNA Physics Tutorial 2: "Un"risky Business: Easing the Uncomfortable Relationship Between Risk and Benefit in Medical Imaging

Sunday, Nov. 30 2:30PM - 3:30PM Room: N226

Ehsan Samei, PHD (*Moderator*) Grant/Research Support; GE. Grant/Research Support; Siemens. Owner; Metis. Consultant; Imalogix. Consultant; SunNuclear. Consultant; Nanox

LEARNING OBJECTIVES

1) Understand the relationship between radiation dose reduction and diagnostic performance – Learners will analyze how reducing x-ray exposure in radiology impacts image quality and diagnostic accuracy, including the risks of false negatives in screening programs. 2) Evaluate patient-specific risk factors in radiology – Learners will explore how age, sex, and race influence risk assessment and prognosis, and how these factors can be incorporated into clinical decision-making. 3) Apply risk-to-benefit assessment models in clinical practice – Learners will examine analytical models that quantify the trade-off between radiation risk and diagnostic benefit, which can assist in decision-making, using case studies to integrate theoretical knowledge into real-world radiological practice.

COURSE DESCRIPTION

As with many medical interventions, imaging examinations also carry associated risks, including those induced by X-ray exposure. It is estimated that 74 million computed tomography (CT) procedures are performed in the US each year, with the related radiation dose accounting for over 60% of the total patient medical radiation exposure. This has led, over the years, to a constant effort to reduce patient x-ray exposure. In particular, between 2006 and 2016, the estimated effective dose (E) per person in the U.S. population from diagnostic and interventional x-ray procedures dropped by 20%, from 2.92 mSv to 2.33 mSv. Since the amount of radiation used for a radiological examination is directly correlated with the quality of the diagnostic image, reducing radiation exposure can negatively impact diagnostic performance. As an example, excessive dose reduction can lead to false negatives in CT screening programs; currently reported 8% to 15% in lung cancer screening studies. To what extent radiation dose reduction can have a consequential impact on image quality and diagnostic performance remains unclear, a question of paramount priority in the radiological field. This tutorial will discuss how the informed practice of radiology can incorporate a comprehensive and holistic approach to radiation risk and benefit, including quantitative measures such as the likelihood of a correct diagnosis. This quantification has been a significant challenge as the risk and benefit rarely use comparable units. Moreover, the radiological risk, as well as the prognosis following a diagnosis, depend on patient age, sex, and race, thus adding other factors that should be considered in the justification and the proper performance of an examination. The speakers will introduce the problem of age-, sex-, and race-specific comprehensive risk estimations, as well as the recent introduction of mathematical models that describe the risk-to-benefit ratio of a CT study within a risk-to-risk framework. Specific clinical cases will be presented and discussed, providing both the medical physicist's and radiologist's points of view, encouraging attendee participation.

RSNA Deep Learning Lab: ChatGPT - DICOM De-Identification Using ChatGPT (Beginner Friendly) (Registration Fee Required)

Sunday, Nov. 30 2:30PM - 3:30PM Room: RADIOLOGY LEARNING LAB

George L. Shih, MD, MS (*Moderator*) Other-Consultant and Shareholder;Board of Directors; MD.ai. Other-Unpaid Advisor; OpenAI. Other-Board of Directors; SIIM

LEARNING OBJECTIVES

1) Identify and explain PHI within DICOM metadata, pixel data, and radiology report text. 2) Evaluate the challenges and available tools for effective de-identification of imaging and report data. 3) Use large language models to de-identify both DICOM files and associated reports, addressing metadata, pixel-level data, and unstructured text.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This hands-on learning lab introduces participants to the fundamentals of de-identifying both DICOM files and associated radiology reports, combining traditional methods with the power of large language models (LLMs) like ChatGPT. Attendees will gain practical experience using AI tools to remove Protected Health Information (PHI) from DICOM metadata, pixel data, and text reports, and will explore how LLMs can support and streamline the de-identification process. The session will cover: An introduction to DICOM metadata and report content, including common locations where PHI may be stored. Challenges and considerations in de-identifying DICOM files and radiology reports, with an overview of existing tools. Hands-on practice using AI tools such as GPT and LLMs for DICOM and report de-identification. Additional ways LLMs can assist in reviewing, verifying, or enhancing the DeID process. Techniques for identifying and removing PHI from DICOM pixel data (e.g., burned-in annotations). Leveraging open source LLMs for managing PHI.

Obesity: More than Meets the Eye: The Role of the Radiologist (Sponsored by the RSNA Public Information Committee)

Sunday, Nov. 30 2:30PM - 3:30PM Room: E353A

Hildo J. Lamb, MD, PhD (*Moderator*) Consultant; Royal Philips

LEARNING OBJECTIVES

1) Learn about state-of-the-art imaging techniques for evaluation of obesity and related complications. 2) Identify effective strategies how imaging can support obesity care. 3) Learn about the tight interconnection between multiple organs affected by obesity. 4) Learn about automated AI-based image analysis techniques to harvest imaging outcomes more than the human eye can see. 5) Identify imaging and post-processing strategies to implement "opportunistic screening" in your routine clinical imaging program.

COURSE DESCRIPTION

The prevalence of obesity is increasing rapidly worldwide. Obesity is linked to many diseases, including diabetes type 2, cardiovascular disease, liver disease and malignancies. In this educational session strategies will be discussed to detect obesity related complications and how to monitor disease progression and therapeutic effects. The first lecture will show how imaging can help overcome barriers to effective obesity care. The second overview will focus on multi-organ imaging for diagnosis and monitoring of obesity, based on data from the UK biobank. The final presentation aims to explain the concept of 'opportunistic screening', harvesting quantifiable metrics on obesity and related complications based on routine clinical imaging exams performed for general purposes.

Tugba Akinci D'Antonoli, MD (*Presenter*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the key elements of a manuscript on AI in imaging. 2) Apply components of the Checklist for Artificial Intelligence in Medical Imaging (CLAIM) 2024 Update for imaging AI manuscript submissions. 3) Identify and correct errors in example imaging AI manuscripts and abstracts. 4) Apply appropriate use of AI performance metrics.

COURSE DESCRIPTION

It can be daunting to draft a concise, yet detailed manuscript about radiology artificial intelligence (AI) projects. Manuscripts about radiology AI should incorporate key information that enables reviewers to determine the quality and reproducibility of the submitted work, as well as how the submitted work adds to a rapidly evolving field. This session will help attendees improve the quality of their AI manuscripts for submission to the RSNA Journal Suite and guide them as effective peer-reviewers for AI-related submissions. The session will follow a “game show” format based on “Jeopardy!” featuring a panel composed of editorial board members from Radiology and Radiology: Artificial Intelligence. Categories and questions will facilitate discussion on experiences from the editorial board members, including thoughts on best practices for AI-related submissions and frequently seen errors. Topics will include highlights from the CLAIM 2024 Update and general recommendations for effective medical writing. Questions will include examples inspired by manuscript submissions and common scenarios encountered by the editorial review board.

RSNA Hands-On Lab: Breast Ultrasound Guided Biopsy Techniques (Registration Fee Required)

Tuesday, Dec. 2 8:30AM - 10:30AM Room: S504CD

Stamatia V. Destounis, MD (*Moderator*) Grant/Research Support; Hologic, Inc.. Other-Medical Advisory Board; Hologic, Inc.. Other-Medical Advisory Board; iCAD, Inc.

LEARNING OBJECTIVES

1) Become familiar with different biopsy, cyst aspiration, and needle aspiration devices and techniques. 2) Review techniques of spring loaded and vacuum biopsy device methods available today. 3) Practice biopsy techniques with the advice of expert faculty that will advise attendee on biopsy and US technique.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. A brief didactic session will occur fist to discuss techniques, and tricks of performing biopsy under US. Subsequently attendees will be able to rotate to multiple ultrasound stations with different types of biopsy devices and practice biopsy technique while faculty will be available to walk through each different biopsy procedure.

T1-CER06

Gastrointestinal Emergencies: Bridging Core Knowledge and Advances

Tuesday, Dec. 2 8:00AM - 9:00AM Room: N228

James T. Lee, MD (*Moderator*) Nothing to Disclose
Paulina Cewe Jonsson, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Differentiate typical from atypical imaging presentations of adult intussusception, assess clinical significance including diagnostic complexities and prognostic factors, and identify common structural abnormalities that predispose to this condition. 2) Recognize imaging signs of biliary complications underlying post-cholecystectomy syndrome, analyze the full spectrum of early and delayed post-cholecystectomy complications with their corresponding imaging patterns, and compare the diagnostic utility and advantages of different imaging modalities. 3) Recognize classic imaging characteristics of acute appendicitis with particular focus on CT findings, distinguish atypical presentations from common mimics to avoid pitfalls, and gain insight into current literature and guidelines for imaging, diagnosis, and management.

COURSE DESCRIPTION

This lecture session explores three critical abdominal emergencies where imaging serves as the diagnostic cornerstone: adult colonic intussusception, highlighting that malignancy is not always the underlying cause; post-cholecystectomy biliary complications, with focus on identifying imaging features and advantages of different imaging modalities; and atypical acute appendicitis presentations, addressing prevalent mimics and diagnostic pitfalls. Participants will acquire key insights to enhance diagnostic precision in emergency abdominal imaging and strengthen their interpretive approach.

Everyday GU Reporting: Where Are We Now and Where Are We Headed?

Tuesday, Dec. 2 8:00AM - 9:00AM Room: N227B

Anugayathri Jawahar, MD (*Moderator*) Nothing to Disclose
Stuart G. Silverman, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Apply and assess current renal mass classification systems and the potential of a future KI-RADS. 2) Apply and assess VI-RADS following neoadjuvant therapy for bladder cancer. 3) Manage incidentally detected adrenal nodules.

COURSE DESCRIPTION

The ability of radiologists to detect, diagnose, and guide the management of imaging findings in the GU system has been buttressed by the development of evidence-based recommendations and guidelines that predict the likelihood of cancer in an incidental mass, stage tumors, and estimate response to treatment. This course's lectures focus on the care of patients with incidental renal masses (and include an introduction to KI-RADS), incidental adrenal masses, and bladder cancers that have undergone treatment. In addition to being practical and useful in everyday radiology reporting, the lectures will assess both the current state and future developments.

Head and Neck Radiology Around the World (Advanced)

Tuesday, Dec. 2 8:00AM - 9:00AM Room: E352

Jussi Hirvonen, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Analyze advanced CT and ultrasound techniques for the precise diagnosis of head and neck cancers. 2) Describe global clinical considerations for nasopharyngeal and laryngeal cancers. 3) Apply imaging strategies to unfamiliar disease presentations.

COURSE DESCRIPTION

Join leading head and neck radiology experts from around the world in this dynamic educational session, designed for imaging professionals seeking to enhance their expertise in imaging head and neck cancers. Through four didactic lectures, presenters will share their specialized knowledge on advanced CT imaging, nasopharyngeal carcinoma, head and neck ultrasound, and laryngeal cancer management. The session highlights unique disease processes and clinical considerations that may differ from North American practices, offering fresh perspectives on diagnosis and treatment. Interactive discussions will complement the lectures, fostering collaboration and practical application. By the end of the session, participants will be better equipped to integrate advanced imaging techniques into their practice, improving diagnostic accuracy and patient outcomes in diverse clinical settings.

Encoding Equity in AI Algorithms (Sponsored by the RSNA Health Equity Committee)

Tuesday, Dec. 2 8:00AM - 9:00AM Room: E450B

Martha G. Menchaca, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand limitations of AI radiology software. 2) Learn what a radiologist needs to know about AI algorithms and how to modify algorithms for equity. 3) Understand how neuroimaging AI algorithms were successfully used in a target population.

COURSE DESCRIPTION

This course will evaluate limitations that exist in commercially available AI radiology software and how these may disproportionately affect minoritized communities in the US. What any radiologist needs to know about race-based AI Algorithms. How to understand and be able to modifying Algorithms for Equity. Describe how neuroimaging AI algorithms have been used successfully in Sub-Saharan Africa successfully.

Thyroid Interventions

Tuesday, Dec. 2 8:00AM - 9:00AM Room: E351

Juan C. Camacho Vasquez, MD (*Moderator*) Speaker's Bureau; Trisalus. Consultant; Trisalus, Pulse Biosciences. Grant/Research Support; Trisalus. Other Financial or Material Support; Wolters Kluwer, Simposium on Clinical Interventional Radiology, Society of Interventional Oncology

LEARNING OBJECTIVES

1) Review the role of Interventional radiology in the treatment of thyroid pathology from the perspective of dedicated endocrinologists and thyroid surgeons. 2) Discuss the current state of the percutaneous ablation and endovascular techniques for the management of benign and malignant thyroid nodules.

COURSE DESCRIPTION

The flow of patients with thyroid pathology in the USA usually goes from the endocrinologist first and then directed to the surgeon and interventional radiologist accordingly as needed. Familiarity with all available treatment options by these specialists is paramount to helping the patient make the personalized value based decision best for them. That is best accomplished by a complementary team of endocrinologists, surgeons and interventional radiologists who are focused in the care of patients with thyroid pathology. Through the eyes of nationwide experts in a short lecture format, we will share current surgical and endocrinology perspectives and we will review the state of the art of percutaneous and endovascular interventions to approach and treat benign and malignant thyroid nodules in a minimally invasive fashion.

Ankle and Foot Imaging: From Fundamentals to Advanced

Tuesday, Dec. 2 8:00AM - 9:00AM Room: E450A

Dyan V. Flores, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review and compare basic and advanced imaging modalities (e.g., radiography, sonography, CT, MRI) used for diagnosing ankle and foot pathologies, highlighting their indications and limitations. 2) Recognize relevant imaging features and develop a reasonable differential diagnosis for sources of common ankle and foot symptoms.

COURSE DESCRIPTION

This series of lectures offers a high-yield focus on imaging of essential anatomic structures and related abnormalities in the ankle and foot, emphasizing both fundamental and advanced imaging techniques. Upon completion of this course, participants are expected to understand pertinent imaging features, pearls and pitfalls that may aid in formulating concise but meaningful radiology reports.

Comprehensive Review of IgG4-Related Disease

Tuesday, Dec. 2 8:00AM - 9:00AM Room: E350

Margarita V. Revzin, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify the characteristic imaging features of IgG4-related disease involving multiple organ systems. 2) Differentiate IgG4-related disease from mimics using multi-modality imaging. 3) Explore the role of emerging imaging techniques in the evaluation and management of IgG4-RD.

COURSE DESCRIPTION

This session provides a detailed discussion on imaging role and characteristic radiologic features related to immunoglobulin G4 (IgG4)–related disease including intracranial, head and neck, chest, and abdominal involvement, with emphasis on imaging findings that can help differentiate this disease from other inflammatory and neoplastic lesions. A short discussion of proposed pathogenesis and clinical presentation as well as management will also be reviewed.

Consultant; Radionetics. Other-Consultant, speaker; Lilly. Consultant; Telix

LEARNING OBJECTIVES

1) Recognize the clinical utility of PET imaging in the assessment of neurodegenerative diseases. 2) Understand the role of PET/CT in evaluating CNS infections and inflammation. 3) Integrate PET findings into the diagnostic workup and management of neurologic conditions.

COURSE DESCRIPTION

This session provides an overview of the evolving role of PET/CT in neurological imaging. Topics will include the use of molecular imaging in neurodegenerative disorders and CNS infections, with an emphasis on clinical interpretation, integration with other imaging modalities, and practical relevance for patient care. Designed for imaging professionals, the session aims to enhance diagnostic confidence in complex neurologic cases.

Addressing Current Challenges in Representation: Regional and Global Perspectives (Sponsored by the RSNA Committee on Diversity, Equity and Inclusion)

Tuesday, Dec. 2 8:00AM - 9:00AM Room: E451A

Charlotte J. Yong-Hing, MD, FRCPC (*Moderator*) Nothing to Disclose
Cynthia S. Santillan, MD (*Moderator*) Consultant; Alimentiv Clinical Research. Consultant; Clario Clinical Research. Other-Service Agreement; GE Healthcare

LEARNING OBJECTIVES

1) Describe region-specific and global strategies to improve representation and inclusion in radiology. 2) Identify practical approaches to mentorship, sponsorship, and workforce development that support underrepresented groups. 3) Apply data-driven and culturally responsive methods to advance equity and track progress within radiology departments.

COURSE DESCRIPTION

This dynamic session brings together radiologists and healthcare leaders from diverse geographic regions to explore effective approaches to representation challenges in radiology. Our distinguished panel from the Midwest USA, Southern USA, Canada, and France will share region-specific insights while identifying universal principles that can be applied globally. Participants will gain practical strategies for: Building inclusive workplace cultures that attract and retain diverse talent Developing mentorship and sponsorship programs that support underrepresented groups Addressing systemic barriers to advancement within radiology departments Creating educational pathways to increase representation in the field Implementing data-driven approaches to measure progress and outcomes The session will highlight successful initiatives from different regions while acknowledging unique cultural contexts and regulatory environments. Through case studies, panel discussions, and audience engagement, attendees will leave with actionable insights to enhance representation efforts within their own institutions. Join us for this important conversation as we work together to strengthen our specialty through diverse perspectives and inclusive practices.

RSNA Hands-On Lab: Prostate MRI: 1 (Registration Fee Required) (Supported by an Unrestricted Educational Grant from Bayer HealthCare Pharmaceuticals Inc.)

Tuesday, Dec. 2 9:00AM - 10:30AM Room: RADIOLOGY LEARNING LAB

Tharakeswara K. Bathala, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Optimize prostate MRI protocols for diverse clinical applications, including active surveillance, biopsy guidance, staging, focal therapy planning, and post-treatment evaluation. 2) Apply interpretation skills beyond standard PI-RADS assessment to evaluate active surveillance cases, distinguish post-treatment changes from recurrent disease, and assess treatment response. 3) Integrate multiparametric prostate MRI findings with clinical context to provide structured reporting that supports multidisciplinary treatment planning and patient management decisions.

COURSE DESCRIPTION

This comprehensive hands-on prostate MRI course addresses the evolving educational needs in contemporary prostate cancer care, where clinical applications have expanded far beyond traditional PI-RADS interpretation for initial diagnosis. As prostate MRI becomes increasingly integral to patient management across the entire cancer care continuum—from screening and active surveillance to treatment planning and response assessment—radiologists require specialized skills in both technical optimization and advanced interpretation. The course tackles critical knowledge gaps in technical protocol optimization for diverse clinical scenarios, specialized interpretation skills for complex cases including post-treatment imaging and active surveillance, and the integration of emerging technologies such as deep learning algorithms. These skills are essential as healthcare systems increasingly rely on prostate MRI for precision medicine approaches including focal therapy planning, targeted biopsy guidance, and personalized treatment monitoring. The program combines focused didactic presentations with extensive hands-on learning experiences. Following instructor-led lectures on core concepts, participants engage in case-review sessions using DICOM viewers on their devices. Interactive case discussions and real-time faculty guidance enhance collaborative learning, concluding with independent case interpretation and immediate performance feedback. This is a Bring Your Own Device (BYOD) session. In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited.

Hard Conversations, Stronger Teams: Resolving Conflict With Purpose (Sponsored by the RSNA Associated Sciences Consortium)

Tuesday, Dec. 2 9:30AM - 10:30AM Room: N226

Brian Fox, MBA (*Moderator*) Nothing to Disclose
Meredith Gammons, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key principles that support constructive and respectful dialogue in moments of conflict. 2) Apply at least two conflict resolution tools to real-world scenarios through guided collaboration and discussion. 3) Demonstrate increased confidence in initiating difficult conversations by using structured approaches shared during the session.

COURSE DESCRIPTION

Navigating conflict can be a difficult but necessary part of life. This interactive session will provide tools through collaboration which will empower each of us to tackle those difficult conversations with the goal of having as positive a resolution as possible. Having tools to navigate through conflict can empower us to approach challenging situations with confidence instead of avoiding them.

Thoracic Imaging of Medical Devices

Tuesday, Dec. 2 9:30AM - 10:30AM Room: E451A

Linda B. Haramati, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify appropriate and inappropriate positioning of an array of medical devices on thoracic imaging. 2) Describe common and some uncommon thoracic imaging manifestations of complications of medical devices.

COURSE DESCRIPTION

This session addresses a topic of common clinical interest- chest imaging of medical devices. The series of lectures encompasses the breadth of venous access and airways devices as well as ventricular assist and other implantable devices. Device positioning, complications, usual and unusual radiographic and CT appearances will be highlighted.

Imaging Cancer: Biomarkers, Immunotherapy, Update on Liver Directed Therapies

Tuesday, Dec. 2 9:30AM - 10:30AM Room: E451B

Leo L. Tsai, MD, PhD (*Moderator*) Other-Co-Founder, shareholder, and non-paid consultant; Agile Devices, Inc. . Consultant; Geurbet. Grant/Research Support; Geurbet. Consultant; ViTAA Medical

LEARNING OBJECTIVES

1) Describe the role of advanced imaging biomarkers in the diagnosis and monitoring of oncologic diseases. 2) Recognize common and emerging imaging manifestations of immunotherapy-related complications. 3) Evaluate the use of imaging in planning, guiding, and assessing response to liver-directed therapies.

COURSE DESCRIPTION

This educational session will provide a comprehensive overview of the latest treatment and related imaging in oncology, with lectures focused on imaging biomarkers, immunotherapy complications, and liver-directed therapies. Attendees will learn how to interpret imaging findings, understand the role of imaging in managing adverse effects from immunotherapy, and evaluate imaging strategies for guiding and assessing liver-directed treatments.

Improving Radiologists Efficiency: What you Can Do While Waiting for AI (Sponsored by the RSNA Quality Improvement Committee)

Tuesday, Dec. 2 9:30AM - 10:30AM Room: E450B

James V. Rawson, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Explore existing potential tools to provide short-term improvement to radiologists' efficiency. 2) Improve radiologists' workflow to provide short-term improvement to radiologists' efficiency. 3) Optimize radiologist work environment to provide short-term improvement to radiologists' workflow and efficiency.

COURSE DESCRIPTION

It is possible to do more with less if we learn to work smarter, not harder. This session focuses on short-term tactics to improve the Radiologist’s workflow while we wait for long-term efficiencies to arrive. By identifying what currently wastes radiologists’ time and considering a few specific interventions radiologist can optimize their workflow and become more efficient. Interventions include the user interface to PACS (mouse), interruption management, reading room design and system level interventions.

Advanced Musculoskeletal Interventions

Tuesday, Dec. 2 9:30AM - 10:30AM Room: N227B

Alda L. Tam, MD (*Moderator*) Grant/Research Support; Boston Scientific. Grant/Research Support; Johnson & Johnson. Consultant; Cook Medical

LEARNING OBJECTIVES

1) Identify appropriate indications for cement augmentation and osteosynthesis of pelvic lesions. 2) Describe two techniques used to mitigate complications associated with musculoskeletal interventions. 3) Discuss when to integrate musculoskeletal interventions into a multi-modality treatment plan that involves radiation.

COURSE DESCRIPTION

The Musculoskeletal Interventions course provides five lectures that focus on advanced cement augmentation and fixation therapies. Topics to be discussed include the periprocedural management of patients, technical tips, and how to handle the timing of the intervention along with other multi-modality treatments.

Sub-Events

T3-CIR06B **Point/Counterpoint: Ablation, Cementation +/- Fixation Should Occur Prior to Radiation**

PET/CT: Genitourinary Malignancies

Tuesday, Dec. 2 9:30AM - 10:30AM Room: S405

Aileen O'Shea, MBBCh (*Moderator*) Other-Funding for conference attendance ; Novartis
Ming Yang, MD (*Moderator*) Consultant; United Imaging Healthcare

LEARNING OBJECTIVES

1) Master the interpretation of PSMA-PET/CT imaging in prostate cancer. 2) Understand the advanced clinical theranostic approaches for prostate cancer.

COURSE DESCRIPTION

PSMA-PET has revolutionized the imaging of patients with prostate cancer and has become an essential component integrated into Lu177-Pluvicto Theranostic practice. In this session, experts in prostate cancer imaging and Theranostic practice will use clinical cases to demonstrate the best practices for PSMA-PET imaging interpretation and its role in targeted Lu177-Pluvicto treatment of PSMA-positive metastatic castration-resistant prostate cancer.

Finances for Personal and Professional Fulfillment (Sponsored by the RSNA Professionalism Committee)

Tuesday, Dec. 2 9:30AM - 10:30AM Room: S402

R. Paul Guillerman, MD (*Moderator*) Nothing to Disclose
Sherwin S. Chan, MD, PhD (*Moderator*) Consultant; Jazz pharmaceuticals . Grant/Research Support; Jazz pharmaceuticals. Grant/Research Support; Hyperfine Inc. Grant/Research Support; GE Healthcare . Consultant; Deepsight . Consultant; GE Healthcare

LEARNING OBJECTIVES

1) Learn how to align income and investment strategies with career and personal goals. 2) Learn about opportunities for income and career fulfillment outside of radiology clinical practice. 3) Understand the importance of retirement planning well in advance of retirement.

COURSE DESCRIPTION

Many radiologists struggle with work-life balance and are unable to translate their high income into a high net worth while also leaving time for family and personal pursuits. Factors including high student debt, poor financial literacy, lifestyle creep, and reliance on salaried income contribute to physician burnout and life dissatisfaction. Despite the importance of personal financial health, education on finances is absent from many radiology and medical school training programs. Radiologists who contribute enormously to clinical care, research, teaching, and administration may still neglect their personal finances and fail to adequately prepare for retirement. This course will feature lectures designed to improve the financial literacy of radiologists to better enable the fulfillment of professional and personal goals.

Fetal Imaging in Focus: A Practical Look at Chest and Abdominal Findings

Tuesday, Dec. 2 9:30AM - 10:30AM Room: E350

Dorothy J. Shum, MD (*Moderator*) Nothing to Disclose
Teresa Victoria, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify and characterize common and rare fetal chest masses and understand their implications for postnatal management and follow-up. 2) Recognize fetal cardiac masses and congenital cardiac anomalies and outline appropriate diagnostic pathways and treatment considerations. 3) Distinguish among subdiaphragmatic fetal anomalies, including abdominopelvic masses and abdominal wall defects, and evaluate their clinical significance and management strategies.

COURSE DESCRIPTION

This comprehensive fetal imaging program is designed to provide an in-depth review of both common and uncommon abnormalities of the fetal body. Emphasis will be placed on thoracic and cardiac anomalies, as well as subdiaphragmatic masses—including renal abnormalities, cystic and solid lesions, and defects of the fetal abdominal wall. Through a systematic and case-based approach, participants will develop the skills to analyze fetal body anatomy, distinguish normal from abnormal findings, and apply structured frameworks to evaluate complex anomalies. The program aims to enhance diagnostic confidence and consistency in interpreting fetal body pathology across a range of clinical scenarios.

Abdominopelvic Vascular Disease

Tuesday, Dec. 2 9:30AM - 10:30AM Room: S503

Jeremy D. Collins, MD (*Moderator*) Consultant; Circle CVi. Other-Advisory Board; Varian Medical. Grant/Research Support; GE
Roberta Catania, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key imaging findings and diagnostic criteria for mesenteric ischemia, renal artery diseases, acute abdominal aortic pathology, and causes of gastrointestinal bleeding. 2) Understand the role of radiologists in the diagnosis of these conditions and how it can guide management. 3) Review imaging techniques for evaluating abdominopelvic vasculature and protocol optimization.

COURSE DESCRIPTION

This course provides a selection of high-yield topics focused on abdominopelvic vascular diseases. Given the overlap between vascular and abdominal subspecialties, these conditions can represent a challenge for many radiologists across subspecialties. Abdominal radiologists may have less experience with angiographic imaging, specific MR sequences and 3D post-processing, while vascular radiologists may be less familiar with interpreting visceral organ changes associated with these diseases. This session aims to bridge that gap focusing on both vascular and visceral findings that occur in a number of diseases, including mesenteric ischemia, renal artery disorders, acute abdominal aortic diseases and their mimics, and gastrointestinal bleeding. Imaging techniques, key findings and diagnostic criteria will be reviewed, along with the role of radiology in guiding the management of these conditions.

United Arab Emirates (UAE) Presents: Radiology at the Forefront: Reflecting the Nation's Progress

Tuesday, Dec. 2 9:30AM - 10:30AM Room: E353B

Rashid Y. Al Sharhan, MBBS, FRCPC (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe key cultural, social, and professional aspects of living and working in the UAE, highlighting their impact on healthcare delivery. 2) Identify unique challenges and opportunities for life in the UAE. 3) Discuss how cultural competence influences the UAE's diverse population. 4) Explain the structure and regulatory framework of radiology practice in the UAE, including licensing and accreditation requirements. 5) Compare the operational models of radiology services in public versus private healthcare sectors in the UAE. 6) Evaluate the role of multidisciplinary collaboration in optimizing radiology workflows and patient outcomes in UAE healthcare settings. 7) Assess the effectiveness of AI tools currently implemented in breast screening programs in Dubai, focusing on sensitivity and specificity metrics. 8) Apply best practices for integrating AI into mammography workflows, based on Dubai's real-world implementation strategies. 9) Analyze challenges, such as data privacy and algorithm bias, in deploying AI for breast screening in Dubai, proposing at least one solution. 10) Identify key criteria for selecting AI solutions for tuberculosis (TB) screening, including diagnostic accuracy and scalability in Dubai's healthcare system. 11) Method was used to compare commercially available AI tools for TB screening, evaluating their suitability for Dubai's population and infrastructure. 12) Develop a framework for assessing the cost-effectiveness and clinical impact of AI solutions in TB screening programs. 13) Interpret complex neuroradiology cases from the UAE, identifying key imaging findings and differential diagnoses. 14) Apply advanced imaging techniques, such as perfusion MRI or dual-energy CT, to enhance diagnostic accuracy in neuroradiology cases. 15) Discuss the clinical implications of neuroradiology findings in the context of UAE's patient demographics and healthcare resources.

COURSE DESCRIPTION

This session highlights the UAE's rapid progress in radiology, showcasing advances in subspecialty services, AI integration, education, and international collaboration. Attendees will gain insight into how the UAE is shaping the future of imaging through innovation, strategy, and global partnerships.

The Critical Role of the NIH in Advancing Medical Imaging Research: Innovations, Impact, and Possible Consequences of Legislative Reform (Sponsored by the RSNA Government Relations Committee)

Tuesday, Dec. 2 9:30AM - 10:30AM Room: S404

Elizabeth O'Hare, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review existing NIH support mechanisms (i.e. grant programs, funding mechanisms, and collaborative initiatives) that have contributed to advancements in medical imaging. 2) Highlight key innovations and achievements in medical imaging and discuss emerging priorities for research and technological advancement. 3) Review recent NIH policy changes and other proposed reforms and understand the potential impact of these developments on medical imaging research.

COURSE DESCRIPTION

Medical imaging is a cornerstone of modern healthcare and advances in imaging technology and applications have unlocked transformations in disease diagnostics and treatment planning. These advances have been made possible by sustained U.S. federal investment in the National Institutes of Health (NIH), whose funding has been critical to driving innovation, supporting infrastructure, and seeding interdisciplinary collaborations. In 2025 the U.S. Congress and Trump Administration are considering a variety of proposals to reform the NIH, many of which, if enacted into law, would have significant impact on the agency's structure and function with important consequences for medical imaging and radiology research. This session will explore the NIH's multifaceted role in supporting medical imaging research, highlighting key technological advances and extant challenges, and will review the status and scope of recent NIH policy changes and reform proposals.

Cybersecurity in Healthcare: Threat Landscape Beyond the Hospital

Tuesday, Dec. 2 11:00AM - 12:00PM Room: E450B

Benoit Desjardins, MD, PhD (*Moderator*) Nothing to Disclose
Dania Daye, MD,PhD (*Moderator*) Consultant; Medtronic. Consultant; Boston Scientific. Consultant; Sigilon. Grant/Research Support; Trisalus. Consultant; Cook Medical

LEARNING OBJECTIVES

1) Understand the threats emerging from third-party vendors and IoT devices. 2) Understand the risk assessment frameworks for evaluating third-party vendors. 3) Understand the security challenges specific to IoT devices in healthcare.

COURSE DESCRIPTION

2024 was THE year of third-party attacks with catastrophic impact on the US healthcare system. For example, the ransomware attack on Change Healthcare, one of the largest US healthcare technology providers, was a landmark event. The attack not only disrupted the operations of Change Healthcare itself but had widespread implications for the US healthcare system and the global economy, underscoring the vulnerabilities in the interconnections between healthcare organizations, third-party vendors, and Internet of Things (IoT) devices. Change Healthcare provides critical healthcare technology services, including electronic health records (EHR) systems, medical billing services, claims processing, and various other IT solutions for hospitals, physicians, and other healthcare providers. It serves more than 2,000 hospitals and 500,000 healthcare providers across the US. Change Healthcare has a direct line to large swaths of sensitive patient data, making it an attractive target for cybercriminals. On March 3, 2024, Change Healthcare became the victim of a sophisticated ransomware attack, which caused widespread disruption across its core platforms and services. The breach also caused immediate operational disruptions in hospitals, clinics, and healthcare facilities across the U.S. Many healthcare organizations were unable to process claims, update patient records, or communicate effectively due to the downed systems. The overall economic cost of the ransomware attack is estimated to be $4.6 billion. Many smaller hospitals and independent practices that relied on Change Healthcare's services found themselves without access to essential services for weeks. The incident prompted renewed focus on the interconnectedness of healthcare IT systems and third-party vendors. 1- The threat landscape beyond the hospital: After providing a quick overview of the latest attack vectors affecting systems outside the confines of the walls of hospitals, Dr Benoit Desjardins, a leader in cybersecurity, will discuss the devastating impacts that recent cyberattacks had on the entire US healthcare system in 2024. 2- Third party cybersecurity: Hospitals become collateral damage from an attack on a third party. This will be discussed by Richard Staynings, an industry leader in the protection of healthcare enterprises against cybercriminals. He will provide an overview of the interconnectedness of US hospitals with third-party companies, and as a result, the consequences on the entire US healthcare system of third-party attacks. By gaining access to a third-party's technology, they gain a digital pathway to infect multiple covered entities or to extract data. 3- Cybersecurity of the Internet of Things: Hospital networks grow their network interconnections to home for radiologists and to control IoT devices. This will be discussed by Axel Wirth, an industry leader in the protection of medical devices against cybercriminals. The second edition of his book just came out on October 31st, 2024 (Medical Device Cybersecurity: A Guide for Engineers and Manufacturers). He will provide many current examples of how IoT devices are affecting medical centers. This refresher course will bring the radiology community up to date on the latest issues related to the growing interconnectedness of healthcare institutions, including recent attacks, and techniques of defense. The course will be presented by radiologists and top cybersecurity experts. The information technology issues will be addressed at a technical level appropriate for the radiology community at large, to make the community aware of this growing era of digital warfare and its implications for radiology practices. Our refresher course will have practical, actionable suggestions that radiologists and IT administrators could act on now.

ASRT@RSNA: Medical Imaging Labor Shortage: Health Care Systems and Academic Entities Partnering for Solutions

Tuesday, Dec. 2 11:00AM - 12:00PM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify challenges facing health care systems regarding labor shortages in imaging services. 2) Examine strategies to enhance partnerships between health care systems and academic institutions to improve student throughput while maintaining high educational and clinical standards. 3) Discuss approaches to developing student skill sets that align with clinical workforce demands, ensuring graduates are prepared to transition into both clinical and mentoring roles. 4) Analyze the successes and challenges of collaborative initiatives and explore the past, present and ongoing efforts to sustain and strengthen workforce development in medical imaging.

COURSE DESCRIPTION

Labor shortages in medical imaging have become a safety, quality and financial burden on most health care systems across the United States. This interactive course — offered from both a health care system and an academic institution's perspective — explores the root causes of the shortage and proposes collaborative solutions. The speakers will emphasize strategies that increase the number of students graduating from local academic radiologic sciences programs while enhancing their skills. The long-term goal is cultivating future-ready, qualified clinical instructors.

Contrast-Enhanced Mammography: Screening vs. Diagnostic Indications and Expanding Access for Underserved Populations

Tuesday, Dec. 2 1:30PM - 2:30PM Room: S406A

Janice S. Sung, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review the advantages and disadvantages of using CEM for breast cancer screening. 2) Discuss the potential use of CEM in the diagnostic setting including recalls from screening, preoperative staging, and response to neoadjuvant therapy. 3) Explore the potential of CEM to expand access to advanced imaging among underserved populations and barriers to implementation.

COURSE DESCRIPTION

Contrast-enhanced mammography (CEM) is an FDA-approved, vascular-based imaging technique that is increasingly recognized as a valuable alternative to both conventional breast imaging and breast MRI. This session will review current evidence supporting the use of CEM in both screening and diagnostic settings and explore its potential to expand access to advanced imaging—particularly among underserved populations who may face barriers to MRI.

RSNA Hands-On Lab: MRI-Guided Breast Biopsy (Registration Fee Required)

Tuesday, Dec. 2 2:00PM - 4:00PM Room: S504CD

Roberta M. Strigel, MD, MS (*Moderator*) Grant/Research Support; General Electric

LEARNING OBJECTIVES

1) Define indications for MRI-guided breast biopsy and appropriate patient selection including relative and absolute contraindications to MRI-guided breast biopsy. 2) Describe and understand the steps of an MRI-guided breast biopsy procedure, including protocol and requirements for appropriate coil, needle, and approach selection. 3) Identify the benefits and limitations of MRI-guided breast biopsy and understand tips for handling challenging biopsy locations and patient anatomy.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This course is intended to provide both didactic and hands-on experience performing MRI-guided breast biopsy. Those with and without experience with this procedure are welcome and will find this course beneficial. The course begins with a 45-minute lecture covering patient selection criteria, contraindications, appropriate biopsy positioning and troubleshooting, steps of the procedure, lesion targeting using both manual and computer aided techniques, post-biopsy care, radiologic/pathologic concordance, and potential challenges and strategies. The final 75-minutes is a hands-on workshop with 11 stations, each with a breast coil, targeting options (computer and manual), biopsy device and two expert faculty members to teach the performance of an MRI-guided biopsy with live coaching, tips, techniques, and advice, with opportunities for questions.

Cardiac Imaging in Private Practice: The Secrets for Success

Tuesday, Dec. 2 1:30PM - 2:30PM Room: E353C

Michael F. Morris, MD (*Moderator*) Speaker's Bureau; Medtronic. Speaker's Bureau; Heartflow

LEARNING OBJECTIVES

1) Identify strategies for creating a financially viable cardiac MRI and CT practice. 2) Learn how offloading post-processing to a 3D lab improves accuracy and productivity. 3) Discover important pearls for growing your cardiac imaging practice.

COURSE DESCRIPTION

Demand for cardiac CT and MRI are growing rapidly. This course provides key information how to create a financially viable cardiac imaging practice, how to maximize productivity by utilizing a 3D lab, and tips for how to grow your advanced imaging practice!

Sub-Events

Case-Based: GI Post-Operative (Including Transplant)

Tuesday, Dec. 2 1:30PM - 2:30PM Room: N227B

Lauren M. Burke, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify and interpret common and critical post-operative imaging findings in gastrointestinal (GI) surgery patients, including expected post-surgical anatomy and common complications such as leaks, obstructions, and abscesses. 2) Utilize a systematic, case-based diagnostic approach to complex post-operative GI imaging, correlating imaging findings with surgical techniques, timelines, and clinical presentation to optimize diagnostic confidence and reporting clarity.

COURSE DESCRIPTION

This case-based session is designed for radiologists seeking to enhance their diagnostic accuracy in evaluating post-operative gastrointestinal (GI) and transplant imaging. Through a series of curated, real-world cases, participants will review expected post-surgical anatomy and recognize common and high-risk complications following GI surgeries and abdominal organ transplants, including liver, pancreas, and small bowel. Emphasis will be placed on identifying subtle imaging findings, understanding the clinical and surgical context, and applying a systematic interpretive approach.

PET/CT: Lung Cancer and Lymphoma

Tuesday, Dec. 2 1:30PM - 2:30PM Room: S405

Esma A. Akin, MD (*Moderator*) Nothing to Disclose
Munir Ghesani, MD (*Moderator*) Speaker's Bureau; Siemens Healthineers. Speaker's Bureau; Lantheus. Speaker's Bureau; Telix. Consultant; Serac Lifesciences

LEARNING OBJECTIVES

1) Evaluate the contemporary role of FDG PET/CT in the initial staging and treatment planning of both non-small cell lung cancer. 2) Analyze the utility of FDG PET/CT for response assessment and surveillance in Hodgkin lymphoma and aggressive non-Hodgkin lymphoma, including understanding the Deauville score and its implications for clinical management. 3) Identify potential pitfalls and challenges in FDG PET/CT interpretation for lung cancer and lymphoma, such as inflammatory uptake, physiological variants, and artifacts, and discuss strategies to optimize image acquisition and interpretation for improved diagnostic accuracy.

COURSE DESCRIPTION

This comprehensive course will provide a thorough review of the current and evolving role of ^{18}F-FDG PET/CT in the diagnostic workup, staging, treatment response assessment, and surveillance of patients with lung cancer and lymphoma. Designed for practicing radiologists, nuclear medicine physicians, and trainees, the program will delve into both the established guidelines and the latest advancements in PET/CT imaging. Through a combination of didactic lectures, interactive case discussions, and practical insights, participants will gain a deeper understanding of the physiological principles of FDG uptake in these cancers, optimal imaging protocols, and the nuances of interpreting complex PET/CT studies. The course will address critical aspects such as differentiating benign from malignant lesions, assessing the extent of disease, monitoring therapeutic efficacy, and identifying recurrence. Special attention will be given to common pitfalls, technical considerations, and the impact of PET/CT findings on clinical decision-making, ultimately aiming to enhance diagnostic accuracy and improve patient outcomes.

Advanced Quality Improvement Through AI: Automated Monitoring and Real-World Impact (Sponsored by the RSNA Quality Improvement Committee)

Tuesday, Dec. 2 1:30PM - 2:30PM Room: S402

Hari Trivedi, MD (*Moderator*) Owner; Lightbox AI. Consultant; Sirona Medical. Consultant; PMX. Consultant; Flatiron Health. Grant/Research Support; Clairity, Lunit, Nightingale Science. Consultant; Hoppr

LEARNING OBJECTIVES

1) Describe how AI can be used to extract and monitor quality improvement metrics from routine radiology workflows. 2) Identify implementation barriers and human factors that influence the real-world impact of AI tools, including automation bias. 3) Evaluate approaches for post-deployment monitoring and validation of AI tools to ensure ongoing clinical effectiveness and safety.

COURSE DESCRIPTION

Artificial intelligence (AI) tools are increasingly being deployed in clinical practice, but their impact on quality improvement (QI) efforts depends on robust implementation, monitoring, and adaptation in real-world environments. This session brings together experts in radiology, informatics, and AI to explore the role of automated systems in quality assurance, the challenges of clinical deployment, and the potential unintended consequences such as automation bias. Using a lecture and discussion-based format, attendees will gain practical insights into how AI can be leveraged to extract QI insights from large clinical datasets, measure and improve model performance post-deployment, and assess the impact of AI on radiologist behavior and patient outcomes. The session will also highlight tools and strategies for ongoing evaluation of AI models, aiming to help institutions maximize safety, reliability, and effectiveness in clinical settings.

Red Flags: Acute Vascular Imaging Abnormalities Encountered in the Emergency Setting

Tuesday, Dec. 2 1:30PM - 2:30PM Room: S406B

Hediyeh Baradaran, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify non-stroke arterial pathologies that may present with acute neurologic symptoms. 2) Recognize emergent imaging findings in the intracranial venous system. 3) Describe acute vascular abnormalities of the spine and their imaging characteristics. 4) Evaluate the imaging appearance and complications of intracranial vascular malformations in the acute setting.

COURSE DESCRIPTION

This case-based, multi-speaker session highlights acute and emergent vascular conditions beyond typical ischemic stroke. Through focused lectures and real-world examples, expert faculty will review emergent non-ischemic arterial pathologies, intracranial venous emergencies, spinal vascular abnormalities, and vascular malformations. Attendees will improve their ability to recognize critical imaging findings, avoid diagnostic pitfalls, and guide timely clinical management.

Uterine Bleeding: Do You See What I See?

Tuesday, Dec. 2 1:30PM - 2:30PM Room: E351

Nancy Kim, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the role of imaging in evaluating abnormal uterine bleeding. 2) Review how to perform proper US and MRI imaging of the uterus. 3) Identify imaging findings of benign and malignant etiologies that may account for the patient's abnormal uterine bleeding.

COURSE DESCRIPTION

Abnormal uterine bleeding is a common gynecologic symptom that often leads to ultrasound imaging and sometimes MRI. The radiologists' role is to identify if there is a structural or anatomical cause of abnormal uterine bleeding. This course aims to review how imaging should be used to evaluate patients with abnormal uterine bleeding and to review imaging findings of benign and malignant pathologies.

LEARNING OBJECTIVES

1) Review the classification system of pediatric soft tissue tumors (by tissue type). 2) Compare the advantages and limitations of CT and MRI in evaluating pediatric hip and pectus deformities. 3) Provide the necessary tools for proper neonatal hip and shoulder ultrasound performance and understanding, recognizing normal and pathological specific anatomy.

COURSE DESCRIPTION

This session offers four expert-led lectures focused on practical challenges in pediatric musculoskeletal imaging. Topics include imaging strategies for congenital foot deformities, neonatal shoulder and hip ultrasound, modality selection in soft tissue mass evaluation, and CT vs MRI for assessing pediatric hips and pectus deformities. Designed for general radiologists, pediatric radiologists, and residents, the session highlights when and how to use ultrasound, MRI, and CT effectively. Through concise lectures and interactive discussion, attendees will gain actionable insights to improve diagnostic accuracy and optimize clinical decision-making.

ASRT@RSNA: Internationalization of Medical Imaging Education and Practice: Current Trends

Tuesday, Dec. 2 1:30PM - 2:30PM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Explain the internationalization of higher education with a concentration on medical imaging education. 2) Describe the benefits of internationalization for higher education and medical imaging education and practice. 3) Discuss approaches, trends, and barriers to the internationalization of medical imaging education. 4) Illustrate possible avenues for the implementation of an internationalized medical imaging curriculum.

COURSE DESCRIPTION

Are today’s health care professionals equipped for globalization and international health issues? The health care industry continues to call for higher education to produce graduates who will offer a competitive advantage in the global marketplace. Health care delivery requires current and future health care professionals to demonstrate global learning, skills and competencies. An internationalized medical imaging curriculum provides a framework of values and practices for the skills and literacies of a changing world. Global and international education can teach the knowledge, skills and attitudes required to function effectively in an interconnected world. The goals of global and international education should be to prepare students to operate in a globally competitive workforce; increase students’ understanding of different cultures, religions and political systems; instill a globalized view of world events; and promote world peace. One approach to the internationalization of medical imaging education and practice is the provision of an internationalized curriculum that includes a clinical overseas attachment. This course discusses current trends in the internationalization of medical imaging education and practice.

RSNA Deep Learning Lab: Leveraging Pre-Trained Embeddings Models for Your Use Cases and Your Data (Advanced) (Registration Fee Required)

Tuesday, Dec. 2 1:30PM - 2:30PM Room: RADIOLOGY LEARNING LAB

Rory Pilgrim, BEng (*Moderator*) Employee; Google. Stock/Shareholder; EMvision Medical Devices Ltd

LEARNING OBJECTIVES

1) Demonstrate how to adapt and deploy open-weight, pre-trained radiology-specific AI models using public datasets and Colab notebooks. 2) Evaluate the impact of training data curation, validation strategies, and operating point selection on model performance and generalizability across clinical use cases.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. Interactive workshop showing how to use general-purpose, open weight, pre-trained radiology-specific models to build a specific AI application, with an emphasis on how the approach can be generalized to any arbitrary use-case. The session will be run via a Colab notebook and the application will be built via public data. Specific learning areas will be how to actually call and adapt the pre-trained model, the importance of training data curation, validation techniques, and operating point selection.

PET/CT: CNS Tumors and Gastrointestinal Malignancies

Tuesday, Dec. 2 3:00PM - 4:00PM Room: S405

Emily S. Nia, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand best clinical practices for use and interpretation of PET for central nervous system tumors. 2) Understand best clinical practices for use and interpretation of PET for gastrointestinal malignancies.

COURSE DESCRIPTION

PET for gastrointestinal malignancies and CNS tumors is as complex and varied in presentation as the pathologies are. In this session, PET experts will use clinical cases to demonstrate fundamentals of interpretation, as well as pearls and pitfalls to help improve interpretation.

Sub-Events

T7-CNMMI11B PET for CNS Tumors

ASRT@RSNA: Imaging Awareness: It's Not Always Straight Forward

Tuesday, Dec. 2 3:00PM - 4:00PM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize the importance of providing respectful and appropriate imaging experiences for patient populations whose backgrounds or identities may differ from the provider's own. 2) Identify potential barriers patients may face when seeking or receiving care, including legal, anatomical, or personal considerations that may affect communication and imaging practices. 3) Explore strategies for educating health care team members on respectful and patient-centered care practices and fostering allyship. Consider initiatives such as employee resource groups to promote a supportive environment.

COURSE DESCRIPTION

Some patient communities face additional barriers when seeking health care. From scheduling to the final report, members of the health care imaging team can help facilitate positive health outcomes for vulnerable patients. This session will address some of the barriers to positive health outcomes and ways to overcome them in today's environment. Technologists who identify within these communities as both provider and patient will offer their perspectives.

Peripheral Vascular Imaging

Tuesday, Dec. 2 3:00PM - 4:00PM Room: S503

Elizabeth M. Hecht, MD (*Moderator*) Nothing to Disclose
Sasan Partovi, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize characteristic imaging findings of thoracic outlet syndrome, thereby differentiating between neurogenic, venous, and arterial subtypes. 2) Identify appropriate imaging modalities and protocols for accurate diagnosis of thoracic outlet syndrome and guidance of patient management. 3) Learn the conventional and variant anatomy of upper and lower extremity CTA. 4) Utilize 3D reformats and curved planar reconstruction in upper and lower extremity CTA as well as illustration of pathologies via case-based review. 5) Learn the common indications and appropriate use of MRA and MR venography (MRV) for the evaluation of the upper and lower extremities. 6) Learn the essentials of contrast enhanced and non-contrast MRA and MRV techniques including applications of different protocols and troubleshooting. 7) Learn the role of cross sectional imaging for management of PAD patients. 8) Learn the current evidence and value of photon counting CTA in PAD.

COURSE DESCRIPTION

Imaging of the peripheral arterial tree is essential in daily clinical practice, supporting diagnosis, management, and pre-procedural planning of various vascular conditions. Upper extremity vascular imaging frequently addresses conditions such as thoracic outlet syndrome, vasculitis, trauma-related vascular injuries, embolic diseases and complications related to dialysis circuit vascular accesses. Lower extremity imaging predominantly focuses on peripheral artery disease (PAD) and acute limb ischemia. This course highlights advanced cross-sectional angiographic modalities, including computed tomography angiography (CTA), contrast-enhanced and non-contrast magnetic resonance angiography (MRA), as well as provocative maneuvers used in the evaluation of thoracic outlet syndrome. Additionally, emerging CTA technologies for PAD, notably photon-counting CT, will be discussed, focusing on their clinical utility and potential impact on patient care.

France Presents: New Frontiers in Personalised and Integrated Oncological Approaches: The French Experience

Tuesday, Dec. 2 3:00PM - 4:00PM Room: E353B

Marie-France Bellin, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Explain the current applications of radiomics and radiology for stratifying patients with cancer. 2) Describe the early cardiac MRI features of immune checkpoint inhibitor (ICI)-induced myocarditis, a severe complication of ICI therapy in patients with cancer. 3) Explain the current clinical applications of robot-assisted innovative interventional procedures for treating abdominal malignancies.

COURSE DESCRIPTION

The objective of this session is to present the most recent and significant advances in oncological radiology in France. The lectures will address the field's primary challenges and illustrate complementary lines of research, emphasizing the importance of a personalized, integrated approach. The following topics will be discussed: the contributions of radiomics and personalized screening to lesion stratification and patient management; the early detection of immune checkpoint inhibitor (ICI)-induced myocarditis (a severe complication of immunotherapy for which imaging plays an important role); and the use of innovative, robot-assisted techniques for interventional radiology in abdominal oncology.

Climate Change and Radiology: High Impact Actions Toward Environmentally Sustainable Medical Imaging

Tuesday, Dec. 2 3:00PM - 4:00PM Room: N227B

Andrea G. Rockall, FRCR, MRCP (*Moderator*) Other-Advisory Board; RoClub
Kate Hanneman, MD, MPH (*Moderator*) Other-Honoraria; Sanofi Genzyme. Other-Honoraria; Medscape. Other-Honoraria; MRI Online. Other-Honoraria; Bayer

LEARNING OBJECTIVES

1) Discuss the impact of medical imaging on climate change and highlight opportunities for change including mitigation, adaptation, and resiliency. 2) Describe key actionable strategies to reduce energy use and waste in diagnostic radiology and improve environmental sustainability in interventional radiology. 3) Explore the impact of climate change on patient outcomes and the delivery of radiology services. 4) Implement resilience and adaptation strategies including infrastructure upgrades, disaster management protocols, and education on changing disease patterns.

COURSE DESCRIPTION

The purpose of this course is to discuss the impact of radiology on climate change and outline high-impact actionable steps we can take to address climate change in our professional lives including diagnostic and interventional radiology.

Contrast-Enhanced Mammography and MRI and Multimodality Interventions: Case-Based Review

Tuesday, Dec. 2 4:30PM - 5:30PM Room: S406A

Christopher E. Comstock, MD (*Moderator*) Consultant; Bayer Inc. Consultant; GE Medical. Consultant; Hologic. Consultant; Recentric Healthcare Technologies

LEARNING OBJECTIVES

1) Describe the techniques and methods used to perform contrast-enhanced mammography, breast MRI and interventional procedures. 2) Utilize the ACR BI-RADS lexicon for CEM and Breast MRI. 3) Understand strategies and approaches to improve CEM and Breast MRI interpretation accuracy. 4) Identify potential challenges and pitfalls of CEM, Breast MRI and biopsies.

COURSE DESCRIPTION

This educational session will highlight contrast-enhanced mammography (CEM), breast MRI and multimodality interventions. The course will review, through case-based lectures, basic techniques, interpretation, and pitfalls. This session will be informative to breast imaging radiologists who are just starting or currently performing contrast-enhanced mammography, breast MRI and biopsy procedures.

Advances in Interstitial Lung Abnormality and Fibrosis

Tuesday, Dec. 2 4:30PM - 5:30PM Room: E451A

Chi Wan Koo, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Define interstitial lung abnormalities (ILA), differentiate ILA from interstitial lung diseases (ILD), and understand the clinical significance and management of ILA. 2) Comprehend the progression and management strategies of fibrotic ILD, focusing on current clinical guidelines and therapeutic advancements. 3) Recognize the emerging role of artificial intelligence in the diagnosis, surveillance, and prognostication of ILD, including its potential impact on clinical decision-making and disease management.

COURSE DESCRIPTION

This advanced course provides a comprehensive exploration of the latest developments in the understanding, diagnosis, and management of interstitial lung abnormalities (ILA) and interstitial lung diseases (ILD). Through a series of expert-led presentations, participants will gain insights into definitions, radiological patterns, clinical significance and management of ILAs, with a focus on early detection and risk stratification. The course delves into the evolving landscape of progressive pulmonary fibrosis, discussing diagnostic criteria, prognostic indicators, and treatment. Participants will also explore current and emerging therapeutic strategies in fibrotic ILD, highlighting recent clinical trial outcomes and guideline updates. This forward-looking session will also examine the transformative role of artificial intelligence in the assessment of interstitial lung pathology, exploring beyond its potential to enhance diagnostic accuracy, prognostication, and treatment planning.

Advances in Imaging of Diffuse Liver Disease

Tuesday, Dec. 2 4:30PM - 5:30PM Room: E451B

Sudhakar K. Venkatesh, MD, FRCR (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the principles and clinical applications of MR elastography and US elastography in evaluating liver fibrosis and diffuse liver diseases. 2) Recognize fat and iron quantification techniques in liver imaging to accurately assess and monitor hepatic steatosis and liver iron overload. 3) Familiarize with new CT quantitative parameters for chronic liver disease 4) Integrate these advanced imaging techniques into clinical practice to improve the diagnosis and management of patients with diffuse liver diseases.

COURSE DESCRIPTION

This educational session aims to provide participants with a comprehensive understanding of advanced imaging techniques for evaluating diffuse liver diseases, with a focus on MR fat and Iron quantification, MR elastography, US elastography, and CT quantification. The session will delve into the principles, clinical applications, advantages, and limitations of each technique, enabling radiologists (participants) to make informed decisions about their use in clinical practice.

Tuesday, Dec. 2 4:30PM - 5:30PM Room: E353B

Akshay D. Baheti, MD, MD (*Moderator*) Nothing to Disclose
Gaiane M. Rauch, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the role of MRI and ultrasound in evaluating traumatic, infectious/inflammatory, and neoplastic penile conditions. 2) Recognize key imaging features of penile prostheses, including indications, normal anatomy, and common complications. 3) Overview of the various acute/chronic and neoplastic conditions of the testis and scrotum. 4) Identify acute male pelvic conditions in the emergency room.

COURSE DESCRIPTION

This course provides a comprehensive overview of various common and some uncommon pathologies affecting the male pelvis (except for prostate), including testicular, scrotal and penile pathologies. The focus will be on various challenges and pitfalls faced by the radiologist while reporting these conditions, including in the ED setting. Through case-based discussions and imaging pearls, attendees will gain a comprehensive approach to diagnosing various important male pelvic conditions and contributing to patient management.

I've Got a Lump in My Throat! Imaging Work-Up of Neck Masses

Tuesday, Dec. 2 4:30PM - 5:30PM Room: E352

Nikdokht Farid, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the imaging algorithm and search patterns for adult and pediatric patients presenting with a neck mass. 2) Understand the imaging algorithm, search patterns, and clinical management for thyroid and parathyroid lesions. 3) Review best practices for providing an image-guided biopsy service for lesions in the neck.

COURSE DESCRIPTION

In this Head and Neck session, attendees will review the imaging approach to adult and pediatric neck masses and will be presented with clinical case examples, with additional focus on work-up of thyroid and parathyroid lesions. Attendees will also review best practices for a radiology department-based image-guided neck biopsy service. Speakers will emphasize pearls for imaging evaluation including how to differentiate each entity from common mimics, pitfalls of interpretation to avoid, and relevant clinical management considerations with which radiologists should be familiar. This session offers attendees the opportunity to refine their interpretation of complex head and neck imaging studies by incorporating tips from world experts.

LEARNING OBJECTIVES

1) Assess the current reimbursement landscape for AI tools in radiology, including coding and regulatory considerations. 2) Evaluate the financial impact of AI implementation on clinical workflows, productivity, and downstream revenue. 3) Discuss strategic approaches to incorporating AI into radiology practice in a financially sustainable and compliant manner.

COURSE DESCRIPTION

As AI continues to reshape radiology, its financial implications remain an important but largely unexplored aspect. This session will explore current and emerging reimbursement models for AI applications in radiology. Participants will gain a deeper understanding of the intersection between innovation and financial viability of AI in radiology. This session is essential for radiologists, administrators, and other stakeholders seeking to align AI integration with sustainable business strategies.

Eva I. Rubio, MD, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Harness the power of the late career radiologist including their specialized knowledge base and wisdom of experience. 2) Extend fulfilling careers by tailoring clinical and educational responsibilities to individual stamina and desire as well as shifting away from stress at the workstation to areas such as research and trainee education. 3) Aid in retirement process by developing strategies to assess cognitive function, create succession plans, design rewarding golden years, and ensure financial stability.

COURSE DESCRIPTION

A significant portion of the radiology workforce qualifies as "late career" including at least 1/3 of radiology leadership. Additionally, 27% of physicians work past 71yrs of age while many others want to remain involved in the health care setting even after they retire from direct patient care. The challenge radiology and medicine in general faces is how to best help late career physicians maximize their golden years and transition to retirement. Late career radiologists bring a wealth of knowledge to the department including clinical, leadership, research and mentorship skills. Once they shut their workstation down for the last time they can find fulfillment outside the clinical realm through advocacy, administration, consulting etc. All the while balancing the variable effect of age on cognition and physical stamina. Although late career radiologists bring much to the department, including depth of knowledge, experience and psychological resilience/improved wellness compared to younger colleagues, they often feel undervalued. Unfortunately, many, if not most, institutions fail to engage late career radiologists in proactive and meaningful discussions regarding goals and functional abilities. It is crucial to proactively make adaptations for late career radiologists for them to shine in their roles for the mutual benefit of colleagues and patients.

See Pro Flocks to Learn About CNS Infections

Tuesday, Dec. 2 4:30PM - 5:30PM Room: S406B

Mohit Agarwal, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review common and uncommon infections of the CNS including bacterial, mycobacterial, helminthic, protozoan, and viral. 2) Learn to tackle typical and atypical appearances of infections in the CNS.

COURSE DESCRIPTION

The world is becoming increasingly interconnected through the frequent and meaningful exchange of people and cultures. As a result, physicians are now tasked with understanding infections that have global relevance. In this session, featuring four presentations by distinguished international experts, we will explore central nervous system infections from diverse regions across the world.

The Chest Files: From Pleural Puzzles to Lung MRI

Tuesday, Dec. 2 4:30PM - 5:30PM Room: E350

Kevin K. Fung, MBBS, FRCR (*Moderator*) Nothing to Disclose
Taylor Chung, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the current imaging approaches to pediatric pleural disease, vascular rings and slings, and acute pulmonary conditions. 2) Identify the clinical applications of chest MRI in children. 3) Apply appropriate strategies for image-guided management of pediatric pleural diseases.

COURSE DESCRIPTION

This course aims to provide practical updates on advanced imaging of the pediatric chest for the diagnosis of a potpourri of pathologies, including the use of MRI, and image-guided interventional management of pediatric pleural diseases

Prostate Cancer Case Based Multidisciplinary Review

Tuesday, Dec. 2 4:30PM - 5:30PM Room: S401

Tristan Barrett, MBBS, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the typical imaging findings of prostate cancer on mpMRI. 2) Assess the impact of MRI on staging prostate cancer in a multidisciplinary setting. 3) Assess the role of imaging in the diagnosis of prostate cancer through case examples.

COURSE DESCRIPTION

This course uses a case-based approach to diagnostic and management decision making in the work-up of patients presenting with prostate cancer. The panel includes radiologists, urologists and radiation oncologists.

Evolution of Advanced 3D Visualization: Choose Your Own Adventure (Sponsored by the RSNA 3D Printing Special Interest Group)

Tuesday, Dec. 2 4:30PM - 5:30PM Room: S404

David H. Ballard, MD (*Moderator*) Consultant; Merck. Consultant; Direct Biologics
Justin R. Ryan, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the current landscape and key trends in 3D visualization tools used in radiology, including clinical, educational, and research applications. 2) Compare different pathways for engagement with 3D visualization from user-level interaction to collaborative development and innovation. 3) Identify which types of 3D visualization tools align with their individual practice needs or professional goals. 4) Formulate a personalized plan for exploring or deepening their involvement with advanced visualization technologies. 5) Recognize opportunities for interdisciplinary collaboration, institutional support, and ongoing learning in this space.

COURSE DESCRIPTION

This interactive session examines the rapid evolution of advanced 3D visualization in medical imaging and explores how radiologists can engage meaningfully at various levels of involvement. Whether interested in clinical integration, research, education, or innovation, attendees will learn how to identify the right entry points aligned with their goals and skillsets. By highlighting flexible engagement models from plug-and-play tools to collaborative pipeline development. This session empowers radiologists to define their own path in shaping the future of 3D imaging. With technologies becoming increasingly accessible and impactful, there's never been a better time to get involved.

Discussing the FDA's Approach to Regulating AI-Enabled Devices in Radiology: Challenges, Innovations, and Other Considerations (Sponsored by the RSNA Government Relations Committee)

Tuesday, Dec. 2 4:30PM - 5:30PM Room: N226

Elizabeth O'Hare, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand current FDA approaches and regulatory frameworks for AI-enabled devices in radiology. 2) Explore key regulatory challenges for AI-enabled devices in radiology. 3) Promote dialogue among panel members and with the audience on challenges and future considerations.

COURSE DESCRIPTION

Artificial Intelligence (AI) is transforming radiology, medicine, and healthcare with applications across diagnostics, treatment, and workflow management. The rapid development and integration of AI tools in radiology raises critical regulatory, ethical, and patient safety concerns. The U.S. Food and Drug Administration (FDA) plays a pivotal role in ensuring the safety and efficacy of AI-enabled medical devices. Featuring FDA staff, this session will examine the current regulatory framework for AI-enabled tools, highlight challenges in balancing innovation with patient safety and physician responsibilities, and provide a forum to discuss how regulatory and legislative frameworks can adapt to the rapidly evolving Health AI ecosystem while ensuring patient safety and ethical use.

Breast Imaging Best Practices: Essentials for Clinical Excellence

Wednesday, Dec. 3 8:00AM - 9:00AM Room: S406A

Steven P. Poplack, MD (*Moderator*) Stock/Shareholder; Johnson and Johnson. Stock/Shareholder; Merck and Co

LEARNING OBJECTIVES

1) Recognize imaging features of mammographic architectural distortion that are predictive of benign and malignant outcomes. 2) Become familiar with the concept of multiparametric breast ultrasound. 3) Understand the practice standards for breast cancer screening with breast MRI.

COURSE DESCRIPTION

This is a case based interactive session highlighting 'best practices' to navigate common scenarios in breast imaging. The session is organized by breast imaging modality: mammography including digital breast tomosynthesis, ultrasound including elastography, and breast MRI, and is presented by content experts. Illustrative cases are intended to provide a framework for interpretation and rationale for image-based decision making.

Lung Cancer Imaging: Pearls, Pitfalls, and Recent Advances

Wednesday, Dec. 3 8:00AM - 9:00AM Room: E451A

Michelle S. Ginsberg, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the current TNM classification system for lung cancer. 2) Become familiar with common pitfalls in lung cancer staging. 3) Introduction to radiomics imaging biomarkers and discuss the current role in metastatic and locally advanced lung cancer.

COURSE DESCRIPTION

This course provides a concise overview of the key updates in the 9th edition of the TNM staging system for lung cancer, with a focused discussion on T4 tumors. It will also cover imaging considerations in lung cancer patients following localized and systemic therapies. Updates to the N and M categories—central changes from TNM 8 to TNM 9—will be reviewed in detail. The course also includes an introduction to radiomics, highlighting current challenges in the clinical integration of radiomic imaging biomarkers and exploring future directions in this evolving field.

Navigating GU Emergencies: Real Cases, Practical Insights

Wednesday, Dec. 3 8:00AM - 9:00AM Room: N228

Ana Blanco, MD (*Moderator*) Nothing to Disclose
Refky Nicola, MSc, DO (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand categories of urologic surgery and intervention and their indications. 2) Gain awareness of risk factors for surgical/interventional complications. 3) Recognize imaging features of surgical complications for rapid diagnosis. 4) Understand next steps in further imaging and management. 5) Provide useful information about the various postpartum uterine complications with tips and tricks to interpret them with practical advices. 6) Present interesting and tricky cases about post partum uterine complications in order to share the reasoning behind the interpretation of images combined with clinical information. 7) Identify surgical procedures of scrotum and penis that may lead to emergencies. 8) Select appropriate imaging techniques for evaluating post-operative penile and scrotal emergencies. 9) Interpret imaging findings of post-operative penile and scrotal emergency conditions.

COURSE DESCRIPTION

This lecture-based session is aimed to provide radiologists and trainees with practical skills for evaluating and managing acute genitourinary emergencies, including renal and bladder complications following procedures or surgery, postpartum uterine emergencies, and penile and scrotal surgical complications. Through practical case examples, expert faculty will discuss key imaging findings, offer practical interpretation tips, and highlight critical pitfalls to avoid in the acute setting. This session is ideal for those involved in emergency, urogenital, and gynecologic imaging who wish to enhance their diagnostic confidence and reporting accuracy.

Hebert Alberto Vargas, MD (*Moderator*) Nothing to Disclose
Katherine M. Krajewski, MD (*Moderator*) Consultant; Merck, Sharpe & Dohme, LLC

LEARNING OBJECTIVES

1) Describe the role of radiogenomics in identifying imaging biomarkers for renal, urothelial, and prostate cancers. 2) Evaluate how radiogenomic data can inform and optimize personalized cancer treatment strategies. 3) Apply radiogenomic principles to enhance diagnostic accuracy and precision imaging in oncologic radiology.

COURSE DESCRIPTION

This course explores the transformative potential of radiogenomics in advancing personalized imaging and cancer management. We open with a keynote on the integration of radiogenomics into personalized imaging, setting the stage for a deeper understanding of its clinical impact. Participants will examine the integration of radiogenomic techniques in renal cell carcinoma, focusing on the identification of novel biomarkers and their correlation with imaging features. The curriculum also covers strategies for enhancing the management of urothelial cancer through radiogenomic data, emphasizing personalized treatment planning. Additionally, the course highlights the application of radiogenomics in prostate MRI, showcasing its potential to refine diagnostic accuracy and guide targeted therapies. Together, these sessions underscore the growing impact of radiogenomics in transforming cancer imaging and individualized patient care.

Best Practices for AI Model Selection and Deployment

Wednesday, Dec. 3 8:00AM - 9:00AM Room: E450B

Hye Sun Na (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify key considerations and common challenges in AI model selection and deployment, drawing from national-level data and institutional experiences. 2) Evaluate strategies for fostering effective AI vendor-client partnerships that support continuous model improvement and alignment with clinical needs. 3) Compare different approaches to clinical integration of AI tools, including customized workflows and the trade-offs between standalone versus platform-based solutions.

COURSE DESCRIPTION

This lecture format session offers practical insights and real-world experiences to guide institutions in evaluating AI models, managing vendor relationships, and integrating AI into clinical workflows. Presenters will share data-driven insights and best practices for implementing both standalone and platform-based AI systems, with a focus on clinical impact, workflow optimization, and scalable deployment strategies.

RSNA Hands-On Lab: Next-Gen Netter: Harnessing 3D Technology to Bring Anatomy to Life for Radiology Residents and Faculty (Registration Fee Required)

Wednesday, Dec. 3 8:00AM - 9:30AM Room: S504CD

Beth A. Ripley, MD, PhD (*Moderator*) Nothing to Disclose
Summer J. Decker, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the challenges of current anatomy education and the top areas of need in improving radiologists' understanding of complex anatomy. 2) Demonstrate hands-on experience with immersive anatomy tools including digital workstations, interactive 3D PDFs, 3D printed models, and extended reality technologies. 3) Identify and utilize educational materials and digital medical assets to enhance anatomy teaching, and engage in interdisciplinary networking with radiology educators globally.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. This hands-on seminar is designed to address the critical gaps in anatomy education for radiology residents and educators. Participants will gain insights into contemporary challenges in anatomy teaching and explore innovative solutions using technologies such as interactive 3D PDFs, 3D printed models, and extended reality. The course offers practical experience with these tools and access to valuable materials and digital assets for enhancing anatomy instruction. This session also provides an opportunity for networking with fellow radiology educators and professionals interested in medical innovation.

RSNA Hands-On Lab: Contrast Reaction Management (Registration Fee Required)

Wednesday, Dec. 3 8:30AM - 10:30AM Room: E265

Carolyn L. Wang, MD (*Moderator*) Grant/Research Support; GE Healthcare

LEARNING OBJECTIVES

1) Recognize various types of contrast reactions and the proper management of various types of contrast reactions through hands-on simulation-based training. 2) Learn with hands-on practice the proper administration of various routes of epinephrine as well as other medications to treat the more common hypersensitivity contrast reactions. 3) Recognize and manage a contrast reaction in a sedated patient and pediatric patient.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. Through hands-on high-fidelity simulation scenario training, learners will practice recognizing and managing various types of contrast reactions. Following a brief lecture, learners will rotate through multiple stations during the course to gain individual hands-on experience. To enhance the learner's experience and allow for more time in the hands-on stations, we ask all learners for the course to watch this short 15 minute video on contrast reaction management prior to the course https://www.youtube.com/watch?v=9r-_E8dmJ0A .

Body Ablaze: Inflammatory and Autoimmune Disorders of the Brain, Orbit, Neck, and Spine

Wednesday, Dec. 3 8:00AM - 9:00AM Room: S406B

Nancy Pham, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify and describe the key imaging findings of inflammatory and autoimmune disorders affecting the brain, orbit, neck, and spine, and differentiate these disorders from other conditions, such as tumors.

COURSE DESCRIPTION

This session is designed to enhance understanding of the key clinical and imaging findings of inflammatory and autoimmune disorders affecting critical areas of the body. By the end of the session, attendees will be able to apply this knowledge in their clinical practice.

Sub-Events

W1-CNR09B **Brain on Fire: Inflammatory and Autoimmune Disorders of the Brain**

What Every Radiologist Should Know: Second and Third Trimester (Covers Beyond the Fetus)

Wednesday, Dec. 3 8:00AM - 9:00AM Room: E351

Paula J. Woodward, MD (*Moderator*) Other-Book royalties ; Elsevier

LEARNING OBJECTIVES

1) Recognize imaging features and confidently diagnose conditions that are life threatening to either the fetus (e.g., vasa previa) or the mother (e.g. placenta accreta spectrum). 2) Review the radiologic assessment of abdominal pain in the pregnant patient. 3) Critically evaluate ovarian masses to differentiate benign from malignant and learn how that effects pregnancy management.

COURSE DESCRIPTION

Imaging in pregnancy extends beyond just looking at the fetus. This review course is specifically designed to look beyond the fetus and address many conditions that face the radiologist when a pregnant woman presents with bleeding, pain, or an adnexal mass. It will include a multi-modality approach with ultrasound, CT and MRI, highlighting appropriate use of each modality. There will be an emphasis on the unique challenges of both diagnosis and management in pregnancy. Specific topics to be covered include vasa previa, the acute abdomen, diagnosis and management of malignancy, and placenta accreta spectrum; all don't miss diagnoses.

Sub-Events

W1-COB07B **Why it Matters!**

Imaging Biomarkers in Radiotherapy: A Pathway to Precision Medicine

Wednesday, Dec. 3 8:00AM - 9:00AM Room: S404

Anil Sethi, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Examine the utility and untapped potential of imaging biomarkers across MRI, PET, and CT in radiotherapy. 2) Discuss the role of AI and advanced radiotherapy platforms in enhancing treatment precision. 3) Understand the application of imaging biomarkers across different cancer disease sites. 4) Identify current barriers to clinical implementation and pathways for equitable adoption of biological or biomarker guided personalized radiotherapy.

COURSE DESCRIPTION

This session explores the evolving role of imaging biomarkers in radiotherapy, focusing on their capacity to improve target delineation, systemically predict and monitor treatment response, and inform personalized clinical decision making. Recent advances in MRI, PET, and CT/CBCT modalities, coupled with quantitative image analyses and AI-driven analytics, are transforming cancer care by enabling greater personalization. Current key trends include leveraging functional and multiparametric imaging to uncover underlying tumor biology beyond structural morphology. Radiotherapy is evolving with adaptive platforms that generate AI driven high quality longitudinal imaging data to enhance prediction accuracy. Furthermore, molecular imaging probes are emerging to target tumorspecific pathways related to radiotherapy. Through a series of expert-led talks, attendees will learn how innovations in personalized treatment strategies are translating into improved patient outcomes with reduced toxicities. This session will also address potential challenges such as lack of standardization, validation, and equitable access to cutting edge technologies while fostering discussions on inclusive solutions in clinical and research settings.

ASRT@RSNA: Breast Imaging: AI vs. CAD: What's the Big Deal?

Wednesday, Dec. 3 8:00AM - 9:00AM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Develop an understanding of the various artificial intelligence tools available in breast imaging and how they affect the patient, technologist, and radiologist. 2) Evaluate the differences between AI and traditional computer-aided detection tools. 3) Identify applications of AI that may be useful in attendees' practices.

COURSE DESCRIPTION

The speaker will discuss how artificial intelligence is being implemented within breast imaging, as well as other aspects of patient care in breast centers. We will demonstrate how artificial intelligence can co-exist with the radiologist to improve workflow and highlight the differences in AI compared to computer-aided detection. Additionally, we will discuss how AI can help radiologic technologists with workflow and quality measures.

RSNA Deep Learning Lab: An Introduction to Multi-agent Artificial Intelligence Systems in Radiology (Advanced) (Registration Fee Required)

Wednesday, Dec. 3 8:00AM - 9:00AM Room: RADIOLOGY LEARNING LAB

Pouria Rouzrokh, MD, MPH (*Moderator*) Consultant; PaxeraHealth

LEARNING OBJECTIVES

1) Define and describe the attributes of an artificial intelligence (AI) agent as well as a multi-agent system. 2) Explain the fundamental differences between assigning a task to a basic large language model (LLM), to a workflow of LLMs, to an agent, or to a multi-agent system; provide real-life examples and use cases of when each approach can help in day-to-day radiologist practice. 3)Learn the core principles and methods for using an agentic programming framework (Google Agent Development Kit) to design single and multi-agent systems in Python.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. Transform your understanding of artificial intelligence (AI) from simple chatbots to sophisticated problem-solving systems in this hands-on Deep Learning Lab designed specifically for radiologists. As AI rapidly evolves beyond basic language models, radiologists need to understand how to leverage advanced AI architectures—including single AI agents and multi-agent systems—to enhance diagnostic accuracy, streamline workflows, and ultimately, improve patient care. This workshop addresses the critical gap between knowing AI exists and actually implementing it effectively for real scenarios. Through a combination of interactive lectures and practical coding exercises, you'll discover when to use different AI approaches: from simple large language model (LLM) queries for quick information retrieval, to complex multi-agent systems for comprehensive case analysis and workflow optimization. This intensive session combines engaging lectures with hands-on programming using Google Colab and the Google Agent Development Kit (ADK), ensuring you leave with both theoretical knowledge and practical skills. You'll learn to distinguish between AI agents and traditional LLMs, understand the unique capabilities of multi-agent systems, and master the fundamentals of building these systems using Python. By the end of this workshop, you'll be able to design and implement AI agent solutions tailored to real radiology challenges—from automated report generation to complex diagnostic reasoning tasks. Basic familiarity with AI concepts and Python programming is recommended to maximize your learning experience. Join us to move beyond AI basics and become proficient in creating intelligent systems that truly enhance your radiological practice.

Post-Treatment Neuroimaging: A Primer to Changes in the Brain, Skull Base, Neck, and Spine (Joint Session with Neuroradiology)

Wednesday, Dec. 3 9:30AM - 10:30AM Room: N227B

Aubrey McMillan, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize typical and atypical imaging features of post-treatment changes and related complications in the brain, spine, skull base, and neck. 2) Differentiate post-treatment changes from pathologic entities, including infection and disease recurrence.

COURSE DESCRIPTION

In this case-based combined Neuroradiology and Head and Neck session, attendees will be presented with an overview of post-treatment imaging findings in the brain, spine, skull base, and neck. Speakers will emphasize imaging pearls that distinguish postoperative, post-radiation, and post-treatment changes from pathology, including recurrent disease and infection. This session offers attendees the opportunity to refine their interpretation of complex neuroradiology and head and neck imaging studies by incorporating tips from world experts.

Novel Radiopharmaceuticals on the Horizon (Advanced)

Wednesday, Dec. 3 9:30AM - 10:30AM Room: S405

Aileen O'Shea, MBBCh (*Moderator*) Other-Funding for conference attendance ; Novartis

LEARNING OBJECTIVES

1) Provide an introduction and overview to emerging radiotracers and theranostic agents. 2) Recognize the utility of PET imaging in the context of novel immunotherapeutic agents. 3) Understand the breadth of applications of fibroblast activated protein inhibitor (FAPI) PET imaging in oncology and the basic principles of interpretation.

COURSE DESCRIPTION

During these three lectures, experts in their field will provide an overview of novel radiotracers which will play important roles in the diagnosis and treatment of oncologic and inflammatory conditions. This session will highlight some radiotracers which are in early clinical trial phases and those which are poised for routine clinical practice, such as FAPI PET. The impact of these radiotracers in the context of novel immunotherapies will be discussed.

Choose Your Weapon: A Debate on the Merits of Generalist vs. Specialty Training in 2025

Wednesday, Dec. 3 9:30AM - 10:30AM Room: S402

Hanna M. Zafar, MD, MS (*Moderator*) Nothing to Disclose
Michael J. Hicks, MD (*Moderator*) Consultant; GE Healthcare

LEARNING OBJECTIVES

1) Compare and contrast the advantages and challenges of generalist and subspecialist focused training models for modern day academic and private practice radiology settings. 2) Evaluate workforce and healthcare system needs in relation to radiologist training paradigms, considering regional, institutional, and population-specific demands. 3) Identify key factors influencing recruitment and retention strategies for radiologists over the next decade, including the impact of training background on adaptability and marketability. 4) Assess the implications of training pathways on clinical coverage, quality of care, and professional development in radiology practices. 5) Apply insights from the debate to inform strategic decisions in residency program design, radiologist hiring, and departmental planning.

COURSE DESCRIPTION

In this session, participants will debate the merits of training graduating residents to be generalists versus sub-specialists in the context of modern population needs and market demands. Both pro-generalist and pro-subspecialist perspectives will be offered from the private practice and academic viewpoints. This session will be relevant to not only those involved in the training of future radiologists, but also anyone who will be involved in or impacted by recruitment in the next decade.

LEARNING OBJECTIVES

1) Recognize common pediatric sports-related injuries of the shoulders, elbows, knees, and ankles. 2) Compare the mechanisms behind and imaging appearances of acute and overuse injuries in children. 3) Differentiate normal imaging findings from true pathology in the shoulders, elbows, knees, and ankles of children.

COURSE DESCRIPTION

Active children and adolescents are susceptible to unique acute and overuse injuries. Radiologists are challenged with identifying these injuries and distinguishing them from normal developmental findings. This session will review various sports-related injuries that can afflict pediatric athletes through four lectures on shoulder, elbow, knee, and ankle pathologies.

Quantitative CT and MRI

Wednesday, Dec. 3 9:30AM - 10:30AM Room: S404

Michael F. McNitt-Gray, PhD (*Moderator*) Grant/Research Support; Siemens Healthineers. Other-Travel expenses and stipend for speaking; Kyoto Kagaku, LLTravel C

LEARNING OBJECTIVES

1) Understand general statistical approaches in establishing repeatability, reproducibility, precision, variance, and confidence intervals for image-based measurements from quantitative imaging modalities. 2) Understand advances in CT technology and standardization efforts for quantitative imaging. 3) Understand the medical physics workflow for cross-platform harmonization in MRI techniques to enable quantitative use of PDFF and ADC in multi-site clinical trials.

COURSE DESCRIPTION

Novel clinical imaging technologies offer improved image quality, and more importantly, provide quantitative information via image-based measurements. There is a greater need for understanding the physics behind quantitative measurements and evaluating these imaging modalities in terms of study design, statistical methods and models for data analysis to ensure precise, repeatable, and reproducible quantitative measurements. Advanced multi-energy CT systems such as dual-energy CT and photon-counting CT routinely provide quantitative images such as virtual non-calcium or non-contrast image, and virtual monoenergetic image. Similarly, clinical MRI routinely provides parametric maps for proton density fat fraction (PDFF) and apparent diffusion coefficient (ADC). However, these images are still largely used qualitatively in part due to biases in acquisition techniques, lack of standardization, site preferences, and vendor implementations. It is imperative to standardize the imaging methodology to achieve cross-platform harmonization and to enable the routine use of quantitative information available from these advanced imaging systems. This educational course focusing on advances in quantitative CT and MRI, and statistical methods for quantitative imaging are valuable to medical physics and radiology practitioners for developing standardized imaging techniques and analytical approaches that are vital to multicenter clinical trials involving imaging biomarkers.

Percy Lee, MD (*Moderator*) Consultant; AstraZeneca. Consultant; Gententech. Consultant; Varian. Consultant; Johnson and Johnson. Consultant; Roche

LEARNING OBJECTIVES

1) Apply evidence-based multidisciplinary strategies to manage complex thoracic malignancies, including stage III NSCLC, thymic tumors, limited-stage SCLC, and oligometastatic lung cancer. 2) Interpret radiographic findings with clinical nuance to guide treatment sequencing and modality selection in thoracic oncology cases. 3) Discuss the role and optimal timing of radiation therapy through case-based examples across various thoracic malignancy scenarios. 4) Identify key factors influencing systemic therapy decisions, including patient characteristics, disease biology, and evolving clinical evidence. 5) Evaluate considerations for local therapy selection, distinguishing when surgery versus radiation is appropriate based on disease presentation and multidisciplinary input.

COURSE DESCRIPTION

This multidisciplinary session will provide a case-based review of complex thoracic malignancies, bringing together expert perspectives from radiation oncology, medical oncology, thoracic surgery, and diagnostic radiology. Through real-world clinical scenarios—including stage III non-small cell lung cancer, limited-stage small cell lung cancer, thymic tumors, and oligometastatic disease—faculty will demonstrate how evidence-based tumor board strategies can guide nuanced decision-making. Emphasis will be placed on radiographic interpretation as a foundation for determining treatment sequencing and selecting appropriate modalities. Participants will gain insights into the timing and application of radiation therapy, criteria for systemic therapy selection, and the factors that influence local therapy choices between surgery and radiation. This session is designed to enhance the practical application of multidisciplinary collaboration in thoracic oncology and improve patient-centered care.

ASRT@RSNA: Harnessing Generative AI in Medical Imaging: Insights and Critical Appraisal

Wednesday, Dec. 3 9:30AM - 10:30AM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Gain an overview of generative AI. 2) Understand the performance of ChatGPT on CAMRT-style entry-to-practice exam. 3) Learn a framework for critiquing AI-powered applications.

COURSE DESCRIPTION

The rapid evolution of generative artificial intelligence presents transformative opportunities in medical imaging but also necessitates a critical understanding of its capabilities and limitations. This session will provide a comprehensive overview of generative AI focusing on chat-based applications, such as ChatGPT, and their implications for medical imaging professionals. The course will begin by defining generative AI and its relevance to health care, outlining the mechanisms that enable these systems to generate human-like text and interact in real time. A recent study evaluating ChatGPT's performance on a Canadian Association of Medical Radiation Technologists-style entry-to-practice exam will be reviewed, highlighting its strengths, weaknesses and potential as a supplementary tool for education and training. To guide medical imaging professionals in navigating AI developments, a framework for critically appraising AI-powered applications will be presented. This framework will emphasize the roles of transparency, performance and clinical applicability. Special attention will be given to the integration of AI in medical imaging and its potential to enhance quality, workflow efficiency and patient outcomes. The session will conclude with takeaways for medical imaging professionals that will equip attendees with the knowledge and tools to engage with AI advancements responsibly and effectively within their practice. Attendees will leave with a balanced perspective on the promises and challenges of generative AI in medical imaging.

RSNA Deep Learning Lab: Transforming Radiology with LLMs: Fine-Tuning and Explainable AI for Next-Gen Clinical Solutions (Advanced) (Registration Fee Required)

Wednesday, Dec. 3 9:30AM - 10:30AM Room: RADIOLOGY LEARNING LAB

Paul H. Yi, MD (*Moderator*) Consultant; FHOrtho. Consultant; Bunkerhill Health. Stock/Shareholder; Bunkerhill Health. Consultant; Philips

LEARNING OBJECTIVES

1) Identify key limitations of general-domain foundation models in radiology applications and strategies for adaptation through fine-tuning and Retrieval-Augmented Generation (RAG). 2) Apply hands-on techniques for customizing LLMs for radiology-specific data and evaluate their outputs for clinical relevance and interpretability. 3) Hands-on experience understanding methods for explainability to support safe and effective use in radiology workflows.

COURSE DESCRIPTION

In Person Session Only. Tickets must be purchased in advance for this course. This course can be added through the registration portal or by stopping by the Registration Desk. Space is limited. Large language models (LLMs) are increasingly explored across applications in Radiology, including report writing, research, and clinical decision support. However, these models are trained on broad, general-domain data and often underperform with specialized medical/radiology domain-specific tasks. This hands-on lab will provide participants with practical experience adapting LLMs for radiology via fine-tuning techniques, improve accuracy via Retrieval-Augmented Generation (RAG), and methods for interpretability of model "thinking" with explainable AI. The session will include a 30-minute lecture and discussion on the foundational concepts and a 50-minute guided Python notebook, implementing the methods. By the end of the session, participants will be equipped to adapt general-purpose LLMs for domain-specific radiology use cases and assess for transparency in model outputs. Agenda: Lecture & Discussion (30 mins): Overview of LLMs in radiology, introduction to fine-tuning and Retrieval-Augmented Generation (RAG). Discussion of challenges and importance of explainability in clinical settings Hands-On Lab (50 mins): Guided Python exercises covering fine-tuning with radiology data, implementing Retrieval-Augmented Generation workflows, and explainability Wrap-Up and Q&A (10 mins): Summary of key takeaways and discussion of future directions.

RSNA/ESR Symposium: Advances in Prostate Cancer Imaging and Therapy: Prostate Cancer: Developments on Quality Control and Artificial Intelligence

Wednesday, Dec. 3 9:30AM - 10:30AM Room: E352

Andrei S. Purysko, MD (*Moderator*) Consultant; Koelis. Grant/Research Support; Blue Earth Medical. Grant/Research Support; American College of Radiology. Grant/Research Support; Lantheus. Grant/Research Support; Siemens Healthineers
Patrick Asbach, MD (*Moderator*) Grant/Research Support; Siemens Healthineers, Canon Medical Systems, Bayer AG, Bracco S.p.A., Guerbet SA, Visage Imaging. Consultant; Professional Association of the German Radiologist (BDR e. V.)

LEARNING OBJECTIVES

1) Highlight critical insights and practical strategies from initiatives focused on enhancing the quality and diagnostic accuracy of prostate MRI. 2) Understand the concepts of QC in the prostate diagnostic pathway to identify areas requiring quality improvement. 3) Understand and reflect how AI can be integrated into the diagnostic workflow.

COURSE DESCRIPTION

This engaging lecture-based symposium, co-hosted by RSNA and ESR, will explore recent advancements in prostate cancer imaging and therapy with a focus on quality control and artificial intelligence (AI). Prostate MRI has become central to the diagnosis and management of prostate cancer, yet ensuring consistent quality across practices remains a key challenge. This session will highlight collaborative efforts to standardize and elevate prostate MRI performance, discuss the role of structured quality assurance programs, and examine the impact and readiness of AI tools in clinical workflows. Attendees will gain insights from international leaders on how to optimize prostate imaging quality and prepare for AI integration in everyday practice.

Preparing for Oral Boards: Strategies and Exemplar Case-Taking Skills (Sponsored by the RSNA Resident and Fellow Committee)

Wednesday, Dec. 3 9:30AM - 10:30AM Room: E353B

Brandon K.K. Fields, MD (*Moderator*) Consultant; Mendaera
Megan K. Mercer, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Didactic Overview: Presentation on the overall structure of the oral board exam and the primary evaluation criteria; practical tips and "pearls" for successful case-taking, including communication strategies, time management, and handling challenging scenarios will be reviewed. 2) Exemplar Case-Taking: Three attending-level panelists representing different institutions and specialties will be individually presented with different cases in a mock exam format. A moderator will act as the examiner to simulate the experience. Panelists will model effective case-taking approaches, highlighting techniques that trainees can emulate. Panelists will be given ~12 minutes per case.

COURSE DESCRIPTION

Trainees are in the midst of navigating a sea change in certification requirements with the reinstatement of oral board examinations. While the ABR will retain some aspects of the legacy oral board examinations, key differences—such as standardized evaluation criteria—present unique considerations. This session will provide attendees with actionable insights and real-world examples to solidify confidence and competence in preparing for the oral boards in a relatively stress-free environment.

Monika Radike, MD, PhD (*Moderator*) Nothing to Disclose
Sherry S. Wang, MBBS, FRANZCR (*Moderator*) Consultant; Bracco. Other-Book Royalties; Elsevier

LEARNING OBJECTIVES

1) Understand the bridges between creativity, curiosity, and learning/innovation. 2) Understand how art can be used to help educate learners. 3) Explore how to use art as part of your toolkit as a radiologist.

COURSE DESCRIPTION

This didactic and interactive course delves into the utilization of art as a teaching and engagement tool for radiology educators. The course will explore various themes and ideas, with the primary objective of equipping educators with actionable skills for practical application in their daily work. 1) AI art (for the radiologist who cannot draw) 2) The Art of PowerPoint 3) Art, Wellness, and the Radiologist

LLMs in Clinical Practice

Wednesday, Dec. 3 11:00AM - 12:00PM Room: E450B

Ayis T. Pyrros, MD (*Moderator*) Consultant; Inference Analytics. Consultant; Brainnet.ai. Consultant; HOPPR.ai

LEARNING OBJECTIVES

1) Describe the current and potential applications of large language models (LLMs) in radiology and broader clinical practice. 2) Evaluate practical strategies for safely deploying LLMs, including prompt engineering and workflow integration, in a clinical environment. 3) Identify key considerations and best practices for leveraging foundation models to improve efficiency, reporting accuracy, and clinical decision-making.

COURSE DESCRIPTION

The rapid advancement of large language models (LLMs) such as GPT-4 and other foundation models is reshaping the landscape of medical AI, offering new opportunities to streamline workflows and enhance patient care. This session will provide a practical, hands-on overview of LLM applications in radiology practice. Expert faculty will share real-world use cases for LLM-driven report drafting, prompt engineering, and safe model deployment. Attendees will gain actionable insights into integrating LLMs into their daily practice while understanding both the benefits and limitations of these transformative technologies. The session will equip learners to evaluate, implement, and optimize LLM-based tools in a safe and effective manner.

ASRT@RSNA: Multidisciplinary Osteoporosis Care and the Radiographer's Role in Fracture Liaison Services

Wednesday, Dec. 3 11:00AM - 12:00PM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Define osteoporosis and explain the benefits of screening programs for early detection and fracture prevention. 2) Discuss the importance of a multidisciplinary approach in the management of osteoporosis and fracture prevention. 3) Describe the radiographer’s role in a fracture liaison service in the U.K.

COURSE DESCRIPTION

Osteoporosis and fragility fractures are preventable outcomes of aging that are, unfortunately, still underdiagnosed and undertreated. This session will provide an overview of the radiographer’s role in fracture prevention and osteoporosis management through multidisciplinary care and fracture liaison services. Attendees will learn about opportunities for osteoporosis screening within existing patient pathways and how to support patients. The speaker will also discuss the future of early osteoporosis diagnosis using new and innovative technologies.

Cardiac MRI in Systemic Diseases: How Your Diagnosis Guides Treatment

Wednesday, Dec. 3 1:30PM - 2:30PM Room: E353C

Jadranka Stojanovska, MD, MS (*Moderator*) Nothing to Disclose
Luba Frank, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the role of cardiac MR in detecting and characterizing cardiac involvement in systemic diseases such as rheumatologic, oncologic, and infiltrative conditions. 2) Interpret key cardiac MR findings that impact clinical decision-making and guide individualized treatment approaches in patients with systemic disease. 3) Understand evidence-based imaging strategies to enhance multidisciplinary care and improve outcomes for patients with systemic diseases affecting the heart.

COURSE DESCRIPTION

Course Description Cardiac MRI in Systemic Diseases: How Your Diagnosis Guides Treatment This didactic lecture session will explore the pivotal role of cardiac MR in diagnosing and managing systemic diseases with cardiac involvement. As systemic conditions such as rheumatologic disorders, cancer therapies, and infiltrative diseases increasingly impact the heart, advanced imaging is essential for accurate diagnosis and personalized treatment planning. Expert faculty will illustrate how cardiac MRI findings directly inform clinical decisions and optimize patient outcomes. The session will include lectures and interactive discussions, informing participants with practical knowledge to confidently interpret cardiac MR in complex systemic disease scenarios. Format: Lecture and interactive discussion Expected Outcome: Participants will gain an understanding of the diagnostic and prognostic value of cardiac MR in systemic diseases, empowering them to apply imaging findings to guide treatment strategies and engage in interdisciplinary management.

Jeremy R. Wortman, MD, BA (*Moderator*) Consultant; United Imaging Intelligence
Krystal Archer-Arroyo, MD (*Moderator*) Consultant; Siemens Healthineers USA

LEARNING OBJECTIVES

1) Identify how multi-energy CT can improve accuracy in the acute care setting. 2) Explain common pitfalls in the use of multi-energy CT in emergency radiology. 3) Describe how multi-energy CT can be used for common incidental findings.

COURSE DESCRIPTION

This educational session will explore the uses of Multi-Energy CT (MECT) in Emergency Radiology, highlighting the impact of this technology on diagnostic accuracy and clinical decision-making in the acute care setting. Expert speakers will discuss the applications of MECT in the emergent setting, its value in characterizing acute bowel pathology, and its utility in identifying and interpreting incidental findings. Through case-based presentations and practical insights, attendees will gain a deeper understanding of how MECT can improve diagnostic confidence, workflows, and patient outcomes in Emergency Radiology.

LEARNING OBJECTIVES

1) Distinguish between population health applications and hospital care applications of AI in clinical practice. 2) Evaluate the opportunities and pitfalls of (AI-based) prognostication. 3) Propose and appraise potential agentic workflows for personalized, patient-centric healthcare delivery.

COURSE DESCRIPTION

This advanced session is designed for participants with a solid understanding of current AI in clinical practice. Through didactic lectures and interactive discussions, participants will gain insights into the differences between population health applications and hospital care applications of AI. Attendees will understand the opportunities and pitfalls regarding AI-based prognostication with use-cases biologic aging CT biomarkers and breast cancer risk prediction. Potential future agentic workflows for personalized oncology care and shared decision making using AI will be explored as well.

LEARNING OBJECTIVES

1) Understand the principles of image fusion and its role in multimodal imaging. 2) Explore clinical applications in oncology, neurology, musculoskeletal, and vascular imaging. 3) Learn about real-time image fusion for interventional procedures, including biopsies, tumor ablations, and vascular interventions. 4) Discuss the challenges, limitations, and future advancements in fusion imaging technology.

COURSE DESCRIPTION

This course provides a comprehensive overview of image fusion technologies and their applications in clinical practice. Participants will explore the principles of image registration, multimodality fusion (CT, MRI, PET, ultrasound), and real-time navigation systems. The curriculum covers technical aspects of fusion software, workflow integration, and quality assurance. Emphasis is placed on the clinical utility of image fusion in interventional radiology, oncology, surgery, and radiation therapy, with case-based examples illustrating enhanced procedural accuracy, safety, and outcomes.

Advanced Tools for Post-Operative Imaging of Brain Tumors

Wednesday, Dec. 3 1:30PM - 2:30PM Room: S406B

Nikdokht Farid, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the utility of RANO and BT-RADS in the evaluation of post-operative brain tumor imaging, particularly in communicating radiologic interpretation and recommendations to clinical colleagues. 2) Understand how cutting-edge perfusion techniques such as DSC perfusion-derived fractional tumor burden (FTB) and ASL perfusion can differentiate treatment change from recurrent tumor.

COURSE DESCRIPTION

In this Advanced Neuroradiology session, attendees will review the imaging approach to post-operative evaluation of brain tumors. In addition to learning about formal brain tumor assessment and reporting systems including RANO (Response Assessment in Neuro-Oncology) and BT-RADS (Brain Tumor Reporting and Data System), attendees will learn how to use cutting-edge perfusion techniques to differentiate treatment change from recurrent tumor. By the end of this session, participants will be better equipped to accurately interpret post-operative brain tumor imaging and to effectively communicate their interpretation and recommendations to our clinical colleagues.

Fast, Smart, and Data-Driven: Charting the Future Landscape of Pediatric Radiology

Wednesday, Dec. 3 1:30PM - 2:30PM Room: E350

Lane F. Donnelly, MD (*Moderator*) Nothing to Disclose
Marcelo S. Takahashi, MD, PhD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe data-driven strategies and key performance indicators to optimize operational efficiency and patient access in pediatric radiology. 2) Explain the fundamental applications of artificial intelligence (AI) in pediatric imaging, including its role in interpretation, reporting, and addressing unique pediatric challenges. 3) Identify and apply accelerated imaging protocols and other innovative techniques to reduce examination times and minimize the need for sedation and general anesthesia in pediatric patients.

COURSE DESCRIPTION

This educational session will review contemporary advancements in pediatric radiology focused on improving efficiency, diagnostic precision, and patient safety. The curriculum examines the use of departmental data and key performance metrics to inform operational strategies and enhance patient access. The session will cover the practical applications of artificial intelligence (AI) in pediatric imaging, including its role in interpretation and reporting, alongside the challenges specific to pediatric AI development. Further topics include the implementation of accelerated MRI protocols and a discussion of techniques designed to minimize the use of sedation and general anesthesia. The goal is to provide attendees with a clear understanding of these emerging strategies to support their integration into clinical practice.

Gastroesophageal Tumor Multidisciplinary Session

Wednesday, Dec. 3 1:30PM - 2:30PM Room: S401

Ann Raldow, MD, MPH (*Moderator*) Grant/Research Support; Viewray, Inc.. Grant/Research Support; BlueHalo

LEARNING OBJECTIVES

1) Interpret complex imaging findings relevant to gastroesophageal malignancies through expert-led review of radiologic studies. 2) Differentiate appropriate management strategies for localized versus advanced gastroesophageal cancers, integrating input from surgery, medical oncology, radiation oncology, and interventional endoscopy. 3) Assess criteria for resectability and operability, incorporating surgical and radiologic perspectives, including anatomical considerations, patient comorbidities, and tumor stage. 4) Formulate evidence-based treatment plans for gastroesophageal cancer patients, including sequencing of chemotherapy, chemoradiation, and surgery, with attention to current guideline recommendations and recent clinical trial data.

COURSE DESCRIPTION

Gastroesophageal cancers present unique diagnostic and therapeutic challenges that require a nuanced, multidisciplinary approach. This interactive case-based session brings together experts in radiology, surgery, medical oncology, radiation oncology, and interventional gastroenterology to review real-world cases and discuss optimal management strategies. Participants will gain insight into state-of-the-art imaging interpretation, staging criteria, treatment sequencing, and evolving roles for endoscopic and radiation-based therapies. Emphasis will be placed on integrating multiple perspectives to navigate complex decision-making and tailor individualized treatment plans. The format includes case presentations followed by multidisciplinary discussion, enabling learners to engage directly with faculty and peers in collaborative problem-solving. This session is ideal for clinicians seeking to strengthen their understanding of multidisciplinary cancer care and improve coordination across specialties. By the end of the session, learners will be better equipped to apply evidence-based, team-oriented strategies in the care of patients with gastroesophageal tumors.

ASRT@RSNA: Aristotle Meets Kotter: The Role of Communication in Driving Successful Change Management in Healthcare

Wednesday, Dec. 3 1:30PM - 2:30PM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Define the three types of rhetoric as a means of persuasion and how they affect changes in behavior. 2) Identify the basic framework of John Kotter's 8-Step Change Model and why linear communication delivery fails to change behavior. 3) Recognize and apply the basic concepts of rhetoric and communication science to accelerate the transformation to change champions. 4) Demonstrate an understanding of the connection between the art of persuasion, the science of communication, and successful change management efforts via a review of research and examples in health care change management.

COURSE DESCRIPTION

In 1995, John Kotter published what has since become the stalwart guide to successful change management. His 8-Step Change Model centers communication as a key component in driving successful change efforts. We know how important communication is to change management, yet poor communication is still the No. 1 reason change efforts fail. Communication to create changes in behavior is far more complex than simply delivering information. The speaker will discuss Aristotle's beliefs about this concept in the 4th-century B.C., and how John Kotter applied these communication principles in the modern era. Take a quick trip to ancient Greece to learn more about the three types of rhetoric, why we respond or don't respond to each type, and how to leverage this foundational aspect of communication science in change efforts.

Pearls and Pitfalls of Implementing Advanced Practice Providers (APPs) in Radiologist-Led Team

Wednesday, Dec. 3 1:30PM - 2:30PM Room: N227B

Brandon Smith (*Moderator*) Employee; GE Healthcare
Richard E. Heller III, MD, MBA (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify the clinical roles and responsibilities of Advanced Practice Providers (APPs) in both diagnostic and interventional radiology settings. 2) Describe the benefits and limitations of integrating APPs into radiology workflows, including their impact on efficiency, patient care, and physician workload. 3) Identify important billing and compliance issues regarding the use of APPs in radiology.

COURSE DESCRIPTION

This session, intended to help departments and practices considering introducing or refining the use of Advanced Practice Providers (APPs*), will explore the evolving role of APPs in radiology, highlighting both the advantages and challenges of their integration. Speakers will share insights into the clinical impact of APPs in diagnostic and interventional radiology, including workflow optimization, patient communication, and procedural assistance. The session will also address common pitfalls, such as scope-of-practice limitations, variability in training, and oversight concerns as well as include a discussion of billing and compliance issues. *such as nurse practitioner (NP), physician assistant (PA), radiologist assistant (RA), radiology practitioner assistant (RPA), or registered radiologist assistant (RRA)

Challenging Topics in Emergency Radiology

Wednesday, Dec. 3 3:00PM - 4:00PM Room: S401

Ellen X. Sun, MD (*Moderator*) Nothing to Disclose
Lawrence C. Chow, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the common surgeries in gender affirming care and potential associated complications. 2) Review common causes of ED presentation in cancer patients, associated imaging findings, and prognostic implications around emergently diagnosed malignancies. 3) Recognize the mechanisms of injury and imaging findings associated with intimate partner violence (IPV) and define the role of the radiologist in identifying victims of IPV.

COURSE DESCRIPTION

The lectures in this session focus on three potentially less familiar topics in emergency radiology which present unique and specific challenges for the emergency radiologist. Oncology related emergencies and complications of gender affirming surgery are being seen with greater frequency in the emergency department while intimate partner violence remains underdiagnosed. All require specific knowledge to avoid imaging related diagnostic errors and missed diagnoses. By the end of the session, attendees will have greater familiarity and awareness of these entities and be better equipped to recognize and identify their key imaging features.

Nonphysician Providers (NPPs) in Radiology: Practical and Ethical Considerations for Improving Access and Maintaining Quality of Care (Sponsored by the RSNA Professionalism Committee)

Wednesday, Dec. 3 3:00PM - 4:00PM Room: N228

Monica M. Sheth, MD (*Moderator*) Nothing to Disclose
R. Paul Guillerman, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Differentiate the types of radiology NPPs and discuss utilization trends of NPPs in clinical practice. 2) Understand how training programs, professional society guidelines, and governmental regulations affect the scope of NPP practice. 3) Expand access to care in local and global settings by judicious implementation of NPPs. 4) Address ethical and medicolegal considerations arising from independent practice of NPPs.

COURSE DESCRIPTION

The expanded use of nonphysician providers (NPPs) is touted to improve access to patient care in the setting of a limited radiologist workforce and the demands of ever-increasing volumes. However, adequate knowledge and skills are primary professional competencies that must be ensured for the ethical practice of medicine. The full impact of NPPs on radiology practice in terms of patient safety, practice revenue, cost of care, and trainee education remains unclear. Given the likelihood of a continued increase in the number of NPPs in clinical practice and expansion of their scope of practice to include not only performance but also interpretation of imaging studies, it is imperative that this be done with vigilant oversight to ensure preservation of standards of care. These issues will be addressed in a series of lectures from the perspective of both radiologists and NPPs in local and global settings.

ASRT@RSNA: Managing Patient Anxiety in MRI: Achieving Near-Zero Refusals

Wednesday, Dec. 3 3:00PM - 4:00PM Room: N226

Melissa Culp, MEd (*Moderator*) Nothing to Disclose
Peter Rath (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Identify patient-management processes that lead to distress. 2) Implement improvements in managing anxious and claustrophobic patients in magnetic resonance examinations. 3) Select appropriate methods to reduce anxiety.

COURSE DESCRIPTION

Patient refusals and anxiety prior to and during magnetic resonance imaging examinations result in compromised health care and substantial cost to the imaging center. While claustrophobia is a real symptom, it frequently can be managed proactively by attending to a variety of simple factors. In more than 35 years of handling human subjects in research settings, the speakers have experienced a near-zero refusal rate, even though the examination times are often many times longer than typical clinical scans. The speakers will describe the factors in research settings that can be translated directly to imaging centers and that will lead to increased efficiency, income, improved diagnostics and improved patient satisfaction.

Vascular Imaging for the Next Decade: We're Not in Kansas Anymore (Advanced)

Wednesday, Dec. 3 3:00PM - 4:00PM Room: S503

Bradley D. Allen, MD, MS (*Moderator*) Consultant; Circle Cardiovascular Imaging. Owner; Third Coast Dynamics. Speaker's Bureau; MRI Online. Grant/Research Support; Guerbet. Speaker's Bureau; Siemens. Stock/Shareholder; Third Coast Dynamics
Melany B. Atkins, MD (*Moderator*) Consultant; GE Heathcare. Speaker's Bureau; HeartFlow. Consultant; Arterys. Consultant; Bayer Healthcare CTEPH

LEARNING OBJECTIVES

1) Describe the principles, benefits, and limitations of next-generation imaging modalities such as Photon Counting CT and 4D Flow MRI, and assess their potential to transform vascular diagnostics and clinical decision-making over the next decade. 2) Gain practical knowledge on implementing advanced modalities like 4D Flow and utility in daily clinical workflows, including protocol selection, image interpretation, and integration into multidisciplinary care pathways. 3) Identify key AI applications in vascular imaging, critically assess their current capabilities, and apply AI tools to enhance diagnostic accuracy, streamline workflows, and support clinical decision making.

COURSE DESCRIPTION

This lecture series explores the future of vascular imaging with a focus on emerging technologies and clinical applications including photon counting CT and 4D Flow MRI, and practical strategies for using AI in vascular imaging. Attendees will gain insights to enhance diagnostic accuracy and integrate advanced imaging tools into routine clinical practice.

Breast Imaging Interventions: Core Techniques and Best Practices

Wednesday, Dec. 3 4:30PM - 5:30PM Room: S406A

Cherie M. Kuzmiak, DO (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe and discuss the strengths and limitations of each image-guided breast procedure. 2) Identify challenges encountered during image-guided breast biopsy procedures and how to implement effective solutions to optimize sampling. 3) Describe and discuss ways to improve radiology-pathology concordance.

COURSE DESCRIPTION

Image-guided biopsies are crucial in diagnosing breast cancer and other breast/axillary lesions. These procedures, including pre-operative localization of non-palpable breast lesions, have become more accurate with advances in imaging technology, contributing significantly to improved outcomes for breast cancer patients. There are three main imaging modalities used for guidance: mammography/tomosynthesis, ultrasound and magnetic resonance imaging. Each technique has its specific indications, advantages, and limitations, and the choice of modality depends on the clinical context, lesion location, and patient factors. Understanding the strengths and limitations of each technique helps radiologists select the most appropriate method for each individual patient. This session will provide practical core techniques and best practices solutions to challenges that radiologists at all experience levels encounter with interventional breast procedures.

Lung Cancer Screening: Implementation and Advances

Wednesday, Dec. 3 4:30PM - 5:30PM Room: E451A

Palmi N. Shah, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Design and evaluate decentralized lung cancer screening programs. 2) Learn the common diagnostic and operational challenges in lung cancer screening. 3) Assess the utility and limitations of artificial intelligence applications in lung cancer screening. 4) Apply Lung-RADS guidelines with greater accuracy and confidence through case-based review.

COURSE DESCRIPTION

This advanced lecture session is designed for radiologists engaged in or preparing to lead lung cancer screening programs. With a focus on practical implementation, the course explores decentralized screening strategies, common diagnostic and operational challenges, and the transformative role of artificial intelligence in imaging workflows. A case-based review of Lung-RADS will enhance radiologists' diagnostic precision and standardization in nodule assessment. Attendees will gain actionable insights to optimize lung cancer screening processes, contribute to early detection, and improve patient outcomes in diverse clinical environments.

LEARNING OBJECTIVES

1) Recognize challenging cases in emergency radiology. 2) Generate differential diagnoses when appropriate. 3) Utilize these skills to guide management.

COURSE DESCRIPTION

Experts in various organ systems of Emergency Radiology bring challenging cases to share with the audience and to elicit commentary provided from the panel of speakers.

Case-Based: Gastrointestinal Missed Cases: Learn From Our (and Others) Mistakes

Wednesday, Dec. 3 4:30PM - 5:30PM Room: N226

Courtney C. Moreno, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Learn strategies to avoid pitfalls in imaging of the hepatobiliary system, bowel, pancreas, and abdominal vasculature. 2) Identify ways to expand your search pattern to avoid misses.

COURSE DESCRIPTION

Case-based review of missed and challenging cases including the hepatobiliary system, bowel, pancreas, and abdominal vasculature.

Sub-Events

W8-CGI11B Hepatobiliary

Jeong Hee Yoon, MD (*Presenter*) Speaker's Bureau; Bayer. Speaker's Bureau; GE Healthcare. Consultant; Bayer. Speaker's Bureau; Siemens Healthineers. Consultant; AIRS Medical

What's Hot? PET and Theranostics for GU Radiologists

Wednesday, Dec. 3 4:30PM - 5:30PM Room: E353B

Eric M. Rohren, MD, PhD (*Moderator*) Nothing to Disclose
Tharakeswara K. Bathala, MD, MS (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Discuss the complimentary role of conventional GU imaging and molecular imaging in the management of prostate cancer. 2) Understand how the expanding field of theranostics creates opportunities in GU radiology.

COURSE DESCRIPTION

The combination of molecular imaging and therapy, termed Theranostics, is rapidly advancing in the area of prostate cancer. Alignment of these molecular techniques with other advanced imaging modalities (CT and MRI) is crucial to usher in the next phase of targeted therapy for GU malignancies. In this session, the state of imaging and therapy of prostate cancer will be discussed with illustrative case reviews.

Sub-Events

Collaborative AI Development: Multi-Stakeholder Perspectives

Wednesday, Dec. 3 4:30PM - 5:30PM Room: E450B

Walter F. Wiggins, MD, PhD (*Moderator*) Consultant; Qure.ai

LEARNING OBJECTIVES

1) Identify major healthcare AI coalitions and describe how they influence radiology practice, policy, and regulation. 2) Apply key concepts from post-deployment AI monitoring frameworks to assess the safety and effectiveness of deployed AI tools. 3) Evaluate vendor AI offerings using IHE integration profiles and published guidelines to inform purchasing and clinical implementation decisions.

COURSE DESCRIPTION

The successful deployment of radiology AI depends not only on technical accuracy, but also on strong coalitions, shared standards, and post-deployment governance. This didactic session brings together leading voices from across clinical, regulatory, technical, and vendor-facing perspectives to outline the evolving ecosystem of collaborative AI development. Learners will gain a practical understanding of major healthcare AI coalitions, key post-deployment monitoring frameworks, essential IHE profiles, and published guidelines that can guide safe, scalable, and clinically meaningful AI implementation. Attendees will leave with strategies to evaluate vendor readiness, influence enterprise decisions, and contribute to long-term quality assurance.

Mark D. Murphey, MD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Explain the current utility of Bone and Soft Tissue RADS. 2) Identify the common pitfalls in adult musculoskeletal tumor imaging and how to manage cases with radiologic-pathologic discordance. 3) Identify the keys to diagnosis in pediatric musculoskeletal tumors and their patient management implications.

COURSE DESCRIPTION

This course will review the use of bone and soft tissue RADS in the categorization of musculoskeletal masses as to the risk of aggressiveness and potential diagnosis. The management of cases with radiologic pathologic discordance and common pitfalls in adult musculoskeletal tumor imaging is also discussed. Imaging assessment of pediatric musculoskeletal tumors and their implications on patient management are also reviewed.

Clinical Implementation and Standardization of Ultra-High Field MRI for Neuro Applications: Physics, Protocols, Optimization, and Advanced Imaging

Wednesday, Dec. 3 4:30PM - 5:30PM Room: S404

Yuxiang Zhou, PHD (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Review the fundamental physical principles behind ultra-high field MR imaging and explore unique ultra-high field techniques. 2) Identify strategies to develop, optimize, and standardize clinical imaging protocols for ultra-high field MRI. 3) Understand advanced imaging techniques, neuroimaging applications in clinical practice with 5T MRI. 4) Examine emerging neuroimaging applications of 7T MRI in clinical settings.

COURSE DESCRIPTION

This course will add value to medical physics and radiology by addressing the growing use of ultra-high field MRI in clinical practice. Ultra-high field MRI (5T and above) offers significant benefits, such as improved signal-to-noise ratio, higher spatial resolution, and better spectral resolution, which enhance the detection of small anatomical details and subtle pathologies, particularly in neurological diseases like multiple sclerosis, brain tumors, and neurodegenerative conditions. Despite its potential, consistent implementation of ultra-high field MRI remains challenging due to technical standardization issues. This tutorial (4 lectures) will cover the principles of ultra-high field MRI, the latest techniques, and strategies for optimizing clinical protocols to ensure high-quality imaging. It will also explore current and future applications of ultra-high field MRI for brain disease, providing a roadmap for successful implementation in clinical and research settings.

New Horizons in Imaging in Arab Countries (Pan Arab Association of Radiological Societies Session)

Wednesday, Dec. 3 4:30PM - 5:30PM Room: E350

Lamia G. Jamjoom, MD (*Moderator*) Nothing to Disclose
Tarek A. El-Diasty, MD, FRCR (*Moderator*) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize the educational activities of the PAARS and cooperation/partnership with international radiological societies and organizations. 2) Identify the new dimensions in MSK imaging. 3) Learn how imaging can detect pancreatic intraepithelial neoplasia. 4) Understand the Egyptian experience in screening of lung cancer. 5) Get an in-depth view of MRI techniques for imaging pediatric brain tumors. 6) Acquire the essential interpretation skills for Cardiac MRI in assessment of cardiac amyloidosis.

COURSE DESCRIPTION

The course is aimed at participants from the middle east and North Africa to shed light on the radiology advances in a diversity of Arab countries. This course would provide the RSNA annual meeting attendees from these regions with an opportunity to network while in Chicago. It is organized as multimodality/multispecialty course discussing the most relevant imaging protocols used in the Arab region. The faculty consists of five known Arab experts who will ensure high-quality presentations that provide practical insights to improve image interpretation skills and diagnostic confidence of the participants.

Synergy in Real World Practice: The Power of Collaboration between Radiologists and APPS

Wednesday, Dec. 3 4:30PM - 5:30PM Room: N227B

Gloria M. Salazar, MD (*Moderator*) Consultant; Medtronic;Boston Scientific ;TRisalus ;Optimed;Penumbra ;Cook. Speaker's Bureau; Medtronic;Boston Scientific;Cook;BD; Optimed;Penumbra
Leslie Partridge, RRA, MS (*Moderator*) Other-My husband is an employee.; FUJIFILM Heathcare Americas Corporation

LEARNING OBJECTIVES

1) Identify the varying role and functions of advanced practice providers (APPs) within a radiology department. 2) Discuss APP practice as it applies to patient care and interactions before, during, and after imaging procedures. 3) Examine collaborative processes between radiologists and APPs focusing on communication, workflow, benefits, and challenges. 4) Discuss how APPs and radiologists develop confidence and trust with each other in order to benefit daily workflows, establish productive work environments, and support patient access to imaging procedures.

COURSE DESCRIPTION

This course presents the advanced practice provider (APP) role in a radiology department and the interface with radiologists in providing patient care through a day in the life format. For this course APPs in radiology include nurse practitioners (NP), physician assistants (PA), radiologist assistants (RRA/RPA). APP faculty may present how they conduct an exam from pre-procedure preparation to delivering patient focused care through post-procedure responsibilities. They will discuss their tasks within the radiologist-led team and provide insight into the power of teamwork, benefits to a radiologist's workflow, establishing confidence and how they address challenges that arise. Faculty will include an NP, PA and RA allowing the audience to discover practice and collaboration variations among the different APP disciplines. Radiologist faculty will expand upon the utilization and impacts of APPs in their daily practice. How they work with and develop trust in their APPs will be examined. In addition, the presentation will include benefits, challenges and worth from a radiologist's perspective.

Pamela Douglas (*Abstract Co-Author*)
Borek Foldyna, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the association between smoking, CT-derived plaque characteristics, and adverse cardiovascular (CV) events.

METHODS AND MATERIALS

PROMISE participants with stable chest pain, suspected coronary artery disease (CAD) and analyzable CT data were included. Core lab plaque measures included coronary artery calcium (CAC), high-risk plaque features (HRP), obstructive disease, Leaman score, total (TPV), calcified (CPV), noncalcified (NCPV), and low-density plaque volume (LDPV). Associations between ever-smoking and plaque measures were assessed using multivariable logistic and linear regression models, adjusted for age, sex, body mass index, hypertension, dyslipidemia, and a family history of premature CAD. Multivariable Cox time-to-event models and causal mediation analysis assessed associations between ever-smoking and composite endpoints (all-cause death, myocardial infarction (MI), and unstable angina hospitalization; CV death and MI) over 36 months.

RESULTS

Among 4,402 participants (mean age 61 ± 8 years; 51.6% female), 2,252 (51.2%) were ever-smokers (788 [17.9%] current) with higher ASCVD risk scores (medians 13.9 vs. 7.9%, p<0.001) than never-smokers. Ever-smoking was independently associated with CAC>0 (aOR 1.86, 95% CI: 1.61-2.16), any plaque (aOR 1.74, 95% CI: 1.52-2.00), obstructive CAD (aOR 1.50, 95% CI: 1.25-1.79), HRP (aOR 1.60, 95% CI: 1.34-1.90), and Leaman score>5 (aOR 1.72, 95% CI: 1.51-1.97). It was also associated with higher TPV (ß=54.3 mm 3 , 95% CI: 39.8-68.7), CPV (ß=25.9 mm 3 , 95% CI: 19.2-32.6), NCPV (ß=28.3 mm 3 , 95% CI: 19.0-37.7), and LDPV (ß=1.48 mm 3 , 95% CI: 0.67-2.29). Ever-smoking predicted the incident composite endpoint (aHR 1.63, 95%CI: 1.12-2.39, p=0.011) and CV mortality and MI (aHR 2.41, 95% CI: 1.32-4.41, p=0.004), after adjustment for clinical risk factors and TPV. Three separate mediation analyses revealed that 17% of the effect of ever-smoking on adverse events was mediated by TPV (indirect effect OR 1.08, p<0.001), 15% by NCPV (indirect effect OR 1.07, p<0.001), and 8% by LDTPV (indirect effect OR 1.03, p=0.003). The corresponding direct effects for these analyses were OR 1.58, p=0.018; OR 1.62, p=0.013; and OR 1.66, p=0.009, respectively.

CONCLUSION

In stable chest pain patients, ever-smoking was independently linked to distinct coronary plaque phenotypes, such as HRP and high PV, and increased CV event risk. TPV partially mediates the effect of smoking on adverse events.

CLINICAL RELEVANCE/APPLICATION

CT-derived plaque characterization may aid risk stratification in individuals with a smoking history.

M1-SSCA03-3 ONE-YEAR FUNCTIONAL AND STRUCTURAL EFFECTS OF MAVACAMTEN IN OBSTRUCTIVE HYPERTROPHIC CARDIOMYOPATHY: A COMPREHENSIVE CMR STUDY

Kenan Kaya, MD (*Presenter*)
Roman J. Gertz, MD (*Abstract Co-Author*)
Jan Paul Janssen, MD (*Abstract Co-Author*)
Carsten H. Gietzen, MD (*Abstract Co-Author*)
David C. Maintz, MD (*Abstract Co-Author*)
Lenhard Pennig, MD (*Abstract Co-Author*)

PURPOSE

Mavacamten can improve clinical and functional outcomes in obstructive hypertrophic cardiomyopathy (oHCM). However, its long-term effects on myocardial function and structure remain unclear. This study aims to evaluate the one-year remodeling effects of mavacamten using comprehensive cardiovascular magnetic resonance (CMR).

METHODS AND MATERIALS

In this prospective single-center study, consecutive oHCM patients underwent 1.5T-CMR at first referral (baseline) and one-year later. After baseline, patients remained on negative inotropic therapy (control group) or were treated additionally with mavacamten according to patient`s discretion (mavacamten group). CMR assessment comprised volumetric, functional, and strain analysis of all chambers and left ventricular (LV) tissue characterization.

RESULTS

Twenty-two patients were enrolled, of whom 15 (68.2%) received mavacamten. Compared to controls, mavacamten treatment was associated with a significant reduction in left ventricular (LV) mass index (mean change from baseline: -26.5 g/m² [95% CI -37.6 to -12.6 g/m²]; p<0.001), maximal LV wall thickness (-4.5 mm [-3.2 to -5.7 mm]; p<0.001), right ventricular (RV) wall thickness (-0.9 mm [-0.3 to -1.4 mm]; p=0.017), and left atrial volume index (-16.1 mL/m² [-6.9 to -25.3 mL/m²]; p=0.005). LV ejection fraction (-11.4% [-5.3 to -17.4%]; p<0.001) and RV ejection fraction (-9.1% [-4.5 to -13.7%]; p=0.001) decreased, while LV global circumferential strain increased towards more positive values (+7.5% [+3.8 to +11.3%]; p<0.001), indicating attenuation of the hyperdynamic state. Although mavacamten had no significant effect on late gadolinium enhancement mass, native T1 (-30.4 ms [-21.7 to -39.1 ms]; p<0.001) and indexed extracellular volume (-4.0 mL/m² [-1.7 to -6.0]; p=0.004) showed a significant reduction.

CONCLUSION

One-year mavacamten therapy resulted in favourable remodeling with normalization of hyperdynamic state and regression of measures of interstitial fibrosis, all associated with worse outcome in oHCM.

CLINICAL RELEVANCE/APPLICATION

Mavacamten treatment led to a significant reduction in myocardial hypertrophy, the hallmark morphological feature of HCM, as evidenced by decreased LV mass, LV mass index, and maximal LV wall thickness. These findings support its potential as a new first-line therapy for patients.

M1-SSCA03-4 DISCRIMINATORY AND PROGNOSTIC VALUE OF MRI-DERIVED MYOCARDIAL WORK EFFICIENCY IN HEART FAILURE WITH PRESERVED EJECTION FRACTION: BEYOND GLOBAL LONGITUDINAL STRAIN

Leyi Zhu (*Presenter*)
Minjie Minjie, PhD (*Abstract Co-Author*)

PURPOSE

Left ventricular (LV) global longitudinal strain (GLS) is an established diagnostic and prognostic marker in heart failure with preserved ejection fraction (HFpEF); however, it is sensitive to LV afterload. Pressure-volume (PV) loop analysis accounts for LV loading conditions and may provide additional insights beyond GLS into myocardial energetics and work efficiency (WE). Compared with echocardiography, MRI-derived PV loop analysis offers superior geometric accuracy and direct volumetric measurements; nevertheless, evidence supporting its clinical value in HFpEF remains limited. The purpose of this study is to determine the discriminatory and prognostic value of myocardial WE derived from cardiac MRI in patients with HFpEF.

METHODS AND MATERIALS

This retrospective study included 158 participants, comprising 124 patients with HFpEF (age 53.8±13.7 years; 77% male) and 34 sex- and age-matched healthy controls (age 56.4±7.2 years; 65% male). LV GLS was measured using the feature-tracking technique. PV loop analysis was performed by integrating LV myocardial strain with brachial systolic and diastolic blood pressure data, and WE was subsequently calculated. The primary endpoint was a composite of all-cause death and HF hospitalization.

RESULTS

In all participants, WE showed moderate correlations with LVEF (r = 0.62; P < .001) and GLS (r = -0.58; P < .001). Participants were divided into three groups: healthy controls, HFpEF patients with GLS = median, and those with GLS > median. WE demonstrated a stepwise decline across these three groups (P for trend < .001; all Bonferroni-corrected P < .001), and this trend in WE remained significant after adjustment for GLS in the analysis of covariance (P for trend < .001). In multivariable logistic regression analysis, lower WE was significantly associated with higher odds of HFpEF (adjusted odds ratio per 1% decrease, 1.33 [95% CI: 1.03, 1.82; P = .044]), even after adjusting for GLS. During a median follow-up of 5.4 years, 49 patients with HFpEF reached the primary endpoint. Multivariable Cox regression analysis revealed that lower WE (<71.15%) was an independent predictor of the primary endpoint (adjusted hazard ratio, 1.92 [95% CI: 1.03, 3.57; P = .040]) even after adjustment for age, sex, late gadolinium enhancement, and extracellular volume fraction, whereas GLS was not.

CONCLUSION

WE derived from cardiac MRI provided independent discriminatory and prognostic value in patients with HFpEF, even after adjustment for GLS.

CLINICAL RELEVANCE/APPLICATION

MRI-derived myocardial WE is impaired in patients with HFpEF, and it may serve as a promising non-invasive marker for both diagnosis and risk stratification in this condition, providing a new dimension beyond GLS.

M1-SSGU03-1 CT-BASED RADIOMICS DIFFERENTIATION OF HIGH GRADE FROM LOW GRADE CLEAR CELL RENAL CELL CARCINOMA: A META-ANALYSIS

Nima Broomand Lomer, MD (*Presenter*)
Sepideh Abdi, MD (*Abstract Co-Author*)
Drew A. Torigian, MD, MA (*Abstract Co-Author*)

PURPOSE

Low-grade clear cell renal cell carcinoma (ccRCC) (I + II), typically follows an indolent clinical course with a favorable long-term survival. In contrast, high-grade tumors (III + IV) are characterized by more aggressive behavior and a generally poor prognosis. This study aims to assess the diagnostic performance of CT-based radiomics models as a non-invasive approach for pre-operative differentiation of high-grade from low-grade ccRCC.

METHODS AND MATERIALS

This study was conducted in accordance with PRISMA guidelines. A comprehensive search was conducted across PubMed, Scopus, and Embase. Study quality was evaluated using the QUADAS-2 and METRICS tools. Pooled estimates of sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), diagnostic odds ratio (DOR), and area under the curve (AUC) were calculated. Separate comparative analyses were performed based on tumor grading system, imaging phase, and model type. Subgroup analysis and sensitivity analysis were performed to identify potential sources of heterogeneity. Publication bias was assessed using Deek's funnel plot asymmetry test.

RESULTS

A total of 49 studies, including 11,125 patients and 11,922 lesions, were incorporated into this review. Methodological quality, as assessed by the METRICS tool, ranged from 40.7% to 88.0%, reflecting moderate to excellent quality, with a mean score of 62.4% and a median of 62.9%. Of these, 27 studies were eligible for meta-analysis. The pooled diagnostic performance of radiomics models yielded a sensitivity of 0.79, specificity of 0.85, PLR of 4.6, NLR of 0.30, DOR of 19.21, and an AUC of 0.88. Subgroup analysis revealed that studies using the WHO/ISUP tumor grading system achieved significantly higher sensitivity compared to those using the Fuhrman system (0.81 vs. 0.71, $p = 0.03$) and superior AUC (0.88 vs. 0.82, $p < 0.001$). Combined models showed similar performance to radiomics-only models (AUC: 0.87 vs. 0.85, $p = 0.1$). Among imaging phases, the nephrographic phase exhibited lower diagnostic performance (AUC: 0.67) compared to the corticomedullary phase (AUC: 0.82) and non-contrast images (AUC: 0.83). No significant publication bias was detected ($p = 0.73$).

CONCLUSION

CT-based radiomics models show potential as non-invasive methods for grading ccRCC and could serve as useful complements in clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

Accurate preoperative differentiation of high- vs low-grade ccRCC is essential for guiding treatment and improving outcomes. By reliably identifying aggressive tumors pre-operatively, radiomics can aid clinicians in selecting appropriate surgical strategies, optimizing patient counseling, and potentially reducing overtreatment in indolent cases.

M1-SSGU03-3 IMPROVING MRI CHARACTERISATION OF SMALL RENAL MASSES WITH THE CLEAR CELL LIKELIHOOD SCORE

Giorgio Brembilla, MD, PhD (*Presenter*)
Michele Cosenza (*Abstract Co-Author*)
Giulio Imperiale (*Abstract Co-Author*)
Salvatore Lavalle (*Abstract Co-Author*)
Alberto Briganti (*Abstract Co-Author*)
Francesco Montorsi (*Abstract Co-Author*)
Francesco A. De Cobelli, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of the Clear Cell Likelihood Score (ccLS) on radiologists' diagnostic performance in identifying clear cell and papillary renal cell carcinomas (RCC) on MRI.

METHODS AND MATERIALS

This retrospective study included consecutive patients who underwent MRI and percutaneous renal mass biopsy at our institution from 2013 to 2023. Five radiologists, none with subspecialty training in renal imaging, reviewed the MRI scans in two separate sessions: first through subjective assessment, and later after receiving dedicated training on the ccLS system. A four-week washout period separated the two sessions. Diagnostic accuracy and interreader agreement in detecting clear cell RCC (ccRCC) and papillary RCC (pRCC) were compared before and after the ccLS training. Histopathology served as the reference standard.

RESULTS

A total of 60 renal masses (median size: 21 mm, IQR 18-26) from 60 patients were evaluated, comprising 47% ccRCC, 25% pRCC, 18% oncocytomas, 7% chromophobe RCC, and 3% fat-poor angiomyolipomas. After training, all readers showed improved sensitivity and overall accuracy for diagnosing ccRCC, with changes ranging from +4% to +61% in sensitivity and +3% to +20% in accuracy. For pRCC, sensitivity and accuracy improved in all but one reader, with changes ranging from -12% to +31% and from 0% to +14%, respectively. Interreader agreement also improved, with Conger's kappa increasing from 0.29 to 0.59 for ccRCC and from 0.36 to 0.49 for pRCC.

CONCLUSION

The application of the ccLS algorithm improved both diagnostic accuracy and interobserver agreement in the MRI-based characterisation of ccRCC and pRCC.

CLINICAL RELEVANCE/APPLICATION

Incorporating ccLS criteria into routine clinical practice may improve both the diagnostic accuracy and reproducibility of MRI assessment of small renal masses.

M1-SSGU03-4 FULLY AUTOMATED CT-BASED BODY COMPOSITION ANALYSIS: A STRONG INDEPENDENT PREDICTOR OF SURVIVAL IN METASTATIC RENAL CELL CARCINOMA

Johannes Christian Harmes, MD (*Presenter*)
Mathias Holtkamp, MD (*Abstract Co-Author*)
Luca Salhofer, MD (*Abstract Co-Author*)
Rene Hosch, MSc, BSc (*Abstract Co-Author*)
Lea Schnitzler (*Abstract Co-Author*)
Christopher Darr (*Abstract Co-Author*)
Viktor Gruenwald (*Abstract Co-Author*)
Marcel Opitz, MD (*Abstract Co-Author*)
Sebastian Zensen, MD (*Abstract Co-Author*)
Denise Bos, MD (*Abstract Co-Author*)
Michael Forsting, MD (*Abstract Co-Author*)
Felix Nensa, MD (*Abstract Co-Author*)
Lale Umutlu, MD (*Abstract Co-Author*)
Johannes Haubold, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to determine the independent prognostic value of fully automated CT-based body composition biomarkers in patients with metastatic renal cell carcinoma (mRCC).

METHODS AND MATERIALS

In this retrospective single-center study, 77 patients with mRCC (57 men, 20 women; mean age 60.4 ± 12.9 years) who underwent baseline contrast-enhanced abdominal CT before systemic therapy were included. Using a nnU-Net-based pipeline (BOA framework), two body composition biomarkers were automatically extracted: the Sarcopenia Index (SI; muscle-to-bone volume ratio) and the Myosteatotic Fat Index (MFI; intra-/intermuscular fat relative to total fat). Prognostic relevance for OS was assessed using univariable and multivariable Cox regression and Kaplan-Meier analysis. Clinical covariates included age, sex, leukocyte count, calcium, LDH, CRP, hemoglobin, platelet count, prior nephrectomy, and the number of metastatic sites. Laboratory variables were selected based on established prognostic models such as the IMDC score.

RESULTS

Forty deaths occurred during follow-up. In multivariable Cox regression, both SI (p=0.020) and MFI (p=0.001) were independently associated with OS. Kaplan-Meier analysis demonstrated significantly higher 5-year OS in patients with high SI and low MFI (67.9%) compared to those with low SI and high MFI (13.7%; log-rank p=0.027). Among the clinical parameters, leukocyte count (p = 0.009), prior nephrectomy (p = 0.033), and the presence of =2 metastatic sites (p = 0.038) were also independent predictors of overall survival.

CONCLUSION

CT-based body composition biomarkers derived from a fully automated deep learning framework are independent predictors of OS in metastatic RCC and enable robust patient stratification.

CLINICAL RELEVANCE/APPLICATION

The automated extraction of sarcopenia and myosteatosis parameters from routine CT scans enables individualized risk stratification in metastatic RCC without added workload or radiation exposure, supporting personalized therapeutic decision-making.

M1-SSGU03-6 TOWARD BIOPSY-FREE DIAGNOSIS: MULTIPARAMETRIC MRI RADIOMICS ACCURATELY CLASSIFIES RENAL NEOPLASMS

Ali Sheikhy, MD (*Presenter*)
Nathan S. Lay, PhD (*Abstract Co-Author*)
Negin Jarrah, MD (*Abstract Co-Author*)
Ashkan A. Malayeri, MD (*Abstract Co-Author*)

PURPOSE

Renal cell tumors constitute a complex spectrum of kidney neoplasms characterized by diverse genetic backgrounds, histopathological distinctions, and clinical implications. Notable subtypes include clear cell RCC (ccRCC), oncocytoma, chromophobe RCC, papillary RCC, angiomyolipoma, hereditary leiomyomatosis-RCC, and Birt-Hogg-Dubé-related hybrid tumors. Precise phenotypic delineation on MRI is pivotal for individualized therapy, yet most radiomic classifiers have focused on CT. We therefore evaluated a radiomics-based model to noninvasively distinguish these seven renal lesion subtypes on eight MRI sequences.

METHODS AND MATERIALS

With IRB approval, eight-sequence MRI (pre-, arterial-, nephrogenic-, delayed-phase T1; T2; low- and high-b DWI; ADC) from 880 surgically confirmed lesions was retrospectively collected. Seven post-doctoral fellows manually segmented each lesion, all masks were audited by an 11-year body radiologist. PyRadiomics extracted 1400 first-order, texture and filter-based features per ROI. Lesions were split lesion-wise into training (70 %), validation (15 %), and test (15 %) cohorts. An XGBoost classifier was tuned with successive-halving random search and 5-fold cross-validation to maximize balanced accuracy, then retrained on the combined training + validation data and evaluated on the locked test set. Gain importance and SHAP values quantified feature influence.

RESULTS

On the test cohort the model achieved 78 % overall accuracy, macro-averaged ROC-AUC 0.90, and balanced accuracy 0.74. F1-scores were 0.86 for ccRCC, 0.80 papillary, 0.67 hybrid, 0.40 HLRCC, 0.33 AML, 0.29 oncocytoma, and 0.25 chromophobe; ccRCC and papillary were correctly identified in 96 % and 74 % of cases, respectively. Exponential-filtered GLCM JointAverage from ADC, run-length non-uniformity from nephrogenic-phase T1, and the ADC 90th-percentile were the most influential discriminators, as confirmed by SHAP.

CONCLUSION

Our multiparametric-MRI radiomics model, powered by XGBoost, achieved 78 % accuracy (macro-AUC 0.90) in differentiating seven renal tumor subtypes, reliably classifying ccRCC and papillary RCC while offering useful discrimination for rarer lesions. Texture- and diffusion-based features were the key drivers, and SHAP analysis confirmed their biologic plausibility. This work highlights MRI radiomics as a promising, noninvasive tool for precision characterization of renal masses and paves the way for prospective, multi-center validation.

CLINICAL RELEVANCE/APPLICATION

A reliable MRI-based radiomics classifier can noninvasively distinguish benign from malignant renal tumor subtypes, informing personalized management and potentially reducing unnecessary biopsies or surgery.

M1-SSNMMI02-1 DIAGNOSTIC ACCURACY OF 68GA-PENTIXAFOR PET/CT, A NEW TEST FOR PRIMARY ALDOSTERONISM TARGETING THE CXCR4 RECEPTOR: A BIVARIATE DIAGNOSTIC META-ANALYSIS OF SENSITIVITY, SPECIFICITY, AND AUC

Victor Arthur Ohannesian (*Presenter*)
Karina De Lima Andrade (*Abstract Co-Author*)
Ricardo Suruagy-Motta (*Abstract Co-Author*)
Luiz Nascimento (*Abstract Co-Author*)
Bruno Ishizuka (*Abstract Co-Author*)
Mariana Lee Han (*Abstract Co-Author*)
Miguel J. Francisco Neto, MD, PhD (*Abstract Co-Author*)
Solange A. Nogueira, MD (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic performance of 68Ga-Pentixafor PET/CT, a CXCR4-targeted imaging tool, in identifying aldosterone-producing adenomas (APAs) in primary aldosteronism (PA). This study aimed to estimate pooled sensitivity, specificity, diagnostic odds ratio (DOR), and area under the curve (AUC). Given the technical challenges and limited availability of adrenal venous sampling (AVS), the goal was to determine whether PET/CT could serve as a non-invasive alternative for lesion lateralization and subtype classification in PA.

METHODS AND MATERIALS

A bivariate diagnostic meta-analysis was conducted per PRISMA-DTA and registered in PROSPERO. PubMed, Embase, Scopus, CENTRAL, and Web of Science were searched through January 2025. Studies included adults with confirmed PA who underwent 68Ga-Pentixafor PET/CT, using AVS, histology, or immunohistochemistry as reference. Sensitivity, specificity, DOR, and AUC were extracted. Methodological quality was assessed using QUADAS-2, and GRADE was used to rate evidence certainty. Reitsma's bivariate random-effects model (Stata 12.0) was used for analysis. Heterogeneity was tested by ?² and I²; publication bias by Deeks' funnel plot.

RESULTS

Eight studies with 564 patients were included, all from China. The median sample size was 58.5; mean age, 49 years. Bilateral adrenal masses were present in 103 cases. Median lesion size was 10 mm. Pooled sensitivity and specificity were 83% (95% CI: 75-89) and 94% (95% CI: 83-98), respectively. DOR was 27 (95% CI: 12-60), and AUC was 0.91 (95% CI: 0.88-0.93). Significant heterogeneity was found ($I^2 > 50\%$, $p < 0.001$). CXCR4 and CYP11B2 expression confirmed tracer uptake correlation. Inter-rater agreement was excellent (? = 0.93).

CONCLUSION

68Ga-Pentixafor PET/CT shows high accuracy in detecting APAs, with strong specificity (94%) and AUC (0.91). Despite heterogeneity and the geographic concentration of studies, findings support its use as a non-invasive alternative to AVS. The biological correlation with CXCR4 and CYP11B2 strengthens diagnostic confidence. Broader validation through multicenter studies with standardized imaging and histological confirmation is needed.

CLINICAL RELEVANCE/APPLICATION

68Ga-Pentixafor PET/CT is a fast, non-invasive method for PA lesion localization, especially when AVS is unavailable or contraindicated. Its high diagnostic accuracy supports surgical planning and patient stratification. Integration with biochemical and histological data may enhance diagnostic certainty and reduce reliance on invasive procedures, advancing personalized care in PA.

M1-SSNMMI02-4 A NOVEL IMAGING APPROACH IN PRIMARY HYPERPARATHYROIDISM: ^{68}GA-TRIVEHEXIN PET/CT

Dilara Denizmen Zorba, MD (*Presenter*)
Serkan Kuyumcu, MD (*Abstract Co-Author*)
Duygu Simsek, MD (*Abstract Co-Author*)
Emine Goknur Isik (*Abstract Co-Author*)
Arzu Poyanli, MD (*Abstract Co-Author*)
Ayse Kubat Uzum (*Abstract Co-Author*)
Fikret Buyukkaya (*Abstract Co-Author*)
Semen Onder, MD (*Abstract Co-Author*)
Nihat Aksakal (*Abstract Co-Author*)
Ahmet Yalin Iscan (*Abstract Co-Author*)
Zeynep Gozde Ozkan (*Abstract Co-Author*)
Yasemin Sanli, MD (*Abstract Co-Author*)

PURPOSE

Accurate preoperative localization of hyperfunctioning parathyroid tissue is essential for curative surgery in primary hyperparathyroidism (PHPT). 68 Ga-Trivehexin is a novel PET tracer targeting integrin aVß6, which has shown promising results in various malignancies. Its uptake in parathyroid adenomas has been incidentally observed. This study aimes to evaluate the diagnostic utility of 68 Ga-Trivehexin PET/CT (TRV-PET) in PHPT patients, in comparison with 99m Tc-MIBI SPECT/CT (MIBI).

METHODS AND MATERIALS

38 patients with biochemically confirmed PHPT (31 sporadic, 7 MEN-1) were included. All underwent serum calcium, phosphorus, and PTH assessment, along with cervical ultrasonography, MIBI, and TRV-PET. Additional imaging included 4D-CT (n=16) and 18 F-Choline PET/CT (n=8). Two nuclear medicine physicians independently evaluated imaging studies visually and semi-quantitatively. Final diagnoses were based on pathology, PTH wash-out (WO), or concordant imaging findings.

RESULTS

50 parathyroid lesions were evaluated. Of these, 18 were confirmed pathologically, 4 through WO, and others through correlated imaging findings. In 2 patients parathyroid lesion could not be localized by any imaging modality. In patient-based analysis TRV-PET detected lesions of 35/38 (92%) patients while MIBI was positive in 28/38 patients (74%) ($p<0.05$). In lesion-based analysis TRV-PET identified 49/50 lesions (98%), while MIBI only detected 29/50 lesions (58%) ($p<0.01$). TRV-PET showed clear uptake in 18 lesions with equivocal MIBI findings and revealed 2 lesions missed by both MIBI and 18 F-Choline PET/CT. Only one lesion identified by MIBI was negative on TRV-PET. TRV-PET successfully localized the residual lesions in all 7 patients with persistent disease after surgery.

CONCLUSION

TRV-PET offers high sensitivity for detecting hyperfunctioning parathyroid tissue and can potentially serve as an effective alternative when conventional imaging is inconclusive. Its diagnostic performance suggests clinical utility in both initial evaluation and patients with persistant hyperparathyrodism after surgery.

CLINICAL RELEVANCE/APPLICATION

68 Ga-Trivehexin PET/CT improves lesion detection in PHPT, particularly in familial cases, supporting its role in guiding effective surgical management.

M1-SSNMMI02-5 ADVANCING DETECTION: MOLECULAR PET IMAGING IN MRI-OCCULT SMALL FUNCTIONAL PITUITARY ADENOMAS

Yu Cai, MD, PhD (*Presenter*)
Manish Ora (*Abstract Co-Author*)
Neetu Soni, MD, FRCR (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic performance of positron emission tomography (PET) imaging using various tracers such as Fluorine-18 fluorodeoxyglucose (18F-FDG), Carbon-11 methionine (11C-MET), Fluorine-18 fluoroethyl-L-tyrosine (18F-FET), Gallium-68 DOTATATE (68Ga-DOTATATE), Gallium-68 Pentixafor, and Fluorine-18 fallypride (18F-fallypride) in localizing MRI-occult functional pituitary adenomas (PAs), and their impact on clinical management.

METHODS AND MATERIALS

A systematic literature review followed PRISMA guidelines, focusing on studies of patients with biochemically confirmed Cushing disease (CD), acromegaly, hyperprolactinemia and negative/equivocal conventional MRI. Data on PET-CT/MRI outcomes were analyzed.

RESULTS

Recent studies highlight the effectiveness of various PET radiotracers for detecting PAs, due to their high uptake in the pituitary gland and low background activity. These include tracers targeting glucose transport (18F-FDG); amino acid transport (11C-MET, 18F-FET); somatostatin receptor binding (68Ga-DOTATATE); CXCR4 (68Ga-pentixafor); Dopamine receptor binding (18F-fallypride). Tracers like 18F-FDG and 68Ga-DOTATATE exhibited variable physiologic pituitary uptake, reducing lesion conspicuity. 18F-FET PET/MRI localized tumors with 100% sensitivity and specificity, while 11C-MET PET/MRI achieved 89% sensitivity and specificity, based on intraoperative and histopathological confirmation. 68Ga-pentixafor PET/MRI showed higher sensitivity (92.7%) and diagnostic accuracy (88.6%) than contrast-enhanced MRI (78.0% and 77.3%). Combining both modalities improved sensitivity to 100% and accuracy to 95.5% ($P = .01$). SUVmax correlated positively with CXCR4 H-score ($R = 0.5$, $P < .001$) and ACTH levels.

CONCLUSION

Molecular PET improves detection and localization of small functional PAs, especially when conventional MRI is inconclusive. Various radiotracers offer high diagnostic accuracy and lesion conspicuity. Integrating PET into clinical workflows may enhance diagnostic confidence, guide surgical planning, and improve management of hormonally active, MRI-negative PAs.

CLINICAL RELEVANCE/APPLICATION

Molecular PET offers a valuable diagnostic tool for patients with small functional PAs when conventional MRI is inconclusive. By improving lesion detection and localization, particularly in hormonally active but MRI-negative cases, PET/MRI can enhance surgical planning, guide targeted therapy, and potentially improve patient outcomes.

M1-SSNMMI02-6 ACCURACY OF 99MTC-UBI(29-41) IN THE DETECTION OF MUSCULOSKELETAL AND IMPLANT-RELATED INFECTIONS: A SYSTEMATIC REVIEW AND DIAGNOSTIC META-ANALYSIS

Victor Arthur Ohannesian (*Presenter*)
Bruno Ishizuka (*Abstract Co-Author*)
Isabelle Menezes (*Abstract Co-Author*)
Luciano Falcao (*Abstract Co-Author*)
Luiz Nascimento (*Abstract Co-Author*)
Ricardo Suruagy-Motta (*Abstract Co-Author*)
Miriana E. Mariussi, MD (*Abstract Co-Author*)
Miguel J. Neto (*Abstract Co-Author*)
Akemi Osawa, MD (*Abstract Co-Author*)
Solange A. Nogueira, MD (*Abstract Co-Author*)

PURPOSE

Musculoskeletal and periprosthetic infections often resemble sterile inflammation, complicating diagnosis. The radiotracer 99mTc-UBI(29-41), an antimicrobial peptide with affinity for bacterial membranes, may differentiate active infection from non-infectious processes. This study systematically reviewed and meta-analyzed its diagnostic performance in such infections. We aimed to estimate pooled sensitivity, specificity, diagnostic odds ratio (DOR), likelihood ratios, and area under the ROC curve (AUC), assessing its validity compared to microbiological, clinical, and histopathological standards.

METHODS AND MATERIALS

A PRISMA-DTA-compliant review was registered on PROSPERO. PubMed, Embase, Scopus, Web of Science, and CENTRAL were searched (through Nov/2024). Included studies evaluated 99mTc-UBI(29-41) in musculoskeletal/periprosthetic infections with extractable sensitivity and specificity. QUADAS-2 assessed bias. Pooled estimates were calculated using a bivariate model (Reitsma) in Stata 14.2. Heterogeneity was assessed using t^2, I^2, and Q test. Deeks' test assessed publication bias.

RESULTS

Eleven studies (n = 704) were included. Pooled sensitivity was 96.5% (95% CI: 88.4-98.9%), specificity 88.9% (95% CI: 73.3-95.9%), and DOR 87.8 (95% CI: 26.0-295.9), with AUC of 0.946. Negative predictive value reached 95%. Specificity heterogeneity ($I^2 = 82.0\%$) was linked to protocol and reference standard variation. Deeks' test indicated publication bias ($p = 0.02$).

CONCLUSION

99mTc-UBI(29-41) demonstrates high accuracy in detecting bacterial infection in complex musculoskeletal contexts. Its bacterial selectivity offers diagnostic advantage over conventional tracers. Methodological heterogeneity and bias warrant further validation. The tracer is particularly useful when standard tests are inconclusive.

CLINICAL RELEVANCE/APPLICATION

This radiotracer supports non-invasive diagnosis of infection in orthopedic and implant-related cases. It enables early, targeted imaging and can inform clinical decisions, reduce unnecessary procedures, and optimize antibiotic use. Broader adoption requires standardization and cost-effectiveness studies.

M1-SSPD02-3 NON-INVASIVE EVALUATION OF REMOTE ISCHEMIC CONDITIONING ON INTESTINAL PERFUSION IN MICE PUPS USING ULTRASOUND COLOR DOPPLER AND DYNAMIC TISSUE PERFUSION MEASUREMENT

Ricardo Faingold, MD (*Presenter*)
Stella Sabbatini (*Abstract Co-Author*)
Niloofar Ganji (*Abstract Co-Author*)
Agostino Pierro (*Abstract Co-Author*)

PURPOSE

Remote ischemic conditioning (RIC) has been shown to increase bowel perfusion in microvascular vessels in healthy mice using advanced imaging techniques such as two-photon electron microscopy. However, the effects of RIC on splanchnic vessels, particularly in neonatal mice, remain underexplored. Reproducible, non-invasive methods to evaluate these changes are needed to better understand the hemodynamic response to RIC. This study aimed to assess the effects of RIC on intestinal perfusion in 3 day-old mice pups using a non-invasive approach: ultrasound color Doppler combined with Dynamic Tissue Perfusion Measurement (pixel flux software). Previous studies demonstrated no change in SMA blood flow velocity. We hypothesized that RIC would increase perfusion in peripheral mesenteric and mural intestinal vessels, detectable by ultrasound.

METHODS AND MATERIALS

P3 mice pups, fasted for 6 hours, were scanned before and after RIC. Remote ischemic conditioning (RIC) is performed by applying a tourniquet to the hind limb of pups, consisting of four cycles of 5-minute ischemia followed by 5-minute reperfusion. The splanchnic perfusion was evaluated using ultrasound color Doppler (Vevo 3100 imaging system, Fujifilm VisualSonics transducer MX700, 29-71 MHz). Dynamic Tissue Perfusion Measurement (pixel flux software) was used to quantify Doppler color intensity in the peripheral mesenteric and mural intestinal vessels, focusing on the most peripheral vessels (1 mm closest to the abdominal wall). A paired t-test was performed to compare pre- and post-RIC perfusion changes.

RESULTS

Dynamic Tissue Perfusion Measurement revealed a significant increase in perfusion in the peripheral mesenteric and mural intestinal vessels post-RIC ($p = 0.009$).

CONCLUSION

Ultrasound color Doppler, combined with Dynamic Tissue Perfusion Measurement, is a feasible and non-invasive method to evaluate the effects of RIC on intestinal perfusion in P3 mice pups. This technique demonstrates that RIC significantly increases perfusion in peripheral mesenteric and mural intestinal vessels, providing new insights into the microvascular response to RIC in neonates.

CLINICAL RELEVANCE/APPLICATION

Remote ischemic conditioning (RIC) is emerging as a promising therapeutic strategy for pediatric vascular disorders affecting the bowel. Our findings demonstrate that Doppler ultrasound serves as a non-invasive and effective modality for assessing treatment.

M1-SSPD02-4 TWO-DIMENSIONAL ELASTOGRAPHY AND DISPERSION SLOPE FOR DETECTION OF ALLOGRAFT DAMAGE AFTER PEDIATRIC LIVER TRANSPLANTATION

Jeong Min Song, MD (*Presenter*)
Pyeong Hwa Kim (*Abstract Co-Author*)
Hee Mang Yoon, MD, PhD (*Abstract Co-Author*)
Ah Young Jung, MD (*Abstract Co-Author*)
Jin Seong Lee, MD (*Abstract Co-Author*)
Kyung Mo Kim (*Abstract Co-Author*)
Young Ah Cho, MD,PhD (*Abstract Co-Author*)

PURPOSE

This study evaluates the diagnostic efficacy of two-dimensional shear wave elastography (2D SWE) for detecting liver allograft damage in pediatric liver transplant (LT) recipients with left lobe or left lateral segment grafts, with comparison of the diagnostic accuracy of intercostal and subcostal approaches.

METHODS AND MATERIALS

We retrospectively analyzed LT recipients who received left lobe or left lateral segment as a graft during their childhood and who underwent paired 2D SWE and liver biopsy at a single institution between February 2020 and April 2024. Liver elasticity and dispersion slope were obtained via intercostal or subcostal approaches immediately prior to liver biopsy by one of two board-certified pediatric radiologists. Linear regression analysis assessed associations between elastographic parameters and histopathological findings, including METAVIR fibrosis grade and liver allograft fibrosis (LAF) score. Diagnostic performance was evaluated using receiver operating characteristic (ROC) curve analysis. Additionally, subgroup analysis was performed according to ultrasound approach.

RESULTS

A total of 108 patients (median age, 13.4 years; 47 males) were analyzed. Elasticity measured via the intercostal approach demonstrated significant association with both METAVIR fibrosis grade (coefficient, 1.65; p=0.001) and LAF score (coefficient, 0.51; p=0.02), whereas subcostal measurements showed no significant association with any pathologic parameters. Intercostal measurements showed excellent diagnostic performance in detecting severe fibrosis (F0-F2 vs. F3-F4: AUC 0.95; p<0.001) and moderate performance for earlier fibrosis stages (F0-F1 vs. F2-F4: AUC 0.70; p=0.005; F0 vs. F1-F4: AUC 0.70; p=0.003). Dispersion slope, regardless of approach, showed no significant association with any pathological parameter.

CONCLUSION

Liver elasticity measured using 2D SWE via the intercostal approach demonstrated diagnostic value in predicting graft fibrosis in pediatric LT recipients. Neither subcostal elasticity measurements nor dispersion slope values showed diagnostic utility.

CLINICAL RELEVANCE/APPLICATION

2D SWE via the intercostal approach provides a non-invasive, reliable method for early detection of graft fibrosis in pediatric LT recipients, potentially reducing the need for invasive biopsies and facilitating timely clinical intervention. Regarding scan approach, the intercostal approach should be prioritized over the subcostal approach whenever anatomically feasible.

M1-SSPD02-5 PEDIATRIC PANCREAS SEGMENTATION FROM MRI SCANS WITH DEEP LEARNING

Elif Keles, MD, PhD (*Presenter*)
Merve Yazol (*Abstract Co-Author*)
Gorkem Durak, MD (*Abstract Co-Author*)
Ziliang Hong (*Abstract Co-Author*)
Halil Ertugrul Aktas (*Abstract Co-Author*)
Zheyuan Zhang, PhD (*Abstract Co-Author*)
Linkai Peng, BEng (*Abstract Co-Author*)
Cemal Yazici (*Abstract Co-Author*)
Ulas Bagci, MSc, PhD (*Abstract Co-Author*)

PURPOSE

MRI is crucial for diagnosing pancreatitis in children, yet reliable MRI-based pediatric pancreas segmentation algorithms are lacking, impacting diagnostic accuracy and efficiency. While deep learning (DL) is promising, most studies focus on CT, which is less ideal for children. Our study aimed to validate PanSegNet, a DL algorithm for pediatric pancreas segmentation on MRI in children with acute pancreatitis (AP), chronic pancreatitis (CP), and healthy controls.

METHODS AND MATERIALS

In this IRB approved study. we retrospectively analyzed 84 T2-weighted abdominal MRI scans (1.5T/3T Siemens Aera/Verio) acquired between 2015 and 2024 from children aged 2-19 years. The dataset comprised 42 patients diagnosed with AP or CP based on clinical criteria and 42 healthy controls with hypoechoic liver lesions detected on ultrasonography. Manual pancreas segmentations were performed by a pediatric and a general radiologist, with final verification by a senior pediatric radiologist. PanSegNet segmentations were quantitatively evaluated using Dice Similarity Coefficient (DSC), 95th percentile Hausdorff Distance (HD95), and volumetric correlation with ground truth. Inter- and intra-observer agreement was assessed using Cohen’s kappa.

RESULTS

Pancreas MRI T2W scans were obtained from 42 children with AP/CP (mean age: 11.73 ± 3.9 years) and 42 healthy children (mean age: 11.19 ± 4.88 years).PanSegNet achieved DSC scores of 88% (controls), 81% (AP), and 80% (CP), with HD95 values of 3.98 mm (controls), 9.85 mm (AP), and 15.67 mm (CP). Inter-observer kappa was 0.86 (controls) and 0.82 (pancreatitis), and intra-observer agreement reached 0.88 and 0.81. Strong correlations were found between automated and manual volumes (R^2 = 0.85 controls, 0.77 diseased).

CONCLUSION

This is the first study to evaluate PanSegNet , a novel DL algorithm for pediatric pancreas segmentation from MRI. PanSegNet demonstrated robust, accurate performance across both healthy and diseased cohorts. Our software and source code are available at: https://github.com/NUBagciLab/PaNSegNet, annotated dataset can be accessed at https://osf.io/km6yz (PedPanSegData).

CLINICAL RELEVANCE/APPLICATION

PanSegNet was shown to effectively segment the pancreas in children's MRI scans with high accuracy. This open-source tool and its annotated dataset fill a significant gap and enhance clinical outcomes by improving diagnostic precision for pancreatic diseases in children. By providing our validated algorithm, user-friendly software, and well-curated pediatric MRI datasets, we aim to promote transparency and reproducibility and stimulate further advancements in pediatric pancreatic care.

M1-SSPD02-6 DEVELOPMENT OF A SIMPLIFIED PREDICTION MODEL FOR DIAGNOSING PROGRESSIVE CENTRAL PRECOCIOUS PUBERTY USING CLINICAL AND PELVIC ULTRASOUND PARAMETERS

Seungyeon Cha (*Presenter*)
Hyun Joo Shin, MD, PhD (*Abstract Co-Author*)
Hye Sun Lee (*Abstract Co-Author*)

PURPOSE

This study aimed to explore the predictive value of clinical and pelvic ultrasound parameters for diagnosing central precocious puberty (CPP) and to establish a clinically useful simplified prediction model to differentiate progressive CPP (P-CP) from nonprogressive precocious puberty (N-PP).

METHODS AND MATERIALS

Girls aged <9 years with secondary sexual development who underwent a gonadotropin-releasing hormone stimulation test and pelvic ultrasound between September 2020 and November 2023 were retrospectively included and divided into the P-CP and N-PP groups. Logistic regression analysis was used to determine the significant parameters and develop prediction models. The diagnostic performance of the models was compared using the area under the receiver operating characteristic curve (AUC) analysis and the Delong method. The continuous net reclassification improvement (cNRI) and absolute integrated discrimination improvement (IDI) were used to determine the additive effects of ultrasound parameters. A nomogram scoring system was constructed based on a simplified model to predict the probability of developing P-CP.

RESULTS

A total of 109 girls were included, with 64 (58.7%) in the P-CP group. Age, bone age, height, height minus midparental height, basal luteinizing hormone (LH), follicle-stimulating hormone, estradiol, insulin-like growth factor-I, Tanner stage, and cervical and fundus width were significant parameters for the diagnosis of P-CP. The models with ultrasound parameters yielded significantly higher cNRI and IDI values than the models without ultrasound parameters. The simplified model was composed of basal LH, estradiol, and fundus width that showed an AUC value of 0.93 (95% confidence interval: 0.88-0.98) with a cutoff value of 16.

CONCLUSION

In conclusion, adding pelvic ultrasound parameters to traditional clinical results has an additive effect on P-CP screening. A simplified predictive model is effective for CPP screening in real-world clinics. These findings highlight the potential of the prediction model to overcome the limitations of the classical diagnostic approach for CPP

in children.

CLINICAL RELEVANCE/APPLICATION

Our study demonstrated that adding pelvic US parameters to traditional clinical results has an additive effect on P-CP screening. A simplified predictive model comprised of basal LH, estradiol, and fundus width is effective for CPP screening in real-world clinics. These findings highlight the potential of the prediction model, including US parameters, to overcome the limitations of the classical diagnostic approach for CPP in children.

PURPOSE

The goal of this study was to evaluate the performance and clinical impact of two AI-based tools for the opportunistic detection of incidental pulmonary embolism (iPE) and vertebral compression fractures (VCF) on routine CT scans in cancer patients, and to assess their potential to enhance early diagnosis and improve patient management.

METHODS AND MATERIALS

Two retrospective, consecutive analyses were conducted at Gustave Roussy Cancer Center (France) to evaluate CINA-iPE and CINA-VCF Quantix (Avicenna.AI, France), two FDA-cleared and CE-certified AI applications. CINA-iPE was assessed on a cohort of 3,047 oncology patients undergoing follow-up contrast-enhanced CT for iPE detection. Additionally, time from scan to iPE diagnosis was recorded. CINA-VCF was evaluated on a cohort of 1,501 stage IV cancer patients, with the algorithm identifying and quantifying VCFs based on vertebral height loss. AI results were compared to initial radiology reports, with discordant cases reviewed by a radiology resident and senior radiologist. Moreover, severe (grade 3) VCFs were independently reviewed by interventional radiologists to assess eligibility for cementoplasty.

RESULTS

For iPE detection, the AI system generated 104 alerts; 36 were confirmed, yielding a sensitivity of 97.3% and specificity of 97.7%. The majority of false positives were attributed to motion artifacts and lymph nodes. The average time from scan acquisition to diagnosis was 8.13 hours. Seven patients experienced delayed diagnosis, requiring emergency department readmission for treatment. For VCF detection, the AI identified 501 suspected cases, with 436 confirmed (PPV: 87%). Notably, 81% of these confirmed fractures had not been mentioned in the original radiology reports. Among the unreported cases, 10 were classified as severe (grade 3), of which 9 were deemed suitable for cementoplasty.

CONCLUSION

AI-based tools demonstrated high performance in the opportunistic detection of iPE and VCFs on routine CT scans, identifying clinically relevant findings often missed in standard radiological assessments. These tools demonstrate potential to support earlier and more effective interventions in oncology care.

CLINICAL RELEVANCE/APPLICATION

In oncology patients, where early intervention can alter outcomes, AI-driven tools for opportunistic screening may reduce diagnostic delays, streamline workflow, and guide timely therapeutic decision-making.

M2-STCE1-2 EFFECTIVE OPPORTUNISTIC DETECTION OF VISCERAL ARTERIAL ANEURYSMS USING NON-CONTRAST ABDOMINAL CT IMAGING

Yuan Gao, MSc, PhD (*Presenter*)
Yujian Hu (*Abstract Co-Author*)
Jianfeng Zhang (*Abstract Co-Author*)
Zirui Wang (*Abstract Co-Author*)
Yan-Jie Zhou (*Abstract Co-Author*)
Yilang Xiang (*Abstract Co-Author*)
Hongkun Zhang (*Abstract Co-Author*)
Minfeng Xu (*Abstract Co-Author*)

PURPOSE

We developed a model for the detection of visceral arterial aneurysms (VAAs) on non-contrast abdominal CT (NCT) images, which could potentially be used for opportunistic VAAs screening.

METHODS AND MATERIALS

We collected paired abdominal CTA and NCT images from 1388 patients along with their diagnostic reports. Preprocessing involved using a spine landmarks detection model to standardize the field of view (FOV) from T09 to L05 and resample to a uniform resolution. A robust image registration algorithm aligned the NCT images with the CTA images.Two experienced radiologists with over 10 years of experience manually annotated the vessels in the CTA images. Based on the diagnostic reports, they also annotated any aneurysms present in these vessels. To avoid ambiguous annotations, we utilized Curve Planar Reformation (CPR) to straighten small vessels.

Measurements were taken from the proximal to distal ends of the vessels on CPR images. If a segment showed a diameter increase of 1.5 times the baseline, it was labeled as an aneurysm. This process resulted in 791 positive cases (with aneurysms) and 597 negative cases. Each case's mask included 5 labels: aorta, celiac trunk (hepatic and splenic arteries), superior mesenteric artery, right renal artery, and left renal artery. Positive cases also included a sixth label for visceral arterial aneurysms.A multi-class segmentation model was trained to learn the CTA annotations on the registered NCT images. The model was trained on 1110 cases and evaluated on the remaining 278 cases. During evaluation, if the segmentation result did not include the aneurysm class mask, the case was classified as negative. If the aneurysm class mask was present, the average probability within each connected component was compared to a threshold. If at least one component's average probability exceeded the threshold, the case was classified as positive; otherwise, it was classified as negative.

RESULTS

At the patient level, the model achieved an AUC of 0.952 for the classification of VAA-positive versus VAA-negative cases. At the selected operating point, the sensitivity was 0.924, and the specificity was 0.911, with an average of 0.107 false positives per case. At the lesion level, the recall for VAAs was 0.869, and the precision was 0.845.

CONCLUSION

The proposed model effectively detects visceral arterial aneurysms on non-contrast abdominal CT images, achieving high sensitivity while maintaining a high specificity.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the feasibility of using non-contrast abdominal CT scans for opportunistic screening of visceral arterial aneurysms. This method could facilitate the early detection of VAAs, potentially reducing morbidity and mortality associated with these conditions.

M2-STCE1-3 AI-BASED QUANTIFICATION OF BREAST ARTERIAL CALCIFICATION ON MAMMOGRAPHY ADDS INCREMENTAL PROGNOSTIC VALUE TO PREVENT SCORES FOR CARDIOVASCULAR RISK STRATIFICATION

Imon Banerjee, PhD (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)

PURPOSE

Cardiovascular disease (CVD) is the leading cause of death in women, who are often underdiagnosed and undertreated. Screening mammography offers an opportunity to identify asymptomatic women at high CVD risk via breast arterial calcification (BAC). Existing risk calculators may inadequately stratify diverse female populations. We aimed to determine if an automated AI algorithm quantifying BAC adds prognostic value for major adverse cardiovascular events (MACE) and mortality beyond the PREVENT score in a large, diverse, multi-institutional cohort.

METHODS AND MATERIALS

In this retrospective cohort study, we included 123,762 women who underwent screening mammography at two large healthcare systems (internal and external datasets). A hierarchical transformer-based neural network was used for automated semantic segmentation and quantification of BAC area (in mm^2). BAC burden was categorized as zero (0 mm^2), mild (>0-10 mm^2), moderate (>10-25 mm^2), or severe (>25 mm^2). The association between BAC severity and incident MACE was assessed using Kaplan-Meier analysis and Cox proportional hazards models, adjusted for the PREVENT 10-year risk score for total CVD.

RESULTS

Over a 7-year median follow-up, BAC was detected in 16.1% of women. Adding BAC to PREVENT scores improved MACE discrimination ($p<0.01$). Within PREVENT risk strata, Kaplan-Meier analysis showed moderate to severe BAC was associated with significantly lower MACE-free survival. After adjusting for PREVENT, compared to zero BAC, mild (internal HR: 1.32, 1.10-1.59; external HR: 1.28, 1.17-1.39), moderate (internal HR: 1.75, 1.23-2.50; external HR: 1.79, 1.55-2.06), and severe BAC (internal HR: 3.29, 2.15-5.05; external HR: 2.80, 2.36-3.32), were all prognostic for any MACE (all $p<0.005$).

CONCLUSION

Fully automated, AI-driven quantification of BAC is a robust, independent predictor of MACE and all-cause mortality. The incremental prognostic information it provides beyond the new PREVENT risk score demonstrates its distinct value in refining cardiovascular risk assessment in women.

CLINICAL RELEVANCE/APPLICATION

This AI-powered approach transforms a routine breast cancer screening into a dual-purpose, opportunistic test for cardiovascular health without requiring additional time, cost, or radiation exposure. By automatically identifying at-risk women who may be missed by standard risk calculators, this tool can trigger earlier preventive interventions, such as lipid-lowering therapies and cardiology referrals. Implementing this technology can help mitigate sex-based disparities in cardiovascular care and improve outcomes for women on a population scale.

M2-STCE2-1 MATCHING CT IMAGE CHARACTERISTICS TO IMPROVE RADIOMIC REPRODUCIBILITY: A TRANSLATIONAL CALIBRATION PIPELINE USING 3D-PRINTED PHANTOMS

Alper M. Selver, PhD (*Presenter*)
Ismail Ozsoykal, BSC,MSc (*Abstract Co-Author*)
Aysegul YURT (*Abstract Co-Author*)
Ozgur I. Koska, PhD, MD (*Abstract Co-Author*)

PURPOSE

To enhance the clinical integration of radiomics by improving the reproducibility of CT-derived features through real-time correction of acquisition variability using a 3D-printed phantom-based calibration.

METHODS AND MATERIALS

Twenty cylindrical inserts (diameter and height: 4 cm) spanning -400 to +400 HU were scanned using a single CT (Philips Brilliance 64-slice) and imaging protocol (head/neck). Central ROIs (radius = 20 pixels) were taken from each. Mean and standard deviation values were used as reference points for intensity and noise calibration. Alongside these, ten 3D-printed texture phantoms (4 × 4 × 4 cm) with diverse texture patterns were included in each scan. Over six months, 24 acquisitions were performed to simulate scanner drift. A piecewise linear intensity stretching method was applied to match the mean of reference cylinders across scans, correcting for data drift. Standard deviation differences are used to determine level of noise removal or insertion. IBSI-compliant radiomic features were extracted from each texture before and after calibration. Feature variability was quantified using Normalized Standard Deviation (NSD), and image similarity is assesed by Structural Similarity Index Measure (SSIM) and Learned Perceptual Image Patch Similarity (LPIPS) across timepoints.

RESULTS

Prior to calibration, high variability was observed across repeated scans, particularly in frequency- and low-level texture features (e.g., DCT, GLCM). Following calibration, median NSD across all features and textures dropped from 0.28 to 0.09, representing more than 70% improvement in feature reproducibility. Moreover, without calibration, the observed SSIM and LPIPS were 0.87 and 0.17 in average, respectively, which is increased to 0.95 for SSIM, while LPIPS decreased to 0.11. These improvements show that the proposed calibration pipeline effectively minimizes inter-scan radiomics variability while preserving texture-specific signals.

CONCLUSION

This study introduces a practical, scanner-agnostic calibration framework using 3D-printed phantoms to align CT image characteristics across acquisitions. By significantly enhancing radiomic feature reproducibility, the method addresses a key barrier to clinical and regulatory adoption of quantitative imaging biomarkers.

CLINICAL RELEVANCE/APPLICATION

Radiomic features are increasingly used in AI models, prognostic algorithms, and clinical trials. Yet their clinical utility is undermined by poor reproducibility across scanners and timepoints. The proposed method is the first to combine a custom CT phantom with real-time data drift detection and mitigation algorithms, enabling scanner-specific, patient-centric calibration of CT images before quantitative analysis.

M2-STCE2-3 POPULATION-SCALE ARTIFICIAL INTELLIGENCE IN MAMMOGRAPHY SCREENING: POOLED ANALYSIS OF 652 000 EXAMINATIONS FROM THREE NATIONAL COHORTS

Romuald Ferre, MD (*Presenter*)
Cherie M. Kuzmiak, DO (*Abstract Co-Author*)

PURPOSE

The aim of this study was to determine, at program level, whether deployment of contemporary AI decision-support in organized breast-cancer screening increases screen-detected cancers without inflating false-positive callback (recall) rates.

METHODS AND MATERIALS

We extracted prospective numerator-denominator data from three large implementation studies that embedded AI into double-reading workflows: PRAIM 2025 (Germany; 12 centers; 461 818 examinations), MASAI 2023 (Sweden; cluster-randomized trial; 80 020 examinations) and ScreenTrustCAD 2023 (Sweden; paired-reader study; 111 162 examinations). For each cohort we calculated absolute differences between AI and control arms in recalls per 1 000 examinations and cancers detected per 1 000 examinations. Fixed- and random-effects meta-analyses were performed with inverse-variance weighting and Hartung-Knapp adjustment. Heterogeneity was summarized with the I^2 statistic. All source studies had ethics approval and complied with GDPR and the Declaration of Helsinki.

RESULTS

Across 652 000 screening examinations (356 316 with AI support and 295 785 controls), AI increased screen-detected cancers by 0.83 per 1 000 women (95 % CI 0.46 - 1.20) while reducing recalls by 0.54 per 1 000 (95 % CI -1.40 - 0.32). Heterogeneity was low for both outcomes (I^2 = 9 %). Individually, PRAIM and ScreenTrustCAD realized simultaneous gains—more cancers and fewer callbacks—whereas MASAI exchanged approximately one additional cancer for one additional callback, a difference that did not reach statistical significance.

CONCLUSION

In large, population-based screening programmes, modern AI support detects about one extra cancer per 1 000 women and, on average, does not increase—and may even reduce—false-positive callbacks.

CLINICAL RELEVANCE/APPLICATION

These findings suggest that health-systems can implement AI today to improve screening effectiveness while preserving, or modestly improving, patient safety and workflow efficiency.

PURPOSE

To externally validate an AI tool for opportunistic osteopenia/osteoporosis detection on chest radiographs (CXR) with an international, multicenter real-world, consecutive data

METHODS AND MATERIALS

The ongoing study included consecutive, real-world, 1039 adult patients from US [685/1039 (65.9%)], India [251/1039 (24.1%)] and Brazil [103/1039 (9%)], who had both posterior-anterior CXRs and DEXA within 6 months. CXRs with any implanted devices, lines, tubes, prosthesis, moderate-severe scoliosis, or in anterior-posterior projection were excluded. The AI tool (Promedius.Inc) processed the de-identified CXRs to output probability scores for three classes of BMD: normal, osteopenia, osteoporosis. We recorded spinal T and Z scores from DEXA reports. Statistical analyses included ROC AUC, sensitivity, specificity, PPV, NPV and accuracy along with 95% confidence interval for differentiating the three BMD classes.

RESULTS

The mean age and SD for the cases was 65.5 ± 14.8 years (781 females, 258 males). For osteoporosis vs non-osteoporosis groups, the AI model had ROC AUC of 0.836 (95% CI: 0.799 - 0.873), sensitivity of 85.7% (95% CI: 79% - 92.4%), specificity of 68.8% (95% CI: 65.8% - 71.8%), PPV of 23.6% (95% CI: 19.3% - 27.8%), NPV of 97.7% (95% CI: 96.5% - 98.8%) and accuracy of 70.5% (95% CI: 67.7% - 73.3%). For osteopenia vs normal groups, the AI model had ROC AUC of 0.719 (95% CI: 0.681 - 0.758). There was no significant difference in the model performance across the three countries.

CONCLUSION

Our ongoing study supports the generalizability of CXR-based BMD prediction AI model across data from the three countries with high AUC and NPV. Given the global underutilization of dedicated osteoporosis screening with DEXA, such AI-based opportunistic screening using CXRs may help bridge the diagnostic gap.

CLINICAL RELEVANCE/APPLICATION

AI model can be used as an opportunistic screening tool for osteoporosis detection healthy population using CXRs.

M3-SSCH03-2 MULTICENTER VALIDATION OF AN AI SYSTEM FOR DETECTING AND LOCALIZING 13 CHEST X-RAY FINDINGS IN ADOLESCENTS AND ADULTS

Amit T. Kharat, PhD,DMRD (*Presenter*)
Akanksha Ojha (*Abstract Co-Author*)
Richa Pant (*Abstract Co-Author*)
Saumit Paul (*Abstract Co-Author*)
Aalhad Patwardhan (*Abstract Co-Author*)

PURPOSE

This study presents a comprehensive validation of CXR Detect v2.0 (DeepTek), an EU MDR-certified Class IIb CADe device, designed to detect and localize suspicious ROIs on chest radiographs. The device classifies each ROI into one of 13 clinically significant findings: Opacity, Tuberculosis, Pneumonia, Pulmonary Nodules, Atelectasis,

Fibrosis, Lung Mass, Cardiomegaly, Pleural Effusion, Pleural Thickening, Pneumothorax, Rib and Clavicular Fractures, and Hardware. The study assessed the standalone performance of the AI across diverse populations and imaging conditions in patients aged 12 years and above.

METHODS AND MATERIALS

A dataset of 2,100 chest X-rays was curated from multiple sources in the USA, India, and Europe. All scans were independently annotated by a panel of three radiologists (24, 10, and 4 years of experience), with final adjudication by a senior radiologist with 45 years of experience. The primary metrics used were sensitivity, specificity, and AUROC. Localization performance was measured using the weighted alternative free-response receiver operating characteristic (wAFROC) curve, with its area under the curve used as the figure of merit (FOM). Generalizability was tested by analyzing device performance across subgroups stratified by age, gender, radiographic view, site, and acquisition system manufacturer.

RESULTS

CXR Detect v2.0 demonstrated high diagnostic accuracy across all findings, with a sensitivity of 0.944 [95% CI: 0.934-0.952], specificity of 0.910 [0.901-0.919], and an AUROC of 0.951 [0.946-0.957]. The wAFROC-FOM was 0.908 [0.903-0.912], confirming strong localization performance. Subgroup analysis revealed robust performance across confounders: AUROC for males was 0.953 [0.946-0.960], and for females 0.949 [0.940-0.957]; age-based AUROCs ranged from 0.934 to 0.964, indicating reliable performance across adolescent to elderly cohorts. The performance remained high for radiographs acquired in different view positions and from different manufacturers of the acquisition system.

CONCLUSION

The validated AI solution shows excellent standalone performance in detecting and localizing 13 chest X-ray findings in individuals aged 12 years and older. Its high sensitivity, specificity, and generalizability across diverse demographics and imaging conditions underscore its potential to enhance radiographic screening and triage workflows, especially in resource-limited settings.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that CXR Detect v2.0 can be a reliable tool for automated detection of a broad spectrum of chest pathologies, supporting clinical decision-making and radiologist efficiency without requiring manual input.

M3-SSCH03-3 DYNAMIC CHEST RADIOGRAPHY IMPROVES DETECTION AND DIAGNOSTIC CONFIDENCE OF LUNG CANCER LESIONS COMPARED TO CONVENTIONAL RADIOGRAPHY

Koji Takumi, MD, PhD (*Presenter*)
Ryota Nakanosono, MD (*Abstract Co-Author*)
Hiroaki Nagano, MD, PhD (*Abstract Co-Author*)
Tsubasa Nakano (*Abstract Co-Author*)
Fumitaka Ejima (*Abstract Co-Author*)
Masanori Nakajo, MD (*Abstract Co-Author*)
Kiyohisa Kamimura, MD, PhD (*Abstract Co-Author*)
Takashi Yoshiura, MD, PhD (*Abstract Co-Author*)

PURPOSE

To investigate whether dynamic chest radiography (DCR) improves the diagnostic accuracy of conventional chest radiography (CCR) for detecting lung nodules.

METHODS AND MATERIALS

The study included 100 surgically treated lung cancer lesions. All patients underwent preoperative CCR, DCR, and CT examinations. DCR was obtained using a dynamic flat-panel detector imaging system, equipped with the X-ray moving image analysis workstation (KINOSIS, Konica Minolta, Inc., Tokyo, Japan). The diagnostic confidence for the lesions was evaluated by three chest radiologists on a 3-point scale (2: definite presence, 1: probable presence, 0: difficult to identify) for both CCR and DCR, with a score of 1 or higher defined as a detectable lesion. Artificial intelligence (AI)-based software (CXR-AID, Fujifilm, Tokyo, Japan) also evaluated lesions on conventional chest radiographs. The detectability of the lesions was compared between DCR and CCR as evaluated by radiologists and AI-based software.

RESULTS

The detectability of DCR based on radiologists' consensus (81.0% [81/100]) was significantly higher than that of CCR interpreted by radiologists (71.0% [71/100]; $p = 0.002$) and by AI-based software (64.0% [64/100]; $p < 0.001$). Among the 29 lesions that were difficult for radiologists to identify on CCR, 10 were successfully detected using DCR, all of which overlapped with normal anatomical structures on CCR. For almost all lesions (98.6%) that were initially diagnosed with a confidence level of 1 on CCR by radiologists, the confidence level improved on DCR.

CONCLUSION

DCR significantly improves the detectability and diagnostic confidence of lung cancer lesions compared to CCR, with or without AI-based software, particularly in cases complicated by anatomical overlap.

CLINICAL RELEVANCE/APPLICATION

DCR enhances the detectability and diagnostic confidence of lung cancer lesions, particularly in cases where CCR is limited by anatomical overlap, serving as a valuable complement to both conventional interpretation and AI-assisted analysis in clinical practice.

M3-SSCH03-4 QUANTITATIVE COMPARISON AND READER-BASED EVALUATION OF A VISION-LANGUAGE MODEL FOR CHEST RADIOGRAPH INTERPRETATION

Honggeun Cho, MD (*Presenter*)
Bumcheol Hwang (*Abstract Co-Author*)
Jonggwon Park, Phd (*Abstract Co-Author*)
Byungmu Yoon (*Abstract Co-Author*)
Kyoyun Choi, PhD (*Abstract Co-Author*)
Juyeon Yi, MD (*Abstract Co-Author*)
Joon Young Kim (*Abstract Co-Author*)
Hyun S. Choi, MD, PhD (*Abstract Co-Author*)
Jay Yoon (*Abstract Co-Author*)
Hyewon Kang (*Abstract Co-Author*)
Seongeun Lee (*Abstract Co-Author*)
Heeguen Kang (*Abstract Co-Author*)
Ro-Woon Lee, MD (*Abstract Co-Author*)
Kyuhong Lee, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the classification and segmentation capabilities of a vision-language model (VLM) for chest radiograph interpretation through a two-stage study: (1) quantitative comparison with a unimodal segmentation model (uSEG), and (2) reader-based evaluation of interpretability and perceived clinical utility.

METHODS AND MATERIALS

A newly developed VLM generates similarity maps between chest radiographs and textual descriptions. Thresholding the similarity maps allows the model to perform open-vocabulary segmentation. In contrast, the uSEG is a supervised segmentation model trained to detect five common thoracic abnormalities. Classification and segmentation performance of the VLM and uSEG were compared using a publicly available chest radiograph dataset annotated for findings including consolidation, pneumothorax, fibrosis, nodule/mass, and pleural effusion. Classification metrics included area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, and accuracy, with AUROC comparisons performed using the DeLong test. Segmentation performance was assessed using Dice scores and compared using paired t-tests. For reader evaluation, 100 chest radiographs were retrospectively collected from a tertiary care hospital under IRB approval. Two general practitioners and two senior medical students independently evaluated the VLM's heatmaps, rating agreement with findings and perceived helpfulness for clinical or educational use on a 5-point Likert scale. Score distributions and acceptable response rates (scores =3) were analyzed.

RESULTS

The VLM demonstrated comparable classification performance to the uSEG across most findings (e.g., consolidation AUROC: 0.930 vs. 0.929; p = .83). For segmentation, the VLM achieved higher Dice scores for pleural effusion, comparable performance for fibrosis (p = .05), and modestly lower performance for other findings. In the reader evaluation, general practitioners demonstrated moderate agreement and helpfulness ratings, with acceptable rates of 94.0% and 81.0%, respectively, for GP1, and 79.0% and 67.0% for GP2. Medical students demonstrated higher acceptable rates for both agreement and helpfulness compared to general practitioners.

CONCLUSION

The VLM demonstrated performance comparable to a unimodal segmentation model while generating interpretable outputs without requiring manual annotation. Reader evaluations further supported its potential clinical and educational relevance.

CLINICAL RELEVANCE/APPLICATION

The VLM offers a scalable solution for chest radiograph interpretation by producing interpretable visual outputs. It may support clinical practice and education, pending prospective validation.

M3-SSCH03-6 DEEP LEARNING MODEL FOR CORONARY ARTERY CALCIUM DETECTION FROM DUAL-ENERGY CHEST X-RAYS: A SIMULATION STUDY

Adam S. Wang, PhD (*Presenter*)
Linxi Shi, PhD (*Abstract Co-Author*)
Akyl Swaby (*Abstract Co-Author*)
Kaitlin Hellier (*Abstract Co-Author*)
Praveen Gurunath Bharathi (*Abstract Co-Author*)
Dominik Fleischmann, MD (*Abstract Co-Author*)
Shiva Abbaszadeh (*Abstract Co-Author*)

PURPOSE

Coronary artery calcium (CAC) scoring is a key tool in cardiovascular risk stratification, traditionally performed using non-contrast cardiac CT. However, CT is expensive and unsuitable for large-scale screening. Dual-energy chest X-ray (DE-CXR) with material decomposition offers a potential low-cost alternative, but CAC detection is challenged by anatomical overlap with bony structures. This study aims to develop a deep learning model for detecting and segmenting CAC on DE-CXR projections and to identify the optimal projection angle for accurate CAC detection.

METHODS AND MATERIALS

We developed a CAC segmentation model based on DE-CXR bone images using the nn-Unet architecture. A training dataset was generated from two calcium scoring CT datasets of 159 and 391 patients by simulating DE-CXR projections with realistic x-ray physics. Ground truth calcium segmentations from CT were mapped onto the simulated projections. DE-CXR projections were synthesized and post processed by a high-pass filter across five views: AP, lateral, and three intermediate angles. For each view, we calculated the average overlap ratio between CAC and bony structures — hypothesizing the lower the overlap, the better the CAC visibility. We validated this theory by comparing model performance across views, using ~90% of the data for training and ~10% for testing.

RESULTS

Overlap analysis showed that CAC-bone overlap decreased progressively from AP to lateral views, suggesting better visibility in lateral projections. Model performance reflected this trend as well: in a test cohort of 44 patients (12 with CAC >300, 12 with 100-300, 10 with <50, 10 with score 0), lateral projections achieved 89% sensitivity and 100% specificity. The AP view, impacted by spine and sternum overlap, yielded only 53% sensitivity but still 100% specificity. Segmentation also improved when training subsets were stratified by CAC severity (>300), suggesting enhanced model generalization with higher calcium burden.

CONCLUSION

Our deep learning model aligns with theoretical predictions, demonstrating high accuracy in CAC detection from DE-CXR, particularly in lateral projections where bone overlap is minimized. These results support DE-CXR as a scalable, low-dose, and cost-effective alternative to CT for CAC screening, with important implications for population-level cardiovascular risk assessment.

CLINICAL RELEVANCE/APPLICATION

Our deep learning model can help detect Coronary Artery Calcium from dual-energy chest X-ray as an alternative to CT for Calcium Scoring.

PURPOSE

To develop large language models (LLMs) that automatically extract pancreatic cyst lesion (PCL) features from MRI/CT reports and assign risk categories based on clinical guidelines.

METHODS AND MATERIALS

We retrospectively identified a training dataset of 6000 MRI/CT radiology reports from 5134 patients (2005-2024) using a keyword search in our radiology database, the majority of which described a PCL. The training labels for all reports were generated by GPT-4o using chain-of-thought (CoT) prompting to extract key PCL features, including cyst presence, size, growth, wall thickening, mural nodules, pancreatic duct communication, duct dilation or stricture, duct caliber, differential diagnosis, cyst type (e.g., pseudocyst or serous cystadenoma), and presence of pancreatitis. Two open-source LLMs, LLAMA-3.1-8B-Instruct and DeepSeek-R1-8B, were fine-tuned using QLoRA on GPT-4o-generated CoT training data. Extracted features were mapped to cyst risk categories based on the 2017 ACR White Paper. For evaluation, we used a held-out test set of 285 reports, which were manually annotated by two trainees under the supervision of an abdominal radiologist with 9 years of experience. A separate radiologist assessment was performed on 100 PCL cases from the test set, independently reviewed by three radiologists. Feature extraction performance was measured using exact match accuracy, risk categorization with macro-averaged F1 score, and radiologist agreement using average Cohen's kappa across raters.

RESULTS

Fine-tuning with CoT supervision substantially improved PCL feature extraction accuracy for LLaMA (from 80% to 97%) and DeepSeek (from 79% to 98%), reaching performance comparable to GPT-4o with CoT (97%). For PCL risk categorization, fine-tuning also boosted F1 scores for LLaMA (from 79% to 95%) and DeepSeek (from 80% to 94%), though both remained below GPT-4o (97%). In the radiologist assessment study, GPT-4o with CoT achieved an average Cohen's kappa of 0.905 across raters, while fine-tuned DeepSeek with CoT achieved 0.898, indicating strong agreement with expert assessments.

CONCLUSION

LLMs can accurately extract PCL features and assign risk categories. While GPT-4o performed best, fine-tuned open-source models achieved comparable accuracy. Chain-of-thought enhances both performance and interpretability through explicit reasoning traces.

CLINICAL RELEVANCE/APPLICATION

LLMs can automate the labor-intensive and error-prone task of tracking high-risk PCLs with high accuracy, facilitating large-scale data curation crucial for advancing PCL research.

M3-SSGI04-2 IMAGING BIOMARKERS FOR PANCREATIC ADENOCARCINOMA RISK STRATIFICATION IN INCIDENTAL PANCREATIC CYSTS: A MULTI-HOSPITAL COHORT STUDY

Andrea Bejar, BA, MD (*Presenter*)
Gorkem Durak, MD (*Abstract Co-Author*)
Frank H. Miller, MD (*Abstract Co-Author*)
Ulas Bagci, MSc, PhD (*Abstract Co-Author*)
Rajesh Keswani (*Abstract Co-Author*)

PURPOSE

Incidental pancreatic cysts, often premalignant intraductal papillary mucinous neoplasms (IPMNs), rarely progress to pancreatic ductal adenocarcinoma (PDAC). We aimed to identify imaging and patient risk factors for PDAC development in a large, longitudinal cohort to refine surveillance strategies.

METHODS AND MATERIALS

Our IRB approved retrospective study (2010-2024) included 112,361 patients with abdominal CT/MRI, identifying 3,604 incidental pancreatic cysts. Using ICD-9/10 codes, we performed a case-control analysis to compare patients who developed PDAC after > 1 year of follow-up imaging to unmatched cyst patients with >10 years of

follow-up who did not develop PDAC (1 case to 3 controls). Cases: 21 patients developing PDAC >1 year after cyst diagnosis. Controls: 67 patients with cysts and >10 years of surveillance without PDAC. Nine risk factors (patient demographics, cyst morphology) were analyzed via logistic regression. Imaging features (septations, cyst/maximal pancreatic duct [MPD] diameter) were extracted from radiology reports. Statistical analysis included odds ratios (ORs), two-sample t-tests, and 95% confidence intervals (CIs).

RESULTS

Cohort: 3.83% (138/3,604) of cyst patients developed PDAC; 15.2% (21/138) had delayed PDAC (>1 year post-cyst diagnosis). Key risk factors: Male sex (OR=3.36, CI=1.20-9.45). Cyst: Septations (OR=4.96, CI=1.33-18.45), larger cyst diameter (PDAC: 2.1 cm vs. controls: 1.1 cm; *p*=0.003), MPD dilation (PDAC: 23.8% vs. controls: 0%; *p*=3.9×10?5). Time to PDAC: Mean 6.24 years (SD=5.73).

CONCLUSION

Our study provides a detailed, longitudinal evaluation of PDAC development from incidentally identified IPMN in a multi-hospital system. While most patients in our study are diagnosed with PDAC at the same time as their cyst, our case cohort had a mean time to PDAC development from cyst diagnosis of 6.24 years. Improving non-invasive risk stratification methods can potentially reduce over 6 years of surveillance, cost, and patient burden.

CLINICAL RELEVANCE/APPLICATION

Long-term imaging surveillance (>5 years) may be warranted for cysts with specific risk factors, optimizing early PDAC detection while reducing unnecessary follow-up in low-risk patients. This evidence-based approach addresses the growing burden of incidental cyst management.

PURPOSE

To develop and validate a privacy-preserving federated learning (FL) framework for intraductal papillary mucinous neoplasm (IPMN) risk stratification using a multi-institutional MRI data, enabling collaborative model development without compromising patient data security or regulatory compliance.

METHODS AND MATERIALS

We utilized a comprehensive dataset of 652 T1-weighted (T1W) and 655 T2-weighted (T2W) MRI images with corresponding IPMN risk outcomes collected from seven international centers. IPMNs were categorized as: high-risk (high-grade dysplasia or in situ/invasive cancer, confirmed by EUS biopsy/surgery within 6 months of imaging), low-risk (low-grade dysplasia confirmed pathologically or no progression for =3 years), and no-risk (normal or non-IPMN lesions). After preprocessing with regions of interest, we implemented a 3D DenseNet-121 architecture for risk stratification. We developed and compared multiple learning approaches: traditional centralized learning (CL) versus privacy-preserving FL methods (FedAvg and FedProx) for binary classification of high-risk versus non-high-risk. Model performance was assessed and compared using accuracy (ACC) and area under the ROC curve (AUC) through four-fold cross-validation.

RESULTS

The FL approach achieved performance comparable to CL without sharing sensitive patient data across institutions. For T1W images, CL obtained a mean global AUC of 78.13% and an accuracy of 79.90%, while FedAvg and FedProx (μ=0.1) achieved mean global AUCs of 76.19% and 76.46%, with corresponding accuracies of 79.29% and 78.52%, respectively. On T2W images, the FL performed even more favorably: FedProx (μ=0.3) achieved a mean global AUC of 81.81% and accuracy of 79.27%, nearly matching the CL's AUC of 82.37% and accuracy of 78.23%.

CONCLUSION

FL enables effective IPMN risk stratification across multiple institutions while preserving patient privacy and addressing data scarcity challenges in pancreatic imaging. Our results demonstrate that privacy-preserving FL approaches can achieve performance similar to CL, offering a mature solution that maintains high diagnostic accuracy while protecting sensitive patient data.

CLINICAL RELEVANCE/APPLICATION

This study establishes a practical framework for collaborative multi-institutional IPMN risk assessment that maintains data privacy while leveraging diverse datasets to improve model robustness. Our publicly available dataset (the largest multi-center IPMN collection to date), along with open-source code and pre-trained models, provides radiologists with improved tools for identifying high-risk IPMNs requiring timely intervention while establishing a foundation for broader collaborative AI development in pancreatic imaging.

M3-SSGI04-4 AUTOMATED DIAGNOSIS OF PANCREATIC CYSTS ON MRI USING DEEP LEARNING-BASED SEGMENTATION AND INTENSITY THRESHOLDING

Hyena Park (*Presenter*)
Dong Wook Kim, MD, PhD (*Abstract Co-Author*)
June-Goo Lee, PhD (*Abstract Co-Author*)
Ji-Hoon Jung (*Abstract Co-Author*)
Jae Ho Byun, MD (*Abstract Co-Author*)

PURPOSE

To develop and validate an automated model for detecting and measuring pancreatic cysts on pancreatic MRI scans using deep learning-based multi-class segmentation and intensity-based thresholding.

METHODS AND MATERIALS

A total of 345 T2-weighted pancreatic MRI scans from patients with intraductal papillary mucinous neoplasms (IPMN) were used. A multi-class segmentation model (nnU-Net) classifying (1) pancreas parenchyma, (2) pancreatic duct, and (3) bile duct was trained using manually annotated segmentations as ground truth. For

pancreatic cyst extraction, bias field correction and intensity-based thresholding—derived from the mean intensity values of ductal structures—were applied within the pancreas parenchyma segmentation after excluding segmented pancreatic and bile ducts. Cyst sizes were determined through 3D connected component analysis and convex hull geometry. The largest cyst size was defined by selecting the longest axis length among multiple slices corresponding to each cyst. In a separate test cohort of 50 consecutive IPMN patients (25 under surveillance and 25 who underwent surgical resection), the agreement in identifying the largest cyst between automated and expert radiologist analyses was assessed. The largest cyst size and the number of cysts =10 mm obtained via automated analysis were compared with measurements by the radiologist.

RESULTS

Average Dice scores from 5-fold cross-validation were 0.899 ± 0.008 for pancreas parenchyma, 0.727 ± 0.036 for pancreatic duct, and 0.837 ± 0.019 for bile duct, indicating good to excellent segmentation performance. Agreement on the largest cyst between automated and radiologist analyses was observed in 94% (47/50) of cases. Automatically measured largest cyst sizes correlated strongly with radiologist measurements (29.9 ± 15.4 mm vs. 30.7 ± 16.3 mm; Pearson r = 0.949, p < 0.001). There was no statistically significant difference in the number of cysts =10 mm between automated and manual measurements (2.26 ± 1.93 vs. 2.16 ± 1.90; Wilcoxon signed-rank test, p = 0.404).

CONCLUSION

The deep learning- and intensity-based automated approach demonstrated high segmentation accuracy and reliable cyst measurement comparable to expert radiologists. This method provides robust and objective assessment of pancreatic cysts on MRI.

CLINICAL RELEVANCE/APPLICATION

This fully automated method enables standardized, objective, and scalable quantification of pancreatic cysts on routine MRI, aiding surveillance and reducing inter-reader variability in managing cystic pancreatic lesions such as IPMN.

M3-SSGI04-5 IMPROVING PREDICTIVE ACCURACY FOR SURGICAL INDICATION IN THE CURRENT MANAGEMENT GUIDELINES FOR INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM OF THE PANCREAS VIA CUTOFF ADJUSTMENTS

Junghoan Park, MD (*Presenter*)
Jung Hoon Kim, MD (*Abstract Co-Author*)
Seok Jin Hong, MD (*Abstract Co-Author*)

PURPOSE

To evaluate how to improve predictive accuracy for surgical indication in the current international consensus guidelines for malignancy in pancreatic intraductal papillary mucinous neoplasm (IPMN) via cutoff adjustments of imaging criteria.

METHODS AND MATERIALS

We retrospectively analyzed patients who underwent surgical resection for pancreatic IPMN at a single center between January 2011 and March 2023. Two radiologists reviewed preoperative MRI according to the international consensus guidelines and reached a consensus. We calculated ORs for imaging and clinical features and determined the sensitivity and specificity of high-risk stigmata (HRS). ROC analyses for enhancing mural nodule (EMN) size and main pancreatic duct (MPD) diameter identified cutoffs achieving specificities of 85%, 90%, and 95%. Revised HRS criteria (HRS-85, HRS-90, and HRS-95) were established based on these cutoffs and compared with the original HRS. We also adopted a 6-point scale based on HRS and worrisome features (WFs) (0: no WF/HRS; 1: 1 WF; 2: 2 WFs; 3: 3 WFs; 4: = 4 WFs; 5: = 1 HRS) and compared its AUC between the original and revised HRS.

RESULTS

A total of 418 patients (mean age, 66.6 ± 8.2 years; 263 men) were included, with 173 (41.4%) having malignant IPMN. The original HRS had sensitivity, specificity, and PPV of 82.7%, 66.9%, and 63.8%, respectively. The ORs for each HRS feature ranged from 4.91 to 29.93. Obstructive jaundice (specificity, 98.8%) and positive cytology (99.6%) exhibited very high specificity, whereas EMN = 5 mm and MPD = 10 mm were less specific (80.4% each). Feature-level thresholds to achieve specificities of = 85%, 90%, and 95% were identified as 9.5 mm, 12 mm, and 17.5 mm for EMN size and 11.0 mm, 12.0 mm, and 13.5 mm for MPD diameter, respectively. When applying these thresholds to the revised HRS (HRS-85, 90, and 95), the resulting sensitivities and specificities were 74.6%/77.1%, 65.3%/82.9%, and 53.2%/90.6%, respectively. The 6-point scale AUC improved from 0.771 (original HRS) to 0.798, 0.802, and 0.812 for HRS-85, 90, and 95 (p = 0.015-0.028).

CONCLUSION

Given that the current HRS is used as an absolute surgical indication, its high false positive rate for malignancy remains a limitation. Adjusting the cutoffs for EMN size and MPD diameter improves specificity and the 6-point scale AUC, though at the expense of sensitivity. Therefore, cutoff values should be optimized according to the clinical context.

CLINICAL RELEVANCE/APPLICATION

Adjusting cutoff values for EMN size and MPD diameter improves specificity and AUC in predicting malignancy for pancreatic IPMN, potentially guiding more targeted surgical interventions. However, the associated reduction in sensitivity necessitates a balanced, individualized assessment in clinical practice.

M3-SSGI04-6 NATURAL HISTORY OF PANCREATIC CYSTS: SINGLE-CENTER EXPERIENCE OVER TWO DECADES

Chenchan Huang, MD (*Presenter*)
Yiqiu Shen, PhD, BSc (*Abstract Co-Author*)
Ebrahim Rasromani (*Abstract Co-Author*)
Beisong Liu (*Abstract Co-Author*)
Wan Fung Chui, MD (*Abstract Co-Author*)
Felicia Pasadyn, MA, BA (*Abstract Co-Author*)
Zehui Gu (*Abstract Co-Author*)
Stella Kang, MD, MSc (*Abstract Co-Author*)
Ammar Javed, MD (*Abstract Co-Author*)
Vishnu Jayaprakash (*Abstract Co-Author*)
Greg Sacks (*Abstract Co-Author*)
Camila Hidalgo Salinas (*Abstract Co-Author*)
Wenqing Cao (*Abstract Co-Author*)
Tamas Gonda (*Abstract Co-Author*)

PURPOSE

To characterize pancreatic cystic lesions (PCLs) based on MRI or CT reports and track their natural history.

METHODS AND MATERIALS

We retrospectively included individuals with abdominal radiology reports with PCL from 2000 to 2025 using a large language model (LLM) that we have previously validated to have 97% accuracy. For each patient's reports, we identified the dominant or most suspicious PCL and extracted key imaging features (e.g., size, wall thickening, mural nodule, duct caliber) per the ACR 2017 white paper. PCLs were categorized into 3 groups: low risk (LR), worrisome features (WF+), and high-risk stigmata (HRS+). Follow-up data were analyzed to assess A) Radiographic Progression (RP): =1 new WF or HRS on follow-up imaging reports; and B) Pathological progression: malignancy confirmed by biopsy or surgery (high-grade dysplasia [HGD] or pancreatic cancer). Exclusion criteria were (1) known pancreatic malignancy prior or within six months of baseline PCL identification, (2) any pancreatic surgery; (3) < 12 months surveillance. Follow-up continued until a pathological diagnosis or the last imaging study referencing the PCL.

RESULTS

Of 47,801 patients with reported PCLs, 6,078 patients (median age: 69.3, SD: 12.2; female: 3,797) met inclusion criteria. The median follow-up was 2.1 years. Among these, 1,531 patients had =5 years of imaging follow-up (median 4 CT/MRIs, range 2-44) and 157 patients had =10 years of imaging follow-up. At baseline, 89.9% cysts were classified as LR, 9.5% as WF+, and 0.06% as HRS+. For LR cysts, 13.5% (740/5,462) experienced RP, and 1.5% (82/5462) developed malignancy. For WF+ cysts, 22.5% (130/577) experienced RP, and 2.9% (17/577) developed malignancy. For HRS+ cysts, 33.3% (13/39) experienced RP, and 15.4% (6/39) developed malignancy. For those that experienced RP, 3.6% (32/883) developed malignancy, compared to 1.4% (73/5195) in the radiographically stable group. The median time from baseline imaging to RP was 72.6 months (SD 35.9); to HGD was 80.9 months (SD 46.1); and to cancer diagnosis was 22 months (SD 27.4). Out of 105 malignancy cases, 61% (64/105) were diagnosed by year 3, 82.9% (87/105) by year 5, and 98% (103/105) by year 10.

CONCLUSION

This work represents the largest AI-assisted evaluation of PCL progression to date. We found a higher proportion of baseline WF+/HRS+ cysts and those with radiographic progression during follow-up developed malignancy, with most malignancies detected within the first 5 years of the initial PCL description.

CLINICAL RELEVANCE/APPLICATION

This large AI-assisted study of PCL progression defines both radiographic and pathological progression rates, offering data-driven insights into the link between radiological patterns and malignancy.

M3-SSGI05-2 DEEP LEARNING DECODES CT CLUES: PREDICTING POLE MUTATIONS IN MSS COLORECTAL CANCER FOR PRECISION IMMUNOTHERAPY

Zhen Guan (*Presenter*)
Ying-shi Sun, PhD (*Abstract Co-Author*)

PURPOSE

Immunotherapy has shown remarkable efficacy in POLE-mutated microsatellite-stable colorectal cancer (MSS/pMMR CRC), yet these mutations occur in only 2-4% of cases. We developed and validated a deep learning model using routine multi-phase CT scans to non-invasively identify POLE-mutated tumors, potentially enabling broader access to immunotherapy for eligible patients.

METHODS AND MATERIALS

This multicenter study included 119 histologically confirmed MSS/pMMR CRC patients (25 POLE-mutated, 94 wild-type) from January 2008 to June 2022. Patients were randomly divided into training (n=79) and testing (n=40) cohorts at a 2:1 ratio. A novel VGG-GRU hybrid network was developed to analyze manually segmented tumor and peritumoral adipose tissue across four CT phases (non-contrast, arterial, venous, and delayed). The model employed a unique slice-to-patient aggregation strategy, first predicting mutation probability for each CT slice before generating a final patient-level classification. Performance was rigorously evaluated using AUC, sensitivity, specificity, predictive values, decision curve analysis, and the Hosmer-Lemeshow test.

RESULTS

The model achieved exceptional discrimination with a patient-level AUC of 0.957 (95%CI: 0.914-1.000) in the testing cohort, improving to 0.969 in the combined model analysis. Key performance metrics included 90.6% specificity, 93.9% negative predictive value, and 85.7% positive predictive value. Decision curve analysis demonstrated strong clinical utility across all probability thresholds, while the Hosmer-Lemeshow test confirmed excellent model calibration. These results were consistent across different tumor stages and locations.

CONCLUSION

Our CT-based deep learning model accurately identifies POLE-mutated MSS CRC by capturing subtle imaging signatures in both tumor and peritumoral tissues. This approach represents a significant advancement in non-invasive biomarker discovery for precision immunotherapy selection.

CLINICAL RELEVANCE/APPLICATION

This AI model provides a practical, cost-effective solution for screening POLE mutations using existing CT protocols, addressing a critical gap in precision oncology. With its high negative predictive value (93.9%), the model could reduce unnecessary molecular testing costs, while its strong positive predictive value (85.7%) facilitates early identification of immunotherapy candidates. The immediate clinical applicability of this tool may significantly improve treatment selection and patient outcomes in MSS CRC, particularly for cases where molecular testing is unavailable or delayed.

M3-SSGI05-3 DETECTION OF COLORECTAL NEOPLASTIC LESIONSBYCOMBINEENERGY-SPECTRUM CTCOMPARATIVE ROUTINE CT COLONOGRAPHY:A PRELIMINARY STUDY

Yuna Li, BS (*Presenter*)
Shengyuan Lai, MMed,MMed (*Abstract Co-Author*)
Jiawen Luo (*Abstract Co-Author*)
Bin Mu (*Abstract Co-Author*)

PURPOSE

To compare the detection rate of colorectal tumor lesions using abdominal three-phase enhanced spectral CT without bowel preparation versus conventional three-phase enhanced CT colonography (CTC) with bowel preparation.

METHODS AND MATERIALS

A total of 200 patients with colorectal masses who underwent CT examinations were included in this retrospective study. Among them, 100 patients received spectral CT without bowel preparation, while the other 100 underwent conventional enhanced CTC with bowel preparation. All patients underwent colonoscopy within one week. Subjective image quality, rated using a 5-point scale, and objective image quality (including image noise, contrast-to-noise ratio, and signal-to-noise ratio) were compared between spectral CT and enhanced CTC. The diagnostic performance of spectral CT and enhanced CTC was evaluated and compared using pathological findings as the reference standard.

RESULTS

There were no statistically significant differences in age, height, and weight between patients undergoing spectral CT and conventional enhanced CTC (all $p>0.05$).The CT dose-index volumes, dose-length product, and effective dose in CTC colonography were significantly higher than those in spectral CT (CTC:89.58 ± 22.41, 1956.15 ± 586.28, 29.34 ± 8.79; spectral CT:78.27 ± 15.01, 1246.28 ± 144.53, 18.69 ± 2.17)(all $p<0.05$).The pathological results showed that among the patients who underwent CTC, there were 77 cases of adenocarcinoma and 23 cases of adenoma.In cases of Spectral CT, there were 81 cases of adenocarcinoma and 19 cases of adenoma. For diagnosing adenocarcinoma, CTC achieved 93.68% accuracy, 97.40% sensitivity, and 77.78% specificity. Spectral CT demonstrated 98.00% accuracy, 99.10% sensitivity, and 88.23% specificity. The difference between the spectral CT and enhanced CTC in the detection rate of adenocarcinoma and adenoma was statistically significant ($P<0.05$).

CONCLUSION

The spectral CT showed superior diagnostic performance in distinguishing between adenomas and adenocarcinomas compared to conventional enhanced CTC. Moreover, spectral CT requires lower radiation doses and eliminates the need for bowel preparation.

CLINICAL RELEVANCE/APPLICATION

The superior diagnostic performance of spectral CT in distinguishing between adenomas and adenocarcinomas, along with the advantages of lower radiation doses and absence of bowel preparation, make it a promising alternative to conventional enhanced CTC. Incorporating spectral CT into clinical practice may enhance the accuracy and efficiency of colorectal tumor detection, while also improving patient comfort and reducing radiation exposure.

M3-SSGI05-4 EVALUATING THE ADDED VALUE OF TOPOLOGICAL DATA ANALYSIS IN PREDICTING THE EFFICACY OF NEOADJUVANT THERAPY FOR LOCALLY ADVANCED RECTAL CANCER: A COMPARATIVE STUDY WITH RADIOMICS AND DEEP LEARNING APPROACHES

Kui Sun, MMedSc, PhD (*Presenter*)

PURPOSE

In clinical practice, approximately 15-25% of locally advanced rectal cancer (LARC) patients achieve pathological complete response (pCR), which is closely associated with favorable prognosis. However, noninvasive and accurate preoperative assessment methods remain a major clinical challenge. This study aims to integrate topological data analysis (TDA), radiomics, and deep learning (Dl) for predicting the response to neoadjuvant chemoradiotherapy (nCRT) and prognosis in LARC using baseline T2WI, and to further explore the incremental value provided by TDA.

METHODS AND MATERIALS

This multicenter retrospective study included 227 LARC patients from Center 1 as the development cohort and 72 and 55 patients from two separate centers as external validation cohorts 1 and 2, respectively. The bi-region, comprising the tumor and peritumoral lymph node volumes of interest (VOIs), was manually delineated by a highly experienced senior radiologist. Three analytical approaches were implemented, including radiomics, TDA and end-to-end analysis was performed by ResNet-50. The predictive performance was evaluated using the area under the receiver operating characteristic curves (AUROCs). Prognostic indices, including disease-free survival (DFS) and overall survival (OS), were assessed using Kaplan-Meier (KM) analysis, with the Log-Rank test used to compare KM curves.

RESULTS

In the single-model comparison, the AUROCs on the two external validation cohorts were as follows: for Rs-tumor (Rs_T), 0.740 and 0.716; for Rs-peritumoral lymph nodes (Rs_LN), 0.740 and 0.651; for Dl, 0.703 and 0.699; for TDA-tumor (TDA_T), 0.740 and 0.739; and for TDA-peritumoral lymph nodes (TDA_LN), 0.751 and 0.728. Upon integration of the bi-regional Rs and Dl models (Rs_DL), the AUROCs improved to 0.785 and 0.773. Further incorporation of the bi-regional TDA module (Rs_DL_TDA) led to a substantial enhancement in predictive performance, achieving AUROCs of 0.931 and 0.863, respectively. These findings underscore the additive predictive value of the TDA-based features. In terms of prognostic stratification, the Rs_DL_TDA model demonstrated significant capability in stratifying OS ($p < 0.05$) in both cohorts, and effectively distinguished DFS in external validation cohort 2 ($p = 0.0014$), albeit with marginal significance in cohort 1 ($p = 0.051$).

CONCLUSION

A predictive model based solely on baseline T2WI demonstrated effective assessment of nCRT response in LARC patients.

CLINICAL RELEVANCE/APPLICATION

This study presents a non-invasive model that accurately predicts nCRT response in LARC using baseline T2WI. The integration of TDA significantly enhances performance, offering valuable support for early treatment decision-making and personalized therapy.

Seong Ho Park, MD (*Abstract Co-Author*)
Joonseok Lim, MD (*Abstract Co-Author*)

PURPOSE

Consensus on how to integrate T2-weighted imaging (T2WI) and diffusion-weighted imaging (DWI) for predicting pathologic complete response (pCR) of rectal cancer on post-chemoradiotherapy (CRT) MRI remains lacking. This study aimed to explore practical strategies of integrating DWI on post-CRT MRI.

METHODS AND MATERIALS

This multicenter, retrospective study included patients from three different general hospitals who underwent CRT for rectal cancer bewteen 2017 and 2021. In addition to mrTRG, three criteria combining findings of DWI and T2WI were assessed: "AND" criterion (mrTRG 1-2 and absence of DWI restriction considered as CR), "OR" criterion (mrTRG 1-2 or absence of restriction considered as CR), and a modified MR tumor regression grade (modMR-TRG used in the previous literature). Crossed random effects model was used to pool sensitivity and specificity across five radiologists. F1 score and positive predictive value (PPV) were analyzed across varying pCR rates.

RESULTS

In 146 patients (median age [interquartile range], 63 [57-70] years; 87 men), the AND criterion yielded higher specificity (77.4% [63.3%-80.0%] vs. 75.3% [60.5%-79.0%], p=0.001) without significant difference in sensitivity (63.9% [42.8%-75.3%] vs. 67.5% [45.3%-76.0%], p=0.063) compared with mrTRG. The OR criterion yielded higher sensitivity (86.1% [65.3%-89.3%]; p<0.001) but lower specificity (49.5% [36.2%-62.6%]; p<0.001). The modMR-TRG demonstrated similar effects as OR criterion. Assuming 20% pCR rate, PPV and F1 score of the AND criterion (point estimate of 41.4% and 50.3%, respectively) were higher than those of the OR criterion (PPV, 29.9%; F1 score, 44.4%), although the difference diminished with increasing pCR rate.

CONCLUSION

The AND criterion—which utilizes DWI as a complementary tool to further exclude patients with residual tumors after an initial screening on T2W image—increases specificity without significantly compromising sensitivity compared to mrTRG.

CLINICAL RELEVANCE/APPLICATION

Given the currently attainable pCR rates below 30%, the AND criterion should be preferred over criteria giving greater significance to DWI. The OR or modMR-TRG criteria could be considered when higher pCR rates are anticipated such as with total neoadjuvant therapy, but this approach requires further validation.

M3-SSGI05-6 NODE-RADS OUTPERFORMS ESGAR CRITERIA IN RECTAL CANCER NODAL ASSESSMENT WITH NODE-BY-NODE HISTOPATHOLOGICAL VALIDATION

Qingyang Li, PhD (*Presenter*)
YUZHUO GUO (*Abstract Co-Author*)
Jiaqi Wu (*Abstract Co-Author*)
Ying-shi Sun, PhD (*Abstract Co-Author*)

PURPOSE

To investigate the diagnostic performance of the Node Reporting and Data System 1.0 (Node-RADS) for assessing the nodal status in rectal cancer and compare it to the European Society of Gastrointestinal and Abdominal Radiology (ESGAR) criteria using a node-by-node matched postoperative pathologic result as the reference standard.

METHODS AND MATERIALS

Consecutive rectal cancer patients undergoing preoperative MRI followed by direct total mesorectal excision were prospectively enrolled at our institution between December 2021 and August 2023. Multiparametric MRI features of each lymph node which achieved a node-by-node matching between MRI and pathology were analyzed. According to the Node-RADS flowchart, the likelihood of metastases was assigned based on the assessment of the two levels of size and configuration, which together translated into the final Node-RADS score (Figs. 1 and 2). And the nodal status was also determined by the ESGAR criteria combined with short-axis diameter and morphological characteristics. The cutoff value of the Node-RADS score in diagnosing metastatic nodes was determined by the maximum Youden index method, and the diagnostic performance of Node-RADS and ESGAR criteria was evaluated by the areas under the receiver operating characteristic curve (AUCs) and compared by the DeLong method.

RESULTS

A total of 1,019 benign nodes and 283 metastatic nodes in 251 patients were finally included in this study. The optimal cutoff value of Node-RADS score was >2, i.e., a lymph node with a Node-RADS score of 1-2 was diagnosed as benign, whereas a Node-RADS score of 3-5 indicated metastases. Accordingly, the AUC, sensitivity, and specificity of Node-RADS in determining mesorectal nodal status were 0.83 (95% CI: 0.81, 0.85), 75%, and 91%, respectively, significantly outperforming the ESGAR criteria (AUC=0.70 [95% CI: 0.68, 0.73], P <.001) (Figs. 3 and 4).

CONCLUSION

With rigorous nodal-level pathology correlation, this study highlighted the better diagnostic performance of Node-RADS in determining the nodal status in rectal cancer compared to the currently most commonly used ESGAR criteria.

CLINICAL RELEVANCE/APPLICATION

Node-RADS offers a new solution to the long-bothering problem of unsatisfactory diagnostic performance of nodal status in rectal cancer.

Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*)

PURPOSE

The rapid evolution of large language models (LLMs) offers promising opportunities for radiology report annotation, particularly in identifying specific diagnostic findings. This study evaluates the effectiveness of a human-optimized prompt in extracting radiology diagnoses using LLMs across multiple healthcare institutions in the United States.

METHODS AND MATERIALS

To enable a robust, large-scale evaluation of LLMs for radiology diagnosis extraction, we manually annotated 3,000 radiology reports across six major U.S. institutions—500 reports per site—spanning five diagnostic categories with balanced representation (100 per category per site). Prior to multi-site deployment, prompt engineering was centrally conducted at Mayo Clinic through a systematic, three-stage refinement process using 30 separate example reports per category to iteratively optimize LLM performance. A standardized, open-source Python script incorporating the finalized prompt was then distributed to all participating institutions. This script enabled local execution of a common LLM, allowing for consistent analysis and comparison against site-specific reference annotations. Performance was evaluated using accuracy metrics, with results aggregated across institutions to assess generalizability and diagnostic consistency at scale.

RESULTS

The human-optimized prompt demonstrated high consistency across sites and pathologies. Preliminary analysis indicates significant agreement between the LLM's outputs and investigator-provided reference across 6 institutions. At one site, eight LLMs were systematically compared, with Llama 3.1 70b achieving the highest performance in accurately identifying the specified findings. Comparable performance with Llama 3.1 70b was observed at two additional centers, demonstrating the model's robust adaptability to variations in report structures and institutional practices.

CONCLUSION

Our findings highlight the promise of prompt-engineered LLMs as scalable tools for radiology diagnosis extraction across diverse healthcare institutions. By standardizing local deployment with minimal infrastructure needs, this approach demonstrates both feasibility and strong performance in multi-institutional settings. Future work will explore model robustness to diverse report structures and further refine prompts to improve generalizability.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates a practical, collaborative framework for deploying LLMs in real-world radiology settings. By using standardized prompts and local execution, institutions can leverage LLMs to rapidly annotate reports with minimal overhead—laying the groundwork for scalable AI integration in clinical workflows.

M3-SSIN02-3 ONE SLM IS ALL YOU NEED: ADAPTIVE, PRIVACY-PRESERVING SMALL LANGUAGE MODELS FOR MULTI-TASK CLINICAL ASSISTANCE

Guangyao Zheng (*Presenter*)
Peter Kamel, MD (*Abstract Co-Author*)
Michael A. Jacobs, PhD (*Abstract Co-Author*)
Vladimir Braverman, PhD (*Abstract Co-Author*)
Vishwa Parekh, PhD, MS (*Abstract Co-Author*)

PURPOSE

Recent research has shown that smaller, open-source, fine-tuned language models, known as Small Language Models (SLMs), can achieve performance comparable to or better than LLMs for clinical tasks. However, a major limitation of current SLMs is their training for a single task, which poses challenges for institutions with multiple clinical tasks needing numerous SLMs. We propose that training a single multi-task SLM capable of handling multiple clinical applications can maintain similar performance to closed-sourced LLMs. We use Low-Rank Adaptation (LoRA) to fine-tune an SLM on multiple clinical tasks. This allows hospitals to develop one customizable SLM to assist with various tasks.

METHODS AND MATERIALS

We evaluated the efficacy of a multi-task SLM across three different experiments: (1) medical report labeling, (2) DICOM metadata harmonization, and (3) impression generation from findings. For (1) and (3), we used the de-identified, public Chest X-Ray (CXR) data, which consisted of 3665 CXR reports labelled with thirteen diseases.

(2) was evaluated using a brain MRI dataset consisting of 1,395 DICOM metadata series descriptions. We trained the multi-task SLM by fine-tuning the 350 million parameters opt-350m using LoRA. An 80:20 train-test split is done. As a comparison, GPT-4o was tested without fine-tuning with Prompt Engineering. The evaluation metrics are F1 scores, overall accuracy, and the BLEU score.

RESULTS

For task (1), SLM achieved a class average F1-score of 0.894 compared to GPT-4o's 0.728. For task (2), SLM achieved an accuracy of 0.975 compared to GPT-4o's 0.878. For task (3), SLM achieved a BLEU score of 0.518 compared to GPT-4o's 0.098.

CONCLUSION

SLM with LoRA fine-tuning demonstrated excellent performance in adapting to multiple medical tasks compared to GPT-4o.

CLINICAL RELEVANCE/APPLICATION

Fine-tuned SLM enables on-site patient-private training and deployment and improves clinical decision support in institutions with limited computational resources. Additionally, fine-tuning multiple tasks together simplifies the usability and deployment of models.

M3-SSIN02-4 THE EXPERTISE PARADOX: WHO BENEFITS FROM LLM-ASSISTED BRAIN MRI DIFFERENTIAL DIAGNOSIS?

Benedikt Wiestler (*Abstract Co-Author*)
Su Hwan Kim, MD,MSc (*Abstract Co-Author*)

PURPOSE

Several studies demonstrated the potential of large language models (LLM) to perform radiological differential diagnosis based on textual image findings, but the relationship between reader expertise, LLM input quality, and resulting diagnostic benefit remains poorly understood. This study aimed to evaluate how different levels of radiological expertise influence the potential diagnostic benefit gained from LLM assistance in brain MRI differential diagnosis.

METHODS AND MATERIALS

Neuroradiologists (n = 4), radiology residents with an average neuroradiology experience of 1.5 years (n = 4), and two neurology and neurosurgery residents each (n = 4) were recruited. A dataset of complex brain MRI cases was curated from the local imaging database (n = 40). For each case, readers created a textual image descriptions for the main finding, and provided their top-3 differential diagnoses. Three state-of-the-art large language models (GPT-4.1, Gemini 2.5 Pro, DeepSeek-R1) were then prompted to generate the top-3 differential diagnosis, based on a clinical case description and imaging findings by readers. Top-3 diagnostic accuracy for 1) readers alone and 2) LLMs with reader input were determined for each reader subgroup, along with the accuracy gap between the two groups as a measure for potential benefit from LLM assistance. We used a population-averaged logistic regression (GEE) to evaluate its effect on top-3 accuracy per model.

RESULTS

LLM-generated differential diagnoses achieved the highest performance, when provided with image descriptions from neuroradiologists (top-3: 76.3-79.4%), followed by junior residents (top-3: 68.2-72.7%), and other clinicians (top-3: 60.0-65.4%). Logistic regression revealed a significant positive association between reader seniority and the odds of the correct diagnosis being included among the top-3 (Gemini 2.5 Pro: $p = 0.016$, GPT-4.1: $p < 0.001$, DeepSeek-R1: $p < 0.001$). Among neuroradiology and neurosurgery residents, LLM-augmented diagnosis substantially improved top-3 accuracy (e.g. +17.5% for Gemini). Radiology residents experienced only a modest gain (e.g. +6.3% for Gemini), while LLM augmentation reduced top-3 accuracy for neuroradiologists in all three models (e.g. -6.9% for Gemini).

CONCLUSION

With increasing level of reader experience, the diagnostic performance of LLMs based on textual descriptions of brain MRI findings improved, but the accuracy gain relative to reader assessments paradoxically diminished.

CLINICAL RELEVANCE/APPLICATION

These findings put into perspective the clinical relevance of widespread LLM performance metrics and underscore the necessity for evaluating these systems within authentic clinical workflows.

M3-SSIN02-6 OPTIMIZING CLINICAL DECISION-MAKING IN PANCREATIC CANCER: THE ROLE OF GPT-4O AND DEEPSEEK V3 LARGE LANGUAGE MODELS

Kartik Gupta, MD (*Presenter*)
Ankush Jajodia, MD, MBBS (*Abstract Co-Author*)
Mila Ferri Latinovich (*Abstract Co-Author*)
Michael N. Patlas, MD, FRCPC (*Abstract Co-Author*)
Khaled Y. Elbanna, FRCR (*Abstract Co-Author*)

PURPOSE

Multidisciplinary tumor boards (MTB) are considered the gold standard for decision-making, leveraging collective expertise to optimize patient outcomes. This study looks at how useful two well-known LLMs, GPT-4o and DeepSeek V3, are for creating treatment suggestions for pancreatic adenocarcinoma (PDAC).

METHODS AND MATERIALS

This retrospective study included 328 MTB events in 287 patients with PDAC discussed in MTB at a tertiary care center. The data included anonymous patient histories, imaging results, and suggestions from radiologists, and the latest NCCN PDAC guidelines were given to each LLM along with a standard request for a management plan and explanation. Actual MTB decisions established management plans based on ground truth. Model selection was guided by availability on Azure due to HIPAA/REB requirements and the LMarena leaderboard: open-source model DeepSeek V3 as well as the highest-performing closed-source, non-reasoning model available on Microsoft Azure, GPT-4o. Two abdominal radiologists, blinded to one another’s assessments, compared each model’s output with the MTB ground truth.

RESULTS

Overall Concordance DeepSeek V3 exhibited higher overall concordance with MTB recommendations compared to GPT-4o (98.5% vs. 91.2%; p=0.019). Specifically, GPT-4o failed to generate a recommendation in 12 cases (3.7%), whereas DeepSeek V3 successfully produced management plans for all 328 cases. Concordance by Clinical Decision Class DeepSeek V3 had perfect agreement (100%) in most clinical decision classes, such as borderline, metastatic, palliative, radiation, resectable/surgical, and systemic therapy categories. Its agreement was a bit lower in the unresectable/locally advanced category at 91.4%. In contrast, GPT-4o showed

variable concordance, ranging from 86.2% (unresectable/locally advanced) to 100% (palliative and radiation). Analysis of Discordant Cases GPT-4o exhibited a higher incidence of discordance, often recommending overly aggressive treatments despite clear evidence of metastatic or locally advanced disease (19 cases). On the other hand, DeepSeekV3's disagreements mostly came from mistakenly identifying metastatic disease due to small suspicious nodules (4 cases) and one case of incorrectly assessing vascular involvement.

CONCLUSION

Our study shows that LLMs, especially DeepSeek V3, are very helpful in making decisions about managing pancreatic adenocarcinoma.

CLINICAL RELEVANCE/APPLICATION

Using strong LLMs like DeepSeek V3 could greatly enhance how clinical work is done by offering precise initial management suggestions. These models serve as valuable adjuncts rather than replacements for expert judgment, ensuring streamlined decision-making while maintaining clinical oversight.

M3-SSNR03-1 DIAGNOSTIC CT-DERIVED DAMAGE FINITE ELEMENT MODELING FOR PREDICTION OF FRACTURE RISK IN METASTATIC VERTEBRAE

David B. Hackney, BA, MD (*Presenter*)
Zahra Soltani (*Abstract Co-Author*)
Nils Rehtanz (*Abstract Co-Author*)
Gnaneswar Chundi (*Abstract Co-Author*)
Raul A Radovitzky (*Abstract Co-Author*)
Ron N. Alkalay, PhD (*Abstract Co-Author*)

PURPOSE

To establish and validate an end-to-end, CT-based, damage-driven finite element (FE) pipeline that provides fully automated, patient-specific predictions of vertebral mechanical competence—encompassing stiffness, strength, and failure patterns—across osteolytic, osteosclerotic, and mixed metastatic lesions—with the goal of integrating fracture-risk assessment into clinical decision-making and personalized treatment planning in cancer patients with spinal metastases.

METHODS AND MATERIALS

Forty-four cadaveric vertebral bodies—comprising thirteen osteosclerotic, nine mixed, eleven osteolytic, and eleven with no observed lesions—were imaged on a clinical CT scanner at 0.3185 mm isotropic voxels. DICOM volumes were imported into 3D Slicer (v 5.9+) to segment. The binary segmentation of each vertebra was then exported as a surface and passed to Gmsh to produce watertight tetrahedral meshes, thereby yielding a homogenized finite-element (hFE) model of the enclosed vertebral volume. Bone heterogeneity is modeled by mapping CT-derived BV/TV to each element's Young's modulus via the power law. A continuum damage constitutive model— incorporating viscoelastic, viscoplastic components with a halfspacewise generalization of the Hill criterion—was implemented in the FE framework, SMIT (http://summit.mit.edu). Simulated monotonic compressive loading produced load-displacement curves, from which predicted stiffness (slope of 20-80% linear region) and strength (peak load) were extracted for each vertebra. The actual strength and stiffness were measured in vitro.

RESULTS

When calibrated individually, the damage-based hFE model achieved near-perfect prediction of both strength and stiffness ($R^2 = 0.99$, $p < 0.0001$ for each), with simulated load-displacement curves closely overlaying experimental data across all lesion types. The simulated FE results indicate that bone metastasis type affects bone damage evolution based on the distribution of abnormal bone. Damage propagated through the low-modulus regions of the vertebral bodies, the pattern of which depended on metastasis type.

CONCLUSION

The fully automated, CT-based damage FE pipeline demonstrated excellent accuracy in predicting vertebral stiffness and strength across metastatic vertebrae with each lesion type. The results highlight the critical influence of spatial heterogeneity on pathological fracture progression.

CLINICAL RELEVANCE/APPLICATION

By predicting "where and how" metastatic vertebrae will fail, this methodology enables us to quantify vertebral fracture risk in cancer patients, thereby informing personalized prophylactic strategies and optimizing treatment pathways.

M3-SSNR03-2 COMPLICATIONS OF SYNOVIAL CYST RUPTURE: AN INSTITUTIONAL EXPERIENCE

John J. McIntyre IV, MD (*Presenter*)
Burke Pekala (*Abstract Co-Author*)
Maisy Pekala (*Abstract Co-Author*)
Ryan J. Brandt, MD (*Abstract Co-Author*)

PURPOSE

This paper seeks to identify the complication rates of synovial cyst rupture in our cohort of 320 synovial cyst rupture procedures.

METHODS AND MATERIALS

After obtaining IRB approval, a retrospective review was performed at our institution on all patients who have received a synovial cyst rupture spanning an eight year period. All patients who received a CT-guided synovial cyst rupture via trans-facet or direct rupture were included in the study. All procedures were performed under CT guidance with moderate sedation after informed consent. Technical success rate and complications were recorded. Technical success was defined as contrast or air extravasation outside the cyst. The procedure notes were reviewed for immediate complications and follow up notes were reviewed for delayed complications.

RESULTS

In our cohort, 320 procedures were performed on 262 patients. Overall technical success rate was 84% and technical failure rate was 16%, which is similar to previous published results. Complications included six patients with postprocedure worsening pain, five patients with rupture into the subarachnoid space, two patients with subarachnoid hemorrhage, and one patient with subdural hemorrhage. No patients required hospital admission. Our study demonstrates an overall low complication rate, with subarachnoid and subdural hemorrhage occurring in <1% of procedures.

CONCLUSION

Synovial cyst rupture is an established technique for treatment of symptomatic cysts and provides a treatment alternative to surgical intervention. All the complications in our study were managed non-surgically, and none of the complications required admission to the hospital. Synovial cyst rupture is a safe procedure with a low risk of complications.

CLINICAL RELEVANCE/APPLICATION

Synovial cysts have been reported in up to 10% of patients presenting for imaging of low back pain. Treatment options for symptomatic synovial cysts include conservative treatment, percutaneous cyst rupture, and surgical intervention. Percutaneous cyst rupture can provide symptomatic relief in a majority of patients; however, the complications of the procedure have not been previously characterized.

M3-SSNR03-3 CEREBROSPINAL FLUID BETA TRACE PROTEIN LEVELS: COMPARING PATIENTS WITH SPINAL CSF LEAKS TO THOSE WITHOUT LEAKS AS A POTENTIAL BIOMARKER

Parnian Habibi, MD (*Presenter*)
Jared T. Verdoorn, MD (*Abstract Co-Author*)
John C. Benson, MD (*Abstract Co-Author*)
Ajay A. Madhavan, MD (*Abstract Co-Author*)
Loryn Hovelson, ARRT (*Abstract Co-Author*)
Lynsey Ploenzke, BS (*Abstract Co-Author*)
Ian T. Mark, MD (*Abstract Co-Author*)

PURPOSE

Spinal CSF leaks of all types, particularly CSF-Venous Fistula (CVF), are underdiagnosed. Conversely, unnecessary myelograms are performed on patients without spinal CSF leaks. This highlights the need for new biomarkers to better identify patients with spinal CSF leaks. Beta trace protein (BTP) is synthesized in the arachnoid and choroid plexus cells in the CNS and is the most abundant protein in the CSF produced by the CNS. The purpose of this study was to evaluate CSF BTP levels and compare them between patients with spinal CSF leaks and those without leaks.

METHODS AND MATERIALS

56 patients undergoing workup for SIH were prospectively enrolled and had CSF collected from the lumbar spine during a lateral decubitus myelogram (DSM or CTM). CSF samples were analyzed for BTP levels. Myelogram results were assessed by two neuroradiologists specializing in SIH to determine the presence of a spinal CSF leak. The CSF BTP levels were then compared between those two groups (leak vs no leak). Basic patient demographic information including age and sex was recorded.

RESULTS

Of the 56 patients undergoing lateral decubitus dynamic myelography, the mean age was 51.6 years (range 22-77) and 35 (62.5%) were female. 22 patients (39.3%) had a spinal CSF leak, with a mean CSF BTP level of 34.4 mg/L (SD 8.7). Of the 34 patients who did not have a spinal CSF leak, their CSF BTP levels were significantly lower (mean 16.8 mg/L; SD 5.2; $p < 0.001$). The mean difference between BTP levels in patients with a spinal CSF leak and patients without a CSF leak were statically significant -17.66 mg/L (SEM: 2.05; 95% CI -21.85 to -13.47; $p<0.0001$).

CONCLUSION

This study measured CSF BTP levels in patients with spinal CSF leaks and found significantly higher BTP levels compared to patients without spinal CSF leaks.

CLINICAL RELEVANCE/APPLICATION

This study helps to identify individuals with higher probability of CSF leak who may benefit from more invasive imaging modalities including DSM and CTM.

M3-SSNR03-4 AORTIC SURGERY-RELATED SPINAL CORD INFARCTION: IMAGING FEATURES COMPARED TO SPONTANEOUS CASES

Eiko Yamamori, MD (*Presenter*)
Hidenobu Takagi, MD, PhD (*Abstract Co-Author*)
Erina Kato (*Abstract Co-Author*)
Masayuki Otani (*Abstract Co-Author*)
Hideki Ota, PhD (*Abstract Co-Author*)
Yoshikatsu Saiki, MD, PhD (*Abstract Co-Author*)
Kei Takase, MD, PhD (*Abstract Co-Author*)

PURPOSE

Spinal cord infarction (SCI) is a serious complication of aortic surgery and its mechanism remains unclear, with prevention still challenging. MR imaging allows visualization of the distribution of SCI, and characterization of MR findings of surgery-related SCI would provide insights into the mechanism of SCI. The aim of this study was to compare MR findings between aortic surgery-related SCI and spontaneous SCI.

METHODS AND MATERIALS

In this single-center retrospective study, patients who underwent spine MRI for suspected SCI between 2006 and 2024 were included. Patients with unavailable or poor-quality MRI data, suspected SCI associated with other surgeries or procedures, a history of SCI, and an operation before the first MRI examination were excluded. In the cranio-caudal direction, lesion length and pattern (i.e. diffuse, focal, and multiple) were evaluated using sagittal T2-weighted images. In the axial direction, the presence of high-signal lesions in 11 areas was evaluated by two board-certified radiologists using axial T2-weighted images and final decisions were made by consensus. The axial distribution of SCI was categorized by vascular territory as whole, anterior spinal artery (ASA), watershed, and posterior spinal artery (PSA) in each vertebral level. Each MRI finding was compared between surgery-related and spontaneous SCI patients.

RESULTS

A total of 67 patients (mean age 65 ± 15 years; 56 [84%] male; 44 [65%] surgery-related SCI, including 31 aortic replacements and 13 endovascular repairs) were included. Patients with surgery-related SCI were older (68±11 vs. 58±18 years; $p = 0.02$), male dominant (41 [93%] vs. 15 [65%]; $p = 0.01$), and with higher prevalence of smoking history (23 [92%] vs. 3 [38%]; $p = 0.04$). There was no significant difference in lesion length (71 ± 66 vs. 77 ± 50 mm; $p = 0.706$) between groups. Surgery-related SCI was mainly found at the T2 or lower levels, while spontaneous SCI was found across various levels. Patients with surgery-related SCI showed less PSA territory lesions (50 [11%] vs. 38 [23%]; $p = 0.014$). The inter-observer agreement for presence of SCI on MR images was good (kappa = 0.74 [95% confidence interval, 0.72-0.76]).

CONCLUSION

Aortic surgery-related SCI more frequently showed multiple lesions but less often involved the cervical cord or PSA territories, compared to spontaneous SCI. These results may be compatible with underlying mechanisms of SCI related to aortic surgery, such as delayed infarction due to hemodynamic changes or embolic phenomena.

CLINICAL RELEVANCE/APPLICATION

These insights highlight imaging differences between surgery-related and spontaneous cases. These findings may inform surgical strategies for preventing SCI.

M3-SSNR03-5 MAXIMIZING THE CONSPICUITY OF CSF-VENOUS FISTULAS ON CT MYELOGRAPHY: ASSESSMENT OF CONTRAST DENSITY AND TIMING EFFECTS

Daphne Zhu
(*Presenter*)
Peter G. Kranz, MD (*Abstract Co-Author*)
Diogo G. Leao Edelmuth, MD (*Abstract Co-Author*)
Soren Christensen (*Abstract Co-Author*)
Ajay A. Madhavan, MD (*Abstract Co-Author*)
Timothy J. Amrhein, MD (*Abstract Co-Author*)

PURPOSE

Advancements in CT myelography (CTM) have improved visualization of CSF-venous fistulas (CVFs), an increasingly recognized cause of spontaneous intracranial hypotension (SIH). However, the relative impact of the timing of image acquisition and the contrast density in the subarachnoid space remains unclear. This study compared the effects of both image timing and contrast density in the ipsilateral subarachnoid space on CVF conspicuity, using a validated instrument to stratify diagnostic confidence.

METHODS AND MATERIALS

A retrospective review of consecutive ICHD-3 confirmed SIH patients with CVFs was performed. Only fistulas classified as definite by the Duke CVF Confidence Score (DCCS) were included. All available CTMs covering each index fistula site were reviewed, excluding exams occurring after surgery or embolization for a definite CVF. We assigned a DCCS score to each acquisition and recorded contrast density in the subarachnoid space ipsilateral to the known CVF, time from contrast injection to image acquisition, patient positioning, scanner type, and respiratory phase. Logistic regression was used to assess associations with CVF conspicuity and evaluate contrast density performance via receiver operating characteristic (ROC) analysis.

RESULTS

144 patients (mean age 56.1 ± 11.1 years; 61% female) with 149 definite CVFs comprised the final cohort, from which 222 CTMs and 697 acquisitions were assessed. Univariate logistic regression demonstrated strong associations between both contrast density and time with CVF conspicuity ($p < .001$). In multivariate models adjusting for sex, scanner type, and patient positioning, contrast density (OR = 1.001 [95% CI: 1.001-1.002]; $p < .001$) and time (OR = 0.98 [95% CI: 0.97-0.99]; $p < .001$) remained significant. CVF-side-down positioning also improved conspicuity (OR = 3.42 [95% CI: 0.23, 5.16]; $p < .001$). Standardized models showed a 4.2-fold increase in conspicuity per SD increase in density (ß = 1.43; SE: 0.18) and a 29% decrease in conspicuity per SD increase in time (ß = -0.34; SE: 0.1). ROC analysis identified 836 HU as the optimal density threshold for definite CVF detection (12% false negative rate, 81% sensitivity, 80% specificity).

CONCLUSION

Both higher contrast density and shorter time to image acquisition were independently associated with enhanced CVF visualization. However, density showed a fourfold greater standardized effect than time, suggesting that myelogram technique should prioritize maximization of contrast density in cases of suspected CVFs.

CLINICAL RELEVANCE/APPLICATION

Positioning strategies that maximize local contrast density may improve CVF detection more effectively than timing adjustments alone.

M3-SSNR04-1 CENTRAL NERVOUS SYSTEM LYMPHOMA PROGRESSION IN PRIMARY VITREORETINAL LYMPHOMA: A MULTICENTER REAL-WORLD STUDY WITH IMPLICATIONS FOR NEURO-ONCOLOGIC SURVEILLANCE

Zain Hussain, MD (*Presenter*)
Shabber Syed, MD (*Abstract Co-Author*)
Arif Musa, MD, MS (*Abstract Co-Author*)
Robert H. Bixler (*Abstract Co-Author*)

PURPOSE

To characterize the risk, timing, and clinical predictors of primary central nervous system lymphoma (PCNSL) progression in patients with Primary Vitreoretinal Lymphoma (PVRL), and to evaluate the implications for neuroimaging surveillance strategies and treatment escalation.

METHODS AND MATERIALS

This retrospective multicenter cohort study utilized the TriNetX research network to identify patients diagnosed with PVRL using a combination of ICD-10 codes representing diffuse large B-cell lymphoma of the head, neck, and retina (C83.39, C85.91, C85.11, C69.2). CNS involvement was defined as a subsequent diagnosis of primary central nervous system lymphoma (PCNSL, ICD-10: C83.390). Patients were stratified by presence of systemic treatment and prior misclassification as uveitis (H20), a common diagnostic confounder. Time-to-progression to CNS involvement, neuro-oncologic outcomes, and mortality were assessed using Kaplan-Meier analysis and Cox proportional hazards regression.

RESULTS

Among 101 patients with PVRL, 42 (41.6%) developed CNS involvement, all after the initial ocular diagnosis. Median time to PCNSL diagnosis was 857 days (IQR: 498-1213). CNS progression was strongly associated with increased mortality (HR 9.13, 95% CI 2.10-39.75, $p = 0.0032$). Patients initially misclassified as uveitis had a markedly elevated risk of CNS involvement (83.3% vs. 19.7%, $p < 0.0001$), underscoring the radiologic and clinical need for early brain imaging in ambiguous ocular presentations.

CONCLUSION

CNS progression in PVRL is common, severe, and often delayed, emphasizing the critical role of neuroimaging in early diagnosis and longitudinal surveillance. Radiologists and neuro-oncologists should maintain a high index of suspicion for occult CNS involvement in cases of atypical uveitis and PVRL, and consider early brain MRI even in the absence of neurologic symptoms.

CLINICAL RELEVANCE/APPLICATION

Early recognition of Primary Vitreoretinal Lymphoma (PVRL) is critical to prevent Primary Central Nervous System Lymphoma (PCNSL) progression, a complication associated with markedly increased mortality. This study highlights the need for high clinical and radiological suspicion in patients presenting with atypical uveitis, as misdiagnosis can significantly delay treatment. Findings emphasize the value of early neuroimaging in PVRL cases and the importance of multidisciplinary coordination between neuro-oncology, radiology, and ophthalmology. Enhanced surveillance strategies may improve outcomes by enabling timely intervention before CNS dissemination occurs.

M3-SSNR04-4 STAPLE-BASED SPATIAL AND GLOBAL RELIABILITY ANALYSIS OF MULTI-ANNOTATOR BRAIN METASTASIS SEGMENTATION DATA: BRATS-METS LIGHTHOUSE 2025 CHALLENGE

PURPOSE

Expert annotation of brain metastasis necrotic and enhancing tumor margins on MRI is essential for surgical planning, radiation targeting, treatment monitoring, and AI training. There is natural variability in image annotation among expert neuroradiologists, which results in generation of low-quality reference standard that affects translation of AI algorithms to the clinic. We propose a novel method STAPLE for generation of high-quality reference standard that approach the desired gold standard for image annotation. STAPLE is a consensus method that estimates annotator reliability and latent ground truth in a single pass; unlike Dice and other metrics, it does not require fixed references and multiple pairwise comparisons, thus providing a unified approach to label fusion.

METHODS AND MATERIALS

75 MRIs from BraTS-METS 2025 Lighthouse Challenge annotated 8 times by 3 rater-pairs (six board-certified neuroradiologists; 600 total segmentations: 300 manual, 300 AI-refined). Segmentation masks were fused by SimpleITK's STAPLE (200 iterations) to generate a voxel-wise consensus probability map (W). The ROI defined as the union of all rater masks yielded a binary label matrix D (voxels × 8). Within this ROI, per-session sensitivity (p) and specificity (q) were computed as the weighted overlap with W and with (1-W), respectively. Overall agreement was quantified by mean Dice similarity (vs. W > 0.5), Fleiss' ?, and Krippendorff's a; 95% CIs for Dice were estimated via 500-replicate percentile bootstrapping.

RESULTS

72 cases (576 annotations) analyzed after 3 mismatch exclusions probability maps were generated Intra-rater Dice was 0.82 ± 0.14 (sensitivity 0.78, specificity 0.75); inter-rater Dice was 0.79 ± 0.16 (sensitivity 0.73, specificity 0.85). Peak ? = 0.62; mean ? = 0.33 (inter) and 0.14 (intra). Mean Dice vs. STAPLE was 0.81 ± 0.15 (95% CI: 0.68-0.93); Fleiss' ? and Krippendorff's a were both 0.20. nnU-Net-assisted segmentations outperformed manual (+18% Dice, p<0.001) and paired consensus (+10%, p<0.01); paired consensus also exceeded manual (+6%, p<0.01).

CONCLUSION

Manual expert segmentation shows only fair inter- and intra-rater reliability (mean Dice ˜ 0.81; ? ˜ 0.20). STAPLE quantifies this uncertainty and generates probabilistic reference standards, informing annotation protocols, quality assurance, and AI models that account for variability; ultimately improving reliability and clinical applicability.

CLINICAL RELEVANCE/APPLICATION

This framework quantifies annotation variability and generates consensus maps that enhance quality assurance, reproducibility, and AI performance for more reliable clinical decision-making.

M3-SSNR04-5 MRI-DERIVED RADIOMICS AND DEEP LEARNING MODELS FOR PREDICTING EPIDERMAL GROWTH FACTOR RECEPTOR STATUS IN GLIOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIAGNOSTIC TEST ACCURACY STUDIES

Nima Broomand Lomer, MD (*Presenter*)
Amir M. Ahmadzadeh, MD (*Abstract Co-Author*)
Mohammad A. Ashoobi, MD (*Abstract Co-Author*)
Rayehe Rahimi, MD (*Abstract Co-Author*)
Kambiz Nael, MD (*Abstract Co-Author*)

PURPOSE

Alterations in the epidermal growth factor receptor (EGFR) have been linked to prognosis in glioma patients, often contributing to increased tumor aggressiveness and resistance to chemo- and radiotherapy (1-3). This study systematically reviews the diagnostic performance of radiomics and deep learning (DL) models in predicting EGFR alterations.

METHODS AND MATERIALS

A thorough systematic search was performed across multiple databases, including PubMed, Scopus, Embase, and Web of Science. Study quality was evaluated using the METRICS tool. A bivariate meta-analytic model was applied to compute pooled estimates for sensitivity, specificity, positive and negative diagnostic likelihood ratios (DLR+ and DLR-), diagnostic odds ratio (DOR), and the area under the receiver operating characteristic curve (AUC). Subgroup analysis was conducted to investigate potential sources of heterogeneity. Outlier detection was carried out using bivariate boxplots and sensitivity analysis. The presence of potential publication bias was investigated using Deek's funnel plot asymmetry test.

RESULTS

A total of 12 studies were included in the systematic review, with six eligible for meta-analysis. All studies constructed radiomics models, and one also developed a DL model. Study quality according to the METRICS scale was mostly moderate (median: 56.5%), with individual study scores ranging from 38.7% to 83.9%. The pooled results of the radiomics meta-analysis were as follows: sensitivity: 0.74; specificity: 0.88; DLR+: 6.12; DLR-: 0.29; DOR: 21.07; and AUC: 0.87. A significantly higher pooled specificity was observed among studies conducted in Asia compared to those performed in North America Additionally, studies with smaller sample sizes demonstrated a significantly higher pooled sensitivity than those with larger cohorts. Sensitivity analyses did not identify any outliers, and no significant publication bias was detected.

CONCLUSION

Radiomics may have the potential to preoperatively predict EGFR status in glioma patients, improving prognostic assessments and treatment planning.

CLINICAL RELEVANCE/APPLICATION

According to the latest guideline of the World Health Organization for central nervous system tumors, EGFR alterations are among the key biomarkers in glioma, linked to poor prognosis and resistance to conventional therapies. Radiomics may be considered as a non-invasive approach to identify EGFR status, potentially improving prognostic evaluation and facilitating individualized treatment planning in glioma patients.

M3-SSNR04-6 UTILIZING MRI-BASED RADIOMIC FEATURES AND MACHINE LEARNING TO NON-INVASIVELY CHARACTERIZE THE HISTOPATHOLOGY OF ORBITAL LYMPHOMAS

Burak B. Ozkara, MD (*Presenter*)
Samir Dagher, MD (*Abstract Co-Author*)
Max Wintermark, MD (*Abstract Co-Author*)
James M. Debnam, MD (*Abstract Co-Author*)

PURPOSE

Orbital lymphomas (OLs) are rare tumors comprising 6-8% of orbital neoplasms, and their histopathologic characterization typically requires invasive biopsy or surgery. Extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT-lymphoma) is the most common OL subtype and is associated with better prognosis. This study aimed to develop a radiomics-based machine learning model to non-invasively differentiate MALT-lymphomas from other OLs on preoperative contrast-enhanced MRI, an integral component of staging.

METHODS AND MATERIALS

All consecutive OL patients with diagnostic-quality, fat-saturated, contrast-enhanced T1-weighted MRI in our institutional PACS were included. Clinical data (age, gender, ethnicity, histologic subtype) were recorded. OLs were manually segmented using iTK-SNAP under the supervision of a board-certified neuroradiologist. Approximately 15,000 radiomic features were extracted with PyRadiomics. Feature selection was performed using the least absolute shrinkage and selection operator (LASSO). A

TabPFN model, based on a modified Prior-Data Fitted Network architecture, was developed and evaluated using 5-repeat 5-fold cross-validation. SHapley Additive exPlanations (SHAP) were used to assess feature contributions.

RESULTS

The cohort included 122 patients (65 men, 57 women; median age 63) imaged between March 2002 and February 2020. There were 47 biopsy-proven MALT-lymphomas and 75 non-MALT OLs (26 diffuse large B-cell, 12 follicular, 9 mantle cell, 9 T-cell, 17 other). Forty-five radiomic features were selected. Model performance was as follows: AUROC 0.772 (95% CI: 0.745-0.797), AUPRC 0.772 (95% CI: 0.742-0.797), accuracy 0.776 (95% CI: 0.753-0.799), precision 0.758 (95% CI: 0.720-0.796), recall 0.714 (95% CI: 0.671-0.752), F1-score 0.706 (95% CI: 0.678-0.736), MCC 0.555 (95% CI: 0.511-0.600), Brier score 0.198 (95% CI: 0.183-0.212).

CONCLUSION

Radiomics-based machine learning models show promise for distinguishing MALT-lymphomas from more aggressive OL subtypes. Once validated, such models could aid in the non-invasive characterization of OLs and potentially reduce the need for surgical biopsy.

CLINICAL RELEVANCE/APPLICATION

Non-invasively identifying MALT-lymphomas may help avoid biopsy in selected patients, accelerate diagnosis, inform prognosis, and guide treatment decisions, contributing to more personalized and less invasive care.

M3-SSPH04-1 PATIENT-DERIVED DIGITAL TWIN OF THE HUMAN BREAST: A MODEL FOR VIRTUAL CLINICAL TRIALS

Peymon Ghazi, PhD (*Presenter*)

PURPOSE

To create high-fidelity, patient-derived digital twin breast phantoms that reproduce micro-ductal anatomy at x-ray resolution, laying the groundwork for virtual clinical trials (VCTs) that can predict and compare the performance of emerging breast-imaging systems, optimize protocols, and de-risk first-in-human studies.

METHODS AND MATERIALS

Publicly available 3 T breast MRI datasets (0.6 × 0.6 × 1.0 mm) underwent expert-guided correction before being super-sampled to 0.1 × 0.1 × 0.11 mm. Skin, fascia, and adipose compartments were segmented; an L-system algorithm iteratively populated fibroglandular tissue with >106 ductal segments down to 5 μm. Each voxel was assigned mass density and elemental composition compatible with Monte-Carlo-based x-ray transport. A projection engine produced synthetic mammography, tomosynthesis, and breast-CT data, enabling side-by-side assessment of system resolution, dose, and spectral separation within a common digital-twin cohort.

RESULTS

The pipeline generated patient-specific twins that preserved realistic tissue interfaces, achieved <1 mm nipple-localization error, and supported 0.1-mm isotropic voxel rendering. Simulated acquisitions reproduced modulation-transfer-function roll-off and glandular-dose trends measured on physical systems, validating the twins for VCT use. Comparative simulations demonstrated modality-dependent detectability of 2-mm soft-tissue lesions at equalized dose, illustrating the framework's ability to benchmark new designs.

CONCLUSION

Patient-derived digital twins with micron-scale detail have been realized and cross-validated against established x-ray metrics, providing a robust platform for VCTs that accelerate technology evaluation, protocol optimization, and regulatory submission while minimizing patient risk.

CLINICAL RELEVANCE/APPLICATION

Digital-twin VCTs enable rapid, cost-effective assessment of novel breast-imaging modalities, facilitate head-to-head comparison under controlled conditions, and inform clinical-trial design—ultimately expediting the translation of safer, more sensitive x-ray-based breast-cancer screening and diagnostic technologies.

M3-SSPH04-2 PATIENT DATA-BASED VIRTUAL IMAGING TRIAL FOR HALLUCINATION QUANTIFICATION IN DEEP-LEARNING CT IMAGE RECONSTRUCTION

Zhongxing Zhou, PhD (*Presenter*)
Scott S. Hsieh, PhD (*Abstract Co-Author*)
Hao Gong, PHD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Lifeng Yu, PhD (*Abstract Co-Author*)

PURPOSE

Deep learning reconstruction and noise reduction (DLR) methods for low-dose CT show strong promise but can produce hallucinations—false structures resembling real anatomy. Quantifying hallucinations is critical but difficult due to the lack of ground truth. A patient-data-based virtual imaging trial (VIT) is an ideal paradigm to bridge this gap with the availability of reference images. This study aimed to develop a VIT-based method to quantitatively assess hallucinations produced by DLR methods in low-dose CT.

METHODS AND MATERIALS

Starting from patient projection data acquired at routine-dose CT exams, CT images at lower doses were generated by reconstructing simulated projection data after noise insertion. The degree of hallucination (DOH) at lower dose levels by DLR was quantified using the routine-dose images as reference. Specifically, we selected homogeneous regions of interest in patient images that are free of major anatomical structures and calculated a group of radiomics texture features that represent deviations from originally uniform regions. These features include Inverse Difference Moment and Long Run Emphasis, among others. Intraclass correlation coefficients (ICC) of those texture features were calculated between DLR denoised lower-dose images and the routine-dose images, with the DOH computed as (1 - ICC). This method was applied to two clinical cases, one from a chest CT for interstitial lung disease (ILD) and the other CT angiography (CTA) for Circle of Willis, to quantify the hallucination effect of two DLR methods (DLR1 and DLR2).

RESULTS

When the radiation dose was reduced from 100% to 8% in the chest exam, the DOH for DLR1 increased from 0.36 ± 0.08 to 0.59 ± 0.09, while for DLR2 it increased from 0.14 ± 0.07 to 0.54 ± 0.09. Similarly, in the CTA exam, reducing the dose from 100% to 25% resulted in a DOH increase for DLR1 from 0.19 ± 0.10 to 0.57 ± 0.16, and for DLR2 from 0.04 ± 0.03 to 0.15 ± 0.10. Although both methods showed more hallucinations at lower doses, DLR2 consistently exhibited lower absolute DOH values at each dose level, indicating better hallucination suppression.

CONCLUSION

Using a patient-data-based VIT method, we proposed a quantitative metric to assess the degree of hallucination. DLR methods vary in their degree of hallucination, and such metrics will help guide the design and selection of DLR methods with reduced hallucination at lower radiation doses.

CLINICAL RELEVANCE/APPLICATION

Our proposed method enables quantitative evaluation of hallucination effect for deep-learning reconstruction and noise reduction algorithms, ensuring safer deployment of those algorithms at reduced radiation dose in CT.

M3-SSPH04-3 VALIDATION OF A 3D-PRINTED ANTHROPOMORPHIC PEDIATRIC ABDOMEN-CT-PHANTOM: COMPARISON OF IMAGE QUALITY USING A NOVEL PHOTON-COUNTING CT

Thilo Schikorra (*Presenter*)
Matthias S. May, MD (*Abstract Co-Author*)
Thomas G. Flohr, PhD (*Abstract Co-Author*)
Thomas Allmendinger, PhD (*Abstract Co-Author*)
Ido Bitan, BSC (*Abstract Co-Author*)
Michael Uder, MD (*Abstract Co-Author*)
Markus Kopp (*Abstract Co-Author*)

PURPOSE

This study aims to validate the objective and subjective image quality between a patient CT scan and the subsequently 3D-printed, anatomically realistic CT-abdomen phantom on a novel photon-counting CT (PCCT).

METHODS AND MATERIALS

We developed and used a 3D-printed CT phantom based on the DICOM data obtained from a PCCT (NAEOTOM Alpha, Siemens Healthineers, Forchheim, Germany) scan of a 5-year-old boy (70 kV, 458 qRef mAs). We performed one scan on the phantom at 70 kV (461 qRef mAs) and one at 90 kV (148 qRef mAs), reconstructing the scans with three kernels (Br 40/44/60). The objective image quality was measured based on mean HU values and standard deviations of HU values as image noise in circular regions of interest in the liver, V. portae, abdominal aorta, abdominal fat, autochthonous dorsal muscles, spleen, pancreas, and rib bone. The non-normal distributed values were paired and compared with a non-parametric Wilcoxon equivalence test. The conspicuity as the subjective image quality of the kidneys, gallbladder, pancreas, liver-hyperenhancement, V. portae branches, V. splenica, bone cortex, and bone matrix structures was assessed subjectively (5-point Likert-scale) by three trained radiology experts. The ratings were compared between phantom and patient scans.

RESULTS

The CT values in the phantom without bone and fat were equivalent to those in the patient ($p<0.05$). However, fat demonstrated noticeable higher (-48.3 HU vs. -124.5 HU), and bone noticeable lower mean CT values (842.5 HU vs. 1059.5 HU) in the phantom. The image noise was also equivalent between patient and phantom ($p<0.05$). When scanned at 90 kV, the CT values of parenchymal organs increased contrary to observations in humans, while the high CT values of bone, V. portae, and aorta decreased, and the low CT values of fat increased as expected. The scan at 461 qRef mAs (Br40) showed the highest subjective comparability between patient and phantom scan with an overall median rating of 4 (vs. median 5 in the patient). The median rating is equal for the kidneys (5 vs. 5), liver-hyperenhancement (4 vs. 4), slightly lower medians in the conspicuity of the gallbladder, pancreas, V. portae, V. splenica (4 vs. 5), and significantly differing medians in the bone structures (3 vs. 5).

CONCLUSION

This study proves comparable image quality between the 3D-printed pediatric CT phantom and the patient scan at comparable dose parameters. This allows for realistic quantification of the dose-image-quality ratio. Especially for parenchymal organs, the phantom behaves similarly to human CT scans.

CLINICAL RELEVANCE/APPLICATION

In the future, radiation exposure in dose reduction studies can potentially be anticipated beforehand, which is especially relevant in the highly vulnerable pediatric collective.

M3-SSPH04-4 IODINEPRINT: PATIENT-SPECIFIC, IODINE-ENHANCED PHANTOMS FOR SPECTRAL CT IMAGING

Franz Englbrecht (*Presenter*)
Anatoliy Popov, MD (*Abstract Co-Author*)
Kai Mei, PhD (*Abstract Co-Author*)
Olivia Sandvold, BS (*Abstract Co-Author*)
Michael Geagan (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

Iodine-based (I) contrast agents enhance anatomical detail and improve diagnostic accuracy in CT imaging. With advancements in spectral CT, the ability to accurately quantify iodine has further elevated its role as a potential imaging biomarker. However, CT system design and validation still rely on simplistic, non-anthropomorphic phantoms, and there are currently no anatomically realistic, iodine-enhanced phantoms available. To address this gap, we expand upon our previously developed PixelPrint 3D-printing method by introducing a novel iodine-infused Polylactic Acid (PLA) filament (IodinePrint). This filament enables the fabrication of anatomically accurate phantoms with clinically relevant iodine enhancement.

METHODS AND MATERIALS

Iodine-rich compounds were embedded into PLA pellets using a dual-solvent technique—where a “bad” solvent preserve the polymer structure, and a “good” solvent facilitates iodine diffusion into the matrix. Following solvent evaporation, the modified pellets were extruded into a filament with a diameter of 1.75 mm. As an initial test, we printed four calibration cubes with varying infill ratios (ranging from 30% to 90%) and compared them to commercially available iodine inserts. A cylindrical calibration phantom was then fabricated using a dual-extruder 3D printer. It featured pie-slice segments with iodine concentrations ranging from 0.7 to 10.4 mg/mL by modifying the ratio of PLA infill to iodine filament infill. Based on this calibration, an anatomically accurate section of a contrast-enhanced pancreatic CT scan was printed to generate an anatomically accurate, iodine-enhanced phantom. All phantoms were scanned with a dual-layer spectral CT (Spectral CT 7500, Philips Healthcare) to evaluate Hounsfield units (HU) and iodine concentrations.

RESULTS

Spectral CT imaging demonstrated a similar spectral profile between the printed calibration cubes and commercial inserts, as well as a strong linear correlation between Hounsfield units and iodine concentration in the calibration phantom. The pancreatic phantom exhibited contrast levels within physiologically expected ranges and presented realistic textures and anatomical detail in conventional images and iodine maps.

CONCLUSION

IodinePrint demonstrates the feasibility of integrating iodine into PLA filament, enabling the fabrication of anatomically accurate, contrast-enhanced phantoms with consistent material properties and reproducible iodine distribution.

CLINICAL RELEVANCE/APPLICATION

These phantoms serve as a practical and clinically meaningful tool for evaluating key spectral CT performance metrics, including iodine quantification accuracy, contrast resolution, and the consistency of material decomposition algorithms.

M3-SSPH04-5 3D-PRINTED DEFORMABLE CHEST CT RESPIRATORY MOTION PHANTOM WITH MULTI-AXIS DEFORMATION MECHANISM

Jessica Im, BEng (*Presenter*)
Michael Geagan (*Abstract Co-Author*)
Kai Mei, PhD (*Abstract Co-Author*)
Boon-Keng K. Teo, PhD (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

Respiratory motion compensation technologies have been developed to mitigate motion artifacts in CT, but require evaluation with respiratory motion phantoms (RMPs) prior to clinical use. However, most existing RMPs are overly simplistic in structure and motion, with motion typically limited to the superior/inferior (SI) axis. In recent years, the development of nonlinear motion compensation technologies has necessitated more lifelike RMPs that better replicate clinical scenarios. This work describes the development of a deformable chest RMP that features realistic lung structures and a novel multi-axis deformation mechanism.

METHODS AND MATERIALS

A patient 4DCT was selected as a reference for phantom fabrication. Attenuation data within both lungs at end inhale were converted into 3D-printer instructions using PixelPrint software, which continuously varies the density of printed material to mimic patient attenuation profiles. The mediastinum was set to a uniform printed density of 50%. Using a flexible material, thermoplastic polyurethane (TPU), the deformable lung and mediastinum phantom was 3D-printed at 0.5x scale. The chest wall was then printed using a rigid material, polylactic acid (PLA), with a 15 mm coronal strip of TPU to allow for chest wall compression. To model multi-axis deformation, SI linear compression from the diaphragm was facilitated with a lead screw. Additionally, anterior/posterior (AP) compression was achieved with a lacing mechanism which encircled the chest wall. The phantom was scanned at different compression levels to match patient diaphragm and chest wall motion. Deformable image registration was then performed on both patient and phantom datasets to obtain deformation vectors and structural similarity index measures (SSIM).

RESULTS

The chest RMP exhibited realistic lung structures and motion profiles. The SSIM between phantom and patient lungs measured 0.95 and 0.96 at the 0% and 50% respiratory phases respectively, indicating high structural accuracy in both deformed and nondeformed states. Mean motion vector errors measured throughout the lungs between the 50% and 0% phases were -1.1 ± 1.9, -0.9 ± 1.5, and -1.3 ± 1.6 mm in the SI, AP, and right/left (RL) directions respectively.

CONCLUSION

The deformable chest RMP demonstrated realistic lung structures and produced multi-axis deformation patterns that closely matched patient 4DCT images. In future iterations, this 3D-printing process could be easily adapted to produce RMPs representing various clinical scenarios.

CLINICAL RELEVANCE/APPLICATION

Realistic RMPs will enable more clinically relevant assessment during development of motion compensation technologies compared to existing RMPs, facilitating more effective clinical translation.

M3-SSPH04-6 TASK-SPECIFIC EVALUATION OF PHOTON-COUNTING CT USING A 3D-PRINTED ANTHROPOMORPHIC LUNG PHANTOM WITH COPD PATHOLOGY

Fong Chi Ho, MS (*Presenter*)
Kai Mei, PhD (*Abstract Co-Author*)
Shobhit Sharma, PhD (*Abstract Co-Author*)

Peter B. Noel, PhD (*Abstract Co-Author*)
Ehsan Samei, PHD (*Abstract Co-Author*)
Ehsan Abadi, PhD (*Abstract Co-Author*)

PURPOSE

The absence of disease-specific anthropomorphic physical phantoms hinders efforts to evaluate emerging CT technologies in clinically relevant scenarios. We introduce a task-specific 3D-printed lung phantom based on extended cardiac-torso (XCAT) modeling, incorporating pathological features of chronic obstructive pulmonary disease (COPD), including thickened bronchial wall and mucus plugs. Using this novel phantom, this study compares the performance of Normal-Resolution (NR) and Super-High-Resolution (SHR) modes of a photon-counting CT (PCCT) prototype in quantifying airway-specific imaging biomarkers.

METHODS AND MATERIALS

A lung phantom was 3D printed with PixelPrint, a technique converting CT into voxel-based printer instructions by modeling density as a ratio of filament to voxel volume to generate sub-resolution partial volume effects to replicate realistic tissue densities and textures. The phantom was constructed based on anthropomorphic XCAT models derived from a clinical case with COPD pathologies. It included realistic and detailed pulmonary vessels, solid nodules, parenchyma, and airways with pathologically informed bronchitis wall thickening and mucus plugging. The phantom was scanned using a PCCT prototype (Canon) under NR and SHR (0.62 vs. 0.21 mm slice thickness) in multiple thoracic protocols, all reconstructed with an Adaptive Iterative Dose Reduction (AIDR) technique. Quantitative analysis included airway wall thickness, airway wall area percentage, mucus volume, lesion volume, spatial resolution, and global noise index (GNI). The percentage differences between NR and SHR measurements relative to the ground truth model were analyzed.

RESULTS

Compared to NR mode, SHR images, reconstructed with AIDR, showed reduced noise (28.8±4.2%), and improved accuracy in airway wall thickness (0.06±0.03mm), airway wall area percentage (11.40±5.38%), mucus volume (0.83±0.19 mm 3), and lesion volume (1.38±0.24 mm 3). SHR images suppressed noise and preserved anatomical details, notably in the smaller airway generations and mucus-plugged segments.

CONCLUSION

This study introduces the first XCAT-based anthropomorphic lung phantom specifically designed to model COPD, featuring controlled pathological characteristics for evaluating CT technologies. While PCCT offers superior resolution in its standard NR mode, SHR mode offers further advantage in quantifying clinically relevant biomarkers for pulmonary disease.

CLINICAL RELEVANCE/APPLICATION

Task-specific phantoms enable objective comparison of CT technologies for disease-specific imaging. SHR mode demonstrated a major advantage over NR mode in quantifying COPD biomarkers, emphasizing its clinical significance in thoracic imaging and management.

M3-SSPH05-1 SYNERGISTIC INTEGRATION OF AI MATERIAL DECOMPOSITION AND DENOISING IN LOW-ENERGY VIRTUAL MONOENERGETIC CTIMAGING FOR IMPROVED TISSUE CONTRAST AND DELINEATION

Kevin J. Treb, PhD (*Presenter*)
Hao Gong, PHD (*Abstract Co-Author*)
Ahmed O. El Sadaney, MBBCh (*Abstract Co-Author*)
Avinash Nehra, MD (*Abstract Co-Author*)
Joel G. Fletcher, MD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)

PURPOSE

To utilize two cascaded AI modules that capture complementary image features in spatial and energy domains for low-energy virtual monoenergetic imaging (VMI) with reduced noise and improved tissue delineation.

METHODS AND MATERIALS

Fourteen patients underwent contrast enhanced CT of the pelvis using a dual energy protocol on a commercial photon counting detector CT (NAEOTOM Alpha, Siemens). Images were reconstructed with a 180 mm field of view using a quantitative kernel (Qr60) with iterative reconstruction and a slice thickness of 0.6 mm. In one AI module, images were denoised using a modified version of an image-based convolutional neural network (CNN) denoiser (GARNET) trained on an independent subset of patient images using subtraction of adjacent image slices as estimates of patient-specific noise. In the other AI module, low and high energy images were fed into the previously developed AI generalizable algorithm for multi-energy CT (AGATE). AGATE uses a CNN trained on images of phantom material inserts to capture texture and material composition features in the energy domain. The network was modified to output 40 keV VMIs. Two cascaded frameworks were investigated by switching the order in which AGATE and GARNET were applied. Output images from the cascaded frameworks were reviewed by two radiologists and compared to commercial 40 keV VMIs reconstructed directly on the scanner and output images from each AI module individually.

RESULTS

Commercial 40 keV VMI showed noticeable artifacts and unnatural low frequency noise texture. AGATE (energy domain material quantification) images had more natural noise texture, substantially reduced artifacts, and improved tissue delineation, but marginally increased image noise (3.1%) compared to commercial VMI. Applying GARNET (spatial domain denoiser) directly to commercial VMI reduced noise by 7.5% but could not reduce artifacts or address the unnatural noise texture. With the cascaded frameworks, output images had improved tissue delineation and noise reductions of 51.6% (AGATE then GARNET) to 61.9% (GARNET then AGATE) compared to commercial VMI. Qualitative results were confirmed by the radiologist readers.

CONCLUSION

Two AI modules operating in complementary domains improved different aspects of image quality (noise, artifacts, contrast). Cascading the models synergistically improved their respective performance beyond that achieved by the individual models.

CLINICAL RELEVANCE/APPLICATION

Low-energy VMIs can greatly improve iodine contrast but can increase noise and artifacts. Cascading AI models can synergistically address these limitations and could enable routine use of low-energy VMIs to address a major limitation in CT, soft-tissue contrast, to open new opportunities for CT imaging.

M3-SSPH05-2 MEASUREMENT-BASED SPECTRAL DEEP SCATTER ESTIMATION FOR PHOTON-COUNTING CT

Lukas Hennemann, MSc (*Presenter*)
Julien Erath, MSc (*Abstract Co-Author*)
Andreas Heinkele, MSc (*Abstract Co-Author*)
Joscha Maier, PhD (*Abstract Co-Author*)
Eric Fournie (*Abstract Co-Author*)
Martin Petersilka, PhD (*Abstract Co-Author*)
Karl Stierstorfer, PhD (*Abstract Co-Author*)
Marc Kachelriess, PhD (*Abstract Co-Author*)

PURPOSE

To develop a Monte Carlo (MC)-free, scanner-specific deep scatter estimation (DSE) algorithm that may also utilize the energy threshold information of clinical photon-counting CT (PCCT).

METHODS AND MATERIALS

Many neural network-based scatter correction methods, such as the originally proposed DSE, rely on MC simulations that are unlikely to account for inaccuracies inherent to the scanner hardware. We propose a novel approach that avoids the need for scanner specific MC simulations. We introduce the measurement-based spectral deep scatter estimation (mbsDSE), a U-Net (that also utilizes spectral information from energy thresholds), to estimate scatter. Measuring scatter rather than simulating has the advantage that we capture the scanner's true scatter properties, including backscatter and other types, as well potential inaccuracies inherent to the scanner hardware. For training mbsDSE, we employed measured data from a NAEOTOM Alpha.Peak PCCT scanner. Single source scans with 140 kV, 400 mAs, 0.5 s scan time and two energy thresholds were performed using different phantoms in order to capture a large variety of scatter distributions. The scans were conducted with narrow (6×0.4 mm) and with full collimation (144×0.4 mm). The difference between the two scan configurations served as the scatter label. Our mbsDSE approach was tested on a circular scan of a semi-anthropomorphic thorax phantom using the same PCCT scanner. Image quality of mbsDSE was quantified and compared to the convolution

kernel-based scatter correction method according to the pep model of Ohnesorge et al. The ability to correct high frequency scatter artifacts such as those occurring with coarse anti-scatter grids (ASG) in the PCCT scanner, was also investigated.

RESULTS

With mbsDSE, the MAE can be reduced from 14.7 HU in the uncorrected case to 2.5 HU. In comparison, the pep model only achieves an MAE of 10.6 HU. Additionally, mbsDSE is capable of nearly eliminating high-frequency scatter artifacts, which cannot be addressed by conventional methods. It also delivers better results than the pep approach (MAE 17.9 HU) for spectral applications (50 keV VMI), with an MAE reduction from 24.7 HU to 7.2 HU.

CONCLUSION

By using measured data to train the DSE, the network is able to correct for scatter artifacts better than other existing methods. This also applies to spectral applications. This approach potentially enables the correction of artifacts that are difficult or nearly impossible to model accurately using MC simulations.

CLINICAL RELEVANCE/APPLICATION

Diagnostic image quality is significantly improved with mbsDSE, which makes use of the photon energy information and of measured scanner-specific imperfections that can cause artifacts not accounted for by conventional methods.

M3-SSPH05-3 ACCURACY OF VIRTUAL NON-CONTRAST IMAGING IN PHOTON-COUNTING DETECTOR CT: A COMPARATIVE EVALUATION WITH THIRD-GENERATION DUAL-SOURCE ENERGY-INTEGRATING DETECTOR CT

Kazuki Ishikawa (*Presenter*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Tomoki Maebayashi (*Abstract Co-Author*)
Kiyosumi Kagawa (*Abstract Co-Author*)
Takashi Okunaga (*Abstract Co-Author*)
Noriyuki Negi, RT (*Abstract Co-Author*)
Akiko Kusaka, RT (*Abstract Co-Author*)
Kentaro Nishiuchi (*Abstract Co-Author*)
Yoshiko Ueno, MD, PhD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

PURPOSE

Virtual non-contrast (VNC) imaging in multi-energy CT has the potential to reduce radiation exposure and streamline workflow by replacing true non-contrast (TNC) imaging. Photon-counting detector CT (PCD-CT) may further enhance the clinical utility of VNC by enabling retrospective spectral analysis offering flexible protocol design. However, clinical implementation of VNC requires sufficient image accuracy, and thus validation of its performance is essential. This study aimed to compare the accuracy of VNC images generated from PCD-CT with energy-integrating detector CT (EID-CT).

METHODS AND MATERIALS

We retrospectively analyzed quadriphasic liver dynamic CT scans from 32 patients scanned with EID-CT (SOMATOM Force) and 31 with PCD-CT (NAEOTOM Alpha) using identical imaging protocol. Energy separation was assessed using the low-to-high attenuation ratio (L/H ratio), calculated from aortic CT values in low- and high-energy images during the arterial phase (AP). Accuracy of VNC was evaluated by comparing CT values of the liver, spleen, kidneys, and aorta on VNC images derived from AP, portal venous phase (PVP), and equilibrium phase (EP) with corresponding values on TNC images. Equivalence between VNC and TNC was assessed using the two one-sided test (TOST) with a predefined equivalence margin of ±10 Hounsfield Units (HU). For each patient, root mean square error (RMSE) was calculated for each phase based on organ-wise differences between VNC and TNC images and compared.

RESULTS

L/H ratio was higher in EID-CT (2.23 ± 0.06) than in PCD-CT (1.92 ± 0.06), indicating greater energy separation (Welch's t-test, $P < .001$). TOST showed statistical equivalence between VNC and TNC images for all phases and organs in the PCD-CT group ($P < .01$, except for the aorta in the AP ($P = .019$) and the kidneys in the EP ($P = .015$)). In the EID-CT group, statistical equivalence was observed across all phases and organs ($P < .01$), except for the aorta in the PVP ($P = .530$) and EP ($P = .928$). RMSE for EID-CT were 5.7 ± 2.0 HU (AP), 6.9 ± 2.0 HU (PVP), and 7.2 ± 2.2 HU (EP), and for PCD-CT were 6.3 ± 2.5 HU, 5.8 ± 2.1 HU, and 6.5 ± 2.0 HU, with Welch's t-test showing no significant difference in AP ($P = .272$) and EP ($P = .150$), but a significant difference in PVP ($P = .048$).

CONCLUSION

PCD-CT demonstrated superior VNC accuracy compared to EID-CT, achieving statistical equivalence with TNC images within a ±10 HU margin across all evaluated phases and organs, despite exhibiting smaller energy separation.

CLINICAL RELEVANCE/APPLICATION

PCD-CT achieved comparable or superior VNC accuracy compared with EID-CT. With its capability for flexible protocol design and retrospective analysis, PCD-CT has potential to expand the clinical utility of VNC imaging beyond those achievable with conventional EID-CT.

M3-SSPH05-4 NUMERICAL BIAS ESTIMATOR OF TWO BASIS MATERIAL DECOMPOSITION IN SPECTRAL CT

Olivia Sandvold, BS (*Presenter*)
Roland Proksa (*Abstract Co-Author*)
Amy Perkins (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

To enhance the clinical utility of spectral data, such as the use of iodine as a biomarker, it is essential to minimize bias in clinical imaging protocols. This study introduces a flexible statistical framework for quantifying bias in material decomposition basis domains derived in spectral CT.

METHODS AND MATERIALS

The central ray incident X-ray spectrum was modeled from a clinical-grade X-ray tube (Philips Healthcare) with a tube voltage of 120 kVp and a tube current of 50 mA. CZT photon-counting detector bins were derived using realistic responses for a 20 cm PMMA phantom with 10 mm of 2 mg/mL iodine to replicate a contrast-enhanced scan. A 20 keV electronic noise excluding threshold was set, and a second bin threshold was varied from 40-110 keV. We set a sufficiently high photon count and applied the Cramér-Rao lower bound (CRLB) to estimate the lowest achievable variance (s 2) in the iodine and PMMA domains. Then, 250 biased line projection values, ±6s around each expected path length, were generated to encompass >99.9% possible material path lengths. The expected detector data for each pair of biased projections (B 1 , B 2) was determined. Next, the likelihood of obtaining the pair of biased values was computed as the product of the probability of obtaining each individual, independent biased line integral value. A 2D map was generated by plotting the joint likelihood probabilities for each pair of biased line estimates. The x and y center of mass values of the joint likelihood map represented the expected biased B 1 iodine and B 2 PMMA measures. The material bias for each basis was computed as the difference between B 1 and B 2 values and respective expected B 1 and B 2 values.

RESULTS

Both CRLB and bias estimators had worse performance towards the extremes of the tested threshold levels. The iodine domain biases were at a minimum using a 101 keV bin threshold. In contrast, iodine CRLB noise was minimized at 66.9 keV. The estimated noise-induced bias per mg/mL using this threshold was 0.7 mm, implying an expected minimum of 0.7 mm error for every 1 mg/mL iodine. The minimum bias estimate error was 8.7x10 -3 mm per mg/mL.

CONCLUSION

This numerical bias estimator provides a statistical method for estimating spectral quantitative bias without the need for time-consuming simulations. Our results demonstrate that the optimal bin threshold determined by bias minimization differs from that derived through noise minimization, highlighting a key tradeoff in system design.

CLINICAL RELEVANCE/APPLICATION

In the context of clinical imaging, balancing quantitative accuracy and noise is essential. Our model addresses this challenge by offering a tool for researchers to optimize system parameters and design CT acquisition strategies that minimize bias—even in the presence of quantum noise.

PURPOSE

The GLIAA trial evaluated the efficacy and safety of re-irradiation in patients with recurrent glioblastoma (rGBM), using target volume delineation based on either O-(2-[18F]fluoroethyl)-L-tyrosine (FET)-PET or contrast-enhanced T1-weighted MRI (T1Gd-MRI).

METHODS AND MATERIALS

This prospective, multicenter, randomized trial included patients with in-field rGBM (lesion size 1-6 cm) visible on both FET-PET and T1Gd-MRI. Histological confirmation of glioblastoma was required either at initial diagnosis or at recurrence. All patients had received prior radiotherapy (59.4-60 Gy) at least 6 months before enrollment. Re-irradiation was delivered via high-precision stereotactic radiotherapy with a total dose of 39 Gy (3 Gy per fraction, 5 fractions/week). Tumor response was monitored with MRI, and suspected progression was verified via FET-PET or histology when feasible. The primary endpoint was progression-free survival (PFS); secondary endpoints included overall survival (OS), local control (LCS), recurrence patterns, and toxicity.

RESULTS

Between November 26, 2013, and September 2, 2021, 200 patients were randomized. Of these, 98 in the FET-PET arm and 97 in the T1Gd-MRI arm were treated per protocol. The cohort included first, second, and third recurrences; 54% of tumors were multifocal. Mean tumor volume was 10.9 ± 11.2 ml. Chemotherapy (allowed from April 2019) was administered to 41 patients. Median PFS was 4.2 months (95% CI: 3.8-5.3), median OS was 9.2 months (95% CI: 8.3-10.3), and median LCS was 6.5 months (95% CI: 6.1-7.1). The 12-month local control rate was 21%. Patients with tumors =3 cm showed significantly improved outcomes in PFS (HR = 0.64; p = 0.03), OS (HR = 0.50; p = 0.001), and LCS (HR = 0.48; p = 0.0006). Recurrence patterns included in-field (46.2%), out-of-field (29.9%), and marginal (17.9%) relapses. CTCAE grade 3-4 radiotherapy-related adverse events occurred in 11 patients within 90 days of treatment and in 10 patients thereafter. Radiation necrosis was observed in 23.6% of cases and was associated with a trend toward better prognosis (HR = 0.75; p = 0.12).

CONCLUSION

The GLIAA trial confirms that stereotactic re-irradiation with 39 Gy is a safe and feasible treatment for rGBM. It provides meaningful local tumor control with acceptable toxicity. Radiation necrosis may serve as a potential prognostic marker in this setting.

CLINICAL RELEVANCE/APPLICATION

FET-PET- and MRI-based re-irradiation achieves a 6-months locally controlled survival in rGBM and is a safe treatment option.

M3-SSRO02-2 GUARD: A GLIOMA UNIFIED AI-DRIVEN RADIOTHERAPY DECISION SYSTEM

Zihan Wang, MMEd, PhD (*Presenter*)
Yinyan Wang, MD (*Abstract Co-Author*)

PURPOSE

To develop and validate a machine learning system that non-invasively predicts radiotherapy sensitivity in low-grade glioma (LGG), enabling personalized treatment planning.

METHODS AND MATERIALS

Multi-sequence MRI data were collected from six centers at four time points: preoperative, postoperative, pre-radiotherapy(RT), and post-RT. Images were preprocessed using SimpleITK, and tumors were manually segmented in MRIcron. Radiomic features were extracted using PyRadiomics. Radiotherapy sensitivity was evaluated using RANO-LGG criteria. An XGBoost model integrating radiomic and clinical features was constructed, with SHAP analysis for interpretability. Imaging-genomic data from TCGA and CGGA were analyzed using GO and GSEA to explore underlying pathways. The prognostic value of the model was further assessed by Kaplan-Meier survival analysis.

RESULTS

This study reviewed 13,690 LGG patients who underwent craniotomy or stereotactic biopsy at the primary research center between 2008 and 2023. Of these, 963 patients who received postoperative radiotherapy and had complete imaging follow-up were selected, with 11,556 MRI scans collected to develop the GUARD model. Additionally, 1,764 MRI scans from 147 LGG patients across five independent clinical centers were used for external test. A prospective cohort of 328 patients with 3,936 MRI images served as the prospective test set. The GUARD model achieved prediction AUCs of 0.948, 0.911, 0.892, and 0.915 for the training, internal validation, external test, and prospective test sets, respectively. SHAP analysis identified residual tumor, age, and radiomic features such as T2W texture roughness and T1WC pixel intensity changes as key contributors. Radscore-based group analysis showed tumors in the low Radscore group (low RT sensitivity) were enriched in pathways like oxidative phosphorylation, fatty acid metabolism, hypoxia, and DNA damage repair, while those in the high Radscore group (high RT sensitivity) showed downregulation in these pathways. Patients in the high Radscore group also had significantly longer overall survival.

CONCLUSION

GUARD enables accurate preoperative prediction of radiotherapy sensitivity in LGG based on multicenter imaging and clinical data. With robust performance, interpretability, and generalizability, it offers a promising tool for personalized radiotherapy planning in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Leveraging large-scale, multicenter imaging and clinical data, the GUARD model offers accurate, robust, and generalizable preoperative prediction of radiotherapy sensitivity in LGG. This tool holds potential to guide individualized radiotherapy strategies and improve clinical outcomes in glioma care.

M3-SSRO02-3 DEVICE-AWARE SYNTHETIC CT VIA MULTITASK LEARNING FOR IMPROVED MR-ONLY CNS RADIOTHERAPY PLANNING

Ho-Hsin Chang, BS (*Presenter*)
Rex Cardan, PHD (*Abstract Co-Author*)
Sandeep Bodduluri, MS, PhD (*Abstract Co-Author*)
Samantha Simiele (*Abstract Co-Author*)
Joseph Harms, PHD (*Abstract Co-Author*)
John B. Fiveash, MD (*Abstract Co-Author*)
Richard A. Popple, PhD (*Abstract Co-Author*)
Carlos E. Cardenas, PhD (*Abstract Co-Author*)

PURPOSE

Synthetic CT (sCT) predicts Hounsfield Unit information (HU) from MR images, eliminating the need for separate CT in radiotherapy (RT) planning. MR-only workflows reduce registration errors and streamline planning. However, immobilization devices used during CT-based simulation are not visible on MR, limiting the fidelity of MR-derived sCTs. In brain RT, differences in neck position between MR and CT further challenge accurate sCT generation. We developed a multi-task deep learning framework to generate sCTs and segment immobilization devices and organs-at-risk, enabling sCTs that better mimic CT setups for accurate planning.

METHODS AND MATERIALS

We developed a multi-task 3D U-Net framework based on nnU-Net and nnDoseNet, with adaptive training configured by dataset, task, and hardware. The multi-task architecture includes a shared encoder with task-specific decoders for simultaneous sCT prediction and ROI segmentation. MR images from the TCIA GLIS-RT dataset were rigidly registered and resampled to the corresponding CT grid. The paired MR-CT images were split into 164 training, 40 validation, and 25 test cases. Both models used identical hyperparameters (e.g., 200 epochs, batch size of 3 and patch size of [40, 160, 224]), differing only in decoder structure and loss function. The multi-task loss combined structural similarity index measure (SSIM) and mean-square error (MSE) for sCT regression and Dice loss for segmentation.

RESULTS

Among test cases, when compared to the ground truth CT scans, single-/multi-task sCT showed mean-absolute error (MAE) of 14.79/14.93 and SSIM of 0.97/0.97 overall; 20.5/19.74 MAE and 0.93/0.93 SSIM within ROIs; and 331.22/314.33 MAE and 0.56/0.55 SSIM for the skull (outside ROIs). Overall, the multi-task model performed slightly better across all regions.

CONCLUSION

We found ROIs segmentation supports sCT prediction. Improving skull prediction in sCT is essential for accurate patient-to-couch localization and dose calculation in MR-to-plan RT workflows.

CLINICAL RELEVANCE/APPLICATION

This work advances brain MR-only radiotherapy by improving synthetic CT generation and incorporating immobilization device segmentation, addressing MR/CT neck position mismatch to enable more accurate localization and dose calculation for clinical implementation.

M3-SSRO02-4 SAFETY OF CONCURRENT HER-2 ANTIBODY DRUG CONJUGATES WITH SINGLE ISOCENTER MULTI-FRACTION SRS FOR BRAIN METASTASES

Swati Baskiyar (*Presenter*)
Luke Moradi (*Abstract Co-Author*)
Richard A. Popple, PhD (*Abstract Co-Author*)

Christopher D. Willey, MD, PhD (*Abstract Co-Author*)
Drexell Boggs (*Abstract Co-Author*)
John B. Fiveash, MD (*Abstract Co-Author*)

PURPOSE

HER2-targeted therapies have improved outcomes in patients with breast cancer, including those with brain metastases. Antibody drug conjugates including trastuzumab emtansine (Kadcyla) and fam-trastuzumab deruxtecan (Enhertu) offer systemic disease control as well as some degree of intracranial activity. Prior studies have found mixed risk of toxicity and have not fully explored safety with fractionated SRS regimens (fSRS) for larger brain metastases. This study evaluates whether receipt of HER2-targeted mAb drug conjugate within one year of fSRS is associated with an increased incidence of Grade 3 or higher central nervous system (CNS) toxicity.

METHODS AND MATERIALS

We conducted a retrospective review of breast cancer patients treated with SRS for brain metastases from 2015 to 2022. The use of fSRS was up to the physician's discretion and was typically utilized when courses included tumors >2 cm in diameter or in eloquent locations. All tumors were treated with one prescription regardless of size to facilitate single isocenter treatment. The primary endpoint was to compare the incidence of Grade 3 or higher CNS toxicity from tumors treated with and without concurrent Her-2 targeted therapy. Concurrent was defined as HER-2 antibody drug conjugate within 12 months of SRS. Toxicity was assessed on a per-tumor basis using CTCAE v5.0 criteria. Freedom from toxicity was estimated using Kaplan-Meier analysis.

RESULTS

278 brain tumors treated with SRS from 50 patients with breast cancer were identified. There were 87 tumors from 25 patients that were HER-2 positive. HER-2 targeted therapy was delivered concurrently with 44 tumors. The median follow-up was 10 months. A total of six Grade 3+ toxicity events occurred, with only one event in the concurrent group. One-year freedom from toxicity was not significantly different between patients receiving HER2-targeted therapy and those who did not (100% vs. 96%, p = 0.746).

CONCLUSION

The concurrent use of Enhertu or Kadcyla with fSRS for brain metastases from HER2-positive breast cancer was not associated with an increased risk of high-grade CNS toxicity. These findings support the continued use of HER-2antibody drug conjugates without interruption during fSRS.

CLINICAL RELEVANCE/APPLICATION

The findings of this study demonstrate that Enhertu or Kadcyla can be safely administered alongside fSRS. This would allow for continuous patient treatment without compromising safety or treatment interruptions.

M3-SSRO02-5 QUANTIFYING THE BENEFIT OF PLANNING MRI OVER DIAGNOSTIC MRI IN SRS: A PAIRED ANALYSIS

Lakshmi Rekha Narra, MD (*Presenter*)
Taoran Cui, PHD (*Abstract Co-Author*)
Ritesh Kumar, MBBS,MD (*Abstract Co-Author*)
Zohaib Sherwani, MD (*Abstract Co-Author*)
Swati Mamidanna (*Abstract Co-Author*)
Chengzhu Zhang, PhD (*Abstract Co-Author*)
Mihir Patel, MD (*Abstract Co-Author*)
Imraan Jan (*Abstract Co-Author*)
Matthew P. Deek, MD (*Abstract Co-Author*)

PURPOSE

Stereotactic Radiosurgery (SRS) is a preferred modality to treat brain metastases due to its submillimeter accuracy in dose delivery. This precision requires dedicated planning MRI protocols with thin slices (1-1.5mm), independently acquired in all planes for optimal tumor volume delineation. While dedicated SRS planning MRI(s-MRI) offers higher spatial resolutions than standard diagnostic MRI (d-MRI), its clinical utility in terms of lesion detection and volumetric accuracy is not well quantified in real world cohorts. We aimed to evaluate the added value of dedicated SRS Planning MRI by comparing the number of detected lesions and lesion-level volumetric variability with standard d-MRI.

METHODS AND MATERIALS

Patients with Brain Metastases who underwent both d-MRI and s-MRI were retrospectively reviewed. Both d-MRI and s-MRI were acquired using the same contrast enhanced T1-weighted sequence, however with 5-6 mm and 1mm slice thicknesses, respectively. For each patient, metastases were independently identified and contoured on both MRIs. Difference in number of metastases detected was assessed using the Wilcoxon signed-rank test. Intact lesions visible only on d-MRI were contoured separately both on d-MRI and s- MRI, and volumetric data for each lesion is extracted from eclipse treatment planning system. For each lesion, both mean volume and volumetric difference from both MRI's were calculated. Bland-Altman Analysis was used to plot the volumetric variability.

RESULTS

Among twenty patients who underwent both d-MRI and s-MRI, the median age was 65 years (IQR, 61-72). Lung cancer was found to be the primary in (40%, n=8) followed by melanoma (25%, n=5). The median interval between the scans was 17 days (IQR, 13-23). Thin slice (~1mm) acquisitions were present in the diagnostic MRI protocol in 45% of patients (n=9). The difference in count and median number of brain metastases was 2 (IQR: 2-4) on d-MRI and 2 (IQR: 2-5) on s-MRI (p=0.058). Forty-seven intact brain metastases were contoured on both d-MRI and s-MRI. Bland-Altman analysis demonstrated a mean bias of -0.37cc (d-MRI - s-MRI) with 95% limits of agreement from -5.58 cc to 4.83 cc.

CONCLUSION

Lesion count was numerically higher on dedicated planning MRI (s-MRI) suggesting potential benefit in detecting more number of smaller metastatic lesions. Standard diagnostic MRI has shown to underestimate the target volume up to 0.37 cc. A larger sample size is needed to validate these findings. Future work will include larger sample size, assess tumor volume variability between stealth protocol and s-MRI, and evaluate the impact of image distortion on target delineation between 3T and 1.5T scanners.

CLINICAL RELEVANCE/APPLICATION

Stereotactic Radio Surgery

PURPOSE

To evaluate the impact of hippocampal avoidance (HA) in the context of whole brain radiotherapy (WBRT) with a simultaneous integrated boost (SIB) on neurocognitive function and intracranial disease control in patients with multiple brain metastases.

METHODS AND MATERIALS

This double-blind, randomized, prospective multicenter study (DRKS00004598) included patients with 4-10 brain metastases (=5 mm), recruited from 13 institutions across Germany. Participants were randomized 1:1 to receive either WBRT with SIB and hippocampal avoidance (HA-WBRT+SIB; Arm A) or WBRT with SIB without hippocampal sparing (Arm B). The treatment regimen involved 30 Gy WBRT, supplemented by a SIB of 51 Gy to metastases and 42 Gy to brainstem lesions or resection cavities, delivered over 12 fractions (5x/week). The primary outcome was neurocognitive performance at 3 months post-treatment, assessed via the Verbal Learning and Memory Test (VLMT). Secondary endpoints included neurocognitive status at 9 and 18 months, emotional well-being (anxiety, depression), quality of life, and oncologic efficacy.

RESULTS

Out of 170 enrolled patients, 136 were randomized to Arm A (n=67) or Arm B (n=69). At 3 months, 38 patients in Arm A and 42 in Arm B met criteria for primary endpoint analysis. There was no significant difference in verbal learning performance between arms ($p = 0.83$). Both groups demonstrated a decline in VLMT scores at 3 months. At 9 months, cognitive function improved in both arms, with a favorable trend in Arm A. By 18 months, cognitive performance returned to baseline across both groups. HA-WBRT+SIB was associated with lower depression scores at 3 months ($p = 0.047$) and 18 months ($p = 0.048$). One-year distant brain progression rates were 22% in both arms, while local progression was 4% in Arm A vs. 12% in Arm B. Time to hippocampal recurrence did not differ significantly ($p = 0.98$). Neurological mortality at one year was lower in Arm A (4%) compared to Arm B (12%). Treatment-related serious adverse events were observed in 3% (Arm A) and 6% (Arm B).

CONCLUSION

In patients with multiple brain metastases, the integration of hippocampal avoidance into WBRT+SIB was safe and associated with reduced rates of depression and comparable neurocognitive recovery. Oncological outcomes remained robust, with lower local failure and neurological death rates observed in the HA group.

CLINICAL RELEVANCE/APPLICATION

These findings support the clinical feasibility and potential neuroprotective benefit of HA-WBRT+SIB for multiple brain metastases.

M3-STCE1-1 "QUADRUPLE-LOW" CORONARY CT ANGIOGRAPHY WITH DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHMFOR PATIENTS WITH HIGH BMI: IMAGE QUALITY AND DIAGNOSTIC PERFORMANCE ASSESSMENT

Ke Qi (*Presenter*)
Jie Liu (*Abstract Co-Author*)
Luotong Wang (*Abstract Co-Author*)

PURPOSE

This study aims to investigate the feasibility of the "quadruple-low" protocol, which involves reducing radiation dose, contrast media (CM) volume, injection rate, and CM concentration, in the context of CCTA utilizing DLIR algorithm to evaluate image quality and diagnostic performance of the degree of coronary artery stenosis in patients with a high BMI.

METHODS AND MATERIALS

This prospective study comprised 180 patients underwent CCTA with BMI = 26 kg/m². Patients were randomly allocated into three distinct groups: SDCT group utilized a tube voltage of 100 kVp with adaptive statistical iterative reconstruction (ASIR-V) and received a CM dosage of 245 mgI/kg (Iohexol, 350 mgI/mL) in 10s injection duration; Both the triple-LDCT group and the quadruple-LDCT group employed a tube voltage of 80 kVp with DLIR and received a CM dosage of 128 mgI/kg in 7s injection duration. The CM concentration was 350 mgI/mL(Iohexol) in the triple-LDCT group and was 320 mgI/mL (320 mgI/mL) in the quadruple -LDCT group. Image quality was graded based on the SNR, CNR, and on a Likert scale of 1-5. Furthermore, the diagnostic performance of the degree of coronary artery stenosis based on CCTA was evaluated using ICA as the reference standard including sensitivity, specificity, PPV, NPV, and diagnostic accuracy.

RESULTS

Compared with the SDCT group, the DLP was reduced by 32.5%, the CM volume was reduced by 41.5% , the CM flow rate was reduced by 14.5% and the CM concentration was reduced by 8.6% in the quadruple-LDCT group. The quadruple-LDCT achieved a significantly higher SNR, CNR, and subjective image quality (all $p<0.05$). The diagnostic performance of the triple-LDCT group was the highest. The DLP was reduced by 32.5%, the CM volume was reduced by 47.5% and the CM flow rate was reduced by 23.5% in the triple-LDCT group compared with the SDCT group. The triple-LDCT achieved a significantly higher SNR and CNR, while the subjective image quality and diagnostic performance were comparable between the triple-LDCT group and the SDCT group.

CONCLUSION

The 80 kVp CCTA with a 7s duration with iodine load of 128 mgI/kg assisted by DLIR could significantly reduce radiation exposure, CM volume, CM injection rate and CM concentration while improving image quality and diagnostic performance of coronary artery stenosis compared to the conventional 100 kVp protocol in overweight patients.

CLINICAL RELEVANCE/APPLICATION

Both the triple-LDCT and quadruple-LDCT groups, using 80 kVp, the deep learning iterative reconstruction algorithm, and optimized CM protocols, achieved higher image quality. These improvements were made without compromising diagnostic performance for detecting significant coronary artery stenosis, ensuring reliable results for high-BMI patients.

M3-STCE1-2 INDIRECT DEUTERIUM EXCHANGE IMAGING FOR NON-INVASIVE HIGH-RESOLUTION CSF PRODUCTION MAPPING

Arash Nazeri, MD (*Presenter*)
Debolina De (*Abstract Co-Author*)
Helia Hosseini, MD (*Abstract Co-Author*)
Nicholas Bateman (*Abstract Co-Author*)
Shelei Pan (*Abstract Co-Author*)
James D. Quirk, PhD (*Abstract Co-Author*)
Jennifer Strahle (*Abstract Co-Author*)

PURPOSE

Cerebrospinal fluid (CSF) is crucial for brain homeostasis and waste clearance; its disruption impairs brain fluid dynamics, contributing to neurological disease. Existing non-invasive CSF MRI methods often use indirect proxies, miss cumulative production, and have limited spatial resolution/signal-to-noise ratio. We used deuterium oxide (D 2 O) as an IV negative contrast agent and water analog, where 1H-MRI signal loss is proportional to its displacement of new CSF water.

METHODS AND MATERIALS

Twenty-four male Sprague Dawley rats (4-7 mo) were grouped: D 2 O (n=7); Acetazolamide (ACZ)/D 2 O (n=9); H2O controls (n=8). The ACZ/D 2 O group received IP ACZ (40mg/kg) pre-D 2 O infusion to suppress CSF production. Controls received an equivalent IV dose of H 2 O saline. High-resolution 3D balanced steady-state free precession (b-SSFP; 110 μm3 voxel size) was acquired on a 9.4T Bruker MRI before and after D 2 O infusion to detect deuterium-related CSF signal changes. Global % signal reduction from D 2 O displacement was computed from pre/post-infusion images in segmented CSF. Region-of-interest (ROI) analysis used a custom CSF atlas.

RESULTS

IV D 2 O induced marked signal attenuation within the CSF compared to control rats receiving H 2 O (first dose: 10.0% [SD: 2.3%] vs. 2.0% [SD: 3.1%], $p = 2.1 \times 10$-4; second dose: 6.3% [SD: 2.3%] vs. 0.7% [SD: 2.4%], $p = 5.2 \times 10$-4). Rats pretreated with ACZ demonstrated intermediate signal loss following D 2 O infusion (first dose: 5.6% [SD: 1.7%]; second dose: 3.6% [SD: 1.4%]), consistent with partial inhibition of CSF production. Follow-up ROI analysis across 13 ventricular and cisternal compartments revealed a similar pattern of group-wise signal attenuation, with the ACZ group exhibiting intermediate reductions between the D 2 O and H 2 O groups.

CONCLUSION

These findings establish deuterium displacement exchange imaging as a feasible high-resolution, non-invasive method for assessing CSF production and its pharmacological modulation. Future work will refine quantification and explore applications in various brain disorders.

CLINICAL RELEVANCE/APPLICATION

Future studies are needed to refine quantitative, dynamic CSF production mapping and apply this methodology to elucidate CSF production abnormalities underlying neurofluid disorders.

M3-STCE2-2 PHOTO-TRIGGERED ENGINEERED MICROBES FOR CT-GUIDED CANCER THERAPY

Chuyun Lou, PhD (*Presenter*)
Jianbo Gao, MD (*Abstract Co-Author*)

PURPOSE

Effective cancer treatment relies on the integration of precise imaging and targeted drug delivery. Computed tomography (CT) is widely used for cancer staging; however, adverse reactions to traditional contrast agents in some patients limit its application in personalized therapies. The emergence of Mo 1.33 C nanosheets, a two-dimensional material containing high atomic number molybdenum, offers new possibilities for CT imaging due to its excellent X-ray attenuation properties. In this study, we developed a photo-triggered engineered microbial system using tumor-targeting Escherichia coli to deliver Mo1.33C nanosheets to tumor sites, enabling precise CT-based localization. Additionally, Mo1.33C exhibits strong photothermal conversion capability under 808 nm NIR laser irradiation and can be loaded with the epigenetic drug 5-azacytidine (AZA), allowing image-guided photothermal-epigenetic immunotherapy. This multifunctional platform aims to advance image-guided precision cancer therapy.

METHODS AND MATERIALS

We compared Mo 1.33 C with iopromide at equal concentrations using GE Revolution CT to measure HU under identical keV settings. An engineered microbe (AM@Ec) was constructed using E. coli MG1655 to load Mo1.33C. In MFC tumor-bearing mice, PBS (control), Mo1.33C (M), or AZA-Mo1.33C@Ec (AM@Ec) was intravenously injected. CT scans were performed at 0, 2, 6, and 12 h post-injection using a small-animal CT system. Tumor ROI CT values were analyzed via PACS to assess in vivo imaging and accumulation.

RESULTS

Mo 1.33 C showed dose-dependent CT enhancement, with HU values linearly correlated with concentration. Below 5 mg/mL, Mo 1.33 C generated CT signals comparable to iopromide. In vivo, CT values at tumor sites increased from 48.65 ± 1.35 to 90.94 ± 4.30 HU in the M group and from 44.52 ± 0.83 to 265.31 ± 17.08 HU in the AM@Ec group at 12 h. This enhancement reflects E. coli -mediated targeting and accumulation. AM@Ec also enabled NIR-triggered epigenetic therapy, suppressing tumor growth and prolonging survival. H&E and blood analyses confirmed biosafety and biocompatibility.

CONCLUSION

AM@Ec enables tumor-targeted CT imaging and laser-triggered therapy with excellent biosafety, showing potential as a versatile contrast agent for real-time cancer monitoring.

CLINICAL RELEVANCE/APPLICATION

Compared to conventional CT agents, AM@Ec provides tumor-specific imaging with enhanced sensitivity and safe, multimodal functionality—supporting real-time, image-guided cancer therapy.

M3-STCE2-3 SPECTRAL CT-BASED NOMOGRAM FOR EVALUATION OF PD1PDL1INHIBITORS COMBINED WITH CHEMOTHERAPY RESPONSE IN GASTRIC CANCER

Songmei Fan, MD (*Presenter*)

PURPOSE

Objectives The value of spectral CT quantitative parameters in predicting the efficacy of PD-1/PDL1 inhibitor combined chemotherapy for gastric cancer was explored.

METHODS AND MATERIALS

From April 2022 to March 2025, a retrospective study enrolled 185 gastric adenocarcinoma patients who had undergone Spectral CT enhance scans prior to receiving PD-1/PDL-1 inhibitor combination therapy. According to IRECIST criteria, 73 patients (39%) were ultimately classified as the response group (CR and PR), while 112 patients (61%) were categorized as the non-response group (PD and SD).The data was divided into a primary set of 129 and a validation set of 56, maintaining a 7:3 random ratio.Measurements included iodine concentration (IC), normalized iodine concentration (nIC), CT40kev, CT70kev, CT100kev, CT140kev, spectral attenuation curve slope (?HU), and effective atomic number (Zeff) during non-contrast and venous phases (VP). Clinicopathologic characteristics were collected. Univariable and multivariable logistic regressions identi& 7;ed independent predictors of PD-1/PDL1 inhibitors combined with chemotherapy response. The model was visualized using nomograms, and its ef& 7;cacy was assessed via receiver operating characteristic (ROC) curves,Calibration curve, DCA curve.

RESULTS

R esults Multivariate logistic regression analysis identified tumor axial maximum thickness, ZeffAP, nICVP, and venous phase electron cloud density as independent predictors of response to PD-1/PDL1 inhibitor combination chemotherapy. The line plot incorporating all four independent predictors outperformed both spectral parameter models and clinical models. with the highest AUCs of auc 0.843 (95% CI: 0.773-0.912) for the primary set and 0.832 (95% CI: 0.711-0.950) for the validation set (DeLong test: all $p < 0.05$).The consistency between the response evaluation criteria in IRECISTand TRG was good, with a Kappa value of 0.628($p < 0.05$).The consistency between the response evaluation criteria in RECIST1.1and TRG was fair with a Kappa value of 0.469($p < 0.05$),It was visualized using Sangitutu.

CONCLUSION

The spectral CT and clinical models were useful in predicting Response of PD-1/PDL1 inhibitors to combined chemotherapy in gastric adenocarcinoma patients. Combining spectralCTimaging parameters and clinicopathologic characteristics in a nomogram improved predictive accuracy.

CLINICAL RELEVANCE/APPLICATION

This spectral CT-based nomogram is a non-invasive and easily obtainable tool for accurately predicting sdenocarcinoma of stomach response to PD-1/PDL1 inhibitors combined with chemotherapy , aiding clinicians in personalized treatment planning.

M3-STCE2-4 THE VALUE OF MULTI-PARAMETER EARLY PREDICTION OF LYMPH NODE METASTASIS AFTER NEOADJUVANT CHEMOTHERAPY IN GASTRIC CANCER BY NCT CT

Songmei Fan, MD (*Presenter*)

PURPOSE

To investigate the diagnostic value of energy spectrum CT multi-parameter in predicting lymph node metastasis (LNM) of gastric adenocarcinoma.

METHODS AND MATERIALS

This retrospective study retrospectively collected 107 patients with gastric adenocarcinoma undergoing concurrent surgery after neoadjuvant therapy from three medical centers. The patients were divided into a training set (n=74) and a validation set (n=33). Clinical, CT, and energy spectrum parameters were compared between the LNM(+) and LNM(-) groups. Parameters showing statistically significant differences were included in a multivariate logistic regression analysis to identify independent predictors. Clinical models, energy spectrum models, and a combined model (energy spectrum model + clinical model) using score fusion were established. The ROC curves were used to evaluate the predictive efficacy of each model for LNM in gastric adenocarcinoma, with AUC calculations and comparison of discrimination among models.

RESULTS

The training set comprised 36 cases with LNM(+) and 38 cases with LNM(-), while the validation set included 17 cases with LNM(+) and 16 cases with LNM(-). The AUC values for clinical model, energy spectrum model, and combined model in the training set were 0.82,0.89, and 0.94 respectively. In the validation set, these metrics stood at 0.87,0.81, and 0.93. Notably, the combined model demonstrated significantly better or marginally superior performance compared to single-model approaches in both training and validation datasets.

CONCLUSION

The energy spectrum model can effectively predict the lymph node metastasis after neoadjuvant chemotherapy for gastric cancer.

CLINICAL RELEVANCE/APPLICATION

Therefore, this study aims to analyze the application value of preoperative spectral CT quantitative parameters in predicting lymph node metastasis after neoadjuvant chemotherapy for gastric cancer, and provide noninvasive quantitative imaging basis for patient prognosis management.

M5-STCE1-1 SPECTRAL AI-BASED RECONSTRUCTION FOR CRANIAL SPECTRAL DETECTOR DUAL ENERGY CT IMPROVES IMAGE QUALITY BY ENABLING LOW KEV VIRTUAL MONOENERGETIC IMAGING FOR ROUTINE READING

Julia Maria Lueckel, MD (*Presenter*)
Lina Hieronymi (*Abstract Co-Author*)
Stephan Skornitzke (*Abstract Co-Author*)
Lukas Goertz (*Abstract Co-Author*)
David Zopfs, MD (*Abstract Co-Author*)
David C. Maintz, MD (*Abstract Co-Author*)
Nils Grosse Hokamp, MD, MBA (*Abstract Co-Author*)

PURPOSE

The advent of DECT has resulted in use of moderately low keV virtual monoenergetic imaging for routine reading of unenhanced cranial CT (e.g. 60/65 keV). These reconstructions demonstrated improved contrast without increasing noise or distortion of texture as compared to conventional iterative reconstructions. AI-based reconstruction has demonstrated its benefit in reconstruction of conventional images with similar advantages while spectral AI (SAI) -based reconstruction is unavailable to date. We evaluated a vendor provided late-prototype deep-learning based SAI reconstruction for conventional imaging and VMI.

METHODS AND MATERIALS

Retrospectively, 77 unenhanced cranial sdDECT exams were included in this IRB-approved study. HI-R (iDose, Philips), HI-65keV, SAI-R and SAI-VMI (40-200 keV) were reconstructed from the same data. Four regions-of-interest (ROIs) were placed in gray and white matter (GM and WM): thalamic/cortical frontoparietal and juxtacortical/internal capsule. Attenuation and standard deviation (SD) were averaged to calculate signal- and contrast-to-noise ratio (S-/CNR). SD was considered indicative of noise. Task-based image quality assessment included forced-choice ranking of GM-WM differentiation by two neuroradiologists. Statistics was carried out using ANOVA.

RESULTS

Attenuation in HI- and SAI-VMI was higher at 40-50 keV VMI as compared to HI- and SAI-R ($p=0.05$). Noise was lower for SAI reconstructions as compared to corresponding HI reconstructions in GM and WM (-R and -65keV: 3.58±0.48 vs. 5.10±0.69 and 4.03±0.52 vs. 4.46±0.64, $p=0.05$ respectively). Even SAI-50 keV yielded lower noise as compared to HI-R (4.43±0.66 vs. 5.10±0.69, $p=0.05$). This resulted in improvements of SNR for SAI reconstructions (e.g. WM for -R and -50keV: 8.37±1.21 vs. 5.91±0.87 and 7.06±0.95 vs. 5.94±0.96, $p=0.05$ respectively). CNR was superior in SAI-R compared to HI-R (1.80±0.34 vs. 1.27±0.26, $p=0.05$) and in SAI-VMI reconstructions (e.g. SAI-50 keV vs. HI-50 keV: 2.26±0.52 vs. 2.06± 0.48, $p=0.05$). Accordingly, readers rated assessment of GM-WM differentiation superior for SAI-R compared to HI-R and for SAI-VMI at 50 to 65 keV compared to HI-65 keV ($p=0.05$).

CONCLUSION

SAI reconstruction significantly reduces image noise in conventional imaging and VMI. Accordingly, SNR and CNR are superior in SAI compared to HI reconstructions for both, conventional imaging and VMI. These results are supported by significant increase in gray-white differentiation in qualitative reading in SAI reconstructions.

CLINICAL RELEVANCE/APPLICATION

By enhancing gray-white matter differentiation at reduced levels of image noise, SAI reconstructions allow for usage of lower keV virtual monoenergetic imaging in routine reading of unenhanced cranial sdDECT.

M5-STCE1-2 REAL-WORLD IMPLEMENTATION OF AI IN MRI: FIVE YEARS OF PRODUCTIVITY GAINS ACROSS A MULTISITE IMAGING NETWORK

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)
Juan Cruz Gallo, MD, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the operational and clinical impact of integrating AI-based reconstruction into MRI scanners across five imaging centers, focusing on scan time reduction, patient throughput, and year-over-year growth trends.

METHODS AND MATERIALS

From 2021 to 2025, AI algorithms were implemented in five MRI scanners (1.5T and 3T) across five branches. Custom protocols were developed to reduce acquisition time and enhance image quality. Optimization of acquisition protocols with AI was primarily focused on musculoskeletal (knee, shoulder, ankle) and neurological (brain, spine) regions, as these represent the majority of clinical indications in our imaging workflow. Moreover, these anatomical areas demonstrated the highest impact in scan time reduction, given their relatively long acquisition durations and the importance of patient comfort and image quality in these studies. A moderate level of noise reduction was deliberately selected to enhance image quality. Using more aggressive noise suppression would have maintained quality similar to pre-AI protocols, but the moderate setting allowed for both reduced scan time and improved image clarity. Annual MRI volume was tracked per site, comparing pre- and post-AI implementation trends. Growth patterns and ramp-up speed were analyzed based on the time each site had used AI.

RESULTS

Quantitative comparisons between conventional and AI-accelerated sequences showed time reductions of: Knee: from 8:27 to 4:39 minutes (? 46.9%) Spine: from 9:37 to 5:38 minutes (? 42.6%) Shoulder: from 12:30 to 4:42 minutes (? 64.0%) Ankle: from 17:32 to 6:26 minutes (? 63.9%) Brain: from 10:31 to 8:05 minutes (? 21.9%) The mean scan time reduction across all regions was 47.9%, supporting improved scheduling capacity while maintaining image quality. Volume growth post-AI implementation was observed across all sites. Increment of volumes per year, Post vs Pre IA. Location Pilar: year 2022, 16%; 2023, 43%; 2024, 67%; 2025, 80%.

Location Cabildo: year 2022, 16%; 2023, 43%; 2024, 67%; 2025, 80%. Location San Isidro: year 2024, 46%; 2025, 55%. Location Vicente Lopez: year 2024, 52%; 2025, 75%. Location Urquiza: year 2025, 43%. Earlier adopters showed steady year-over-year growth, while newer implementations achieved rapid volume increases within months.

CONCLUSION

AI implementation in MRI scanners led to significant scan time reduction and sustained increases in patient throughput. The ramp-up pattern varied depending on time since AI deployment, suggesting that early adoption enables sustained operational gains over time.

CLINICAL RELEVANCE/APPLICATION

AI implementation in MRI scanners led to significant scan time reduction and sustained increases in patient throughput

M5-STCE1-3 ARTIFICIAL INTELLIGENCE AS A STRATEGIC ALTERNATIVE TO MRI SCANNER REPLACEMENT: FINANCIAL AND OPERATIONAL IMPACT IN AGING SYSTEMS

Patricia M. Carrascosa, MD, PhD (*Presenter*)
Carlos Capunay, MD (*Abstract Co-Author*)
Juan Cruz Gallo, MD, MD (*Abstract Co-Author*)

PURPOSE

To compare the financial and operational outcomes of implementing artificial intelligence (AI) image reconstruction in MRI scanners over 10 years old versus replacing them with new equipment. This analysis focuses on capital efficiency, payback period, and return on investment (ROI).

METHODS AND MATERIALS

Three MRI scanners nearing the end of their expected 10-year lifespan were included. Two investment strategies were compared: AI Upgrade USD 150,000 per unit to install a deep-learning reconstruction algorithm. Scanner Replacement USD 800,000 per new 1.5T MRI scanner. All systems handled an average of 800 studies/month, with a reimbursement of USD 115 per study. AI implementation required temporary downtime of 1-2 weeks; full scanner replacement required 2-3 months of operational interruption. In replacement scenarios, potential upgrades to the RF shielding were also considered (USD 30,000-70,000).Operating costs (technologists, receptionists, physicians) and variables such as paper printing were modeled. Financial projections included three scenarios (optimistic, expected, pessimistic) over a 10-year horizon, using a 20.36% discount rate. Discount rate was determined using the CAPM model, considering a 5-year U.S. treasury rate (risk-free), S&P 500 average return (market), Argentina’s country risk premium (14.89%) at the moment of the analysis and unlevered beta for the healthcare sector from Damodaran.

RESULTS

The comparison of several metrics in expected scenarios between AI model and New scanner model demonstrate that: • Initial Investment, USD 150,000 vs USD 800,000 • Net Present value (NPV), USD 1,030,634 vs USD 325,579 • Internal rate of return (IRR), 120% vs 28% • Payback Period, 14 months vs 48 months • Downtime, 1-2 weeks vs 2-3 months • Infrastructure, no upgrades needed vs RF shielding (up to USD 70,000) • Monthly Exams (Yr 1 ? Yr 4), 2.880 ? 6.720 vs 2.880 ? 6.720 Across all scenarios, AI outperformed scanner replacement in terms of return and speed of capital recovery. The AI model maintained or improved imaging capacity and quality while avoiding costly infrastructure work and extended operational loss.

CONCLUSION

Upgrading older MRI scanners with AI reconstruction offers a high-yield, low-risk alternative to equipment replacement. This approach dramatically improves financial metrics (NPV, IRR, payback), minimizes downtime, and extends system longevity by another 10 years. AI-based upgrades represent a strategic and scalable solution for high-volume radiology centers aiming to optimize performance and delay capital reinvestment.

CLINICAL RELEVANCE/APPLICATION

AI-based upgrades represent a strategic and scalable solution for radiology centers aiming to optimize performance and delay capital reinvestment.

M5-STCE2-1 NON-CONTRAST DIFFUSION TENSOR IMAGING FOR GLYMPHATIC ASSESSMENT IN ALZHEIMER'S DISEASE AND MILD COGNITIVE IMPAIRMENT

Omar Moustafa Fathy, MD, PhD (*Presenter*)
Odette Ganem (*Abstract Co-Author*)
Hana Farzaneh (*Abstract Co-Author*)
Bashar S. Kako, MD (*Abstract Co-Author*)
Jeremy N. Ford, MD,MBA (*Abstract Co-Author*)

PURPOSE

To test whether a non-contrast diffusion tensor imaging (DTI) metric of glymphatic function—the Along-the-Perivascular-Space (ALPS) index—differs across the cognitive spectrum (healthy controls [HC], mild cognitive impairment [MCI], Alzheimer's disease [AD]) and relates to clinical severity, plasma tau, amyloid burden, and perfusion measures.

METHODS AND MATERIALS

DTI data were obtained from 44 subjects classified into HC (n=15), MCI (n=19), and AD (n=10) groups. ALPS-index was calculated using DSI studio by taking the average of left and right hemisphere metrics after EDDY correction. Differences among groups were assessed using ANOVA with post hoc analysis. Spearman correlation analyses evaluated relationships between ALPS-indices and CDR scores, plasma and imaging biomarkers (pTau217, Centiloid values and regional standardized uptake value ratio (SUVR) for beta-amyloid), and arterial spin labeling (ASL) imaging measures (Whole brain CBF, Arterial transit time (ATT), and blood-brain barrier water exchange (k W).

RESULTS

The ALPS index declined stepwise across the diagnostic spectrum—highest in healthy controls, intermediate in MCI, and lowest in Alzheimer's disease—with an overall significant group effect ($p = 0.03$). After correction, HC > AD remained significant ($p = 0.02$), whereas MCI did not differ significantly from either group. The ALPS-index correlated negatively with clinical severity measures including CDR ($r = -0.363$, $p = 0.0154$) and CDR-SoB ($r = -0.418$, $p = 0.0066$), as well as with Plasma pTau217, ATT, k W /CBF ratio, Centiloid values, and regional SUVRs in the cingulate and parietal cortices. In contrast, positive associations were observed with Whole Brain CBF ($r = 0.383$, $p = 0.0103$). No significant correlations were found with Vascular Risk Factors ($r = -0.10$) or Whole Brain k W ($r = -0.16$).

CONCLUSION

These findings indicate a progressive reduction in the ALPS-index from healthy aging through MCI to AD, with the ALPS-index tracking clinical severity, tau pathology, amyloid burden, and perfusion. The lack of association with k W suggests that the ALPS-index and k W may probe different aspects of the glymphatic circuit—the former assessing perivenous efflux, and the latter estimating aquaporin-4-mediated influx and blood-brain barrier injury. Moreover, the absence of correlation between ALPS-index and vascular risk factors suggests possible specificity for AD. While these findings support DTI-ALPS as a potential contrast-free imaging biomarker for early detection and longitudinal monitoring of AD, further longitudinal studies are needed with expanded sample size.

CLINICAL RELEVANCE/APPLICATION

ALPS index from DTI could serve as a non-invasive biomarker for AD by probing glymphatic function.

M5-STCE2-2 DEEP LEARNING DENOISING ENABLES DIAGNOSTIC-QUALITY IMAGING FROM PEDIATRIC LOW-DOSE CT

Thomas C. Arnold, PhD (*Presenter*)
Zhihao Zhang (*Abstract Co-Author*)
Lei Xiang (*Abstract Co-Author*)
Qian Wang (*Abstract Co-Author*)
Guo Chen, MD (*Abstract Co-Author*)
Li Wei Hu, BEng (*Abstract Co-Author*)
He Xiaofang (*Abstract Co-Author*)
Yumin Zhong, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pediatric low-dose CT is standard practice due to radiation sensitivity, but often results in noisy, low-quality images that may hinder diagnosis. We propose a deep learning-based denoising method to improve image quality and assess its clinical feasibility.

METHODS AND MATERIALS

We curated a large-scale low-dose CT dataset spanning multiple vendors, scanner models, and anatomical regions. A denoising model was trained using the Nonlinear Activation Free Network (NAFNet), known for strong performance in natural image restoration.To evaluate clinical feasibility, 39 pediatric patients under 5 years of age were prospectively enrolled. CT scans included coronary CT angiography (CCTA) and thin-slice lung CT (1.25 mm).Objective image quality was assessed using signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and noise power spectrum (NPS) to quantify frequency-domain noise and texture fidelity. Subjective evaluation was performed by two radiologists who independently rated noise, contrast, artifacts, sharpness, and diagnostic confidence on a 5-point Likert scale (1 = poor, 5 = excellent) in a randomized, blinded setting. To enhance sensitivity and mitigate ceiling effects, A/B testing was conducted with randomly ordered image pairs, with readers indicating preference.Statistical significance in Likert scores was evaluated using the Wilcoxon signed-rank test. A/B test results excluding ties were analyzed using a binomial test. Inter-reader agreement was assessed using Cohen's ?. Significance was defined as $p < 0.05$.

RESULTS

Denoising led to significant improvements in SNR and CNR across both sequences. For thin-slice lung series, SNR increased from 20.67 to 45.33 and CNR from 3.29 to 8.00. For CCTA series, SNR improved from 6.22 to 8.29 and CNR from 5.43 to 7.99. NPS analysis showed marked reduction of high-frequency noise while preserving low-frequency details.On the 5-point Likert scale, denoised images consistently exhibited lower subjective noise and better tissue-to-lesion contrast. Artifact presence showed no significant difference. In A/B testing, denoised images were favored, with at most two cases per dimension rated below raw data in CCTA or thin-slice lung series. Inter-reader agreement was excellent, with ? > 0.75 across all dimensions.

CONCLUSION

We evaluated a deep learning-based denoising model trained on a large-scale low-dose CT dataset for pediatric imaging. Objective and subjective assessments showed significant improvements in image quality and diagnostic confidence, supporting clinical applicability.

CLINICAL RELEVANCE/APPLICATION

The proposed method improves image quality and diagnostic confidence in pediatric low-dose CT, providing a safe, practical solution for routine use.

M5-STCE2-3 FEASIBILITY AND CLINICAL VALUE OF HALF-DOSE CONTRAST-ENHANCED MRI FOR PITUITARY AT 5.0 TESLA: A PRELIMINARY STUDY

Zhengmei Hao (*Presenter*)
Zhiwei Qin (*Abstract Co-Author*)
Shaofeng Duan (*Abstract Co-Author*)
Chunhong Hu, PhD (*Abstract Co-Author*)

PURPOSE

This study evaluated the feasibility of using half-dose gadolinium-based contrast agents for pituitary-enhanced MRI at 5.0T and compared with full-dose imaging to provide a basis for optimizing Gd agent dosage in clinical applications of ultra-high field MRI.

METHODS AND MATERIALS

Ten subjects (7 females, 3 males, ages ranging from 8 to 69 years; with 4 microadenomas, 2 Rathke's cysts, 1 pituitary tumor) underwent 5.0T magnetic resonance scans. After the injection of half-dose and full-dose contrast agents, a same high-resolution 3D T1-weighted modulated flip angle technique in refocused imaging with extended echo train (T1 Matrix3D) sequence was performed. The post-contrast images were compared through SNR, contrast-to-noise ratio (CNR) and subjective evaluation (artifact, homogeneity, edge sharpness, diagnostic efficacy) based on a 5-point Likert scale (1=poor; 5=excellent). The paired t-test was applied to assess the quantitative indices and the Wilcoxon signed-rank test was carried out to compare the qualitative scores. A p value less than 0.05 indicates a statistically significant difference.

RESULTS

For quantitative comparisons, no significant difference in pituitary SNR between half-dose and full-dose images (246.97±42.25 vs. 261.68±46.16, p=0.18), but the CNR between the pituitary gland and temporal lobe in the full dose was better than that in the half dose (122.76±32.98 vs. 95.27±27.28, p<0.05). For qualitative assessments, half-dose images achieved non-inferiority scores in terms of image homogeneity (half-dose 4.20±0.87 vs. full-dose 4.70±0.46, p=0.27), and were comparable to full-dose images in terms of artifacts (half-dose 4.50±0.67 vs. full-dose 4.40±0.66, p=0.73) and sharpness of the boundary between the pituitary gland and the cavernous sinus (half-dose 3.70±0.46 vs. full-dose 3.60±0.49, p=0.71). Ultimately, the two dose groups were consistent in terms of diagnostic performance (half-dose 4.90±0.30 vs. full-dose 4.90±0.30, p=1.00), meaning that half-dose images met clinical diagnostic requirements.

CONCLUSION

Quantitative and qualitative comparison results reveal that 5.0T MRI enables 50% Gd-based contrast agents reduction for pituitary imaging without compromising clinical diagnostic quality. This solution significantly decreases Gd exposure, aligning with goals of reducing environmental contamination and potential long-term tissue retention risks, while maintaining high diagnostic performance at ultra-high field strengths.

CLINICAL RELEVANCE/APPLICATION

This study provides the first and preliminary clinical evidence for pituitary-enhanced imaging using low-dose contrast agents at 5.0T MRI, advancing the development of strategies to minimize exogenous contrast agents in the next-generation imaging.

Masami Yoneyama (*Abstract Co-Author*)
Shuji Sakai, MD, PhD (*Abstract Co-Author*)

PURPOSE

Fontan circulation often causes persistent lymphatic congestion, leading to seriouscomplications such as refractory ascites and protein-losing enteropathy. However,existing imaging techniques inadequately visualize lymphatic abnormalities. Wedeveloped a novel 3D turbo spin-echo (3D-TSE) MR lymphangiography with dualinversion recovery (DIRECTION) for safe, noncontrast, high-resolution lymphaticimaging.

METHODS AND MATERIALS

Twenty-five post-Fontan patients (mean age 25 years) underwent Gd-EOB-DTPA-enhanced MRI on a 3.0T scanner (Ingenia Elition X, Philips Healthcare). DIRECTION was performed pre-contrast, with conventional heavily T2-weighted imaging 10 min post-contrast. DIRECTION uses two sequential nonselective inversion pulses (TI1=1000 ms, TI2=250 ms) to exploit T1 differences, selectively suppressing fat, blood, and nerve signals while enhancing lymphatic fluid, and includes a broadband inversion pulse for robustness against B0/B1 inhomogeneities. Imaging parameters: FOV 380×380 mm^2, voxel size 1.3×1.6×2.0 mm^3, TR/TE 4000/324 ms, TSE factor 80, scan time 2 min 24 sec. Lymphatic vessel visualization was assessed in three anatomical regions (peri-lumbar vertebrae, peri-bile duct to peri-duodenum, thoracic ducts) on a 4-point scale (0: none, 1: poor, 2: good, 3: excellent).

RESULTS

DIRECTION provided significantly higher lymphatic visualization scores than heavily T2-weighted imaging in all three regions (Wilcoxon matched-pairs test, $p<0.0001$). DIRECTION vs heavily T2 •Peri-lumbar vertebrae: 2.64 vs, 0.92 •Peri-bile duct to peri-duodenum: 2.44 vs 0.76 •Thoracic ducts: 2.52 vs 0.60 Detection rates (visualization score =1) were: •Peri-lumbar vertebrae: 100% (25/25) vs 76% (19/25) •Peri-bile duct to peri-duodenum: 100% (25/25) vs 44% (11/25) •Thoracic ducts: 92% (23/25) vs 64% (16/25) DIRECTION images showed minimal background noise without window adjustment, allowing delineation of congested lymphatic pathways not visible on contrast-enhanced CT. Short scan time (<3 min) supports clinical feasibility. Figure 1 shows representative images.

CONCLUSION

DIRECTION MR lymphangiography significantly outperforms conventional heavily T2-weighted imaging in detecting and visualizing congested lymphatic vessels in Fontan circulation, offering a reliable, noninvasive, noncontrast technique.

CLINICAL RELEVANCE/APPLICATION

DIRECTION MR lymphangiography addresses a critical unmet clinical need by enabling safe, noncontrast, high-resolution visualization of lymphatic abnormalities in Fontan patients, improving diagnostic accuracy and facilitating interventional treatment planning.

M6-SSCA04-2 RIGHT VENTRICULAR REVERSE REMODELING AND PULMONARY ARTERY HEMODYNAMICS POST-TPVI: PREDICTIVE ROLE OF 4D FLOW-DERIVED REGURGITANT FRACTION AND WALL SHEAR STRESS

Hirozumi Mori, MD (*Presenter*)
Michinobu Nagao, MD, PhD (*Abstract Co-Author*)
Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*)
Akihiro Inoue, MD (*Abstract Co-Author*)
Masahiro Jinzaki, MD, PhD (*Abstract Co-Author*)

PURPOSE

Transcatheter pulmonary valve implantation (TPVI) is a treatment for worsening pulmonary regurgitation in patients with tetralogy of Fallot (TOF). This study evaluated the utility of 4D Flow MRI in assessing right ventriular remodeling and pulmonary artery hemodynamics before and after TPVI by Hamony TPV25, FDA-approved in 2021, including a comparison with conventional 2D phase contast.

METHODS AND MATERIALS

In this prospective, single-center study, 30 patients (45.1±14.8 years, 19 women) who underwent TPVI were assessed pre- and 3 months post-TPVI using cardiac MRI (CMR) including 4D flow. Of these, 15 patients underwent additional evaluation with CMR at 1 year.

RESULTS

1) Postoperative RVEDVi showed a favorable reduction at 3 months in the subgroup with preoperative RVEDVi =200 mL (from 150.6 ± 29.8ml to 98.9 ± 20.1ml). Among predictive factors, the preoperative regurgitant fraction (RF) calculated from 5 cross-sections using 4D flow (RF-4D; 41.5 ± 11.8%) demonstrated superior predictive accuracy compared to the RF obtained from a single 2D phase contrast MRI slice (RF-2D; 45.5 ± 9.9%) (AUC = 0.85 vs 0.72). At 1 year postoperatively, 13

out of 14 patients with a preoperative RVEDVi <200 mL achieved normalization (RVEDVi <108 mL). RF-4D continued to show a higher predictive value than RF-2D (AUC = 0.82 vs 0.73). 2) The pre-TPVI main pulmonary artery (MPA) cross-sectional area, as a morphological indicator of pulmonary artery dilation, correlated more strongly with the preoperative RF-4D (r = 0.514, p = 0.003) than with RF-2D (r = 0.329, p = 0.076). 3) Wall shear stress (WSS) pre-TPVI exhibited a biphasic pattern: it increased during early diastole due to pulmonary regurgitation and significantly decreased following TPVI. WSS is considered a key factor in the pathophysiological mechanism of pulmonary artery dilatation and is thought to contribute to a vicious cycle of further dilatation and regurgitation. WSS demonstrated a significant inverse correlation with MPA cross-sectional area, reflecting vascular reactivity to WSS.

CONCLUSION

The regurgitant fraction measured by 4D flow demonstrated a stronger correlation with both right ventricular remodeling improvement and the extent of pulmonary artery dilation compared to 2D phase contrast measurements, suggesting that 4D flow provides more reliable and valid assessments. Furthermore, 4D flow enables the evaluation of WSS, a key factor in vascular remodeling, and may serve as a potential predictor of long-term progression of pulmonary regurgitation.

CLINICAL RELEVANCE/APPLICATION

4D flow MRI provides clinically meaningful measurements of the regurgitant fraction and serves as an important marker of pathophysiology in adult patients following repair of Tetralogy of Fallot.

M6-SSCA04-3 RELATIONSHIP BETWEEN RIGHT VENTRICULAR OUTFLOW WAVEFORMS AND NEOPULMONARY STENOSIS SEVERITY: A MULTI-INSTITUTIONAL RETROSPECTIVE COHORT STUDY OF PATIENTS WITH TRANSPOSITION OF THE GREAT ARTERIES

Brendan Crabb, MD (*Presenter*)
Sophie Y. Wong, MD (*Abstract Co-Author*)
Parker Rushworth (*Abstract Co-Author*)
Shant T. Malkasian, MD,BS (*Abstract Co-Author*)

Laith Alshawabkeh, MD,MSc (*Abstract Co-Author*)
Daniela Valdez-Jasso (*Abstract Co-Author*)
Albert Hsiao, MD, PhD (*Abstract Co-Author*)

PURPOSE

Four-dimensional (4D) Flow has been increasingly adopted as an essential component of cardiac MRI, especially for congenital heart patients undergoing surveillance after surgical repair. We hypothesized that characteristics of the right ventricular (RV) outflow waveform might be useful as an alternative benchmark of downstream pulmonary vascular resistance. We observed that patients who undergo arterial switch repair for dextro-Transposition of the Great Arteries (d-TGA) often have varying degrees of neopulmonary stenosis, making this a potential population to study this relationship.

METHODS AND MATERIALS

This multi-institutional, retrospective cohort study included pediatric and adult patients with d-TGA and arterial switch repairs (n=44, mean age 19.9, range 6-34 years) and a reference population of patients with morphologically normal hearts (n=15, mean age 44.2, range 18-72 years) who had cardiac MRI including 4D Flow as part of clinical care between 2015 and 2024. Synchronous pulmonic and aortic blood flow waveforms from 4D Flow were collected and quantified using several metrics, including the right ventricular (RV) ejection time (RV-ET), RV time to peak flow (RV-TTP), and time to peak flow difference between the RV and left ventricle (RVLV-dTTP). Differences between d-TGA and controls were assessed using two-sample t-tests and Mann-Whitney U tests. Lastly, the relationship between each metric and the neopulmonary stenosis pressure gradient, which was estimated with the modified Bernoulli equation on 4D flow, was assessed using Spearman's rank correlation (r).

RESULTS

Patients with d-TGA showed significantly altered and delayed RV systolic waveforms compared to normal controls. RV systolic waveforms in d-TGA were prolonged (RV-ET 422 ± 45 vs. 385 ± 46 ms, p=0.011) and delayed (RV-TTP 209 ± 30 vs. 169 ± 29 ms, p<0.001; RVLV-dTTP 43 ± 33 vs. 17 ± 26 ms, p<0.01) relative to normal controls, despite having no significant difference in RV ejection fraction (56.4 ± 5.9 vs. 55.4 ± 6.0%, p=0.58). Patients with d-TGA had neopulmonary stenosis of varying severity, ranging from 3 to 45 mmHg, which correlated strongly with RVLV-dTTP (r=0.72, p<0.001).

CONCLUSION

Delayed time to peak (RVLV-dTTP) of the RV waveform correlates strongly with the severity of neopulmonary stenosis, which may be useful as an alternative marker of stenosis severity in patients in whom the pressure gradient cannot be directly measured.

CLINICAL RELEVANCE/APPLICATION

4D Flow waveforms may provide additional hemodynamic data to guide management of patients in whom downstream pulmonary vascular resistance cannot be measured non-invasively. Additional investigation of this metric in pulmonary hypertension and other diseases of the pulmonary vasculature may be warranted.

M6-SSCA04-4 COMPARATIVE EFFECTIVENESS OF GADOPICLENOL FOR CONGENITAL HEART MRA AND 4D FLOW

Roshun Sankaran, MD, MPH (*Presenter*)
Marlene Goetz (*Abstract Co-Author*)
Albert Hsiao, MD, PhD (*Abstract Co-Author*)

PURPOSE

Gadopiclenol is an FDA-approved, intravenous, extracellular macrocyclic gadolinium-based contrast agent. Its high T1 relaxivity may reduce total gadolinium administered, which is particularly desirable in patients with adult congenital heart disease (ACHD), who require routine, lifelong MRI surveillance. However, the performance of gadopiclenol for cardiovascular imaging, particularly for ACHD evaluation, is unknown. We therefore sought to assess noninferiority of gadopiclenol compared to gadobenate dimeglumine for image quality of MR angiography and 4D Flow in this patient population.

METHODS AND MATERIALS

We designed a prospective, single center, parallel group, double-blinded, randomized clinical trial (NCT 6517) in which adult patients undergoing routine cardiac MRI and chest MRA, including 4D Flow MRI, for monitoring of ACHD were eligible. Pregnant patients, lactating patients, and patients with renal insufficiency (eGFR < 60 mL/min/1.73m2) were excluded. Consecutive patients were prospectively enrolled and randomized to one of four study arms: 0.15 mmol/kg gadobenate dimeglumine (active control), 0.075 mmol/kg gadopiclenol, 0.10 mmol/kg gadopiclenol, 0.15 mmol/kg gadopiclenol. Signal to noise ratio (SNR) during first-pass contrast-enhanced MRA was assessed in the aorta (AO), main pulmonary artery (MPA), and ventricular septal myocardium (VSM). Flow measurement error on 4D Flow MRI was assessed in the AO and MPA. Kruskal-Wallis tests were used to compare median SNR and flow measurement error between study arms in a per-protocol analysis, with p-values adjusted for multiple comparisons.

RESULTS

Our study cohort included 40 patients (13 female, 32.5%) with a mean age of 40.28 years (range 21-75 years). Twelve received 0.15 mmol/kg gadobenate dimeglumine, 10 received 0.075 mmol/kg gadopiclenol, 11 received 0.10 mmol/kg gadopiclenol, and 7 received 0.15 mmol/kg gadopiclenol. Kruskal-Wallis tests revealed no significant differences between groups in median SNR in the AO (H = 4.61, p = 0.20), MPA (H = 2.43, p = 0.49), or VSM (H = 1.92, p = 0.59). Similarly, no significant differences between groups were found in 4D Flow measurement error in the AO (H = 2.78, p = 0.43) or MPA (H = 3.85, p = 0.28).

CONCLUSION

In this interim analysis of a randomized clinical trial comparing image quality of gadopiclenol with gadobenate dimeglumine in ACHD patients, we found no significant differences in SNR or flow measurement error between gadopiclenol at three different doses and gadobenate dimeglumine.

CLINICAL RELEVANCE/APPLICATION

Gadopiclenol can provide quantitatively noninferior images to gadobenate dimeglumine at a lower gadolinium dose among ACHD patients undergoing cardiac MRI/MRA, thereby minimizing overall gadolinium exposure.

M6-SSCA04-5 LEFT VENTRICULAR TORSION DERIVED FROM 3D ANALYSIS OF CARDIAC CINE MAGNETIC RESONANCE: INTERVENTRICULAR INTERACTION OF TRANSCATHETER PULMONARY VALVE IMPLANTATION FOR REPAIRED TETRALOGY OF FALLOT

Akihiro Inoue, MD (*Presenter*)
Michinobu Nagao, MD, PhD (*Abstract Co-Author*)
Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*)
Kei Inai (*Abstract Co-Author*)
Masaki Watanabe, MD (*Abstract Co-Author*)
Seiko Shimizu (*Abstract Co-Author*)
Shuji Sakai, MD, PhD (*Abstract Co-Author*)

PURPOSE

In the long term after tetralogy of Fallot (TOF) repair, right ventricular (RV) volume expansion due to pulmonary regurgitation is common and right heart failure due to its worsening is prognostic. Recently, developed transcatheter pulmonary valve implantation (TPVI) is minimally invasive and requires only a short hospital stay. TPVI is effective for pulmonary regurgitation, resulting in a decrease in RV volume. However, the effect on the left ventricle (LV) is not clear, no good kinetic parameter has been found to identify LV function after TPVI. We hypothesized that the improvement in LV pump function underlies the relief of clinical symptoms after TPVI, and LV torsion could be used instead of LV ejection fraction (LVEF). In this study, LV torsion was calculated by 3-dimensional analysis of cardiac cine MRI, and was analyzed longitudinally before and after TPVI.

METHODS AND MATERIALS

We analyzed 30 patients with repaired TOF (mean age, 42.0 years)who underwent cardiac cine MRI with a 3-tesla scanner before TPVI, 3 months and 1 year after TPVI. We calculated the time-torsion curve all around in each segments using LV short-axis cine images of the basal to apex of the left ventricle and the motion tracking method. The LV torsion (degrees/cm) in each segment during ventricular contraction was extracted. The analysis was performed using the peak value of the global torsion. At the same time, both ventricular functions and pulmonary regurgitation fraction (PRF, %) were calculated. Serial measurements were compared by Wilcoxon matched-pairs signed rank test.

RESULTS

The torsion was significantly increased in the following order: before TPVI, 3 months, 1 year after TPVI (0.82±0.42 degree/cm vs 0.98±0.48 degree/cm vs 1.18±0.55 degree/cm ; pre vs 3 months, p=0.0098; pre vs. 12 months, p=0.0004; 3 months vs 12 months p=0.0026). On the other hand, there was no significant difference in LVEF between before TPVI and 3 months, 1 year after TPVI (52.1 ± 11.0% vs 53.7 ± 9.3% vs 55.3 ± 9.9%). And RVEDVI and PRF before TPVI were significantly decreased than those after one year (RVEDVI: 159.0 ± 31.5mL vs. 95.4 ± 17.2mL; PRF: 46.4 ± 10.4 % vs 3.3 ± 1.6%, p<0.0001).

CONCLUSION

Despite no change in LVEF before and after TPVI, LV torsion improved over the course of the first postoperative year. LV torsion is a LV pump function index that is independent of LVEF and reveals interventricular interactions with TPVI.

CLINICAL RELEVANCE/APPLICATION

The LV torsion is a new parameter that improves LV rotational mechanics and may be useful for predicting postoperative prognosis and determining additional treatment.

M6-SSCA04-6 AORTIC MORPHOLOGY IN BICUSPID VS TRICUSPID AORTIC VALVE PATIENTS: A MATCHED CT-BASED ANALYSIS BEYOND ASCENDING DIAMETER

Andre Lupp Mota, MD, PhD (*Presenter*)
Patricia Gonzalez Pagan (*Abstract Co-Author*)
Benjamin Bonner (*Abstract Co-Author*)
Sadia Sultana, MRCP,FRCR (*Abstract Co-Author*)
Borek Foldyna, MD (*Abstract Co-Author*)
Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*)
Sandeep S. Hedgire, MD (*Abstract Co-Author*)

PURPOSE

Bicuspid aortic valve (BAV) is the most common congenital cardiac valvular defect and is associated with an increased risk of aortic dilatation and dissection. Current surgical thresholds rely primarily on the ascending aortic diameter, with a recommended cutoff of 55 mm. However, some studies have proposed lower thresholds and suggested that additional CT-based thoracic aortic parameters may better characterize BAV-associated aortopathy. This study aims to evaluate the differences in aortic morphometric measurements between BAV and tricuspid aortic valve (TAV) patients and assess their relationship with ascending aortic dilation.

METHODS AND MATERIALS

In this retrospective matched-pair study, 41 BAV patients were matched 1:1 to TAV controls by age, sex, and ascending aortic diameter using contrast-enhanced, ECG-gated chest CTs. The mean age was 49.1 ± 15.7 years, and 85% were male. Quantitative imaging parameters included root, ascending, and descending aortic diameters; aortic annulus and ascending aorta angles; and aortic and greater curvature lengths. The ratio of ascending to descending aortic diameters (A:D ratio) was also calculated. Ascending aortic dilation was defined as a diameter =4.0 cm. Wilcoxon signed-rank tests assessed differences between matched pairs. Pearson correlation coefficients were used to assess associations between ascending dilation and other morphologic features.

RESULTS

BAV patients (Table 1) had significantly greater aortic length (mean difference = +9.4 mm, $p < 0.001$), ascending aortic diameter (mean difference = +2.6 mm, $p = 0.003$), and A:D ratio (mean difference = +0.26, $p < 0.001$) compared to matched TAV controls. The aortic annulus angle was significantly smaller in BAV (mean difference = -6.0°, $p = 0.005$) (Figure 1). No significant differences were found in ascending aorta angle or root diameter. Among BAV patients, ascending aortic dilation showed strong positive correlations with ascending diameter (? = 0.80), greater curvature length (? = 0.64), and A:D ratio (? = 0.53) .

CONCLUSION

Despite matching for ascending aortic diameter, BAV patients demonstrated distinct aortic morphologies—including increased aortic length, A:D ratio, and decreased annulus angle—supporting the role of these additional morphometric measures in the assessment of BAV aortopathy.

CLINICAL RELEVANCE/APPLICATION

Reliance solely on ascending aortic diameter may underestimate disease severity in BAV patients. Incorporating CT-based morphometric parameters into routine evaluation may improve risk stratification and guide more personalized surgical decision-making.

PURPOSE

In patients with type 2 diabetes mellitus (T2DM), the chronic elevation in the activity of the sympathetic system has been identified as an important factor contributing to the lack of glycemic control. Preclinical studies have shown that the removal of celiac ganglion, which contains sympathetic nerves that supply the liver and pancreas, can lead to improvement in glucose tolerance/control. The purpose of this study was to retrospectively review glucose control in patients with T2DM who underwent CT-guided celiac plexus neurolysis.

METHODS AND MATERIALS

In patients with type 2 diabetes mellitus (T2DM), the chronic elevation in the activity of the sympathetic system has been identified as an important factor contributing to the lack of glycemic control. Preclinical studies have shown that the removal of celiac ganglion, which contains sympathetic nerves that supply the liver and pancreas, can lead to improvement in glucose tolerance/control. The purpose of this study was to retrospectively review glucose control in patients with T2DM who underwent CT-guided celiac plexus neurolysis.

RESULTS

A total of 17 patients were included in the study (Age 62 ± 14.3 years; 29.4% Female) with mean BMI of 23.5 ± 5. 88.2% (15/17) had active cancer history with the most common being pancreatic cancer in 70.6% (12/17) patients. 47.1% (8/17) patients had metastasis at the time of procedure. The average duration of T2DM in these patients was 3.3 ± 2.7 years with mean HbA1c of 7.2 ± 1.8 and random blood sugar of 162.4 ± 73.5 mg/dL. 58.8% (10/17) patients were on insulin for T2DM management. All of the neurolysis procedures were performed with ethanol injection. All procedures were technically successful without any adverse events during the procedure or post-procedurally. Average HbA1c levels (6.9 ± 2.1, p=0.06) and random blood sugar (123.6 ± 27.6 mg/dL; p=0.03) were lower compared to the baseline at 3 months post-procedurally.

CONCLUSION

CT-guided celiac plexus neurolysis is a technically feasible and safe procedure which may be useful in patients with T2DM for providing glucose control.

CLINICAL RELEVANCE/APPLICATION

The management of T2DM currently mainly consists of hypoglycemic drugs and insulin; however, even in patients who are compliant with these medications, glycemic control can be inadequate. This study demonstrates that adjunctive use of celiac plexus neurolysis may be useful in these patients by improving glucose control.

M6-SSIR01-2 NON-INVASIVE, REAL-TIME TEMPERATURE MONITORING OF THERMAL ABLATION WITH SPECTRAL CT THERMOMETRY: IN VIVO EVALUATION

Leening P. Liu, PhD (*Presenter*)
Amy Perkins (*Abstract Co-Author*)
Thomas Schaer (*Abstract Co-Author*)
Ali H. Dhanaliwala, MD, PhD (*Abstract Co-Author*)
Daniel Depietro, MD (*Abstract Co-Author*)
Michael C. Soulen, MD (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

Non-invasive, real-time temperature monitoring for thermal ablation provides intraprocedural feedback on the treated ablation zone to ensure complete ablation of both the tumor and ablative margin critical to reducing local tumor recurrences. Spectral CT thermometry enables visualization of temperature distributions during ablation by relating physical density to temperature and has demonstrated potential in previous phantom studies. Thus, we assessed the feasibility of spectral CT thermometry for intra-ablation temperature monitoring in vivo .

METHODS AND MATERIALS

To establish the feasibility of spectral CT thermometry in vivo , microwave ablation was performed on the liver of a Yorkshire pig at 65 W for 5 minutes. During the ablation, ground truth temperatures adjacent to the ablation probe (PR15, Neuwave Medical) were measured with three optical fiber thermometers (Fiber Optic Thermometer, Omega Engineering). Additionally, scans were performed with a dual-layer spectral CT (Spectral CT 7500, Philips Healthcare) every 30 seconds at a tube voltage of 120 kVp. Spectral results at each time point were utilized to calculate physical density maps with a previously developed spectral physical density

quantification model. Physical density was measured at each thermometer, avoiding metal artifacts and gas formation. A linear regression was then applied to the ratio of the initial physical density to the measured physical density and ground truth temperature to determine the feasibility of spectral CT thermometry in vivo .

RESULTS

Intra-ablation temperatures reached a maximum of 81.3, 45.4, and 40.1 °C for the three thermometers. For the thermometer farthest from the ablation probe tip, the 3.2 °C increase in temperature resulted in a minimal change in the physical density ratio from 0.999 to 0.997. With a larger rise in temperature of 44.8 °C from the closest thermometer, the physical density ratio increased from 1.008 to 1.025, which matched values observed in previous phantom studies. The physical density ratio and temperature demonstrated a strong linear relationship with a correlation coefficient of 0.88, illustrating the feasibility of spectral CT thermometry.

CONCLUSION

In vivo ablation of a porcine liver demonstrated the feasibility of spectral CT thermometry for non-invasive, real-time temperature monitoring of thermal ablations. Validation of spectral CT thermometry encourages its clinical translation, where it may facilitate a reduction in local tumor recurrence rates.

CLINICAL RELEVANCE/APPLICATION

Intraprocedural surveillance of temperature changes during ablation enables more precise and careful treatment of liver tumors to prevent thermal injury to adjacent structures and reduce local recurrence rates.

M6-SSIR01-3 A SYSTEMATIC REVIEW AND META-ANALYSIS ON PULMONARY FUNCTION PARAMETERS AFTER THERMAL ABLATION VS STEREOTACTIC BODY RADIATION THERAPY OF LUNG TUMORS

Andreas K. Papadopoulos, MD, MSc (*Presenter*)

PURPOSE

Literature suggests that stereotactic body radiation therapy (SBRT) has a greater impact on pulmonary function when compared to percutaneous thermal ablation (TA), among patients treated for lung tumors. We sought to systematically review and quantify through a meta-analysis changes in pulmonary function tests following either TA or SBRT in patients treated for primary lung cancer or oligo-metastatic lung disease.

METHODS AND MATERIALS

Following the PRISMA guidelines, PubMed, Embase, and the Cochrane Library were systematically searched for records examining pulmonary function before and after either TA or SBRT. Eligible were considered reports quantifying changes in FVC, FEV 1 , or DLCO. Pooled incidence ratios were computed using a random-effects meta-analysis model, utilizing the DerSimonian and Laird variance estimator.

RESULTS

Our search yielded 2,729 records, of which 12 studies published between 2008 and 2022 were ultimately included, comprising a total of 759 patients (TA, 179; SBRT, 580). SBRT was associated with an estimated mean FVC reduction of 4.0% (95% CI, -0.6 to 8.6, p=0.16) compared to 0.1% (95% CI, -2.3 to 2.2, p=0.74) for TA; however, no statistically significant difference between the two techniques was found (p=0.12). SBRT was further associated with an estimated mean FEV 1 decrease of 9.0% (95% CI, 5.8 to 12.1, p<0.001) compared to only 0.3% (95% CI, -2.5 to 3.2, p=0.80) for TA. Similarly, SBRT was associated with an estimated mean DLCO decrease of 16.9% (95% CI, 12.5 to 21.3, p<0.01) compared to 1.3% (95% CI, -9.9 to 12.5, p=0.99) for TA. When compared to TA, the decrease of FEV 1 and DLCO was statistically significantly greater after SBRT (p<0.001 and p=0.01, respectively).

CONCLUSION

Our results indicate that SBRT may lead to a significantly greater reduction of both FEV 1 and DLCO compared the effect of TA, which was found to be minimal.

CLINICAL RELEVANCE/APPLICATION

When both TA and SBRT are valid treatment options, the use of TA is linked to better preservation of post-treatment lung function.

Florian J. Fintelmann, MD (*Abstract Co-Author*)

PURPOSE

Pulmonary hypertension (PH) has been listed as a minor criterion for surgical ineligibility by the American College of Surgeons Oncology Group in the treatment of primary lung cancer and lung metastases. Hence, local therapy options in this setting focus on image-guided thermal ablation (IGTA) and radiation therapy. However, outcomes following IGTA in patients with PH have not been previously reported. This study aims to compare the safety profile of IGTA of lung tumors in patients with and without PH.

METHODS AND MATERIALS

This retrospective bi-institutional cohort study included consecutive adults who underwent microwave or cryoablation of lung tumors from 2/2015 to 10/2024. Patients were classified as having PH based on the best available evidence. PH status was determined using a tiered approach: right heart catheterization as gold standard (mean pulmonary arterial pressure =20 mmHg), followed by echocardiography (peak tricuspid regurgitant jet velocity >2.8 m/s), and then CT-based metrics (pulmonary artery to aortic diameter ratio >1.1, >1.0, or >0.9 in populations with low, intermediate, and high risk of PH, respectively; or, in cases of aortic dilation [>40 mm], pulmonary artery diameter >34 mm, >32 mm, or >30 mm). Major adverse events (AE) within 30 days (defined as CTCAE grade 3 or higher), hospital length of stay =2 days (HLOS), hemorrhagic events within 30 days (defined as hemoptysis, bronchopulmonary hemorrhage, or hemothorax), 90-day mortality, and overall survival (OS) were compared between groups.

RESULTS

Overall, 310 patients (58% females; median age 65 years) underwent 512 ablation sessions to treat 741 lung tumors (83% metastases), including 50 patients with PH and 260 patients without. Patients with PH had higher Eastern Cooperative Oncology Group and Charlson Comorbidity scores (medians: 1 vs. 0, and 9 vs. 8; both p=.003). No patient had more than one major AE per session, and 44 major AEs occurred across 512 sessions (9%), including 11 hemorrhagic events (2%). Median HLOS was 1 day. After adjusting for applicator number, ablation modality, and tumor location by zone, there was no significant difference between patients with and without PH regarding major AE rate (14% vs. 8%, p=.07), HLOS (p=.72), hemorrhagic events (p =.10), 90-day mortality (p=.08). OS was also not significantly different (p=.70).

CONCLUSION

There was no significant difference in terms of major AEs, hemorrhagic events, HLOS, 90-day mortality, and OS following IGTA between patients with and without PH. IGTA of lung tumors is a safe option in patients with PH.

CLINICAL RELEVANCE/APPLICATION

Although PH is a relative contraindication to lung tumor resection due to increased risk of morbidity and mortality, it had no significant effect on the safety of IGTA of lung tumors.

M6-SSIR01-5 COMMON CULPRIT OF IATROGENIC CHYLOTHORAX- THE SUBCARINAL TRANSVERSE THORACIC DUCT COLLATERAL

Hsien-Tzu Liu, MD (*Presenter*)

PURPOSE

This study describes an anatomical variation of the thoracic duct-the subcarinal transverse collateral. Injury to this collateral branch during mediastinal lymph node dissection is a predominant cause of iatrogenic chylothorax.

METHODS AND MATERIALS

A total of 21 patients with lymphatic leakage who underwent lymphangiography with thoracic duct catheterization were included. The thoracic duct was catheterized and the anatomical variation of the thoracic duct, its collaterals, and the exact point of contrast extravasation were evaluated.

RESULTS

The patterns of thoracic duct were identified: a single duct, transverse collaterals crossing the mediastinum at the subcarinal level, transverse collaterals at the thymic level, and plexiform appearance. Further analysis of 11 patients with iatrogenic chylothorax based on the types of surgery they underwent, revealed that 8 (72.7%) had a subcarinal transverse collateral duct. All of them underwent mediastinal lymph node dissection and the subcarinal transverse collateral lymph duct were culprits of chylothorax.

CONCLUSION

This study on patients with various types of lymphatic leakages revealed that the common cause of iatrogenic chylothorax was injury to a subcarinal transverse collateral branch, rather than injury to the thoracic duct itself. Surgeons are generally more aware of the anatomical location of the thoracic duct, while the subcarinal transverse collateral branch is often overlooked. While the prevalence of this variant collateral in the general population is unknown, injury to it during mediastinal lymph node dissection without proper management of the cut end is a common cause of post-operative chylothorax.

CLINICAL RELEVANCE/APPLICATION

The subcarinal transverse collateral of the thoracic duct is crucial in clinical practice because it lies near the subcarinal and hilar lymph nodes, which are often dissected during surgical resection for lung cancer. Because this collateral duct is located away from the known anatomical location of the thoracic duct, and is often imperceptible during surgery, it can sometimes be transected unintentionally, resulting in iatrogenic chylothorax. This study alerts surgeons to the presence of this transverse collateral lymph duct and that its prevalence might be more common than traditionally perceived. Also, identifying this subcarinal transverse collateral as a common culprit of iatrogenic chylothorax gives cause for choosing minimally invasive embolization for treatment over surgical ligation. Because superselective embolization of only this collateral lymph duct helps preserve the patency of the thoracic duct. Thus, reducing potential long term obstructive complications related to blockage of the central lymphatic channel.

M6-SSMK03-1 AI-AUGMENTED MSK ULTRASOUND REPORTING: STREAMLINING CLINICAL WORKFLOW AND RESIDENT TRAINING IN A HIGH-VOLUME TERTIARY CARE GOVERNMENT HOSPITAL"

Daksh D. Mehta, MD, MBBS (*Presenter*)
Mahak K. Balani, MD (*Abstract Co-Author*)
Ashwini Sankhe, MD (*Abstract Co-Author*)
Anagha R. Joshi, MD, MBBS (*Abstract Co-Author*)

PURPOSE

Musculoskeletal (MSK) ultrasound is a dynamic, operator-dependent imaging modality with a steep learning curve, especially in high-volume tertiary care government hospitals. Challenges such as variability in reporting, time pressure, and resident fatigue affect consistency and training. This study evaluated the role of artificial intelligence (AI) in improving efficiency, completeness, and standardization of MSK ultrasound reporting using AI-assisted draft generation and real-time guidance.

METHODS AND MATERIALS

A multiphase study was conducted at a high-volume tertiary care government hospital. In Phase 1, baseline challenges in MSK ultrasound reporting and training were documented through observation and feedback. In Phase 2, an open AI-assisted draft report generator was developed, using joint-specific structured templates and anatomical checklists for common MSK pathologies. Phase 3 involved a 3-month pilot study with 12 radiology residents alternating between conventional and AI-assisted reporting weeks. Outcomes included report completeness (scored by blinded radiologists), reporting time, and subjective cognitive load (NASA Task Load Index).

RESULTS

AI-assisted reporting reduced reporting time by 31% ($p < 0.01$) and improved report completeness from a mean of 6.8 to 9.3. NASA-TLX scores showed a 23% reduction in cognitive workload. The system prompted scanning of often-missed structures and enhanced diagnostic quality. Residents reported high usability and supported further integration across subspecialties.

CONCLUSION

AI-assisted draft reporting and checklist guidance improve efficiency, standardization, and education in MSK ultrasound. Structured templates reduce variability, ease cognitive load, and improve report quality. Beyond routine draft reporting, large language models supported voice-guided scanning assistance, clinician-specific report refinement, differential generation, resident skill tracking, research dataset creation and automated error detection—extending their impact across clinical, educational, and research domains.

CLINICAL RELEVANCE/APPLICATION

Integrating AI and language models into MSK ultrasound workflows can streamline reporting, support personalized communication, enhance resident training, and build structured datasets for research and future AI tools—addressing key gaps in consistency, speed, and quality.

M6-SSMK03-2 REDUCING UNREPORTED VERTEBRAL COMPRESSION FRACTURES: PERFORMANCE OF AN AI-BASED SCREENING TOOL ON OPPORTUNISTIC CT IMAGING

Sarah Quenet, MEng (*Presenter*)
Jin-Kyeong Sung, MD (*Abstract Co-Author*)
Subhash R. Doni, MBBS (*Abstract Co-Author*)
Julia O'Connor (*Abstract Co-Author*)
Julie Kiewsky (*Abstract Co-Author*)
Charlotte Castineira (*Abstract Co-Author*)
Christophe Avare (*Abstract Co-Author*)
Yasmina Chaibi, PhD (*Abstract Co-Author*)
Angela Ayobi, MENG,MSc (*Abstract Co-Author*)

PURPOSE

Osteoporosis-related vertebral compression fractures (VCF) are fragility fractures, often progressing silently and remaining undetected. Their severity is typically classified using Genant’s semiquantitative method based on the vertebral height loss (VHL). As VCFs are frequently asymptomatic, opportunistic identification on CT scans acquired for unrelated clinical reasons offers a solution for early diagnosis without additional radiation exposure or imaging costs. This study aims to evaluate an AI-based system designed to automatically label vertebrae, quantify VHL, calculate mean Hounsfield Units (mean HU) of vertebral bone attenuation at L1-L4 and detect unsuspected VCF cases (VHL=25%) on real-world CT.

METHODS AND MATERIALS

We retrospectively and consecutively analyzed chest and abdominal CT scans acquired for any clinical indication other than VCF at two major teleradiology networks in the US and France. Both contrast-enhanced and non-contrast-enhanced CT acquired on 37 different scanner models from 5 manufacturers were included. Patients under 50 years old and scans with slice thickness >3mm were excluded. Reference Standard (RS) was established by consensus of three senior musculoskeletal radiologists who measured and labelled vertebrae following Genant’s method. All cases were analyzed by the AI tool CINA-VCF Quantix v1.0 (Avicenna.AI, France) and its diagnostic performance was evaluated against the RS and the original radiology report.

RESULTS

Of the 319 initially screened patients, 271 (mean age 72.4±10.4[SD] years old; 47.6% male, 23.3% VCF prevalence) met inclusion criteria, spanning 3,141 vertebrae (6.9% with VHL=25%). The AI achieved a vertebral labelling accuracy of 95.3% (95%CI: 94.6%-96.0%). Agreement with the RS for VHL and mean HU quantification yielded 95% limits of agreement of [-9.2%, 8.6%], and [-20.7, 16.7] HU, respectively. Sensitivity and specificity for detecting VCF cases were 83.6% (95%CI: 75.8%-89.7%) and 95.3% (95%CI: 90.5%-98.1%), respectively. Figure 1 shows an example of a positive case. Main causes of disagreements were Schmorl's nodes and osteophytes. Notably, 63.5% (40/63) of VCF cases confirmed by the RS were not reported in the radiology report; the AI tool successfully detected 75% (30/40) of these unreported cases, suggesting the potential to reduce the missed rate from 55% to 15.9% (10/63).

CONCLUSION

The AI tool shows strong performance in opportunistic VCF assessment. The integration into clinical workflow may enhance early recognition of osteoporotic VCF.

CLINICAL RELEVANCE/APPLICATION

Automated opportunistic detection of VCF on routine CT may enable earlier treatment of osteoporosis and reduce fracture-related morbidity without the need for additional imaging or radiation.

M6-SSMK03-3 AUTOMATION BIAS REDUCES RADIOLOGIST ACCURACY IN AI-ASSISTED SCAPHOID FRACTURE DETECTION ON WRIST RADIOGRAPHS

Patrick Stein, MD (*Presenter*)
Yasmin Lasheb (*Abstract Co-Author*)
Constantin M. Seibold, MSc (*Abstract Co-Author*)
Kai Schlamp, MD (*Abstract Co-Author*)
Hans-Ulrich Kauczor, MD (*Abstract Co-Author*)
Matthias A. Fink, MD, BSc (*Abstract Co-Author*)

PURPOSE

Automation bias, the tendency of clinicians to over-rely on automated decision support, is a potential threat to diagnostic accuracy. We evaluated how disclosure of AI-generated fracture overlays and confidence affects radiologists' scaphoid fracture detection, and whether reader experience or case order modulates this effect.

METHODS AND MATERIALS

Twenty-four radiologists (12 residents, 12 attendings) participated in a prospective, two-read study of 213 wrist radiographs obtained between 2019 and 2024 that prompted confirmatory CT (mean patient age 44 ± 15 years; 56% male; 81% CT-proven fractures). In Read 1, each reader reviewed 48 unique cases without AI assistance; after a 6-week washout period, they reviewed the identical images again in Read 2, this time overlaid with AI-generated bounding boxes at suspected fracture sites and a three-level confidence indicator (high/medium/low). To assess any "warm-up" effect of early correct or incorrect AI predictions, cases were presented in false-first, random, or true-first order. A mixed effects regression model with random intercepts for each reader quantified the effects of AI disclosure, reader expertise, and presentation order. On the same images, the AI's stand-alone performance achieved 71% sensitivity, 100% specificity, 100% PPV, and 65% NPV.

RESULTS

Without AI, radiologist accuracy averaged 69.1 ± 3.1%. Displaying AI overlays in Read 2 reduced accuracy by 8.7 percentage points (ß = -0.087 ± 0.039; P = .026), demonstrating a significant negative automation bias. Reader experience did not attenuate this effect (interaction P = .64), nor did case order (all P > .30). Reader-AI agreement increased from 76% in Read 1 to 83% in Read 2 (P = .025), confirming the increased reliance on algorithmic suggestions. Interreader variance was negligible after accounting for fixed effects (s^2 ˜0.001).

CONCLUSION

Disclosure of AI-generated fracture flags and confidence levels paradoxically decreased radiologist performance in scaphoid fracture detection by encouraging uncritical adoption of algorithmic output. This decline reflects an automation bias, not a deficiency in the AI itself. Neither greater experience nor strategic case ordering prevented this bias. To safely integrate AI into clinical workflows, measures such as mandatory critical review prompts, confidence thresholds, or selective gating of AI output are essential to preserve independent diagnostic judgment.

CLINICAL RELEVANCE/APPLICATION

Automation bias is a significant, under-appreciated risk in AI-assisted diagnostic imaging; even powerful algorithms can reduce overall accuracy if their suggestions are adopted uncritically. Targeted safeguards are therefore critical to preserve the independent judgment of clinicians.

M6-SSMK03-4 IMPACT OF AI ASSISTANCE ON KNEE MRI READING TIME: A REAL-WORLD MULTICENTER STUDY

Benoit Rizk, MD (*Presenter*)
Natalie Heracleous, PhD (*Abstract Co-Author*)
Sergey Morozov, PhD, MPH (*Abstract Co-Author*)
Benoit Dufour (*Abstract Co-Author*)
Cyril Thouly (*Abstract Co-Author*)
Philippine Cordelle (*Abstract Co-Author*)
Federica Zanca, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of seamless AI integration on knee MRI reporting time in a prospective multicentric setting by comparing 3 reporting workflows: standard reporting without AI, reporting with AI-generated results available but not integrated and fully AI-assisted structured reporting with integrated AI outputs.

METHODS AND MATERIALS

A prospective multicenter study was conducted across 10 private radiology centers in Switzerland (September 2023-October 2024). 8 radiologists (4 musculoskeletal [MSK] subspecialists; 4 generalists [GEN]) participated. 1,285 knee MRI exams were consecutively allocated across 3 phases: (1) baseline standard reporting without AI, (2) partial AI integration of KEROS (Incepto), a CE-marked Class IIa knee-MRI multifaceted AI tool intended to assist radiologists with automatic assessment of cartilage/menisci/ligaments, with AI findings available in DICOM Secondary Capture format, and (3) full AI integration with AI-generated findings autopopulating structured report templates. Reporting time, measured automatically via Radiology Information System (RIS, EDL), was the primary outcome. Statistical analysis included Kruskal-Wallis test and inverse-variance weighted means to compare reporting times across phases and radiologist subgroups. A post-study questionnaire assessed user satisfaction and perceived workflow impact.

RESULTS

Fully integrated AI-assisted reporting reduced overall knee MRI reporting time by 13.4% compared to standard reporting ($p < 0.01$). The largest reduction was observed among general radiologists (17.5%, $p < 0.01$), while MSK specialists also benefited, albeit to a smaller extent due to already optimized workflows. Partial AI integration did not yield time savings and, in some cases, slightly increased reporting time, likely due to workflow modifications. Qualitative feedback revealed that 75% of radiologists felt AI facilitated their work, and 62.5% found structured report integration beneficial, particularly for straightforward cases. Suggestions for further optimization included extending the scope of lesion characterization.

CONCLUSION

Direct integration of AI-generated findings into structured knee MRI reports significantly reduces reporting time, especially for general radiologists. Partial AI integration without workflow embedding does not confer similar efficiency gains.

CLINICAL RELEVANCE/APPLICATION

AI-assisted structured reporting for knee MRI can meaningfully enhance radiology workflow efficiency, particularly for non-specialist readers, by reducing reporting time and cognitive workload. Effective integration into existing reporting systems is crucial to realizing these benefits in routine clinical practice.

M6-SSMK03-5 EARLY NONINVASIVE PREDICTION OF INSULIN RESISTANCE THROUGH MUSCLE ULTRASOUND RADIOMICS

Sameed Khan (*Presenter*)
Chad L. Klochko, MD (*Abstract Co-Author*)
Steven B. Soliman, DO (*Abstract Co-Author*)

PURPOSE

Current methods for detecting insulin resistance (IR) and type 2 diabetes (T2D) are often invasive and costly. Previous work has shown retrospective success of machine learning models using muscle radiomics. This study aimed to prospectively evaluate the performance of a gradient-boosted decision tree model trained on retrospective deltoid muscle ultrasound radiomics to identify individuals with IR despite normal glycemic markers.

METHODS AND MATERIALS

A model was initially trained on 1191 retrospective patients using deltoid muscle radiomics to predict prediabetes/diabetes risk status (diagnosis in EHR). For prospective validation, 17 subjects (age 18-40) were recruited: 8 with obesity (BMI 34.3 +/- 2.7 kg/m 2 , 87.5% male, mean age 37) and 9 healthy lean controls (BMI 22.5 +/- 1.4 kg/m 2 , 28.6% male, mean age 25). All 17 subjects had normal HbA1c (<5.7%). Standardized ultrasound (12-MHz linear transducer) of the dominant deltoid muscle was performed by an experienced radiologist. Subjects then underwent a 2-hour 75g oral glucose tolerance test with insulin levels to calculate the Matsuda Index. All subjects with obesity were confirmed to have IR (Matsuda Index <4), while all lean controls had normal insulin sensitivity (Matsuda Index mean 12). Radiomics features were extracted from the deltoid ultrasound images, and the pre-trained model was applied.

RESULTS

On the prospective cohort of 17 subjects, all with normal HbA1c, the model trained on retrospective data demonstrated an Area Under the Receiver Operating Characteristic curve (AUROC) of 0.78 in distinguishing individuals with IR (n=8) from those without (n=9). At an optimal threshold determined by Youden's J-index (0.43), the model achieved a sensitivity of 0.88 and a specificity of 0.56. The model showed an internal validation AUROC of 0.79 +/- 0.036 over 10-fold cross-validation on the larger retrospective training set.

CONCLUSION

This pilot study demonstrates promising potential for ultrasound muscle radiomics to prospectively identify individuals with underlying insulin resistance despite normal HbA1c levels. These initial findings suggest muscle imaging may detect early metabolic dysfunction related to impaired glycogen synthesis. Patient follow-up is ongoing, and future directions include integrating multimodal data and higher-powered but lower-interpretability predictive methods, such as deep learning.

CLINICAL RELEVANCE/APPLICATION

With millions unaware of their prediabetes or T2D, a non-invasive ultrasound approach could offer accessible screening for insulin resistance. A positive finding on ultrasound screen could prompt further testing, enabling timely, targeted interventions, particularly in underserved communities.

M6-SSMK03-6 TASK-AGNOSTIC DXA FEATURES: A DEEP LEARNING FOUNDATION FOR DIVERSE RADIOLOGICAL TASKS

Yannik Glaser, PhD (*Presenter*)
Thomas K. Wolfgruber, PhD (*Abstract Co-Author*)
Arianna Bunnell (*Abstract Co-Author*)
Peter Sadowski, PhD (*Abstract Co-Author*)
John A. Shepherd, PhD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a deep learning model that extracts clinically meaningful imaging features directly from hip, spine, and whole-body DXA scans for opportunistic risk prediction, such as 10-year mortality and hip fracture. The model is designed using self-supervised deep learning (SSL) to be robust across anatomical sites and scan protocols, enabling broad applicability in diverse clinical settings.

METHODS AND MATERIALS

A total of 85,461 DXA scans were used to train the model, sourced from NIH-supported studies (MrOS, HANDLS, HealthABC, and Shape Up!). The scans included 33,360 whole-body, 28,928 hip, and 23,173 spine images. Using a SSL approach, a vision transformer model was trained to learn shared imaging patterns across scans without requiring labels. The resulting image-based features ("embeddings") were then evaluated on two clinical prediction tasks. For 10-year all-cause mortality prediction, 17,218 whole-body scans were used, including 6,911 participant deaths. For 10-year hip fracture prediction, 4,199 hip scans were used, including 258 fractures. Each task used logistic regression models trained solely on the extracted imaging features, without access to demographics, bone mineral density, or laboratory values.

RESULTS

The model achieved an area under the receiver operating characteristic curve (AUROC) of 0.70 for 10-year mortality prediction. For hip fracture prediction, the AUROC was 0.74. These results are comparable to prior task-specific models developed using the HealthABC cohort, which achieved AUROCs of 0.71 and 0.75, respectively, but required multiple clinical variables including bone mineral density, biomarkers, and fitness measures.

CONCLUSION

This study demonstrates that DXA images alone, when processed with advanced deep learning, can reveal imaging features predictive of long-term clinical outcomes. The model is trained on multiple anatomical regions (hip, spine, and whole body), making it inherently agnostic to scan site and capable of generalizing across imaging protocols. Unlike traditional end-to-end models trained for specific tasks, these general-purpose features can be reused across new prediction problems, supporting a modular and scalable approach to DXA-based risk assessment.

CLINICAL RELEVANCE/APPLICATION

This model can enable automated, opportunistic screening for fracture risk or mortality directly from DXA scans. It requires no additional imaging, clinical data, or patient burden, thereby potentially enhancing the value of routine DXA exams in everyday practice.

M6-SSMS01-1 PROGNOSTIC FACTORS FOR METASTATIC PATIENTS: NUMERIC TUMOR FRACTION IN LIQUID BIOPSY, TUMOR VOLUME AND ANTHROPOMETRY IN CT SCANS

Aurelie Choucair, MD (*Presenter*)
Jules Dupont (*Abstract Co-Author*)
Ghina Jardali, MD (*Abstract Co-Author*)
Lama DAWI, MD (*Abstract Co-Author*)
Littisha Lawrance (*Abstract Co-Author*)
Vincent GOLDSCHMIDT (*Abstract Co-Author*)
Samy Ammari, MD, PhD (*Abstract Co-Author*)
Christophe Massard (*Abstract Co-Author*)
Antoine Italiano (*Abstract Co-Author*)
Nathalie B. Lassau, MD, PhD (*Abstract Co-Author*)

PURPOSE

Total tumor volume on CT scan and circulating tumor DNA from liquid biopsy, known as tumor fraction (TF), are parameters to predict metastatic patients' overall survival (OS). While TF was previously binary (below or above 10%), numerical values are now available. The goal is to predict OS correlating numeric TF, Total Tumor Volume (TTV) and 3D anthropometry.

METHODS AND MATERIALS

This is a retrospective study including metastatic patients between January 2021 and December 2023 who had a baseline CT scan and liquid biopsy (STING study, NCT04932525, Gustave Roussy). The collected data include age, sex, cancer type, treatment line, and date of death. Thoraco-abdomino-pelvic CT scans were anonymized and manually annotated in 2D on the slice with the largest diameter by senior radiologists on the SPYD platform. A 3D estimate was made (Tumor volume = 2/3 x Mesh surface area x Minor axis). The numerical values of the TF were reported as a percentage. The Anthropometer3DNet software was used to obtain 3D measurements, allowing the calculation of muscle, superficial and deep fat masses. TTV and anthropometric measurements were combined using coefficients of a cox model, resulting in a CT scan risk score. Patients were first divided into two groups based on their TF: equal to or superior to 0%. They were further divided into two subgroups based on the CT scan risk score: below or above its median. The primary endpoint was OS. Analyses were performed using Kaplan-Meier estimators and log-rank statistics.

RESULTS

Among 720 patients with a liquid biopsy and baseline CT scan, 38,283 metastases were outlined. The median OS of patients was 13.11 months (95% CI: 11.50-15.11). The median TF was 3.30% (IQR 20%) and the median TTV was 91.61 cm^3 (IQR 213.68 cm^3). A TF of 0% was found in 213 patients (29.58%), despite having tumor burden on the CT scan, with a median of 35.34 cm^3 (IQR 84.00 cm^3). The OS median of patients with TF=0% was 10.15 months (95% CI: 8.71-11.60), compared to 25.46 months (95% CI: 21.26-30.09) for those with a TF above 0%. In the TF=0% group, patients with a low CT-scan risk score had a median OS of 35.35 months (95% CI: 27.10- superior to 44 months), compared to 19.35 months (95% CI: 13.37-25.36) for those with a high CT-scan risk score. In the group with TF > 0%, patients with a low CT-scan risk score had a median OS of 13.24 months (95% CI: 6.54-13.24) compared to 7.46 months (95% CI: 6.54-13.24) for those with a TTV above the median. Survival curves were significantly different, with $p=0.003$ and $p<0.001$, respectively.

CONCLUSION

TTV and anthropometry, in conjunction with TF, provide a more accurate prediction of OS compared to TF alone.

CLINICAL RELEVANCE/APPLICATION

The assessment of tumor burden and 3D anthropometry are a promising prognostic tool in the management of metastatic patients.

M6-SSMS01-2 ADDITIONAL PROGNOSTIC VALUE OF TUMOR BURDEN IN STAGE I/II COMPARED TO STAGE III/IV LYMPHOMA PATIENTS UNDERGOING CAR T-CELL THERAPY

Matthias Kassube (*Presenter*)
Viktoria Blumenberg (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)
Michael von Bergwelt-Baildon (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Marion Subklewe (*Abstract Co-Author*)
Wolfgang G. Kunz, MD, MBA (*Abstract Co-Author*)
Michael Winkelmann, MD (*Abstract Co-Author*)

PURPOSE

Chimeric Antigen Receptor (CAR) T-cell therapy has revolutionized the treatment landscape for relapsed or refractory B-cell lymphomas. While disease stage remains a cornerstone of risk stratification, emerging evidence suggests that tumor burden (TB) quantified through imaging may provide additional prognostic insights. The differential impact of TB in early-stage (I/II) versus advanced-stage (III/IV) lymphoma remains underexplored. In stage I/II patients, tumor burden may serve as an enhanced risk stratifier due to lower baseline disease heterogeneity. We evaluated the additional prognostic value of the Lugano-based sum of product diameters (SPD) for stage I/II patients compared to stage III/IV patients in terms of progression-free survival (PFS) and overall survival (OS).

METHODS AND MATERIALS

This retrospective analysis was conducted on a cohort of 103 patients treated with CAR T-cell therapy. Tumor burden at baseline was quantified using SPD according tu Lugano Criteria. Patients were stratified by Ann Arbor stage and SPD levels. PFS and OS were analyzed using Kaplan-Meier curves and log-rank tests.

RESULTS

Median age was 67 years; 38% patients were female. Patients with Stage III/IV disease had significantly higher baseline SPD compared to Stage I/II (median SPD: 6,088 mm^2 vs. 1,504 mm^2; $p<0.001$). Survival analysis demonstrated significantly inferior PFS ($p<0.001$) and OS ($p=0.018$) in patients with advanced disease (III/IV). The additional subdivision of the early stage patients according to their median SPD of 1,504 mm2 resulted in a significant separation of the two groups. The early stage patients with a low SPD showed a significantly longer OS and a slightly longer PFS than those with a high SPD. Interestingly, stage I/II patients with higher tumor burden showed a similar overall survival curve as the advanced stage patients.

CONCLUSION

Baseline tumor burden, as measured by SPD, had a significant prognostic value in early-stage (Ann Arbor Stage I/II) lymphoma patients undergoing CAR T-cell therapy. In this subgroup, higher SPD was associated with markedly inferior OS and slightly inferior PFS. In contrast, SPD did not show a clear prognostic impact among patients with advanced-stage (Stage III/IV) disease.

CLINICAL RELEVANCE/APPLICATION

These findings suggest that tumor burden may be particularly useful for risk stratification in early-stage lymphoma and should be considered when evaluating candidates for CAR T-cell therapy in this population. Understanding the prognostic implications of tumor burden can guide clinical decision-making and therapeutic strategies.

PURPOSE

Current guidelines for intraductal papillary mucinous neoplasm (IPMN) risk stratification lack specificity, leading to unnecessary surgeries and costs. We developed a radiomics-deep learning fusion algorithm to improve malignancy risk prediction using cyst segmentation on T2W-MRI.

METHODS AND MATERIALS

This IRB approved multicenter retrospective study included 746 T2W MRI scans from seven institutions. Inclusion criteria: IPMNs with confirmed dysplasia grade determined by EUS-FNA or surgical histopathology. Lesions were categorized as Low Risk (low-grade dysplasia) or High Risk (high-grade dysplasia or invasive carcinoma). Excluded: inadequate imaging quality or incomplete follow-up. IPMNs were manually segmented by an interdisciplinary team using ITK-SNAP. We developed and compared three algorithms:Radiomics: Features were extracted, selected, and used to train a random forest model with both 2D and 3D analyses.DL: six convolutional neural networks (CNNs) were developed and evaluated.Radiomics-DL Fusion: The best-performing CNN (DenseNet121) was integrated with radiomic features.Additionally, images were scored by three expert radiologists using T1W and T2W images. Performance was evaluated with AUC, accuracy (Acc), sensitivity, and specificity.

RESULTS

359 cases met the inclusion criteria; 217 were Low Risk (38.5% MD-IPMN) and 142 were High Risk (27.7% BD-IPMN). Expert radiologist scorers achieved a mean Acc of 66.9% on cases with majority agreement (n=349). Similar performance was seen when using 2D and 3D features across all three algorithms. The mean AUC was 66.4% and 66.5%, and the Acc was 65.9% and 66.1% on testing for the radiomics-only analysis using 2D and 3D features, respectively. On DL-only analysis, DenseNet121 demonstrated the highest AUC of 73.3% and Acc of 68.0% among the six evaluated CNNs on cross-validation. The fusion algorithm demonstrated weighted average AUC of 74.3% and 73.4%, and Acc of 71.0% and 98.4% on cross-validation using 2D and 3D features. On testing, the fusion algorithm achieved 69.2% and 68.3% AUC, and 61.6% and 62.7% Acc on testing with 2D and 3D features.

CONCLUSION

Our fusion algorithm achieves comparable accuracy or even better to expert radiologists in IPMN risk stratification using T2W MRI alone, despite lacking clinical data or T1W sequences.

CLINICAL RELEVANCE/APPLICATION

Advanced image analysis methods like our fusion algorithm can enhance IPMN malignancy risk assessment, potentially reducing invasive interventions, minimizing patient harm, and lowering healthcare expenditures. This approach demonstrates the value of combining complementary quantitative imaging techniques in pancreatic lesion characterization.

M6-SSMS01-4 MAXIMUM LYMPHOMA SPREAD (DMAX) AS A PROGNOSTIC IMAGING BIOMARKER IN LYMPHOMA PATIENTS UNDERGOING CD19 CAR T-CELL THERAPY

Michael Winkelmann, MD (*Presenter*)
Matthias Kassube (*Abstract Co-Author*)
Viktoria Blumenberg (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)
Michael von Bergwelt-Baildon (*Abstract Co-Author*)

Jens Ricke, MD, PhD (*Abstract Co-Author*)
Marion Subklewe (*Abstract Co-Author*)
Wolfgang G. Kunz, MD, MBA (*Abstract Co-Author*)

PURPOSE

CD19-directed chimeric antigen receptor (CAR) T-cell therapy using autologous T cells has become a promising treatment option for patients with relapsed or refractory (r/r) lymphoma. As imaging biomarkers gain relevance in risk stratification, the maximum distance (Dmax) between lymphoma lesions—a surrogate of disease dissemination—has emerged as a potential prognostic factor in patients receiving conventional therapy. However, its role in the context of CAR T-cell therapy remains unexplored. This study aimed to evaluate baseline Dmax as a predictive biomarker for metabolic and overall response, progression-free survival (PFS), and overall survival (OS) in r/r lymphoma patients treated with CD19-specific CAR T cells.

METHODS AND MATERIALS

We retrospectively analyzed consecutive r/r lymphoma patients with available baseline PET/CT or CT imaging and 3-month follow-up (FU) PET/CT after CAR T-cell infusion. Baseline Dmax was calculated in centimeters and patients were stratified into tertiles: low, intermediate, and high-risk groups. Ann Arbor staging was used for comparative purposes. Tumor burden (TB) was quantified as the sum of product diameters (SPD) in mm^2 of up to six target lesions. Treatment response was assessed using the Lugano criteria and Deauville score on FU PET/CT scans.

RESULTS

Among 103 patients with measurable Dmax at baseline, 63 had available FU PET/CT scans. The median baseline Dmax was 40.0 cm (IQR: 16.4-70.3 cm). Median TB decreased from 4,095 mm^2 at baseline to 770 mm^2 at FU. The intermediate- and high-risk Dmax groups had significantly higher baseline TB compared to the low-risk group ($p = 0.005$), with medians of 7,222 mm^2, 4,649 mm^2, and 1,739 mm^2, respectively. Higher Dmax was also associated with more advanced Ann Arbor stages ($p < 0.001$). PFS was significantly shorter in the high-risk Dmax group (median: 91 vs. 364 days, $p = 0.030$), while OS did not differ significantly ($p = 0.151$), mirroring findings based on Ann Arbor staging. No significant differences were observed in Deauville scores or overall response rates (ORR) across groups.

CONCLUSION

Patients with high baseline Dmax experienced significantly shorter PFS, though OS and treatment response rates were unaffected. While Dmax did not outperform Ann Arbor staging in risk stratification, its continuous nature offers a nuanced and scalable alternative for prognostic evaluation.

CLINICAL RELEVANCE/APPLICATION

Dmax represents a simple, quantifiable imaging biomarker that could enhance multiparametric risk models and aid in optimizing individualized treatment strategies in CAR T-cell therapy.

M6-SSMS01-6 ARTIFICIAL INTELLIGENCE PIPELINE FOR DETECTION, SEGMENTATION AND CLASSIFICATION OF METASTATIC LYMPH NODES OF TUMOR ACROSS WHOLE BODY

Linmei Zhao, MD, PhD (*Presenter*)
Gaofeng Huang (*Abstract Co-Author*)
Daniel Kargilis, BA (*Abstract Co-Author*)
Yuwei Dai, MD (*Abstract Co-Author*)
Weihua Liao (*Abstract Co-Author*)
Xue Feng (*Abstract Co-Author*)
Ihab R. Kamel, MD, PhD (*Abstract Co-Author*)
Harrison X. Bai, MD (*Abstract Co-Author*)

PURPOSE

To develop and deploy a robust multi-modality artificial intelligence (AI) pipeline for the automated detection, segmentation, and classification of lymph nodes in whole-body imaging datasets, further improve the evaluation and management of metastatic tumors.

METHODS AND MATERIALS

A total of 801 cases involving breast, liver, rectal, and other tumor types were collected from The Cancer Imaging Archive and multiple international institutions to train (n=534) and validate (n=267) an AI pipeline for lymph node detection and segmentation. All cases underwent either CT or MRI imaging. Lymph node segmentations were performed by two experienced radiologists, with a third radiologist reviewing all cases and revising the segmentations as necessary. A subset of 53 cases of malignant lymph nodes, pathologically confirmed with biopsy or surgery, was used specifically to train (n=35) and validate (n=18) the classification task. The AI pipeline, designed for both CT and MRI modalities, comprised three stages: (1) lymph node localization using Retina-UNet-3D with additional false positive reduction networks, (2) segmentation using UNet-3D, and (3) malignancy classification using EfficientNetV2S. Performance evaluation was based on the following metrics: (1) sensitivity and false positives per true positive (FPs/TP); (2) Dice similarity coefficient; and (3) accuracy and area under the receiver operating characteristic curve (AUC).

RESULTS

The pipeline demonstrated robust performance across imaging modalities and anatomical regions. For lymph node detection, it achieved an average sensitivity of 77.39% with 1.69 false positives per true positive (FPs/TP) for CT, and 65.8% with 1.65 FPs/TP for MRI. Segmentation performance yielded a mean Dice similarity coefficient of 0.638±0.091 for CT and 0.639 ± 0.177 for MRI. For malignancy classification, the model achieved an accuracy of 0.633 and an AUC of 0.659 in distinguishing benign from malignant lymph nodes.

CONCLUSION

This AI-based pipeline provides a comprehensive tool for automated lymph node analysis in different tumor types across the whole body, with the potential to facilitate rapid and accurate staging of metastatic tumors.

CLINICAL RELEVANCE/APPLICATION

Assessment of lymph nodes is essential for tumor staging, treatment planning, and prognosis. Detecting abnormal lymph nodes remains a challenge for radiologists, particularly in clinical settings with diverse tumor types and imaging modalities. The proposed AI pipeline offers an automated tool for lymph node detection, segmentation, and classification across CT and MRI, potentially assisting radiologists in large-scale lymph node evaluations, reducing their workload, and streamlining workflows in oncological imaging practices.

M6-SSNPM01-4 PROJECTIONS OF FUTURE HEAT-RELATED EMERGENCY MEDICAL IMAGING UNDER CLIMATE CHANGE SCENARIOS

Eray Yilmaz, BSc (*Presenter*)
Chloe DesRoche, MD,MSc (*Abstract Co-Author*)
Pierre Masselot (*Abstract Co-Author*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)

PURPOSE

Short-term exposures to ambient heat is associated with higher demand for health care services including medical imaging. However, empirical evidence is lacking regarding future projections of heat-related medical imaging utilization. The purpose of this study was to estimate projections of excess medical imaging associated with ambient heat exposures under future climate change scenarios.

METHODS AND MATERIALS

In the baseline period (2013-2023), short-term associations of ambient heat exposure with emergency department medical imaging utilization over a lag of 0-5 days were determined based on data from four local emergency departments in Toronto, Canada, using conditional Poisson regression models. Baseline data was then applied to statistically downscaled climate projections through the year 2100. Future temperature projections were based on an ensemble mean of 35 global climate models (GCMs) from the Government of Canda. Heat-related excess medical imaging utilization was projected under future climate change scenarios based on Shared Socioeconomic Pathways (SSPs) overall and stratified by imaging modality.

RESULTS

Based on baseline data between 2013-2023, including a total of 1,946,465 emergency department medical imaging studies (mean 485±61/day) and mean daily temperature of 13.7 °C, short-term exposure to ambient heat was associated with overall imaging utilization increases of 3.3% (incidence rate ratio [IRR], 1.033; 95% CI: 1.028, 1.037, P <0.001) for a 10°C rise in the 5-day moving average of mean daily temperature. In 2083-2093, heat-related excess medical imaging utilization is projected to increase by 0.55% (95% CI: 0.48, 0.63) under the SSP1-2.6 low-emissions scenario and by 1.43% (95% CI: 1.24, 1.63) under the SSP3-7.0 high-emissions scenario compared to the baseline period. These projections correspond to an excess absolute increase of 9871 (95% CI: 7150, 12,744) and 25,908 (95% CI: 18,757, 33,460) local imaging studies per decade, respectively. Projected absolute increases in local imaging utilization under the SSP2-4.5 medium-emissions scenario are 1441 radiographs (95% CI: 1017, 1891), 373 CTs (95% CI: 172, 614), and 119 ultrasounds per year (95% CI 28, 245).

CONCLUSION

Future heat-related impacts on medical imaging utilization are expected to increase toward the end of this century across all future emission scenarios.

CLINICAL RELEVANCE/APPLICATION

Climate change adversely impacts human health and increases demand for health care. The projections in this study can be used to develop resilient radiology organizations and health systems by informing adaptation strategies to prepare for the impacts of climate change.

M6-SSNPM01-5 QUANTIFYING THE ENVIRONMENTAL IMPACT OF LOW-VALUE L-SPINE MRIS IN A SAFETY-NET HEALTHCARE SYSTEM

Isa Abdul Cader, MD (*Presenter*)
Anton A. Mlikotic, MD (*Abstract Co-Author*)
Andrew M. Hernandez, PhD (*Abstract Co-Author*)

PURPOSE

Early MRI of the lumbar spine (L-spine) for low back pain rarely improves outcomes. Unnecessary L-spine MRIs waste resources, cost the US healthcare sector $300 million annually, and confer an additional, underappreciated impact: planetary harm. The US healthcare sector generates roughly 8.5% of all nationwide greenhouse gas emissions. Medical imaging accounts for up to 1% of global greenhouse gas emissions, and MRI is the most energy-intensive modality. The purpose of this study was to quantify low-value L-spine MRIs and their environmental impact in a large, safety-net academic healthcare system.

METHODS AND MATERIALS

We conducted a multicenter retrospective chart review quantifying low-value L-spine MRIs ordered outside American College of Radiology (ACR) Appropriateness Criteria for Low Back Pain. The study period was 6 weeks in 2023: the first weeks of January - March and July - September. We measured energy consumption on a 3T and 1.5T MRI scanner. Energy data was synchronized with scanner logs to determine scan time and quantify energy consumption for L-spine protocols at the exam-level after adjusting for scan time differences. We approximated transportation emissions using zip codes and assuming transport via gas-powered vehicles.

RESULTS

During the study period, 534 L-spine MRIs were conducted in 4 centers. Of these, 92 (19%) were deemed low-value. Most low-value MRIs (97%) were conducted on 3T or 1.5T MRI scanners. We found that an L-spine MRI with and without contrast on a 3T scanner consumed the most energy at 12.1 kilowatt-hours (kWh)/scan, while an L-spine MRI without contrast on a 1.5T scanner used the least at 10.0 kWh/scan. The low-value L-spine MRIs (N=89) on 3T/1.5T scanners consumed 650.7 kWh of

energy, equivalent to 360 kg CO2 equivalents (CO2e). Patient travel generated 1119 kg CO2e. During the study period, low-value L-spine MRIs generated 1479 kg CO2e. Projecting our findings across 1 year, inappropriate L-spine MRIs generated 12,818 kg CO2e.

CONCLUSION

We found that ordering L-spine MRIs within ACR criteria in our system would have averted emissions equal to driving >32,500 miles in a gas vehicle in 1 year. Our method ignores energy consumption of MRI system modes without active patient scanning - suggesting that our findings likely underestimate total environmental impact. Our findings suggest that a collaborative approach involving frontline providers is crucial to decreasing emissions. Implementing this approach at scale could reduce the negative environmental impact associated with low-value MRIs.

CLINICAL RELEVANCE/APPLICATION

Reducing low-value L-spine MRIs can substantially mitigate the environmental impact of medical imaging.

M6-SSNPM01-6 ENERGY-SAVING EFFICIENCY OF A NOVEL SILICON CARBIDE MRI GRADIENT POWER AMPLIFIER

Liu Bi (*Presenter*)
Hui Huang (*Abstract Co-Author*)
Jianguo Xiao (*Abstract Co-Author*)
Ning Yang, MD (*Abstract Co-Author*)
Zhe Zhang (*Abstract Co-Author*)
Bin Liu (*Abstract Co-Author*)
Bin Cao (*Abstract Co-Author*)
Xu Chu (*Abstract Co-Author*)
Xiaopeng Song (*Abstract Co-Author*)
Danjiang Yuan (*Abstract Co-Author*)

PURPOSE

Magnetic Resonance Imaging (MRI) systems contribute substantially to healthcare energy costs and environmental impact, driven largely by inefficient gradient power amplifiers (GPAs). This study evaluates the energy efficiency of a novel Silicon Carbide (SiC)-based GPA compared to conventional silicon (Si) GPAs in 1.5T MRI systems, aiming to quantify potential energy savings and support sustainable medical imaging practices.

METHODS AND MATERIALS

A comparative analysis was conducted using two 1.5T MRI scanners (uMR 600 with SiC GPA and uMR 580 with Si GPA, United Imaging Healthcare) at Jingzhou Central Hospital. Identical imaging protocols (T1w/T2w SE, STIR, DWI-EPI) were applied to image the head, spine, knee, and pelvis of healthy subjects (four on SiC GPA, three on Si GPA). A power meter isolated to each GPA recorded energy consumption at 1 Hz. System logs synchronized energy data with scanning activities to calculate mean power per scan. Paired t-tests compared total power consumption, while subgroup analyses assessed sequence-specific differences. Additionally, clinical operational usage data were collected over five weeks (SiC GPA) and two weeks (Si GPA), analyzed via mixed-effects models to account for clinical variability.

RESULTS

In controlled experiments, the SiC GPA system consumed 109.34 kWh/person versus 237.13 kWh/person for the Si GPA system, demonstrating 53.89% reductions ($p<0.001$). Sequence-specific savings ranged from 47.75% (STIR) to 58.86% (PDw-SE). Clinically, the SiC GPA operated at 2.91±1.12 kW versus 8.40±2.86 kW for the Si GPA. Clinical operational data confirmed consistent energy reductions across diverse clinical workloads ($p<0.001$). Image quality (resolution, contrast, artifacts) was equivalent between systems (radiologist ratings, $p>0.05$). For a hospital performing 5,000 annual patient scans matching the protocols used in controlled experiments, adopting the SiC GPA could yield energy savings totaling 638,940 kWh—comparable to the annual electricity consumption of 123 households (each requiring 5,200 kWh/year).

CONCLUSION

The SiC GPA significantly reduces MRI energy consumption by over 50% without compromising image quality, validating its potential to enhance sustainability in medical imaging.

CLINICAL RELEVANCE/APPLICATION

Replacing conventional GPAs with SiC technology could substantially lower healthcare costs and carbon footprints. For a mid-sized hospital, annual savings exceeding 600,000 kWh would translate to reduced operational expenses and align with global green healthcare initiatives. This innovation supports broader adoption of energy-efficient technologies across medical imaging infrastructure, addressing both economic and environmental challenges in healthcare.

M6-SSNPM01-7 SEX-SPECIFIC ASSOCIATIONS OF SHORT-TERM ENVIRONMENTAL EXPOSURES WITH UTILIZATION OF MEDICAL IMAGING IN THE EMERGENCY DEPARTMENT

Michael N. Patlas, MD, FRCPC (*Abstract Co-Author*)
Joseph Choi (*Abstract Co-Author*)
Felipe Castillo Aravena, MD (*Abstract Co-Author*)

PURPOSE

To determine short-term associations of climate-related environmental exposures with utilization of emergency department medical imaging by patient sex.

METHODS AND MATERIALS

In this retrospective, time-stratified, case-crossover study, daily imaging utilization counts from four local emergency departments were linked to local daily environmental data over a 11-year period (2013-2023). Moving daily averages of each environmental exposure were calculated to account for lagged exposure effects. Conditional Poisson regression models were used to evaluate short-term associations of daily variations in environmental exposures with daily utilization of medical imaging stratified by patient sex, controlling for day-of-week, month, and year.

RESULTS

A total of 1,946,465 emergency department medical imaging studies were included. Short-term exposures to higher fine particulate matter ($PM_{2.5}$) air pollution (incidence rate ratio [IRR] 1.039; 95%CI 1.033, 1.046, $p<0.001$ for a 10 μg/m 3 rise in the 6-day moving average), gaseous nitrogen dioxide (NO_2) air pollution (IRR 1.034; 95%CI 1.028, 1.040, $p<0.001$ for a 10 ppb rise in the 5-day moving average), and outdoor temperature (IRR 1.033; 95%CI 1.028, 1.038, $p<0.001$ for a 10°C rise in the 5-day moving average) were associated with higher utilization. Short-term exposure to higher wind speeds (IRR 0.810; 95%CI 0.775, 0.846, $p<0.001$ for a

100 km/h rise in the 4-day moving average), rain (IRR 0.913; 95%CI 0.876, 0.951, p<0.001 for a 10 cm rise in the 2-day moving average), and snow (IRR 0.942; 95%CI 0.929, 0.956, p<0.001 for a 10 cm rise in the 2-day moving average) were associated with lower utilization. Associations remained significant when stratified by patient sex, with larger effect sizes in men compared to women for all exposures. When stratified by imaging modality, associations were significant between all environmental exposures and both CT and radiography utilization; whereas associations with ultrasound utilization were only significant for exposures to PM 2.5 , temperature, and snow.

CONCLUSION

Short-term environmental exposures are associated with daily utilization of emergency department medical imaging with larger effect sizes in men compared to women. Short-term exposures to particulate and gaseous air pollution and higher outdoor temperatures are associated with higher short-term imaging utilization, while short-term exposures to higher wind speeds, rain, and snow are associated with lower short-term imaging utilization.

CLINICAL RELEVANCE/APPLICATION

These results advance our understanding of the impact of climate related environmental exposures on medical imaging and can be used to inform preparations in radiology departments to build resilience

M6-SSNPM01-8 AWARENESS DRIVES ACTION: CARBON FOOTPRINT MEASUREMENT OF A RADIOLOGY DEPARTMENT IN A HIGH-COMPLEXITY HOSPITAL

Catalina Ramirez, MD (*Presenter*)

PURPOSE

To describe the carbon footprint and define the contribution of its components in the Radiology Department of a high-complexity hospital from January to December 2024.

METHODS AND MATERIALS

Retrospective descriptive study based on data collected between January and December 2024 in the Radiology Department of a high-complexity hospital. Carbon footprint measurement focused on indirect emissions, following international standards developed by the International Organization for Standardization (ISO), and included Scope 2 and 3 variables such as electricity consumption, medical supplies (including contrast agents), staff commuting, and special waste generation. Data obtained from the local database and hospital information system were tabulated and analyzed using descriptive statistics. Emissions were quantified in metric tons of CO2 equivalent (tons CO2eq). Additionally, results were compared with existing data on the carbon footprint, electricity consumption, and associated costs of the hospital.

RESULTS

Total emissions from the Radiology Department between January and December 2024 were 1,404.6 tons CO2eq. The main contributor was special waste (717.7 tons CO2eq, 51%), followed by medical supplies (431.5 tons CO2eq, 31%), electricity consumption (214.7 tons CO2eq, 15%), and staff commuting (40.7 tons CO2eq, 3%). Electricity use accounted for 37.3% of the hospital's total and cost USD 931,321.5 annually. The radiology department's carbon footprint represented 25% of the total footprint of the hospital.

CONCLUSION

A limitation of this study was the inability to quantify household-type waste, as such waste is collected at the hospital-wide level rather than by individual department. Consequently, the carbon footprint attributable to waste—and specifically to the Radiology Department—is likely underestimated. Proper segregation of waste, reducing single-use plastics, selecting recyclable or biodegradable supplies, minimizing standby mode in high-energy equipment such as CT and MRI, and promoting low-emission transport and carpooling are impactful measures to reduce emissions.

CLINICAL RELEVANCE/APPLICATION

Identifying the key contributors to the department's carbon footprint enables the implementation of targeted strategies and efficient resource allocation.

M6-SSVA02-2 AN EXPLAINABLE MACHINE LEARNING MODEL FOR PREDICTING 4-YEAR RISK OF CORONARY PLAQUE PROGRESSION IN EARLY-STAGE ATHEROSCLEROSIS: INSIGHTS FROM A COMMUNITY-BASED SERIAL CT STUDY

Yanping Su (*Presenter*)
Chenying Lu (*Abstract Co-Author*)
Jiansong Ji, MD (*Abstract Co-Author*)

PURPOSE

Coronary atherosclerosis (CAS) treatment decisions are critical for optimal patient outcomes. This study develops a clinically interpretable machine learning model for early-stage CAS by integrating traditional cardiovascular risk factors and quantitative coronary computed tomography angiography (CCTA)-derived plaque features to predict short-term plaque progression in asymptomatic populations.

METHODS AND MATERIALS

This retrospective cohort study analyzed serial CCTA data from 329 adults with early-stage CAS (median follow-up: 56 months). Feature selection combined Spearman correlation and minimal-redundancy-maximal relevance (mRMR). Eight machine learning algorithms were tested, with Random Forest selected for SHapley Additive exPlanation (SHAP) analysis.

RESULTS

The cohort (mean age 62.51±6.51 years, 57% male) demonstrated distinct plaque progression patterns in early-stage disease. Among the eight ML algorithms, Random Forest performed best (training AUC=0.94; testing AUC=0.84), outperforming traditional methods (DeLong test $p<0.05$). SHAP analysis identified key progression drivers: fibrofatty plaque volume, plaque composition heterogeneity, and monocyte count.

CONCLUSION

The ML-SHAP framework provides quantifiable insights into early-stage CAS, enabling personalized risk stratification before disease onset. The model outperforms conventional approaches in capturing complex biomarker interactions while ensuring clinical interpretability.

CLINICAL RELEVANCE/APPLICATION

This model facilitates proactive management strategies for early-stage CAS by integrating plaque characteristics and systemic inflammation markers, potentially delaying atherosclerotic progression in community-based populations.

M6-SSVA02-4 LATENT GROWTH OF THE DESCENDING THORACIC AORTA IS A MARKER OF GENETIC AORTOPATHY

Carlos Alberto Campello Jorge, MD (*Presenter*)
Prabhvir S. Marway, BA, MBBChir (*Abstract Co-Author*)
Gregory Spahlinger (*Abstract Co-Author*)
Nic Tjahjadi (*Abstract Co-Author*)
Nicholas S. Burris, MD (*Abstract Co-Author*)

PURPOSE

Accurate determination of disease etiology in ascending thoracic aortic aneurysm (aTAA) is crucial for best management. Specifically, identifying patients with heritable thoracic aortic diseases (HTAD) caused by genetic mutations (e.g., Marfan syndrome) is critical as the risk of aortic complications in this population is 250 times higher than the general population. Diffuse aortic involvement in HTAD is commonly observed, however, the importance of growth in non-dilated descending aortic segments, termed latent aortic growth (LAG), remains unclear. Vascular deformation mapping (VDM), an image analysis technique, accurately quantifies 3D aortic growth from CT angiography (CTA). We aimed to determine the association between LAG and HTAD diagnosis in a population of aTAA patients.

METHODS AND MATERIALS

This single-center retrospective cohort study (2004-2024) included adult patients (=18 years) with aTAA, non-dilated descending aortas (<30mm), and =2 gated thoracic CTAs over =2 years. Exclusions included poor imaging, aortitis, or prior descending aortic intervention. Patients were grouped based on genetic testing: 1) Tested/HTAD - pathogenic variant; 2) Tested/VUS - variant of uncertain significance; 3) Tested/Negative - negative or likely benign variant; 4) Untested/Community - aTAA patients without genetic testing or strong HTAD suspicion. Descending thoracic aortic growth rate was quantified by VDM, with LAG defined as >0.3 mm/year (90th percentile).

RESULTS

Of 717 patients (Tested/HTAD n=112; Tested/VUS n=35; Tested/Negative n=101; Untested/Community n=471), LAG was present in 32%, 23%, 9%, and 18% of these groups, respectively. Presence of LAG was associated with greater odds of HTAD diagnosis versus a Negative result (OR = 4.8 [95% CI: 2.2 - 10.7], $p < 0.01$). Multivariable analysis confirmed LAG as an independent predictor of HTAD diagnosis (OR = 4.69 [95% CI: 1.63 - 13.53], $p < 0.01$), while older age (OR = 0.93, $p < 0.01$) and bicuspid aortic valve (OR = 0.31, $p = 0.02$) were associated with decreased odds.Patients with LAG in the Untested/Community group had higher rates of tobacco use (63% vs. 39%, $p = 0.02$), family history of aTAA (42 vs. 29%, $p = 0.03$), and met AHA guidelines for genetic testing more frequently (72% vs. 56%, $p = 0.01$), but had lower rates of hyperlipidemia (50% vs. 64%, $p = 0.01$). LAG prevalence in this group was higher than in Tested/Negative group (18% vs. 9%; $p = 0.04$).

CONCLUSION

In patients with aTAA, the presence of growth in a non-dilated descending aorta (LAG) indicates a more diffuse disease phenotype, and one that is significantly associated with genetic aortopathy.

CLINICAL RELEVANCE/APPLICATION

Three-dimensional growth phenotyping by VDM may be helpful in defining disease etiology and severity in patients with aTAA.

M6-SSVA02-5 QUANTIFYING VARIABILITY OF ASCENDING AORTIC GROWTH MEASUREMENTS BETWEEN MANUAL, AI-BASED, AND THREE-DIMENSIONAL METHODS

Prabhvir S. Marway, BA, MBBChir (*Presenter*)
Carlos Alberto Campello Jorge, MD (*Abstract Co-Author*)
Timothy Baker, PhD (*Abstract Co-Author*)
Gregory Spahlinger (*Abstract Co-Author*)
Nicholas S. Burris, MD (*Abstract Co-Author*)

PURPOSE

Imaging surveillance to track growth of ascending thoracic aortic aneurysm (aTAA) is central to management. Increased growth rates (>3-5 mm/year) are a criterion for prophylactic repair and confer a 2-3-fold risk of aortic dissection. However, the large degree of measurement variability (±2-5 mm) seen with manual diameter measurements significantly hinders reliable tracking of aortic growth. To address this challenge, emerging image analysis methods have emerged that employ either an AI-based approach (multi-task U-net for aortic diameter measurement) or a registration-based technique that yields a 3D aortic growth map (vascular deformation mapping, VDM). The purpose of this study was to compare the consistency of ascending aortic (AsAo) growth trajectories between manual, AI and VDM based methods.

METHODS AND MATERIALS

Manual AsAo diameters were collected retrospectively from all available clinical CTA reports (Jan 2000 - Dec 2023), performed by 3D technicians using standardized protocols. U-Net and VDM pipelines were applied to CTAs from 4664 patients from an institutional cardiovascular research database, matching outputs to respective manual diameters where available. VDM was used for 3D growth analysis at each CTA surveillance interval, with the 90th percentile radial growth value (in mm) at each interval added to the baseline diameter to yield a trajectory. Patients with ascending aortic repair or < 2 available CTAs were excluded. Growth trajectories were classified as "inconsistent" if the diameter decreased by >1 mm over any interval. Among subjects with =3 intervals, growth variability was further quantified using isotonic regression by analyzing residuals from the fitted monotonic function.

RESULTS

11,867 Manual diameters (8,504 intervals) were collected from 3,363 patients. 2,456 paired U-Net diameters (1,611 intervals) were collected from 731 patients, alongside 712 paired VDM intervals in 406 patients. Inconsistent intervals were present in 29.4% of Manual trajectories, 21.1% for U-Net trajectories ($p<0.001$) and 1.4% for VDM-derived trajectories ($p<0.001$). After fitting isotonic regressions, residuals were much more widely distributed for Manual diameters (95% CI: -1.233, 1.220 mm, 9,133 measures), compared to U-Net (95% CI: -0.670, 0.706 mm, 1,426 measures) and VDM (95% CI: -0.327, 0.325 mm, 589 measures) (Figure 1).

CONCLUSION

Automated AI and image registration-based approaches for tracking AsAo growth demonstrate less variability compared to manual measurements.

CLINICAL RELEVANCE/APPLICATION

Reduced variability in aortic growth measurements from automated approaches improve distinction between stable and progressive disease.

M6-SSVA02-6 HIPATH: A MULTIMODAL DEEP LEARNING TOOL FOR VESSEL SEGMENTATION AND PRECISION DIAGNOSIS OF PAD

Eniko Pomozi, MD (*Presenter*)

PURPOSE

Peripheral Artery Disease (PAD) is a major global health issue, resulting in lower limb amputations. Comprehensive disease understanding of its pathophysiology remains limited. Conventional imaging often fails to delineate soft tissue and plaque components, limiting clinical decision-making. To address this gap, we established our unique Biorepository, comprising 109 cadaveric legs from patients with chronic limb-threatening ischemia. From this collection, selected specimens undergo multimodal imaging and histologic analysis. We have already shown strong correlations between UTE MRI imaging and vascular lesion characteristics, although precise integration of these modalities remains challenging. For the solution, we introduce HiPath, a deep-learning model for enhanced tissue characterization.

METHODS AND MATERIALS

We analyzed 15 vessel samples from 15 amputated legs, each scanned using ultra-short echo time (UTE) 9.4T MRI and processed with H&E and Movat histology staining, yielding 114 cross-sections. Our workflow includes: training HiPath to generate virtual histology from real histology slices, aligning virtual histology to high-resolution MRI images, performing transcriptomics sequencing for further integration and ultimately building an automated pipeline for MRI-only-based virtual histology generation.

RESULTS

9.4T ex vivo ultra-high resolution UTE MRI images were successfully co-registered with histologic sections. HiPath outperformed already existing PLIP and CONCH models in tissue segmentation and classification. Natural language annotations were used to enhance MRI interpretation via NLP-based model training. Transcriptomic sequencing was performed to integrate gene expression data for molecular-level tissue characterization.

CONCLUSION

Our novel biorepository and MRA imaging platform represent a significant step forward in AI-driven PAD diagnostics. By integrating deep learning and multimodal imaging, HiPath enables high-precision segmentation, automated tissue characterization, and improved diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

Our workflow enables non-invasive, biopsy-free tissue characterization using UTE MRI, supports precision diagnostics and individual care in vascular medicine, establishes a standardized, scalable framework for AI model training and validation in PAD research, as well as provides critical insights into plaque characteristics and vessel remodeling processes.

M6-STCE1-1 ASSESSING THE EFFECTIVENESS OF MICROVASCULAR FLOW IMAGING FOR ULTRASOUND-BASED DIAGNOSING FOCAL NODULAR HYPERPLASIA

Pal Novak Kaposi, MD, PhD (*Presenter*)
Aladar D. Ronaszeki, MD (*Abstract Co-Author*)
Robert Stollmayer (*Abstract Co-Author*)
Viktor Berczi, MD, PhD (*Abstract Co-Author*)
Pal Maurovich-Horvat, PhD (*Abstract Co-Author*)
Gabriella Gyoriga (*Abstract Co-Author*)

PURPOSE

To identify the characteristic vascular features of focal nodular hyperplasia (FNH) using microvascular flow imaging (MVI) and evaluate the effectiveness of MVI in diagnosing FNH.

METHODS AND MATERIALS

This retrospective study involved the use of B-mode ultrasound (US) and MVI scans of 41 FNHs, 21 hepatocellular carcinomas (HCCs), 20 metastases (METs), 10 hepatocellular adenomas (HCAs), and 8 hemangiomas (HEMs) from a total of 80 patients. Diagnoses were confirmed through contrast-enhanced imaging or histological analysis. Two independent observers assessed the vascular patterns on MVI. We calculated interobserver agreement and developed logistic regression models based on either B-mode or MVI features to differentiate FNH from other focal liver lesions (FLLs).

RESULTS

Interobserver agreement for MVI patterns showed substantial consistency, with a ? value of 0.641 ($p < 0.001$). The spoke-wheel pattern had a strong association with FNH, indicated by odds ratios (OR) of 51.53 and 35.28, while the central artery displayed ORs of 4.96 and 1.95. However, the spoke-wheel pattern was also observed by the two observers in subsets of HCAs (20-30%), HCCs (14-19%), and METs (5-15%). Rim vascularity was frequently seen but lacked specificity. The model based on MVI features showed significantly better performance in distinguishing FNHs, achieving an area under the curve (AUC) of 0.891 ($p < 0.001$). In comparison, the B-mode model had an AUC of 0.814. For lesions measuring 3 cm or larger, the accuracy of the MVI model was even higher, with an AUC of 0.944 ($p < 0.001$).

CONCLUSION

MVI enhances diagnostic confidence for FNH, particularly in asymptomatic patients with low malignancy risk. However, due to overlapping features with a subset of malignant FLLs, MVI must be interpreted with caution.

CLINICAL RELEVANCE/APPLICATION

MVI can be applied to all incidentally detected FLLs and in cases with equivocal imaging or clinical findings to narrow down or confirm the differential diagnosis.

M6-STCE1-3 CYCLEGAN BASED HYBRID MULTIDIMENSIONAL MRI SYNTHESIS FOR RAPID NONINVASIVE CHARACTERIZATION OF PROSTATE CANCER MICROARCHITECTURE

Aritrick Chatterjee, PhD (*Presenter*)
Dianning He (*Abstract Co-Author*)
Guantian Huang (*Abstract Co-Author*)
Abel Lorente Campos, PhD (*Abstract Co-Author*)
Aytekin Oto, MD (*Abstract Co-Author*)
Gregory S. Karczmar, PhD (*Abstract Co-Author*)

PURPOSE

Hybrid multidimensional MRI (HM-MRI) offers a novel avenue for in-vivo characterization of prostate cancer (PCa) microstructure by probing the interaction between diffusion and relaxation parameters using two dimensional sampling. However, the need to acquire multiple combinations of diffusion weightings (b values) and echo times (TEs) in conventional HM-MRI leads to prolonged scans, which limits clinical application. To overcome this barrier, we propose a deep learning based HM-MRI synthesis framework that dramatically shortens scan time without compromising tissue composition mapping accuracy.

METHODS AND MATERIALS

18 patients with biopsy-proven PCa underwent HM-MRI on a 3T MRI. The HM-MRI protocol comprised b values (0, 150 and 1000 s/mm²) and TEs (57, 70 and 150 ms), requiring 9-12 minutes of acquisition. Histopathology provided ground truth of epithelium, stroma, and lumen. We trained CycleGAN based model to infer HM-MRI from a reduced acquisition subset. Key methodological innovations included: (1) ROI guided generator training restricted to prostate gland; (2) three channels prediction of microstructure fractions with sum-to-one softmax; and (3) evaluation of all b value/TE pairings, identifying the combination of b = 0, 150 and 1000 s/mm² with TE = 150, 70 and 57 ms as the best optimal. Performance was quantified by peak signal to noise ratio (PSNR) and structural similarity index measure (SSIM).

RESULTS

Our framework reduced the acquisition time by 65%. Averaged across the five patients test set, epithelium yielded PSNR = 16.38 ± 1.04 dB and SSIM = 0.83 ± 0.05; stroma yielded PSNR = 12.62 ± 1.22 dB and SSIM = 0.83 ± 0.06; lumen yielded PSNR = 16.61 ± 1.48 dB and SSIM = 0.86 ± 0.05. In normal regions, predicted epithelium was 24.86 ± 6.46% (vs. 24.28 ± 7.23%), stroma 54.11 ± 7.41% (vs. 54.78 ± 10.06%), and lumen 21.03 ± 8.13% (vs. 21.27 ± 10.87%). Within PCa zones, epithelium was 39.01 ± 6.53% (vs. 42.20 ± 1.32%), stroma 44.08 ± 4.86% (vs. 43.27 ± 10.25%), and lumen 16.91 ± 4.76% (vs. 14.53 ± 10.68%).

CONCLUSION

The proposed CycleGAN based HM-MRI synthesis framework achieves a drastic reduction in scan time while delivering accurate maps showing volume fractions of three tissues. By optimizing b value/TE selection and incorporating anatomical constraints, it enables rapid, noninvasive delineation of PCa microstructure, with potential to improve lesion grading and guide precision therapy.

CLINICAL RELEVANCE/APPLICATION

This deep learning-accelerated HM-MRI framework effectively reduces the time to acquire patient images. Quantitative epithelium, stroma, and lumen fractions derived from this approach hold promise as biomarkers for distinguishing clinically significant PCa, optimizing targeted biopsy, and monitoring therapeutic response.

Walter R. Witschey, PhD (*Abstract Co-Author*)

PURPOSE

Hepatic steatosis is common but often underreported in abdominal imaging, despite its diagnostic significance and screening potential. Automated AI systems with orchestrated liver segmentation offer scalable steatosis detection. This study examined how such an AI orchestrator impacted radiologist reporting and concordance with quantitative findings on routine unenhanced abdominal computed tomography (CT) scans.

METHODS AND MATERIALS

We deployed an orchestrated AI liver segmentation model in a multihospital network consisting of a tertiary care center and community hospitals. We describe the performance characteristics of the AI orchestrator among eligible abdominal imaging studies. We analyzed 12,086 abdominal CT studies from February 2024 to March 2025, integrating natural language processing (NLP) to identify documentation of hepatic steatosis and comparing to AI-derived attenuation measurements. Readers were stratified into groups based on AI utilization: Group 1A (used AI), Group 1B (past AI users not using AI for these reports), and Group 2 (never used AI). Positivity rates and AI-enhanced detection rates (AEDR) were compared among these readers. AEDR was defined as AI-positive cases not documented in the radiology report divided by AI-positive cases that were documented.

RESULTS

NLP identified steatosis in 12.2% of reports overall. The AEDR for Groups 1A (n = 248 cases), 1B (n = 3,408), and 2 (n = 8,587) was 0.318, 4.500, and 3.359, respectively. Quantitative thresholds captured numerous cases not documented by radiologists, suggesting underreporting. Liver attenuation was higher in females (mean = 53.15 HU, 95% CI: 52.86-53.44) than males (50.89 HU, 95% CI: 50.59-51.19), while spleen-hepatic attenuation difference (SHAD) was more negative in females (-11.78 HU, 95% CI: -12.05 to -11.52) than males (-10.42 HU, 95% CI: -10.69 to -10.15). SHAD demonstrated a small but statistically significant decline with age (slope = -0.099 HU/year, $p < 0.0001$), while liver attenuation did not ($p = 0.545$).

CONCLUSION

Quantitative imaging traits identify many potential cases of hepatic steatosis not documented in clinical reports. Usage of attenuation and liver volume metrics in reporting is associated with higher concordance between quantitative findings and NLP-detected steatosis. These findings support the potential utility of automated tools to surface underreported imaging biomarkers and standardize detection across practice settings.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the potential of AI-derived quantitative metrics to enhance opportunistic screening for hepatic steatosis. This enables earlier detection of hepatic steatosis through analysis of routine patient scans, adding clinical value at no additional cost.

M6-STCE2-2 MULTI-ORGAN MACHINE LEARNING ANALYSIS OF COMPUTED TOMOGRAPHY BODY COMPOSITION AND MYOCARDIAL INFARCTION AND MORTALITY IN THE SCOT-HEART TRIAL

Damini Dey, PhD (*Abstract Co-Author*)
David E. Newby, PHD, MRCP (*Abstract Co-Author*)

PURPOSE

Coronary computed tomography angiography (CCTA) contains valuable prognostic information beyond coronary findings. We assessed 10-year prognostic implications of machine learning-based multi-organ body composition assessment in the Scottish COmputed Tomography of the HEART (SCOT-HEART) trial.

METHODS AND MATERIALS

Wide field-of-view images were processed using the TotalSegmentator model. Volume and mean attenuation were calculated for organ segmentations. Multivariable models were constructed for all-cause mortality and myocardial infarction (MI), adjusted for age, sex, and scan length, with odds ratio (aOR) or hazard ratio (aHR) and 95% confidence interval (CI) calculated per 10-unit increment.

RESULTS

In 1722 patients (age 57.5±9.5 years, 55.7% male) mortality occurred in 133 (7.7%) and MI in 106 (6.2%). Coronary artery disease was associated with lower lung (aOR 1.04, 95% CI 1.03, 1.06, p<0.001) and liver (aOR 0.87, 95% CI 0.8, 0.95, p=0.034) attenuation and higher torso fat volume (aOR 1.01, 95% CI 1.01, 1.02, p<0.001). Mortality was associated with volume of skeletal muscle, costal cartilage, vertebrae, torso fat, aorta, left ventricle, right ventricle and oesophagus, and with attenuation of ribs, vertebrae and skeletal muscle. Lower skeletal muscle attenuation was an independent predictor of all-cause mortality (aHR 0.61, 95% CI 0.47, 0.79, p<0.001). MI was associated with myocardial volume (aHR 1.09, 95% CI 1.01, 1.16, p=0.018) and attenuation of ribs (aHR 0.98, 95% CI 0.96, 1.0, p=0.043) and skeletal muscle (aHR 0.96, 95% CI 0.89, 1.02, p=0.002). However, when additionally adjusted for coronary calcium, only skeletal muscle attenuation was associated with MI (aHR 0.72, 95% CI 0.57, 0.91, p=0.007). Patients with skeletal muscle attenuation below the median were more likely to die (HR 1.85, 95% CI 1.30, 2.64, p<0.001) or suffer MI (HR 1.58, 95% CI 1.07, 2.33, p=0.022).

CONCLUSION

Multi-organ body composition analysis from CCTA provides additional prognostic information, and skeletal muscle attenuation is particularly important.

CLINICAL RELEVANCE/APPLICATION

Machine learning-based body composition analysis from CCTA provides prognostic information beyond the assessment of the coronary arteries, identifying both myocardial infarction and all cause mortality. Skeletal muscle in particular provided important prognostic information. This information could be used to identify high risk groups who could benefit from additional treatment.

M6-STCE2-3 PREVALENCE AND CLINICAL SIGNIFICANCE OF WHOLE-BODY MAGNETIC RESONANCE IMAGING (MRI) FINDINGS IN A LARGE COHORT

Sean D. Raj, MD, MBA (*Presenter*)
Xiaowei Hong (*Abstract Co-Author*)
Erik Sober (*Abstract Co-Author*)
Barry J. Sadegi, MD (*Abstract Co-Author*)
John Simon, MD (*Abstract Co-Author*)

PURPOSE

Determine prevalence, anatomical distribution, and clinical significance of abnormalities detected using standardized whole-body MRI (WB-MRI).

METHODS AND MATERIALS

Radiology reports from WB-MRI examinations performed from July 2024 to Jun 2025 at SimonMed Imaging centers were retrospectively analyzed. The imaging protocol included brain imaging (axial T2 FLAIR, 3-D T1, axial DWI), neck imaging (axial T2), non-contrast 3D time-of-flight MRA of the circle of Willis and carotid arteries (stenosis quantified per NASCET criteria), lumbar spine imaging (sagittal T2), and multiplanar multisequence imaging of the chest, abdomen, and pelvis. Partial or full protocols applied per clinical need. clinical need. A large language model and keyword search were used to extract information from radiology reports. All reported abnormalities were categorized by anatomical region and follow-up recommendations were classified as: no follow-up needed, additional imaging required, biopsy, recall, or others.

RESULTS

The study included radiology reports from 2773 unique patients underwent WB-MRI examination from 59 imaging center locations. WB-MRI detected abnormalities in 2,576 of 2,773 patients (92.9%), totaling 13,971 distinct findings. Anatomical distribution analysis revealed abdominal abnormalities as most frequent (5089 findings, 36.4%), followed by osseous structures (2773, 19.6%), head (2,245, 16.1%), pelvis (2046, 14.6%), neck (976, 7.0%), chest (648, 4.6%), and limbs (234, 1.7%). Follow-up recommendations were made for 2,559 findings (18.3%): imaging surveillance or further imaging for more definite diagnosis was suggested for 1997 findings (14.3%) most commonly for thyroid, hepatic and hepatic lesions, biopsy for 67 (0.5%) primarily for prostate lesions and thyroid lesions. Overall, 48.6% (1,252/2,773) of patients were recommended with imaging follow-up. There is a positive correlation between patient age and the average number of findings per patient.

CONCLUSION

WB-MRI offers a comprehensive, single-session evaluation of asymptomatic adults, commonly identifying abnormalities (predominantly abdominal and osseous). WB-MRI demonstrates high diagnostic yield and effectively differentiates findings requiring intervention from benign variants.

CLINICAL RELEVANCE/APPLICATION

This study provides valuable data on the prevalence and significance of WB-MRI findings in asymptomatic adults. These results support the development of evidence-based follow-up strategies, which can help optimize resource utilization by potentially reducing unnecessary downstream imaging while maintaining diagnostic accuracy for clinically significant lesions.

M7-SSBR03-1 DO DEEP LEARNING BREAST CANCER RISK SCORES CHANGE MEANINGFULLY OVER TIME? A LONGITUDINAL ANALYSIS

Constance D. Lehman, MD, PhD (*Presenter*)
Sarah Mercaldo, PhD (*Abstract Co-Author*)
Shadi Azam (*Abstract Co-Author*)
Andrew R. Carney, MS (*Abstract Co-Author*)
Leslie Lamb, MD, MSc (*Abstract Co-Author*)

PURPOSE

Prior studies show that AI-based breast cancer detection scores may rise years before diagnosis, but these reflect models trained to identify visible abnormalities. We evaluated whether image-only deep learning (DL) risk scores—generated by a model trained to predict 5-year future breast cancer risk—change meaningfully over time and whether trajectories differ between women who develop breast cancer and those who remain cancer-free.

METHODS AND MATERIALS

We applied a validated image-only DL model, trained to estimate 5-year future breast cancer risk from four-view digital screening mammograms, to exams from 54,361 women (2009-2024). The model uses no clinical or demographic data. We analyzed 159,556 consecutive screening digital mammograms from women who either remained cancer-free or were diagnosed with breast cancer within 1 year of their final ("index") exam. All exams within 6 years prior to the index exam were included. Women were categorized into "future cancer" (n=817) and "cancer-free" (n=53,544) groups. We summarized DL risk scores at each time point using medians and interquartile ranges (IQR), and we used Wilcoxon rank-sum tests to compare groups. Linear mixed-effects models estimated longitudinal slopes, with and without adjustment for age.

RESULTS

Median patient age was 61 years (IQR: 52-70); the median number of mammograms per woman was 3 (IQR: 2-4). Risk scores increased over time in the future cancer group (slope = 1.13/year; 95% CI: 1.08-1.18; $p < .001$) and remained flat in the cancer-free group (slope = 0.09/year; 95% CI: 0.08-0.10; $p < .001$); the between-group slope difference was 1.04 ($p < .001$). At each annual interval, DL risk scores were significantly higher in the future cancer group than in the cancer-free group: at 5-6 years (median 2.1 [IQR: 1.5-2.8] vs 1.8 [1.4-2.4]; $p = .003$), 4-5 years (2.3 [1.8-3.1] vs 2.0 [1.5-2.7]; $p < .001$), 3-4 years (2.8 [2.0-5.0] vs 2.1 [1.5-3.0]; $p < .001$), 2-3 years (2.7 [2.0-5.6] vs 2.1 [1.5-3.1]; $p < .001$), 1-2 years (3.2 [2.1-7.1] vs 2.1 [1.5-3.1]; $p < .001$), and at the index exam (6.6 [2.7-12.5] vs 2.2 [1.6-3.1]; $p < .001$). Adjustment for age yielded similar slope estimates.

CONCLUSION

Image-only DL risk scores demonstrate dynamic changes over time, rising as early as 6 years before breast cancer diagnosis. This suggests value in monitoring longitudinal risk patterns.

CLINICAL RELEVANCE/APPLICATION

These findings position DL risk scores as dynamic biomarkers. Monitoring changes over time may enhance personalized screening strategies and support more effective risk-reduction interventions.

M7-SSBR03-2 IMPACT OF BREAST DENSITY CHANGE OVER TIME ON RISK MODEL CALIBRATION AND PREDICTION ACCURACY

Stamatia V. Destounis, MD (*Presenter*)
Melissa L. Hill, PhD (*Abstract Co-Author*)
Jessica Salamone, MS (*Abstract Co-Author*)
Andrea L. Arieno, BS (*Abstract Co-Author*)
Brian Drohan, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate how changes in breast density over time affect the calibration and predictive performance of breast cancer risk models in a screening population, using both volumetric and BI-RADS-equivalent density measures.

METHODS AND MATERIALS

This retrospective study analyzed breast cancer risk assessments in a screening mammography cohort from 12/1/2016 to 4/3/2024. Included were women aged 40-79 with =5 years of screening and no prior cancer history. Volumetric breast density (VBD) was measured via Volpara software, and BI-RADS-like categories were derived. Risk scores were calculated using the Tyrer-Cuzick v8 model, which adjusts for density through a density residual (DR) based on age and BMI. DR values were analyzed over time to assess their variance and associated relative risk (RR). Calibration was evaluated by comparing observed vs. expected cancer incidence using four inputs: no density, initial VBD, initial BI-RADS-equivalent density, and 5-year average VBD. Discrimination was measured using the area under the curve (AUC). Risk results presented are TC 5-year risk.

RESULTS

The dataset included 335,328 images from 15,105 patients (median follow-up 5.3 years); 420 developed breast cancer. AUC values were similar across models, with average VBD performing best (AUC = 0.647) and no density the lowest (AUC = 0.632). Calibration improved with VBD input. Expected cancers were underestimated without density (370.8; $p<0.05$) and with BI-RADS (348.4; $p<0.001$) but closely matched observed with VBD (433.8) and average VBD (424.4). E/O ratios were 0.88, 0.83, 1.03, and 1.01, respectively. The median maximum RR shift per patient was greater using VBD vs. BI-RADS (0.281 vs. 0.220).

CONCLUSION

Breast density changes over time meaningfully impact risk prediction. Although AUC differences were minimal, longitudinal VBD improves calibration and may enhance the reliability of model-based screening decisions. These findings align with emerging evidence that incorporating density change over time enhances predictive accuracy and model reliability.

CLINICAL RELEVANCE/APPLICATION

Tracking VBD over time provides more accurate breast cancer risk estimates than static or categorical density measures, supporting its use in longitudinal screening and high-risk patient management.

M7-SSBR03-3 MAMMOGRAPHY AI RISK SCORE PERFORMANCE STRATIFIED ACROSS BI-RADS BREAST DENSITY AMONG A COHORT OF 183,441 WOMEN WITH A NEGATIVE SCREENING MAMMOGRAM OVER 15 YEARS

PURPOSE

Compare performance of BI-RADS breast density and Mirai, a mammography AI risk model, in predicting breast cancer occurrence after a negative screening mammogram in a large and diverse cohort.

METHODS AND MATERIALS

Negative screening full-field digital mammograms and BI-RADS assessments from 183,441 women with no observable breast cancer history or high-penetrant gene mutation were drawn from a large medical system from 2003-2022. 5-year Mirai risk scores were generated from 4 standard mammographic views. Ability to predict invasive or DCIS breast cancer for three models (BI-RADS, Mirai, and BI-RADS + Mirai) was estimated using a 1000 bootstrap, 5-fold cross-validated Cox proportional-hazards model at various time thresholds using Harrell's c-index and restricted cubic splines in the combined model. Mirai performance alone was further stratified by BI-RADS density. Cancer yield of Extremely Dense BI-RADS breasts and Mirai were compared at the threshold corresponding to the population percentage of women classified with Extremely Dense breasts.

RESULTS

Of the 183,441 women in the cohort, 6,998 women developed breast cancer within 15 years. AUCs for BI-RADS, Mirai, and the combined models were 0.60 (0.58-0.61), 0.70 (0.69-0.72), 0.71 (0.70-0.73) at 2 years, and 0.55 (0.55-0.56), 0.67 (0.66-0.67), 0.67 (0.66-0.68) at 10 years. AUCs for Mirai stratified by breast density were 0.76 (0.68-0.82) for Density A, 0.70 (0.67-0.73) for Density B, 0.69 (0.67-0.71) for Density C, 0.65 (0.60-0.69) for Density D at 2 years, and 0.67 (0.64-0.70) for Density A, 0.66 (0.65-0.67) for Density B, 0.66 (0.65-0.67) for Density C, 0.65 (0.62-0.67) for Density D at 10 years. Extremely dense women (~7% of population) only had mild increased risk for cancers (detecting 9% of all cancers, relative risk of 1.3). Mirai detected approximately double the cancers at the same proportion of density D women, with low overlap between the two measures (see accompanying figure).

CONCLUSION

Mirai had higher discrimination than BI-RADS breast density for short and long time horizons, with no improvement in the combined model. Mirai performed similarly when stratified by breast density and time horizons, except in density A women at 2 years, likely due to Mirai's diagnostic ability to detect cancers missed at screening.

CLINICAL RELEVANCE/APPLICATION

AI substantially improves risk stratification beyond breast density. Decisions for supplemental imaging and screening frequency should not rely on density alone in the age of AI risk models.

M7-SSBR03-4 IMAGE-ONLY DEEP LEARNING RISK MODEL VS BREAST DENSITY TO PREDICT FALSE NEGATIVE EXAMINATIONS

Leslie Lamb, MD, MSc (*Presenter*)
Sarah Mercaldo, PhD (*Abstract Co-Author*)
Andrew R. Carney, MS (*Abstract Co-Author*)
Constance D. Lehman, MD, PhD (*Abstract Co-Author*)

PURPOSE

As of September 2024, the US FDA mandated that women be informed of their breast density, both as a biomarker of future cancer risk and as a cancer masking factor. Image-only deep learning (DL) mammography-based risk models have demonstrated superior performance in predicting future cancer compared to breast density, but less is known of the potential role of DL models to predict risk of false negative (FN) examinations. The purpose of this study was to compare the performance of a DL risk model versus breast density in predicting FN screening examinations.

METHODS AND MATERIALS

This retrospective, multisite study included consecutive patients aged 30 years or older undergoing routine bilateral screening mammography from 2009-2018 across five facilities at a large academic medical center. A DL 5-year risk model (Mirai) was used to assess breast cancer risk. Based on National Comprehensive Cancer Network (NCCN) guidelines, patients were classified as low risk if their DL score was <1.7%, intermediate if > 1.7% and <3.0% and high risk if > 3.0%. Patient demographics and radiologist-assigned BI-RADS breast density were obtained from electronic medical records. Cancer outcomes were obtained through linkage to state

and regional cancer registries. FN rates (FNR) were calculated per 1000 screening mammograms and compared across risk and density groups using the Pearson chi-squared test.

RESULTS

123,091 bilateral screening mammograms in 67,019 patients met inclusion criteria. Median age was 58.0 years (IQR: 50.0-67.0). 82.1% (101,016/123,091) of exams were in White/non-Hispanic patients, 17.9% (22,075/123,091) in races other than White/non-Hispanic, and 1.6% (1996/123,091) in Hispanic. 9.0% (11,023/123,091) had fatty breasts, 49.6% (61,094/123,091) scattered fibroglandular, 37.2% (45,771/123,091) heterogeneously dense, and 4.2% (5203/123,091) extremely dense. FNRs in examinations classified as high, intermediate, and low risk by Mirai were 2.1 (59/27,906), 1.0 (50/50,683), and 0.6 (26/44,502); FNRs in dense and non-dense exams were 1.7 (89/50,974) and 0.6 (46/72,117).

CONCLUSION

A DL breast cancer risk model applied at screening mammography not only predicts future cancer but also identifies patients more likely to experience FN mammograms, providing added clinical value beyond breast density alone.

CLINICAL RELEVANCE/APPLICATION

Breast density notifications are now federally mandated. A DL risk model derived automatically at screening mammography offers a more individualized and potentially superior approach to identify patients at risk for both future cancers and missed diagnoses.

M7-SSBR03-5 IMPACT OF MAMMOGRAPHIC POSITIONING AND BREAST DENSITY ON AI-BASED SHORT-TERM BREAST CANCER RISK PREDICTION: PRELIMINARY RESULTS

Georgia G. Spear, MD (*Presenter*)
Mohamed Abdolell, MSc, BSc (*Abstract Co-Author*)
Laurie R. Margolies, MD (*Abstract Co-Author*)
Katharine Yao, MD (*Abstract Co-Author*)

PURPOSE

Artificial intelligence (AI) models offer the potential for scalable, image-based breast cancer risk stratification; however, the acquisition factors that may influence their accuracy require further understanding. This study quantifies the impact of mammographic positioning quality and the Breast Imaging Reporting and Data System (BI-RADS) breast density category on the discriminatory performance of a short-term AI risk model, with the objective of assessing calibration and performance in clinical deployment. This investigation examines the influence of mammographic positioning quality and breast density on the predictive accuracy of AI-based short-term breast cancer risk models.

METHODS AND MATERIALS

A retrospective cohort analysis included 11,136 screening mammograms (1,562 breast cancer cases, 9,574 controls) acquired between May 2017 and April 2023 from an urban healthcare network. Eligible mammograms had standard four-view sets without implants. Controls required negative follow-up mammograms =1 year post-screening. AI algorithms categorized mammographic positioning quality (Perfect, Good, Moderate, Inadequate) and breast density (BI-RADS 5th ed., categories A-D). Short-term risk predictions from the Mirai image-based model were evaluated using area under receiver operating characteristic curves (AUC) at 1-4-year intervals. Stratified analyses assessed the influences of positioning quality and breast density on prediction accuracy. Preliminary results were considered statistically significant at $p < 0.10$.

RESULTS

Performance of the Mirai risk model varied with mammographic positioning; mammograms rated Perfect had higher AUCs compared to Inadequate (2-year AUC, p=0.076). Breast density similarly impacted performance, with BI-RADS category A consistently demonstrating superior accuracy relative to the more dense categories (B,C,D; 2-year AUC, p=0.11). Both breast density and positioning quality independently affected AI model accuracy with less dense and higher quality positioning yielding higher AUCs.

CONCLUSION

Preliminary results show that inadequate mammographic positioning quality and higher breast density reduce the predictive accuracy of AI-based short-term breast cancer risk models. Ensuring optimal image quality is critical for reliable AI-driven risk assessment.

CLINICAL RELEVANCE/APPLICATION

Maintaining high-quality mammography and accurately assessing breast density are essential for effectively integrating AI-driven personalized breast cancer screening, particularly in patients with dense breast tissue or compromised image quality.

M7-SSBR03-6 INCREASING CANCER DETECTION IN DENSE BREASTS: A REAL-WORLD DEPLOYMENT OF A MULTISTAGE AI-DRIVEN WORKFLOW IN BREAST SCREENING WITH STRATIFIED ANALYSES ON OVER 570,000 CASES

Annie Ng, PhD (*Presenter*)
Leeann Louis, BS, PhD (*Abstract Co-Author*)
Edgar Wakelin (*Abstract Co-Author*)
Matthew McCabe, PhD (*Abstract Co-Author*)
Jiye G. Kim, PhD (*Abstract Co-Author*)
Christoph I. Lee, MD,MS (*Abstract Co-Author*)
Diana S. Buist, PhD,MPH (*Abstract Co-Author*)
Bryan Haslam, PhD (*Abstract Co-Author*)

PURPOSE

Women with dense breasts have a higher risk of developing breast cancer and a higher risk of cancer going undetected given cancer is more challenging to detect in dense breast tissue. AI has been shown to support increased cancer detection in breast screening, however, large-scale stratified analyses by breast density are required to assess the clinical impact across these relevant subgroups. This study assesses the clinical outcomes of a large-scale deployment of a multistage AI-driven workflow, including stratified analyses by breast density.

METHODS AND MATERIALS

A multistage AI-driven workflow was deployed across 109 sites and four states in the United States and involved concurrent reading with a CADe/x device, followed by an AI-facilitated safeguard review routing potentially missed findings to breast imaging experts. The standard of care (SOC) cohort included screens between Sept 2021 to May 2022. The AI-driven workflow cohort included screens between Aug 2022 and Dec 2022. Cancer detection outcomes including cancer detection rate (CDR), positive predictive value (PPV1), and cancer subtype proportions (grade, invasivity, and hormone receptor status (ER, PR, HER2)) were stratified for women with dense and non-dense breasts, defined as BIRADS categories C or D and A or B, respectively. Results for women with dense and non-dense breasts were compared using an unadjusted chi-square test.

RESULTS

The deployment of the multistage AI-driven workflow (N = 208 891) resulted in significantly increased CDR (6.18 vs 5.04, p<0.001) and PPV1 (4.25 vs 3.68, p=0.008) for women with dense breast as well as non-dense (CDR: 5.10 vs 4.21, p<0.001; PPV1: 6.09 vs 5.35, p=0.014) compared to SOC (N = 307 692). The majority of cancers detected by the AI-driven workflow were intermediate or high grade (80.6%) and invasive (67.5%). No differences were found in the distribution of cancer grade, invasiveness, and hormonal receptor status (p>0.05) for women with dense versus non-dense breasts.

CONCLUSION

The deployment of a multistage AI-driven workflow significantly improved clinical outcomes (CDR and PPV1) for women with dense and non-dense breasts, with the majority of cancers detected being clinically relevant.

CLINICAL RELEVANCE/APPLICATION

Detecting more clinically relevant cancers in women across all breast densities demonstrates the effectiveness and generalisability of an AI-driven workflow to support equitable clinical outcomes in screening mammography.

M7-SSBR04-1 EVOLUTION OF BREAST CANCER SCREENING: FROM HUMAN-ONLY DOUBLE READING VIA AI-INTEGRATED DOUBLE READING TO AI-INTEGRATED SINGLE READING

Karin Dembrower, MD, PhD (*Presenter*)
Frida Pilblad (*Abstract Co-Author*)
Fredrik Strand, MD, PhD (*Abstract Co-Author*)

PURPOSE

At Capio S:t Göran hospital the interventional trial ScreenTrustCAD (NCT04778670) demonstrated that AI could safely replace one of two human radiologists in breast cancer screening. After the study, AI-integrated single-reading was implemented. Here, we compare screening metrics before and with AI.

METHODS AND MATERIALS

We analyzed three time periods with different reader settings. AI made blinded standalone binary flagging decisions similar to the radiologists. Any flagged exam was referred to a consensus discussion where at least two breast radiologist decided to recall or not. - PERIOD 1: Two radiologists without AI (Sep 2020- Mar 2021) - PERIOD 2: Two radiologists with AI (Apr 2021-Jun 2023) - PERIOD 3: One radiologist with AI (Jun 2023-Jun 2024). Women reporting symptoms, prior breast cancer or in a high-risk surveillance program were excluded. The AI system Lunit Insight MMG was used for all full-field mammograms from Philips equipment. For each time period, we determined the Recall Rate (RR), Cancer Detection Rate (CDR), Positive Predictive Value (PPV). Statistical estimations and tests were performed on Stata software.

RESULTS

During PERIOD 1, there were 24,770 screening examinations with a RR of 2.62% (649/24,770), CDR of 0.44% (108/24,770), PPV of 16.6%, CDR of invasive cancers 0.29% (71/24770). Below, percentages of positive or negative change represent comparison with period 1 (double-reading without AI).During PERIOD 2, there were 110,591 screening examinations with a RR of 2.96% (2,603/110,591) (+13.1%), CDR of 0.53% (+20.5%), PPV of 22.6% (+36.1%), CDR of invasive cancers 0.37% (410/110,591) (+28.9%)During PERIOD 3, there were 58,462 screening examinations with a RR of 2.54% (2,603/58,462) (-3.1%), CDR of 0.51% (+16.1%), PPV of 25.6% (+54.2%), CDR of invasive cancers 0.39% (+34,5%)Statistical significance was shown for the differences between: Lower RR for period 2 vs. period 1 (p=0.013), period 3 vs. period 1 (p<0.001); Lower PPV for period 2 vs. period 1 (p=0.001) and period 2 vs. period 3 (p=0.036); Higher invasive CDR for period 3 vs. period 1 (p=0.022). All other apparent differences were not significant.

CONCLUSION

When using the AI system Insight MMG as a standalone reader of screening mammograms paired with one radiologist, there were more invasive cancers detected and fewer healthy women recalled compared to double-reading radiologists. Compared to pairing AI with one radiologist, adding a second radiologist, the only difference was recalling more healthy women.

CLINICAL RELEVANCE/APPLICATION

The real-world results, comparing periods before and after AI implementation, reinforce the findings from the previous ScreenTrustCAD trial that AI may be favorably used as one reader of screening mammograms.

M7-SSBR04-3 COMPARISON OF BREAST DENSITY AND AJCC BREAST CANCER PATHOLOGICAL PROGNOSTIC STAGE IN SCREEN DETECTED AND INTERVAL CANCERS IN A UK PROGRAMME

Fleur Kilburn-Toppin, MBBChir, MA (*Presenter*)
Joshua Rothwell (*Abstract Co-Author*)
Nicholas R. Payne, PhD, MSc (*Abstract Co-Author*)
Sarah Hickman, MBBS (*Abstract Co-Author*)
Fiona J. Gilbert, MBChB, FRCR (*Abstract Co-Author*)

PURPOSE

To compare the relationship of breast density and tumour subtype using newer American Joint Committee on Cancer (AJCC) breast cancer staging 8 th edition pathological prognostic staging. Incorporated biomarkers have been shown to improve mortality prediction compared to anatomic TNM staging.

METHODS AND MATERIALS

All women screened in a three-year cohort (2017-2020) from a single site were included. Screen detected cancers (SDC) and interval cancer (IC) tumour characteristics were compared and related to breast density, AJCC prognostic staging and, for ICs, retrospective radiological classification ('normal/benign mammographic features' vs 'seen on retrospective review'). Tumour subtypes (tumour size, grade, lymph node status, ER/PR/HER2 status) were obtained from histological databases. BI-RADS breast density was estimated using Volpara and two deep learning algorithms and classified as non-dense (a+b) and dense (c+d).

RESULTS

55,010 women were screened and 723 cancers were diagnosed (463 SDCs; 260 ICs). 38% SDCs and 69% ICs were in dense breasts. Time to IC diagnosis was longer in dense breasts vs non-dense breasts (median: 636 days vs 759 days). 49% of all ICs were detected in the third year, irrespective of density. 19.2% of SDCs were stage 2A and above, compared to 45% for ICs. No significant difference was seen comparing SDC and IC tumour subtypes grouped by density but women with dense breasts were more likely to require neo-adjuvant chemotherapy (NAC) than those with non-dense breasts for both SDCs (12% vs 7.5%) and ICs; (21% vs 14%). Compared to other years, ICs diagnosed in the first year had the worst prognostic AJCC staging (64.7% year 1 vs 37.7.% year 2 vs 42.9% year 3 stage 2A and above). ICs classified

'as seen on retrospective review' were more likely to be stage 2A and above compared to radiological classification 'normal/benign mammographic features' (60.9% vs 43.1%).

CONCLUSION

ICs demonstrate worse prognostic staging than SDCs and are more likely to occur in dense breasts. ICs demonstrate a longer time from screen to diagnosis in dense breasts, but there is no prognostic difference for ICs based on breast density. Women with dense breasts are however more likely to undergo NAC. Prognostically worse ICs are more likely to occur in the first year and demonstrate retrospective radiological signs on mammography.

CLINICAL RELEVANCE/APPLICATION

Detection of biologically important cancers is crucial in reducing mortality with screening. Prognostically worse ICs are more likely in the first year and if radiological signs are present, highlighting an important opportunity for AI tools to support screening programs and improve breast cancer mortality.

M7-SSBR04-4 ASSOCIATION BETWEEN FALSE POSITIVE MAMMOGRAMS AND RETURN TO SCREENING IN A RACIALLY DIVERSE COHORT

Medha Gupta, BS (*Presenter*)
Janice M. Newsome, MD (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)
Rohan Satya Isaac (*Abstract Co-Author*)

PURPOSE

False positive (FP) results from mammography screening can cause financial and emotional burdens, increased healthcare costs, missed work, and patient anxiety. FP rates can reach 10- 12% among women aged 40-49. Prior studies have evaluated whether women with FP results return to screening, but certain findings report higher return rates compared to those with true negative results while others report lower rates. We evaluated the association between FP mammography and the likelihood of returning to screening within overall and stratified by race and age.

METHODS AND MATERIALS

We analyzed data from the Emory Breast Imaging Dataset (EMBED), from which we analyzed screening mammograms between January 1, 2013 and January 1, 2018. 75,429 patients with a BI-RADS 0 result ("needs additional imaging") were followed through their diagnostic pathway. Of these patients, 22,587 (29.9%) underwent diagnostic mammography, ultimately resulting in 19,741 patients with no suspicious findings (FP- imaging only) and 684 who required further biopsy which resulted in benign findings (FP- biopsy). FPs were classified based on the diagnostic outcome: either imaging showed no suspicious findings, or biopsy confirmed benign pathology. The measured outcomes were whether a patient returned to screening within 9-36 months and median time to return. Kaplan-Meier curves and log-rank tests were used to assess time to return and differences by race, age, and FP type.

RESULTS

Over the five-year period, the overall FP rate was 13.77% per screening exam. The highest FP rates were in Black patients (43.3%) and in age groups 40-49 (32.0%). Among patients who returned to screening, 52.3% were Asian, 57.4% Black and 65.1% White. The rate of return among patients with a true negative (TN) return (90.1%) was significantly greater than that of patients with any false positive result (58.0%) ($p<0.001$). Median time to return was significantly shorter among TN patients (388 days) and FP patients (423 days)($p<0.001$). Between FP types, there was no significant difference in rates of return between imaging only (61.3%) and biopsy (57.9%) groups ($p<0.05$). The median time to return was longer in the imaging only group (483 days) than the biopsy group (420 days) ($p>0.001$).

CONCLUSION

We found a higher FP than reported in previous studies, with Black patients and young patients experiencing a higher proportion of FPs compared to other race and age groups.

CLINICAL RELEVANCE/APPLICATION

Since FPs result from BI-RADS 0 findings, interventions are needed to reduce uncertainty and decrease recall rates. These interventions include AI-assisted interpretation and workflow changes to accommodate same-day diagnostic imaging, reducing time and opportunity cost associated with false positives.

M7-SSBR04-5 AUTOMATIC QUANTIFICATION OF BREAST ARTERIAL CALCIFICATION (BAC) ON SCREENING MAMMOGRAPHY IS AN INDEPENDENT PREDICTOR OF PERIPHERAL ARTERIAL DISEASE (PAD) IN WOMEN

Theodorus Dapamede, MD, PhD (*Presenter*)
Vedant Joshi (*Abstract Co-Author*)
Aisha Urooj (*Abstract Co-Author*)
Chad Robichaux (*Abstract Co-Author*)
Frank Li, PhD (*Abstract Co-Author*)
Seyed Mohammadreza Chavoshi, MD (*Abstract Co-Author*)

Aawez Mansuri, BS, MS (*Abstract Co-Author*)
Rohan Satya Isaac (*Abstract Co-Author*)
Beatrice Brown-Mulry (*Abstract Co-Author*)
Janice M. Newsome, MD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)
William C. O'Neill, MD (*Abstract Co-Author*)
Imon Banerjee, PhD (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)

PURPOSE

Studies have shown that automatic quantification of BAC on routine screening mammography can opportunistically screen women at increased risk of major adverse cardiac events (MACE). We evaluated if BAC can also independently predict future diagnosis of peripheral artery disease (PAD) and vascular intervention.

METHODS AND MATERIALS

This retrospective cohort study included 59,854 women undergoing screening mammography at our institution between 2012-2020. An in-house AI model quantified BAC area (mm2) into Zero (0 mm2), Mild (>0-5 mm2), Moderate (>5-25 mm2) and Severe (>25mm2). Incident PAD diagnoses (ICD codes) and vascular interventions (CPT codes) were identified over a median of 8 years follow-up. We used Cox proportional hazard models to calculate adjusted Hazard Ratios (aHRs) for BAC categories (vs. Zero) in predicting time-to-PAD events, adjusting for age, DM, HTN, HLD, CKD, and smoking status.

RESULTS

Increasing BAC severity showed significant, graded associations with higher risk for both incident PAD diagnosis and intervention. Compared to Zero BAC, Moderate BAC (aHR 1.49, 95%CI: 1.24-1.78) and Severe BAC (aHR 2.59, 2.03-3.30) significantly predicted PAD diagnosis . For PAD intervention, Moderate (aHR 2.43, 1.50-3.94) and Severe BAC (aHR 3.62, 1.93-6.82) also showed significantly elevated risk ($p<0.001$). BAC remained a significant independent predictor for PAD diagnosis within all analyzed subgroups (age <50, DM, HTN, HLD, CKD, smoking history) after adjustment. Significant associations for Severe BAC and vascular intervention were seen in most subgroups.

CONCLUSION

AI-quantified BAC on screening mammograms independently predicts long-term risk of both PAD diagnosis and vascular intervention, with a significant graded effect. Its predictive value in younger women (<50) suggests utility for identifying premature risk. Furthermore, BAC significantly refines risk stratification within diverse high-risk subgroups (DM, HTN, HLD, CKD, smoking history), highlighting the value of opportunistic cardiovascular risk assessment derived from routine breast imaging.

CLINICAL RELEVANCE/APPLICATION

Mammogram BAC opportunistically identifies women at increased PAD risk, including younger individuals (<50) and those within major risk groups (DM, HTN, etc.), guiding targeted prevention.

M7-SSBR04-6 TRENDS IN BREAST CANCER INCIDENCE IN YOUNG WOMEN: EXPERIENCE AT AN OUTPATIENT COMMUNITY BREAST FACILITY

Stamatia V. Destounis, MD (*Presenter*)
Andrea L. Arieno, BS (*Abstract Co-Author*)

PURPOSE

To assess longitudinal trends in breast cancer incidence, method of detection, and tumor characteristics among women aged 18-49 over an 11-year period at an outpatient breast imaging practice.

METHODS AND MATERIALS

A retrospective review was conducted of breast cancer cases diagnosed in women aged 18-49 between 2014 and 2024 at a community outpatient breast imaging facility. This age group comprised 21-25% of the annual patient volume during the study period. Clinical and imaging data were reviewed, including detection modality, tumor grade, receptor status, size, and stage at presentation. Non-breast malignancies and cases lacking follow-up were excluded.

RESULTS

A total of 1,799 breast cancers were diagnosed in 1,290 women aged 18-49. Annual diagnoses in this group ranged from 145 to 196, with a mean age of 42.6 years (range 23-49). Of these, 731 (41%) were detected on screening and 1,068 (59%) on diagnostic evaluation. Invasive cancers comprised 1,451 cases (80.7%), while 347 (19.3%) were non-invasive. Twenty-three patients (1.8%) presented with metastatic disease. The average tumor size was 27 mm for DCIS and 22 mm for invasive cancers. A family history of breast cancer was documented in 381 cases (21%). Tumor grade distribution included 347 (19.3%) low-grade, 790 (43.9%) intermediate-grade, and 593 (33.0%) high-grade tumors; 154 (8.6%) were triple-negative. Age-stratified analysis showed that 423 cancers (24%) occurred in women under 40, and 1,376 (76%) in women aged 40-49. Annual cancer diagnoses in women under 40 ranged from 17 to 56, peaking in 2019, while cancers in women aged 40-49 consistently exceeded 98 per year. Total patients under 50 declined slightly from 24% in 2014 to 21% in 2024, but the absolute number of breast cancers in this cohort remained stable, representing approximately 20-24% of total breast cancer volume each year.

CONCLUSION

Women under 50 consistently represent a substantial portion of the breast cancer burden at our center. A significant percentage of these tumors are invasive, high-grade and triple negative, particularly among those under 40. These findings support the need for ongoing vigilance in imaging protocols and consideration of earlier or more intensive screening for higher-risk younger populations.

CLINICAL RELEVANCE/APPLICATION

Emerging national trends highlight a rising incidence of breast cancer in younger women, prompting re-evaluation of age-based screening thresholds and risk stratification strategies. Understanding age-specific tumor behavior and detection patterns can inform optimized imaging guidelines and early intervention approaches.

M7-SSCH04-1 AGE-RELATED CHANGES IN LUNG PERFUSION USING PHOTON-COUNTING CT: EXPLORING A POTENTIAL IMAGING BIOMARKER FOR PULMONARY HYPERTENSION

Bjarne Kerber, MD (*Presenter*)
Jasmin Maria-Theresia Happe (*Abstract Co-Author*)
Thomas Frauenfelder, MD (*Abstract Co-Author*)
Sabine Franckenberg, MD (*Abstract Co-Author*)

PURPOSE

To assess age-related changes in lung perfusion using photon-counting CT (PCD-CT) and evaluate its potential as a diagnostic marker for chronic thromboembolic pulmonary hypertension (CTEPH) and pulmonary arterial hypertension (PAH).

METHODS AND MATERIALS

In this retrospective study, 50 patients aged 20 to 80 years (20 male, 30 female; mean age: males 57.2 ± 14.0 years, females 49.9 ± 19.7 years) underwent clinically indicated PCD-CT scans using a standardized CTEPH protocol. Scans were considered unremarkable based on initial radiology reports and secondary review, and patients with any pulmonary or vascular pathology were excluded to form a "healthy" reference cohort. Iodine maps were generated from spectral data and analyzed using a research version of a commercially available quantitative imaging platform. For each pulmonary lobe, mean enhancement, perfusion index (mean enhancement normalized to pulmonary trunc enhancement), and segmented lung volume were computed. Linear regression analysis was performed to evaluate associations with age and to derive age-adjusted reference values. A second cohort comprising 28 patients with confirmed pulmonary hypertension (PAH, CTEPH, lung disease, or multiple etiologies) was analyzed for comparison, using independent t-tests against healthy controls to assess perfusion deficits.

RESULTS

In healthy individuals, mean enhancement significantly declined with age across all lobes (e.g., LLL: r=-0.51, p<0.001; RLL: r=-0.52, p<0.001). Perfusion index similarly declined (e.g., RLL: r=-0.67, p<0.001). Lung volume showed a moderate positive correlation with age, especially in the upper lobes (RUL: r=0.48, p<0.001; LUL: r=0.38, p=0.007). Compared to controls, patients with PAH and CTEPH had significantly lower mean enhancement, especially in CTEPH (e.g., RLL: p=0.001; LLL: p=0.016). PAH patients especially with higher disease severity showed lower mean enhancement diffusely in all lobes (e.g., RUL: p=0.023), while CTEPH exhibited regional reduction consistent with vascular obstruction.

CONCLUSION

PCD-CT perfusion parameters correlate with age and are significantly reduced in pulmonary artery hypertension and CTEPH-affected lobes. These findings suggest potential for PCD-CT perfusion metrics as non-invasive imaging biomarkers for pulmonary hypertension (PH).

CLINICAL RELEVANCE/APPLICATION

Pulmonary hypertension, especially CTEPH, carries high morbidity and mortality but is treatable if detected early. Spectral CT allows quantitative lung perfusion imaging, revealing both age-related decline and disease-specific patterns, enabling potential early identification and severity estimation of PH using routine imaging protocols.

M7-SSCH04-2 A PREDICTION MODEL FOR PULMONARY EMBOLISM FROM CLINICAL AND CHEST X-RAY DATA

Nicoletta Raciti, MD (*Presenter*)
Caterina B. Monti, MD, PhD (*Abstract Co-Author*)
Francesco Rizzetto, MD (*Abstract Co-Author*)
Davide Capra, MD (*Abstract Co-Author*)
Moreno Zanardo, PhD (*Abstract Co-Author*)
Francesco Sardanelli, MD (*Abstract Co-Author*)
Francesco Secchi, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pulmonary embolism (PE) is a common cause for emergency imaging referrals. The main imaging studies that patients with suspected PE usually undergo are represented by chest X-ray (CXR) and computed tomography (CT). The aim of our study was to build a machine learning model to identify patients with PE from CXR.

METHODS AND MATERIALS

We retrospectively included all adult patients who had undergone CXR and CT within one day of each other at our institution. For each patient we recorded age and sex, clinical variables such as D-dimer, a personal history of cancer, deep vein thrombosis, tachycardia and presence of dyspnea or cough, and imaging variables, namely Westermark sign, Fleischner sign, Hampton hump, and presence of pleural effusion. We subsequently divided our population with an 85:15 split into training and testing datasets and trained a classificator (XGBoost) with 5-fold cross-validation on our training dataset to predict the presence of PE.

RESULTS

Our study population counted 255 patients, 150 (59%) of whom males, with a median age of 75 years (interquartile range, IQR, 61-83 years). Overall, 80 (31%) patients had PE. Median D-dimer was 3.19 (IQR 1.54-8.08), 52 (20%) patients had a history of cancer, 16 (6%) presented with deep vein thrombosis, 42 (16%) with tachycardia, 150 (59%) with dyspnea and 48 (19%) with cough. Westermark sign was positive in 2 (1%) patients, Fleischer sign in 25 (10%) patients, 4 (2%) presented with Hampton hump and 95 (37%) with pleural effusion. The accuracy for our classificator on the testing set was 85%, with 67% sensitivity and 93% specificity and an area under the curve of 0.92.

CONCLUSION

A model using clinical data and information from CXR predicts the presence of pulmonary embolism with substantial accuracy.

CLINICAL RELEVANCE/APPLICATION

M7-SSCH04-3 UNEXPECTED EARLY PULMONARY THROMBI IN WAR INJURED PATIENTS

Itai Sasson (*Presenter*)
Vera Sorin, MD (*Abstract Co-Author*)
Tomer Ziv-Baran, PhD (*Abstract Co-Author*)
Edith M. Marom, MD (*Abstract Co-Author*)
Sharon Z. Adam, MD (*Abstract Co-Author*)
Galit Aviram, MD (*Abstract Co-Author*)

PURPOSE

Pulmonary embolism (PE) is commonly associated with deep vein thrombosis and the components of Virchow`s triad: hypercoagulability, stasis, and endothelial injury. High-risk patients are traditionally considered those with prolonged immobility and hypercoagulable conditions. Recent findings of pulmonary thrombosis (PT) in young, healthy combat soldiers, found on CT performed for initial trauma assessment, challenge this assumption. Our objectives were to investigate the prevalence and characteristics of incidental PT detected in relation with acute traumatic war injuries, and to evaluate the effectiveness of an artificial intelligence (AI) algorithm in these settings.

METHODS AND MATERIALS

This retrospective study analyzed immediate post-trauma CT scans of war-injured patients aged 18-45, from two tertiary hospitals between October 7, 2023, and January 7, 2024. Thrombi were retrospectively detected using an AI algorithm and confirmed by 2 senior radiologists. Findings were compared to the original CT reports. Clinical and injury-related data were recorded.

RESULTS

Of 190 patients (age 25.91±6.05, 183 males), the AI identified 10 confirmed patients with PT (5.6%). Of them, six (60%) were not originally diagnosed. The only difference between patients with PT to patients without PT was an increase in complexity and severity of the injuries in cases with PT (higher Injury Severity Score, 22.83±5.67 versus 13.05±10.60 respectively, p - =-0.01). Notably, despite the presence of thrombi, significant right ventricular dilatation was absent in all patients

CONCLUSION

To our knowledge, this is the first report of early PT in war injured patients, providing a unique opportunity to characterize these findings. PT occur more frequently than anticipated, without clinical suspicion, highlighting the need for improved radiologists' awareness and the crucial role of AI systems.

CLINICAL RELEVANCE/APPLICATION

Pulmonary Thrombosis is a distinct clinical entity separate from traditional venous thromboembolism, which raises the need for further investigation of the appropriate treatment paradigm.

M7-SSCH04-4 DEEP LEARNING RECONSTRUCTION COMBINED WITH CONTRAST-ENHANCEMENT BOOST IN DUAL-LOW DOSE CT PULMONARY ANGIOGRAPHY: TWO-CENTER PROSPECTIVE TRIAL

Leilei Shen, MD (*Presenter*)
Jinjuan Lu (*Abstract Co-Author*)
Zhenghong Bi (*Abstract Co-Author*)
Zicheng Zhao (*Abstract Co-Author*)
Mengsu Zeng, PhD (*Abstract Co-Author*)
Mingliang Wang, MD (*Abstract Co-Author*)

PURPOSE

To investigate whether the deep learning reconstruction (DLR) combined with contrast-enhancement-boost (CE-boost) technique can improve the diagnostic quality of CT pulmonary angiography (CTPA) at low radiation and contrast doses, compared with routine CTPA using hybrid iterative reconstruction (HIR).

METHODS AND MATERIALS

This prospective two-center study included 130 patients who underwent CTPA for suspected pulmonary embolism. Patients were randomly divided into two groups: the routine CTPA group reconstructed using HIR; the dual-low dose CTPA group reconstructed using HIR and DLR, following the CE-boost was additionally performed to generate HIR-boost and DLR-boost images. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of pulmonary arteries were quantitatively assessed. Two experienced radiologists independently ordered CT images (5, best; 1, worst) based on overall image noise and vascular contrast. Diagnostic performance for PE detection was calculated for each dataset.

RESULTS

Patient demographics were similar between groups. Compared to HIR images of the routine group, DLR-boost images of the dual-low dose group were significantly better at qualitative scores ($p < 0.001$). The CT values of pulmonary arteries between the DLR-boost and the HIR images were comparable ($p > 0.05$), whereas the SNRs and CNRs of pulmonary arteries in the DLR-boost images were the highest among all five datasets ($p < 0.001$). The AUCs of DLR, HIR-boost, and DLR-boost were 0.933, 0.924, and 0.986, respectively (all $p > 0.05$).

CONCLUSION

DLR combined with CE-boost technique can significantly improve the image quality of CTPA with reduced radiation and contrast doses, facilitating a more accurate diagnosis of pulmonary embolism.

CLINICAL RELEVANCE/APPLICATION

DLR-boost based low-radiation and low-contrast-dose CTPA protocol offers a novel strategy to further enhance the image quality and diagnosis accuracy for pulmonary embolism patients.

M7-SSCH04-5 EXTERNAL VALIDATION AND COMPARISON OF TWO AI MODELS FOR PE TRIAGE ON PCD-CTPA AND EID-CTPA EXAMINATIONS

Javier Contreras Yametti, MD (*Presenter*)
Anushree M. Burade, MBBS (*Abstract Co-Author*)
Seyedehelaheh Hosseini, MD (*Abstract Co-Author*)
Parisa Kaviani, MD (*Abstract Co-Author*)
Chelsea Dunning, PhD (*Abstract Co-Author*)
Saikiran Rapaka, PhD (*Abstract Co-Author*)
Julian Anhaus (*Abstract Co-Author*)
Andrei Chekkoury (*Abstract Co-Author*)
Lina Karout, MD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)
Florin Condrea (*Abstract Co-Author*)

PURPOSE

Comparing the performance of two CT pulmonary angiogram (CTPA)-based AI models for triaging patients for pulmonary emboli (PE) on photon-counting detector CT (PCD-CT) and energy-integrating detector (EID-CT) scanners.

METHODS AND MATERIALS

Our consecutive patients, IRB-approved, cross-sectional study included 745 CTPA examinations performed on either PCD-CT (Siemens NAEOTOM Alpha) (n= 345 patients; =18 years; mean age 60 years, female: male 179:166) or multivendor EID-CT scanners (GE/Philips/Siemens) (n= 400 patients; =18 years; mean age 61 years, female: male 242:158). Thin-section (1-1.25mm) were exported at 50 keV for PCD-CT, conventional images for EID-CT then all CT DICOM image datasets were processed separately with a prototype (Siemens Healthineers) and commercial (Avicenna.ai) CTPA-AI model (Blinded as A1 and A2) to obtain information on the presence and location of PE. Neither model was trained using data from the external validation site. A thoracic radiologist conducted the failure analysis to evaluate potential causes for false-positive and false-negative AI outputs. Data were tabulated in EXCEL and analyzed with SPSS (Statistical Package for the Social Sciences) to estimate the ROC area under the curve (AUC). We performed the DeLong test to assess differences in AI tool performance between PCD-CT and EID-CT.

RESULTS

PE were present in 51/345 PCD-CTPA (15%: central PE 11/51, peripheral PE 40/51) and 21/400 EID-CTPA (5%: central PE 17/51, peripheral PE 4/51). The respective NPV, PPV, AUC (95% CI), sensitivity, and specificity for detecting PE in PCD-CT were AI-1 model: 0.9, 0.84, 0.9, 0.83, 0.98; AI-2 model: 0.94, 0.89, 0.83,0.68, 0.99. The respective statistics for triaging PE on EID-CT were AI-1: 0.99, 0.32, 0.9, 0.9, 0.99; and AI-2: 0.98, 0.6, 0.82, 0.66, 0.99. Although there was a significant difference in the two vendors' AUCs ($p<0.01$), there was no AUC difference between PCD-CT and EID-CT ($p>0.1$). Despite a 51% lower dose with PCD-CT (median CTDIvol 6 mGy) versus EID-CT (CTDIvol 11 mGy), both models had higher specificity (rule out PE) on PCD-CT than EID-CT but similar AUCs ($p>0.1$)

CONCLUSION

Despite half-radiation doses with PCD-CT compared to EID-CT, both PE detection AI models performed at a similar or higher level on PCD-CT than on EID-CT exams.

CLINICAL RELEVANCE/APPLICATION

Higher image quality at lower radiation doses associated with PCD-CT scanners likely contributed to similar/improved diagnostic performance of the two assessed AI models on PCD-CT data without any prior PCD-CT-based training.

M7-SSCH04-6 ASSESSMENT OF DIFFERENCES IN RIGHT VENTRICULAR REMODELING IN ACUTE AND CHRONIC PULMONARY EMBOLISM ON NON-ECG GATED CHEST COMPUTED TOMOGRAPHY

Neel Vora, MBBS (*Presenter*)
Jennifer Bullen, MSc (*Abstract Co-Author*)
Michael A. Bolen, MD (*Abstract Co-Author*)
Rahul D. Renapurkar, MD (*Abstract Co-Author*)

PURPOSE

Right ventricular (RV) dilation is a nonspecific finding that can be seen in patients with both acute and chronic pulmonary embolism (PE). The aim of the study was to evaluate if there is a simplified approach to understand differences in RV remodeling in patients with acute versus chronic PE on non-ECG gated chest computed tomography (CT).

METHODS AND MATERIALS

This is a retrospective analysis of RV parameters among patients with acute PE, chronic PE, and normal controls. 216 patients were included; 89 patients without PE, 66 with chronic PE, and 61 with acute PE. We measured RV basal (RVBD), mid (RVMD), and apical (RVAD) diameter including the RVBD/RVAD ratio of the patients on an approximate four chamber axial view on non-ECG gated chest CT. The Kruskal-Wallis rank sum test was used to assess differences in the RV parameters among the three cohorts and if statistically significant, follow-up Wilcoxon rank sum tests were used. For RV parameters with a statistically significant association with diagnosis, an empirical receiver operating characteristic (ROC) curve and its area (AUC) was also estimated.

RESULTS

RVBD, RVMD, and RVAD were higher and statistically significant among patients with chronic PE (median: 44, 38, and 21, respectively) and acute PE (median: 48, 43, and 21, respectively) compared to patients without PE (median: 40, 33, and 20, respectively), except for the difference in RVAD between patients with acute PE and those with no PE ($p = 0.19$). The RVBD/RVAD ratio was higher among patients with acute PE compared to patients without PE and chronic PE ($p < 0.001$). This ratio was not statistically significant between patients with chronic PE and normal controls. RVBD and RVMD tended to be better than RVAD at distinguishing the PE diagnoses. RVBD and RVMD had the highest accuracies when distinguishing patients with acute PE versus patients without PE (AUC: 0.80 and 0.83) and the lowest accuracies when distinguishing patients with acute versus chronic PE (AUC: 0.60 and 0.63). RVBD/RVAD ratio had the highest accuracy when distinguishing patients with acute PE versus patients without PE (AUC: 0.75) and when distinguishing patients with acute versus chronic (AUC: 0.75); the ratio performed poorly when distinguishing patients with chronic PE and those without PE (AUC: 0.54).

CONCLUSION

This study shows the potential of using simple RV measurements in differentiating RV remodeling in patients with acute versus chronic PE. RVBD/RVAD ratio can be used as an effective marker in distinguishing the different cohorts.

CLINICAL RELEVANCE/APPLICATION

A simplified assessment of RV remodeling on routine non-ECG gated chest CT, using RV diameters and the RVBD/RVAD ratio, offers a practical and accessible tool to aid in differentiating acute PE, chronic PE, and normal cases.

M7-SSNMMI03-1 SPECT TO PET IMAGE TRANSLATION WITH A CONDITIONAL GENERATIVE ADVERSARIAL NETWORK (GAN) IMPROVES ASSESSMENT OF 177LU-PSMA POST THERAPY SCANS

Tomoaki Otani, PhD (*Presenter*)
Farshad Moradi, MD (*Abstract Co-Author*)
Hong Song, MD, PhD (*Abstract Co-Author*)
Guido A. Davidzon, MD (*Abstract Co-Author*)
Kip E. Guja, MD, PhD (*Abstract Co-Author*)
Andrei Iagaru, MD (*Abstract Co-Author*)

PURPOSE

Direct comparison between SPECT/CT after 177Lu-PSMA treatment and PSMA PET could be challenging due to differences in image quality and visual appearance. We used a conditional GAN (Pix2Pix) to transformed SPECT into PET-quality images (synthetic PET).

METHODS AND MATERIALS

97 prostate cancer patients treated with ¹77Lu-PSMA therapy were divided into training sets (n = 72) and test sets (n = 25). For model training, the input data consisted of SPECT images acquired at the time of the first 177Lu-PSMA treatment cycle, and the ground truth data comprised PSMA PET/CT images obtained prior to the first treatment. In the test set, SPECT/CT images acquired after the first and last cycles of Lu-PSMA therapy were converted into synthetic PET images by the trained model. Therapeutic response to ¹77Lu-PSMA therapy was assessed using the Response Evaluation Criteria in PSMA Imaging (RECIP), based on synthetic PET images versus the original SPECT images. The results derived from the two imaging modalities were then compared. The treatment response assessment based on post-therapy PSMA PET/CT was used as the gold standard. The ¹77Lu-PSMA-617-positive total tumor volume (Lu-TTV) and lesion count for each modality were quantified using the Segment Lesion workflow (MIM Software Inc., Cleveland, OH).

RESULTS

Treatment response assessment was concordant between SPECT and synthetic PET in 22 of 25 cases, with discrepancies observed in the remaining three. In all three discordant cases, the response classification based on synthetic PET was consistent with that derived from PSMA PET/CT. Specifically, two of the discordant cases were classified as complete response (CR) on SPECT but as partial response (PR) on synthetic PET. In the third case, the response was assessed as stable disease (SD) on SPECT and as PR on synthetic PET. The total tumor volume (Lu-TTV) derived from SPECT was significantly higher than that from synthetic PET in both the first and last treatment cycles (paired t-test, $p = 0.033$ and $p = 0.136$, respectively). Furthermore, the number of lesions detected on SPECT was significantly lower than that detected on synthetic PET for both the first and last cycles ($p = 0.014$ and $p = 0.015$, respectively).

CONCLUSION

This study demonstrates that synthetic PET from post-therapy SPECT using the pix2pix model added value for the assessment of treatment response following 177Lu-PSMA therapy.

CLINICAL RELEVANCE/APPLICATION

Synthetic PET images generated from post-therapy SPECT using a conditional GAN improve the accuracy of treatment response assessment in ¹77Lu-PSMA therapy. This approach may enhance clinical decision-making by offering PET-like image quality even in post-therapy settings where only SPECT is available.

M7-SSNMMI03-3 AUTOMATED RECIP SCORING VIA DEEP LEARNING PREDICTS SURVIVAL IN PROSTATE CANCER PSMA PET/CT

Sizhuo Meng, BSc, MSc (*Presenter*)
Ruohua Chen (*Abstract Co-Author*)
Wenchi Hsu, MD (*Abstract Co-Author*)
Linmei Zhao, MD, PhD (*Abstract Co-Author*)
Yitao Mao (*Abstract Co-Author*)
Andrei Gafita, MD (*Abstract Co-Author*)
Jeffrey P. Leal, BA (*Abstract Co-Author*)
Junyu Chen (*Abstract Co-Author*)
Fabio Raman, MD, PhD (*Abstract Co-Author*)
Yong Du, PhD (*Abstract Co-Author*)
Bennett B. Chin, MD (*Abstract Co-Author*)
Zhicheng Jiao, PhD, BS (*Abstract Co-Author*)
Lilja B. Solnes, MD, MBA (*Abstract Co-Author*)
Harrison X. Bai, MD (*Abstract Co-Author*)

PURPOSE

Accurate prognostication based on PSMA PET/CT remains clinically challenging. This study aimed to evaluate the feasibility of using a deep learning-based automatic segmentation pipeline to derive RECIP scores for predicting overall survival (OS) in prostate cancer patients, and to compare its performance against manual and empirical RECIP scoring.

METHODS AND MATERIALS

PSMA PET/CT scans from 172 patients were retrospectively analyzed. Of these, 170 had analyzable paired scans before and after treatment, with a median interval of 206 days (range: 1-2366; mean: 517). Automatic segmentation of PSMA-avid lesions was performed using a nnUNetv2 3D full-resolution model trained on manually annotated data. For each patient, three RECIP scores were generated: (1) Auto RECIP (based on ?TTV from automatic segmentation), (2) Manual RECIP (based on ?TTV from expert delineation), and (3) Empirical RECIP (based on physician judgment). RECIP progression was defined as =20% increase in total tumor volume (TTV).

RESULTS

The model successfully extracted TTV values for all analyzable patients and achieved a mean Dice coefficient of 0.738. Manual RECIP categorization: 36.6% PD, 14.5% SD, 18.6% PR, 30.3% CR; Auto RECIP: 29.0% PD, 11.7% SD, 20.0% PR, 39.3% CR. Inter-rater agreement for empirical scoring was high (Cohen's Kappa = 0.897; accuracy = 92.4%; PD agreement = 95.9%). Agreement between Auto/Manual RECIP and physicians was moderate (Kappa = 0.467-0.536; PD accuracy = 73-77%), and Auto vs. Manual was also moderate (Kappa = 0.541; accuracy = 66.2%; PD agreement = 73.8%). Kaplan-Meier analysis showed significant OS stratification using Auto and Manual RECIP ($p = 0.001$ and 0.043, respectively). Cox regression confirmed Auto RECIP PD status as an independent predictor of OS (HR = 2.33; 95% CI: 1.15-4.72; $p = 0.02$), along with post-PSMA PSA (HR = 1.04; 95% CI: 1.02-1.06; $p < 0.005$). Manual RECIP yielded comparable results (PD HR = 2.23; PSA HR = 1.05; both $p = 0.02$). Age was not significant ($p > 0.05$). Concordance indices were 0.72 (Auto) and 0.71 (Manual).

CONCLUSION

Automatic RECIP scoring using deep learning-derived lesion segmentation offers prognostic performance comparable to expert manual assessment. By capturing treatment-related tumor burden changes objectively and consistently, it serves as a viable surrogate marker for OS risk stratification.

CLINICAL RELEVANCE/APPLICATION

This work demonstrates a scalable, fully automated pipeline—from lesion segmentation to RECIP scoring—that enables rapid, reproducible, and clinically actionable prognostic assessment. The workflow can be integrated into PSMA PET/CT interpretation to support real-time decision-making.

M7-SSNMMI03-4 PSMA PET-DERIVED BONE TUMOR VOLUME AS A FACTOR ASSOCIATED WITH HEMATOLOGIC ADVERSE EVENTS IN ^{177}LU-PSMA-617 THERAPY FOR METASTATIC CASTRATION-RESISTANT PROSTATE CANCER (MCRPC)

Roman Gulati (*Abstract Co-Author*)
Amir Iravani, MD (*Abstract Co-Author*)

PURPOSE

Lutetium-177 prostate-specific membrane antigen (Lu-PSMA) is a life prolonging treatment in mCRPC and is used in later lines, when patients often have bone involvement and limited marrow reserve. Hematologic adverse events (AEs) are common, and can lead to treatment delay or interruption. We developed a multivariate regression model to study the association between PSMA PET-derived bone tumor volume and hematologic AEs.

METHODS AND MATERIALS

This retrospective cohort study included patients with mCRPC who received =1 cycle of Lu-PSMA treatment between June 2022 and January 2025. Hematological parameters were recorded at baseline and every three weeks during treatment. AE severity was assessed using the CTCAE V5. Baseline PSMA PET/CT scans were quantitatively analyzed with a semi-automated whole-body tumor segmentation workflow to extract bone volume. Time to AE was defined as the number of cycles from first cycle of Lu-PSMA to the first grade =3 AE. Kaplan-Meier estimation compared grade =3 AEs based on PSMA PET bone volume above or below the median. Multivariate Cox regression assessed the relationship between PSMA PET bone volume and grade =3 AE adjusting for other baseline characteristics, including baseline hematological parameters, patient age, prior radiation, radium-223, and lines of chemotherapy.

RESULTS

A total of 237 patients (median age: 73 years; IQR: 68, 79) received a median of 3 cycles (IQR: 2, 5) of Lu-PSMA. Prior chemotherapy was administered in 91% (59% with one line, 32% with =2 lines); 64% had prior radiation, and 13% received Radium-223; 37 patients (16%) experienced grade =3 anemia, 12 (5%) grade =3 leukopenia, and 16 (7%) grade =3 thrombocytopenia. Univariate Kaplan-Meier analysis showed a significantly shorter time to develop grade =3 AEs in patients with higher PSMA PET bone volume for anemia ($p<0.001$) and thrombocytopenia ($p<0.001$). Multivariable Cox regression showed PSMA PET bone volume was significantly associated with the occurrence of grade =3 anemia (HR=1.47, 95% CI 1.04-2.1, $p=0.031$), grade =3 thrombocytopenia (HR=2.74, 95% CI 1.75-4.31, $p<0.001$) when adjusting for other baseline characteristics. Additionally, baseline hematologic parameter levels were significantly associated with grade = 3 AEs during treatment.

CONCLUSION

Higher PSMA PET bone tumor volume was significantly associated with a higher risk of grade =3 anemia and thrombocytopenia, in patients with mCRPC treated with Lu-PSMA when adjusted for other risk factors.

CLINICAL RELEVANCE/APPLICATION

PSMA PET bone tumor volume can help identify patients with mCRPC at higher risk for severe hematologic AEs during Lu-PSMA therapy, informing attempts for early recognition and best supportive care during treatment to improve outcomes.

M7-SSNMMI03-5 IMAGING RESPONSE ASSESSMENT USING QUANTITATIVE POST-THERAPY ^{177}LU-PSMA SPECT/CT IN MCRPC PATIENTS

Geoffrey Johnson, MD, PhD (*Abstract Co-Author*)
Eugene D. Kwon, MD (*Abstract Co-Author*)
Oliver Sartor (*Abstract Co-Author*)
Matthew P. Thorpe, MD, PhD (*Abstract Co-Author*)

PURPOSE

177 Lu-PSMA therapy benefits patients with metastatic castration-resistant prostate cancer (mCRPC), but individual outcomes vary, and reliable survival predictors are lacking. This study evaluated early post-therapy SPECT/CT imaging 24 hours post-infusion to assess changes in quantitative parameters across cycles for predicting overall survival (OS)

METHODS AND MATERIALS

This was a single-center, retrospective study of patients with mCRPC treated with at least three cycles of 177 Lu-PSMA -617 between May 2022 and November 2023. Post-therapy whole-body SPECT/CT imaging was performed 24hr after each infusion, using a vertex-to-thighs acquisition protocol. Images were quantified using MIM software; 177 Lu-PSMA-positive lesions were segmented semi-automatically based on absolute thresholds reviewed and edited by radiology research assistants to reject false positive lesions; known lesions with uptake below threshold SUV < 3 were ignored. Total Lesion volume (TLV), maximum lesion standardized uptake value (SUV), mean lesion SUV, and lesion uptake volume product (UVP= mean * volume) were extracted for each timepoint. Baseline imaging from cycle 1 was compared with subsequent cycles (2 through 6), and changes in these quantitative metrics were correlated with OS using Conditional Change Cox Regression to evaluate the prognostic value of early SPECT/CT, testing the hypotheses that tumor uptake and burden conceptualized as total lesion mean SUV, max SUV, avid volume and UVP predict hazard ratio at a = 0.05

RESULTS

A total of 50 patients were included in the analysis; 5 received four cycles, 12 received five cycles, and 33 completed six cycles of 177 Lu-PSMA therapy. Mean OS for the cohort was 24.7 months, interquartile range (IQR) 12 months. Quantitative changes in tumor burden were associated with OS, particularly at cycles 4 and 5. The strongest association was observed at cycle 4, where change in lesion UVP from baseline was linked to predicted survival (HR 3.1, p = 0.0009). TLV changes from baseline to cycles 4 and 5 also reached significance (HR 2.0, 2.0, p = 0.009, 0.011). Lesion SUV Max was predictive only at cycle 5 (HR 1.7, p = 0.019), but predicted uptake independently of tumor volume at this cycle.

CONCLUSION

Change in tumor burden quantified on post-therapy SPECT/CT during 177 Lu-PSMA treatment predicted OS in patients with mCRPC. The strongest associations were observed at cycles 4 and 5, particularly for UVP and TLV. These findings highlight the potential prognostic value of timepoint-specific post-therapy SPECT/CT metrics during treatment.

CLINICAL RELEVANCE/APPLICATION

Quantitative post-therapy SPECT/CT during 177 Lu-PSMA treatment may help identify patients at higher risk of poor outcomes and support early response evaluation in mCRPC.

M7-SSNR05-1 COMPARATIVE EVALUATION OF MANUAL AND VOLUMETRIC PROGRESSION ASSESSMENT IN GLIOBLASTOMA USING RANO 2.0 CRITERIA

John Kim, BA (*Presenter*)
Thomas Nelson (*Abstract Co-Author*)
Zhou Lan (*Abstract Co-Author*)
Gilbert Youssef (*Abstract Co-Author*)
Patrick Y. Wen, MD (*Abstract Co-Author*)
Raymond Y. Huang, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate concordance between manual 2D measurements and automated volumetric segmentation for determining progression-free survival (PFS) in glioblastoma using the updated Response Assessment in Neuro-Oncology (RANO) 2.0 criteria.

METHODS AND MATERIALS

We retrospectively analyzed brain MRIs from 394 patients with newly diagnosed (nGBM) and/or recurrent glioblastoma (rGBM) treated between 2014-2020, comprising 614 treatment segments. Segments were defined as treatment intervals ending in progression, death, or loss to follow-up. Manual 2D progression was determined by expert readers using bidimensional area products per RANO 2.0. Volumetric segmentations were generated using a commercial tool, and an in-house algorithm applied RANO 2.0 criteria to automatically track lesions and assess response. Progression of disease (PD) was defined as a new measurable contrast-enhancing lesion (=1.0 × 1.0 cm in 2D or =1000 mm^3 in 3D) or increase (=25% in 2D, =40% in 3D) in the sum of target lesions. Spearman correlation between PFS and overall survival (OS) was computed with left-censoring handled using iterative multiple imputation described previously by Schemper et al. (2013).

RESULTS

Overall discordance between manual 2D and automated volumetric assessments was observed in 338/614 (55.0%) treatment segments. In discordant cases, volumetric criteria identified progression earlier than manual reads in 234 cases (69%), while manual reads were earlier in 104 cases (31%). Discordance rates were similar between nGBM (58.2%) and rGBM (52.9%) cohorts. Volumetric criteria tended to call PD earlier in both nGBM (74%) and rGBM (66%) cases. The median time difference in progression among discordant cases was 56 days earlier by volumetric criteria (IQR: 158 days), with a range of -634 to 1078 days. Automated volumetric criteria for both nGBM (0.40) and rGBM (0.32) resulted in weaker survival rank correlation between PFS and OS compared to manual criteria (nGBM = 0.58, rGBM = 0.48).

CONCLUSION

Automated volumetric criteria identified progression earlier than manual reads in most discordant cases, but this earlier detection was associated with weaker correlation to OS. These findings suggest that the volumetric approach may determine progression prematurely, warranting further refinement and validation before clinical adoption.

CLINICAL RELEVANCE/APPLICATION

RANO 2.0 introduced the option of using volumetric tumor measurements for response assessment, which, when paired with automated segmentation, offers a promising framework for standardized and scalable response evaluation. Further refinement of automatic volumetric methods may be needed to optimize their utility in determining treatment response.

M7-SSNR05-2 DIAGNOSTIC PERFORMANCE OF GA-68 DOTATATE PET/MRI IN THE EVALUATION OF PATIENTS WITH MENINGIOMA IN THE EARLY POSTOPERATIVE PERIOD

PURPOSE

DOTATATE PET is a powerful adjunct to MRI in the post-surgical management of meningioma. However, due to the potential risk of false positive findings from mild SSTR2 expression in inflammatory cells, DOTATATE PET is often delayed until 3 months post-resection. Given the importance of timely adjuvant radiotherapy (RT) planning, particularly in patients with intermediate and high risk meningiomas, our purpose was to retrospectively evaluate the diagnostic performance of DOTATATE PET in the first 3 months post-resection.

METHODS AND MATERIALS

This study is based on our prospectively enrolled cohort of patients with Brain DOTATATE PET/MRI. All patients consecutively enrolled in our registry from 2018 - October 2024 were assessed for inclusion. Inclusion criteria were 1) Brain DOTATATE PET and MRI within 13 weeks post-resection of pathology-proven meningioma and 2) follow-up MRI within 1.5 years after resection (reference standard). One patient was excluded due to severe MRI motion degradation. Lesions were classified as Treatment-Related Change (TRC), Probable TRC, Indeterminate, Probable Meningioma, or Meningioma based on the interpretation in the clinical PET/MRI and MRI reports. For the reference standard, indeterminate lesions and lesions not assessable by report were adjudicated by a neuroradiologist. Probable TRC was reclassified as TRC while Indeterminate and Probable Meningioma were reclassified as Meningioma, consistent with clinical treatment practices. Sensitivity and specificity were determined for the overall period (weeks 1-13), the early period (weeks 2-7), and the late period (weeks 8-13). Diagnostic performance of PET/MRI in the early and late periods was compared using Fisher's Exact Test.

RESULTS

24 patients with 94 lesions (71/23 TRC/Meningioma) were analyzed (11 women; 1/19/4 with WHO grade 1/2/3). Sensitivity of DOTATATE PET/MRI over the first three months post-resection was 95.7% (95% CI 79.0% - 99.2%) and specificity was 94.4% (95% CI 86.4% - 97.8%). During the early period, sensitivity was 100% (95% CI 70.1% - 100%) and specificity was 82.4% (95% CI 59.0% - 93.8%). During the late period, sensitivity was 92.9% (95% CI 68.5% - 98.7%) and specificity was 98.1% (95% CI 90.2% - 99.7%). The specificity of DOTATATE PET/MRI differed between the early and late periods ($p = 0.04$), while the sensitivity did not ($p = 1.0$).

CONCLUSION

Early postoperative DOTATATE PET/MRI demonstrated excellent diagnostic performance, with increased specificity in weeks 9-13.

CLINICAL RELEVANCE/APPLICATION

Postoperative DOTATATE PET/MRI demonstrates excellent diagnostic performance for the detection of residual meningioma as early as 9 weeks after surgery, without concern for reduced specificity, allowing timely adjuvant RT planning.

M7-SSNR05-3 IS CONTRAST NECESSARY FOR POSTOPERATIVE FOLLOW-UP PITUITARY MRI? A RETROSPECTIVE MULTI-READER COMPARISON OF UNENHANCED AND CONTRAST-ENHANCED SEQUENCES

Eliana Sacher (*Presenter*)
Sukhmanjit Singh Ghumman, MD,MSc (*Abstract Co-Author*)
Eshetu Atenafu (*Abstract Co-Author*)
Pejman Jabehdar Maralani, MD, FRCPC (*Abstract Co-Author*)

PURPOSE

Transsphenoidal surgery is the most common procedure for resection or debulking of pituitary macroadenomas. Patients often undergo multiple surveillance MRIs, raising concerns about gadolinium use, cost, and scan time. This study evaluates whether gadolinium-based contrast adds diagnostic value over unenhanced MRI post-surgery.

METHODS AND MATERIALS

A retrospective single-center cohort study included adults (=18 years old) who underwent transsphenoidal surgery for pituitary macroadenoma between January 2008 and January 2023. Inclusion required at least two post-surgical MRIs (postoperative baseline and most recent or last before reintervention), each with and without contrast. Three readers (neuroradiologists/ fellows), blinded to clinical data, independently scored each exam on: Residual tumor volume (on T1/T2 pre-gadolinium and T1 post-gadolinium images). Mass effect on the optic pathway (3-point scale: no contact, contact without displacement, displacement). Cavernous sinus invasion (Knosp grade 0-4). Paired t-tests were performed for volume comparison; weighted kappa for agreement between pre-contrast and post-contrast MRI for categorical data (optic pathway and Knosp grading). Inter-reader reliability was assessed with intra-class correlation coefficients (ICC) for volume and overall kappa between readers for categorical scores. Significance was defined as $p < 0.05$.

RESULTS

91 cases met inclusion criteria. Across all three readers: ICC for volume across readers was excellent (>0.75; ICC range 0.89-0.96). Optic pathway agreement was moderate to substantial (kappa 0.53-0.77); Knosp grading was fair (kappa 0.33-0.38). No significant difference between unenhanced and contrast-enhanced volumes for most readers ($p = 0.10$-0.63), except one ($p = 0.047$). Optic pathway agreement between pre- and post-contrast was substantial to almost perfect (kappa 0.67-0.95). Knosp agreement ranged from fair to substantial (kappa 0.39-0.85). In the subgroup requiring re-intervention due to tumor growth (N=42), most readers found no significant difference in tumor volumes between pre- and post-contrast MRI, except one ($p=0.047$ at baseline and $p=0.014$ at most recent). Agreement for optic pathway involvement was substantial to almost perfect (kappa 0.63-1.00), and for Knosp grading, fair to almost perfect (kappa 0.37-0.86).

CONCLUSION

Postoperative unenhanced MRI offers comparable information to contrast-enhanced MRI for assessing residual volume, Knosp grade, and optic pathway involvement in pituitary macroadenomas.

CLINICAL RELEVANCE/APPLICATION

Routine follow-up using non-contrast MRI may streamline protocols, reduce contrast use, and still detect clinically significant growth.

M7-SSNR05-4 BRAIN FES PET STANDARDIZED UPTAKE VALUE ASSOCIATION WITH ESR1 AND PIK3CA MUTATIONS

Massimo Cristofanilli, MD (*Abstract Co-Author*)
Jana Ivanidze, MD, PhD (*Abstract Co-Author*)

PURPOSE

Breast cancer (BC) is the second most common cancer linked to brain metastases (BM), with 70% of patients having estrogen receptor positive (ER+) disease. [F18]Fluoroestradiol (FES) is a PET radiotracer that targets ER, and brain FES PET has shown promise as an adjunct diagnostic tool in BC BM. Liquid biopsies including circulating tumor DNA (ctDNA), circulating tumor cells (CTCs) and exosomes are emerging non-invasive diagnostic and monitoring tools. Our purpose was to combine FES PET with liquid biopsy in a pilot cohort to assess the potential of this multi-modal biomarker in evaluating response to endocrine and radiotherapy in patients with ER+ BC BM.

METHODS AND MATERIALS

Following informed consent, patients with ER+ BC and known or suspected BM who underwent dedicated brain FES PET/CT and blood ctDNA analysis were included in this IRB-approved prospective study. Demographic and clinical data were collected. Dedicated brain PET/CT dynamic acquisition was performed. FES PET was co-registered to post-gadolinium contrast 3D T1 MRI. All patients also underwent Two 10-mL blood samples were collected and analyzed using the Guardant360 next-generation sequencing platform to detect genetic alterations. Codon variants of ESR1 and PIK3CA mutations were analyzed, and mutant allele frequency was assessed for personalized treatment. The average of maximum standardized uptake values (SUV) in ESR1 and PIK3CA-positive and ESR1 and PIK3CA-negative groups was compared separately. Mann-Whitney and Spearman correlation tests were performed.

RESULTS

7 patients with FES-positive lesions were stratified by PIK3CA and ESR1 mutations. 5/7 (71%) were PIK3CA-positive, and 4/6 (67%) were ESR1-positive. The mean FES PET SUV was 5.26 in the PIK3CA-positive and 1.3 in the PIK3CA-negative subgroup ($p = 0.095$). The mean FES PET SUV was 3.8 in the ESR1-positive and 1.8 in the ESR1-negative subgroup ($p = 0.533$). Strong correlation found between FES PET SUV and mutation count approaching statistical significance ($r=0.94$, $p=0.06$).

CONCLUSION

We observed a trend for higher FES PET SUV in patients with PIK3CA and ESR1 mutations, as well as a trend for greater SUV in patients with greater number of mutations, noting limitations of small sample size.

CLINICAL RELEVANCE/APPLICATION

Integrating brain FES PET with liquid biopsy has the potential to optimize treatment response in patients with ER-positive BC BM. This multi-modal approach has the potential to enhance our understanding of therapy resistance mechanisms by integrating biologically targeted PET with molecular profiling to guide treatment decisions in patients with ER+ BCBM.

M7-SSNR05-5 THE 3D NNU-NET CONVOLUTIONAL NEURAL NETWORKS FOR DETECTION AND QUANTITATIVE ASSESSMENT OF VESTIBULAR SCHWANNOMA

Uyen Nguyen, BS (*Presenter*)
Maria Correia de Verdier, MD, PhD (*Abstract Co-Author*)
Rachit Saluja, MS,BEng (*Abstract Co-Author*)
Krish Suresh (*Abstract Co-Author*)
Michael Brandel (*Abstract Co-Author*)
Jessica Schulte (*Abstract Co-Author*)
Nikdokht Farid, MD (*Abstract Co-Author*)
Jeffrey Rudie, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop and validate an automated image-processing 3D convolutional neural network (CNN) for detection and quantitative assessment of pre- and post-treatment vestibular schwannoma (VS).

METHODS AND MATERIALS

A retrospective study of 571 MRIs from 191 sporadic VS patients (mean age of 60 +/- 16[SD], 98 male, 93 female) from 12/2015 to 5/2024. Of these patients, 35% underwent surgery, 18% underwent radiation, and 47% did not receive treatment. Preliminary segmentations were generated by an nnU-Net CNN trained on T1-weighted post-contrast images from 242 patients from the TCIA Vestibular-Schwannoma-SEG dataset. These were then revised and approved by a neuroradiologist to create reference standard segmentations. The sample was randomly split into 153 training patients (452 MRIs) and 38 testing patients (119 MRIs). The nnU-Net CNN with a batch size of 4 and a patch size of 80x160x160 was used for model training.

RESULTS

Median Dice score was 0.90 (IQR 0.71-0.95) for all segmentation and varied by tumor size: 0.63 (IQR 0.00-0.84), 0.92 (IQR 0.84-0.95), and 0.95 (IQR 0.94-0.96) for small (V=100mm3), medium (100mm = V < 1000mm3), and large (V > 1000mm3) respectively. Median volume similarity was 95% (IQR 80%-98%) for all segmentation and was 73% (IQR 0%-90%), 96% (IQR 91%-98%), and 98% (IQR 97%-99%) for small, medium, and large size respectively. For pre-treatment group, the median Dice score was 0.93 (IQR 0.82-0.95) and volume similarity was 97% (IQR 85%-99%), which were better compared to 0.81 (IQR 0.00-0.91) and 88% (IQR 0%-96%) for the post-treatment group. Within the post-treatment group, average Dice score was significantly lower for post-surgery (0.36 +/- 0.41[SD]) compared to post-radiation (0.90 +/- 0.08[SD]) group (p-value <0.01). The model had 100% sensitivity for VS detection, but 41% of cases had false positive (FP) predictions with more FP in the small group (66%) compared to medium (27%) and large (31%) group.

CONCLUSION

3D nnU-Net CNN was able to segment VS at various volume sizes (optimal for medium size and exceptional for large size VS) with perfect sensitivity for VS detection. It performed well in the pre-treatment group and for patients who had undergone radiation. However, performance was affected by FP predictions and was suboptimal in patients with small VS and those who had undergone surgery.

CLINICAL RELEVANCE/APPLICATION

VS is a common tumor that can lead to hearing loss and hydrocephalus. Regardless of treatment approach, nearly all patients undergo multiple MRIs to determine growth behavior. Current longitudinal surveillance relies on manual measurements, which are time-consuming and error-prone. Thus, an automated model for detection and quantitative assessment of VS may improve clinical management of these patients.

M7-SSNR05-6 [^{68}GA]-DOTATATE PET SUV REDUCTION AFTER BEVACIZUMAB IN HIGH-GRADE MENINGIOMA: A POTENTIAL TREATMENT RESPONSE BIOMARKER

Kathryn F. Beal, MD (*Abstract Co-Author*)
Susan C. Pannullo, MD (*Abstract Co-Author*)
Jonathan P. Knisely, MD (*Abstract Co-Author*)
RAJIV MAGGE (*Abstract Co-Author*)
Mary Welch (*Abstract Co-Author*)
Jana Ivanidze, MD, PhD (*Abstract Co-Author*)
Peter Pan (*Abstract Co-Author*)
Fabio Iwamoto (*Abstract Co-Author*)

PURPOSE

Meningiomas are the most common primary intracranial neoplasms, but treatment options are limited for high-grade cases that progress despite surgery and radiotherapy. Bevacizumab, an anti-angiogenic agent, has been reported to improve progression-free survival and reduce tumor growth in this setting; however, most

radiographic assessments have relied on MRI-based criteria that may underestimate biologic effects. [68 Ga]-DOTATATE PET/MRI, which targets somatostatin receptor 2 (SSTR2), offers enhanced sensitivity and specificity over MRI alone in meningioma detection, with emerging evidence linking SSTR2 expression to vascularity, but changes in [68 Ga]-DOTATATE avidity following bevacizumab are not well studied. We present a case series of patients with high-grade meningioma who underwent [68 Ga]-DOTATATE PET/MRI before and after bevacizumab, to further characterize its therapeutic effects.

METHODS AND MATERIALS

We selected patients from our prospective registry of meningioma and other SSTR2-positive brain tumors who met the following criteria: (1) WHO grade 3 meningioma; (2) [68 Ga]-DOTATATE PET/MRI before or within 60 days of starting bevacizumab; and (3) [68 Ga]-DOTATATE PET/MRI after completing bevacizumab. We performed lesion-by-lesion analysis to track SUV max changes between pre- and post-treatment scans. A linear mixed effects model was used to assess bevacizumab's effect on [68 Ga]-DOTATATE uptake, accounting for within-patient clustering and lesion-level variability.

RESULTS

3 male patients (ages 55, 57, and 81) met the inclusion criteria, contributing 18 evaluable lesions. Following bevacizumab therapy, SUV max decreased in 15 out of 18 lesions (83%). Mixed effects modeling confirmed a mean decrease of 5.13 SUV units post-treatment ($p = 0.002$), with random effects accounting for patient- and lesion-level heterogeneity.

CONCLUSION

We observed significant decreases in [68 Ga]-DOTATATE PET SUV max following bevacizumab therapy in patients with recurrent high-grade meningioma, reinforcing its potential utility as a treatment option. These findings support further clinical evaluation of bevacizumab and suggest a future role for [68 Ga]-DOTATATE PET in guiding management in this setting.

CLINICAL RELEVANCE/APPLICATION

By demonstrating consistent [68 Ga]-DOTATATE SUV reductions following bevacizumab in high-grade meningioma, this case series supports further investigation of bevacizumab as a treatment option and reinforces the role of [68 Ga]-DOTATATE PET in assessing response.

M7-SSNR06-1 QUANTITATIVE ANALYSIS OF MULTIMODAL MRI MARKERS AND CLINICAL RISK FACTORS FOR CEREBRAL SMALL VESSEL DISEASE BASED ON DEEP LEARNING

Zhiliang Zhang (*Presenter*)
Caiyun Mou (*Abstract Co-Author*)
Jianjun Zhang (*Abstract Co-Author*)
Qing Chen (*Abstract Co-Author*)
Jianhua Mao (*Abstract Co-Author*)

PURPOSE

Cerebral small vessel disease lacks specific clinical manifestations, and extraction of valuable features from multimodal images is expected to improve its diagnostic accuracy. In this study, we used deep learning techniques to segment cerebral small vessel disease imaging markers in multimodal magnetic resonance images and analyze them with clinical risk factors

METHODS AND MATERIALS

We recruited 211 lacunar stroke patients and 83 control patients. The patients' cerebral small vessel disease markers were automatically segmented using a V-shaped bottleneck network, and the number and volume were calculated after manual correction.

RESULTS

The segmentation results of the V-shaped bottleneck network for white matter hyperintensity and recent small subcortical infarction were in high agreement with the ground truth (DSC>0.90). In small lesion segmentation, cerebral microbleed (average recall=0.778; average precision=0.758) and perivascular spaces (average recall=0.953; average precision=0.923) were superior to lacunar infarct (average recall=0.339; average precision=0.432) in recall and precision. Binary logistic regression analysis showed that age, systolic blood pressure, and total cerebral small vessel disease load score were independent risk factors for lacunar stroke ($P<0.05$). Ordered logistic regression analysis showed age was positively correlated with cerebral small vessel disease load score and total cholesterol was negatively correlated with cerebral small vessel disease score ($P<0.05$).

CONCLUSION

Lacunar stroke patients exhibited higher cerebral small vessel disease imaging markers, and age, systolic blood pressure, and total cerebral small vessel disease score were independent risk factors for lacunar stroke patients. V-shaped bottleneck network segmentation network based on multimodal deep learning can segment and quantify various cerebral small vessel disease lesions to some extent.

CLINICAL RELEVANCE/APPLICATION

This study offers a new perspective and tool for the diagnosis and risk assessment of cerebral small vessel disease (CSVD). Using a V-shaped bottleneck network, a deep learning technique, we can automatically segment and quantify CSVD markers in multimodal MR images.

M7-SSNR06-2 COMPARISON OF DANTE BLOOD SUPPRESSED AND CONVENTIONAL T1-WEIGHTED POST-CONTRAST SPACE INTRACRANIAL VESSEL WALL MRI IN MOYAMOYAVASCULOPATHY PATIENTS

Dan Cheng, MD (*Presenter*)
Mona Kharaji, MD (*Abstract Co-Author*)
Beibei Sun (*Abstract Co-Author*)
Cristina Sanchez-Vizcaino (*Abstract Co-Author*)
Javid Azadbakht, MD (*Abstract Co-Author*)
Yin Guo, PhD (*Abstract Co-Author*)
Chun Yuan, PhD (*Abstract Co-Author*)
Mahmud Mossa-Basha, MD (*Abstract Co-Author*)

PURPOSE

To compare the wall enhancement characteristics between delay alternating with nutation for tailored excitation (DANTE) blood suppressed and conventional sampling perfection with application optimized contrasts (SPACE) postcontrast 3D T1 weighted imaging (T1WI) intracranial vessel wall MRI (IVW) in Moyamoya vasculopathy patients.

METHODS AND MATERIALS

A total of 29 Moyamoya vasculopathy subjects who underwent both Dante and SPACE postcontrast 3D T1WI during the same IVW scanning session were included. 43 affected internal carotid artery and middle cerebral artery segments were analyzed. Two neuroradiologists blinded to clinical data qualitatively evaluated imaging features including overall image quality, signal-to-noise (SNR), severity of artifacts, arterial and venous suppression, and lesion assessment by using 4-point or 5-point Likert scales on DANTE and SPACE images independently and blinded to the acquisition, in a random order. Quantitative wall SNR and contrast-to-noise ratio (CNR) were determined for affected segments on both sequences. MRI findings including collateral extent, presence, pattern and intensity of post-contrast enhancement were also assessed. Interrater agreement was assessed using the intraclass correlation coefficient (ICC). Group comparisons were performed using bootstrapping, the Wilcoxon signed-rank test, or the chi-square test.

RESULTS

Inter-rater reliability coefficients ranged from 0.53 (concentric/eccentric morphology in SPACE sequences) to 0.97 (overall image quality in SPACE sequences). DANTE showed significantly reduced arterial (1 [1, 1] versus 2 [1, 2], P < .001) and venous flow artifacts (1 [1, 1] versus 2 [2, 3], P < .001) compared with SPACE. Quantitative wall SNR and CNR for the lesions did not differ between DANTE and SPACE sequences (wall SNR: 31.28 [22, 49] versus 38.03 [25.79, 52.86], P = 0.126; CNR: 16.56 [10.74, 29.64] versus 20.94 [12.59, 30.11], P = 0.124). DANTE demonstrated significantly lower distal enhancement compared with SPACE (16.7% versus 56.0%), P < .001). No significant differences were observed in stenosis/occlusion classification, concentric/eccentric morphology, proximal enhancement, or pattern enhancement between the two sequences.

CONCLUSION

DANTE blood suppression on T1-SPACE post-contrast IVW can significantly improve arterial and venous blood flow artifacts and reduce the intensity of wall enhancement without an impact on image quality, relative to conventional SPACE.

CLINICAL RELEVANCE/APPLICATION

Improved artifact suppression and consistent image quality are crucial for precise assessment of vessel wall pathology, aiding in the diagnosis, monitoring, and treatment planning for patients with Moyamoya vasculopathy.

M7-SSNR06-3 CHARACTERIZING ATHEROSCLEROTIC INTRAPLAQUE HEMORRHAGE WITH COMPUTED TOMOGRAPHY ANGIOGRAPHY AND A TRAINED RADIOMICS MODEL: A HISTOPATHOLOGICAL CORRELATION STUDY

Martin Cabarique, MD (*Presenter*)
Carlos Dier, MD (*Abstract Co-Author*)
Navami Shenoy (*Abstract Co-Author*)
Andres Gudino (*Abstract Co-Author*)
Sebastian Sanchez (*Abstract Co-Author*)
Elena Sagues (*Abstract Co-Author*)

Ruben Calle (*Abstract Co-Author*)
Pablo S. Martinez (*Abstract Co-Author*)
Bruno A. Policeni, MD, MBA (*Abstract Co-Author*)
Minako Hayakawa, MD (*Abstract Co-Author*)
Edgar Samaniego (*Abstract Co-Author*)

PURPOSE

Characterizing carotid plaque composition with CTA can help identify vulnerable plaques. A radiomics-based algorithm, derived from imaging-histology matching, may assist in detecting intraplaque hemorrhage (IPH).

METHODS AND MATERIALS

Patients with severe carotid stenosis who underwent CTA prior to carotid endarterectomy (CEA) were included, and their samples were histologically analyzed. Regions of IPH, lipid-rich necrotic core (LRNC), and calcification were identified through imaging-histology matching. Radiomic features (RFs) were extracted from these regions using 3D Slicer. RFs with the highest area under the curve (AUC) for each component were selected, and cutoff values were determined using receiver operating characteristic analysis, with optimal thresholds identified through Youden's index. The DeLong test was applied to compare AUCs, and the RFs with the best diagnostic performance were used to build a classification model. Whole plaque segmentations were also performed on CTA using 3D Slicer. Voxel-wise plaque composition estimation from the entire plaque segmentations were generated with an in-house Python algorithm, based on the previously identified thresholds. The components percentages from the algorithm were validated by comparison with those obtained from histological analysis. A registry of patients who underwent CTA neck as part of the stroke protocol was then analyzed. Multivariate analysis was performed to assess the association between plaque morphology and the presence of IPH.

RESULTS

Six patients (mean age: 73.7 ± 8.16 years; 3 men) with severe carotid stenosis (>70%) underwent CEA. Histological analysis showed median percentages of 1.49 ± 0.86% for IPH, 25.75 ± 8.59% for LRNC, and 19.22 ± 22.57% for calcification. The voxel-wise radiomics model yielded median values of 1.28 ± 2.77% for IPH, 28.52 ± 59.91% for LRNC, and 69.57 ± 63.03% for calcification. No significant differences were observed between the two methods for IPH and LRNC percentages ($p > 0.05$). The inter-method agreement for detecting IPH was 83%. A retrospective analysis of 173 plaques identified 50 (29%) with IPH. In patients with cryptogenic stroke, 25% (7/28) had plaques with IPH on the ipsilateral side of the stroke territory. Multivariable analysis indicated that ulcerated plaques were more likely to present IPH (OR: 4.81, 95% CI: 2.24-10.8, $p < 0.001$).

CONCLUSION

A radiomics-based model, developed through imaging-histology correlation, can identify voxel-level differences in plaque composition on CTA.

CLINICAL RELEVANCE/APPLICATION

Voxel-based radiomics analysis can help identify vulnerable plaques with IPH

M7-SSNR06-6 QUANTITATIVE ASSESSMENT OF CAROTID PERIVASULAR ADIPOSE TISSUE ON CAROTID CTA: CORRELATION WITH HIGH-INTENSITY PLAQUES AND HISTOLOGICALLY CONFIRMED INTRAPLAQUE HEMORRHAGE

Shun Okuyama, RT (*Presenter*)
Hiroki Nakajima, RT (*Abstract Co-Author*)
Rin Shimada (*Abstract Co-Author*)
Masaki Sakurai (*Abstract Co-Author*)
Tatsuya Nishii, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

High-Intensity Plaques (HIPs) on MPRAGE have been associated with changes in carotid perivascular adipose tissue (PVAT).In previous methods requires the manual placement of small regions of interest (ROIs) with an area of 2.5 mm^2 near the carotid wall, which may limit reproducibility. Therefore, we hypothesized that a more reproducible assessment of PVAT could be achieved by adopting the approach used in coronary CTA.

METHODS AND MATERIALS

We retrospectively analyzed 125 patients who underwent carotid CTA using a 320-detector row CT scanner at 100 kV from January 2022 to December 2023. Patients with significant carotid stenosis, stents, or PVAT volumes less than 0.1 cm^3 were excluded. PVAT was measured by two radiological technologist over axial segments of 4 cm and 8 cm centered on the carotid bifurcation. Interobserver agreement was evaluated using intraclass correlation coefficients (ICCs), and measurement differences were compared using Bland-Altman analysis. PVAT values were compared between MPRAGE HIPs-positive and HIPs-negative groups. Additionally, comparisons were made between HIPs-positive patients with pathological IPH (intraplaque hemorrhage) and HIPs-negative patients. Statistical analyses were performed using the Wilcoxon rank-sum test.

RESULTS

We analyzed 125 patients (median age 77, IQR 70-81; 82% male) with 233 carotid arteries (121 right, 112 left). Of these, 111/233 were MPRAGE HIP-negative and 122/233 were HIP-positive, including 16 with pathologically confirmed IPH. Interobserver agreement for PVAT was high, with ICCs of 0.97 (95% CI 0.96-0.98) for 4 cm and 0.98 (95% CI 0.97-0.98) for 8 cm measurements. Intraobserver correlation between 4 cm and 8 cm segments was R = 0.80 (95% CI 0.75-0.84, P < 0.001), with 8 cm measurements being slightly lower by -1.1 HU (95% CI -0.41 to -1.7). PVAT at 4 cm did not differ significantly between MPRAGE HIP-positive (-60.6 [IQR, -66.8 to -53.7] HU) and HIP-negative (-61.8 [IQR, -66.5 to -55.1] HU) groups (P = .68). Pathologically confirmed IPH cases also showed a trend toward lower PVAT (-58.6 [IQR, -64.4 to -53.4] HU) compared to HIP-negative cases, but this was not significant (P = .34).

CONCLUSION

The PVAT measurements obtained using this method demonstrated high reproducibility and objectivity. When the measurement range was doubled, PVAT values decreased slightly. There was no significant difference in PVAT between the MPRAGE HIP-positive and HIP-negative groups, nor between the MPRAGE HIP-negative group and the pathologically confirmed IPH group.

CLINICAL RELEVANCE/APPLICATION

This method provides high reproducibility and objectivity, but it did not replicate the diagnostic accuracy reported by other methods in detecting associations with HIPs

M7-STCE1-1 AI ENHANCED SILICOSIS SCREENING FROM CHEST RADIOGRAPHS: AN OPPORTUNISTIC APPROACH FOR OCCUPATIONAL LUNG DISEASE

Sivasailam Kalyan (*Presenter*)
Vasantha Kumar Venugopal, MD (*Abstract Co-Author*)
Bargava Subramanian (*Abstract Co-Author*)
Anandakumar D (*Abstract Co-Author*)
Charulatha K (*Abstract Co-Author*)
Elakkiya R (*Abstract Co-Author*)
Karthika M (*Abstract Co-Author*)
Saianiruth M (*Abstract Co-Author*)
Revathi Ezhumalai (*Abstract Co-Author*)

PURPOSE

To develop and validate a deep learning model capable of detecting radiographic patterns of silicosis on chest X-rays with high diagnostic accuracy. The model is designed for deployment in opportunistic screening workflows targeting high-risk occupational groups such as miners, construction workers, and sandblasters, particularly in resource-limited settings.

METHODS AND MATERIALS

A retrospective dataset of 75,000 posteroanterior and anteroposterior chest radiographs was assembled from occupational health archives. Each image was annotated by expert readers according to International Labour Organization (ILO) classification standards. A ResNet-50 convolutional neural network was trained using stratified sampling to ensure representative coverage of all ILO profusion categories. Data augmentation techniques were used to simulate acquisition variability and strengthen generalizability. External validation was performed on a separate dataset of 2,500 chest radiographs from a silicosis surveillance program. Grad-CAM-based heatmaps were generated for visual localization to support clinical explainability. Model performance was compared to expert consensus using sensitivity, specificity, AUC, and Cohen's kappa.

RESULTS

The model achieved an area under the ROC curve (AUC) of 0.921, with a sensitivity of 88.4% and specificity of 91.2% for silicosis detection. Agreement with expert consensus yielded a Cohen's kappa of 0.772, indicating substantial inter-rater reliability. For early-stage silicosis (ILO 1/0 category), the model maintained a sensitivity of 83.1%, suggesting strong utility in identifying subclinical disease. False positives in healthy controls were limited to 4.3%. The heatmap visualization module demonstrated high overlap with expert-annotated nodular regions, enhancing model transparency for clinical users.

CONCLUSION

The deep learning model exhibits high diagnostic accuracy and robustness for detecting silicosis on chest radiographs. Its performance across early and late disease stages, combined with visual explainability and external validation, supports its potential integration into screening workflows.Limitations: Model performance may vary across chest X-ray machines with non-standard settings. Lack of clinical correlation limits staging accuracy. Prospective field validation is pending.

CLINICAL RELEVANCE/APPLICATION

This AI tool offers a practical and scalable approach for opportunistic silicosis screening in occupational health settings. By leveraging existing chest radiograph infrastructure, it can help bridge diagnostic gaps in high-risk populations, enabling early detection and timely intervention for pneumoconiosis.

M7-STCE1-3 A PIPELINE FOR EXTRACTION OF NOVEL FLAIR BIOMARKERS FOR DIAGNOSIS OF ALZHEIMER'S DISEASE AND VASCULAR DEMENTIA

Matthew So, MD (*Presenter*)
April Khademi, BEng (*Abstract Co-Author*)

PURPOSE

Alzheimer's disease (AD) is a neurodegenerative clinical syndrome primarily characterized by impairments in memory. While AD is a clinical diagnosis, neuroimaging is used to rule out reversible causes of dementia. This represents an ideal role for deriving opportunistic biomarkers, as FLAIR sequences are routinely acquired. While volumetric biomarkers have been previously described, new research suggests the utility of whole-brain FLAIR texture biomarkers in AD diagnosis including macrostructural damage (MAD) and microstructural integrity (MII). The objective of this study was to validate an end-to-end FLAIR biomarker extraction method for neurodegenerative conditions including Alzheimer's disease (AD) and mixed vascular dementia and AD (vAD), including texture, volume, and summary statistical biomarkers.

METHODS AND MATERIALS

Data was obtained from the COMPASS-ND trial, a large Canadian multicenter prospective cohort study of dementia and aging. Patient diagnoses included: cognitively unimpaired (CU), mild cognitive impairment (MCI), AD, vascular MCI (vMCI), and vAD. A convolutional neural network was used to segment anatomical regions from FLAIR images. Texture, statistical, and volumetric biomarkers were computed. Binary classification using random forests with 5-fold cross-validation were used for the following tasks: CU compared to MCI, AD, vMCI, vAD, AD+MCI, vAD+vMCI, all respectively; MCI vs vMCI, MCI vs AD, vMCI vs vAD, AD vs vAD, vAD+vMCI vs AD+MCI.

RESULTS

582 patients were analyzed. A classifier using texture, volume, and summary statistics showed stronger performance (Area under the curve (AUC)=0.86 for tasks involving CU and AUC=0.8 for tasks without) compared to texture (AUC=0.84, 0.75), volume (AUC=0.84, 0.67), and summary statistics (AUC=0.83, 0.79) alone.

Notable tasks include CU vs vAD and CU vs AD (AUC=0.95, AUC=0.92) respectively, and MCI vs AD (AUC=0.80). Post-hoc analyses showed important univariate predictors across multiple tasks included whole-brain volume, MAD, MII, and volume of the hippocampus, and MII of the white matter.

CONCLUSION

A machine learning-based classifier using a combination of FLAIR biomarkers showed strong classification performance on neurodegenerative tasks along the AD spectrum. The strongest predictors included both new and novel biomarkers including texture biomarkers of the white matter and hippocampus.

CLINICAL RELEVANCE/APPLICATION

A fast, highly interpretable neurodegenerative biomarker extraction pipeline is described using routinely acquired FLAIR sequences. This may be used to improve diagnosis in unclear clinical cases (such as differentiation from pseudodementia), to quantify and track the degree of parenchymal degeneration, and to prognosticate the course of disease.

M7-STCE2-1 CLINICAL VALUE OF ARTIFICIAL INTELLIGENCE ITERATIVE RECONSTRUCTION IN ULTRA-LOW-DOSE UPPER EXTREMITY CTA FOR ASSESSING ARTERIOVENOUS FISTULAS/GRAFTS AMONG HEMODIALYSIS PATIENTS

Beili Shou (*Presenter*)
Jing Li (*Abstract Co-Author*)
Wenming Zhang (*Abstract Co-Author*)
Xi Hu (*Abstract Co-Author*)
Yangheng Zhou (*Abstract Co-Author*)
Hongjie Hu, MD (*Abstract Co-Author*)

PURPOSE

To investigate the clinical value of artificial intelligence iterative reconstruction (AIIR) in ultra-low-dose upper extremity CT angiography for arteriovenous fistula or graft (AVF/G) assessment in hemodialysis patients.

METHODS AND MATERIALS

Ninety patients with suspected or known AVF/G dysfunction among hemodialysis patients were prospectively enrolled and randomized into three groups: routine-dose group (RD, n=30; 100 kVp; 1.0 ml/kg contrast; hybrid iterative reconstruction), low-dose group (LD, n=30; 80 kVp; 0.6 ml/kg contrast; AIIR) and ultra- low-dose group (ULD, n=30; 60 kVp; 0.5 ml/kg contrast; AIIR). Two radiologists independently scored the overall image quality using a 4-point scale (1=poor; 4=excellent). Diagnostic performance (area under the curve, accuracy, sensitivity, specificity) for detecting significant (>50%) stenosis was evaluated on a per-segment basis, using digital subtraction angiography as the reference standard. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) in anastomotic stoma were also analyzed.

RESULTS

No significant differences in demographic characteristics were observed among the three groups (all p >0.05). Compared to the RD and LD, the ULD (77.09 mGyxcm, 28 mL contrast) demonstrated 83.91% and 65.67% reductions in radiation dose and 55.56% and 22.22% decreases in contrast dosage, respectively. Subjective image quality scores showed no intergroup differences (RD: 3.86±0.36 vs. LD: 3.68±0.48 vs. ULD: 3.64±0.38, p >0.05). In the per-segment analysis, diagnostic performance metrics (AUC/accuracy/sensitivity/specificity) remained comparable among three groups, with RD at (0.91, 90%, 92%, 90%), LD at (0.94, 90%, 100%, 87%), and ULD at (0.93, 88%, 100%, 86%). Notably, the ULD exhibited significantly higher SNR (39.71 vs. 23.18, p <0.001) and CNR (43.91 vs. 22.13, p <0.001) compared with RD, though lower than LD (SNR: 61.03; CNR: 57.24, both p <0.05) in anastomotic stoma.

CONCLUSION

Ultra-low-dose CTA with AIIR significantly reduces radiation and contrast doses while providing superior image quality and maintaining high diagnostic accuracy for AVF/G stenosis, offering a viable alternative to routine-dose CTA.

CLINICAL RELEVANCE/APPLICATION

The AIIR algorithm could be a promising reconstruction technique to improve image quality and maintain diagnostic performance of stenosis detection in upper extremity CTA for hemodialysis arteriovenous fistula/graft.

M7-STCE2-3 BOOSTING VASCULAR CONTRAST: ENERGY-AWARE DIFFUSION MODEL TO SALVAGE SUBOPTIMAL CT PULMONARY ANGIOGRAMS

Chang Yong Choi, MS (*Presenter*)
Seongyong Pak (*Abstract Co-Author*)
Hyunki Lee (*Abstract Co-Author*)
Joon Park, MD (*Abstract Co-Author*)
Yoojin Nam, MD (*Abstract Co-Author*)
Seungjoo Park (*Abstract Co-Author*)
Gil-Sun Hong, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

To salvage suboptimal enhanced CT pulmonary angiograms (CTPA) by generating contrast-boosted images using an energy-aware diffusion model (EADM), thus avoiding additional contrast media or repeat CT scans.

METHODS AND MATERIALS

A total of 212 contrast-enhanced dual-energy CTPA studies were used for model training, and evaluation was conducted on a temporally separated test set of 95 cases collected from a tertiary hospital. For each case, suboptimal enhanced CTPA (SE-CTPA) images were simulated at 80, 84, 90, 100, 110, and 125 keV using dual-energy simulation software (syngo.via, Siemens Healthineers) and paired with the corresponding optimally enhanced CTPA (OE-CTPA) images at 70 keV to serve as reference targets. EADM was designed to translate SE-CTPA into OE-CTPA by embedding energy-specific features extracted from the input images via an energy-aware encoder, aiming to restore optimal vascular contrast in SE-CTPA. EADM were compared to Image-to-Image Schrödinger Bridge (I²SB) and Pix2PixHD. The contrast boosting ratio percentage (CBR%) was calculated as the percentage of progress toward the target pulmonary artery attenuation of 400 HU. For quantitative metrics, root-mean-square error (RMSE), peak signal-to-noise ratio (PSNR), and structural-similarity index (SSIM) were calculated. Two expert radiologists performed a visual quality assessment of synthesized OE-CTPAs from 80, 100, and 125 keV SE-CTPA inputs in 16 PE-positive cases. This evaluation focused on pulmonary embolism (PE) conspicuity and was performed using a five-point Likert scale.

RESULTS

EADM achieved a mean CBR% of 74.59% ± 26.7% across the test set, indicating substantial progress toward the target pulmonary artery enhancement of 400 HU. For quantitative evaluation, EADM outperformed I²SB and Pix2PixHD in image similarity metrics, achieving the lowest RMSE (11.63 ± 7.27), highest PSNR (50.26 ± 3.76 dB), and highest SSIM (0.992 ± 0.007), all with statistically significant differences ($p < 0.001$). In the visual assessment of 16 PE-positive cases, synthesized OE-CTPAs generated by EADM demonstrated significantly improved conspicuity of pulmonary embolism, achieving a mean Likert score of 4.18 ± 1.13, compared with 3.33 ± 1.07 for I²SB and 3.53 ± 0.52 for Pix2PixHD ($p < 0.01$).

CONCLUSION

EADM effectively restores vascular contrast in SE-CTPA by generating diagnostically reliable synthetic images with improved visual quality compared to existing baseline models and achieved contrast enhancement.

CLINICAL RELEVANCE/APPLICATION

This technique can enhance pulmonary embolism detection, potentially reducing the need for repeat scans or additional contrast administration in clinical settings.

R1-SSBR10-1 DOES SLAB RECONSTRUCTION TECHNOLOGY IMPACT SCREENING MAMMOGRAPHY PERFORMANCE? A COMPARATIVE ANALYSIS OF SCREENING DBT PERFORMANCE METRICS BEFORE AND AFTER IMPLEMENTATION

Manisha Bahl, MD, MPH (*Presenter*)
Sarah Mercaldo, PhD (*Abstract Co-Author*)
Leslie Lamb, MD, MSc (*Abstract Co-Author*)

PURPOSE

Standard digital breast tomosynthesis (DBT) uses 1 mm slices, resulting in large image volumes and longer interpretation times. Slab reconstruction technologies address this challenge by generating thicker slices, thus reducing image count, improving efficiency, and lowering storage needs. However, their impact on screening performance remains unknown. The purpose of this study was to compare screening DBT performance metrics before and after implementation of a slab reconstruction technology.

METHODS AND MATERIALS

Performance metrics from consecutive screening DBT exams acquired before and after implementation of 3DQuorum ® Imaging (Hologic, Inc.; Marlborough, MA) at an academic medical center were retrospectively reviewed. 3DQuorum is a slab reconstruction technology that generates 6-mm synthetic slices with 3-mm overlap. The pre-implementation period was January 2018-December 2019 and post-implementation period was October 2021-December 2022. Exams were categorized as true-positive, false-positive, true-negative, or false-negative based on one-year follow-up data. Multivariable logistic regression was used to compare screening performance metrics in the pre- and post-implementation periods, after adjusting for age, race, breast density, presence of a prior screening mammogram, and reader.

RESULTS

A total of 157,532 screening DBT exams in 81,416 women were included: 89,218 exams (60,692 women, mean age 60, SD 11) in the pre-implementation period and 68,314 exams (60,338 women, mean age 61, SD 12) in the post-implementation period. In the pre- and post-implementation periods, cancer detection rates (CDRs) were 6.0 per 1000 exams (537/89,218) and 6.6 per 1000 exams (454/68,314), respectively. Multivariable analysis showed no significant differences in CDRs in the pre- and post-implementation periods (adjusted odds ratio [aOR] 1.05, p =0.54), nor in sensitivity (82.0% vs 87.0%, aOR 1.53, p =0.06) or false-negative rates (1.3 per 1000 vs 1.0 per 1000, aOR 0.72, p =0.10). The abnormal interpretation rate (AIR) was lower (6.6% vs 5.9%, aOR 0.85, p <0.001) and specificity higher (94.0% vs 94.7%, aOR 1.2, p <0.001) in the post-implementation period. Positive predictive value (PPV) 1 was also higher in the post-implementation period (9.1% vs 11.2%, p =0.01).

CONCLUSION

Implementation of a slab reconstruction technology maintained comparable CDRs and sensitivity while significantly improving specificity and reducing AIRs.

CLINICAL RELEVANCE/APPLICATION

Slab reconstruction technologies may optimize screening DBT workflows by reducing image volume and interpretation time without compromising - and potentially improving - diagnostic performance. These findings support their broader integration into clinical practice.

R1-SSBR10-2 REASSESSING RADIAL SCARS ON DBT: LOW MALIGNANCY UPGRADE RATES SUPPORT CONSERVATIVE MANAGEMENT

Romuald Ferre, MD (*Presenter*)
Cherie M. Kuzmiak, DO (*Abstract Co-Author*)

PURPOSE

Digital breast tomosynthesis (DBT) has enhanced the detection of radial scars (RS), often identified as incidental findings. Although RS are generally benign, concerns regarding associated malignancy often lead to surgical excision. However, limited data exist on the malignancy risk of RS detected exclusively by DBT. This meta-analysis aimed to estimate the pooled malignancy rate of DBT-detected RS and evaluate potential publication bias.

METHODS AND MATERIALS

A systematic meta-analysis was conducted across nine studies. Data on malignancy events and total cases were extracted from each study. Event rates and their variances were calculated. A random-effects model (DerSimonian and Laird method) was employed to estimate the pooled malignancy rate. Heterogeneity was assessed visually with a funnel plot and quantitatively via Egger’s regression test.

RESULTS

A total of 593 cases were included. The pooled malignancy event rate was 3.8% (95% CI: 2.5-5.9%), reflecting a low incidence across studies. Visual inspection of the funnel plot revealed no significant asymmetry, and Egger’s test yielded an intercept of -4.44 (p = 0.071), indicating no significant evidence of publication bias. Overall, findings were consistent and robust across the included studies.

CONCLUSION

RS detected on DBT demonstrate a low malignancy upgrade rate, which would support conservative management instead of surgical excision.

CLINICAL RELEVANCE/APPLICATION

This meta-analysis supports a conservative approach to managing RS identified exclusively on DBT, potentially reducing unnecessary surgeries and minimizing patient morbidity. Further prospective studies are needed to refine and validate these management strategies.

R1-SSBR10-4 AI PRE-READING OF DIGITAL BREAST TOMOSYNTHESIS: A MULTI-SITE VALIDATION OF A NOVEL IMAGING BIOMARKER FOR CONFIDENT IDENTIFICATION OF NORMAL DBT EXAMINATIONS

Joep Stevens (*Presenter*)
Santiago Pires (*Abstract Co-Author*)
Alejandro Rodriguez-Ruiz (*Abstract Co-Author*)
Andreas Lauritzen, PhD (*Abstract Co-Author*)
Nico Karssemeijer, PhD (*Abstract Co-Author*)
Christoph I. Lee, MD,MS (*Abstract Co-Author*)
Roger S. Yang, MD (*Abstract Co-Author*)
Ioannis Sechopoulos, PhD (*Abstract Co-Author*)
Hannah Milch, MD (*Abstract Co-Author*)
Marina Alvarez Benito, MD,PhD (*Abstract Co-Author*)
Katja Pinker-Domenig, MD, PhD (*Abstract Co-Author*)
Ritse M. Mann, MD, PhD (*Abstract Co-Author*)

PURPOSE

To validate the accuracy of a novel AI-driven imaging biomarker specifically engineered to identify normal breast tomosynthesis (DBT) examinations in breast cancer screening.

METHODS AND MATERIALS

The effect of AI pre-reading using the novel imaging biomarker was retrospectively evaluated in an independent multi-site dataset of 4-view DBT exams gathered across 15 institutions in the US (53%) and Europe (47%). In total, 6,344 DBT exams were included in this study, of which 614 led to diagnosis of biopsy proven screen-detected cancers (SDC), 159 were non-cancer recall cases and 5,571 were normal. DBT exams were acquired with Hologic (30%), Siemens (15%), GE (27%) and Fujifilm (28%) systems.The imaging biomarker was engineered to identify normal DBT exams using an AI ensemble including a multi-modal foundation model to distinguish normal from malignant and abnormal exams. The imaging biomarker was pre-calibrated to identify one-third (1/3) of the normal screening exams. Percentage of total normal examinations, negative predictive value (simulating a screening cancer incidence of 5.8/1000) and sensitivity for excluding SDC, and their corresponding 95% confidence intervals (CI) were computed. Sub-analyses were done per DBT acquisition vendor to test robustness of the imaging biomarker.

RESULTS

Pre-reading with the imaging biomarker correctly identified 35% (1951/5571, 95% CI: 34-36%) of the normal DBT exams, while achieving a sensitivity of 99.67% (612/614, 95% CI: 98.83-99.96%) to exclude SDC (2/614 missed). 16/159 (10%, 95% CI:6%-16%) of non-cancer recall cases were identified as normal. Assuming a SDC incidence of 5.8/1,000 exams, applying the pre-reading biomarker to a cohort of 54,000 women would misclassify only one DBT exam that contains a SDC for every 18,000 exams it labels as normal. This corresponds to an NPV of 99.995 % (95 % CI: 99.98-100%).The imaging biomarker performance was not significantly influenced by the DBT acquisition system, achieving NPV values of 99.982% (95% CI: 99.94-100%), 100% (95% CI: 99.87-100%), 100% (95% CI: 99.97-100%) and 100% (95% CI: 99.97-100%) while identifying 31% (504/1650), 30% (253/837), 37% (553/1507) and 41% (641/1577) of normal exams for Hologic, Siemens, GE and Fujifilm respectively.

CONCLUSION

A novel AI-driven imaging biomarker for pre-reading of DBT can confidently identify approximately one-third of normal DBT examinations in breast cancer screening with a negative predictive value nearing 100%.

CLINICAL RELEVANCE/APPLICATION

This AI-driven imaging biomarker can enable pre-reading in breast cancer screening, potentially allowing radiologists to skip or significantly accelerate the reading of this group of DBT exams, safely improving radiologist efficiency and reducing workload.

R1-SSBR10-5 CAN NEW CONCEPT SYNTHESIZED MAMMOGRAMS (SM) REPLACE DIGITAL BREAST TOMOSYNTHESIS (DBT) WITH DIGITAL MAMMOGRAPHY (DM)? : SM ALONE READING VERSUS DM WITH OR WITHOUT DBT READING

Takayoshi Uematsu, MD, PhD (*Presenter*)

PURPOSE

To evaluate the efficacy of new standalone synthesized mammograms (SM) in maintaining or improving diagnostic accuracy while reducing reading time compared to digital breast tomosynthesis (DBT) combined with digital mammography (DM), or DM alone.

METHODS AND MATERIALS

The SM were generated as a kind of artificial intelligence (AI)-supported DBT reading method. AI recognized characteristic breast objects in DBT images and generated them into the SM without marks or outlines, allowing readers to avoid scrolling through DBT images and to perform natural image reading without distractions. A study involving 12 readers assessed the performance of SM alone across 200 examinations (including 50 cancer cases) and compared it to DM with or without DBT. Key metrics—area under the receiver operating characteristic curve (AUC), sensitivity, specificity, and reading time—were analyzed using statistical methods designed for multireader, multicase studies. Power and sample size calculations for the endpoints were conducted according to parameter estimates from our prior reader study. This study has received funding from FUJIFILM (Tokyo, Japan) .

RESULTS

The AUC improved from 0.906 (DBT with DM) to 0.912 (SM alone), indicating noninferiority for SM alone reading (95% CI: -0.013 to 0.026; $p = 0.538$). Similarly, SM showed noninferiority when compared to DM, with an AUC increase from 0.897 to 0.912 (95% CI: -0.005 to 0.037; $p = 0.13$). Sensitivity improved from 88.1% (DBT with DM) to 90.9% (SM alone) (95% CI: -0.0015 to 0.0072; $p = 0.152$) and significantly improved from 86.6% (DM) to 90.9% (SM) (95% CI: 0.0001 to 0.089; $p = 0.042$). Specificity values for SM alone, DBT with DM, and DM alone were 84.5%, 85.9%, and 86.5%, respectively, with no significant reduction observed. Importantly, mean reading time decreased by 53.2% (95% CI: 58.1%, 49.0%; $p < 0.001$), from 122.6 seconds (DBT with DM) to 57.5 seconds (SM alone).

CONCLUSION

New concept standalone SM reading was shown to maintain the diagnostic performance of DBT combined with DM, significantly reducing reading time. Additionally, the SM demonstrated statistically higher sensitivity compared to DM without significant reduction in specificity.

CLINICAL RELEVANCE/APPLICATION

This innovative SM has enough potential to replace DBT with DM reading for breast cancer screening with magnificent work efficiency decreasing radiologists' workload.

R1-SSBR10-6 FEASIBILITY OF REDUCING COMPRESSION FORCE IN DIGITAL BREAST TOMOSYNTHESIS: A MULTIVENDOR PHANTOM STUDY WITH MULTIREADER ASSESSMENT

Hee Jeong Kim, MD, PhD (*Presenter*)
Hak Hee Kim, MD, PhD (*Abstract Co-Author*)
Hye Joung Eom (*Abstract Co-Author*)
Woo Jung Choi, MD (*Abstract Co-Author*)
Eun Young Chae, MD, PhD (*Abstract Co-Author*)
Hee Jung Shin, MD, PhD (*Abstract Co-Author*)
Joo Hee Cha, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the feasibility of reducing compression force during digital breast tomosynthesis (DBT) acquisition by comparing image quality and radiation dose across varying compression levels using a compressible breast phantom and multiple DBT systems.

METHODS AND MATERIALS

A compressible mammography phantom embedded with simulated lesions and parenchymal structures was imaged using four different DBT systems under four compression forces (20, 15, 10, and 5 daN) and two angulated positions (0° and 45°), using automatic exposure control. Each acquisition was repeated three times, generating 96 image sets. Slice, slab, and synthetic 2D images were independently assessed by seven dedicated breast radiologists, scoring lesion visibility, margin sharpness, and overall image quality. System-recorded average glandular dose (AGD) and compression thickness were also collected. Statistical comparisons were performed using linear mixed models.

RESULTS

Slice images maintained consistent visibility, sharpness, and overall quality scores across all compression levels, with no significant degradation observed down to 5 daN in all readers ($P = 0.181$). In slab images, visibility and overall quality at 5 daN were comparable to those at 20 daN in 57% (4/7) and 86% (6/7) of readers, respectively ($P = 0.077$), and were even rated higher than 20 daN by 43% (3/7) and 14% (1/7) of readers, respectively ($P = 0.004$-0.043). Sharpness scores in slab images remained unchanged in all readers ($P = 0.101$). For synthetic 2D images, image quality at 10 and 15 daN remained comparable to 20 daN in all readers for all metrics ($P = 0.096$), while at 5 daN, visibility, sharpness, and overall quality were significantly reduced in 86% (6/7), 57% (4/7), and 57% (4/7) of readers, respectively ($P = 0.035$). AGD values were 1.4, 1.5, 1.6, and 1.9 mGy at 20, 15, 10, and 5 daN, respectively, with no significant increase observed down to 10 daN ($P = 0.179$).

CONCLUSION

Reducing compression force to 10 daN did not compromise diagnostic image quality or increase AGD, supporting the feasibility of lower compression protocols in DBT. These findings suggest that moderate reductions in compression could enhance patient comfort without sacrificing diagnostic performance or safety. Further clinical validation in diverse patient populations is warranted.

CLINICAL RELEVANCE/APPLICATION

This phantom study demonstrates that reducing compression force to 10 daN during DBT acquisition maintains diagnostic image quality and does not significantly increase radiation dose. These findings support the clinical feasibility of implementing lower compression protocols, which may improve patient comfort and enhance participation in breast cancer screening programs.

R1-SSCA09-3 SEX-SPECIFIC ASSOCIATIONS OF LONG-TERM AIR POLLUTION EXPOSURE WITH CORONARY ARTERY STENOSIS ON CARDIAC CT

Felipe Castillo Aravena, MD (*Presenter*)
Chloe DesRoche, MD,MSc (*Abstract Co-Author*)
Scott Delaney (*Abstract Co-Author*)
Rachel Nethery (*Abstract Co-Author*)
Paaladinesh Thavendiranathan, MD (*Abstract Co-Author*)
Heather Ross (*Abstract Co-Author*)
Kate Hanneman, MD, MPH (*Abstract Co-Author*)

PURPOSE

Exposure to air pollution is associated with cardiovascular mortality. However, evidence on the relationship between air pollution and obstructive coronary artery disease (CAD) is lacking. The purpose of this study was to evaluate the association of long-term air pollution exposure with coronary artery stenosis on cardiac CT.

METHODS AND MATERIALS

Adult patients who had undergone coronary CT angiography at one of three hospitals between 2015-2023 were retrospectively evaluated. Luminal stenosis was categorized using CAD-RADS 2.0 stenosis categories and obstructive CAD was defined as >50% diameter stenosis. Mean daily fine particulate matter (PM2.5) and gaseous nitrogen dioxide (NO2) air pollution concentrations in the 10-year period prior to cardiac CT were assessed based on direct measurements from the nearest monitoring station to each patient's home. Ordinal logistic (CAD-RADS categories) and logistic (obstructive CAD) regression models were adjusted for sex, distance to monitoring station, rural residence, CT unit, and socioeconomic status.

RESULTS

2172 patients were included (51.5% male, mean age 58.2±12.3 years). Median 10-year exposure to PM2.5 was 7.5 (range 4.6-9.3) μg/m3 and NO2 was 12.2 (range 2.0-20.2) parts per billion (ppb). A 1 μg/m3 increase in ten-year PM2.5 exposure was associated with 1.24 times greater odds of moving to a higher CAD-RADS stenosis category (OR 1.24; 95% CI: 1.04, 1.48, P=0.02) and 1.33 times greater odds of obstructive CAD (OR 1.33; 95% CI: 1.01, 1.75, P=0.04). A 1 ppb increase in ten-year NO2 exposure was associated with 1.04 times greater odds of obstructive CAD (OR 1.04; 95% CI: 1.01, 1.09, P=0.03), although the association with CAD-RADS stenosis category was not significant (OR 1.02; 95% CI: 0.99, 1.05, P=0.09). When stratified by sex, a 1 μg/m3 increase in ten-year PM2.5 exposure was associated with 1.47 times greater odds of moving to a higher CAD-RADS stenosis category in men (OR 1.47; 95% CI: 1.16, 1.87, P=0.002); however, the association was not significant in women (OR 1.03; 95% CI: 0.79, 1.35, P=0.81, interaction term P=0.03). A 1 ppb increase in ten-year NO2 exposure was associated with 1.04 greater odds of moving to a higher CAD-RADS stenosis category in men (OR 1.04; 95% CI: 1.00, 1.07, P=0.02); however, the association was not significant in women (OR 1.01; 95% CI: 0.98, 1.05, P=0.51, interaction term P=0.28).

CONCLUSION

Higher long-term exposure to air pollution, particularly PM2.5, is independently associated with coronary artery stenosis and obstructive CAD in men but not women.

CLINICAL RELEVANCE/APPLICATION

Atherosclerosis may be one of the underlying pathophysiological mechanisms by which air pollution leads to adverse cardiovascular outcomes in men.

R1-SSCA09-4 MITRAL ANNULAR DISJUNCTION IN MARFAN SYNDROME ASSESSED USING CARDIOVASCULAR MAGNETIC RESONANCE

Lenhard Pennig, MD (*Presenter*)

Tilman S. Emrich, MD (*Abstract Co-Author*)
Patrick Krumm, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Kenan Kaya, MD (*Abstract Co-Author*)

PURPOSE

To assess prevalence, extent, and distribution of mitral annular disjunction (MAD) in Marfan syndrome (MFS) using cardiovascular magnetic resonance (CMR) and to examine its association with left heart parameters, aortic dimensions, and cardiovascular events.

METHODS AND MATERIALS

This retrospective multicenter study included CMR studies of patients treated for MFS at four tertiary care medical centers with a (likely) pathogenic fibrillin-1 gene variant. Two radiologists (five and eight years of experience in CMR) evaluated CMR for MAD (at four points around the annulus, including measurement of extent) and mitral valve prolapse (MVP). Furthermore, left ventricular (LV) function and volumes, left atrial size, and aortic root diameters were analyzed. Cardiovascular events included aortic (aortic surgery or aortic dissection), arrhythmic (sustained ventricular tachycardia or sudden cardiac death), and mitral events (mitral valve surgery, MVS).

RESULTS

Among 91 patients (28.9±14.0 years, 47.3% female), 81.3% had MAD (extent: 6.1±2.6 mm). MAD was mostly found at the inferior insertion (72.5% of patients) and generally affected all sites (39.6% of patients). Left heart parameters and aortic dimensions did not differ between MAD and no MAD groups (p>0.05). MAD extent and localizations showed significant correlations with LV dilatation (e.g., inferior MAD: r=0.62 for end-diastolic volume index), decreased LV ejection fraction (e.g., anterolateral MAD: r=-0.46), and MVP (e.g., MAD distance: r=0.83), which was found in 44.6% of patients with MAD while only affecting 11.8% of patients without MAD (p=0.017). After a mean follow-up of 4.0±3.0 years, cardiovascular events (aortic: 14.3%, both arrhythmic and mitral: 2.2% of patients) did not differ significantly (all p>0.05) between groups albeit MVS being exclusively performed in MAD.

CONCLUSION

MAD is highly prevalent in MFS, mostly affects the inferior site, and usually involves all sites. Left heart parameters, aortic dimensions, and cardiovascular events did not differ between patients with and without MAD. However, localization and extent of MAD yielded distinct correlations with LV dilatation and dysfunction as well as the presence of MVP, which almost exclusively occurred in MAD.

CLINICAL RELEVANCE/APPLICATION

MAD´s high prevalence, large extent, and pan-annular distribution suggest a systemic annular pathology in MFS. While overall presence of MAD was not associated with changes to left heart parameters including aortic dimensions and the occurrence of cardiovascular events, MAD might serve as a potential marker of disease progression given its correlation of localization and distance with LV dysfunction and dilatation as well as the formation of MVP.

R1-SSCA09-5 OPPORTUNISTIC SCREENING FOR ADVERSE CARDIOVASCULAR EVENTS USING ROUTINE CLINICAL CHEST COMPUTED TOMOGRAPHY - A STUDY ON PERFORMANCE AND GENERALIZATION

Amara Tariq, PhD, MS (*Presenter*)
Theodorus Dapamede, MD, PhD (*Abstract Co-Author*)
Hari Trivedi, MD (*Abstract Co-Author*)
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*)
Matthew T. Stib, MD (*Abstract Co-Author*)
Imon Banerjee, PhD (*Abstract Co-Author*)

PURPOSE

Traditional methods for major adverse cardiovascular events (MACE) risk estimation, e.g., pooled cohort equation, do not incorporate radiology imaging directly, rely on known clinical and demographic risk factors and achieve suboptimal performance when applied to external institutions with clinical and demographic distributions shift. We developed a 3D CNN model to estimate MACE risk from chest computed tomography (CT) with causal intervention to enhance model's generalizability to 'shifted' external cohorts.

METHODS AND MATERIALS

Causal intervention was introduced into 3D CNN by a learnable codebook that simulated distribution of 'unknown' confounding variable (P(U)). The underlying assumption is that the learned relationship between input (chest CT) and output (MACE risk) is affected by an unobserved variable (U) like complex socioeconomic factors that limits model's generalization capabilities. P(U) was partially estimated using auxiliary tasks of concepts (hypertension, diabetes, chronic kidney disease) and proxy (demographics) prediction in addition to MACE prediction. Baseline performance was estimated by a machine learning model using demographic and body composition statistics (visceral and subcutaneous fat and muscle) computed from CT. Composite MACE labels (myocardial infarction, cardioembolic stroke, acute heart failure, all cause mortality) with 5 years followup were curated using structured diagnosis codes (ICD10).

RESULTS

4431 CTs (4231 patients) from multi-site healthcare institute X formed the internal cohort (MACE: 47%, Age: 62+/-18 years; 10% African American); 20% data held out for testing. Random set of 201 CT (191 patients) without history of MACE (MACE: 50%, Age: 62+/-15 years; 29% African American patients) was used for external validation from geographically distant healthcare institute Y. 3D CNN with and without causal intervention achieved comparable performance (0.73 AUROC) on the internal test set but outperformed the baseline (0.67 AUROC, +0.06). In external validation, CNN3D with causal intervention (0.69 AUROC) outperformed CNN3D without causal intervention (0.65 AUROC, +0.04) proving the benefits of causal intervention for model generalization.

CONCLUSION

We developed a 3D CNN model to estimate MACE risk from chest CT and incorporated causal intervention to improve model generalization. Our model outperformed comparative models and generalized well to external data with significant shift in patient populations.

CLINICAL RELEVANCE/APPLICATION

Leveraging AI to analyze rich, underutilized data within routinely performed chest CTs holds significant promise for enhancing early MACE risk estimation across diverse patient populations beyond the capabilities of current clinical tools.

R1-SSGU06-1 TIME-DEPENDENT DIFFUSION MRI HELPS PREDICT HISTOLOGIC FINGDINGS AND TREATMENT RESPONSE TO NEOADJUVANT TREATMENT IN BLADDER CANCER

Lingmin Kong, MD (*Presenter*)
Qian Cai (*Abstract Co-Author*)
Yan Guo (*Abstract Co-Author*)
Huanjun Wang (*Abstract Co-Author*)

PURPOSE

To investigate the capability of time dependent diffusion MRI (td-dMRI) based microstructural parameters in the characterization and differential diagnosis of bladder cancer (BCa).

METHODS AND MATERIALS

From August 2023 to April 2025, BCa participants who underwent MRI examination, including oscillating and pulsed gradient encoded sequences, were prospectively enrolled. The td-dMRI data were fitted with a two-compartment model to estimate cell diameter (d), cellularity, intracellular volume fraction (f in) and extracellular diffusivities (D ex). The correlation between the td-dMRI-based microstructural parameters and histopathology as well as patients' response to the neoadjuvant treatment (NAT) was investigated. A P value < 0.05 was considered significant.

RESULTS

A total of 150 participants (mean age, 65.53 years ± 11.50 [SD]; 131 men) was included in this prospective study. More aggressive tumors (high grade, muscle invasive and tumor with the presence of VH) tend to have higher f in and cellularity as well as lower D ex and ADC 0,17 and 33HZ values (all P < 0.05). For patients who achieved pathological complete response after NAT, lower d and ADC 0,17 and 33HZ values were observed (all P < 0.05).

CONCLUSION

The td-dMRI could noninvasively depict tumor pathologic findings and may be useful for predicting the prognosis of BCa patients.

CLINICAL RELEVANCE/APPLICATION

Noninvasively characterizing the pathologic properties of bladder cancer (BCa) plays a crucial role in modern risk stratification in the management of BCa. The newly development of time-dependent diffusion MRI (td-d MRI) has further enhanced the capacity to probe tissue microstructure. In this study, we found that the td-dMRI-based microstructural parameters not only were correlated with the aggressiveness of bladder tumor but also shed lights on helping to predict pCR to neoadjuvant treatment in participants with BCa. The present study demonstrated time-dependent diffusion MRI had promising application in BCa.

R1-SSGU06-2 IMAGING OF THE RENAL ALLOGRAFT VASCULATURE WITHOUT GADOLINIUM CONTRAST: INTRAINDIVIDUAL COMPARISON BETWEEN RELAXATION-ENHANCED ANGIOGRAPHY WITHOUT CONTRAST AND TRIGGERING (REACT) AND 4D CONTRAST-ENHANCED MR-ANGIOGRAPHY

Carsten H. Gietzen, MD (*Presenter*)
Jan Paul Janssen, MD (*Abstract Co-Author*)
Kenan Kaya, MD (*Abstract Co-Author*)
Roman J. Gertz, MD (*Abstract Co-Author*)
Thorsten Persigehl, MD (*Abstract Co-Author*)
Kilian Weiss, PhD (*Abstract Co-Author*)
Lenhard Pennig, MD (*Abstract Co-Author*)

PURPOSE

To evaluate Relaxation-Enhanced Angiography without Contrast and Triggering (REACT), a novel 3D isotropic flow-independent non-CE-MRA sequence, for imaging of the renal allograft vasculature by performing an intraindividual comparison to 4D CE-MRA at 3Tesla.

METHODS AND MATERIALS

Forty studies of 39 patients were included in this retrospective, single-centre study. Two board-certified radiologists independently evaluated MRA datasets for TRAS and rated their diagnostic confidence and the image quality of pelvic vessels using 5-point Likert scales (5=excellent). Apparent signal- and contrast-to-noise ratios (aSNR/aCNR) were measured for arterial and venous graft vessels.

RESULTS

REACT (median acquisition time 04:33 min [IQR 3:58-5:20 min]) showed 90.0% sensitivity and 100.0% specificity for TRAS in almost perfect agreement (r=0.97) with 4D CE-MRA (03:41 min [3:38-4:46 min], p=0.001) and similar diagnostic confidence (REACT: 4.0 [4.0-4.0] vs. 4D CE-MRA: 4.0 [3.0-4.0], p=0.54). Arterial image quality was comparable (4.0 [3.7-4.4] vs. 4.0 [4.0-4.4], p=0.49) whereas veins yielded higher scores in REACT (3.2 [3.0-3.5] vs. 2.4 [2.0-3.0], p<0.001). Transplant renal artery (mean±SD; 44.5±18.2 vs. 45.9±21.0, p=0.71; 36.3±15.0 vs. 41.0±20.0, p=0.16) and vein (37.1±19.8 vs. 30.3±15.2, p=0.06; 29.4±17.1 vs. 25.0±14.7, p=0.17) showed no difference in aSNR and aCNR.

CONCLUSION

Contrast-enhanced MRA (CE-MRA) has limitations, including potential allergic reactions, limited use in kidney failure, and uncertain long-term effects of gadolinium retention. REACT provides accurate detection of TRAS with image quality comparable to 4D CE-MRA, offering a risk-free alternative for imaging after renal transplantation.

CLINICAL RELEVANCE/APPLICATION

In a short scan time of less than five minutes, REACT provides high diagnostic performance for identifying TRAS and other vascular findings. These findings highlight the potential of REACT for imaging of the renal allograft vasculature without the use of gadolinium contrast in patients after renal transplantation to identify complications after kidney transplantation.

R1-SSGU06-3 PHOTON-COUNTING CT TO CHARACTERIZE INDETERMINATE RENAL LESIONS - A TWO-CENTER STUDY

Olga Sliwicka, MD, PhD (*Presenter*)
Khanin Khanungwanitkul, MD (*Abstract Co-Author*)
Fides Schwartz, MD (*Abstract Co-Author*)
Aaron D. Sodickson, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the role of Photon-Counting Computed Tomography (PCCT) to definitively characterize incidental indeterminate renal lesions identified during routine abdominal imaging, aiming to reduce follow-up examinations.

METHODS AND MATERIALS

Retrospective analysis was performed on 2733 consecutive portal-venous phase PCCT scans obtained between July 2023 and October 2024 from three scanners (NAEOTOM Alpha) at two institutions. Renal lesions with indeterminate attenuation >20 HU (or heterogeneous lesions with components > 20 HU) were included. Reference standard criteria used to define lesions as benign or non-benign were: Benign: 1) No growth over two years OR 2) No enhancement on MRI, renal protocol CT or non-contrast CT within two years, (if 1-3 thin enhancing septations were present, lesions were considered non-enhancing). Non-benign: 1) Contrast enhancement on MRI or renal protocol CT; 2) rapid growth in patients with a known malignancy; 3) FDG-avidity on PET/CT; 4) lesion biopsy. PCCT iodine measurements were made on dual-energy iodine-overlay maps using an ROI covering two-thirds of homogeneous lesions to prevent volume averaging, on 0.4 mm (n=130), 1.0 mm (n=36) and 1.5 mm (n=49) slice thickness (depending on scanner protocol). The cut-off (mg/mL) in iodine concentration for benign lesions was calculated from ROC analysis to maintain 100% sensitivity in order to avoid mischaracterizing enhancing lesions as benign.

RESULTS

Of 2733 scans performed on the three PCCT scanners, 169 contained 216 indeterminate lesions with reference standard imaging, of which 190 (87%) were benign, and 26 (13%) were non-benign. Median iodine concentration [25-75% IQR] was 0.4 [0.1 - 0.7] mg/mL for benign lesions, and 2.0 [1.4 - 2.8] mg/mL for non-benign lesions (Wilcoxon $p<0.005$). At the ROC operating point that maintains 100% sensitivity for non-benign lesion detection, specificity was 88%. This was accomplished at an iodine concentration cut-off value of 1.0 mg/mL.

CONCLUSION

PCCT can accurately characterize up to 88% of indeterminate renal lesions as benign non-enhancing complex cysts, at an iodine threshold that avoids incorrectly characterizing any truly enhancing lesions as benign.

CLINICAL RELEVANCE/APPLICATION

Using spectral information from PCCT to characterize indeterminate renal lesions has the potential to substantially reduce the need for downstream imaging workup.

R1-SSGU06-5 PELVIC CALCIUM MEASURED BY NON-CONTRAST ABDOMINOPELVIC RADIOTHERAPY PLANNING CT CORRELATES WITH CORONARY ATHEROSCLEROTIC BURDEN AND PREDICTS NEAR-TERM CORONARY ARTERY PLAQUE PROGRESSION IN PROSTATE CANCER MEN UNDERGOING ANDROGEN DEPRIVATION THERAPY

Sagar A. Patel, MD (*Abstract Co-Author*)

PURPOSE

Prostate cancer (PCa) men, especially those receiving androgen deprivation therapy (ADT), are at increased risk of cardiovascular (CV) morbidity. This analysis aims to identify an imaging biomarker to predict CV risk from PCa treatment.

METHODS AND MATERIALS

Men with localized PCa pursuing definitive radiotherapy (RT) alone or RT + 6 months ADT were enrolled on a prospective trial (NCT05320406). All patients underwent pre-treatment and 12-month post-treatment coronary CT angiography (CCTA) to measure change in coronary artery total plaque volume (TPV), non-calcified plaque volume (NCPV), calcified plaque volume (CPV), and calcium score (CACS). Non-contrast abdominopelvic CT for RT treatment planning was used to quantify lower aortic and iliac artery calcium volume (i.e. pelvic artery calcium, PAC (mm^3)) prior to treatment, using commercially available software. The Spearman test was used to assess correlation between PAC and baseline coronary plaque features. PAC associations with 12-month CCTA were assessed via ANCOVA adjusted for baseline respective plaque volume/CACS, age, and statin use.

RESULTS

The study included 47 PCa men (N=13 RT alone; N=34 RT +ADT). There were no significant demographic differences between treatment groups. Median PAC was 500 mm^3. PAC volume correlated with baseline coronary TPV (rho 0.332, p=0.02), NCPV (rho 0.333, p=0.02), CPV (rho 0.326, p=0.03), and CACS (rho 0.298, p=0.04). Median (IQR) 12-month change in TPV was +13.00 mm^3 (-3.00-49.50) versus +25.50 mm^3 (-7.50-62.00) in men with less than versus greater than median total PAC, respectively. Among the entire cohort, patients with elevated baseline PAC volume = 500.0 mm^3 had greater post-treatment CPV change compared to those below this threshold (estimated difference +15.6 mm^3, 95% CI: -0.7 to 32.0, p=0.06). This change was driven by post-treatment CPV increase in men receiving ADT, which exhibited an increase in mean-adjusted CPV of 20.9 mm^3 (95% CI: -1.1 to 42.9, p=0.06), compared to no change in the RT alone cohort (2.9 mm^3, 95% CI: -7.0 to 12.9, p=0.52).

CONCLUSION

In men with localized prostate cancer, pelvic artery calcium burden, measured on non-contrast CT scans used for RT treatment planning, correlated with baseline coronary atherosclerosis, including specific CCTA imaging features that are validated predictors of adverse CV events. Further, elevated baseline PAC >500 mm^3 is associated with increases in coronary CPV after treatment, specifically in patients receiving ADT.

CLINICAL RELEVANCE/APPLICATION

Non-contrast abdominopelvic CT scans used for RT treatment planning may offer a cost-effective, accessible biomarker to identify men at elevated CV risk from ADT

R1-SSGU06-6 CLINICALLY SIGNIFICANT PROSTATE CANCER CHARACTERIZATION USING RAPID B1-INSENSITIVE MR FINGERPRINTING

Dheeman Futela, MBBS (*Presenter*)
Zhiqing Yin (*Abstract Co-Author*)
Sohrab Afshari Mirak, MD (*Abstract Co-Author*)
Nikhil H. Ramaiya, MD (*Abstract Co-Author*)
Chris A. Flask, PhD (*Abstract Co-Author*)
Leonardo K. Bittencourt, MD, PhD (*Abstract Co-Author*)
Mark A. Griswold, PhD (*Abstract Co-Author*)
Yong Chen (*Abstract Co-Author*)
Sreeharsha Tirumani, MD (*Abstract Co-Author*)

PURPOSE

MR fingerprinting (MRF) has shown utility in characterization of focal prostate lesions, especially when combined with apparent diffusion coefficient (ADC). However, prior studies were retrospective and employed an MRF acquisition with long scan times and prone to B1 field inhomogeneities. In addition, inconsistent sampling techniques were applied for histopathologic correlation. This study aimed to determine the utility of MRF, combined with ADC and clinical parameters, in prostate lesion characterization by adopting a rapid, B1-insensitive MRF technique.

METHODS AND MATERIALS

Between 2020 and 2024, consecutive biopsy-naïve adult men with clinical suspicion of prostate cancer were prospectively enrolled and bi- or multi-parametric MRI was performed. Axial T1 and T2 maps were acquired using a rapid MRF technique (15 sec/slice) with low flip angles (5°-12°), which is relatively insensitive to B1 inhomogeneities. Lesions with PI-RADS 3-5 were selected and quantitative tissue properties (T1, T2, and ADC) were extracted from region of interests. The target region was sampled using MR-transrectal ultrasound fusion biopsy. ROC analysis was performed to differentiate focal lesions with clinically significant prostate cancer (Gleason 3+4 or above, csPCa) from clinically insignificant lesions (Gleason 3+3 or benign).

RESULTS

51 peripheral zone lesions from 40 patients (age 65 ± 12) were included. csPCa had lower mean T2 (56 ± 12 ms) and ADC (668 ± 111 x 10-6 mm2/s) compared to clinically insignificant lesions (80 ± 20 ms and 876 ± 181 x 10-6 mm2/s respectively, P<.001). To separate csPCa (n=22) from insignificant lesions (n=29), T2 was the strongest univariate predictor (AUC T2 = 0.87 [95% CI: 0.76-0.97], AUC ADC = 0.83 [0.71-0.95], and AUC T1 = 0.63 [0.48-0.79]). Combined MRF and ADC yielded excellent differentiation (AUC ADC+T2 = 0.90, AUC ADC+T1+T2 = 0.91), significantly outperforming univariate models (P<0.05). Among clinical parameters, adding PSA density further improved the AUC to 0.94 (P=0.01). Using thresholds of ADC 650 x 10-6 mm2/s and T2 63 ms, 20/29 (68%) of unnecessary biopsies could have been avoided, at the expense of missing only 1/22 (4%) of csPCa.

CONCLUSION

csPCa have significantly lower ADC and MRF-T2 values compared to insignificant lesions. Combination of ADC and MRF relaxometry provides excellent differentiation of csPCa from insignificant lesions. In addition, inclusion of PSA density has incremental value when combined with ADC and MRF.

CLINICAL RELEVANCE/APPLICATION

Quantitative MRI using ADC and rapid B 1 -insensitive MRF provides objective non-invasive assessment of focal prostate lesions with excellent differentiation of csPCa from insignificant lesions, with the potential to eliminate unnecessary biopsies.

R1-SSNMMI07-1 FRACTAL ANALYSIS OF FDG UPTAKE FOR DIFFERENTIATING PHYSIOLOGICAL MYOCARDIAL UPTAKE FROM ACTIVE CARDIAC SARCOIDOSIS

Ryuji Sakai, RT (*Presenter*)
Emi Tateishi (*Abstract Co-Author*)
Takuji Nanno (*Abstract Co-Author*)
Yoshifumi Nouno (*Abstract Co-Author*)
Akihide Shimizu (*Abstract Co-Author*)
Midori Fukuyama, MD (*Abstract Co-Author*)
Masateru Kawakubo, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

18 F-fluorodeoxyglucose (FDG) PET is used to assess disease activity in cardiac sarcoidosis (CS); however, distinguishing active inflammatory lesions from physiological myocardial uptake remains challenging when relying solely on FDG uptake. Recently, heterogeneity of FDG uptake has been shown to help differentiate malignant from benign tumors in oncologic imaging. We applied fractal analysis to myocardial FDG uptake to quantify spatial complexity and heterogeneity, and evaluated their ability to differentiate pathological uptake from physiological uptake.

METHODS AND MATERIALS

We retrospectively analyzed 51 patients who underwent FDG PET/CT for evaluation of disease activity or clinical diagnosis of CS. Based on visual interpretation by two experts, patients were classified into a physiological group (n = 21, with physiological myocardial FDG uptake) and a pathological group (n = 30, with FDG uptake suggesting active inflammatory lesions). Short-axis images of the left ventricle were reconstructed to generate polar maps. Fractal analysis of FDG uptake was performed on these maps using a custom MATLAB script to calculate the fractal dimension (FD). Spatial complexity was quantified as the peak ratio of FD (PR-FD), defined as max / mean FD. Heterogeneity was assessed as the coefficient of variation of FD (CV-FD), defined as SD / mean FD. FD, PR-FD, and CV-FD were compared between two groups. Reproducibility of FD calculation was assessed by two radiological technologists.

RESULTS

FD values significantly differed between the physiological and pathological groups (1.37 vs. 1.16, $p < 0.001$). PR-FD and CV-FD were significantly elevated in the pathological group compared to the physiological group (PR-FD: 1.20 vs. 1.07, $p < 0.001$; CV-FD: 0.13 vs. 0.06, $p < 0.001$). Based on ROC analysis, the optimal cutoff values for differentiating pathological uptake from physiological uptake were 1.115 for PR-FD and 0.093 for CV-FD, demonstrating excellent discrimination. Reproducibility of FD calculation was excellent, with an intra-observer ICC of 0.981 and an inter-observer ICC of 0.961.

CONCLUSION

Fractal analysis of FDG PET images can quantify the spatial complexity and heterogeneity of myocardial FDG uptake in patients with CS. PR-FD and CV-FD demonstrated high accuracy in differentiating pathological uptake from physiological myocardial uptake, suggesting their potential as objective imaging biomarkers for assessing disease activity in CS.

CLINICAL RELEVANCE/APPLICATION

Fractal analysis of myocardial FDG uptake can evaluate spatial complexity and heterogeneity in cardiac sarcoidosis (CS). Fractal dimension-based indices may serve as novel imaging biomarkers for assessing disease activity in CS.

R1-SSNMMI07-2 AI-BASED DENOISING TO FULLY EXPLOIT PATHOPHYSIOLOGICAL MEANING AND CLINICAL IMPACT OF EARLY PERFUSION AMYLOID PET IMAGING

Maarten Larmuseau, DPhil (*Presenter*)
Alessandro Coccarelli (*Abstract Co-Author*)
Michela Zotta (*Abstract Co-Author*)
Simon Dekeyser (*Abstract Co-Author*)
Vic De Ridder (*Abstract Co-Author*)
Tomas Brants (*Abstract Co-Author*)
Guido Rovera (*Abstract Co-Author*)
Silvia Daniela Morbelli (*Abstract Co-Author*)

PURPOSE

Early-perfusion-amyloid PET is considered able to capture neurodegeneration. However, scanner occupancy during early-image acquisition is an unresolved issue. Moreover, while the first 3-minutes post-injection better represents cerebral blood-flow, such a short acquisition-time may result in noisy images, making pattern identification challenging. We investigated the feasibility of AI-based denoising of 3-minute early-phase-amyloid-PET and simulated its clinical use using visual and voxel-based approaches.

METHODS AND MATERIALS

Because 10-minute scans underrepresent hypoperfusion, we used a model trained on low-dose datasets that preserve signal, and compared it to one using 10-minute scans as ground truth. Expert and non-expert readers evaluated 92 original and enhanced scans from 23 patients, assessing AD pattern detection (positive/negative) in 3-, 5-, and 10-minute frames versus enhanced 3-minute images. Diagnostic confidence was rated on a 5-point scale. Single-subject SPM12 analyses evaluated voxel-level sensitivity using a normative early-phase amyloid PET dataset.

RESULTS

The model trained on low-dose datasets preserved true signals in 3-minute scans, unlike the 10-minute-trained model. Enhanced 3-minute images improved diagnostic confidence (75% vs. 55% score 5), interobserver agreement (?=0.88 vs. 0.75), and voxel-based sensitivity (807±233 vs. 210±160 voxels) compared to longer acquisitions. In one case, hypoperfusion was detected only in the enhanced 3-minute scan.

CONCLUSION

The investigation into early-phase 3-minute scans highlighted the limitations of traditional supervised learning approaches, as the high-count data (10-minute scans) lack some clinically relevant perfusion signals. The method based on low-dose-enhancement seems promising as it was able to enhance images without suppressing the hypoperfusion pattern and allowed to increase readers' agreement, diagnostic confidence and voxel-based sensitivity.

CLINICAL RELEVANCE/APPLICATION

AI-based denoising restores diagnostic quality in noisy 3-minute early-phase amyloid PET scans, enabling reliable same-tracer assessment of both perfusion and amyloidosis within routine workflows.

R1-SSNMMI07-3 SPLENIC SWITCH-OFF ON MYOCARDIAL PET IN HEMODIALYSIS AND RENAL TRANSPLANTATION DEFINES THE PROGNOSIS

Mitsuru Momose, MD,PhD (*Abstract Co-Author*)
Shuji Sakai, MD, PhD (*Abstract Co-Author*)

PURPOSE

Hemodialysis is a cause of arteriosclerosis, resulted in major adverse cardiac events (MACEs). Approximately half of the deaths are due to cardiovascular disease. Myocardial flow reserve (MFR) obtained from 13 N-ammonia positron emission tomography (NH 3 -PET) is a prognostic factor for patients with ischemic heart disease (IHD). In NH 3 -PET imaging, the splenic switch-off (SSO) sign, which visually assesses the decrease in splenic 13 N-ammonia uptake during adenosine stress, is a hemodynamic indicator of a favorable response to adenosine. This phenomenon is assumed to be due to the fact that adenosine receptor stimulation produces coronary artery dilation while producing vasoconstriction in the splenic circulation. Previous study indicated SSO was a predictor of coronary artery event after heart transplantation. We hypothesized patients with hemodialysis had arteriosclerosis of the systemic blood vessels, and splenic reactivity to adenosine was reduced.We aimed to compare the splenic blood flow evaluated using NH 3 -PET among patients with hemodialysis, non-hemodialysis and renal transplantation, and examine its prognostic value for MACE.

METHODS AND MATERIALS

100 patients (hemodialysis:40, non-hemodialysis:50, renal transplantation:10) who underwent NH 3 -PET were enrolled. Using NH 3 -PET projection images, we placed an ROI on the spleen and measured the mean standardized uptake value (SUV). The spleen ratio (SR) was defined as the mean SUV of the spleen at stress divided by that at rest, and compared among the three groups. The endpoint was the occurrence of MACEs comprising acute coronary syndrome, heart failure hospitalization, and all-cause mortality. SSO was determined by a cutoff obtained using receiver operating characteristic (ROC) analysis for the SR. The patients were divided into two groups according to the presence or absence of SSO, and the frequency of MACE was compared by Kaplan-Meier and log-rank test.

RESULTS

The hemodialysis group had reduced MFR. The SR was significantly higher in patients with hemodialysis than without hemodialysis (0.92±0.16 vs. 0.78±0.21, p=0.014). The ROC curve analysis of the SR for MACE showed a cutoff value of 0.96 (sensitivity, specificity, and AUC of 55%, 72%, and 0.67). Patients without SSO had higher rate of MACE than with SSO (p=0.0074).

CONCLUSION

Splenic reactivity to adenosine in patients with hemodialysis was reduced compared to those with non-hemodialysis. SSO might be associated with the endothelial function of systemic blood vessels and was a prognostic factor for MACE.

CLINICAL RELEVANCE/APPLICATION

SSO is a quantitative index which reflects the severity of arteriosclerosis and provides additional predictive ability for MACE non-invasively without additional exposure or imaging.

R1-SSNMMI07-5 ASSOCIATION BETWEEN NON-ALCOHOLICFATTY LIVER DISEASE AND MYOCARDIAL INFARCT SIZE IN PATIENTS WITH ST ELEVATION MYOCARDIAL INFARCTION:A CROSS-SECTIONAL STUDY AND BIOINFORMATICS ANALYSIS BASED ON THE GEO DATABASE

Jun Liu, PhD (*Abstract Co-Author*)

PURPOSE

We aim to explore the association between nonalcoholic fatty liver disease (NAFLD), intrathoracic fat (IF), pericardial fat (PF) and myocardial infarct size (MIS) in patients with ST-elevation myocardial infarction (STEMI).

METHODS AND MATERIALS

SPECT-MPI was used to detect MIS, while CT scans were used to measure IF, PF, and NAFLD in patients with STEMI. Firstly, we categorised the patients into two groups (those with measurable and nonmeasurable MIS). The difference in fat between the two groups was compared using a two-sample t-test to determine which type of fat might be correlated with MIS. Secondly, the association between the related fats obtained in the aforementioned steps and MIS was evaluated using linear regression

analysis. Third, to further verify this association at the molecular level, we explored the potential shared genes associated with related fat obtained in the above steps and acute myocardial infarction via bioinformatics analysis using the Gene Expression Omnibus (GEO) database. Finally, the association between the expression of shared genes in the serum of patients with STEMI and related fat was confirmed using Pearson's correlation analysis.

RESULTS

The volume and fat attenuation index of IF and PF showed no difference between patients with MIS and those without. However, the L/S of NAFLD on CT reduced significantly in patients with MIS (P =0.001). The L/S of NAFLD on CT was an independent predictor of MIS on SPECT-MPI in patients with STEMI (P =0.042). We identified ST2, THBD, LEPR, and CEBP-a in NAFLD and acute myocardial infarction cases from the GEO database (P <0.05). Compared to patients with STEMI without NAFLD, those with NAFLD exhibited a reduction in sST2 levels (P =0.042); however, no differences were observed in THBD, LEPR, and CEBP-a levels. Correlation analysis showed a positive correlation between L/S and sST2 levels (r=0.459, P =0.032).

CONCLUSION

Among patients with STEMI, the L/S of NAFLD, but not IF or PF, was associated with MIS on SPECT-MPI. Additionally, the L/S of NAFLD on CT emerged as an independent predictor of MIS.

CLINICAL RELEVANCE/APPLICATION

Our findings demonstrate among patients with STEMI, the presence of NAFLD identified through CT imaging, but not IF or PF, was associated with MIS on SPECT-MPI, highlighting the importance of considering hepatic fat accumulation in cardiovascular risk assessment. Notably, we observed that the liver-to-spleen (L/S) ratio of NAFLD on CT imaging independently predicted MIS, providing a novel diagnostic tool for risk stratification in patients with STEMI. Furthermore, our study revealed a correlation between sST2 levels and NAFLD, shedding light on the molecular mechanisms underlying this association and further verifying the association between NAFLD and MIS.

R1-SSNMMI07-6 PIB PET/CT FOR DETECTION AND SUBTYPE DIFFERENTIATION OF CARDIAC AMYLOIDOSIS

Takashi Norikane, MD, PhD (*Presenter*)
Yuka Yamamoto, PhD (*Abstract Co-Author*)
Yasukage Takami (*Abstract Co-Author*)
Takahisa Noma (*Abstract Co-Author*)
Yoshihiro Nishiyama, MD (*Abstract Co-Author*)

PURPOSE

Various imaging modalities, including echocardiography, CMRI, and PYP scintigraphy, are widely utilized and valuable for diagnosing cardiac amyloidosis (CA). However, identifying disease subtypes remains challenging with echocardiography and CMRI, and PYP scintigraphy has limited sensitivity for detecting the AL type. Recently, amyloid PET/CT using C-11 Pittsburgh compound B (PiB) has gained recognition for its potential to detect all amyloid types. This study aimed to evaluate the utility of PiB PET/CT for detecting CA and differentiating its subtypes.

METHODS AND MATERIALS

A total of 81 patients underwent PiB PET/CT imaging. Of these, 60 were diagnosed with CA (8 AL-type and 52 ATTR-type). Dynamic PET emission scanning was performed over 30 minutes, starting with an intravenous bolus injection of PiB. Retention index (RI) images and SUV images were reconstructed from the dynamic data. The RI was calculated as the mean myocardial radioactivity concentration from 15-25 minutes divided by the integral of the arterial time-activity curve from 0-20 minutes. SUV images were reconstructed by summing data from 0-10 min (SUV010), 10-20 min (SUV1020), and 20-30 min (SUV2030). Quantitative evaluation used the myocardial-to-blood pool ratio (MBR), defined as the maximum myocardial uptake normalized to blood pool activity.

RESULTS

MBR-RI showed moderate correlation with MBR-SUV010 (? = 0.438, p = 0.002) and strong correlations with MBR-SUV1020 (? = 0.688, p < 0.001) and MBR-SUV2030 (? = 0.589, p < 0.001). A very strong correlation was found between MBR-SUV1020 and MBR-SUV2030 (? = 0.904, p < 0.001). Across all images , AL-CA cases exhibited significantly higher MBR values compared with both ATTR-CA and non-CA cases. ATTR-CA cases also demonstrated significantly higher myocardial uptake than non-CA cases on RI, SUV010, and SUV1020 images. ROC analysis showed that SUV2030 images yielded the highest diagnostic accuracy for differentiating cardiac amyloidosis from non-amyloidosis (AUC = 0.960, cutoff 0.985; sensitivity, 93.3%; specificity, 95.2%). For distinguishing AL-CA from ATTR-CA, SUV010 images provided the best performance (AUC = 0.851, cutoff 1.605; sensitivity, 87.5%; specificity, 73.5%).

CONCLUSION

PiB PET/CT demonstrated robust capability for detecting cardiac amyloidosis and accurately differentiating AL-CA from ATTR-CA. SUV2030 images optimized amyloidosis detection, while SUV010 images maximized subtype discrimination. PiB PET/CT shows strong promise as a next-generation diagnostic tool for cardiac amyloidosis.

CLINICAL RELEVANCE/APPLICATION

PiB PET/CT enables accurate detection and subtype differentiation of cardiac amyloidosis, offering a potential adjunct to current diagnostic strategies.

R1-SSRO04-2 METAL ARTIFACT REDUCTION IN SPECTRAL COMPUTED TOMOGRAPHY FOR INTRACAVITY BRACHYTHERAPY IN CERVICAL CANCER PATIENTS:A PROSPECTIVE STUDY

Yining Chen (*Presenter*)
Zheng Zeng (*Abstract Co-Author*)
Junfang Yan (*Abstract Co-Author*)
Fuquan Zhang (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the effectiveness of combining virtual monochromatic images (VMI) with metal artifact reduction (MAR) algorithms in reducing metal artifacts in cervical cancer patients treated with intracavitary brachytherapy.

METHODS AND MATERIALS

A total of 50 cervical cancer patients underwent intracavitary brachytherapy were included in the study, and their spectral computed tomography (CT) images were acquired. VMI±MAR were reconstructed at energy levels ranging from 40 to 140 keV. CT attenuation and image noise were measured to calculate the signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) for the most prominent artifacts, and the artifact index (AI) for the cervix, bladder, and rectum. These objective metrics were compared between the VMI+MAR and VMI+no-MAR groups. Subjective image quality was evaluated using a relative visual grading analysis on a 5-point Likert scale, focusing on artifact reduction, soft tissue contrast, and contouring preference for clinical use.

RESULTS

Quantitative analysis demonstrated that VMI+MAR significantly reduced the AI for both the cervix (by 34.74% to 88.51%) and rectum (by 11.31% to 81.35%) compared to VMI+no MAR across all energy levels (all $p < 0.05$). Image quality evaluation revealed that both the SNR and CNR were consistently higher in MAR-corrected images. Specifically, SNR improved significantly at all energy levels, increasing from 0.70-1.00 to 1.75-1.97 (an increase of 95.00%-152.11%, all $p < 0.001$), while CNR showed significant enhancement from 90 keV onwards ($p < 0.05$). Among all energy levels, VMI with MAR at 140 keV achieved the greatest artifact reduction, evidenced by the highest SNR and CNR and the lowest AI. Subjective assessment further confirmed that 140 keV+MAR offered the best balance between artifact suppression and soft tissue contrast, receiving significantly higher scores for artifact reduction and contouring preference than other energy levels ($p < 0.001$).

CONCLUSION

High-energy VMI combined with MAR, especially at 140 keV, provides effective artifact suppression while maintaining clinical utility in brachytherapy.

CLINICAL RELEVANCE/APPLICATION

The metal reduction efficacy of VMI+MAR have potential for improvement of delineation of metal-affected structures in CT-based brachytherapy, enhancing treatment accuracy.

R1-SSRO04-3 INTEGRATING CT BASED RADIOMICS, CLINICAL AND GENOMIC FEATURES TO PREDICT PSMA AVIDITY IN OLIGOMETASTATIC CASTRATE SENSITIVE PROSTATE CANCER (OMCSPC): UPDATED LESION LEVEL ANALYSIS

Lakshmi Rekha Narra, MD (*Presenter*)
Ritesh Kumar, MBBS,MD (*Abstract Co-Author*)
Chengzhu Zhang, PhD (*Abstract Co-Author*)
Ke Nie, PhD (*Abstract Co-Author*)
Matthew P. Deek, MD (*Abstract Co-Author*)

PURPOSE

To determine whether radiomic features extracted from Computed-Tomography (CT) visible lesions, combined with clinical and High-risk genomic variables, can predict PSMA-PET avidity in patients with oligometastatic castrate sensitive prostate cancer (omCSPC)

METHODS AND MATERIALS

In this lesion level analysis, 84 patients with (omCSPC) who underwent PSMA PET imaging and had clinical and high-risk genomic mutation data were included. Lesions visible on CT Component of PSMA PET are manually contoured using velocity AI software to generate 3D-Volume of Interest (VOI). CT-based radiomic features were extracted using PyRadiomics Total of 107 features were extracted for each lesion which include shaped based metrics (Volume, surface area, sphericity), first-order features include distribution of voxel intensities represented by histogram & second order features include textural analysis which assess intralesional heterogeneity by capturing spatial relationships between neighboring voxels. These are derived from gray-level co-occurrence matrix (GLCM), gray-level run-length matrix (GLRLM), gray-level size zone matrix (GLSZM), and neighborhood gray-level difference matrix (NGLDM). Clinical Variables include lesion site, number of lesions, and premetastatic PSA and Genomic data on high-risk mutations (TP53, BRCA1/2, ATM, RB1, PTEN, CHEK2, ATRX) are included in the analysis.Machine learning models: ensemble RU boosted trees are used to test and validate the model on training data in 5 distinct sets and the overall model performance was assessed using receiver operating characteristic curve

RESULTS

A total of 1,492 metastatic lesions were included in the analysis, of which 234 (15.7%) were PSMA-avid and 1,258 (84.3%) were non-avid. Among 1,016 lymph node lesions, 164 (16.1% were PSMA-avid). Of 332 bone lesions, 47 (14.2% : PSMA-Avid). Of 144 other lesions, 23 (16%: PSMA Avid) In the validation set, the ensemble RUS Boosted tree model achieved the highest AUC using all features, including radiomics, clinical and genomic data - (AUC = 0.93, Sensitivity 84.4%, Specificity 87.4%)

followed by Clinical variables with specified lesion location (AUC = 0.85, Sensitivity 88.9%), Clinical variables without specified lesion location (AUC = 0.75), Radiomic features alone (AUC = 0.70) and High-risk gene mutations alone (AUC = 0.50)

CONCLUSION

Lesionlevel PSMA Avidity was best predicted using a combined model incorporating all radiomic, clinical and genomic features. Lesion Location with clinical features has shown high sensitivity, whereas radiomics, clinical or genomic data alone has limited predictive value. Studies in larger independent cohorts are required to validate these findings.

CLINICAL RELEVANCE/APPLICATION

Radiogenomics

R1-SSRO04-4 DOES SPACEOAR GEL MORPHOLOGY CHANGE DURING THE COURSE OF RADIATION? : AN ANALYSIS OF OVER 1000 TREATMENT SCANS

Sravya Koduri, MD (*Presenter*)
David Barbee, PHD (*Abstract Co-Author*)
Tal Sherman (*Abstract Co-Author*)
Michael J. Zelefsky, MD (*Abstract Co-Author*)

PURPOSE

The purpose of this study is to explore whether spaceOAR gel morphology changes during the course of SBRT radiation to the prostate.

METHODS AND MATERIALS

180 patients with 1080 MRI scans (1 simulation, 5 on-treatment) received a SpaceOAR gel prior to MR-Linac based SBRT between October 2023 and March 2025. A U-Net deep learning model was implemented using nnUNetv2 (Isensee 2021). This model was iteratively trained using inference images from 50 training sets, resulting in a Dice Similarity Coefficient (DSC)>0.96, and then applied to all patient images. Geometric/spatial comparison metrics include: volume, sphericity, compactness, flatness, elongation, eccentricity, surface area, and surface/volume ratio. Test contours were compared to reference contours using DSC, Jaccard, Hausdorff, and average surface distance.

RESULTS

Average time between spaceOAR placement and MR simulation and between simulation and first treatment was 7.1 days and 20.3 days respectively, with 2-3 day intervals between treatments. Across all scans, mean spaceOAR volume was 12.5 (std dev. 3.0) cc, with mean dimensions of 42.1 (8.9), 23.6 (7.4), and 48.0 (9.7) mm in the left-right, anterior-posterior, and superior-inferior orientations, respectively. Shape descriptors revealed a mean sphericity of 0.39 (0.13), compactness of 0.74 (0.16), flatness of 0.72 (0.16), and elongation of 0.45 (0.12). Average eccentricity was 0.95 (0.03), indicating highly elongated shapes, and mean surface-to-volume ratio was 0.61 (0.23), consistent with irregular, enclosed geometries. Compared to reference scans, on-treatment scans showed a mean volume difference of +1.36 (1.57) cc over time with increases in sphericity +0.01, compactness by +0.02, and elongation by +0.006, while flatness decreased by -0.02. Eccentricity remained stable (+0.003), and surface-to-volume ratio decreased by -0.12, reflecting smoother but more voluminous segmentations. Median percent changes across A-P dimension from simulation to last scan and first to last scan were both 0%. Mean volume change from first to last scan was 4.1%.

CONCLUSION

Although a mild increase in volume was noted, the results demonstrated no clinically significant changes in the spaceOAR gel morphology changes following simulation and during the course of treatment.

CLINICAL RELEVANCE/APPLICATION

The use of a spaceOAR gel to limit high-dose exposure to the rectum is a staple of stereotactic body radiation therapy (SBRT) for prostate cancer. However, the question arises of whether there may be inter- and intra-fractional change in the morphology of the spaceOAR gel between simulation and 5 fractions of SBRT. Such change would impact the accuracy of dosimetric calculations of rectal exposure in standard CT-based treatment paradigms.

R1-SSRO04-5 5-YEAR OUTCOMES OF A PHASE II INTERVENTIONAL CLINICAL TRIAL OF PROSTATE BED STEREOTACTIC BODY RADIATION THERAPY FOR PROSTATE CANCER WITH HIGH-RISK FEATURES FOLLOWING RADICAL PROSTATECTOMY

Alan Zhu, BS (*Presenter*)
Carlos Vargas (*Abstract Co-Author*)
Molly Voss (*Abstract Co-Author*)
Thomas B. Daniels, MD (*Abstract Co-Author*)
William W. Wong, MD (*Abstract Co-Author*)
Sameer R. Keole, MD (*Abstract Co-Author*)
Jean-Claude M. Rwigema, MD (*Abstract Co-Author*)
Brian J. Davis, MD, PhD (*Abstract Co-Author*)
Bradley J. Stish, MD (*Abstract Co-Author*)
Brady Laughlin (*Abstract Co-Author*)
Joshua R. Niska, MD (*Abstract Co-Author*)

PURPOSE

This study reports the 5-year safety and efficacy outcomes of stereotactic body radiation therapy (SBRT) to the prostate bed in patients with high-risk features following radical prostatectomy.

METHODS AND MATERIALS

Between May 2018 and May 2020, 49 patients were prospectively treated post-prostatectomy and stratified into three groups: Group I received adjuvant SBRT (PSA <0.2 ng/mL with adverse features including positive margins, seminal vesicle invasion, or extraprostatic extension); Group II received salvage SBRT (PSA =0.2 and <2.0 ng/mL); and Group III included patients with oligometastatic disease (=5 sites). All patients underwent staging with choline C11 PET, and those with biochemical failure (PSA >0.2 ng/mL) were restaged with PSMA PET. SBRT using photons or protons was delivered to the prostate bed at a total dose of 30-32 Gy in five fractions, administered every other day. Salvage patients received 6 months of androgen deprivation therapy (ADT), and oligometastatic patients received 18 months of ADT. The primary endpoint was freedom from failure, defined as PSA <0.5 ng/mL without clinical progression or re-initiation of ADT. Secondary endpoints included freedom from failure with a PSA <0.2 ng/mL post-treatment, toxicity rates graded by CTCAE v5.0, clinical failure, and patterns of first recurrence.

RESULTS

The median follow-up was 60 months. Baseline characteristics included a pre-radiotherapy T stage of T2-T3b (47% T3a-b), a median pre-radiotherapy PSA of 0.4 ng/mL (range <0.1-1.9), a median Gleason score of 8 (range 6-9), and positive surgical margins in 48.8% of patients. Sites of oligometastatic disease included lymph nodes and bone. Treatment was well tolerated overall, with grade 2 or higher toxicities limited to one case of hematuria (Group I) and one case of rectal bleeding (Group II); no significant adverse events were observed in Group III. Clinical failures occurred in one patient in Group I, eight patients in Group II, and none in Group III. Five-year freedom from failure rates, as defined by the primary endpoint or using a PSA threshold of >0.2 ng/mL, were 50% for Group I, 62.5% for Group II, and 80% for Group III.

CONCLUSION

Prostate bed SBRT demonstrated excellent long-term safety with low rates of grade 2 or higher treatment-related adverse events. The observed low rates of clinical failure support the efficacy of this treatment approach in the postoperative setting. Freedom from failure improving from Group I to Group III is consistent with the known association of longer ADT durations.

CLINICAL RELEVANCE/APPLICATION

These findings support the use of prostate bed SBRT as a safe and effective strategy in selected high-risk post-prostatectomy patients.

R1-SSVA04-1 DIAGNOSTIC PERFORMANCE OF MICROVASCULAR ULTRASOUND IN DETECTION OF ENDOLEAKS AFTER EVAR: COMPARISON WITH CEUS AND CTA

Marcin Czeczelewski, MD, MBA (*Presenter*)
Maryla Kuczynska (*Abstract Co-Author*)
Eryk Mikos (*Abstract Co-Author*)
Anna Drelich-Zbroja (*Abstract Co-Author*)

PURPOSE

Patients after endovascular aneurysm repair (EVAR) require long-term surveillance to detect late complications. Computed tomography angiography (CTA) is the gold standard for follow-up imaging but involves exposure to high dose ionizing radiation and iodinated contrast agents. Doppler ultrasound is a safe, accessible, and cost-effective alternative, but its sensitivity and specificity are lower than CTA according to current literature. Contrast-enhanced ultrasound (CEUS) offers improved accuracy, while microvascular ultrasound (MVUS) is a novel, contrast-free technique. The aim of this study was to compare the diagnostic accuracy of MVUS with CEUS and CTA in detecting endoleaks in patients after EVAR.

METHODS AND MATERIALS

A prospective cross-sectional study was conducted involving consecutive patients after EVAR. All participants underwent ultrasound within one week of the procedure, including both MVUS and CEUS techniques. CEUS involved intravenous administration of 1.6 mL of SonoVue (Bracco, Italy). Triple-phase CTA was performed within one month postoperatively and served as the reference standard. Endoleaks were classified according to the Mayo Clinic classification.

RESULTS

Between July 2024 and the time of analysis, 52 patients (42 males, 10 females) who underwent EVAR were enrolled. Graft types included Zenith Flex (26.9%), Zenith t-Branch (38.5%), Gore Excluder (23.1%), and Medtronic Endurant II (11.5%). Ultrasound prior to discharge revealed 28 endoleaks detectable by both MVUS and CEUS, with an additional 8 endoleaks seen only on MVUS. One month later, CTA confirmed 22 of the 28 endoleaks initially detected in CEUS and MVUS, 2 had resolved, and 4 patients were lost to follow-up. Of the 8 endoleaks detected only by MVUS, one was confirmed by CTA. These MVUS-only endoleaks were characterized by fine, linear flow patterns perpendicular to the transducer. Endoleak types identified on ultrasound were: type Ia - 1 (3%), type Ib - 4 (11%), type II (lumbar) - 12 (33%), type II (IMA) - 5 (14%), type IIIa - 2 (6%), and type IIIc - 12 (33%).

CONCLUSION

MVUS demonstrates high sensitivity in detecting endoleaks after EVAR and may identify subtle, linear flow patterns.

CLINICAL RELEVANCE/APPLICATION

Microvascular ultrasound (MVUS) offers a non-invasive, contrast-free method for detecting endoleaks after EVAR with high sensitivity, including subtle leaks. Its routine use could reduce reliance on ionizing radiation and iodinated contrast agents in long-term follow-up protocols.

R1-SSVA04-2 THE MINIMUM PRE-EMPTIVE EMBOLIZATION OF AORTIC SIDE BRANCHES FOR PREVENTION OF TYPE II ENDOLEAK AFTER EVAR

Akihiro Murata (*Presenter*)
Hiroki Horinouchi (*Abstract Co-Author*)
Akiyuki Kotoku, MD, PhD (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)
Teruhito Hayashi (*Abstract Co-Author*)
Kazuki Hara, RT (*Abstract Co-Author*)

PURPOSE

Type II endoleak (T2EL) is the most common complication following endovascular abdominal aortic repair (EVAR) for abdominal aortic aneurysm (AAA). The efficacy of pre-emptive aortic side branch embolization for prevention of T2EL has been reported, however, no reasonable endpoint of embolization has been established. We hypothesized that minimal embolization would be sufficient to prevent T2EL after EVAR. The purpose of this study was to investigate the predictors of T2EL and to define the minimal endpoints of pre-emptive embolization.

METHODS AND MATERIALS

We retrospectively reviewed our institutional data to identify patients who underwent pre-emptive side branch embolization before EVAR from 2020 to 2025. Patients with insufficient data, dissecting or inflammatory AAA were excluded. Aortic side branches and endoleaks were assessed on contrast-enhanced CT images before and after EVAR. Volume embolization ratio (VER) was calculated as the percentage of coil volume relative to embolized vessel volume. Patient characteristics and anatomical factors were evaluated for association with T2EL after EVAR.

RESULTS

We identified 96 patients (median age 81 years, 75 men) who underwent EVAR with pre-emptive embolization. Among patent 469 aortic side branches (321 lumbar arteries, 79 inferior mesenteric arteries, 69 median sacral arteries) associated with AAA, 211 (45.0%) branches were embolized with coils. The median VER of embolized branches was 13.2% (IQR: 10.0-16.2%). T2EL and type I endoleak were identified in 22 (22.9%) and 7 (7.3%) patients, respectively. There were no T2EL from embolized branches. In contrast, 51 (19.8%) non-embolized branches were associated with T2EL. In multivariate analysis, number of non-embolized branches (OR =

2.85, 95% CI: 1.55-6.12, p < 0.05), concomitant internal iliac embolization, female, and Excluder device were independent predictors of T2EL after EVAR with pre-emptive embolization. The ROC analysis revealed that the optimal cutoff values of the number of non-embolized branches was three.

CONCLUSION

Independent of VER, T2EL from embolized branches was sufficiently preventable. It was suggested that the minimal endpoint of pre-emptive embolization should be to reduce the number of patent aortic side branches to two or fewer. Furthermore, patients with risk factors for T2EL require more aggressive embolization.

CLINICAL RELEVANCE/APPLICATION

Defining the minimal endpoint of pre-emptive aortic side branch embolization for prevention of T2EL can optimize coil use and reduce contrast and radiation doses. To achieve clinically sufficient prevention of T2EL, it is essential to reduce the number of patent aortic side branches to two or fewer, regardless of VER.

R1-SSVA04-3 DOPPLER ULTRASOUND FINDINGS IN FILLER-RELATED VASCULAR COMPLICATIONS: A MULTICENTRIC STUDY

Rosa Maria Silveira Sigrist, MD (*Presenter*)
Claudia Gonzalez (*Abstract Co-Author*)
Leonie Schelke (*Abstract Co-Author*)
Ximena L. Wortsman, MD (*Abstract Co-Author*)
Stella Desyatnikova, MD (*Abstract Co-Author*)
Fernanda A. Cavallieri, MD (*Abstract Co-Author*)
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*)

PURPOSE

The global surge in the use of cosmetic fillers—particularly hyaluronic acid (HA)—has led to a significant rise in vascular adverse events (VAEs) in the face, including necrosis, blindness, and stroke. The facial vasculature is uniquely complex and extensively anastomosed, differing from territories such as the carotids or extremities, where Doppler criteria are well established. No such reference standards exist for the face. This study aimed to identify the most frequent Doppler ultrasound findings in filler-induced VAEs to support diagnosis and management as well as to evaluate their association with prior use of hyaluronidase, the enzyme commonly used for treatment.

METHODS AND MATERIALS

A retrospective, international, multicenter, cross-sectional study was conducted across four radiology, one dermatology, and one plastic surgery centers between May 2022 and April 2025. Patients presenting with clinical signs of facial VAEs following filler injections were evaluated using high-frequency color or power Doppler ultrasound and in some cases microvascularity software (echoangio). Data regarding Doppler findings, clinical signs, arterial involvement, and prior hyaluronidase use were extracted from records. Statistical analysis was performed using R software, with Fisher's exact test applied to assess associations ($a<0.05$).

RESULTS

Among 100 patients, 93% were female, 98% had received HA fillers and 79% received hyaluronidase prior to Doppler evaluation. The most common color Doppler findings were absent flow in perforator vessels (42%), absent flow in major vessels (35%), compensatory flow (26%), string sign (18%), and increased peak systolic velocity (16%). No significant association was found between hyaluronidase use and specific Doppler findings ($p>0.05$). A moderate correlation was observed between absent flow in perforators and compensatory flow ($F = 0.37$, $p = 0.0004$). Lateral nasal artery involvement was significantly associated with absent major vessel flow ($p = 0.0004$).

CONCLUSION

The most frequent color Doppler ultrasound findings in filler-related VAEs were absent flow in perforator and major vessels. Although no association was found between hyaluronidase use and Doppler patterns, significant correlations emerged between specific findings and arterial territories, suggesting that color Doppler ultrasound can provide relevant hemodynamic information to support diagnosis.

CLINICAL RELEVANCE/APPLICATION

Recognizing Doppler ultrasound patterns may help radiologists more precisely identify cosmetic filler-induced VAEs and support timely clinical decision-making.

R1-SSVA04-4 ANEURYSM ECHO - THE ROLE OF ULTRASONOGRAPHY IN THE DIAGNOSIS OF VISCERAL ARTERY ANEURYSMS

Monika Zbroja-Putowska (*Presenter*)
Katarzyna Drelich (*Abstract Co-Author*)
Eryk Mikos (*Abstract Co-Author*)
Maryla Kuczynska (*Abstract Co-Author*)
Krzysztof Pyra (*Abstract Co-Author*)

PURPOSE

This study aims to highlight the role of ultrasonography in the diagnosis of visceral artery aneurysms (VAAs).

METHODS AND MATERIALS

During 11 years ultrasound evaluation of visceral vessels was performed in a group of 12540 patients (6850 men and 5690 women), aged 16-85. All patients underwent fasting examination. For each case, a morphological assessment in the B-mode presentation with an additional hemodynamic evaluation with color and spectral Doppler was made. Power Doppler and B-Flow were used in specific cases. 3D reconstructions were not used routinely.

RESULTS

Of the 12540 patients examined, aneurysms were diagnosed in 94 (51 men and 43 women). No case of multiple aneurysms has been detected. None of the 94 subjects presented characteristic symptoms, while 36 of them reported non-specific abdominal pain. There were 52 cases of splenic, 16 hepatic, 14 celiac trunk, 4 gastro-duodenal, 6 superior mesenteric and 2 inferior mesenteric artery aneurysms. In 62 cases (66%) the diameter of the aneurysm exceeded >2 cm. Each of the 36 symptomatic patients who presented as emergency admission underwent a CT scan. All of the ultrasound examinations performed afterwards turned out to be non-diagnostic. Diagnoses of >2 cm aneurysms were verified by CT examination. 36 of these aneurysms were successfully embolized. Patients with <2 cm aneurysms were referred for a follow-up Doppler ultrasound at 6 months.

CONCLUSION

Ultrasound examination demonstrates diagnostic effectiveness comparable to CT in detecting non-ruptured visceral artery aneurysms larger than 2 cm in diameter. Appropriate imaging techniques such as B-Flow and Doppler modalities (color, pulsed, and power Doppler) enable precise evaluation of vessel morphology and hemodynamic blood flow parameters. However, sonographic methods are less effective in cases of vessel wall rupture, where free intraperitoneal blood obscures vascular morphology, and the patient's critical condition limits effective cooperation during the examination.

CLINICAL RELEVANCE/APPLICATION

Ultrasound offers a valuable, non-invasive, and widely accessible alternative to CT in the diagnosis of non-ruptured visceral artery aneurysms (VAAs) larger than 2 cm. Its ability to accurately assess vessel structure and hemodynamics supports its use in routine screening and follow-up.

R1-SSVA04-5 PREVALENCE OF VASCULAR COMPRESSION SYNDROMES IN PATIENTS WITH POSTURAL ORTHOSTATIC TACHYCARDIA SYNDROME AND POSTURAL SYMPTOMS WITHOUT TACHYCARDIA

(*Presenter*)
Jawad Shahid (*Abstract Co-Author*)
Amna Butt (*Abstract Co-Author*)
Kazma Kulsoom (*Abstract Co-Author*)
Nidhi Shah (*Abstract Co-Author*)
Amer Suleman, MD (*Abstract Co-Author*)

PURPOSE

Postural Orthostatic Tachycardia Syndrome (POTS) is an autonomic nervous system dysfunction characterized by an incremental heart rate increase of =30 bpm within 10 minutes of standing. Postural Symptoms Without Tachycardia (PSWT) is a related autonomic dysfunction that presents similarly to POTS but with a heart rate increase of <30 bpm. Vascular compression syndromes result from the compression of blood vessels by surrounding anatomical structures, leading to symptoms of pain, blood pooling, discoloration, etc., that may worsen POTS or PSWT conditions. The objective of this study is to determine the prevalence of vascular compression syndromes, including Median Arcuate Ligament Syndrome (MALS), May-Thurner Syndrome, Nutcracker Syndrome, and Thoracic Outlet Syndrome (TOS) in patients diagnosed with Postural Orthostatic Tachycardia Syndrome (POTS) and Postural Symptoms Without Tachycardia (PSWT).

METHODS AND MATERIALS

A retrospective analysis was conducted using a random sample of 392 patients diagnosed with POTS or PSWT via tilt table testing. The study population included 30 males (7.7%) and 362 females (92.3%), with 311 (79.3%) diagnosed with POTS and 81 (20.7%) with PSWT. CT angiogram results of the abdomen and pelvis were reviewed to diagnose cases of MALS, Nutcracker Syndrome, and May-Thurner Syndrome, whereas Thoracic Doppler studies were used to diagnose TOS. Out of 392 patients, 367 patients (93.6%) had CT scans, and 310 patients (79.1%) had Thoracic Doppler studies. Frequency analysis was performed using SPSS 29.0.

RESULTS

May-Thurner syndrome was the most common compression syndrome, affecting 138 POTS patients (44.4%) and 33 PSWT patients (40.7%). Nutcracker syndrome was identified in 117 POTS patients (37.6%) and 24 PSWT patients (29.6%). MALS affected 107 POTS patients (34.4%) and 32 PSWT patients (39.5%). TOS was present in 61 POTS patients (19.6%) and 10 PSWT patients (12.3%). Eight patients (2.0%) were diagnosed with all four compression syndromes.

CONCLUSION

There is a high prevalence of vascular compression syndromes in patients with POTS and PSWT. May-Thurner Syndrome is the most commonly identified, followed by Nutcracker Syndrome, MALS, and then TOS. These findings highlight vascular compression as a potential contributing factor in autonomic dysfunction and support its consideration in diagnostic and treatment strategies.

CLINICAL RELEVANCE/APPLICATION

Early detection of vascular compression syndromes in patients with POTS and PSWT may help guide treatment and improve symptoms such as blood pooling, heaviness in the extremities, abdominal pain, nausea, dizziness, lightheadedness, etc., by addressing the potential underlying vascular etiology.

R1-SSVA04-6 EFFECTIVENESS OF DOPPLER ULTRASOUND IN THE EVALUATION OF VENOUS THORACIC OUTLET SYNDROME: A BIVARIATE DIAGNOSTIC META-ANALYSIS

Carlos Augusto V. Pinto, MD (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic accuracy of Doppler ultrasound in detecting venous thoracic outlet syndrome (vTOS), characterized by subclavian vein compression. The objective was to estimate sensitivity, specificity, diagnostic odds ratio (DOR), and overall diagnostic performance. Study heterogeneity and the influence of different reference standards (venography, CT, clinical criteria) were also analyzed.

METHODS AND MATERIALS

Following PRISMA-DTA guidelines and PROSPERO registration (CRD42024621782), a comprehensive search was conducted in PubMed, Embase, Scopus, and Web of Science through November 2024. Eligible studies included adult patients undergoing Doppler ultrasound for vTOS diagnosis, with available sensitivity and specificity data. Extracted variables included TP, FP, FN, TN, AUC, and DOR. Study quality was assessed using QUADAS-2. A bivariate random-effects model was applied using R software (v4.4.2). Analyses included SROC curves, heterogeneity testing (I^2, t^2), and publication bias assessment (Deeks' funnel plot).

RESULTS

Five studies with 293 patients were included. Pooled sensitivity was 91.4% (95% CI: 83.5-95.7%) and specificity was 91.1% (95% CI: 63.8-98.3%). AUC was 0.919, indicating excellent diagnostic performance. Pooled DOR was 54.1 (95% CI: 13.59-215.49). Sensitivity heterogeneity was moderate (I^2 = 25.4%) and specificity heterogeneity was high (I^2 = 82.0%). Excluding one study reduced sensitivity heterogeneity to I^2 = 0% (adjusted sensitivity: 88.6%). No significant publication bias was identified (p = 0.3819). Heterogeneity was mainly due to differences in reference standards.

CONCLUSION

Doppler ultrasound with sensitivity >90% and AUC of 0.919 is an effective tool for vTOS screening. While it shows excellent sensitivity, specificity varies due to methodological heterogeneity. Diagnostic performance was influenced by the type of reference standard used. Doppler should be adopted as a first-line assessment in clinically suspected cases, though additional imaging is advised in anatomically complex or preoperative scenarios.

CLINICAL RELEVANCE/APPLICATION

Doppler ultrasound is a non-invasive, rapid, and widely available tool suitable for initial vTOS screening, especially in resource-limited settings. Its high sensitivity supports early detection and reduces diagnostic delay. However, in cases of asymptomatic compression or challenging anatomy, sole reliance on Doppler may lead to false positives. Combining Doppler findings with venous CT and clinical data enhances diagnostic accuracy and risk stratification.

R2-STCE1-2 BREAST ARTERIAL CALCIFICATION ON MAMMOGRAMS: NATURAL HISTORY ANALYSIS USING ARTIFICIAL INTELLIGENCE IN OVER 10,000 WOMEN

Alyssa T. Watanabe, MD (*Presenter*)
Richard Mantey (*Abstract Co-Author*)
Junhao Wang (*Abstract Co-Author*)
Nitesh Nerlekar (*Abstract Co-Author*)

PURPOSE

Presence and extent of breast arterial calcifications (BAC) correlates with cardiovascular disease risk. The rate of BAC progression may also be tied to increased risk. BAC progression rate was evaluated in a large screening cohort using an artificial intelligence model.

METHODS AND MATERIALS

In this retrospective study, 27,780 full-field digital mammograms from 10,348 women (age 26-94 years, mean 56) performed 2006-2016 at a single Southwestern U.S. academic center were analyzed. Using an artificial intelligence model (AI) , BAC scores (0-100) for each exam were obtained. BAC-positive scores were age-adjusted to derive percentiles, then binned by quartile (Q): 1st-25th (Q1, n=529), 26-50th (Q2, n=566), 51-75th (Q3, n=469), and 76-100th (Q4, n=461) percentiles. The majority of women (n=8,323) were classified as BAC-negative. Kaplan Meier and Aalen-Johansen multi-state models were used to estimate probabilities of transitioning to higher quartiles between 1 to 5 years.

RESULTS

Using Aalen-Johansen estimation, the one-year cumulative probability of progression to a higher BAC quartile was 2% among BAC-negative women, 7% among those in the Q1, 5% in Q2, and 6% in Q3. By five years, these cumulative transition probabilities increased to 10%, 39%, 29%, and 23%, in the same categories.

CONCLUSION

BAC progression on sequential mammograms was seen in as little as 1 year. Women with mild baseline BAC (defined as BAC score in the 1st quartile at index) exhibited the greatest likelihood of progression over time. AI scoring of BAC progression may be used to identify subgroups of women who may be at higher cardiovascular risk.

CLINICAL RELEVANCE/APPLICATION

Breast arterial calcification on mammography is a known cardiovascular marker in women. Opportunistic BAC reporting on mammograms is recommended and may aid in improving cardiovascular outcomes and mortality in women. Using artificial intelligence scoring, temporal BAC progression rates can be obtained, which may be useful for further research in risk stratification.

R2-STCE1-3 AI-DRIVEN OPPORTUNISTIC LIVER-BASED ASSESSMENT OF METABOLIC HEALTH ON CORONARY ARTERY CALCIUM CT IS ASSOCIATED WITH CARDIOVASCULAR RISK

GOURAV MODANWAL (*Presenter*)
Rohan Dhamdhere (*Abstract Co-Author*)
Mendel Lebowitz (*Abstract Co-Author*)
Amritpal Singh (*Abstract Co-Author*)
Santosh Kumar Sirasapalli (*Abstract Co-Author*)
Sanjay Rajagopalan (*Abstract Co-Author*)
Sadeer Al-Kindi (*Abstract Co-Author*)
Anant Madabhushi, PhD (*Abstract Co-Author*)

PURPOSE

Hepatic steatosis, a manifestation of metabolic dysfunction, is increasingly associated with cardiovascular disease (CVD). Coronary artery calcium CT (CAC-CT), routinely performed for coronary artery disease risk assessment, presents an underused opportunity for opportunistic assessment of metabolic dysfunction. In this large cohort study, we evaluated whether AI-derived liver CT attenuation—measured opportunistically from CAC-CT as a non-invasive surrogate of steatosis—is associated with major adverse cardiovascular events (MACE).

METHODS AND MATERIALS

DeHFT, a validated deep learning model for automated liver attenuation estimation from CAC-CT, was applied to 43,518 participants in the CLARIFY Registry (NCT04075162). Participants were stratified into risk groups based on liver attenuation tertiles (T1-T3) and were followed for MACE (myocardial infarction, stroke, revascularization, heart failure, and all-cause mortality). MACE-free survival was assessed using Kaplan-Meier analysis, and hazard ratios (HRs) were estimated via Cox proportional hazards model.

RESULTS

Over a median follow-up of ~ 3.75 years, 3868 had MACE. Compared to individuals in the highest attenuation group (T3, > 57.08 HU), those in the lowest (T1, < 50.41 HU) and intermediate (T2, 50.41-57.08 HU) groups exhibited significantly elevated risk, with HR of 1.63 [95% CI: 1.51-1.77] and 1.36 [95% CI: 1.25-1.47], respectively ($p<0.001$ for all comparisons). These associations remained robust even after adjusting for age, sex, smoking, BMI, diabetes, hypertension, and CAC score with HR of 1.19 [95% CI: 1.08-1.30, $p < 0.001$] for T1 and 1.16 [95% CI: 1.06-1.27, $p < 0.01$] for T2 versus T3.

CONCLUSION

AI-derived liver attenuation, previously validated as a surrogate for hepatic steatosis, was opportunistically extracted from routine CAC-CT to assess metabolic health. In this study, lower liver attenuation—indicative of greater hepatic fat—was associated with higher MACE risk. These findings highlight the prognostic value of liver routinely captured on CAC-CT and support the integration of AI analysis into clinical workflows.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that AI-derived liver attenuation can be repurposed from routine CAC-CT to stratify cardiometabolic risk without the need for additional imaging. By enabling non-invasive, scalable identification of at-risk individuals during standard care, this approach supports earlier intervention and extends the preventive value of existing cardiovascular imaging workflows.

R2-STCE2-1 MULTI-FREQUENCY MR ELASTOGRAPHY FOR CERVICAL BIOMECHANICAL PROPERTY ASSESSMENT: A PRELIMINARY STUDY

Jing Lu (*Presenter*)
Yi Fu, PhD,MD (*Abstract Co-Author*)
Yajia Gu (*Abstract Co-Author*)

PURPOSE

Cervical cancer (CC) is the leading cause of cancer-related death among women worldwide. While MRI assesses morphology, MR elastography (MRE) quantifies biomechanical properties, potentially offering novel biomarkers. This prospective study investigated cervical stiffness (c) and viscosity (f) in healthy women and CC patients, correlating them with menopaus and clinicopathological features.

METHODS AND MATERIALS

This study included 65 CC patients and 34 healthy participants (HHs) who underwent 3.0T multifrequency MRE (40-70 Hz) between April and July 2025 at a single center. HHs were stratified by reproductive status. MRE quantitative parameters (c , f) were compared among groups and correlated with tumor size, growth pattern, histology (squamous cell carcinoma [SCC] vs. non-SCC), lymphovascular space invasion, stromal invasion, lymph node metastasis, parametrial invasion and patient-derived organoids (PDO)-derived stiffness in a subset (n = 9). Univariate statistical analyses were performed.

RESULTS

Premenopausal HHs had higher mean c value (1.16 m/sec ± 0.21 vs. 0.95 m/sec ± 0.18, P = 0.004) and f value (0.67 radians ± 0.11 vs. 0.56 radians ± 0.15, P = 0.028) than postmenopausal HHs. CC tissues showed elevated mean c value (median, 1.81 m/sec [IQR, 1.01, 1.61 m/sec] vs. 1.04 m/sec [IQR, 0.90, 1.27 m/sec], P = 0.002) and f value (0.86 radians ± 0.19 vs. 0.63 radians ± 0.14, P < 0.001) versus HHs. Premenopausal CCs showed significantly higher values in mean c (median, 1.38 m/sec [IQR, 1.09, 1.89 m/sec] vs 1.07 m/sec [IQR, 0.98, 1.37 m/sec], P = 0.008), and minimum f (0.41 radians ± 0.13 vs 0.32 radians ± 0.11, P = 0.002) compared to postmenopausal cases. SCCs had significantly greater mean c value (median, 1.21 m/sec [IQR, 1.03, 1.62 m/sec] vs 1.00 m/sec [IQR, 0.95, 1.21 m/sec], P = 0.033), and mean f value (0.88 radians ± 0.19 vs 0.72 radians ± 0.14, P = 0.038) than non-SCCs. Maximum tumor diameter correlated with maximum c value (r s = 0.590, P < 0.001). MRE c value moderately correlated with PDO stiffness (r s = 0.700, P = 0.036).

CONCLUSION

Cervical biomechanics vary significantly across reproductive phases. MRE quantifies distinct biomechanical properties in CCs, correlating with histology and tumor size. It may enhance CC characterization, offering potential prognostic biomarkers. The PDO-MRE correlation underscores MRE's translational relevance.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that MRE-based assessment of cervical biomechanical properties can help differentiate malignant from healthy tissue and may serve as a biomarker for tumor characterization. The findings suggest potential clinical utility in improving diagnosis, risk stratification while offering a non-invasive alternative for tracking disease progression.

R2-STCE2-2 FERROQUANT: A STEP TOWARD CLINICALLY RELEVANT IRON TYPING USING T1 MRI IN SUBDURAL HEMATOMAS

Ogechukwu Pamela Ngwu-Hyacinth, MSc, MBBS (*Presenter*)

PURPOSE

Blood breakdown products (BBPs) evolve in predictable patterns after cerebral hemorrhage and are key imaging biomarkers for injury progression and lesion age. Radiologists currently rely on subjective interpretation of T1 and T2 signal changes to infer these stages. However, no quantitative method exists for iron mapping in different BBPs. Quantifying iron in a hematoma is necessary to correlate signal changes to biological or pathological processes, including inflammation, white matter injury and toxicity; monitor progression/resolution over time and inform clinical decisions. We propose FerroQuant, a multimodal MRI technique integrating Quantitative Susceptibility Mapping (QSM), T2, T2*, and T1 to characterize iron in ferritin phantoms and in ex vivo human subdural hematomas, complementing the traditional T2 and Susceptibility Weighted MRI.

METHODS AND MATERIALS

Ferritin phantoms (0.0195-5.0 mg/mL) were scanned at 3T using inversion recovery spin-echo (T1), T2, and QSM MRI. T1 mapping and relaxivity were estimated using a reproducible MATLAB technique. Similarly, human subdural hematoma samples (obtained from craniotomy) were scanned to capture temporal evolution of BBPs.

RESULTS

T1 decreased with rising ferritin concentration, consistent with its paramagnetic nature. The T1 results were consistent and reproducible across the ferritin phantoms and clot samples.

CONCLUSION

We present the first step toward iron quantification in intracranial hemorrhage. In clot samples, spatial T1 contrast reflected BBP evolution in ways complementary (not redundant) to T2 and QSM. T1 is sensitive to tissue composition, directly reflecting the effects of iron. T2 is sensitive to edema or tissue microenvironment, important in hemorrhage staging. Our approach expands conventional T2 and susceptibility-based paradigms by incorporating quantitative T1 relaxometry. To the best of our knowledge, this is the first study to quantify iron in surgically removed human (subdural) hematomas, with translational potential for image-guided prognosis in stroke, trauma and cerebrovascular malformations.

CLINICAL RELEVANCE/APPLICATION

Radiologic interpretation of hemorrhagic lesions is often qualitative and dependent on reader experience. No single MRI modality can effectively distinguish all forms of iron due to overlapping effects on MRI signals and the complex magnetic interactions within brain tissue. To address these limitations, FerroQuant introduces a multiparametric approach for iron quantification; it focuses on leveraging endogenous contrast from iron in BBPs, the hallmark of non-contrast imaging innovation. FerroQuant has the potential to enhance diagnostic accuracy, monitoring, and clinical decisions in the management of intracranial hemorrhage.

R2-STCE2-3 SIMULTANEOUS REAL-TIME IMAGING OF NEUROFLUID AND NEUROVASCULAR DYNAMICS USING ULTRAFAST FLOW-WEIGHTED ECHO-PLANAR IMAGING

Amir Shaker, BSc (*Presenter*)
Helia Hosseini, MD (*Abstract Co-Author*)
Cihat Eldeniz, PhD (*Abstract Co-Author*)
Bryn A. Martin, PhD (*Abstract Co-Author*)
Aristeidis Sotiras, PhD (*Abstract Co-Author*)
Jennifer Strahle (*Abstract Co-Author*)
Arash Nazeri, MD (*Abstract Co-Author*)

PURPOSE

Understanding connection between cerebrospinal fluid (CSF) and blood flow is crucial for brain pressure regulation, waste clearance, and homeostasis. Phase-contrast (PC) MRI measures CSF flow but requires gating and velocity encoding, limiting temporal resolution and simultaneous vascular-CSF capture.

METHODS AND MATERIALS

We present self-gated ultrafast echo planar imaging method enabling bi-directional inflow-weighted imaging with 47 ms temporal and 1.3 mm² spatial resolution capturing both neurovascular and CSF flow. This approach was done alongside PC MRI at C2-C3 in 21 participants on 3T Siemens Prisma scanner. Frequency-domain and event-related analyses assessed vascular-CSF coupling and reconstructed CSF waveforms across cardiac cycle.

RESULTS

Spectral analysis of CSF signals showed clear respiratory and cardiac peaks, with higher-order harmonics. Coherence analysis revealed stronger CSF-neurovascular coupling at cardiac frequencies, peaking at third harmonic, indicating arterial and venous pulsations drive spinal CSF flow. Systolic peaks from vertebral artery waveforms enabled event-related CSF cycle reconstruction without external gating. Time segments around these events were averaged to generate voxel-wise CSF waveforms. We compared cardiac cycle lengths from SURF-EPI with physiological logs ($n = 15$; 14 ICC > 0.60; error < 47 ms in 14). In addition, waveform comparisons with PC MRI showed strong/very strong correlation ($r > 0.60$) in 75% of participants, and moderate correlation ($r = 0.49$-0.58) in the rest. We compared ventral and dorsal CSF columns using (i) systole/diastole ratio, defined as peak systolic signal intensity divided by mean diastolic signal intensity, and (ii) variability metrics, quantified as coefficients of variation over cardiac cycles for (a) peak systolic signal, (b) late diastolic signal, and (c) systole/diastole ratio. (iii) systolic and diastolic outlier proportions, defined separately as fraction of cardiac cycles in which peak systolic or late diastolic signal intensity exceeded twice the corresponding peak systolic or late diastolic signal intensity of ROI's average waveform. These findings suggest increased beat-to-beat variability and more complex flow dynamics in ventral CSF.

CONCLUSION

SURF-EPI enables rapid (>20 Hz), simultaneous CSF and neurovascular imaging, capturing cardiac-driven flow without external gating. By avoiding velocity encoding, it overcomes dynamic range and phase noise limitations of real-time PC MRI, offering a robust, efficient alternative.

CLINICAL RELEVANCE/APPLICATION

SURF-EPI quantified ventral CSF flow variability in 14 subjects with Chiari I malformation and matched controls, showing trend of greater diastolic variability in Chiari ($p = 0.08$).

R3-SSCA10-1 FULL FREE-BREATHING CARDIAC MAGNETIC RESONANCE IMAGING: CLINICAL FEASIBILITY, EFFICIENCY, AND DIAGNOSTIC CONCORDANCE

Wenli Zhou (*Presenter*)
Kai Yang (*Abstract Co-Author*)
Jing An (*Abstract Co-Author*)
Gang Yin SR, BS (*Abstract Co-Author*)
Xinling Yang (*Abstract Co-Author*)
Minjie Minjie, PhD (*Abstract Co-Author*)

PURPOSE

To validate a comprehensive full free-breathing CMR protocol integrating motion correction and compressed sensing for clinical feasibility, efficiency, and diagnostic accuracy.

METHODS AND MATERIALS

In a prospective study, 605 patients underwent paired free-breathing and breath-holding CMR (3.0 scanner) across four cohorts. Primary evaluations included cine, T1 mapping, and late gadolinium enhancement (LGE) sequences, assessing scan time, image quality, cardiac function and tissue characterization.

RESULTS

The full free-breathing CMR protocol significantly reduced scan time by 39% (20.9 ± 3.1 vs. 34.4 ± 7.5 minutes, $P < 0.001$), with cine, T1 mapping, and LGE shortened by 54%, 28%, and 33%, respectively. A 10-minute focused protocol (cine+ +LGE) retained diagnostic fidelity. Free-breathing LGE demonstrated superior image quality versus breath-holding (median score 5 vs. 4, $P < 0.001$), particularly in arrhythmia/heart failure patients, while T1 mapping maintained equivalent quality (median 5 vs. 5, $P = 0.77$). Free-breathing cine showed minor but clinical acceptable quality reduction (median 4 vs. 5, $P < 0.001$). Quantitative analysis revealed marginally higher LV volumes (?EDV +5.01 mL, ?ESV +5.71 mL, $P < 0.001$) and lower LVEF (-1.67%, $P < 0.001$) with free-breathing, yet maintained excellent agreement (ICC 0.98-0.99). Native T1 and LGE mass were slightly elevated in free-breathing ($P = 0.001$) but obtained excellent consistency.

CONCLUSION

Full free-breathing CMR with MOCO and CS significantly reduces scan duration while maintaining diagnostic accuracy and strong concordance with breath-holding techniques.

CLINICAL RELEVANCE/APPLICATION

Full free-breathing CMR significantly shortens scan time while preserving diagnostic accuracy, enhancing accessibility in resource-limited settings.

R3-SSCA10-2 COMPARING THE PROGNOSTIC SIGNIFICANCE OF DUAL BOLUS AND DUAL SEQUENCE QUANTITATIVE STRESS PERFUSION CARDIAC MAGNETIC RESONANCE

Victor Goh (*Abstract Co-Author*)
Konrad Werys (*Abstract Co-Author*)
Randall Stafford (*Abstract Co-Author*)

PURPOSE

Quantitative stress perfusion (QP-stress) cardiac magnetic resonance (CMR) has the ability to diagnose and assess coronary artery disease and predict major adverse cardiovascular events (MACEs). Two techniques for QP-stress are Dual Bolus (DB) and Dual Sequence (DS). Our aim was to compare the prognostic significance of DB and DS.

METHODS AND MATERIALS

Both DB and DS were simultaneously performed on the same patient. Patients were excluded due to QP-stress protocol error, inadequate stress response, ECG pulse gating error, suboptimal images, primary congenital coronary abnormality and implanted cardiac device. Myocardial blood flow (MBF) was quantified for both stress and rest sequence to estimate myocardial perfusion reserve (MPR). Composite MACE comprised of acute coronary syndrome, stroke, heart failure (HF) hospitalisation, late (>90days) revascularisation and all-cause death was regarded as the primary study endpoint. Cox proportional hazard models and Kaplan-Meier survival estimate curves with log-rank tests were performed to determine the prognostic significance of DB and DS stress MBF and MPR.

RESULTS

577 patients (mean age 63.1±12.3 years and 61.8% male) were eligible for final analysis. Median follow-up was 737 days (interquartile range, 408-1142 days). 54 events were documented. All QP-stress CMR variables demonstrated significance in univariate Cox proportional hazard models [DB stress MBF (p=0.008), DB MPR (p=0.020), DS stress MBF (p<0.001) and DS MPR (p<0.001)]. After adjustment for age, left ventricular ejection fraction, left ventricular mass index and the presence of late gadolinium enhancement, only DS quantifications remained significant for MACE [DS stress MBF (95% CI, hazard ratio: 0.23-0.53, p<0.001), DS MPR (95% CI, hazard ratio: 0.15-0.36, p<0.001)]. Sub-analyses with Kaplan-Meier survival estimate curves were performed on HF hospitalisation (16 cases) [DS stress MBF (p<0.001), DS MPR (p=0.017), DB stress MBF (p=0.17), DB MPR (p=0.20)] and on all-cause death (15 cases) [DS stress MBF (p=0.01), DS MPR (p<0.001), DB stress MBF (p=0.17), DB MPR (p=0.046)].

CONCLUSION

DS stress MBF and MPR demonstrated a better prognostic ability than DB stress MBF and MPR. This provides an additional reason to use DS QP-stress instead of DB QP-stress as the standardised technique for QP-stress CMR examinations, on top of its easier workflow.

CLINICAL RELEVANCE/APPLICATION

To the best of our knowledge, there is no study directly comparing the prognostic significance of DB and DS QP-stress on MACE. This study provides key insights into MACE predictability by DB and DS QP-stress and shows DS out-performing DB, providing an additional reason to use the DS technique which is already a much easier technique to utilise and less time-consuming.

R3-SSCA10-3 FEASIBILITY OF FREE-RUNNING 3D CARDIAC CINE IMAGING ON A 0.6T MRI

Jacinta Browne, PhD (*Abstract Co-Author*)
Ece Ercan (*Abstract Co-Author*)
Michal Povazan (*Abstract Co-Author*)
Omer Demirel (*Abstract Co-Author*)
Tim Leiner, MD, PhD (*Abstract Co-Author*)

PURPOSE

Free-running (FR) whole-heart 5D cardiovascular magnetic resonance (FR-5DCMR) continuously collects data without the need for breath-holding and cardiac gating. Cardiac and respiratory motion resolved images are reconstructed by compressed sensing reconstruction. 3D cine images can be obtained using a balanced steady-state free precession (bSSFP) sequence with the FR-5DCMR, and most studies have been performed at 1.5T and 3.0T field strengths. Compared to higher field strengths, a low field scanner has beneficial features for bSSFP FR-5DCMR, such as more uniform static magnetic field and lower specific absorption rate. However, low field CMR also presents the major challenge of the significantly decreased signal-to-noise ratio. The purpose of this work is to study the feasibility of FR 3D cine CMR on a 0.6T MRI system.

METHODS AND MATERIALS

The 3D radial phyllotaxis bSSFP FR-5DCMR sequence was implemented on a 0.6 T scanner (Philips Healthcare, Best, The Netherlands). FR-5DCMR data of six volunteers were acquired using field of view of 220 mm 3 , voxel size of 1.38 mm 3 , TE/TR of 2.85/5.7 ms and flip angle of 90 o with a scan time of 9 min. Readout length was 2.76 ms, resulting in 48% of the scan time for data acquisition. Data were reconstructed to four respiratory and 14-18 cardiac phases with a 50 ms temporal resolution. The 3D cine images of one respiratory phase were reformatted to short-axis (SA), two-chamber (2ch) and four-chamber (4ch) views and compared to cine images acquired by conventional 2D breath-holding cardiac gated acquisitions. End-diastolic volume (EDV), end-systolic volume (ESV) and ejection fraction (EF) were assessed for both left (LV) and right ventricles (RV) by two radiologists using CVI42 (Circle, Calgary, Canada). Paired student t-test and Bland-Altman plots were used to compare quantitative measurements.

RESULTS

The reformatted 3D SA, 2ch and 4ch views are compared to conventional 2D cine in fig.1(a). Despite the visually lower image quality in terms of contrast and sharpness, contouring was successfully performed on all volunteer data. LVEDV was 142±25 ml /130±23 ml (p = 0.11), LVESV was 56±12ml /54±12 ml (p = 0.24), and LVEF was 58.2±4.5% /61.6±2.5% (p = 0.08) for 3D and 2D respectively. RVEDV was 145±28 ml /141±30ml (p = 0.48), RVESV was 78±10ml /77±12 ml (p = 0.65), the RFEV was 55.50±4.7% /55.2±4.4% (p = 0.53) for 3D and 2D respectively. Bland-Altman plots of LVEF and RVEF are shown in fig.1 (b).

CONCLUSION

This study demonstrates the feasibility of FR 3D cine CMR at 0.6 T with acceptable image quality and quantitative LV and RV parameters.

CLINICAL RELEVANCE/APPLICATION

FR-5DCMR has the potential to significantly simplify the workflow of CMR. The results could have profound impacts on improvement on efficiency and accessibility of CMR.

Jeremy D. Collins, MD (*Abstract Co-Author*)

PURPOSE

Cardiac MR myocardial quantitative perfusion (MQP) measures myocardial blood flow (MBF) in ml/min/g. Quantitative methods are more sensitive than semiquantitative ones for detecting ischemia and predicting cardiac events. We investigated single bolus MQP in consecutive patients (pts) referred for stress perfusion imaging and assessed rest only perfusion in pts receiving contrast for non stress imaging on a 1.5T vendor platform

METHODS AND MATERIALS

We included pts referred for contrast-enhanced stress or non-stress cardiac perfusion MRI. Imaging was performed at 1.5T on a single scanner with a dedicated cardiac coil (Optima 450W, GE Healthcare, WI) using a developmental MQP pulse sequence. Stress perfusion was performed with regadenoson (0.4 mg over 10 sec). Rest imaging followed stress imaging after a 10-min washout. Gadobutrol (0.05 mmol/kg) was given at 2 cc/sec for both phases. Aminophylline (100 mg IV) was given post-

stress at the radiologist's discretion. An additional 0.10 mmol/kg Gadobutrol was given post-rest (total 0.2 mmol/kg). Stress and rest imaging included three short-axis slices (base, mid, apex). MQP analysis used investigational software (QP, CVi42 v5.17, Circle, Canada). Cine and conventional myocardial delayed enhancement (MDE) imaging were obtained. LVEF and MDE were extracted from clinical reports. Pts were grouped by LVEF (=50% vs. <50%) and by presence/absence of scar on MDE. Resting MBF was compared between those who received vasodilator vs rest-only imaging, and global values were analyzed using a two-tailed Student's t test.

RESULTS

94 pts (50 female; 19-84 yrs) underwent MQP imaging with off-line resting MBF analysis. Automated MQP contours required correction in 10 pts. Pts were grouped by LVEF and scar. Mean ± SD are reported. Pts with preserved LVEF and no scar had higher global resting MBF than those with preserved LVEF and scar ($p < 0.001$). Resting MBF differed between those with and without aminophylline reversal ($p < 0.05$). Resting MBF was similar between pts with preserved LVEF and no scar and those undergoing stress imaging with reversal

CONCLUSION

Single bolus off line MBF quantification is feasible in a heterogeneous clinical population using an investigational 1.5T sequence. Residual regadenoson effects beyond 10 minutes elevated resting MBF unless reversed with aminophylline, potentially lowering perfusion reserve when rest follows stress without reversal. Resting MBF was higher in pts with LVEF >50% without scar vs. those with scar, with consistent absolute differences

CLINICAL RELEVANCE/APPLICATION

Single bolus off line MBF quantification is feasible and may help identify discrepancies in myocardial perfusion reserve, especially in patients with residual vasodilatory effects or myocardial scarring.

R3-SSCA10-5 ULTRAFAST DEEP LEARNING-BASED SINGLE-BEAT CARDIOVASCULAR MAGNETIC RESONANCE IN PATIENTS WITH SUSPECTED MYOCARDIAL DISEASE

Daniel Kuetting, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the diagnostic interchangeability of a novel deep-learning (DL) enhanced single-beat cardiovascular magnetic resonance (CMR) protocol compared to standard CMR protocol in patients with suspected myocardial disease.

METHODS AND MATERIALS

In this prospective study, participants with suspected myocardial disease consecutively underwent both standard and DL single-beat CMR protocol including cine, T2-STIR, and late gadolinium enhancement (LGE) sequences at 1.5T. Single-beat images were reconstructed using a DL super-resolution algorithm provided by Philips Healthcare that combines and integrates compressed sensing with two convolutional neural networks: Adaptive-CS-Net and Precise-Image-Net. Three readers assessed wall motion abnormalities, edema, LGE, and CMR diagnosis. Interchangeability was evaluated using individual equivalence indices (IEIs, margin ±5%). Interreader agreement was analyzed using Fleiss ?. Total scan time (including acquisition and breath-hold time) was compared using Student's t'test. Diagnostic certainty was evaluated using a 5-point Likert scale. For total examination time comparison, examinations were retrospectively identified which used either a DL single-beat or standard CMR protocol only (each n=10).

RESULTS

In total, 107 participants were included (mean age 56±21 years, 61% male). Total scan time of the short-axis DL single-beat sequences was reduced by 66% in cine (92±7 vs. 274±8 sec; p<.0001), 73% in LGE (77±4 vs. 286±4 sec; p<.0001), and 86% in T2-STIR (35±4 vs. 244±18 sec; p<.0001) compared to standard CMR. Total examination time for the full CMR protocol using the DL single-beat approach was reduced by 54% (24.2±8.2 vs. 52.3±1.7 min; p<.0001). Interreader agreement was comparable between DL single-beat and standard CMR, e.g. CMR diagnosis (0.88 vs. 0.89). Interchangeability analysis confirmed no clinically significant differences, with IEIs within the predefined equivalence margin (e.g. CMR diagnosis: 0.01 [CI: -0.02, 0.05]). Diagnostic certainty was rated significantly higher for DL single-beat CMR protocol (5 [IQR: 4.7-5] vs. 4.7 [IQR: 4.3-5]; p<.0001).

CONCLUSION

DL-based single-beat CMR enables an ultrafast, clinically equivalent cardiomyopathy protocol (approximately 24 min) without compromising diagnostic accuracy. This approach can enhance workflow efficiency and serve as a robust alternative for comprehensive CMR evaluations in myocardial disease.

CLINICAL RELEVANCE/APPLICATION

DL-based single-beat CMR offers a time-efficient and robust diagnostic alternative to standard CMR. Faster imaging techniques using DL may improve patient comfort and compliance and could be a possible concept for overcoming increasing CMR investigations in the future.

R3-SSCA10-6 PROGNOSTIC VALUE OF CMR CINE-BASED HEMODYNAMIC FORCES ANALYSIS IN ACUTE PERICARDITIS

Annemarie Proff, MD (*Presenter*)
Thomas M. Vollbrecht, MD (*Abstract Co-Author*)
Taraneh Aziz-Safaie, MD (*Abstract Co-Author*)
Leon Bischoff, MD (*Abstract Co-Author*)
Dmitrij Kravchenko, MD (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

Cardiac magnetic resonance (CMR) enables advanced functional evaluation including strain imaging and quantification of hemodynamic forces (HDF). HDF represents the intraventricular forces exchanged between the myocardium and blood, offering a non-invasive assessment of pressure gradients. This study aimed to investigate the prognostic value of HDF in patients with acute pericarditis.

METHODS AND MATERIALS

I n this retrospective single-center study, patients with CMR-confirmed acute pericarditis (08/2008- 12/2024) were analyzed. In addition to standard left ventricular (LV) functional metrics (e.g., ejection fraction), strain parameters (endocardial global longitudinal strain [GLS] and circumferential strain [GCS]) and HDF parameters (e.g., HDF strength root mean square in apex-base and lateral-septal direction, HDF average angle, hemodynamic work), were assessed using standard cine imaging (Medis

Suite QStrain). Major adverse cardiac events (MACE) were defined as constrictive pericarditis, tamponade, recurrence of pericarditis, or cardiac decompensation. Follow-up was available up to 5 years. Statistical tests included Mann-Whitney U and Kaplan-Meier analysis.

RESULTS

Among 150 patients (mean age 56 ± 17 years; 39% female), 17 (11.3%) experienced MACE. MACE included constrictive pericarditis (n=4, 23.5%), recurrence (n=7, 41.2%), tamponade (n=1, 5.9%), and cardiac decompensation (n=5, 29.4%). Patients with MACE had significantly lower apex-base HDF values at baseline compared to those without MACE (17.0 ± 7.6% vs. 21.9 ± 9.0%, p=0.032); other parameters (LVEF, GLS, GCS, lateral-septal HDF, angle, work) showed no significant differences (p>0.05 for each parameter). On Kaplan-Meier analysis an apex-base HDF threshold of <19.6% was associated with MACE (log-rank p=0.002).

CONCLUSION

Reduced apex-base HDF at initial diagnosis is independently associated with increased risk of long-term cardiac complications in patients with acute pericarditis.

CLINICAL RELEVANCE/APPLICATION

CMR-derived HDF may serve as a non-invasive marker for prognostic risk stratification in pericarditis.

Michael T. Lu, MD, MPH (*Abstract Co-Author*)
Joanne Murabito (*Abstract Co-Author*)
Kathryn Lunetta (*Abstract Co-Author*)
Nicolai Birkbak (*Abstract Co-Author*)
Hugo Aerts, PhD (*Abstract Co-Author*)

PURPOSE

While the thymus is critical for T cell maturation in childhood, its later role in adult health is uncertain. We hypothesized that thymic functionality remains essential across the lifespan and evaluated its relevance to mortality and disease risk.

METHODS AND MATERIALS

We developed a deep learning system to quantify preserved thymic tissue on computed tomography as a proxy for its functionality, referred to as thymic health. This fully automatic system was applied to two large prospective cohorts of asymptomatic adults: the Framingham Heart Study (FHS) and the National Lung Screening Trial (NLST). Participants were categorized as low, average, or high thymic health based on percentiles. We assessed associations of thymic health with all-cause mortality, cancer, and cardiovascular disease. In a subset, we also evaluated plasma protein levels and lifestyle factors.

RESULTS

We included 27,612 individuals (2,581 FHS and 25,031 NLST) with a 12-year follow-up. In FHS, participants with high thymic health had a lower mortality risk than those with low thymic health (hazard ratio [HR], 0.24; 95% confidence interval [CI], 0.16-0.38); similar results were observed in NLST (HR, 0.49; 95% CI, 0.45-0.53). These associations remained significant independent of age, sex, and smoking (FHS, P=0.012; NLST, Type III P<0.001). High thymic health was also associated with reduced risk of lung cancer (HR, 0.64; 95% CI, 0.53-0.76) and cardiovascular disease (HR, 0.26; 95% CI, 0.16-0.40), as well as lower disease-specific mortality from lung cancer (HR, 0.52; 95% CI, 0.44-0.63) and cardiovascular causes (HR, 0.08; 95% CI, 0.02-0.34). Again, these associations remained significant independent of sex, age, and smoking (P < 0.02). Inflammatory protein levels and markers of chronic inflammation, including Interleukin-6 and C-reactive protein, were negatively associated with thymic health. Thymic health was further negatively associated with metabolic dysregulation and unhealthy lifestyle factors such as smoking and physical inactivity.

CONCLUSION

Our findings challenge long-standing assumptions about thymic redundancy in adulthood and open new avenues for targeted preventive and regenerative strategies.

CLINICAL RELEVANCE/APPLICATION

CT-based quantification of thymic health enables non-invasive, automated assessment of immune competence, offering a scalable biomarker for stratifying risk in asymptomatic populations. This approach may enhance early and opportunistic identification of individuals at elevated risk for death, cancer, and cardiovascular disease, informing personalized prevention and the potential for future regenerative approaches.

R3-SSCH09-2 AI-DRIVEN DETECTION OF THORACIC MEDICAL DEVICES IN PEDIATRIC CHEST RADIOGRAPHS: ENHANCING SAFETY AND EFFICIENCY IN IMAGING INTERPRETATION

Amit T. Kharat, PhD,DMRD (*Presenter*)
Siddhant Pardeshi (*Abstract Co-Author*)
Richa Pant (*Abstract Co-Author*)

PURPOSE

Accurate identification of medical devices in pediatric chest radiographs (CXRs) is essential for timely clinical decision-making. In fast-paced clinical settings, especially in pediatric care, subtle hardware can be overlooked that may lead to diagnostic errors or delayed interventions. While existing AI models have shown promise in adult populations, pediatric radiology remains underserved due to anatomical variation and limited datasets. To address this gap, we validated a deep learning model to automatically detect and localize thoracic medical devices: invasive, non-invasive, and postsurgical materials in pediatric CXRs. The goal was to support radiologists in interpreting images more efficiently and reliably, thereby improving the overall quality and safety of care.

METHODS AND MATERIALS

The study included 9,719 pediatric patients under the age of 18 who underwent chest radiography. The dataset was collected from 353 institutions and spanned over 20 different DX and CR acquisition system manufacturers. Of the total cohort, 5,690 were male and 4,006 were female, with an average age of 7.1 years (0-11 years). A convolutional neural network was trained to detect the following devices and postsurgical material: sternal sutures, central venous lines, endotracheal tubes, and chest

leads. Radiologists' reports served as the reference standard. Model performance was evaluated using sensitivity, specificity, and AUROC. Metrics were calculated at a decision threshold of 0.5. Bootstrapping was used to calculate confidence intervals.

RESULTS

The model achieved an overall sensitivity of 0.92 [0.85 - 0.98], specificity of 0.81 [0.80 to 0.82], and an AUROC of 0.86 [0.84 - 0.89] across all medical device types. Performance was strong across individual device categories: sternal sutures (AUROC 0.99, sensitivity 0.82, specificity 1.00), central venous lines (AUROC 0.98, sensitivity 0.88, specificity 0.96), endotracheal tubes (AUROC 0.98, sensitivity 0.96, specificity 0.92), and chest leads (AUROC 0.95, sensitivity 0.85, specificity 0.93).

CONCLUSION

The AI model demonstrated high sensitivity and specificity in detecting most hardware in pediatric chest radiographs, including sternal sutures, central venous lines, endotracheal tubes, and chest leads. With AUROCs exceeding 0.95 for all, the tool shows strong potential as a reliable assistant in pediatric imaging workflows.

CLINICAL RELEVANCE/APPLICATION

AI offers a scalable and sustainable approach to enhancing the accuracy, efficiency, and safety of pediatric chest imaging, with potential to significantly support radiologists and improve patient outcomes in clinical practice.

R3-SSCH09-3 DEVELOPMENT AND IMPLEMENTATION OF A GENERATIVE CHEST XR MACHINE LEARNING MODEL AT A LARGE-SCALE RADIOLOGY PRACTICE

Robert J. Harris, PhD (*Presenter*)
Shwan Kim, MD (*Abstract Co-Author*)
Michael Rethy, MD (*Abstract Co-Author*)
Michael J. Cooney, MD (*Abstract Co-Author*)
Kenneth H. Segel, MD (*Abstract Co-Author*)
Brian Baker (*Abstract Co-Author*)

PURPOSE

Our radiology practice interprets over 1 million Chest XR studies per year but like many practices experiences radiologist capacity limitations resulting from the national radiologist shortage. We hypothesized that a generative model could be trained that inputs a Chest XR study and outputs a clinical report with accuracy comparable to a radiologist. We further hypothesized that single-pathology outputs from this model could be used for worklist prioritization and quality assurance of prospective data.

METHODS AND MATERIALS

All available Chest XR studies and their corresponding reports were extracted from our database, yielding 1,604,083 studies. The model utilized a Swin encoder and BERT decoder. Pneumothorax sensitivity was used during the validation step to determine the best epoch to save. Following training the model was deployed in a large-scale radiology system to analyze all prospective Chest XR data for a 2-week period. An NLP model with 155 outputs representing 155 findings on Chest XR was run on the generated text report and the ground truth radiologist report for all studies. Studies for which the model-generated and radiologist reports were discrepant for pneumothorax were sent to secondary review. Studies for which the generated report was positive for pneumothorax were prioritized in the reading queue. A report comparison tool was developed that displays study images, the corresponding radiologist report, and the model-generated report to blinded annotating radiologists; these radiologists classified 300 studies using this tool, selecting which report they thought was more accurate.

RESULTS

The optimal training epoch was epoch 64 with a validation pneumothorax sensitivity of 58.7% and specificity of 100.0%. The model ran on 34,680 studies over the 2-week prospective period. During this time, sensitivity and specificity for pneumothorax were 62.4% and 99.3%, respectively. There were 36 studies flagged for secondary review; 25.0% were positive for missed pneumothorax. Radiologists using the report comparison tool selected the model-generated report 22% of the time and the radiologist report 34% of the time, with the remaining 44% rated as equivalent in quality.

CONCLUSION

A generative Chest XR model was trained and implemented to generate text reports in a large-scale production workflow. This model shows utility for worklist prioritization and QA, producing reports of equivalent or better quality than a radiologist for a majority of cases.

CLINICAL RELEVANCE/APPLICATION

Chest XR studies have a degree of interpretation error related to inherent modality and visualization limitations. A generative model that interprets Chest XR imaging could mitigate radiologist workload and help alleviate the national radiologist shortage.

R3-SSCH09-6 DIAGNOSTIC PERFORMANCE OF A LARGE LANGUAGE MODEL IN MULTIMODAL RETRIEVAL-AUGMENTED RADIOLOGY REPORT GENERATION: A COMPARATIVE STUDY WITH AN EXPERIENCED HUMAN READER

Yeon Joo Jeong, MD, PhD (*Presenter*)
Jong Eun Lee, MD, PhD (*Abstract Co-Author*)
Kyubin Kim, MD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the diagnostic performance of a large language model (LLM) in multimodal retrieval-augmented radiology report generation for chest radiographs, comparing its performance with that of an experienced human reader.

METHODS AND MATERIALS

This retrospective study included 1260 anonymized chest radiographs obtained from five clinical settings: screening, outpatient non-respiratory clinics, outpatient respiratory clinics, inpatient wards, and emergency departments. The evaluation focused on posteroanterior and anteroposterior radiographs, with chest computed tomography (CT) performed on the same day or within one week serving as the standard reference. Diagnostic accuracy and report quality (assessed using a 5-point Likert scale) were compared between LLM-generated reports and those from an experienced human reader, using the McNemar test for diagnostic accuracy and the Wilcoxon Signed-Rank test for report quality. Efficiency was assessed by measuring the time required for LLM interpretation, and hallucinations in the generated reports were analyzed to evaluate the reliability of LLM interpretations.

RESULTS

The human reader achieved an overall diagnostic accuracy of 90.3% (1138/1260), significantly higher than the LLM's accuracy of 62.1% (783/1260) ($P < 0.001$). The average Likert score for report quality was 4.51 for the human reader and 3.34 for the LLM ($P < 0.001$). The LLM demonstrated a hallucination rate of 6.1% (77/1260). The mean reporting time for the LLM was 3.4 seconds (SD 0.9), ranging from 2.0 to 9.6 seconds. Across all clinical settings, the human reader consistently achieved higher diagnostic accuracy than the LLM (all $P < 0.001$). The highest accuracy for both was observed in the screening setting (96.4% [241/250] vs. 79.2% [198/250]), while the largest performance gap occurred in outpatient respiratory clinics (87.3% [227/260] vs. 45% [117/260]). In inpatient wards and emergency departments, the human reader maintained accuracies above 89%, significantly outperforming the LLM (60.8% [152/250] and 62.4% [156/250, respectively).

CONCLUSION

These findings underscore the superior diagnostic accuracy and report quality of the human reader across all clinical settings. However, the LLM demonstrated acceptable diagnostic accuracy in screening examinations, highlighting its potential utility in specific scenarios where efficiency and scalability are prioritized.

CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of large language models as efficient support tools in screening chest radiographs, while emphasizing the essential role of human expertise for accurate interpretation in diverse clinical settings.

R3-SSGI15-1 BIOLOGY-GUIDED MULTIMODAL DEEP LEARNING RADIOMICS FOR PREDICTION OF IMMUNOTHERAPY RESPONSE IN GASTRIC CANCER: A MULTICENTER STUDY

Qingyu Yuan (*Presenter*)

PURPOSE

Immunotherapy is a standard treatment for many tumor types. However, clinical benefit is limited to a minority of patients and reliable predictive biomarkers of immunotherapy response are lacking. Deep learning has advanced cancer detection and diagnosis but has had limited success in predicting immunotherapy response. A significant hurdle for clinical translation of current data-driven AI models is lack of interpretability, often due to a disconnect from the underlying pathobiology. Here, we aim to predict immunotherapy response of gastric cancer patients by developing biology-guided multimodal deep learning radiomics model.

METHODS AND MATERIALS

We present a biology-guided multi-modal deep learning radiomics approach to predict immunotherapy response using both clinical data and computed tomography (CT) images. We present a biology-guided deep learning radiomics approach that enables simultaneous prediction of the tumor immune and stromal microenvironment status as well as immunotherapy response from clinical data and CT images.Besides deep learning features, 584 quantitative features were extracted from intratumoral and peritumoral regions on contrast-enhanced CT scans. We validate the model for predicting immunotherapy response and progression-free survival in the multicenter study. To overcome limitations of small training data, we leverage an additional dataset of 2,200 patients who did not receive immunotherapy in a pretrained framework using self-supervised learning to learn intrinsic imaging phenotypes of the disease. We trained and validated the model in three independent cohorts of 260 patients treated with immunotherapy. We compared the proposed biology-guided multi-modal model with the traditional deep learning and radiomics approaches.

RESULTS

The AI model achieved area under receiver operating characteristics curve (AUC) of 0.80 to 0.83 for predicting immunotherapy response in the internal and external validation cohorts. The proposed biology-guided multi-modal model significantly improved the performance of immunotherapy response prediction with AUCs 0.80-0.83 vs. 0.69-0.76 compared with the traditional deep learning and radiomics approaches. The model was significantly associated with progression-free survival ($p<0.001$).

CONCLUSION

The deep learning model achieved promising performance in predicting immunotherapy response from routine clinical and image data. The proposed biology-guided multi-modal deep learning radiomics approach is general and can improve prediction of immunotherapy response.

CLINICAL RELEVANCE/APPLICATION

This model noninvasively and accurately predicts immunotherapy response in gastric cancer, enabling personalized treatment and better clinical outcomes.

R3-SSGI15-3 DUAL-LAYER SPECTRAL DETECTOR CT-BASED SCORING SYSTEM FOR NONINVASIVE TP53 EXPRESSION ASSESSMENT AND ADJUVANT CHEMOTHERAPY RESPONSE PREDICTION IN GASTRIC CANCER: A MULTICENTER STUDY

Yinchen Wu (*Presenter*)
Dairong Cao, MD (*Abstract Co-Author*)
Dejun She (*Abstract Co-Author*)

PURPOSE

Noninvasive early prediction of TP53 is a key strategy for improving the prognosis of gastric cancer (GC) patients. To establish a novel, noninvasive and simple scoring system using dual-layer spectral detector CT (DLCT) for preoperative prediction of TP53 expression, prognosis and response to adjuvant chemotherapy (ACT) with retrospective and prospective validation.

METHODS AND MATERIALS

Between April 2021 and March 2025, 568 GC patients were retrospectively and prospectively recruited from two hospitals into a training cohort (TC), a validation cohort (VC), an internal test cohort (ITC), and an external test cohort (ETC). A nomogram prediction model was constructed based on clinical characteristics and DLCT quantitative parameters, which was further simplified to a scoring system. The performance of the system was assessed by discrimination, calibration and clinical applicability. The patients' recurrence-free survival (RFS) and benefit of ACT were evaluated by survival analysis.

RESULTS

The nomogram outperformed clinical, conventional CT and DLCT models for TP53 prediction. The scoring system exhibited comparable predictive efficacy to the nomogram. The areas under the curve (AUCs) of the scoring system were 0.864 (0.815-0.914) for TC, 0.887 (0.802-0.972) for VC, 0.893 (0.844-0.942) for ITC, and 0.912 (0.838-0.985) for ETC, respectively. There were differences in RFS between patients with different TP53 types predicted by the scoring system (P =0.006, 0.018, 0.015), in consistent with the results from truth labels. RFS differed between the patients who received the system-recommended ACT regimen and those who did not (P =0.006, 0.027, 0.032). Furthermore, the scoring system was superior to other currently used testing techniques by using cost-effectiveness analysis (incremental cost-effectiveness ratio and incremental cost-utility ratio were 0).

CONCLUSION

The simple DLCT-based scoring system enables noninvasively, cost-effectively and rapidly predict TP53 expression, prognosis, and benefit from ACT in GC patient, which is expected to guide individualized treatment.

CLINICAL RELEVANCE/APPLICATION

1. To the best of our knowledge, this is the first simple scoring system based on DLCT for predicting TP53 expression. It allowed direct estimation of TP53 mutation probability by rapid and simple measurement of the scanning images without additional complex processing. 2. Physicians should focus on patients with scores greater than 21.5, recommend them for ACT, and concentrate on following up this group of patients to make timely adjustments to their treatment regimens.

PURPOSE

To develop and evaluate AI in detecting early-stage pancreatic ductal adenocarcinoma (PDAC) and compare the performance with board-certified radiologists.

METHODS AND MATERIALS

We develop an automated system, ePAI (early Pancreatic cancer detection with Artificial Intelligence), that can detect early-stage PDAC in contrast-enhanced CT scans. ePAI consists of three stages. Stage 1: An nnU-Net model was trained for anatomical segmentation of the pancreas (head, body, tail), surrounding vessels (arteries and veins), and visible dilated ducts. Stage 2: The same nnU-Net model was fine-tuned to detect pancreatic lesions. It was trained on both real and synthetic lesions (improved sensitivity) and on a large cohort of normal scans to reduce false positives (improved specificity). Stage 3: Detected lesions were classified into three categories—PDAC, non-PDAC, and Normal—using an auxiliary transformer-based module considering image features such as lesion texture, location, and pancreas morphology. ePAI was trained on data from 1,598 patients (each has both portal venous and arterial phase CT scans) at a single center. ePAI is interpretable, as it can directly output segmentation masks of the detected PDAC, pancreas, and other anatomical structures. Our study first evaluated ePAI internally on 1,012 patients and then validated ePAI on a large external multicenter test cohort (n = 140 centers) involving 43,038 patients. Moreover, we compared ePAI's performance in detecting early-stage PDAC to that of 40 radiologists using the same CT scans, including scans with small PDAC (<2 cm) and prediagnostic scans in which radiologists had previously overlooked the PDAC.

RESULTS

ePAI achieved an area under the receiver operating characteristic curve (AUC) of 0.975 (95% CI: 0.941 - 1.000; n =345) for detecting early-stage PDAC (<2 cm) in the internal validation, detected PDAC as small as 2 mm, and 0.941 (95% CI: 0.922 - 0.958; n = 3,421) in the external validation, detected PDAC as small as 5 mm, and outperformed 40 radiologists by ### (P = ###) in sensitivity and ### (P = ###) in specificity. Importantly, ePAI successfully detected early-stage PDAC in 7 of 19 patients that had been overlooked by radiologists, with a median lead time of 244 days before clinical diagnosis.

CONCLUSION

AI can accurately detect small PDAC (<2 cm) at a substantial lead time before clinical diagnosis (prediagnostic), suggesting its potential as an assistive tool for radiologists to improve early detection of pancreatic cancer.

CLINICAL RELEVANCE/APPLICATION

The development of ePAI will result in safe and effective detection of early-stage cancer missed by standard of care diagnostic techniques, and in some cases, will enable timely treatment with intent to cure.

Masoom A. Haider, MD (*Abstract Co-Author*)

PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) has a 5-year survival rate of <10%, which is dramatically improved when detected in early stages. However, early detection remains a challenge due to the subtle changes in CT associated to it than can be easily missed. AI models might be a reporting adjunct for radiologists by highlighting potential cancer regions during routine portal phase CT that might otherwise be missed

METHODS AND MATERIALS

A nnU-Net v2 based AI model was trained on a labelled dataset of 683 patients (501PANORMA open source, 182 internal) with PDAC. The trained model was tested in a retrospective cohort of patients with pathology proven PDAC that had had a contrast enhanced CT scan of the abdomen for any indication prior to the index CT at our institution. Prior imaging of this cohort was reviewed to determine whether the PDAC was already present prior to diagnosis. Performance of the trained model, clinical characteristics of the patients, size of the lesion at diagnosis and delay in diagnosis if a lesion was missed were tabulated for analysis. Radiologist, AI and combined retrospective miss rates (RMR) were calculated. For false positive rate 488 normal control cases from the KiTS23 open-source data set for small renal masses were used.

RESULTS

A retrospective cohort of 141 patients with prior imaging before PDAC diagnosis was identified. At the time of final diagnosis, 60% (85/141) had a lesion >=2cm. An average delay of 512 days to diagnosis was observed in patients that had a retrospective lesion on prior imaging. Radiologist, AI and joint RMR was 40% (57/141), 32% (45/141) and 25% (35/141) for the overall cohort respectively (p=0.04); 36% (20/56), 46% (26/56) and 30% (17/56) for lesions <=2cm respectively (p=0.1); and 44% (37/85), 22% (19/85) and 21% (18/85) for lesions >2cm respectively (p<0.001). Of the latter group (lesions >2cm), 27 (32%) where missed when <=2cm with 12/27 (44%) that would have been spotted by the AI model. The false positive rate on normal controls was manageable at 8% (38/488).

CONCLUSION

A nnU-NET trained AI model can significantly reduce the retrospective miss rate of radiologists on single phase contrast enhanced CT in the context of PDAC with a joint approach (AI+radiologist) being the most beneficial. The largest impact was observed in lesions >2cm at diagnosis where almost half of the radiologist misses that progressed in stage could have been detected early had our AI model been used at the moment of prior imaging.

CLINICAL RELEVANCE/APPLICATION

AI assisted radiology reporting shows promise in reducing the number of missed PDAC on routine imaging when used as a radiologist aid with a manageable false positive rate. Issues of effect on interpretation bias and tolerance to false positives still need to be assessed.

R3-SSGI16-4 DEEP LEARNING DETECTION OF MULTIPLE IMAGING FEATURES ASSOCIATED WITH PANCREATIC CANCER ON NON-CONTRAST AND CONTRAST-ENHANCED CT SCANS

Takeru Yamaguchi, MD, PhD (*Presenter*)
Keitaro Sofue, MD (*Abstract Co-Author*)
Atsuhiro Masuda (*Abstract Co-Author*)
Nobuyuki Hirahara (*Abstract Co-Author*)
Aya Ogasawara (*Abstract Co-Author*)
Eisuke Ueshima (*Abstract Co-Author*)
Akihiro Umeno (*Abstract Co-Author*)
Naoya Ebisu (*Abstract Co-Author*)
Mizuki Takei (*Abstract Co-Author*)
Yuzo Kodama (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

PURPOSE

Previous studies have reported that indirect imaging features, such as main pancreatic duct (MPD) abnormalities and parenchymal atrophy, can assist in the detection of pancreatic cancer (PC). This study aimed to develop deep learning (DL) models capable of identifying these PC-associated features on both non-contrast CT (NCCT) and contrast-enhanced CT (CECT) scans, and to compare their diagnostic performance with that of physicians.

METHODS AND MATERIALS

Two DL models were trained to recognize four PC-associated imaging features (mass, parenchymal atrophy, MPD dilatation, and MPD stenosis) on NCCT and CECT, and to diagnose PC based on these features. A dataset of 3,916 abdominal CT scans collected from multiple institutions was manually labeled and annotated for training and validation. Model performance was assessed using two external datasets: a CECT dataset (90 PCs and 100 controls) and an NCCT dataset (87 PCs and 100 controls). The diagnostic performance of the DL models in identifying PC-associated imaging features and diagnosing PC was compared to that of six physicians.

RESULTS

The DL models achieved area under the receiver operating characteristic curves (AUROC) values of 0.938, 0.901, 0.937, and 0.943 on CECT, and 0.877, 0.883, 0.954, and 0.926 on NCCT for mass, parenchymal atrophy, MPD dilatation, and MPD stenosis, respectively. For PC diagnosis, the models' AUROCs were comparable to and significantly higher than the physicians' mean (0.987 vs. 0.987, p=0.84 on CECT; 0.933 vs. 0.913, p=0.026 on NCCT). The DL models also demonstrated significantly higher sensitivity for the detection of small PCs (= 20mm) on CECT (97.7% vs. 82.6%; p<0.001) and NCCT (86.0% vs. 41.1%; p<0.001).

CONCLUSION

The proposed DL models could identify PC-related imaging features and diagnose PC more accurately than physicians on NCCT and CECT scans.

CLINICAL RELEVANCE/APPLICATION

The proposed DL models could alert readers to subtle lesions and imaging features associated with PC and help detect PC on NCCT and CECT scans. In particular, they may aid in identifying small and early-stage PCs, which are more amenable to curative surgical resection and could ultimately lead to improved patient outcomes.

R3-SSGI16-5 DEVELOPMENT OF A MULTIMODAL DATA-BASED MODEL FOR PRECISE PROGNOSTIC STRATIFICATION IN RESECTED PANCREATIC CANCER

Wei Liu, MD (*Presenter*)
Zheng-rong Zhou (*Abstract Co-Author*)
Yi Chen, BMedSc, MMedSc (*Abstract Co-Author*)

PURPOSE

Accurate prognosis in pancreatic cancer (PC) is crucial for treatment decisions. This study developed a deep learning model integrating clinical, radiological, and pathological data to improve risk stratification for resected PC patients.

METHODS AND MATERIALS

Retrospectively enrolled PC patients who underwent radical surgery with histopathological confirmation at our institution between February 1, 2012, and December 30, 2020, were divided into training and internal validation cohorts. An external validation cohort was derived from a public database. Patients were stratified by 3-year overall survival (OS). A radiomics model was built from preoperative CT tumor features, while a Swin-Trans model captured spatial tumor features; these were combined into a hybrid DRadiomics model. Pathomic features from H&E-stained WSIs formed a pathomics model, and clinical variables were used for a clinical model. Multimodal and multiomics models integrated clinical, radiological, and pathological data. Prognostic scores were generated for internal and external validation cohorts. Model performance was compared using receiver operating characteristic (ROC) curves with area under the curve (AUC). The predictive efficacy was evaluated by time-dependent ROC analysis. Patients were stratified into high/low-risk groups by optimal cutoff value, with survival analyzed via Kaplan-Meier/log-rank tests. Immunohistochemical (IHC) markers were compared between risk groups in the internal validation cohort. $p < 0.05$ was considered significant.

RESULTS

n this study, 202 patients from our institute (140 training, 62 internal validation) and 48 from a public database (external validation) were analyzed. The multimodal (AUC: 0.95 training, 0.85 internal validation) and multiomics models (AUC: 0.94 training, 0.85 internal validation) outperformed others, with the multiomics model leading in external validation (AUC=0.76 vs. 0.56-0.69 for other models). Patients were stratified into low- and high-risk groups by the multimodal model's cutoff value. The OS and disease-free survival (DFS) were significantly differentiated between the low and high risk groups ($p < 0.05$). High-risk patients exhibited elevated Ki-67 expression ($p < 0.05$).

CONCLUSION

The model integrating clinical, radiological, and pathological data achieves a superior prognostic prediction performance in resected PC compared to AJCC staging. The multiomics model retains robust predictive capability even with missing clinical variables, offering a potential tool for prognostic stratification of resected PC.

CLINICAL RELEVANCE/APPLICATION

The framework can provide more precise and individualized prognostic assessments for patients who have undergone surgical resection.

R3-SSGI16-6 THE IMPACT OF RADIOLOGIST EXPERIENCE ON PANCREATIC CANCER DETECTION IN ROUTINE CONTRAST-ENHANCED CT

Tijmen De Haas, MSc (*Presenter*)
Megan Schuurmans (*Abstract Co-Author*)
Natalia Alves, MSc (*Abstract Co-Author*)
Henkjan Huisman, PhD (*Abstract Co-Author*)
John J. Hermans, MD, PhD (*Abstract Co-Author*)

PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) is highly lethal and early and accurate detection via CT imaging is crucial but challenging. Radiologist performance in detecting pancreatic cancer is believed to rely on clinical experience, though current literature provides only limited evidence. This study aimed to quantify the relationship between various experience metrics and detection performance in PDAC on routine contrast-enhanced CT (CECT). We hypothesized that greater experience would be associated with improved detection performance.

METHODS AND MATERIALS

The PANORAMA study is the largest multi-institutional reader study on PDAC detection using routine CECT. It included 391 cases (144 PDAC, 247 controls) and 68 radiologists from 12 countries and 40 institutions. PDAC cases were histologically confirmed, and negative cases were confirmed by =3 years of clinical follow-up or histopathology. Each reader interpreted ~97 cases using a 0-100 likelihood scale. Detection performance of readers was assessed using the area under the receiver operating curve (AUC). Experience was assessed using six self-reported metrics: (1) years of reading abdominal CTs, (2) total of abdominal CTs read, (3) abdominal CTs read per year, (4) total of pancreatic CTs read, (5) pancreatic CTs read per year, and (6) residency status (n=11). For each variable, a split was made to create a low and a high experience group. The five continuous variables were split at the median; residency was already binary. Performance differences between the groups were tested using Mann-Whitney U tests with Holm-Bonferroni correction.

RESULTS

Radiologists reported 1-30 years of abdominal CT reading experience (median 9) and 0-1800 pancreatic CTs read per year (median 100). AUCs ranged from 0.75 to 0.96 (median 0.89). Higher detection performance was observed for readers with more total abdominal CTs read (?AUC=0.020, p=0.002), abdominal CTs read per year (?AUC=0.026, p<0.001), total pancreatic CTs read (?AUC=0.020, p=0.002), and pancreatic CTs read per year (?AUC=0.015, p=0.009). No significant differences were found for years of experience (p=0.12) or residency (p=0.48).

CONCLUSION

Reading volume of abdominal and pancreatic CTs was associated with improved PDAC detection, while years of experience and residency status were not.

CLINICAL RELEVANCE/APPLICATION

AI tools could help radiologists in low-volume centers improve PDAC detection.

PURPOSE

To develop MAIRA-X, a multimodal AI model for chest X-ray (CXR) report generation focused on lines and tubes (L&T) reporting to enhance critical patient management, and to conduct the first large-scale L&T-specific quantitative evaluation of AI-generated reports.

METHODS AND MATERIALS

This retrospective study utilized a large-scale, multi-center, longitudinal dataset of 3.1 million CXR studies from a prominent medical institution (23% with L&T; 49% F / 51% M; mean age 62±16 years; 73% with priors). MAIRA-X, built on the MAIRA-2 multimodal large-language model (MLLM) architecture, was trained, validated, and tested on an 80/10/10 split. MAIRA-X incorporates current frontal and lateral CXR images, prior frontal CXR images, prior report, current indication and comparison, to generate current findings. It was tuned for L&T-specific elements, including image encoder fine-tuning, LLM selection, hyperparameter optimization, and prompt modifications. L&T-specific generation performance was assessed using a novel GPT-based structured report metric suite on L&T type (PICC, Chest tube, ETT, NGT, CVC, IABP, Swan-Ganz, Mediastinal Drain, or Tracheostomy), count (0, 1, 2, 3 or more), longitudinal change (new, moved, removed, unchanged, or unclear), and placement (correct, incorrect, unclear, or NA). Clinical quality was measured with RadFact, a published LLM-based metric for comparing text reports. The L&T GPT structuring prompt was evaluated on 115 manually labeled reports. Three radiologists performed a qualitative analysis of 100 AI-generated reports.

RESULTS

MAIRA-X demonstrated significant improvements over MAIRA-2, with L&T F 1 -scores [95% CIs] increasing from 62.6% [61.6, 63.5] to 83.6% [82.9, 84.3] for type, 73.4% [72.3, 74.6] to 83.6% [82.7, 84.7] for longitudinal change, and 54.4% [53.1, 55.5] to 72.8% [71.7, 74.0] for placement. RadFact F 1 -score rose from 48.5% [48.2, 48.7] to 63.3% [63.1, 63.6]. Evaluation of L&T GPT structuring prompt achieved F 1 -scores as 94% for L&T type and 91% for tip locations. In qualitative analysis, AI-generated reports were found congruent with radiologists' written reports.

CONCLUSION

Training MAIRA-X models on large-scale longitudinal datasets has significantly improved AI generated reports over MAIRA-2, enhancing L&T and clinical reporting quality. Future work includes retrospective user evaluation of MAIRA-X, and deployment in a clinical setting for prospective evaluation.

CLINICAL RELEVANCE/APPLICATION

Frequent and accurate L&T reporting is crucial for critical patient management. MAIRA-X can improve longitudinal CXR report generation, serving as a radiologist's AI assistant to enhance clinical efficiency, decision-making, and patient outcomes, specifically in high-volume settings.

R3-SSIN07-2 EFFICIENCY IMPACTS OF GENERATIVE AI-ASSISTED COMPUTED TOMOGRAPHY REPORTING

Jonathan Huang, PhD (*Presenter*)
Matthew Wittbrodt (*Abstract Co-Author*)
Caitlin Teague (*Abstract Co-Author*)
Eric Karl (*Abstract Co-Author*)
Galal Galal (*Abstract Co-Author*)
Konrad Rauscher (*Abstract Co-Author*)
Andrii Sadovyi (*Abstract Co-Author*)
Samir Abboud, MD (*Abstract Co-Author*)
Mozziyar Etemadi, MD,PhD (*Abstract Co-Author*)

PURPOSE

Use of generative artificial intelligence (AI) to assist documentation of computed tomography (CT) reports has the potential to provide more timely results to patients while reducing provider workload and burnout. However, application in live clinical settings is to date unstudied. This study evaluated the impact on reporting time of a

generative model capable of providing draft radiological reports for CT studies that was integrated into the radiologist clinical workflow across a tertiary care health system.

METHODS AND MATERIALS

Model-generated reports were automatically populated within reporting software (PowerScribe, Nuance Communications) as a selectable template; thus, radiologists could elect to document by verifying and editing these model-generated reports within their normal workflow. Model-assisted CT reads of all anatomy were identified from January 5, 2025 through April 15, 2025. Reads without model assistance, matched by radiologist, were randomly sampled from January 3, 2024 through January 4, 2025. Reads with trainee involvement were excluded. Reporting time, defined as time from study opening to report signing, was determined using the PowerScribe database and compared for studies read with and without the model using a linear mixed-effects model with fixed effects of model usage and procedure type (brain, chest, abdomen/pelvis, and other) and random effect of radiologist. Data are presented as estimated marginal means with standard errors. The a level was set to P = 0.05 for significance.

RESULTS

In total, 52,230 CT studies were included, comprising 21,591 (41.3%) brain, 18,521 (35.5%) abdomen/pelvis, 11,208 (21.5%) chest, and 910 (1.7%) other studies. There was a significant association of model assistance with decreased reporting time (F = 7.4; P = 0.01). Interpretations with model assistance (17.9 ± 2.1 minutes; n = 9,074) were faster than a baseline set of those without (23.6 ± 2.3 minutes; n = 43,156; P = 0.007), representing a 24.2% reporting efficiency increase with a per-report time savings of 5.7 minutes. The procedure type by model assistance interaction was not significant (F = 0.7; P = 0.55), indicating that no evidence was found for a modifying effect by procedure type on model impact. There was no difference in addendum rate for studies read with (114, 1.3%) and without (571, 1.3%) model assistance (? 2 = 0.26; P = 0.61).

CONCLUSION

Use of the model was associated with improved reporting efficiency with no change in addendum rate. This study demonstrates potential for improved care delivery with radiologist-generative AI collaboration in CT reporting.

CLINICAL RELEVANCE/APPLICATION

Improved CT reporting efficiency via adoption of generative AI may streamline clinical care, benefiting patients and clinicians.

R3-SSIN07-3 EXTERNAL VALIDATION OF A CT ABDOMEN-PELVIS FOUNDATION MODEL FOR DETECTION OF 348 FINDINGS

Pranav Rajpurkar, PhD (*Presenter*)
Deepanshu Jindal (*Abstract Co-Author*)
Julian Acosta (*Abstract Co-Author*)
Michael Moritz (*Abstract Co-Author*)
Sraavya Sambara (*Abstract Co-Author*)
Siddhant Dogra, MD (*Abstract Co-Author*)
Jenanan Vairavamurthy (*Abstract Co-Author*)
Samir Rajpurkar (*Abstract Co-Author*)

PURPOSE

CT abdomen-pelvis (CTAP) scan interpretation is complex due to anatomic and pathologic diversity, often resulting in diagnostic variability and errors. Recent advancements in CTAP foundation models have shown promise but typically focus on relatively few findings, limiting their clinical applicability. We developed and validated a comprehensive CTAP radiology foundation model (a2z-3) capable of automated detection across 348 clinically significant findings.

METHODS AND MATERIALS

348 target pathologies spanning 36 CTAP anatomic groups were identified by an abdominal fellowship-trained radiologist. Over 280,000 paired CTAP exams and radiology reports from 2 distinct health systems were used for model training. Pathology labels from each report were extracted using a validated large language model based annotation pipeline. These labels served as reference standards to train a transformer-based deep learning model to recognize each pathology on paired CT images. An internal validation set (6,116 paired CTAP exams and reports) from the same data source as the training set was used to select the best-performing model. No data overlapped between training and internal validation. External validation assessed generalizability using 19,263 paired CTAPs and radiology reports from 2 geographically distinct health systems not involved in training or internal validation. Performance was quantified using receiver operating characteristic (ROC) curves and area under the curve (AUC) calculated individually per pathology.

RESULTS

Across 348 pathologies, mean AUC was 0.9097 (standard deviation 0.06) on external validation. Notably, 100 findings (28.7%) demonstrated excellent discrimination (AUC >0.95), while 221 findings (63.5%) exceeded AUC of 0.90. Highest individual performance was observed for splenic injury (AUC 0.9995); the lowest were benign bone lesions, sacroiliac degenerative changes, and bone islands (AUC range 0.6346-0.6830). Anatomic group analysis demonstrated strongest collective performance for ureteral findings (mean AUC 0.9685), whereas stomach findings exhibited the weakest performance (mean AUC 0.8439).

CONCLUSION

The a2z-3 CTAP foundation model demonstrated strong diagnostic performance across 348 findings, with 63.5% of findings having AUC over 0.90 and 28.7% of findings having AUC over 0.95. Its capability to accurately detect a wide range of critical and incidental findings supports potential integration into clinical practice.

CLINICAL RELEVANCE/APPLICATION

The a2z-3 CT foundation model provides comprehensive automated detection across diverse abdominal-pelvic pathologies, significantly reducing potential for diagnostic variability, perceptual errors, and overlooked incidental findings.

R3-SSIN07-4 PROMPT-BASED FEW-SHOT IN-CONTEXT LEARNING FOR RADIOLOGY REPORT GENERATION: ENHANCING REPORT GENERATION WITHOUT FINE-TUNING

Krishna Nand Keshava Murthy, PhD, MSc (*Presenter*)
Chirag Mahajan (*Abstract Co-Author*)
Nathaniel Swinburne, MD (*Abstract Co-Author*)
Sarah Eskreis-Winkler, MD, PhD (*Abstract Co-Author*)
Joseph N. Stember, MD, PhD (*Abstract Co-Author*)
Etay Ziv, MD,PhD (*Abstract Co-Author*)
Chinmay Hegde (*Abstract Co-Author*)

PURPOSE

To demonstrate that few-shot in-context learning (ICL), without any model fine-tuning can unlock significant gains in generating the reports, rivaling what is typically achieved only through dedicated domain adaptation.

METHODS AND MATERIALS

The IU-X-Ray dataset contains 7,470 chest X-ray image-report pairs; studies with empty FINDINGS were dropped and remaining data was stratified 60/40 by pathology into training and test sets. For each k ? {0, 2, 4, 6, 8}, k-shot examples were sampled and prepended to prompts for four models - GPT-4.1, Gemini 2.5 Flash, Claude 3.7 Sonnet, and a medical model - Med Flamingo. Outputs were evaluated against reference FINDINGS using BLEU-4, METEOR, ROUGE-L, BERTScore and RaTEScore.

RESULTS

As k increased from 0 to 6, both BLEU-4 and ROUGE-L scores approximately doubled, before plateauing or even dipping slightly at k = 8. Meanwhile, METEOR and BERTScore climbed steadily through k = 8, reflecting progressively richer semantic and contextual alignment. The RaTEScore reached its peak between k = 6 and k = 8, underscoring substantial gains in clinical-domain accuracy achieved solely via prompting. Notably, by k = 6, Gemini 2.5 Flash (0.6309) and GPT-4.1 (0.6275) attained RaTEScores equivalent to those of Med Flamingo's domain-tuned performance, demonstrating that simple few-shot in-context learning with general-purpose models can match specialized accuracy without any fine-tuning.

CONCLUSION

Few-shot ICL alone yields substantial gains across lexical, semantic and clinically focused metrics, matching or exceeding performance typically reserved for fine-tuned systems. Prompt-engineering, therefore, is a first-class adaptation strategy for deploying LLMs on specialized medical reporting tasks without additional training.

CLINICAL RELEVANCE/APPLICATION

Few-shot prompting with a handful of examples yields significant gains in report accuracy and coherence, enabling rapid, low-cost LLM integration into radiology workflows without custom retraining.

R3-SSIN07-5 EXPLORING VISION-LANGUAGE AI-ASSISTED DOUBLE READING FOR ERROR DETECTION IN CHEST RADIOGRAPH REPORTS USING SYNTHETIC ERRORS

Honggeun Cho, MD (*Presenter*)
Jonggwon Park, Phd (*Abstract Co-Author*)
Kyoyun Choi, PhD (*Abstract Co-Author*)
Bumcheol Hwang (*Abstract Co-Author*)
Byungmu Yoon (*Abstract Co-Author*)
Eui Jin Hwang, MD, PhD (*Abstract Co-Author*)
Jiyoung Song, MD (*Abstract Co-Author*)

PURPOSE

To explore the feasibility of using a vision-language model (VLM) as an AI-assisted double reading system to detect discrepancies between chest radiographs and corresponding radiology reports.

METHODS AND MATERIALS

We developed an AI system utilizing a VLM that computes the similarity between chest radiographs and radiology report sentences. The system analyzes input chest X-rays and associated reports through three methods: (1) identifying semantically inconsistent sentences using image-text similarity scoring; (2) flagging false-positive (FP) findings when the image is classified as normal but the report mentions abnormality; and (3) identifying false-negative (FN) cases where findings detected by the model are not described in the report. To assess performance, we conducted experiments on 500 randomly selected cases from the publicly available MIMIC-CXR test split. Synthetic errors were introduced in three ways: (a) reversing horizontal directional terms in reports by swapping "left" and "right" (side-swap); (b) injecting two randomly selected abnormal findings into normal reports (FP-injection); and (c) randomly removing one or two sentences describing abnormal findings from reports containing at least one abnormality (FN-injection).

RESULTS

The AI system detected discrepancies in 52.0% of original reports, where side-swap increased the error detection rate to 65.0%. For FP-injection and FN-injection, the error detection rate increased from 49.1% to 89.1% and from 52.4% to 74.8%, respectively. For FP-injection, the inconsistency detection and FP-detection rates increased from 16.4% to 80.0% and from 7.3% to 49.1%, respectively. For FN-injection, FN-detection increased from 33.0% to 63.6%. An aggregate analysis of 10 targeted abnormalities showed that the system identified 69.1% of the inserted FPs and detected 28.5% of the removed FNs.

CONCLUSION

The vision-language model-based system showed potential as an AI-assisted double reading tool by identifying report-image discrepancies introduced through synthetic errors, particularly false-positive and directional changes. Detection of omitted findings was moderate, indicating areas for improvement. Further development and validation on real-world errors are needed to support safe and effective integration of AI into radiology double reading workflows.

CLINICAL RELEVANCE/APPLICATION

AI-assisted double reading with VLMs may enhance report accuracy and safety while offering scalable support for radiologists in routine chest imaging workflows.

R3-SSMK11-1 OPPORTUNISTIC BODY COMPOSITION ASSESSMENT: CORRELATION BETWEEN VOLUMETRIC AND L3-BASED CT MEASUREMENTS

Jennifer Gotta, MD (*Presenter*)
Vitali Koch, MD (*Abstract Co-Author*)
Scherwin Mahmoudi, MD (*Abstract Co-Author*)
Christian Booz, MD (*Abstract Co-Author*)
Simon S. Martin, MD (*Abstract Co-Author*)
Jan-Erik Scholtz, MD (*Abstract Co-Author*)
Ibrahim Yel, MD (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)
Leon D. Gruenewald, MD (*Abstract Co-Author*)

PURPOSE

Standardized single-slice measurements at the third lumbar vertebra (L3) are widely accepted for body composition assessment. However, comprehensive volumetric analyses may better capture the distribution and quality of muscle and adipose tissues. This study evaluates the correlation between volumetric body composition measurements and traditional L3-based metrics across multiple tissue compartments.

METHODS AND MATERIALS

In this retrospective cohort study, 25,251 patients were included, among them 9,005 females (35.7%) and 16,246 males (64.3%). For each subject, volumetric measurements of skeletal muscle, myosteatosis, visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), and intramuscular fat were extracted. Standard single-slice measurements at L3, including skeletal muscle area (SMA_L3), muscle radiodensity (SMRA_L3), VAT and SAT areas, and VAT/SAT ratios, were also collected. Pearson correlation coefficients (r) were calculated to determine the association between volumetric and L3-based measures. Subgroup analyses by sex were performed. Statistical significance was set at $p < 0.05$.

RESULTS

Volumetric and L3-based measurements demonstrated strong positive correlations across all assessed compartments. Skeletal muscle volume showed a high correlation with skeletal muscle area at L3 (SMA_L3; $r = 0.87$, $p < 0.001$). Similarly, volumetric myosteatosis measurements correlated strongly with muscle radiodensity at L3 (SMRA_L3; $r = 0.84$, $p < 0.001$). Visceral fat volume exhibited a robust correlation with visceral adipose tissue area at L3 (VAT_L3; $r = 0.89$, $p < 0.001$), while subcutaneous fat volume correlated very strongly with subcutaneous adipose tissue area at L3 (SAT_L3; $r = 0.91$, $p < 0.001$). The strength of these correlations remained consistent across male and female patients.

CONCLUSION

Volumetric body composition analysis is strongly correlated with traditional L3 single-slice measurements and may serve as a comprehensive and reliable alternative for assessing muscle mass, muscle quality, and adipose tissue distribution.

CLINICAL RELEVANCE/APPLICATION

Volumetric body composition analysis from routine CT scans provides a comprehensive and reliable alternative to traditional single-slice L3 measurements, enabling opportunistic assessment of muscle mass, muscle quality, and adipose tissue distribution without additional imaging or radiation exposure.

R3-SSMK11-2 HYBRID [18F]FDG PET/MRI FOR IDENTIFICATION OF PAIN GENERATORS IN DIAGNOSTICALLY CHALLENGING CHRONIC MUSCULOSKELETAL PAIN

Edwin H. Oei, MD, PhD (*Presenter*)
Jacob Mostert (*Abstract Co-Author*)
Rianne A. Van der Heijden, MD, PhD (*Abstract Co-Author*)

PURPOSE

Chronic musculoskeletal pain is a common health problem with large impact on patients' quality of life. The majority of patients with chronic pain do not receive proper treatment and hence do not achieve adequate pain relief, partly due to our inability to accurately identify pain generators with conventional anatomical imaging. Hybrid imaging with [18F]FDG PET/MRI can visualize both structural and metabolic abnormalities, and could therefore potentially be more accurate in identifying musculoskeletal pain generators. This study aims to evaluate the value of [18F]FDG PET/MRI in two patient groups often presenting with musculoskeletal pain of unknown origin: chronic low back pain (LBP) or persistent pain after total hip replacement (THR).

METHODS AND MATERIALS

Patients (18-75 years) with chronic LBP or hip pain after THR of unknown origin according to a pain specialist or orthopedic surgeon were recruited. Participants were randomized to either the control arm comprising of standard clinical care or the intervention arm consisting of [18F]FDG PET/MRI. Potential pain generators were identified by increased FDG uptake on PET and/or structural abnormalities on MRI. Findings were discussed with the referring physicians and treatment outcomes were recorded.

RESULTS

75 patients were included, 57 with LBP and 18 with hip pain after THR. After randomization 33 patients successfully underwent PET/MRI. PET/MRI identified potential pain generators in 27 patients (82%) which were treated in 23 patients. Low Back Pain: 14 patients in the PET/MRI group underwent PET/MRI guided treatment (targeted injection or surgery), with positive outcome in 10 (success rate 71%). In the control group, 13 patients underwent treatment based on clinical symptoms or other imaging, with positive outcome in 6 (success rate 46%). The number of patients that reported pain relief was similar in both groups (50% vs 52%), but 45% of control group participants had increased their pain medication or used transcutaneous electrical nerve stimulation, compared to 33% in the PET/MRI group. Pain after Total Hip Replacement: PET/MRI guided treatment in 9 patients was successful with pain relief in 6 (67%). In the control group, 5 participants underwent targeted treatment and 2 patients reported pain relief (40%).

CONCLUSION

[18F]FDG PET/MRI can reveal previously unidentified pain generators in patients with chronic LBP or persistent pain after THR. PET/MRI guided targeted treatment is more successful than treatment based on other imaging modalities or clinical symptoms only.

CLINICAL RELEVANCE/APPLICATION

Our results indicate that [18F]FDG PET/MRI could be useful for detecting pain generators in patients with chronic musculoskeletal pain, but evaluation of patient outcomes is still needed.

R3-SSMK11-3 QUANTITATIVE MRI ASSESSMENT OF SKELETAL MUSCLE CHANGES AFTER TIME-RESTRICTED EATING AND SUPERVISED EXERCISE IN ADULTS WITH OBESITY: PRELIMINARY RESULTS FROM THE TEMPUS RANDOMIZED CONTROLLED TRIAL

Rocio Martin Marquez, MD (*Presenter*)
Alba Camacho-Cardenosa (*Abstract Co-Author*)
Antonio Clavero-Jimeno (*Abstract Co-Author*)
Juan Jose Martin Olmedo (*Abstract Co-Author*)
Balma Boira Nacher (*Abstract Co-Author*)
Adrian Cortes-Martin (*Abstract Co-Author*)
Marcos Molina-Fernandez (*Abstract Co-Author*)
Rafael Cabeza Laguna (*Abstract Co-Author*)
Mara De La Caridad Concepcion Alvarez (*Abstract Co-Author*)
JOSE LUIS MARTIN RODRIGUEZ (*Abstract Co-Author*)
Jonatan Ruiz (*Abstract Co-Author*)

PURPOSE

Magnetic Resonance Imaging (MRI) offers unparalleled precision in evaluating skeletal muscle tissue (SMT) changes, a critical aspect of obesity management strategies. Nutritional weight loss interventions, such us Time-restricted eating (TRE) may lead to reductions in SMT, while combining supervised exercise, particularly resistance training, could counteract this effect. However, MRI-based evaluations in this context remain limited. This study aimed to investigate the effects of a 12-week intervention combining TRE and supervised exercise on changes in mid-thigh SMT area (assessed using 3T MRI) compared to TRE or supervised exercise alone, and a usual care (UC) group in men and women with obesity, and to highlight the clinical utility of MRI in monitoring body composition changes.

METHODS AND MATERIALS

187 adults with obesity (50% women; age: 48.4±8.9 years; BMI: 34.8±3.7 kg/m²) were randomized into four groups: UC (n=48), TRE (n=46), Exercise (n=47), and TRE+Exercise (n=46). All participants received a Mediterranean diet-based education program. TRE and TRE+Exercise groups self-selected an 8-hour eating window, maintained throughout the intervention. Exercise and TRE+Exercise groups completed 24 supervised sessions combining resistance and high-intensity interval aerobic training, plus a weekly walking program. Mid-thigh SMT area was quantified at baseline and after the 12-week intervention using a 3T MRI scanner (Siemens 3T Magnetom Vida).

RESULTS

MRI revealed significant increases in mid-thigh SMT area in the Exercise group (mean difference [MD]: 6 cm²; 95% confidence interval [CI]: 3-9; P <0.001) and the TRE+Exercise group (MD: 3 cm²; 95% CI: 0-6; P =0.04) compared with the UC group. Similarly, Exercise (MD: 8 cm²; 95% CI: 5-11; P <0.001) and TRE+Exercise (MD: 5 cm²; 95% CI: 2-8; P <0.001) groups showed greater SMT increases compared to the TRE-only group. No statistically significant differences were observed between the Exercise and TRE+Exercise groups (P =0.12).

CONCLUSION

Combined TRE and supervised exercise intervention improved mid-thigh SMT area in adults with obesity. These findings suggest that incorporating supervised exercise into TRE protocols can mitigate potential adverse effects on SMT, supporting this combined approach as a effective strategy for obesity management.

CLINICAL RELEVANCE/APPLICATION

MRI serves as a powerful tool to accurately monitor skeletal muscle adaptations during lifestyle interventions for obesity. Its application enables clinicians to personalize treatment strategies and track therapeutic outcomes more precisely, reinforcing the role of imaging not only in diagnostics but also in optimizing patient management.

R3-SSMK11-4 HIGH DIAGNOSTIC ACCURACY OF CONTRAST-ENHANCED FIVE-PHASE ABDOMINAL CT FOR OPPORTUNISTIC BONE MINERAL DENSITY ASSESSMENT USING UNENHANCED CT AS REFERENCE STANDARD

Mengqiang Xiao, MMEd (*Presenter*)
Rulin Xu (*Abstract Co-Author*)
Jun Chen (*Abstract Co-Author*)

PURPOSE

To evaluate whether volumetric bone mineral density (vBMD) measurements obtained during contrast-enhanced CT phases yield diagnostic accuracy for osteoporosis comparable to unenhanced CT, using unenhanced vBMD as the reference standard.

METHODS AND MATERIALS

In this IRB-approved, retrospective study, we screened 479 consecutive patients who underwent five-phase abdominal CT (unenhanced; arterial, 30 ± 2 s; portal venous, 63 ± 2 s; late venous, 4 min; excretory, 30 min) from February 2022 to August 2024. After excluding cases with hip fractures, adjacent implants or pathology (n = 38), metastatic or hematologic bone disease (n = 12), 429 patients (227 women; 202 men; mean age 60.5 ± 12.3 years) remained. Volumetric BMD and T-values for the femoral head, neck, and proximal shaft (1 cm below trochanters) were measured twice on each phase by an AI-based QCT workstation (iCare QCT), with the mean values used for analysis. Osteoporosis was defined as T = -2.5 on unenhanced CT. Statistical analyses included ANOVA (LSD or Dunnett's T3 post-hoc) for inter-phase comparisons, subgroup analyses by age, sex, malignancy history, and ROC curve analysis for each phase.

RESULTS

Based on unenhanced CT, 378 patients had osteoporosis and 51 were non-osteoporotic (2 normal, 49 osteopenia). Diagnostic accuracy for osteoporosis detection was 98.14% in both the arterial and portal venous phases (misclassifications: arterial, 5 non-osteoporotic as osteoporotic; 3 osteoporotic as osteopenic; portal venous, 3 and 5 respectively), 99.30% in the late venous phase (2/51 non-osteoporotic; 1/378 osteoporotic misclassified), and 99.53% in the excretory phase (2/51 non-osteoporotic misclassified; no osteoporosis misclassification). Mean vBMD and T-values did not differ significantly across phases (vBMD: 231.5-235.9 mg/cm³, P = 0.49; T-values:

-3.54 to -3.65, P = 0.68). Subgroup analyses confirmed stable vBMD and T-values across all clinical strata (P = 0.45-0.95). ROC AUCs were 0.999 (95% CI, 0.991-1.000) for the overall cohort and 0.999 (95% CI, 0.982-1.000) across subgroups for every phase.

CONCLUSION

Contrast-enhanced phases of five-phase abdominal CT demonstrate near-perfect agreement with unenhanced CT for opportunistic femoral bone density assessment. Any post-contrast phase can reliably opportunistically screen for osteoporosis without compromising diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

Contrast-enhanced CT phases from routine abdominal scans can be reliably used for opportunistic osteoporosis screening, enabling bone mineral density assessment without the need for additional unenhanced imaging or radiation exposure.

R3-SSMK11-5 DIAGNOSTIC ACCURACY OF PHOTON-COUNTING CT VIRTUAL NON-CALCIUM IMAGING IN OSTEOPOROSIS: A HEAD-TO-HEAD COMPARISON WITH QUANTITATIVE CT

Yaojun Jiang (*Presenter*)
Yan Wu, MD,PhD (*Abstract Co-Author*)
Jianbo Gao, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate the diagnostic accuracy of photon-counting CT (PCCT) virtual non-calcium (VNCa) technology for osteoporosis using quantitative CT (QCT) as the reference standard.

METHODS AND MATERIALS

In this cross-sectional study, 445 patients undergoing L1-L3 lumbar PCCT scans were retrospectively enrolled. Among them, 30 cases served as an internal test set to establish a decalcification density ratio calibration model, and 415 independent cases were included in an external validation set to assess the correlation between decalcification density and BMD. All participants underwent concurrent PCCT quantitative parameter acquisition and QCT BMD measurement (QCT Pro software; Mindways, USA). By inversely reconfiguring dual-energy analysis software parameters, the VNCa output variable was remapped from iodine value to calcium density for decalcification measurement. Pearson correlation and multivariate linear regression were employed to analyze the association between decalcification density and BMD. The diagnostic threshold of decalcification density was determined by ROC curve analysis based on QCT criteria (BMD <80 mg/cm³).

RESULTS

The calibration model identified a calcium ratio of 1.57. Multivariate regression revealed a significant equation (F=749.2, p<0.0001): BMD=24.68×decalcification density -0.4297×age -0.4139×sex -0.4354×BMI +6.556. Decalcification density (ß=24.68, p<0.0001), age (ß=-0.4297, p<0.0001), and BMI (ß=-0.4354, p=0.0341) were independent predictors of BMD, while sex showed no significant effect (p=0.792). The AUC of decalcification density for osteoporosis diagnosis was 0.9917 (95% CI: 0.9856-0.9997, p<0.0001), with an optimal threshold of 4.685 mg/cm³ (sensitivity 97.61%, specificity 96.3%).

CONCLUSION

Dual-energy CT VNCa technology demonstrates high concordance with QCT in quantifying bone mineral content, suggesting its potential as a non-invasive screening tool for osteoporosis.

CLINICAL RELEVANCE/APPLICATION

Photon-counting CT (PCCT) with virtual non-calcium (VNCa) technology provides a rapid, non-invasive alternative to quantitative CT (QCT) for osteoporosis screening, eliminating the need for additional calibration phantoms or specialized software.

R3-SSMK11-6 FEASIBILITY OF USING TWELFTH THORACIC VERTEBRA (T12)-BASED COMPUTED TOMOGRAPHY (CT) PARAMETERS AS SURROGATES FOR THIRD LUMBAR VERTEBRA (L3) IN BODY COMPOSITION ASSESSMENT

Vitali Koch, MD (*Presenter*)
Jennifer Gotta, MD (*Abstract Co-Author*)
Scherwin Mahmoudi, MD (*Abstract Co-Author*)
Christian Booz, MD (*Abstract Co-Author*)
Jan-Erik Scholtz, MD (*Abstract Co-Author*)
Simon S. Martin, MD (*Abstract Co-Author*)
Ibrahim Yel, MD (*Abstract Co-Author*)
Philipp Reschke, MD (*Abstract Co-Author*)
Elena Hohne, MD (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)
Leon D. Gruenewald, MD (*Abstract Co-Author*)

PURPOSE

Computed tomography (CT)-based body composition analysis is conventionally performed at the level of the third lumbar vertebra (L3), due to its strong correlation with whole-body muscle and fat distribution. However, thoracic CTs, which include the twelfth thoracic vertebra (T12) but not L3, are more commonly available in routine clinical care. This study aims to evaluate whether T12-based measurements can reliably approximate L3-derived parameters.

METHODS AND MATERIALS

A retrospective cohort (n = 9.915, median age 62 years) was analyzed, in which skeletal muscle area (SMA), visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), muscle radiodensity (SMRA), and intramuscular fat were extracted at both T12 and L3 levels from CT images. Pearson correlation coefficients (r) and linear regression models were calculated to quantify the association between T12 and L3 parameters. Coefficient of determination (R^2), intercepts, and slopes were used to assess model fit and predictive validity.

RESULTS

Strong correlations were observed between L3 and T12 measurements, particularly for SMA (r > 0.85), VAT (r > 0.80), and SAT (r > 0.75), with corresponding linear models yielding R^2 values above 0.70 in all valid cases. Regression slopes approached unity, and intercepts remained close to zero, suggesting a consistent and predictable linear relationship. The quality of T12-derived estimations varied across different tissue compartments, with muscle parameters outperforming fat-related indices.

CONCLUSION

T12-based body composition parameters demonstrate strong statistical agreement with L3 values and may serve as reliable surrogates when L3-level imaging is unavailable. This finding could broaden the applicability of body composition analysis in thoracic CT datasets, enabling wider clinical and prognostic use.

CLINICAL RELEVANCE/APPLICATION

These results support the clinical utility of T12 as a practical and reliable surrogate for opportunistic body composition analysis in patients undergoing thoracic imaging, including those with cancer, chronic illness, or during acute hospital admissions. By enabling muscle and fat quantification without additional scanning, T12-level assessment facilitates broader integration of nutritional and prognostic markers into routine care.

Kimberly O'Neill (*Abstract Co-Author*)
Els Fieremans, PhD (*Abstract Co-Author*)
Yiqiu Shen, PhD, BSc (*Abstract Co-Author*)

PURPOSE

To develop a deep learning (DL) model for predicting multiple sclerosis (MS) using brain structural MRI (sMRI) and diffusion MRI (dMRI).

METHODS AND MATERIALS

We collected an internal dataset consisting of 7,651 brain MRI studies from 6,564 patients scanned between 2014 and 2020 at a multicenter health system in New York. The dataset includes 7,472 T1-weighted (3,117 3D; 4,355 2D), 2,769 contrast-enhanced T1-weighted (2,025 3D; 744 2D), 7,998 FLAIR (2,604 3D; 5,394 2D), and 4,466 multi-shell diffusion MRI scans with derived quantitative maps including diffusion tensor imaging (DTI), diffusion kurtosis imaging (DKI), and standard model imaging (SMI). The cohort comprised 1,333 MS cases (per 2010/2017 McDonald criteria) and 2,484 non-MS cases with white matter lesions associated with migraine (n=1,332), cerebrovascular disease (n=1,143), non-MS demyelinating disorders (n=83), and other conditions. Data were split at the patient level into training (n=6,432), validation (n=331), and test (n=888; 467 with both 3D FLAIR and dMRI). An external test set of 490 patients (70 MS, 420 non-MS with white matter lesions) from four public datasets was used for validation. A deep learning model was developed to extract visual features from multimodal MRI scans, produce modality-specific saliency maps that predict MS at the voxel level, and fuse them into a single subject-level MS probability. Model performance was evaluated using ROC-AUC and partial AUC (pAUC) with a maximum false positive rate of 5%.

RESULTS

On the internal test set (n=467, 95 MS patients), DL model using 3D FLAIR alone achieved an ROC-AUC of 0.957 (95% CI: 0.936-0.976). Adding T1-weighted and contrast-enhanced T1-weighted images improved ROC-AUC to 0.970 (95% CI: 0.950-0.986, p=0.0342). Further incorporation of dMRI raised the ROC-AUC to 0.975 (95% CI: 0.956-0.990). Clinically relevant pAUC (FPR <5%) was improved from 0.875 to 0.905. On the external validation set (n=490), performance with FLAIR alone remained robust (ROC-AUC 0.891, 95% CI: 0.845-0.933) and improved with adding T1-weighted sequences (ROC-AUC 0.918, 95% CI: 0.876-0.955, p=0.0013).

CONCLUSION

Deep learning models can accurately differentiate MS from other white matter lesions using structural MRI, with strong generalization to external datasets. Incorporating diffusion MRI further improves prediction performance, especially at clinically relevant specificity levels (false-positive rate <5%).

CLINICAL RELEVANCE/APPLICATION

Deep learning models show strong potential to support MS diagnoses and reduce diagnostic uncertainty. Our findings provide preliminary evidence for incorporating diffusion MRI into routine MS imaging protocols.

R3-SSNR13-2 PERFORMANCE COMPARISON OF TWO AI-BASED ICH DETECTION TOOLS ON HEAD CT IN A REAL-WORLD CLINICAL SETTING

Mark Marino, BS (*Presenter*)
Connor Parrish (*Abstract Co-Author*)
Thomas Renfrew (*Abstract Co-Author*)
Kavya Sudanagunta, MD (*Abstract Co-Author*)

PURPOSE

To perform a comparative evaluation of the diagnostic sensitivity of two FDA-cleared artificial intelligence (AI) algorithms—Vendor A (Aidoc, Tel Aviv, Israel) and Vendor B (Viz.ai, San Francisco, USA)—for the detection of intracranial hemorrhage (ICH) on non-contrast head CT in a real-world, single-institution clinical setting.

METHODS AND MATERIALS

A retrospective analysis was conducted over a six-week period (June 7 - July 16, 2023) at a single academic medical center. Consecutive non-contrast head CT cases were collected during this interval, and results from both Vendor A and Vendor B were obtained for comparison. To enforce a one-to-one correspondence between patients and scans, follow-up examinations were excluded. For cases in which only one algorithm identified the presence of ICH, independent adjudication by board-certified radiologists was conducted to establish reference ground truth.

RESULTS

The study cohort included 1,192 individual CT scans of which 147 scans had confirmed ICH, establishing a cohort prevalence of 12.3%. A total of 87 discordant cases were identified between Vendor A and Vendor B. Of these, 43 were confirmed as true positives following radiologist review and analysis. Vendor A was unable to process

10 cases that were successfully analyzed by Vendor B. Vendor A demonstrated a sensitivity of 99.2%, specificity of 96.8%, Positive Predictive Value (PPV) of 79.6%, and Negative Predictive Value (NPV) of 99.9%. Vendor B demonstrated a sensitivity of 68.7%, specificity of 99.6%, PPV of 95.7%, and NPV 96.2%.

CONCLUSION

In a real-world clinical setting, Vendor A demonstrated superior diagnostic sensitivity for detecting intracranial hemorrhage on non-contrast head CT compared to Vendor B, while maintaining high specificity. These findings highlight meaningful differences in the diagnostic performance of FDA-cleared AI algorithms.

CLINICAL RELEVANCE/APPLICATION

As AI tools are increasingly integrated into radiology practice, understanding real-world diagnostic performance is essential for safe and effective implementation. This study provides comparative evidence on two commercial AI solutions for ICH detection, offering data to optimize patient triage and enabling appropriate clinical management.

R3-SSNR13-3 AI-ASSISTED CEREBRAL ANEURYSM DETECTION ENHANCES DIAGNOSTIC PERFORMANCE ON HEAD CT ANGIOGRAPHY: A MULTICENTER RETROSPECTIVE, PIVOTAL, RANDOMIZED READER TESTS

Inpyeong Hwang, MD (*Presenter*)
Tae Jin Yun, MD (*Abstract Co-Author*)
Jin Wook Choi, MD, PhD (*Abstract Co-Author*)
Hoon Na (*Abstract Co-Author*)
Miran Han, MD (*Abstract Co-Author*)
Woo Sang Jung (*Abstract Co-Author*)
Roh-Eul Yoo, MD, PhD (*Abstract Co-Author*)
Ji Ye Lee, MD, PhD (*Abstract Co-Author*)
Sun Won Park, MD, PhD (*Abstract Co-Author*)

PURPOSE

To validate the diagnostic performance of head CT angiography (CTA) interpretation assisted by an AI-based automatic aneurysm detection algorithm for identifying cerebral aneurysms.

METHODS AND MATERIALS

We conducted a multi-center, pivotal, randomized clinical trial for a reader test of an AI-based aneurysm detection algorithm on head CTA source images. The algorithm was trained on 2,094 patients from two institutions and provided aneurysm localization on CTA source images. The external test dataset for the reader test was retrospectively collected from three academic institutions and comprised 872 patients (392 patients with 532 aneurysms, and 480 patients without aneurysm), confirmed by MRA or DSA. The patients were randomly split into two equal sized groups (A and B). Nine reviewers (3 non-radiologist physicians, 3 board-certified radiologists, 3 neuroradiologists) interpreted head CTA for aneurysm presence and location first without AI (group A) and with AI (group B), then crossed over after a four-week washout. Reviewers assessed CTA source images and thick-slab MIP images in three orthogonal planes. Patient-wise sensitivity, specificity and accuracy with/without AI assistance were calculated and compared with generalized estimating equation. Statistical significance was defined as a P-value < 0.05.

RESULTS

Across all readers, the AI-assisted reading demonstrated higher sensitivity than the unassisted reading (75.74% vs. 65.08%, respectively; $P < 0.001$) and slightly higher specificity (94.70% vs. 93.80%; $P = 0.50$). Overall accuracy was greater with AI assistance (86.17% vs. 80.89%; $P < 0.001$). By reader subgroup, sensitivity improved significantly with AI assistance in neuroradiologists (88.01% vs. 84.95%, $P = 0.03$), board-certified radiologists (73.38% vs. 66.75%; $P < 0.001$), and non-radiology physicians (65.82% vs. 43.54% $P < 0.001$). Specificity increased significantly only for non-radiology physicians (90.69% vs. 87.01%; $P = 0.002$). Accuracy gains were significant for board-certified radiologists (86.66% vs. 83.94%; $P = 0.006$) and non-radiology physicians (79.51% vs. 67.47%; $P < 0.001$), but not for neuroradiologists (92.35% vs. 91.25%; $P = 0.14$).

CONCLUSION

AI-assisted head CTA interpretation for cerebral aneurysm detection demonstrated superior diagnostic performance compared to unassisted reading. The greatest improvement in detection accuracy with AI assistance was observed in the non-radiologist physician subgroup.

CLINICAL RELEVANCE/APPLICATION

Implementation of AI-based aneurysm detection on head CTA can meaningfully enhance diagnostic accuracy—especially for less experienced readers—thereby supporting earlier and more reliable identification of cerebral aneurysms in clinical practice.

R3-SSNR13-4 THE IMPACT OF ARTIFICIAL INTELLIGENCE ON LONGITUDINAL ASSESSMENT OF MULTIPLE SCLEROSIS: A COMPARISON OF RADIOLOGIST REPORTS AND EFFECT ON BLINDED RETROSPECTIVE INTERPRETATION

Matheus Luis Silva (*Presenter*)
Mariana Cerdeira Machado, MD (*Abstract Co-Author*)
Khatya Gonzales de Holanda, BMedSc (*Abstract Co-Author*)
Patricia Oliveira-Szejnfeld, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of artificial intelligence (AI) tools in measuring brain volume and lesion count in serial brain MRIs of patients with multiple sclerosis (MS), comparing their results with radiologist assessments. A secondary objective was determining whether radiologists would modify their interpretations of a blinded retrospective review when presented with AI-derived results.

METHODS AND MATERIALS

We initially selected 53 patients from our institutional database with confirmed MS. We excluded those unsuited for analysis. Then, we performed a retrospective analysis of at least two serial brain MRIs (within 6 to 24 month apart), including 3D-FLAIR and 3D-T1 sequences. Finally, we processed the images utilizing a previously validated AI tool (volBrain). We conducted the study in 3 phases: Initial Assessment : 3 experienced blinded neuroradiologists independently reviewed all MRI series, estimating brain atrophy throughout subjective and corpus callosum index analysis as much as the number and location of new and persistent white matter lesions. The AI tool extracted brain volume and lesion metrics. Performance Comparison : Statistical comparisons between AI and radiologist data for categorical lesion and/or encephalic atrophy progression classification. Blinded Reassessment : After a 12-week washout interval, radiologists re-evaluated a random subset of cases with access to prior AI results without knowledge of having reviewed the case before. Changes in diagnostic interpretation, reading time, and diagnostic confidence were recorded.

RESULTS

Our preliminary results showed that the AI tools used presented an inferior capacity for detecting MS lesions, especially subcortical, infratentorial, and cavitated lesions. However, it showed usefulness in demonstrating comparative volume loss in sequential exams, even in short intervals, when our subjective evaluation might not be sensitive enough to access. The most significant changes were observed when assessing parenchymal atrophy, since most radiologists altered their initial interpretation of encephalic volume loss at some point after reviewing AI-derived outputs.

CONCLUSION

In a preliminary analysis, AI-based tools have demonstrated potential auxiliary influence on radiologists' retrospective interpretations when incorporated into the workflow. These results might support the improvement of the wide usage of AI as a decision-support tool in serial imaging of MS patients.

CLINICAL RELEVANCE/APPLICATION

Incorporating AI into evaluating longitudinal brain MRI studies in MS may improve diagnostic sensitivity, reduce interobserver variability, and enhance clinical efficiency, offering a pathway toward more personalized disease monitoring.

R3-SSNR13-5 FALSE POSITIVE AI DETECTION OF INTRACRANIAL HEMORRHAGE ON EMERGENCY DEPARTMENT HEAD CT: INCIDENCE AND IMAGING PATTERNS

Emily Mungovan, BA (*Presenter*)
Samantha A. Furlong, MD (*Abstract Co-Author*)
Owen Donnelly, RT (*Abstract Co-Author*)
Debra Desmarais, MBA (*Abstract Co-Author*)
Daniel Sacchetti (*Abstract Co-Author*)
John A. Mungovan, MD (*Abstract Co-Author*)

PURPOSE

This study aims to characterize the incidence and common causes of false positive intracranial hemorrhage (ICH) identified by artificial intelligence (AI) on noncontrast computed tomography (CT) scans in the emergency department (ED). It was hypothesized that AI generates a significant number of false positive notifications by misclassifying hyperdense structures on CT as hemorrhage.

METHODS AND MATERIALS

All noncontrast head CT scans with positive AI notifications for ICH across a multi-institutional hospital network over a 12- month period were reviewed. A single commercially available AI platform was used at all sites. Each CT examination was classified as either a true positive or false positive, with documentation of the structure flagged by AI in false positives. Studies performed between 10 PM and 7:30 AM were excluded, as overnight radiologists did not have access to AI.

RESULTS

Out of 14,707 total ED CT scans in 2024, 632 were flagged as positive for ICH by AI. There were 243 false positives (38%), corresponding to a positive predictive value of 72.2%. An AI widget and CT heat maps were used to identify the flagged regions; these showed that unusual hyperdense areas could trigger a positive notification. False positives flagged by AI included normal anatomic structures that often calcify with age, including the choroid plexus, falx cerebri, and tentorium cerebelli. Additional common causes included postoperative and post-ischemic findings such as dural thickening and cortical or dural calcifications. Non-hemorrhagic intracranial neoplasms (e.g., meningiomas), motion artifacts, beam-hardening artifacts, and calcifications in the dentate nuclei and basal ganglia were also frequent contributors.

CONCLUSION

While AI has been shown to aid in detecting ICH on noncontrast head CT, high false positive rates may distract from or delay identification of true positive ICH. At this institution, radiologists can review AI notifications and flagged imaging via a desktop widget without opening the full study. Familiarity with common false positive sources and efficient use of this tool may enable radiologists to triage cases more effectively and expedite true positive reporting.

CLINICAL RELEVANCE/APPLICATION

High rates of AI false positive notifications can distract from or delay reporting of new ICH in the ED. Awareness of common false positive sources can assist radiologists in accurately and promptly reporting new ICH in the ED.

R3-SSNR13-6 GLIO-LLAMA-VISION: A ROBUST VISION-LANGUAGE MODEL FOR MOLECULAR STATUS PREDICTION AND RADIOLOGY REPORT GENERATION IN ADULT-TYPE DIFFUSE GLIOMAS

Yaewon Park, MD, PhD (*Presenter*)
Sung Soo Ahn, MD (*Abstract Co-Author*)
Kyunghwa Han, PhD (*Abstract Co-Author*)
Seung-Koo Lee, PhD (*Abstract Co-Author*)

PURPOSE

To establish a robust vision-language model ("Glio-LLaMA-Vision") for molecular status prediction and radiology report generation (RRG) in adult-type diffuse gliomas.

METHODS AND MATERIALS

Multiparametric MRI data (T1, T2, FLAIR, and postcontrast T1-weighted images) and paired radiology reports (in English) from 1,001 patients with adult-type diffuse gliomas (144 oligodendrogliomas, 157 IDH-mutant astrocytomas, and 700 IDH-wildtype glioblastomas) diagnosed according to the 2021 WHO classification were included as the institutional training set. A vision-language model, Glio-LLaMA-Vision, was developed based on LLaMA 3.1, pre-trained on 2.79 million biomedical image-text pairs from PubMed Central, and further optimized through fine-tuning using the institutional training set. Performance was validated in 100 patients from an institutional validation set, patients from another tertiary institution, and in 170 and 477 patients with MRI from TCGA and UCSF, respectively. The performance for IDH mutation status prediction was evaluated, and the performance for RRG was assessed both quantitatively and qualitatively, with comparison to original reports in terms of "correctness," "readability," and "preference."

RESULTS

For IDH mutation status prediction, Glio-LLaMA-Vision achieved areas under the curve ranging from 0.89 to 0.95 in internal and external validation sets. For RRG, the BLEU-1, ROUGE-L, and METEOR scores were 0.49, 0.42, and 0.24, respectively. Compared with the original reports, the "correctness" was significantly lower in the generated reports (3.32 vs. 3.95, $P < 0.001$), while the "readability" was significantly higher (4.60 vs. 4.34, $P < 0.001$). In terms of "preference," the majority (91.3%) of generated reports were considered clinically acceptable.

CONCLUSION

Glio-LLaMA-Vision demonstrated promising performance in molecular status prediction and RRG for adult-type diffuse gliomas, showing potential for clinical application.

CLINICAL RELEVANCE/APPLICATION

Glio-LLaMA-Vision enables accurate prediction of molecular status and generates clinically acceptable radiology reports for adult-type diffuse gliomas. This model may assist radiologists by improving diagnostic efficiency and supporting clinical decision-making. Its promising performance suggests potential integration into clinical workflows for glioma management.

Nov. 30 – Dec. 4
RSNA® 2025

R3-SSNR14-1 A LOW-DOSE TWO-VOLUME CT PERFUSION TECHNIQUE FOR ABSOLUTE CEREBRAL BLOOD FLOW MEASUREMENT

Alireza Shojazadeh, MD (*Presenter*)
Qiyu Zhang (*Abstract Co-Author*)
Caedin Miller (*Abstract Co-Author*)
Ciprian N. Ionita, PhD (*Abstract Co-Author*)
Sabee Y. Molloi, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate a patient-specific post-trigger delay (PTD) protocol for a prospective low-dose CT brain perfusion technique based on only two volume scans.

METHODS AND MATERIALS

A total of 45 patients (41-87 years old) suspected of cerebral ischemia who underwent standard dynamic cerebral CT perfusion (320 slices, slice thickness of 0.5 mm) were used. For each patient, 19 scans were acquired within 49.3 s (50 mL of Omnipaque-350, rate of 5 mL/s), reconstructed, and registered to simulate all arterial input function curves at the level of the Internal Carotid Artery. Using only two systematically selected volume scans, one at the base (simulating bolus tracking) and one at the peak of the time attenuation curve, brain blood flow (mL/min/g) was quantified with first-pass analysis technique. In the retrospective method, the peak scan was selected by reviewing the full contrast enhancement curve, while the prospective method estimated the peak timing using a previously developed patient-specific PTD method (half the injection duration + 2.5 seconds). Perfusion values derived from the prospective two-volume approach were compared to those from the retrospective method using the Wilcoxon signed-rank test, linear regression, and Bland-Altman analysis.

RESULTS

Mean retrospective and prospective cerebral blood flow (CBF) were 0.240 ± 0.127 mL/min/g and 0.239 ± 0.125 mL/min/g, respectively. Shapiro-Wilk tests confirmed non-normal distribution in both datasets ($p < 0.001$). No significant difference was observed between methods (Wilcoxon $p = 0.23$). Linear regression showed strong agreement between retrospective and prospective estimates (slope = 0.97, $p < 0.001$, $R^2 = 0.98$), with a minimal bias of 0.0008 mL/min/g on Bland-Altman analysis (limits of agreement: -0.035 to 0.036 mL/min/g).

CONCLUSION

An optimal two-volume scan acquisition at the base and peak of the aortic enhancement was retrospectively validated. This technique has the potential for clinical implementation of an accurate brain perfusion technique, streamlining perfusion imaging and reducing radiation exposure.

CLINICAL RELEVANCE/APPLICATION

Conventional CT perfusion techniques are limited by variability in blood flow measurements across postprocessing algorithms and high radiation doses (66-452 mGy) from repeated scans. The proposed two-volume approach offers a simplified, low-dose alternative that supports the feasibility of prospective protocols while maintaining measurement reliability.

R3-SSNR14-2 ASSOCIATION OF CORTICAL IRON LEVELS WITH IN-VIVO MAGNETIC SUSCEPTIBILITY IN COMMUNITY-BASED OLDER ADULTS

Rasheed Abid, BSc (*Presenter*)
Md Tahmid Yasar, PhD (*Abstract Co-Author*)
Abdur Raquib Ridwan, PhD (*Abstract Co-Author*)
Mohammad Rakeen Niaz (*Abstract Co-Author*)
Arnold M. Evia JR, PhD (*Abstract Co-Author*)
Shengwei Zhang, PhD (*Abstract Co-Author*)
Yingjuan Wu, MS,BEng (*Abstract Co-Author*)
David A. Bennett, MD (*Abstract Co-Author*)
Julie A. Schneider, MD (*Abstract Co-Author*)
Konstantinos Arfanakis, PhD (*Abstract Co-Author*)

PURPOSE

Quantitative Susceptibility Mapping (QSM) offers a non-invasive technique to evaluate brain iron content, a biomarker implicated in aging and neurodegeneration. While previous research has focused on subcortical regions, this study investigates the relationship between in-vivo cortical magnetic susceptibility and post-mortem iron concentrations in older adults.

METHODS AND MATERIALS

This study included 20 well-characterized community-based older adults (ages 71-101; 16 females) who underwent 3D multi-echo GRE MRI before death. QSM was reconstructed using the Morphology Enabled Dipole Inversion (MEDI) algorithm. T1-weighted images were segmented and registered to native space using ANTs. Following death, cortical tissue samples were obtained from one hemisphere (14 left, 6 right), and the contralateral side was preserved. Tissue was harvested from the anterior cingulate cortex (ACC), middle frontal cortex (MFC), and inferior temporal cortex (ITC). Iron concentrations were quantified via inductively coupled plasma mass spectrometry (ICP-MS) and log-transformed to reduce skewness. Median susceptibility values were extracted for each region. Pairwise correlations were computed among iron levels, susceptibility, age, and antemortem interval. Multiple linear regression was performed to assess the adjusted relationship between susceptibility and iron concentrations.

RESULTS

A strong positive correlation was observed between post-mortem iron concentration and in-vivo magnetic susceptibility across all three cortical regions. Multiple linear regression analysis—controlling for age, sex, and antemortem interval—revealed a significant association ($R^2 = 0.85$, $p < 0.005$). Pairwise analyses further confirmed consistent relationships among the studied variables.

CONCLUSION

Our findings demonstrate that in-vivo cortical magnetic susceptibility significantly reflects post-mortem iron concentrations in older adults, even after adjusting for age, sex, and antemortem interval. These results support the potential of QSM as a non-invasive proxy for cortical iron content, with implications for aging and neurodegenerative disease research.

CLINICAL RELEVANCE/APPLICATION

In-vivo QSM may serve as a valuable imaging biomarker for estimating cortical iron deposition and understanding iron dysregulation in the aging brain.

R3-SSNR14-4 WHITE MATTER MICROSTRUCTURE AND COGNITIVE DECLINE IN SUBACUTE ISCHEMIC STROKE: INSIGHTS FROM FREE WATER IMAGING AND GLYMPHATIC DYSFUNCTION

Xin Li (*Presenter*)
Yue Qin (*Abstract Co-Author*)
Lei Wang, MD, PhD (*Abstract Co-Author*)
Yanqiang Qiao (*Abstract Co-Author*)
Juan Tian (*Abstract Co-Author*)
Yifan Qian (*Abstract Co-Author*)

PURPOSE

To investigate white matter microstructural changes and their relationship with cognitive function in subacute ischemic stroke (IS) using free water diffusion tensor imaging (FW-DTI) and tract-based spatial statistics (TBSS).

METHODS AND MATERIALS

Thirty-nine subacute IS patients (31 males, 59.21±11.24 years) and 39 well-matched healthy controls (HC, 30 males, 58.54±7.69 years) underwent diffusion spectrum imaging. FW, fractional anisotropy (FA), mean diffusivity (MD), and FW-corrected DTI metrics (FA T and MD T) were analyzed using TBSS. Cognitive function was assessed using the Montreal Cognitive Assessment (MoCA). Group differences and correlations with imaging metrics, cognitive performance, and clinical variables were examined.

RESULTS

Compared with the HCs, IS patients showed significantly higher FW in both the whole-brain ($t = -3.03$, $p = 0.0034$) and white matter skeleton ($t = -3.20$, $p = 0.0022$), and reduced skeleton FA ($t = 3.81$, $p = 0.0003$) and FA T ($t = 3.60$, $p = 0.0059$). In the IS group, MoCA scores were negatively correlated with whole-brain FW ($r=-0.44$, $p=0.0069$) and skeleton MD ($r=-0.33$, $p=0.047$), and positively correlated with skeleton FA ($r=0.34$, $p=0.044$) and FAT ($r=0.35$, $p=0.035$). Skeleton FW was positively associated with time since stroke onset (? = 0.48, $p = 0.0391$). Age was negatively correlated with skeleton FA ($r = -0.35$, $p = 0.0295$) and FA T ($r = -0.38$, $p = 0.0183$), but positively with whole-brain FW ($r = 0.59$, $p = 7.57\times10?5$) and skeleton MD ($r = 0.38$, $p = 0.0179$).

CONCLUSION

Free water imaging offers valuable insights into white matter microstructure alterations and cognitive impairment following subacute IS. In this study of patients within one month post-stroke, we observed elevated whole-brain FW, indicative of vasogenic edema, neuroinflammation, and glymphatic system dysfunction. FW provides a novel metric for assessing white matter damage in the subacute phase and may serve as a potential imaging biomarker of poststroke cognitive health. Future large-scale, longitudinal studies are needed to investigate how FW-corrected DTI metrics evolve over time and relate to long-term cognitive outcomes.

CLINICAL RELEVANCE/APPLICATION

These findings suggested that subacute IS may lead to the disruption of white matter integrity, dysfunction of the glymphatic system, and subsequent white matter-related cognitive impairment. The results provide a theoretical foundation for the development of therapeutic strategies targeting white matter injury and glymphatic dysfunction during the subacute phase of stroke.

R3-SSNR14-5 CLINICAL VALIDATION OF A NOVEL ARTIFICIAL INTELLIGENCE METAL ARTIFACT CORRECTION ALGORITHM IN CT PERFUSION FOR POSTPROCEDURAL EVALUATION OF INTRACRANIAL ANEURYSM CLIPPING AND COILING

Jianjun Shen, PhD (*Presenter*)
Haonan Zhao (*Abstract Co-Author*)
Manman Zhu (*Abstract Co-Author*)
Yixuan Zou, MS (*Abstract Co-Author*)
Jingfeng Huang (*Abstract Co-Author*)
Pan Yuning, MD (*Abstract Co-Author*)

PURPOSE

To explore the clinical value of a novel artificial intelligence metal artifact correction (AI-MAC) algorithm in CT perfusion (CTP) imaging for postprocedural evaluation of intracranial aneurysm clipping and coiling.

METHODS AND MATERIALS

This retrospective study included 24 patients (8 males; 60.5±11.2 years; 23±2.5 kg/m 2) with unilateral intracranial clips or coils, who underwent CT perfusion for postprocedural evaluation, and 5 of the patients had the digital subtraction angiography (DSA) results ipsilateral to clips and coils. CT data were reconstructed using three methods: hybrid iterative reconstruction (HIR) algorithm (uncorrected group), HIR with conventional metal artifact correction algorithm (MAC group), HIR with AIMAC algorithm (AI-MAC group). For three groups, the artifact area ratio caused by clips or coils was assessed using a 5-point Likert scale (1: <10%; 2: 10-30%; 3: 30-50%; 4: 50-70%; 5: >70%), and the maximum diameter of stripe artifacts was also measured. For the five patients with DSA reference, cerebral blood flow (CBF), cerebral blood volume (CBV), mean transit time (MTT), time to peak (TTP) and time-to-maximum (Tmax) were measured to identify the ischemia in frontal lobe, temporal lobe, parietal lobe, occipital lobe and basal ganglia regions ipsilateral to clips and coils.

RESULTS

Compared to the uncorrected group, the AI-MAC group demonstrated a 31.3% significant reduction in the metal artifact area, whereas the MAC group had a 34.4% significant increase. The maximum artifact diameter of the AI-MAC group (13.8±13.4 mm) was significantly lower than that of the MAC group (66.1±21.3 mm) and the uncorrected group (34.9±24.9 mm), with 79.1% and 60.5% reduction (both $p <0.001$), respectively. For the ischemia diagnosis across all measured brain regions, the AI-MAC group achieved higher specificity (95.5%), higher positive predictive value (PPV; 66.7%), and higher accuracy (95.8%), compared to the uncorrected group (specificity: 77.3%; PPV: 28.6%; accuracy: 79.2%) and the MAC group (specificity: 72.7%; PPV: 25.0%; accuracy: 75.0%).

CONCLUSION

The AI-MAC algorithm significantly improves the correction of metal artifacts in postprocedural CTP of intracranial aneurysm patients compared to the conventional MAC. It reduces secondary artifacts and increases the stability of CTP parameters.

CLINICAL RELEVANCE/APPLICATION

The AI-MAC algorithm effectively reduces metal artifacts in postprocedural CTP for intracranial aneurysm patients, thereby improving diagnostic accuracy and providing more reliable perfusion parameters for clinical decision-making.

R3-SSNR14-6 DIFFUSION TENSOR IMAGING IN TRIGEMINAL NEURALGIA: QUANTITATIVE EVALUATION OF THE ROOT ENTRY ZONE

Amitnandan D. Dwivedi, MBBS, MD (*Presenter*)
Mohammad Aamir, MBBS (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic role of Diffusion Tensor Imaging (DTI) in patients with Trigeminal Neuralgia (TN) by evaluating fractional anisotropy (FA) and apparent diffusion coefficient (ADC) values at the root entry zone (REZ) of the trigeminal nerve, and to compare these metrics with the contralateral unaffected side

METHODS AND MATERIALS

In this prospective observational study, 29 patients clinically diagnosed with unilateral TN underwent 3T MRI with DTI sequences. FA and ADC values were measured at the affected and contralateral REZ of the trigeminal nerve. The data were statistically analyzed to evaluate the significance of DTI metrics in identifying microstructural alterations in TN. Presence of neurovascular compression (NVC) was noted, though not all patients exhibited it

RESULTS

Mean FA values at the affected REZ were significantly reduced compared to the contralateral side (0.27 ± 0.05 vs. 0.36 ± 0.04; $P < 0.001$). Similarly, ADC values were significantly elevated on the affected side ($1.31 \pm 0.19 \times 10?^{3}$ mm²/s vs. $1.01 \pm 0.13 \times 10?^{3}$ mm²/s; $P < 0.001$). Among 29 patients, 17 showed vascular loop compression. DTI changes were consistently observed irrespective of NVC, indicating DTI's capability to detect neural microstructural damage beyond compressive etiology

CONCLUSION

DTI offers a valuable non-invasive imaging biomarker for assessing trigeminal nerve microstructural integrity in TN. Reduced FA and elevated ADC at the REZ serve as objective indicators for early diagnosis, even in the absence of demonstrable neurovascular compression on conventional MRI

CLINICAL RELEVANCE/APPLICATION

Incorporating DTI into standard MRI protocols may enhance the diagnostic accuracy for TN and guide tailored therapeutic strategies, especially in ambiguous or early-stage cases

R3-SSPH13-1 DEVELOPING A NOVEL X-RAY SOURCE AND A 6TH GENERATION ULTRA-FAST AND GENERAL-PURPOSE CT

Hui Hu, PhD (*Presenter*)
Vitaliy Ziskin, PhD (*Abstract Co-Author*)
Andrew Cross (*Abstract Co-Author*)
Hong Chen (*Abstract Co-Author*)
Botao Zhao (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a novel X-Ray source technology, referred to as the Magnetically-Scanning Stationary (MSS) X-Ray source, and a CT platform, referred to as the 6th generation (6th-gen) CT, that combines the MSS X-Ray source and a rotating detector array. A 6th-gen CT avoids the need to rotate heavy X-Ray source(s) and high-voltage power supply, thus promising a much faster rotation speed.

METHODS AND MATERIALS

Several iterations of the MSS X-Ray source and the 6th-gen CT prototype have been developed. The X-Ray focal spot movement is synchronized with the detector rotation using encoder-based scan trigger electronics. The performance of the MSS X-Ray source and the 6th-gen CT were evaluated using hardware prototypes.

RESULTS

The MSS X-Ray source has achieved: 1) Ultra-fast scan down to 30 ms of image temporal resolution, far exceeding the 125-250 ms range achieved by today's high-end CT; 2) sufficient X-Ray flux (up to over 1000 mA) that is required for general-purpose diagnostic CT; 3) An X-Ray focal spot size down to 1x0.6 mm. Currently, the 6th-gen CT prototype has achieved 260 RPM rotation speed measured by a home-position trigger, and the X-Ray focal spot motion is synchronized with the detector rotation as evident by the sinogram data collected.

CONCLUSION

The MSS X-Ray source has demonstrated the capability to match the X-Ray power performance of leading CTs on the market. The focal spot size of 1 mm has been demonstrated, with a sub-millimeter focal spot is being developed in the next prototype. The current 6th-gen CT prototype has demonstrated a rotational speed of 260 RPM, which is slightly faster than that of the leading CTs. A 480 RPM rotation speed is being developed in the next prototype. A ~960 RPM (i.e., an image temporal resolution of 30-40 ms range) is potentially achievable, which constitutes ~4x the speed of today's CT, a speed that can be achieved because the current physical constraint of mechanical rotation of the CT tube has been eliminated in the 6th-gen CT

CLINICAL RELEVANCE/APPLICATION

The MSS X-Ray source and the 6th-gen CT will transform the entire field of CT. It is a flexible system that is compatible with all other state-of-the-art technology innovations, such as photon-counting detectors, Spectral CT, dose-reduction techniques, more detector rows, AI, as well as software-based technologies. The 6th-gen CT will transform many CT applications, from general-purpose CT to cardiac CT. Since the 6th-gen CT will be lighter and more compact than conventional CT, it will also open up special applications such as emergency room (ER) / operating room (OR) CT, mobile CT, and miniaturized vehicle-based CT. Due to its stationary source design, it is expected to be more economical compared with high-end CT systems, such as dual-source/dual-detector CT.

R3-SSPH13-2 ULTRA-LOW DOSE, HIGH-RESOLUTION SPECTRAL CT IMAGING ENABLED IN HYBRID RAPID-KVP SWITCHING AND PHOTON-COUNTING DETECTOR SYSTEM

Olivia Sandvold, BS (*Presenter*)
Roland Proksa (*Abstract Co-Author*)
Amy Perkins (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

While spectral CT has improved adult diagnostic imaging, it remains primarily optimized for larger body sizes, neglecting key pediatric imaging challenges, namely, small anatomical detail, low intrinsic contrast, and high radiation sensitivity. Ultra-low dose protocols in pediatrics limit photon fluence, confounding the generation of high-resolution, quantitative spectral images even using state-of-the-art photon-counting technology. This work proposes a novel sparse spectral imaging paradigm tailored to pediatric needs, enabling low-dose, ultra-high resolution spectral CT through a hybrid CT technology combination.

METHODS AND MATERIALS

The proposed method acquires most of the scan using a low tube voltage, with a photon-counting detector operating in a high-resolution mode that sums photon counts across energy bins, effectively functioning in a non-spectral mode, excluding electronic noise. During designated sparse intervals, the system transitions into a rapid kilovolt-peak mode to activate spectral imaging in conjunction with the detector's energy-discriminating functionality. A Monte Carlo simulation demonstrated this pediatric imaging protocol, using a tube voltage of 70 kVp with intermittent 110 kVp pulses for spectral data. The detector pixel size was set to 0.5x0.5 mm^2 and 1x1 mm^2. Dose was changed through varying the high kVp pulse duration from 25-125 μs. A 150 mm pediatric phantom was simulated. Spectral signal-to-noise ratio (SNR) in virtual monoenergetic images was estimated using the Cramér-Rao Lower Bound, and the area under the monoenergetic curve (AUMC) was calculated by integrating spectral SNR over 35-120 keV. Bias was estimated in the photoelectric and Compton scatter domains.

RESULTS

The sparse spectral protocol obtained AUMC 124% relative to a constant 100 kVp photon-counting scan using the same dose level and pixel size. Binning pixels to 1x1 mm 2 , the sparse spectral performance was over 267% of the 100 kVp reference scan AUMC. Bias in the photoelectric domain decreased using the sparse spectral protocol compared to the reference system bias by 89% for 0.5x0.5 mm 2 pixel sizes and over 97% in resolution binned mode.

CONCLUSION

This work demonstrates a novel sparse spectral CT acquisition strategy optimized for pediatric imaging, successfully balancing ultra-high spatial resolution, spectral quantification, and ultra-low radiation dose.

CLINICAL RELEVANCE/APPLICATION

The hybrid CT combination of kVp-switching and photon-counting detectors may reduce quantitative noise and bias in pediatric imaging while maintaining ultra-low radiation doses necessary to facilitate adaptation of spectral CT for pediatric populations.

R3-SSPH13-3 ANALYSIS OF CT DOSE REDUCTION AND RECONSTRUCTION ACCURACY USING AN ADJUSTABLE SEMI-RADIOLUCENT COLLIMATOR

Stephanie Leon, PhD (*Presenter*)
Timothy Olson (*Abstract Co-Author*)
Philip A. Templeton, MD (*Abstract Co-Author*)

PURPOSE

Standard CT reconstruction algorithms require relatively uniform detector dose. However, the clinical focus is often on a smaller anatomic region of interest (ROI), resulting in tissue dose without diagnostic utility. An experimental technology uses a novel reconstruction with a moving semi-radiolucent collimator that adjusts position in real-time during tube rotation, transmitting the full dose within an ROI but blocking dose outside the ROI. This work assesses the reconstruction fidelity and measures the dose reduction as a function of ROI diameter and position.

METHODS AND MATERIALS

An initial trial simulated the collimator by scanning a cadaver on a clinical CT scanner at 17 mGy and 1.7 mGy. The images were digitally combined into a single image representing a typical dose in the ROI with a 90% reduction off-ROI. The combined image was processed and compared with the 17 mGy image for HU accuracy. A difference image assessed the preservation of detail. Then, images of a water phantom were acquired using a research scanner with the experimental collimator installed, using all available kVs and a scanner-reported CTDI of 20 mGy. Scans were performed with the collimator producing a 10-cm diameter ROI, as well as with the collimator blades fully retracted. The algorithm was applied to the ROI images. HU values within the ROI were compared to those from the uncollimated scan. To assess dose, scans of the 32-cm CTDI phantom were performed with centered ROIs of 0 cm (collimator fully closed), 5 cm, 10 cm, 20 cm, and fully open. ROIs were also moved to offsets from phantom center of 5 cm and 10 cm. CTDI was calculated for each scenario using standard methodology.

RESULTS

The difference image from the cadaver test showed no discernable structures within the ROI, indicating no loss of detail. The majority of CT number errors were from 2-4 HU, with no errors greater than 20 HU. The experimental water phantom reconstructions showed errors averaging -0.1 HU, with all values within 20 HU, regardless of kV. Dose reduction depended strongly on ROI size and location, but not kV. A reduction of 90% was seen with the collimator fully closed, dropping to a low of 16% for a centrally-located 20-cm ROI. For a reasonably-sized 10 cm ROI, CTDI reduction was 44% when centrally-located and 60% when offset.

CONCLUSION

The experimental collimator accurately preserves HU values and image detail within the ROI. The magnitude of dose reduction depends strongly on ROI size and location; for a typical application with a medium-sized ROI located off-center within the patient, CTDI reductions of 40-60% are reasonable.

CLINICAL RELEVANCE/APPLICATION

Dose to tissues not of clinical interest can be reduced dramatically using the experimental collimator, without loss of image detail and accuracy.

R3-SSPH13-4 MULTI-SOURCE STATIC CT: SCATTER CORRECTION AND NOISE ANALYSIS

Andreas Heinkele, MSc (*Presenter*)
Lukas Hennemann, MSc (*Abstract Co-Author*)
Julien Erath (*Abstract Co-Author*)
Marc Kachelriess, PhD (*Abstract Co-Author*)
Karl Stierstorfer, PhD (*Abstract Co-Author*)
Joscha Maier, PhD (*Abstract Co-Author*)
Eric Fournie (*Abstract Co-Author*)
Johan Sunnegaardh (*Abstract Co-Author*)
Martin Petersilka, PhD (*Abstract Co-Author*)
Christian Hofmann (*Abstract Co-Author*)

PURPOSE

To provide a scatter correction for static CT of 4th generation geometry.

METHODS AND MATERIALS

In recent years, static CT scanners gained attention in CT research as they may offer some advantages compared to today’s clinical CT systems. Our static CT is composed of a detector ring and a source ring array. This expands the acquisition possibilities from sequential and spiral trajectories to arbitrary patterns. Moreover, the static nature of the scanner inherently avoids ring artifacts. Operation with more than one x-ray source operating simultaneously is possible to enhance temporal resolution, e.g. for cardiac CT. One major drawback is that the deployment of anti-scatter grids (ASGs) is not feasible due to the 4 th generation geometry. This increases the risk of artifacts and eventually leads to increased image noise when using scatter correction algorithms, especially in the case of multiple sources. Deep learning-based methods offer an approach to tackle scatter artifacts: Deep scatter estimation (DSE) is based on a U-net architecture, and we trained it to predict Monte Carlo (MC) scatter estimates in projection domain. Scatter correction can then be done by subtraction of the DSE estimate from the total signal in intensity domain. For operation with 2 and 3 sources, the sources are fired in an angular distance of 120 degree to prevent primary beams from overlapping. As an entire 360° detector ring is available in static CT, this allows the measurement of cross-scatter as additional information that DSE can use for more accurate scatter estimation. DSE was trained on circular and elliptic water phantoms as well as semi-anthropomorphic thorax phantoms. Noise is added to the reconstructions with a Poisson-noise generator in projection domain. The noise level was matched to resemble a realistic scan.

RESULTS

In our test scenario, scatter can be well corrected even for operation with three sources. However, DSE cannot avoid increased image noise after applying scatter correction. With scatter correction, the noise level for a 32 cm water phantom with 3-source operation and same dose increases by 63.5% compared to a scan with a single source. This means that the 2.7-fold dose would be necessary to achieve the same noise level as with single-source operation.

CONCLUSION

Scatter correction with DSE shows promising results. However, it still results in a strong increase in noise, especially for operation with 2 and 3 sources. Hence, this operation might only be reasonable when combined with physical scatter rejection like some sort of ASG.

CLINICAL RELEVANCE/APPLICATION

In the future, static CT might serve as a complementary CT system to clinical scanners today. Its advantages might make it a preferable option for cardiac CT or interventional applications.

R3-SSPH13-5 IMPROVED SPECTRAL QUANTIFICATION WITH K-EDGE FILTRATION: AN EXPERIMENTAL STUDY IN PEDIATRIC CT

Yinglin Ge, MS (*Presenter*)
Olivia Sandvold, BS (*Abstract Co-Author*)
Amy Perkins (*Abstract Co-Author*)
Roland Proksa (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

Accurate quantitative imaging at low radiation doses is essential for diagnostic pediatric spectral CT. In this experimental study, we demonstrate that integrating a K-edge filter with a dual-layer spectral CT system enhances quantitative performance without increasing radiation exposure.

METHODS AND MATERIALS

To optimize the setup for follow-up experiments, we simulated a dual-layer spectral CT system with fan beam geometry. A reference pediatric dose was generated using a 100 kVp tube voltage and a 70 mA tube current. A holmium (Ho) filter was simulated at varying thicknesses while the tube current was increased and optimized to obtain an equivalent dose to the reference configuration. Optimal spectral performance with the highest overall signal-to-noise ratio (SNR) was identified at a Ho thickness of 0.3 mm and an adjusted tube current of 438 mA. To validate the simulation results, an experimental spectral CT bench system equipped with a clinical-grade x-ray tube and a dual-layer detector (Philips Healthcare) was operated with the optimized current for the 0.3 mm thick Ho filter attached to the collimation box and the reference parameters without a filter for comparison. For both configurations, a 100 mm diameter phantom containing four tissue-mimicking inserts (iodine 1, 2, 5 mg/mL, and solid water; Sun Nuclear) was scanned. A 2D projection-based material decomposition was performed. Iodine and water basis images were created using a 150 mm field of view. No denoising or scatter correction was applied. To estimate spectral sensitivity with and without Ho filtration, noise was measured in each insert, and bias was calculated by comparing the iodine density measurement to the value measured with a clinical dual-layer CT scanner (Spectral CT 7500, Philips Healthcare).

RESULTS

Using the Ho filter, noise was reduced by over 20% on average across all inserts compared to the reference scan for iodine/water images. Noise reduction was greater in the water inserts than in the iodine inserts. Compared to non-filtered acquisitions, bias analysis of filtered images showed 19-61% reduction across all inserts, and all biases were less than 0.21 mg/mL. Water density measurements remained accurate within a 2% error margin in both filtered and non-filtered cases.

CONCLUSION

The combination of Ho K-edge filtration and dual-layer spectral CT significantly enhances quantitative imaging at low pediatric dose levels. This improvement in iodine accuracy may reduce reliance on extra non-contrast scans, streamlining workflow and minimizing radiation exposure in pediatric care.

CLINICAL RELEVANCE/APPLICATION

Given the increase in CT imaging and the associated safety concerns for pediatric patients, it is crucial to provide high-quality, low-dose spectral CT imaging.

R3-SSPH13-6 REVISITING FILL FACTOR LIMITATIONS OF HIGH-RESOLUTION, ENERGY-INTEGRATING DETECTOR CT WITH A FALSE FOCAL SPOT

Scott S. Hsieh, PhD (*Presenter*)

PURPOSE

The most important clinical draw for photon counting detector (PCD) CT today is its excellent spatial resolution. It is often stated that energy integrating detectors cannot match this resolution without suffering from poor fill factor, because more dead space would be occupied by reflective septa placed between scintillator pixels. We propose a different system geometry that accommodates reflective septa without suffering from poor fill factor.

METHODS AND MATERIALS

We propose that the detector be pointed towards a “false focal spot,” 4 cm from the true focal spot in both x- and z- directions. The reflective septa are no longer parallel to X-rays originating from the true focal spot, such that X-rays incident on reflective septa can penetrate the septa and deposit energy in scintillator buried underneath. To characterize this system, we calculated the modulation transfer function (MTF) and zero-frequency detective quantum efficiency (DQE(0)) for (1) a conventional detector with 0.1 mm wide septa, (2) a false focal spot detector with 0.1 mm wide septa, and (3) an idealized detector without septa. We assumed monochromatic radiation at 80 keV, that detectors were 3 mm thick with attenuation of 34 cm -1 (gadolinium oxysulfide), that reflective septa had attenuation of 0.3 cm -1 (PMMA-equivalent with 0.25 g/cc TiO 2), that the source was a point, that the anti-scatter grid was absent, and that photons deposited their whole energy at first scattering. Resolution measurements are reported at the detector, before de-magnification or reconstruction. While scatter was not modeled, any grid that is used must be pointed towards the true (not false) focal spot.

RESULTS

With a 0.5 mm pixel pitch, the DQE(0) of conventional, false focal spot, and ideal detectors were 64%, 92%, and 100%, respectively. This corresponds to recovering 77% of the lost fill factor using the false focal spot. The MTFs at 10% for conventional, proposed, and ideal detector were 22.9, 19.2, and 18.2 lp/cm, respectively. The MTF of the conventional detector outperforms the ideal detector because of the increased aperture area. The aperture of false focal spot is intermediate and slightly asymmetric. The DQE(0) of false focal spot had minor spatial variation across the fan beam, decreasing by 1% at the periphery.

CONCLUSION

Most of the fill factor penalty of high resolution energy integrating detectors is recovered with a false focal spot geometry.

CLINICAL RELEVANCE/APPLICATION

Dose efficient, high resolution CT could be achieved with energy integrating (not just photon counting) detectors if a false focal spot geometry is used. This could improve clinical access to high resolution CT.

Benoit Rizk, MD (*Abstract Co-Author*)
Cyril Thouly (*Abstract Co-Author*)
Benoit Dufour (*Abstract Co-Author*)
Natalie Heracleous, PhD (*Abstract Co-Author*)
Octave Novarina (*Abstract Co-Author*)
Simon Pericou (*Abstract Co-Author*)

PURPOSE

To assess efficiency gains and radiologist adoption of AI tools in musculoskeletal, chest, breast, and neurologic imaging across Switzerland’s largest radiology network, establishing benchmarks for AI processing times, turnaround time improvement, and user acceptance.

METHODS AND MATERIALS

Retrospective analysis of 397,694 AI-processed studies from 20 Swiss centers (Jan 2022-Jun 2025) was combined with a radiologist survey (91.4% response, 53/58) and report turnaround analysis. Evaluated AI included musculoskeletal tools (bone age, trauma/orthopedic radiography, knee/spine MRI), mammography, chest CT and radiography, and brain MRI for MS and volumetry. Metrics: AI processing latency, report turnaround with/without AI, usage frequency, trust, and Net Promoter Scores (NPS).

RESULTS

Musculoskeletal AI made up 67.8% of utilization (trauma radiography 37%). Breast, chest, and brain applications had 76% specialty adoption. 66.1% of radiologists were frequent AI users, most engaged mid-career. AI was valued for protection against errors (71.7%) and time saving (56.6%). Requests included faster AI (48%) and automated report integration (34%). NPS ranged from bone age (+86.7) and orthopedic XR (+65.2) to spine MRI (-55.3). Chest CT scored highest NPS among non-musculoskeletal AI (+38.5, 73.6% use). Innovation indices ranged 43.0-74.0. Broader AI use found among musculoskeletal/general radiologists; median productivity sentiment was 2/5. Bottlenecks were data transfer for radiography/mammography (2.1-3.5min) and AI computation for brain/spine MRI (8.2min). Only 21.6% of AI results were ready pre-report and 5% missing at validation. In subgroup analysis, AI reduced report times: knee MRI 16?14min (12%), trauma radiography 7?3min (57%), bone age 3.5?1.6min (55%).

CONCLUSION

Large-scale AI yielded 12-57% turnaround reductions and 90%+ adoption, with persistent speed and integration challenges. Future priorities include technical improvements, feedback mechanisms, and site-specific initiatives. User demand for increased AI interoperability and seamless EHR/report integration was a common theme, highlighting the need for optimized workflows and continuous AI performance evaluation requiring collaborative multidisciplinary efforts.

CLINICAL RELEVANCE/APPLICATION

This multi-year study presents benchmarks for AI adoption across specialties, supporting it as a strategy to meet imaging demand, improve quality, and enhance radiologist confidence. Notably, AI tools demonstrated variable clinical impact across modalities, emphasizing the importance of tailored solution selection according to specialty-specific needs and diagnostic workflows.

R3-STCE1-3 DEEP LEARNING-ENHANCED PHOTON-COUNTING CT FOR CARDIAC DELAYED IODINE IMAGING: A STEP FORWARD IN MYOCARDIAL TISSUE CHARACTERIZATION

Jose Osoria-Velasquez, MD (*Presenter*)
James Griggers (*Abstract Co-Author*)
Milan Vecsey-Nagy, MD, PhD (*Abstract Co-Author*)
Tilman S. Emrich, MD (*Abstract Co-Author*)
Akos Varga-Szemes, MD, PhD (*Abstract Co-Author*)
Muhammad Taha Hagar, MD (*Abstract Co-Author*)

PURPOSE

Spectral photon-counting detector CT (PCD-CT) enables high-resolution myocardial imaging but is limited by elevated noise, particularly in low-keV reconstructions required for late iodine enhancement (LIE). To address this, we incorporated a convolutional neural network-based denoising model derived from U-Net into the reconstruction pipeline. This study evaluates its impact on image quality and diagnostic performance in cardiac LIE imaging.

METHODS AND MATERIALS

In this IRB-approved retrospective study, 27 patients underwent cardiac LIE imaging with PCD-CT and same-day cardiac MRI with late gadolinium enhancement (LGE) as reference. CT images were reconstructed with and without a U-Net-based AI post-processing module applied after quantum iterative reconstruction (QIR3). The network was trained to suppress stochastic noise while preserving anatomical structures using synthetically degraded input. Attenuation, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were measured on iodine maps and 40-keV virtual monoenergetic images (VMI). Two blinded cardiovascular radiologists evaluated enhancement patterns, with diagnostic accuracy compared to LGE-MRI. Inter-reader agreement was measured using Cohen’s ?.

RESULTS

AI denoising reduced noise (iodine: 39%; VMI: 32%) and significantly improved SNR and CNR ($p < 0.001$). Sensitivity and NPV reached 100% on iodine maps, with diagnostic accuracy rising from 85.2% to 88.9%. Similar improvements were observed for VMI. Inter-reader agreement increased (?: iodine 0.70-0.77; VMI 0.63-0.70).

CONCLUSION

Integrating U-Net-based deep learning denoising into the PCD-CT workflow improves objective image quality and interpretability in myocardial LIE imaging. This AI-driven approach reduces quantum noise while preserving diagnostic fidelity, advancing the clinical viability of low-keV spectral imaging.

CLINICAL RELEVANCE/APPLICATION

By enhancing image quality and diagnostic performance without altering acquisition protocols or increasing radiation dose, U-Net-based AI denoising in photon-counting CT improves the reliability of myocardial scar detection in late iodine enhancement imaging. This supports the clinical utility of CT-based late enhancement as a viable, rapid, and accessible alternative to cardiac MRI for myocardial viability assessment, especially in patients with implanted devices, arrhythmias, or MRI contraindications.

R3-STCE2-1 COMBINING CT-BASED HEPATIC STEATOSIS ASSESSMENT AND CORONARY ARTERY CALCIUM SCORE FOR IMPROVED CARDIOVASCULAR RISK STRATIFICATION IN ASYMPTOMATIC ADULTS

KANG HEE CHO (*Presenter*)
Ijin Joo, MD, PhD (*Abstract Co-Author*)
Bo Yun Hur (*Abstract Co-Author*)
Yoonseong Lee, MD (*Abstract Co-Author*)

PURPOSE

To assess the value of combining CT-based hepatic steatosis evaluation and coronary artery calcium (CAC) score for cardiovascular risk stratification in asymptomatic adults, and to determine whether CT provides comparable added value to conventional noninvasive steatosis markers such as ultrasound and fatty liver index (FLI).

METHODS AND MATERIALS

This single-center retrospective study included 2,701 asymptomatic adults who underwent health screening with low-dose chest CT, abdominal ultrasound, and coronary calcium scoring CT (January 2023-June 2024). CT images were analyzed using 3D organ segmentation to measure mean CT attenuation values of the liver and spleen. Hepatic steatosis was evaluated via: (1) CT-based parameters (liver Hounsfield units [HU] and liver-spleen HU difference), (2) ultrasound grading, and (3) fatty liver index (FLI), a non-invasive score based on clinical and laboratory data to classify liver fat content. CAC scores were divided into five categories by Agatston score. Cardiovascular disease (CVD) risk groups were determined using Atherosclerotic Cardiovascular Disease (ASCVD) 10-year risk thresholds (>5%, >7.5%, >20%). Logistic regression identified predictors for CVD risk classification, and receiver operating characteristic (ROC) curve analysis compared CAC score alone versus models with hepatic steatosis markers.

RESULTS

CAC grade alone showed good performance across ASCVD risk thresholds, with AUROCs of 0.710-0.720. Adding CT-based hepatic steatosis parameters to CAC significantly improved AUROCs at all thresholds (P<0.001). Specifically, adding liver HU increased AUROCs from 0.712 (95% CI: 0.694-0.729) to 0.752 (0.735-0.768) for ASCVD >5%, from 0.710 (0.693-0.727) to 0.735 (0.718-0.751) for >7.5%, and from 0.720 (0.703-0.737) to 0.736 (0.719-0.753) for >20%. Similarly, the liver-spleen HU difference combined with CAC yielded AUROCs of 0.736 (0.719-0.753), 0.725 (0.708-0.742), and 0.730 (0.713-0.747) at the same thresholds. Ultrasound and FLI also improved performance when added to CAC, with no significant differences among markers (all P>0.05).

CONCLUSION

Combining CAC grade with CT-based hepatic steatosis parameters significantly improves the identification of CVD high-risk status.

CLINICAL RELEVANCE/APPLICATION

Integrated CT-based imaging biomarkers for coronary artery calcium and hepatic steatosis enable enhanced cardiovascular disease screening and risk stratification in asymptomatic adults.

R3-STCE2-2 PANCREATIC FIBRO-INFLAMMATION DETECTED VIA STANDARDISED T1 MAPPING IS CAUSALLY LINKED TO PANCREATIC CANCER: A UK BIOBANK STUDY

Michele Pansini, MD (*Presenter*)
Edward Jackson (*Abstract Co-Author*)
Alessandro Fichera (*Abstract Co-Author*)
Yameng Deng (*Abstract Co-Author*)
George Ralli, DPhil (*Abstract Co-Author*)
Alexandre Triay Bagur, MSc (*Abstract Co-Author*)
Giovanni Morana, MD (*Abstract Co-Author*)
Filippo del Grande, MD (*Abstract Co-Author*)
Andrea Dennis (*Abstract Co-Author*)
Mustafa F. Akisik, MD (*Abstract Co-Author*)
Philip Awadalla (*Abstract Co-Author*)

PURPOSE

To determine whether pancreatic fibroinflammation measured from a population-based abdominal MRI protocol using standardised T1 mapping (srT1) is associated with future pancreatic cancer development and to assess its genetic architecture and causal relevance via Mendelian randomisation.

METHODS AND MATERIALS

In 54,227 UK Biobank participants undergoing a standardised, non-contrast abdominal MRI protocol, we extracted pancreatic srT1 and pancreatic fat content using an automated, scanner-independent pipeline. Incident pancreatic cancer was identified via linked healthcare records. Cox models assessed associations between srT1/PDFF and cancer risk. GWAS and two-sample Mendelian randomisation were conducted to explore genetic determinants and causal inference.

RESULTS

Among participants, 41 developed new-onset pancreatic cancer. Elevated srT1 was significantly associated with cancer risk (adjusted HR per SD = 1.5, 95% CI: 1.1-2.0, p<0.05), independent of confounders and genetic risk. PDFF was not associated with cancer. In MR analyses, srT1 showed a significant causal effect on pancreatic cancer after correcting for pleiotropy (p<0.05), while PDFF did not. GWAS identified 20 loci associated with srT1, including SLC39A8, ABO, and BANK1, genes implicated in inflammation and immune function. Radiological review revealed elevated srT1 in parenchyma and tumours up to two years before diagnosis.

CONCLUSION

Pancreatic fibro-inflammation, quantified via standardised T1 mapping, is causally associated with future pancreatic cancer development. This biomarker captures early parenchymal changes linked to fibroinflammatory processes, suggesting a potential role in cancer risk stratification, especially in non-hereditary populations.

CLINICAL RELEVANCE/APPLICATION

Where implemented, srT1 mapping provides non-invasive, biologically sensitive assessment of pancreatic tissue characteristics, supporting its potential inclusion in future abdominal MRI protocols for early cancer risk stratification.

PURPOSE

CT is the most widely used cross-sectional imaging modality in clinical practice worldwide. Left ventricular ejection fraction (LVEF) remains a cornerstone dynamic metric for diagnosing heart failure, stratifying risk, and guiding guideline-directed medical and device therapies. LVEF assessment is not currently possible from non-contrast, ungated CT scans. We aimed to develop an artificial intelligence model to predict LVEF from such scans.

METHODS AND MATERIALS

We considered patients from 9 different clinical sites within the large multi-site registry REFINE PET, which includes gated PET and low-dose, non-contrast CT attenuation correction scans (N = 19,542). LVEF was determined from the gated rest PET scans using standard clinical software. Deep learning models employing ungated CT were applied to quantify cardiac chamber volumes (left and right ventricles, left and right atria), aortic and pulmonary artery volumes, coronary artery calcium score and volume, and epicardial fat volume density. Clinical variables, including age, sex, heart rate, and systolic/diastolic blood pressure, were also incorporated. Subsequently, a boosting regressor was trained to predict the actual LVEF value from ungated CT scans and clinical variables using a leave-one-site-out (LOSO) strategy: 9-fold training on 8 sites and external validation in the 9 th site. External validation results were then concatenated.

RESULTS

The CT-predicted LVEF correlated with the gated PET LVEF (intraclass correlation coefficient = 0.80), with a mean absolute error of 5.7%. Out of 19,542 patients, 18,218 (93%) were correctly classified as LVEF < 40%. The positive predictive value was 80% and the negative predictive value was 96%. The area under the operating-characteristic curve for predicting PET LVEF < 40% was 0.95 [0.94 - 0.95].

CONCLUSION

LVEF can be predicted from non-contrast, ungated, low-dose chest CT, demonstrating strong correlation and high classification accuracy for a clinically relevant threshold in external validation.

CLINICAL RELEVANCE/APPLICATION

We show in rigorous external validation that LVEF can be accurately predicted from low-dose ungated chest CT. This novel approach enables opportunistic, non-invasive, and cost-effective identification of patients with reduced cardiac function.

R4-SSHN03-2 INTEGRATED DEEP LEARNING-RADIOMICS PROGNOSTIC MODEL AND HBV-DRIVEN T-CELL EXHAUSTION SYNERGISTICALLY REVEAL EBV-MEDIATED RISK IN NASOPHARYNGEAL CARCINOMA

Song Xinyang, MS (*Presenter*)

PURPOSE

We aimed to develop an integrated prognostic model combining deep learning (DL) features, handcrafted radiomics, and clinical variables to predict progression, metastasis, relapse, and survival in Nasopharyngeal carcinoma. Additionally, we explored whether HBV coinfection amplifies EBV-driven risk through immune exhaustion.

METHODS AND MATERIALS

Retrospectively analyzed 1,308 NPC patients. Pretreatment imaging yielded deep learning features via an EfficientNet-B0 network and handcrafted radiomic features selected by LASSO cross-validation. Clinical predictors and, pretreatment plasma EBV DNA load (dichotomized at an optimal threshold), HBV infection status , and an EBV×HBV interaction term. XGBoost models were trained for binary classification of progression, metastasis,dead, and relapse, while a custom XGBoost-Cox model predicted overall survival. Performance was assessed by area under the ROC curve (AUC) and Harrell's C-index using cross-validation. 16 patients , single-cell RNA sequencing of tumor-infiltrating immune cells profiled CD8+ T-cell exhaustion markers. Interaction and mediation analyses evaluated the combined effect of EBV and HBV and the role of liver injury (AST/ALT) as a mediator.

RESULTS

The integrated model achieved AUCs of 0.84-0.92 and C-indices of 0.82-0.90 across endpoints, outperforming single-modality models. Deep learning imaging features alone yielded highest single-modality AUCs (up to 0.91), compared to radiomics (0.59-0.65) and clinical variables (0.51-0.67). EBV×HBV interaction significantly amplified risk: for distant metastasis, interaction OR=5.09 ($p<0.01$) and HR=1.87 ($p<0.01$); for progression, OR=2.60 ($p=0.02$), HR=1.45 ($p=0.06$). HBV status alone had little effect in EBV-negative cases. In HBV?/EBV-high tumors, single-cell data showed CD8? T cells with high PD-1 and CTLA-4 expression, indicating pronounced immune exhaustion, with not mediation by liver injury($P>0.05$).

CONCLUSION

1.A multimodal XGBoost model that integrates deep learning-derived imaging features, radiomics, and clinical variables enables accurate prognostic prediction and risk stratification in nasopharyngeal carcinoma.2.In patients with high EBV viral load, HBV positivity identifies a high-risk subgroup characterized by immune exhaustion.

CLINICAL RELEVANCE/APPLICATION

Our integrated prognostic model combined with radiomics and deep learning, precisely identifies NPC patients at high risk of poor outcomes, especially highlighting that EBV stratification significantly guides prognosis in HBV-positive patients. Recognizing HBV-driven immune exhaustion as a key risk factor provides a rationale for tailored surveillance and targeted immune interventions (anti-PD-1/CTLA-4 therapies).

R4-SSHN03-4 RADIOMIC MODEL ASSOCIATED WITH TUMOR MICROENVIRONMENT PREDICTS IMMUNOTHERAPY RESPONSE AND PROGNOSIS IN PATIENTS WITH LOCOREGIONALLY ADVANCED NASOPHARYNGEAL CARCINOMA

Jie Sun (*Presenter*)
Bin Zhang, MD (*Abstract Co-Author*)
Shuixing Zhang (*Abstract Co-Author*)

PURPOSE

No robust biomarkers have been identified to predict the efficacy of programmed cell death protein 1 (PD-1) inhibitors in patients with locoregionally advanced nasopharyngeal carcinoma (LANPC). We aimed to develop radiomic models using pre-immunotherapy MRI to predict the response to PD-1 inhibitors and the patient prognosis

METHODS AND MATERIALS

This study included 246 LANPC patients (training cohort, n=117; external test cohort, n=129) from 10 centers. The best-performing machine learning classifier was employed to create the radiomic models. A combined model was constructed by integrating clinical and radiomic data. A radiomic interpretability study was performed with whole slide images (WSIs) stained with hematoxylin and eosin (H&E) and immunohistochemistry (IHC). 150 patient-level nuclear morphological features (NMF) and 12 cell spatial distribution features (CSDF) were extracted from WSIs. The correlation between the radiomic and pathological features was assessed using Spearman correlation analysis.

RESULTS

The radiomic model outperformed the clinical and combined models in predicting treatment response (AUC: 0.760 vs. 0.559 vs. 0.652). For overall survival estimation, the combined model performed comparably to the radiomic model but outperformed the clinical model (C-index: 0.858 vs. 0.812 vs. 0.664). Six treatment response-related radiomic features correlated with 50 H&E- (146 pairs, $|r|= 0.31-0.46$) and 2-26 IHC-derived NMF, particularly for CD45RO (69 pairs, $|r|= 0.31-0.48$), CD8 (84, $|r|= 0.30-0.59$), and PD-L1 (73, $|r|= 0.32-0.48$), and CD163 (53, $|r| = 0.32-0.59$). Eight prognostic radiomic features correlated with 11 H&E- (16 pairs, $|r|= 0.48-0.61$) and 2-31 IHC-derived NMF, particularly for PD-L1 (80 pairs, $|r|= 0.44-0.64$), CD45RO (65, $|r|= 0.42-0.67$), CD19 (35, $|r|= 0.44-0.58$), CD66b (61, $|r| = 0.42-0.67$), and FOXP3 (21, $|r| = 0.41-0.71$). In contrast, fewer CSDF features exhibited correlations with specific radiomic features.

CONCLUSION

The radiomic model and combined model are feasible in predicting immunotherapy response and outcomes in LANPC patients. The radiology-pathology correlation suggests a potential biological basis for the predictive models.

CLINICAL RELEVANCE/APPLICATION

We aimed to develop radiomic models using pre-immunotherapy MRI to predict the response to PD-1 inhibitors and the patient prognosis

R4-SSHN03-5 THE PROGNOSTIC VALUE OF INTRA- AND PERI-TUMORAL HABITAT ANALYSIS IN NASOPHARYNGEAL CARCINOMA: COMBINING IVIM AND ASL

Feier Ding, PhD (*Presenter*)
Fan Yang (*Abstract Co-Author*)
Hongmei Zhang, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the value of intravoxel incoherent motion (IVIM) and arterial spin labeling (ASL)-based habitat analysis of intra- and peri-tumoral regions for predicting overall survival (OS) and progression-free survival (PFS) in nasopharyngeal carcinoma (NPC).

METHODS AND MATERIALS

A total of 106 patients were prospectively included. Primary tumors were delineated on T2-weighted imaging, and three peritumoral regions (3, 5, and 10 mm) were automatically dilated and manually corrected according to the clinical tumor volume outlining criteria. The pure diffusion coefficient (D) and mean kurtosis (MK) maps of IVIM, and blood flow (BF) map of ASL were used for habitat analysis. Volume fraction and histogram parameters (Mean, Kurtosis and Skewness) were extracted for each subregion. Univariate and multivariate Cox analyses were used to construct intra- and peri-tumoral, Clinic, and combined models, which were assessed by the C-index. Nomogram, calibration curves, and Kaplan-Meier curves were also plotted.

RESULTS

The intra-tumoral subregion 4 was characterized by high D and low BF and MK value, representing the radiotherapy-resistant subregion and patients with treatment failure had higher proportion of subregion 4. Patients with treatment failure had higher intra-tumoral fraction of habitat 4 (f4). The Intra-score independently predicted OS (hazard radio [HR]: 1.023, P = 0.002) and PFS (HR: 1.028, P = 0.001). The 3 mm ring was selected as the representative region. The combined model showed the highest performance (C-index: 0.800 [OS] and 0.774 [PFS]) and outperformed the Clinic model (C-index: 0.673 [OS] and 0.652 [PFS], P = 0.03). Post-hoc subgroup analysis confirmed robustness.

CONCLUSION

Peri-tumoral regions provide valuable prognostic information. Combining IVIM-ASL-based habitat analysis offers a non-invasive approach to predicting treatment outcomes.

CLINICAL RELEVANCE/APPLICATION

Focus on tumor heterogeneity and the peri-tumoral microenvironment, our study utilized the IVIM-ASL-based habitat analysis to predict long-term survival outcomes in NPC.

Scott Tagawa, MD (*Abstract Co-Author*)

PURPOSE

Prostate-specific membrane antigen (PSMA) is a validated therapeutic target in mCRPC. 225Ac-J591, an alpha-emitting radionuclide linked to an anti-PSMA antibody, has been studied in early phase clinical trials. We evaluated baseline and post-treatment (12-week) PSMA PET metrics (SUVmax, SUVmean, and total tumor volume [TTV]) and their association with biochemical response (PSA50), overall survival (OS), and toxicity.

METHODS AND MATERIALS

Patients enrolled in phase I dose-escalation trials of 225Ac-J591 monotherapy (NCT03276572, NCT04506567; n=87) or combination therapy (with 177Lu-PSMA-I&T, NCT04886986, n=18; or pembrolizumab and androgen receptor (AR) inhibitors, NCT04946370, n=12) were included. 68Ga-PSMA-11 PET metrics were quantified using MIM Encore. Endpoints included PSA50, OS, and adverse events. Statistical analyses utilized univariate and multivariate logistic regression for PSA50, Cox regression for OS and Kruskal-Wallis and Wilcoxon rank sum tests for adverse events.

RESULTS

117 patients (median age 71; PSA 58 ng/mL) were included. Prior therapies: chemotherapy (62%), >1 AR inhibitor (53%), immunotherapy (42%), 177Lu-PSMA (28%), radium-223 (17%). Metastases: bone (88%), lymph nodes (63%), visceral (29%). High CALGB (Halabi) risk: 56%. Median baseline SUVmax, SUVmean, and TTV were 50 (31-85), 8.3 (5.7-11.8), and 308 (105-1066), respectively. Baseline SUVmean (OR 1.13, p=0.006) and SUVmax (OR 1.01, p=0.018) were associated with PSA50; only SUVmean remained significant in multivariable analysis (OR 1.11, p=0.023). Baseline SUVmean and TTV were associated with OS (HR 0.95, p=0.025; HR 1.000, p<0.001). TTV, prior chemotherapy, and CALGB risk remained significant in multivariable models (HR 1.00, p = 0.007, HR 1.45, p < 0.001, HR 1.84, p = 0.014). TTV reduction was associated with PSA50 (OR 1.31, p=0.015); SUV changes were not. High TTV was associated with greater myelosuppression (anemia Gr 3/4 vs 1/2 vs 0, p=0.041), but less xerostomia and nausea, suggesting a potential tumor sink effect.

CONCLUSION

Higher baseline PSMA PET metrics, including SUVmean, SUVmax, and TTV are associated with PSA50 response and survival in patients receiving antibody-delivered alpha emitter 225Ac. Higher TTV, yielding more radionuclide delivery to tumor (most commonly bone) is associated with higher grade myelosuppression. However, the tumor antigen sink effect may decrease exposure to other PSMA+ organs leading to less xerostomia and nausea.

CLINICAL RELEVANCE/APPLICATION

Quantitative PSMA PET biomarkers can help radiologists identify patients most likely to benefit from actinium-225-based radioligand therapy and anticipate potential hematologic toxicity, supporting more personalized imaging-guided care in advanced prostate cancer.

R4-STCE2-1 FROM SIGNAL TO SYMPTOM: NON-CONTRAST TRACTOGRAPHY AS A DIAGNOSTIC BIOMARKER IN SPINAL TUBERCULOSIS

Meemansa Jindal, MD (*Presenter*)
Alpana Manchanda, MBBS,MD (*Abstract Co-Author*)
Anjali Prakash, DMRD (*Abstract Co-Author*)
Sumit Sural (*Abstract Co-Author*)

PURPOSE

To evaluate diffusion tensor imaging (DTI) and tractography as a next-generation, non-contrast neuroimaging technique for assessing epidural extension and spinal canal compromise in spinal tuberculosis (TB), without the need for exogenous contrast agents.

METHODS AND MATERIALS

This cross-sectional study comprised of 30 patients (mean age: 33.7 ±16.7 years) with clinically suspected spinal tuberculosis above L1 (adults) and L3 (children) vertebral levels, who underwent 3.0T MRI with DTI before initiation of treatment. Neurological status was assessed using Japanese Orthopaedic Association (JOA) score. DTI parameters, including fractional anisotropy (FA), apparent diffusivity coefficient (ADC), radial diffusivity (RD) were measured at the site of cord compression and one level above it. Conventional MRI metrics including T2 hyperintensities and spinal canal encroachment (SCE) were also recorded. FT was qualitatively graded into types I-IV (types I,III: no disruption of fibers; types II, IV: with disruption of fibers). Statistical analysis included paired t-tests, Spearman correlation, ROC curve analysis, and Fisher's exact test.

RESULTS

Tractography provided visually intuitive evidence of white matter disruption, even in cases where conventional T2 imaging underestimated neural compromise. Epidural collections exerting mass effect were evident as tract thinning, displacement, or complete fiber loss, without the need for contrast enhancement. Fiber disruption, as seen in type II and IV FT patterns, was significantly associated with JOA<13 (OR 7.5, p=0.0318) and correlated negatively with JOA scores (?= -0.621, p<0.0013). DTI-derived metrics (notably reduced FA and elevated RD) reliably distinguished patients with demyelination and neurological deficit. Significant decrease in FA and increase in ADC and RD were seen at the site of compromise (p<0.001). ROC analysis identified the decrease in FA at the site of cord compromise, as the strongest predictor of neurological deficit (AUC=0.77, sensitivity 100%, specificity 62%).

CONCLUSION

Tractography offers an invaluable tool to visualize and quantify neural involvement and mass effect due to epidural collections, without gadolinium, which not only improves diagnostic efficacy and patient safety, but also aligns with sustainable imaging goals by reducing contrast-related costs and environmental burden.

CLINICAL RELEVANCE/APPLICATION

DTI offers quantitative insights of the spinal cord microstructure in spinal tuberculosis, thereby surpassing conventional MRI in predicting neurological deficit. Incorporating DTI-metrics and tractography in routine MR imaging may enhance prognostication and guide timely intervention.

R4-STCE2-2 FEASIBILITY AND IMAGE QUALITY ASSESSMENT OF ECG-LESS CORONARY CT ANGIOGRAPHY: A COMPARATIVE STUDY WITH CONVENTIONAL ECG-GATED CCTA

Seyedali Nabipoorashrafi, MD (*Presenter*)
Hamid Chalian, MD (*Abstract Co-Author*)
Sanaz Asadian, MD (*Abstract Co-Author*)
Farbod Khosravi, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the image quality of a novel ECG-less coronary CT angiography (CCTA) technique and compare it with conventional ECG-gated CCTA.

METHODS AND MATERIALS

Forty-three subjects with clinically indicated CCTA were prospectively enrolled. ECG-less CCTA was performed throughout the cardiac cycle using a wide-detector CT scanner with fast gantry rotation. Images were reconstructed across seven temporal subranges: one full phase, one ¾-phase, two 1/2-phases, and three ¼-phases. An additional 21 patients, matched for age, sex, BMI, and heart rate, who underwent conventional ECG-gated CCTA, served as the reference group for comparison. CCTA images were evaluated for image quality by two expert readers, using both qualitative (6-point Likert scale) and quantitative (signal-to-noise ratio, SNR) assessments. Evaluations were performed across key coronary vessels, including the left main coronary artery (LMCA), left anterior descending artery (LAD), left circumflex artery (LCX), and right coronary artery (RCA).

RESULTS

There were no significant differences in image quality between the full-phase, 3/4-phase, and 1/2-phase reconstructions and the conventional CCTA across multiple vascular locations, as assessed by both qualitative and quantitative metrics. Likewise, late 1/4-phase reconstructions did not show any significant changes in image quality compared to conventional CCTA, based on Likert scores and SNR for the LMCA. For instance, SNR in the LAD was 22.63 for conventional CCTA, 24.48 for full-phase, and 21.90 for the early ½-phase ($P > 0.05$). However, early and middle 1/4-phase reconstructions showed a statistically significant decline in quantitative and qualitative image quality compared to conventional CCTA ($P < 0.05$).

CONCLUSION

ECG-less CCTA with full-phase, 3/4-phase, and 1/2-phase reconstruction provides diagnostic image quality comparable to conventional ECG-gated CCTA.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the feasibility of ECG-less CCTA using modern wide-detector CT systems for routine clinical evaluation of the coronary arteries. Achieving reliable image quality without ECG leads may simplify protocols, reduce time of imaging, and expand usage CCTA.

R4-STCE2-3 DYNAMIC DIGITAL RADIOGRAPHY-DERIVED PERFUSION INDICES REFLECT STRUCTURAL AND FUNCTIONAL IMPAIRMENT IN COPD WITH EMPHYSEMA

Kojiro Ono (*Presenter*)
Masahiro Okada, MD, PhD (*Abstract Co-Author*)
Takashi Oki (*Abstract Co-Author*)
Yasuhiro Gon (*Abstract Co-Author*)

PURPOSE

Pulmonary emphysema in chronic obstructive pulmonary disease (COPD) leads to reduced alveolar perfusion and impaired gas exchange. While high-resolution CT (HRCT) quantifies structural changes, non-invasive functional assessment of perfusion remains limited. We aimed to evaluate whether perfusion imaging using dynamic digital radiography (DDR) could serve as a quantitative biomarker for emphysema severity.

METHODS AND MATERIALS

This prospective single-center study enrolled 40 patients with stable COPD who underwent DDR, HRCT, and spirometry. From breath-hold DDR sequences, pulmonary perfusion maps were generated, and low signal area (LSA) ratios were calculated based on histogram thresholds (5%, 10%, 15%). CT-derived low attenuation volume (%LAV) and Goddard scores were used as reference structural indices. Pulmonary vessel volume and lung function parameters, including DLco, FEV1, and FVC, were also assessed. Correlations and ROC analyses were performed.

RESULTS

DDR-derived LSA ratios significantly correlated with Goddard scores, with the strongest correlation observed for DDR-10%LSA ratio ($r = 0.672$, $p < 0.0001$). DDR-10%LSA ratio was also positively correlated with CT-%LAV ($r = 0.691$) and negatively with FEV1 %pred ($r = -0.459$) and DLco %pred ($r = -0.380$). In ROC analysis, DDR-10%LSA ratio demonstrated good diagnostic performance for detecting FEV1 %pred < 80% (AUC = 0.863) and DLco %pred < 80% (AUC = 0.794), comparable to CT-%LAV.

CONCLUSION

Pulmonary perfusion mapping using DDR provides a non-invasive method to quantify functional impairment in emphysema. DDR-10%LSA ratio reflects both structural and functional disease burden and may serve as a practical imaging biomarker and potential screening tool for COPD.

CLINICAL RELEVANCE/APPLICATION

DDR-derived pulmonary perfusion maps, particularly DDR-10%LSA ratio, provide a non-invasive, low-radiation marker that reflects both structural damage and perfusion impairment in COPD. This modality holds promise as a practical imaging biomarker for emphysema assessment and clinical decision-making in routine practice.

R5-STCE1-1 ARTERIAL SPIN LABELLING: A CONTRAST-FREE ALTERNATIVE TO DCE FOR PERFUSION EVALUATION OF PERIPHERAL ZONE PROSTATE LESIONS

Riccardo Valletta, MD (*Presenter*)
Vincenzo Vingiani, MD (*Abstract Co-Author*)
Bernardo Proner, MD (*Abstract Co-Author*)
Valentina Corato (*Abstract Co-Author*)
Armin Pycha (*Abstract Co-Author*)
Matteo Bonatti, MD (*Abstract Co-Author*)

PURPOSE

To assess the correlation between perfusion parameters derived from arterial spin labelling (ASL) and the enhancement pattern observed on dynamic contrast-enhanced (DCE) MRI in patients with histologically uncharacterized focal lesions in the peripheral prostate zone.

METHODS AND MATERIALS

This prospective, IRB-approved study included 52 patients with peripheral zone lesions =4 mm and PI-RADS scores =3. All patients underwent 3T MRI with a FAIR True-FISP ASL sequence. Lesions were classified as DCE-positive (DCE+) or DCE-negative (DCE-). Prostatic blood flow (PBF) was measured in both the lesion and adjacent healthy peripheral zone by two radiologists in consensus. PBF ratios (lesion/healthy tissue) were calculated. Statistical analysis included Mann-Whitney U and Wilcoxon tests, with ROC curve evaluation for diagnostic performance.

RESULTS

Lesions had a median diameter of 8 mm (IQR: 6-12 mm). DCE+ lesions (31/52, 60%) showed significantly higher PBF than DCE- lesions (39.17 vs. 19.04 ml/100g/min, $p = 0.0001$). Median PBF ratio was 2.6 (IQR: 1.92-3.15) for DCE+ and 1.09 (IQR: 0.77-1.27) for DCE- lesions ($p < 0.0001$). ROC analysis showed that PBF ratio effectively discriminated between DCE+ and DCE- lesions (AUC = 0.97; 95% CI: 0.87-0.99; $p < 0.0001$). A threshold of >1.66 yielded 86% sensitivity and 100% specificity.

CONCLUSION

ASL shows strong potential as a contrast-free technique for assessing vascularity in peripheral zone prostate lesions. It may serve as a reliable alternative to DCE in patients for whom contrast administration is contraindicated or undesirable.

CLINICAL RELEVANCE/APPLICATION

Arterial spin labelling (ASL) is a promising, contrast-free alternative to dynamic contrast-enhanced MRI for assessing perfusion in peripheral zone prostate lesions, demonstrating high diagnostic performance and potential clinical utility, especially in patients with contraindications to contrast agents.Arterial spin labelling (ASL) is a promising, contrast-free alternative to dynamic contrast-enhanced MRI for assessing perfusion in peripheral zone prostate lesions, demonstrating high diagnostic performance and potential clinical utility, especially in patients with contraindications to contrast agents. Originating from neuroradiological applications, this sequence could become a true alternative to intravenous administration of gadolinium-based chelates in prostate MRI.

R5-STCE1-2 EVALUATION OF RAT SCIATIC NERVE REGENERATION WITH MULTI-PARAMETRIC QUANTITATIVE ULTRASOUND

Yuanshan Wu, PhD (*Presenter*)
Sameer Shah (*Abstract Co-Author*)
Eric Y. Chang, MD (*Abstract Co-Author*)
Michael P. Andre, PhD (*Abstract Co-Author*)
Aiguo Han, PhD (*Abstract Co-Author*)
Victor Barrere, PhD (*Abstract Co-Author*)
Xin Cheng (*Abstract Co-Author*)
Kaixin Pan (*Abstract Co-Author*)

PURPOSE

To evaluate the efficacy of high-frequency quantitative ultrasound (qUS) and multi-parametric analysis in tracking peripheral nerve regeneration after acute and delayed repair of a rat sciatic nerve injury.

METHODS AND MATERIALS

Male Lewis rats underwent sciatic nerve procedures: sham injury (n=8), transection and immediate autograft repair (n=16), or transection and delayed isograft repair (n=14). High-frequency ultrasound imaging (UHF 48 probe, Vevo MD system) was performed at 1-, 2-, and 3-months post-surgery at proximal, intra-graft, and distal nerve locations (Figure A). Quantitative outcomes were extracted from the raw RF data and B mode images, including backscatter coefficient (BSC)-based measurements (iBSC and midband fitted slope), envelope statistics (homodyned K-distribution parameters kappa and mu), and textural/gray-level co-occurrence matrix (GLCM) parameters. A histological grading scheme was applied to classify trichrome-labeled axial nerve sections into low, medium, and high pathological severity. Multi-parametric assessment was performed using principal component analysis (PCA) with support vector machine (SVM) classification. Means were compared using two-way ANOVA and Tukey's Honestly Significant Difference post-hoc test.

RESULTS

qUS parameters showed significant differences among experimental groups at different time and scanning locations. For example, integrated BSC and K parameter revealed differences between sham versus repair groups at graft and distal locations at 1-month, but not 2- or 3-months (Figure B). To better reveal the relationships among qUS parameters, repair efficacy and nerve pathological state, each subject was reclassified based on histological grade (Figure C). Four parameters (mu, cross-

sectional area, normalized iBSC, midband fitted slope) significantly differentiated groups with varying pathological severity. PCA-SVM analysis achieved excellent classification performance (Figure D) with area under ROC curve of 0.90 for distinguishing healthy versus severely injured nerves.

CONCLUSION

Multi-parametric qUS effectively distinguished among experimental groups varying in pathological severity, despite high variability. The integration of multiple qUS parameters indicates that complementary qUS parameters provide information about nerve microstructural changes during early or delayed nerve repairs.

CLINICAL RELEVANCE/APPLICATION

This non-invasive multi-parametric qUS approach could serve as a valuable clinical tool for monitoring peripheral nerve degeneration or regeneration, potentially improving timing and effectiveness of therapeutic interventions before functional connectivity is established.

R5-STCE1-3 GADOLINIUM-FREE MR PERFUSION IMAGINGBASE ON GENERATIVE ADVERSARIAL NETWORKFOR PRIMARY INTRACRANIAL TUMOR DIAGNOSIS

Guoqi Lin, MS (*Presenter*)
Junhuan Hong (*Abstract Co-Author*)
Zhuoting Huang (*Abstract Co-Author*)
Dejun She (*Abstract Co-Author*)

PURPOSE

We aimed to develop a gadolinium-free neural network to generate synthesis CBV (sCBV) maps from non-contrast MRI sequences with diagnostic performance equivalent to DSC-PWI derived CBV maps.

METHODS AND MATERIALS

This multi-center retrospective study analyzed 1092 MRI examinations in the patients with primary intracranial tumors, comprising an internal cohort (train/validation/test: 438/126/63) and an external cohort (test: 465). TA-GAN was developed a tumor-aware generative adversarial network (TA-GAN) to synthesize sCBV maps from various non-contrast MRI sequence combinations. The quality of sCBV maps was evaluated using structural similarity index (SSIM), peak signal-to-noise ratio (PSNR). The diagnostic performance of the sCBV maps was compared against with real CBV (rCBV) maps using area under the curve (AUC), Net Reclassification Improvement and Integrated Discrimination Improvement

RESULTS

The TA-GAN, trained on T2-weighted and Diffusion-weighted non-contrast MRI sequences, achieved the best performance in generating sCBV maps, with a PSNR of 25.52 ± 1.33 dB and SSIM of 67.53 ± 5.88, indicating strong fidelity to original CBV maps. Neuroradiologists rated 95.34% of the synthesized maps as diagnostically acceptable, with a mean quality score of 2.70 ± 0.55 on a 4-point scale, demonstrating both high quality and clinical viability. When compared to rCBV maps, diagnostic performance for glioma grading was comparable. AUCs were 0.66 for sCBV maps vs. 0.61 for rCBV maps (P = 0.51) for all glioma cases, 0.57 vs. 0.60 (P = 0.57) for pediatric gliomas, and 0.73 vs. 0.68 (P = 0.56) for adult gliomas, with no significant differences. These results suggest that TA-GAN-generated sCBV maps offer diagnostic performance nearly equivalent to rCBV maps, making them a promising alternative, particularly when contrast agents are contraindicated or unavailable.

CONCLUSION

The proposed TA-GAN can synthesize sCBV maps from non-contrast MRI, demonstrating diagnostic equivalence to rCBV maps for primary intracranial tumor.

CLINICAL RELEVANCE/APPLICATION

1.TA-GAN generated high-quality sCBV maps from T2WI and DWI-ADC sequences, achieving the best performance among non-contrast inputs (PSNR = 25.52 ± 1.33 dB; SSIM = 67.53 ± 5.88).2.Neuroradiologists rated 95.3% of sCBV maps as clinically acceptable, with an average score of 2.70 (4-point scale), comparable to rCBV maps.3.sCBV maps showed comparable diagnostic performance to rCBV in glioma grading across all subgroups (i.e., pediatric and adult) (P > 0.5), supporting their clinical utility.

R6-SSBR11-1 PERFORMANCE METRICS OF SUPPLEMENTAL SCREENING ULTRASOUND IN WOMEN WITH DENSE BREASTS AS A FUNCTION OF AGE

Liane E. Philpotts, MD (*Presenter*)
Katie Jolin, MD (*Abstract Co-Author*)
Lawrence H. Staib, PhD (*Abstract Co-Author*)
Regina J. Hooley, MD (*Abstract Co-Author*)

PURPOSE

Screening ultrasound is a supplemental screening modality for women with dense breasts. Breast density and cancer rates vary with age. Recent federal legislation requires notification of breast density on mammography reports. Medicare has recently denied coverage for supplemental screening ultrasound in women with dense breasts. The purpose of this study is to determine the abnormal interpretation rates (AIR) and supplemental cancer detection of WBUS in conjunction with digital breast tomosynthesis (DBT) screening and compare with women not undergoing WBUS as a function of age.

METHODS AND MATERIALS

An IRB-approved, consent waived, retrospective search of our breast imaging electronic database (PenRad) was performed to identify women with dense breasts who underwent same day DBT and WBUS for a 3-year period (8/1/2020 - 7/31/2023). All exams were batch read (offline). The BI-RADS final assessment category for DBT and WBUS were independently and prospectively reported. The abnormal interpretation rate (AIR= BI-RADS 0,3,4,5) for each were determined. Additional cancers found on WBUS were reviewed. The data was compared for women less than 65 years old (<65) versus those 65 years or older. Statistics analysis was performed using R (Version 4.3.3, 2024, The R Foundation for Statistical Computing) using Fisher's exact test.

RESULTS

93,189 DBT screenings were performed over the study period. Of 60,152 screenings in women <65, 23,672 were dense (39%) and 14,702 (62%) underwent same day DBT+WBUS. Of 33,037 screenings in women 65 and older, 8444 were dense (26%) and 5837 (69%) underwent same day DBT+WBUS. The AIR for women <65 for DBT alone was 16.6% (1492/8970), significantly higher than women undergoing DBT+WBUS 12.5% (1841/14702) (DBT=6.8%, WBUS=7.8%) (p<0.0001). The AIR for women 65 and older undergoing DBT alone was 8.1% (211/2607) and not significantly different than for women undergoing DBT+WBUS, 9.1% (531/5837) (DBT=5.1%, WBUS=5.4%) (p=.13). 24 additional cancers (23 invasive, 1 DCIS) were detected by WBUS for a supplemental CDR of 1.1/1000. Half the cancers were in women <65 (12/14,702, CDR 0.8/1000) and half in women 65 and older (12/5837, CDR 2/1000) for a significantly higher PPV in women 65 and older (p=.024).

CONCLUSION

The metrics for DBT and WBUS varies with age. For women <65, the AIR is less with combined DBT+WBUS than DBT alone whereas for women 65 and older the AIR is similar. The PPV of WBUS in women 65 and older is significantly higher than for those <65.

CLINICAL RELEVANCE/APPLICATION

Combined DBT and WBUS in women 65 years and older with dense breasts has a similar AIR to DBT only, yet has a high PPV for supplemental cancers detected.

R6-SSBR11-2 REDUCING BENIGN BREAST BIOPSIES: REAL-WORLD EVALUATION OF AI-BASED ULTRASOUND DECISION SUPPORT AT TWO ACADEMIC CENTERS

Michael D. Fishman, MD (*Presenter*)
Leslie Lamb, MD, MSc (*Abstract Co-Author*)
Hana L. Haver, MD, MSc (*Abstract Co-Author*)
Catherine S. Giess, MD (*Abstract Co-Author*)

Leah H. Portnow, MD (*Abstract Co-Author*)
Mansi A. Saksena, MD (*Abstract Co-Author*)
Fatima Salah, MD, FRCR (*Abstract Co-Author*)
Gary X. Wang, MD,PhD (*Abstract Co-Author*)
Manisha Bahl, MD, MPH (*Abstract Co-Author*)

PURPOSE

Approximately 60-80% of breast biopsies performed in the United States result in benign pathology, highlighting a need for improved diagnostic specificity. The purpose of this study was to evaluate the potential impact of a Food and Drug Administration (FDA)-cleared artificial intelligence (AI)-based decision support tool for breast ultrasound in reducing unnecessary benign biopsies.

METHODS AND MATERIALS

This IRB-approved and HIPAA-compliant study was conducted at two academic medical centers in March and April 2025 following the clinical implementation of an FDA-cleared AI-based decision support tool for breast ultrasound interpretation (Koios DS; New York, NY). Fourteen breast imaging radiologists voluntarily participated by

prospectively documenting cases categorized as BI-RADS 4 with a recommendation for ultrasound-guided biopsy, along with the corresponding Koios DS output. All included cases underwent ultrasound-guided core biopsy, ultrasound-guided aspiration, or surgical excision, with final histopathology serving as the reference standard. Koios DS assessments were compared with biopsy results to evaluate the tool's diagnostic performance and its potential to reduce the benign biopsy rate.

RESULTS

Results : Over the study period, 107 ultrasound-guided biopsies were performed in 102 patients (mean age 55.4 years, range 27-92 years). Of these, 23.4% (25/107) yielded malignant pathology, while 76.6% (82/107) were benign. The AI algorithm classified 96.0% (24/25) of malignant lesions as BI-RADS 4 and 4.0% (1/25) as BI-RADS 3. The single malignancy assessed as BI-RADS 3 by the AI tool was a 6-mm grade 1 invasive ductal carcinoma in a 77-year-old woman. Among benign cases, the AI tool assigned 46.3% (38/82) as BI-RADS 2, 22.0% (18/82) as BI-RADS 3, and 31.7% (26/82) as BI-RADS 4. Retrospective application of the AI output to biopsy triage decisions suggests that 68.3% (95% CI 58.3-78.3%) of benign biopsies could have been avoided, with only one malignant case potentially missed.

CONCLUSION

The AI-based decision support tool demonstrates strong potential to reduce unnecessary biopsies of benign breast lesions - by nearly 70% - while maintaining high sensitivity for the detection of malignancies. These findings suggest that AI integration can enhance the specificity of breast ultrasound interpretation in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Integrating AI into breast ultrasound workflows may substantially decrease benign biopsy rates and enhance clinical decision-making.

R6-SSBR11-3 DEEP LEARNING WITH MULTI-MODAL ULTRASOUND FOR CLASSIFICATION OF METASTATIC AND REACTIVE AUXILIARY LYMPH NODES

Manali Saini, MEng, PhD (*Presenter*)
Tanin Adl Parvar, MD (*Abstract Co-Author*)
Mostafa Fatemi, PhD, PhD (*Abstract Co-Author*)
Azra Alizad, MD (*Abstract Co-Author*)

PURPOSE

To develop and validate a deep learning (DL) network based on multi-modal ultrasound (US) imaging for precisely classifying metastatic and non-metastatic axillary lymph nodes (ALNs) in breast cancer patients.

METHODS AND MATERIALS

The proposed method utilized tri-modal US imaging consisting of conventional ultrasound B-mode images with shear wave elastography (SWE) and color Doppler (CD) images to train a customized deep learning network for ALN classification. The proposed network comprised convolutional layers with mixed pooling, weighted sum mixed pooling and squeeze-and-excite attention mechanisms for the first time in the context of ALN classification. We validated the method using in-vivo dataset comprising tri-modal US images of ALNs of 174 breast cancer patients. This prospective study was conducted under an Institutional Review Board-approved and HIPPA-compliant protocol with signed informed consent obtained from each enrolled patient.

RESULTS

The proposed method achieved a classification accuracy (Acc) of 0. 93, a specificity (Sp) of 1. 00, an area under the ROC curve (AUC) of 0. 99, a sensitivity (Se) of 0. 90, an F-1 score of 0. 95 and an area under precision-recall curve (AUC p) of 0. 99. The use of multi-modal US with proposed deep learning model showed a classification accuracy of 0.93 compared to single-modal, B-mode, SWE, and CD US with accuracy of 0.81, 0.88, 0.84, respectively. The proposed mixed pooling and attention mechanisms considerably improved the specificity from 0. 96 and 0. 94 respectively to 1, and AUC from 0. 94 and 0. 93 respectively, to 0. 99. Further, the proposed network (Acc : 0.93) outperformed state-of-the-art deep learning networks (Acc : 0. 67- 0. 88) for ALN classification.

CONCLUSION

Integrating multi-modal ultrasound imaging with a novel customized deep learning network improves the classification of metastatic and reactive ALNs in breast cancer patients. Comparison studies indicate the proposed method's superiority over the state-of-the-art networks trained with our multi-modal US dataset. The finding shows its ability to accurately identify all metastatic ALN cases, reducing unnecessary biopsies.

CLINICAL RELEVANCE/APPLICATION

Integrating multimodal ultrasound with a customized deep learning model boosts diagnostic specificity, reduces unnecessary biopsies and accurately identifies metastatic axillary lymph node in breast cancer patients.

R6-SSBR11-4 PERFORMANCE OF STANDALONE AI IN AUTOMATED BREAST US FOR BREAST CANCER SCREENING: OUTCOMES ACROSS DIFFERENT APPLICATION STRATEGIES

Eun Kyung Park, MD, PhD (*Presenter*)
Jung Min Chang, MD (*Abstract Co-Author*)
Su Min Ha, MD (*Abstract Co-Author*)
Inyoung Youn, MD (*Abstract Co-Author*)
Mi-Ri Kwon, MD (*Abstract Co-Author*)
Heera Yoen, MD (*Abstract Co-Author*)
Su Hyun Lee, MD, PhD (*Abstract Co-Author*)
Jung-Oh Lee, MD, MSc (*Abstract Co-Author*)

PURPOSE

To evaluate diagnostic performance of supplemental automated breast US (ABUS) interpreted by a radiologist (ABUS-radiologist) or standalone AI (ABUS-AI) with digital mammography (DM), compared to DM alone in asymptomatic women, and to assess the effectiveness of DM and ABUS-AI based selective ABUS reading strategy for breast cancer screening.

METHODS AND MATERIALS

In this multicenter retrospective study, asymptomatic women who underwent DM and supplemental ABUS screening for breast cancer between March 2022 and March 2023 were analyzed. We evaluated the performance measures including cancer detection rate (CDR), sensitivity, specificity and abnormal interpretation rate (AIR) of DM alone, DM plus ABUS reading by radiologists (DM+ABUS-radiologist) and DM plus standalone ABUS-AI report (DM+ABUS-AI). We assessed performance gains and workload reduction by applying a selective ABUS reading strategy to DM- or ABUS-AI-recalled cases, compared to DM+ABUS radiologist reassessments.

RESULTS

Among 2275 screening examinations in 2275 women (mean age, 56.1 years±8.6 [SD]), 13 cancers were diagnosed (mean invasive tumor size, 1.1 cm). With DM alone, DM+ABUS-radiologist, and DM+ABUS-AI, the CDRs were 3.1 per 1000 screening examinations (7/2275, 95% CI: 1.2, 6.3), 4.4 per 1000 screening examinations (10/2275, 95% CI: 2.1, 8.1), and 4.8 per 1000 screening examinations (11/2275, 95% CI: 2.4, 8.6), respectively. The AIRs were 6.5% (149/2275, 95% CI: 5.6, 7.6), 16.7% (379/2275, 95% CI: 15.1, 18.3), and 16% (365/2275, 95% CI: 14.6, 17.6). Two cancers not detected by both DM and ABUS-AI was 0.4cm invasive ductal carcinoma and 1.8 cm mucinous carcinoma. Implementing a selective ABUS reading strategy—triaging cases with negative results on both DM and ABUS-AI as negative, and reviewing ABUS images only when either indicated a recall—resulted in an 84% workload reduction, with 1,910 cases triaged as negative and 365 recalled. With a selective ABUS reading strategy, AIR decreased to 7.6% (345/4450; P<.001) and specificity improved to 92.9% (4201/4524, P<.001), while CDR 4.8 per 1000(22/4550; P=.564) and sensitivity 84.6% (22/26; P=.559) were maintained, compared to DM+ABUS-radiologists reading.

CONCLUSION

The addition of ABUS, whether interpreted by a radiologist or AI, to DM resulted in a modest increase in the CDR but was accompanied by a substantial rise in the AIR. A screening strategy that uses standalone ABUS-AI and DM for initial triage, with subsequent radiologist review of ABUS images only in selected cases, appears feasible.

CLINICAL RELEVANCE/APPLICATION

Selective ABUS reading strategy based on DM and ABUS-AI results may decrease number of false positive recalls and reduce radiologists' workload without compromising cancer detection.

R6-SSBR11-5 ECHOGENIC RIND ASSOCIATED WITH SUSPICIOUS MASSES: WHAT CAN IT PREDICT?

Derek L. Nguyen, MD (*Presenter*)
Lars J. Grimm, MD (*Abstract Co-Author*)
Victoria A. Wells, MD (*Abstract Co-Author*)
Yekaterina S. Shpanskaya, MD (*Abstract Co-Author*)
Jay A. Baker, MD (*Abstract Co-Author*)

PURPOSE

In the upcoming BI-RADS Atlas, 6 th edition, "echogenic rind", defined as a thick echogenic band surrounding part or all of a mass, is a proposed new ultrasound associated feature. This study's purpose is to determine the pathological outcomes associated with an echogenic rind in the setting of a suspicious mass.

METHODS AND MATERIALS

This retrospective cohort study reviewed all BI-RADS 4 and 5 final assessment masses that underwent ultrasound-guided biopsy at our academic institution from 7/1/2022 to 12/12/2022. Following a training session, two fellowship-trained breast radiologists (experience: 9 and 25 years), who were blinded to all outcomes, independently reviewed pre-biopsy ultrasound images to identify the presence of an echogenic rind and record rind and mass size measurements. Echogenic rind presence was defined as surrounding at least 25% of the mass by both readers. Outcome data were analyzed using bivariable analysis.

RESULTS

There were 200 patients (mean age 53 years, range: 17-97) with 224 suspicious masses for analysis. The cohort's malignancy rate was 41% (91/224): 86% (78/91) IDC, 8% (8/91) ILC, 5% (5/91) DCIS. The incidence of an echogenic rind was 27% (60/224). Suspicious masses with a rind were more likely to be malignant (82%, 49/60) than masses without a rind (26%, 42/164), $p<0.001$. Of 91 malignancies, 54% (49/91) had a rind. Malignancies with a rind were more likely to be IDC (95%, 44/19 than malignancies without a rind (81%, 34/42), $p=0.02$. Malignancies with a rind were associated with luminal A molecular subtype (84%, 42/49) compared to malignancies without a rind (48%, 20/42), $p<0.01$. There was no association with nuclear grade or lymphovascular invasion. Compared to the final surgical pathology measurements, imaging underestimated the tumor size measurements. However, measurements were more accurate when the rind was included (mean underestimation 1 mm [r=0.90] for reader 1 and 3 mm [r=0.84] for reader 2) than when the rind was excluded (mean underestimation 3 mm [r=0.84] for reader 1 and 5 mm [r=0.89] for reader 2).

CONCLUSION

An echogenic rind is significantly associated with malignancy among suspicious masses. Malignant masses with a rind are more likely to be IDC and luminal A molecular subtype. Measurements including the rind will reduce imaging underestimation of tumor size.

CLINICAL RELEVANCE/APPLICATION

Radiologists should pay close attention when an echogenic rind is associated with a suspicious mass as this not only increases the likelihood of malignancy and ensures more accurate measurements, but also suggests a more favorable biological profile when the mass is malignant.

R6-SSBR11-6 COMPARISON OF INTEGRATED VS. SEQUENTIAL AI-CAD IN BREAST US: A PROSPECTIVE PILOT STUDY ON SCAN TIME, REPRODUCIBILITY, AND DIAGNOSTIC PERFORMANCE

Myoung Kyoung Kim (*Abstract Co-Author*)

PURPOSE

This study aimed to compare the scan time, reproducibility, and diagnostic performance of two types of artificial intelligence-based computer-aided diagnosis (AI-CAD) systems for breast ultrasound (US).

METHODS AND MATERIALS

We enrolled 242 patients who visited the breast imaging center for US examination between January and February 2025. Breast US was performed using two types of real-time AI-CAD: integrated AI-CAD (for lesion detection and diagnosis) and sequential AI-CAD (for these tasks separately). Scan time was compared in 97 patients by performing two breast US examinations using each AI-CAD in the same patient, with the order randomized. Reproducibility of each AI-CAD was assessed and compared in another 145 patients (215 lesions) by applying both systems to the same lesion twice, separately. Diagnostic performance of two AI-CAD was compared in all 242 patients in terms of sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and area under the receiver operating characteristic curve (AUC).

RESULTS

The scan time was significantly longer for sequential AI-CAD compared to integrated AI-CAD ($p < 0.001$), regardless of scan order. Reproducibility was excellent for both (integrated: 0.809, sequential: 0.83). Integrated AI-CAD had higher reproducibility in malignant (0.918 vs. 0.762) and non-mass lesions (1.0 vs. 0.75), while sequential AI-CAD performed better in mass lesions (0.837 vs. 0.792). Integrated AI-CAD showed higher sensitivity (87.6% vs. 76.9%) but lower specificity (74.2% vs. 90.0%). Sequential AI-CAD showed higher positive predictive value (PPV) (83.3% vs. 68.8%), while integrated AI-CAD had higher negative predictive value (NPV) (90.2% vs. 85.7%). AUC was not different. Both systems had lower accuracy in non-mass lesions, with no significant difference.

CONCLUSION

Sequential AI-CAD showed higher specificity, while integrated AI-CAD had better sensitivity and shorter scan time. Both systems had high reproducibility, with integrated AI-CAD excelling in malignant and non-mass lesions, and sequential AI-CAD in mass lesions.

CLINICAL RELEVANCE/APPLICATION

Understanding the strengths and trade-offs of integrated versus sequential AI-CAD systems can guide optimal selection based on clinical priorities. These insights support tailored application of AI-CAD systems in real-time breast US practice.

R6-SSCA11-2 PROGNOSTIC ROLE OF CT-DERIVED EXTRACELLULAR VOLUME FRACTION IN AORTIC STENOSIS PATIENTS UNDERGOING TRANSCATETHER AORTIC VALVE IMPLANTATION ACROSS FLOW-GRADIENT PATTERNS

Chiara Gnasso, MD (*Presenter*)
Davide Vignale (*Abstract Co-Author*)
Anna Palmisano, MD (*Abstract Co-Author*)
Antonio Esposito, MD (*Abstract Co-Author*)

PURPOSE

Aortic stenosis (AS) causes myocardial microstructural modifications, such as the development of interstitial fibrosis, which negatively impacts patients' prognosis. Echocardiography, the gold standard for AS phenotypization, recognizes different AS subtypes, with the low-flow low-gradient (LF-LG) having the worst prognosis; however, it can't investigate myocardial microstructural changes. CT -routinely performed for pre-procedural Transcatheter Aortic Valve Implantation (TAVI) planning- can be implemented with delayed scans to assess myocardial fibrosis as extracellular volume fraction (ECV) quantification. The prognostic role of ECV in these patients has already been demonstrated. However, it is unknown whether ECV delivers additional prognostic information compared to the echocardiographic flow-gradient pattern. Hence, the study aims to investigate the capacity of ECV to improve risk stratification on top of echocardiographic classification (LFLG AS vs high-gradient -HG-AS).

METHODS AND MATERIALS

In this single-center prospective observational study, consecutive patients undergoing TAVI (October 2020-March 2023) were enrolled and categorized as LF-LG or HG AS based on echocardiography. ECV was calculated from a 5-minute delayed CT-scan. After 1 year, a composite endpoint of death and heart failure hospitalization was collected.

RESULTS

392 patients were enrolled (median age 82 [78-86] years), and 87 reached the endpoint. ECV was higher in patients developing the outcome (30.2 [27.4-34.3] vs 28 [25.4-31.4] %, p<.001) and in those with LF-LG AS (31.9 [27.6-35.6] vs 28.0 [25.4-31.0]% in HG, p<0.001). At Kaplan-Meier analysis, the ECV cut-off of 29% and the flow-gradient pattern significantly differentiated patients reaching the endpoint (Log-rank p<0.001). Adding ECV to the echocardiographic classification improved risk stratification: patients with low ECV had the best prognosis regardless of the flow-gradient pattern, whereas LF-LG AS with high ECV had the worst (log-rank p<.001). The result was also confirmed after excluding patients with ECV>40%, who have a high suspicion of concomitant cardiac amyloidosis.

CONCLUSION

In patients with severe AS who are candidates for TAVI, ECV improves risk stratification in addition to the echocardiographic classification.

CLINICAL RELEVANCE/APPLICATION

The results of this study enlighten the pivotal role of interstitial fibrosis in determining AS patients' prognosis and remark the importance of CT as a tool to non-invasively quantify fibrosis in TAVI candidates, which could become the target of anti-remodeling and anti-fibrotic therapies. Hence, CT is emerging as a powerful tool for patient selection, treatment monitoring, and personalized management of AS.

R6-SSCA11-3 CALCIUM VOLUME VS. DENSITY IN PREDICTING MAJOR ADVERSE CARDIAC EVENTS: AN ANALYSIS ON CALCIUM CHARACTERISTICS ON CAC CT

Brian Zhou, BS (*Presenter*)
Gabrielle Gershon, BS (*Abstract Co-Author*)
Jaret Barr (*Abstract Co-Author*)
Carlo N. De Cecco, MD, PhD (*Abstract Co-Author*)
Marly Van Assen, MSc, PhD (*Abstract Co-Author*)

PURPOSE

The purpose of this study is to evaluate the effect of calcium density and volume concordance and discordance in predicting major adverse cardiac events (MACE) outcomes.

METHODS AND MATERIALS

This retrospective study included coronary artery calcium (CAC) CT imaging from 2,647 individuals without known cardiac disease, not taking lipid-lowering medications, between 2010-2023 who had positive CAC and a minimum of a 3-year follow up period. Cardiac CT images were analyzed using a previously validated convolutional neural network to derive CAC scores (Agatston), CAC average density and CAC total volume. MACE events were determined from ICD9, ICD10, and CPT codes. The population was divided into four mutually exclusive groups based on characteristics of their calcium: high density and high volume, high density and low volume, low density and high volume, and low density and low volume. The high/low thresholds were made based on median calcium density median volume of the 2,647 patients. Time-to-event outcomes were analyzed using Kaplan-Meier curves to estimate cumulative incidence, with group comparisons performed using the log-rank test.

RESULTS

Out of the 2,647 patients, the mean age was 60 years, 9% (235) patients were Black, and 36% (949) patients were female with a mean follow-up time of 5.5 years. The total number of patients who experienced MACE was 263 (9%). The median total CAC score was 46 (IQR 8 - 198). The median calcium density was 195 HU (IQR 165 - 224), and the median calcium volume was 49 mm3 (IQR 14 - 187 mm3). From these medians, 37% (978) of patients were classified in the high density and high

volume group, 13% (345) of patients were classified in the high density and low volume group, 13% (345) of patients were classified in the low density and high volume group, and 37% (979) of patients were classified in the low density and low volume group. The MACE cumulative incidence curves demonstrated that groups with high calcium volume- regardless of density- had significantly higher rates of MACE compared to low volume groups (p<0.001).

CONCLUSION

This finding suggests that calcium volume is the primary driver of MACE prediction. Discordance in CAC volume and density showed no added predictive value.

CLINICAL RELEVANCE/APPLICATION

These findings suggest that calcium volume is the main driver of MACE risk in a patient population not on lipid lowering medication.

R6-SSCA11-4 DEEP LEARNING-DRIVEN VIRTUAL CORONARY CT ANGIOGRAPHY FOR QUANTITATIVE STENOSIS EVALUATION

Weifeng Guo, MD (*Presenter*)
Shan Yang (*Abstract Co-Author*)
Zuopeng Tan (*Abstract Co-Author*)
Longfei Zhao (*Abstract Co-Author*)
Qiqi Xu, MBBS, MMEd (*Abstract Co-Author*)
Zicheng Zhao (*Abstract Co-Author*)
Hang Jin, PhD (*Abstract Co-Author*)
Mengsu Zeng, PhD (*Abstract Co-Author*)

PURPOSE

To develop a deep learning algorithm for synthesizing virtual Coronary CT Angiography (CCTA) images from Non-Contrast CT (NCCT) images, and evaluate its feasibility for quantitative stenosis analysis.

METHODS AND MATERIALS

In this single-center prospective study (June 2024-February 2025), we enrolled 560 patients (mean age ± SD: 61.8 ± 11.6 years; 288 males and 272 females) with paired NCCT and CCTA acquired in the same session. Each image pair underwent registration to ensure anatomical alignment. The dataset was split into 398 for the training set, 50 for the validation set, and 112 for the internal test set. A pix2pix conditional generative adversarial network (GAN) was trained to generate virtual CCTA from NCCT. Coronary stenosis in virtual CCTA was assessed using a clinical algorithm, with real CCTA stenosis, labeled by an experienced radiologist, as the reference standard. Then, the stenosis of virtual CCTA was quantitatively evaluated by two metrics: sensitivity and specificity for detecting stenosis (>50% or >75% threshold) across three main coronary branches: left anterior descending (LAD), left circumflex (LCX), and right coronary artery (RCA).

RESULTS

Of 336 main coronary branches in 112 test patients, 243 were analyzed after excluding 93 with severe artifacts or stents. Real CCTA identified 23 branches with >50% stenosis and 9 with >75% stenosis by radiologist. Virtual CCTA achieved 87% sensitivity (20/23; 95% CI: 71-100%) and 84% specificity (185/220; 95% CI: 79-89%) at the >50% threshold, and 78% sensitivity (7/9; 95% CI: 50-100%) and 90% specificity (211/234; 95% CI: 86-94%) at the >75% threshold.

CONCLUSION

A pix2pix GAN effectively synthesized virtual CCTA from NCCT, demonstrating high concordance with real CCTA for stenosis quantification.

CLINICAL RELEVANCE/APPLICATION

Virtual CCTA offers a potential alternative to contrast-enhanced CCTA, reducing iodinated contrast media use and mitigating stenosis overestimation from calcified plaque blooming artifacts.

R6-SSCA11-5 NORMAL-RESOLUTION VS. SUPER-RESOLUTION DEEP LEARNING RECONSTRUCTION FOR DIAGNOSIS OF FUNCTIONALLY SIGNIFICANT CORONARY STENOSIS USING CARDIAC CT

Nobuo Tomizawa, MD, PhD (*Presenter*)
Ruiheng Fan (*Abstract Co-Author*)
Yui Nozaki, MD (*Abstract Co-Author*)
Yuko Kawaguchi (*Abstract Co-Author*)
Takamura Kazuhisa (*Abstract Co-Author*)
Tadao Aikawa (*Abstract Co-Author*)
Makoto Hiki (*Abstract Co-Author*)
Shinichiro Fujimoto (*Abstract Co-Author*)
Tohru Minamino (*Abstract Co-Author*)
Koji Kamagata, MD, PhD (*Abstract Co-Author*)

PURPOSE

The purpose of this study was to compare the diagnostic performance of CT fractional flow reserve (CT-FFR) using normal-resolution deep learning reconstruction (NR-DLR) and super-resolution deep learning reconstruction (SR-DLR) for the detection of functionally significant stenosis as assessed by invasive FFR.

METHODS AND MATERIALS

This single-center retrospective study included 129 patients (mean age, 69 years ± 11 [SD]; 94 men) who underwent coronary CT angiography followed by invasive FFR between February 2022 and March 2025. Computational fluid dynamics was used to calculate the CT-FFR using NR-DLR and SR-DLR images. Per-vessel diagnostic performance for detecting FFR =0.80 on coronary angiography was compared by analyzing receiver operating characteristic (ROC) curves.

RESULTS

Of the 157 vessels evaluated, 70 vessels (45%) had functionally significant stenosis. The median (interquartile range) calcium score was 421 (142-896). CT-FFR calculated with NR-DLR (mean difference: -0.056; 95% CI: -0.086, -0.026; p <0.001) overestimated ischemia compared to invasive FFR. However, there was no evidence of a difference between CT-FFR and invasive FFR using SR-DLR (mean difference: -0.017; 95% CI: -0.037, 0.004; p = 0.11). The area under the ROC curve for the diagnosis of functionally significant stenosis was higher for SR-DLR (0.85; 95% CI: 0.78, 0.91) than for NR-DLR (0.72; 95% CI: 0.64, 0.81; p = 0.002). The diagnostic accuracy of SR-DLR (85%; 134 of 157 vessels; 95% CI: 79, 90) was better than that of NR-DLR (74%; 116 of 157 vessels; 95% CI: 66, 81; p <0.001). The sensitivity of SR-DLR (87%; 61 of 70 vessels; 95% CI: 77, 94) was also better than that of NR-DLR (70%; 49 of 70 vessels; 95% CI: 58, 80; p = 0.002). There was no evidence of a difference in specificity between SR-DLR (84%; 73 of 87 vessels; 95% CI: 74, 91) and NR-DLR (77%; 67 of 87 vessels; 95% CI: 67, 85; p = 0.08).

CONCLUSION

SR-DLR improved the diagnostic performance of CT-FFR over NR-DLR in detecting functionally significant stenosis as assessed by invasive FFR.

CLINICAL RELEVANCE/APPLICATION

SR-DLR would increase the feasibility of coronary CT angiography by improving the accuracy of computational fluid dynamics to detect functionally significant stenosis compared to NR-DLR.

R6-SSCA11-6 CORONARY CT ANGIOGRAPHY TO DIAGNOSE HEALING OF SPONTANEOUS CORONARY ARTERY DISSECTION: COMPARISON WITH INVASIVE ANGIOGRAPHY

Tristan Thorben Demmert (*Presenter*)
Konstantin Klambauer, MD (*Abstract Co-Author*)
Lukas Jakob Moser (*Abstract Co-Author*)
Victor Mergen, MD (*Abstract Co-Author*)
Andrea Biondo (*Abstract Co-Author*)
Alexander Gotschy (*Abstract Co-Author*)
Robert Manka (*Abstract Co-Author*)
Matthias Eberhard, MD (*Abstract Co-Author*)
Hatem Alkadhi, MD (*Abstract Co-Author*)

PURPOSE

Spontaneous coronary artery dissection (SCAD) is a rare, underdiagnosed cause of myocardial infarction (MI), especially in younger women without traditional cardiovascular risk factors. Diagnosis and follow-up imaging is usually performed with invasive coronary angiography (ICA). This study aimed to evaluate the accuracy of coronary computed tomography angiography (CCTA) to diagnose healing of SCAD.

METHODS AND MATERIALS

In this prospective single-center study, 20 patients with 24 coronary segments showing SCAD underwent ICA and CCTA both in the acute phase (median time after symptom onset to CCTA 3 days) and during follow-up (median time 106 days). SCAD was classified at follow-up CCTA as healed or non-healed using ICA as the reference standard.

RESULTS

At follow-up, ICA showed healing in 19 (79%) and no healing in 5 (21%) SCAD lesions. CCTA had an overall accuracy of 79% in diagnosing SCAD healing, with a positive predictive value of 100%. 20 (83%) Segments were evaluable with CCTA and were significantly larger (median 2 mm, IQR, 1.5-2.7 mm) than those (n=4, 17%) being non-evaluable (median 1 mm, IQR, 0.8-1.2 mm, $p<0.001$), and vessel size with a median above 1.5 mm (IQR, 1.3-2.5 mm) showed a higher accuracy to diagnose SCAD healing with CCTA than below (median 0.7mm, IQR, 0.7-0.8mm, $p<0.001$).

CONCLUSION

Our study indicates that CCTA can serve as a non-invasive alternative to ICA for monitoring SCAD healing, especially in proximal and mid-coronary lesions with diameters >1.5 mm.

CLINICAL RELEVANCE/APPLICATION

The high positive predictive value of CCTA and its safety profile support the use in follow-up imaging to reduce the risks associated with repeated invasive angiography.

R6-SSCH10-3 THORACIC INJURY PATTERNS IN FEMALE PATIENTS REPORTING INTIMATE PARTNER VIOLENCE COMPARED TO MATCHED CONTROLS

Emma Blassel, MD (*Presenter*)

PURPOSE

To investigate thoracic injury patterns, including fractures, visceral, pleural, and soft tissue injuries, among female survivors of intimate partner violence (IPV) compared to age- and race-matched female trauma controls, aiming to identify imaging features that may aid in recognizing IPV.

METHODS AND MATERIALS

This retrospective case-control study analyzed radiology reports from female IPV patients (n = 1,183) and matched controls (n = 4,105) at a large academic center (2013-2018). Thoracic injuries, including rib, clavicle, scapula, sternum, thoracic spine fractures; visceral injuries (lung, aorta, mediastinum); pleural injuries (effusion, hemothorax); and soft tissue injuries were compared between groups. Adjusted incidence rate ratios (IRRs) and p-values were calculated using Poisson regression, and injury distributions were summarized as percentages.

RESULTS

Cases showed significantly more thoracic injuries (11%, 131/1,183) compared to controls (3.5%, 145/4,105; IRR 4.02, $p < 0.0001$). Among thoracic injuries, fractures (rib, clavicle, scapula, sternum) accounted for 51% in cases vs. 63% in controls (IRR 3.24, $p < 0.0001$); thoracic spine fractures, 29% vs. 25% (IRR 4.78, $p < 0.0001$); visceral injuries, 7% vs. 2% (IRR 12.84, $p = 0.0002$); pleural injuries, 7% vs. 9% (IRR 3.00, $p = 0.01$); soft tissue injuries, 5% vs. 1% (IRR 1.20, $p = 0.003$). Among rib fractures, IPV cases showed significantly more posterior (27.7% vs. 24.5%), lower (67.9% vs. 74.2%), and bilateral (21% vs. 9%) fractures (all $p < 0.01$). Demographic analysis showed significantly more IPV cases aged 30-39 and fewer aged 60-69 ($p < 0.01$), as well as significantly more Black IPV patients and fewer White IPV patients ($p < 0.01$) compared to controls.

CONCLUSION

Female IPV survivors demonstrate distinctive thoracic injury patterns, including higher rates of rib and thoracic spine fractures, elevated visceral and pleural injury rates, and a greater overall thoracic injury burden compared to controls. Recognizing these patterns on imaging may help radiologists raise suspicion for IPV, improving early identification and clinical intervention.

CLINICAL RELEVANCE/APPLICATION

This study highlights distinct thoracic injury patterns in female survivors of intimate partner violence (IPV), which differ significantly from matched trauma controls. Recognizing these imaging features, particularly patterns of rib and thoracic spine fractures along with associated visceral and pleural injuries, can help radiologists raise suspicion for IPV. Early identification through imaging may support timely clinical intervention, improve patient outcomes, and enhance multidisciplinary care for a vulnerable population.

R6-SSCH10-4 PREDICTION OF PULMONARY FUNCTION FOR PATIENTS WITH PULMONARY TUBERCULOSIS VIA A MULTI-TASK LEARNING MODEL

Joon Park, MD (*Presenter*)
Namkug Kim, PhD (*Abstract Co-Author*)
Young Ae Kang (*Abstract Co-Author*)
Sei Won Lee (*Abstract Co-Author*)
Jimin Kwon, MD (*Abstract Co-Author*)
Hyunjung Park, MSc (*Abstract Co-Author*)
Seonggyu Jegal (*Abstract Co-Author*)
Jongjun Won, BS (*Abstract Co-Author*)

PURPOSE

Pulmonary function testing (PFT) is essential for assessing respiratory impairment, but conducting these tests in patients with tuberculosis (TB) can be technically challenging due to severe structural abnormalities and limited availability in underdeveloped countries. To develop a multi-task deep learning (MTL) model that predicts PFT values as a main task, with lung and TB lesion segmentation and reconstruction as sub-tasks in simple chest X-ray.

METHODS AND MATERIALS

We implemented a MTL model based on the Inception-ResNet-v2 architecture, with an auxiliary injection layer to incorporate patient height and gender. The model was trained using 32,627 paired chest X-rays (posteroanterior or anteroposterior) and PFT within 6 months collected between 2013 and 2022. Patients were included if they had a diagnosis of active TB, TB sequelae, or radiologic reports of chest computed tomography (CT) or radiography (CXR) containing TB-related terms (e.g., tuberculosis, tuberculoma, and tubercle). A temporally independent test set of the most recent 3,262 cases was used for evaluation. Remaining 29,365 cases were randomly split into train and valid dataset with 8:1 ratio.

RESULTS

On the test set, the MTL model achieved Pearson correlation coefficients of 0.876 (99% CI: 0.863-0.888) for forced vital capacity (FVC) and 0.800 (99% CI: 0.781-0.818) for forced expiratory volume in one second (FEV1). The mean absolute error (MAE, mean ± SD) for FVC prediction by the MTL model was 0.340 ± 0.285 L, which was significantly lower than that of the single-task model (0.352 ± 0.299 L; paired t -test: $t = -2.543$, $p < 0.01$). In contrast, for FEV1 prediction, the difference in MAE

between the MTL model (0.329 ± 0.279 L) and the single-task model (0.331 ± 0.286 L) was not statistically significant (t = -0.374, p = 0.71). Bland-Altman analysis of the MTL model showed 95% limits of agreement (LoA) of -0.859 L to 0.880 L (mean = 0.010 L) for FVC and -0.895 L to 0.783 L (mean = -0.056 L) for FEV1. In the subgroup of patients with FVC values below the test-set mean of 2.93 L, the model showed reduced error variability, with LoAs of -0.902 L to 0.681 L (mean = -0.111 L) for FVC and -0.851 L to 0.621 L (mean = -0.115 L) for FEV1, suggesting stable predictive performance in individuals with reduced lung function.

CONCLUSION

The proposed MTL model accurately predicts FVC and FEV 1 in TB-affected patients, including those with significant architectural abnormalities of the lungs.

CLINICAL RELEVANCE/APPLICATION

This model could be used as accurate, non-invasive estimation of pulmonary function from chest X-rays in tuberculosis patients, especially where resources are limited or structural abnormalities hinder conventional testing.

R6-SSCH10-5 CORRELATION BETWEEN THE THICKENING FRACTION AND DIAPHRAGMATIC EXCURSION MEASURED BY ULTRASOUND WITH THE REINTUBATION FREQUENCY IN MECHANICALLY VENTILATED PATIENTS, IN ADDITION TO THE UNIFIED CLINICAL STANDARD PROTOCOL

Lourdes Marcos Ramirez, MD (*Presenter*)
Antonio Augusto Gordillo Moscoso (*Abstract Co-Author*)
GABRIELA VIRGINIA ESCUDERO LOURDES (*Abstract Co-Author*)
Jorge Guillermo Reyes Vaca (*Abstract Co-Author*)

PURPOSE

The study aims to assess the correlation between diaphragmatic thickening fraction and excursion, measured by ultrasound, with reintubation frequency in mechanically ventilated patients, and the impact of a unified clinical protocol. Secondary objectives include evaluating intubation duration and patient pathologies.

METHODS AND MATERIALS

A prospective cohort study with a 48-hour follow-up was conducted in the ICU in San Luis Potosí, Mexico. The study included intubated patients over 18 who met criteria for a spontaneous breathing trial, with consent. Approved by the ethics committee. The dependent variable was "unsuccessful extubation," defined as reintubation within 48 hours. Independent variables included diaphragmatic thickening fraction, excursion, sex, age, days intubated, and underlying pathology. Data quality was ensured through concordance between the principal investigator and physicians using tests like Lin's correlation coefficient, Bland-Altman limits, and ICC III. The sampling method was non-probabilistic, consecutive by quota, with sample size calculated using logistic regression.

RESULTS

A total of 120 patients were recruited from November 2022-2023, aged 18-80 years (average 39.5 years), with 59 women (49.4%) and 61 men (50.8%). No significant differences in age or sex were found between reintubated and non-reintubated groups. A significant difference in diaphragmatic thickening rates was found (p = 0.04), with reintubated patients showing 35.2% (+9.6 SD) vs. 32.1% (+15.7 SD) in non-reintubated patients. Five patients (4.1%) were reintubated with varying reintubation times. Logistic regression showed no correlation between diaphragmatic thickening fraction or excursion and reintubation (p = 0.36 and p = 0.19). The most common conditions were traumatic brain injury (32.5%) and septic shock (23.3%). Forty percent of reintubated patients had thickening fractions below 30%. Diaphragmatic excursion values were low, with reintubated patients showing 0.38 cm vs. 0.70 cm in non-reintubated patients. The lower reintubation rate (4.1%) may be due to standardized weaning protocols. High inter-observer reliability was achieved, with ICC values of 0.99 for both thickening and excursion.

CONCLUSION

No correlation was found between diaphragmatic thickening fraction and excursion, with reintubation failure. This difference may be due to the specific characteristics of the studied population.

CLINICAL RELEVANCE/APPLICATION

A. Standardizing clinical criteria for ventilatory weaning and reintubation likely contributed to the lower reintubation failure rate, which is recommended. B. Diaphragmatic excursion may be the most reliable ultrasound parameter for assessing diaphragmatic weakness.

R6-SSCH10-6 THE PROGNOSTIC ROLE OF PREOPERATIVE SUBCUTANEOUS ADIPOSE TISSUE MEASUREMENT IN LUNG TRANSPLANTATION

Shuangxiang Lin, MSc (*Presenter*)
Xinhong Wang (*Abstract Co-Author*)
Jianzhong Sun, MMed (*Abstract Co-Author*)
Jiaxing Wu (*Abstract Co-Author*)

PURPOSE

This study aimed to determine whether the cross-sectional area of subcutaneous adipose tissue (SAT) at the T12 vertebral level, measured on routine preoperative chest CT, is associated with post-transplant outcomes in lung transplant recipients.

METHODS AND MATERIALS

We retrospectively analyzed lung transplant recipients who underwent routine pretransplant chest CT. Subcutaneous adipose tissue area at the T12 level was measured on axial CT slices using standardized tissue attenuation thresholds. The primary outcome was post-transplant overall survival. Secondary outcomes included length of stay, need for ventilator support, grade III primary graft dysfunction (PGD), and acute rejection. Associations between T12 SAT and outcomes were assessed using univariable and multivariable Cox regression models. Predictive performance was evaluated using ROC curves, net reclassification improvement (NRI), and integrated discrimination improvement (IDI).

RESULTS

This study enrolled 280 lung transplant recipients (237 males, median age 56.5 ± 11.5 years). Among them, 29 (10.4%) experienced the primary outcome, and 75 (26.8%) developed secondary outcomes. Lower T12 SAT area was independently associated with poorer post-transplant survival. Kaplan-Meier analysis indicated that lower SAT levels were linked to reduced survival (log-rank P < 0.01). Incorporating SAT into the predictive model improved discrimination, increasing the AUC from 0.65 to 0.75, with sensitivity of 66%, and specificity of 73% (NRI = 0.82, P < 0.01). For secondary outcomes, adding SAT increased the AUC from 0.59 to 0.85, with sensitivity of 75%, and specificity of 86% (NRI = 0.37, P = 0.01).

CONCLUSION

Preoperative SAT measurement at the T12 level is a valuable, non-invasive biomarker for predicting adverse outcomes in lung transplant recipients. This metric can aid in patient risk stratification and optimize pre- and post-transplant management.

CLINICAL RELEVANCE/APPLICATION

CT-derived SAT at T12 is a rapid, non-invasive marker of frailty and nutritional status in lung transplant candidates. Incorporating SAT into preoperative assessment helps identify high-risk patients for targeted interventions, potentially improving post-transplant outcomes.

R6-SSGI17-1 VALUE OF COMBINED DYNAMIC HISTOGRAM PARAMETERS AND CLINICAL INDICATORS FOR PREOPERATIVE DIFFERENTIATION BETWEEN ATYPICAL HEPATOCELLULAR CARCINOMA AND INTRAHEPATIC CHOLANGIOCARCINOMA

Haisheng Wang (*Presenter*)
Wei Ren (*Abstract Co-Author*)
Yuhao Li (*Abstract Co-Author*)
Yamin Sun (*Abstract Co-Author*)
Hong Liu (*Abstract Co-Author*)

PURPOSE

To investigate the diagnostic value of combining whole-tumor dynamic histogram parameters (T1-weighted precontrast, arterial phase, and arterial phase-T1 difference) with clinical indicators for differentiating atypical hepatocellular carcinoma (HCC) from intrahepatic cholangiocarcinoma (ICC).

METHODS AND MATERIALS

We retrospectively analyzed preoperative clinical, pathological, and MRI data from 91 patients with HCC and ICC. Whole-tumor histogram parameters (including mean, standard deviation, coefficient of variation, entropy, skewness, and percentile values [1% to 99%]) were extracted from T1-weighted precontrast and arterial-phase images using histogram analysis software, with arterial phase-T1 difference parameters calculated. Differences in histogram parameters between atypical HCC and ICC were analyzed using independent t-test, Mann-Whitney U test, or χ^2 test. Statistically significant parameters were incorporated into multivariable logistic regression to construct clinical, histogram, and combined predictive models. Diagnostic performance was evaluated using ROC curves, with AUC differences compared via DeLong test ($P < 0.05$).

RESULTS

Significant differences were observed in T1pre-standard deviation, arterial phase-entropy, AP-T1 difference-5%, alpha-fetoprotein (AFP), and carbohydrate antigen 19-9 (CA-199) between atypical HCC and ICC ($P < 0.05$). Among individual parameters, AP-T1 difference-5% demonstrated the highest predictive value (AUC = 0.890). The combined model incorporating T1pre-standard deviation, arterial phase-entropy, AP-T1 difference-5%, AFP, and CA-199 achieved superior diagnostic performance (AUC = 0.947, sensitivity = 94.2%, specificity = 84.6%), significantly outperforming the histogram model (AUC = 0.933), clinical model (AUC = 0.800), and individual histogram parameters (AUC range: 0.746-0.890). The DeLong test confirmed statistically significant differences between the combined model and other models/parameters ($P < 0.05$).

CONCLUSION

The whole-tumor dynamic histogram model exhibits high diagnostic efficacy for preoperative differentiation of atypical HCC from ICC. When combined with clinical parameters, its discriminative power is further enhanced, suggesting its potential as a non-invasive preoperative diagnostic tool.

CLINICAL RELEVANCE/APPLICATION

Accurate preoperative differentiation between HCC and ICC significantly impacts clinical treatment decisions. The combination of whole-tumor dynamic histogram parameters (T1pre-standard deviation, arterial phase-entropy, and AP-T1 difference-5%) with clinical indicators (particularly AFP) provides optimal diagnostic performance for distinguishing these tumor types preoperatively.

R6-SSGI17-2 THE AI ADVANTAGE: DEEP LEARNING DETECTS CHOLANGIOCARCINOMA BEFORE VISIBLE MASS FORMATION

Yashbir Singh, PhD, MEng (*Presenter*)

PURPOSE

To evaluate whether a deep learning approach can improve detection of early-stage perihilar cholangiocarcinoma (pCCA) in primary sclerosing cholangitis (PSC) patients compared to conventional radiological assessment.

METHODS AND MATERIALS

We conducted a multicenter study including 398 PSC patients who underwent contrast-enhanced MRI. Patients were divided into training (n=150, with 64 pCCA cases) and test cohorts (n=248, with 166 pCCA cases). All pCCA patients were early-stage and eligible for liver transplantation. We trained a 3D DenseNet-121 deep learning model on MRI scans and compared its diagnostic performance against expert abdominal radiologists' interpretations in the independent test cohort.

RESULTS

The deep learning model achieved significantly higher sensitivity for pCCA detection (87.9% vs. 50.0%, $p<0.001$) with good specificity (84.1% vs. 100.0%, $p<0.001$) compared to radiologists. The model excelled particularly in detecting non-mass forming pCCA (sensitivity 91.6% vs. 50.6%, $p<0.001$) and non-invasive neoplasia (sensitivity 100.0% vs. 38.2%). When applied to earlier MRIs (up to 14 months before diagnosis) in 39 patients, the model maintained reasonable sensitivity (75.0%) and specificity (71.6%).

CONCLUSION

The deep learning approach substantially outperforms expert radiological assessment in detecting early-stage pCCA in PSC patients, particularly in challenging cases without distinct mass formation.

CLINICAL RELEVANCE/APPLICATION

This AI model represents a promising advance in PSC management by enabling earlier detection of pCCA when curative therapy is still possible. Implementation could facilitate more timely intervention, potentially improving survival outcomes and reducing the variability in care delivery across different centers.

R6-SSGI17-3 SEEING THE INVISIBLE: AI ALGORITHM SURPASSES RADIOLOGISTS IN DETECTING EARLY BILIARY CANCER

Yashbir Singh, PhD, MEng (*Presenter*)

PURPOSE

To develop and evaluate a deep learning model that analyzes magnetic resonance imaging (MRI) for early detection of perihilar cholangiocarcinoma (pCCA) in patients with primary sclerosing cholangitis (PSC), and to compare its diagnostic performance with expert radiologists.

METHODS AND MATERIALS

In this multicenter, retrospective cohort study, we analyzed contrast-enhanced MRI scans from 398 adults with large duct PSC (training cohort: n=150; test cohort: n=248). All patients with pCCA (n=230) had early-stage cancer and were eligible for liver transplantation. A 3D DenseNet-121 deep learning model was trained using MRI images from the training cohort with 5-fold cross-validation. The model's performance was assessed in a separate test cohort and compared with expert radiologists' interpretations.

RESULTS

In the test cohort, the deep learning model demonstrated superior performance compared to expert radiologists with sensitivity of 87.9% versus 50.0% ($p<0.001$), specificity of 84.1% versus 100.0% ($p<0.001$), and area under receiving operating curve of 86.0% versus 75.0% ($p<0.001$). The model maintained high sensitivity (91.6%) and specificity (84.1%) even when a mass was absent, unlike radiologists whose sensitivity dropped significantly in these cases.

CONCLUSION

The 3D DenseNet-121 model effectively detects early-stage pCCA in PSC patients, outperforming expert radiologists particularly in cases without obvious mass formation. This automated approach significantly reduces the number of missed cancer cases while maintaining good specificity.

CLINICAL RELEVANCE/APPLICATION

This deep learning model addresses a critical unmet need in PSC management by improving early detection of pCCA when curative interventions are still possible. Implementation could standardize care across centers, reduce diagnostic variability, and potentially improve patient outcomes by enabling earlier intervention.

R6-SSGI17-5 EVALUATING THE PERFORMANCE OF MULTIPHASIC CT IN ASSESSING BILIARY TUMOR EXTENT AND RESECTABILITY IN PERIHILAR CHOLANGIOCARCINOMA: INSIGHTS FROM A WESTERN POPULATION

Tae-Hyung Kim, MD, MS (*Presenter*)
Wyanne Law, MD (*Abstract Co-Author*)
Maria El Homsi, MD (*Abstract Co-Author*)
Pamela A. Argiriadi, MD (*Abstract Co-Author*)
Ally Rosen, MD (*Abstract Co-Author*)
Jonathan Kuten (*Abstract Co-Author*)
Danielle Silliman (*Abstract Co-Author*)
Lee Rodriguez (*Abstract Co-Author*)
William Jarnagin (*Abstract Co-Author*)
Richard Kinh Gian Do, MD, PhD (*Abstract Co-Author*)

PURPOSE

Accurate preoperative assessment of perihilar cholangiocarcinoma on CT is essential for curative resection. This study evaluates the performance of multiphasic CT in determining longitudinal tumor extent in a Western population, based on the Korean Society of Abdominal Radiology (KSAR) consensus recommendations.

METHODS AND MATERIALS

This retrospective study included patients with perihilar cholangiocarcinoma who underwent multiphasic CT prior to surgery between 2007 and 2021. Only patients who underwent curative-intent surgery without neoadjuvant therapy were included, those with suboptimal preoperative imaging were excluded. Four abdominal radiologists independently evaluated longitudinal tumor extent, hepatic artery and/or portal vein involvement, and resectability, following the KSAR guidelines. Patients were categorized into two cohorts: no prior biliary intervention at the time of CT (cohort A) and those with biliary intervention (cohort B). Diagnostic performance was measured by sensitivity, specificity, accuracy, and the area under the receiver operating characteristic curve (AUC). Pathology, including assessment of biliary extent and resection margins (R0 vs R1 [microscopic tumor]/R2 [macroscopic tumor]), served as the gold standard for all patients. Interreader agreement was assessed using kappa statistics. Consensus reading was defined as at least two radiologists having identical assessment.

RESULTS

A total of 97 patients (median age: 68 years, range: 29-87; 65 male) were included with 41 patients in cohort A and 56 in cohort B. Accuracy in assessing biliary tumor extent was comparable between cohorts, ranging from 0.61 to 0.89 in cohort A and 0.61 to 0.92 in cohort B. In consensus readings, sensitivity in cohort A ranged from 0.50 to 1.0, while specificity ranged from 0.75 to 1.00. In cohort B, sensitivity decreased (0.50 to 0.63); specificity remained high (0.82 to 1.00). AUC values for predicting R0 resection (n=59 patients) was between 0.48 and 0.53 among the four radiologists. Interreader agreement showed kappa values of 0.23-0.35 for biliary tumor extent, 0.07-0.41 for hepatic artery involvement, and 0.21-0.50 for portal vein involvement.

CONCLUSION

Multiphasic CT demonstrates high specificity and moderate sensitivity in assessing biliary tumor extent in perihilar cholangiocarcinoma. However, accurately predicting R0 resection remains challenging, highlighting the need for further optimization of imaging techniques and guidelines in assessing resectability.

CLINICAL RELEVANCE/APPLICATION

CT shows high specificity but limited sensitivity for tumor extent; R0 prediction remains challenging in perihilar cholangiocarcinoma.

R6-SSGI17-6 DEVELOPMENT AND VALIDATION OF A SEVERITY SCORING SYSTEM FOR PROGNOSTICATION OF RECURRENT PYOGENIC CHOLANGITIS

Riya Fathima, MBBS (*Presenter*)
Thara Pratap, DMRD,DMD (*Abstract Co-Author*)

PURPOSE

To develop a semi-quantitative imaging-based scoring system for recurrent pyogenic on CT/ MRCP for prognostication of recurrent pyogenic cholangitis. To correlate the total score with the disease severity. To analyze the association between each parameters in the scoring system individually with the severity of recurrent pyogenic cholangitis.

METHODS AND MATERIALS

Imaging based multiparametric scoring system is developed comprising of 10 parameters and a maximum score of 20. Single-center study with a sample size of 50 subjects. Retrospective analysis is made by correlating the total score with the clinical recurrence rate, number and frequency of stenting required (ERCP/PTBD) and requirement of surgical resections (resection/ hepaticojejunostomy) over a period of 5 years using spearman correlation done. ROC curve was analyzed to determine the cut-off score for predicting severe disease.

RESULTS

Most of the cases we studied had a predilection for left lobe of liver. Statistically significant association observed between location of ductal calculi and disease severity. Hilar stones and stones > 10 mm were symptomatic and required endotherapy in majority of the cases. A score more than 8 was associated with severe disease.

CONCLUSION

A score more than 8 was associated with severe disease. Statistically significant association observed between location of ductal calculi and disease severity. Hilar stones and stones > 10 mm were symptomatic and required endotherapy in majority of the cases.

CLINICAL RELEVANCE/APPLICATION

1. Aid in standardizing recurrent pyogenic cholangitis reporting. 2. Help predict the prognosis and hence in counselling the patient3. Guide interventions.4. Lay the groundwork for AI-based imaging analysis of recurrent pyogenic cholangitis.

PURPOSE

To evaluate the real-world impact of quantitative cine MRI motility scoring on radiologists' interpretation of ileal Crohn's disease (CD), and to compare its influence with standard post-contrast gadolinium-enhanced MRE.

METHODS AND MATERIALS

Ten NHS radiologists across six UK sites identified CD patients with baseline and 1-year follow-up MR-enterography including T1-weighted post-contrast and small bowel motility sequences. For both timepoints, GIQuant (Motilent) motility scores were derived by placing ROIs in the most active SB segments . Radiologists interpreted the MREs at both time points initially using standard MRE sequences, excluding GIQuant scores and post-contrast imaging, and graded overall and segmental disease status on a 5-point scale (transmural remission to stable disease). Radiologists were then asked to enter the GIQuant scores and update their assessment. The process was then repeated after examining IV gadolinium enhanced images. Radiologists also rated the impact of both IV gadolinium and motility scores on their diagnostic confidence using a 7-point scale: no-impact, confidence-decreased/increased, or diagnosis-changed to active/inactive.

RESULTS

277 CD patients (60% male, mean age 35±13 yrs) scanned between Nov 2017- Aug 2024 were included. 202 had T1-weighted post-IV contrast imaging. GIQuant scores led to changes in overall disease status impression (e.g., stable disease to progression of disease) in 55 (19.8%). Radiologists stated that GIQuant scores increased their diagnostic confidence in 120 (43%) cases. After examining the change in GIQuant scores, radiologists reclassified patient status (e.g., active to inactive or vice-versa) in 40/277 (14.4%) cases. In comparison, unmasking to post-contrast IV Gad images led to changes in overall disease status impression in just 13/202 patients (6%) compared to 42/202 (20%) for GIQuant scores. Radiologists reclassified patient status (e.g., active to inactive) in just 11 (5.3%) after unmasking to post-contrast IV Gad images, compared with 33 (16.3%) for GIQuant scores. Radiologists indicated that post-contrast IV Gad imaging impacted diagnosis or confidence in 52% of cases compared to 63% for GIQuant scores.

CONCLUSION

GIQuant motility scores have more impact on radiologists' assessment of disease response on MRE compared to IV gadolinium, and improves diagnostic confidence in 43% of patients suggesting it utility as a biomarker of disease activity and response and as a potential replacement for routine IV gadolinium administration.

CLINICAL RELEVANCE/APPLICATION

These findings support incorporating GIQuant into MRE protocols as a quantitative biomarker of small bowel disease activity and a potential alternative to contrast-enhanced imaging.

R6-SSGI18-5 DIAGNOSTIC ACCURACY OF COMPUTED TOMOGRAPHY (CT) FOR IDENTIFYING SURGICAL ISCHEMIA AND NECROSIS IN SMALL BOWEL OBSTRUCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Paul Le Corre, MD (*Presenter*)
Maelle Youinou (*Abstract Co-Author*)
Gilles Chatellier (*Abstract Co-Author*)
Marc Zins, MD (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic performance of CT signs in detecting surgical bowel ischemia and necrosis in patients with small bowel obstruction (SBO).

METHODS AND MATERIALS

A systematic search was conducted in MEDLINE, Embase and Web of Science databases up to April 30, 2024. We included studies evaluating the diagnostic performance of CT signs to identify small bowel ischemia and/or necrosis in patients with SBO using surgical and pathological examination or an uneventful clinical outcome as the reference standard. The QUASDAS-2 tool was used to assess the risk of bias and applicability. Meta-analyses were performed using a bivariate random-effects model and summary receiver operating characteristic (SROC) curve models for CT signs reported in at least 3 studies and involving more than 100 patients.

RESULTS

Nineteen studies (2453 patients, 1741 with surgery, 861 with ischemia and 343 with necrosis) were included. Meta-analyses evaluated 14 signs for small bowel ischemia and 11 signs for small bowel necrosis.For ischemia, the following CT findings demonstrated the highest pooled specificity and positive likelihood ratio (PLR): reduced bowel wall enhancement (specificity: 92% [95% CI: 88%, 95%], PLR: 7.45 [95% CI: 4.22, 12.30]); diffuse mesenteric haziness (specificity: 89% [95% CI: 85%, 92%], PLR: 6.78 [95% CI: 4.84, 9.29]); closed-loop mechanism (specificity: 85% [95% CI: 76%, 91%], PLR: 5.25 [95% CI: 3.05, 8.58]); increased unenhanced bowel wall attenuation (specificity: 98 % [95% CI: 95%, 99%], PLR: 19.30 [95% CI: 7.24, 42.10]).For small bowel necrosis, only one sign had significant performances: increased unenhanced bowel wall attenuation (specificity: 92% [95% CI: 72%, 98%], PLR: 8.75 [95% CI: 2.20, 26]). Other CT findings had lower diagnostic performance. No single CT finding showed a negative likelihood ratio large enough to rule out ischemia or necrosis.

CONCLUSION

Reduced bowel wall enhancement, diffuse mesenteric haziness, and a closed-loop configuration are key CT findings supporting the diagnosis of bowel ischemia in patients with SBO. Increased unenhanced bowel wall attenuation is informative for diagnosing both ischemia and necrosis, with high specificity. Study limitations included retrospective design and a focus on surgical cohorts.

CLINICAL RELEVANCE/APPLICATION

Increased unenhanced bowel wall attenuation is a highly specific CT indicator for diagnosing small bowel ischemia and necrosis in the setting of small bowel obstruction.

R6-SSGI18-6 ASSOCIATION OF CT-BASED OPPORTUNISTIC BIOMARKERS WITH DISEASE PROGRESSION IN CROHN'S DISEASE

Shravya Srinivas Rao, MD (*Presenter*)
Soumyadeep Ghosh, MBBS, MD (*Abstract Co-Author*)
Nikitha Uma Baskaran, MBBS (*Abstract Co-Author*)
Ashwin Ananthakrishnan (*Abstract Co-Author*)
Avinash R. Kambadakone, MD, FRCR (*Abstract Co-Author*)

PURPOSE

Crohn's disease (CD) presents with varying severity, from mild to severe. Approximately 20-30% of patients have mild disease without perianal, stricturing, or penetrating complications and often do not require surgery, hospitalization, or long-term therapy. However, a subset of this may progress to severe, penetrating disease. Identifying such high-risk mild CD patients is crucial to guide treatment decisions and balance the risks of disease progression against overtreatment. The aim of this study is to evaluate whether CT-based opportunistic biomarkers, including visceral and subcutaneous fat quantification, muscle volume and vertebral cortical bone density, can predict disease progression in patients with mild CD.

METHODS AND MATERIALS

This IRB-approved retrospective study, 1151 CT scans from 901 patients with CD between 2004 and 2019 were screened. After applying inclusion criteria—age >18, baseline contrast-enhanced CT without features of severe disease, no prior use of immunosuppressants or surgery, and at least one clinical or radiological follow-up >5 years, 184 patients were included. CT-based opportunistic biomarkers were semi-automatically measured at the L1 vertebral level, including visceral fat (area, volume, and attenuation), subcutaneous fat (area, volume, and attenuation), muscle volume, and vertebral cortical bone density. Patients were stratified into two groups: stable mild CD and high-risk mild CD (those who progressed). Disease progression was defined by initiation of immunomodulators/biologics, surgical resection, or development of penetrating, stricturing, or extraintestinal complications. Statistical comparisons between groups were performed.

RESULTS

On 5-year follow-up, 34% of patients (n=63/184) progressed to severe disease. Predictors of disease progression included higher visceral fat attenuation (-76.8 ± 11.0 vs. -86.8 ± 63.1 HU; p = 0.019) and lower vertebral cortical bone density area (2.9 ± 1.2 vs. 3.8 ± 1.9 cm^2; p = 0.01). No significant differences were observed in weight, BMI, fat area/volume (visceral or subcutaneous), or muscle volume between the groups.

CONCLUSION

In patients with mild Crohn's disease, higher visceral fat density, which may reflect underlying inflammation, and lower vertebral cortical bone density on baseline CT were significantly associated with progression to severe disease.

CLINICAL RELEVANCE/APPLICATION

CT-based opportunistic imaging biomarkers may help identify high-risk patients with mild CD, guiding earlier therapeutic intervention.

R6-SSGU07-1 ENHANCED DETECTION OF PROSTATE CANCER LESIONS ON BIPARAMETRIC MRI USING ARTIFICIAL INTELLIGENCE: A MULTICENTER, FULLY-CROSSED, MULTI-READER MULTI-CASE TRIAL

Jiule Ding (*Presenter*)
Zhaoyu Xing (*Abstract Co-Author*)
Jie Chen (*Abstract Co-Author*)
Pan Liang (*Abstract Co-Author*)
Yingwei Qiu (*Abstract Co-Author*)
Yang Zhang (*Abstract Co-Author*)
Wang Qian (*Abstract Co-Author*)
Ruonan Cheng (*Abstract Co-Author*)
Wei Xing, MD (*Abstract Co-Author*)

PURPOSE

To assess artificial intelligence (AI)’s added value in detecting prostate cancer lesions on MRI by comparing radiologists’ performance with and without AI assistance.

METHODS AND MATERIALS

A fully-crossed multi-reader multi-case clinical trial was conducted across three institutions with ten non-expert radiologists. Biparametric MRI cases comprising T2WI, apparent diffusion coefficient, and diffusion weighted images were retrospectively collected. Three reading modes were evaluated: AI alone, radiologists alone (unaided) and radiologists with AI (aided). Aided and unaided readings were compared using the Dorfman-Berbaum-Metz method. Reference standards were established by senior radiologists based on annotation results and pathological reports. Performance was quantified via sensitivity, specificity, and area under the alternative free-response receiver operating characteristic curve (AFROC-AUC).

RESULTS

Among 407 eligible male patients (69.5 ± 9.3 years), aided reading significantly improved lesion-level sensitivity from 67.3% (95% CI: 58.8%, 75.8%) to 85.5% (95% CI: 81.3%, 89.7%), with a substantial increase of 18.2% (95% CI: 10.7%, 25.7%, $p < 0.001$). Case-level specificity slightly increased from 75.9% (95% CI: 68.7%, 83.1%) to 79.5% (95% CI: 74.1%, 84.8%), demonstrating non-inferiority ($p < 0.001$). AFROC-AUC was also significantly higher for aided reading (0.869 vs 0.761, $p < 0.001$). AI alone achieved robust performance, with lesion-level sensitivity of 88.4% (95% CI: 84.0%, 92.0%) and case-level specificity of 77.8% (95% CI: 71.5%, 83.3%). Subgroup analysis revealed improved detection for lesions with smaller size and lower PI-RADS scores.

CONCLUSION

AI-aided reading significantly enhances lesion detection compared to unaided reading, while AI alone also demonstrates high diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

A deep learning-based artificial intelligence system (uAI-prostateMR) significantly enhances the diagnostic performance of non-expert radiologists in detecting prostate cancer lesions on biparametric MRI. This system improves lesion-level sensitivity, particularly for smaller lesions and lower PI-RADS scores, while maintaining specificity, thereby demonstrating its value as an adjunct diagnostic tool.

PURPOSE

We hypothesize that a state-of-the-art artificial intelligence (AI) system, trained using tens of thousands of exams across several sites worldwide, is diagnostically interchangeable to the radiology readings for clinically significant prostate cancer detection on MRI, in population-based screening and primary diagnostic settings across an external global, multiethnic population.

METHODS AND MATERIALS

In this intercontinental, confirmatory study, we include a retrospective cohort of >21,900 MRI examinations (>20,750 patients; >45 cities in 22 countries) to train and externally validate the PI-CAI-2 model, i.e., an efficient, next-generation iteration of the state-of-the-art AI system that was developed for detecting Gleason grade group = 2 prostate cancer on MRI during the PI-CAI study. Of these examinations, >20,000 cases (>18,850 patients; 26 cities in 14 countries) from two EU Horizon projects (ProCAncer-I, COMFORT) and 12 independent centers based in Europe, North America, Asia and Africa, are used for training and internal testing. Additionally, >1900 cases (>1900 patients; >19 external cities in 12 countries) from population-based screening (STHLM3-MRI, IP1-PROSTAGRAM trials) and primary diagnostic settings (PRIME trial) based in Europe, North and South Americas, Asia and Australia, are used for external testing. Primary endpoint is the proportion of AI-based assessments in agreement with the standard of care diagnoses (i.e., clinical assessments made by expert uropathologists on histopathology, if available, or at least two expert urogenital radiologists in consensus; with access to patient history and peer consultation) within the external testing cohorts. Our statistical analysis plan is prespecified with a hypothesis of diagnostic interchangeability to radiology readings at the PI-RADS = 3 cut-off, considering a margin of 0.05 and reader estimates derived from the PI-CAI observer study (62 radiologists reading 400 cases). Secondary measures comprise the area under the receiver operating characteristic curve (AUROC) of the AI system stratified by imaging quality, patient age and patient ethnicity to identify any underlying biases.

RESULTS

All data has been collected, analysis will be ready for presentation.

CONCLUSION

All data has been collected, analysis will be ready for presentation.

CLINICAL RELEVANCE/APPLICATION

AI systems can alleviate the increasing workload, prevent overdiagnosis, and reduce the dependence on expert radiologists across the diagnostic pathway of prostate cancer. If deemed robust across population shifts, geographical sites, acquisition protocols and the disease spectrum, such systems have the potential to improve workflow efficiency, patient outcomes and healthcare equity at scale.

R6-SSGU07-3 PERFORMANCE EVALUATION OF ARTIFICIAL INTELLIGENCE MODEL FOR AUTOMATED DETECTION AND CHARACTERIZATION OF ADRENAL LESIONS ON NON-CONTRAST CT

Ryuya Yoshida (*Presenter*)
Yasunori Nagayama, MD (*Abstract Co-Author*)
Naoki Kobayashi, MD (*Abstract Co-Author*)
Takumi Osaki (*Abstract Co-Author*)
SOICHIRO ISHIUCHI (*Abstract Co-Author*)
Mahiro Akao (*Abstract Co-Author*)
Yasuaki IGARASHI (*Abstract Co-Author*)
Takeshi Nakaura, MD (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of a commercially available artificial intelligence (AI) model for detection and characterization of adrenal lesions on non-contrast CT.

METHODS AND MATERIALS

This retrospective study included 502 patients with 592 adrenal lesions who underwent non-contrast CT and had available diagnostic reference standards. A commercial AI model enabling automated detection and attenuation measurement of adrenal lesions was applied. Lesion detection performance was assessed per gland (1004 glands) using sensitivity, specificity, and accuracy. Attenuation values were measured manually by radiologists using 2D ROI placement and automatically by the AI model using 3D volumetric segmentation. Agreement between manual and automated attenuation measurements was evaluated using Pearson correlation, Wilcoxon signed-rank test, and Bland-Altman analysis. To evaluate performance in differentiating benign from malignant lesions, the area under the ROC curve (AUC), as well as sensitivity and specificity at the <10 HU threshold, were compared between manual and AI-derived measurements.

RESULTS

Adrenal lesions were detected by the AI model with sensitivity 90.5% (536/592), specificity 96.1% (396/412), and accuracy 92.8% (932/1004). Manual and AI-derived attenuation values showed strong correlation (r=0.846), although the AI model tended to underestimate attenuation compared to manual measurements (mean bias -6.2 HU; 15.0±18.0 vs 8.8±16.7 HU; p<0.001). The AUC for differentiating benign from malignant lesions was not significantly different between manual and AI-derived measurements (0.938 vs 0.941, p=0.813). When applying the <10 HU threshold, sensitivity and specificity were 49.5% and 100% for manual measurements, and 72.0% and 95.6% for AI-based measurements, respectively.

CONCLUSION

AI model demonstrated high accuracy in detecting adrenal lesions and provided attenuation values that were strongly correlated with manual radiologist measurements. Diagnostic performance for differentiating benign from malignant lesions was comparable to radiologist manual assessment, with improved sensitivity and slightly reduced specificity at the conventional 10 HU threshold.

CLINICAL RELEVANCE/APPLICATION

Use of the AI model for non-contrast CT supports accurate detection and characterization of adrenal lesions, potentially facilitating appropriate clinical management in patients with adrenal incidentaloma.

R6-SSGU07-4 DEEP LEARNING FOR DETECTION AND SEGMENTATION OF FOCAL LESIONS IN THE UPPER URINARY TRACT ON MPMRI

Rile Nai, MD (*Presenter*)
Zuqiang Xi (*Abstract Co-Author*)
Kexin Wang (*Abstract Co-Author*)
Xiaodong Zhang, MD, PhD (*Abstract Co-Author*)
Xiaoying Wang, MD (*Abstract Co-Author*)

PURPOSE

Multiparametric MRI (mpMRI) exhibits high specificity for the evaluation of focal lesions in the upper urinary tract; however, the complex anatomical structures and heterogeneous nature of lesions can limit its detection sensitivity. To address this challenge, we propose a deep learning-based approach designed to enhance lesion detection sensitivity within this anatomically intricate region.

METHODS AND MATERIALS

The model was developed using retrospective T2-weighted imaging (T2WI), diffusion-weighted imaging (DWI), and apparent diffusion coefficient (ADC) datasets, which were acquired from 390 patients (comprising 475 imaging series and 1,401 sequences). It was subsequently validated on an independent hold-out set of 955 patients (involving 1,285 series and 3,700 sequences). Lesion contours were initially delineated by a junior radiologist and then meticulously reviewed and confirmed by a senior specialist to ensure precision and reliability. The development dataset was stratified into three subsets: training (n = 311), validation (n = 37), and internal testing (n = 42). A 3D V-Net architecture was utilized for model training and optimization. Segmentation performance was rigorously assessed using the Dice similarity coefficient (DSC), volume similarity (VS), and Hausdorff distance (HD). Furthermore, lesion-level and patient-level detection capabilities were comprehensively evaluated in the hold-out test set.

RESULTS

The segmentation models for DWI, ADC, and T2WI sequences in the test set achieved excellent lesion detection performance with 100% sensitivity, demonstrating robust segmentation accuracy: DSC values ranging from 0.808 to 0.856, HD values between 3.62 mm and 4.29 mm, and VS metrics from 0.875 to 0.939. In the hold-out test set, the lesion-level sensitivity for detecting lesions with a maximum diameter of =2 cm was 73.6% for DWI, 77.8% for ADC, and 76.0% for T2WI. At the patient level, the models exhibited sensitivities of 81.1% (DWI), 80.8% (ADC), and 74.3% (T2WI).

CONCLUSION

The 3D V-Net-based deep learning model exhibited promising capabilities for the detection and segmentation of focal space-occupying lesions in the upper urinary tract, offering clinically relevant decision support to optimize diagnostic workflows.

CLINICAL RELEVANCE/APPLICATION

This study represents the inaugural validation of AI for detecting focal lesions in the upper urinary tract using mpMRI. It lays a methodological foundation for the development of AI-assisted diagnostic systems within the field of urological radiology practice.

R6-SSGU07-6 PERFORMANCE OF A FULLY AUTOMATED MACHINE LEARNING ADRENAL MASS DETECTION TOOL IN OVER 60,000 CONSECUTIVE ABDOMINAL CT EXAMS

Borna E. Dabiri, MD, PhD (*Presenter*)
Jay B. Patel, PhD (*Abstract Co-Author*)
Melissa Viator, MS (*Abstract Co-Author*)
Christopher Bridge, DPhil (*Abstract Co-Author*)
Daniel I. Glazer, MD (*Abstract Co-Author*)
Oleg S. Pianykh, PhD (*Abstract Co-Author*)
William W. Mayo-Smith, MD (*Abstract Co-Author*)
Bernardo C. Bizzo, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the performance of a fully automated classification tool for identifying adrenal masses.

METHODS AND MATERIALS

This IRB-approved retrospective study was performed at a multisite academic health system. Consecutive patients undergoing unenhanced and contrast-enhanced abdominal CT examinations from 6/1/2023 through 3/31/2025 were included, and their basic demographic data were extracted from the electronic health record. Utilizing an internally developed automated machine learning segmentation and classification tool, the adrenal glands were classified as normal or containing a mass. To serve as a reference standard, radiology reports from these exams were categorized as normal or containing an adrenal mass >1 cm using the Qwen2.5 large language model (LLM). The performance of the algorithm relative to the reported adrenal findings from the radiology report was evaluated utilizing accuracy, sensitivity, and specificity.

RESULTS

A total of 68,213 consecutive scans were performed in 42,291 patients (23,658 female) with a mean age of 60.9 years. The overall proportion of reports describing adrenal masses was 7.4% (5,063) while the segmentation and classification model detected a mass in 8.3% (5,643) of the scans. The overall accuracy of the segmentation model using the report as ground truth was 92.5% (95% CI 92.3-92.7) with a sensitivity of 55.2% (95% CI 54.8-55.6) and a specificity of 95.5% (95% CI 95.3-95.6).

CONCLUSION

An automated machine learning adrenal segmentation and classification model was able to detect adrenal masses with high accuracy and specificity but lower sensitivity in a large population of consecutive CT examinations.

CLINICAL RELEVANCE/APPLICATION

An automated, machine learning adrenal mass detection tool can detect adrenal masses at scale in routine clinical practice. This may provide more consistency in detection of adrenal nodules compared to variable radiologist reporting.

R6-SSMK12-1 ACCELERATED WHOLE-BODY DIFFUSION-WEIGHTED MRI IN MULTIPLE MYELOMA PATIENTS USING DEEP LEARNING IMAGE RECONSTRUCTION: A RETROSPECTIVE COMPARISON WITH STANDARD DIFFUSION-WEIGHTED IMAGING

Johannes B. Hofmann (*Presenter*)
Saif Afat, MD (*Abstract Co-Author*)
Konstantin Nikolaou, MD, MBA (*Abstract Co-Author*)
Judith Herrmann, MD (*Abstract Co-Author*)

PURPOSE

Whole-body magnetic resonance imaging (WB-MRI) is a routine but time-intensive examination in patients with multiple myeloma, typically requiring approximately 45 minutes. The prolonged scan duration may result in decreased image quality due to motion artifacts, reduced throughput, and increased patient discomfort. This study aimed to evaluate the impact of deep learning-accelerated diffusion-weighted imaging (DWIDL) in 3T WB-MRI on overall and medullary image quality, sharpness, noise, lesion detectability, and diagnostic confidence.

METHODS AND MATERIALS

This retrospective study included 40 patients with multiple myeloma (21 men, 19 women; mean age, 62 ± 11 years; range, 35-82 years) who underwent 3T WB-MRI, including DWI with two b-values (50 and 800 s/mm²) between February 2023 and April 2024. Single-average raw data were processed using a deep learning image reconstruction algorithm, yielding a simulated acquisition time of 3 minutes 3 seconds for DWIDL compared with 7 minutes 6 seconds for standard DWI (DWIStd) by reducing the number of signal averages. Two experienced radiologists independently evaluated all DWI datasets using a 5-point Likert scale assessing noise level, artifact severity, sharpness, overall image quality, and diagnostic confidence.

RESULTS

There were no significant differences between DWIDL and DWIStd regarding artifact severity, sharpness, overall image quality, lesion detectability, or diagnostic confidence. However, DWIDL demonstrated significantly lower noise and higher contrast compared with DWIStd ($P < .05$).

CONCLUSION

Deep learning-based image reconstruction for WB-DWI at 3T is feasible and enables a significant reduction in acquisition time without compromising image quality.

CLINICAL RELEVANCE/APPLICATION

Accelerated acquisition particularly benefits multiple myeloma patients, who often present with vertebral fractures, by reducing motion artifacts, improving comfort, and minimizing the need for sedation. The shorter scan time may also allow patients otherwise limited to CT imaging to undergo MRI, enabling superior assessment of bone marrow infiltration.

R6-SSMK12-2 UNVEILING BONE METASTASES: COMPARING WHOLE-BODY DIFFUSION-WEIGHTED IMAGING WITH ADC AT 3T AND PET-CT FOR ENHANCED DETECTION

Jitin Goyal, MBBS (*Presenter*)
Likhith N, MBBS (*Abstract Co-Author*)
Sunil Kumar Puri, MD (*Abstract Co-Author*)

PURPOSE

This study aimed to assess the diagnostic performance of whole-body diffusion-weighted imaging (WB-DWI) with background body suppression (DWIBS) combined with the calculation of the apparent diffusion coefficient (ADC) at 3T MRI, and to compare it with PET-CT for detecting bone metastases.

METHODS AND MATERIALS

A prospective observational study was conducted over two years (2021-2022) with 43 patients with histopathologically confirmed malignancies and suspected bone metastasis who underwent PET-CT. The patients were subjected to WB-DWIBS within one week of PET-CT. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis and the area under the ROC curve (AUROC), with findings compared to PET-CT results.

RESULTS

The study found a higher detection rate of bone metastases on MRI (WB DWIBS) compared to PET-CT. The sensitivity of WB DWIBS was higher (96.4%) compared to PET-CT (89.3%), while specificity was higher in PET-CT (86.7%) compared to WB DWIBS (80%). ADC values below 1100 provided significant differentiation between malignant and benign lesions, contributing to improved diagnostic accuracy.

CONCLUSION

WB-DWI with ADC estimation demonstrated high sensitivity for detecting bone metastases, with a lower specificity compared to PET-CT. The integration of ADC values enhanced the diagnostic performance of WB-DWI, making it a promising imaging technique for the detection and assessment of bone metastasis, offering a non-invasive, radiation-free alternative to PET-CT.

CLINICAL RELEVANCE/APPLICATION

WB-DWI with ADC calculation offers a non-invasive, radiation-free alternative to PET-CT for detecting bone metastases, particularly beneficial for patients with renal issues or those requiring repeated imaging. Its high sensitivity enhances early detection, improving treatment outcomes. This technique may complement PET-CT, reducing radiation exposure and providing a cost-effective solution for monitoring metastatic cancer.

R6-SSMK12-3 CT "HALO SIGN" AND IMAGING FEATURES TO DISTINGUISH BENIGN FROM OSTEOBLASTIC PELVIC LESIONS IN PROSTATE CANCER

Simon Sun, MD (*Presenter*)
Alecio F. Lombardi, MD (*Abstract Co-Author*)
Mohammad Ali K. El Amine, MD (*Abstract Co-Author*)
Robert A. Lefkowitz, MD (*Abstract Co-Author*)
Stephanie Lobaugh (*Abstract Co-Author*)
Junting Zheng (*Abstract Co-Author*)
Natalie Gangai (*Abstract Co-Author*)
Sinchun Hwang, MD (*Abstract Co-Author*)

PURPOSE

To assess whether a lucent rim ("halo sign") and other imaging features help distinguish benign sclerotic bone lesions from osteoblastic metastases in pelvic CT of treatment-naïve prostate cancer patients, and to assess corresponding interobserver agreement.

METHODS AND MATERIALS

This retrospective study included 100 pelvic CTs from 99 men with newly diagnosed, treatment-naïve prostate cancer, acquired between 2010-2022. One sclerotic lesion per scan was analyzed; 89% were biopsied, while the rest had =2 years of imaging follow-up only. Three musculoskeletal radiologists (R1-R3) independently reviewed anonymized images for a "halo sign" (a lucent rim thinner than the lesion with lower attenuation than adjacent marrow), presence of spiculated borders, lesion size, and Hounsfield units (HU). Associations between benignity (defined as biopsy-proven or imaging stability over =2 years) and imaging features were analyzed for each reader using Fisher's exact and the Wilcoxon rank-sum tests. Interrater agreement was evaluated using Fleiss' kappa (?), Light's averaged pairwise ?, and intraclass correlation coefficient (ICC).

RESULTS

The halo sign was more frequent in benign vs. malignant ones for all readers (R1: 69% vs 31%, R2: 82% vs 18%, R3: 58% vs 42%), achieving statistical significance ($p < 0.05$) for R1 and R2. Interobserver agreement was fair [? = 0.33; 95% CI: 0.21-0.47]. Spiculated borders were more common in benign lesions (R1: 60% vs 40%, R2: 64% vs 36%, R3: 73% vs 27%) than malignant ones, with statistically significant associations for all readers and fair agreement [? = 0.32; 95% CI: 0.19-0.47]. Lesion size and HU were not significantly associated with benignity; interobserver agreement was good for size (ICC = 0.83; 95% CI: 0.768-0.879) and moderate for HU (ICC = 0.591; 95% CI: 0.485-0.688).

CONCLUSION

The CT halo sign and spiculated borders were statistically significantly associated with benignity in two of three readers and all readers, respectively; interobserver agreement was fair for both features. These features may help differentiate benign from malignant sclerotic lesions.

CLINICAL RELEVANCE/APPLICATION

The halo sign or presence of spiculated borders on CT may indicate a higher likelihood of a benign lesion, helping support imaging surveillance over biopsy, potentially reducing the rate of unnecessary bone biopsy.

R6-SSMK12-4 MRI RADIOMICS AND CONVENTIONAL IMAGING FOR PREDICTING PROLIFERATIVE ACTIVITY AND HISTOLOGICAL GRADE IN SOFT TISSUE SARCOMAS

Sam Sedaghat, MD (*Presenter*)
Fabian Schmitz (*Abstract Co-Author*)
Martin Groezinger (*Abstract Co-Author*)
Hans-Ulrich Kauczor, MD (*Abstract Co-Author*)
Hyungseok Jang (*Abstract Co-Author*)

PURPOSE

This study investigated whether soft tissue sarcomas (STS) can be stratified by both proliferative activity (Ki-67 index) and histological grade using conventional MRI features and radiomics. Additionally, it evaluated the diagnostic performance of a machine learning model trained on the extracted imaging-based biomarkers.

METHODS AND MATERIALS

In this multi-center study, 139 patients with histologically confirmed STS were evaluated. Tumors were classified as high- or low-proliferative based on Ki-67 index (cutoff 20%) and as high- or low-grade based on histopathology. Conventional MRI features—including tumor size, heterogeneity, necrosis, hemorrhage, cystic degeneration, peritumoral edema, contrast enhancement, and margin definition—were assessed. Apparent diffusion coefficient (ADC) values and radiomics features were extracted from T2-weighted (T2w) and contrast-enhanced T1-weighted (CE-T1w) sequences. A random forest machine learning algorithm was trained to differentiate tumor aggressiveness and grade.

RESULTS

High-grade and high-proliferative STS showed significantly greater tumor heterogeneity ($p < 0.001$ - 0.003), especially on T2w and CE-T1w imaging. Peritumoral edema and contrast enhancement were significantly more common in aggressive and high-grade tumors ($p < 0.001$). Ill-defined margins were more frequent in high-proliferative tumors ($p = 0.001$-0.008). Mean tumor ADC values and tumor-to-muscle ADC ratios were significantly lower in high-grade STS ($p = 0.001$ and 0.005, respectively). Metastases occurred more frequently in high-proliferative tumors ($p < 0.001$), and metastasis-free interval negatively correlated with Ki-67 ($r = -0.43$, $p = 0.021$). Several radiomics features representing intratumoral heterogeneity differed significantly between low- and high-grade/-proliferative STS, especially in T2w and CE-T1w sequences. The random forest model based on conventional and radiomics features predicted high-grade tumors with an AUC of 0.97 and F1-score of 0.93. Biopsy-underestimated tumors showed marked differences in heterogeneity and peritumoral features.

CONCLUSION

MRI-based radiomics and conventional features reliably distinguish between low- and high-proliferative and low- and high-grade STS. Key indicators include tumor heterogeneity, peritumoral edema, contrast enhancement, and several radiomics parameters, while machine learning models add strong predictive capability.

CLINICAL RELEVANCE/APPLICATION

Non-invasive imaging biomarkers can help assess STS aggressiveness, complement histopathology, and inform clinical decisions—especially in cases of limited or non-representative biopsy samples.

R6-SSMK12-6 PERFORMANCE OF RADIOMICS AND DEEP LEARNING MODELS IN PREDICTING DISTANT METASTASES IN SOFT TISSUE SARCOMAS: A META-ANALYSIS

Peyman Mirghaderi, MD, MPH (*Presenter*)
Parya Valizadeh (*Abstract Co-Author*)
Sara Haseli, MD (*Abstract Co-Author*)
Hyun Su Kim, MD, PhD (*Abstract Co-Author*)
Stephanie K. Schaub, MD (*Abstract Co-Author*)
Arash Azhideh, MD, MPH (*Abstract Co-Author*)
Matthew J. Nyflot, PhD (*Abstract Co-Author*)
Chankue Park, MD, PhD (*Abstract Co-Author*)
Majid Chalian, MD (*Abstract Co-Author*)

PURPOSE

Predicting distant metastases in soft tissue sarcomas (STS) is vital for guiding clinical decision-making. Recent advancements in radiomics and deep learning (DL) models have shown promise, but their diagnostic accuracy remains unclear. This meta-analysis aims to assess the performance of radiomics and DL-based models in predicting metastases in STS by analyzing pooled sensitivity and specificity.

METHODS AND MATERIALS

Following PRISMA guidelines, a thorough search was conducted in PubMed, Web of Science, and Embase. A random-effects model was used to estimate the pooled area under the curve (AUC), sensitivity, and specificity. Subgroup analyses were performed based on imaging modality (MRI, PET, PET/CT), feature extraction method (DL radiomics [DLR] vs. handcrafted radiomics [HCR]), and incorporation of clinical features. Heterogeneity by I^2 statistic, leave-one-out sensitivity analyses, and publication bias by Egger's test assessed model robustness and potential biases.

RESULTS

Eighteen studies involving 1,712 patients were included. The pooled AUC for predicting metastasis was 0.88 (95% CI: 0.80-0.92). The pooled AUC values were 88% (95% CI: 77%-89%) for MRI-based models, 80% (95% CI: 76%-92%) for PET-based models, and 91% (95% CI: 78%-93%) for PET/CT-based models, with no significant differences ($p = 0.75$). DL-based models showed significantly higher sensitivity than HCR models ($p < 0.01$). Including clinical features did not significantly improve model performance (AUC: 0.90 vs. 0.88, $p = 0.99$). Significant heterogeneity was noted ($I^2 > 25\%$), and Egger's test suggested potential publication bias ($p < 0.001$).

CONCLUSION

Radiomics models showed promising potential for predicting metastases in STSs, with DL approaches outperforming traditional HCR. While integrating this approach into routine clinical practice is still evolving, it can aid physicians in identifying high-risk patients and implementing targeted monitoring strategies to reduce the risk of severe complications associated with metastasis. However, challenges such as heterogeneity, limited external validation, and potential publication bias persist. Future research should concentrate on standardizing imaging protocols and conducting multi-center validation studies to improve the clinical applicability of radiomics predictive models.

CLINICAL RELEVANCE/APPLICATION

By accurately identifying patients at high risk for metastasis, these models have potential guide personalized treatment strategies, improve surveillance protocols, and reduce complications associated with delayed or inadequate intervention.

Riham H. El Khouli, MD, PhD (*Abstract Co-Author*)

PURPOSE

Thyroid cancer is a common endocrine malignancy and papillary thyroid carcinoma is the most common subtype among differentiated thyroid cancers (DTC). Despite ongoing debate regarding optimal management strategies, surgical resection followed by radioactive iodine (RAI) therapy remains the standard of care in most cases. Biochemical recurrence, defined as elevated thyroglobulin levels after radioactive iodine treatment without evidence of structural disease, varies in incidence by risk stratification ranging from 5-10% in low-risk patients up to 50% in high-risk patients. The best management strategy remains an area of debate. This study aims to assess the recurrence rate and progression free survival of patients who underwent at least one repeat RAI treatment for biochemical recurrence.

METHODS AND MATERIALS

We retrospectively reviewed all patients with DTC who presented for biochemical recurrence and received second RAI treatment in our nuclear medicine department between 2016 and 2022. Demographics, histologic subtypes, and disease stages data were collected. Thyroglobulin values (stimulated and non-stimulated), time to recurrence, and nadir thyroglobulin levels were recorded.

RESULTS

A total of 164 patients met our inclusion criteria, only 37% (61/164) had recurrence, while 63% (103/164) did not have recurrence after second RAI treatment. Stimulated thyroglobulin was <4 in 76% (111/146) and was > 4 in 24% (35/146) of cases. Among patients with <4 stimulated thyroglobulin level, 31% (34/146) had recurrence, while 69% (77/146) did not have recurrence after the second RAI treatment. On the other hand, among patients with > 4 stimulated thyroglobulin levels, 54.3% had recurrence while 45.7% did not have recurrence after the second RAI treatment (p-value 0.015). The initial number of metastatic lymph nodes (LNs) at the time of surgery was 5 or more LNs in 27% (38/139) and was less than 5 in 73% (101/139) of patients. Among patients with > 5 LNs 55% had recurrence while 45% did not have recurrence after the second RAI treatment. On the other hand, among patients with <5 LNs, 69% had recurrence while 31% did not have recurrence after second RAI treatment (p-value 0.006).

CONCLUSION

Empirical RAI treatment for biochemical recurrence in thyroid cancer patient resulted in disease control in 63% of patients. Higher risk of recurrent disease in patients with > 5 metastatic LNs at initial surgery and > 4 stimulated thyroglobulin level at the time of second treatment, yet close to third of patients with < 5 LNs and <4 stimulated thyroglobulin showed recurrent disease.

CLINICAL RELEVANCE/APPLICATION

Management of biochemical recurrence in thyroid cancer patients is a controversial topic and guidance that might help patient selection is of clinical value.

R6-SSNMMI08-5 IMPACT OF READER EXPERIENCE ON THE TIME-SAVING POTENTIAL OF A NOVEL COMPUTER-AIDED TOOL FOR ANN ARBOR STAGING IN PEDIATRIC HODGKIN LYMPHOMA

Iryna Vasyliv, MD (*Presenter*)

PURPOSE

Accurate staging of Hodgkin lymphoma in children is important for selecting appropriate therapies. However, difficulties in assigning an Ann Arbor stage based on tumor detection on whole-body PET scans can compromise the timeliness and accuracy of diagnoses. The purpose of the study was to determine if a novel computer-aided staging tool can improve the time-efficiency of Ann Arbor staging.

METHODS AND MATERIALS

PET/MRI scans of 56 pediatric patients, divided into two groups with matched Ann-Arbor stages, were staged by one radiology resident, four radiologists and two nuclear medicine physicians with different level of experience, via traditional inspection (Group 1) or with a newly developed web-based staging tool (Group 2). The time to generate the Ann Arbor score was compared between group 1 and 2 with the Wilcoxon Rank-Sum test. We performed a linear regression analysis to examine if there was association between reader experience, measured as the number of PET cases interpreted per year, and the time saved through use of the tool.

RESULTS

The least experienced reader, a radiology resident, saved 6.05 minutes per case by using the tool, while the most experienced nuclear medicine physician experienced a slight increase in reading time (-0.54 minutes). Overall, the tool resulted in a mean time savings of 3.1 ± 0.9 minutes per case. Importantly, the time saved showed a significant inverse correlation with reader experience ($r = -0.866$, $p = .012$), indicating that the tool was particularly beneficial for less experienced readers.

CONCLUSION

The computer-aided staging tool improved the time-efficiency and consistency of Ann Arbor staging, especially for non-experts.

CLINICAL RELEVANCE/APPLICATION

By streamlining the staging process, this tool supports faster clinical decision-making, improves workflow efficiency, and may help reduce variability in PET interpretation across experience levels.We provide the tool as a freely accessible web resource.

R6-SSNMMI08-6 PREDICTING AVASCULAR NECROSIS POST FIXATION: THE ROLE OF SKELETAL SCINTIGRAPHY IN SLIPPED CAPITAL FEMORAL EPIPHYSIS AND HIP FRACTURES

Jamison Ash, MD (*Presenter*)
Heather A. Cole, MD (*Abstract Co-Author*)

PURPOSE

The pediatric proximal femoral epiphysis is uniquely vulnerable to ischemic injury due to developmental vascular isolation across the physis, with limited collateral circulation until skeletal maturity. Current imaging modalities such as MRI, while sensitive in non-operative settings, suffer from significant limitations in the presence of fixation hardware. This study evaluates the utility of post-operative bone scintigraphy in predicting avascular necrosis (AVN) after surgical fixation of Slipped Capital Femoral Epiphysis (SCFE) and femoral neck fractures,

METHODS AND MATERIALS

A retrospective cohort of pediatric patients who underwent surgical fixation for SCFE or femoral neck fracture was evaluated with post-operative bone scintigraphy. Presence of femoral head photopenia was correlated with subsequent development of AVN on follow-up imaging and clinical outcomes. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated.

RESULTS

Among 64 patients, 17 demonstrated photopenia; of these, 11 developed AVN (PPV 67%). Only one case of AVN occurred among patients without photopenia (NPV 98%). Photopenia demonstrated a sensitivity of 92% and specificity of 89% for AVN prediction. The presence of photopenia identified patients at high risk for AVN, while absence strongly predicted vascular preservation.

CONCLUSION

Bone scintigraphy offers a highly sensitive and specific method for early functional assessment of femoral head viability after surgical fixation. It bridges a critical gap where MRI and CT are degraded by metal artifact, providing clinicians with actionable prognostic information.

CLINICAL RELEVANCE/APPLICATION

Understanding the developmental vascular biology of the pediatric proximal femur reveals why functional imaging, rather than purely anatomic imaging, is essential in post-operative settings.The use of post-operative bone scintigraphy enables clinical decision-making by stratifying patients based on their risk of developing avascular necrosis (AVN). In cases where photopenia suggests compromised femoral head viability, early identification may prompt timely surgical interventions aimed at revascularization, potentially preserving joint function and mobility. Alternatively, normal bone scintigraphy correlates with a low risk of AVN allowing clinicians to safely reduce follow-up imaging, minimize radiation exposure, lower healthcare costs, and may facilitate earlier return to weight bearing activities.

R6-SSNR15-1 COMPARISON OF READER SCORING AND QUANTITATIVE IMAGE QUALITY OF NEUROLOGICAL CT EXAMS ON ENERGY-INTEGRATING DETECTOR AND SILICON PHOTON-COUNTING DETECTOR CT

Aria Salyapongse, MSc (*Presenter*)
Brian E. Nett, PhD (*Abstract Co-Author*)
Meghan Yue, BS (*Abstract Co-Author*)
Nick Mathew (*Abstract Co-Author*)
Greg D. Avey, MD (*Abstract Co-Author*)
Tabassum A. Kennedy, MD (*Abstract Co-Author*)
Aaron S. Field, MD, PhD (*Abstract Co-Author*)
Staffan Holmin, MD,PhD (*Abstract Co-Author*)
Hakan Almqvist, MD (*Abstract Co-Author*)
Timothy P. Szczykutowicz, PhD (*Abstract Co-Author*)

PURPOSE

To compare subject and objective image quality metrics of non-contrast neuro CT exams between clinically available energy-integrating detector (EID) CT and a prototype deep silicon (dSi) photon-counting detector (PCD) CT.

METHODS AND MATERIALS

7 subjects underwent clinically indicated neurological scanning on commercially available EID CT scanners and then were scanned on the dSi PCD CT (GE Healthcare, Waukesha WI). All subjects provided informed consent under an IRB. Scanning parameters of the EID scans followed the institutions' clinical protocols. Scans on the dSi PCD were dose-matched (within 2% CTDI vol) or below (35-40% dose reduction) the EID prior dose. Contrast to noise ratio (CNR) was calculated by selecting five slices where both gray matter (GM) and white matter (WM) were visible to calculate contrast (GM - WM CT numbers) and noise (standard deviation of WM CT number). Statistically significant differences were determined via the Student's t-test for paired samples. Reader scoring based image quality was assessed by 4 neuroradiologists using a 5-point Likert scale (1 = worse than standard of care, 3 = equivalent to standard of care, 5 = much better than standard of care) on structural confidence (caudate head, insular ribbon, internal capsule, lentiform nuclei, and M1-M6 cortical contrast), low contrast detectability, noise, spatial resolution, artifacts, and diagnostic quality. Reader agreement was assessed with a linearly weighted Cohen's Kappa, and statistical significance between Likert scores was assessed with the Wilcoxon rank sum test on the median of the four reader scores.

RESULTS

The images from the prototype dSi PCD CT were found to be significantly better than the EID images on all reader-based image quality metrics ($p < 0.03$) except noise. Reader agreement was fair on average ($k=0.27$). No significant difference ($p = 0.12$) was found between the physics-based CNR of the EID priors and the dSi PCD scans.

CONCLUSION

Compared to the clinical EID CT neuro images, the images from the prototype dSi PCD CT have statistically significant improved reader scores and measured CNR was not statistically different.

CLINICAL RELEVANCE/APPLICATION

Improved grey-white matter differentiation on PCD CT could enhance the ability to detect early ischemic changes, subtle traumatic injuries, or evolving edema—particularly in the acute setting where rapid and confident diagnosis is critical. Greater soft tissue contrast and reduced noise may also improve diagnostic confidence and reduce the need for follow-up imaging.

R6-SSNR15-2 REPRODUCIBILITY STUDY OF HIGH-FIELD (5T) BRAIN TUMOR CEST IMAGING (AMIDE PROTON TRANSFER IMAGING (APT-CEST) AND GLUTAMATE PROTON TRANSFER IMAGING (GLU-CEST))

Hao Chen (*Presenter*)

PURPOSE

Chemical exchange saturation transfer (CEST) technique is a new molecular imaging method for noninvasive measurement of metabolites in biological tissues. It uses the chemical exchange process between unstable groups of metabolites and water molecules to detect and image weak metabolic signals. High field magnetic resonance has a stronger ability to distinguish metabolites, but it also faces the challenge of inhomogeneity of B0 and B1. In this study, amide proton transfer imaging CEST (APT-CEST) and glutamate CEST (Glu-CEST) images were collected in brain tumor patients to explore the repeatability of CEST technique in different tissues under high field magnetic resonance (5Tesla).

METHODS AND MATERIALS

Forty patients with brain tumors were recruited, and APT-CEST and Glu-CEST images were performed on all patients twice, respectively. Two regions of interest (ROI) (tumor region and contralateral normal brain tissue) were delineated in each patient. The mean of the magnetization transfer ratio of the ROI was evaluated. The standard deviation across all participants of the within-participant difference between two scans (SD diff) and the interclass correlation coefficient (ICC) of the mean of the difference between the mean of the lesion and the opposite healthy tissue were calculated.

RESULTS

(1) Both types of CEST imaging showed good repeatability on 5T magnetic resonance; (2) Compared with normal tissue, tumor tissue showed better repeatability of CEST imaging on 5T magnetic resonance, showing as lower SD diff and higher ICC.

CONCLUSION

The CEST technique under 5T field resonance has a good repeatability, especially in the tissue of the brain tumor.

CLINICAL RELEVANCE/APPLICATION

The CEST technique under 5T field resonance provides a reliable basis for the application of CEST in the imaging study of brain tumors.

R6-SSNR15-4 DISTINCT BRAIN ALTERATIONS AND NEURODEGENERATIVE PROCESSES IN COGNITIVE IMPAIRMENT ASSOCIATED WITH POST-ACUTE SEQUELAE OF COVID-19

Yangsean P. Choi, MD, PhD (*Presenter*)

PURPOSE

Although brain alterations have been reported in post-acute sequelae of SARS-CoV-2 infection (PASC), the extent to which they are universally present and associated with neurodegenerative processes remains unclear. This study aimed to investigate blood protein profiles and brain MRI findings in individuals with a history of mild COVID-19 to elucidate the neurological consequences of PASC.

METHODS AND MATERIALS

In this single-center prospective study, participants who had experienced mild COVID-19 approximately one year prior were categorized into three groups: PASC with cognitive impairment (Cog-PASC), PASC without cognitive impairment (Other-PASC), and no significant PASC symptoms (NS-PASC). Multimodal brain MRI was performed to obtain biomarkers including cortical thickness and choroid plexus volumes (from 3D T1-weighted images), diffusion tensor imaging along the perivascular spaces (DTI-ALPS), and quantitative susceptibility mapping (QSM) to assess paramagnetic susceptibility. Group-wise comparisons were conducted using the Kruskal-Wallis test with adjustment for age and sex.

RESULTS

Patients in the Cog-PASC group (median age [interquartile range, IQR]: 64 [53-68]) were significantly older than those in the NS-PASC (56 [45-63]) and Other-PASC (51 [41-60]) groups ($P<0.001$), and had worse cognitive performance (MoCA score: 24 [22-25] vs. 28 [27-29] in both other groups; $P<0.001$). MRI revealed reduced cingulate cortical thickness in Cog-PASC (2.445 mm [2.356-2.517]) compared to NS-PASC (2.449 mm [2.374-2.531]) and Other-PASC (2.497 mm [2.442-2.581]; $P=0.035$). QSM indicated increased paramagnetic susceptibility, consistent with iron deposition, particularly in the cingulate cortex and hippocampus ($P=0.005$). Choroid plexus volume was also significantly higher in Cog-PASC compared to Other-PASC, correlating with markers of neuronal/astroglial damage and iron accumulation. No significant differences were observed in DTI-ALPS metrics across the three groups. Blood proteomics revealed significant alterations in proteins associated with oxidative stress and synaptic function in Cog-PASC, implicating neurodegenerative pathways.

CONCLUSION

These results suggest that individuals with Cog-PASC, even after mild COVID-19 infection, exhibit distinct neurodegenerative changes.

CLINICAL RELEVANCE/APPLICATION

This study identifies structural and molecular brain changes specific to cognitively impaired PASC patients, which were absent in other PASC subgroups. The findings provide evidence of persistent neurodegeneration in a subset of non-hospitalized individuals following mild COVID-19.

R6-SSNR15-5 USEFULNESS OF CONJUGATE GRADIENT RECONSTRUCTION TECHNIQUE FOR EVALUATING INTRACRANIAL ARTERIES WITH 4D ULTRASHORT TE MR ANGIOGRAPHY

Hiroyuki Uetani, PhD (*Presenter*)
Takeshi Nakaura, MD (*Abstract Co-Author*)
Koya Iwashita (*Abstract Co-Author*)
Kanako Sato (*Abstract Co-Author*)
Kosuke Morita (*Abstract Co-Author*)
Mika Kitajima, MD (*Abstract Co-Author*)
Akitake Mukasa (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)

PURPOSE

4D MR angiography (MRA) by using an ultrashort TE (UTE) combined with an arterial spin-labeling technique (4D UTE-MRA) is a valuable tool for follow-up evaluations of intracranial aneurysms post-endovascular treatment (EVT); however, its prolonged acquisition time remains a significant drawback. A conjugate gradient reconstruction (CG-recon) technique has been developed to correct for trajectory errors and concomitant field artifacts in non-cartesian imaging. The purpose of this study was to evaluate the usefulness of a CG-recon technique in 4D UTE-MRA for the depiction of intracranial arteries in patients with intracranial aneurysm after EVT.

METHODS AND MATERIALS

This study included 25 patients (21 women; mean age 63 years) with intracranial aneurysms treated with EVT. All patients underwent DSA and 4D UTE-MRA with the number of 9600 trajectories after EVT. We hypothetically reduced the number of 4D UTE-MRA trajectories to 1/2, 1/3, 1/4, and 1/5 and reconstructed images using both conventional and CG-recon techniques. Two neuroradiologists qualitatively assessed the 4D UTE-MRA images and scored the depiction of the internal carotid arteries (ICAs), middle cerebral arteries (MCAs), anterior cerebral arteries (ACAs), vertebral arteries (VAs), and basilar artery (BA) with reference to DSA.

RESULTS

With conventional reconstruction, median scores for qualitative evaluations were significantly lower with reducing the number of trajectories by more than 1/2 than with all trajectories for ICAs, MCAs, ACAs, and VAs ($P < 0.05$). For ICA and VA, CG-recon, which reduced the number of trajectories to 1/4, had significantly higher median scores than conventional reconstruction using all trajectories. There was no significant difference in median scores for all arteries between conventionally reconstructed images with all trajectories and CG-recon images with trajectory reductions from 1/2 to 1/5.

CONCLUSION

CG-recon technique can improve the depiction of intracranial arteries in 4D UTE-MRA images with reduced number of trajectories.

CLINICAL RELEVANCE/APPLICATION

CG-recon can enhance the visualization of intracranial arteries in 4D UTE-MRA and holds potential for reducing acquisition time.

R6-SSNR15-6 HABITAT RADIOMICS BASED ON T1ρ IMAGING FOR PREDICTING IDH-1 MUTATION STATUS IN GLIOMAS: A PRELIMINARY STUDY

Hao Li (*Abstract Co-Author*)
Liping Qing (*Abstract Co-Author*)
Demin Xu (*Abstract Co-Author*)
Qin Zhao (*Abstract Co-Author*)
Meiying Chen (*Abstract Co-Author*)
Zhonghua Li (*Abstract Co-Author*)
Yulong Qi (*Abstract Co-Author*)
Guanxun Cheng, PhD (*Abstract Co-Author*)

PURPOSE

Magnetic resonance spin-locked imaging (T1? imaging), a magnetic resonance sequence sensitive to tissue microstructure and metabolic activity, could reflect tumor biochemical characteristics and heterogeneity. This study aimed to evaluate the feasibility of habitat radiomics features derived from T1? imaging at different spin-lock frequency (FSL) in predicting the IDH-1 mutation status in gliomas.

METHODS AND MATERIALS

A total of 42 glioma patients (mean age, 49.2 ± 13.1 years [SD]) were retrospectively enrolled and classified into IDH-1 wild-type and IDH-1 mutated groups. Tumor core and peritumoral edema regions were manually delineated on contrast-enhanced T1-weighted (T1CE) and T2-weighted-fluid-attenuated inversion recovery (T2-FLAIR) images, respectively, registered to the T1? imaging space acquired with FSL of 100 Hz, 200 Hz, and 500 Hz. Habitat maps were generated by applying K-means clustering (K=3) to signal intensities within the combined masks. Within each habitat subregion, both first-order statistics and second-order texture features were extracted. Features were standardized and subjected to least absolute shrinkage and selection operator (LASSO) regression for dimensionality reduction. Logistic regression models were constructed based on the selected features. Model performance was evaluated using 5-fold cross-validation by plotting receiver operating characteristic (ROC) curves and calculating the sensitivity, specificity, and area under the curve (AUC). DeLong's test was used to compare model performance across different FSL.

RESULTS

Among the three FSL-T1? imaging conditions, the model based on 500 Hz demonstrated the best diagnostic performance, with a sensitivity of 0.833, specificity of 0.913, and AUC of 0.901 ($P < 0.001$), significantly outperforming the models based on 200 Hz (sensitivity = 0.556, specificity = 0.783, AUC = 0.780, $P = 0.049$) and 100 Hz (sensitivity = 0.778, specificity = 0.625, AUC = 0.708, $P = 0.013$). According to DeLong's test, the AUC of the 500 Hz model was significantly higher than that of the 100 Hz model ($P < 0.05$). In contrast, the differences in AUC between 100 Hz and 200 Hz and between 200 Hz and 500 Hz were not statistically significant ($P > 0.05$).

CONCLUSION

Habitat radiomics based on T1? imaging effectively predicted IDH mutation status in gliomas. Among different FSL, the 500 Hz-T1? imaging demonstrated superior predictive performance compared to 100 Hz and 200 Hz.

CLINICAL RELEVANCE/APPLICATION

Higher FSL in T1? imaging may better capture the underlying biological heterogeneity of gliomas and contribute to the development of more robust radiomics models for clinical prediction.

PURPOSE

Postmortem magnetic resonance imaging (PMMRI) following fetal and perinatal demise is increasingly used in clinical practice as a non-invasive adjunct or alternative to autopsy. From expert consensus, we aimed to develop two PMMRI protocols for pragmatic clinical perinatal imaging: first, a standardized "minimal" PMMRI clinical protocol (with the minimum essential sequences needed per body part), and second, an "ideal" PMMRI clinical protocol with the ideal full protocol, time allowing.

METHODS AND MATERIALS

A modified Delphi survey was conducted, between July and November 2024, amongst members of the European Society of Pediatric Radiology (ESPR) postmortem (PM) Task Force, the PM imaging committee of the Society for Pediatric Radiology (SPR) and the Australian and New Zealand Society for Pediatric Radiology (ANZSPR). The survey was based on two pre-existing published PMMRI protocols and consisted of two multiple-choice tables which included all the MRI sequences in different planes according to each body part with an additional 10 PMMRI organizational questions (three of which were free text, seven multiple choice). An email containing the link of the survey was sent to 22 members of the different international PM imaging taskforces, recruited on a voluntary basis, given their clinical interest and experience in practicing perinatal PM imaging. The results were collected and analyzed in a descriptive manner and a point-of-care PMMRI clinical protocol was established based on the recommendations of our expert panelists.

RESULTS

Nineteen PM imaging specialists from 17 centers worldwide (Europe, USA, Canada, Australia, and New Zealand) completed the survey and formed our expert panel. By consensus (defined as >60% agreement), the final "minimal" PMMRI clinical protocol includes three-dimensional (3-D) isovolumetric T2 and T1 weighted sequences of brain (72.2% and 77.8% respectively) and chest-abdomen-pelvis (83.3% and 77.8% respectively). The "ideal" PMMRI clinical protocol includes 3-D isovolumetric T2 and T1 weighted sequences of the whole body (66.7 - 100%; 61.1 - 91.7% respectively) with axial SWI (81.3%) and DWI (68.8%) of the brain. Additional sequence if time allows is axial T2 TSE (56.3%) of the brain. Both protocols are illustrated in Figure 1.

CONCLUSION

As a minimum, 3-D isovolumetric T1 and T2 weighted sequences of the brain and body should be performed as part of a perinatal clinical PMMRI protocol. We hope these recommendations will facilitate the standardization and globalization of perinatal PMMRI in clinical practice.

CLINICAL RELEVANCE/APPLICATION

We have obtained expert recommendations on perinatal PMMRI protocols that balance efficiency with accuracy for clinical implementation.

R6-SSPD05-4 OPTIMIZING PHOTON-COUNTING CT FOR CONGENITAL HEART DISEASE: THE VALUE OF ULTRASHARP KERNELS IN NEONATES AND INFANTS

PURPOSE

To evaluate the diagnostic yield of kernel and sharpness settings for cardiac high-pitch CT in pediatric patients using Photon-counting CT (PCCT).

METHODS AND MATERIALS

This retrospective multi-center study analyzed clinical PCCT data from pediatric patients with congenital heart defects acquired between August 2021 and August 2023 at two specialized centers. Images were reconstructed using vascular kernels with alternating kernel sharpness levels (KS; 36,40,44,48,56,60) and iterative reconstruction levels (IR; Q1 to Q4) at a slice thickness of 1 mm. Image sharpness was evaluated with the edge-rise distance (ERD) as an objective measure. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated using standardized region-of-interest analyses. Visual image quality was assessed by three independent reviewers using a 5-point scale. For each patient reviewers selected one reconstruction with the best diagnostic yield. Statistical comparisons were performed using linear mixed models (values reported as regression estimates [95% confidence interval]).

RESULTS

A total of 47 patients (28 male, 19 female; median age: 82 days) were included in the analysis. Subjective overall image quality improved with increasing KS and IR levels (0.07 [0.06-0.09] and 0.21 [0.19-0.23], respectively; both P<.001). The highest image quality was achieved with KS 60 (79/141 votes) and IR Q4 (131/141 votes). ERD improved significantly with increasing KS and IR (-0.07 [-0.08 to -0.06] and -0.06 [-0.06 to -0.04], respectively; both P<.001).

CONCLUSION

Selection of kernel and iterative reconstruction impacts diagnostic quality in pediatric PCCT examinations with ultrasharp reconstruction delivering the best objective and subjective quality for imaging complex coronary and structural heart anomalies.

CLINICAL RELEVANCE/APPLICATION

This study highlights the clinical value of ultrasharp reconstruction kernels in photon-counting CT for neonates and infants with congenital heart disease. By optimizing diagnostic image quality through tailored reconstruction settings, photon-counting CT enables improved visualization of critical cardiac structures while maintaining low radiation exposure — supporting more accurate diagnosis and safer imaging in this vulnerable patient group.

R6-SSPD05-5 THE DEVELOPMENT OF PERIVASCULAR SPACES ON FETAL MRI IN HEALTH AND DISEASE

PURPOSE

Perivascular spaces (PVS) are thought to play a crucial role in brain waste clearance. While extensively studied in adults, research on the development of PVS is still scarce. We therefore investigated prenatal PVS using fetal MRI.

METHODS AND MATERIALS

Fetal MRI was performed on 3T between 08/2019 and 01/2024 in 457 cases. Whole body assessment of the fetus was performed using T2-weighted sequences in 3 orthogonal planes. Perivascular spaces, identified as areas of high signal intensity on coronal T2-weighted fetal brain MRI sequences, located parallel to arteries in the inferior part of the basal ganglia, were segmented by trained experts. Across the cohort a total of 248 radiological diagnostic items were recorded per patient as present or absent and grouped into five categories: central nervous system (CNS), thoraco-abdominal-, craniofacial-, limb- and placental/umbilical cord pathologies. In 219 cases detailed data on delivery were available. PVS count and volume were related to gestational age, sex and MRI findings, using generalized linear regression models in R.

RESULTS

Seventy/457 cases were excluded due to insufficient image quality. In those remaining, fetal age ranged between 106 - 265 days (mean: 182.7, sd: 32.95), with 153 females. CNS pathologies were identified in 138, craniofacial pathologies in 72, thoraco-abdominal pathologies in 31, limb pathologies in 36, and placental/umbilical cord pathologies in 45 fetuses. No PVS were visible prior to gestational ages of 116 days. PVS volume increased with gestational age by 0.06mm 3 /d (CI: 0.04-0.08, p<0.001), PVS counts by 0.01/d, (CI: 0.00 - 0.01, p=0.007). In cases with presence of any MRI visible structural CNS pathology, the PVS volume, adjusting for age and gender, decreased on a group level by 2.83mm 3 (CI: -4.75 - -0.91, p=0.004), the count by 0.61 (CI: -0.99 - -0.23, p=0.002). A near-significant trend in PVS count was observed in cases with placental/umbilical cord pathologies (p= 0.066). However, no significant influence was observed from factors such as sex (p=0.353 and p=0.594), craniofacial abnormalities (p=0.183 and p=0.082), thoraco-abdominal abnormalities (p=0.185 and p=0.646), or limb abnormalities (p=0.983 and p=0.555) on PVS volume or count.

CONCLUSION

In fetal MRI, visibility of PVS in the basal ganglia is a feature of normal CNS development, that is statistically delayed by CNS pathologies.

CLINICAL RELEVANCE/APPLICATION

The visibility of perivascular spaces on fetal MRI is indicative of physiological aging.

R6-SSPH14-1 RELIABILITY OF TASK-DRIVEN EVALUATION OF RADIOMICS FEATURES FOR LOW-CONTRAST LIVER LESION DETECTION ACROSS VARYING DOSE AND RECONSTRUCTION SETTINGS IN PHOTON-COUNTING DETECTOR CT

Shravani Kharat, MS (*Presenter*)
Jarod Wellinghoff (*Abstract Co-Author*)
Ahmed O. El Sadaney, MBBCh (*Abstract Co-Author*)
Joel G. Fletcher, MD (*Abstract Co-Author*)
Lifeng Yu, PhD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Hao Gong, PHD (*Abstract Co-Author*)

PURPOSE

Radiomics features are affected by CT data acquisition and reconstruction settings, hampering generalizability. Using a low contrast liver lesion detection task and varying dose and reconstruction settings, we used a task-driven evaluation to assess radiomic feature reproducibility and variability, optimize feature selection, and enhance generalizability

METHODS AND MATERIALS

Patient photon counting detector (PCD) CT scans (n=12) without liver lesions were retrospectively collected. Lower dose scans were simulated with a validated projection domain noise insertion tool. Lesion images were digitally modified in diameter (range 7 to 12 mm) and contrast (15 to 45 HU). A validated projection domain lesion insertion tool was used to insert the modified lesions into liver. At each dose level, 175 lesions were inserted. The modified projections were reconstructed with commercial software across different experimental conditions, involving 4 dose levels (100%, 75%, 50%, 25% routine dose), 3 keV levels (55, 67, 76 keV), 3 reconstruction kernels (Br36, Br44, Br56), 2 denoising strengths, and 2 slice thickness / increment (3 / 3, 1 / 1 mm). We extracted 93 radiomics features from lesion locations and liver parenchyma. We analyzed feature reproducibility and variability using intraclass correlation coefficient (ICC), concordance correlation coefficient (CCC), coefficient of variation (CV), and quartile coefficient of dispersion (QCD). The features showing good-to-excellent reproducibility across different conditions were selected using frequency-based criteria and were used to classify lesion and background images across different conditions to demonstrate feature reproducibility and model robustness. K-mean clustering was used in classification

RESULTS

Reproducibility was most affected by slice thickness/ increment, radiation dose and lower keV. Range of percentage of robust features using ICC and CCC thresholds were [7%, 79%] and [7%, 92%], respectively. Compared to liver background, features at lesion locations showed lower reproducibility at lower dose levels (percentage of robust features at lesion / background): 50% dose: 60% / 79%, 75% dose: 76% / 92%. Feature variability was relatively consistent: percentage of robust features using CV and QCD thresholds [17%, 32%] and [21%, 35%], respectively. 57 features were selected. Overall clustering accuracy (robust / unrobust features): 83.3% / 66.9%

CONCLUSION

Robust radiomics features were identified for lesion detection task and improved classification accuracy

CLINICAL RELEVANCE/APPLICATION

Task-driven evaluation can provide deeper insights on radiomic feature robustness to facilitate the optimization of feature selection and radiomics model performance

R6-SSPH14-2 RADIOMICS-DRIVEN CLINICAL CLASSIFICATION OF MYOCARDIAL FDG PET IMAGING

Khaldoun Hamade (*Abstract Co-Author*)
Eugene Storozynsky (*Abstract Co-Author*)
Wookjin Choi (*Abstract Co-Author*)

PURPOSE

Myocardial Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET) scans are utilized to clinically diagnose cardiac sarcoidosis and inflammation. Due to the low prevalence of cardiac sarcoidosis, radiologists at low-volume centers may have limited experience interpreting myocardial FDG PET scans. Functional radiomics and machine learning (ML) methods have the potential to aid with imaging-based diagnosis but have yet to be applied to myocardial FDG PET imaging. The purpose of this work was to develop a novel FDG PET radiomics classifier for the prediction of cardiac sarcoidosis

METHODS AND MATERIALS

From 2019 to 2023, 169 consecutive myocardial FDG PET-CT scans were analyzed from 141 patients with suspected cardiac sarcoidosis. Fluorodeoxyglucose was intravenously injected, and a PET and CT were acquired from the aortic root to the upper abdomen. A board-certified radiologist classified the myocardial FDG PET scans as having a binary presence or absence of cardiac sarcoidosis. The heart was contoured, and 200 novel functional radiomics features were extracted from the myocardial FDG PET scan. The data were divided into 70%/30% training/testing datasets, and the ability of the cardiac FDG PET radiomics to predict cardiac sarcoidosis was evaluated using ML pipelines with XGBoost and TPOT (Tree-based Pipeline Optimization Tool). Feature reduction was performed using the Wilcoxon test and hierarchical clustering. Both XGBoost and TPOT were evaluated using 10-fold cross-validation on the training set and validated on the testing set independently. The ability of myocardial FDG PET radiomics to predict cardiac sarcoidosis is assessed using accuracy, area under the curve (AUC), sensitivity, and specificity

RESULTS

38 out of 169 (22.5%) FDG PET scans were interpreted as having cardiac sarcoidosis. XGBoost, using 69 radiomics PET features, achieved an accuracy of 90%, AUC of 0.93, sensitivity of 0.82, and specificity of 0.93, on the testing dataset. TPOT, using 44 radiomics PET features, resulted in an accuracy of 86%, AUC of 0.92, sensitivity of 0.73, and specificity of 0.90, on the test set. After feature optimization, a TPOT model with 4 radiomics features was developed that achieved an accuracy of 82% and an AUC of 0.82 on the testing dataset

CONCLUSION

The study develops an innovative functional cardiac PET radiomics model to predict cardiac sarcoidosis with promising accuracy. The novel radiomics-based signature offers an automated method to help radiologists interpret myocardial PET scans and diagnose cardiac sarcoidosis

CLINICAL RELEVANCE/APPLICATION

A radiomics classifier model using FDG PET scans aids in predicting myocardial inflammation and cardiac sarcoidosis, providing promising automated diagnostic support for radiologists

R6-SSPH14-3 A COMPARISON OF THE BIOMECHANICAL ASSESSMENT BETWEEN UPRIGHT AND SUPINE INSPIRATORY-EXPIRATORY AREA-DETECTOR CT IN PATIENTS WITH PROGRESSIVE PULMONARY FIBROSIS

Yoshiharu Ohno, MD, PhD (*Presenter*)
Kota Aoyagi (*Abstract Co-Author*)
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)
Hirona Kimata (*Abstract Co-Author*)
Yuya Ito (*Abstract Co-Author*)
Kenji Fujii (*Abstract Co-Author*)
Naruomi Akino (*Abstract Co-Author*)
Takahiro Ueda, MD, PhD (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Masahiro Endo (*Abstract Co-Author*)

PURPOSE

Upright area-detector computed tomography (ADCT) offers substantial advantages over supine ADCT. However, no study has compared the results of biomechanical evaluations from paired inspiratory-expiratory ADCT data with computed tomography (CT) findings in patients with progressive pulmonary fibrosis (PPF). This study directly compared the capabilities of quantitatively assessed paired inspiratory-expiratory ADCT for pulmonary functional loss and disease severity evaluations between upright and supine ADCT in PPF patients.

METHODS AND MATERIALS

This retrospective study cohort consisted of age-, sex-, and underlying disease-matched patients with PPF who underwent paired inspiratory-expiratory CT on upright ADCT (n=40) or supine ADCT (n=40), pulmonary function tests, and semi-quantitatively assessed CT-based (CT-assessed) disease severity. Based on CT data, the absolute values of the logarithm of the Jacobian determinant and warp field magnitude of the whole lung and all lobes were computationally calculated using a proprietary software program. To determine the influence of lung biomechanics in all lobes on pulmonary function tests and CT-assessed disease severity, stepwise regression analyses were performed.

RESULTS

On supine ADCT, absolute values of the logarithm of the Jacobian determinant and warp field magnitude of the left lower lobe (LLL) were the first and only steps for pulmonary function test results and CT-assessed disease severity (absolute value of the logarithm of the Jacobian determinant: $0.14=r^2=0.16$, $p<0.05$; absolute value of the warp field magnitude: $0.37=r^2=0.39$, $p<0.05$). However, on upright ADCT, both indices indicated that LLL was the first step and the right lower lobe the second step for pulmonary function test results and CT-assessed disease severity (absolute value of the logarithm of the Jacobian determinant: $0.47=r^2=0.61$, $p<0.05$; absolute value of the warp field magnitude: $0.47=r^2=0.65$, $p<0.05$).

CONCLUSION

Upright ADCT has better potential than supine ADCT for detecting pulmonary functional loss and evaluating disease severity when paired inspiratory-expiratory ADCT is applied in PPF patients.

CLINICAL RELEVANCE/APPLICATION

Upright ADCT has better potential than supine ADCT for pulmonary functional loss and disease severity evaluations when paired inspiratory-expiratory ADCT is performed in patients with progressive pulmonary fibrosis.

R6-SSPH14-4 ARE PIXEL-WISE METRICS RELIABLE FOR COMPUTERIZED TOMOGRAPHY RECONSTRUCTION?

Zongwei Zhou, PhD (*Presenter*)
Tianyu Lin (*Abstract Co-Author*)
Xinran Li (*Abstract Co-Author*)
Qi Chen (*Abstract Co-Author*)
Yuanhao Cai (*Abstract Co-Author*)
Kai Ding, PHD (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)

PURPOSE

To address a fundamental problem in tomographic reconstruction: success on pixel-wise metrics does not guarantee the preservation of anatomical structures in reconstructed CT scans.

METHODS AND MATERIALS

We introduced a new anatomy-centered metric assessing anatomical completeness, covering large (N = 5) and small (N = 5) organs, vessels (N = 5), and pancreatic tumors (N = 3). Moreover, we propose Completeness-Aware Reconstruction Enhancement (CARE) framework, a novel method that implemented these anatomy-centered metrics as an additional learning objective for enhanced tomographic reconstruction. CARE is built on a simple latent diffusion model pre-trained on 6,212 contrast-

enhanced CT scans of 2,870 patients. Then, for each reconstruction method under a fixed number of X-rays, CARE leveraged multi-structural segmentation AI models from prior work and fine-tuned the diffusion model on 25 CT scans (20 patients) to gain generalizable enhancement ability. CARE was compared against four widely used reconstruction methods.

RESULTS

Under the NeRF reconstruction baseline, CARE preserved anatomical structures with 53.9% (44.8%-66.6%) NSD for large organs, 55.5% (45.9%-68.5%) clDice for vascular structures, and outperformed the original reconstruction with +27.9% NSD for large organs, +20.3% NSD for small organs, +22.3% clDice for vascular boundaries, and +3.0% NSD for PDAC. In contrast, the original NeRF reconstruction poorly preserved small objects and vascular structures, e.g., 3.0% (0.0%-5.7%) NSD for small organs; 33.2% (8.2%-42.1%) clDice for vascular structures; 1.1% NSD for PDAC. Qualitative results of CT reconstruction and CARE enhancement are presented in the Figure.

CONCLUSION

Our anatomy-centered metrics reveal that despite seeming successful in pixel-wise metrics, state-of-the-art tomographic reconstruction methods fail in preserving anatomical structures. CARE, when integrated into these methods, can significantly enhance anatomical preservation.

CLINICAL RELEVANCE/APPLICATION

CARE improves the anatomical accuracy of CT reconstructions from 2D X-ray projections. This enhancement supports safer and more effective image-guided interventional radiology by enabling clearer visualization of small and critical structures, improving diagnosis, treatment planning, and patient outcomes.

R6-SSPH14-5 DEVELOPMENT OF A ROBUST MOTION CORRECTION TECHNIQUE FOR DYNAMIC JOINT IMAGING

Chunming Gu, PhD, MS (*Presenter*)
Aeden Davis, BS (*Abstract Co-Author*)
Kristin D. Zhao, PhD (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)
Hao Gong, PHD (*Abstract Co-Author*)

PURPOSE

Recent advancements in 4DCT showed promise in diagnosing of dynamic joint pathology but are limited by motion artifacts that compromise kinematic accuracy. We aim to develop and validate a physics-informed deep learning method to reduce these motion artifacts and enhance diagnostic precision for assessing dynamic joint conditions.

METHODS AND MATERIALS

A retrospective cohort of static wrist CT scans (n=109) was included, which was split into training (n=75), validation (n=17), and testing (n=17) sets. Artifact-free static wrist CT images (i.e., ground truth) at multiple angular positions (10 phases, angular range: -10° to 10°) were generated using elastic deformation guided by an analytically derived 3D motion vector field, following a trapezoidal velocity profile. Simulated motion-corrupted CT images were generated by a motion generation model using ASTRA toolbox. A neural network with at tention gates and transfor m ers (ATM) was trained using simulated motion-corrupted images from two phases (phase no.5 and 6) with most severe motion. The corresponding static CT image of middle phase was used as ground truth. A tailored coarse-to-fine training strategy was used to progressively optimize model weights. This approach involved 4 training stages. In the initial 3 stages, the training and validation images were down-sampled to resolution of 64 x 64, 128 x 128, and 256 x 256, while the final stage utilized images at the standard size of 512 x 512. Three motion artifact metrics: standard deviation (std), entropy, and low-intensity region score (LIRS) were used to evaluate motion before and after correction. A temporal sliding window was applied to use images from other phases as input for inference, in order to assess the model's generalizability in temporal dimension. The visualization of phalanges and metacarpals before and after motion correction was compared. Paired sample t-tests were conducted.

RESULTS

ATM was able to reduce motion artifacts for different input phases using a sliding window approach. Streak and shadowing artifacts caused by motion were substantially reduced. LIRS, std and entropy within the region around bone (mean ± std): 0.32 ± 0.04, 63.73 ± 23.59, and 7.07 ± 0.24 before correction, 0.46 ± 0.08, 47.73 ± 17.13, and 6.90 ± 0.18 after correction, respectively. The increase of LIRS and the decrease of the std and entropy indicate the reduction of the motion artifacts. P-values < 0.05 for all metrics.

CONCLUSION

The proposed ATM model can reduce motion artifacts and generalize across different temporal phases which were excluded from training.

CLINICAL RELEVANCE/APPLICATION

The ATM model developed from simulated motion-corrupted CT images could reduce motion artifacts. It has the potential to be extended to dynamic joint imaging.

R6-SSPH14-6 ARTIFICIAL INTELLIGENCE (AI-) BASED CAST SYSTEM FOR WHOLE-BODY CT: UTILITY FOR PULMONARY FUNCTIONAL LOSS AND LUNG ABNORMALITY CLASSIFICATION CAPABILITY AS COMPARED WITH AI-BASED CT TEXTURE ANALYSIS FOR CHEST CT IN JAPANESE HEALTH CHECKUP TEST COHORT

Yoshiharu Ohno, MD, PhD (*Presenter*)
Kota Aoyagi (*Abstract Co-Author*)
Yoshihiro Ikeda (*Abstract Co-Author*)
Yota Noda (*Abstract Co-Author*)
Hirona Kimata (*Abstract Co-Author*)
Yuya Ito (*Abstract Co-Author*)
Kenji Fujii (*Abstract Co-Author*)
Naruomi Akino (*Abstract Co-Author*)
Takahiro Ueda, MD, PhD (*Abstract Co-Author*)
Masahiko Nomura, MD, PhD (*Abstract Co-Author*)
Takeshi Yoshikawa, MD (*Abstract Co-Author*)
Daisuke Takenaka, MD (*Abstract Co-Author*)
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*)

PURPOSE

Artificial intelligence (AI-) based CT texture analysis system is currently testing for evaluation of lung parenchymal diseases. Moreover, respiration associated muscles such as erector spinae or psoas muscles are also suggested as having the potential for pulmonary functional loss on chest CT. Recently, we developed AI-based computer-aided simple triage (CAST) systems with automatic CT texture and respiration associated muscle analyses for pulmonary functional loss and discrimination among healthy, COPD, interstitial lung abnormality (ILA) and interstitial lung disease (ILD) subjects. The purpose of this study was to compare capabilities for pulmonary functional loss assessment and discrimination capability for lung abnormalities between AI-based CAST for whole-body CT and AI-based CT texture analysis for chest CT in Japanese health checkup test cohort.

METHODS AND MATERIALS

This study cohort consisted of 192 subjects who underwent pulmonary function test and whole-body CT by an upright ADCT on the same day. According to Fleischner Society Glossary, each lung radiological finding volume normalized by total lung volume was automatically determined. Moreover, volume and mean density of erector

spinae muscle (EV and ED) and proas muscle volume (PV and PD) were also automatically calculated. To determine pulmonary functional loss assessment capability on each method, stepwise regression analysis was performed. To determine significant descriptors for classifying healthy, COPD, ILA and ILD groups, a likelihood test was also performed. Then, discrimination accuracy was compared between two methods by McNemar's test.

RESULTS

Based on stepwise regression analysis, CT texture analysis was assessed ground glass opacity (GGO), honeycomb or emphysema as significant factors ($0.10=r^2=0.24$, $p<0.05$). Moreover, CAST was determined GGO, reticulation, honeycomb, emphysema, EV, PV, ED or consolidation as significant factors ($0.34=r^2=0.71$, $p<0.05$). To classify 4 groups, CT texture analysis was assessed GGO, reticulation and emphysema as significant descriptors ($p<0.05$). However, CAST was determined GGO, reticulation and emphysema and PD as significant descriptors ($p<0.05$). Furthermore, discrimination accuracy of CAST (54.2%) was significantly higher than that of CT texture analysis (49%, $p=0.0002$).

CONCLUSION

AI-based CAST for whole-body CT has better potential than AI-based CT texture analysis for chest CT to assess pulmonary functional loss and discrimination of lung abnormalities in Japanese health checkup test cohort.

CLINICAL RELEVANCE/APPLICATION

AI-based CAST has superior potential to CT texture analysis for pulmonary functional loss assessment and lung abnormality discrimination in Japanese health checkup test cohort.

R6-STCE1-1 BEYOND BI-RADS: ENHANCING BREAST MRI ACCURACY AND BIOPSY AVOIDANCE WITH KAISER SCORE AND ADC INTEGRATION

Prerna Garg, MD, MBBS (*Presenter*)
Jitin Goyal, MBBS (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic accuracy of combining the Kaiser Score (KS) and apparent diffusion coefficient (ADC) in distinguishing benign from malignant breast lesions on MRI, and to evaluate the added value of threshold-based and logistic regression models in biopsy reduction.

METHODS AND MATERIALS

This retrospective study included 107 women (140 lesions; 93 malignant, 47 benign) who underwent contrast-enhanced breast MRI with diffusion-weighted imaging. Two radiologists independently assessed lesions using the KS decision flowchart and measured ADC values. Diagnostic performance was analyzed for KS, ADC, and their combination using threshold-based (KS =4 and ADC =1.4 × 10?³ mm²/s) and logistic regression approaches. ROC curves, sensitivity, specificity, and AUCs were computed. Inter-reader agreement was evaluated.

RESULTS

KS >4 alone: Sensitivity 93.5%, Specificity 85.1%, AUC 0.96 ADC <1.4 × 10?³ mm²/s: Sensitivity 94.6%, Specificity 51.1%, AUC 0.81 Combined benign rule (KS =4 and ADC =1.4 × 10?³ mm²/s): Specificity 96.8%, PPV 88.9%, biopsy avoidance in 24/47 benign lesions (51%) Logistic regression (KS + ADC as continuous variables): AUC 0.925 Logistic model with interaction term (KS × ADC): AUC 0.964 Inter-reader agreement: ICC = 0.956 (ADC), ? = 0.969 (KS)

CONCLUSION

Combining KS with ADC enhances the diagnostic performance of breast MRI and offers a clinically safe, evidence-based approach to reduce unnecessary biopsies. Logistic regression further enables individualized malignancy risk prediction, supporting integration into structured reporting and clinical decision-making.

CLINICAL RELEVANCE/APPLICATION

A multiparametric KS + ADC strategy can substantially reduce false positives and biopsy rates in breast MRI while maintaining high sensitivity, offering a robust framework for real-world implementation in breast imaging workflows.

R6-STCE1-2 MAMMOVLM: A GENERATIVE LARGE VISION-LANGUAGE MODEL FOR MAMMOGRAPHY-RELATED DIAGNOSTIC ASSISTANCE

Jie Ma (*Presenter*)
Zhenjie Cao (*Abstract Co-Author*)
Yuanyang WANG (*Abstract Co-Author*)
Tingfeng Zhang (*Abstract Co-Author*)
Yuting Yang (*Abstract Co-Author*)
Tingting Liao (*Abstract Co-Author*)

PURPOSE

To introduce MammoVLM, a generative vision-language model (VLM) designed to assist patients with mammography-related diagnostic queries. This model aims to address the lack of diagnostic assistants for follow-up questions after mammography screenings, leveraging large foundation models to improve medical service efficiency and accuracy in breast cancer detection.

METHODS AND MATERIALS

MammoVLM comprises three components: a Visual-Mixture-of-Experts (Visual-MoE) module, a projection module (UMiCon), and a language model (GLM-4 9B). The Visual-MoE uses three encoders (CLIP, ConvNeXt-Tiny, Dinov2) tailored to breast density categories (A, B, C, D) selected by a ResNet-50 classifier. UMiCon employs unimodal and multimodal contrastive learning, pre-trained on BI-RADS 3 vs. 4 classifications using 4,557 mammograms and diagnostic reports. The model was trained on a dataset of 33,630 mammograms from 30,495 patients, with subjective evaluations by 12 senior radiologists and objective comparisons against SOTA VLMs (vision-language models).

RESULTS

Subjective Evaluation: MammoVLM outperformed leading VLMs, scoring 91.5 (correctness), 82.6 (rationality), 91.2 (helpfulness), 94.6 (professionalism), and 96.5 (completeness) vs. LLaVA-1.5 (81.3, 77.8, 91.0, 80.6, 96.6) and BiomedGPT (91.5, 80.3, 86.4, 88.8, 90.8). Performance was comparable to junior radiologists (90.6, 83.0, 93.4, 91.1, 93.0) and approached senior radiologists (92.7, 86.1, 96.3, 95.1, 97.1). Ablation Studies: Full MammoVLM (with Visual-MoE, UMiCon, and SFT) achieved 91.5 correctness, vs. 71.5 for single encoder models.UMiCon's AUC of 0.70 in BI-RADS 3 vs. 4 classification surpassed previous methods. Zero-Shot Malignancy Screening: MammoVLM achieved AUC 0.9270 and specificity 0.9902 at 20% sensitivity, outperforming QWen-VL (AUC 0.9070, specificity 0.9808) and LLaVA-1.5 (AUC 0.8671, specificity 0.9405).

CONCLUSION

MammoVLM demonstrates superior performance in mammography-related Q&A tasks, outperforming leading VLMs and approaching junior radiologist capabilities. The model's effectiveness is validated by both subjective and objective metrics, highlighting its potential for clinical deployment. Future work will explore fine-tuning UMiCon for broader BI-RADS classification and integrating additional imaging modalities.

CLINICAL RELEVANCE/APPLICATION

MammoVLM can serve as a diagnostic assistant, enhancing radiologists' efficiency by providing accurate, AI-driven answers to patient queries. Its ability to reduce workload while maintaining diagnostic accuracy could improve breast cancer screening outcomes and patient care. The model's adaptability to new scenarios further underscores its clinical utility.

R6-STCE2

Science Session (Next-Generation Imaging: Advances in Low- and Non-Contrast Techniques)

Thursday, Dec. 4 2:15PM - 2:45PM Room: LEARNING CENTER THEATER 2

Sub-Events

R6-STCE2-1 NEXT-GENERATION LOW-CONTRAST ANGIOGRAPHY: A PROSPECTIVE VALIDATION OF GADOLINIUM-ENHANCED DUAL-SOURCE DECT WITH NOISE-OPTIMIZED 40-KEV VMI FOR PATIENTS WITH IODINE ALLERGY OR RENAL INSUFFICIENCY

Jigang Geng (*Presenter*)
LIHAO XIAO (*Abstract Co-Author*)
Lihua Liu (*Abstract Co-Author*)
Xiaoshi Li (*Abstract Co-Author*)
Yue Qin (*Abstract Co-Author*)

PURPOSE

To prospectively evaluate the diagnostic efficacy of a novel low-contrast thoracic computed tomography angiography (CTA) strategy in patients with contraindications to iodinated contrast media (ICM).

METHODS AND MATERIALS

This prospective, single-center study was HIPAA-compliant and approved by our Institutional Review Board; Between and, we enrolled 100 consecutive patients with absolute or relative contraindications to ICM (n=[e.g., 65] with prior severe allergic-like reaction; n=[e.g., 35] with severe renal insufficiency. All examinations were performed using a standardized GBCA-enhanced DECT protocol, which constituted an off-label use of the contrast agent. Detailed technical parameters for image acquisition and reconstruction are provided in Table 4. From the DECT dataset, conventional linearly blended images and a noise-optimized 40-keV VMI+ series were reconstructed for primary analysis. Two board-certified cardiothoracic radiologists (>10 years of experience) independently assessed all images for diagnostic quality on a 5-point Likert scale (score =3 considered diagnostic). Quantitative analysis involved placing regions-of-interest (ROIs) in the ascending aorta and paraspinous muscle to measure mean attenuation (HU) and image noise (SD of HU), from which the contrast-to-noise ratio (CNR) was calculated.

RESULTS

Qualitative analysis revealed an absolute difference in diagnostic utility: 100% (100/100) of 40-keV VMI+ examinations were rated as diagnostic (mean Likert score, 4.5 ± 0.5), whereas 0% (0/100) of conventional mixed-energy images were diagnostic (mean score, 1.2 ± 0.4) (P<.0001). Inter-reader agreement was excellent (Cohen's ? = 0.92). Quantitative analysis confirmed these findings, with mean aortic attenuation increasing from 160 ± 25 HU on mixed-energy images to 471 ± 68 HU on 40-keV VMI+ images (P<.0001). Despite a modest, statistically significant increase in image noise on VMI+ (22 ± 4 HU vs. 35 ± 7 HU, P<.001), the CNR improved dramatically from 6.4 ± 1.5 to 11.8 ± 2.9 (P<.0001). The protocol's robust performance enabled confident diagnosis of major pathologies. The mean effective radiation dose was 1.8 ± 0.5 mSv.

CONCLUSION

Gadolinium-enhanced DECT with noise-optimized low-keV VMI is a safe, effective, and prospectively validated technique for thoracic CTA in patients with ICM contraindications. It reliably transforms an otherwise non-diagnostic examination into a high-confidence diagnostic study, establishing a new imaging standard for this challenging patient population.

CLINICAL RELEVANCE/APPLICATION

This novel, low-dose gadolinium-DECT protocol provides diagnostic-quality thoracic CTA for patients with iodine contraindications, directly addressing a critical, unmet clinical need.

R6-STCE2-2 FROM DISAGREEMENT TO DIAGNOSIS: CROSS-MODAL DISCREPANCY DETECTION IN RADIOLOGY

Vedant Malik (*Presenter*)
Krish Malik (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a fully automated, vision-based Large Language Model (LLM) framework that identifies inconsistencies between segmentation and report-generation LoRA adapters in radiology, automatically flagging only the most discordant studies for expert review.

METHODS AND MATERIALS

Two parameter efficient LoRA adapters (low rank adaptation) were trained on Llama 3.2 7B vision model. First LoRA was trained on ROCO dataset captioning task and Second LoRA was trained on BraTS MRI dataset segmentation task. For each dataset, a test data of 105 images were run on both LoRA adapters to generate corresponding mask and caption during inference. Then we calculated mask volume from each of the outputs from two adapters and measures cosine distance between them. In addition, calculated shape based mismatch features. The resulting cosine distance mismatch if below 75% threshold is flagged for manual review. No subsequent fine tuning or human review were involved. ROCO data of 2405 image+caption pairs were used to fine tune first LoRA adapter. 1505 image+mask pairs were use to fine tune second LoRA adapter. The hardware used to fine tune was one NVIDIA A100 80GB GPU based AI System with 128 GB system RAM and 64vCPUs with 1TB SSD hard disk, with Ubuntu 22.04.5 OS.

RESULTS

With a precision of 89.5 %, 17 of the 19 flagged images were true mismatches, and with a recall of 81.0 %, the system detected 17 out of the 21 actual mismatches.

CONCLUSION

The proposed vision-based LLM framework accurately flags only the most discordant studies—achieving 89.5 % precision and 81.0 % recall while flagging just 19.95 % of cases—thereby reducing manual QA workload by roughly 80 % and enabling seamless, zero-retraining deployment in clinical radiology.

CLINICAL RELEVANCE/APPLICATION

The proposed automated QA framework can be seamlessly integrated into existing radiology workflows (e.g., PACS) to flag only those studies where segmentation and reporting conflict is found, enabling radiologist to focus on the most critical cases, reducing QA time by up to 80 %, and enhancing diagnostic accuracy and patient safety.

R6-STCE2-3 NON-CONTRAST RESTING-STATE FMRI FOR MAPPING LANGUAGE DYSFUNCTION AND COMPENSATION IN BRAIN TUMOR PATIENTS

Saeed Rahmani, MD, MPH (*Presenter*)
Luca Pasquini, MD, PhD (*Abstract Co-Author*)
Samra Iftikhar, MBBS (*Abstract Co-Author*)
Antonio Napolitano (*Abstract Co-Author*)
Amirali Aali (*Abstract Co-Author*)

PURPOSE

To evaluate the utility of non-contrast resting-state functional MRI (rs-fMRI) combined with graph theory to distinguish functional network alterations associated with aphasia and language compensation in patients with left-hemispheric brain tumors.

METHODS AND MATERIALS

We prospectively analyzed rs-fMRI data from 120 subjects, including 40 healthy controls and 80 patients with left-hemispheric brain tumors, stratified into aphasic (n=40) and non-aphasic (n=40) based on standardized language assessment. Functional connectivity was assessed using ROI-to-ROI analysis across seven canonical brain networks. Graph-theoretical metrics, including global and local efficiency, clustering coefficient, path length, and centrality, were extracted at whole-brain and network levels. Between-group differences were tested using FDR-corrected non-parametric analyses. Multinomial and binary logistic regressions were used to identify diagnostic predictors of aphasia status.

RESULTS

Aphasic patients demonstrated maladaptive hyperconnectivity within the default mode and sensorimotor networks, including significantly increased local efficiency and clustering in the medial prefrontal cortex and lateral sensorimotor cortex (FDR $p < 0.05$). In contrast, non-aphasic patients exhibited adaptive network remodeling with elevated efficiency and centrality in Broca's area, frontoparietal control, dorsal attention, and cerebellar networks (FDR $p < 0.05$). Whole-brain regression models identified global efficiency ($p = 0.008$), average path length ($p = 0.026$), and betweenness centrality ($p = 0.021$) as significant predictors of aphasia. Hemisphere-specific models were not predictive. Classification accuracy for aphasia using whole-brain metrics reached 64%.

CONCLUSION

Non-contrast rs-fMRI combined with graph theoretical analysis reveals distinct network signatures of language impairment and compensation in brain tumor patients. Aphasia is linked to inefficient global architecture and DMN overconnectivity, whereas preserved language function is supported by compensatory engagement of control and cerebellar networks.

CLINICAL RELEVANCE/APPLICATION

This study highlights non-contrast rs-fMRI as a powerful next-generation imaging tool for detecting functional language reorganization in brain tumor patients. It offers a safe, repeatable, and contrast-free approach to guide presurgical planning and risk stratification in neuro-oncology.

S1-SSCH01-2 RADIOLOGIC TERNARY CLASSIFICATION MODEL IN PREDICTING PATHOLOGIC INVASIVENESS OF NON-SOLID NODULES

Ye Qing Zhu, MD, PhD (*Presenter*)
Qi Wan (*Abstract Co-Author*)
Xinchun Li (*Abstract Co-Author*)
David F. Yankelevitz, MD (*Abstract Co-Author*)
Claudia I. Henschke, PhD, MD (*Abstract Co-Author*)

PURPOSE

Preoperative evaluation of the invasiveness of non-solid nodules (NSNs) at computed tomography (CT) influences clinical decision-making but can be challenging. The purpose of this study is to investigate CT characteristics of NSNs associated with pathologic invasiveness and to develop a radiological ternary classification model for differentiating among preinvasive lesions, minimally invasive adenocarcinoma (MIA), and invasive adenocarcinoma (IAC).

METHODS AND MATERIALS

This retrospective study enrolled 1683 patients with pathologically confirmed lung adenocarcinoma and suspicious malignant NSNs measuring 3.0-30.0 mm on preoperative CT scans between January 2012 and June 2024. For each NSN, the size, location, margin, shape, nodule CT attenuation, uniformity of density, lobulation sign, reticulation sign, vascular cluster sign, bubble-like lucency sign, air bronchogram sign and pleural retraction sign were independently evaluated by two radiologists blinded to clinical information and pathology results. Multinomial logistic regression and diagnostic accuracy analysis were performed.

RESULTS

This study included 1683 patients (1145 [68.0%] female) with 2125 NSNs. The median age was 53 years (interquartile range: 45-61 years). Multinomial logistic regression analysis demonstrated that nodule size (OR=1.23, CI: 1.14-1.32 for MIA; OR=1.76, CI: 1.62-1.92 for IAC), number of vessels (OR=3.25, CI: 2.73-3.87 for MIA; OR=2.81, CI: 2.00-3.93 for IAC), CT attenuation (OR=1.01, CI: 1.00-1.01 for MIA; OR=1.01, CI: 1.01-1.01 for IAC), uniformity of density (OR=1.80, CI: 1.26-2.57 for MIA; OR=6.82, CI: 3.48-13.37 for IAC), pleural retraction (OR=2.07, CI: 1.29-3.32 for MIA; OR=2.98, CI: 1.70-5.23 for IAC), bubble lucency (OR=1.71, CI: 1.01-2.92 for MIA; OR=2.58, CI: 1.39-4.80 for IAC) and air bronchogram (OR=2.13, CI: 1.15-3.95 for MIA; OR=2.97, CI: 1.53-5.76 for IAC) were significant predicting the pathological subtypes (IAC vs MIA vs AIS/AAH). The overall diagnostic performance of the radiological ternary classification model was excellent (AUC = 0.90).

CONCLUSION

The radiological ternary classification model demonstrated significant diagnostic efficacy in differentiating among preinvasive lesions, MIA and IAC, suggesting potential clinical utility for decision-making.

CLINICAL RELEVANCE/APPLICATION

Our results demonstrated that nodule size, number of vessels, CT attenuation, uniformity of nodule density, and the presence of pleural retraction, bubble lucency, and air bronchogram were significant in predicting the pathological subtypes (IAC vs MIA vs AIS/AAH). The overall diagnostic performance of the radiological ternary classification model was excellent (AUC = 0.90).

S1-SSCH01-3 IMAGE BIOMARKERS FOR POSTOPERATIVE SURVIVAL IN NEVER-SMOKER LUNG CANCER PATIENTS

Jing Wang (*Presenter*)
Tong Yu (*Abstract Co-Author*)
Xin Meng (*Abstract Co-Author*)
David Wilson (*Abstract Co-Author*)
Jiantao Pu, PhD (*Abstract Co-Author*)

PURPOSE

Never-smoker lung cancer represents a distinct and increasingly recognized clinical entity, more common in younger individuals and females, and characterized by unique molecular profiles. Despite surgical resection being the primary treatment for early-stage disease, prognostic tools tailored to this population remain limited. This study investigates the association between CT-derived lung, airway, and body composition features and overall survival following surgical resection in never-smokers.

METHODS AND MATERIALS

We retrospectively analyzed 112 never-smoker lung cancer patients who underwent surgery. During follow-up, 29 patients died, with a median overall survival of 9.67 years. Pretreatment CT scans were utilized to quantify volumes (Liter) of lung, emphysema, airway, and five body tissue types, as well as densities (Hounsfield Unit) of body tissues across all image slices from lung apex to base. Overall survival was estimated using Kaplan-Meier method. Associations with postoperative survival were assessed using Cox proportional hazards regression both unadjusted and adjusted for demographics, cancer stage and subtype, surgery type, and treatment with

chemotherapy and radiation therapy. The prognostic performance was evaluated using the time-dependent area under the receiver operating characteristic curve (AUC-ROC) at year 5 with 5-fold cross-validation.

RESULTS

Univariate Cox proportional hazards analysis identified higher visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), and intramuscular adipose tissue (IMAT) volumes, higher IMAT and airway ratio, and lower bone density as predictors of poorer survival. In multivariate analysis, only lower bone density (HR=0.64, 95% CI: 0.45-0.92) and higher airway ratio (HR=1.62, 95% CI: 1.18-2.22) remained significant. The association persisted after adjusting for demographic and clinical covariates. The model incorporating bone density, airway ratio, and an interaction term between age and cancer stage achieved an average 5-year AUC of 0.70 (SD: 0.05).

CONCLUSION

Lower bone density and higher airway ratio on pretreatment CT scans are associated with poorer survival in never-smoker lung cancer patients and may serve as prognostic imaging biomarkers.

CLINICAL RELEVANCE/APPLICATION

Never-smoker lung cancer is a distinct and understudied subtype with unique clinical and molecular characteristics. Our findings show that lower bone density and higher airway ratio on preoperative CT are associated with worse postoperative survival in these patients. Incorporating these imaging biomarkers into preoperative assessment may aid in risk stratification and personalized care, potentially improving outcomes in this vulnerable population.

S1-SSCH01-4 PRETRAINED TRANSFORMER-BASED FRAMEWORK FOR PREDICTING IMMUNOTHERAPY EFFICACY IN ADVANCED NON-SMALL CELL LUNG CANCERPATIENTS

Jianbin Zhu (*Presenter*)
Zhuofeng Liang (*Abstract Co-Author*)
Wen Zhibo, BA (*Abstract Co-Author*)

PURPOSE

Immune checkpoint inhibitors (ICIs) have transformed oncology practice, yet pinpointing patients most likely to benefit remains elusive. This study introduces an interpretable Transformer-based deep learning framework, complemented by conventional machine learning (ML) techniques, to identify advanced non-small cell lung cancer (NSCLC) patients who may respond favorably to first-line immunotherapy.

METHODS AND MATERIALS

We retrospectively analyzed data from 207 advanced NSCLC patients treated with ICIs at our institution between 2021 and 2024. Comprehensive clinical, demographic, and pre-treatment CT imaging data were collected, yielding 1,834 radiomic features extracted from primary tumor regions. Patients were stratified into training (80%) and testing (20%) cohorts. The primary efficacy endpoint was durable clinical benefit (DCB), defined as progression-free survival (PFS) of =6 months. Our approach integrated high-dimensional imaging with clinical data, addressing challenges such as feature sparsity and missing values within a unified multimodal framework. Model development included a pretrained Transformer architecture, alongside comparison with traditional ML algorithms (LightGBM, LR, Random Forest, XGBoost). Rigorous feature selection was performed using univariate analysis, Pearson correlation, and LASSO regression. Model evaluation utilized ROC analysis (AUC), Delong test, IDI/NRI, decision curve analysis (DCA), and calibration plots to assess clinical utility.

RESULTS

While the Random Forest model exhibited the highest training AUC (0.951, 95% CI 0.917-0.984), the Transformer-based model demonstrated superior generalizability with a testing AUC of 0.742 (95% CI 0.583-0.901) and a robust training AUC of 0.856 (95% CI 0.793-0.918). The Transformer model showed significant improvements in reclassification metrics (IDI > 0, NRI > 0) and optimal clinical utility on DCA. Multimodal feature analysis highlighted tumor heterogeneity radiomics and inflammatory biomarkers as critical predictors of immunotherapy response.

CONCLUSION

Our pretrained Transformer framework enables clinically interpretable prediction of immunotherapy efficacy through effective multimodal data fusion, surpassing conventional ML models. This innovative approach holds promise for enhancing patient selection and guiding personalized treatment strategies in NSCLC immunotherapy, potentially improving clinical outcomes and resource allocation.

CLINICAL RELEVANCE/APPLICATION

This Transformer-based model helps identify advanced NSCLC patients who may benefit from immunotherapy by effectively integrating multimodal data, offering a more precise than conventional ML models.

S1-SSCH01-5 PREDICTING HIGH TUMOR MUTATION BURDEN IN LUNG CANCER USING CT RADIOMICS AND HISTOPATHOLOGIC TEXTURE FEATURES: AN EXPLORATORY STUDY

Motohiko Yamazaki, MD, PhD (*Presenter*)
Hideaki Sugino (*Abstract Co-Author*)
Yuma Fuzawa, MD (*Abstract Co-Author*)
Masaki Tominaga (*Abstract Co-Author*)
Takuya Yagi (*Abstract Co-Author*)
Riuko Ohashi (*Abstract Co-Author*)
Hiroyuki Ishikawa, MD, PhD (*Abstract Co-Author*)

PURPOSE

To explore whether integrating CT radiomic features and histopathologic texture features can improve the prediction of high tumor mutation burden (TMB) in patients with primary lung cancer.

METHODS AND MATERIALS

This retrospective study included 98 surgically resected lung cancer cases, among which 27 (27.6%) had high TMB (=20 mutations/Mb). A total of 204 radiomic features were extracted from both intratumoral and peritumoral regions on preoperative CT scans. From whole-slide pathology images, 95 histopathologic texture features of tumor tissue were computed using ten randomly sampled 2560×2560-pixel patches per case, and their mean values were used to represent each case. Tumor segmentation was performed using in-house developed AI models for both modalities. Clinical variables (age, sex, histology, and smoking status) were also included. Four predictive models were constructed: (1) CT features alone, (2) histopathologic texture features alone, (3) combined CT and histopathologic texture features, and (4) combined CT and histopathologic texture features with clinical variables. In each of five cross-validation folds, the top 10 CT and top 10 histopathologic texture features were selected from the training set based on random forest feature importance and applied to predict high TMB in the test set. The area under the receiver operating characteristic curve (AUC) was used for performance evaluation.

RESULTS

The mean AUCs across five cross-validation folds were 0.693 for CT features alone, 0.682 for histopathologic texture features alone, 0.769 for the combination of CT and histopathologic texture features, and 0.776 when clinical variables were additionally included. The most important CT-derived feature was glszm_GrayLevelVariance, which captures intratumoral intensity heterogeneity and was lower in TMB-high tumors. The most important histopathology-derived feature was glrlm_RunLengthNonUniformity, a measure of texture irregularity in tumor tissue, showing higher values in TMB-high tumors.

CONCLUSION

This exploratory study suggests that the integration of CT radiomic features and histopathologic texture features may enhance the multi-modal image-based prediction of high TMB in lung cancer. These findings warrant further validation in larger and more diverse cohorts.

CLINICAL RELEVANCE/APPLICATION

As high TMB predicts better response to immune checkpoint inhibitors, this multi-modal imaging approach may assist in identifying suitable candidates for immunotherapy.

PURPOSE

Micro-Ultrasound (microUS) is an emerging imaging modality with promising potential to identify and target suspicious prostate cancer (PCa). Recent studies indicate that microUS can complement multiparametric MRI (mpMRI) when compared to biopsy pathology results. We aim to comprehensively evaluate and compare the performance of microUS, mpMRI, and PSMA PET/CT in the detection of PCa and assessment of extraprostatic extension (EPE), using wholemount histopathology (WMHP) as a reference.

METHODS AND MATERIALS

Patients with PCa who underwent microUS, mpMRI and PSMA PET/CT prior to radical prostatectomy were included. WMHP histopathology findings served as the reference standard. Imaging findings were mapped onto a standardized 36-sector map and correlated with WMHP to assess PCa involvement. Detection rates (DRs) of PCa and clinically significant PCa (csPCa) were evaluated at both the lesion and sector levels. Diagnostic performance for detecting PCa, csPCa, and EPE was assessed using receiver operating characteristic (ROC) analysis. Chi-square test and Delong test were used to compare the DRs and area under the ROC curve (AUC) across different imaging modalities.

RESULTS

The study included a total of 42 patients, of whom, 20 patients (47.6%) had EPE. Lesion-level DRs for PCa and csPCa were 50% and 70% for microUS, 55% and 77% for mpMRI, and 50% and 74% for PSMA PET/CT, respectively. For predicting patient-level EPE, AUCs were 0.667 (0.515-0.790) for MicroUS, 0.714 (0.564-0.828) for mpMRI, and 0.545 (0.399-0.688) for PSMA PET/CT, where the differences were not statistically significant ($p>0.05$).At the sector-level, mpMRI outperformed microUS and PSMA PET/CT for detecting PCa (AUC: 0.698 vs. 0.658/0.630, $p=0.017/p<0.001$), csPCa (AUC: 0.720 vs. 0.671 and 0.649, $p=0.004/p<0.001$), and EPE (AUC: 0.789 vs 0.567/0.695, $p<0.001/p<0.001$).In the diagnosis of csPCa, AUCs of mpMRI were higher than those of microUS in the base, anterior, and transition zone ($p<0.05$). In the diagnosis of EPE, AUCs of mpMRI were higher than those of microUS and PSMA PET/CT in base and midgland ($p < 0.05$).

CONCLUSION

MicroUS demonstrates comparable performance to mpMRI for lesion-level detection of csPCa and assessment of patient-level EPE. However, mpMRI shows superior diagnostic accuracy in the sector-level analysis, particularly for detecting csPCa and EPE.

CLINICAL RELEVANCE/APPLICATION

MicroUS can complement existing imaging modalities for prostate cancer evaluation, particularly in settings where MRI may be less accessible. Its comparable lesion-level performance supports its potential role in targeted biopsy strategies, potentially improving diagnostic accuracy.

S1-SSGU01-3 IMPACT OF CONTRALATERAL SYSTEMATIC BIOPSY OMISSION ON PATHOLOGICAL FEATURE DETECTION IN SOLITARY PI-RADS 4/5 LESIONS

Kevin An (*Presenter*)
Cassandra J. Jeavons, MBBS (*Abstract Co-Author*)
Yilin Zhang (*Abstract Co-Author*)
Sobhan Mardan, MSc (*Abstract Co-Author*)
Silvia D. Chang, MD, FRCPC (*Abstract Co-Author*)

PURPOSE

To assess whether omitting contralateral systematic biopsies in solitary PI-RADS 4 or 5 lesions would affect management approach and outcomes by determining the presence of adverse pathological features associated with more aggressive disease in the contralateral biopsies.

METHODS AND MATERIALS

A retrospective analysis identified 835 patients who underwent MRI-ultrasound fusion targeted and systematic prostate biopsy (May 2020-February 2023). Of these, 301 patients had a solitary PI-RADS 4 (n=206) or PI-RADS 5 (n=95) lesion. The number of cases of clinically significant prostate cancer (csPCa) was identified and correlating pathological features of the contralateral biopsies were reviewed. This included more aggressive features such as cribriform pattern, perineural invasion (PNI), and extraprostatic extension (EPE).

RESULTS

Of the 301 patients that had a PI-RADS 4 (n=206) or PI-RADS 5 (n=95) solitary lesion, there were 83 cases (40.3%) and 66 cases (69.5%) of csPCa, respectively. Omission of contralateral systematic biopsies would miss 1 case of csPCa in the PI-RADS 4 group (1.2%) and 2 cases in PI-RADS 5 group (3.0%). Cribriform pattern was present in 31 cases (37.3%) in PI-RADS 4 lesions with csPCa and 25 cases (37.9%) in PI-RADS 5 lesions. Omission of contralateral systematic biopsy would only miss 1 case of cribiform patttern (1.2%) in the PI-RADS 4 category. PNI was present in 30 cases (36.1%) in PI-RADS 4 lesions and 21 cases (31.8%) in PI-RADS 5 lesions. Omission of contralateral systematic biopsy would miss 1 case (1.2%) of PNI in PI-RADS 4 lesions and 2 cases (3.0%) in PI-RADS 5 lesions. EPE was present in 2 cases (2.4%) in PI-RADS 4 lesions and 9 cases (13.6%) in PI-RADS 5 lesions. Omission of contralateral systematic biopsy would only miss 1 case (1.5%) in the PI-RADS 5 category. Of the 3 csPCa patients that would have been missed with omitting contralateral biopsy, there were no aggressive pathological features detected.

CONCLUSION

Omitting contralateral systematic biopsy appears safe and effective in solitary PI-RADS 4 and 5 lesions.

CLINICAL RELEVANCE/APPLICATION

Omitting contralateral SB maintains high sensitivity for detecting csPCa and adverse pathology while minimizing procedural morbidity, infection risk, healthcare burden, and overtreatment. This approach improves patient-centered outcomes and supports cost-effective and time efficient biopsy practice without compromising oncologic safety.

PURPOSE

To compare microultrasonography-guided and MRI fusion-guided biopsy for prostate cancer diagnosis.

METHODS AND MATERIALS

This was a multicenter, international, randomized, noninferiority trial of biopsy-naive men from 20 centers (8 countries) with clinical suspicion of prostate cancer (elevated prostate-specific antigen [PSA] and/or abnormal digital rectal examination) from December 2021 to September 2024 [NCT05220501]. Participants were assigned to receive either microultrasonography-guided biopsy, microultrasonography/MRI fusion-guided biopsy (microultrasonography/MRI, in which microultrasonography biopsies were performed prior to unblinding the MRI), or MRI/conventional US fusion-guided biopsy (MRI/conventional ultrasonography) in a 1:2:3 ratio. All participants received synchronous systematic biopsy. The primary outcome was the difference in detection of Gleason Grade Group (GG) = 2 cancers using microultrasonography plus systematic biopsy vs MRI/conventional ultrasonography plus systematic biopsy. The secondary outcome was the difference in detection of GG = 2 cancers using microultrasonography/MRI plus systematic biopsy vs MRI/conventional ultrasonography plus systematic biopsy. The noninferiority margin was set at 10%.

RESULTS

A total of 802 men underwent randomization and 678 underwent biopsy. Median (IQR) age was 65 (59-70) years and prostate-specific antigen level was 6.9 (5.2-9.8) ng/mL. Gleason Grade Group 2 or higher cancer was detected in 57 of 121 participants (47.1%) in the microultrasonography group, in 141 of 331 participants (42.6%) in the MRI/conventional ultrasonography group, and in 106 of 226 participants (46.9%) in the microultrasonography/MRI group. Microultrasonography-guided biopsy was noninferior to MRI fusion-guided biopsy (difference, 3.52% [95% CI, -3.95% to 10.92%]; noninferiority P < .001). Combined biopsy with microultrasonography/MRI was also noninferior to MRI/conventional ultrasonography software-assisted MRI fusion biopsy using conventional ultrasonography devices (difference, 4.29% [95% CI, -4.06% to 12.63%]; noninferiority P < .001). The rate of Gleason Grade Group 2 or higher cancer diagnosed by targeted biopsy only was 38.0% in the microultrasonography group, 34.1% in the MRI/conventional ultrasonography group, and 40.3% in the microultrasonography/MRI group; these differences were not significant.

CONCLUSION

The use of microultrasonography-guided biopsy was noninferior to MRI/conventional ultrasonography fusion-guided biopsy for the detection of Gleason Grade Group 2 or higher prostate cancer in biopsy-naive men.

CLINICAL RELEVANCE/APPLICATION

Microultrasonography may provide an alternative to MRI for image-guided prostate biopsy.

S1-SSGU01-6 USING PROTON SPECTROSCOPY TO IMPROVE CRIBRIFORM PROSTATE CANCER DETECTION AT PRE-BIOPSY MRI

Nikita Sushentsev, MD, PhD (*Presenter*)
Mary A. McLean, PhD (*Abstract Co-Author*)
Jonathan Birchall (*Abstract Co-Author*)
Ferdia A. Gallagher, PhD, FRCR (*Abstract Co-Author*)
Tristan Barrett, MBBS, MD (*Abstract Co-Author*)

PURPOSE

Explore the potential of proton magnetic resonance spectroscopic imaging (1 H-MRSI) for non-invasive differentiation between cribriform and non-cribriform prostate cancer (PCa) compared to standard multiparametric MRI (mpMRI).

METHODS AND MATERIALS

Our prior multi-omics studies identified enriched lipid biosynthesis as distinctive for cribriform PCa. Here, we performed pre-biopsy 1 H-MRSI in addition to standard mpMRI protocol to evaluate tumor fat fraction in a prospective cohort of 12 patients. All patients underwent 1 H-MRSI across a 4.5mm axial slice through the tumor (FOV 32 cm, interpolated matrix 128x128, 30° flip, TR 88.7ms, TE 2.1ms, 5 kHz full-receiver bandwidth, 256 spectral points). 1 H-MRSI acquisition time was 4min:47 s. Magnitude spectra were corrected for bias used to calculate Fat/(Fat + Water). Regions-of-interest (ROIs) encompassing biopsy-proven tumor and benign areas were drawn by a genitourinary radiologist; the resulting fat fractions and 1 H-MRI ADCratio values (tumour/urine) were compared using the Mann-Whitney U test.

RESULTS

1 H-MRSI-derived fat fraction showed an almost five-fold increase in cribriform Gleason score (GS) 7 lesions compared to all other tissue types, including GS7 non-cribriform tumors, GS6 tumors, and histologically benign regions ($P < 0.05$). Conversely, no distinction between the three tumor types could be made using the ADCratios ($P > 0.05$ for all). Representative 1 H-MRSI fat fraction maps with corresponding spectra are presented in the attached figure.

CONCLUSION

This study shows the feasibility of performing 1 H-MRSI for improving non-invasive detection of cribriform PCa. Based on these findings, we are prospectively recruiting patients in whom 1 H-MRSI and mpMRI are performed prior to radical prostatectomy (RP). This study aims to identify a quantitative 1 H-MRSI-derived tumor fat fraction cut-off that would yield a =20% increase in the sensitivity of detecting cribriform PCa compared to mpMRI-targeted biopsy against RP as a histological gold standard. Another objective is correlating the 1 H-MRSI-derived tumor fat fraction with tumor epithelial lipid abundance measured using spatial metabolomics. Having recruited 27 patients, we expect to complete recruitment of 40 patients by July, with the full results available for presentation at RSNA and inclusion in extended abstract if accepted for presentation and Trainee Prize competition.

CLINICAL RELEVANCE/APPLICATION

Differentiating cribriform from non-cribriform PCa is critical but challenging with mpMRI alone. Preliminary results, currently evaluated in a full-scale prospective study, indicate that proton spectroscopy provides a biologically-informed, clinically relevant imaging approach to address this diagnostic gap.

Jaeil Kim, PhD (*Abstract Co-Author*)
Jung Hyun Yoon, MD, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the effect of using artificial intelligence (AI)-based decision support system for interpreting thyroid ultrasonography (US) according to experience levels.

METHODS AND MATERIALS

From January 2020 to December 2020, a total of 481 thyroid US images from 481 patients were included. Eight readers (4: board-certified radiologists with 3-23 years of experienced, 4: endocrine surgeon, first year radiology resident, nurse, radiographer with less than 1 year of experience) were recruited for this reader study. A deep learning based AI system (CadAI-T for Thyroid TM) was used to assist readers (Fig.1). The 481 thyroid US images were independently reviewed in two sessions; session 1, grayscale US alone, and after 3 weeks of washout, session 2, grayscale US with AI results. US interpretation was given based on the K-TIRADS final assessments. Readers were asked to describe whether they had confidence in the AI results for each case. Diagnostic performances of readers in session 1 and 2 were calculated and compared.

RESULTS

Among 481 images, 184 (38.3%) nodules were malignant, 157 (32.6%) nodules were benign, and 140 (29.1%) were negative US images without focal abnormality (mean size of nodules: 16.7mm ± 8.8, range, 5 - 51mm). Average AUC showed significant improvement in session 2 compared to session 1 for the less experienced readers, 0.842 (95% confidence interval [CI]: 0.814-0.869) vs. 0.755 (95% CI: 0.730-0.780), respectively (P<0.001). No significant changes were seen in AUC between the session 1 and 2 for the experienced readers, 0.900 (95% CI: 0.879-0.921) to 0.907 (95% CI: 0.887-0.928)(P=0.092). Mean sensitivity and NPV was significantly improved in experienced readers (all P<0.05), while all diagnostic indices was significantly improved in inexperienced readers in session 2 (all P<0.001, respectively). Both experienced and inexperienced readers had confidence in AI results when used for assessing malignant nodules. The standalone performance of the AI system yielded an AUC of 0.903 when using the AI score and 0.874 when using TI-RADS.

CONCLUSION

Average AUC for inexperienced readers was significantly improved after using AI for thyroid US interpretation.

CLINICAL RELEVANCE/APPLICATION

AI for thyroid US interpretation can assist less experienced readers in differential diagnosis of thyroid nodules.

S1-SSHN01-2 TARGETED DEFACING USING DEEP LEARNING METHODS FOR PEDIATRIC COHORTS WITH A HUMAN IN THE LOOP INTERFACE

Benedikt Wichtlhuber, BSc (*Presenter*)
Konrad Wienecke (*Abstract Co-Author*)
Marcel Eicke (*Abstract Co-Author*)
Eric Frodl, MSc (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)
Andreas Bucher, MD (*Abstract Co-Author*)
Diane M. Renz, MD (*Abstract Co-Author*)

PURPOSE

To create and test user-friendly software that removes identifying facial and dental features from pediatric head and neck MRI and CT scans while preserving important diagnostic areas, especially submandibular and cervical lymph nodes.

METHODS AND MATERIALS

This study is part of a retrospective multi-center research project involving pediatric patients with non-Hodgkin lymphoma (NHL). The dataset comprises up to 8,000 DICOM imaging series' per site across more than 25 sites, including CTs, MRIs, X-rays, and patient protocols, with a substantial portion of images containing facial and dental features.We developed a software called Defacer, allowing users to easily tag series and adjust automatically generated face and teeth segmentations for the purpose of de-identification. Teeth segmentations are generated by the nnUNet model, trained and 5-fold cross-validated on a diverse dataset of pediatric patients (ages 1-21) from the University Hospital [blinded]. Facial masks are based on the TotalSegmentator tool. Ear segmentation models will be included in a future version. Every automated step encompasses human oversight and allows for manual correction.

RESULTS

The segmentation system achieved consistent results for teeth with a Dice score (DSC) of 0.80 (±0.07) for MR (304 training samples), as well as a DSC of 0.80 (±0.06) for CT (170 training samples). Our approach enables precise de-identification while retaining diagnostically relevant anatomy. The system supports resource-efficient workflows by only generating segmentations when needed and is tailored for use by non-technical clinical staff. Our results show that new, non-technical users can tag series with a speed of 572 series per hour. Experienced users achieve upwards of 1500 series per hour. Notably, users were able to identify problematic defacing results with a sensitivity over 0.99.

CONCLUSION

The proposed solution enables compliant and efficient de-identification of pediatric imaging data across CT and MR imaging series, preserving the integrity of critical anatomical regions. The inclusion of human oversight and quality management ensures reliability and adaptability in clinical workflows.

CLINICAL RELEVANCE/APPLICATION

Our method supports the secure sharing and analysis of sensitive pediatric imaging data in large-scale studies without compromising diagnostic quality and patient privacy rights. Defacer facilitates regulatory compliance in multicenter research settings and offers a practical tool for clinical teams with limited technical expertise. We will integrate our method in a nationwide multicentric initiative for radiological research with a focus on multicentric collaboration.

S1-SSHN01-3 DEEP LEARNING CLASSIFICATION OF NASAL ANATOMICAL VARIANTS ON COMPUTED TOMOGRAPHY FOR ENDOSCOPIC SINUS SURGERY

Abdul Rafay (*Presenter*)

PURPOSE

Endoscopic sinus surgery (ESS) is one of the most commonly performed procedures in otolaryngology. However, it carries a major complication rate of up to 1% due to the proximity of critical structures within the surgical field. Anatomical variants such as a free-floating anterior ethmoidal artery (FFAEA), Onodi cells, and Haller cells further elevate this risk when unrecognised, yet are inconsistently reported on pre-operative CT. Convolutional neural networks (CNNs) have shown promising results in detection and segmentation tasks across head and neck radiology, but these high-risk variants have not previously been targeted. This study aimed to develop and evaluate a CNN capable of detecting FFAEA, Onodi cells, and Haller cells on sinus CT.

METHODS AND MATERIALS

CT scans from 122 patients referred for ESS at our centre (February - April 2025) were anonymised, and screenshots were captured in the coronal plane at standardised anatomical locations. All images were resized to 224 × 224-pixel greyscale and augmented with random flips, rotations, and affine shifts. Five ImageNet pre-trained CNN backbones (MobileNetV2, ResNet-18, DenseNet-121, VGG-16, SqueezeNet) were fine-tuned using repeated 5-fold patient-wise cross-validation. A grid search explored 40 training configurations derived from every combination of 2 optimisers (Adam, SGD-momentum), 2 learning rates (LR) (0.001, 0.0005), and 2 epoch counts (15, 25) for each of the 5 architectures (5 × 2 × 2 × 2 = 40 unique training recipes). Balanced accuracy and area under the ROC curve (AUC) were primary metrics; accuracy, precision, recall, and F1-score were recorded as secondary metrics.

RESULTS

Of 122 patients, 23 (18.9%) had FFAEA, 8 (6.6%) Haller cells, and 29 (23.8%) Onodi cells. FFAEA : ResNet-18 (Adam, LR 0.001, 25 epochs) achieved balanced accuracy 77.8 ± 2.3% and AUC 0.830 ± 0.018. Haller : MobileNetV2 (SGD, LR 0.0005, 15 epochs) achieved balanced accuracy 63.7 ± 6.2% and AUC 0.779 ± 0.059. Onodi : MobileNetV2 (Adam, LR 0.001, 15 epochs) achieved balanced accuracy 74.6 ± 2.5% and AUC 0.823 ± 0.026.

CONCLUSION

This pilot study demonstrates the feasibility of CNN-based detection of clinically significant nasal variants on sinus CT, with good to excellent classifier performance for two of the three variants assessed (AUC = 0.80).

CLINICAL RELEVANCE/APPLICATION

As a pilot study, this work lays the groundwork for a future AI tool that could assist radiologists by flagging rare, clinically significant anatomical variants—such as FFAEA, Onodi cells, and Haller cells—on sinus CT. By highlighting high-risk features that are often underreported, such a tool has the potential to support surgical planning and reduce preventable complications during ESS.

S1-SSHN01-4 DEEP LEARNING DETECTS PROGNOSTICALLY SIGNIFICANT MRI EDEMA PATTERNS IN PATIENTS WITH ACUTE NECK INFECTIONS

Jussi Hirvonen, MD, PhD (*Presenter*)
Oona Rainio (*Abstract Co-Author*)
Heidi Huhtanen, MD (*Abstract Co-Author*)
Jari-Pekka Vierula, MD (*Abstract Co-Author*)
Janne Nurminen (*Abstract Co-Author*)
Jaakko A. Heikkinen, MD (*Abstract Co-Author*)
Riku Klen (*Abstract Co-Author*)

PURPOSE

In acute neck infections, magnetic resonance imaging (MRI) reveals retropharyngeal edema (RPE), a prognostic indicator of severe disease progression. This study aimed to develop a deep learning algorithm for the automated detection of RPE in MRI scans.

METHODS AND MATERIALS

A deep neural network was developed using axial T2-weighted water-only Dixon MRI images from 479 patients with acute neck infections. Radiologists annotated the dataset at both slice and patient levels. The model comprised two components: (1) a convolutional neural network (CNN) for classifying individual slices and (2) an algorithm for patient-level classification based on stacks of slices. Performance metrics, including accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve (AUC), were compared against radiologists' assessments as the reference standard. The proposed CNN was benchmarked against InceptionV3, and the patient-level classification algorithm was evaluated against traditional machine learning models.

RESULTS

Of the 479 patients, 244 (51%) were RPE-positive and 235 (49%) were RPE-negative. At the slice level, the model achieved an accuracy of 94.6%, sensitivity of 83.3%, specificity of 96.2%, and AUC of 94.1%. At the patient level, it had an accuracy of 87.4%, sensitivity of 86.5%, specificity of 88.2%, and AUC of 94.8%. Compared to InceptionV3, the proposed CNN demonstrated equivalent accuracy with significantly reduced computational time. The patient-level classification algorithm outperformed traditional machine learning approaches.

CONCLUSION

This deep learning model demonstrated high accuracy in detecting the prognostically significant RPE pattern on MRI in patients with acute neck infections. Leveraging weakly annotated data and computationally efficient training, this approach can potentially enhance the early identification of high-risk patients in emergency settings.

CLINICAL RELEVANCE/APPLICATION

Our deep learning algorithm accurately detects RPE in MRI scans of acute neck infection patients, a key prognostic marker. Its computationally efficient design, outperforming models like InceptionV3 with reduced processing time, supports rapid identification of high-risk cases in emergency settings, potentially improving triage, treatment, and outcomes.

S1-SSHN01-5 ORBITAL MRI-BASED DEEP LEARNING AUTOMATED EXOPHTHALMOS TOOL IN THYROID ASSOCIATED ORBITOPATHY

Xinyi Gou (*Presenter*)
Jin Cheng, MD (*Abstract Co-Author*)
Nan Hong, MD (*Abstract Co-Author*)

PURPOSE

To develop an orbital magnetic resonance imaging (MRI)-based automated measurement tool for exophthalmos in thyroid-associated orbitopathy (TAO).

METHODS AND MATERIALS

One senior radiologist and two junior radiologists (Junior No.1 and Junior No.2) calculated exophthalmos measurements based on 2D and 3D MRI data, respectively, in 177 patients with TAO. Hertel-based exophthalmos measurements were performed in 122 of these patients. Following MRI-based exophthalmos measurement procedures, models for automatically identifying the most anterior point of the zygomatic prominence and orbital segmentation were developed. An automated tool for assessing exophthalmos using orbital MRI was developed. The consistency of exophthalmos measurements across different methods was also evaluated.

RESULTS

The results of the paired t-test indicated a high degree of consistency between 2D and 3D orbital MRI, with no significant differences observed. In the 2D MRI analysis, no statistically significant differences were found between the senior radiologist and Junior No.1. However, both the senior radiologist and Junior No.1 exhibited statistically significant discrepancies when compared with Junior No. 2 ($p<0.05$) in both 2D and 3D MRI. All intergroup comparisons of 3D MRI revealed significant differences. Pearson correlation analysis revealed a significant positive correlation ($r = 0.75$-0.77) between Hertel exophthalmos measurements and orbital MRI-based assessments. In the 2D MRI, the Intraclass Correlation Coefficient(ICC) between the senior radiologist and the automated measurement tool was 0.82 (0.77-0.86), higher than that between the senior radiologist and Junior No. 2 (ICC 0.80 (0.35-0.91)).

CONCLUSION

Orbital MRI-based exophthalmos demonstrated a strong correlation with Hertel exophthalmometer measurements, although with inherent inter-observer variability. The implementation of an automated orbital MRI assessment tool offers superior accuracy and objectivity in quantifying proptosis.

CLINICAL RELEVANCE/APPLICATION

The use of orbital MRI for proptosis measurements by different radiologists can result in inconsistent outcomes due to subjective judgment and variations in individual skills, which may impact the accuracy of diagnostic and therapeutic decisions. Furthermore, in clinical practice, some participants' eyes are not directed forward in orbital MR images, potentially leading to measurement errors. Rescanning is time-consuming. Developing the orbital MRI-based automated exophthalmos tool can minimize errors and ensure the stability and objectivity of the measurement results.

Atsushi Yamamoto, MD, PhD (*Abstract Co-Author*)
Yoko Satoh (*Abstract Co-Author*)
Shuji Sakai, MD, PhD (*Abstract Co-Author*)

PURPOSE

In breast cancer patients undergoing repeated chemotherapy, cancer therapy-related cardiac dysfunction is an important prognostic factor. However, there are no useful tools for its prediction. Myocardial accumulation on FDG PET is influenced by blood glucose level and insulin activity and fluctuates between individuals with poor reproducibility. Therefore, it is difficult to distinguish physiologic from pathologic accumulation, and myocardial accumulation on FDG PET during oncology has not been used for complication assessment. We quantitatively evaluated myocardial accumulation using FDG PET performed serially during breast cancer chemotherapy to assess the potential for cardiotoxicity by chemotherapy regimen.

METHODS AND MATERIALS

We analyzed 535 FDG PET examinations performed before and after chemotherapy in 108 patients with breast cancer between January 2014 and February 2025. On pre- and post-treatment FDG PET, the mean values within the volume of interest (size 1.5cm 3) of myocardium with the highest accumulation and descending aorta on the same cross-section were measured, and the ratio of the two was defined as the myocardial standard uptake ratio (M-SUR). Chemotherapy was classified into four regimens: anthracyclines, human epidermal growth factor receptor 2 (HER2) inhibitors, immune check inhibitors (ICI), and others. When single or multiple chemotherapy regimens were administered in the same patient, the pre- and post- data sets for each chemotherapy regimen were compared using Wilcoxon matched-pairs signed rank test.

RESULTS

The average observation period and number of PET scans per patient is 39 months and 5.0 scans. A total of 309 pre- and post-chemotherapy data sets were obtained, of which 34 were for anthracyclines (n=17), 146 were for HER2 inhibitors (n=40), 20 were for ICI (n=9), and 109 were for others (n=54). M-SUR after chemotherapy was significantly higher than before chemotherapy in the anthracyclines (4.66±3.94 vs. 3.19±2.10, p<0.0001) and ICI (4.98±4.27 vs. 3.02±2.21, p=0.0328) groups. On the other hand, in the HER2 inhibitor and the other groups, M-SUR tended to be lower after chemotherapy than before, but the difference was not significant (HER2 inhibitor: 4.91±4.44 vs. 4.31±3.22; the other: 4.22±3.16 vs. 3.76±3.01).

CONCLUSION

Serial analysis of pre- and post-chemotherapy FDG PET revealed different responses to myocardial accumulation depending on the chemotherapy regimen. With anthracycline and ICI, there is a significant increase in myocardial uptake after chemotherapy.

CLINICAL RELEVANCE/APPLICATION

Cardiac accumulation of FDG PET was underutilized in oncology. However, the serial analysis provides clues for detecting cardiotoxicity of chemotherapy.

S1-SSNMMI01-3 HIGH-RESOLUTION SEMICONDUCTOR PET/CT FOR THE DIAGNOSIS OF EXTENSIVE INTRADUCTAL COMPONENTS OF BREAST CANCER: COMPARISON WITH MR IMAGING

Rika Yoshida, MD (*Presenter*)
Takeshi Yoshizako, MD (*Abstract Co-Author*)
Akina Miyamoto (*Abstract Co-Author*)
Yasushi Kaji, MD, PhD (*Abstract Co-Author*)

PURPOSE

To retrospectively compare the usefulness of high-resolution semiconductor PET/CT (WB-SiPM-PET/CT) in prone position with dynamic MRI in diagnosing the extent of extensive intraductal components (EIC) in breast cancer.

METHODS AND MATERIALS

61 patients with 64 breast cancers underwent WB-SiPM-PET/CT (prone) and dynamic MRI preoperatively without chemotherapy. Lesions were histopathologically confirmed. Based on the PET accumulation values (SUVmean and standard deviation [SD]) of normal breast tissue, four tumor thresholds (SUVmean+2SD/3SD, 1.5SUVmean+2SD/3SD) were used for semi-automatic tumor size measurement. The pathological size (invasive tumor and EIC) was compared with MRI size and the four SUV thresholds sizes in relation to EIC rate, menopausal status and Ki-67.

RESULTS

All lesions were detected by both MRI and PET. Strong correlation was observed between the pathological size and the MRI size, as well as the four SUV thresholds size (strong relationship: 0.667-0.734). In particular, SUVmean+2SD showed strongest correlation (P < 0.01). The mean error from pathological size were 12.1±17.1mm for dynamic MRI and 5.90±16.0mm for SUVmean+2SD. The accuracy of the imaging tumor size plus the surgical margin (2 cm) > the pathological size was significantly

higher for SUVmean+2SD (90.6%) than for dynamic MRI (78.1%) (P < 0.01). In the EIC > 50% in the pathological size group (N=25), there was no significant difference in the accuracy between dynamic MRI (56%) and SUVmean+2SD (68%). However, in the EIC < 50% in the pathological size group (N=39), the accuracy was significantly higher for SUVmean+2SD (100%) than for dynamic MRI (89.7%) (P < 0.05). In premenopausal patients (N=27), the accuracy of SUVmean+2SD (85.2%) was significantly higher than that of dynamic MRI (70.4%) (P < 0.05). In postmenopausal patients (N=37), the accuracy was 83.8% for dynamic MRI and 94.6% for SUVmean+2SD. In the low (=20%) Ki-67 group (N=36), the accuracy of SUVmean+2SD (88.9%) was significantly higher than that of dynamic MRI (77.8%) (P < 0.01). In the high (> 21%) Ki-67 group (N=28), the accuracy was high for both dynamic MRI (82.1%) and SUVmean+2SD (89.2%).

CONCLUSION

The SUVmean+2SD threshold of prone WB-SiPM-PET/CT accurately reflected the pathological size and demonstrated good diagnostic performance in diagnosing the extent of EIC in breast cancer. Prone WB-SiPM-PET/CT may be particularly useful in premenopausal patients and in low Ki-67. However, the accuracy of both modalities in EIC > 50% in the pathological size group was unsatisfactory.

CLINICAL RELEVANCE/APPLICATION

WB-SiPM-PET/CT (SUVmean+2SD) accurately reflects pathological size, outperforming MRI, especially in premenopausal and low Ki-67 patients, suggesting improved surgical planning.

S1-SSNMMI01-4 ENABLING CLINICAL TRANSLATION OF PROGNOSTIC BIOMARKERS BY AUTOMATED AI-BASED TOTAL METABOLIC TUMOR VOLUME AND TOTAL LESION GLYCOLYSIS ASSESSMENT FOR PROGRESSION-FREE SURVIVAL IN NSCLC PATIENTS

Ricarda Ebner, MD (*Presenter*)
Maurice Heimer, MD (*Abstract Co-Author*)
Felix Herr, MD (*Abstract Co-Author*)
Christian Alexander Dascalescu, MD (*Abstract Co-Author*)
Michael Ingrisch (*Abstract Co-Author*)
Jens Ricke, MD, PhD (*Abstract Co-Author*)
Lalith Kumar Shiyam Sundar, PhD, MS (*Abstract Co-Author*)
Rudolf A. Werner (*Abstract Co-Author*)
Paul Blanc-Durand, MD,MSc (*Abstract Co-Author*)
Clemens C. Cyran, MD (*Abstract Co-Author*)

PURPOSE

Total metabolic tumor volume (TMTV) and total lesion glycolysis (TLG) derived from [¹8F]FDG-PET/CT are established biomarkers reflecting tumor burden and metabolic activity. Despite their prognostic value, implementation is constrained by time-intensive and inconsistent manual segmentation, limiting routine applicability. In this study, TMTV and TLG were quantified using fully automated lesion segmentation. We assessed the prognostic impact of baseline and longitudinal TMTV and TLG for progression-free survival (PFS) in non-small cell lung carcinoma (NSCLC), to evaluate their potential role in individualized risk stratification and treatment guidance.

METHODS AND MATERIALS

120 patients with NSCLC who received tumor board-approved, stage-appropriate treatment were retrospectively included and underwent baseline and follow-up [¹8F]FDG-PET/CT. Disease progression was defined by physician documentation or tumor board consensus. Automated segmentation was conducted using Pionus v1.2.2 (PAIRE, Paris, France), a CE-marked, AI-based software for PET lesion segmentation. TMTV and TLG were calculated using standardized thresholds at 41% of SUVmax. Cox and time-dependent Cox models were applied using both continuous and dichotomized values to assess prognostic relevance.

RESULTS

Continuous baseline TMTV41% and TLG41% were not significantly associated with PFS (TMTV41%: HR = 1.00, p = 0.889; TLG41%: HR = 1.00, p = 0.696). In dichotomized models, patients with low baseline TLG had significantly longer PFS than those with high TLG (HR = 0.54, p = 0.017). A similar trend was observed for low TMTV (HR = 0.55), although not statistically significant (p = 0.107). Time-dependent analysis identified higher TMTV during follow-up as a significant predictor of increased progression risk (HR = 1.0015, p = 0.001).

CONCLUSION

Metabolic parameters such as TMTV and TLG have shown prognostic value in therapy monitoring; however, manual segmentation remains impractical in clinical routine due to time requirements and interobserver variability. This study highlights the utility of metabolic tumor biomarkers derived from fully automated PET/CT segmentation in NSCLC. While continuous baseline metrics showed limited value, low baseline TLG was a significant predictor of longer PFS. Longitudinal modeling revealed that rising TMTV over time was associated with increased progression risk. AI-based extraction of FDG-PET/CT parameters offers a scalable approach to integrating biomarkers into clinical workflows.

CLINICAL RELEVANCE/APPLICATION

Automated AI-based PET/CT analysis enables standardized quantification of TMTV and TLG, supporting longitudinal risk assessment and facilitating clinical integration of prognostic biomarkers in NSCLC.

S1-SSNMMI01-6 ANALYSIS OF FDG-PET/CT FOR MANAGEMENT OF HIGH-RISK PULMONARY NODULES IDENTIFIED ON CT LUNG CANCER SCREENINGS

Rui Dai, MD, PhD (*Presenter*)
Karen Rodriguez, MD (*Abstract Co-Author*)
Suzanne Byrne, MD (*Abstract Co-Author*)
Shaunagh McDermott, MBBCh (*Abstract Co-Author*)
Matthew S. Robertson, MD (*Abstract Co-Author*)
Thomas S. Ng, MD, PhD (*Abstract Co-Author*)
Eric Schmidlin, MD (*Abstract Co-Author*)

PURPOSE

Following CT lung cancer screening, evaluation with FDG-PET/CT (PET), short-term chest CT, or tissue biopsy is recommended in some patients with high probability of malignancy (Lung-RADS category 4A, 4B, or 4X). Theoretically, FDG-PET/CT provides noninvasive molecular analysis of lung nodules, potentially impacting the need for subsequent pathologic analysis. However, it remains unclear how much utility PET contributes to this setting. The objective of this study is to examine the utility of FDG-PET/CT in patients identified with Lung-RADS 4 during lung cancer screening, and identify conditions for which FDG-PET/CT is clinically impactful.

METHODS AND MATERIALS

Retrospective analysis of 466 patients (pts) at a multi-institutional academic radiology practice with Lung-RADS 4 on CT lung cancer screening in 2022 and their subsequent clinical course following recommendations for PET, short-term CT, or tissue biopsy were performed. Demographics and clinical data, including smoking status, pulmonary nodule characteristics on CT and PET, prior imaging, and reported level of suspicion for lung cancer were analyzed.

RESULTS

109/466 pts presenting with Lung-RADS 4 findings received FDG-PET/CT (PET). 25% of PET (28/109) was ordered for staging purposes and 0.9% (1/109) was ordered to determine which nodule was most avid for biopsy. The rest were ordered to evaluate the likelihood of malignancy of a lung nodule. Pulmonary nodules characteristics on PET were heterogeneous (Intensely avid: 37/109, 35%, moderately avid: 29/109, 27%, mildly avid: 23/109, 21%, not avid: 29/109, 27%). Pathologic diagnosis was available for 107/109 pts (2 treated empirically with radiation), determined via biopsy, surgery, or chest CT follow-up. Nodules in 65/107 (61%) of these pts were

malignant, with intensely/moderately-avid nodules being more likely to be malignant (87%) than mildly/non-avid nodules (35%; p-value <0.001). Beyond the indications for staging, PETs ordered to evaluate the likelihood of malignancy of nodules did not significantly alter the clinical management of pts compared to those who were monitored with short-term CTs or biopsies only.

CONCLUSION

Preliminary results suggest that, while the FDG-avidity of suspicious lung nodules in Lung-RADS 4 pts correlated with their malignant potential, the use of PET does not significantly impact the clinical decision for subsequent tissue sampling, except in cases for staging purposes and workup of incidentally found metastases on CT.

CLINICAL RELEVANCE/APPLICATION

Guidance for subsequent work-up of Lung-RADS 4 lesions is ambiguous. The use of FDG-PET/CT in this setting may be limited for most pts and do not clinically impact subsequent management.

S1-SSPH01-1 CLINICAL END-USER EVALUATION OF PHOTON COUNTING DETECTORS IN WHOLE-BODY PCD-CT SCANNERS USING DICOM IMAGES

Ke Li, PhD (*Presenter*)
Xinming Liu, PhD (*Abstract Co-Author*)
Megan C. Jacobsen, PhD (*Abstract Co-Author*)
Xiujiang J. Rong, PhD (*Abstract Co-Author*)
Frank Dong, PhD (*Abstract Co-Author*)

PURPOSE

Photon counting detector (PCD) CT imaging performance is heavily influenced by the physical characteristics of the PCD. Previous evaluations of PCDs were limited to within factory settings due to the need for raw data access. The purpose of this study was to assess the detective quantum efficiency (DQE) and dead time of PCDs from the perspective of PCD-CT end users, using reconstructed DICOM images.

METHODS AND MATERIALS

This study evaluated the performance of PCDs in two NAEOTOM Alpha scanners. Air-only PCD-CT scans were conducted across four tube potentials (70-140 kV) and seventeen different tube currents (ranging from 4 to 1300 mA), and two scan modes (UHR and standard Quantum+ mode). DICOM PCD-CT images were reconstructed with a small field-of-view (5 cm) near the isocenter, at a slice thickness of 0.4 mm, using the same reconstruction kernel (Br44). The 3D NPS of PCD-CT images was used to estimate the average number of detector counts, employing a validated parametric method. The expected number of input X-ray photons was derived from exposure and beam-quality measurements. Detector NPS was assessed using the Z-component of the 3D NPS. Detector MTF was measured based on a series of images of a copper edge placed parallel to the detector row direction. These measurements were then used to determine the frequency-dependent detector DQE. Finally, the PCD's deadtime was assessed by analyzing the relationship between image variances and tube current levels.

RESULTS

For the Alpha detector systems equipped with the anti-scatter grid, the zero-frequency DQE was measured to be 76% ± 2%. The frequency corresponding to 50% DQE is 6.8 ± 0.2 lp/cm. No significant dependence of DQE on tube potential (kV) was observed. The estimated PCD deadtime is 5.4 ± 0.5 ns. UHR and standard Quantum+ modes showed similar deadtime. The DQE and deadtime of the two scanners are consistent, with less than 2.4% difference.

CONCLUSION

The CdTe PCDs in the Alpha scanner exhibit excellent high-frequency DQE performance and fast counting speed. Based on the shape of the detector NPS, crosstalk between detector pixels is negligible. The zero-frequency DQE appears to be primarily influenced by the geometric efficiency of the grid system, rather than the thickness of the CdTe sensor.

CLINICAL RELEVANCE/APPLICATION

Clinical users have a critical need to routinely assess the performance of PCDs in PCD-CT scanners to support protocol optimization, troubleshooting, and informed decisions regarding future scanner acquisitions. Historically, this has been challenging due to limited access to raw data, preventing direct evaluation of CT detector performance. This study addresses that gap by presenting the first application of a novel DICOM image-based method to evaluate PCDs in clinical PCD-CT scanners.

S1-SSPH01-2 TASK-BASED EVALUATION OF A SILICON-BASED PHOTON-COUNTING CT PROTOTYPE FOR CORONARY STENOSIS GRADING WITH REALISTIC CORONARY ARTERY PHANTOMS

Maria Jose Medrano Matamoros, PhD (*Presenter*)
Jed Pack, PhD (*Abstract Co-Author*)
Stephen Araujo (*Abstract Co-Author*)
Grant M. Stevens, PhD (*Abstract Co-Author*)
Koen Nieman, MD,PhD (*Abstract Co-Author*)
Ge Wang, PhD (*Abstract Co-Author*)
Bruno De Man, PHD (*Abstract Co-Author*)
Adam S. Wang, PhD (*Abstract Co-Author*)

PURPOSE

To objectively evaluate the performance of a novel silicon-based photon-counting CT (PCCT) prototype for coronary artery grading using a custom-made coronary artery phantom with realistic calcification geometries. To our knowledge, this is the first evaluation of a silicon-based PCCT system using a realistic coronary phantom with known ground truth.

METHODS AND MATERIALS

Custom coronary artery phantoms were developed from clinical CCTA datasets using casting materials replicating 10 mg/mL iodine and calcified plaque attenuation, incorporating five calcification configurations based on cross-sectional quadrant coverage. Phantoms were embedded in a Gammex phantom and scanned at 120 kVp on a silicon-based PCCT prototype. For comparison, scans were acquired on a clinical Revolution Apex scanner with energy-integrating detectors (EID). Ground truth imaging was obtained with micro-CT at 120 kVp and 20 µm resolution. Automatic segmentations of Type I and Type IV calcifications were generated via Gaussian mixture model thresholding and morphological operations, following registration to a common grid. To account for blooming, effective vessel area for Type IV calcifications was defined as the region enclosed by connected plaques. Percent errors in calcification area, vessel area, and stenosis ratio were calculated by comparing

PCCT and EID segmentations to micro-CT ground truth. A composite metric, defined as a weighted sum of relative percent errors in vessel area (20%), calcification area (30%), and stenosis (50%), was used to assess system performance and account for compensatory errors in percent stenosis estimation.

RESULTS

Twenty slices of mild (Type 1, 20% stenosis) and moderate (Type IV, 41% stenosis) calcifications were analyzed. Visually, blooming-induced luminal narrowing was less pronounced in PCCT than in EID images. PCCT reduced percent error in calcification area by ~80% for Type I and ~60% for Type IV versus EID. Vessel area error for Type I dropped by over 60% with PCCT and was comparable between systems for Type IV. Relative percent errors in predicted stenosis and composite metrics were reduced by over 50% for both calcification types with PCCT.

CONCLUSION

Preliminary results show that high-resolution silicon-based PCCT imaging substantially reduces blooming artifacts, improving vessel and calcification area estimation and stenosis grading, especially in moderate calcifications. Ongoing work will extend analysis to all five calcification types.

CLINICAL RELEVANCE/APPLICATION

This carefully controlled study using a realistic coronary artery phantom shows the potential of high-resolution silicon-based PCCT to mitigate blooming and improve stenosis assessment accuracy.

S1-SSPH01-3 METAL ARTIFACT REDUCTION IN ULTRA-HIGH RESOLUTION PHOTON COUNTING DETECTOR CT IMAGING OF MIDDLE EAR PROSTHESES USING ARTIFICIAL INTELLIGENCE

Kevin J. Treb, PhD (*Presenter*)
Maryam Sadeghian Sharafi, BSc, MSc (*Abstract Co-Author*)
Wenchao Cao (*Abstract Co-Author*)
Christopher P. Favazza, PhD (*Abstract Co-Author*)
Andrea Ferrero, PhD (*Abstract Co-Author*)
Andrew Missert, PhD (*Abstract Co-Author*)
Matthew Carlson, MD (*Abstract Co-Author*)
Shuai Leng, PhD (*Abstract Co-Author*)

PURPOSE

Photon counting detector CT (PCD-CT) enables ultra-high resolution (UHR) capabilities for improved imaging of submillimeter structures in the inner and middle ear. However, PCD-CT can be more susceptible to metal artifacts near middle ear prostheses than conventional energy integrating detector CT. Commercial metal artifact reduction software is insufficient in removing these artifacts and is not available with high resolution reconstructions. This work aims to utilize an image-domain convolutional neural network (CNN) to reduce metal artifacts in UHR PCD-CT.

METHODS AND MATERIALS

Three different middle ear prostheses containing titanium and platinum were randomly oriented within a uniform head-sized phantom and imaged on a commercial PCD-CT (NAEOTOM Alpha, Siemens) using a UHR temporal bone protocol (120 kV, Hr84 kernel, 0.2 mm slice thickness, 80 mm field of view, 1024x1024 matrix). Training data were then curated in two steps: First, images of the phantom without any prosthesis were subtracted to isolate the metal + artifact signal. A separate artifact-free metal-only image set was then created by masking and segmenting the metal + artifact images. In the second step, these two image sets were superimposed onto images of human cadaver heads scanned with the same UHR protocol to create paired training inputs and labels. Standard data augmentation strategies were used to enlarge the training dataset. The trained network was then applied to images of a different cadaver head that was implanted with middle ear prostheses. Artifact severity was compared by measuring the variance in uniform regions with and without metal artifacts and calculating the artifact index = v(s 2 artifact - s 2 background). Image spatial resolution was compared by measuring CT number line profiles through the metal.

RESULTS

In the input images, artifacts obscured surrounding anatomical structures, with some bright artifacts mimicking the appearance of metal prostheses. After AI processing, metal artifacts were substantially reduced, and the false metal artifact was fully removed to enable visualization of underlying anatomy. AI output images reduced artifact index by 86% compared to the input images. Line profiles demonstrated no noticeable differences in spatial resolution or metal signal between the AI inputs and outputs.

CONCLUSION

An image-based AI framework can significantly reduce the severity of metal artifacts while maintaining UHR capabilities in PCD-CT for middle ear prosthesis imaging.

CLINICAL RELEVANCE/APPLICATION

Enabling metal artifact reduction with UHR imaging can improve visualization of middle ear prostheses and surrounding anatomy for improved assessment of prosthesis placement accuracy post stapedectomy.

S1-SSPH01-4 MULTI-MATERIAL DECOMPOSITION IN PHOTON-COUNTING COMPUTED TOMOGRAPHY USING IN-VIVO DUAL CONTRAST MEDIA BASED ON IODINE AND HOLMIUM OR GADOLINIUM IN A PIG MODEL: EVALUATION OF OPTIMAL AMOUNT OF ENERGY THRESHOLDS

Elisabeth Shanblatt, PhD (*Presenter*)
Tristan Nowak, PhD (*Abstract Co-Author*)
Jonas Neumann (*Abstract Co-Author*)
Ralf Gutjahr, PhD (*Abstract Co-Author*)
Hubertus Pietsch, VMD, PhD (*Abstract Co-Author*)
Gregor Jost, PhD (*Abstract Co-Author*)
Michael Grasruck, PhD (*Abstract Co-Author*)
Bernhard Schmidt, PhD (*Abstract Co-Author*)

PURPOSE

Multi-threshold imaging using photon-counting detectors (PCDs) in computed tomography (CT) enables the differentiation of more than two true basis materials from a single scan. To take advantage of this for diagnostic purposes, new contrast media based on high-Z elements need to be developed. In this study, we evaluated the potential of sequential intravenous (IV) dual contrast media (CM) injection in a Göttingen minipig using a standard iodine-based CM followed by an established gadolinium-based MRI CM or an experimental high-Z CM based on holmium (Ho).

METHODS AND MATERIALS

A research 4-threshold scan mode on a commercial CT system (NAEOTOM Alpha Peak, Siemens Healthineers, Forchheim, Germany) was used to perform two sets of thorax and abdomen scans on two different anaesthetized Göttingen minipigs. For the first pig, we performed timed IV injections of iopromide and gadobutrol (Bayer AG, Leverkusen Germany) with a delay of 33 s between both injections using bolus monitoring, a tube voltage of 140 kV, and the threshold set T1/T2/T3/T4 of 20/52/72/75 keV. For the second pig, iopromide and the Ho-based CM were injected with the same timing approach and tube voltage using the threshold set 20/55/72/90 keV. We then performed the following image-based material decompositions and analyzed the loss in contrast-to-noise (CNR) compared to the respective T1 image: [T1, T3], [T1, T2, T3], [T1, T3, T4] and [T1, T2, T3, T4] into water and I for both pigs; [T1, T2, T3] into water, I and Gd/Ho for pig 1 and pig 2, respectively; as well as [T1, T2, T3, T4] to water, I, Gd/Ho for pig 1 and pig 2, respectively. Contrast and noise were assessed from cylindrical regions placed inside the aorta.

RESULTS

For the 2-material decompositions into water and I, the CNRs relative to the respective T1 images were: 31.2% for [T1, T3], 31.8% for [T1, T2, T3], 31.4% for [T1, T3, T4] and 32.0% for [T1, T2, T3, T4] for pig 1, and, respectively, 28.5%, 28.7%, 29.0% and 29.2% for pig 2. For the 3-material decompositions into water, iodine and gadolinium (pig 1) were: 11.2% for [T1, T2, T3], 11.1% and 11.4% for [T1, T2, T3, T4]. For water, iodine and holmium (pig 2), the relative CNRs were: 17.3% and 17.5%, respectively.

CONCLUSION

Using more energy thresholds than materials did not significantly increase the CNRs of the decomposed images for our measurements. This provides evidence that - with optimally selected energy thresholds - additional thresholds over the minimum required for a material decomposition provide little benefit in spectral CT.

CLINICAL RELEVANCE/APPLICATION

The demonstrated findings in this animal study on a PCD-CT show that an optimized, reduced set of energy thresholds preserves diagnostic performance and thus demonstrate a practical path to lowering system complexity.

S1-SSPH01-5 PITFALLS OF FWHM-BASED DETECTOR ENERGY RESOLUTION METRICS IN PHOTON COUNTING CT: TOWARD IMPROVED METRICS

Shanli Ding (*Presenter*)
Linying Zhan, MS, BSc (*Abstract Co-Author*)
Ke Li, PhD (*Abstract Co-Author*)

PURPOSE

Energy resolution in photon-counting detectors (PCDs) is traditionally quantified using the full width at half maximum (FWHM) of the primary photopeak in the detector's pulse-height spectrum (PHS) in response to a ?-ray source. This value, expressed in keV or as a percentage of the ?-ray energy, is widely used in nuclear medicine, where high-energy thresholds are applied to exclude scattered and background signals. However, in PCD-based computed tomography (PCD-CT), the entire polychromatic X-ray spectrum contributes to image reconstruction. As such, FWHM-based metrics—which largely ignore low-energy tails of PHS—may not adequately reflect the energy resolution relevant to PCD-CT applications. This study aims to highlight the limitations of FWHM-based energy resolution metrics in this context and proposes a new detector energy resolution metric tailored for spectral CT.

METHODS AND MATERIALS

To generate PHS of varying shapes, we modified the sensor material and electronic noise levels within an in-house PCD-CT simulation platform, which has been validated using experimental data from NEOTOM Alpha scanners. For each PHS configuration, energy resolution was assessed in the context of water-iodine decomposition tasks, using a 140 kV X-ray spectrum from the NEOTOM Alpha scanner. The Cramér-Rao Bound (CRB) was used as the gold standard for quantifying spectral CT performance. The classical energy resolution metric (FWHM of the PHS) was compared to a novel metric we introduce—the Separability Index of Detected Energy-spectrum (SIDE)—evaluated across energy bins.

RESULTS

The Pearson correlation coefficient between classical FWHM and CRB was 0.357 ($p = 0.191$), indicating no significant correlation. Notably, FWHM substantially overestimated PCD energy resolution in cases with narrow photopeaks and prominent low-energy tails and underestimated it in spectra with broader peaks but minimal tails. For the proposed SIDE metric, its Pearson correlation coefficient is -0.965 ($p<0.001$), indicating a strong negative correlation with CRB: namely, a higher SIDE corresponds to a lower noise in material images.

CONCLUSION

FWHM-based metrics can misrepresent PCD energy resolution in spectral CT tasks, depending on PHS shape and threshold placement. The proposed SIDE metric overcomes these limitations and shows stronger agreement with task-specific performance as quantified by the CRB.

CLINICAL RELEVANCE/APPLICATION

A robust, task-relevant measure of energy resolution enables more informed clinical decisions when selecting between PCD-CT and dual-energy EID-CT systems. It also facilitates more accurate comparisons across PCD systems with varying semiconductor materials and readout architectures for CT imaging applications.

S1-SSPH01-6 PHOTON-COUNTING CT AND DEEP LEARNING RECONSTRUCTION IN LUNG LESION ASSESSMENT

Kai Mei, PhD (*Presenter*)
Shobhit Sharma, PhD (*Abstract Co-Author*)
Leening P. Liu, PhD (*Abstract Co-Author*)
Leonid Roshkovan, MD (*Abstract Co-Author*)
Steven Ross, PhD (*Abstract Co-Author*)
Ali H. Dhanaliwala, MD, PhD (*Abstract Co-Author*)
Sandra S. Halliburton, PhD (*Abstract Co-Author*)
Naruomi Akino (*Abstract Co-Author*)
Zhou Yu, PhD (*Abstract Co-Author*)
Richard Thompson, PhD (*Abstract Co-Author*)
Peter B. Noel, PhD (*Abstract Co-Author*)

PURPOSE

This study investigates how super high-resolution (SHR) photon-counting CT (PCCT) integrated with deep learning reconstruction (DLR) performs in characterizing lung lesions with different sizes and degrees of spiculation at various CT dose levels, using PixelPrint 3D-printed lesion phantoms.

METHODS AND MATERIALS

For this study, 18 computational lung lesions were selected, consisting of 2 lesion types: semisolid lesions with 2 contrast levels (40 and -285 HU) and full solid lesions (40 HU). Each lesion type was modeled with 3 spiculation levels (high, medium, and low) and 3 diameters (13 mm, 6 mm, and 3 mm). All lesions were 3D-printed using PixelPrint with a -600 HU background and placed in a multi-energy CT phantom (Gammex). Scan was performed using a prototype CdZnTe-based PCCT (Canon Medical Systems Corporation, Japan) at 120 kVp across 6 dose levels (20 to 1 mGy), each with 3 repetitions. The lowest dose used in this study is below clinically routine levels for a phantom of this size. Image reconstruction was carried out in SHR mode (pixel spacing/thickness: 0.25 / 0.21 mm) using a lung kernel with adaptive iterative dose reduction (AIDR) and DLR. Radiologists evaluated the images with a focus on spiculation and the solid component of semisolid nodules. Quantitative lesion metrics, specifically uniformity and sphericity, were extracted using PyRadiomics for analysis.

RESULTS

Lesions of all 3 types were clearly visualized in PCCT scans across both reconstruction methods. Notably, lesions > 13 mm in diameter could be consistently identified as semisolid across all dose levels. Highly spiculated lesions > 6 mm were distinguishable from mid and low spiculation levels in both semisolid and full solid forms. DLR demonstrated sharper images compared to AIDR, although contrast-to-noise ratios showed no significant differences when dose > 5 mGy. However, for smaller lesions, reduced dose levels affected accuracy of morphological assessment. As dose decreased, it became increasingly challenging to evaluate lesion surface roughness. Although key radiomic features exhibited dose-dependent variability, standard deviation across all lesions for uniformity, was approximately 25% lower with DLR compared to AIDR, indicating greater stability and robustness in DLR-based reconstructions.

CONCLUSION

This study demonstrates that SHR PCCT, particularly when combined with DLR, enables robust visualization and characterization of lung lesions across varying sizes, spiculation levels, and dose.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the clinical potential of PCCT with DLR to improve lung lesion assessment while maintaining image quality across reduced dose levels, supporting safer and more accurate low-dose CT protocols.

S1-STCE1-1 PREDICTIVE FACTORS OF LOCAL RECURRENCE AND OVERALL SURVIVAL IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH TRANSARTERIAL CHEMOEMBOLIZATION

Uuganbayar Batbayar, MD, MBA (*Presenter*)
Erdenebulgan Batmunkh (*Abstract Co-Author*)

PURPOSE

To determine predictive risk factors of local recurrence after transarterial chemoembolization (TACE) and to compare the efficacy and safety of long-versus short-interval of transarterial chemoembolization (TACE) in hepatocellular carcinoma (HCC) patients.

METHODS AND MATERIALS

This retrospective cohort study involved 500 patients diagnosed with hepatocellular carcinoma who underwent transerterial chemoembolization at the Angiography Department of Second State Cental hospital between 2021 and 2025. The patients were divided into a short-interval group (SIG) and a long-interval group (LIG) based on the median TACE interval of the first two sessions with subgroup of BCLC grade. The data analysis was performed using STATA software programm. The overall survival was calculated as the interval between the date of initial TACE and the last follow-up. We used the Kaplan-Meier method and logistic regression test to estimate and compare overall survival.

RESULTS

The results of the study indicated that the lipiodol uptake was 205.59 ± 76.06 HU (p=0.041) and the tumor size was 4.18 ± 2.79 cm (p=0.010). These factors were found to have a significant impact on the occurrence of local recurrence after transarterial chemoembolization. The median TACE interval was 7.5 months and 58.6% of patients have short interval (=7.5 months) and 41.4% have long interval (=7.5 months) of TACE treatment. TACE interval plays important role for determining overall survival. The long interval group had a longer overall survival than the short interval group in Barcelona Clinic liver cancer (BCLC) stage C patients.

CONCLUSION

Non-compact lipiodol uptake (<200 HU) and tumor size are important risk factors influencing the local recurrence after transarterial chemoembolization in patients with hepatocellular carcinoma. A long interval between the first two sessions of TACE resulted in a better overall survival than a short interval in patients with BCLC C-stage HCC.

CLINICAL RELEVANCE/APPLICATION

Hepatocellular carcinoma (HCC) is the third most common cause of cancer-related death worldwide (incidence rate of 16 per 100,000 people) with 700,000 deaths annually attributed due to the hepatocellular carcinoma. Curative treatment of the hepatocellular carcinoma includes partial surgical resection of liver segment, radiofrequency ablation (RFA) and transarterial chemoembolization (TACE), but more than 50% of cases are diagnosed in the advanced stages. Several research studies have shown that local recurrence often occurs after transarterial chemoembolization. And several risk factors have been identified as contributing local recurrence after transarterial chemoembolization.

S1-STCE1-2 COMPREHENSIVE MULTI-OMICS ANALYSIS FOLLOWING CONVENTIONAL TRANSARTERIAL CHEMOEMBOLIZATION FOR INTERMEDIATE-STAGE HEPATOCELLULAR CARCINOMA PATIENTS

Rafael Duran, MD (*Presenter*)
Jonathan Thevenet (*Abstract Co-Author*)
Antonia Digklia (*Abstract Co-Author*)
Jean Paul Rivals (*Abstract Co-Author*)
Petra Baumgaertner (*Abstract Co-Author*)
Antonella Diciolla (*Abstract Co-Author*)
Clarisse Dromain, MD, PhD (*Abstract Co-Author*)
Georgia Tsoumakidou, MD (*Abstract Co-Author*)
Alban L. Denys, MD (*Abstract Co-Author*)
Nicolas Villard, MD (*Abstract Co-Author*)
Julien Dagher (*Abstract Co-Author*)
Christine Sempoux (*Abstract Co-Author*)
Montserrat Fraga (*Abstract Co-Author*)

PURPOSE

Conventional transarterial chemoembolization (cTACE) remains a cornerstone therapy for patients with intermediate-stage hepatocellular carcinoma (HCC). However, outcomes such as treatment response and overall survival vary considerably among individuals, and reliable predictive biomarkers are still unavailable. This study aims to characterize the molecular and immune alterations triggered by cTACE in HCC.

METHODS AND MATERIALS

Prospective, single center, IRB-approved study. Consent was obtained in all patients. Paired liver and tumor biopsies were obtained at baseline and four weeks following cTACE, along with blood samples collected at baseline, 7-10 days, 4 weeks, and at 3- and 6-months post-treatment. Spatial proteomic and transcriptomic analyses were conducted on the tumor and tumor microenvironment (TME) compartments, complemented by comprehensive systemic blood profiling.

RESULTS

A total of 44 cTACE procedures were performed in 16 patients. Molecular profiling revealed substantial alterations in both the tumor and TME. Notably, there was a marked downregulation of CD4+ T-cell markers in the TME and reduced expression of tumor-related proliferation and survival markers. Baseline RNA signatures

demonstrated changes in gene expression associated with splicing, transcriptional regulation, and mitochondrial protein synthesis, while post-cTACE profiles showed changes in cellular differentiation and ion transport. Pathway analysis revealed distinct immune-related pathway activation patterns between patient responders and non-responders. Specific ligand-receptor dynamics reflected shifts in immune cell activity. Non-responders exhibited upregulation of various immune checkpoint molecules, suggesting potential targets for combined therapeutic strategies. Importantly, distinct transcriptomic and proteomic signatures were identified that correlate with clinical outcomes, particularly overall survival.

CONCLUSION

cTACE induces profound molecular changes in HCC, influencing both tumor biology and the immune microenvironment. The integration of multi-omics data enhances patient stratification and could help identify those most likely to benefit from cTACE. These findings support the development of combination approaches involving both locoregional and systemic therapies to improve patient outcomes.

CLINICAL RELEVANCE/APPLICATION

Our study provides new biomarkers that could substantially impact the prediction of progression free survival and overall survival in HCC patients. It underscores specific molecular and immune targets suitable for concurrent targeting with cTACE and presents strategic avenues for fortifying treatment outcomes and improving patient survival.

S1-STCE1-3 NONINVASIVE DEEP LEARNING SYSTEM FOR PREOPERATIVE DIAGNOSIS OF FOLLICULAR-LIKE THYROID NEOPLASMS USING ULTRASOUND IMAGES: A MULTICENTER, RETROSPECTIVE STUDY

Hui Shen (*Presenter*)
Bin Zhang, MD (*Abstract Co-Author*)

PURPOSE

To propose a deep learning (DL) system for the preoperative diagnosis of follicular-like thyroid neoplasms (FNs) using routine ultrasound images. Preoperative diagnosis of malignancy in nodules suspicious for an FN remains challenging. Ultrasound, fine-needle aspiration cytology, and intraoperative frozen section pathology cannot unambiguously distinguish between benign and malignant FNs, leading to unnecessary biopsies and operations in benign nodules.

METHODS AND MATERIALS

This multicenter, retrospective study included 3634 patients who underwent ultrasound and received a definite diagnosis of FN from 11 centers, comprising thyroid follicular adenoma (n=1748), follicular carcinoma (n=299), and follicular variant of papillary thyroid carcinoma (n=1587). Four DL models including Inception-v3, ResNet50, Inception-ResNet-v2, and DenseNet161 were constructed on a training set (n=2587, 6178 images) and were verified on an internal validation set (n=648, 1633 images) and an external validation set (n=399, 847 images). The diagnostic efficacy of the DL models was evaluated against the ACR TI-RADS regarding the area under the curve (AUC), sensitivity, specificity, and unnecessary biopsy rate.

RESULTS

When externally validated, the four DL models yielded robust and comparable performance, with AUCs of 82.2%-85.2%, sensitivities of 69.6%-76.0%, and specificities of 84.1%-89.2%, which outperformed the ACR TI-RADS. Compared to ACR TI-RADS, the DL models showed a higher biopsy rate of malignancy (71.6% -79.9% vs 37.7%, $P < 0.001$) and a significantly lower unnecessary FNAB rate (8.5% -12.8% vs 40.7%, $P < 0.001$).

CONCLUSION

This study provides a noninvasive DL tool for accurate preoperative diagnosis of FNs, showing better performance than ACR TI-RADS and reducing unnecessary invasive interventions.

CLINICAL RELEVANCE/APPLICATION

We expect that the DL models may assist in minimizing the need for unnecessary invasive procedures like biopsies and operations.

S1-STCE2-2 EFFORT-INDEPENDENT, NON-CONTRAST VENTILATORY ASSESSMENT OF INTERSTITIAL LUNG DISEASE PROGRESSION USING RESTING-STATE DYNAMIC CHEST RADIOGRAPHY

Kojiro Ono (*Presenter*)
Takefumi Nikaido (*Abstract Co-Author*)
Ryoichi Watanabe (*Abstract Co-Author*)
Akinori Tsunomori (*Abstract Co-Author*)
Yoshinori Tanino (*Abstract Co-Author*)
Yoko Shibata (*Abstract Co-Author*)
Tsutomu Yoneyama (*Abstract Co-Author*)

PURPOSE

This study aimed to evaluate an effort-independent, non-contrast method using resting-state dynamic chest radiography (DCR). Our scheme, Resting-State Silhouette Tracking for Thoracic Respiratory Assessment and Characterization of Kinetics (REST-TRACK), tracks respiratory motion via silhouettes and derives four ventilatory indices based on lung area and diaphragmatic displacement to distinguish healthy lungs from interstitial lung disease (ILD) and to monitor its progression.

METHODS AND MATERIALS

This IRB-approved retrospective study included 18 ILD patients (=6 months apart DCR) and 8 healthy controls with no smoking history. DCR was performed in the supine position during resting breathing (15 fps; entrance surface dose of ~1.8 mGy). Respiratory motion was extracted using REST-TRACK, which applies template-matching and deep learning models for silhouette segmentation and tracking. Diaphragm displacement (?DD) was defined as the average excursion of the highest points on bilateral domes; lung area change (?PLA) was calculated from expiratory and inspiratory frames. Respiratory rate (RR) was calculated based on diaphragmatic motion frequency. Four indices were derived: VE PLA = RR * ?PLA, RSBI PLA = RR / ?PLA, VE DD = RR * ?DD, and RSBI DD = RR / ?DD. Patients were classified into progressive (n=7; =5% annual FVC decline) or stable (n=11; <5%) groups. Statistical comparisons and correlation analyses with spirometry were performed.

RESULTS

Compared to controls, ILD patients showed significantly increased VE PLA and decreased RSBI PLA (both $p < 0.01$). Over time, the progressive group showed declining VE PLA , rising RSBI PLA and RSBI DD (all $p < 0.05$). In the stable group, VE PLA declined and RSBI PLA increased (both $p < 0.01$), despite stable spirometry, suggesting that REST-TRACK detects subclinical changes. VE PLA correlated with tidal volume ($r = 0.64$, $p < 0.01$); RSBI PLA inversely with FVC ($r = -0.48$, $p < 0.05$). RSBI DD demonstrated an emerging role as a potential biomarker for early diaphragmatic dysfunction, showing a trend toward inverse correlation with %FVC during follow-up ($r = -0.44$, $p = 0.069$) and significantly increasing only in the progressive group ($p < 0.05$).

CONCLUSION

REST-TRACK enables effort-independent, contrast-free ventilatory imaging and may detect latent ventilatory and diaphragmatic dysfunction not captured by spirometry. It also shows promise for monitoring disease progression in patients with ILD.

CLINICAL RELEVANCE/APPLICATION

Spirometry is the standard for monitoring ILD, but effort-dependent testing is difficult in elderly, frail, or critically ill patients. Advanced alternatives like contrast-enhanced or hyperpolarized gas MRI are costly or complex. REST-TRACK offers a contrast-free, effort-independent solution using DCR.

S1-STCE2-3 ROLE OF CEREBRAL PERFUSION USING 3 TESLA ARTERIAL SPIN LABELING MRI IN DEMENTIA PATIENTS

Shaheen Haidrus, MD, MBBS (*Presenter*)

PURPOSE

This study aimed to evaluate cerebral perfusion patterns in dementia patients using 3 Tesla ASL-MRI, compare findings with healthy controls, and analyze the correlation of perfusion parameters with cognitive impairment severity.

METHODS AND MATERIALS

A total of 92 participants, including 53 DSM-5-diagnosed dementia patients and 39 age- and sex-matched healthy controls, were enrolled to assess regional cerebral perfusion using 3T ASL-MRI. A fully automated Python-based computational pipeline was developed to extract quantitative perfusion metrics and integrate machine learning tools for early detection of dementia-related changes. The pipeline comprised ten sequential steps, each implemented using Jupyter Notebook and Python libraries (e.g., NiBabel, Nilearn, Scikit-learn, CatBoost, Matplotlib, and Pandas). This custom workflow enabled end-to-end analysis of ASL MRI data with minimal manual intervention.

RESULTS

Dementia cases demonstrated significantly reduced mean global CBF (43.12 ± 5.12 ml/100g/min) compared to controls (53.96 ± 13.01 ml/100g/min; $p < 0.0001$) and lower normalized z-CBF values (-0.65 ± 0.78 vs. 0.59 ± 1.12; $p < 0.0001$). Global CBF correlated positively with MMSE scores ($r = 0.40$, $p = 0.0051$) and inversely with risk level ($r = -0.41$, $p = 0.0037$). Alzheimer's disease patients exhibited pronounced hypoperfusion in the frontal opercular cortex, lingual gyrus, and temporal lobes, while vascular dementia showed diffuse hypoperfusion.

CONCLUSION

This study concludes that 3 Tesla Arterial Spin Labeling (ASL) MRI is a highly effective, non-invasive screening and monitoring tool for detecting cerebral perfusion deficits in dementia, particularly in settings lacking PET/SPECT. It differentiates patients from healthy controls, identifies dementia subtype-specific regional

hypoperfusion, and correlates strongly with cognitive impairment severity. Hypoperfusion emerges as an early neurodegeneration marker, with ASL-MRI mirroring FDG-PET findings without ionizing radiation or contrast agents. Frontal, temporal, and occipital lobes are most affected, especially in Alzheimer's disease.

CLINICAL RELEVANCE/APPLICATION

In our study, automated pipelines enabled standardized extraction of regional cerebral blood flow using the Harvard-Oxford atlas, while machine learning models such as CatBoost facilitated accurate classification of dementia subtypes and individualized risk stratification. Brain age estimation and z-score thresholding further improved interpretability. The integration of artificial intelligence in our study not only enhanced diagnostic accuracy but also improved reproducibility, reduced operator dependence, and paved the way for objective, quantitative assessment of perfusion abnormalities.

S2-SSBR01-1 DIAGNOSTIC PERFORMANCE OF ABBREVIATED VS FULL BREAST MRI PROTOCOLS IN BRCA MUTATION CARRIERS

Wendelien Sanderink, PhD (*Presenter*)
Suzanne L. Van Winkel, RN,MSc (*Abstract Co-Author*)
Marloes van der Leest, MD (*Abstract Co-Author*)
Susanne Lardenoije (*Abstract Co-Author*)
Mechli W. Imhof-Tas, MD, PhD (*Abstract Co-Author*)
Marialena Tsarouchi (*Abstract Co-Author*)
Ritse M. Mann, MD, PhD (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic accuracy of an abbreviated breast MRI protocol in comparison with the full diagnostic breast MRI protocol for screening BRCA-gene mutation carriers.

METHODS AND MATERIALS

This retrospective study compared the diagnostic accuracy of an abbreviated breast MRI protocol consisting of DWI, one pre- and one post contrast T1-weighted image and an ultrafast T1 during inflow with a full diagnostic breast MRI protocol (including DWI, one pre- and five post contrast T1-weighted images, ultrafast T1 during inflow and a T2-weighted acquisition) in women with a BRCA-gene mutation. Women with a BRCA-gene mutation and at least one screening MR in our hospital between January 2012 and December 2024 were analyzed. Information on age, screening round and eventual tumor characteristics was extracted from the medical record.

RESULTS

4409 MRI-screens were performed in 1058 women with a BRCA-gene mutation. In 790 women (age mean 40.1 y.o., range 23-72), 2905 full-protocol MRI examinations were obtained between January 2012 and March 2020 (average 3.7 screenings per woman, range 1 to 10). In 661 women (age mean 39.9 y.o., range 24-72), 1504 abbreviated MRI examinations were obtained between April 2020 and December 2024 (average 2.3 screenings per woman, range 1 to 7). Cancer was detected in total in 65 women (12 DCIS and 46 invasive). The cancer detection rate for first round screenings was 7/1000 [2/275] vs 22/1000 [9/414], P=0.13, for abbreviated MR and full-protocol MRI, respectively. For the follow-up rounds the cancer detection rate was 12/1000 [15/1229] vs 16/1000 [41/2491], P=0.26. Average tumor diameter was 11.4±9.8 mm with full protocol and 5.7±4.3 mm with abbreviated protocol (p=0.04). 20% was LN positive compared to 21% (p=0.90) for abbreviated MRI and full-protocol MRI, respectively.

CONCLUSION

Abbreviated MRI showed comparable cancer detection rates compared to the full-protocol MRI in women with a BRCA-gene mutation. Cancers detected by abbreviated MRI were on average smaller than those detected by the full protocol.

CLINICAL RELEVANCE/APPLICATION

Abbreviated breast MRI protocols provide a comparable cancer detection rate to full diagnostic protocols in BRCA mutation carriers, suggesting that abbreviated MRI can be a time-efficient and resource-saving alternative for high-risk breast cancer screening without compromising diagnostic performance.

S2-SSBR01-2 CLASSIFICATION OF BREAST DCIS WITH ULTRAFAST MRI

Carla Sitges, MD (*Presenter*)
Tianyu Zhang, PhD (*Abstract Co-Author*)
Miguel Braga, MD (*Abstract Co-Author*)
Xavier Bargallo, MD (*Abstract Co-Author*)
Ritse M. Mann, MD, PhD (*Abstract Co-Author*)

PURPOSE

Ductal carcinoma in situ (DCIS) is a heterogeneous lesion that accounts for 20% of all newly diagnosed breast neoplasms. Detecting DCIS can potentially prevent progression to invasive breast cancer (IBC); however, in cases of lower-grade DCIS, it often results in overtreatment. Therefore, classifying DCIS grade with imaging techniques could help identifying cases with biological significance and distinguish them from indolent ones that might benefit from surveillance and avoid standard treatment. In this study, we aim to evaluate the potential of UF-MRI parameters to predict the grade classification of DCIS.

METHODS AND MATERIALS

160 patients from the institutional database diagnosed with pure DCIS who underwent UF-MRI, were analyzed. DCIS grade (1-3) was obtained from the pathological report. UF parameters recorded included: time to enhancement (TTE) relative to that in the descending aorta and the maximum slope (MS) of the enhancement curve. Mean and standard deviations of TTE and MS were calculated by grade. The association between UF-MRI parameters, using previously determined threshold values, and DCIS grade was assessed using chi-squared statistical test and presented graphically.

RESULTS

The mean and standard deviation of TTE for each DCIS grade were as follows: Grade 1: 13.05 ± 3.58 s, Grade 2: 11.52 ± 4.19 s, and Grade 3: 9.68 ± 3.01 s. A consistent trend in which higher-grade lesions are associated with shorter TTE was observed ($p < 0.05$). Only 6% of DCIS grade 3 lesions was associated with a TTE > 15 s.The mean and standard deviation of MS for each grade were: Grade 1: 12.34 ± 5.37%/s, Grade 2: 11.63 ± 8.52%/s, and Grade 3: 11.30 ± 5.84%/s. No clear trend was observed between MS and DCIS grade. Statistical analysis indicated no significant differences among the grades ($p > 0.05$).

CONCLUSION

Higher-grade DCIS is associated with statistically significant shorter TTE. In contrast, MS showed no consistent relationship with DCIS grade. These findings suggest that TTE may serve as a imaging biomarker and prognostic factor for DCIS.

CLINICAL RELEVANCE/APPLICATION

Integrating the Ultrafast MRI parameter TTE into clinical practice could enhance DCIS stratification, support treatment de-escalation, and allow for more personalized management. Further research is needed to investigate its relationship with other tumor biology-related molecular factors.

S2-SSBR01-5 DIAGNOSIS OF CARCINOMA IN SITU ON THE ULTRAFAST SEQUENCE: IS IT POSSIBLE TO INCREASE THE SENSITIVITY OF BREAST MRI?

Izabella Melo, MD (*Presenter*)
IVIE BRAGA DE PAULA (*Abstract Co-Author*)

PURPOSE

To highlight the role of the Ultrafast sequence in the characterization of ductal carcinoma in situ (DCIS) on breast MRI, distinguishing it from background parenchymal enhancement (BPE).

METHODS AND MATERIALS

This is a retrospective cross-sectional study that evaluated medical records of patients diagnosed with DCIS who underwent breast MRI using a full protocol (T2, diffusion-weighted imaging B0/800, Ultrafast, and pre- and post-contrast dynamic sequences). Examinations were performed at a private healthcare institution in Brazil between January 2023 and July 2023. Eligible participants included female patients over 18 years of age with a diagnosis of DCIS who underwent breast MRI and signed informed consent. The qualitative variables analyzed were: background parenchymal enhancement (BPE), findings on the Ultrafast sequence, and findings on post-contrast dynamic sequences.

RESULTS

During the study period, 26 cases of DCIS were identified at the institution. Of these, 12 patients underwent breast MRI: 11 MRIs showed abnormalities (10 with non-nodular enhancement and 1 with a nodular lesion), and 1 MRI was unremarkable. Among the 11 abnormal MRIs: 10 were Ultrafast-positive; 1 was Ultrafast-negative. Among the 10 Ultrafast-positive MRIs: 5 showed findings identified only on the Ultrafast sequence; 4 with findings better visualized on the Ultrafast sequence than on the other sequences; 1 showed Ultrafast findings similar to other sequences. Notably, among the 10 Ultrafast-positive cases, 4 were high-grade DCIS and 2 were intermediate-grade DCIS .

CONCLUSION

The Ultrafast sequence may enhance MRI performance by detecting early enhancement of DCIS, which can occur before the peak of background parenchymal enhancement. In cases with marked BPE, DCIS enhancement may be obscured in post-contrast sequences obtained one minute after contrast injection.

CLINICAL RELEVANCE/APPLICATION

Larger studies are needed to confirm whether the Ultrafast sequence improves the sensitivity of MRI in detecting DCIS across histologic grades. The potential for underdiagnosis when Ultrafast is not included in MRI protocols deserves attention in future research

S2-SSBR01-6 ADDED VALUE OF MRI IN MULTIMODAL AI FOR BREAST CANCER DIAGNOSIS AND LONG-TERM RISK ASSESSMENT IN INTERMEDIATE TO HIGH-RISK WOMEN

Artie Shen (*Presenter*)
Laura Heacock, MD, MS (*Abstract Co-Author*)
Yanqi Xu (*Abstract Co-Author*)
Jungkyu Park, MS (*Abstract Co-Author*)
Felicia Pasadyn, MA, BA (*Abstract Co-Author*)
Beatriu Reig, MD, MPH (*Abstract Co-Author*)
Linda Moy, MD (*Abstract Co-Author*)
Krzysztof J. Geras (*Abstract Co-Author*)

PURPOSE

Mammography and ultrasound AI models have high accuracy in breast cancer detection and long-term risk prediction. The purpose of this study was to evaluate if use of breast MRI in a multimodal model improved breast cancer detection and/or risk prediction in women with intermediate to high lifetime risk of breast cancer.

METHODS AND MATERIALS

In this IRB-approved retrospective study, we evaluated a multimodal transformer (MMT) model. The MMT trains modality-specific feature extractions for mammography (FFDM), digital breast tomosynthesis (DBT), ultrasound (US) and breast MRI, combines them with additional clinical variables, and uses a transformer to predict immediate and long-term risk of breast cancer. The development set was 1,291,657 exams from 274,388 patients (age mean 57.5 years, SD 12.1 years) between 2010 and 2022. The trained model was then tested on intermediate to high lifetime risk of breast cancer patients (family history, prior cancer, dense, high-risk genetic mutation) with at least one MRI in our records. Model performance was assessed with 2- and 5-year AUCs and concordance index (C-index).

RESULTS

The cohort was 1,944 women, 18,201 exams (age 57.8 ± 10.0), 214 cancers in 5 years. 48.0% (939/1,944) had dense breasts. Model AUROCs were compared on FFDM/DBT and MRI exams with the corresponding baselines. For FFDM/DBT, MMT achieved an AUROC of 0.899 (95% CI: 0.879, 0.907) for cancer detection and a C-index of 0.640 (95% CI: 0.614, 0.666]) for 5-year risk prediction across all modalities. The MMT model including past MRI data achieved an AUROC of 0.940 (95% CI: 0.927, 0.946) for cancer detection and a C-index of 0.698 (95% CI: 0.673, 0.723) for 5-year risk, improving the baseline MMT model without MRI by 0.041 and 0.058 (two-sided DeLong's test, $P < 0.01$ for both) respectively. For MRI exams, the MMT model had AUROC of 0.947 (95% CI: 0.934, 0.958) for cancer detection, improving by 0.029 (two-sided Delong's test, $P < 0.01$) compared to MRI-only baseline. When evaluating 5-year risk, use of MRI alone to evaluate risk on MRI exams had AUROC of 0.591 [95% CI: 0.518 0.662], which improved to 0.682 [0.612 0.751] with use of the MMT. However, use of FFDM/DBT only to predict risk on corresponding FFDM/DBT had higher AUROC of 0.809 [95% CI: 0.786 0.832].

CONCLUSION

Using MRI into a multimodal model improves cancer detection and risk prediction in increased-risk patients. For breast MRI evaluation, FFDM/DBT only and multimodal risk prediction outperforms breast MRI alone.

CLINICAL RELEVANCE/APPLICATION

Adding MRI to multimodal models improves breast cancer risk prediction in women at increased risk of breast cancer. Granular identification of true high risk women within these cohorts allows for better targeting of supplemental screening and chemoprevention.

S2-SSCA01-1 DEEP LEARNING IMAGE RECONSTRUCTION COMBINED WITH LOW-TUBE-VOLTAGE SCANNING AND ADAPTIVE CONTRAST INJECTION FOR CORONARY CT ANGIOGRAPHY: A PROSPECTIVE RANDOMIZED TRIAL

Xiao Meng (*Presenter*)
He Chunyan, BArch (*Abstract Co-Author*)

PURPOSE

To validate a triple-optimized coronary CTA protocol integrating 80-kVp scanning, deep learning image reconstruction (DLIR), and low-iodine adaptive injection for simultaneous radiation/iodine reduction while improving vascular enhancement, with emphasis on renal-impaired populations (eGFR 30-60 mL/min/1.73m²).

METHODS AND MATERIALS

A total of 120 patients (eGFR 30-60: n=78) were prospectively enrolled and divided into two groups:Group A (Standard): 120-kVp scanning with filtered back projection (FBP), fixed-rate injection (50 mL Ioversol 350 mgI/mL at 5 mL/s + 30 mL saline).Group B (Experimental): 80-kVp DLIR (TrueFidelity™, GE Healthcare) with body weight-adjusted variable-rate injection (20 mL Ioversol + 60 mL saline dynamically optimized).Primary endpoints included vascular attenuation (target >325 HU per SCCT guidelines), noise reduction ratio (NRR), interpretability (5-point Likert scale by three blinded cardiothoracic radiologists; ?-interrater calculated), and CTDIvol. Safety outcomes (contrast extravasation, CIN) were assessed via Fisher's exact test. Statistical analysis used mixed-effects models with pre-specified non-inferiority margin (?=5% for interpretability).

RESULTS

Radiation/Contrast Reduction:51% lower CTDIvol (14.3 vs. 29.1 mGy, P<0.001).60% iodine reduction (20 vs. 50 mL, P<0.001).Vascular Enhancement:Higher attenuation in Group B: LMCA: 452±38 HU vs. 368±49 HU (P<0.001); proximal RCA: 438±42 HU vs. 354±51 HU (P=0.002).All segments exceeded SCCT threshold (>325 HU).Image Quality:63% higher NRR with DLIR (P=0.005) and 109% SNR improvement (24.1±3.8 vs. 11.5±2.9, P=0.001).Fewer beam-hardening artifacts (11.2% vs. 28.7%, P=0.003).Diagnostic Performance:Non-inferior interpretability (97.3% vs. 95.8%; ?=1.5%, 95%CI [-0.8,3.8]).Excellent inter-reader agreement (?=0.88).Safety Outcomes:88% lower extravasation risk (1/60 vs. 8/60, P=0.03).Zero CIN events in Group B vs. 3 in Group A (P=0.24, Fisher's test).

CONCLUSION

The triple-optimized protocol achieved superior vascular enhancement (400-500 HU range) with 51% radiation and 60% iodine reduction, demonstrating that low-kVp DLIR combined with adaptive injection synergistically improves contrast utilization. This approach provides a renal-safe alternative without compromising diagnostic confidence.

CLINICAL RELEVANCE/APPLICATION

Enhanced vascular opacification at ultra-low iodine doses may expand coronary CTA applications to patients with severe renal insufficiency, pending validation in larger cohorts.

S2-SSCA01-3 CLINICAL UTILITY OF DYNAMIC FRACTIONAL FLOW RESERVE COMPUTED TOMOGRAPHY (FFR-CT) IN PATIENTS WITH CHEST PAIN

Kyeong Jin Park, MD (*Presenter*)
Eun Ju Chun, MD, PhD (*Abstract Co-Author*)

PURPOSE

While fractional flow reserve computed tomography (FFR-CT) is widely used to identify fixed coronary ischemia, its role in detecting dynamic, phase-dependent ischemia such as that seen in vasospastic angina (VA) remains unclear. This study evaluated whether cardiac phase-specific FFR-CT measurements provide insight into coronary vasospasm beyond the identification of obstructive coronary artery disease (CAD).

METHODS AND MATERIALS

Between January 2020 and December 2021, we retrospectively analyzed 185 patients (mean age 64.9±12.4 years; 67.0% male) who presented to the emergency department with chest pain and underwent both coronary CT angiography (CCTA) and invasive coronary angiography. Patients were categorized into three groups: CAD, VA, and control (ergonovine negative). FFR-CT values were obtained for three major coronary arteries during both systolic and diastolic phases. Ischemia was classified as (1) fixed ischemia (FFR = 0.75 in both phases), (2) vasospastic ischemia (FFR = 0.75 in either phase), and (3) no ischemia (FFR > 0.75 in both). Group-wise ischemia types and FFR changes (?FFR) were compared using chi-square tests and descriptive statistics.

RESULTS

Fixed ischemia was significantly more frequent in the CAD group (32/85) than in both the VA (13/61; p = 0.045) and control groups (3/39; p < 0.001). In contrast, vasospastic ischemia in the VA group (16/61) did not differ significantly from the CAD (26/85; p = 0.585) or control groups (4/39; p = 0.072). Notably, 30.6% of CAD patients (n=26) had vasospastic ischemia, suggesting the coexistence of a dynamic functional component alongside fixed anatomical stenosis. Additionally, 21.3% of VA patients (n=13) showed fixed ischemia, suggesting a mixed ischemic mechanism involving both vasospasm and anatomical stenosis. In the control group, most patients (32/39) showed no ischemia. ?FFR analysis revealed the highest phase-to-phase variability in the LAD among CAD patients (0.082 ± 0.074), while VA patients exhibited greater ?FFR variability in the RCA and LCX (0.065 ± 0.078 and 0.059 ± 0.069, respectively). The control group demonstrated the lowest and most stable ?FFR values across all vessels.

CONCLUSION

Dynamic FFR-CT enhances ischemia characterization by detecting phase-dependent coronary changes not visible in single-phase evaluation. These findings highlight the potential coexistence of vasospasm and anatomical stenosis, and support more tailored treatment strategies based on individual ischemic physiology.

CLINICAL RELEVANCE/APPLICATION

Dynamic FFR-CT facilitates the detection of coronary spasm in VA and dynamic change in CAD that are difficult to detect on single-phase scan, helping to identify patients who may benefit from vasodilators or spasm-focused treatment.

S2-SSCA01-4 EVALUATION OF IN-LINE AUTOMATED DEEP LEARNING-BASED SLICE PRESCRIPTION FOR CARDIAC MRI

Thekla H. Oechtering, MD (*Presenter*)
Gaspar Delso (*Abstract Co-Author*)
Jitka Starekova, MD (*Abstract Co-Author*)
Geng Li (*Abstract Co-Author*)
Sheena Chu (*Abstract Co-Author*)
Nikolaos Panagiotopoulos, MD (*Abstract Co-Author*)
Karl Vigen, PHD (*Abstract Co-Author*)
Orhan Unal, PhD (*Abstract Co-Author*)
Dan W. Rettmann, BS (*Abstract Co-Author*)
Sherry Huang, PhD (*Abstract Co-Author*)
Ty A. Cashen, MD, PhD (*Abstract Co-Author*)
Prashant Nagpal, MD (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)

PURPOSE

A prototype deep learning algorithm (TeslaFlow, TF; GE HealthCare, WI) provides automated slice prescription for cardiac MRI, aiming to improve workflow efficiency, enhance consistency, and reduce operator dependence. This study prospectively validates TF, comparing its performance both without and with manual adjustments (TF+M) against manual prescription (M).

METHODS AND MATERIALS

Following IRB approval and consent, healthy volunteers underwent a 45-minute exam at 3T (Signa Premier, GE HealthCare) which was repeated after repositioning. Cine bSSFP images were acquired in 2-, 3-, and 4-chamber views and a short axis (SAX) stack. Prescriptions were performed using M, TF, and TF+M in random order. Test and retest exams were conducted by the same or different technologists. Additionally, TF prescriptions were added to the protocol in patients undergoing clinical cardiac MRI at 1.5T. Two cardiovascular radiologists rated image quality. Left ventricular (LV) function was quantified for all diagnostic datasets using cvi42 (Circle Cardiovasc. Imaging, Canada). Reproducibility was assessed by radiologists' quality and similarity scores, LV function repeatability, and differences in plane angle. Statistical analysis included Bland-Altman analysis, intraclass correlation coefficients (ICC), and t-tests.

RESULTS

30 healthy subjects (22-62y) and 11 patients (37-87y) were enrolled. Radiologists rated 85-92% of TF acquisitions in volunteers and 88% in patients as diagnostic. Technologists reported clinically necessary manual adjustments in 26% for TF+M acquisitions, and no/minor changes in 74%. M and TF+M showed excellent agreement in LV volumes and myocardial mass (ICC=0.903-0.991), while TF alone showed good to excellent correlation (ICC=0.882-0.991). TF did not improve intra- or inter-technologist reproducibility of LV function compared to TF+M or M. Angles between prescriptions were significantly lower between TF+M and M (SAX, 4.4±2.8°) compared to TF and M (SAX, 9.1±11.9°, p=0.001). Differences in LV function estimates between methods were similar or smaller than test-retest exams.

CONCLUSION

The automated cardiac MRI prescription prototype achieved at least an 85% success rate. Manual adjustments improved prescription quality. Differences in quantitative results and plane angles between methods were minor and unlikely to be clinically significant. Future studies should focus on performance in larger patient cohorts and potential time savings.

CLINICAL RELEVANCE/APPLICATION

The deep learning-based prototype enables automated, in-line cardiac MRI prescription. Although not sufficiently robust to use without supervision, the prototype improves prescription quality and consistency when used by a trained technologist.

S2-SSCA01-5 A STUDY TO MEASURE THE UTILITY OF AN AI-ENHANCED REPORTING TOOL IN ASSISTING BUSY CCTA READERS WITH REPORT GENERATION (SMART-REPORT)

Wesley O'Neal, MD (*Presenter*)
Harish Gudi, MD, MBBS (*Abstract Co-Author*)
Christopher Schumann (*Abstract Co-Author*)
Autumn Birch (*Abstract Co-Author*)
Nicholas Ng (*Abstract Co-Author*)
Sarah Mullen (*Abstract Co-Author*)
Mahesh Chandrasekhar (*Abstract Co-Author*)
Michael F. Morris, MD (*Abstract Co-Author*)

PURPOSE

Coronary CT angiography (CCTA) interpretation and reporting are time intensive. In addition to coronary stenosis quantification, AI-enabled quantitative coronary plaque analysis and fractional flow reserve CT (FFR CT) require multiple reports to be generated which can substantially lengthen interpretation time. The SMART-REPORT study sought to determine if an integrated structured reporting (SR) tool for CCTA can increase reader efficiency and reproducibility and reduce cognitive load.

METHODS AND MATERIALS

80 CCTAs from patients with stable chest pain or symptoms of coronary artery disease were analyzed. Five independent readers (3 cardiologists and 2 radiologists; all SCCT Level 3) from 2 sites were included. CCTA datasets were used to generate combined reports for AI-enabled stenosis quantification, plaque analysis, and FFR CT, , and provided to each reader. Interpretation of one batch of 10 CCTAs was permitted per day using local site software for post-processing and reporting. Each reader interpreted 40 cases without SR using a site defined clinical workflow and 40 cases using a SR tool which provided a pre-populated fully editable template. Differences in reporting times from initiation of case interpretation through report signing were compared with vs. without the SR tool. Reporting times were stratified by Coronary Artery Disease-Reporting and Data System (CAD-RADS) 2.0 category. Cognitive load was assessed using a validated 9-point Likert scale (scores >5 indicating high mental effort) and compared by SR use. The agreement between readers (text similarity) was also determined.

RESULTS

Interpretation time per case was 40.2% shorter with vs. without the SR tool (5.99 ± 1.96 vs. 10.01 ± 3.31 min; P<0.0001). This difference was independent of stenosis severity (Table). Report agreement also significantly higher with vs. without the SR tool (94.6% ± 2.3% vs. 45.3% ± 9.2%; P<0.0001). Average cognitive load was significantly lower with the SR tool than without (3.8 ± 1.2 vs. 6.1 ± 1.5; P<0.0001), independent of stenosis severity (Table).

CONCLUSION

A SR tool for CCTA incorporating AI-enabled coronary stenosis quantification, AI-enabled quantitative coronary plaque analysis, and FFR CT significantly reduced reporting time and cognitive load for CCTA interpretation.

CLINICAL RELEVANCE/APPLICATION

As the demand for CCTA grows, this SR tool may facilitate physician efficiency in CCTA reporting while reducing individual mental effort.

S2-SSCA01-6 REAL-WORLD IMPLICATIONS OF FDA'S PREDETERMINED CHANGE CONTROL PLAN (PCCP) FOR AI-ENABLED MEDICAL DEVICES: IS THE NEWER VERSION ALWAYS BETTER?

Syed Muhammad Awais Bukhari, MD (*Presenter*)
Sreyes Venkatesh (*Abstract Co-Author*)
Brian Zhang (*Abstract Co-Author*)
Robert C. Gilkeson, MD (*Abstract Co-Author*)
Amit Gupta, MD, MBBS (*Abstract Co-Author*)

PURPOSE

The FDA's guidance on the Predetermined Change Control Plan, while intended to promote innovation and rapid iteration, this process also raises concerns regarding real-world performance. We evaluated two versions (v1.3 and v1.4) of an FDA-cleared AI algorithm for automated coronary artery calcium (CAC) scoring (Bunkerhill Inc.), used on non-gated low-dose CT (LDCT) scans. To compare the clinical performance of CAC AI versions 1.3 and 1.4 following concerns by cardiothoracic radiologists of reduced accuracy after upgrading to version 1.4. The vendor reported internal improvements in version 1.4, including 5× more training data, 30% more model parameters, enhanced stent detection ,and improved CAC segmentation.

METHODS AND MATERIALS

In this retrospective study, 110 consecutive LDCT exams (Nov 1-30, 2025) were analyzed using both AI versions (Average age: 65 years; M: F:: 57:53). Agatston CAC scores and risk categories were compared (minimal: 0; mild: 1-99; moderate: 100-399; severe: 400-1000; extremely high: >1000). A board-certified cardiothoracic radiologist (15 years' experience) independently reviewed images to assess risk categorization, stent detection, and version preference. Statistical analysis included descriptive measures and paired t-tests.

RESULTS

Among 110 patients, 10 had coronary artery stents. Version 1.4 correctly identified 8 of these, whereas version 1.3 identified none. In patients without stents, the mean CAC score was significantly higher with version 1.3 (452.7) than with version 1.4 (288.5) ($p < 0.001$; mean difference: 164.2, 95% CI: 107.3-221.1). Risk category distributions were: minimal: 19% (CAC v 1.3) vs. 22.8% (1.4); mild: 19% (CAC v 1.3) vs. 33.7% (1.4); moderate: 32.7% (CAC v 1.3) vs. 31.7% (CAC v 1.4); severe: 22.8% (CAC v 1.3) vs. 10.9% (CAC v 1.4); extremely high: 6.9% (CAC v 1.3) vs. 1% (CAC v 1.4). Eighteen patients were reclassified into lower-risk categories by version 1.4. For example, 17 patients shifted from 400-1000 to 100-399; 6 from >1000 to 400-1000; 18 from 100-399 to 1-99; and 1 from 400-1000 to 1-99. The radiologist preferred version 1.3 in 58.2% (64/110) of cases, version 1.4 in 5.5% (6/110), and had no preference in 30.9% (34/110). In 5.5%(6/110) of cases, the radiologist disagreed with both outputs.

CONCLUSION

While CAC v1.4 demonstrated improved stent detection, it consistently underestimated CAC scores relative to v1.3, prompting concerns about misclassification of cardiovascular risk. Despite technical enhancements, radiologist preference and statistical evidence favored version 1.3 in majority of cases.

CLINICAL RELEVANCE/APPLICATION

These findings highlight the importance of local validation and ongoing performance monitoring before adopting AI updates under the PCCP framework.

S2-SSPD01-2 FMRI STUDY OF BRAIN FUNCTIONAL ALTERATIONS IN CHILDREN WITH AUTISM SPECTRUM DISORDER AFTER UMBILICAL CORD BLOOD MONONUCLEAR CELL INFUSION

Cong Zhang (*Presenter*)
Duo Gao (*Abstract Co-Author*)
Ning Zheng (*Abstract Co-Author*)
Zhijuan Li (*Abstract Co-Author*)
Jing Peng (*Abstract Co-Author*)
Lixia Zhou (*Abstract Co-Author*)

PURPOSE

This study aimed to investigate the brain functional changes in children with autism spectrum disorder (ASD) before and after treatment with umbilical cord blood mononuclear cell (UCB-MNC) infusion using blood oxygen level-dependent functional magnetic resonance imaging (BOLD-fMRI). Furthermore, by integrating clinical assessment scales, we examined the therapeutic efficacy of UCB-MNC infusion in ASD and assessed the potential of BOLD-fMRI as biomarker for evaluating treatment outcomes.

METHODS AND MATERIALS

A total of 20 preschool children diagnosed with ASD and treated at the Hospital between August 2021 and July 2022 were enrolled. The Childhood Autism Rating Scale (CARS) and Autism Behavior Checklist (ABC) were used to evaluate clinical symptoms before and 9-12 months after UCB-MNC infusion. BOLD-fMRI was employed to analyze changes in regional homogeneity (ReHo) and amplitude of low-frequency fluctuation (ALFF). Paired sample t-tests were conducted to compare spontaneous brain activity before and after treatment. Pearson correlation analysis was used to assess the associations between post-treatment changes in CARS scores and alterations in ReHo and ALFF values.

RESULTS

At 9-12 months post-treatment, significant increases in ReHo values were observed in several brain regions, including the left postcentral gyrus and left lingual gyrus. ALFF values also showed distinct increases in areas such as the left postcentral gyrus, with statistically significant differences (FDR corrected, $P < 0.001$). Further analysis revealed a significant negative correlation between the change in mean ReHo in the right precuneus and the change in CARS scores ($R = -0.7565$, $P = 0.0001$). A similarly significant negative correlation was found between the change in mean ALFF in the left postcentral gyrus and the change in CARS scores ($R = -0.8574$, $P < 0.0001$). Clinical assessments showed that CARS scores significantly decreased after treatment ($P < 0.05$), indicating symptomatic improvement. Notably, in the 3 children whose CARS scores did not improve, ReHo in the cingulate gyrus and ALFF in the angular gyrus exhibited significant increases (FDR corrected, $P < 0.05$).

CONCLUSION

UCB-MNC treatment effectively alters brain functional status in children with ASD. BOLD-fMRI demonstrates strong potential for detecting changes of brain activities, and these changes are closely associated with improvements in clinical symptoms as reflected by CARS scores.

CLINICAL RELEVANCE/APPLICATION

These findings offer valuable evidence for assessing the therapeutic efficacy of UCB-MNC infusion in ASD and underscore its potential significance in clinical practice.

S2-SSPD01-4 NON-INVASIVE AND END-TO-END PREDICTION OF MOLECULAR AND IMMUNE SUBGROUPS OF PEDIATRIC LOW-GRADE GLIOMAS VIA TRANSFER LEARNING

Fadel Batal, BEng, MEng (*Presenter*)
Bhavyasri Vunnava (*Abstract Co-Author*)
Adam Kraya (*Abstract Co-Author*)
Deep Gandhi (*Abstract Co-Author*)
Ariana Familiar (*Abstract Co-Author*)
Dimosthenis Chrysochoou (*Abstract Co-Author*)
Phillip Storm (*Abstract Co-Author*)
Arastoo Vossough, PhD, MD (*Abstract Co-Author*)
Adam Resnick (*Abstract Co-Author*)
S. Ali Nabavizadeh, MD (*Abstract Co-Author*)
Anahita Fathi Kazerooni (*Abstract Co-Author*)

PURPOSE

Pediatric low-grade gliomas (pLGGs) exhibit heterogeneous prognoses and treatment responses, largely driven by underlying molecular and immunological differences. Specifically, BRAF alterations influence tumor biology and guide targeted therapy decisions, with KIAA1549-BRAF fusion and BRAF V600E mutation linked to distinct treatment pathways. Additionally, we have previously identified an immune-enriched ("immune-hot") pLGG subgroup associated with poor prognosis but potential responsiveness to immunotherapy. Non-invasive prediction of tumor subtypes and immune profiles from imaging can support early, personalized treatment strategies.

We developed an end-to-end, segmentation-free deep learning (DL) framework to predict BRAF mutational status and immunological subgroup in pLGGs using T2-weighted MRI.

METHODS AND MATERIALS

We implemented a two-stage transfer learning pipeline based on a 3D ResNet-34 architecture. The model was first pre-trained on tumor segmentation using T2-weighted MRIs from 794 pediatric brain tumor cases in the Children's Brain Tumor Network (CBTN), then fine-tuned for molecular and immune classification in a subset of 251 pLGG patients with matched whole-genome and RNA sequencing data (184 with immune subgroup labels). Preprocessing included skull-stripping, intensity normalization, and resampling to a pediatric atlas space. Binary classifiers were trained to predict KIAA1549-BRAF fusion, BRAF V600E mutation, non-BRAF alterations, and immune-enriched ("immune-hot") subgroups using 5-fold cross-validation. Final predictions were generated via a soft-voting ensemble on an independent test set.

RESULTS

The segmentation model achieved a mean Dice score of 0.81 ± 0.03 on the test set. For molecular classification, the model demonstrated high AUC for KIAA1549-BRAF fusion (train: 0.82 ± 0.04, test: 0.91), moderate performance for BRAF V600E (train: 0.78 ± 0.01, test: 0.76), and non-BRAF-altered tumors (train: 0.73 ± 0.05, test: 0.64). Immune-enriched subgroup classification achieved AUCs of 0.69 ± 0.07 (train) and 0.67 (test), indicating moderate predictive capability.

CONCLUSION

This ResNet-34-based deep learning approach demonstrates potential for non-invasive, segmentation-free prediction of molecular and immune subtypes directly from T2-weighted MRI, with strong performance for KIAA1549-BRAF fusion detection. Incorporating additional MRI sequences may further improve classification accuracy.

CLINICAL RELEVANCE/APPLICATION

Our non-invasive, MRI-based method facilitates early molecular and immune stratification in pLGGs, particularly valuable when biopsy is not feasible, supporting precision diagnostics and treatment planning in pediatric neuro-oncology.

S2-SSPD01-5 OBSTRUCTIVE HYDROCEPHALUS DUE TO MASSA INTERMEDIA ABNORMALITIES AND ITS MANAGEMENT: A CASE SERIES

Fatemeh Dehghani Firouzabadi, MD (*Presenter*)
Vanessa E. Rameh, MD (*Abstract Co-Author*)
Edward Yang, MD, PhD (*Abstract Co-Author*)

PURPOSE

The massa intermedia (MI), is a normal band of tissue bridging the third ventricle where it connects the right and left thalami. Although its function and variable appearance remain incompletely understood (1,2), its location near critical CSF pathways suggests that congenital anomalies involving the MI may contribute to obstructive hydrocephalus.

METHODS AND MATERIALS

We retrospectively reviewed the radiology database at a tertiary pediatric hospital to identify congenital anomalies involving the MI. Nine cases were identified, and their imaging findings, anatomic configuration of MI bands, and clinical histories were analyzed.

RESULTS

Nine cases of congenital bands involving the massa intermedia were identified, falling into two distinct anatomic configurations (types A and B). Five patients had type A bands , characterized by connections between the massa intermedia and the floor of the third ventricle at the superior midbrain. In all patients with type A bands, supratentorial ventriculomegaly was detected in utero, with four undergoing surgical intervention within the first month of life and one by five months of age. One of these case was associated with L1CAM syndrome. The remaining four patients had type B bands , which extended from the massa intermedia to the tectal plate and obscured the posterior and habenular commissures. These cases exhibited more variable presentations: one was detected prenatally at 21 weeks gestation, one at birth, one during the first year of life, and one remained asymptomatic with normal ventricular size through 14 years of age. Only two Type B cases required surgical intervention for hydrocephalus. Of the seven cases requiring treatment overall, six underwent endoscopic third ventriculostomy (ETV), with three ultimately necessitating ventriculoperitoneal (VP) shunting. One patient underwent primary VP shunt placement without prior ETV.

CONCLUSION

Congenital bands arising from the massa intermedia are rare but significant cause of obstructive hydrocephalus. Type A bands (MI to floor of third ventricle) were associated with early-onset hydrocephalus, while Type B bands (MI to tectum) showed more variable clinical presentations.

CLINICAL RELEVANCE/APPLICATION

Recognition of massa intermedia bands on neuroimaging is important in evaluating causes of obstructive hydrocephalus. Differentiation between band types may aid in prognostication and management decisions.The embryologic basis of these bands is not yet understood.

S2-SSPD01-6 PREDICTING MALIGNANCY OF PEDIATRIC HEAD AND NECK LYMPHADENOPATHY BY APPLYING MULTIMODAL DEEP LEARNING APPROACHES

Gal Ben Arie, MD (*Presenter*)
Anouar Nouri (*Abstract Co-Author*)
Adam Hilbert (*Abstract Co-Author*)
Liat Ashkenazi-Hoffnung (*Abstract Co-Author*)
Orhun Utku Aydin (*Abstract Co-Author*)
Eyal Elron (*Abstract Co-Author*)
Dietmar Frey, MD,JD (*Abstract Co-Author*)

PURPOSE

Definitive diagnosis of pediatric craniocervical lymphadenopathy typically requires invasive tissue biopsy, often to rule out Hodgkin lymphoma. Radiological evaluation of head and neck ultrasound can aid non-invasive diagnosis, but it lacks objectivity and sensitivity. We sought to analyse the potential of multi-modal deep learning to utilize routinely collected ultrasound and clinical data for noninvasive diagnosis of malignant lymphadenopathy in children.

METHODS AND MATERIALS

In this retrospective single-center study, 283 pediatric patients (median age 10 years; range 1-17 years) between 2008 and 2022 with sub-acute craniocervical lymphadenopathy were included. Thirty-six cases (13%) were confirmed as malignant via biopsy. The clinical data comprised 15 routinely collected variables—spanning demographics, node-specific features, systemic signs, and laboratory tests. A feedforward neural network (FFNN) was trained on the clinical data using a two-step approach: 1) predicting surgical intervention as an auxiliary task, 2) fine-tuning for predicting malignancy. Ultrasound data was processed with a novel Encoder-Sampler-Attention-Predictor (ESAP) architecture. Fusion of both the clinical (FFNN) and imaging (ESAP) models was also explored. We evaluated performance in a five-fold stratified cross-validation and compared single modality models and the multimodal fusion model using classification measures. Explainability analysis was performed using SHAP for the clinical model and saliency maps for the imaging model.

RESULTS

The multi-modal model achieved an AUC of 0.91, balanced accuracy of 0.85, sensitivity of 0.89, and specificity of 0.81—significantly outperforming single-modality clinical (0.78, 0.72, 0.63, 0.81) and imaging (0.81, 0.74, 0.61, 0.87) models. SHAP identified nodal size and duration of lymphadenopathy as top predictors, while saliency maps highlighted cortical thickening and hilar vascularity—findings that aligned with expert radiologic assessment.

CONCLUSION

By combining key clinical parameters with ultrasound imaging in a multi-modal deep learning framework, we demonstrated high potential for accurate, non-invasive diagnosis of malignant pediatric lymphadenopathy.

CLINICAL RELEVANCE/APPLICATION

A clinical decision support system integrating our solution could reduce unnecessary biopsies while ensuring timely tissue diagnosis for malignant lymphadenopathy; promising better outcomes in pediatric patients.

S2-SSRO01-1 OCTOGENARIANS WITH EARLY-STAGE LUNG CANCER: A CLINICAL, RADIOLOGICAL, AND PATHOLOGICAL COMPARISON OF PATIENTS TREATED WITH SURGERY VERSUS STEREOTACTIC BODY RADIATION THERAPY

Wenchao Ma (*Presenter*)
Jeffrey Zhu (*Abstract Co-Author*)
Louis Gros, MD (*Abstract Co-Author*)
Rowena Yip, PhD, MPH (*Abstract Co-Author*)
Claudia I. Henschke, PhD, MD (*Abstract Co-Author*)
David F. Yankelevitz, MD (*Abstract Co-Author*)

PURPOSE

As lung cancer screening expands, more older adults are diagnosed with early-stage lung cancer, where surgical resection and stereotactic body radiation therapy (SBRT) are potentially curative. Our research showed comparable lung cancer-specific survival for tumors =20 mm with both treatments. While treatment depends on patient characteristics and preference, clinical judgment, and institutional practices, this study specifically focuses on octogenarians with early-stage lung cancer, aiming to identify factors that differentiate those who undergo surgery vs SBRT and to assess how treatment type affects outcomes.

METHODS AND MATERIALS

We reviewed all patients (ages 80+) with first primary NSCLC, =20mm in maximum diameter (cT1a-T1bN0M0), 8 th ed TNM), enrolled in the Initiative for Early Lung Cancer Research on Treatment (IELCART) study from 2016-2021, who underwent SBRT or surgical resection. Differences were compared using the ? 2 test or Fisher's exact test for categorical variables and two-sample t test or Wilcoxon ranked sum test for parametric and nonparametric continuous variables. Cox proportional hazard models with LASSO selection were used to examine differences in lung cancer-specific survival between SBRT and surgical patients, after adjusting for clinical and pathologic covariates.

RESULTS

Of 90 patients, 59 received surgery and 31 SBRT. They were mostly female (64%), White (74% vs 14% Black, 7% Asian, 4% Other), non-Hispanic (91%), and former smokers (71% vs 24% never, 4% current). Those who received SBRT were more likely to have HTN (77% vs 51%; p=0.014), COPD (29% vs 10%; p=0.023), DM (39% vs 20%; p=0.061), cardiac disease (23% vs 12%; p=0.2) and worse lung function (FEV1% pred. (72% vs 95%; p=0.017), and DLCO% pred. (69% vs 76%; p=0.017). Those who received SBRT had larger nodules on CT (15.0 vs 13.7 mm; p=0.031) and were less likely to have adenocarcinoma (71% vs 88%; p=0.024). There were no differences in nodule consistency (p=0.8) and location (p=0.2). In the LASSO Cox model, treatment type was not retained as a predictor of lung cancer-specific survival.

CONCLUSION

Octogenarians treated with SBRT had more comorbidities and worse lung function than those with surgery, reflecting selection based on surgical fitness. No demographic differences were observed. SBRT patients also had larger nodules and were less likely to have adenocarcinoma. Consistent with our previous findings, this study showed that treatment type was not associated with differences in lung cancer-specific survival.

CLINICAL RELEVANCE/APPLICATION

Octogenarians with early-stage lung cancer =20 mm treated with SBRT typically have more comorbidities, worse lung function, and larger nodules than those with surgery, with comparable lung cancer-specific survival.

S2-SSRO01-3 FROM SPARSE RADIOLOGIST ANNOTATIONS TO PRECISE IMAGE-GUIDED INTERVENTIONS: AN EFFICIENT MEDSAM2-ENHANCED STRATEGY FOR LUNG TUMOR SEGMENTATION ON 4D CT

Yi Luo, MS, BEng (*Presenter*)
Kai Ding, PHD (*Abstract Co-Author*)

PURPOSE

This study aims to develop and validate an efficient workflow utilizing radiologist-placed isocenters (ISO) as weak annotations to guide MedSAM2-driven automatic lung tumor segmentation on 4D CT, thereby enhancing image-guided interventions.

METHODS AND MATERIALS

A novel segmentation workflow was developed and implemented, where radiologist-placed ISO markers served as weak annotations to initialize a MedSAM2 foundation model for 4D CT image segmentation. This workflow's efficacy was evaluated on a cohort of 42 patients who had previously undergone radiotherapy at Johns Hopkins Hospital. Segmentation performance was quantified by comparing automatically generated contours against expert-delineated internal gross tumor volumes (IGTVs) using established metrics, including Dice coefficient, Sensitivity, Precision, Hausdorff Distance, and Average Surface Distance. This performance assessment was specifically conducted and compared for two distinct input conditions: (1) utilizing all available respiratory phases and (2) employing only a pre-defined set of clinically important respiratory phases (phase 0, phase 50, and phase 60). Finally, to understand the contribution of individual respiratory phases, an correlation analysis was performed to determine the impact of excluding each phase on overall segmentation performance.

RESULTS

The proposed MedSAM2-enhanced segmentation approach achieved a mean Dice coefficient of 0.5705±0.2264 across the test cohort. The average processing time was 114.04±41.22 seconds per patient, demonstrating notable computational efficiency. When analysis was restricted to conventionally used clinical phases (phases 0, 50,

and 60), the Dice coefficient was 0.5503±0.2702, while sensitivity notably increased to 0.6239±0.2173. A correlation analysis further indicated that omitting either phase 0 or phase 90 from the input data resulted in the most significant performance decline.

CONCLUSION

Our MedSAM2-enhanced workflow successfully leverages sparse radiologist annotations to generate clinically viable lung tumor contours on 4D CT with remarkable computational efficiency. The approach demonstrates good agreement with expert-delineated contours and requires minimal additional clinician effort due to its integration with existing ISO placement practices. Furthermore, this study underscores the importance of phase 90 for optimizing segmentation accuracy.

CLINICAL RELEVANCE/APPLICATION

This efficient segmentation strategy streamlines the clinical workflow by automatically generating lung tumor contours from existing radiologist ISO annotations, potentially reducing contouring time and effort in radiation therapy planning while maintaining acceptable accuracy.

S2-SSRO01-4 PATIENT STUDY ON JOINT RESPIRATORY AND CARDIAC PHASE BINNING 4DCT BASED ON MMWAVE SIGNALS

Yao Hao, PhD (*Presenter*)
Jingxuan Zhu (*Abstract Co-Author*)
Tiezhi Zhang, PhD (*Abstract Co-Author*)
Clifford Robinson (*Abstract Co-Author*)
Gregory R. Vlacich, MD,PhD (*Abstract Co-Author*)
Michael Waters (*Abstract Co-Author*)
Pamela Samson, MD (*Abstract Co-Author*)

PURPOSE

Cardiac radioablation requires both respiratory- and cardiac-gated Four-dimensional computed tomography (4DCT) imaging for accurate treatment planning and gated treatment delivery. Due to the asynchronous nature of respiratory and cardiac motion, the ablation target undergoes complex displacement, which can lead to geometric miss and potential radiation treatment failure. Therefore, a device capable of simultaneously monitoring both respiratory and cardiac phases is essential for 4DCT acquisition and gated therapy. Current respiratory 4DCT systems, such as the RPM system from Varian, are limited to capturing respiratory motion only. This technological gap in cardiac imaging and cardiac-gated treatment delivery may compromise the overall effectiveness of cardiac ablation treatments. In this study, we investigated the feasibility of joint respiratory and cardiac phase binning 4DCT based on mmWave signals from cancer patients.

METHODS AND MATERIALS

Six patients (all receiving simulation for lung cancer) were enrolled in a prospective mmWave study. Standard respiratory 4DCT was acquired without abdominal compression. A mmWave radar sensor (mounted on the CT gantry) concurrently recorded surface reflections corresponding to respiratory and cardiac motion. Respiratory and cardiac waveforms were extracted via Fast Fourier Transform and phase unwrapping algorithms. Cardiac phase bins were retrospectively aligned with CT acquisition timestamps to reconstruct dual-gated 4DCT volumes.

RESULTS

Dual-phase 4DCT reconstruction was successful in all six patients. No significant motion artifacts were observed. Respiratory rate (mean ± SD) ranged from 7.0-25.5 rpm, and heart rate from 57.1-109.1 bpm. The mean absolute difference between mmWave and CT-derived respiratory rates was 0.75% ± 0.70%, indicating excellent concordance.

CONCLUSION

This study demonstrated the feasibility to reconstruct respiratory and cardiac phase binning 4DCT using non-invasive mmWave technology. All six patients' data acquisition and phase binning were successful. Motion artifacts were not observed, and the anatomical structures were well-defined across all respiratory and cardiac phases.

CLINICAL RELEVANCE/APPLICATION

mmWave technology offers a great opportunity for joint respiratory and cardiac phase binning 4DCT. It can substantially reduce patient simulation time and imaging dose, and provide precise cardiac radioablation imaging during their treatment.

S2-SSRO01-5 CRANIOCAUDAL SPREAD PATTERNS OF RETROPHARYNGEAL LYMPH NODE METASTASIS IN PATIENTS WITH HYPOPHARYNGEAL CARCINOMA

Ryo Toya, MD, PhD (*Presenter*)
Satomi Yoshimi (*Abstract Co-Author*)
Mika Nakatake (*Abstract Co-Author*)
Reiko Ideguchi (*Abstract Co-Author*)
Hirofumi Koike (*Abstract Co-Author*)
Hideki Ishimaru, MD, PhD (*Abstract Co-Author*)
Shinya Shiraishi (*Abstract Co-Author*)
Toshinori Hirai, MD, PhD (*Abstract Co-Author*)
Satomi Yoshimi (*Abstract Co-Author*)

PURPOSE

With the wide adoption of intensity-modulated radiotherapy (RT), an extended neck position is unnecessary, whereas a more comfortable treatment position, such as that for diagnostic imaging, is favored. The craniocaudal border of the retropharyngeal lymph node (RPLN) was defined as the area between the upper edge of the body of the C1/hard palate and the cranial edge of the hyoid bone body. However, no studies have comprehensively evaluated the spread patterns of RPLN metastases (RPLNMs) in patients with hypopharyngeal carcinoma (HPC). In this study, the appropriate craniocaudal border of the RPLN was assessed based on diagnostic and RT images in patients with HPC for recommendation of appropriate target volume for elective nodal irradiation (ENI).

METHODS AND MATERIALS

Two board-certified radiation oncologists evaluated the craniocaudal spread of RPLNMs and the position of the hyoid bone using magnetic resonance images (diagnostic position) and RT-planning computed tomography (CT) simulator images (RT position with neck extension).

RESULTS

Of the 154 patients in whom 308 sides were assessed, 19 (12.3%) were diagnosed with RPLNMs in 24 (7.8%) sides. In all patients, the hard palate level was the same as or above the cranial edge of the C1 body. The cranial border of the RPLNMs was found above the hard palate on 3 (1.0%) and 1 (0.3%) side, between the hard palate and cranial edge of the C1 body on 10 (3.2%) and 13 (4.2%) sides, and at the C1 body on 11 (3.6%) and 10 (3.2%) sides in the diagnostic and RT positions, respectively. The caudal border of the RPLNMs was observed between the hard palate and the caudal edge of the C2 body on 22 (7.1%) and 22 (7.1%) sides, at the C2/3 disk level on 1 (0.3%) and 1 (0.3%) side, and at the C3 body level on 1 (0.3%) and 1 (0.3%) side in the diagnostic and RT positions, respectively. In the 19 patients with RPLNMs, the most common level of the caudal edge of the hyoid bone body was at the C4 body in 10 (52.6%) and C3 body in 8 (42.1%) patients in the diagnostic and RT positions, respectively.

CONCLUSION

RPLNMs above the hard palate and below the C2/3 disk level extremely rarely develop in patients with HPC. The cranial edge level of the hyoid bone varied significantly among the treatment positions. Regardless of the treatment position, the cranial and caudal borders of the RPLN for ENI should be defined as the hard palate and the

cranial edge of C3, respectively.

CLINICAL RELEVANCE/APPLICATION

The results of this study provide an optimized clinical target volume of RPLN for ENI in patients with HPC. Based on our recommendations, many patients with HPC benefit from a reduction in the unnecessary irradiation volume when undergoing ENI.

S2-SSRO01-6 VIRTUAL CLINICAL TRIAL SIMULATING A PHASE III TRIAL TO EVALUATE THE EFFICACY OF HIGH-DOSE INTENSITY MODULATED RADIATION THERAPY FOR OROPHARYNGEAL SQUAMOUS CELL CARCINOMA USING VIRTUAL PATIENTS CREATED FROM LOW-DOSE RADIOTHERAPY PATIENTS

Kimika Matsuo, BS (*Presenter*)
Taiki Magome, PhD (*Abstract Co-Author*)

PURPOSE

Virtual clinical trials (VCTs) are a potential approach for simulating clinical trials on a computer using artificial intelligence (AI) models. This study aims to develop AI models for VCTs simulating a phase III trial to evaluate the efficacy of high-dose intensity modulated radiation therapy (IMRT) for oropharyngeal squamous cell carcinoma using virtual patients from low-dose radiotherapy.

METHODS AND MATERIALS

To assess the potential of VCTs to simulate actual clinical trials, a public dataset of 385 oropharyngeal squamous cell carcinoma patients treated with IMRT from The Cancer Imaging Archive (TCIA) was retrospectively analyzed. Patients were stratified by total radiation dose into two groups: those who received less than 66 Gy (low-dose) and 66 Gy or more (high-dose). The VCT was designed to simulate a phase III trial evaluating the efficacy of high-dose radiotherapy on local recurrence as the primary endpoint. To improve prediction performance for local recurrence in high-dose radiotherapy patients, virtual patients were created by mixing characteristics of low-dose radiotherapy patients. This study compared the prediction performance for local recurrence in high-dose radiotherapy patients, using three strategies for training AI models in VCT: only original data, virtual data created by mixing the characteristics of two low-dose patients using a uniform ratio across all characteristics, and virtual data created by mixing their characteristics using varied ratios for each characteristic. The prediction performance in VCTs was evaluated by calculating the area under the receiver operating characteristic curve (AUC) 100 times using bootstrap resampling for high-dose patients.

RESULTS

Prediction performance for high-dose patients was significantly improved when using virtual data mixed at varied ratios for each characteristic, compared to the other strategies (P < 0.05, Wilcoxon signed-rank test). Mean AUCs and standard deviations were 0.698 ± 0.057 (original data), 0.731 ± 0.046 (virtual data mixed at a uniform ratio), and 0.748 ± 0.038 (virtual data mixed at varied ratios).

CONCLUSION

Models in VCT were developed to simulate a phase III trial evaluating the efficacy of high-dose IMRT for oropharyngeal squamous cell carcinoma. The model using virtual data created by mixing the characteristics of two low-dose patients using varied ratios for each characteristic showed significantly improved predictions of local recurrence in high-dose radiotherapy patients.

CLINICAL RELEVANCE/APPLICATION

Developing higher-performing models in VCT before time-consuming clinical trials may help prioritize trials with higher anticipated efficacy, potentially accelerating new treatment evaluations.

Science Session (Opportunistic Screening: Enhancing Diagnostic Impact from Routine Imaging)

Sunday, Nov. 30 10:30AM - 11:00AM Room: LEARNING CENTER THEATER 1

Sub-Events

S2-STCE1-1 OPPORTUNISTIC CARDIOVASCULAR RISK ASSESSMENT FROM ROUTINE CHEST CT: AI-DRIVEN CORONARY ARTERY CALCIUM SCORING AND AORTIC VALVE ANALYSIS

Elshan Abdullayev, MD (*Presenter*)

PURPOSE

To validate an AI-powered tool that automatically quantifies coronary artery calcium (CAC) scores from routine non-cardiac chest CT examinations, testing whether this opportunistic screening approach provides cardiovascular risk stratification equivalent to dedicated cardiac CT while expanding screening reach to unselected populations.

METHODS AND MATERIALS

Retrospective analysis of 8,547 routine chest CT examinations from six academic centers (2022-2024). Adults >40 years undergoing chest CT for non-cardiac indications were included. AI algorithm automatically detected and quantified CAC using Agatston scoring methodology. Reference standard was manual scoring by two cardiovascular radiologists. Primary outcomes: diagnostic accuracy for CAC categories (0, 1-99, 100-399, =400). Secondary outcomes: cardiovascular events during 2-year follow-up and workflow integration metrics. Statistical analysis included sensitivity/specificity calculations and survival analysis.

RESULTS

AI achieved excellent diagnostic accuracy for CAC scoring: sensitivity 94.8% (95%CI:93.2-96.1%), specificity 97.2% (95%CI:96.4-97.8%) across categories. For severe CAC (=400), sensitivity was 98.3% with specificity 99.1%. Among 6,234 patients with complete follow-up, AI-detected high CAC scores predicted major adverse cardiovascular events with hazard ratio 3.8 (95%CI:2.9-4.9, p<0.001). Of 2,847 patients with previously unknown cardiovascular risk, 23.4% were reclassified to higher risk categories, leading to preventive interventions in 18.2%. Processing time averaged 12 seconds per case.

CONCLUSION

AI-driven opportunistic cardiovascular screening from routine chest CT provides accurate risk stratification equivalent to dedicated cardiac imaging while identifying high-risk patients who would otherwise remain undiagnosed. This approach successfully reclassified nearly one-quarter of patients to appropriate higher risk categories.

CLINICAL RELEVANCE/APPLICATION

This validated screening tool integrates into existing radiology workflows to provide population-level cardiovascular risk assessment without additional imaging. Implementation could prevent thousands of cardiovascular events annually through early identification of high-risk asymptomatic patients, representing a paradigm shift toward proactive population health management using existing imaging infrastructure.

S2-STCE1-2 ADVANCING OPPORTUNISTIC PDAC SCREENING: VISION-LANGUAGE FOUNDATION MODELS VERSUS CONVENTIONAL CNN APPROACHES

David Le, PhD (*Presenter*)
Ramon Correa-Medero, BS (*Abstract Co-Author*)
Gokul Ramasamy (*Abstract Co-Author*)
Vedant Joshi (*Abstract Co-Author*)
Amara Tariq, PhD, MS (*Abstract Co-Author*)
Yifan Peng, PhD, MEng (*Abstract Co-Author*)
George L. Shih, MD, MS (*Abstract Co-Author*)
Zhen J. Wang, MD (*Abstract Co-Author*)
Motoyo Yano, MD, PhD (*Abstract Co-Author*)
Imon Banerjee, PhD (*Abstract Co-Author*)

PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) is often diagnosed at an advanced stage. Clinical risk factors, e.g., obesity, new-onset diabetes, can manifest through surrogates on imaging. However, to date, the quantitation of such imaging features is neither practical nor scalable. We compared a CT-CLIP vision-language fusion model (VLM) to a conventional image-only 3D convolutional backbone for stratifying PDAC risk on pre-diagnostic CT scans.

METHODS AND MATERIALS

Retrospective pre-diagnostic abdominal CT scans (within 5 years before diagnosis, 2006-2023) and corresponding radiology reports from 2,997 PDAC patients and 4,254 noncancer controls across three sites (2011-2023) were collected. Pancreatic volumes were segmented using TotalSegmentator, manually reviewed, resampled to 1 mmx3 resolution, and cropped to 384 × 384 × 160 voxels centered on the pancreas. Windowing (-135 to 215 HU) and zero-padding to fit model input were applied. Corresponding radiology reports were deidentified, standardized (non-ASCII characters removed, whitespace normalized) and parsed into Clinical history and pancreas-specific sections, then concatenated. The 3D CNN model took preprocessed CT volume as input, while the fusion model first used CT-CLIP VLM to generate separate image and text embeddings, concatenated these vectors, and fed them into a multilayer perceptron trained with a negative partial log-likelihood loss. Model discrimination was evaluated by Harrell's concordance index (C-index) and calibration by Kaplan-Meier (KM) curves, with log-rank tests comparing predicted high (> 0) and low (= 0) risk groups on internal and external validation cohorts.

RESULTS

For the PDAC cohort, the average interval from CT to PDAC diagnosis was 58 months (72% censored). The CT-only 3D CNN achieved a C-index of 0.6773 (95% CI: 0.6495-0.7037) internally and 0.6780 (95% CI: 0.6478-0.7031) on externally. In contrast, the CT-CLIP fusion model attained a C-index of 0.8225 (95% CI: 0.8034-0.8403) on internal and 0.7555 (95% CI: 0.7229-0.7849) on the same external validation. KM analysis revealed a clear separation between high- and low-risk groups (p < 0.001).

CONCLUSION

Integrating CT imaging and radiology report embeddings through a vision-language foundation model significantly enhances prognostic stratification of PDAC risk on pre-diagnostic scans, outperforming CT-only convolutional neural networks - highlighting the promise of vision-language pretraining for opportunistic cancer detection from routine radiologic imaging.

CLINICAL RELEVANCE/APPLICATION

The fusion of volumetric CT data and free-text radiology reports in prognostic modeling may enable earlier identification of patients at high risk for PDAC at an earlier stage thereby supporting timely intervention.

S2-STCE1-3 OPPORTUNISTIC MEASUREMENT OF CARDIOVASCULAR AGING TRAJECTORIES ON CAC CT

Mendel Lebowitz (*Presenter*)
GOURAV MODANWAL (*Abstract Co-Author*)
Amritpal Singh (*Abstract Co-Author*)
Rohan Dhamdhere (*Abstract Co-Author*)
Saumya Diwan (*Abstract Co-Author*)
Sena Azamat (*Abstract Co-Author*)
Santosh Kumar Sirasapalli (*Abstract Co-Author*)
Sanjay Rajagopalan (*Abstract Co-Author*)
Sadeer Al-Kindi (*Abstract Co-Author*)
Anant Madabhushi, PhD (*Abstract Co-Author*)

PURPOSE

Cardiovascular (CV) aging varies across individuals. Biological age (BA) better captures this heterogeneity than chronological age, but most BA tools are costly, invasive, or lack CV specificity. Peri-aortic fat, routinely captured on coronary artery calcium (CAC) CT, is a biologically active modulator of CV health. We evaluated whether CV-specific biological age (CV-age) could be opportunistically estimated from peri-aortic fat radiomics, and whether its divergence from chronological age (?age) could stratify patients into aging trajectories associated with major adverse cardiovascular events (MACE).

METHODS AND MATERIALS

We analyzed CAC CTs from 46,410 patients in the CLARIFY trial (NCT04075162). Peri-aortic fat was segmented as an 8 mm circumferential region within the adipose attenuation range and 1,316 radiomic features were extracted. A supervised regression model trained on 20% of patients estimated CV-age and SHAP (SHapley Additive exPlanations) identified the most predictive features driving CV-age. To adjust for age-related bias, patients were stratified into low, intermediate, and high-risk aging trajectories based on ?age percentiles within 5-year chronological age bins. MACE risk across groups was assessed using Kaplan-Meier (KM) survival analysis and age-adjusted Cox regression.

RESULTS

Peri-aortic fat radiomics captured biologically meaningful variation in CV aging, with the CV-age model achieving a mean absolute error of 6.02 years and R^2 of 0.38 (n=37,128). SHAP revealed that CV-age was most influenced by fat shape and texture heterogeneity. Stratifying patients by ?age revealed resilient (n=7,434), normative (n=22,250), and accelerated (n=7,444) agers. Despite similar chronological ages (Resilient: 65.6; Accelerated: 64.7 years), MACE-free survival differed significantly (log-rank $p<0.001$). Accelerated agers had a 2.31-fold increased MACE risk (HR: 2.31, 95% CI: 2.06-2.58) and normative agers a 1.42-fold increase (HR: 1.42, 95% CI: 1.28-1.57) vs. the resilient group ($p<0.001$).

CONCLUSION

Radiomics-derived CV-age, informed by peri-aortic fat, opportunistically captures biologically relevant variation in CV aging from routine CT. Stratification by ?age uncovers resilient, normative, and accelerated CV aging trajectories that predict MACE risk, despite similar chronological age. These findings support ?age as a scalable, image-based biomarker for subclinical CV aging and early risk identification.

CLINICAL RELEVANCE/APPLICATION

Peri-aortic fat radiomics enables opportunistic detection of accelerated or resilient CV aging, revealing risk patterns not apparent from chronological age. This scalable, non-invasive biomarker may enhance early, individualized CV risk assessment using routinely acquired CT.

S2-STCE2-1 CELL-SPECIFIC GENE EXPRESSIONS OF BRAIN REGIONAL VULNERABILITY IN COVID-19 PATIENTS

Tao Liu (*Presenter*)

PURPOSE

Exploring the variations of cell-specific gene expression contributed to the selective white matter changes following Covid-19 infection.

METHODS AND MATERIALS

Participants49 patients with confirmed COVID-19 infection within one month.18 healthy tested negative controls (HCs), matched for age, sex.34 returned for a follow-up assessment at three months post-infection.MRI acquisition and i mage processing 3D-T1-weighted images were acquired using a 48-channel head coil on a 3.0T Premier MRI system. The specific acquisition parameters were as follows: repetition time (TR) = 7.2 ms, echo time (TE) = 3.0 ms, field of view = 256 × 256 mm².Using FreeSurfer Software to automated reconstruction and segmentation to extract WM volumes across 68 cortical regions defined by the Desikan-Killiany atlas.Gene-expression profilesThrough the standardized processing pipeline of the Allen Human Brain Atlas , integrated with the Desikan-Killiany atlas , and using the homologene R package , mouse gene labels were mapped to human homologs. This yielded a final white matter region-specific gene expression matrix (34 brain regions × 1,921 genes) encompassing expression profiles for nine distinct cell types. Gene enrichment analysisWe using Metascape (https://metascape.org), a comprehensive online tool for multi-omics data integration and gene prioritization.

RESULTS

White matter volumes :Covid-19 patients showed significant increased WM volumes in the bilateral frontal, right precentral gyrus and lingual gyrus within one-month post-infection ($p < 0.05$). Persistent increased WM volumes was also found in the right frontal pole, precentral gyrus and lingual gyrus at 3 months post-infection ($p < 0.05$).Association between cell-specific gene expression and WM volume alternations one month post-infection : S1 pyramidal neurons ($p<0.001$).The mean correlation coefficient for the S1 pyramidal was 0.13 . 3 months post-infection : S1 pyramidal ($p < 0.001$), CA1pyramida ($p < 0.001$) .The mean correlation coefficients for the S1 pyramidal and CA1 pyramidal was 0.10 and 0.06.Gene enrichment analysis . S1 pyramidal neurons were associated with GO terms of regulation of membrane potential . CA1 pyramidal neurons appeared to be associated with GO terms of neural plasticity .

CONCLUSION

COVID-19 patients exhibited more severe white matter increase compared with HCs. The selective brain expansion might be partly attributed to gene expression of specific cell types in COVID-19 patients, particularly pyramidal.

CLINICAL RELEVANCE/APPLICATION

This work may provide new clues for making informed medication decisions to prevent white matter alternations.

S2-STCE2-2 COMPARATIVE EVALUATION OF COMMERCIAL AI ALGORITHMS FOR FRACTURE DETECTION ON MUSCULOSKELETAL RADIOGRAPHS

James Vaz, MD (*Presenter*)
Katrina Nash, MBChB (*Abstract Co-Author*)
Alex Novak, MBChB (*Abstract Co-Author*)
Nabeeha Salik (*Abstract Co-Author*)
Cosmin Mihaiu (*Abstract Co-Author*)
Sarim Ather, PhD, MBChB (*Abstract Co-Author*)

PURPOSE

To conduct a novel direct comparative evaluation of commercial AI tools designed to detect fractures on musculoskeletal radiographs, assessing diagnostic performance across vendors.

METHODS AND MATERIALS

Six commercial vendors were invited of which three participated in this retrospective evaluation. A dataset of 500 anonymised radiographs was collected from Oxford University Hospitals and enriched to ~50% fracture prevalence to ensure anatomical and pathological diversity. Each case's ground truth was labelled through independent review by two expert musculoskeletal radiologists (>10 years' experience), with arbitration from a third where required. All images were processed in batch by vendors. Vendors had up to 72 hours to return binary results. Accuracy, sensitivity, and specificity were calculated. Pairwise McNemar's tests were used to compare diagnostic performance across tools.

RESULTS

All participating vendors returned results within the 72-hour period. One vendor processed all images within their intended use case; whilst two vendors did not return results for between 16-18 cases. Accuracy ranged from 80.4% (95% CI: 76.4-83.8) to 87.2% (83.9-89.8). Sensitivity ranged from 70.4% (63.5-76.5) to 89.7% (84.8-93.2) and specificity from 73.9% (68.5-78.7) to 87.7% (83.1-91.2). McNemar's test revealed significant differences in accuracy, sensitivity, and specificity across tools ($p <0.001$), with some tools excelling in sensitivity and others in specificity.

CONCLUSION

Multiple commercial AI tools demonstrated high overall accuracy in detecting fractures on radiographs. However, there was notable variation in diagnostic performance between vendors. Sensitivity and specificity showed the greatest divergence, two tools prioritised either specificity or sensitivity, and one offered a more balanced performance profile. These differences may influence clinical outcomes and should be carefully considered when selecting AI tools for deployment.

CLINICAL RELEVANCE/APPLICATION

There is a paucity of evidence directly comparing commercial fracture detection AI tools in the literature and this study highlights significant variability in diagnostic performance profiles across commercial AI tools for fracture detection. Tools with lower sensitivity may risk missed fractures, while lower specificity may lead to over-investigation. As default thresholds have been used to calculate sensitivity and specificity, further calibration could be conducted locally to balance clinical priorities. Nonetheless, the significant variability underscores the need for independent, comparative evaluations of AI tools using diverse, real-world datasets prior to clinical adoption.

Jenanan Vairavamurthy (*Abstract Co-Author*)
Lester J. Fahrner, MD, MS (*Abstract Co-Author*)
Samir Rajpurkar (*Abstract Co-Author*)

PURPOSE

Abdominopelvic CT (CTAP) is among the most common CT studies in the US. Reviewing CTAPs and generating complete reports can be challenging given complex anatomy and pathology. We developed an integrated AI system (a2z-Drafter) to detect 63 findings and automatically produce a preliminary structured report. To our knowledge, this is the first investigation of AI-assisted CTAP draft report generation and its effects on pathology-level agreement and reporting.

METHODS AND MATERIALS

Using a training set of >280,000 CTAPs, we created an integrated AI system that identifies 63 findings and populates a structured report template with draft text. 7 radiologists each reviewed 50 CTAP cases, each with at least one acute finding. Case order alternated in 5-case blocks between AI-assisted drafting and unassisted drafting (block size = 5), with the initial condition (assisted vs unassisted) randomized per reader to mitigate systematic order effects. For each case-level pathology, reader's determination (present/absent) was compared to a consensus derived from all reports. Overall agreement, positive percent agreement (PPA), and negative percent agreement (NPA) were calculated for all pooled and individual pathologies, comparing assisted and unassisted conditions, with false discovery rate correction for multiple comparisons. Comparisons used chi-square tests (for =5 observations) or Fisher's exact tests (for <5 observations). Reporting time was tracked for each case and analyzed using a mixed-effects model to account for intra-reader and intra-case correlation.

RESULTS

Across 81 findings appearing in at least one case, AI-assisted reports had higher overall agreement (97.6% vs 96.6%, $p<0.001$), PPA (80.3% vs 66.3%; $p<0.001$), and NPA (98.5% vs 98.1%; $p=0.03$). For acute conditions, assisted reports had a higher overall agreement (98.5% vs 96.2%, $p<0.001$) and PPA (91.1% vs 66.1%, $p<0.001$), with similar NPA (99.0% vs 98.4%, $p=0.10$). Greatest AI-assisted improvements in acute finding agreement were for hemoperitoneum (16.7% to 100%), unruptured aortic aneurysm (64.7% to 100%), and acute appendicitis (68.8% to 100%). Unadjusted reporting time was less for assisted reports (mean 267 seconds vs 312 seconds). After accounting for intra-reader and intra-case correlations, AI assistance resulted in a 54 second decrease in reporting time (17%).

CONCLUSION

AI-assisted draft report generation increases agreement with consensus while improving reporting time.

CLINICAL RELEVANCE/APPLICATION

AI-assisted draft report generation can meaningfully improve CTAP interpretation while enhancing workflow efficiency, particularly reducing missed acute findings that require immediate clinical intervention, potentially accelerating time-to-treatment in emergency settings.

S4-SSCH02-1 SCREENLUNGNET: PERSONALIZED LONG-TERM PREDICTION OF LUNG CANCER RISK FROM A SINGLE LDCT SCREENING

Chengting Lin (*Presenter*)
Lei Shi (*Abstract Co-Author*)

PURPOSE

Low-dose computed tomography (LDCT) is effective for lung cancer screening, but improvements in accuracy and individualized risk prediction are needed. To develop and validate ScreenLungNet, a deep learning-based model for long-term lung cancer risk prediction to optimize lung cancer screening efficiency.

METHODS AND MATERIALS

In this retrospective study, we developed and compared four predictive models—single-nodule, multiple-nodules, global lung, and a comprehensive fusion model (ScreenLungNet). ScreenLungNet integrates local nodule features based on malignancy scores, global lung features extracted using a Vision Transformer architecture, and a fusion module for final risk prediction. Model performance was evaluated by AUC, accuracy, specificity, sensitivity, positive predictive value (PPV), and negative predictive value (NPV).

RESULTS

A total of 19,869 participants (mean age 60.93 ± 6.30 years; 13,123 males; 343 lung cancer cases) from the **** cohort were divided into training (n=12,837), validation (n=3,070), and internal test (n=3,962) sets. An additional 1,802 participants from **** Hospital served as a secondary training set. Independent and external validation were conducted on the **** (n=9,932) and NLST (n=14,966) cohorts, respectively. ScreenLungNet consistently outperformed other models across the above test sets, achieving AUCs of 0.93-0.94 for three-year lung cancer risk prediction. In the NLST cohort, ScreenLungNet achieved an AUC of 0.93 (95% CI: 0.89-0.98), with accuracy of 94.8%, sensitivity of 84.9%, specificity of 95.2%, and NPV of 99.3%. The global lung model showed higher sensitivity, while the multiple-nodules model improved PPV. ScreenLungNet effectively combined these advantages to deliver robust and precise risk assessment.

CONCLUSION

A model based on a multiple-nodules strategy and global lung features significantly improves long-term lung cancer risk prediction, supporting more accurate and individualized screening strategies.

CLINICAL RELEVANCE/APPLICATION

A model integrating nodule and global lung features significantly improves long-term lung cancer risk prediction, enabling focused monitoring of high-risk individuals and extended intervals for low-risk groups.

S4-SSCH02-2 ELIGIBILITY FOR LUNG CANCER SCREENING AMONG PATIENTS DIAGNOSED WITH LUNG CANCER: A RETROSPECTIVE ANALYSIS OF EMR DOCUMENTATION AND USPSTF CRITERIA

Omar Cespedes-Gomez, MD, MPH (*Presenter*)
Maedeh Sharifian, MD (*Abstract Co-Author*)
Gelareh Sadigh, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the proportion of patients with a confirmed lung cancer diagnosis who would have been eligible for lung cancer screening (LCS) based on 2021 U.S. Preventive Services Task Force (USPSTF) guidelines, and to assess the completeness of smoking history documentation in electronic medical records (EMR).

METHODS AND MATERIALS

This retrospective study included patients aged 50-80 years diagnosed with lung cancer between January 2018 and December 2024. Demographic variables, insurance type, structured smoking history (pack-years, smoking initiation and cessation dates), and evidence of low-dose computed tomography (LDCT) screening within two years prior to diagnosis were extracted from our health system EMR. Multivariable logistic regression was used to identify sociodemographic factors associated with missing smoking data and to assess predictors of LCS eligibility. Statistical analysis was conducted using STATA MP 18.0; p-values <0.05 were considered statistically significant.

RESULTS

2,554 patients with lung cancer (mean age 66; 48% female; 53% white, 31% Asian, 3% Black, 13% other races and mixed races) were included. 13.5% were of Hispanic ethnicity. Only 23% (594/2,554) had documented smoking history as structured data in EMR. Of these, 36% (214/594) met 2021 USPSTF eligibility criteria for LCS, and only 5% (11/214) of those eligible underwent LDCT screening within the preceding two years. Patients who were male (OR: 0.44; 95% CI: 0.36-0.54), had Medicare (vs. Private) (OR: 0.61; 95%CI: 0.47-0.79), and Medicaid (vs. private) (OR: 0.60; 95%CI: 0.45-0.81) were less likely to have missing smoking data in EMR. While those who were married/living with a partner (vs. not married) (OR: 1.3; 95% CI: 1.04-1.58), Asian race (vs. white) (OR: 1.6; CI: 1.20-2.11), and mixed/other race (vs. white)(OR: 1.46; 95%CI: 1.05-2.03) were more likely to have missing data. Patients who were older were less likely to be eligible for LCS (OR: 0.96; 95%CI: 0.94-0.98); but we did not observe any association between LCS eligibility and sex, race, or Hispanic ethnicity.

CONCLUSION

Incomplete documentation of smoking history in EMR hinders accurate assessment of LCS eligibility. Furthermore, current USPSTF screening criteria exclude a significant portion of individuals ultimately diagnosed with lung cancer, indicating a need for improved risk-stratification approaches in screening protocols.

CLINICAL RELEVANCE/APPLICATION

Incomplete smoking history documentation in EMRs and limitations of current USPSTF guidelines result in many lung cancer cases being missed by screening programs, highlighting the need for better data capture and more inclusive risk-based screening strategies.

S4-SSCH02-3 BENCHMARKING RADIOLOGISTS AND AI FOR INDETERMINATE LUNG NODULE MALIGNANCY RISK ESTIMATION ON SCREENING CT: THE LUNA25 CHALLENGE

PURPOSE

The global expansion of lung cancer screening will significantly increase radiologist workloads, particularly due to indeterminate lung nodules (5-15 mm) often requiring short-term follow-up to rule out malignancy. Accurate risk classification of these nodules can reduce unnecessary procedures, improve management, and ease radiologist burden. Artificial intelligence (AI) may assist in malignancy risk estimation, but rigorous benchmarking against human readers is limited. The LUNA25 challenge provides a validated benchmark to compare AI and radiologist performance in malignancy risk estimation of indeterminate nodules on low-dose CT (LDCT).

METHODS AND MATERIALS

The LUNA25 challenge consists of an AI competition and a reader study. AI teams develop algorithms using a publicly available dataset of 4,069 LDCT scans from the National Lung Screening Trial (NLST), containing 555 malignant and 5,608 benign nodules. Final evaluation uses a hidden external test set of indeterminate solid and part-solid nodules from baseline scans of the Danish Lung Cancer Screening Trial (DLCST), Dutch-Belgian NELSON trial, and Multicentric Italian Lung Detection (MILD) trial. The reader study, launching in May 2025, uses a subset of 300 nodules from this hidden test set. Nodules are enriched for malignancies and size-matched to benign nodules. Radiologists assess each case by assigning a malignancy risk score (0-100) and management recommendation: low risk (routine screening), intermediate risk (short-term follow-up), or high risk (referral). Performance metrics include area under the ROC curve (AUC), sensitivity, and specificity at clinically relevant thresholds.

RESULTS

Dataset curation for AI evaluation and the reader study is complete. Over 80 radiologists from diverse international centers have enrolled, with recruitment ongoing. The reader study is expected to conclude by late August 2025. Results, including a head-to-head comparison of radiologist performance and best-performing AI algorithm in malignancy risk estimation and management recommendations, will be available by year-end for presentation at RSNA.

CONCLUSION

The LUNA25 challenge will deliver the first international benchmark comparing radiologist and AI performance for malignancy risk estimation of indeterminate lung nodules on screening CT. It will provide critical insights into the potential for AI to improve early cancer detection and minimize unnecessary follow-ups.

CLINICAL RELEVANCE/APPLICATION

As lung cancer screening is adopted globally, validated AI tools could help manage diagnostic burden. The LUNA25 challenge offers evidence on comparative performance of AI and radiologists for indeterminate nodules, supporting safe clinical use and regulatory evaluation.

S4-SSCH02-4 LUNG CANCER SCREENING: USING RISK ASSESSMENT SCORES TO DETERMINE BIANNUAL SCREENING ELIGIBILITY

David Gao, MD (*Presenter*)
Joshua Rattee, MD (*Abstract Co-Author*)
Scott J. Adams, MD, PhD (*Abstract Co-Author*)
Peter Greenstreet (*Abstract Co-Author*)
Paula N. Patino, MD (*Abstract Co-Author*)
Suman T. Prabhakar, MD, FRCR (*Abstract Co-Author*)
Oscar Osorio, MD (*Abstract Co-Author*)
Robert Lim, MD (*Abstract Co-Author*)

PURPOSE

The purpose of this study to evaluate the use of risk assessment scores to determine the clinical impact of biannual lung cancer screening and detection of malignancy.

METHODS AND MATERIALS

A retrospective analysis of all patients enrolled in the XXXXX Lung Cancer Screening (LCS) Program associated with XXXXXX Hospital from January 2017 to December 2023, was performed. Patients were categorized based on their lung cancer risk assessment (RA) score. Clinical LCS results using Lung-RADS at timepoints: Baseline, 12 month (T1) and 24 months (T2) were recorded. All abnormal/positive screening results were confirmed with pathology proven malignancy for positive results and follow up CTs confirmed true negative results. Malignancy and false positive rates were recorded with subgroup analysis of patients with RA<3% and RA>3%.

RESULTS

A total of 4825 patients were included. All patients at baseline, Lung-RADS 1/2 were 4268/4825 (88%), Lung-RADS 3 were 294/4825 (6.1%), Lung-RADS 4A/4B/4X was 263/4825 (5.5%) with 104/2425 (4.3%) malignancies detected and 453/4825 (9.4%) false positives. For patients at T1 with RA<3%, Lung-RADS 1/2 were 1069/1119 (96%), Lung-RADS 3 were 17/1119 (1.5%), Lung-RADS 4A/4B/4X was 33/1119 (2.9%), with 45/1119 (4.0%) false positives. For patients at T1 with RA>3%, Lung-RADS 1/2 was 1982/2109 (94%), Lung-RADS 3 was 40/2109 (1.9%), Lung-RADS 4A/4B/4X 87/2109 (4.1%), with 159/2109 (7.5%) false positives. If patients with a RA<3% skipped T1, 4/1029 (0.4%) malignancies would be missed. If patients with a RA>3% skipped T1, 27/2109 (1.3%) malignancies would be missed. If biannual LCS occurred, patients with a RA<3% are less likely to have malignancy missed than RA>3%; and 28/1029 (2.7%) false positive results would have been avoided (p=0.02).

CONCLUSION

Patients with risk assessment scores<3% have low malignancy rates and RA scores can safely guide extended screening intervals

CLINICAL RELEVANCE/APPLICATION

Biannual LCS screening can reduce the harms associated with frequent annual screening

S4-SSCH02-5 COMPARISON OF SURGICAL OUTCOMES AND CANCER RECURRENCE IN A REAL-WORLD LUNG CANCER SCREENING PROGRAM COMPARED TO THE NATIONAL LUNG SCREENING TRIAL (NLST) COHORT

Aparna Singh, MD (*Presenter*)
Jo-Anne O. Shepard, MD (*Abstract Co-Author*)
Yolonda Colson, MD, PhD (*Abstract Co-Author*)
Suzanne Byrne, MD (*Abstract Co-Author*)
Michael Jaklitsch (*Abstract Co-Author*)
Scott D. Swanson, PhD (*Abstract Co-Author*)
Mark M. Hammer, MD (*Abstract Co-Author*)

PURPOSE

The National Lung Screening Trial (NLST) established low-dose CT lung cancer screening (LCS) as an effective method for reducing lung cancer mortality in high-risk populations. However, the translation of these results into clinical practice has been complicated by concerns regarding overdiagnosis, false positives, and patient selection. We sought to compare complication rates and cancer recurrence outcomes between patients undergoing surgical resection in a real-world LCS program and those in the NLST.

METHODS AND MATERIALS

We conducted a retrospective cohort analysis of patients undergoing lung cancer screening in our healthcare system from January 2015 to June 2023 and compared these outcomes with those from the NLST's CT screening cohort. We reviewed rate of surgery for benign diagnoses, surgical complication rates, oncologic outcomes, and recurrence data using multivariable logistic regression and survival analysis.

RESULTS

Our cohort included 387 patients from our real-world LCS program, compared to 812 from the NLST. The proportion of benign surgeries was significantly lower in the LCS group compared to the NLST group (12% vs. 18%, p=0.016). The LCS cohort also experienced a lower rate of complications (24% vs. 32%, p=0.003), although major complications were not significantly different (11% vs. 14%, p=0.11). Notably, the LCS group exhibited significantly better recurrence-free survival, with a hazard ratio of 0.60 (95% CI 0.39 to 0.94, p=0.026) compared to the NLST.

CONCLUSION

We found that the real-world implementation of lung cancer screening is associated with lower complication rates and improved oncologic outcomes compared to historical data from the NLST. These results underscore the effectiveness and safety of LCS in contemporary clinical settings and highlight the importance of increasing screening accessibility and education to optimize early lung cancer detection and patient outcomes.

CLINICAL RELEVANCE/APPLICATION

Real-world implementation of lung cancer screening resulted in lower complication rates, improved recurrence-free survival, and better patient selection for surgery compared to the NLST, highlighting advancements in surgical and oncologic practices.

S4-SSIN01-2 DEEP LEARNING SEGMENTATION COMPARED TO VOLUME ESTIMATION FORMULA FOR THE QUANTIFICATION OF TRAUMATIC HEMOTHORAX ON CHEST CT

Suzie Byun, MD (*Presenter*)
Grace Tewkesbury, MD (*Abstract Co-Author*)
Carl Beyer (*Abstract Co-Author*)
Kevin Eddinger (*Abstract Co-Author*)
Nathaniel McLauchlan (*Abstract Co-Author*)
Anne Tran (*Abstract Co-Author*)
Jeremy W. Cannon, MD,MS (*Abstract Co-Author*)
Friedrich D. Knollmann, MD, PhD (*Abstract Co-Author*)
Hersh Sagreiya, MD (*Abstract Co-Author*)

PURPOSE

Hemothorax is common in thoracic trauma, with 300,000 cases annually in the United States. Hemothorax size is important for clinical management; 300mL is used as a threshold to decide if tube thoracostomy should be performed. One commonly used volume estimation formula is from Mergo (1999): V=d 2 *h, where d=maximum depth and h=maximum height of effusion. A previous study used the same dataset as this study to evaluate the formula's performance, finding low accuracy in stratifying hemothorax volumes close to 300mL and high inter-reader variability. TotalSegmentator is a deep learning model trained to segment anatomical structures. This study evaluated TotalSegmentator's performance in quantifying acute traumatic hemothorax volumes compared to the estimation formula.

METHODS AND MATERIALS

46 adult patients with acute traumatic hemothorax on chest CT were prospectively identified at a trauma center in 2016. Volume estimations were calculated using V=d 2 ×h. Manual segmentation was performed in 3D Slicer (version 5.6.2, www.slicer.org). Studies were converted from DICOM to NIfTI and the TotalSegmentator pleural effusion subtask was applied (version 2.1.0, www.totalsegmentator.com). 41 studies were manually segmented by five readers, with five studies excluded for errors in collection. Statistics included Dice similarity coefficient (DSC), Pearson's r, intraclass correlation coefficient (ICC), and Bland-Altman analysis.

RESULTS

Hemothorax volumes ranged from 9-1379mL (manual), 0-1605mL (automated), and 13-3528mL (Mergo formula). The automated method correctly stratified 93% of cases (n=43/46) as above or below 300 mL, and 73% (n=8/11) of borderline cases (200-400 mL) compared to 85% (n=40/46) and 73% (n=8/11) of borderline cases by the Mergo formula. Pearson's r was 0.98 for the automated method and 0.81 for the Mergo formula. The automated method had a mean bias of -8mL and limits of agreement (LOA) of -122 to +106mL, compared to the Mergo formula's mean bias of +101mL and LOA of -748 to +949mL. Median DSC between manual and automated segmentations was 0.77. ICC among the five human readers was 0.97 [0.94-0.98] and 0.96 [0.94-0.98] when including TotalSegmentator.

CONCLUSION

Rapid and accurate quantification of acute hemothorax volume can guide clinical management. Deep learning-based segmentation was more accurate and reliable than formula-based estimation, demonstrating performance comparable to human readers.

CLINICAL RELEVANCE/APPLICATION

Deep learning-based segmentation such as TotalSegmentator is a more reliable tool for making rapid volume estimations of acute traumatic hemothorax compared to existing methods, and can provide better guidance to clinicians making management decisions in the acute setting.

S4-SSIN01-3 DEEP LEARNING-BASED FATTY LIVER CLASSIFICATION FROM CHEST X-RAYS: INTEGRATING UNCERTAINTY QUANTIFICATION FOR RELIABLE PREDICTIONS

SOOHO AHN, MS (*Presenter*)
Ja Kyung Yoon (*Abstract Co-Author*)
Young Han Lee, MD (*Abstract Co-Author*)
Naeun Park (*Abstract Co-Author*)
Dasom Kim (*Abstract Co-Author*)
Hyungjin Rhee, MD, PhD (*Abstract Co-Author*)

PURPOSE

To develop a deep learning model classifying fatty liver status using only inexpensive, routinely acquired chest X-rays (CXR), incorporating uncertainty quantification to assess confidence in the predicted outcomes.

METHODS AND MATERIALS

We retrospectively enrolled patients who underwent CXR and liver MRI including proton density fat fraction (PDFF) within 30 days between January 2021 and December 2024. Patients with history of malignancy or liver surgery, polycystic liver disease, large-volume ascites, or abdominal shielding during CXR were excluded. The cohort was temporally divided into a training set (MRI from 2022-2024) and a validation set (MRI from 2021). An abdominal radiologist measured PDFF as the average of single measurements from each of the nine liver segments. Based on PDFF values, fatty liver was classified as none (=5.1%), mild (5.2-14.1%), or moderate to severe (=14.2%). We developed a deep learning model using CXR images to predict fatty liver status. The model quantifies the prediction uncertainty through the Ensemble Monte Carlo Dropout (EMCD) method. Multiple probabilistic inferences were performed for each image in the test, and the prediction distribution and confidence were

calculated based on the results. The classification performance was evaluated by the area under the receiver operating characteristic curve (AUC), accuracy, F1-score, and expected calibration error (ECE), and an uncertainty-based data retention strategy was applied to analyze the confidence-based prediction performance. The reliability of the predictions was visualized by confidence interval, posterior distribution, and uncertainty class activation map.

RESULTS

This study included 1,094 pairs of CXR and liver MRI exams: training set, 838 pairs (none, n=594; mild, n=172; moderate to severe, n=72); validation set, 256 pairs (none, n=190; mild, n=48; moderate to severe, n=18). In validation set, the EMCD model achieved an AUC of 0.76, an accuracy of 0.75, an F1-score of 0.76, and an ECE of 0.12 for fatty liver classification. After excluding the 50% most uncertain predictions, the accuracy and F1-score improved to 0.88 and 0.82, respectively.

CONCLUSION

The developed deep learning model effectively classifies fatty liver status using CXR, and its integrated uncertainty quantification significantly enhances clinical reliability.

CLINICAL RELEVANCE/APPLICATION

This model could potentially facilitate cost-effective screening and risk stratification of fatty liver disease in clinical settings. The integration of uncertainty quantification further enhances clinical confidence in diagnostic decisions.

S4-SSIN01-4 AI UNDERESTIMATES ASPECTS WHEN ASSESSED ON FULL DEPLOYMENT SCALE

Sameed Khan (*Presenter*)
Jennifer Bullen, MSc (*Abstract Co-Author*)
Stephen E. Jones, MD, PhD (*Abstract Co-Author*)
Chintan Shah, MD, MS (*Abstract Co-Author*)

PURPOSE

Automated ASPECTS scoring applications are indicated for use in patients with a large-vessel occlusion (LVO) in the ICA or MCA. Previous evaluations thus focused on LVO patients. However, the tool is commonly deployed to be run on all stroke alert non contrast head CTs prior to knowledge of LVO presence. Assessing the performance in this expanded scope may reveal discrepancy between published studies and real-world performance. We hypothesized that the difference between reader and automated ASPECTS scores will differ across LVO and non-LVO patients.

METHODS AND MATERIALS

We retrospectively reviewed images and reports from stroke alert non-contrast head CT exams processed by automated software (RAPID ASPECTS, iSchemaView) from 1/1/2020 to 12/31/2020. LVO presence was determined from follow-up CTA reports. Reader and automated ASPECTS were extracted from the radiologist report and image annotations, respectively. Agreement was evaluated using Lin's concordance correlation coefficient (CCC) and Bland-Altman plots. Significance testing was performed using the Wilcoxon rank sum test and Fisher's exact test.

RESULTS

998 stroke alert CT scans were performed during the study period. 191 records were excluded (133 not processed, 18 reader ASPECTS not reported, 40 repeat exams) for a final sample of 807 exams (400 female). 53 patients (~7%) had LVO confirmed on follow-up CTA. Mean automated and report ASPECTS for LVO patients were 6.8 (SD: 2.5) and 8.6 (SD: 2.0) versus 8.1 (SD: 2.1) and 9.9 (SD: 0.7) for non-LVO patients. The CCC was 0.12 (95% CI: 0.09, 0.15). Absolute difference between report ASPECTS and automated ASPECTS did not differ significantly based on LVO status ($p = 0.2$). The proportion of patients considered thrombectomy-eligible (ASPECTS >= 6 per AHA guidelines) was significantly higher with the report (795/807 = 98.5%) compared to the automated score (704/807 = 87.2%) ($p < 0.001$). This was true among both LVO ($p=0.004$) and non-LVO patients ($p = 0.028$).

CONCLUSION

Automated ASPECTS software underestimated scores in all patients, leading to significant differences in thrombectomy eligibility consideration. However, the amount of score difference between automated and report ASPECTS was similar between LVO and non-LVO patients. Automated ASPECTS score was available to the reading radiologist, which likely informed the agreement between scores independent of LVO status. Future directions will include blinded review of LVO and non-LVO scans to examine agreement with automated score.

CLINICAL RELEVANCE/APPLICATION

AI software evaluations should match the deployment clinical context. In this study, we examine the performance of one such tool for automated ASPECTS assessment in all patients where the tool would be deployed.

S4-SSIN01-5 REWINDING LATE-STAGE CT SCANS TO TRAIN AI FOR EARLY PANCREATIC CANCER DETECTION

Wenxuan Li, BS (*Presenter*)
Qi Chen (*Abstract Co-Author*)
Kang Wang, MD,PhD (*Abstract Co-Author*)
Heng Li (*Abstract Co-Author*)
Alan Yuille, PhD (*Abstract Co-Author*)
Zongwei Zhou, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate whether a "Time-Machine" generative model that transforms late-stage pancreatic ductal adenocarcinoma (PDAC) CT scans into realistic early-stage PDAC (<2 cm) can expand the training data for early detection AI models, given the extreme rarity of real early-stage PDAC scans.

METHODS AND MATERIALS

We curated 3,144 contrast-enhanced CT scans, comprising 2,098 voxel-wise annotated PDAC cases and 1,046 normal controls. Tumor stages were T1 = 285, T2 = 396, T3 = 367, T4 = 45, and unknown = 1,005. A previously published whole-body segmenter generated masks for the pancreas, vessels, ducts, and 20 other organs in each scan. A reverse-temporal cellular-automata model—conditioned on patient age, clinical history, and scan phase as growth cues—traced every PDAC backward to plausible size, shape, and location of its earlier stage. A diffusion model then blended these smaller PDAC into their original anatomy, preferentially within visible dilated ducts, to generate paired early-stage scans. An nnU-Net model was trained on the late-stage scans augmented by their synthetic earlier versions. Internal testing included 650 patients (51 with T1 PDAC, 599 controls), while external validation used 3,592 CT scans from six international hospitals. A retrospective set of 19 prediagnostic scans acquired 3-36 months before clinical diagnosis were retrieved to assess lead-time performance.

RESULTS

On internal validation, AI models, trained on real, late-stage tumors augmented by their earlier version of synthetic, early-stage tumors, achieved an AUC of 0.975 (95% CI: 0.939 - 1.000), a sensitivity of 95.3% (95% CI: 84.5 - 98.7%), and a specificity of 98.7% (95% CI: 96.6 - 99.5%) for detecting small PDAC (<2 cm). External testing yielded an AUC of 0.940 (95% CI: 0.922 - 0.956), a sensitivity of 93.2% (95% CI: 89.4 - 95.6%), and a specificity of 86.2% (95% CI: 84.9 - 87.3%). Notably, the AI achieved a sensitivity of 36.8% (95% CI: 19.1 - 59.0%) in detecting PDAC at the prediagnostic stage (3-36 months before clinical diagnosis) where radiologists had missed 100% of these PDAC in the original clinical reads of the images.

CONCLUSION

A reverse-temporal generative model synthesizes realistic early-stage CT scans from late-stage cases, enabling AI to learn small-tumor patterns without extensive early-stage annotations and improving small tumor (<2 cm) detection sensitivity by 6% over models trained only on real-world tumors.

CLINICAL RELEVANCE/APPLICATION

Early-stage PDAC scans are 10-20 times less common than late-stage scans in clinical datasets. If validated, this "Time-Machine" approach offers a scalable strategy to overcome the early-stage data bottleneck and support earlier AI-driven tumor detection.

S4-SSMK01-1 SHEAR WAVE ELASTOGRAPHY EVALUATION OF PLANTAR FASCIITIS AFTER PLATELET-RICH PLASMA INJECTION: A MULTICENTER PROSPECTIVE STUDY

Adel Almohammady, MBBS (*Presenter*)
Emad H. Emara, BMBCh (*Abstract Co-Author*)
Engy M. Tantawy II, MD (*Abstract Co-Author*)

PURPOSE

To investigate the role of shear wave elastography (SWE) in evaluating the efficacy of platelet-rich plasma (PRP) injections in the treatment of plantar fasciitis (PF).

METHODS AND MATERIALS

In this prospective multicenter study, 144 patients with unilateral PF persisting for = 6 months were included. Patients received a single PRP injection prepared from their blood using the peppering technique. Outcome measures included the visual analog scale (VAS) for heel pain, foot functional index (FFI), sonographic measurement of plantar fascia thickness, and changes in tissue elasticity and shear wave velocity using SWE. These measures were evaluated before and up to 12 months post-injection.

RESULTS

Both the VAS and FFI scores demonstrated significant improvements following the injection ($p < 0.001$). A significant reduction was observed in plantar fascia thickness from pre-injection (5.14±1.1 mm) to post-injection (4.63±0.86 mm) ($p< 0.001$). SWE showed significant improvements in shear wave velocity and elasticity over time. The mean shear wave velocity increased from 3.08 ± 0.71 m/s pre-injection to 3.39 ± 0.77 m/s at 6 months and 4.23 ± 4.61 m/s at 12 months post-injection ($p= 0.032$). Similarly, shear wave elasticity increased from 32.12 ± 9.29 kPa pre-injection to 35.39 ± 8.23 kPa at 6 months and 39.24 ± 8.15 kPa at 12 months post-injection ($p < 0.001$). The interobserver agreement analysis demonstrates a predominantly good level of reliability across most parameters (?= 0.55-0.78)

CONCLUSION

SWE is a valuable tool for monitoring treatment outcomes in PF patients after PRP injection.

CLINICAL RELEVANCE/APPLICATION

Shear wave elastography can is a non-invasive, objective, and quantitative monitoring tool that help in evaluation of the efficacy of PRP injections for treating planter fascitis . The significant improvements in shear wave velocity and elasticity suggest that PRP therapy enhances the biomechanical properties of the plantar fascia over time

S4-SSMK01-2 HIP ARTHROPLASTY AND COMPUTED TOMOGRAPHY OF ABDOMEN: A RETROPERITONEAL INDICATOR OF POST ARTHROPLASTY HIP FLEXOR IMPINGEMENT

Mohammed Alfaqih, MD (*Presenter*)

PURPOSE

To evaluate if a tangible association exists between the psoas muscle (PM) atrophy with ipsilateral acetabular component version in patients with total hip arthroplasty.

METHODS AND MATERIALS

A retrospective, IRB-approved search of two institutions Picture archiving and communication system archives. Subjects with unilateral total hip arthroplasty (THA) on CT scan of abdomen and pelvis acquired between January 2008 through December 2018 were included after meeting inclusion and exclusion requirements (N=67). The maximum anterior-posterior length of uncovered acetabular component (UAC) was measured on sagittal reformats. The acetabular version angle was measured on both axial (AAV) and sagittal (SAV) reformats. The percentage difference between ipsilateral and contralateral PM in terms of quantitative radiodensity in Hounsfield unit (DHU) and cross-sectional area measurement (AM) in cm2 was assessed. The UAC, AAV and SAV were measured blindly to DHU and AM and the ensuing data was compiled and computed. Additional analysis was then performed by dividing patients into two groups; Group A patients had DHU values over 50% and Group B patients had DHU values less than 50%. UAC, AAV, SAV were compared between groups A and B.

RESULTS

Findings revealed significant positive correlation between DHU and UAC ($r2 =0.7$, $P <0.05$). A significant negative correlation was demonstrated between AAV, SAV and DHU ($r2 = - 0.4$, $P <0.05$). Group A and B included 26 and 41 patients respectively. Group A was found to have an increased UAC (7 mm ±4, $P<0.05$), decreased SAV (19o ±10, $P<0.05$) and decreased ASV (22o±11, $P<0.05$) compared to Group B (0mm± 0.5,33o±11,35o±10).

CONCLUSION

There is a strong association between ipsilateral psoas muscle atrophy in patients with THA who have an increased length of the uncovered acetabular component and decreased acetabular version angle.

CLINICAL RELEVANCE/APPLICATION

Our findings suggest that a suboptimally positioned acetabular component may lead to chronic flexor impingement.

S4-SSMK01-3 EVALUATION OF DEEP LEARNING-BASED TECHNIQUES FOR REDUCING MAGNETIC SUSCEPTIBILITY ARTIFACTS IN A 3.0T MRI ENVIRONMENT

WON JAE LEE (*Presenter*)
Kyoo Jin Yeon, RT (*Abstract Co-Author*)
Minji Kim (*Abstract Co-Author*)
Dong Hwan Kim (*Abstract Co-Author*)

PURPOSE

High-bandwidth and OMAR (Orthopedic Metal Artifact Reduction) techniques used to reduce magnetic susceptibility artifacts in MRI have been associated with increased noise and edge blurring. Artificial Intelligence Compressed SENSE (AICS) may reduce noise in MR images. This study aimed to evaluate the effectiveness of AICS combined with artifact reduction techniques in improving image quality.

METHODS AND MATERIALS

A 3.0T MRI system (MR7700, Philips Healthcare) was used to scan a phantom consisting of a 5 mm titanium rod and a 10 mm acrylic rod immersed in copper sulfate (CuSO4) solution. Imaging sequences included 2D T1-, T2-, PD-, FS PD-weighted, and 3D PD VISTA, acquired using Compressed SENSE (CS) and AICS. CS images were obtained with routine (low-bandwidth), high-bandwidth, and OMAR; AICS images were acquired using high-bandwidth and OMAR. Artifact size and full width at half maximum (FWHM) were measured using MATLAB. Signal-to-noise ratio (SNR) was calculated from the mean and standard deviation of signal intensity. Statistical analysis was performed using Kruskal-Wallis tests, with significance defined as $p<0.05$ (SPSS v.23).

RESULTS

Artifact size was smallest with OMAR across all sequences (mean reduction: 31.2%, $p<0.05$). High-bandwidth techniques reduced artifact size compared to routine, with significant differences observed in PD with AICS, and FS PD and T2 with CS ($p<0.05$). No significant CS-AICS difference in high-bandwidth and OMAR. AICS improved SNR in all sequences compared to CS (mean increase: 30.8%). In PD-weighted images, AICS OMAR showed higher SNR than routine (mean increase: 24.1%). FWHM was largest in OMAR ($p<0.05$). No significant differences in FWHM were found between CS and AICS high-bandwidth, and with routine ($p>0.05$).

CONCLUSION

AICS-enhanced high-bandwidth and OMAR techniques demonstrated substantial effectiveness in reducing susceptibility artifacts at 3T MRI. Among them, OMAR showed the greatest artifact reduction but also led to noticeable SNR loss and boundary blurring. In contrast, AICS consistently improved SNR across all pulse sequences. These findings support the routine application of AICS as a fundamental component of artifact reduction. We propose combining AICS with OMAR for maximal artifact suppression. However, in clinical scenarios where delineation of fine structural boundaries is critical—such as evaluation of subtle lesions—the combination of high-bandwidth and AICS may be preferable, as it offers artifact reduction comparable to OMAR while preserving image sharpness better than routine sequences.

CLINICAL RELEVANCE/APPLICATION

This study provides a foundation for selecting optimal deep learning-based artifact reduction techniques based on various clinical needs.

Robert D. Boutin, MD (*Abstract Co-Author*)

PURPOSE

To establish consensus regarding appropriate utilization of radiographic exams for 12 potentially low-yield anatomic sites among a multidisciplinary, multi-institutional panel of expert radiologists, emergency medicine (EM) physicians, and surgeons.

METHODS AND MATERIALS

A three-round Delphi consensus study with 34 subspecialty faculty (16 radiologists, 9 EM physicians, 4 orthopedic surgeons, 5 ENT surgeons) from 21 major academic centers was performed. In Round 1, each expert completed anonymized preliminary voting with free-text and structured responses on the utilization of radiographs at 12 anatomic sites. In Round 2, each expert was assigned to a 5-6 member multidisciplinary team comprised of radiologists, EM physicians, and surgeons. Each team (n=6) was assigned 2 anatomic sites: Ribs and Scapula; Sacrum and Coccyx; Sternum and SC Joint; Nasal Bone and Mandible; Facial Bone and Sinus; Skull and Neck Soft Tissue. Each team performed a literature review prioritizing the highest level of scientific evidence and drafted 4-6 consensus statements for each of their 2 anatomic sites. Statements and supporting text were submitted to the full panel for voting. Anonymized voting was performed using an online voting platform (JotForm; San Francisco, CA) using a 9-point Likert scale (1-3=disagree, 4-6=uncertain, 7-9=agree). Consensus was defined a priori as =80% of experts voting 7-9, with a median score =7 and interquartile range (IQR) <4. Statements that did not meet consensus in Round 2 were required to be revised and submitted to the panel in Round 3. In Round 3, a final round of voting was performed. Descriptive statistics were performed.

RESULTS

In Round 1, radiologists (n=16) and EM physicians (n=9) answered 7 questions for each of the 12 anatomic sites (n=2100 responses), ENT surgeons answered questions for the 6 "ENT" sites (n=210 responses), and orthopedic surgeons answered questions for the 6 "orthopedic" sites (n=168 responses). In Round 2, 58 total statements were submitted to the panel for voting. Radiologists and EM physicians voted on all 58 statements (n=1450 votes), ENT surgeons voted on 32 statements

(n=160 votes), and orthopedic surgeons voted on 26 statements (n=104 votes). One statement (2%) did not reach consensus in Round 2; the remaining 57 statements (98%) reached consensus. In Round 3, all statements achieved consensus.

CONCLUSION

Expert consensus recommendations were established for appropriate utilization of radiographs in 12 anatomic sites through a multidisciplinary and multi-institutional deliberative process.

CLINICAL RELEVANCE/APPLICATION

Expert consensus guidelines on appropriate utilization of radiography may improve quality of care by reducing unnecessary radiographic exams, radiation exposure, and costs.

S4-SSMK01-5 CORRELATING FOOT LONGITUDINAL ARCH SHAPE WITH PERONEAL TENDON PATHOLOGIES THROUGH RADIOGRAPHIC ANGLE MEASUREMENTS

Adil Basha, BA (*Presenter*)
Muhammad R. Akram, BS (*Abstract Co-Author*)
Natalie Velez (*Abstract Co-Author*)
Dhilip Andrew, MD (*Abstract Co-Author*)
Naveen Rajamohan, MD,MBBS (*Abstract Co-Author*)
Avneesh Chhabra, MD, MBA (*Abstract Co-Author*)
Flavio Duarte Silva, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study assesses whether a correlation exists between the shape of the medial longitudinal arch of the foot measured using angles on weight-bearing radiographs and the risk for peroneus longus and brevis tendon pathologies.

METHODS AND MATERIALS

After institutional approval, a retrospective search was conducted for patients who presented between 2017 and 2023 with foot and ankle pain, and for whom ankle MRIs and weight-bearing ankle radiographs were performed within 6 months of each other. 141 cases of peroneal tendon dysfunction that met the criteria were identified. Talonavicular uncoverage angle, Meary’s angle, calcaneal pitch, cuneiform to fifth metatarsal height, and Djian-Annonier's (DA) angle were calculated on weightbearing ankle radiographs. MRI was used to assess the peroneus brevis tendon, peroneus longus tendon, common peroneal tendon sheath, and the peroneus brevis and longus tendon sheaths. Associations between radiographic angles and MRI findings were explored through one-way ANOVA followed by Fisher's least significant difference method for multiple comparisons.

RESULTS

Of the five angles compared using ANOVA, Meary's angle was shown to have a statistically significant difference in individuals with peroneus brevis tears compared to individuals with healthy tendons. The study also demonstrated statistically significant differences between the calcaneal pitch angle in patients with peroneus longus tenosynovitis and those with healthy peroneus longus tendons.

CONCLUSION

This study demonstrated that the utilization of Meary’s angle can help assess a patient's risks for tears of the peroneus brevis tendon with moderate accuracy and calcaneal pitch can assist in stratifying risk for peroneus longus tenosynovitis when used with the MRI modality. Future research could focus on adding more modalities for comparison, such as weight-bearing 3D CT, as well as increasing the number of patient scans that fit the exclusion criteria.

CLINICAL RELEVANCE/APPLICATION

The results of this study can be applied in the clinical setting to assist in the diagnosis of peroneal tendon tears and other tendon injuries, especially when used complementarily to MRIs of the foot and ankle, speeding up the diagnostic process and improving patient outcomes for those who may be suffering from untreated chronic ankle pain.

S4-SSMK01-6 METAL ARTIFACTS IN LUMBAR SPINE INSTRUMENTATION: A COMPARISON OF PCD-CT VS. EID-CT, ITERATIVE METAL ARTIFACT REDUCTION AND VIRTUAL MONOENERGETIC IMAGING IN 100 EXAMINATIONS

Thomas Marth, MD (*Presenter*)
Adrian Marth, MD (*Abstract Co-Author*)
Christoph Laux (*Abstract Co-Author*)
Daniel Nanz (*Abstract Co-Author*)
Reto Sutter, MD (*Abstract Co-Author*)

PURPOSE

Photon-counting detector (PCD) computed tomography (CT) systems allow the reconstruction of virtual monoenergetic images (VMIs) from inherently available spectral data. However, qualitative and quantitative evaluations of VMI in combination with tin-prefiltration (Sn) and iterative metal artifact reduction (iMAR) and their comparison to energy-integrating detector (EID) CT are limited.

METHODS AND MATERIALS

Retrospectively, 100 clinical Sn CT scans (50 EID and 50 PCD) of the lumbar spine following fusion surgery with pedicle screws and intervertebral cages were included. Metal artifacts were quantitatively and qualitatively assessed in standard EID (EID std), standard PCD (PCD std), and reconstructed VMI at 120 keV (PCD VMI120), iMAR (PCD iMAR), and VMI at 120 keV + iMAR (PCD VMI120+iMAR) images. Regions of interest were placed in the most hyperdense and hypodense areas, near metal artifacts, and the standard deviation of Hounsfield Units was assessed as a quantitative artifact surrogate. For qualitative image analysis, six image features were rated by two readers. The Kruskal-Wallis Test was used for statistics.

RESULTS

73 patients were included, of which 27 patients received both an EID and a PCD scan. EID CT was conducted at 140 kVp with a mean CTDI vol of 12.4 ± 1.9 mGy, and PCD CT at 100 (n=23) or 140 (n=27) kVp with a mean CTDI vol of 6.5 ± 2.1 mGy. Hypodense artifacts were significantly more severe (higher SD) in PCD std (SD: 372 HU) and PCD iMAR (332 HU), both p<.01, and comparable in PCD VMI120 (149 HU) and PCD VMI120+iMAR (106 HU), both p>.05, compared to EID std (151 HU). Hyperdense artifacts were more pronounced in PCD std (SD: 286 HU) and PCD iMAR (204 HU), and reduced in PCD VMI120 (85 HU) and PCD VMI120+iMAR (66 HU), although not significantly different from EID std (p=.45 -.89). Qualitative artifact extent was rated significantly less severe in PCD VMI120 , PCD iMAR , and PCD VMI120+iMAR images compared to EID std (p =.014). Trabecular and cortical bone visibility was rated lowest in PCD VMI120+iMAR . Significantly more signal distortion artifacts were present in the PCD VMI subgroup acquired at 100 kVp compared to the PCD VMI subgroup at 140 kVp (p<.01).

CONCLUSION

PCD CT in combination with VMI and VMI + iMAR was comparable to EID CT for metal artifact reduction in the lumbar spine at nearly half the radiation dose. VMI + iMAR at PCD CT led to the strongest artifact reduction at the cost of lower cortical and trabecular bone visibility.

CLINICAL RELEVANCE/APPLICATION

The results show VMI reconstruction of Sn CT scans of the lumbar spine to be effective and useful for reducing metal artifacts and favor PCD over EID due to the inherently available spectral reconstruction possibilities and their potential for radiation dose reduction.

S4-SSMK02-2 MRI-ASSESSED OUTCOMES AFTER MICROFRACTURE VERSUS SCAFFOLD-ASSOCIATED PROCEDURES IN KNEE CARTILAGE DEFECTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Eduardo Graniel Palafox, MD (*Presenter*)
Marcelo Robles Rodriguez (*Abstract Co-Author*)
Valeria Soriano Pineda (*Abstract Co-Author*)
Luis E. Graniel Palafox, MD (*Abstract Co-Author*)
Renata V. Leao, MD (*Abstract Co-Author*)

PURPOSE

This Systematic Review and Meta-Analysis aims to compare MRI-assessed outcomes following microfracture and scaffold-associated procedures for the treatment of knee cartilage defects. By analyzing morphologic and compositional imaging parameters such as MOCART scores and T2 mapping across multiple studies, this work seeks to summarize the current evidence regarding cartilage repair as visualized through magnetic resonance imaging.

METHODS AND MATERIALS

A systematic search was performed in PubMed, Embase, and the Cochrane Library up to April 28th, 2025, to identify studies comparing MRI-assessed outcomes between microfracture (MFx) and scaffold-associated procedures in patients with knee cartilage defects. Eligible studies included those reporting morphologic and/or compositional cartilage repair outcomes evaluated through magnetic resonance imaging, specifically using the Magnetic Resonance Observation of Cartilage Repair Tissue (MOCART) score and/or T2 mapping. Data were extracted and synthesized to calculate mean differences between groups.

RESULTS

Out of 256 articles initially identified, 5 studies met the inclusion criteria (3 randomized clinical trials and 2 cohort studies), comprising a total of 285 patients. At 3-month follow-up, no significant difference in MOCART scores was observed between groups ($P = 0.6010$), with high heterogeneity across studies ($P < 0.0001$). At 2 years, scaffold-associated procedures demonstrated significantly higher MOCART scores ($P = 0.0031$) with no observed heterogeneity ($P = 0.9932$). T2 mapping at 2 years showed no significant difference ($P = 0.9193$), accompanied by substantial heterogeneity ($P = 0.0029$).

CONCLUSION

Scaffold-associated procedures show superior morphologic repair at 2-year follow-up with consistent improvements in MOCART scores. No significant differences were found in T2 mapping, and heterogeneity among studies persists. These findings support the long-term structural benefits of scaffolds but underscore the need for standardized imaging protocols and further high-quality studies to validate these results.

CLINICAL RELEVANCE/APPLICATION

This study provides evidence to inform surgical decision-making and follow-up imaging strategies by highlighting MRI-based differences in cartilage repair quality between microfracture and scaffold-associated procedures.

S4-SSMK02-3 IMAGING DIAGNOSTIC DELAY IN AXIAL SPONDYLOARTHRITIS: DATA FROM THE INTERNATIONAL AIDA NETWORK

Francesca Martini, MD (*Presenter*)
Cristian Sica, MD (*Abstract Co-Author*)
Raffaello Martini (*Abstract Co-Author*)
Nunzia Di Meglio (*Abstract Co-Author*)
Armando Perrella, MD (*Abstract Co-Author*)
Antonio Vitale (*Abstract Co-Author*)
Luca Cantarini (*Abstract Co-Author*)
Maria Antonietta Mazzei, MD (*Abstract Co-Author*)

PURPOSE

To assess the contribution of imaging misdiagnosis and underdiagnosis to the overall diagnostic delay in Axial Spondyloarthritis (axSpA), a complex inflammatory condition affecting the axial skeleton, including the sacroiliac joints and the spine.

METHODS AND MATERIALS

A multicenter observational study was conducted in a cohort of 100 consecutive patients with a definitive clinical-radiological diagnosis of axSpA, all of whom had experienced a measurable imaging diagnostic delay. These patients were enrolled in the AIDA (AutoInflammatory Disease Alliance) Network axSpA Registry between March 2024 and February 2025. For each patient, we analyzed the MRI study that was responsible for the definitive diagnosis (included in imaging group 1) and the earliest radiological examination (not necessarily an MRI exam) in which signs of disease were retrospectively evident but not initially recognized (included in imaging group 2). For both imaging groups, we collected data on imaging modality, use of contrast agent, anatomical region examined (pelvis, spine, or both), and radiological findings (sacroiliitis, spinal inflammation, or both); for group 2 only, we also recorded whether the initial report was negative or described degenerative changes.

RESULTS

Imaging group 1 included 100 MRI studies, whereas imaging group 2 consisted of 94% MRI scans, 4% CT scans, 1% PET scans, and 1% conventional X-rays. In imaging group 2, only 28% of the studies were performed with intravenous contrast, whereas 72% were performed without contrast. In terms of anatomical focus, 42%

examined only the spine, 34% only the pelvis, and 24% included both regions. Radiological reports were classified as negative in 82% of cases and as degenerative in 18%. The average diagnostic delay—the time between the earliest potentially diagnostic examination and the final diagnostic MRI—was 2 years, 9 months, and 27 days .

CONCLUSION

The diagnosis of axSpA remains highly challenging, with delays often extending over several years and involving multiple contributing factors, including radiological misinterpretation. The role of an experienced musculoskeletal radiologist is essential to avoid misdiagnosis or underdiagnosis and to improve early detection of the disease.

CLINICAL RELEVANCE/APPLICATION

Accurate and timely interpretation of early inflammatory signs on imaging may reduce the diagnostic delay in axSpA, with a direct impact on patient care and disease management.

S4-SSMK02-4 DEEP LEARNING FOR AUTOMATED GRADING OF RADIOGRAPHIC SACROILIITIS

Xinyi Meng (*Presenter*)
Xiaoyue Zhang (*Abstract Co-Author*)

PURPOSE

The aim of this study was to develop and validate an artificial intelligence system to help physicians in assessing and diagnosing sacroiliitis from standard X-ray images.

METHODS AND MATERIALS

In this retrospective study, a deep learning model for the automated grading assessment of radiographic sacroiliitis was developed using pelvic X-ray images from a training set of 465 individuals (930 single sacroiliac joints) and a validation set of 195 individuals (390 single sacroiliac joints). The algorithm was tested using an external test set of 223 individuals (446 single sacroiliac joints). The receiver operating characteristic (ROC) curve was used to calculate the area under the curve (AUC), sensitivity, and specificity to assess the model's performance. The findings of the model were used as a reference to determine its utility in aiding radiologists in the diagnosis and grading assessment of sacroiliitis.

RESULTS

The neural network model demonstrated proficiency in assessing grading of sacroiliitis. In the external test set, the model achieved a grading accuracy rate of 63.90% for radiographic sacroiliitis, and its diagnostic accuracy for determining the presence of radiographic sacroiliitis reached 90.13%. With the assistance of the model, the diagnostic accuracy of radiological sacroiliac arthritis by two junior imaging physicians improved significantly, increasing from 92.45% and 91.10% to 97.17% and 95.29%, respectively. Furthermore, the accuracy of image grading (grades 0 to 4) also showed notable improvement, rising from 75.00% and 74.08% to 88.89% and 80.90%, respectively.

CONCLUSION

The artificial intelligence model demonstrated high diagnostic accuracy and can greatly enhance the precision of radiographic sacroiliitis grading.

CLINICAL RELEVANCE/APPLICATION

In clinical practice, the model can serve as a valuable computer-aided diagnostic tool, assisting radiologists and rheumatologists in making more accurate and efficient diagnoses, especially in cases with ambiguous or early-stage lesions. It can also be used as an educational tool for training junior radiologists and medical students, improving their diagnostic skills. Further validation with larger sample sizes and multicenter studies is needed to refine the model and ensure its effectiveness across diverse patient populations. Integrating the model into the clinical workflow can enhance the overall efficiency and quality of patient care by providing real-time diagnostic support.

S4-SSMK02-5 EVALUATING THE RELIABILITY AND CLINICAL UTILITY OF CARPAL COLLAPSE & MALALIGNMENT INDICES IN RHEUMATOID ARTHRITIS VERSUS CONTROLS

Yasir Mian (*Presenter*)
Veena Peraka (*Abstract Co-Author*)
Sang Bum Lee (*Abstract Co-Author*)
Swami Sadanala (*Abstract Co-Author*)
Parham Pezeshk, MD (*Abstract Co-Author*)
Avneesh Chhabra, MD, MBA (*Abstract Co-Author*)

PURPOSE

To assess the reliability of traditional radiographic measurements of carpal collapse and malalignment in rheumatoid arthritis (RA) patients and to compare these measurements between RA patients and controls.

METHODS AND MATERIALS

43 RA patients and 58 controls were retrospectively studied. Three independent readers measured five radiographic indices on hand radiographs: Carpal Height Ratio (CHR), Revised Carpal Height Ratio (rCHR), Stahl Index (STI), Radioscaphoid Angle (RSA), and Ulnar Translocation of the Carpus (UTC). Interobserver agreement was assessed using intraclass correlation coefficients (ICCs). Multiple linear regression was used to assess differences in carpal indices between groups, adjusting for relevant clinical and demographic variables. Post hoc t-tests were conducted for significant categorical predictors. A p-value < 0.05 was considered significant.

RESULTS

There were 27/43 women (63%) in the RA group and 31/58 (53%) in the control group ($p = 0.348$). The mean age in the RA group was 62.3 ± 13.6 years, compared to 49.9 ± 14.7 years in the control group ($p < 0.001$). Mean duration of disease in the RA group was 73.9 ± 107.7 months. ICCs for the control group were: CHR, 0.77 (95% CI, 0.61-0.86); rCHR, 0.52 (0.37-0.66); STI, 0.11 (-0.04-0.28); RSA, 0.67 (0.55-0.78); and UTC, 0.71 (0.58-0.81). For the RA group, ICCs were: CHR, 0.60 (0.42-0.74); rCHR, 0.29 (0.11-0.49); STI, 0.52 (0.34-0.68); RSA, 0.52 (0.28-0.70); and UTC, 0.85 (0.77-0.91). After adjusting for covariates, no significant differences were observed between RA and controls for each of the measurements. Subgroup analysis showed that RA patients with motor symptoms had significantly higher UTC than those without motor symptoms ($p < 0.05$).

CONCLUSION

UTC demonstrated good interobserver agreement, while CHR, STI, and RSA showed moderate agreement, and rCHR showed poor agreement. In this cohort of RA patients with short-to-midterm disease duration, traditional radiographic measures of carpal alignment did not significantly differ between RA patients and controls. However, RA patients with motor symptoms had significantly higher UTC than those without, suggesting that ulnar translocation may be linked to clinical impairment even in the early stages of disease.

CLINICAL RELEVANCE/APPLICATION

Ulnar translocation of the carpus is a reliable and clinically meaningful radiographic measure of wrist malalignment in rheumatoid arthritis. Its correlation with motor symptoms highlights its potential to connect imaging findings with functional impairment, enhancing diagnostic efficacy.

S4-SSNR01-1 EVALUATION OF AN MRI SCORING SYSTEM FOR VENOUS AND PARENCHYMAL BRAIN ABNORMALITIES IN STURGE-WEBER SYNDROME

Ajay Kumar, MD, PhD (*Presenter*)
A Luat, MD (*Abstract Co-Author*)
Michael E. Behen, PhD (*Abstract Co-Author*)
Csaba Juhasz (*Abstract Co-Author*)

PURPOSE

Sturge-Weber syndrome (SWS) is a rare neurocutaneous disorder characterized by facial capillary malformation and leptomeningeal venous abnormalities. While pial enhancement on post-contrast MRI is the hallmark of brain involvement, other findings—such as cortical atrophy, calcification, and deep venous remodeling—are also common and associated with neurological deficits. Recent collaborative efforts have emphasized imaging-based phenotyping to track disease progression and guide treatment. This study evaluated a novel MRI scoring system designed to comprehensively capture SWS brain abnormalities and their clinical relevance, with high reproducibility.

METHODS AND MATERIALS

MRI scans from 20 children with unilateral SWS (ages 1-14 years; mean: 8.3 years) were analyzed from a prospectively collected single-center database. Each MRI included native T1, T2, FLAIR, SWI, and post-contrast T1 sequences at 3T. Two independent raters scored five imaging features across all lobes: pial enhancement, enlarged deep veins, atrophy, calcification (0 = none, 1 = small/limited, 2 = extensive), and choroid plexus enlargement (0: normal/symmetric, 1: slightly enlarged, 2: severely enlarged). Interrater reliability was assessed using intraclass correlation coefficients (ICC). Final consensus scores were correlated with clinical measures including age, seizure history, and motor function using Spearman's rank correlation.

RESULTS

Interrater reliability was excellent for all sub-scores (ICC: 0.957-0.995) and for total MRI score (ICC: 0.992; all $p<0.001$). Higher total MRI scores were strongly associated with lower motor functions ($r = -0.8$, $p<0.001$), which correlated with greater pial enhancement ($p<0.001$), atrophy, and calcification ($p=0.003$ for both). No significant correlations were found between MRI scores and seizure variables or age.

CONCLUSION

This novel MRI scoring system reliably captures both vascular and parenchymal brain abnormalities in SWS which correlate with motor severity. Its high interrater reliability supports its use in multi-rater or multicenter studies.

CLINICAL RELEVANCE/APPLICATION

This simple, reproducible SWS MRI scoring tool can aid in characterizing disease severity, monitoring progression, and evaluating treatment effects in clinical research and trials.

S4-SSNR01-2 BRAIN ANATOMICAL CHANGES IN IDIOPATHIC INTRACRANIAL HYPERTENSION

Mahsa Alborzi Avanaki, MD (*Presenter*)
Donnella S. Comeau, MD,PhD (*Abstract Co-Author*)
Marc Bouffard (*Abstract Co-Author*)
Jeremy N. Ford, MD,MBA (*Abstract Co-Author*)
Yu-Ming Chang, MD, PhD (*Abstract Co-Author*)

PURPOSE

This study explores the relationship between arachnoid granulations (AGs), venous sinus stenosis, and glymphatic function in idiopathic intracranial hypertension (IIH).

METHODS AND MATERIALS

We conducted a retrospective analysis of imaging data from IIH patients and controls (all female). Patients with IIH were stratified into two groups: those with presently-active, untreated intracranial hypertension and those with a history of IIH but currently-normal intracranial pressure via treatment/cure (T/C). AGs in the dural sinuses were quantified and measured. Transverse/sigmoid sinus stenosis ratios were calculated bilaterally and were compared with ALPS-indices.

RESULTS

Data from 15 IIH patients (9 untreated, 6 T/C, mean ages 34.5 and 32) and 16 controls (mean age 40) were analyzed. Mean AG numbers in the superior sagittal sinus (SSS) were; Controls: 6.88, untreated IIH: 3.78, and T/C: 8 ($P= 0.085$). Mean stenosis ratios were R:68.99 and L:75.68 in the T/C group, 64.48 (R) and 67.14(L) in untreated IIH patients and among controls. Controls had significantly lower stenosis ratios compared to both untreated (P-values: $R = 0.01$, $L = 0.06$) and T/C groups (P-values: $R = 0.02$, $L = 0.01$). The untreated vs. C/T comparison shows no significant difference (corrected $p > 0.05$). In the T/C group, a strong negative correlation was found between AG count in the SSS and right-sided stenosis ($P = 0.02$). ALPS-indices correlated poorly with and AG count ($P = 0.5$) and sinus stenosis (P-values ranging from 0.32 to 0.86) in all groups.

CONCLUSION

This pilot study indicates potentially dynamic arachnoid granulation (AG) anatomy with fewer visualized AGs among patients with untreated IIH than among controls. Interestingly, AGs were more abundant in patients with treated or cured IIH than among controls. Also of interest was not only persistence of venous sinus stenosis in the treated/cured IIH group, but greater stenosis ratios than seen in patients with untreated disease and current intracranial hypertension. It was only in the group of T/C IIH patients that an inverse correlation was noted between arachnoid granulations and venous sinus stenosis ratios. The absence of correlation between stenosis ratios or AG numbers and ALPS-indices may reflect a greater importance of meningeal lymphatic drainage over venous drainage in downstream glymphatic drainage.

CLINICAL RELEVANCE/APPLICATION

Comprehensive understanding of neurofluid movement must take into account glymphatic, meningeal lymphatic, and venous sinus processes.

S4-SSNR01-3 TAKING THE STAGE - A FAST MRI ACQUISITION TECHNIQUE TO EVALUATE BRAIN VASCULAR AND PARENCHYMAL ABNORMALITIES IN STURGE-WEBER SYNDROME

E. Mark Haacke, PhD (*Presenter*)
Scotty G. McKay, MD (*Abstract Co-Author*)
Yongsheng Chen, PhD (*Abstract Co-Author*)
Yang Xuan, BS (*Abstract Co-Author*)
Csaba Juhasz, PhD (*Abstract Co-Author*)

PURPOSE

Sturge-Weber syndrome (SWS) is a rare neurocutaneous disorder characterized by a facial port-wine birthmark and venous vascular brain involvement. One of the major barriers to the research of SWS and other childhood neurological disorders is the lack of early serial imaging to evaluate developmental changes due to concerns for patient harm from repeated sedation and contrast administration. One emerging area of radiology to greatly aid not only in improving the understanding of pediatric neurological diseases but also improving patient care is image standardization and rapidly acquired imaging. Strategically-acquired gradient echo (STAGE) imaging is one such method that provides multiple qualitative images, including susceptibility-weighted imaging (SWI) and quantitative maps, in 7 min or less at 3 T.

METHODS AND MATERIALS

In this prospective study, 22 patients (13 females, mean age 14 years, range 2-22 years) diagnosed with SWS with prior imaging with unilateral brain involvement underwent MR imaging using the STAGE protocol without the administration of contrast material or the use of sedation. All STAGE data were evaluated by two reviewers, and presence vs. absence of abnormalities were assessed within each lobe including leptomeningeal venous malformations (LVM), enlarged deep veins, cerebral atrophy and calcifications, and choroid plexus enlargement; these were then compared to conventional MRI including SWI and post-contrast images.

RESULTS

Despite the lack of contrast administration, presence of all vascular and parenchymal brain abnormalities noted on conventional MRI were reliably visualized on STAGE images. In cases of limited (such as unilobar) brain involvement, some features were more subtle on STAGE. The most challenging feature to identify was LVM, best assessed with STAGE-derived SWI and R2* images. Visualization of calcifications was also challenging in some cases, but comparison of SWI phase and proton density-weighted images allowed for their reliable detection and differentiation from venous abnormalities.

CONCLUSION

Utilization of rapidly acquired non-contrast STAGE MR imaging allows for accurate assessment of a variety of brain venous vascular and parenchymal involvement in SWS across a wide age range comparable to conventional MR.

CLINICAL RELEVANCE/APPLICATION

Fast image acquisition allows for the avoidance of sedation eliminating a source of potential adverse effects from imaging and making serial MRI examinations more feasible. Early serial imaging can detect evolution of brain abnormalities and monitor the effects of interventions. This standardized imaging method also allows for more effective multi-institutional studies for researching rare pediatric neurological conditions.

S4-SSNR01-6 MORPHOMETRIC SIMILARITY MAPPING IN PEDIATRIC MIGRAINE WITHOUT AURA: UNRAVELLING THE ROLE OF BIOLOGICAL SEX

Alessia Guarnera, MD (*Presenter*)
Antonio Napolitano (*Abstract Co-Author*)
Francesco Dellepiane, MD (*Abstract Co-Author*)
Alessia Carboni, MD (*Abstract Co-Author*)
Maria Camilla Rossi Espagnet, MD (*Abstract Co-Author*)
Giulia Moltoni (*Abstract Co-Author*)
Carlo Gandolfo (*Abstract Co-Author*)
Daniela Longo (*Abstract Co-Author*)

PURPOSE

Pediatric migraine without aura (pmwa) is suspected to cause structural and functional alterations in the brain connectome. MSM (morphometric similarity mapping), which has never been applied to pmwa, is an advanced and non-invasive technique that identifies brain cortex and cerebral connectivity anomalies, as well as neuronal plasticity changes. The paper aims to: a) identify differences in morphometric similarity networks (MSNs) in pediatric patients affected by mwa compared to healthy controls and in subgroups of patients; and b) correlate these differences in MSNs with patients' demographic and clinical characteristics.

METHODS AND MATERIALS

498 patients (6-18 years) and 100 controls were retrospectively recruited from our Institution's archive if the subjects showed: normal MRI exams, normal neurological examination, and no comorbidities. 3D T1 MPRAGE and DWI were pre-processed to obtain eleven cortical parameters for the MSN analysis (Tab. 1). The global mean morphometric similarity (MS) and the regional mean MS were calculated. The statistical analysis included separate linear regression models for all subjects and subgroups of patients in the global and regional models, followed by an ANOVA with an FDR correction and a p-value threshold of 0.05. For significant predictors, a post hoc analysis using the Benjamini-Hochberg method was performed.

RESULTS

83 patients and 81 controls (6-18 years) were included (Fig. 1). MSM identified significant differences in MSNs in patients based on the clinical parameters nausea and vomiting, photophobia and phonophobia, number of migraine days per month, and mostly on the demographic parameter biological sex (Tab. 2,3). The cerebral pathways that showed the most significant alterations encompassed the executive function pathway, the nociceptive pathway, and the default mode network (Fig. 2,3).

CONCLUSION

Differences in MSNs identified in patients related to clinical parameters and, above all, biological sex demonstrated that migraine shapes the cerebral connectome and favours neuronal plasticity. The resulting abnormalities in the executive function pathway, the nociceptive pathway, and the default mode network may lead chronic migraine symptoms. Biological sex is confirmed as a paramount parameter in migraine, supporting the hypothesis of a "sex-specific phenotype".

CLINICAL RELEVANCE/APPLICATION

The identification of in vivo migraine biomarkers linked to anomalies of the brain cortex and cerebral connectivity, or to demographic parameters such as biological sex, is crucial in pediatric patients affected by migraine without aura to offer tailored therapy and improve their quality of life.

PURPOSE

To determine if the presence of brain hypoxia on acute phase MRI of cerebral malaria (CM) patients predicts the severity of clinical course and the presence of neurologic sequela.

METHODS AND MATERIALS

This retrospective study used existing MRI, clinical, and demographic data from children diagnosed with CM at Queen Elizabeth Central Hospital in Blantyre, Malawi between 2009 and 2015. All subjects met the diagnostic criteria for CM coma. MRI was performed within 12 hours of admission and repeated daily during admission. Follow up MRI at 1, 6, and 12 months was obtained in survivors. Imaging was acquired on a 0.35T scanner. Hypoxic injury was quantified on DWI sequences through a previously validated severity scoring system assessing diffusion restriction across 14 brain regions. Scores ranged from 0 (no injury) to 28 (most severe), incorporating cortical, deep grey, and posterior fossa structures. Clinical information collected include temperature, plasma lactic acid, blood pressure, glucose, hemoglobin, hematocrit, platelets, white blood cell count, among other parameters. Neuropsychological follow up assessments were used to evaluate the long-term cognitive impact.

RESULTS

Preliminary results on 69 out of a total 270 MRI scans have been analyzed. In this preliminary data, mean hypoxia score is 1.16 (SD .63). The mean MRI hypoxia score was lowest among those who fully recovered (0.54), higher among who recovered with sequela (2.75) and highest among those who died (2.82). Higher hypoxia scores were associated with higher plasma lactate (r= .27, p= .025), deeper coma (r= -.41, p< .001) and worse anemia (r= -.14 p= .002). MRI in pediatric CM demonstrates evidence of hypoxic brain injury.

CONCLUSION

MRI in pediatric CM imaging demonstrates evidence of hypoxic brain injury. More severe hypoxia changes on imaging are associated with a more severe clinical disease course and worse outcomes. Data on long term imaging and clinical outcomes is forthcoming.

CLINICAL RELEVANCE/APPLICATION

Cerebral malaria (CM) is a life-threatening condition that disproportionality affects children in low resource settings. Findings from this research offer new insight into the role of brain hypoxia in driving structural changes and disease severity. This improved understanding of CM pathophysiology can inform targeted interventions that address its high rate of mortality and long-term neurological deficits.

S4-SSNR02-3 FREE WATER FRACTION CORRELATES WITH DISABILITY IN MULTIPLE SCLEROSIS AND REFLECTS PERIVASCULAR SPACE ENLARGEMENT

Valentin N. Stepanov, MD (*Presenter*)
Santiago Coelho, PhD (*Abstract Co-Author*)
Dmitry S. Novikov, PhD (*Abstract Co-Author*)
Els Fieremans, PhD (*Abstract Co-Author*)

PURPOSE

The glymphatic system is essential for clearing metabolic waste from the brain via perivascular spaces (PVS). Its impairment can lead to the accumulation of neurotoxic substances, contributing to neuroinflammation and neurodegeneration in multiple sclerosis (MS). Enlarged PVS (EPVS) visible on MRI are indicative of glymphatic dysfunction. This study investigates free water fraction (FW), extracted from diffusion-relaxation data using the Standard Model (SM) of diffusion in white matter (WM), as a potential biomarker of glymphatic impairment in MS. We assess its correlation with cognitive decline and overall disability and compare it to the commonly used DTI-ALPS technique.

METHODS AND MATERIALS

This IRB-approved, prospective study included 32 MS patients (19 females, 13 males; mean age 49, range 24-73; mean disease duration 13.8 years). Clinical scores included the Expanded Disability Status Scale (EDSS) and the Symbol Digit Modalities Test (SDMT). MRI was performed on a 3T Siemens Prisma using advanced diffusion protocols with varying echo times and B-tensor shapes, and structural T1-weighted MPRAGE. Diffusion MRI (dMRI) data were preprocessed with the DESIGNER pipeline, and FW maps were extracted from global WM, using biophysical modeling based on the SM. For comparison, DTI-ALPS index was calculated using ROIs in projection and association fibers.

RESULTS

EPVS on T1-weighted MRI aligned with regions of elevated FW, supporting its sensitivity to glymphatic impairment. FW negatively correlated with SDMT (rho = -0.46, p = 0.009) and showed a trend toward positive correlation with EDSS (rho = 0.34, p = 0.06). DTI-ALPS did not correlate with either clinical score or with FW, though the &82;; 2 /& 82;; 3 diffusion tensor eigenvalue ratio averaged over WM did correlate with FW.

CONCLUSION

SM estimates FW from multi-shell dMRI as a compartment with isotropic diffusivity of ~3μm 2 /ms and long T2 relaxation times (1.5s) compared to WM. In pathology, PVS may enlarge beyond the typical diffusion length of water, approximately 20-30μm at clinically used diffusion times, and thereby be captured by FW. In MS, increased FW, reflecting EPVS, correlated with cognitive decline and showed a trend with disability (SDMT, EDSS), while DTI-ALPS showed no correlation. This highlights FW's greater sensitivity to EPVS-related pathology. Future studies will assess & 82;; 2 /& 82;; 3 as an alternative DTI-derived marker and validate multi-shell derived FW's role in larger, longitudinal cohorts.

CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of dMRI-derived free water fraction as a sensitive marker of glymphatic dysfunction and disease burden in MS, supporting its use in clinical monitoring.

S4-SSNR02-4 DIAGNOSTIC EVALUATION OF DEEP LEARNING ACCELERATED 3D FLAIR IMAGING AT 1.5T AND 3T FOR VISUALIZATION OF CEREBRAL WHITE MATTER LESIONS

Sittaya Buathong, MD (*Presenter*)
Alexandra Filippakis (*Abstract Co-Author*)
Eugene Milshteyn, PhD (*Abstract Co-Author*)
Chen-Hua Chiang, MD (*Abstract Co-Author*)
Christopher Hemond (*Abstract Co-Author*)
Dan W. Rettmann, BS (*Abstract Co-Author*)
Susie Y. Huang, MD, PhD (*Abstract Co-Author*)
Ivan Jambor, MD,PhD (*Abstract Co-Author*)

PURPOSE

FLAIR imaging is a standard sequence used for the detection of white matter lesions. The goal of this clinical feasibility study was to evaluate a prototype acquisition and reconstruction technique that enables very high acceleration rates for 3D FLAIR (designated as DLS FLAIR) and compare it with the standard 3D FLAIR.

METHODS AND MATERIALS

Fifteen and 52 consecutive patients underwent brain MRI at 1.5T and 3T, respectively. The standard 3D FLAIR (isotropic 1mm3 acquisition voxel size) was obtained using a commercially available deep learning reconstruction algorithm. DLS FLAIR (isotropic 1mm3 acquisition voxel size) was performed using a prototype acquisition and reconstruction technique which combines a highly undersampled data acquisition with an unrolled deep learning-based reconstruction. Two neuroradiologists performed blinded, head-to-head qualitative assessments of lesion conspicuity, motion, noise, and overall diagnostic quality. Quantitative lesion volume and lesion counts were derived from automated segmentation. Cohen kappa scores were calculated for interrater agreement. A one-sided t-test for non-inferiority margin using the specified margin of 15% and alpha 0.05 was performed in each qualitative assessment. Comparison of lesion volumes and numbers with p-value < 0.05 for statistic significant were calculated using paired t-test.

RESULTS

At 1.5T, DLS FLAIR (4m53s) reduced scan times by 15% compared to standard 3D FLAIR (5m43s) while at 3T, DLS FLAIR (2m45s) achieved a 35% reduction in scan time compared to standard 3D FLAIR (4m15s). At both 1.5T and 3T, there were no statistically significant differences in image quality except for significantly reduced noise for the accelerated DLS FLAIR. Moderate to almost perfect interrater agreement (Cohen's kappa 0.55-0.85) was achieved. There were no statistically significant differences in lesion volumes or counts between DLS and standard 3D FLAIR.

CONCLUSION

The faster acquisition time of DLS FLAIR may enable a greater use of high-resolution isotropic 3D FLAIR sequences in the evaluation of patients with suspected white matter diseases both at 1.5T and 3T.

CLINICAL RELEVANCE/APPLICATION

Routine 3D FLAIR imaging with 1 mm isotropic imaging can take 4-6 minutes at 1.5T and 3T using routine methods, limiting routine use of high-resolution 3D FLAIR imaging. In our study a prototype deep learning-based acquisition and reconstruction technique (DLS FLAIR) was shown to be feasible with ~35% scan time reduction compared to the standard 3D FLAIR in the evaluation of cerebral white matter lesions.

S4-SSNR02-5 ASSESSMENT OF CORTICAL MYELINATION IN PATIENTS WITH MULTIPLE SCLEROSIS VIA T1W/FLAIR RATIO: A LONGITUDINAL FOLLOW-UP STUDY

DONGJUN LEE, MD (*Presenter*)
Yangsean P. Choi, MD, PhD (*Abstract Co-Author*)

PURPOSE

T1-weighted (T1w)/FLAIR ratio may reflect cortical myelin integrity in patients with multiple sclerosis (PwMS), but its clinical relevance remains unclear. This study investigated the longitudinal significance of cortical T1w/FLAIR ratio in PwMS.

METHODS AND MATERIALS

Brain MRIs were obtained from PwMS and clinically isolated syndrome (CIS) patients between September 2021 and December 2023. T1w and FLAIR images were preprocessed to calculate cortical gray matter (GM) and superficial white matter (WM) T1w/FLAIR ratios. Baseline and follow-up MRI were analyzed for T1w/FLAIR ratio.

RESULTS

Among 63 MS and 5 CIS patients (mean age: 40.5 years; 73.5% female), the baseline median Expanded Disability Status Scale (EDSS) score was 1.5. GM T1w/FLAIR ratio changes were negatively correlated with EDSS changes in whole-brain ($r = -0.201$, $p = 0.020$), occipital ($r = -0.269$, $p = 0.002$), and insular ($r = -0.18$, $p = 0.038$) cortices. Patients with stable ($p = 0.044$) or improved ($p < 0.001$) EDSS scores exhibited significant GM T1w/FLAIR ratio increases. T1w/FLAIR ratio changes were positively correlated with disease duration ($r = 0.285$, $p = 0.018$).

CONCLUSION

Longitudinal GM T1w/FLAIR ratio changes were associated with neurologic disability in PwMS, supporting its potential role as a biomarker for cortical myelination and disease monitoring.

CLINICAL RELEVANCE/APPLICATION

The T1w/FLAIR ratio as a potential marker for assessing cortical demyelination is significantly correlated with the clinical severity of multiple sclerosis. The T1w/FLAIR ratio of the outermost gray matter is most vulnerable to demyelination. The evolution of white matter lesions is not associated with cortical T1w/FLAIR ratio changes.

S4-SSNR02-6 THE USE OF ARIA-E SCORES IN CATEGORIZING INFLAMMATORY CEREBRAL AMYLOID ANGIOPATHY

Tabassum Sami, BS (*Presenter*)
Andrew D. Schweitzer, MD (*Abstract Co-Author*)
Michelle Roytman, MD (*Abstract Co-Author*)

PURPOSE

Cerebral amyloid angiopathy (CAA) is characterized by the accumulation of beta-amyloid peptides within small- to medium-sized cerebral blood vessels. The inflammatory forms of CAA, including CAA-related inflammation (CAA-ri) and Aß-related angiitis (ABRA), are associated with the immune response to amyloid deposition and are potentially treatable with immunosuppressive therapies. Current methods for grading CAA rely on the Boston Criteria. However, previous studies have proposed that the MRI grading scale for Amyloid-Related Imaging Abnormalities with Edema or Effusion (ARIA-E) may also be applicable to amyloid-related pathologies such as iCAA. The purpose of this study is to assess the inter-rater reliability of the ARIA-E grading scale in a cohort of 28 patients with iCAA.

METHODS AND MATERIALS

We performed a retrospective review of 28 clinically and radiographically confirmed cases of iCAA evaluated by MRI at Weill Cornell Medical Center. Two radiologists independently graded each case using the ARIA-E grading criteria. Inter-rater reliability was assessed for the Barkhof Grand Total Scale (BGTS) as well as the 3- and 5-point Severity Scales of ARIA-E (SSAE-3 and SSAE-5). Weighted and unweighted Cohen's kappa coefficients were calculated to assess the strength of agreement. In addition, we evaluated the scores in relation to their recurrence of symptoms attributable to iCAA.

RESULTS

In our iCAA cohort, inter-rater reliability was strong, with a weighted Cohen's kappa of 0.705 and an unweighted Cohen's kappa of 0.735 for BGTS scores. Similarly strong agreement was observed for SSAE-3 (weighted kappa: 0.760; unweighted kappa: 0.870) and SSAE-5 (weighted kappa: 0.776; unweighted kappa: 0.804). Among patients who experienced clinical recurrence (n = 7), the median BGTS score was 7 (IQR: 3-11.5), median SSAE-3 score was 3 (IQR: 2- 5), and SSAE-5 score was 2 (IQR: 2). Among patients without recurrence (n=21), there was a median BGTS score of 12 (IQR: 8-21), a median SSAE-3 score of 4 (IQR: 2.25-5), and a median SSAE-5 score of 2 (IQR: 3-3). There were no statistically significant differences in BGTS, SSAE-3, and SSAE-5 between patients who experienced recurrence versus those who did not.

CONCLUSION

Our study demonstrates that the ARIA-E grading criteria can be reliably applied to iCAA cases, achieving a high degree of inter-rater reliability. Further studies with larger cohorts are warranted to explore whether ARIA-E metrics can predict disease progression and relapse.

CLINICAL RELEVANCE/APPLICATION

Applying the ARIA-E grading system to categorize iCAA patients may provide valuable prognostic information and guide treatment decisions in an aging population.

S4-SSPH02-1 HIGH-FIDELITY ASSESSMENT OF X-RAY ANGIOGRAPHY SYSTEM PERFORMANCE: APPLICATION TO DEVICES USED TO TREAT PEDIATRIC CONGENITAL HEART DISEASE

Kenneth A. Fetterly, PhD (*Presenter*)

PURPOSE

The wide variety of implantable devices used to treat pediatric congenital heart disease (CHD) results in substantial variation in their conspicuity in X-ray fluoroscopy and angiography images. A shortcoming of common methods to assess medical imaging system performance is that they utilize simple test objects which do not represent the spatial complexity of clinical devices. The purpose of this work was to measure system performance using a clinically relevant range of implantable devices and exposure levels used to treat CHD.

METHODS AND MATERIALS

A method to measure pixel specific contributions (t 2) to Hotelling's T 2 was recently developed. The method preserves the spatial detail of the imaging system and accounts for noise correlation between pixels via the covariance matrix. One result is a 2D t 2 map for which the 2D integral is T 2 . d' was calculated as the square root of T 2 . 1200 unprocessed images of 4 stationary vascular plugs and a 14.4 mm 0.018" guidewire positioned within a 10 cm Plastic Water phantom were acquired. Exposure parameters were consistent with 5 fps pediatric fluoroscopy and 30 fps angiography (including 2x angiography exposure as a reference). The summation of t 2 values over the device area was used to calculate T 2 and d'. The device-specific area of t 2 values greater than 0.2 was measured to assess changes to the area of the devices represented in the images as exposure level changed.

RESULTS

Pixel-specific t 2 and device-specific T 2 and d' estimates varied as expected with exposure level to a quantum limited system. For vascular plugs, the fiducial markers demonstrated substantially greater t 2 than the device bodies. Considering 5 devices tested and 3 exposure levels, d' ranged from 16.6 to 65.3 (3.9x). For each exposure level, inter-device d' varied by 2.5x. For 4 devices, the fraction of the device area which exceeded t 2 > 0.2 was in the range 0.87 to 0.95 for the angiography exposure and 0.56 to 0.72 for the fluoroscopy exposure. For a covered vacular plug with very fine wire struts, these fractions were 0.37 and 0.18.

CONCLUSION

The measurements presented herein quantified the clinical observation of substantial variation in the conspicuity of a variety devices used to treat pediatric CHD. That t 2 , T 2 , and d' of spatially complex objects can be measured accurately opens a new pathway to assess medical imaging system performance using clinically-relevant rather than stylized test objects.

CLINICAL RELEVANCE/APPLICATION

This work uniquely measured the ability of an X-ray angiography system to create images of implantable devices used to treat pediatric CHD. These findings can be used to guide device-specific protocol development and further optimize the balance between technical image quality and patient radiation dose.

S4-SSPH02-2 SENSITIVITY OF QUANTITATIVE DIGITAL SUBTRACTION ANGIOGRAPHY TO CONTRAST AGENT DIFFUSION COEFFICIENT

Marlin Keller, MS (*Presenter*)
Grace Minesinger, MS (*Abstract Co-Author*)
Martin Wagner, PhD (*Abstract Co-Author*)
Paul F. Laeseke, MD, PhD (*Abstract Co-Author*)
Michael Speidel, PhD (*Abstract Co-Author*)

PURPOSE

Quantitative Digital Subtraction Angiography (qDSA) is a method for quantifying blood flow based on spatial tracking of blood/contrast mixing in x-ray images. Computational fluid dynamics (CFD) simulations are being used to gain a theoretical understanding of qDSA. There is currently no consensus on the choice of the diffusion coefficient (DC) for iodinated contrast. The purpose of this study was to determine the sensitivity of qDSA to the DC of iodinated contrast, and experimentally determine the DC for iohexol 300 mgI/mL (a commonly used contrast agent).

METHODS AND MATERIALS

CFD was performed in OpenFOAM for a 20 cm long straight vessel with a 5 Fr catheter injecting 2.0 mL/s of contrast into 7 different pulsatile blood flows (15 - 45 cm/s). Three DCs within literature range were used (A) 4e-5 , (B) 4e-7 , and (C) 4e-9 m 2 /s . 3D CFD data was saved at 30 frames/s and a 2D x-ray forward projector was used to simulate DSA images. For each setup, time-attenuation curves were measured at points along the vessel centerline (collectively referred to as a time-attenuation map, TAM). The qDSA algorithm was applied to the TAM to determine blood velocity. Linearity of qDSA velocity vs. CFD-based velocity (ground truth) was evaluated for each DC. TAM inputs for qDSA were also compared by computing the normalized root mean square error (nRMSE). To measure DC of iohexol, a diffusion cell was fabricated with 2 chambers separated by a semi-permeable membrane. The chambers were filled with iohexol and water and then repeatedly imaged 5 times with cone-beam CT to measure changes in iodine concentration. DC was determined through application of Fick's law.

RESULTS

The measured DC of iohexol in water was D =3.61 e-8 m 2 /s , (R 2 =0.99, 95% CI: [3.55, 3.68] e-8 m 2 /s). In simulations, the qDSA velocity was linear with respect to CFD velocity along the vessel centerline (CL) (R 2 =0.97), but with slopes and offsets dependent on DC. For the 3 DCs simulated, the relationships between qDSA and CFD velocities were (A) qDSA=0.59· CL+1.37 cm/s (95% CI: slope [0.48,0.69], intercept [-5.0,7.73]; R 2 =0.97), (B) qDSA=0.74· CL+2.78 cm/s (95% CI: slope

[0.62,0.86], intercept [-4.40,9.95]; R 2 =0.98), and (C) qDSA=0.99· CL-15.48 cm/s (95% CI: slope [0.87,1.19], intercept [-23.16,-7.80]; R 2 =0.99) . Comparing the TAMs for cases (A) and (C), the nRMSE ranged from 10.4% to 19.5% depending on the blood velocity.

CONCLUSION

qDSA velocity is linear with respect to ground truth velocity over a range of DC, however the relationship depends on the value of DC. This effect should be accounted for in future experimental and theoretical studies.

CLINICAL RELEVANCE/APPLICATION

qDSA promises to provide quantitative measurements of blood flow changes during interventional procedures such as transhepatic arterial embolization.

S4-SSPH02-3 IMPROVED Z-RESOLUTION ASSESSMENT FOR DIGITAL BREAST TOMOSYNTHESIS

Priyash Singh, MS (*Presenter*)
Bruno Barufaldi, PhD (*Abstract Co-Author*)
Andrew D. Maidment, PhD (*Abstract Co-Author*)
Raymond Acciavatti, PhD (*Abstract Co-Author*)

PURPOSE

The EUREF Digital Breast Tomosynthesis (DBT) QC protocol quantifies the system's point-spread function (PSF) via the z-resolution measured as the full-width half maximum (FWHM) of the artifact spread function (ASF). In using the EUREF method to evaluate a novel DBT system, we identified inconsistencies and biases that were supported by a critical evaluation of published reports.

METHODS AND MATERIALS

We trace these discrepancies to the discordant use of mean and maxima within the ASF formula. We propose an alternative protocol that uses multiplanar reconstruction to track the oblique BB signal, and uses the means of the background and BB signals to generate the ASF. We further use a functional fit for more accurate estimation of the FWHM. We validated the performance of the modified protocol using simulated and experimental reconstructions of phantoms.

RESULTS

The PSF is dependent upon the apparent angle of the BB which in turn depends on its location in the reconstructed plane, height above the detector, acquisition geometry, and the reconstruction technique. The EUREF protocol systematically overestimates FWHM due to stochastic noise in the reconstructed image. The FWHM is also biased for anteriorly displaced BBs due to the obliquity of their PSF. In contrast, the modified protocol was able to capture the expected z-resolution trends for both superior and anterior BB displacements more accurately. It also substantially reduced bias due to noise, by 97% in simulations and 65% in physical experiments, relative to the EUREF protocol.

CONCLUSION

The EUREF DBT QC protocol demonstrates systematic deviations, arising both from stochastic noise and the PSF obliquity, which limits its reliability in characterizing the z-resolution. Our modified protocol addresses these shortcomings, provides enhanced accuracy and precision, and demonstrates robustness across various BB positions and imaging conditions.

CLINICAL RELEVANCE/APPLICATION

Quantifying the z-resolution in DBT requires a rigorous approach. The current EUREF protocol, while simple, is susceptible to systematic errors. We proposed and developed a protocol that offers improved accuracy, precision, and robustness to acquisition conditions. Use of this protocol has revealed that z-resolution is largely predetermined by acquisition geometry and reconstruction algorithm. Thus, testing of z-resolution may be better suited for development of DBT systems rather than for routine QC, where simpler more targeted tests may be preferable to reduce the clinical workload of physicists.

S4-SSPH02-4 SYNTHESIZING VIRTUAL HIGH-DOSE IMAGES FROM LOW-DOSE IMAGES USING DD-MNET WITH DUAL-DOMAIN DENOISING AND DETAIL RECONSTRUCTION IN DIGITAL MAMMOGRAPHY

Ze Jin, PhD (*Presenter*)
Jifeng Zu (*Abstract Co-Author*)
Wahyu Rahmaniar (*Abstract Co-Author*)
Kenji Suzuki, PhD (*Abstract Co-Author*)

PURPOSE

Balancing image quality and radiation dose is critical in digital mammography. Unlike conventional dose-reduction methods that risk obscuring subtle lesions, we propose a dual-domain deep learning framework combining noise reduction in the signal-independent domain with detail reconstruction in the signal-dependent domain to enhance low-dose mammogram quality while preserving essential anatomical features.

METHODS AND MATERIALS

The proposed DD-MNet integrates denoising techniques through a dual-domain framework for digital mammography: (1) In the signal-independent domain (D1), quantum noise is stabilized via Anscombe transformation (AT) and suppressed using Wiener filtering. MNet is trained on paired AT low-dose (LD) and high-dose (HD) patches; (2) In the signal-dependent domain (D2), wavelet decomposition, structural filtering (Sobel gradient, bilateral filtering, anisotropic diffusion), and adaptive feature fusion refine details from the initial denoised output, enhancing anatomical feature preservation and clarity. The dataset includes paired LD and HD mammograms from an anthropomorphic phantom (Gammex 169 "Rachel", Gammex RMI, Middleton, WI) acquired at 1.5-39.0 mGy. Clinical validation involved 30 patients with LD (1.0-1.6 mGy) and standard-dose (SD, 3.6-6.2 mGy) acquisitions at 10%, 25%, and full-dose levels. Training used randomly sampled patches from phantom LD and HD images, with five-fold cross-validation ensuring robustness. Virtual HD mammograms were quantitatively evaluated using SSIM, FSIM, PSNR, and ISNR. Detailed qualitative analysis was also conducted on patient mammograms, particularly focusing on challenging lesions like microcalcifications.

RESULTS

Our DD-MNet outperformed state-of-the-art methods (BM3D, DnCNN, RED-CNN, EDCNN), achieving SSIM of 0.921, FSIM of 0.978, PSNR of 32.64 dB, ISNR of 0.711, and enabled a 66% radiation dose reduction by generating virtual HD images from LD (1.5 mGy) mammograms, comparable to SD (4.4 mGy) images. Qualitative analysis confirmed superior preservation of subtle anatomical and lesion details critical for accurate diagnosis and early breast cancer detection.

CONCLUSION

DD-MNet effectively combines quantum and electronic noise reduction with anatomical detail preservation through a dual-domain approach, significantly improving image quality for low-dose mammography. This method achieves up to 66% radiation dose reduction, promising safer breast cancer screening, especially for repeated examinations.

CLINICAL RELEVANCE/APPLICATION

The proposed method significantly reduces radiation exposure during digital mammography while maintaining diagnostic image quality, enabling safer and more effective breast cancer screening protocols.

S4-SSPH02-5 REAL-WORLD, POST-MARKET SURVEILLANCE STUDY OF A CHEST X-RAY AI MODEL IN A MULTICENTER STUDY

Seyedehelaheh Hosseini, MD (*Presenter*)
Gaurav Fotedar (*Abstract Co-Author*)
Richa Pant (*Abstract Co-Author*)
Subba R. Digumarthy, MD (*Abstract Co-Author*)
Amit T. Kharat, PhD,DMRD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)

PURPOSE

As the number of FDA-cleared AI algorithms increase, there's still a lack of data on how they perform in real-world clinical settings. To address this gap, we conducted a multicenter, post-market surveillance study to evaluate a chest X-ray AI algorithm's performance in real-world clinical practice.

METHODS AND MATERIALS

Our IRB-approved study included 875 CXRs from 17 sites in India. The inclusion criteria were the availability of CXR AI algorithm (Deeptek.ai) outputs at the time of interpretation of CXRs as part of the standard of care workflow. AI outputs were extracted in three classes (normal/abnormal; region of abnormality - lungs, pleura, hardware and heart; specific finding description such as opacity, nodule, mass, cardiomegaly, pleural effusion, pneumothorax). The radiologists' reports were converted into similar stratified outputs. Each CXR was reviewed in an blinded manner with the two sets of outputs (AI and radiologists) by an external thoracic radiologist without prior clinical use experience of the algorithm. The external radiologist recorded his agreement or disagreement, separately for each of the three class outputs. We estimated the agreement rates between the blinded external radiologist, AI output and reporting radiologists' outputs.

RESULTS

Of the 875 chest x-rays reviewed, there was complete agreement among all readers (AI, R1, and R2) in 736 cases (84%). Radiologists (R1 and R2) agreed but differed from the AI in 88 cases (10%). There were 17 cases where the AI and R1 agreed but R2 disagreed (2%), and 30 cases where the AI and R2 agreed but R1 disagreed (3%). No cases showed complete disagreement among all three readers. Only 4 cases (0.5%) showed total diagnostic discrepancy, highlighting high overall concordance and the potential of AI to support radiologist interpretation.

CONCLUSION

Our study demonstrates high concordance and acceptability of AI outputs for normal/abnormal radiographs, as well as at the level of region of interest and specific finding details.

CLINICAL RELEVANCE/APPLICATION

Our post-market surveillance of a chest x-ray AI algorithm supports the positive impact of AI on reporting of CXRs.

S4-SSPH02-6 COMPRESSION-FREE DIGITAL BREAST TOMOSYNTHESIS: PROOF OF CONCEPT

Peymon Ghazi, PhD (*Presenter*)

PURPOSE

This study demonstrates the technical feasibility of a compression-free spectral digital breast tomosynthesis system that, while operating within the screening-mammography radiation-dose limit defined in MQSA, is intended for frontline cancer detection.

METHODS AND MATERIALS

A proof-of-concept scanner was built in which independent, synchronized robotic arms carried a narrow-beam x-ray source and a curved digital detector. Breast is allowed to hang freely through a table aperture, eliminating mechanical compression. During imaging, a ±140° angular coverage sweep in a 2-D plane along with a +35° out of plane, was executed by the source in pulsed-fluoroscopy mode while counter-rotation of the detector was performed to maintain a quasi-parallel-beam geometry. Scatter-to-primary ratio (SPR) was quantified with the aperture method across all gantry angles, and a Monte Carlo model was employed to measure mean glandular dose for an average size and density breast. System spatial resolution was assessed from the modulation-transfer function (MTF) with limiting resolution defined at 10 % MTF. 140 projections were reconstructed by means of a GPU-accelerated compressed-sensing algorithm at 0.1-mm isotropic voxels. For all measurements, detector operates in spectral mode in two energy levels, with a thresholding set to 34 keV.

RESULTS

Mean SPR remained below 0.05 for all projection angles, confirming near-scatter-free acquisition. Average glandular dose was 3.8 mGy. A limiting spatial resolution of 7.8 lp mm?¹ was achieved, comparable to state-of-the-art DBT. The spectral differentiation between the soft tissue and high-attenuating non-tissue.

CONCLUSION

Near-scatter-free imaging with substantial radiation-dose savings was delivered by the prototype while painful breast compression was eliminated and neither spatial resolution nor throughput was compromised.

CLINICAL RELEVANCE/APPLICATION

By eliminating compression hardware and employing narrow-beam geometry, key barriers to broader tomosynthesis adoption—including patient discomfort, elevated scatter, and higher dose—are addressed by this system, which is therefore expected to improve screening compliance, extend high-quality imaging to women with dense or augmented breasts, and enable safer, more accurate interventional guidance.

S4-SSPH03-1 MEASURING AND MONITORING NOISE, DOSE, AND MODEL-OBSERVER-BASED LESION DETECTABILITY IN PATIENT CT EXAMS

Zhongxing Zhou, PhD (*Presenter*)
Jarod Wellinghoff (*Abstract Co-Author*)
Cynthia H. McCollough, PhD (*Abstract Co-Author*)
Lifeng Yu, PhD (*Abstract Co-Author*)

PURPOSE

Reporting noise and dose in patient CT exams has become a mandatory requirement for some quality programs. However, one of the required quality measures, global noise, is fundamentally flawed to characterize the image quality of each patient, especially for non-linear reconstruction algorithms. In this work, we developed a patient-specific channelized Hotelling observer (CHO)-based method to estimate lesion detectability for each individual patient scan and provided a solution to measure and monitor noise, dose, and lesion detectability in patient CT exams.

METHODS AND MATERIALS

To measure lesion detectability, a patient-specific channelized Hotelling observer (CHO) was developed. Lesion signals were modeled from lesions of varying sizes and contrast levels (3mm/-30HU, 6mm/-10HU, 6mm/-30HU, 6mm/-50HU, 9mm/-30HU) after incorporating the effect of contrast-dependent spatial resolution caused by nonlinear reconstructions such as iterative reconstruction (IR) and deep-learning reconstruction (DLR). An ensemble of backgrounds was extracted from patient images to include both relatively uniform areas and anatomically varying regions. The detectability index (d') was estimated using a scatter matrix computed from background regions of interest (ROIs) and a channelized mean signal. Both global d' for the entire image series and local d' every 5 cm along the z-axis of the scan were computed. Global noise levels were measured by identifying the peak values of the standard deviation histogram and noise power spectrum was computed from background ROIs. Size-specific dose estimates (SSDE) were also calculated according to the AAPM Reports 204 and 220 and IEC 62985.

RESULTS

The proposed method was applied to patient images from three different CT scanner models. A report on noise level, SSDE, and d', globally and as a function of z coordinate, for each image series was successfully generated. The global noise levels were 13.2, 25.0, and 30.2 HU, and the average d' were 3.78, 1.69, and 1.39 for the three different test patients.

CONCLUSION

A patient-specific CHO-based method was developed to estimate lesion detectability from individual image series. Along with the report on noise and dose, this method provides an objective, quantitative, and task-based approach to measuring and monitoring image quality and dose for each individual CT patient exam.

CLINICAL RELEVANCE/APPLICATION

The proposed patient-specific CHO method and the reporting on noise, dose, and lesion detectability enable task-based quantitative measurement and monitoring of image quality and radiation dose for each CT exam.

S4-SSPH03-2 STATISTICAL EQUIVALENCE BUT CLINICAL UNCERTAINTY: INTER-SCAN REPRODUCIBILITY OF THE CORONARY PERIVASCULAR FAT ATTENUATION INDEX

Tatsuya Saito, RT (*Presenter*)
Mihoko Fujimura (*Abstract Co-Author*)
Rina Sakai (*Abstract Co-Author*)
Tatsuya Nishii, MD, PhD (*Abstract Co-Author*)
Yuji Matsuzaki, RT (*Abstract Co-Author*)
Tomoro Morikawa, MD (*Abstract Co-Author*)
Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*)
Keizo Murakawa (*Abstract Co-Author*)
Tetsuya Fukuda, MD, PhD (*Abstract Co-Author*)

PURPOSE

The coronary perivascular fat attenuation index (FAI) is gaining attention as a quantitative imaging biomarker for coronary inflammation. A meta-analysis reported a 4.5 HU FAI difference between high-risk and non-high-risk plaques, suggesting that minor changes may reflect plaque risk. However, the inter-scan reproducibility of FAI remains insufficiently validated. This study aimed to assess the reproducibility of FAI using the same CT scanner.

METHODS AND MATERIALS

We retrospectively analyzed coronary CT scans acquired from August to November 2024 using a 256-row CT scanner. Prospective ECG-gated imaging was performed at 100 kV in two separate heartbeats, acquiring mid-diastole and end-systole individually. After motion correction, images with quiescent coronary arteries were selected for each phase. Automatic FAI analysis was performed for the three main coronary branches, excluding those with failed analyses. The equivalence test used a ±2.5 HU margin (approximately 55% of the reported 4.5 HU difference). Bland-Altman analysis was used to evaluate measurement error and limits of agreement (LOA).

RESULTS

Of 116 cases, 20 without a quiescent phase in both cardiac cycles and 18 with failed FAI analysis were excluded. A total of 220 branches from 78 cases (median age 67 years [56-76], 60 males [76.9%], heart rate 60 bpm [51-67]) were included. The mean FAI was -81.1±7.2 HU in diastole and -81.4 ± 7.4 HU in systole. The mean difference was -0.3 HU (90% CI: -0.8 to 0.3 HU), within the ±2.5 HU equivalence margin, indicating statistical equivalence ($p < .01$). Bland-Altman analysis showed no fixed or proportional error; however, LOA ranged from -9.7 HU (95% CI: -10.8 to -8.6) to +9.2 HU (95% CI: 8.1 to 10.3), indicating wide variability.

CONCLUSION

FAI measurements taken during two phases from different cardiac beats on the same CT scanner showed statistical equivalence. Nevertheless, the Bland-Altman analysis indicated inter-scan variability, with a limit of agreement of ±9 HU.

CLINICAL RELEVANCE/APPLICATION

The observed inter-scan LOA necessitates caution despite the statistical equivalence. FAI should be interpreted within a broader clinical context, ensuring appropriate margins around cut-off values.

S4-SSPH03-3 EVALUATION OF IMAGE QUALITY IMPROVEMENT AND DOSE REDUCTION USING DLIR AND IMAGE FILTER IN LUNG CT IMAGING

Kazuki Ishikawa (*Presenter*)
Kiyosumi Kagawa (*Abstract Co-Author*)
Takashi Okunaga (*Abstract Co-Author*)
Noriyuki Negi, RT (*Abstract Co-Author*)
Akiko Kusaka, RT (*Abstract Co-Author*)
Izumi Imaoka, MD (*Abstract Co-Author*)
Takamichi Murakami, MD, PhD (*Abstract Co-Author*)

PURPOSE

The purpose of this study was to evaluate the potential for image quality improvement and radiation dose reduction using Lung Kernel-Like (LKL) images, which apply a lung-specific image filter in combination with deep learning image reconstruction (DLIR), to expand their clinical applicability in lung imaging.

METHODS AND MATERIALS

All scans were acquired on a 256-slice CT scanner under standard-dose (noise index [NI] = 10) and low-dose (NI = 15) conditions. Three reconstruction methods were compared: filtered back projection (FBP), iterative reconstruction (IR) at 40% strength, and LKL images reconstructed using medium-strength DLIR. FBP and IR were performed using a conventional lung kernel. Physical image quality was assessed using the Catphan phantom, with metrics including modulation transfer function (MTF), standard deviation (SD) of CT values, and noise power spectrum (NPS). Clinical image quality was evaluated in 29 standard-dose and 30 low-dose chest CT cases using the Perception-based Image Quality Evaluator (PIQE) metric.

RESULTS

The CTDI vol was 16.5 mGy for standard-dose and 6.8 mGy for low-dose in phantom scans, and 9.2 ± 4.1 mGy and 5.3 ± 1.9 mGy, respectively, in clinical cases. The 50% MTF values were 0.68 for FBP, 0.70 for IR, and 0.69 for LKL at standard-dose, and 0.68, 0.70, and 0.70 at low-dose, respectively. The SD of CT values were 48.8 for FBP, 39.0 for IR, and 23.8 for LKL at standard-dose, and 67.0, 53.3, and 33.1 at low-dose, respectively. The average NPS spatial frequencies were 0.45 for FBP, 0.43 for IR, and 0.41 for LKL at standard-dose, and 0.44, 0.43, and 0.40 at low-dose, respectively. PIQE scores were 54.2 ± 6.9 for FBP, 42.8 ± 7.0 for IR, and 34.1 ± 6.2 for LKL at standard-dose, and 61.2 ± 5.2, 53.4 ± 6.5, and 39.6 ± 6.5 at low-dose, respectively. Significant differences were observed among all methods (repeated-measures ANOVA, $p < .001$; Bonferroni-corrected post hoc test, $p < .001$). In particular, low-dose LKL showed better PIQE scores than standard-dose FBP ($p < .001$) and was not significantly different from standard-dose IR ($p = .063$).

CONCLUSION

LKL images demonstrated superior noise characteristics while maintaining spatial resolution compared to conventional FBP and IR using the lung kernel. These findings suggest that a reduction in radiation dosage up to 50% can be achieved while maintaining overall image quality.

CLINICAL RELEVANCE/APPLICATION

While this study focused on lung imaging, the strategy of optimizing DLIR in combination with anatomically tailored image filters is applicable to other regions such as bone and vasculature. Customizing filters based on spatial resolution, noise, and contrast requirements enhances the versatility of DLIR and supports broader clinical adoption across various diagnostic tasks.

S4-SSPH03-4 3D LANDMARK SCANS PROVIDE PROSPECTIVE AND ACCURATE ESTIMATIONS OF WATER EQUIVALENT DIAMETER IN PATIENT CT EXAMINATIONS

Andrew M. Hernandez, PhD (*Presenter*)
Sarah Yoon (*Abstract Co-Author*)
Michael T. Corwin, MD (*Abstract Co-Author*)
Eric S. Diaz, MD (*Abstract Co-Author*)
Ahmadreza Ghasemiesfe, MD (*Abstract Co-Author*)
Misagh Piran, MD (*Abstract Co-Author*)
John M. Boone, PhD (*Abstract Co-Author*)
Sarah E. McKenney, PhD (*Abstract Co-Author*)

PURPOSE

3D Landmark (3DLM) scans have recently been introduced in some modern CT scanners for automatic scan planning in lieu of paired 2D localizers, but 3DLMs may offer extended capabilities. The purpose of this work is to quantify the accuracy of 3DLM scans for estimations of water equivalent diameter (D_w) in patient CT exams.

METHODS AND MATERIALS

A cohort of 100 patients scanned with at least one non-contrast series on a new model CT scanner, equipped with 3DLM capabilities, were retrospectively collected. All diagnostic, non-contrast scans (Dx) were generated according to our institution's clinical protocol and the 3DLM scans were generated according to the manufacturer's default protocol. The cases were composed of head (N=37), chest (N=18), and abdomen-pelvis (N=45) exams for a range of patients varying in age and size. D_w values were measured at the central plane on all Dx and corresponding 3DLM series using established methods. Agreement between D_w measurements from 3DLM scans and from reference Dx scans was assessed using Bland-Altman analysis, with differences reported as a percentage, and a limit of agreement (LOA) equal to +/- 1.96XSD.

RESULTS

The mean bias [lower LOA, upper LOA] in D_w measurements for 3DLM scans was -1.2% [-2.1,-0.2], -1.5% [-5.3,2.3], and -0.5% [-4.8,3.7] for head, chest, and abdomen-pelvis exams, respectively, but with a 60.0% to 99.7% reduction in scanner-indicated CTDIvol values. For head, chest, and abdomen-pelvis cases 8.1%, 5.6%, and 6.7% of cases, respectively, were outside the LOAs observed. Linear regression also revealed that agreement between the two methods for D_w estimations was not influenced by patient size for any of the exam types.

CONCLUSION

3DLM scans accurately estimate D w , and hence SSDE, for common exam types at radiation dose levels comparable to conventional 2D localizers, with the added benefit of being acquired before the diagnostic CT scans.

CLINICAL RELEVANCE/APPLICATION

3D Landmark scans can be utilized beyond their intended purpose to support prospective and accurate estimations of SSDE. We anticipate that adapting manufacturer software to support this capability is relatively straightforward. This extended capability is clinically relevant as it provides a more accurate estimate of average absorbed dose prior to the CT exam and could be useful for size-based selection of tube current modulation settings which is particularly important for pediatric CT imaging.

S4-SSPH03-5 CT KERNEL CONVERSION FOR SLICE-WISE QUANTITATIVE ASSESSMENT IN INTERSTITIAL LUNG DISEASE USING AN IMAGE-TO-IMAGE SCHRöDINGER BRIDGE MODEL

Doa Kim (*Presenter*)
Wooseok Choi (*Abstract Co-Author*)
Chang Yong Choi, MS (*Abstract Co-Author*)
Hyunki Lee (*Abstract Co-Author*)
Mi Jeong Song (*Abstract Co-Author*)
Sang Min Lee, MD, PhD (*Abstract Co-Author*)
Namkug Kim, PhD (*Abstract Co-Author*)

PURPOSE

To develop and evaluate a diffusion-based deep learning model for CT kernel conversion, translating soft-kernel (B30f) images into sharp-kernel (B70f) equivalents for improved depiction of interstitial lung disease (ILD) features.

METHODS AND MATERIALS

In this retrospective study, 150 patients with paired chest CT images reconstructed using both soft and sharp kernels from identical sinograms were collected, comprising 99 cases with diverse pulmonary abnormalities for training and 17 ILD cases for testing. A thoracic radiologist selected two representative axial slices per patient based on ILD feature visibility. We implemented diffusion model (Image-to-Image Schrödinger Bridge, I²SB) and compared it with pix2pixHD and UNet as baseline models using image similarity metrics (Peak signal-to-noise ratio, PSNR; structural similarity, SSIM; root mean square error, RMSE), absolute difference maps (ADM), and slice-wise Dice similarity coefficients (DSC) for ILD pattern segmentation. High attenuation area (HAA) proportions were quantified using commercial software (Aview Lung Texture, Coreline Soft, Seoul, South Korea).

RESULTS

I²SB demonstrated superior performance across all metrics. For image similarity, I²SB achieved the highest scores (PSNR: 40.6, SSIM: 0.963, RMSE: 39.0), outperforming both pix2pixHD (36.5, 0.916, 62.0) and UNet (37.3, 0.919, 57.0). Mean of ADM between model-based kernel conversion and ground truth sharp-kernel images revealed significantly lower errors with I²SB (30.9 ± 4.4) compared to both pix2pixHD (43.6 ± 5.1) and UNet (46.4 ± 5.0), with statistical significance confirmed by paired t-test ($p < 0.001$). For ILD pattern segmentation, I²SB demonstrated highest DSCs: 0.910 for ground-glass opacity (GGO), 0.860 for reticular opacity, and 0.923 for honeycombing. These results significantly surpassed both pix2pixHD (0.829, 0.815, 0.890) and UNet (0.822, 0.767, 0.867) across all pattern types. Bland-Altman analysis further validated I²SB's superior performance in HAA quantification, demonstrating minimal bias and the tightest limits of agreement among all tested methods.

CONCLUSION

Our proposed I²SB model demonstrates superior performance in CT kernel conversion for ILD assessment compared to alternative baseline models, providing enhanced image fidelity and quantitative accuracy.

CLINICAL RELEVANCE/APPLICATION

I²SB CT kernel conversion enables accurate quantification of ILD-related features from archived soft-kernel CT scans, improving imaging analysis workflows and clinical decision-making in ILD management.

S4-SSPH03-6 IMPACT OF CARDIAC PHASES ON CORONARY CALCIUM SCORING IN NON-GATED CT SCANS: A DYNAMIC CARDIAC PHANTOM STUDY

Chao Guo, PhD (*Presenter*)
Xinhua Li, PhD (*Abstract Co-Author*)
Yifang Zhou, PhD (*Abstract Co-Author*)

PURPOSE

Lung cancer screening (LCS) is gaining popularity, and the same scan has the potential for detecting coronary artery calcium (CAC). We aim to evaluate the impact of cardiac phase on the accuracy of CAC scoring in non-gated LCS scans across heart rates (50-100 BPM), using prospective ECG-triggered CT scans as the benchmark. We further identify optimal LCS acquisition phases that minimize motion artifacts and enhance the reliability of Agatston scores, particularly at different heart rates.?

METHODS AND MATERIALS

A CIRS dynamic cardiac phantom simulating cardiac motion was scanned using a Siemens Force CT scanner. Nine different calcification inserts (diameter: 1.2-5 mm; density: 100-400 mg/cc) were scanned at heart rates from 50 to 100 bpm. Two scan protocols were used: ECG-gated CAC scoring (CTDI vol = 1.74 mGy) and non-gated LCS (CTDI vol = 2 mGy), with the same recon kernel. Both ECG-gated and non-gated scans were performed at every 10% R-R interval. In the gated scan, a distinct angular position of the air gap line in the phantom was correlated with the cardiac phase of the ECG-gated CT acquisition. Such correlation was used to label the non-gated LCS scan phase , and that near 50-55% of the R-R interval was identified. Calcium scores were calculated using clinical software, with non-gated LCS scores compared to gold standard ECG-gated scores.

RESULTS

ECG-gated scans showed consistency in Agatston scores across five runs at 60 BPM (CACs: 57.2, 60.9, 59.1, 55.4, 61.3; coefficient of variation (CV) ˜ 0.04). Non-gated scans exhibited significant variability, with the score of one run significantly lower than that of another run (LCS at 60 BPM: 9, 24.1, 10.8, 27.2, 14.3; CV ˜ 0.42). This variability was most pronounced at cardiac phases near 50-55% of the R-R interval and was reproducible across heart rates (50-100 BPM) and calcification inserts (diameter = 3 mm; density = 100 mg/cc). Excluding two runs acquired near the above phase, CV was 0.25.

CONCLUSION

Non-gated LCS calcium scoring is highly dependent on acquisition phase. Calcium scores in LCS scans decreased significantly when image acquisition occurred near 50-55% of the R-R interval, a phase marked by rapid ventricular volume expansion and blood filling.

CLINICAL RELEVANCE/APPLICATION

This study supports the feasibility of using LCS scans for concurrent CAC detection. Optimizing the LCS acquisition phase could enhance early detection of cardiovascular disease without additional CT scans or cost.

S4-SSVA01-1 GADOLINIUM-BASED PHOTON-COUNTING DETECTOR CT ANGIOGRAPHY OF THE LOWER EXTREMITY: A VIABLE ALTERNATIVE TO IODINE

Kristina Krompass, MD (*Presenter*)
Jan-Lucca Hennes, MD (*Abstract Co-Author*)
Jan P. Grunz, MD (*Abstract Co-Author*)
Henner Huflage, MD (*Abstract Co-Author*)
Viktor Hartung (*Abstract Co-Author*)
Thorsten A. Bley, MD (*Abstract Co-Author*)
Philipp Gruschwitz, MD (*Abstract Co-Author*)

PURPOSE

The aim of this experimental study was to evaluate the application of gadoteric acid as an alternative contrast agent for photon-counting detector CT (PCD-CT) angiography of the lower extremities.

METHODS AND MATERIALS

PCD-CT angiograms of the femoral arteries were performed in a human body donor of 80 kg after establishing extracorporeal perfusion. Gadoteric acid (279.32 mg/ml) was administered for contrast and three clinically approved concentrations were tested: 0.2 ml/kg (16 ml, standard dose for body MRI), 0.4 ml/kg (32 ml), and 0.6 ml/kg (48 ml, maximum approved dose for cranial MRI). PCD-CT scans were acquired using ultra-high resolution mode (120 × 0.2 mm) with a tube voltage of 120 kVp and reconstructed as 40 keV virtual monoenergetic images. For reference, identical scans were performed with iodine-based contrast (400 mg/ml). Intraluminal and muscle attenuation as well as image noise were measured to calculate contrast-to-noise ratios (CNR). Three radiologists independently analyzed image quality, noise and vascular contrast using a five-point rating scale (5 = excellent, 1 = poor).

RESULTS

Intraluminal attenuation (r 2 = 1, p<.001) and CNR (r 2 = 0.98, p<.001) were directly proportional to the concentration of gadoteric acid, with significant differences between the investigated dosages (p<.001). Administration of 0.2 ml/kg gadoteric acid resulted in an intraluminal attenuation of 240.9 ± 10.7 HU (equals 3.2 ml of iodine contrast agent), while the 0.4 ml/kg protocol yielded 435.1 ± 15.8 HU (equals 6.3 ml of iodine contrast agent); the latter was considered diagnostically sufficient in all subjective categories (e.g., median vascular contrast 3 of 5 [IQR 3-4], p<.05). The maximum dose of 0.6 ml/kg gadoteric acid achieved an intraluminal attenuation of 647.2 ± 16.0 HU (equals 9.2 ml of iodine contrast agent) and was consistently deemed "good" in subjective assessment (e.g., median vascular contrast 4 of 5; [IQR 4-4], p<.05).

CONCLUSION

The combination of gadoteric acid as contrast agent and low-keV VMI from PCD-CT allows for diagnostic image quality in angiograms of the femoral arteries at clinically approved concentrations.

CLINICAL RELEVANCE/APPLICATION

Gadoteric acid represents a viable alternative for CT angiography in patients with contraindications to iodinated contrast agents, such as hyperthyroidism or allergy.

S4-SSVA01-2 GADOLINIUM-BASED K-EDGE PHOTON-COUNTING DETECTOR CT ANGIOGRAPHY OF THE THORACOABDOMINAL AORTA IN A CADAVERIC PERFUSION MODEL: A FEASIBILITY STUDY

Jan-Lucca Hennes, MD (*Presenter*)
Kristina Krompass, MD (*Abstract Co-Author*)
Henner Huflage, MD (*Abstract Co-Author*)
Jan P. Grunz, MD (*Abstract Co-Author*)
Viktor Hartung (*Abstract Co-Author*)
Philipp Gruschwitz, MD (*Abstract Co-Author*)

PURPOSE

Aim of this study was to evaluate the feasibility of gadoteric acid as an alternative contrast agent in photon-counting CT angiography (PCD-CTA) of the thoracoabdominal aorta using k-edge imaging.

METHODS AND MATERIALS

PCD-CTA was performed using an extracorporeal transfemoral perfused fresh-frozen body donor. For vascular contrast, a gadolinium-based contrast agent (279mg gadoteric acid/ml) was administered at the maximum clinically approved dose for cranial MRI of 0.6ml/kg body weight. The perfusion fluid was diluted based on the assumption of homogeneous distribution of the contrast agent through the entire arterial blood volume. According to the formula (70 x weight / [v(BMI/22)]), a person who weighs 80kg and is 1.75m tall has a blood volume of ~5liters. With an arterial blood fraction of about 10%, this results in a volume of ~500ml of arterial blood. Therefore, a total of 548ml perfusion fluid consisting of 500ml Ringer's solution and 48ml contrast agent (0.6ml/kg body weight x 80kg; =13.4g gadoteric acid) was used to assess the feasibility of gadoteric acid as a contrast agent for PCD-CTA. The CT scan was acquired with a tube voltage of 120kVp in standard mode (140x0.4mm) and a fixed radiation dose of 5mGy. 50keV virtual monoenergetic images near the k-edge of gadolinium were reformatted with a medium sharp kernel (Bv60), medium iterative reconstruction level (Q3) in 1mm slice thickness. For objective assessment, intraluminal attenuation and contrast-to-noise ratio were determined. Luminal contrast and diagnostic assessability were subjectively rated by consensus of three radiologists.

RESULTS

At 50keV, a mean intraluminal attenuation of 511.6±33.1HU was achieved, which is considered sufficient for diagnostic evaluation even in comparison to PCD-CTA with iodinated contrast agents. The resulting CNR was 14.4±1.1. Narrow caliber arteries such as the visceral and lumbar arteries could be visualized with sufficient intraluminal contrast. Parenchymal organs were well contrasted due to a gap of several minutes between application and scanning. Contrast mirroring occurred due to low perfusion pressure. Subjectively, luminal contrast and diagnostic assessment were consistently rated as good.

CONCLUSION

Gadoteric acid at clinically approved doses is a feasible alternative contrast agent to iodine for aortic k-edge PCD-CTA.

CLINICAL RELEVANCE/APPLICATION

Gadolinium-based PCD-CT angiography combines iodine-independence and fast, high-resolution imaging, providing an alternative especially for patients with a history of iodine allergy, hyperthyroidism and/or contraindications to MRI imaging.

S4-SSVA01-3 MINIMALLY ACCEPTABLE OR ACCEPTABLY MINIMAL? SUBMILLISIEVERT THORACOABDOMINAL PHOTON-COUNTING DETECTOR CT FOR ASSESSMENT OF THE ARTERIOSCLEROTIC BURDEN PRIOR TO CARDIACTHORACIC SURGERY

Jan-Lucca Hennes, MD (*Presenter*)
Kristina Krompass, MD (*Abstract Co-Author*)
Henner Huflage, MD (*Abstract Co-Author*)
Viktor Hartung (*Abstract Co-Author*)
Jan P. Grunz, MD (*Abstract Co-Author*)
Philipp Gruschwitz, MD (*Abstract Co-Author*)

PURPOSE

Aim was to assess the feasibility of an ultra-low-dose thoracoabdominal photon-counting detector CT (PCD-CT) protocol to evaluate the aortoiliacal calcification level prior to cardiothoracic surgery.

METHODS AND MATERIALS

Over a 1-year period (Jan to Dec 2024), preoperative non-contrast CT scans for the assessment of aortoiliac calcification were performed using a PCD-CT protocol with image quality level 1 (lowest technically possible) and tube voltage of 140 kVp. Images were reconstructed with standard settings: soft body kernel (Bv36), medium iterative reconstruction level (Q3); slice thickness/increment of 3 mm. The radiation exposure of the PCD-CT was compared to a) alternative imaging of the calcifications using chest x-ray (2 planes; ~0.1 mSv) and pelvic x-ray (2 planes; ~1.1-1.8 mSv); b) postoperative chest follow-up radiographies. Diagnostic usability was assessed subjectively and independently by five radiologists based on two criteria: diagnostic image quality and discernibility of calcifications. Interrater agreement was calculated using Kendall W.

RESULTS

A total of 35 patients were included (72 ± 6 years; 5 women). The mean effective radiation dose of the PCD-CT was 0.46 ± 0.05 mSv, which is at least 60% less radiation than the alternative X-ray images (~1.2-1.9 mSv). The average 5 ± 2 follow-up chest radiographies after surgery caused significantly higher radiation doses than the CT scan (0.80 ± 0.22; p=.001). All CT examinations had good diagnostic quality (4; [IQR 4-5]) with regard to the intended indication and rated as good in discernibility of calcifications quality (4; [IQR 4-5]). The readers' agreement was good (W=0.83/0.77). In some cases, PCD-CT revealed underlying conditions (e.g., metastatic tumors) that changed the treatment decision, sometimes even outside the examination volume covered by the radiographs (chest and pelvis).

CONCLUSION

Thoracoabdominal PCT-CD with minimal technical dose allows adequate detection of aortoiliac calcifications below the radiation dose of the alternative radiographs.

CLINICAL RELEVANCE/APPLICATION

The ultra-low dose PCD-CT protocol presented allows for improved preoperative planning with minimal radiation exposure by enabling features such as 3D reconstruction and optimized diagnostic evaluation of the additional depicted body parts compared to radiographs.

S4-SSVA01-4 ASSESSMENT OF CONTRAST AGENT-REDUCED CT PROTOCOLS FOR TRANSCATHETER AORTIC VALVE RECONSTRUCTION PLANNING ON PHOTON COUNTING DETECTOR CT: A COMPARATIVE STUDY

Yannik Christian Layer, MD (*Presenter*)
Alexander Isaak, MD (*Abstract Co-Author*)
Narine Mesropyan, MD (*Abstract Co-Author*)
Patrick A. Kupczyk, MD (*Abstract Co-Author*)
Tatjana Dell (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)

PURPOSE

The extensive use of iodine-containing contrast media is increasingly controversial due to the accumulation in groundwater with unclear environmental effects as well as the recent supply difficulties during the Covid-19 pandemic. The aim of this study was the evaluation of contrast agent-reduced CT protocols for transcatheter aortic valve reconstruction (TAVR) planning on a photon counting detector CT (PCD-CT).

METHODS AND MATERIALS

A total of 54 BMI-matched examinations with standard dose contrast media (SCD; 80 ml) and reduced contrast media dose (RCD; 50 ml) for TAVR planning on a PCD-CT were included. Virtual monoenergetic reconstructions of the contrast agent-reduced examinations at 50 keV, 60 keV and 70 keV were used for comparison. Quantitatively, ROIs were placed in the abdominal aorta, abdominal aorta at kidney level, iliac bifurcation, common femoral artery, left ventricle and musculature and SNR and CNR were calculated. Qualitatively, the diagnostic quality and contrast were assessed on a Likert scale of 1 (non-diagnostic) -5 (excellent) and the contrast agent dose was estimated. Aortic annulus measurements were performed in all reconstructions.

RESULTS

The CNR was 23.98 ± 10.51 (RCD: 14.16 ± 6.38; RCD VMI 50keV : 27.05 ± 13.49) and the SNR 24.18 ± 6.62 (RCD: 18.38 ± 5.42; RCD VMI 50keV : 31.95 ± 10.7) in the ascending aorta on PCD-CT in SCD as an example. Averaged over all measured organs, the SNR was reduced by 19.98% (RCD VMI 50keV : + 25.76%) and the CNR by 27.91% (RCD VMI 50keV : + 38.12%) when the contrast media dose was reduced on the PCD-CT. The median diagnostic assessability for SCD was 5 (RCD: 4; RCD VMI 50keV : 5). 59.26% (32/54) of the contrast-reduced examinations were classified as SCD. There was no significant difference in aortic annulus measurements.

CONCLUSION

The diagnostic efficacy of transcatheter aortic valve replacement (TAVR) planning assessment using Photon Counting Detector CT (PCD-CT) with minimized contrast agent dosing is validated, presenting a practical approach to conserve contrast media.

CLINICAL RELEVANCE/APPLICATION

The study demonstrates the potential of contrast media reduction of PCD-CT in clinical routine. This can benefit patients with renal impairment, for example, and reduce negative effects of iodinated contrast media on the environment.

S4-SSVA01-5 WHAT'S YOUR FLAVOR? COMPARING THE DIFFERENT OPTIONS OF ITERATIVE METAL ARTIFACT REDUCTION IN ULTRA-HIGH-RESOLUTION PHOTON-COUNTING CT ANGIOGRAPHIES OF THE LEG

Jan P. Grunz, MD (*Presenter*)
Henner Huflage, MD (*Abstract Co-Author*)
Caroline Bestler, MD (*Abstract Co-Author*)
Theresa Sophie Patzer, MD (*Abstract Co-Author*)
Pauline Pannenbecker, MD, BA (*Abstract Co-Author*)
Viktor Hartung (*Abstract Co-Author*)
Andreas Kunz, MD (*Abstract Co-Author*)
Thorsten A. Bley, MD (*Abstract Co-Author*)

PURPOSE

Ultra-high-resolution (UHR) photon-counting CT angiography (PCCTA) has become the reference standard for non-invasive assessment of peripheral artery disease. In the presence of total knee endoprosthesis, however, metal artifacts hamper visualization of the popliteal vasculature. While iterative metal artifact reduction (MAR) is a powerful tool to address this issue, the variety of flavor options requires careful consideration for different imaging tasks. This study investigated the effect of the different MAR flavors in patients with knee joint replacement.

METHODS AND MATERIALS

Twenty-two patients with total knee endoprosthesis (mean age, 74.5 ± 9.3 [SD] years, 13 women) underwent UHR-PCCTA of the leg at 140 kVp between August 2024 and April 2025. Datasets were reconstructed with the seven available MAR flavors (i.e., 'Extremity', 'Hip', 'Pacemaker', 'Lung coils', 'Shoulder', 'Dental', and 'Neuro') at maximum applicable sharpness (Bv56, spatial frequency at 10% of the modulation transfer function: 10.8 line pairs per cm). MAR strength was assessed with regions of interest positioned in the most pronounced artifacts, measuring the respective attenuation. In addition, six independent radiologists documented their flavor preferences using a forced-choice comparison tool (1,487 pairwise tests). Results were compared with Friedman's rank-based ANOVA and chi-square tests. Fleiss kappa was computed to analyze interrater reliability.

RESULTS

Compared with non-MAR datasets and the other six flavors, 'Dental' MAR resulted in the strongest reduction of hyperdense artifacts (all P <.001; e.g., MAR off versus 'Dental' MAR, median 4131.6 [IQR 1464.1] HU versus 179.7 [930.5] HU). Similarly, the reduction of hypodense artifact was most effective with 'Dental' MAR (all P <.001; -3862.6 [3191.9] HU versus -142.3 [168.1] HU). Image noise was not affected by any of the MAR flavors (P =.199). Subjective evaluation of popliteal artery assessability also favored 'Dental' MAR, which recorded the most wins in pairwise comparison (all P <.001). Interrater agreement was substantial, indicated by Fleiss kappa of 0.658 (95% confidence interval 0.581-0.736).

CONCLUSION

Despite its misleading name, 'Dental' MAR provides the strongest reduction of metal artifacts in UHR-PCCTA of the leg, allowing for the best assessability of the popliteal artery in patients with total knee endoprosthesis.

CLINICAL RELEVANCE/APPLICATION

The seven flavor settings available for iterative metal artifact reduction in ultra-high-resolution photon-counting CT have different effects on the diagnostic assessability of adjacent tissues.

S4-SSVA01-6 VALUE OF CONTRAST ENHANCEMENT BOOST TECHNIQUE AT SUBMILLISIEVERT CT ANGIOGRAPHY OF THE LOWER EXTREMITIES: EFFECT ON IMAGE QUALITY AND DIAGNOSTIC ACCURACY

Qilin Xiao (*Presenter*)
Meng Wang (*Abstract Co-Author*)
Sheng Jiexin (*Abstract Co-Author*)
Lin Sheng Zheng (*Abstract Co-Author*)
Min Xu, PhD (*Abstract Co-Author*)
Wang Hui (*Abstract Co-Author*)

PURPOSE

Contrast enhancement boost (CE-boost) is a postprocessing technique designed to increase the degree of contrast enhancement on contrast-enhanced CT. This study aimed to investigate the impact of the CE-boost technique on image quality and diagnostic accuracy in low-dose, low-contrast medium CT angiography (CTA) of the lower extremities.

METHODS AND MATERIALS

Twenty-one patients with peripheral arterial disease who underwent lower extremity CTA and DSA were prospectively enrolled. This lower extremity CTA protocol was optimized to minimize radiation dose and contrast medium volume, using a 320-detector CT scanner (Aquilion ONE Genesis Edition, Canon Medical Systems, Japan). The scan parameters were as follows: 80 kV, variable helical pitch (VHP) scanning, and bolus tracking with a trigger ROI placed in the popliteal artery, alongside a personalized body surface area (BSA) based contrast injection protocol (11gI/m2). CE-boost images were generated and compared with the original CTA images. Qualitative parameters, including overall image quality, diagnostic confidence, distal vessel visualization, were rated by two radiologists independently according to a five-point scale. Quantitative parameters, including the CT value, noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were computed and compared.

RESULTS

The average effective radiation and contrast medium doses for this protocol were 0.83 ± 0.17 mSv and 49.00 ± 5.07 mL, respectively. The CE-boost images demonstrated significantly higher CT values, SNRs, and CNRs compared to the original images (all $p < 0.05$). Moreover, when evaluating image quality characteristics, CE-boost images received significantly higher scores than the original images (all $p < 0.05$). The CE-boost images exhibited fewer non-diagnostic segments (CT values <200 HU, 2.8% vs. 11.4%, $p = 0.02$) and suboptimal segments (CT values<350 HU, 26.7% vs. 51.4%, $p<0.001$) compared to the original images. In terms of diagnostic performance, the segment-based analysis indicated no significant difference between these two groups (all $p >0.05$).

CONCLUSION

CE-boost technology significantly improves both objective and subjective image quality in optimized, submillisievert lower extremity CTA while preserving diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

CE-boost can significantly improve image quality in submillisievert lower extremity CTA without requiring any additional scanning settings or modifications to the clinical workflow.

Edgar Wakelin (*Abstract Co-Author*)
Bryan Haslam, PhD (*Abstract Co-Author*)

PURPOSE

Screening mammography volumes continue to increase while radiologist availability remains limited, creating workflow challenges that can lead to fatigue and burnout. Through radiologist-industry collaboration, an Efficient Clickable Reporting Tool (ECRT) was co-developed to address reporting inefficiencies identified by practicing radiologists. This study evaluates the real-world impact of this collaborative innovation on mammography read times following large-scale clinical deployment.

METHODS AND MATERIALS

The ECRT emerged from radiologist-identified workflow pain points and was refined through iterative industry collaboration to create a standardized clickable interface with keypad shortcuts, eliminating dictation dependency. The tool was originally developed at a radiology practice in Maryland, and was then deployed across 12 Arizona imaging facilities to rigorously assess its impact on radiologists in the real world. Read times were measured before (Aug 2023-Aug 2024, n=15,685 exams) and after (Sept 2024-July 2025, n=15,943 exams) implementation. Analysis included 9 radiologists reading >100 mammograms in both periods. Read times were calculated as intervals between consecutive exam signings, excluding <5 seconds or >5 minutes. Because read times are not normally distributed, a Generalized Linear Mixed Effects Model was used to assess the statistical significance of read time reduction before and after ECRT deployment while adjusting for radiologist variability and clinical case complexity factors including breast density, AI cancer suspicion levels, and recalls.

RESULTS

Post-ECRT deployment, we saw that the proportion of exams requiring less than 1.5 minutes to review and interpret increased from 39.9% to 49.2%. Model-adjusted results indicate ECRT significantly reduced read times by an average of 16% (95% CI: 5-26%, p=0.003). Additionally, 6 out of 9 radiologists improved significantly, with individual read-time reductions ranging from 5% to 28%. The tool continues to be rolled out to new locations and iteratively developed through continuous radiologist feedback and integration of AI.

CONCLUSION

Radiologist-industry collaboration successfully translated clinical workflow insights into a deployed technology solution, achieving measurable efficiency improvements. The partnership model enabled rapid iteration from concept to validated clinical tool with demonstrable real-world impact.

CLINICAL RELEVANCE/APPLICATION

This collaboration demonstrates how radiologist-driven innovation combined with industry development capabilities can address pressing workflow challenges at scale. The measured efficiency gains support sustainable screening mammography capacity as population demands increase.

PURPOSE

To evaluate whether the industry general-purpose large reasoning model can achieve clinically meaningful performance in radiograph interpretation, we assess OpenAI's o3 on both diagnostic accuracy against radiology residents and quality of visual reasoning through comprehensive expert evaluation.

METHODS AND MATERIALS

We evaluated o3, a multimodal large reasoning model, on 300 chest radiographs through visual question-answering tasks, comparing performance to three radiology residents. Fourteen board-certified radiologists and pulmonologists evaluated the model's chain-of-thought processes on 100 cases. Assessment included question-answering accuracy, quantitative scoring using 5-point Likert scales, and qualitative textual feedback.

RESULTS

The model achieved 68.1% accuracy (95% CI: 63.0-73.2%), with no significant differences from any individual resident: Reader 1 (61.9% [95% CI: 0.563,0.675], p=0.127), Reader 2 (67.1% [0.62,0.725], p=0.856), or Reader 3 (72.6% [95% CI: 0.675,0.776], p=0.242). Average resident performance was 67.2% (95% CI: 61.9%, 72.5%). Expert radiologist evaluation revealed coherent visual reasoning with scores of 3.57±1.31 for consistent reasoning (Reasoning process matches answer), 3.39±1.36 for radiological logic (Thinks like a radiologist), 3.49±1.34 for visual-verbal correlation (Descriptions match what's actually visible), and 3.65±1.23 for clinical prioritization (Highlights what matters most). However, qualitative feedback identified persistent challenges including anatomical orientation errors, difficulty with support device identification, and tendency to repeatedly examine incorrect regions.

CONCLUSION

While o3 achieves resident-level diagnostic accuracy, the gap between high performance and moderate reasoning scores reveals that correct conclusions can emerge despite suboptimal diagnostic pathways. This finding underscores that chain-of-thought transparency is essential for identifying when AI reasoning processes require refinement before broader clinical deployment, even when diagnostic outcomes appear satisfactory.

CLINICAL RELEVANCE/APPLICATION

The transparent reasoning process demonstrated by o3 enables clinical deployment in supervised settings where radiologists can verify diagnostic logic, offering particular value for quality assurance and residency education where understanding the reasoning behind interpretations is as crucial as the diagnosis itself.

S4-STCE1-3 RADIATION SAFE NEUROINTERVENTIONS WITH CNT MULTI BEAM X-RAY: AN ACADEMIC-INDUSTRY PATHWAY TO NEXT-GENERATION IMAGING

Jinho Choi (*Presenter*)
Hanna Lee, BS, MS (*Abstract Co-Author*)
Jaeik Jung (*Abstract Co-Author*)
Seung Jun Yeo (*Abstract Co-Author*)
Seung Hoon Kim (*Abstract Co-Author*)
Jehwang Ryu, PhD (*Abstract Co-Author*)

PURPOSE

In this academic-industry collaboration, we aim to integrate a novel carbon nanotube (CNT) multi-beam X-ray system into clinical practice by focusing on radiation dose reduction. This follow-up to a RSNA2024 phantom study evaluates whether pulsed, low-dose emission from X-ray source based on CNT technology can significantly reduce operator and patient exposure during prolonged neurointerventional procedures without compromising image quality. We also assess the system's miniaturized design for use in operating room (OR).

METHODS AND MATERIALS

A prototype CNT X-ray tube was integrated with an angiographic head phantom to simulate neurointerventional procedures. We measured radiation dose metrics (dose-area product and entrance skin dose) and scatter at the operator position under various digital pulsing protocols (different pulse widths and duty cycles), comparing them to a conventional continuous fluoroscopy system. Phantom images at each setting were analyzed for signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) to quantify image quality. The CNT unit's physical footprint and weight were documented relative to a standard X-ray system to evaluate space utilization benefits for hybrid ORs or mobile setups.

RESULTS

Under a 50% duty cycle pulsed mode, the CNT system reduced radiation dose by ~45-50% compared to conventional continuous X-ray, with a commensurate reduction in scatter to the operator. Image quality was preserved: SNR and CNR remained equivalent to the conventional system across pulse settings. The CNT X-ray source was also ~70-75% smaller in volume and 45-50% lighter than a standard 120 kV tube, enabling easy integration into confined clinical spaces such as mobile C-arms, bedside imaging units.

CONCLUSION

This collaboration demonstrates that a CNT multi-beam X-ray system can substantially lower radiation exposure during interventional fluoroscopy without loss of image quality. The system's digitally pulsed operation and compact design make it well-suited for clinical integration, potentially enhancing safety and workflow in neurointerventional suites.

CLINICAL RELEVANCE/APPLICATION

By reducing radiation exposure to patients and staff while maintaining image quality, this CNT-based fluoroscopy technology can improve safety in neurointerventional procedures that require long fluoroscopy times. Its small footprint and low power needs enable use in modern hybrid ORs and even at the bedside, exemplifying the effective translation of an innovative imaging technology into clinical practice.

S4-STCE2-2 DIAGNOSTIC VALUE OF PHOTON-COUNTING CT LOW-DOSE SCANNING COMBINED WITH ITERATIVE ALGORITHMS IN SMALL INTESTINAL DISEASES

Wenjie Zhang (*Presenter*)

PURPOSE

To investigate the diagnostic value of low-dose scanning with photon-counting detector CT (PCD-CT) combined with iterative algorithms in small bowel enterography.

METHODS AND MATERIALS

Patients undergoing small bowel CT enterography were randomly divided into group A and group B. Group A with conventional dose in three phases, while group B in three phases on PCD-CT, with the venous phase dose being half of that in the arterial phase. The diagnostic accuracy of low-dose images for small bowel diseases was evaluated through objective and subjective image analysis of the two groups. Meanwhile, in group B, six sets of venous phase images were obtained by changing different convolution kernels (Bv40, Bv44, Bv48) and quantum iterative reconstruction (QIR3, QIR4) algorithms to explore the optimal reconstruction parameters for diagnosing small bowel diseases.

RESULTS

A total of 100 patients were included, including 48 cases of inflammatory bowel disease, 20 cases of small bowel tumor diseases, and 32 normal cases. The total radiation dose in group A was 21.45 ± 4.46 mSv, and that in group B was 17.18 ± 4.47 mSv. The radiation dose in group B was approximately 20% lower than that in group A, with a significant difference ($P < 0.05$). There were no significant differences in CT values of the intestinal wall and subcutaneous fat, signal-to-noise ratio, and contrast-to-noise ratio between the arterial and venous phase images of group A and group B ($P > 0.05$). Among the six sets of images in group B, there were no significant statistical differences in image noise, signal-to-noise ratio, and contrast-to-noise ratio between the Bv40 Q3 group and Bv40 Q4 group and the venous phase images of group A ($P > 0.05$), while there were significant statistical differences between the Bv44 Q3 group, Bv44 Q4 group, Bv48 Q3 group, and Bv48 Q4 group and the images of group A ($P < 0.05$). Among them, the image quality of the Bv40 Q3 group was the highest, with a high-quality image rate of 78%.

CONCLUSION

Low-dose scanning with PCD-CT combined with iterative algorithms for small bowel enterography is feasible and can significantly reduce radiation dose without affecting image quality.

CLINICAL RELEVANCE/APPLICATION

Achieving more accurate diagnostic performance under low-dose conditions helps in the decision-making of clinical treatment plans and the evaluation of disease recurrence.

S4-STCE2-3 FEASIBILITY AND DIAGNOSTIC PERFORMANCE OF GADOXETIC ACID-ENHANCED LIVER MRI AT ULTRA-HIGH-FIELD5T

Yuan-Cheng Wang, MD, PhD (*Presenter*)
Tong Wu (*Abstract Co-Author*)
Jiaqi Wang (*Abstract Co-Author*)
Ran Tang (*Abstract Co-Author*)
Zi Ying Sun (*Abstract Co-Author*)

PURPOSE

This study was aimed to evaluate the feasibility and diagnostic performance of ultra-high-field magnetic resonance imaging (MRI) in clinical liver imaging.

METHODS AND MATERIALS

This retrospective study enrolled 63 patients undergoing gadoxetic acid-enhanced hepatic MRI on a 5T whole-body MR scanner between April and June 2025. Fat-saturated 3D T1-weighted images of pre-contrast, early arterial, late arterial, portal venous, transitional, and hepatobiliary phase were evaluated independently by three experienced radiologists utilizing 4-point Likert scales for: overall image quality, enhancement fidelity, vascular delineation, artifacts and diagnostic confidence.

RESULTS

Of all patients, 62 (98%) were successfully performed liver MRI examinations with only one patient failing to complete the enhanced scan due to post-contrast breath-holding difficulties. More than 85% of the T1WIs were rated as good quality (3 or 4 point) with minimal artifacts except in the dual-arterial phases. Notably, in the challenging arterial phase, over 60% of images achieved good image quality and mild artifact. Enhanced images exhibited favorable vascular enhancement delineation, with particularly outstanding performance in the portal venous, transitional, and hepatobiliary phases - where over 80.7% of images scored =3. The overall diagnostic confidence score was 3.26 (on a 4-point scale).

CONCLUSION

At 5T, gadoxetic acid-enhanced liver MRI demonstrated diagnostically superb image quality with mild artifacts and definitive diagnostic confidence, revealing the potential clinical benefits of ultra-high-field abdominal imaging.

CLINICAL RELEVANCE/APPLICATION

The successful implementation of 5T gadoxetate-enhanced liver MRI confirms the clinical feasibility at ultra-high-field. The inherent properties of high-field MRI systems may offer additional potential for contrast-enhanced abdominal imaging. The elevated magnetic field strength at 5T prolongs T1 while accelerating T2/T2* relaxation, enabling reduced repetition times to maintain T1 contrast, which may enable lowered dose of contrast agent but achieve satisfied contrast. Additionally, the inherent SNR gain facilitates higher-resolution imaging within equivalent scan times, enhancing detection of subtle abdominal lesions.

S5-SSBR02-1 COMPARING HIGH RISK ESTIMATIONS USING VOLUMETRIC BREAST DENSITY WITH TYRER-CUZICK AND BOADICEA RISK MODELS

Stamatia V. Destounis, MD (*Presenter*)
Brian Drohan, PhD (*Abstract Co-Author*)
Jessica Salamone, MS (*Abstract Co-Author*)
Andrea L. Arieno, BS (*Abstract Co-Author*)
Melissa L. Hill, PhD (*Abstract Co-Author*)

PURPOSE

Recent NCCN guidelines emphasize including breast density in breast cancer risk assessment, traditionally centered on family history (FHx). This study compares how volumetric breast density (VBD) affects high-risk classification using Tyrer-Cuzick (TC) and BOADICEA (BA) models. BA now includes VBD and a more detailed FHx component with additional genes and SNPs not captured in TC.

METHODS AND MATERIALS

Risk factor data were collected during screening mammography from 12/1/2024 to 4/30/2025. Women aged 40-75 with no prior history of breast cancer were included. VBD was calculated using Volpara Imaging Software (v3.4 & 3.5). Lifetime risk was assessed using TC v8 with and without competing mortality (CM) and BA v7.3. High risk was defined as lifetime risk =20%, using the default age of 85 for TC and age 80 to align with BA. Relative risk (RR) contributions from VBD and FHx were derived from model outputs. FHx RR was calculated as the ratio of lifetime risk using only FHx inputs to baseline population risk.

RESULTS

A total of 44,651 women met inclusion criteria. The percentage classified as high risk was 9.8% (BA), 14.8% (TC with CM at age 80), and 19.1% (TC with CM). Without CM, TC classified 27.4% as high risk at age 85 and 19.0% at age 80. Mean RR due to density was higher in TC (1.21) than BA (1.16; $p < 2.2e-16$). Similarly, RR due to FHx was higher in TC (1.21 vs. 1.17; $p < 2.2e-16$). Among patients identified as high risk by TC, 1,269 (2.8%) had a FHx that did not significantly increase their risk, based on model-calculated RR from FHx. These women were still classified as high risk due to elevated breast density, with a mean density RR of 2.25. A similar group was found in the BA model, comprising 1,053 women (2.4%) whose FHx contributed little or no increased risk, but who had high density-related risk (mean density RR = 2.26).

CONCLUSION

TC identified more women as high risk, largely due to greater influence from VBD and FHx inputs. BA classified fewer patients as high risk without strong FHx, requiring greater VBD RR to offset a more protective family history.

CLINICAL RELEVANCE/APPLICATION

Tyrer-Cuzick and BOADICEA are both recommended models for calculating lifetime breast cancer risk according to multiple guidelines and societies. As guidelines evolve and high risk screening choices are driven by risk model outputs, more informed choices around which models to use will be key and data around how the models are working are necessary to align with clinical judgement and screening goals.

S5-SSBR02-2 IMAGE-ONLY AI MODEL COMPARED WITH BREAST DENSITY FOR IDENTIFYING WOMEN AT 5-YEAR INCREASED RISK OF BREAST CANCER: MULTICENTER U.S.-EUROPEAN ANALYSIS

Christiane K. Kuhl, MD, PhD (*Presenter*)
Constance D. Lehman, MD, PhD (*Abstract Co-Author*)
David Miller (*Abstract Co-Author*)
Mark Scully (*Abstract Co-Author*)
Emily Hipp (*Abstract Co-Author*)
Elizabeth A. Morris, MD (*Abstract Co-Author*)
Toni W. Vomweg (*Abstract Co-Author*)
Lora D. Barke, DO (*Abstract Co-Author*)
Louie Enriquez, MD, JD (*Abstract Co-Author*)
Philippe Raffy, PhD (*Abstract Co-Author*)

PURPOSE

To compare an image-only AI model performance with that of breast density in stratifying 5-year breast cancer risk, and to assess whether AI-derived risk adds predictive value beyond density in a large, diverse international screening population.

METHODS AND MATERIALS

The AI model was trained on 421,499 mammograms from 27 facilities in Europe, South America, and the U.S., using a deep convolutional neural network and calibrated on an independent test set to generate 5-year risk probabilities. We applied the model to a cohort of 245,344 bilateral 2D screening mammograms (236,442 from five U.S. sites; 8,810 from one European site) acquired from 2011-2017. Radiologist-reported breast density (dense vs. not dense) was extracted from medical records and five-year cancer outcomes from tumor registries. AI-predicted risks were categorized using NCCN thresholds: average (<1.7%), intermediate (> 1.7-3.0%), and high (> 3.0%). Univariable and multivariable time-to-event models accounting for interval censoring were fit to obtain hazard ratios (HRs) for AI risk and breast density.

RESULTS

Breast density alone was associated with modestly increased cancer risk (HR 1.16, 95% CI 1.11-1.22). Relative to average risk, HRs were 2.06 for intermediate (95% CI 1.93-2.20) and 4.49 for high risk (95% CI 4.24-4.76), regardless of density. When both factors were considered together, the increased risk for breast density adjusted for AI risk was 1.12 (95% CI 1.07-1.17), and the increased risks for AI intermediate and high-risk categories adjusted for density were 2.04 (95% CI 1.92-2.18) and 4.47 (95% CI 4.22-4.73), respectively. Thus, accounting for breast density, shifting from average to intermediate AI risk is associated with a twofold increase in cancer risk, while moving to high risk increases risk more than fourfold. In contrast, the increased risk for breast density adjusting for AI risk is minimal.

CONCLUSION

While breast density remains an important factor in breast cancer screening, particularly for its role in masking cancers, this large-scale analysis shows that an image-only AI model offers more precise risk stratification for 5-year cancer prediction and provides additional predictive value, including in dense-breasted women. These findings support its use as a complement to traditional markers for guiding personalized screening.

CLINICAL RELEVANCE/APPLICATION

AI-derived image-based risk assessment can enhance decision-making in screening programs by identifying women at increased 5-year risk, including those with dense breasts, where cancer risk and detection challenges often coexist. Used alongside density, this approach may better inform supplemental imaging and prevention strategies.

S5-SSBR02-3 ROBUSTNESS OF AN AI SHORT-TERM BREAST CANCER RISK MODEL IN A CLINICAL SETTING WITH DIVERSE MAMMOGRAPHY MODALITIES: PRELIMINARY RESULTS

Georgia G. Spear, MD (*Presenter*)
Mohamed Abdolell, MSc, BSc (*Abstract Co-Author*)
Laurie R. Margolies, MD (*Abstract Co-Author*)
Katharine Yao, MD (*Abstract Co-Author*)

PURPOSE

This study aims to evaluate the clinical performance of an AI image-based short-term breast cancer risk prediction model within a routine mammography screening program. Specifically, it assesses the discriminatory accuracy of the model to determine its performance in clinical practice, in the context of a mix of mammography unit models.

METHODS AND MATERIALS

The study is a retrospective analysis of a cohort of patients in an urban breast screening program. Participants included women screened between May 2017 and April 2022, excluding those with breast implants or incomplete standard mammographic imaging sets (RCC, RMLO, LCC, LMLO). Controls required a subsequent negative screening mammogram at least one year following the index examination, without censoring. Data collection included index screening mammograms, clinical outcomes, and study processing outputs such as breast density evaluations, image quality scores, and risk assessments. Preliminary analyses focused on evaluating discrimination, using a subset comprising 1562 breast cancer cases and 9574 controls. The performance of the image-based model (Mirai) was assessed via Area Under the Receiver Operating Characteristic Curve (AUC), evaluated across intervals ranging from 1 to 5 years post-screening and stratified by mammography machine type.

RESULTS

A total of 11,136 mammograms were analyzed, including 3850 Selenia FFDM, 1773 C-View synthetic 2D images, and 5513 Intelligent2D synthetic images. The Mirai model exhibited strong overall discriminatory performance, demonstrating consistent accuracy across various imaging types. Notably, the model, originally trained on FFDM images, showed comparable efficacy when applied to synthetic 2D images. The 2-year AUCs for the risk model were statistically significantly different between the machine types (p-val=0.002). Annual AUC measurements (1- to 4-year intervals) confirmed sustained predictive accuracy, indicating robust performance across different clinical scenarios and imaging modalities.

CONCLUSION

This study demonstrates that the Mirai image-based breast cancer risk prediction model maintains high discriminatory accuracy within a real-world clinical screening environment. The results support its integration into clinical workflows, potentially enabling more personalized, efficient, and scalable breast cancer screening strategies.

CLINICAL RELEVANCE/APPLICATION

Adopting image-based breast cancer risk prediction models could significantly streamline screening workflows. This approach promises a practical, robust, and scalable short-term risk solution for personalized breast cancer screening protocols that may complement traditional lifetime risk models.

S5-SSBR02-4 ADDED VALUE OF BREAST CANCER RISK PREDICTION VERSUS DETECTION OVER A TWO-YEAR TIME PERIOD WITH MAMMOGRAPHY

Yao-Kuan Wang, MSc (*Presenter*)
Lesley Cockmartin, PhD, MSc (*Abstract Co-Author*)
Tobias Wagner (*Abstract Co-Author*)
Zan Klanecek (*Abstract Co-Author*)
Nicholas Marshall (*Abstract Co-Author*)
Valerie Jeanne Marie Celis (*Abstract Co-Author*)
Chantal van Ongeval, MD (*Abstract Co-Author*)
Andrej Studen (*Abstract Co-Author*)
Robert Jeraj, PhD (*Abstract Co-Author*)
Hilde Bosmans, PhD (*Abstract Co-Author*)

PURPOSE

To evaluate the added value of risk prediction compared to detection, using publicly available and commercial models, over a two-year screening interval with mammography.

METHODS AND MATERIALS

This retrospective study used the Swedish case-control screening dataset, CSAW-CC (2008-2016, Hologic). First-time invasive and in situ cancers were included, with interval cancers defined as time-to-diagnosis > 6 months. Four models were included: Mirai risk predictor, RSNA CAD (winner of 2023 RSNA Breast Cancer Detection Challenge), and Transpara Detection and Risk (ScreenPoint Medical). Predictions of 2-year cancer onset were compared using the area under the receiver operating characteristic curve (AUC) in detection (screen-detected and interval cancers) and risk (interval cancers only) regimes. AUCs were compared via the DeLong test and bootstrap. Operating points were set based on a double-reading true positive rate (TPR) in the detection regime, and a 10% recall rate in the risk regime.

RESULTS

A total of 24,647 exams from 8,697 women were included. Within them, 741 exams developed cancer within 2 years (78 in situ, 650 invasive, 13 unknown), 524 screen-detected and 217 interval cancers, resulting in a TPR of 71%. For the detection regime, Transpara Detection and Risk outperformed RSNA CAD and Mirai, with AUCs of 0.92 (0.91-0.93) and 0.92 (0.91-0.93) vs. 0.90 (0.88-0.91) and 0.86 (0.84-0.87), all p < 0.001. Transpara Detection and Risk performed similarly (p: 0.83), and showed no differences across in situ and invasive cancers (p: 0.11 and 0.44). However, RSNA CAD and Mirai performed better for in situ than invasive cancers (p: 0.008 and <0.001). For the risk regime, Transpara Risk demonstrated the best performance, with an AUC of 0.81 (0.79-0.84), all p < 0.001. Interestingly, Transpara Detection showed no difference compared to Mirai and outperformed RSNA CAD, with AUCs of 0.76 (0.73-0.79) vs. 0.75 (0.72-0.78) and 0.72 (0.69-0.76), p: 0.55 and

0.01. After setting operating points, in the detection regime, Transpara Detection achieved the lowest false positive rates (FPR) of 2.84%, similar to 3% in European screening. In contrast, Transpara Risk, RSNA CAD, and Mirai had higher FPRs of 5.9%, 5.8%, and 15.2%. In the risk regime, Transpara Risk achieved the best TPR of 49% for interval cancers, while Transpara Detection, RSNA CAD, and Mirai had TPRs of 41%, 37%, and 33%.

CONCLUSION

Detection models excelled in screen-detected cancers, while risk models performed better for interval cancers. Further research on combining both models for screening or referral for supplemental screening is needed.

CLINICAL RELEVANCE/APPLICATION

A risk model adds value to screening by improving interval cancer detection, although it is associated with higher false positive rates.

S5-SSBR02-5 EXTERNAL VALIDATION OF DISCRIMINATION AND CALIBRATION OF AN IMAGE-ONLY AI MODEL FOR 5-YEAR BREAST CANCER RISK PREDICTION ACROSS GEOGRAPHICALLY DIVERSE SCREENING SITES

Constance D. Lehman, MD, PhD (*Presenter*)
David Miller (*Abstract Co-Author*)
Emily Hipp (*Abstract Co-Author*)
Mark Scully (*Abstract Co-Author*)
Lora D. Barke, DO (*Abstract Co-Author*)
Louie Enriquez, MD, JD (*Abstract Co-Author*)
Christiane K. Kuhl, MD, PhD (*Abstract Co-Author*)
Elizabeth A. Morris, MD (*Abstract Co-Author*)
Toni W. Vomweg (*Abstract Co-Author*)
Philippe Raffy, PhD (*Abstract Co-Author*)

PURPOSE

Early identification of women at elevated breast cancer risk is critical for personalized early detection and risk reduction strategies. We aimed to externally validate an image-only AI model for 5-year breast cancer risk prediction using independent and geographically diverse U.S. screening mammography data, and to assess calibration performance critical for clinical deployment.

METHODS AND MATERIALS

The AI risk model was developed on 421,499 mammograms from 27 facilities in Europe, South America, and the U.S., using a deep convolutional neural network, and was calibrated via an independent test set to generate 5-year risk probabilities. We measured external validation performance on 122,993 consecutive full-field digital screening mammograms (RCC, LCC, RMLO, LMLO) from 67,776 patients acquired from 10 facilities across four geographically diverse U.S. health systems (2011-2017). All bilateral screening mammograms were included, without exclusions for implants. All mammograms were unseen during model training and internal testing and evaluated only after model finalization. Age, self-reported race/ethnicity, and cancer outcomes within the 5-year follow-up period after the index mammogram were extracted from health records and tumor registries. Discrimination was quantified via traditional AUC and the more conservative time-dependent AUC(t), suitable for time-to-event outcomes. Calibration was evaluated by mean calibration error across risk deciles.

RESULTS

The cohort included 2,584 cancer-positive exams (2.1%). Overall AUC computed on exams with known outcome over the 5-year period (n=69,120) was 0.72 (95% CI: 0.71 - 0.73) with site-specific estimates between 0.69 and 0.73. Overall AUC(t) was 0.70 (95% CI: 0.69-0.72) with site-specific estimates between 0.68 and 0.72. Average AI risk in the 10 deciles ranged from 0.88% to 8.45% compared to observed risks of 0.69% to 8.60%. The mean miscalibration error was an underestimate of 0.11% with all errors smaller than an underestimate of 0.34% or an overestimate of 0.19%.

CONCLUSION

The image-only AI model achieved robust calibration and exceeded pre-specified discrimination targets when applied to fully external, geographically diverse U.S. screening data. These findings support its readiness for clinical integration and prospective validation in clinical practice.

CLINICAL RELEVANCE/APPLICATION

Accurate calibration ensures that AI-derived risk estimates are reliable to support personalized screening and risk reduction interventions as recommended by clinical practice guidelines. External validation of both discrimination and calibration is essential to translate AI breast cancer risk models into real-world practice.

S5-SSBR02-6 MULTIMODAL AI MODEL BREAST CANCER RISK PREDICTION: PERFORMANCE IN AN INCREASED GENETIC RISK COHORT

Laura Heacock, MD, MS (*Presenter*)
Yanqi Xu (*Abstract Co-Author*)
Jungkyu Park, MS (*Abstract Co-Author*)
Felicia Pasadyn, MA, BA (*Abstract Co-Author*)
Linda Moy, MD (*Abstract Co-Author*)
Krzysztof J. Geras (*Abstract Co-Author*)
Artie Shen (*Abstract Co-Author*)

PURPOSE

AI-based breast cancer risk prediction models have demonstrated superior accuracy to standard of care empirical risk models in general cohorts. The purpose of this study is to evaluate the performance of a multimodal long-term risk predictor including longitudinal mammography (FFDM), ultrasound (US) and breast MRI in an increased genetic risk cohort.

METHODS AND MATERIALS

The multimodal risk model was IRB-approved and developed using a dataset with 1,291,657 screening and diagnostic FFDM, digital breast tomosynthesis (DBT), US, and MRI exams from 2010-2022 in 274,388 patients (mean age 57.5, SD 12.1). The validated model was tested on a cohort with genetic mutations conferring intermediate to high lifetime risk of breast cancer (BRCA1/2, CHEK2, ATM, PALB2, TP53). Model estimates individualized 1-5 year breast cancer risk using modality-specific neural networks with a temporal transformer, and a risk prediction layer. Model performance was assessed with 2- and 5-year AUCs and concordance index (C-index); 95% CIs were computed via bootstrapping with 5000 iterations. Model performance on FFDM was compared to MIRAI model score on the same exam and the exam date Tyrer-Cuzick (T-C) score.

RESULTS

The increased risk genetic cohort consisted of 247 women, 1792 exams (55.0 ± 12.87), 16 cancers in patients with 5 year follow up. 45.3% (112/247) of women had dense breasts. The multimodal model had 2 year AUROC of 0.739 [0.656, 0.820], 5 year AUROC of 0.761 [0.698, 0.820] and C-index of 0.701 [0.643, 0.758], compared to MIRAI 2 year AUROC of 0.611 [0.586, 0.752], 5 year AUROC of 0.644 [0.591, 0.712] and C-index of 0.619 [0.518, 0.721]. The Tyrer-Cuzick model had 2 year AUROC of 0.389 [0.290, 0.492], 5 year AUROC of 0.505 [0.430, 0.579], and C-index of 0.454 [0.386, 0.524]. Model performance was better in non-dense breasts (2 year AUROC of 0.925 [0.826, 0.987], 5 year AUROC of 0.787 [0.681, 0.88] and C-index of 0.776 [0.692, 0.852]) than dense breasts (2 year AUROC of 0.618 [0.505 0.728], 5 year AUROC of 0.734 [0.652, 0.81] and C-index of 0.627 [0.552 0.703]).

CONCLUSION

Use of multimodal and longitudinal breast imaging has improved performance in a high-risk cohort compared to single timepoint FFDM-based AI models and empirical risk calculators that use breast density.

CLINICAL RELEVANCE/APPLICATION

In higher-risk populations, standard-of-care models fail to distinguish between patients who did and did not develop cancer, as all were uniformly labeled "high-risk". AI-based multimodal models can achieve finer risk stratification in this cohort.

S5-SSCA02-1 MR IMAGING IN 7,324 PATIENTS WITH IMPLANTED CARDIAC DEVICES: A 10-YEAR RETROSPECTIVE COHORT EXPERIENCE

Arash Bedayat, MD (*Presenter*)
Pedram Keshavarz, MD (*Abstract Co-Author*)
Zahra Mohammadigoldar, MD (*Abstract Co-Author*)
Aileen Joy Salamanca Bayoneta (*Abstract Co-Author*)
Jungsik Seo (*Abstract Co-Author*)
J. Paul Finn, MD (*Abstract Co-Author*)
Noel Boyle (*Abstract Co-Author*)

PURPOSE

To evaluate the implementation and safety of a protocolized workflow for MR imaging in patients with cardiac implanted electronic devices (CIEDs) over a 10-year period at a large U.S. tertiary center.

METHODS AND MATERIALS

With IRB approval and HIPAA compliance, the retrospective cohort study included all CIED patients who underwent MRI from January 2015 to December 2024. Device type, lead configuration, and MRI-conditionality were reviewed via chest radiographs; complex cases were assessed by electrophysiologists. Scans were performed on 1.5T Avanto, Avanto FIT, or Sola scanners. Radiology nurse practitioner monitored cardiac rhythm; defibrillators and crash carts were present. MRI-conditional devices were set to protection mode, and tachycardia therapies were disabled in legacy systems. Post-scan device checks were mandatory, and any immediate adverse effects, such as rhythm changes, device rebooting, or device non-function, were documented.

RESULTS

A total of 7,324 patients (mean age of 70.5 years, intra quartile range [IQR]: 64-81 years, 60.4% male) underwent MRI during the study period. Annual exam volume increased significantly from 181 in 2015 to 1,224 in 2024, with average monthly volumes rising from 15 to 102. Among all patients, 44.8% (3,280/7,324) had non-MRI-conditional devices, and 25.5% (1,866/7,324) were device-dependent. Most common clinical indications were neurologic (54.3%, 3,975/7,324), gastrointestinal/genitourinary (GI/GU) (16.4%, 1,200/7,324), cardiac (15.6%, 1,146/7,324), musculoskeletal (11.2%, 819/7,324), and others (2.5%, 184/7/324). Device-related issues were documented in 14.4% (1,056/7,324) of cases; the two most frequently encountered issues involved active CIEDs with epicardial leads (6.2%, 66/1,056) and active CIEDs with abandoned transvenous or epicardial leads (3.9%, 41/1,056). Despite these device-related issues, no major adverse events were reported. The center maintains up to twenty dedicated outpatient time slots weekly for patients with CIEDs, resulting in a waiting list of approximately 6-8 weeks.

CONCLUSION

This study demonstrates that a standardized workflow with proper device evaluation, safety measures, and interdisciplinary collaboration enables safe MRI in patients with cardiac devices, including legacy and non-MRI-conditional systems.

CLINICAL RELEVANCE/APPLICATION

These findings support the safe and necessary expansion of MRI access for patients with cardiac implanted electronic devices, including those with legacy systems. Broader adoption of standardized workflows across institutions can improve diagnostic accuracy, facilitate timely clinical decision-making, and promote equitable care for this high-risk and historically underserved population.

S5-SSCA02-3 SOCIOECONOMIC AND RACIAL DISPARITIES IN CORONARY CT ANGIOGRAPHY OUTCOMES: A RETROSPECTIVE COHORT ANALYSIS FROM 2015-2024

Mehrad Rokni, MD (*Presenter*)
Kamhung Lam (*Abstract Co-Author*)
Linh Vo (*Abstract Co-Author*)
Michelle Wang (*Abstract Co-Author*)
Majid Hassan, MD (*Abstract Co-Author*)
Sofiya Ghazaryan (*Abstract Co-Author*)
Shotaro Naganawa, MD, PhD (*Abstract Co-Author*)
Misagh Piran, MD (*Abstract Co-Author*)
Ahmadreza Ghasemiesfe, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of socioeconomic status (SES), race, income, and other social determinants on Coronary CT Angiography (CCTA) outcomes in adults aged 40-79, alongside traditional cardiovascular risk markers.

METHODS AND MATERIALS

We retrospectively analyzed 1,171 patients (median age: 63; 50% female) who underwent CCTA between 2015-2024. SES was assessed using median income (<$50k, $50-99.9k, $100-149.9k, =$150k) and zip code-level GINI index. Additional predictors included race, ethnicity, marital and retirement status, smoking, diabetes, hypertension, BMI, triglycerides, HDL, and total cholesterol. Primary outcomes were ASCVD risk score (n=1171), coronary artery calcium score (n=478), and CAD-RADS (n=945). ANOVA, linear regression, and ordinal logistic regression were performed ($p<0.05$).

RESULTS

Lower income, African American or Hispanic race/ethnicity, and widowed or retired status were independently associated with worse outcomes: higher ASCVD risk, coronary artery calcium score, and CAD-RADS category ($p<0.001$). The median calcium score was 350 in the <$50k income group compared to 240 in the =$150k group, with median ASCVD risk scores of 14% and 9%, respectively. CAD-RADS 4A/4B was observed in 20% of patients in the <$50k group versus 10% in the =$150k group. Higher income and HDL levels were predictive of lower ASCVD risk and imaging scores, whereas higher GINI index, BMI, and triglycerides were associated with worse outcomes ($p<0.05$).

CONCLUSION

Socioeconomic and racial disparities significantly affect CCTA outcomes beyond traditional cardiovascular risk factors, with worse outcomes defined as ASCVD risk =7.5%, calcium scores =300, and CAD-RADS =4.

CLINICAL RELEVANCE/APPLICATION

Integrating SES and social determinants into cardiovascular risk stratification is essential. Targeted interventions, such as affordable CCTA screenings in low-income areas or culturally tailored educational programs for underserved racial/ethnic groups, could reduce disparities in cardiovascular outcomes.

S5-SSCA02-4 IMPACT OF READER EXPERIENCE ON CAD-RADS 2.0 AND ITS CORRELATION WITH CT-DERIVED FFR

Jonas Heinrich Lund, MD (*Presenter*)
Mathias Meyer, MD (*Abstract Co-Author*)
Thomas Henzler, MD (*Abstract Co-Author*)
Gerhard B. Adam, MD (*Abstract Co-Author*)
Enver G. Tahir, MD (*Abstract Co-Author*)
Isabel Molwitz, MD, MBA (*Abstract Co-Author*)
Jennifer Erley, MD (*Abstract Co-Author*)

PURPOSE

To assess how the level of reader experience impacts the reliability of the Coronary Artery Disease Reporting and Data System (CAD-RADS) 2.0 and its relationship with obstructive coronary artery disease (CAD), as assessed by non-invasive CT-derived fractional flow reserve (CT-FFR).

METHODS AND MATERIALS

Patients undergoing CCTA using third-gen dual-source CT were included. Four readers with varying experience in cardiac imaging (Level I: first-/third-year resident, Level II, Level III-certified) assessed the visual stenosis category (CAD-RADS 0 to 5). After = 30 days, each reader performed a blinded second read to assess intra-observer reliability. Inter- and intra-observer agreement was evaluated using intraclass correlation coefficients (ICC). CT-FFR was computed via machine learning. CAD-RADS & CT-FFR were correlated using Spearman's rank.

RESULTS

100 patients (29% female, age 63 ± 12 years) with median Agatston score of 267 and plaque burden of P2 were included. Inter-observer agreement was good for CAD-RADS on a per-patient and per-vessel basis (ICC = 0.69-0.77). For CAD-RADS >2 (functional testing threshold), experienced readers (Level II & III) upgraded 44% of stenoses (e.g. CAD-RADS 2 to 3) and downgraded 56% (e.g. CAD-RADS 4A to 3) compared to less experienced (Level I) readers. Intra-observer reliability varied by experience, with good agreement among less experienced readers (ICC = 0.77-0.84) and excellent agreement among experienced readers (ICC = 0.96-1.00). CAD-RADS and CT-FFR showed a strong inverse correlation in experienced readers (? = -0.96 for LM, -0.88 for LAD, -0.95 for LCX, -0.85 for RCA). Correlations for a Level I reader were worse (? = -0.53 for LM, -0.76 for LAD, -0.54 for LCX, 0.57 for RCA, $p < 0.001$). Reclassification of CAD-RADS between experienced and less experienced readers was linked to CT-FFR differences. Stenoses that were downgraded by experienced readers had higher CT-FFR (0.85 ± 0.11 vs 0.75 ± 0.07; $p = 0.008$), stenoses that were upgraded had significantly lower CT-FFR values ($p<0.01$).

CONCLUSION

Experience impacts CAD-RADS 2.0 category and correlation with CT-FFR, with higher inter- and intra-reader agreement among experienced readers. Less experienced readers tend to overestimate stenoses, potentially causing unnecessary ICA referral instead of functional testing. Thus, our findings indicate that advanced readers identify ischemic CAD based on CT-FFR better.

CLINICAL RELEVANCE/APPLICATION

Our findings highlight the impact of reader experience in interpreting CAD-RADS 2.0. Reclassifications by experienced readers were aligned with functional assessment using CT-FFR, supporting better identification of hemodynamically relevant CAD and more accurate, cost-effective patient management.

S5-SSCA02-5 CARDIAC MRI MONITORING IN ACUTE MYOCARDITIS: PREDICTING OUTCOMES THROUGH SERIAL IMAGING

Anna Palmisano, MD (*Presenter*)
Elisa Bruno (*Abstract Co-Author*)
Davide Vignale (*Abstract Co-Author*)
Marco Gatti, MD (*Abstract Co-Author*)
Nicola Galea, MD (*Abstract Co-Author*)
Riccardo Faletti, MD (*Abstract Co-Author*)
Antonio Esposito, MD (*Abstract Co-Author*)

PURPOSE

Myocarditis is a common disease at risk of chronic progression. Aim is to assess MRI parameters changes during serial monitoring in patients with acute myocarditis (AM) and their prognostic implication for prediction of major adverse cardiac events (MACE).

METHODS AND MATERIALS

In this prospective multicenter study, patients with MRI confirmed AM between 2016 to 2020 underwent serial MRI: at baseline (6 [interquartile range (IQR), 3-10] days after symptom onset), short-term (median 36 [IQR, 33-42] days) and long-term (392 [IQR, 358-435] days). Cardiac MRI parameters including mapping were evaluated. MACE at 5 years follow-up were collected.

RESULTS

A total of 105 patients (age 38 [IQR, 28-45 years]; men 75, 71%) were enrolled. Infarct-like clinial presentation (80, 76%) was the most common, was followed by heart failure (18, 17%) and arrhythmia (7, 7%). MACE occurred in 20/105 patients (28.5%). Persistence of active disease using LLc 2018 was found in 91% (87) of patients at short-term and 61.5% (48) of patients at long-term MRI. Lateral LGE pattern was associated to better prognosis (HR [95% CI]= 0.19 [0.09;0.38]; p-value<.0001), while scar burden at long-term MRI was associated to MACE (HR[95% CI]=1.15 [1.07;1.24];p-value<.001). Native T1 at short-time MRI (HR[95% CI]=1.02[1.01;1.02];p-value<.0001) and T2 mapping at long-term MRI (HR[95% CI]=1.27[1.07;1.52];p-value:.006) resulted independent predictors of events at multivariate analysis. MRI parameters changes at different time-point were not predictors of MACE.

CONCLUSION

Cardiac MRI allows to monitor healing process. Persistence of inflammation after 1 year from onset is associated to unfavourable outcome.

CLINICAL RELEVANCE/APPLICATION

The introduction of mapping allow to identify persistence of active inflammation in a huger percentage of patients with myocarditis, the kinetics of its resolution will have impact on prognosis. In particular, behind known risk stratificators, peristence of T2 mapping alteration at 1 years is associate to unfavourable prognosis.

S5-SSCA02-6 OPPORTUNISTIC AI-DERIVED MEASUREMENTS OF ADIPOSITY IN CORONARY ARTERY CALCIUM SCANS PREDICT NEW ONSET DIABETES IN NORMOGLYCEMIC NON-OBESE ADULTS: THE AI-CVD STUDY WITHIN THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS (MESA)

Morteza Naghavi (*Presenter*)
Kyle Atlas (*Abstract Co-Author*)
Chenyu Zhang (*Abstract Co-Author*)
Anthony P. Reeves, PhD (*Abstract Co-Author*)
Jakob Wasserthal (*Abstract Co-Author*)
Tom Atlas, MD (*Abstract Co-Author*)
Nathan Wong, PhD (*Abstract Co-Author*)
Andrea Branch, PhD (*Abstract Co-Author*)
David F. Yankelevitz, MD (*Abstract Co-Author*)
Claudia I. Henschke, PhD, MD (*Abstract Co-Author*)

PURPOSE

The Artificial Intelligence-Cardiovascular Disease (AI-CVD) study aims to extract opportunistic screening information from coronary artery calcium (CAC) and lung computed tomography (CT) scans beyond the CAC score to improve CVD prediction. In this study, we present new data demonstrating that AI-CVD measures of adiposity in CAC scans predict new-onset diabetes in normoglycemic, non-obese adults.

METHODS AND MATERIALS

We analyzed baseline CAC scans and up to 19 years of follow-up data from 2,935 normoglycemic (fasting blood glucose <100 mg/dL), non-obese (Body mass index <30 kg/m²) participants in the Multi-Ethnic Study of Atherosclerosis (MESA). Diabetes incidence was identified using the American Diabetes Association's 2003 criteria. AI-CVD measures of adiposity in CAC scans indexed by body surface area included liver fat (LF), total visceral fat (TVF), subcutaneous fat (SF), and pericardial fat (PF). Hazard ratios (HRs) for incident diabetes, comparing the highest to the lowest quartiles of each measurement, were calculated using Cox proportional hazards regression models. Additionally, we performed a multivariable Cox regression analysis incorporating all AI-enabled adiposity measures and calculated the chi-squared statistic to determine feature importance.

RESULTS

Over a 19-year period, 205 participants (7.0%) developed diabetes. Significant predictors of diabetes were LF (HR: 2.54, 95% CI: 1.67-3.85), TVF (HR: 2.50, 95% CI: 1.64-3.83), SF (HR: 3.19, 95% CI: 2.01-5.06), and PF (HR: 1.64, 95% CI: 1.08-2.50). These associations were consistent across genders, except for PF in females. The cumulative incidence of diabetes in the highest quartiles was 12.2% (95% CI: 9.8%-15.1%) for LF, 11.7% (95% CI: 9.3%-14.8%) for TVF, 11.7% (95% CI: 9.4%-14.6%) for SF, and 9.4% (95% CI: 7.2%-12.2%) for PF. In multivariate analysis, chi-square values for adiposity measures were: liver fat (35.32), subcutaneous fat (9.04), pericardial fat (6.29), and total visceral fat (2.44), with liver fat showing the strongest association with incident diabetes.

CONCLUSION

Opportunistic AI-enabled measures of adiposity such as LF, TVF, and SF in MESA CAC scans identified normoglycemic, non-obese adults at high risk of future diabetes. Liver fat emerged as the strongest contributor to development of type 2 diabetes.

CLINICAL RELEVANCE/APPLICATION

AI-enabled opportunistic screening in CAC scans can identify individuals at risk for diabetes before the onset of conventional risk factors, enabling early preventive interventions.

S5-SSGI01-1 COMPARING FIB-4, VCTE, PSWE, 2D-SWE, AND MRE THRESHOLDS AND DIAGNOSTIC ACCURACIES FOR DETECTING HEPATIC FIBROSIS IN PATIENTS WITH MASLD: A SYSTEMATIC REVIEW AND META-ANALYSIS

Shyam Mehta, BSc, MPH (*Presenter*)
Mitchell Wilson, MD, FRCPC (*Abstract Co-Author*)
Ranjit Singh, MBBS, BMedSc (*Abstract Co-Author*)
Christopher I. Fung, MD (*Abstract Co-Author*)
Gavin Low, FRCR (*Abstract Co-Author*)

PURPOSE

To compare thresholds and accuracies of FIB-4, vibration controlled transient elastography (VCTE), point shear wave elastography (pSWE), 2D shear wave elastography (2D-SWE), and MR elastography (MRE) for detecting hepatic fibrosis in MASLD.

METHODS AND MATERIALS

A systematic search of MEDLINE, EMBASE, Cochrane Library, Scopus and the grey literature from inception to March 2024 was performed. Studies evaluating accuracies of FIB-4, VCTE, 2D-SWE, pSWE and/or MRE for detecting significant (=F2) and/or advanced (=F3) hepatic fibrosis in MASLD patients compared to histology were identified. Full-text review and data extraction was performed independently by two reviewers. Multivariate meta-analysis and subgroup analysis were performed by index test and fibrosis grading. Risk of bias was assessed using QUADAS-2.

RESULTS

207 studies with over 80,000 patient investigations were included. FIB-4 1.3 threshold sensitivity was 71% (95%CI 66-75%) for detecting advanced hepatic fibrosis which improved to 88% (85-91%) using a <0.75 threshold. FIB-4 specificity using a 2.67 threshold was 96% (94-97%). Sensitivities of 88-91% were achieved using thresholds of 3.2 kPa for pSWE, 4.92 kPa for 2D-SWE, 7.18 kPa for VCTE and 2.32 kPa for MRE. No significant differences were identified for sensitivities in subgroup analysis with thresholds between 7-9 kPa. Most imaging-based studies were high risk-of-bias for index test.

CONCLUSION

A FIB-4 threshold of <0.75 and modality-dependent thresholds (VCTE <7 kPa; pSWE <3 kPa; 2D-SWE <5 kPa; MRE <2.5 kPa) would achieve sensitivities of around 90% when defining low-risk MASLD in population screening.

CLINICAL RELEVANCE/APPLICATION

A modified two-tier algorithm aligning with existing Society of Radiologists in Ultrasound guidelines would improve risk stratification accuracies compared to existing guidelines by European and American liver societies.

S5-SSGI01-2 DEEP LEARNING NETWORK FOR AUTOMATED STAGING BY USING EQUILIBRIUM ENHANCED PHASE MR IMAGES

Yaoyao Yu (*Presenter*)
Junhao Zha, MD (*Abstract Co-Author*)
Shenghong Ju, MD, PhD (*Abstract Co-Author*)

PURPOSE

While conventional non-invasive methods like liver stiffness measurement (LSM) and serological tests are widely used, their accuracy in staging hepatic fibrosis remains limited. This study developed an nnU-Net-based liver segmentation model and proposed a novel deep learning framework that integrates multi-task contrastive learning with attention mechanisms to automatically identify key MRI patches for fibrosis staging.

METHODS AND MATERIALS

A retrospective study was conducted on 706 treatment-naive chronic hepatitis B patients. Data from 655 patients (center 1) were used for model training, validation, and internal testing, while 51 patients from center 2 served as an external test set. Biopsy within 6 months of MRI served as the reference standard. A VGG-16-based network performed contrastive learning to select the most informative patches and classify significant fibrosis (F=2). Equilibrium-phase MRI and LSM values were used as input, and segmentation accuracy was assessed using the Dice Similarity Coefficient (DSC). Diagnostic performance was evaluated using AUC and Integrated Discrimination Improvement (IDI).

RESULTS

The nnU-Net achieved a DSC of 0.95. For F=2 fibrosis, the patch-based model reached AUCs of 0.853 (training), 0.835 (validation), 0.818 (internal test), and 0.805 (external test). Diagnostic performance decreased when averaging predictions across more patches, with the best performance from the top-ranked patch. The model significantly outperformed LSM alone (IDI = 0.287, $P < 0.0001$).

CONCLUSION

This contrastive learning-based model enables accurate, non-invasive fibrosis staging by automatically selecting informative image regions, improving diagnostic performance while reducing reliance on manual annotation.

CLINICAL RELEVANCE/APPLICATION

We developed an AI-based radiomics model that automates liver patch selection for staging hepatic fibrosis, achieving diagnostic performance comparable to manual expert selection while reducing operator dependency. By minimizing human intervention and enhancing reproducibility, this approach offers a scalable and objective tool to support non-invasive, clinically relevant fibrosis assessment.

S5-SSGI01-3 AI-BASED DETECTION OF LIVER IRON OVERLOAD FROM MRI LOCALIZERS: A PRELIMINARY STUDY

Yura Oh, BS (*Presenter*)
Dheerendranath Battalapalli (*Abstract Co-Author*)
Marwa Ismail (*Abstract Co-Author*)
Julius F. Heidenreich, MD (*Abstract Co-Author*)
Jitka Starekova, MD (*Abstract Co-Author*)
David T. Harris, PhD (*Abstract Co-Author*)
Garrett Fullerton, MS (*Abstract Co-Author*)
Shreyas S. Vasanawala, MD, PhD (*Abstract Co-Author*)
Scott B. Reeder, MD, PhD (*Abstract Co-Author*)
Pallavi Tiwari, PhD (*Abstract Co-Author*)
Diego Hernando, PhD (*Abstract Co-Author*)

PURPOSE

Liver iron overload requires accurate detection and quantification. Dedicated MRI iron quantification is accurate but is not routinely acquired in most abdominal protocols. Routinely acquired MRI localizer images, however, contain relevant tissue-contrast information that is rarely exploited diagnostically. We propose a deep learning model to detect liver iron overload directly from Single Shot Fast Spin Echo (SSFSE) localizer images. Our hypothesis is that deep learning models can reliably detect liver iron overload opportunistically to identify patients who require additional dedicated MRI iron quantification in the same exam.

METHODS AND MATERIALS

We used SSFSE localizer images from 396 examinations (Center 1: n = 366; Center 2: n = 30; age range: 0-86 years) acquired between 1/2012 and 11/2024. Liver iron concentration (LIC) was measured in the same exam using calibrated and validated R2* relaxometry methods. A clinically-relevant threshold of 3.2 mg/g defined "Iron Overload" (LIC = 3.2 mg/g) versus "No Iron Overload" (LIC < 3.2 mg/g). The dataset had a median LIC of 3.19 mg/g (IQR 0.87-6.51 mg/g). Preprocessing included axial view extraction, isotropic resampling, bias-field correction, selection of a single slice with the largest liver cross-section, histogram equalization, and exclusion of signals outside the abdominal region. An EfficientNet-B4 model was trained for binary classification on an 80% training set (n = 316, including 10% for validation) and 20% testing set (n=80) split. Hyperparameters were tuned via Optuna over five-fold cross-validation. To provide a human benchmark, two experienced radiologists independently interpreted the test set, fully randomized and in blinded fashion after a calibration review of the training images.

RESULTS

The model achieved an Area Under the ROC Curve of 89.7%. Youden's Index identified an optimal probability threshold of 0.30 for the model's classification, resulting in a test accuracy of 85.0% (30/40 correctly classified as No Iron Overload and 38/40 correctly classified as Iron Overload). The cross-validation accuracy was 84.2% ± 0.05%, with a test set sensitivity of 95.0% and a specificity of 75.0%. Radiologist 1 achieved 90.0% accuracy (35/40 No Iron Overload, 37/40 Iron Overload), while Radiologist 2 achieved 80.0% accuracy (32/40 No Iron Overload, 32/40 Iron Overload).

CONCLUSION

A deep learning algorithm applied to routine SSFSE localizers has potential for detection of liver iron overload and patient triage, achieving promising accuracy similar to expert level.

CLINICAL RELEVANCE/APPLICATION

Automated AI detection of liver iron overload may guide iron quantification MRI. Further training and validation on large datasets are needed.

S5-SSGI01-4 DIXON-BASED WATER T1 MAPPING FOR FAT-CORRECTED ASSESSMENT OF HEPATIC FIBROSIS IN CHRONIC LIVER DISEASE

Narine Mesropyan, MD (*Presenter*)
Elizabeth Huaroc (*Abstract Co-Author*)
Christoph Katemann (*Abstract Co-Author*)
Kilian Weiss, PhD (*Abstract Co-Author*)
Oliver M. Weber (*Abstract Co-Author*)
Johannes M. Peeters, PhD (*Abstract Co-Author*)
Tatjana Dell (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)
Mariya Doneva (*Abstract Co-Author*)
Dimitrios C. Karampinos (*Abstract Co-Author*)
Can Yuksel, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

The diagnostic value of conventional T1 mapping for non-invasive assessment of liver fibrosis is limited in the presence of hepatic steatosis. To evaluate the diagnostic value of water T1 (wT1) with continuous inversion-recovery Look-Locker (CIR-LL) method, integrating spiral readout, Dixon, and dictionary-based processing, for the fat-corrected assessment of hepatic fibrosis in patients with chronic liver disease (CLD).

METHODS AND MATERIALS

In this prospective study, consecutive participants with CLD underwent liver MRI, which included assessment of MRE-derived liver stiffness, PDFF, T1 relaxation times (T1-MOLLI) and ECV, and wT1 relaxation times. MRE served as the reference standard to evaluate the diagnostic performance of MRI-based mapping parameters. Significant fibrosis(=F2) was defined as MRE-derived liver stiffness >3.66 kPa in patients with PDFF= 5%, or >3.14 kPa in patients with PDFF>5%. Statistical analysis included Student's t-test, receiver operating characteristic (ROC) analysis, and Spearman's correlation coefficient.

RESULTS

A total of 81 CLD patients (mean age, 50±14years; 32 female; 40 patients with PDFF>5%) were included. All measured mapping values were significantly higher in patients with significant fibrosis compared to those without (e.g., wT1: 628 ± 82 vs. 546 ± 41 msec, P <.001). wT1 showed a strong correlation with MRE-derived liver stiffness, outperforming T1-MOLLI and ECV mapping (whole cohort: r=0.67 [wT1] vs. 0.53 [T1-MOLLI] vs. 0.48 [ECV]; cohort with PDFF>5%: r=0.69 [wT1] vs. 0.44 [T1] vs. 0.49 [ECV]; P<.05 in each case, respectively). wT1 had a superior diagnostic performance for the detection of significant fibrosis (whole cohort, AUC: 0.82[wT1]; 0.77 [T1-MOLLI]; 0.73 [ECV], P <.001 in each case; cohort with PDFF>5%, AUC: 0.84, P =.002 [wT1], 0.70, P =.04 [T1-MOLLI], 0.70, P =.04 [ECV]).

CONCLUSION

Compared to T1-MOLLI and ECV mapping, the proposed fat-corrected CIR-LL wT1 method proved to be a more robust marker of hepatic fibrosis in CLD, also in the presence of hepatic steatosis.

CLINICAL RELEVANCE/APPLICATION

The proposed continuous inversion-recovery Look-Locker method, integrating spiral readout, Dixon, and dictionary-based processing, enables fat-corrected assessment of hepatic fibrosis in patients with CLD.

S5-SSGI01-5 CLINICAL VALIDATION OF T1ρ MAPPING FOR THE ASSESSMENT OF HEPATIC FIBROSIS IN PATIENTS WITH CHRONIC LIVER DISEASE

Narine Mesropyan, MD (*Presenter*)
Oliver M. Weber (*Abstract Co-Author*)
Christoph Katemann (*Abstract Co-Author*)
Tatjana Dell (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)
Claus C. Pieper, MD (*Abstract Co-Author*)
Can Yuksel, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

Experimental studies suggest that hepatic T1? might be an accurate and robust alternative to T1 and ECV mapping for hepatic fibrosis assessment in chronic liver disease (CLD), inl. steatotoc liver disease (SLD). To evaluate the diagnostic usefulness of T1? mapping for the fat-corrected assessment of hepatic fibrosis in patients with CLD, including those with SLD.

METHODS AND MATERIALS

In this prospective study, consecutive participants with CLD underwent multiparametric quantitative liver MRI, which included assessment of MRE-derived liver stiffness, PDFF, T1 relaxation times and extracellular volume fraction (ECV), and T1? relaxation times. MRE served as the reference to evaluate the diagnostic performance of MRI-based mapping parameters. Significant fibrosis (=F2) was defined as MRE-derived liver stiffness >3.66 kPa in patients with PDFF= 5%, or >3.14 kPa in patients with PDFF>5%. Statistical analysis included Student’s t-test, receiver operating characteristic (ROC) analysis, and Spearman's correlation coefficient.

RESULTS

A total of 112 CLD patients (mean age, 48±16 years; 46 female; 53 patients with PDFF>5%) were included. All measured mapping values were significantly higher in patients with significant fibrosis compared to those without (e.g., T1?: 110±15 vs. 92±6 msec, P <.001). T1? showed a moderate to strong correlation with MRE-derived liver stiffness, superior to T1 and ECV mapping (whole cohort: r=0.75 [T1?] vs. 0.49 [native T1] vs. 0.68 [ECV]; cohort with PDFF>5%: r=0.67 [T1?] vs. 0.32 [native T1] vs. 0.62 [ECV]; P<.05 in each case, respectively). T1? provided the highest diagnostic performance for the detection of significant fibrosis (whole cohort: AUC 0.90 [T1?] vs. 0.73, P <.001 [native T1], vs. 0.81, P =.05 [ECV]; cohort with PDFF>5%: AUC 0.87 [T1?] vs. 0.67, P =.03 [native T1], vs. 0.79, P =.047 [ECV]), P values are given vs. T1?.

CONCLUSION

Hepatic T1? might be a more accurate marker of hepatic fibrosis in CLD, including SLD, compared to T1 and ECV mapping.

CLINICAL RELEVANCE/APPLICATION

Our study supports the clinical use of T1? mapping as a more robust imaging-based alternative to conventional native T1, ECV, and T2 mapping for the non-invasive assessment of hepatic fibrosis across the full spectrum of CLD, including patients with SLD.

S5-SSGI01-6 T1ρ MAPPING FOR HEPATIC FIBROSIS ASSESSMENT IN PRECLINICAL MODELS OF STEATOTIC LIVER DISEASE

Narine Mesropyan, MD (*Presenter*)
Christoph Katemann (*Abstract Co-Author*)
Oliver M. Weber (*Abstract Co-Author*)
Johannes M. Peeters, PhD (*Abstract Co-Author*)
Tatjana Dell (*Abstract Co-Author*)
Claus C. Pieper, MD (*Abstract Co-Author*)
Daniel Kuetting, MD (*Abstract Co-Author*)
Julian A. Luetkens, MD (*Abstract Co-Author*)
Alexander Isaak, MD (*Abstract Co-Author*)

PURPOSE

To histologically validate T1? mapping and compare it with conventional mapping parameters for assessing hepatic fibrosis across different animal models of steatotic liver disease.

METHODS AND MATERIALS

In male Sprague-Dawley rats different models of steatotic liver disease were induced using a high-fat diet (HFD) and carbon-tetrachloride (CCl4) inhalation: (1) 12w HFD group resulting in steatosis/steatohepatitis without fibrosis; (2) 6w HFD+CCl4 group resulting in steatohepatitis with fibrosis; (3) 12w HFD+CCl4 resulting in steatohepatitis-associated cirrhosis. Hepatic T1, ECV, T2, and T1? were assessed by quantitative MRI. Portal pressure was invasively measured. Hepatic fibrosis was assessed using Sirius red, alpha-smooth muscle actin (a-SMA) staining, and measurement of hydroxyproline content. Hepatic fat content was estimated in Oil red staining and triglyceride content.

RESULTS

57 animals were analyzed (12w HFD, n=15; 6w HFD+CCl4, n=14; 12w HFD+CCl4; n=16; controls, n=12). T1? values were higher in the fibrosis groups, e.g. 12w HFD+CCl4 versus HFD group (71 msec ±5 versus 60 msec ±3, P<.001). T1? values correlated with fibrosis markers (Sirius red r=0.41; a-SMA: r=0.67; hydroxyproline: r=0.76; each P<.001) and portal pressure (r=0.55, P<.001). T1? had the highest diagnostic performance for the detection of histologically defined fibrosis and invasively measured portal hypertension (e.g., for fibrosis, T1?: AUC 0.96, P<.001; T1: AUC 0.74, P=.017; ECV: AUC 0.79, P=.043; T2: AUC 0.51, P<.001). T1? was an independent marker for the detection of histologically defined fibrosis (odds ratio: 3.81, P=.02).

CONCLUSION

In preclinical models of steatotic liver disease, T1? mapping could most reliably detect hepatic fibrosis and portal hypertension across different mapping parameters.

CLINICAL RELEVANCE/APPLICATION

Hepatic T1? might be an accurate and robust imaging-based biomarker for assessing hepatic fibrosis and portal hypertension and, therefore, has a potential to be implemented in humans.

S5-SSGI02-3 AN INTERPRETABLE RADIOMICS MODEL BASED ON PANCREATIC CONTRAST-ENHANCED COMPUTED TOMOGRAPHY PREDICTING THE PROGNOSIS OF POST-ACUTE PANCREATITIS DIABETES MELLITUS

Xiaomin Liu (*Presenter*)
Ran Hu (*Abstract Co-Author*)
Zhixuan Song (*Abstract Co-Author*)

PURPOSE

To develop a radiomics model utilizing contrast-enhanced computed tomography (CECT) for predicting the prognosis of post-acute pancreatitis diabetes mellitus (PPDM-A) and to explain the model's internal predictive mechanisms using Shapley Additive exPlanations (SHAP).

METHODS AND MATERIALS

226 PPDM-A patients were retrospectively recruited from three centers, with 107 in training, 46 in internal, and 73 in external cohorts. There were 34, 15 and 28 patients with complications in each cohort. The complications included microvascular complications, infection, diabetic ketosis and hypoglycemia. In PPDM-A patients' first pancreatitis episode, 2398 radiomics features were extracted from CECT images (arterial and venous phases). FeAture Explorer (FAE) generated the machine learning pipeline and selected important radiomics features. Gaussian processes classifiers built radiomics and clinical-radiomics models, while Naive Bayes classifiers built the clinical model. The SHAP method was applied to provide insights into the model's predictive process.

RESULTS

The radiomics model predicted PPDM-A complications with the area under the receiver operating characteristic curve (AUC) of 0.95, 0.888, and 0.948 in training, internal, and external cohorts. In external cohort, the radiomics model significantly outperformed the clinical model (AUC 0.948 vs. 0.714, $p = 0.002$), while the combined model showed no significant difference from the radiomics model (AUC 0.933 vs. 0.948, $p = 0.638$). The SHAP technology provided physicians with insights into the global and individual impacts of radiomic features on model predictions.

CONCLUSION

The CECT-based radiomics model performed well in predicting PPDM-A prognosis. SHAP enhances understanding of the model's predictive process, boosting its credibility.

CLINICAL RELEVANCE/APPLICATION

High incidence of post-acute pancreatitis diabetes, lacking quantitative method to predict its prognosis. The radiomic model can be useful for predicting post-acute pancreatitis diabetes mellitus prognosis. Shapley additive explanations can explain and visualize radiomics model's predictive process for clinicians.

S5-SSGI02-4 COMBINED PANCREATIC ATTENUATION AND PANCREAS-TO-SPLEEN RATIO ON NON-CONTRAST CT IMPROVE DIABETES RISK STRATIFICATION OVER SINGLE BIOMARKERS: A RETROSPECTIVE ANALYSIS

Leona Alizadeh, MD (*Abstract Co-Author*)
Tommaso D'Angelo, MD, PhD (*Abstract Co-Author*)
Katrin Eichler, MD (*Abstract Co-Author*)
Thomas J. Vogl, MD, PhD (*Abstract Co-Author*)

PURPOSE

Non-invasive imaging biomarkers derived from routine CT may assist in the early identification of individuals at risk for diabetes mellitus (DM). While both decreased pancreatic attenuation and a reduced pancreas-to-spleen attenuation ratio (PSR) have been associated with dysglycemia, it remains unclear whether a combination of both parameters yields additional diagnostic benefit. This study aimed to evaluate the added value of combining pancreatic attenuation and PSR for risk stratification of DM.

METHODS AND MATERIALS

We retrospectively analyzed non-contrast abdominal CT scans from 5624 patients (51% male; mean age 52 ± 10 years). Patients were categorized into normoglycemic (n=2900), prediabetic (n=1569), and diabetic (n=1155) groups based on clinical and laboratory data. Mean pancreatic attenuation (HU) was measured in head, body, and tail regions and compared to splenic attenuation to calculate PSR. ROC curve analyses and multivariate logistic regression were used to evaluate diagnostic performance for identifying diabetic status using individual and combined CT parameters.

RESULTS

Mean pancreatic attenuation decreased progressively from normoglycemic (43 HU) to prediabetic (36 HU) to diabetic patients (32 HU) (all $p < 0.001$). PSR showed stronger correlation with HbA1c ($r = -0.90$) than pancreatic HU alone ($r = -0.76$) ($p<0.0001$). The AUC for PSR alone was 0.88, outperforming pancreatic HU (AUC: 0.79). However, combining both parameters slightly improved diagnostic accuracy (AUC: 0.92; $p = 0.01$ vs. PSR alone). In multivariate models, the combined approach remained an independent predictor of diabetes, offering both improved sensitivity and specificity.

CONCLUSION

Although PSR is a superior single CT-derived biomarker for assessing diabetes risk, the combination of PSR and pancreatic attenuation provides a small but statistically significant improvement in diagnostic performance. This supports the use of combined attenuation-based metrics for more precise opportunistic screening in routine CT.

CLINICAL RELEVANCE/APPLICATION

Opportunistic assessment of diabetes risk using routine non-contrast abdominal CT is feasible and may benefit from combined evaluation of PSR and pancreatic density to enhance diagnostic accuracy in diverse patient populations.

S5-SSGI02-5 DEEP LEARNING-BASED PANCREATIC AGE ESTIMATION FROM MRI PREDICTS INCIDENT DIABETES BEYOND KNOWN RISK FACTORS IN THE GENERAL POPULATION

Matthias Jung, MD (*Presenter*)
Zeynep Berkarda, MD (*Abstract Co-Author*)
Michael T. Lu, MD, MPH (*Abstract Co-Author*)
Marco Reisert (*Abstract Co-Author*)
Fabian Bamberg, MD, MPH (*Abstract Co-Author*)
Vineet K. Raghu, PhD (*Abstract Co-Author*)
Jakob Weiss, MD, PhD (*Abstract Co-Author*)

PURPOSE

Aging is a heterogeneous process, with individuals and organs aging at different rates. Chronological age poorly reflects this variability, whereas biological age measures could improve risk assessment and prevention. We propose a deep learning (DL) framework (MRI-PancAge) for estimating pancreas age from MRI and investigate its value for predicting incident diabetes risk.

METHODS AND MATERIALS

MRI-PancAge was developed in two steps using data from 30,389 individuals (20-75 years) from the German National Cohort. Model 1 was developed to segment the pancreas on abdominal MRI. Model 2 was trained to take the 3D pancreas segmentation as input and output MRI-PancAge in years. For further analyses, MRI-PancAge was converted to a z-score, where a $z>0$ refers to an older and $z<0$ to younger MRI-PancAge compared to chronological age. We validated this framework in an independent testing set of 33,559 UK Biobank (UKB) participants free of diabetes at time of imaging to predict incident diabetes beyond risk factors. Primary outcome was incident diabetes. Cumulative incidence curves and Cox regression assessed the association between MRI-PancAge (categorized as younger: $z<-1$; ref: z -1 to 1; older: $z>1$) and incident diabetes after adjustment for age, sex, BMI, race, pancreas volume and fat fraction, hypertension, alcohol consumption, and smoking status. To assess whether MRI-PancAge carries incremental value beyond these risk factors, nested models with and without MRI-PancAge were compared using Harrell's C. Results are for the UKB only.

RESULTS

In 33,559 UKB participants (64.8±7.7 years, 50.9% female; 1.9% incident diabetes; median follow up 4.7 years), cumulative incidence curves showed a higher incidence of diabetes in those with older and a lower incidence in those with younger MRI-PancAge compared to the reference (Log-rank $p<0.001$). Multivariable Cox regression revealed an independent association between older MRI-PancAge and incident diabetes (aHR: 1.35, 95% CI [1.10-1.65], $p=0.005$) after adjustment for all covariates. Adding MRI-PancAge to a baseline model with traditional risk factors showed a small but significantly improved discrimination for incident diabetes (C-index 0.780 to 0.781, $p=0.009$).

CONCLUSION

DL can estimate pancreas age from MRI and predict incident diabetes in the general population beyond chronological age, pancreas volume and fat fraction, and cardiometabolic risk factors.

CLINICAL RELEVANCE/APPLICATION

Our DL model leverages currently unused information about age-related changes in the pancreas, which are widely available on existing clinical MRIs. Applying our model to routine MRIs can automatically extract measures of pancreas age and inform opportunistic diabetes risk assessment and clinical decision-making.

S5-SSGI03-5 CHANGES OF BONE, ADIPOSE, AND MUSCLE-RELATED BODY COMPOSITIONS IN GASTRIC CANCERS AFTER GASTRECTOMY USING DEEP LEARNING BASED AUTOMATIC SEGMENTATION

Mengying Xu, MD (*Presenter*)
Zhengyang Zhu, MD (*Abstract Co-Author*)
Song Liu (*Abstract Co-Author*)
Zhengyang Zhou (*Abstract Co-Author*)

PURPOSE

To investigate bone, adipose, and muscle-related body compositions changes in gastric cancers (GCs) 12 months after gastrectomy utilizing an artificial intelligence (AI) based segmentation tool and to conduct subgroup analyses based on clinicopathological characteristics.

METHODS AND MATERIALS

This retrospective study included 146 GCs (median age, 60 years; range, 29-84 years) who underwent gastrectomy. Body compositions of GCs at baseline and 12 months after surgery were automatically measured utilizing the AI-based segmentation tool. The differences in body compositions at baseline and 12 months after surgery were assessed. Subgroup analyses of body composition changes split by clinicopathological characteristics were conducted.

RESULTS

BMD, adipose-related, and muscle-related body compositions decreased significantly 12 months after surgery (all p <0.001), in which adipose-related losses were the largest. The proportions of sarcopenia (from 37.7% to 55.5%) and osteoporosis (from 13.7% to 26.7%) showed significant increases. Subcutaneous and visceral adipose tissues, abdominal wall muscle, and skeletal muscle losses indicated significant differences in gender and body mass index (BMI) subgroups (all p <0.05). Adipose- and muscle-related losses differed significantly in GCs underwent different gastrectomy (all p <0.05), while BMD loss showed no significant difference. Subgroup analyses based on pathological stages showed no significant difference for body composition changes.

CONCLUSION

BMD, adipose-related, and muscle-related body compositions showed significant losses over 12 months in GCs underwent gastrectomy, in which adipose-related composition losses were the largest. The proportions of sarcopenia and osteoporosis showed significant increases. Gender, baseline BMI, and gastrectomy differences affected adipose- and muscle-related body composition losses but showed no significant effect on BMD.

CLINICAL RELEVANCE/APPLICATION

The application of AI-based segmentation tool for automated measurement of bone, adipose, and muscle-related body compositions changes in gastric cancers after gastrectomy could reflect body's macroscopic metabolism and immune status and help individualized management in clinical practice.

S5-SSGI03-6 DYNAMIC BODY COMPOSITION AS A POTENTIAL IMAGING BIOMARKER FOR PREDICTING SURGICAL RISK IN CROHN'S DISEASE WITH SMALL BOWEL STENOSIS

Shushan Dong (*Presenter*)
Mengting Huang (*Abstract Co-Author*)
Shen Gui (*Abstract Co-Author*)
Heshui Shi, MD (*Abstract Co-Author*)

PURPOSE

To determine whether dynamic body composition parameters derived from computed tomography enterography (CTE) predict high-risk surgical outcomes in Crohn' disease (CD) patients with small bowel stenosis.

METHODS AND MATERIALS

A retrospective analysis of 385 CD patients with small bowel stenosis between January 2018 and June 2022 included paired CTE scans. Patients who required intestinal surgery due to complications such as recurrent intestinal obstruction and fistulas after the diagnosis of CD small bowel stenosis were defined as the high-risk group, otherwise, they were into the low-risk group. Skeletal muscle (SM), subcutaneous adipose (SAT), visceral adipose tissue (VAT), and intermuscular adipose tissue (IMAT) area/density at L3-L5 vertebral levels were measured, normalized by vertebral height. Dynamic body composition parameters and clinical variables were analyzed using Cox regression.

RESULTS

There were 289 cases in the low-risk group and 96 cases in the high-risk group. Interaction terms (time and gender) were tested, males showed significant reductions in L3-L4 skeletal muscle index (SMI) (P<0.001), L3-L4 IMAT index (P<0.001, P=0.04), and L4-L5 VAT density (P=0.008, P=0.005). Females demonstrated decreased L3 SMI (P=0.001) and L4-L5 VAT density (P=0.018, P=0.026). Independent predictors of surgical risk included baseline L3 SMI (P<0.001), L4 VAT ratio (P=0.009), delta L4 SMI (P=0.002), age (P<0.001), platelet count (P=0.003), erythrocyte sedimentation rate (P<0.001), albumin (P=0.042), and stenosis length (P<0.001).

CONCLUSION

Dynamic changes in SMI and VAT density are valuable biomarkers for stratifying surgical risk in CD small bowel stenosis. Monitoring these parameters may improve personalized management.

CLINICAL RELEVANCE/APPLICATION

Assessing body composition based on SMI and VAT parameters is straightforward and can facilitate personalized management and aid in therapeutic decision, thereby reducing the occurrence of high-risk surgical outcomes.

S5-SSGU02-1 AI-RADIOLOGIST CONCORDANCE IN PROSTATE MRI: INFLUENCE OF PI-QUAL V2 IMAGING CRITERIA AND PROTOCOL LIMITATIONS

Satoru Takahashi, MD, PhD (*Presenter*)

PURPOSE

To evaluate the diagnostic concordance between an artificial intelligence (AI) software and radiologists in prostate MRI, and to investigate how PI-QUAL v2 scores, individual imaging criteria, and lesion characteristics influence concordance.

METHODS AND MATERIALS

This retrospective study included 336 patients (72.7 ± 9.1 years) who underwent prostate MRI (bp-MRI, n=328; mp-MRI, n=8) using either 1.5T (n=136) or 3T (n=200) scanners. At 1.5T, a 4-mm slice thickness was used to maintain adequate SNR. In 47 cases with severe DWI artifacts, rescanning was performed using an alternative MPG direction. A total of 383 studies were analyzed using a AI-based detection research software (Prostate AI v1.3.5, Siemens Healthineers), which provided lesion-based PI-RADS scores, suspicion levels, lesion sizes, volumes, and ADC values. An experienced radiologist independently reviewed all studies for PI-RADS v2.1 categorization and PI-QUAL v2 image quality assessment. Diagnostic concordance between AI and the radiologist was assessed, and logistic regression was performed to identify factors associated with correct AI interpretation.

RESULTS

The radiologist identified 196 lesions (PI-RADS 4: 126; PI-RADS 5: 70), while the AI detected 146 lesions. In case-based analysis, the Cohen’s ? coefficient was 0.492. The AI demonstrated a sensitivity of 0.628, specificity of 0.854, accuracy of 0.755, and an AUC of 0.820. PI-QUAL v2 scores were distributed as follows: score 1 (n=154), score 2 (n=97), and score 3 (n=132), with no significant difference in concordance across the scores (p=0.56). However, among the individual PI-QUAL criteria, a 4-mm T2WI slice thickness and use of 1.5T scanners were significantly associated with lower concordance. DWI rescans were also associated with reduced concordance, but rescanning did not improve agreement. Lesions rated as PI-RADS 4 by the radiologist or PI-RADS 3 by the AI were more likely to result in disagreement. In addition, lesions located in the peripheral zone, smaller lesion size, and higher ADC values were independently associated with lower concordance.

CONCLUSION

Diagnostic concordance between AI and radiologists in prostate MRI is significantly influenced by protocol-dependent T2WI parameters, particularly slice thickness, while DWI image quality appears to play a lesser role. These findings underscore the importance of adhering to PI-QUAL mandatory criteria and optimizing acquisition protocols when implementing AI tools in clinical prostate MRI.

CLINICAL RELEVANCE/APPLICATION

Lesions with smaller size and higher ADC values were more likely to result in discordant interpretations, suggesting that AI performs more consistently in evaluating clinically significant, high-grade lesions.

S5-SSGU02-2 CAN AI BRIDGE THE EXPERTISE GAP? A MULTI-READER STUDY ON PROSTATE MRI USING AN OPEN DATASET

Guillaume Herpe, MD (*Presenter*)
Gaspard d'Assignies, MD, PhD (*Abstract Co-Author*)
Roberto Ardon (*Abstract Co-Author*)
Camille Ruppli (*Abstract Co-Author*)
Leo Alberge (*Abstract Co-Author*)
Raphaele Renard-Penna, MD (*Abstract Co-Author*)

PURPOSE

The aim of this study was to evaluate the effect of a deep learning AI software on interpretation accuracy and efficiency of radiologists with varying expertise.

METHODS AND MATERIALS

A total of 201 prostate MRI cases from a publicly available data set (PROSTATEx Challenge) were analyzed in a multi-reader, multi-case study. The panel of radiologists consisted of 6 certified radiologists; one expert (> 1000 prostate MRI readings) and five non expert radiologists (between 250-500 prostate MRI readings) . They were asked to read each cases twice in two reading blocks with a minimum of 4weeks separation, without and with AI software assistance (PAROS v1.0.0, Incepto Medical, Paris, France). Reading tasks consisting in classifying and locating lesions according to PIRADS V2.1 scoring system. The ground truth was established using biopsy results, with csPCa defined as ISUP grade =2, and PI RADS score of the expert reader.

RESULTS

The average accuracy of radiologist in terms of AUC in detecting csPCa (ISUP grade =2) was 55% (95% confidence interval CI [52,58]) without and 65% (95% CI [62,68]) with AI assistance (p=0.04). Accuracy of non-expert radiologists in detecting cases with PIRADS >3 (ou >= 3) improved by 10 % (p=.001) . Inter-reader agreement improved from fair (? = 0.28) to substantial (? = 0.64, p < .001). Standalone AI remained significant superior with higher sensitivity (91% vs. 65%), specificity (64% vs. 50%, p = 0.04), and accuracy (73% vs. 65%, p = 0.04).The expert radiologist obtained the highest accuracy (79% [95% CI: 72%-84%], p < 0.001), outperforming both the AI and AI-assisted non-experts.

CONCLUSION

This AI software increased the diagnostic accuracy of non-expert radiologists and reduced interreader variability, and therefore has the potential to support the MRI process for biopsy decision-making and target identification.

CLINICAL RELEVANCE/APPLICATION

The integration of deep learning AI in prostate MRI interpretation has the potential to enhance the diagnostic accuracy of non-expert radiologists, reducing variability and improving lesion classification. This could lead to more consistent detection of clinically significant prostate cancer (csPCa), optimizing biopsy decision-making and target identification. By bridging the expertise gap, AI-assisted MRI interpretation may improve patient outcomes, particularly in settings with limited access to highly experienced radiologists.

S5-SSGU02-5 AI DIAGNOSTIC PERFORMANCE IN PROSTATE CANCER DECLINES WITH MRI QUALITY REDUCTION, UNLIKE RADIOLOGIST PERFORMANCE

Ailin Dehghanpour, MD (*Abstract Co-Author*)
Regina G. Beets-Tan, MD, PhD (*Abstract Co-Author*)
Tomas Janssen (*Abstract Co-Author*)
Ivo Schoots, MD, PhD (*Abstract Co-Author*)

PURPOSE

To assess the diagnostic performance of an artificial intelligence (AI) model and radiologists in detecting Gleason Grade Group (GG) =2 prostate cancer on diagnostic biparametric MRI (bpMRI), accounting for variations in scan quality as measured by PI-QUAL scores.

METHODS AND MATERIALS

A nnU-Net GG?2 cancer segmentation model used 1500 bpMRI scans for training, 1000 for testing (PI-CAI cohort), and 573 scans for external validation (PROMIS cohort). The external cohort analysis included MRI assessment by two readers (R) using PI-RADSv2.1 (R1) and malignancy Likert scores (R2), while a third reader assigned PI-QUALv2 (MRI-quality) scores. MRI-positive scans were defined as PI-RADS 3-5 scores (R1) and Likert 4-5 scores (R2). The outcome measurement was GG?2 cancer, confirmed by transperineal saturated biopsy. The model's and radiologists' diagnostic performance (AUCs) were compared. Bootstrap testing (1000 iterations) was used to calculate 95% CIs and determine the statistical significance (p-values) of the performance differences between the two quality subgroups.

RESULTS

Overall, the trained AI model achieved an AUC of 0.89 (95% CI: 0.87-0.91) on the PI-CAI test set and an AUC of 0.68 (95% CI: 0.64- 0.73) during external validation. The human readers achieved AUCs on the external data of 0.85 (95% CI: 0.82-0.88) and 0.76 (95% CI: 0.73-0.79) for R1 and R2, respectively. On reduced-quality scans (PI-QUAL 1; n = 162), the AI performance declined to an AUC of 0.61 (95% CI: 0.52-0.70), whereas on high-quality scans (PI-QUAL 2-3; n = 411), it significantly increased ($p < 0.03$) to an AUC of 0.71 (95% CI: 0.66-0.76). In contrast, the diagnostic performance of both readers remained consistent across scan quality: for R1, AUCs were 0.82 (95% CI: 0.76-0.88) on PI-QUAL 1 and 0.86 (95% CI: 0.82-0.89) on PI-QUAL 2-3 ($p = 0.25$); for R2, AUCs were 0.74 (95% CI: 0.67-0.81) and 0.77 (95% CI: 0.73-0.81), respectively ($p = 0.52$).

CONCLUSION

The diagnostic performance of the AI model declined significantly on reduced-quality MRI scans, whereas radiologists maintained consistent performance regardless of scan quality.

CLINICAL RELEVANCE/APPLICATION

To ensure optimal performance, consistently high-quality MRI scans are required for a successful implementation of AI in clinical practice.

S5-SSOB01-1 DOES CONTRAST ENHANCED ULTRASOUND ADD DIAGNOSTIC VALUE TO ORADS ULTRASOUND, IOTA'S SR, SR RISK AND IOTA'S ADNEX MODEL - A PROSPECTIVE COMPARATIVE STUDY

Shabnam B. Grover, MD, DMRD (*Presenter*)
Sayantan Patra, MD (*Abstract Co-Author*)
Pratima Mittal, MS (*Abstract Co-Author*)
Geetika Khanna, MD (*Abstract Co-Author*)
Hemal Grover, MD (*Abstract Co-Author*)

PURPOSE

Ovarian malignancy is amongst leading female cancers, typically has high mortality due to asymptomatic early stage and late stage diagnosis. ACR, recently proposed ORADS ultrasound algorithms for ovarian -adnexal tumor evaluation, towards categorization and risk stratification along with specific management guidelines.European fraternity follows IOTA algorithms, applying three popular strategies (Simple Rules-SR, Simple Rules Risk Score- SRR and Assessment of Different NEoplasias in adneXa-ADNEX-Model),for similar goals.Few recently published validation studies have reported limitations in both systems.Contrast Enhanced Ultrasound (CEUS) based on tumor micro-vascularity,is a novel modality with potential to augment these algorithms,however, studies evaluating this supplementary technique with ORADS and IOTA are sparse.Therefore, purpose of this study was to compare diagnostic accuracy of ORADS, IOTA's SR, SRR and ADNEX, firstly as standalone and subsequently with CEUS combined; using histopathology results as reference standard.

METHODS AND MATERIALS

This IRB approved prospective study comprised 89 patients with 100 adnexal masses. Ultrasound tumor evaluation by ACR-ORADS and IOTA's three strategies; was followed by CEUS evaluation, using second generation contrast agent. Qualitative and quantitative CEUS parameters were combined in each case for tumor categorization. Diagnostic accuracy of algorithms was assessed as standalone and with CEUS results amalgamated.

RESULTS

Sensitivity, Specificity, PPV, NPV and Diagnostic Accuracy of standalone parameters were, ORADS, 94.83, 52.38, 73.33, 88.00 and 77.00 respectively; IOTA-SR, 85.00, 83.33, 85.00, 83.33 and 84.21 respectively; IOTA-SRR, 86.20, 71.42, 80.64, 78.95 and 80.00, respectively and ADNEX, 86.20, 90.48, 92.59, 82.61 and 88.00, respectively. For ORADS-plus-CEUS,100, 95.24, 96.67,100 and 98.00 respectively; IOTA strategies, all three, revealed identical result with CEUS combined,93.10, 92.86, 94.74, 90.70 and 93.00, respectively (Fig1). For standalone best accuracy was IOTA-ADNEX and with CEUS integrated,ORADS was best.

CONCLUSION

Addition of CEUS to ultrasound evaluation, whether ORADS or IOTA-strategies, significantly enhances diagnostic performance. Multicenter studies may be considered towards integrating CEUS into ultrasound evaluation of ovarian-adnexal masses.

CLINICAL RELEVANCE/APPLICATION

CEUS, an ultrasound technique is more economical and widely available compared to CE-MRI, especially in resource poor locations. Further, since CEUS contrast-agents are excreted through respiration, this technique can be safely applied in patients with deranged renal functions, wherein Gadolinium-CE-MRI is contraindicated.

S5-SSOB01-2 ENHANCING COMPONENTS IN MATURE CYSTIC OVARIAN TERATOMAS: ADDING DRAMA TO BENIGNITY OR JUST KEEPING RADIOLOGISTS ON THEIR TOES?

Om B. Panta, MD (*Presenter*)
Santosh Maharjan, MBBS, MD (*Abstract Co-Author*)
Karen S. Lee, MD (*Abstract Co-Author*)
Rudra P. Upadhyaya II, MD (*Abstract Co-Author*)

PURPOSE

To assess the prevalence, size, and morphological characteristics of enhancing components in mature cystic ovarian teratomas (MT) using magnetic resonance imaging (MRI).

METHODS AND MATERIALS

This single-center retrospective study analyzed pelvic MRI examinations from January 2005 to September 2023. Cases were identified through report searches for "dermoid" or "teratoma." Inclusion criteria comprised pathologically confirmed mature teratoma or fat-containing adnexal lesions with minimum 12-month stability on imaging or clinical follow-up. Two radiologists independently evaluated the images, blinded to clinical data, documenting mature teratoma characteristics (size, laterality), enhancement patterns (septal, nodular, or combined), nodular features (size, location, margin characteristics, wall angle), presence of transmural growth, and enhancement intensity relative to myometrium. Interobserver agreement for enhancement characteristics was assessed using Cohen's Kappa.

RESULTS

The study cohort included 139 patients (mean age 40.4 ± 15 years) with 154 mature teratomas, of which 124 (80.5%) were pathologically confirmed. Enhancement was observed in 89/154 (56%) mature teratomas, with nodular enhancement in 52/89 (58%) cases, septal enhancement in 23 cases (25.9%), and combined enhancement patterns in 14/89 (16%) cases. The mean largest dimension was 59.4 ± 35 mm with a mean volume of 148 ± 333 cc. Enhancing nodules demonstrated a mean largest dimension of 15.6 ± 12.3 mm and mean volume of 4.6 ± 28.8 cc, representing an average nodule-to-mature teratoma volume ratio of 2.7%. Only 11 cases (16.6%) exhibited nodules larger than 20 mm. Nodule location was predominantly split between mural (31; 47%) and intra cystic (35; 53%) positions, with no

extramural cases identified. Most nodules displayed regular margins (49; 74%), and 90% of mural nodules (28/31) formed acute angles with the wall. Enhancement patterns were either similar to myometrium (22; 33%) or less intense (43; 65.1%), with no cases showing transmural growth. Interobserver agreement was substantial for both enhancement presence (? = 0.80) and nodular enhancement (? = 0.81).

CONCLUSION

Enhancing nodular components are common in mature teratoma, however, these nodules are typically small, have regular margins and enhancement equal to or less than myometrium, with no evidence of transmural growth.

CLINICAL RELEVANCE/APPLICATION

The identification of typical characteristics of benign enhancing nodules (size less than 20 mm, volume less than 20% of the cyst volume, regular borders, and absence of transmural growth) provides radiologists and clinicians with more confident parameters for risk stratification.

S5-SSOB01-3 DIFFERENTIATING LEIOMYOSARCOMA FROM LEIOMYOMA USING MRI: CONSENSUS GUIDELINES VERSUS ALGORITHM USING ALL MRI CRITERIA

Kumaresan Sandrasegaran, MD (*Presenter*)

PURPOSE

To evaluate the algorithm published in the consensus guidelines paper by Hindman et al 1 in differentiating leiomyoma (LM) from leiomyosarcoma (LMS) and to compare this with an algorithm (henceforth called enhanced algorithm) which included contour, morphology, T1 and T2 signal, diffusion weighted (DWI) analysis and time-intensity curve analysis. Reference: 1. Hindman N, Kang S, Fournier L, Lakhman Y, Nougaret S, Reinhold C, et al. MRI Evaluation of Uterine Masses for Risk of Leiomyosarcoma: A Consensus Statement. Radiology. 2023;306(2):e211658.

METHODS AND MATERIALS

In this case-controlled retrospective study, the institutional records were searched for LMS and "atypical LM". After excluding those without pre-resection MRI, inadequate MRI or definite pathological classification, a study cohort of 137 with LM (group 1) and 28 with LMS (group 2) was derived. MRI pelvis with IV contrast were analyzed by six board-certified abdominal radiologists, blinded to pathology and clinical course. They gave a determination of LM or LMS using both the consensus guidelines algorithm and the enhanced algorithm.

RESULTS

Group 1 patients were younger than those in group 2 (median age of 46.1 vs. 54.9 years, p <0.001) and had lower serum lactate dehydrogenase (LDH) (median 190 U/L vs 288 U/L, p =0.10). Table 1 gives the breakdown of tumor sizes and ADC in groups 1 and 2. Sensitivity (95% CI in parentheses) of enhanced algorithm was 96.4% (89.6-100%), and similar to the consensus guideline algorithm 92.9% (83.3-100%). However, the specificity of enhanced algorithm was 90.5% (85.6-95.4%), and higher than the consensus guideline algorithm 75.9% (68.8-83.1%). The C-statistic (area under ROC curve) of enhanced algorithm was significantly higher than that of consensus guideline algorithm (0.817 vs. 0.715, p =0.02).

CONCLUSION

In the MRI differentiation of LMS from LM, the enhanced algorithm, using all MRI characteristics including morphology, was superior to the performance of published consensus guideline algorithm.

CLINICAL RELEVANCE/APPLICATION

Diffusion-weighted imaging forms part of the imaging criteria for differentiation of LMS from LM. However, absolute ADC thresholds may vary based on the MR protocol. Other MRI parameters, such as morphology, may be important in differentiating atypical LM, including cellular LM, from LMS.

S5-SSOB01-4 PREOPERATIVE STAGING OF UTERINE CERVICAL CANCER: TIME TO SHIFT FROM CYSTOSCOPY TO MRI

Matteo Bonatti, MD (*Presenter*)
Riccardo Valletta, MD (*Abstract Co-Author*)
Miriam Dolciami, MD (*Abstract Co-Author*)
Luca D'Erme, MD (*Abstract Co-Author*)
Vincenzo Vingiani, MD (*Abstract Co-Author*)
Evis Sala, MD, PhD (*Abstract Co-Author*)
Giacomo Avesani, MD (*Abstract Co-Author*)

PURPOSE

To evaluate the impact of MRI-defined bladder wall invasion from uterine cervical cancer (CC) on disease recurrence and overall survival.

METHODS AND MATERIALS

This IRB-approved multicenter retrospective study included 219 women who underwent MRI for local staging of histologically confirmed CC between January 2015 and December 2020. MR image analysis was independently performed by two experienced radiologists. Bladder wall invasion was diagnosed if at least three of the following criteria were met: loss of the cervix-bladder fat plane, bladder wall thickening, loss of bladder wall T2-hypointensity, and presence of endoluminal tumor growth. MRI findings were compared with endoscopy/cytology. The impact of MRI-defined bladder wall invasion (any layer) on tumor recurrence and survival was assessed using logistic regression. Survival curves for patients with and without MRI-defined bladder wall invasion were compared using the log-rank test.

RESULTS

6.4% patients had MRI stage I neoplasms, 27.9% stage II, 43.5% stage III, and 23.3% stage IV. MRI-defined bladder wall invasion was observed in 20.1% of patients. Cystoscopy revealed bladder mucosal infiltration in 9 (4.1%) cases, all of whom also demonstrated MRI-defined bladder wall invasion; no patients without MRI-defined bladder wall invasion showed mucosal infiltration on cystoscopy/urinary cytology. The median follow-up was 31 months: 47.5% of patients experienced disease recurrence, and 24.7% hade CC-related death. Logistic regression demonstrated that MRI-defined bladder wall invasion was an independent risk factor for both tumor recurrence (OR 2.46, P = 0.015) and mortality (OR 3.65, P = 0.004), whereas cystoscopy-defined bladder mucosa infiltration wasn't. The log-rank test demonstrated a significant difference in survival between patients with and without MRI-defined bladder wall invasion ($?^2$ = 5.45, P = 0.019).

CONCLUSION

MRI-defined bladder wall invasion represents an independent negative prognostic factor in patients with cervical cancer.

CLINICAL RELEVANCE/APPLICATION

MRI can safely replace cystoscopy in the preoperative staging of patients with uterine cervical cancer. Cystoscopy is unnecessary both when MRI rules out bladder invasion and when bladder wall invasion is detected on MRI. This approach can reduce costs and expedite the staging process.

S5-SSOB01-5 PRECISION SEGMENTATION OF PRIMARY EPITHELIAL OVARIAN TUMORS IN CONTRAST-ENHANCED CT: MULTI-CENTER VALIDATION, PERFORMANCE FACTOR ANALYSIS, AND RADIOMIC FEATURE ALIGNMENT

Wenyi Deng (*Presenter*)
Fuze Cong, PhD (*Abstract Co-Author*)
Jing Ren, MD (*Abstract Co-Author*)

Yonglan He, MD (*Abstract Co-Author*)
Huadan Xue, MD (*Abstract Co-Author*)

PURPOSE

To develop an AI model for automated segmentation of primary epithelial ovarian tumors (EOTs) in contrast-enhanced CT, validated across multi-center cohorts. We explored factors influencing segmentation accuracy and assessed radiomics consistency between AI and manual segmentations for reliable clinical feature extraction.

METHODS AND MATERIALS

We retrospectively collected contrast-enhanced CT scans from surgically resected and pathologically confirmed EOTs across three independent medical centers. The dataset (n=760) was partitioned into: training cohort (n = 403), internal test cohort (n = 135), and two external test cohorts (n=136/86). Expert radiologists manually delineated primary tumor lesions on portal venous phase CT images, which served as the ground truth. A 3D Res-UNet architecture was implemented for automated segmentation following nnUnet framework. Model was evaluated using Dice similarity coefficient (DSC) across all test cohorts. To identify key factors of segmentation accuracy, a multivariable linear regression model was constructed, incorporating tumor morphological, imaging acquisition, and anatomical covariates. Finally, intraclass correlation coefficient (ICC) analysis was performed to assess inter-segmentation radiomics feature stability between automated and manual annotations.

RESULTS

The automated segmentation model achieved robust performance across all test cohorts, with mean DSC of 0.925 (internal test), 0.926 (external test 1), and 0.908 (external test 2), with no statistically significant inter-cohort variation ($p=0.101$). Subgroup analysis revealed significant performance disparities across malignancy grades ($p=0.004$) and tumor volume ($p=0.009$), with superior segmentation accuracy observed in larger lesions. Multivariable regression confirmed tumor volume as a key positive predictor of model performance (ß=0.019/1000, $p<0.001$). Radiomics feature stability analysis demonstrated high consistency (ICC > 0.8) in 83.3% of features between automated and manual segmentations, particularly in original and Laplacian of Gaussian-transformed features, compared to wavelet-derived features.

CONCLUSION

The 3D Res-UNet model demonstrated high accuracy strong multi-center generalizability for EOTs segmentation, with tumor volume identified as a key factor affecting performance. Also, high radiomics feature stability is observed between automated and manual segmentations.

CLINICAL RELEVANCE/APPLICATION

This AI-driven tool standardizes ovarian tumor segmentation in CT, enhancing precision oncology workflows. High segmentation accuracy and radiomics stability enable reliable biomarker extraction for prognosis and therapy optimization in multi-center settings.

S5-STCE1-1 TEMPORAL DYNAMICS OF FERUMOXYTOL UPTAKE IN ABDOMINAL ORGANS ON MRI: A NON GADOLINIUM APPROACH

Arely Corro Sanchez (*Presenter*)
Prakash Ambady (*Abstract Co-Author*)
Lisa Muir (*Abstract Co-Author*)
Ramon F. Barajas JR, MD (*Abstract Co-Author*)

PURPOSE

Gadolinium based contrast agents (GBCAs) are the most widely used magnetic resonance imaging (MRI) agents. However individuals with chronic kidney disease (CKD) pose rare but serious risks such as developing nephrogenic systemic fibrosis (NSF), necessitating safer alternatives. Ferumoxytol (Fe) originally approved to treat iron deficiency anemia is being further investigated as a potential non-GB MRI contrast agent. Its advantages include a longer imaging window, multi-sequence detection and reduced risk of NSF. A pitfall to Fe is the systemic biodistribution and long term imaging behavior remaining poorly characterized. This study evaluates the temporal behavior of Fe on four abdominal organs: liver, spleen, bone marrow, and pancreas using MRI sequence. Initially hypothesizing rapid uptake of Fe in the body with a gradual release over time.

METHODS AND MATERIALS

Twelve patients received a single intravenous dose of Fe (= 510 mg). Abdominal T2-weighted MRIs were performed at seven intervals: pre-administration, immediately post, 24 hours, 1, 2, 3, and 6 months post administration. Regions of interest (ROIs) were placed on the liver, spleen, pancreas, and bone marrow using Visage Client software. A single-factor ANOVA was performed to assess aerial signal changes across time, followed by pairwise comparison to characterize signal progression in each organ by their mean voxel intensities tracking iron deposition and clearance patterns in order to understand organ specific iron handling.

RESULTS

The spleen showed the most significant and prolonged T2 signal reduction ($p < 0.01$), indicating a high uptake and slow clearance. The liver also represented a strong uptake but a moderate signal drop while the pancreas displayed delayed uptake, at a peak 1-2 months post administration, suggesting secondary redistribution. In comparison the bone marrow had no significant difference ($p = 0.544$) indicating low uptake or rapid clearance. Percent change was also calculated for each organ.

CONCLUSION

These findings highlight Fe's differential biodistribution along with distinct and organ specific signal behavior across abdominal organs. Fe's comparatively prolonged imaging window, and the ability for sustained signal alterations make it a great option to continue exploring as a supplementary imaging modality especially for patients with contraindications to GBCAs.

CLINICAL RELEVANCE/APPLICATION

This study contributes to insights into not just how Fe behaves systemically but also offers a foundation for optimizing imaging protocols, reducing unnecessary contrast use and informing timing for follow ups. Future studies with larger cohort groups and expanded organs analysis are warranted to further validate these findings and refine clinical protocols involving MRI.

S5-STCE1-2 MANGANESE PRUSSIAN BLUE NANOZYMES FOR MRI-VISIBLE ORAL ALCOHOL DETOXIFICATION: A NEXT-GENERATION IMAGING APPROACH

Qiuhui Hu JR, MD (*Presenter*)
Hongjie Hu, MD (*Abstract Co-Author*)
Xiaoyuan Chen (*Abstract Co-Author*)

PURPOSE

To demonstrate a next-generation MRI-monitoring platform for alcohol intoxication management, we developed an orally administered system (MPASS) combining manganese Prussian blue nanozymes (MPB) with acetic acid bacteria (AAB). MPB's high relaxivity enables real-time MRI tracking while synergizing with AAB's metabolic activity, exemplifying advanced low-contrast imaging capabilities.

METHODS AND MATERIALS

MPASS preparation MPB nanozymes were synthesized via redox-precipitation and electrostatically conjugated to AAB surfaces, with characterization by transmission electron microscope (TEM), zeta potential, and flow cytometry (FCM).In vitro studies ROS scavenging was quantified using DCFH-DA; MPB's longitudinal relaxivity (R1) was measured at 3.0T MRI; AAB metabolic activity was assessed in simulated gastric fluid (pH 2.5, 37°C) via ethanol oxidation.Animal models C57BL/6 mice with acute alcohol intoxication (5 g/kg ethanol) received oral MPASS, MPB, or PBS. Blood ethanol/acetaldehyde and hepatic oxidative markers (MDA, ALT/AST) were analyzed.MRI protocol 3.0T MRI (Discovery 750w, GE Healthcare) with T1-weighted sequences was performed pre- and post-administration (0-8 h) to quantify gastrointestinal retention.

RESULTS

Characterization TEM and zeta potential analyses confirmed the successful synthesis of MPB and formation of MPASS. Stability and activity MPASS maintained 62.47% ± 3.21% of AAB activity after 30-minute exposure to simulated gastric fluid, demonstrating significantly higher stability compared to free AAB (18.92% ± 2.45%; $p < 0.01$). In vitro assays revealed an ROS scavenging efficiency of 88.9%.MRI monitoring MPB exhibited an R1 of 4.2 ± 0.3 mM -1 s -1 (8.4-fold higher than Prussian blue). AAB-mediated mucosal adhesion enabled MPASS gastrointestinal retention for more than 6 hours (vs. 4 hours for MPB alone), confirming prolonged residence. In vivo efficacy MPASS reduced blood ethanol by 76.86% ± 5.12% within 4 h ($p < 0.001$) and decreased ALT/AST (48.7%/52.1%; $p < 0.05$).

CONCLUSION

MPASS leverages MPB's exceptional relaxivity for real-time MRI monitoring, advancing low-contrast imaging applications in metabolic therapy.

CLINICAL RELEVANCE/APPLICATION

MPASS addresses the unmet need for real-time monitoring in alcohol-related disorders. Its high-contrast MRI visibility and extended gastrointestinal retention offer a novel strategy for personalized intervention and treatment surveillance.

S5-STCE1-3 CONTRAST-FREE 3D LYMPH NODE MICROIMAGING OF THE MESOESOPHAGUS: A HIGH-RESOLUTION MRI APPROACH USING A NOVEL NEUROGRAPHY-BASED SEQUENCE

Felicitas Christine Knieper (*Presenter*)
Jan Philipp Masthoff (*Abstract Co-Author*)
Emily Hoffmann (*Abstract Co-Author*)
Sebastian Kubasch (*Abstract Co-Author*)
Mazen Juratli (*Abstract Co-Author*)
Jens Peter Holzen (*Abstract Co-Author*)
Michael Tischendorf (*Abstract Co-Author*)
Barbara Braden (*Abstract Co-Author*)
Tobias Krahling (*Abstract Co-Author*)
Andreas Pascher (*Abstract Co-Author*)
Walter Heindel, MD, PhD (*Abstract Co-Author*)
Marc-David Kunnemann (*Abstract Co-Author*)
Gesa Helen Pohler (*Abstract Co-Author*)

PURPOSE

To evaluate feasibility of high-resolution contrast-free 3D T2-weighted lymph node MRI for first in-vivo detection of lymph node hila in mesoesophageal stations and compare with axillary reference nodes in distal esophageal carcinoma patients.

METHODS AND MATERIALS

Prospectively, monocentric, 30 patients (mean age 46 ±5 years, 70% males) with distal esophageal carcinoma (>T2N1M0) underwent multiparametric MRI including contrast-free 3D T2-weighted MRI (3T Philips 7700, voxel size 0.6×0.6×1 mm^3) and T1-weighted contrast enhanced 3D Vane before treatment. Two radiologists categorized mesoesophageal lymph nodes up to 3 mm diameter stations as described by the Jap. Soc. for Esophaegal Diseases (No. 108, 110, 111, 112) and bilateral axillary reference nodes (smallest detectable size 3 mm) and quantified for: lymph node detectability, fatty hilum occurrence, diameters, nodal areas/volumina, signal intensities.

RESULTS

28 patients were examined successfully. Mesoesophageal lymph nodes were detected in 43% patients, exclusively station 110 as described. Mean short-axis diameters showed no significant differences ($p>0.05$). Technical feasibilitiy was shown by no significant differences in mean short-axis diameters. Axillary detection rates were higher (compared to no. 108, 111, 112): right 18/28 (64.3%), left 16/28 (57.1%). Fatty hila occurred in 7/28 (25.0%) mesoesophageal versus 18/28 (64.3%) and 14/28 (50.0%) axillary nodes. Crucially, in patients with detected mesoesophageal nodes, fatty hila were identified in 7/12 cases (58.3%).

CONCLUSION

First successful in-vivo demonstration of lymph node categorization and microstructure detection in mesoesophagus using contrast-free 3D MRI. Despite lower detection rates than axillary references, the technique achieved clinically meaningful hilum categorizing. This approach may enhance N-staging accuracy by providing morphological benign criteria beyond size, potentially improving selection for neoadjuvant therapy and surgical planning.

CLINICAL RELEVANCE/APPLICATION

Contrast-free 3D lymphonodular MRI offers potential for sentinel lymph node-like staging in esophageal cancer through cataloguing lymphatic stations and detection of preserved fatty hila as benign architecture indicators.

Sanjay Rajagopalan (*Abstract Co-Author*)
Sadeer Al-Kindi (*Abstract Co-Author*)
Anant Madabhushi, PhD (*Abstract Co-Author*)

PURPOSE

Population based clinical risk tools like PREVENT provide valuable estimates of cardiovascular (CV) risk but fail to account for inter-individual variability in CV resilience. Perivascular fat, particularly around the aorta, is metabolically active and reflects underlying inflammation and atherogenesis, features linked to true CV risk. We hypothesized that opportunistic radiomic profiling of peri-aortic fat on coronary artery calcium (CAC) CT could uncover hidden extremes of CV risk that are not reflected in clinical scores.

METHODS AND MATERIALS

We analyzed CAC CTs from 51,506 patients in the CLARIFY trial (NCT04075162). Peri-aortic fat was segmented as an 8 mm circumferential dilation within the adipose attenuation range and1,316 radiomic features were extracted. To identify latent imaging phenotypes, we used UMAP for dimensionality reduction followed by unsupervised clustering with HDBSCAN. SHAP (SHapley Additive exPlanations) analysis identified the most predictive features driving cluster formation. MACE-free survival was compared across clusters using Kaplan-Meier (KM) analysis, with hazard ratios (HR) and 95% confidence intervals (CI) reported. Differences in PREVENT scores and age were assessed using t-tests.

RESULTS

Clustering of peri-aortic fat radiomics identified three distinct phenotypes: a large population group (n=41,937) and two smaller subgroups (n=8,587 and n=532). SHAP analysis revealed that clustering was driven by texture heterogeneity and morphological shape. KM analysis revealed significant differences in MACE-free survival across clusters (log-rank $p<0.001$). Strikingly, one subgroup exhibited lower MACE risk despite being older (59.9 vs. 58.0 years, $p<0.05$) and having higher PREVENT scores (0.16 vs. 0.13, $p<0.001$) compared to the other (HR: 0.39, 95% CI: 0.22-0.72, $p<0.01$). This paradox, higher predicted clinical risk but lower event rates, highlights a limitation of conventional risk tools and underscores the potential of opportunistic radiomic phenotyping to uncover CV resilience.

CONCLUSION

Opportunistic radiomic phenotyping of peri-aortic fat microarchitecture from routine CAC CTs reveals hidden extremes of CV risk, uncovering biologically resilient individuals whose true risk may be overestimated by clinical models. These findings demonstrate the potential of opportunistic imaging biomarkers to personalize risk assessment and move beyond population-based averages toward individualized CV care.

CLINICAL RELEVANCE/APPLICATION

Radiomic phenotyping of peri-aortic fat reveals the PREVENT paradox—patients with higher predicted risk but low event rates—highlighting hidden CV resilience and enabling more personalized, biologically informed prevention strategies.

S5-STCE2-3 OPPORTUNISTIC SCREENING OF CHEST AND ABDOMEN CT WITH ORGAN SEGMENTATION MODEL: THE SEARCH FOR OVERSCANNING AND OVER-RADIATION

Ryan Krishna (*Presenter*)

Shivangi Jha (*Abstract Co-Author*)
Subba R. Digumarthy, MD (*Abstract Co-Author*)
Mannudeep K. Kalra, MD (*Abstract Co-Author*)
Aarushi Innanje (*Abstract Co-Author*)
Yash Saboo (*Abstract Co-Author*)

PURPOSE

CT-based organ segmentation models (OSM) offer the possibility of opportunistic screening for the presence and quantification of over-scanning and over-radiation. We modified and tested an OSM-based opportunistic screening AI model to estimate the frequency and magnitude of overscanning in chest (CCT) and abdomen-pelvis abdomen-pelvis CT (APCT) exams.

METHODS AND MATERIALS

With IRB approval, our study included 2674 consecutive adult patients (age range >18 years) who underwent CCT or APCT for emergent and non-emergent clinical reasons. In addition, we used 20 APCT exams from The Cancer Imaging Archive (TCIA) to manually mark the precise location of the pubic symphysis (3D Slicer) and the top of femoral heads (TotalSegmentator) and train an AI model with the Ultralytics YOLO11 backbone to identify the pubic symphysis and output its section location. We

embedded OSM (TotalSegmentator) into the model to identify and find z-position for the remaining anatomic landmarks for APCT (femoral head and top of liver and spleen) and CCT (lung apices, adrenals, top of kidneys). Two study coinvestigators reviewed each anatomic landmark on all 2675 CTs to check for correct and incorrect landmark recognition, cranial and caudal underscanning (landmarks not included in scan range) and overscanning (scan range >3 cm beyond landmarks). Data were analyzed with mixed model linear tests, descriptive analyses, and box-whisker plots.

RESULTS

Our model successfully identified anatomic landmarks for overscanning in > 99% CCT and APCT exams (2668/2674 CTs). Caudal overscaning was greater in both frequency and magnitude than cranial over-scanning for both CCT (24.6% vs. 9.9%; 14 ± 14 mm vs. 10 ± 13 mm) ($p<0.001$) and APCT (98.4% vs. 36.3%; 45 ± 25 mm vs. 5 ± 10 mm) ($p<0.001$). Underscanning was reported in 0.98 % APCT (11/1119) and 1.4 % CCT (22/1555). Without thresholding, overscanning was associated with 13.6% and 21.9% extra radiation dose for CCT and APCT, respectively.

CONCLUSION

Organ segmentation models can be modified for accurate opportunistic screening of overscanning in chest and abdomen CT which is important for estimating over-radiation.

CLINICAL RELEVANCE/APPLICATION

Our OSM-based, open-access opportunistic screening model automates estimation of overscaning with display of summary statistics and graphic display of findings; these can help reduce overscanning, radiation dose, and risk of incidental findings detection.

PURPOSE

To identify imaging and clinical features predictive of interstitial lung abnormality (ILA) progression to idiopathic pulmonary fibrosis (IPF), and to validate a risk stratification model across multiple international cohorts.

METHODS AND MATERIALS

This retrospective, multi-center study included 743 patients with CT-detected ILA, of whom 220 progressed to IPF (high-risk) and 523 did not (low-risk). Model development used 220 high-risk cases and 100 low-risk cases with at least five years of imaging stability. Key imaging features (subpleural fibrosis, cranial and central fibrosis, anterior lung involvement, moderate-to-severe emphysema) and demographics (age, sex) were assessed by univariate and multivariate logistic regression. Model performance was evaluated using AUC and externally validated on four independent cohorts (n = 277 total).

RESULTS

Univariate analysis showed strong associations with high-risk ILA: subpleural fibrosis (OR 7.55, $p < 0.0001$), cranial extent (OR 19.4, $p < 0.0001$), central extent (OR 32.2, $p < 0.0001$), anterior involvement (OR 23.6, $p < 0.0001$), and emphysema (OR 3.13, $p = 0.003$). In multivariate analysis, central fibrosis (OR 10.78, $p < 0.001$) and anterior involvement (OR 5.92, $p < 0.001$) remained independently predictive. Internal validation achieved an AUC of 0.915. External validation showed AUCs of 0.922, 0.935, and 0.812 across three cohorts. In a fourth cohort composed entirely of high-risk cases, sensitivity and PPV were both 96.8%.

CONCLUSION
