RF heating was measured near the electrodes of deep brain stimulation (DBS) lead placed in a gel phantom using fluoroptic temperature probes in a commercial 3T scanner during MRI. Four transmit and receive RF coil combinations were used, a circularly polarized head transmit and receive coil, a 20-channel head and neck, a 32-channel head, or a 64-channel head and neck receive-only coil with a whole-body transmit coil. RF heating was induced by running a 2D GRE sequence with two RF pulse types (fast and normal) with varying flip angles of 30, 60, and 90 degrees and by turning the receive-only coils off and on. The scanner-reported B1+rms and RF power were recorded.

**RESULTS**

Measurements show that the induced temperature change (dT) correlated linearly with both the scanner-reported RF power and the square of the B1+rms for each coil combination. However, the variation in the induced heating for various RF coil combinations appeared to be much larger for the scanner-reported B1+rms compared to the scanner-reported RF power.

**CONCLUSION**

Additional studies across other MR scanners are needed to better understand the full extent of the variation in the induced heating near implanted conductive devices as a function of the scanner-reported B1+rms and RF power to develop conservative and reliable patient labeling.

**CLINICAL RELEVANCE/APPLICATION**

RF-induced heating near implants, RF transmit power and B1+rms depend on the combinations of RF coils routinely used in radiological practice and must be considered for imaging patients with implants safely.

## T5A-SPNR-15 OPTIC RADIATION MICROSTRUCTURAL TISSUE DIFFERENCES IN PEDIATRIC ANTI-MOG DISEASE AND MULTIPLE SCLEROSIS WITH OPTIC NEURITIS

Navoda Perikala, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

Pediatric optic neuritis (PON) is a predominant manifestation of many pediatric demyelinating diseases but varies broadly in clinical disability. Patients with myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) have similar degrees of optic nerve injury as those with multiple sclerosis (MS), but comparatively better visual outcomes. We hypothesize that this may be attributed to tissue microstructural differences in the retro-chiasmatic visual pathway, occult to fundoscopic examination and optical coherence tomography (OCT). The goal was to address limitations of current clinical tools in characterizing visual pathway disease burden in MOGAD and MS patients with PON by using advanced diffusion and myelin-sensitive MR imaging.

**METHODS AND MATERIALS**

We evaluated focal lesions and normal appearing white matter (NAWM) in the optic radiations (OR) of 25 adolescent subjects with PON and either MS or MOGAD using multi-shell diffusion (neurite orientation dispersion and density index [NODDI]) and myelin (macromolecular tissue volume [MTV]) imaging techniques. We calculated MRI-based estimates for microstructural tissue integrity with myelin volume fraction (MVF) from MTV, neurite density index, and the g-ratio, which serves as a biomarker for the relative degree of axon myelination. Using the unpaired t-test and Wilcoxon rank sum, we compared means of G-ratio, MVF, and NDI for focal lesions and NAWM along the OR.

**RESULTS**

We found the g-ratio to be significantly greater in MS lesion and NAWM when compared to MOGAD. The significantly greater g-ratio in MS indicates disproportionately greater myelin loss in OR compared to MOGAD and supports the existing pattern of differences in vision outcome.

**CONCLUSION**

Through advanced diffusion and myelin-sensitive imaging, we found that MS patients with PON have a greater demyelinating disease burden in their OR compared to MOGAD patients. We show the utility of the g-ratio in advanced MRI as a sensitive and non-invasive marker of pathology with potential application in treating PON.

**CLINICAL RELEVANCE/APPLICATION**

The importance of this finding is in its potential to aid in predicting progression of visual outcomes in patients with pediatric demyelinating disease by combining the g-ratio, diffusion, and myelin-sensitive MR imaging. In PON, early recognition of findings associated with higher likelihood of progression to MS help to distinguish among alternate diagnoses, minimize delay in treatment, mitigate subsequent attacks and reduce the likelihood and extent of permanent vision loss.

## T5A-SPNR-16 3D CATHETER TIP SHAPE ENABLES SELECTION OF LEFT VERTEBRAL ARTERY VIA RADIAL ACCESS

Scott B. Raymond, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nathan T. Franssen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

While the use of radial access in neurointervention is increasingly popular, some tasks such as selection of the left vertebral artery, are much more difficult than the traditional femoral access, with failure rates approaching 50% {1}. A 3D catheter shape should make it easier to select the left vertebral artery from a right radial approach. We tested a series of different tip shapes to determine the optimal orientation for left vertebral artery selection.

**METHODS AND MATERIALS**

We used the standard Simmons 2 glide catheter (Microvention; Aliso Viejo, California) as a base model and created variant catheters using computer aided design (CAD, Onshape; Boston, MA). We rotated the distal tip 90, 180 and 270 degrees to make 3 new tip shapes (c90, c180, and c270). Their performance was tested in a silicone vascular phantom approximating human anatomy including a right radial approach (Mentice; Gothenburg, Sweden). The silicone-aortic arch was 3D printed using a patient CTA from our human arch database {2}, selected for type-I geometry and median size/shape characteristics. Up to 6 operators tested 4 catheters on three tasks: left vertebral artery selection, reforming at the arch with a wire, and reforming without a wire. Trials were video recorded and scored for speed and accuracy.

**RESULTS**

In our aortic arch model, selection of the left vertebral artery was challenging, with only one success out of 70 attempts using the Simmons 2 catheter (control). The success rate with the 3D variants ranged from 26-93%, best for the c90 variant. The average time to select the left vertebral artery was 80, 17.3, 36.1, and 18.2 s for the Simmons 2, c90, c180, and c270 catheters respectively. The variant catheters were easily reformed at the arch using standard technique without a wire, with average times ranging from 6.9 - 8.2 s with no statistical difference between catheters. The c90 and c180 variants were much harder to reform using the wire, averaging 30.1 and 27.2 s compared to 11 s for the Simmons.

**CONCLUSION**

Catheter shape affects performance of different tasks and there are tradeoffs when shape is optimized for a specific task. A 3D catheter shape with the tip rotated out of plane (c90) simplifies selection of the left vertebral artery from a right radial approach while remaining easy to reform in the aortic arch without a wire.

**CLINICAL RELEVANCE/APPLICATION**

Some tasks such as selection of the left vertebral artery via right radial are much more difficult than the traditional femoral access. A 3D catheter shape makes it easier to select the left vertebral artery from a right radial approach.

## T5A-SPNR-17 DIFFERENT BRAIN STRUCTURAL AND FUNCTIONAL MECHANISMS FOR COGNITIVE FUNCTION AND GAIT CHARACTERISTICS IN IDIOPATHIC NORMAL PRESSURE HYDROCEPHALUS

Zhang Zhang (*Abstract Co-Author*) Nothing to Disclose
Huijie Yu (*Abstract Co-Author*) Nothing to Disclose

Zeyang Yu (*Abstract Co-Author*) Nothing to Disclose
Wenjin Zhao (*Abstract Co-Author*) Nothing to Disclose
Chen Zhang (*Abstract Co-Author*) Nothing to Disclose
Che Zhang (*Abstract Co-Author*) Nothing to Disclose
Ningnannan Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Yunfei Zhao (*Abstract Co-Author*) Nothing to Disclose
Han Zhang (*Abstract Co-Author*) Nothing to Disclose
Jie Sun, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To identify the brain structural and functional abnormalities related to potential idiopathic normal pressure hydrocephalus (iNPH) before and after the cerebrospinal fluid (CSF) tap test, aiming to understand iNPH pathophysiology with different clinical phenotypes of responders.

**METHODS AND MATERIALS**

Thirty iNPH patients (age 67.6±4.8 year-old; nine females) were underwent MR scan before tap test, included 3D T1WI and T2WI, pseudo-continuous arterial spin labeling, and phase-contrast cine MR imaging. The clinical indicators such as mini-mental state examination (MMSE), the Timed Up and Go (TUG) test, 10-meter walk test, 180° and 360° Spin Test were collected before and 24h after CSF tap test.

**RESULTS**

Before/after the tap test, MMSE scores were positively correlated with global gray matter volume (GMV) and negatively correlated with CSF volume. Besides, GMV in parietal, temporal, and occipital lobes were positively correlated with MMSE scores before test. Specifically, the whole brain GMV was positively correlated with MMSE improvement after tap test. The cerebral blood flow (CBF) in lenticular nucleus before tap test were negatively correlated with spin test and TUG; while the length of midbrain tegmentum diameters and the temporal horn diameters were positively correlated with 10-meter walk test. After tap test, aqueductal CSF stroke volume and net flow volume and the temporal horn diameters were positively correlated with TUG. Additionally, the rates of TUG improvement were positively correlated with global and parietal lobe white matter volume, and the reverse average velocity. Furthermore, reverse average velocity was found to be an independent factor for TUG improvement (ß = 0.696, P = 0.048, 95%CI: 0.008, 1.384).

**CONCLUSION**

Our results suggest the presence of a clinical phenotype-dependent brain structural and functional mechanism in iNPH. Patients with no significant cognitive improvement after tap test exhibit more severe global cerebral atrophy. On the other hand, the impact on gait is in a regional distribution pattern but comprehensive, involving regional CBF in basal ganglia, parietal lobe white matter volume and aqueductal CSF flow parameters.

**CLINICAL RELEVANCE/APPLICATION**

The tap test, which serves as an effective pre-evaluation method, has already been implemented as the strong evidence for cerebrospinal fluid shunt surgery. However, this study showed the improvement of cognitive and gait following the tap test is heavily reliant on brain imaging. Therefore, it is important to fully consider the clinical phenotype-dependent brain structural and functional mechanism to determine whether it truly bring surgery benefits for individual iNPH patients.

## T5A-SPNR-18 DIFFUSION MRI AND BIOPHYSICAL MODELING FOR LINKING WHITE MATTER MICROSTRUCTURE AND DISABILITY IN MULTIPLE SCLEROSIS

Benjamin Ades-Aron, PhD (*Abstract Co-Author*) Stockholder, Microstructure Imaging Inc
Els Fieremans, PhD (*Abstract Co-Author*) Scientific Advisory Board, Microstructure Imaging, Inc;Stockholder, Microstructure Imaging, Inc;Royalties, General Electric Company
Dmitry S. Novikov, PhD (*Abstract Co-Author*) Scientific Advisor, Microstructure Imaging, Inc;Stockholder, Microstructure Imaging, Inc
Santiago Coelho, PhD (*Abstract Co-Author*) Nothing to Disclose
Timothy M. Shepherd, MD, PhD (*Abstract Co-Author*) Co-founder, MICroStructure Imaging
Ilya Kister (*Abstract Co-Author*) Nothing to Disclose
Filip Szczepankiewicz, PhD (*Abstract Co-Author*) Nothing to Disclose
Valentin N. Stepanov, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to elucidate the cellular pathology of white matter (WM) underlying cognitive and motor decline in Multiple Sclerosis (MS) using diffusion MRI biophysical modeling (the Standard Model (SM), in combination with conventional diffusion tensor imaging (DTI) and diffusion kurtosis imaging (DKI)).

**METHODS AND MATERIALS**

This IRB-approved study enrolled 85 MS patients (64 females, mean age 48 ± 11.4 years, median EDSS 3 ± 2.3). Cognitive and motor functions were assessed using the Symbol Digit Modalities Test (SDMT), Expanded Disability Status Scale (EDSS) and the 25-foot walk test (FWT). MRI was performed on 3T Siemens Prisma, and included multi-shell diffusion MRI (2mm isotropic resolution). The following SM maps were generated: (axonal water fraction [f], free water fraction [fw] , intra-axonal diffusivity [Da] , extra-axonal axial/radial diffusivities [De||/De_perp], fODF anisotropy [p2] intra/extra-axonal T2 [T2a/T2e]) in addition to conventional DTI (axial -AD, mean -MD and radial -RD diffusivities and fractional anisotropy -FA) and DKI (axial -AK, mean -MK and radial -RK kurtosis) metrics. Average values were extracted from corona radiata and corpus callosum using registration to the JHU atlas. Spearman rank tests were performed, adjusted for age at disease onset, with correlation coefficients (?) reported, and significance set at $p < 0.05$.

**RESULTS**

For cognitive function, AD, RD and MD showed consistent negative correlations with SDMT (-0.46, -0.46, -0.40 respectively), while MK and RK correlated positively (0.43, 0.44). SM metrics T2e and fw negatively correlated with SDMT (-0.50, -0.46), suggesting edema. Positive correlation with f (0.41) was indicative for axonal loss. For motor function, the alternative metric FWT demonstrated the strongest correlations: Da in the corticospinal tract (-0.41) indicative for axonal swelling, and both T2e (0.42) and De|| (-0.40) in the corpus callosum suggested gliosis. Conversely, the EDSS showed weaker correlations with SM metrics, such as f (-0.33) in the posterior corona radiata and extra-axonal diffusivity perpendicular to the axon De_perp (0.34), indicative of demyelination.

**CONCLUSION**

Diffusion MRI, enhanced by biophysical modeling using the Standard Model (SM), provides specificity to different white matter pathological processes changes underlying both cognitive and motor declines in MS.

### CLINICAL RELEVANCE/APPLICATION

Our findings suggest that incorporating advanced diffusion metrics, especially the SM, could improve the sensitivity and specificity of MRI in monitoring MS, potentially influencing therapeutic decision-making and patient management.

## T5A-SPNR-19 A MACHINE LEARNING-DRIVEN MODEL TO IDENTIFY FREEZING OF GAIT IN INDIVIDUALS WITH PARKINSON'S DISEASE

Virendra Mishra, PhD (*Abstract Co-Author*) Nothing to Disclose
Gaurav Nitin Rathi, MS (*Presenter*) Nothing to Disclose

### PURPOSE

To identify predictive MRI biomarkers of freezing of gait (FoG) in individuals with Parkinson's Disease (PD) using T1-weighted MRI data and machine learning techniques.

### METHODS AND MATERIALS

Thirty-seven participants, including 16 PD-FoG (4 females) and 21 PD-nFoG (7 females), underwent a standard 1mm3 T1-weighted MRI on a 3T Siemens Skyra scanner. In addition, age (PD-FoG: 68.81± 6.56 years; PD-nFoG: 69.05±6.68 years), sex, handedness (PD-FoG: 1 left-handed; PD-nFoG: 3 left-handed), and years of education (PD-FoG: 15.19± 2.29 years; PD-nFoG: 15.76±2.95 years) were matched between the groups. FreeSurfer-7 was used to estimate various measures, such as subcortical volume, cortical volume, cortical mean curvature, cortical area, cortical local gyrification index (LGI), and cortical thickness from different regions of interest (ROIs). Thirteen PD-FoG and 15 PD-nFoG participants were included in the discovery cohort, and 3 PD-FoG and 6 PD-nFoG participants made up the independent testing cohort. To predict PD-FoG, three machine learning models: the Random Forest Classifier, the Support Vector Machine (SVM) with Linear Kernel, and the Support Vector Machine (SVM) with Non-Linear (RBF) Kernel—were trained on the chosen biomarkers from the LASSO regression over the discovery cohort for a total of 127 combinations of various measures from different ROIs along with the clinical measurements (Affected Side, Levodopa Equivalent Doses, MDS-Unified Parkinson's Disease Rating Scale-III (OFF-state), Disease Duration). The most appropriate biomarkers from each category of brain measures were chosen using LASSO regression, to decrease the high-dimensional biomarker space. Area Under the Curve (AUC), precision, sensitivity (recall), and specificity were the metrics used to assess the trained models' performance on the independent testing cohort.

### RESULTS

LGI from 25 ROIs could differentiate PD-FoG from PD-nFoG with an AUC of 0.75, 83.33% precision (7/9 PD-Fog/nFoG), 83.33% sensitivity (5/6 PD-nFoG), 67.77% specificity (2/3 PD-FoG). A significant correlation between the identified biomarkers and the clinical measures was observed using multivariate statistics.

### CONCLUSION

Our study demonstrates the potential of LGI from volumetric ROIs to identify PD-FoG.

### CLINICAL RELEVANCE/APPLICATION

Identifying the biomarkers that could identify PD-FoG individuals using routine MRI and our proposed ML algorithm aids clinical accuracy. It enhances the understanding of the pathophysiology of poorly understood PD-FoG.

## T5A-SPNR-3 DIFFUSION TENSOR IMAGE ANALYSIS ALONG THE PERIVASCULAR SPACE OF BRAIN GLYMPHATIC SYSTEM ABNORMALITIES IN MESIAL TEMPORAL LOBE EPILEPSY

Qiang Xu (*Abstract Co-Author*) Nothing to Disclose
Jianrui Li (*Abstract Co-Author*) Nothing to Disclose
Guangming Lu (*Abstract Co-Author*) Nothing to Disclose
Zhiqiang Zhang, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Fang Yang (*Abstract Co-Author*) Nothing to Disclose
Zhaojie Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the functional differences of the brain glymphatic system (GS) between patients with medial temporal lobe epilepsy with hippocampal sclerosis (mTLE-HS) and healthy controls and between different seizure types using DTI-ALPS, and to analyze the correlation between GS function and the course of disease, and to predict the surgical outcomes.

### METHODS AND MATERIALS

A total of 171 patients with mTLE-HS who were treated at our hospital, from July 2009 to July 2021 were retrospectively enrolled, and 75 healthy volunteers were included as healthy control group. The MPRAGE and DTI sequence images were collected, and the cerebrospinal fluid volume was segmented and calculated using the VBM analysis method. The ALPS index of bilateral brain was calculated using the Atlas-based DTI-ALPS method. Independent sample t test was used to compare the differences between mTLE-HS group and HC group, and between different seizure types. Pearson correlation analysis was performed between bilateral ALPS index and disease duration. ROC curve was used to evaluate the diagnostic value of ALPS index for surgical outcome, and the predictive efficacy was tested by leave-one-out cross-validation between patients with good and poor surgical outcomes.

### RESULTS

The ALPS index was significantly lower in the patient group than in the control group. The ALPS index on the affected side of patients with secondary generalized seizures was significantly lower than that of patients with only partial seizures. There was no significant difference between the healthy sides of patients with different seizure types. There was a significant negative correlation between the bilateral ALPS index and the disease duration in LHS patients, but no significant correlation between the bilateral ALPS index and the disease duration in RHS patients. The DTI-ALPS index has a good diagnostic and predictive efficacy for surgical outcomes. The AUC of ALPS index on the affected side for the classification of surgical efficacy was 0.778, and the accuracy of leave-one-out cross-validation was 70.3%.

### CONCLUSION

The patients with mTLE-HS have brain glymphatic system dysfunction, and the degree of damage is related to the type of seizure and the course of epilepsy. ALPS index, which characterizes GS function, has good predictive and prognostic efficacy for surgical outcomes.

### CLINICAL RELEVANCE/APPLICATION

Our study demonstrates the robustness of DTI-ALPS method. GS function may serve as a potential feature of postoperative seizure free. Combining GS function may not only improve the prediction model of surgical efficacy, but also provide new objective quantitative indicators for the diagnosis and treatment of epilepsy patients, and accelerate the clinical transformation of brain imaging science.

## T5A-SPNR-8 TRANSIENT SYMPTOMS EXPERIENCED DURING SONICATION WHILE UNDERGOING MAGNETIC RESONANCE-GUIDED FOCUSSED ULTRASOUND (MRGFUS) THALAMOTOMY FOR MEDICALLY REFRACTORY TREMOR

Lubdha M. Shah, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Shervin Rahimpour (*Abstract Co-Author*) Nothing to Disclose
Samantha Yost, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the spectrum of transient symptoms experienced by patients undergoing magnetic resonance-guided focused ultrasound (MRgFUS) thalamotomy at the time of sonication.

### METHODS AND MATERIALS

Patients with essential tremor or tremor-dominant Parkinson's disease undergoing MRgFUS treatment, were prospectively included. Exclusion criteria included hearing impairment, and difficulty communicating. Immediately after each sonication, patients were asked to describe any sensations they experienced (e.g., heat, pain, vertigo, pressure) and to numerically rate (i.e. 1-10).

### RESULTS

26 patients (81% male, mean age 73[± 8]) were included in the analyses. During the treatment sonications, 62% experienced heat, 65% experienced pain, 69% experienced vertigo and 46% experienced pressure. Commonly, heat was experienced along the forehead (50%) and pain in the temporal regions (53%). Of those that experienced vertigo, 61% and 27% had backward and forward rotation sensation, respectively. The mean intensity of the sensation for each category was 4.5 (±2.1) for heat, 4.0 (± 1.9) for pain, 3.6 (±1.7SD) for vertigo and 2.75 (±2.2SD) for pressure.

### CONCLUSION

Patients undergoing MRgFUS experience transient vertigo and pain during sonications. Heterogeneity in FUS lesion location and subjective perception may explain the differences in evoked sensations between patients and will be further studied.

### CLINICAL RELEVANCE/APPLICATION

MRgFUS is a common procedure for drug-refractory tremor as well several other emerging indications. Patients may experience transient and sometimes uncomfortable symptoms during treatment that may lead to aborting therapy. Symptoms include heat, pain, nausea, vertigo, and pressure. Little is known regarding the frequency and likelihood of these symptoms. More knowledge as to why and how often patients experience such transient symptoms could help in the consenting process with the goal of adjusting protocol to help patients complete their treatment.

## T5A-SPOB-4 MRI-BASED ENSEMBLE MACHINE LEARNING APPLICATION FOR EVALUATING INTRAOPERATIVE BLOOD LOSS IN PATIENTS WITH SUSPECTED PLACENTA ACCRETA SPECTRUM

Guang Yang (*Abstract Co-Author*) Research Consultant, Shanghai Colorful Magnetic Resonance Co, LtdResearch partner, General Electric Company
He Zhang (*Abstract Co-Author*) Nothing to Disclose
Qi Zhang (*Abstract Co-Author*) Nothing to Disclose
Xiaoyun Liang (*Abstract Co-Author*) Nothing to Disclose
Wenyi Yue (*Abstract Co-Author*) Nothing to Disclose
Ruxue Han (*Abstract Co-Author*) Nothing to Disclose
Haijie Wang (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to establish a predictive model for intraoperative blood loss (IBL) in pregnancies complicated by Suspected Placenta Accreta Spectrum (PAS) which could substantially guide delivery planning, facilitate transfusion requirements and reduce maternal risks.

### METHODS AND MATERIALS

From January 2015 to December 2023, 538 patients underwent MRI due to suspected PAS were retrospectively retrieved from two medical centers. All patients underwent cesarean delivery. Images from 1.5T and 3.0T MR scanners were examined and Estimated Blood Loss (EBL) and postpartum PAS diagnosis were obtained from medical records. All visible placental tissue was marked by two radiologists. We built an ensemble machine learning framework includes four classifiers, Elastic Net, Support Vector Regression (SVR), Random Forest (RF) and Convolutional Neural Networks (CNN) to predict EBL. The Center 1 data was randomly divided into a training set (n=358) and an internal test set (n=154). The Center 2 data was used as an external test set (n=26). We processed the data using a radiomics pipeline adhered to IBSI standards for feature extraction, normalization, and selection. DenseNet architecture was chosen as the CNN model. Severity of EBL was divided into three categories: moderate (EBL <= 1000 ml), severe (EBL 1000-2000 ml), and extremely severe (EBL >= 2000 ml). We optimized hyperparameters of algorithms with ranges. Clinical features including maternal age, gravidity, parity, gestational week and placenta position were used to build a clinical model. The scores from different algorithms were used to train an ensemble model with 5-fold cross-validation. Mean Absolute Error (MAE) and triple classification accuracy (ACC) were used to quantify the calibration of the models. The Spearman correlation coefficient and p-value between the predicted IBL and observed EBL were computed to quantify the discriminative power.

### RESULTS

Clinical model achieved a Spearman r of 0.55 (ACC=0.81) and 0.29 (ACC=0.33) in the internal and external test sets, respectively. With substantial predictive capability, our ensemble model demonstrated a significant correlation with patient outcomes (internal set: r=0.60, ACC=0.85; external set: r=0.63,ACC=0.64). The correlation between the predicted blood loss and EBL was shown.

### CONCLUSION

Our research introduces a sophisticated, integrative machine learning model for the precise prediction of IBL in PAS-suspected patients and helps guide delivery planning.

### CLINICAL RELEVANCE/APPLICATION

Our frame work helps guide delivery planning, facilitate transfusion requirements and reduce maternal risks.

## T5A-SPPD-1 TIPS IN PEDIATRIC PATIENTS: COMPARISON BETWEEN THE STANDARD TRANSJUGULAR APPROACH AND HYBRID PERCUTANEOUS TECHNIQUES

Francesco S. Carbone, MD (*Abstract Co-Author*) Nothing to Disclose
Riccardo Muglia (*Abstract Co-Author*) Nothing to Disclose
Ludovico Dulcetta, MD (*Abstract Co-Author*) Nothing to Disclose
CLAUDIO SALLEMI (*Abstract Co-Author*) Nothing to Disclose
Sandro Sironi, MD (*Abstract Co-Author*) Nothing to Disclose
Paolo Marra, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare technical success, safety and clinical outcomes of TIPS performed with conventional technique or assisted by percutaneous approach in pediatric patients and young adults with altered anatomy.

### METHODS AND MATERIALS

From January 2019 consecutive pediatric patients or young adults with native liver or split liver grafts undergoing TIPS were retrospectively reviewed. Patients were retrospectively allocated to group A if they underwent TIPS through a standard transjugular approach; to group B if they underwent TIPS aided with a percutaneous approach, either transhepatic or transplenic, including the gun-sight technique. Technical success in terms of correct TIPS placement, safety in terms of complications and clinical outcomes in terms of bleeding and ascites control were assessed and compared between groups.

### RESULTS

Sixteen patients underwent TIPS placement due to portal hypertension and variceal bleeding (n=10), portal vein thrombosis (n= 4), Budd-Chiari syndrome (n=1) or refractory ascites (n=1). Out of 6 patients with portal vein thrombosis, 4 were affected by chronic portal vein thrombosis and cavernous transformation, who failed percutaneous portal vein recanalization or surgical meso-rex shunt. In 2 cases TIPS was a bridge to liver transplant. In group A, 8 patients (n= 4 with regular anatomy; n=3 with cavernoma; n=1 with Budd-Chiari) successfully underwent TIPS with septic shock in 1 patient with cavernoma and portal biliopathy. In group B, 8 patients (n=4 with regular anatomy; n=4 with cavernoma) successfully achieved TIPS creation with severe bleeding and precipitating liver failure in 1 case that was managed with urgent liver transplantation. No technical failures were recorded. Clinical outcome was good in all patients. Despite the median age did not differ between groups, group B included 3 patients with the lowest age (1, 2 and 4 year-old) and a higher prevalence of altered anatomy.

### CONCLUSION

Hybrid percutaneous techniques for TIPS creation provide high technical and clinical success rates with a complication rate comparable to the standard approach. In pediatric patients and altered anatomy transhepatic- and transplenic-assisted TIPS may be considered.

### CLINICAL RELEVANCE/APPLICATION

Advanced techniques and alternative percutaneous approaches for TIPS creation may provide good outcomes in small pediatric patients and young adults with altered anatomy.

## T5A-SPPD-3 STRUCTURAL ASSESSMENT AND ASIA IMPAIRMENT SCALE PREDICTION IN PEDIATRIC SPINAL CORD INJURIES: INTEGRATING IMAGING PARAMETERS AND DEEP LEARNING METHODS

Sara Naghizadehkashani (*Abstract Co-Author*) Nothing to Disclose
Zahra Sadeghi Adl, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

Spinal cord injuries (SCI) in pediatric populations present unique challenges in diagnosis and prognosis due to the ongoing development of the central nervous system. Accurate assessment of structural changes in the spinal cord is essential for effective treatment planning. The International Standards

for Neurological Classification of Spinal Cord Injury (ISNCSCI) rating offers a standardized framework for evaluating the severity of spinal cord injury. This study aimed to use high resolution MRI images to assess structural changes in pediatric SCI by comparing cross-sectional area (CSA), anterior-posterior (AP) width, and right-left (RL) widths between typically developing (TD) and SCI subjects. Additionally, the study aimed to utilize these structural measures, alongside deep learning methods, to detect SCI subjects and predict their ASIA Impairment Scale category.

**METHODS AND MATERIALS**

Sixty pediatric subjects (ages 6-18), including 20 SCI patients and 40 TD controls, were enrolled, and scanned on a 3T scanner. All SCI subjects underwent ASIA tests to assess their neurological function and determine their ASIA Impairment Scale category. T2-weighted MRI scans were utilized to measure CSA, AP width, and RL widths along the entire cervical and thoracic cord. These measures were automatically extracted at every vertebral level using the SCT toolbox. Deep learning techniques, particularly convolutional neural networks (CNN), were utilized to classify subjects into SCI/TD groups and predict their ASIA Impairment Scale based on structural parameters.

**RESULTS**

Significant differences ($P<0.05$) in all the structural measures were observed between SCI and TD subjects, reflecting structural alterations associated with SCI. The CNN-based models achieved an accuracy of 96.59% in classifying subjects into TD/SCI groups. Furthermore, integrating structural parameters with deep learning models enabled prediction of ASIA impairment scale categories with 94.92% accuracy.

**CONCLUSION**

This study demonstrates the utility of integrating cross sectional structural imaging measures with deep learning for pediatric SCI assessment. The findings underscore the potential of this approach in enhancing diagnostic accuracy and prognostic capabilities, improving patient care and outcomes in pediatric SCI management.

**CLINICAL RELEVANCE/APPLICATION**

This study will advance neuroimaging as a biomarker for SCI. With objective imaging biomarkers, decisions about treatment paradigms could be tailored to individuals. The ability to predict outcomes SCI with greater degree of certainty would also guide rehabilitation therapies and allow for better clinical trial design and efficiency by optimizing patient stratification.

### PURPOSE

The exposure index (EI) gives an important real-time feedback mechanism for imaging technologists to identify the appropriateness of detector plate exposure. This study explored the feasibility of establishing diagnostic reference levels (DRLs) based on EI.

### METHODS AND MATERIALS

A method was developed to normalize system reported clinical EI values to a nominal (EIdet) value corresponding to the detector air kerma (Kdet) from the Automatic Exposure Control (AEC) system under a set of uniform field conditions. A procedure for estimating EIdet, which utilized an RQA-5 filter, was built to account for the dependence of EIdet on x-ray tube potential and correct for density and/or AEC speed adjustments. Clinical EI data was collected for each unit using machine-produced exposure log files and was sorted by Bucky, body part, view, and AEC settings including speed, density, and active imaging cells. Eight protocols with seven different body parts were examined in this study.

### RESULTS

Over thirty-seven thousand images from twenty-five x-ray systems of six different equipment manufacturers were included in this study. The results demonstrate that clinical EI (EIclinical) varies significantly ($p<0.05$) with body part, view, and manufacturer for comparable Kdet. Normalized ratios (Rnorm = EIclinical/EIdet) measured in this study may be used to correct for these factors and convert clinical EI values to EIdet.

### CONCLUSION

The utilization of EI as a DRL quantity requires unique context, separating it from other DRLs which are more straight-forward in their derivation. The potential of converting clinical EI values to EIdet via measured Rnorm and utilizing EIdet as a DRL is promising but should be explored further to define nuances associated with AEC characterization.

### CLINICAL RELEVANCE/APPLICATION

DRLs play a key role in radiology protocol optimization. While the current presence of EI in the clinic lends itself as a promising DRL quantity, there are many ill-defined factors affecting this EI value that must first be characterized. This work defines these factors, developing a full understanding of EI clinical application in representation of standard DRL values.

## T5A-SPPH-10 USEFULNESS OF THE SECOND-GENERATION WHOLE-HEART MOTION CORRECTION ALGORITHM (SSF2) IN FURTHER IMPROVING CLARITY AND DIAGNOSTIC CONFIDENCE FOR CORONARY STENT OF CORONARY CT ANGIOGRAPHY

Jianying Li, PhD (*Abstract Co-Author*) Employee, General Electric Company
Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Tingting Qu (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the usefulness of the second-generation whole-heart motion correction algorithm (SSF2) on further improving image quality and diagnostic confidence of coronary stent in coronary CT angiography (CCTA) compared to the first-generation motion correction (SSF1).

**METHODS AND MATERIALS**

A total of 51 patients (with 70 stents) underwent CCTA were included, and images were generated with both SSF1 and SSF2. Subjective scoring (5-point method) and objective evaluation were performed. Subjective evaluation included the severity of stent motion artifacts, clarity of stent display, and diagnostic confidence within the stent. Objective evaluation included CT and SD values of the fat outside the stent with the most severe stent artifacts, in-stent lumen diameter, external stent diameter and severity of blooming artifact (blooming artifact = (external stent diameter - in-stent lumen diameter)/external stent diameter * 100). Paired sample T test was used for objective data that conforms to a normal distribution, while the Wilcoxon test was used for data that does not conform to a normal distribution and the subjective scores of two groups.

**RESULTS**

The stent motion artifacts score of SSF2 (0.27±0.48) was statistically lower than SSF1 (0.84±0.75) (P<0.001). The clarity of stent (4.30±0.62) and the diagnostic confidence score (3.77±1.11) of SSF2 were significantly higher than SSF1 (3.70±0.84, 3.37±1.12) (all P<0.001). SSF2 had statistically lower CT and SD values for the fat outside the stent with the most severe stent artifacts than SSF1 (all P<0.001). The stent reconstructed with SSF2 had the statistically larger in-stent lumen diameter (1.46±0.55mm) and the smaller blooming artifact (73.67±8.63) compared to SSF1 (1.35±0.56mm, 75.90±9.49) (all P<0.001).

**CONCLUSION**

The application of SSF2 technology in CCTA further reduces the motion artifacts of the coronary stents compared to SSF1, resulting in better display of the coronary arteries inside the stents and improved diagnostic confidence.

**CLINICAL RELEVANCE/APPLICATION**

SSF2 technology can make coronary stent display clearer and improve diagnostic confidence, making it a highly recommended coronary reconstruction technique.

## T5A-SPPH-2 VIRTUAL HUMAN TWINS IN LUNG HEALTH: A COMPREHENSIVE IN SILICO SCREENING APPROACH

**PURPOSE**

To enhance lung cancer screening by integrating in silico trials with statistical modeling, minimizing traditional trial limitations such as cost, time, and radiation exposure. This approach simulates the entire imaging chain and diagnostic process, improving screening efficiency and accuracy.

**METHODS AND MATERIALS**

We created 313 unique virtual patient models based on actual patients with mean age of 59 ± 14 years with 44% female representation. Within this cohort, 174 models include a total of 512 digitally inserted lung nodules, distributed between uniform (n=202) and variable (n=310) textures, with a range of diameters to mirror the distribution in the National Lung Screening Trial (NLST) for true-to-life simulation. The virtual cohort was digitally imaged employing a verified CT simulation software, and subsequently reconstructed with the agnostic MCR toolkit, ensuring broad applicability and adherence to standard imaging protocols. Our virtual reader emulates clinical diagnostics by combining detection and classification in a 3D AI model. Simulated nodules were "statistically labeled" as benign or malignant with random probability informed by radiomics features, thus facilitating the important transition in tasks from nodule identification to cancer diagnosis. The primary outcome focused on the variation in the Receiver Operating Characteristic Area Under the Curve (AUC) for both patient-level nodule detection and cancer diagnosis, supplemented by a detailed lesion-level analysis within sub-groups.

**RESULTS**

Using the in silico pipeline on a parallel computing cluster, we produced 1,878 simulated chest CT scans in 52 hours, averaging 36 scans per hour. Analysis of 313 virtual patients yielded a patient-level nodule detection AUC of 0.85 (95% CI: 0.80-0.89), compared to the more difficult task of cancer diagnosis with AUC of 0.70 (95% CI: 0.61-0.78). Subgroup evaluations revealed that the virtual reader model was more effective in identifying homogeneous lesions (AUC 0.97) than heterogeneous lesions (AUC 0.71), with particularly high performance for nodules larger than 8 mm (AUC 0.98).

**CONCLUSION**

Our research demonstrates the value of in silico trials in enhancing the calibration and efficacy of imaging-based diagnostic technologies. Our statistical labeling of simulated lung nodules demonstrates a new approach to bridge in silico trials toward clinically relevant endpoints. Future work will also consider the additional in silico modeling of demographic and clinical data.

**CLINICAL RELEVANCE/APPLICATION**

This study confirms the practicality of in silico trials and their potential to enhance diagnostic accuracy, directly informing the advancement of imaging techniques and patient care strategies in lung health.

## T5A-SPPH-4 DYNAMIC MEASUREMENT OF THE MITRAL VALVULAR-VENTRICULAR COMPLEX IN MITRAL VALVE PROLAPSE PATIENTS USING MOTION-COHERENT MODELING-BASED IMAGE PROCESSED 4D-CT

### PURPOSE

To evaluate whether 4D-dynamic tracking based on ECG-gated CT of the mitral valve provides quantitative information on dynamic measurements of the mitral valve complex and to investigate geometry changes in patients with mitral valve prolapse (MVP)

### METHODS AND MATERIALS

Retrospective ECG-gated dual-source CT data from 15 patients (68±13 years) with mitral valve prolapse scheduled for robotic mitral valve repair and 15 control subjects (82±6 years) were analyzed. The CT data set was converted to 40 phases/cycle by motion coherence imaging, and voxel position tracking in the cardiac cycle was calculated at the workstation. The dynamic changes of the mitral valve annulus, papillary muscle, and apical geometry were automatically tracked. Mitral valve annular perimeter, trigone distance, area, the distance among annular point and papillary muscles, inter-papillary muscle distance (IPD), and papillary muscle angle (PMA) are dynamically measured over the cardiac cycle. Multiple comparisons were used to investigate the hallmarks of the mitral valvular-ventricular complex and evaluate the feasibility of anatomical differences between MVP patients and control subjects.

### RESULTS

On average, the annular dimensions were dynamically changed during the cardiac cycle ($p < 0.001$) and significantly larger in MVP than in control subjects ($p < 0.001$). Mitral annulus perimeter (11.9±7.2 vs. 6.5±3.1mm, $p=0.012$) and inter-trigone distance (3.9±2.8mm vs. 1.7±0.5mm, $p=0.0053$) were elongated in patients with MVP compared to control subjects (MVP vs. control). The inter-cycle differences between IPDs and PMA were significantly higher in the MVP group than in the control group (12.7±3.8mm vs. 8.5±1.7mm, $P<0.001$) (16.5±5.1° vs. 12.0±3.4°, $p=0.009$), and inter-cycle change was affected by the disease ($p<0.001$)

### CONCLUSION

The results of this study render the clinical feasibility of mitral valve measurement to provide physiological motion of the mitral valve components during the cardiac cycle.

### CLINICAL RELEVANCE/APPLICATION

The dynamic measurement by using motion-coherent modeling provides a better in vivo evaluation of 3-dimensional geometric changes of the mitral valvular-ventricular complex for surgical repair techniques or transcatheter mitral interventions.

## T5A-SPPH-5 AI-BASED DENOISING ON DIGITAL BREAST TOMOSYNTHESIS USING IN-SILICO IMAGING TOOL: FEASIBILITY STUDY FOR CLINICAL APPLICATION

Chul kyun Ahnn (*Abstract Co-Author*) Nothing to Disclose
Jong H. Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
AHYEONG LEE, BEng (*Presenter*) Nothing to Disclose

### PURPOSE

To validate the performance of a deep learning (DL)-based denoising algorithm trained on in-silico breast imaging data and to check the feasibility of its application to clinical digital breast tomosynthesis (DBT) images.

### METHODS AND MATERIALS

Throughout the U.S. Food and Drug Administration (FDA) proven Virtual Imaging Clinical Trial for Regulatory Evaluation (VICTRE) pipeline, Monte Carlo based digital mammography (mcDM), mcDBT simulator and voxelized anthropomorphic breast phantoms were used for conducting in-silico imaging trials. This study used The Cancer Imaging Archive (TCIA) VICTRE dataset (2986 virtual phantom data) and Korean population dataset (80 virtual phantom data). The Korean population dataset was simulated using 3D anthropomorphic breast phantoms that reflected the breast density, a size and thickness of women through the VICTRE pipeline. Training dataset consisted of pairwise mcDM and center projected mcDBT images simulating with 6% dose level of the mcDM image. A modified U-net was trained to predict the noise map in the mcDBT. Among the 3066 cases (313 for dense, 1220 for heterogeneously, 1220 for scattered, 313 for fatty), 2766 cases were used for AI-model training and the rest 300 cases were used for evaluating the AI algorithm performance. Peak signal-to-noise ratio (PSNR) and Haar wavelet-based perceptual similarity index (HaarPSI) were measured to assess how the noisy images were restored closely to the mcDM images after the AI-denoising. This study used DBT images of thirty clinical patients as independent test set to evaluate the denoising performance using the signal-to-noise ratio (SNR).

### RESULTS

In virtual DBT images, through the AI-denoising, PSNR was increased from 10.9 to 20.0. The HaarPSI were 0.26 for original image and 0.39 for denoised image. Denoised virtual DBT images were much closer to the less noisy mcDM. In clinical data of DBT, the SNR increased as 10% in the denoised image compared to the original image (Mean SNR of denoised images vs original images: 158.6 vs 143.8). It demonstrated denoised clinical DBT image showed same trend in virtual phantom experiment; significantly lower noise level than that of original DBT images.

### CONCLUSION

The AI-denoising algorithm trained with in-silico phantom data demonstrated the potential to restore images closely to the mcDM and to improve image quality. It was able to successfully reduce noise and applicable to human subject DBT.

### CLINICAL RELEVANCE/APPLICATION

Application of DL-based denoising algorithm with in-silico imaging can be applied to clinical DBT images to reduce the radiation dose for DBT scan.

## T5A-SPPH-6 QUANTITATIVE ACCURACY OF BONE MINERAL DENSITY MEASUREMENTS FROM MULTI-ENERGY LOCALIZER RADIOGRAPHS ON A CLINICAL PHOTON-COUNTING-DETECTOR CT SYSTEM

Francis I. Baffour, MD (*Abstract Co-Author*) Nothing to Disclose

Kishore Rajendran, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the quantitative accuracy and stability of areal bone mineral density (aBMD) measured using photon-counting-detector (PCD) CT localizer radiographs.

### METHODS AND MATERIALS

An anthropomorphic spine phantom (European Spine Phantom, ESP) with hydroxyapatite inserts (HA, 0.5, 1.0, and 1.5 g/cm2) was scanned on a clinical PCD-CT system (Siemens NAEOTOM Alpha) at 120 kV and 140 kV tube potentials. To assess aBMD accuracy, four phantom thicknesses (18, 26, 34, and 40 cm) were emulated using synthetic soft tissue and scanned using eight tube current values (15-120 mA for 120 kV and 10-80 mA for 140 kV). Additionally, multi-energy localizers for the 18 cm phantom were acquired twice daily for a week, and once per week for five weeks to assess reproducibility. Quantitative HA maps were reconstructed using a prototype two-material decomposition software. One-way analysis of variance (ANOVA) was performed to test for statistical significance. Coefficient of variation was used to quantitate the stability of aBMD for daily and weekly measurements. Mean absolute percent error (MAPE) was calculated to quantify error in aBMD measurements. To demonstrate clinical feasibility, a patient (59-year-old male) was scanned using PCD-CT localizer at 140 kV and 40 mA, and the corresponding aBMD values were compared with patient's dual-energy x-ray absorptiometry (DXA) results.

### RESULTS

The aBMD measurements from phantom localizers showed excellent day-to-day stability (coefficient of variation 0.42%-0.53%, MAPE=5%) and excellent week-to-week stability (0.17%-0.60%, MAPE=5%). The MAPE range was 4.65% to 5.71% across different tube currents and phantom sizes. No significant difference in accuracy was observed between different tube currents for each phantom size and tube potential. PCD-CT showed lower MAPE (3.3%) than DXA (11.2%) for 18 cm ESP. Lumbar aBMD values from patient PCD-CT localizer showed 0.07% to 9.8% deviation relative to DXA measurements.

### CONCLUSION

Multi-energy PCD-CT localizers demonstrate accurate aBMD measurements across different patient thickness and tube potential with less than 10% deviation relative to current clinical standard (DXA). Reproducible aBMD values can be obtained from PCD-CT localizers.

### CLINICAL RELEVANCE/APPLICATION

Our study demonstrates the accuracy and reproducibility of bone mineral density values obtained from clinical PCD-CT localizers, which is suitable for opportunistic bone quality measurements.

## T5A-SPPH-7 CEREBRAL CT ANGIOGRAPHY USING A PATIENT-SPECIFIC ACQUISITION TIME

Justin Truong (*Abstract Co-Author*) Nothing to Disclose
ABDELRAHMAN ALSALEH (*Abstract Co-Author*) Nothing to Disclose
Sabee Y. Molloi, PhD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation
Alireza Shojazadeh, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop an optimal acquisition timing for cerebral CT angiography with optimal image quality.

### METHODS AND MATERIALS

A total of six swine (55 ± 24 kg) underwent multiple consecutive cerebral CT angiograms over 30 seconds post-contrast injection (1 mL/kg, 5 mL/s, Isovue 370) to capture the entire carotid enhancement curves and determine true peak time totaling 21 acquisitions. We hypothesize that contrast enhancement peak time following bolus tracking is directly proportional to the duration time for contrast injection. Specifically, the optimal time to peak corresponds to half of the injection duration time plus a predetermined dispersion time. To apply this theory, a gamma variate function was used to calculate the reference time to peak (TTP) of carotid enhancement from 21 scans. The calculated time to peak was then correlated to one-half contrast injection time where the intercept was used as the dispersion time for developing patient-specific optimal acquisition protocol. To evaluate the accuracy of the optimized TTP, nine patients (41-87 years old) suspected of cerebral ischemia were used to compare attenuations at the internal carotid artery in addition to contrast to noise ratio (CNR) in the middle cerebral artery (MCA) at the level of circle of Willis. The results from our protocol were then compared with the standard TTP of 5 seconds and the reference peak. Statistical analysis for all data was conducted using mixed regression analysis, box-and-whisker plot, and root-mean-square error.

### RESULTS

Linear regression analysis demonstrated a significant correlation between half contrast injection time ( TInj) and reference TTP (TRef) in swine, described by TRef = 1.04 (TInj/2) + 2.50 (Pearson's r= 0.94, root mean square error= 2.73 s). In patient studies, enhancements in the internal carotid artery under optimal and standard CT protocols differed from reference values by 19 ± 13 and 100 ± 72 Hounsfield units respectively. Additionally, the mean CNR values in the MCA from the optimal and standard CT acquisitions relative to reference were calculated to be 1.30 ± 1.41 and 3.89 ± 2.24, respectively.

### CONCLUSION

This study develops a patient specific technique for acquisition of cerebral angiograms at peak contrast enhancement. As a result, this study shows potential to visualize intracranial arteries at the peak of contrast enhancement and improve CNR for clinical applications.

### CLINICAL RELEVANCE/APPLICATION

Currently two main techniques are used for cerebral CT angiograms including fixed scan-delay following bolus tracking and the test bolus technique and no globally accepted protocol. Optimizing cerebral enhancement during CT angiogram is of key clinical importance for the assessment of both ischemia and aneurysm.

## T5A-SPPH-8 DEEP LEARNING-BASED MOTION CORRECTION (CLEAR MOTION): CAPABILITY OF QUANTITATIVE AND QUALITATIVE IMAGE QUALITY IMPROVEMENTS ON CHEST CT IN PATIENTS WITH THORACIC DISEASES

### PURPOSE

Motion artifacts including cardiac motion are main causes for decreasing image quality on chest CT in patients with pulmonary diseases. Recently, we have developed and clinically set deep learning (DL)-based motion correction algorithm (CLEAR Motion) for chest CT examination. The purpose of this study was to directly compare the utility of CLEAR Motion for image quality improvements with conventional reconstruction method on chest CT examination in patients with various thoracic diseases.

### METHODS AND MATERIALS

56 consecutive patients with various thoracic diseases who underwent non-electrocardiogram gated chest helical CT examination at a 320-detector row CT system and reconstructed with conventional reconstruction method and CLEAR Motion. On quantitative image quality evaluations on both CT protocols, CT value, cardio-pulmonary edge distance(C-PED) and slope (C-PES) were measured by ROI measurements or profile curve assessments by a board-certified chest radiologist. On qualitative image quality assessments on each CT protocol, two board-certified chest radiologists independently and visually assessed overall image quality and artifacts at lung and mediastinal window settings and region conspicuity at lung window setting on axial, sagittal and coronal planes. Then, each final value was determined as consensus of two readers. To compare each quantitative image quality index between CLEAR Motion and conventional method, paired t-test was performed. To determine each inter-observer agreements, kappa statistics followed by ?2 test. To compare each qualitative image quality index between two methods, Wilcoxon's signed-rank test was performed.

### RESULTS

C-PED and C-PES of CLEAR Motion were significantly superior to those of conventional method ($p<0.05$). Each interobserver agreement was determined as almost perfect (CLEAR Motion: 0.84=?=0.92, $p<0.0001$; conventional method: 0.87=?=0.94, $p<0.0001$). At lung window setting, overall image quality, artifacts and region conspicuity of CLEAR Motion were significantly better than those of conventional method ($p<0.0001$).

### CONCLUSION

DL-based motion correction is considered as more useful for image quality improvement than conventional method on chest CT in patients with various thoracic diseases.

### CLINICAL RELEVANCE/APPLICATION

DL-based motion correction is considered as more useful for image quality improvement than conventional method on chest CT in patients with various thoracic diseases.

## T5A-SPPH-9 IMPROVING CORONARY STENOSIS ASSESSMENT IN ENERGY-INTEGRATING-DETECTOR (EID) CT THROUGH DEEP LEARNING-BASED MONOENERGETIC IMAGING: A COMPARISON WITH ULTRA-HIGH RESOLUTION PHOTON-COUNTING-DETECTOR (PCD) CT

Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Hao Gong, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Emily Koons (*Abstract Co-Author*) Nothing to Disclose
Cynthia H. McCollough, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Jamison Thorne, BSc (*Abstract Co-Author*) Nothing to Disclose
Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Photon counting detector (PCD) CT has been shown to reduce blooming artifacts and enhance the accuracy of stenosis quantification through its ultra-high-resolution (UHR) and multi-energy imaging capabilities. However, most coronary CT angiography (cCTA) exams are performed using single-energy mode with conventional energy-integrating detector (EID) CTs. We aim to produce virtual mono-energetic images (VMIs) for single-energy EID-CT to improve stenosis assessment through Deep-learnIng bAsed MONoenergetic imaging at Different energies (DIAMOND).

### METHODS AND MATERIALS

DIAMOND was developed by training a simplified U-Net model on ten cCTA exams scanned with multi-energy mode on a clinical PCD-CT (NAEOTOM Alpha, Siemens Healthineers). The 70 keV PCD VMIs (equivalent to the single-energy EID-CT scanned at 120 kV) were used as input, and 100 keV PCD VMIs as target. All VMIs were reconstructed following the standard clinical protocol, using an iterative reconstruction (IR) algorithm at strength 4, Bv60 kernel, and 0.6 mm slice thickness. For inference, DIAMOND was deployed on unseen EID-CT cCTA patient cases (n=10), reconstructed using IR-4, Bv40 kernel, and 0.6 mm slice thickness. In addition to visual evaluation, we quantitatively assessed percent diameter stenosis using commercial software (Syngo.Via, Siemens) and compared results across EID, DIAMOND, and PCD images.

### RESULTS

DIAMOND effectively reduced blooming artifacts from the calcium and provided better visualization of the lumen compared to the EID-CT inputs, resulting in images closer to PCD-CT. The percent diameter stenosis determined from DIAMOND showed a reduction across all ten patients compared to their

original EID-CT images. Specifically, the average percent diameter stenosis from the original EID-CT was 43.3%, which is known from phantom experiments to overestimate the stenosis severity. It was decreased to 30.5% when processed with DIAMOND, aligning more closely with the 28.6% observed in UHR PCD-CT, which is considered a more accurate reflection of true stenosis. Using UHR PCD-CT as a reference, DIAMOND overestimates the percent stenosis by only 6.6%, which represents a significant improvement over the 51% overestimation by the original EID-CT data.

**CONCLUSION**

DIAMOND equips EID-CT systems with virtual mono-energetic imaging capabilities, reducing blooming artifacts, enhancing stenosis assessments, and achieving results that approximate the quality of PCD-CT.

**CLINICAL RELEVANCE/APPLICATION**

DIAMOND enhances the performance of EID-CT by reducing blooming artifacts and improving the accuracy of coronary stenosis assessments, which has a significant impact on patient care due to the widespread installation of EID-CT (>99% of installed CT scanners are EID-CT).

## T5A-SPRO-1 ADENOVIRUS-MEDIATED TRANSFERRIN RECEPTOR REPORTER GENE (TFRC) EXPRESSION IN COLORECTAL CANCER MODELS AND MRI IMAGING STUDY

Zhijun Wang, MMedSc (*Abstract Co-Author*) Nothing to Disclose
Xinxin Guo (*Abstract Co-Author*) Nothing to Disclose
Na Gao (*Abstract Co-Author*) Nothing to Disclose
Hua He, MMedSc (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the overexpression of adenovirus vector-mediated transferrin receptor reporter gene (TFRC) transfection in colorectal cancer LoVo cells and to observe the imaging changes of a colorectal cancer model (7.0T MRI) in vivo.

### METHODS AND MATERIALS

TFRC-luciferase adenovirus was used to infect human colorectal cancer LoVo cells. Bioluminescence imaging was used to detect luciferase expression in vitro cultured LoVo cells. Real-time fluorescent quantitative polymerase chain reaction (QPCR) was used to detect and analyze TFRC gene expression in LoVo cells. Cell Counting Kit-8 (CCK-8) was utilized to test cell toxicity. Transferrin-coupled ultrasmall superparamagnetic iron oxide (TFTC-USPIO) was used to label the reporter gene adenovirus in vitro. A LoVo colon tumor model was established by subcutaneously inoculating 1×107 double-labeled LoVo cells into the groin of BALB/c mice. Then TFTC-USPIO molecular probes were administered intravenously via the tail vein, and dynamic monitoring of signal changes in the tumor was conducted using T2, T2map and T2*map sequences with 7.0T MRI. Signal intensity was analyzed and the tumor was dissected for Prussian blue staining.

### RESULTS

Real-time fluorescent quantitative PCR results showed that TFRC reporter gene was significantly overexpressed in LoVo cells transfected with Ad-TFRC-luciferase. CCK-8 tests demonstrated that the double-reporter gene expression labeled with Ad-TFRC-luciferase had no adverse effects on cell proliferation and vitality. In vitro, the signal intensity of USPIO-labeled LoVo cells decreased. In vivo, the low signal area of tumor cells expanded rapidly with time. Prussian blue staining showed iron accumulation in tumor tissue.

### CONCLUSION

MRI combined with a bioluminescence double-reporter gene imaging system can achieve dual-mode tracking of labeled cells and dynamically monitor and evaluate changes in tumor growth during treatment in vivo.

### CLINICAL RELEVANCE/APPLICATION

This study provides basic research data for the diagnosis and targeted treatment of colorectal cancer.

## T5A-SPVA-3 CLINICAL AND ULTRASONOGRAPHIC CORRELATES OF POSTTHROMBOTIC VENOUS REMODELING IN BEHÇET'S SYNDROME: A CROSS-SECTIONAL STUDY

Ibrahim Adaletli (*Abstract Co-Author*) Nothing to Disclose
Omer Faruk Sariahmetoglu, MD (*Abstract Co-Author*) Nothing to Disclose
Seyfullah Karagoz, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to determine the clinical and ultrasonographic parameters affecting venous remodeling.

### METHODS AND MATERIALS

Patients diagnosed with Behcet's syndrome (BS) according to international criteria and who had venous thrombosis in upper leg veins were included in the study. Clinical-Etiology-Anatomy-Pathophysiology (CEAP) and Villalta scores were used to evaluate the clinical severity of postthrombotic syndrome (PTS). Two independent radiologists blinded to the clinical diagnosis of the patients performed the ultrasound examinations. The measurement results of the wall thickness and diameter of the common femoral vein (CFV) and great saphenous vein were recorded bilaterally. If a thrombus was present, B-mode ultrasound were used first to assess the thrombus morphology. Thrombus location, echogenicity, thickness, and longitudinal extent were noted. CFV wall elastography was also performed bilaterally in each patient.

### RESULTS

79 BS patients (71M/8F) were included in this study. A total of 35 obvious thrombi were observed in 32 patients. Although no significant difference was detected in thrombus stiffness over time, the stiffness of thrombi tended to be higher in the first six months. While there was a trend towards an increase in the probability of severe PTS as the stiffness of the CFV wall increased, we found a negative relationship between CFV wall thickness and severe PTS. Moreover, as venous reflux time (sc) increased, the probability of severe PTS) and stasis ulceration increased.

### CONCLUSION

Our study shows venous reflux and fibrotic bands within the veins are the most critical parameters for severe PTS. Also, thrombus material in the veins probably causes venous reflux by disrupting the structure of the venous valves. Fibrosis in the vein wall, possibly due to chronic thrombus, contributes to venous insufficiency by making the vein wall stiffer and thinner. Age, disease duration, relapses, and thrombotic events in both legs stand out as clinical factors that trigger adverse venous remodeling and predispose to severe PTS. Achieving complete recanalization of the thrombus and preventing recurrent thrombotic attacks are the ultimate goals of treating BS thrombus.

### CLINICAL RELEVANCE/APPLICATION

This study underlines the importance of detailed ultrasonographic evaluation in predicting severe PTS in BS.

## T5B-SPBR-1 CONTRAST ENHANCED MAMMOGRAM BIOPSY CANNOT REPLACE MRI-GUIDED BIOSPY FOR SUSPICIOUS BREAST MRI FINDINGS

Vilert A. Loving, MD, MMM (*Abstract Co-Author*) Nothing to Disclose
Hannah A. Lawther, MD (*Abstract Co-Author*) Nothing to Disclose
Molly Harrison, MD (*Abstract Co-Author*) Nothing to Disclose
Danielle E. Summers, MD (*Abstract Co-Author*) Nothing to Disclose
Leslie A. Welk, MD (*Abstract Co-Author*) Nothing to Disclose
Shayna Klein, MD (*Abstract Co-Author*) Nothing to Disclose
Brian Johnston, MD (*Abstract Co-Author*) Nothing to Disclose
Michael F. Morris, MD (*Presenter*) Educator, Medtronic plc

### PURPOSE

Contrast enhanced mammogram (CEM) has similar diagnostic accuracy to breast MRI, however it is uncertain if CEM biopsy can be used instead of MRI-guided biopsy to obtain tissue samples of suspicious findings on breast MRI.

### METHODS AND MATERIALS

Consecutive patients from 2 sites within an integrated healthcare network with BIRADS 4/5 findings on breast MRI and a recommendation for MRI-guided breast biopsy were referred for attempted CEM biopsy as part of an institutional protocol. Patients with more than one suspicious finding on MRI, a mass or non-mass enhancement <5mm diameter, or history of iodinated contrast reaction were excluded from the protocol. A modified Likert scale assessed conspicuity of CEM findings, ranging from much less conspicuous than MRI (score 1) to much more conspicuous than MRI (score 5). For abnormalities not identified at attempted CEM biopsy, MRI-guided biopsies were performed. Descriptive statistics were performed.

### RESULTS

From 5/2023 to 10/2023, 21 breast MRI patients were referred for CEM biopsy (Hologic, Marlborough, MA), including 95% (20/21) for non-mass enhancement and 5% (1/21) for a mass. CEM targets corresponding to MRI findings were identified in 28.5% (6/21) patients and CEM biopsies were performed. Findings on MRI did not significantly differ between patients with a CEM correlate compared to patients without a CEM correlate (Table). CEM targets were rated as being either much less conspicuous or slightly less conspicuous than the MRI findings (mean 1.83 +/- 0.4). All CEM biopsy results were benign, with no interval suspicious findings at 6-12 month follow-up mammography, Patients without a CEM correlate (71.5%; 15/21) were subsequently referred to MRI-guided biopsy, with interval resolution of MRI findings in two patients. In the remaining cohort, MRI-guided biopsy yielded malignancy in 23% (3/13), high-risk histology in 15% (2/13), and benign histology in 62% (8/13). One high-risk lesion upstaged to cancer at surgical excision (total cancers 4/13; 31%). Having no CEM correlate to the MRI finding yielded a negative predictive value of 73% for malignancy.

### CONCLUSION

In patients with predominately suspicious non-mass enhancement referred for MRI-guided breast biopsy, only 28.5% had corresponding targets for CEM biopsy. Lack of enhancement at CEM biopsy had a negative predictive value of 73% for malignancy. However, all cases of malignancy diagnosed by MRI-guided biopsy were not detected at initial attempted CEM biopsy.

### CLINICAL RELEVANCE/APPLICATION

In patients with suspicious breast MRI findings, CEM biopsy should not be used as a replacement for MRI-guided biopsy.

## T5B-SPBR-10 IMPACT OF MENSTRUAL CYCLE ON BACKGROUND PARENCHYMAL ENHANCEMENT AND BREAST CANCER DETECTABILITY IN CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY

Huizhi Cao (*Presenter*) Nothing to Disclose

### PURPOSE

Prominent background parenchymal enhancement (BPE) in contrast-enhanced spectral mammography (CESM) may hinder lesion detection and diminish diagnostic performance. This study aimed to investigate the effect of the menstrual cycle on BPE and cancer detectability in a large cohort of breast cancer patients undergoing CESM.

### METHODS AND MATERIALS

After ethical approval, we identified 1253 potentially eligible patients under through CESM from five china hospitals in different regions. 512 patients were examined in menstrual phase (days 1-4), 444 patients in the proliferative phase (days 5-14), and 505 patients in the secretory phase (days 15-30). The BPE on CESM were evaluated independently by three experienced radiologists and classified as minimal, mild, moderate, marked. The caner detectability was assessed as Excellent, good, or poor, respectively. Using ROC curve to analyze the diagnostic performance of CESM in breast cancer patients with different phase of menstrual cycle.

### RESULTS

1369 breast lesions were found in 1253 patients, in which 688 were benign and 681 were malignant according to histopathological results. Most patients had minimal BPE (1020/1369; 74.5%) at CESM modality. BPE was determined as marked in 1.6%, 3.6% and 12.1% at the menstrual, proliferative and secretory phases ($p < 0.001$), respectively, indicating that the degree of BPE is demonstrated significant associated with secretory status. The detectability of breast cancer was classified as poor in 0.2%, 2.4% and 10.0% at menstrual, proliferative and secretory phases, respectively, showing the secretory phases reduce the detection rate of breast cancer. On the basis of ROC curve analysis, the CESM from patients of menstrual or proliferative phase is higher than that from secretory phase phase (0.901 vs. 0.887vs. 0.702, $p<0.05$), Additionally, the CESM with menstrual or proliferative phase groups show higher sensitivity and specificity(menstrual phase:0.914, 0.892; proliferative phase:0.892,0.801; secretory phase group:0.758,0.655;), and a lower False-Negative and False Positive (menstrual phase:0.022, 0.112; proliferative phase:0.040,0.168; secretory phase group:0.231,0.564).

### CONCLUSION

The menstrual phase and the proliferative phase seem to be suitable for breast CESM.

### CLINICAL RELEVANCE/APPLICATION

The menstrual and proliferative phases appear to be more suitable for breast CESM, as they offer better diagnostic performance and higher cancer detectability while minimizing the impact of background parenchymal enhancement.

### PURPOSE

Mammogram-based deep learning (DL) breast cancer (BC) risk prediction models show huge potential for personalized BC screening. To enhance the explainability and generalizability of the risk prediction, we propose a global-local transformer framework-based (GL) risk prediction model.

### METHODS AND MATERIALS

We collected two datasets: an IRB-approved large inhouse (internal) and a public CSAW (external) dataset. The inhouse dataset is collected from 2004-2020, and involves 171,168 mammograms from 9,133 patients. All methods are built on the inhouse dataset, which is split into training/validate/test sets based on patient level. The external public dataset including 98,776 images on 8,723 patients is used to evaluate the models' generalizability. Our DL risk model was designed to mimic the process of mammogram reading by radiologists, which firstly figure out globally high-risk characteristics (e.g. dense tissue, architectural distortion et al.), and then further analyze the local suspicious areas (such as micro-calcifications). The GL risk model outputs the risks at multiple time points from 1 year to 5 years and bounding boxes of the high-risk areas. We compared the models' performance with AUC and Precision-Recall AUC (PR-AUC) metrics for each risk assessment interval and overall C-index metric on both datasets with baseline methods.

### RESULTS

For the internal test set (25,244 images / 1,706 positives within 5 years), the proposed GL risk model achieved the best 5-year C-index of 0.774±0.005, with the highest AUC of 0.864±0.005 and PR-AUC of 0.504±0.013 at 1-year risk prediction. The AUC and PR-AUC of the GL model for the long-term 5-year risk prediction are 0.769±0.005 and 0.457±0.009, respectively. The GL risk model improved upon the two baseline models for all metrics (?C-index=0.7-2.4%; ?AUC= 0.5-4.4%; ?PR-AUC=0.34-11.3%). For the external validation on the public CSAW-CC dataset (98,776 images / 3,652 positives within 5 years), our model achieved the best performance compared with both baseline methods, with 5-year C-index of 0.693±0.003. Our model surpasses other baselines on all metrics. The visualization results also show that the GL model could accurately figure out the high-risk area.

### CONCLUSION

Compared with baseline risk prediction models, the global-local transformer-based risk prediction model enhances explainability and generalizability.

### CLINICAL RELEVANCE/APPLICATION

The global-local mechanism provides a clear focus on the potential high-risk areas from whole mammograms. It can guide radiologists in their decision-making process. Besides, the improved generalization performance of the risk model may facilitate the clinical application enabling the development of a personalized screening policy.

## T5B-SPBR-3 CANCERS SEEN BY ONE OBSERVER ON CONTRAST-ENHANCED MAMMOGRAPHY IN WOMEN WITH PERSONAL HISTORY OF BREAST CANCER

**PURPOSE**

In the prospective TOCEM trial, women with a personal history of breast cancer have three annual rounds of screening with digital breast tomosynthesis (DBT) and contrast-enhanced mammography (CEM). We sought to evaluate factors affecting cancer detection by one versus two specialist breast imaging radiologists.

**METHODS AND MATERIALS**

In an IRB-approved, HIPAA-compliant trial, from 10/19/19 through 4/15/24, 1647, 1227, and 819 women completed year 1, 2, and 3 screening, respectively. Two radiologists interpret each paired examination: reader 1 (R1) interprets DBT first and records findings, then CEM, and reader 2 (R2) interprets CEM first. For recalled findings, we recorded which modality prompted recall, and if the finding was seen only in retrospect on DBT. We examined influence of lesion and breast factors on cancer detection by only one vs. both readers: lesion size, conspicuity (low=1, moderate=2, high=3), seen on only one view (on retrospective review), breast density, and background parenchymal enhancement (BPE). Statistical differences were inferred by using nonparametric bootstrapping of 10,000 replicates (R Studio).

**RESULTS**

There were 87 malignant lesions in 68 women. Of these 87, 41 (47%) were seen by at least one reader on DBT: 35 (40%) were identified by R1 on DBT as were 30 (34 %) by R2 [24 (28%) by both]. Of 87 malignant lesions, 60 (69%) were seen by R1 on CEM as were 58 (67%) by R2 [49 (56%) by both]. Twenty cancers were seen only by one reader on CEM, including: 9 DCIS (four grade 3, five grade 2), 2 IDC (0.6, 1.0 cm, both grade 2), 4 IDC-DCIS (0.6, 1.0, 1.2, 2.0 cm), all grade 2, 3 ILC (0.5 cm each, all grade 2), 1 ILC-DCIS, 0.9 cm, grade 2, and 1 pleomorphic LCIS. Of 69 (79% of all) malignant lesions seen by either observer on CEM, 32 (46%) were also seen on DBT, 11 (16%) were deemed visible in retrospect on DBT, and 26 (38%) were not visible even in retrospect by either reader. Three malignancies were seen only on DBT and low-energy (LE) images, all DCIS. Two malignancies were manifest as calcifications seen only on DBT, not visible on LE images, one 0.4 cm IDC-DCIS and one DCIS. Mean size of cancers seen by both readers on CEM was larger at 16.4 mm vs. 7.9 mm by only one reader (P=0.001) and mean CEM conspicuity was higher (mean 2.5 vs. 2.0, P=0.0048). One-view findings, binarized breast density, and BPE did not significantly influence one- vs. two-reader detection on CEM.

**CONCLUSION**

A substantial proportion of malignant lesions are subtle on CEM, with 20/69 (29%) seen by only one reader; this compares with 17/41 (41%) seen by only one reader on DBT.

**CLINICAL RELEVANCE/APPLICATION**

Interpreting radiologists need to be attentive to small enhancing lesions and those of low conspicuity on CEM. Further study of the role of DBT with CEM is warranted.

## T5B-SPBR-4 BENIGN AND SUSPICIOUS CONTRAST-ENHANCED MAMMOGRAPHY FINDINGS AT THE SITE OF BREAST-CONSERVING THERAPY

Shiva Yagobian, BS (*Abstract Co-Author*) Nothing to Disclose
Marie A. Ganott, MD (*Abstract Co-Author*) Nothing to Disclose
Madyson McDougal (*Abstract Co-Author*) Nothing to Disclose
Wendie A. Berg, MD, PhD (*Abstract Co-Author*) Institutional Research Grant, Koios Medical, Inc
Jeremy M. Berg, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuying Cao, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To identify benign and suspicious findings on contrast-enhanced mammography (CEM) at the lumpectomy scar in women with a personal history of breast cancer (PHBC).

**METHODS AND MATERIALS**

In an IRB-approved, prospective clinical trial, 1647 women with PHBC are undergoing three rounds of annual screening with digital breast tomosynthesis (DBT) and CEM. From 10/19/2019 - 4/15/2024, 1647 women had year 1, 1227 year 2, and 819 women year 3 screening, including 3261 breasts with BCT in 1369 women. We prospectively recorded enhancement at or near (< 2 cm) the scar. Enhancing scars were then retrospectively reviewed, and imaging features recorded, as were all ipsilateral malignancies diagnosed during the study to date. Lesion features (+/- rim enhancement; mass, or nonmass enhancement [NME]) were compared between breasts with benign and malignant results with Fisher exact test.

**RESULTS**

Median age of participants with BCT was 67 years (range 34 to 87). Among 3261 breasts with BCT, there were 53 (16.6/1000) diagnosed with cancer, including 15 at the scar, 7 near, 29 > 2 cm away, and 2 in the axilla. A total of 687 breasts were described as having enhancement at or near the scar, with 318 of those only in overlying skin on review, leaving 369/3261 (11.3%) breasts for this analysis. Enhancement at the scar was described as rim or partial rim for 205/369 (55.6%) with median rim thickness 2 mm (range 1 to 21): 105 rims were described as smooth and 100 as nodular; 2 malignancies showed rim enhancement at the scar, one DCIS with thin rim enhancement and 15-mm NME and grouped coarse heterogeneous calcifications similar to the primary cancer, and one thick, nodular enhancement (10 mm) and grouped coarse heterogeneous calcifications. There were 42 breasts with an enhancing mass at or near the scar with 13/42 malignant (31%). Of 100 with NME at or near the scar, 9 (9%) were malignant and 11 with enhancing asymmetry, none malignant. Rim enhancement at the scar was significantly associated with benign etiology ($p < 0.001$). Among non-rim enhancing findings at/near the scar, lesion type (mass vs NME) was more strongly associated with malignancy ($p = 0.002$). Of 40 also with ipsilateral enhancing findings > 2 cm from the scar, 29 (73%) were malignant.

**CONCLUSION**

More than half of CEM-enhancing findings at/near the BCT scar were rim enhancement. Rim enhancement at the scar alone was not associated with recurrent malignancy, but an associated enhancing mass or NME at or near the scar should be viewed as suspicious, with 13/42 (31%) such masses and 9/100 (9%) NME malignant.

### CLINICAL RELEVANCE/APPLICATION

Knowledge of benign and suspicious appearances of post-lumpectomy changes on CEM assists in appropriate interpretation and recommendations and should reduce unnecessary biopsies.

## T5B-SPBR-5 DISTANCE TO ACCREDITED BREAST MR FACILITIES COMPARED WITH MAMMOGRAPHY AND ULTRASOUND FACILITIES

Anand K. Narayan, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth Y. Rula, PhD (*Abstract Co-Author*) Nothing to Disclose

Eric Christensen, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

For high-risk women, breast magnetic resonance (MR) is the preferred supplemental imaging option, but spatial access differences may exacerbate outcome disparities. Accordingly, the purpose of this study is to determine (for accredited breast imaging facilities) the relative distance to the nearest MR facility compared with mammography and ultrasound facilities.

### METHODS AND MATERIALS

Cross-sectional study examining distance between U.S. ZIP codes and the nearest breast imaging facility by imaging type (MR, mammography, ultrasound) using data for accredited breast imaging facilities from the Food and Drug Administration and the American College of Radiology. Linear regression was used to assess distance differences controlling for Area Deprivation Index (ADI), urbanicity, and population size.

### RESULTS

Among the 29,629 ZIP codes with an ADI and known urbanicity, unadjusted mean distance (in miles) to breast MR was 23.2±25.1 (SD) compared with 8.9±10.0 for mammography and 22.2±25.0 for ultrasound. Hence, the relative distance was 61% less for mammography than breast MR while the distances to breast MR and breast ultrasound were comparable. ADI and urbanicity were associated with increased distance to the nearest breast imaging facility. The added distance associated with the least advantaged areas compared with most advantaged areas was 12.2 (95%CI: 11.3, 13.2) for MR, 3.9 (95%CI: 3.6, 4.3) for mammography, and 11.5 (95%CI: 10.6, 12.3) for ultrasound. Compared with metropolitan areas, the added distance to breast MR facilities was 13.7 (95%CI: 12.8, 14.6) for micropolitan and 23.2 (95%CI: 22.5, 24.0) for small/rural areas.

### CONCLUSION

Spatial access differences are substantially less for standard mammography sites compared with breast MR or breast ultrasound sites. Spatial access differences increase with area deprivation and rurality.

### CLINICAL RELEVANCE/APPLICATION

For high-risk women, MR is the preferred supplemental screening option, yet there are distance-based access disparities. While lessening these MR access disparities is desirable, doing so is economically impractical. Therefore, access to contrast-enhanced mammography, which can be offered at mammography sites with minimal upgrades, may mitigate the more important breast cancer outcome disparities. Given the substantially lower spatial access disparities for standard mammography compared with MR, expanding the use of contrast-enhanced mammography at these sites can potentially lessen outcome disparities for women needing supplement screening.

## T5B-SPBR-6 BREAST CANCERS CHARACTERISTICS IN WOMEN IDENTIFIED TO BE AT HIGH-RISK FOR FUTURE BREAST CANCER BY A MAMMOGRAPHY-BASED BREAST CANCER RISK MODEL THAT COMBINES ARTIFICIAL INTELLIGENCE FOR LESION DETECTION AND MAMMOGRAPHIC TEXTURE

Nico Karssemeijer, PhD (*Abstract Co-Author*) CEO, ScreenPoint Medical BV;Shareholder, ScreenPoint Medical BV;Shareholder, Volpara Health Technologies Limited;Shareholder, QView Medical, Inc

Ilse Vejborg, MD (*Abstract Co-Author*) Nothing to Disclose
Martin Lillholm (*Abstract Co-Author*) Shareholder Biomediq A/S;Shareholder, Cerebriu A/S
Ritse M. Mann, MD, PhD (*Abstract Co-Author*) Researcher, Siemens AG;Consultant, Siemens AG;Researcher, Bayer AG;Consultant, Bayer AG;Researcher, Medtronic plc;Consultant, Medtronic plc;Researcher, Becton, Dickinson and Company;Consultant, Becton, Dickinson and Company;Researcher, ScreenPoint Medical BV
Andreas Lauritzen, PhD (*Presenter*) (Former) Researcher, ScreenPoint Medical BV, NL Scientific Assistant at Gentofte Hospital, DK

### PURPOSE

A recent mammography-based risk model combined an artificial intelligence (AI) detection model, mammographic texture, breast density, and age. This study aims to retrospectively validate an updated version of this model and compare breast cancer characteristics among women classified as high-risk and non-high-risk.

### METHODS AND MATERIALS

The risk model was trained on a development sample of women screened in a Danish program, from 2012-2015, and a Dutch program from 2003-2015. This sample comprised 197.957 negative screenings, with 5-10 years of follow-up, where 5.976 were in women with a future breast cancer diagnosis. The risk model combined an AI score indicating probability of cancer, texture, volumetric breast density, and age to a single risk score. The risk model was validated on a consecutive screening sample of Danish women from January 2016 to December 2017 with 5-7 years of follow-up. Risk prediction performance was evaluated using area under the ROC curve (AUC) for cancers (invasive and in situ) diagnosed at least 180 days after screening. Cancer characteristics were determined for high-risk (10th risk decile) and non-high-risk women, in terms of invasive cancers (IC), ICs >1cm in size, and lymph node positive (NP) ICs.

### RESULTS

The validation sample comprised 47.388 unique women of whom 978 were diagnosed with breast cancer at least 180 days after screening. In this sample, the risk model achieved an AUC of 0.74 (95% CI: 0.72, 0.75). Limiting follow-up to 2, 4, and 6 years the AUC was 0.79 (95% CI: 0.76, 0.82), 0.76 (95% CI: 0.74, 0.78), and 0.74 (95% CI: 0.72, 0.76), respectively. In the high-risk group 36.9% (361/978) of cancers were found. Of those, 91.1% (329/361) were invasive at diagnosis, while for cancers in the non-high-risk group, 89.5% (552/617) were invasive, which was not different from the

high-risk group (P=.40). For the high-risk group with a measured lesion size, 74.1% (240/324) of ICs were >1cm in comparison to 67.0% (354/528) for the non-high-risk group, which was lower (P=.03). For the high-risk group with a lymph node test, 19.1% (60/314) of ICs were NP, while for non-high-risk group 6.4% (33/515) of ICs were NP, which was lower (P<.001).

**CONCLUSION**

In an independent screening sample, the risk model achieved an AUC of 0.79 at 2 years after screening and retained high risk prediction performance 6 years after screening with an AUC of 0.74. Invasive cancers in the high-risk group were more likely to be larger in size and to be node positive relative to the non-high-risk group.

**CLINICAL RELEVANCE/APPLICATION**

The risk model may be used to select high-risk women for supplemental screening, e.g. MRI, US, tomosynthesis, or contrast enhanced mammography, which might lead to earlier diagnosis of up to 36.9% of breast cancers in women attending screening.

## T5B-SPBR-7 REDUCING BIOPSY RATES OF BREAST ULTRASOUND BIRADS 4 LESIONS IN OUTPATIENT SETTINGS THROUGH CONTRAST-ENHANCED MAMMOGRAPHY

Huizhi Cao (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic efficacy of contrast-enhanced mammography(CEM)in assessing breast ultrasound BIRADS 4 lesions in outpatient settings and to reduce benign biopsy rates.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on patient data from September 2021 to July 2023. Patients with ultrasound-diagnosed BIRADS 4 lesions who underwent CEM examination were included. During CEM, a nonionic iodinated contrast agent (Iohexol 350 mg I/mL, 1.5 mL/kg) was power-injected intravenously. Images were evaluated independently by two breast radiologists. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were calculated. Diagnostic efficacy of CEM and combined examination (CEM + ultrasound) for BIRADS 4 lesions was evaluated against pathological diagnosis.

**RESULTS**

Out of 232 outpatient patients,166 lesions were classified as BIRADS 4. Pathologically,125 lesions were benign (predominantly fibroadenomas) and 41 were breast cancer cases. CEM demonstrated a sensitivity of 95.1%, specificity of 86.5%, accuracy of 88.6%, PPV of 69.6%, and NPV of 98.2%. Ultrasound showed a sensitivity of 65.9%, specificity of 83.2%, accuracy of 78.9%, PPV of 56.3%, and NPV of 88.1%. Combined US + CEM exhibited a sensitivity of 100%, specificity of 93.6%, accuracy of 98.1%, PPV of 83.7%, and NPV of 100%. The addition of CEM significantly reduced benign biopsy rates by 77.6%.

**CONCLUSION**

Incorporating CEM examination for ultrasound BIRADS 4 lesions in outpatient settings can effectively decrease the benign biopsy rate.

**CLINICAL RELEVANCE/APPLICATION**

CEM enhances diagnostic accuracy and reduces unnecessary biopsies, particularly in cases of indeterminate BIRADS 4 lesions. Its high NPV provides radiologists with confidence in imaging assessment, alleviating patient anxiety and conserving healthcare resources.

## T5B-SPBR-8 DIAGNOSTIC VALUE OF CONTRAST-ENHANCED MAMMOGRAPHY FOR SUSPECTED BREAST CALCIFICATION: A TWO-CENTER STUDY

Huizhi Cao (*Presenter*) Nothing to Disclose

**PURPOSE**

Exploring the clinical value and significance of contrast-enhanced mammography for suspicious calcification.

**METHODS AND MATERIALS**

Retrospective study of 160 patients with suspected calcification (diagnostic report defined as BI-RADS4) on dual center conventional FFDM from 2020 to 2023, all of whom underwent CEM examination. The calcified area was observed for enhanced signs through CEM images, and the correlation between these imaging features and pathology was studied. Finally, the diagnostic value of the images and differential diagnostic ability of CEM for suspected calcification were evaluated using pathological results as the gold standard.

**RESULTS**

The mean age of patients was 50.1 years (range: 18-71 years). Among the 160 lesions, 85 were benign and 75 were malignant. The consistency in BI-RADS classification was higher with CEM than FFDM (0.86 vs. 0.74). CEM demonstrated a sensitivity of 94.5%, specificity of 90.2%, positive predictive value of 93.2%, negative predictive value of 95.4%, and accuracy of 95% in identifying suspicious calcifications.

**CONCLUSION**

CEM has a high diagnostic efficacy for suspected breast calcification. Therefore, CEM has reliable clinical practical value in determining calcified lesions, locating suspicious calcifications through puncture, and evaluating the nature of lesions before surgery.

**CLINICAL RELEVANCE/APPLICATION**

Contrast-enhanced mammography exhibits high diagnostic efficacy for suspected breast calcifications and is useful in guiding the localization of suspicious calcifications for biopsy.

## T5B-SPBR-9 ASSESSING DIAGNOSTIC PERFORMANCE AND TUMOR SIZE ACCURACY OF CONTRAST-ENHANCED SPECTRAL MAMMOGRAPHY WITH LOW-DOSE CONTRAST AGENTS FOR BREAST LESIONS DETECTION

Huizhi Cao (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to investigate the clinical value of contrast-enhanced spectral mammography (CESM) with low-dose contrast agents in evaluating breast lesions, considering diagnostic performance and tumor size accuracy.

## METHODS AND MATERIALS

A total of 223 patients undergoing CESM were randomly assigned to two protocols: 113 patients underwent the examination with a conventional dose of Iohexol (1.5ml/kg body weight; 300-350 mg/ml), while the remaining 100 patients received the exam with a low dose of Iohecol (1 ml/kg body weight; 300-350 mg/ml). All patients also underwent MRI examination within one week. The images from CESM, MRI, and histopathological data were analyzed. The clinical utility of CESM performed with low-dose contrast agents or conventional dose contrast agents, in conjunction with MRI, was evaluated based on histopathological results. The ROC curve was applied to analyze clinical efficiency. Tumor size measurements were obtained from CESM, MRI modalities, and pathological data. Bland-Altman analysis was utilized to assess the consistency of the maximum tumor size among different imaging methods.

## RESULTS

Histopathologic analyses revealed 33 benign and 67 malignant lesions in low dose group (100 patients), 35 benign and 78 malignant lesions in conventional dose group. By evaluating diagnostic value, CESM obtained from conventional group had similar AUC area, sensitivity, specificity, PPV, NPV to MRI imaging (0,928, 0.962, 0.846,0.783,0.821 vs. 0.903,0.974,0.809,0.805,0.856). CESM from low dose group showed a comparison of clinical performance to MRI as well. (AUC area: 0.944 vs. 0.925; sensitivity:0.990 vs.0.941; specificity:0.825vs.0.831; PPV:0.802 vs. 0.825; NPV:0.855 vs. 0.895). For tumor size measurement, mean tumor size was 3.51 cm for CESM (conventional dose) and 3.61 cm for MRI, compared with 3.38 cm on histopathological results, the average difference of diameters between CESM (conventional dose ), MRI and Histopathologic size was -0.02, -0.10cm, respectively. Additionally, average sizes were measured as 4.02 cm, 3.76 cm, 3.96 cm for CESM (low dose ), MRI and Histopathologic result, and the difference diameters compared to Pathologic data were -0.05, -0.08. Bland-Altman analysis showed best consistency on tumor size between CESM (low dose ), MRI and pathological results.

## CONCLUSION

Low doses (1.0ml/kg) of contrast agents for CESM exhibit comparable diagnostic performance and accuracy in tumor size assessment compared to CESM with conventional doses.

## CLINICAL RELEVANCE/APPLICATION

CESM performed with low-dose contrast agents can fulfill clinical and imaging requirements without compromising diagnostic accuracy, offering a promising alternative for breast lesion evaluation.

## T5B-SPCA-1 HEAD-TO-HEAD COMPARISON OF TWO COMMERCIAL ARTIFICIAL INTELLIGENCE SOFTWARE FOR CORONARY CT ANGIOGRAPHY WITH CORONARY ANGIOGRAPHY IN PATIENTS WITH CAD-RADS CATEGORIES 4 AND 5

Ji Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Hui Zhou, MD (*Abstract Co-Author*) Nothing to Disclose
Jing Luo (*Abstract Co-Author*) Nothing to Disclose
Yangzhen Hou (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the automated diagnostic results of coronary stenosis provided by two commercial artificial intelligence (AI) software for coronary CT angiography (CCTA) with coronary angiography (CAG) in patients with CAD-RADS categories 4 and 5.

### METHODS AND MATERIALS

This retrospective study included 123 consecutive patients with CAG-confirmed severe stenosis (stenosis 70%-99%) or occlusion (stenosis 100%) in at least one vessel. The same set of CCTA raw images of the patients were simultaneously sent to two commercial AI software (K-software and M-software) servers for analysis. The maximum degree of stenosis of the left main(LM), left anterior descending(LAD), left circumflex(LCX) and right coronary artery(RCA), number of stenosed vessels, number of vessels with stenosis =70% were recorded and compared.

### RESULTS

The maximum degree of stenosis of LAD, LCX and RCA calculated by both software are lower than that of CAG (all $p < 0.001$), with the measurements in M-software being lower than those of K-software (all $p < 0.001$). The number of vessels with stenosis and vessels with stenosis =70% provided by both software are significantly less than that shown by CAG (all $p < 0.001$). On Spearman correlation analyses analysis, the degree of stenosis measured by two software is significantly correlated in LM, LAD, LCX and RCA ($r=0.431$, 0.350, 0.618, 0.522, respectively; $p < 0.001$). On Bland-Altman analysis, the mean difference (95% limits of agreement) between CAG and K-software in LM, LAD, LCX and RCA is 9%(5%-13%), 23%(19%-27%), 34%(29%-39%), 18%(13%-22%), respectively. The mean difference (95% limits of agreement) between CAG and M-software in LM, LAD, LCX and RCA is 14% (10%-19%), 51%(47%-55%), 56%(51%-60%), 51%(47%-56%), respectively.

### CONCLUSION

The degree of coronary artery stenosis automatically measured by two commercial AI software were both significantly lower than the results of CAG, and both two AI software identified significantly fewer stenosed vessels than CAG.

### CLINICAL RELEVANCE/APPLICATION

This study shows that two commercial AI software for CCTA both significantly underestimate the extent and number of coronary stenosis. It is essential that the results provided by the AI software should be reviewed and corrected by experienced radiologists.

## T5B-SPCA-2 THERAPEUTIC EFFICACY OF TAFAMIDIS IN ADVANCED-STAGE PATIENTS WITH TRANSTHYRETIN AMYLOID CARDIOMYOPATHY

Seitaro Oda, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Masafumi Kidoh, MD, PhD (*Abstract Co-Author*) Endowed Chair, Koninklijke Philips NV
Shinpei Yamaguchi (*Abstract Co-Author*) Nothing to Disclose
Yasunori Nagayama, MD (*Abstract Co-Author*) Nothing to Disclose

### PURPOSE

Tafamidis improves prognosis in patients with transthyretin amyloid cardiomyopathy (ATTR-CM). While it is recommended to initiate tafamidis treatment at an early disease stage for optimal therapeutic efficacy, real-world data on its effectiveness in advanced-stage patients are scarce. This study aimed to evaluate the efficacy of tafamidis in advanced-stage ATTR-CM, defined by extracellular volume fraction (ECV).

### METHODS AND MATERIALS

This is a single-center, retrospective observational study. We assessed the clinical characteristics and outcomes of 80 patients with wild-type ATTR-CM treated with tafamidis. Patients were categorized into advanced-stage (ECV = 59%) and early-stage (ECV < 59%) groups based on ECV values obtained from cardiac MRI at tafamidis initiation. The 12-month therapeutic effect of tafamidis was determined using NYHA classification, blood biomarkers, and left ventricular ejection fraction criteria. We evaluated differences in treatment resistance rates 12 months post-treatment initiation between advanced-stage and early-stage groups.

### RESULTS

The mean ECV values for the advanced-stage (n=35) and early-stage (n=45) groups were 70.7±8.2% and 47.5±7.4%, respectively. There were no significant differences in treatment resistance rates based on NYHA classification criteria (18.8% vs. 7.0%, p = 0.14), blood biomarkers criteria (28.6% vs. 33.3%, p = 0.65), left ventricular ejection fraction criteria (37.1% vs. 31.1%, p = 0.57), and combined criteria (62.1% vs. 60.0%, p = 0.84) between advanced-stage and early-stage groups. No relationship between ECV and the 12-month therapeutic effect of tafamidis was observed.

### CONCLUSION

Even in advanced-stage patients (ECV = 59%), the 12-month therapeutic effect was comparable to that in early-stage patients (ECV < 59%).

### CLINICAL RELEVANCE/APPLICATION

The therapeutic effect of tafamidis can be anticipated even in advanced-stage ATTR-CM patients with ECV = 59%.

## T5B-SPCA-3 EXPLORING THE CAUSE OF THE DARK-BLOOD LGE PHENOMENON IN CARDIAC AMYLOIDOSIS USING CHANGES IN MYOCARDIAL CONTRAST MEDIUM CONCENTRATION THROUGH PHARMACOKINETIC ANALYSIS

### PURPOSE

To investigate the 'dark-blood' phenomenon's etiology in cardiac amyloidosis, evident by lower left ventricle signal on delayed contrast, compared with hypertrophic cardiomyopathy (HCM) that is important for differentiating hypertrophic hearts, through contrast medium concentration by pharmacokinetic analysis.

### METHODS AND MATERIALS

Twenty subjects (73 yrs, IQR 42,87) referred for CMR examination were included in this study, in which 7 subjects are biopsy-proven cardiac amyloidosis, and 13 subjects are HCM. A two-compartment pharmacokinetic model from dynamic T1 maps predicted myocardial contrast medium concentration (MCC) and left ventricular blood pool concentration (LVC), estimating myocardial ECV and contrast differences between MCC and LVC (diffConc). We calculated T1 values for the myocardium (MCT1) and left ventricle (LVT1), assessing their disparities (diffT1). PSIR images at 10 minutes after contrast administration were used to qualitatively evaluate the presence of dark-blood blood pool.

### RESULTS

MCC was higher in amyloidosis than in HCM during the entire evaluation time ($p<0.01$), ranging from 0.53 to 0.19 mM/L in amyloidosis and decreasing over time from 0.32 to 0.12 mM/L in HCM ($p<0.01$). LVC was lower in amyloidosis than in HCM at all time points ($p<0.01$), with significant ($p<0.01$) decreases over time from 0.63 to 0.24 mM/L in amyloidosis and from 0.74 to 0.29 mM/L in HCM. The diffConc at the time of observation ranged from -0.06 to 0.04 mM/L for amyloidosis and from -0.35 to -0.15 mM/L for HCM, showing a significant difference between the disease groups. ECV values ranged from 51% to 61% in amyloidosis, showing an upward convex pattern with maxima at 10 minutes, significantly higher than in HCM ($p<0.01$).HCM showed a convex pattern with maxima at 10 and 15 minutes, ranging from 27% to 33%. The MCT1 was consistently lower in amyloidosis (from 289 to 544 msec) than in HCM (from 404 to 651 msec) during the evaluation time and increased over time ($p<0.01$). LVT1 increased over time from 280 to 540 msec in amyloidosis ($p<0.01$), and from 239 to 465 msec in HCM, which is higher in amyloidosis. The diffT1 (6,-26,-49,-55,-48,-25msec) showed negative values in amyloidosis except after 5 min. In contrast, in HCM, all diffT1 values were positive (160,140,128,130,145,170msec).

### CONCLUSION

The LGE dark-blood phenomenon in amyloidosis is caused by blood T1 values higher than blood values, which may be due to contrast agent concentrations equal to or higher than the blood pool.

### CLINICAL RELEVANCE/APPLICATION

Pharmacokinetic methods can elucidate the dark-blood phenomenon and, in addition to T1 maps, can help distinguish between cardiac amyloidosis and HCM.

## T5B-SPCA-4 METABOLIC IMAGING BIOMARKER USING LIPID-SPECIFIC PEAK IN SINGLE BREATH-HOLD 1H-MR SPECTROSCOPY FOR ASSESSMENT OF MYOCARDIAL DISEASE ASSOCIATED WITH TYPE 2 DIABETES MELLITUS(T2DM)

Yasutoshi Ohta, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Ryogo Enoki, RT (*Abstract Co-Author*) Nothing to Disclose
Masaru Shiotani, RT (*Presenter*) Nothing to Disclose

**PURPOSE**

Increasing evidence is emerging that lipid oversupply to cardiomyocytes plays a role in the development of myocardial dysfunction in type 2 diabetes mellitus (T2DM), by causing lipotoxic injury and myocardial steatosis.Therefore, measurement of myocardial lipid deposition is important.1H-MR Spectroscopy (MRS) has a potential as lipid-specific biomarker to directly measure the abnormal accumulation.A single breath-hold ECG-gated 1H MRS acquisition can be applied as a time-efficient approach to measure myocardial lipid.This study aimed to assess the feasibility of MRS for detection of myocardial lipid accumulation in patients with myocardial disease associated with T2DM.

**METHODS AND MATERIALS**

Written informed consent was obtained from all subjects enrolled in the study. Thirty-five patients with myocardial disease associated with T2DM, 12 patients with non-ischemic cardiomyopathies without T2DM (NICM group), and 16 healthy volunteers underwent cardiac MRS. Among the T2DM patients, 23 patients were diagnosed with myocardial infarction (=MI group), 12 patients with cardiac dysfunction (LV hypertrophy, LV diastolic dysfunction and LA dilatation) without MI (=Non-MI group). MRS was obtained using single voxel PRESS sequence positioned within LV septum with single breath-hold. The peak of lipid (0.9+1.3 ppm) and water (4.7 ppm) were used as metabolic indicators of triglyceride content. Lipid/water ratio (LWR) was compared among T2DM patients, NICM group and volunteers. ROC analysis determined cutoff values for differentiation of these groups using LWR.

**RESULTS**

The LWR in T2DM patients was significantly higher compared to volunteers (0.296 vs. 0.105, $p < 0.05$). The cutoff value of LWR for distinguishing between T2DM patients and volunteers was 0.127 (sensitivity 81.1%, specificity 75.0%, AUC 0.846).Also, compared with NICM group patients, the LWR in T2DM patients were significantly higher in both MI and Non-MI groups (0.149, 0.321 and 0.248, $p<0.05$, respectively).The cutoff value of LWR for distinguishing between non-MI group and NICM group was 0.260 (sensitivity 58.3%, specificity 100%, AUC 0.764).

**CONCLUSION**

The LWR using single breath-hold 1H MRS acquisition showed the higher values in T2DM associated myocardial disease and enabled the detection of abnormal lipids deposition with high diagnostic accuracy.

**CLINICAL RELEVANCE/APPLICATION**

Single breath-hold MRS can acquire the direct and rapid quantification of myocardial lipid contents. Lipid peak of MRS could be disease-specific imaging biomarker for assessing myocardial triglyceride accumulation of T2DM associated myocardial disease beyond the conventional sequences. This metabolic imaging has a potential for evaluation of the disease severity and indication of therapy.

## T5B-SPCA-5 EVALUATION OF CARDIAC CHANGES IN PATIENTS WITH HIGH-ALTITUDE HEART DISEASE BY MAGNETIC RESONANCE MAPPING AND LGE

Hai Hua Bao (*Abstract Co-Author*) Nothing to Disclose
Li Meng (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate cardiac function and right ventricular myocardial changes in patients with high-altitude heart disease (HAHD) by magnetic resonance mapping and late gadolinium enhancement (LGE).

**METHODS AND MATERIALS**

12 HAHD patients and 15 matched healthy volunteers (the same altitude gradient and age range) in the same period were selected for cardiovascular magnetic resonance (CMR) mapping using 3.0 T magnetic resonance imaging (MRI) .

**RESULTS**

(1)The right ventricular end-diastolic volume (RVEDV, 169 ± 66 mL) and right ventricular end-systolic volume (RVESV, 97 ± 43 mL) were significantly higher in the HAHD group than in the control group. The right ventricular ejection fraction (RVEF, 43 ± 9 mL) was lower in the HAHD group. The right ventricular stroke volume (RVSV, 71 ± 30 mL), right ventricular cardiac index (RVCI, 2.6 ± 1.1 L/min/m2), and right ventricular cardiac output (RVCO, 4.9 ± 1.9 L/min) were higher in the HAHD group. The left ventricular end-systolic volume (LVESV, 77 ± 39 mL) and left ventricular cardiac output (LVCO, 5.7 ± 1.1 L/min) were significantly higher in the HAHD group. The left ventricular end-diastolic volume (LVEDV, 153 ± 60 mL), left ventricular stroke volume (LVSV, 84 ± 15 mL), and left ventricular cardiac index (LVCI, 3.1 ± 0.9 L/min/m2) were higher in the HAHD group than in the control group.The left ventricular ejection fraction (LVEF, 54 ± 10 mL) was lower in the HAHD group than in the control group.(2) In the HAHD group, pre-/post-enhancement T1 values and the extracellular volume fraction (ECV)% of all myocardial segments of the right ventricle (RV) were higher than those in the control group. For the right ventricle, the mean pre-enhancement T1 value was 1,374.3 ± 157.6, the mean post-enhancement T1 value was 551.7 ± 42.2, and the mean ECV% was 34.2 ± 6.8; the differences were significant.(3) The T2 value of the RV middle myocardial segment (42.1 ± 4.6) was significantly lower in the HAHD group than in the control group.However, the mean T2 value of the RV myocardium (42.8 ± 3.5) was lower in the HAHD group.(4)Delayed enhancement of the ventricular septum or RV endocardium was observed in some patients.

**CONCLUSION**

(1)In the HAHD group, RV enlargement and myocardial hypertrophy, right heart insufficiency;the disease might involve the left ventricle.(2) the patients might have different degrees of myocardial edema and inflammatory changes. The post-enhancement T1 values and ECV% of HAHD patients were significantly higher, and delayed enhancement in the ventricular septum and right ventricular endocardium was observed in some patients, indicating the possibility of fibrosis in the RV myocardium of the patients.

**CLINICAL RELEVANCE/APPLICATION**

To provide a new diagnostic basis and methods for HAHD patients and guide treatment.

## T5B-SPCA-6 EVALUATION OF THE MYOCARDIAL DAMAGE IN DUCHENNE MUSCULAR DYSTROPHY USING CARDIAC MAGNETIC RESONANCE IMAGE INTRA-VOXEL INCOHERENT MOTION ANALYSIS

Masami Yoneyama (*Abstract Co-Author*) Employee, Koninklijke Philips NV
Risako Nakao, MD (*Abstract Co-Author*) Nothing to Disclose

Akihiro Inoue, MD (*Abstract Co-Author*) Nothing to Disclose
Michinobu Nagao, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Koichiro Kaneko, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Shuji Sakai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akiko Sakai, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Yamamoto, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Duchenne muscular dystrophy (DMD) is characterized by progressive and fatal myopathy due to dystrophin protein deficiency. Myocardial involvement appearing after the teenage years, resulting in heart failure. Heart failure has become an increasing cause of death in recent years, however, the lack of imaging examination that can assess myocardial damage is a problem. Diffusion-weighted image (DWI) provides diffusion-limited proton molecules within cells as a high signal intensity. Cardiac magnetic resonance image intra-voxel incoherent motion (CMR-IVIM) using DWI is a new technique to simultaneously quantify tissue perfusion and diffusion. The quantitative values of diffusion and perfusion fraction are expressed as D and F values, and they have the potential to detect early myocardial damage not visualized by late gadolinium enhancement. We aimed to assess myocardial damage using D and F values measured by IVIM analysis quantitatively in patients with DMD.

**METHODS AND MATERIALS**

Data of CMR for 12 patients with DMD (mean age, 14 years) between January 2021 to December 2023 was retrospectively analyzed. Imaging was performed with 3 tesla CMR scanner. D and F values were measured placing region of interest on the septum of the mid myocardium. 6 healthy volunteers (age range: 22-48 years) were analyzed as the comparison group. The parameters of two groups were compared using the Mann-Whitney U test.

**RESULTS**

Mean D and F values of patients with DMD were 2.45 and 0.61. D value in patients with DMD was significantly higher than that in healthy volunteers (2.45 vs. 1.87, p=0.0057). F value in DMD group was equivalent to that in healthy volunteer group (0.61 vs. 0.57, p=0.60). The result suggested that diffusion was increased in the myocardium of mid-stage DMD compared to normal volunteers. Previous autopsy study has reported hypertrophy of cardiomyocytes in the myocardium of Duchenne muscular dystrophy, and this disease-specific mechanism and compensatory hypercontraction of the residual myocardium could be the reason for the increased diffusion in the damaged myocardium.

**CONCLUSION**

D and F values derived from CMR IVIM analysis are new indicators to evaluate the properties of myocardial tissue in patients with DMD.

**CLINICAL RELEVANCE/APPLICATION**

The new quantitative values obtained from IVIM analysis using DWI are useful for further detailed assessment of myocardial properties without radiation exposure and contrast media. Therefore, it is suitable for repeated imaging for follow-up of patients with DMD cardiomyopathy, who are mostly young.

## T5B-SPCA-8 PERIPARTUM CARDIOMYOPATHY IS ASSOCIATED WITH ABNORMALITIES OF MYOCARDIAL DEFORMATION AND LATE GADOLINIUM ENHANCEMENT

Elsie Nguyen, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose

Jacques Du Plessis, MBChB, FFRad(D)SA (*Presenter*) Nothing to Disclose

**PURPOSE**

Peripartum cardiomyopathy (PPCM) affects women in late pregnancy and in the postpartum period. Cardiovascular magnetic resonance (CMR) can contribute to the diagnosis and management of women with PPCM. The aim of this study was to explore CMR findings in PPCM with a focus on myocardial strain quantification and late gadolinium enhancement (LGE) pattern.

**METHODS AND MATERIALS**

In this retrospective single-center study, women with a clinical diagnosis of PPCM and clinically indicated CMR performed between 2010 to 2018 were included. Exclusion included other causes for cardiomyopathy. CMR parameters, including ventricular function, LGE, and quantitative myocardial strain, were compared between the PPCM group and a control group of healthy women.

**RESULTS**

Thirty-two women with PPCM were included (mean age 42±6 years) and 26 healthy women (mean age 43±14 years). Women with PPCM had significantly lower left ventricular (LV) ejection fractions (median 37.5%, 25.5-45.5 vs. 60.5%, 57.0-63.0, p<0.001), higher LV end-diastolic volumes (median 108 ml/m2, 93.5-135.5 vs. 76 ml/m2, 71.0-88.0, p<0.001), reduced global LV circumferential strain (mean -11.1±4.5 vs -19.2±1.6 p<0.01), reduced global LV radial strain (mean 16.0±8.1 vs 33.2±4.5, p<0.001), and reduced global LV longitudinal strain (mean -11.4±4.2 vs -18.6±1.4, p<0.001), compared to controls. Eighteen patients (58%) had non-ischemic pattern LGE, with no LGE in the controls. LGE was most prevalent in the basal anteroseptum (n=12) and mid anteroseptum (n=8). LGE patterns observed included linear mid-wall (n=8), linear subepicardial (n=6), and right ventricular side of the interventricular septum (n=3).

**CONCLUSION**

LGE is frequent in patients with PPCM, most often in a non-ischemic pattern at the basal or mid anteroseptum. Quantitative myocardial strain values are also abnormal in PPCM compared to heathy controls.

**CLINICAL RELEVANCE/APPLICATION**

We identified a non-ischemic pattern LGE that is nonspecific in isolation but could suggest PPCM in the correct clinical context along with abnormal CMR strain values. Future study should evaluate the clinical application of these findings to facilitate earlier diagnosis and enhance management.

## T5B-SPCA-9 CLINICAL-RADIOLOGIC CORRELATION OF COMMON CONDUCTION SYSTEM ABNORMALITIES AND POSITIVE IMAGING FINDINGS IN CARDIAC SARCOIDOSIS

Dhiraj Baruah, MBBS, MD (*Abstract Co-Author*) Grant, Blue Eye Soft Corp;Consultant, ImBio, LLC
Ismail M. Kabakus, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Brendan McNeal (*Abstract Co-Author*) Nothing to Disclose
Jordan H. Chamberlin, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Major conduction abnormalities such as third-degree heart block and ventricular tachycardia have long been considered suspicious for cardiac involvement in sarcoidosis as identified by Fludeoxyglucose-18 Positron Emission Tomography (18FDG-PET) or cardiac MRI (CMR). However, there is substantial uncertainty regarding the implications of the much more common "low-grade" conduction abnormalities and ectopy discovered on routine electrocardiogram (ECG) screening. Recent advances in non-invasive cardiac imaging and prophylactic treatment necessitate an updated assessment of prevalence and predictive value.

### METHODS AND MATERIALS

126 patients with biopsy-proven systemic sarcoidosis who underwent advanced imaging (18FDG-PET and CMR) were retrospectively included. Cardiac sarcoidosis (CS) diagnosis was defined by the 2017 Japanese Circulation Society (JCS) criteria. Before the advanced imaging, ECGs and cardiac event monitors recorded the presence of atrioventricular blocks (AVB), bundle branch blocks (BBB), and ectopy. Prevalence, odds ratios, and positive predictive values (PPV) were then calculated.

### RESULTS

58 (46.0%) patients were found to have CS by JCS criteria. The most prevalent conduction system abnormality in patients with CS was ectopy (Premature Ventricular Contraction PVCs = 51.7%; Premature Atrial Contraction PACs = 29.3%), followed by any BBB (27.7%; RBBB = 17.2%), and any AVB (15.5%, 1° = 12.1%). Incomplete BBBs had the highest PPV (83.3%), followed by 1° AVB (77.8%). PVCs only had a PPV of 50.8%. Positive LGE, T2, or FDG-PET uptake was observed in over 50% of patients with 1° AVB and Incomplete BBBs, and greater than 25% of patients with PVCs, PACs, LBBBs, and RBBBs. The average prevalence of LGE, FDG-PET uptake, and T2 hyperintensity was 75%, 72.1%, and 87.1%, respectively.

### CONCLUSION

Ectopy and "low-grade" conduction system abnormalities were observed to have a higher-than-expected prevalence in conjunction with imaging findings of CS.

### CLINICAL RELEVANCE/APPLICATION

Cardiac imagers and clinicians should be aware of increased associations and consider potential indications for expedited advanced cardiac imaging for earlier diagnosis of disease.

Kuan Yu Chen (*Presenter*) Nothing to Disclose

### PURPOSE

Computed tomography-based deep learning (CT-DL) shows promise in predicting high-grade lung adenocarcinoma histologic patterns (HGP), aiding the novel prognostic grading of adenocarcinoma. However, texture variation due to CT parameters challenges the model's generalizability. This study investigated whether solely utilizing binary tumor masks can reduce texture dependence and predict HGP, potentially enhancing model generalizability.

### METHODS AND MATERIALS

A retrospective study enrolled patients (2012-2021) with complete lung resection, non-/ contrast-enhanced chest CT, and confirmed pathology. The Texture-Less Deep Learning (TL-DL) model, comprising a convolutional neural network (CNN) and graph convolutional network, employed only binary tumor masks was developed in this study. Specifically, the tumor mask was automatically extracted with U-net and refined by the physicians, and it was then partitioned into a ground-glass opacity (GGO) mask by a threshold of -534 HU. The tumor and GGO mask intend to provide the texture-independence shape message and basic texture information (i.e., consolidation-to-tumor [C/T] ratio) for deep feature learning. The model performance was evaluated by the AUC and compared with CT-DL (CNN with CT images alone) and C/T ratio by DeLong's test in the testing set. Furthermore, for the model interpretation, the deep features were visualized by the integrated gradients, and correlated with shape features using Spearman's rank correlation coefficient.

### RESULTS

A total of 539 patients were studied, including 422 in the training set and 117 in the testing set. The proposed TL-DL achieved an AUC of 0.88 for the internal 5-fold cross-validation, and an AUC of 0.93 (sensitivity of 91% [10/11], specificity of 90% [95/106]) in external validation which significantly outperformed the CT-DL (AUC of 0.87, $P < .05$) and C/T ratio (AUC of 0.86, $P < .05$). The deep features represent different lesion types and demonstrate a strong correlation with shape irregularity (Spearman's ? = 0.7).

### CONCLUSION

We have proposed a new TL-DL model relying solely on binary tumor masks, which reduces texture dependence, yielding promising results for HGP prediction (0.93 AUC). The model's interpretability, revealing deep features' correlation with shape irregularity, offers a potential biomarker to radiologists in HGP diagnosis.

### CLINICAL RELEVANCE/APPLICATION

Training DL with only binary tumor masks holds promise for histologic pattern prediction, mitigating texture dependence and potentially increasing generalizability for varying CT settings. Furthermore, the interpretable deep features of the proposed method may provide valuable insights for radiologists' clinical diagnosis of HGP.

## T5B-SPCH-5 AI-BASED CLASSIFICATION USING PRE-RECONSTRUCTION IMAGES OF TOMOSYNTHESIS: SYSTEM DEVELOPMENT AND VALIDATION

Myung Jin Chung, MD (*Abstract Co-Author*) Research Consultant, Samsung Electronics Co, Ltd;Research Consultant, Pharmex Advanced Laboratories, SL;Research Grant, Lunit Inc;Research Grant, VUNO Inc
Hakje Yoo (*Abstract Co-Author*) Nothing to Disclose
Seongje Oh, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

Chest Digital Tomosynthesis (CDTS) is a medical device supporting three-dimensional visual diagnosis while minimizing patient radiation exposure compared to CT scans. However, CDTS provides lower image quality compared to CT scans due to limited angles, and the under-sampling during the reconstruction process may lead to inaccurate results. Hence, there is a need for a sophisticated artificial intelligence (AI) model for automated detection of chest diseases in CDTS that minimizes the information loss resulting from the reconstruction process, ensuring accurate diagnosis. Accordingly, we proposed an AI model for CDTS diagnosis.

**METHODS AND MATERIALS**

We propose a CDTS-specific AI model called 2Dto3D, which minimizes information loss due to reconstruction compared to conventional methods that learn from reconstructed CDTS. our approach utilizes the pre-reconstruction projection images for diagnosis. Specifically, we acquire feature maps of projected images through a 2D classifier. These maps are then fused into 3D feature maps, which are subsequently diagnosed using a 3D classifier. we collected 1000 CT scans, including 500 normal, 200 tuberculosis, and 300 pneumonia cases. These CT scans were acquired using the same imaging technique as CDTS, generating seven projection images at 120-degree intervals. We compared our method with conventional 3D model using CDTS reconstructed into seven views and CDTS reconstructed into 26 views.

**RESULTS**

The proposed AI system demonstrated an AUC (Area Under the Receiver Operating Characteristic Curve), accuracy, sensitivity, and specificity of 0.937, 0.870, 0.860, and 0.880, respectively. Compared to the conventional method (0.914, 0.829, 0.822, and 0.840, respectively) trained on CDTS images reconstructed with the same dose, it showed performance improvements of 2.3%, 4.1%, 3.8%, and 4%, respectively. Additionally, despite using only 7 views, the proposed AI system exhibited similar AUC results to the conventional method using CDTS images reconstructed into 26 views (0.937 vs. 0.930), while also achieving enhanced accuracy (0.870 vs. 0.847), sensitivity (0.860 vs. 0.838), and specificity (0.880 vs. 0.856) compared to the conventional method.

**CONCLUSION**

The proposed AI model improved the diagnostic performance of lung diseases based on tomosynthesis. Additionally, it demonstrated similar results to those obtained from higher radiation dose data when compared with reconstructed CDTS, validating its efficacy in minimizing radiation exposure.

**CLINICAL RELEVANCE/APPLICATION**

Our AI model has been validated based on CDTS, but we expect it to be applicable to other data reconstructed into three dimensions based on projection images similar to CDTS.

## T5B-SPCH-6 A MULTI-CLASSIFICATION MODEL BASED ON RADIOMICS TO DISTINGUISH PATHOLOGICAL TYPES OF PULMONARY GGNS

Kai Ji (*Abstract Co-Author*) Nothing to Disclose
Junyan Yue (*Abstract Co-Author*) Nothing to Disclose
Haipeng Liu (*Abstract Co-Author*) Nothing to Disclose
Xiaoyun Liang (*Abstract Co-Author*) Nothing to Disclose
Mengzhou Sun (*Presenter*) Nothing to Disclose

**PURPOSE**

This study performed three classifications (IA: invasive adenocarcinoma, MIA: minimally invasive adenocarcinoma, and PIA: pre-invasive adenocarcinoma) on CT images of patients with pulmonary ground glass nodules (GGN) based on different multi-classification model. The aim is to help clinicians accurately intervene and treat different types of pulmonary nodules.

**METHODS AND MATERIALS**

A total of 282 CT images of patients with pulmonary nodules were included. According to the types of pulmonary nodules, they were allocated into one of three groups: IA (127), MIA (80) and PIA (117). A total of 1609 radiomics features were extracted from radiologist annotations based on segmented results of nodular lesions by using the U-Net network . In addition, 16 sets of clinical and imaging feature data corresponding to the patients (age, smoking, density, etc.) were collected as well. Two comparative experiments were conducted as follows: prediction based on radiomics features and prediction based on radiomics features plus clinical and imaging features. Firstly, 90 features were selected from 1609 radiomics features with the recursive feature elimination method; the clinical and imaging features were reduced from 16 to 5 through univariate linear regression. Secondly, the data were divided into a training set (80%) and a test set (20%), and five-fold cross-validation was used to select the optimal model. We used three machine learning models in the sklearn package on Python: Random Forest (RF), Support Vector Machine (SVM), and Logistic Regression (LR). Finally, three weak classifiers were integrated into one strong classifier (ensemble learning).

**RESULTS**

Four metrics were employed to evaluate the developed models (Table 3): accuracy, precision, recall and F1-score. Among the 3 models, the model with the best performance in prediction based on radiomics classification is LR, with an accuracy of 0.719, and the accuracy of SVM and RF are 0.707 and 0.7, respectively. Further combination of clinical and radiomics features improved the performance of all three models, yielding accuracy values of 0.753, 0.717, and 0.747 for LR, SVM, and RF models, respectively. As expected, the best model was the ensemble learning model (clinical plus radiomics features), with values of 0.817, 0.797, and 0.779 for the accuracy, recall, and precision metrics, respectively.

**CONCLUSION**

In conclusion, our results have demonstrated that the fused model proposed in this article can effectively distinguish pathological types of pulmonary nodules, which may benefit diagnosis and clinical treatment.

**CLINICAL RELEVANCE/APPLICATION**

The employment of ensemble learning can predict the category of pulmonary nodules more accurately, thus improving the treatment outcomes.

## T5B-SPCH-7 3D RADIOMICS IN LONGITUDINAL FOLLOW-UP CT SCANS AS USEFUL MARKERS IN DIFFERENTIATING MALIGNANT POTENTIAL FOR PURE GROUND GLASS OPACITY IN LUNG

YUAN TING CHANG (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate whether 3D radiomics can differentiate malignant potential of pure ground glass opacities (pGGO) in baseline and longitudinal follow-up CT scans.

**METHODS AND MATERIALS**

Participants with pGGO who underwent surgery from 2017-2019 with at least two prior CT scans available in Mackay Memorial Hospital, a tertiary medical center in Taiwan, were retrospective recruited. Pathological results of atypical adenomatous hyperplasia and adenocarcinoma in situ were classified as non-invasive group, while minimal invasive adenocarcinoma and invasive adenocarcinoma as invasive group. Radiomics for analysis were preselected based on previous literature and clinical relevance. The volume of the lesions were also collected. Baseline and follow-up CT scans, as well as the difference across time span were analyzed. Wilcox test was applied to compare the radiomics between non-invasive and invasive lesions.

**RESULTS**

A total of 30 patients with 79 pGGOs was analyzed in this study. In both baseline and follow-up CT scans, invasive lesions had significantly higher entropy, maximum, mean absolute deviation, range, and variance than non-invasive lesions. Moreover, the difference of the abovementioned radiomics between baseline and follow-up CT as well as the difference accounted for follow-up interval was also larger in the invasive group; albeit only the result of variance reached significance (variance by time, median: invasive 23.0, non-invasive 4.4, p=0.04). In contrast, no significant difference between invasive and non-invasive groups was found for volume of the lesion at either time point. The difference of volume between baseline and follow-up CT was not significant, either.

**CONCLUSION**

This pilot study suggests that certain 3D radiomics, including entropy, maximum, mean absolute deviation, range, and variance, but not volume, are higher and may progress more rapidly over time in invasive pGGOs compared to the non-invasive pGGOs.

**CLINICAL RELEVANCE/APPLICATION**

Certain radiomics may be useful in assisting clinicians in evaluating pGGOs, improving risk stratification and guiding treatment strategy.

## T5B-SPCH-8 PROGNOSTIC VALUE OF AI-DRIVEN PREOPERATIVE CHEST RADIOGRAPH ANALYSIS IN SURGICALLY RESECTED PATHOLOGIC STAGE 1 NON-SMALL CELL LUNG CANCER

Eun Hye LEE (*Abstract Co-Author*) Nothing to Disclose
Hyun Joo Shin, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Young Joo Suh, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Nayoung Kim (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the prognostic value of the artificial-intelligence (AI)-driven analysis of preoperative chest radiographs (CXR) in patients with surgically resected pathologic stage 1 non-small cell lung cancers (NSCLCs).

**METHODS AND MATERIALS**

We retrospectively enrolled consecutive patients who underwent curative surgical resection for pathological stage 1 NSCLCs from March 2020 to February 2021 at two referral hospitals. AI-driven preoperative CXR analysis was performed for the detection for nodules, consolidation, fibrosis, and atelectasis, from which abnormality scores were derived. The visibility of lung cancer lesions on preoperative CXRs and lesion detectability on AI (abnormality score threshold of = 15) were assessed by experienced radiologists. Logistic regression analysis was performed to evaluate the association of lesion detectability on AI with pathological or radiological factors. Cox proportional hazards regression analyses were performed to determine predictors of recurrence-free survival.

**RESULTS**

Among 416 patients (mean age, 65.6 years ± 9.9; 197 men), 257 patients (61.8%) had CXR-visible lung cancers. Among CXR-visible lung cancers, 208 lesions (80.9%) were detected by AI (197 nodules, 53 consolidations, 48 fibroses, and 8 atelectases). AI-detectable lung cancers were associated with a larger solid portion size on preoperative CT (odds ratio [OR] 1.17, 95% confidence interval [CI] 1.14-1.21 per 1 mm increase; P<0.001), lesion type of part-solid nodule or solid nodule (OR 9.6 [95% CI 3.7-25.1] and OR 30.3 [95% CI 11.4-80.6]; P<0.001), and higher pathologic stage (P<0.001) compared to AI non-detectable lung cancers. During a follow-up period of 1060 ± 200.7 days, 34 patients (8.2%) experienced disease recurrence. Both AI abnormality score and AI detectability were significant independent risk factors for poor recurrence-free survival (hazard ratio [HR] 1.03 [95% CI 1.02-1.04] per score increase; P<0.001, HR 7.04 [95% CI 2.47-20.10]; P<0.001) when adjusting for clinical variables. A prognostic model based on AI abnormality score and clinical variables showed similar performance (C-index 0.8 [95% CI 0.741-0.859]) compared to the models based on pathological stage and clinical variables (C-index 0.821 [95% CI 0.762-0.881]), and solid portion size on CT and clinical variables (C-index 0.846 [95% CI 0.798-0.894]; P>0.05 for all comparison).

**CONCLUSION**

AI-driven analysis of preoperative CXR can enhance the preoperative prediction of postoperative prognosis in patients who undergoing surgical resection for early stage of NSCLCs.

**CLINICAL RELEVANCE/APPLICATION**

AI abnormality score on preoperative CXR can aid to predict postoperative recurrence in patients with surgically resected pathologic stage 1 NSCLCs.

## T5B-SPCH-9 THE DIAGNOSTIC PERFORMANCE OF AN AI-BASED COMPUTER-AIDED DETECTION SYSTEM FOR PULMONARY NODULES CONSIDERING LOCALIZATION AND LUNG-RADS CATEGORIES: A MULTI-CENTER, RETROSPECTIVE CLINICAL TRIAL

Dahye Lee (*Abstract Co-Author*) Nothing to Disclose
Soobum Kim (*Abstract Co-Author*) Nothing to Disclose

Kibok Nam (*Abstract Co-Author*) Nothing to Disclose
Yeon Joo Jeong, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hoseok I, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Juyoung Lee (*Abstract Co-Author*) Nothing to Disclose
Gucheol Jung (*Presenter*) Nothing to Disclose

**PURPOSE**

We evaluated the diagnostic performance of a deep-learning based computer-aided detection (CAD) system, which provides information on the texture (solid, ground-glass opacity and part-solid), size, malignancy classification, lung-RADS category and localization of pulmonary nodules in low-dose Computed Tomography (LDCT) images.

**METHODS AND MATERIALS**

This clinical trial was designed as a multi-center, retrospective using external validation datasets of 455 LDCT (malignant 135, benign 190, normal 130) images. Using medical image annotation software, two radiologists from each institution independently annotated the texture and size of abnormalities on each radiograph and marked the localized abnormal regions with a freehand drawing tool. After radiologists completed the annotation, the medical device software (DEEP:LUNG, DL-LN-02, DEEPNOID Inc., Seoul, Korea) interpreted the LDCT images. As a primary endpoint in a clinical trial, we evaluated localization-adjusted sensitivity, specificity for detecting lung nodules and AUROC for classifying malignancy of lung nodules. The secondary endpoint evaluated the performance according to the lung-RADS categories. We also compared the sizes directly measured by radiologists using annotation software with the size predicted by the CAD.

**RESULTS**

As a primary endpoint, the sensitivity for pulmonary nodule detection was 91.38%, the specificity for pulmonary nodule detection was 93.08% and the AUROC for malignancy classification was 89.62%. As a secondary endpoint, the sensitivities for lung-RADS category 1 to 4A, 4B were 93.08%, 68.92%, 23.81% and 88.15%, while the specificities for lung-RADS category 1 to 4A, 4B were 100.00%, 90.55%, 89.35% and 90.62%, respectively. In solid nodules and ground-glass opacity nodules, the sizes were equivalent with a margin of 2mm and 3mm, respectively, according to the equivalence test ($p=0.0458$, $p=0.0004$).

**CONCLUSION**

In conclusion, DL-LN-02 indicates that its sensitivity, specificity, and malignancy classification AUROC demonstrate superior performance in the detection and classification of pulmonary nodules and malignancies by radiologists. It is anticipated that the proposed medical device software could offer valuable assistance in clinical diagnosis within medical practice.

**CLINICAL RELEVANCE/APPLICATION**

To apply deep-learning based automated analysis algorithm into actual practice, we propose a detection and segmentation model to select the subject image for analysis of lung nodules, which is required to be low-dose CT images.

### PURPOSE

Pneumomediastinum is an incidental but importantfinding on chest x-rays. A prompt detection and clinical correlation plays avital role in urgent patient management. We assessed the performance of an AIalgorithm for detecting the presence of pneumoperitoneum on CXRs as compared toradiologists.

### METHODS AND MATERIALS

With IRB (Institutional Review Board)approval, a total of 600 cases were included in the study, in a consecutive andretrospective manner. Out of 600 cases, 300 cases were positive forpneumomediastinum, and 300 were negative for pneumomediastinum, based on theoriginal radiology reports. Following the image quality review, ground truthinterpretation by 1st/2nd radiologists yielded results for 234 (39.0%) positiveand 366 (61.0%) negative cases for pneumomediastinum. 87 (14.5%) cases requiredadjunct review by 3rd radiologist, for the discrepant cases. After AI modelinference, 599 (99.8%) cases were inferenced and 1 case was excluded due tofailure in processing by the model. Descriptive analyses were performed todetermine the AUC, sensitivity, and specificity of the AI model to detect thepresence of pneumomediastinum finding on chest x-rays.

### RESULTS

The mean age and SD for the cases was 62.5 ±17.0, ranging from age 22 to 99 years. The cohort consisted of 341 males(58.8%), and 239 females (41.2%). The AUC for the identification ofpneumomediastinum by the AI model was calculated to be 0.886 (95% CI:0.856-0.912). At predetermined operating point of 0.0368, AI model hadsensitivity of 59.9% (95% CI: 53.2%-66.2%), and specificity of 95.0% (95% CI:92.7%-97.2%). The AUC, sensitivity and specificity for females are 0.868,53.8%, and 93.2% and males are 0.9, 64.1% and 96.2% respectively. The AUC,sensitivity and specificity for patient positioning in erect subgroup are0.934, 75.5%, and 95.0% and in supine subgroup are 0.828, 43%, and 95%,respectively. The AUC, sensitivity and specificity for CXR AP or PA withoutlateral projection are 0.877, 57.7%, and 95.1% respectively. The AUC,sensitivity and specificity for CXR AP or PA with lateral projection are 0.934,75%, and 94.4% respectively.

### CONCLUSION

The AI algorithm can detect the presence ofpneumomediastinum with high specificity.

### CLINICAL RELEVANCE/APPLICATION

AI model can be used as an adjunct in detectionof pneumomediastinum for equivocal or non-specific chest x-rays in suspectedpneumomediastinum patients.

## T5B-SPER-2 1.EXPLORING THE EFFECTIVENESS OF ENERGY SPECTRUM CT WATER-HYDROXYAPATITE DECOMPOSITION TECHNIQUE IN CHRONIC OSTEOMYELITIS-RELATED BONE MARROW EDEMA

Kaibo He (*Abstract Co-Author*) Nothing to Disclose
Jing Liu (*Abstract Co-Author*) Nothing to Disclose

Zhang Zekun (*Abstract Co-Author*) Nothing to Disclose
Qian Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of dual-energy CT hydroxypatite(HAP) Water decomposition technique in chronic osteomyelitis.

**METHODS AND MATERIALS**

The CT and MRI data of 15 patients with chronic osteomyelitis examined in our hospital were retrospectively analyzed. Taken MRI results as reference standards, the colored image of Water(HAP) obtained by energy spectrum CT scan was evaluated,and the water density, the HAP density, effective atomic number(Zeff) of the bone marrow edema area and the contralateral position of the healthy side was compared by t-test.The consistency of Water(HAP) image and MRI image was tested by Kappa.

**RESULTS**

The water density of bone marrow edema area was significantly higher than that in healthy side,there was statistically significant differences between the two groups of data,t=6.473,P=0.00<0.05.The HAP density of bone marrow edema area was significantly lower than that in healthy side,there was statistically significant differences between the two groups of data,t=-2.975,P=0.01<0.05.There was no statistically significant differences between the two groups of Zeff.The diagnostic results of bone marrow edema by Water(HAP) image and MRI image were in moderate agreement,kappa=0.432,P=0.04<0.05.

**CONCLUSION**

Energy spectrum CT scan can be used in the diagnosis and quantitative analysis of bone marrow edema in chronic osteomyelitis.

**CLINICAL RELEVANCE/APPLICATION**

Energy spectrum CT is helpful for the diagnosis and quantitative analysis of bone marrow edema in chronic osteomyelitis, and improves the diagnostic efficacy of CT in bone marrow edema.

## T5B-SPGI-1 THE CLINICAL VALUE OF MACHINE LEARNING MODELS BASED ON MRI AND CLINICAL INDICATORS IN PREDICTING DISTANT METASTASIS OF HEPATIC HYDATID CYSTS

Changyou Long (*Abstract Co-Author*) Nothing to Disclose
Pengqi Tian (*Abstract Co-Author*) Nothing to Disclose
Xueqian Zhang (*Abstract Co-Author*) Nothing to Disclose
Yujie Xing (*Abstract Co-Author*) Nothing to Disclose
Yeang Tenzin (*Abstract Co-Author*) Nothing to Disclose
Hai Hua Bao (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the feasibility of machine learning models in predicting distant metastasis of hepatic hydatid cysts.

### METHODS AND MATERIALS

This study recruited a total of 257 patients diagnosed with hepatic hydatid cysts who underwent magnetic resonance imaging (MRI) at our hospital between January 2014 and March 2024 (distant metastasis: without metastasis = 88:169). Clinical baseline indicators and imaging features on MRI of hepatic hydatid cysts were collected for each patient. Features closely associated with multi-organ metastasis of hepatic hydatid cysts were selected through basic statistical methods. These selected features were then used to construct five independent classification models based on random forest (RF), support vector machine (SVM), logistic regression (LR), bagging decision tree (Bagging DR), and Gaussian process (GP) algorithms using 10-fold cross-validation. The efficiency of the models was evaluated using receiver operating characteristic (ROC) curves and the area under the curve (AUC), and compared with the diagnoses of seven resident physicians with two years of experience and two professionally trained radiologists with seven years of experience using the DeLong test.

### RESULTS

Eleven optimal features were selected based on traditional statistical methods, and machine learning models were constructed. In both the training and validation sets, the model based on clinical and MRI imaging features performed best under the Bagging decision tree (AUC: training = 0.946; validation = 0.926). The AUC values of resident physicians and professionally trained radiologists were both lower than the best-performing Bagging decision tree model (test set AUC: 0.640 and 0.766, respectively).

### CONCLUSION

Machine learning models based on MRI and clinical indicators have achieved high accuracy in predicting multi-organ metastasis of hepatic hydatid cysts, demonstrating their potential to assist in early clinical intervention.

### CLINICAL RELEVANCE/APPLICATION

These models improve early detection and prognosis, helping doctors tailor treatments and enhance patient outcomes in hepatic hydatid cyst management. By blending MRI with clinical data, they boost diagnostic accuracy, guiding more informed decisions for better care.

## T5B-SPGI-10 PREDICTION OF HISTOPATHOLOGIC GROWTH PATTERNS AND PROGNOSIS OF COLORECTAL LIVER METASTASES WITH MR IMAGING FEATURES

Kumi Ozaki, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To identify the distinguishable MR imaging features of replacement histopathologic growth pattern (rHGP) of colorectal liver metastasis (CRLM) from that of desmoplastic HGP (dHGP).

### METHODS AND MATERIALS

One hundred and four CRLMs in 79 patients (46 men and 33 women, mean age, 66.1) who underwent gadoxetic acid-enhanced MRI followed by partial hepatectomy between January 2011 and December 2021 were included. CRLMs were pathologically divided into rHGP or dHGP according to international consensus guidelines. Clinical data and imaging findings of MR imaging (contrast-to-noise ratio [CNR] at T1-, T2-, diffusion-weighted images [WI], ADC value, CNR and enhanced ratio at enhanced images) with focusing on the both tumor itself and segmented tumor-liver interface zones (peritumoral area) of CRLMs were evaluated, and were statistically analyzed.

### RESULTS

No patients with more than one CRLM revealed the different HGPs. No significant difference was found in any factors between the patients with CRLMs of rHGP and dHGP other than in overall survival. Forty-three CRLMs were diagnosed as rHGP, while 61 were diagnosed as dHGP. In quantitative assessment of the tumor itself, there were no significant differences between rHGP and dHGP in the maximum diameter, location, CNR at T2-, T1-, and diffusion WI, ADC value, CNR and enhanced ratio at arterial, portal, and hepatobiliary phase images. At peritumoral area, thickness of peritumoral area at arterial phase image, CNR and enhanced ratio at arterial and portal phase images are significantly larger in rHGP than those of in dHGP (plt;0.05). Area under the receiver operating characteristic curves of distinguishing rHGP from dHGP were 0.920 [0.871-0.969] in CNR at arterial phase image, 0.839 [0.766-0.911] in thickness of peritumoral area, and 0.795 [0.706-0.885] in enhanced ratio at arterial phase image, 0.727 [0.629-0.824] in enhanced ratio of arterial phase to portal phase, 0.665 [0.553-0.777] in CNR at portal phase image, 0.612 [0.498-0.726] in enhanced ratio at portal phase image. Kaplan-Meier overall survival curves were significantly worse in the patients with CRLMs predicting rHGP by MR images of CNR at arterial phase image, enhanced ratio at arterial phase image, and thickness of peritumoral area (p lt; 0.05).

### CONCLUSION

MR imaging features of CRLMs can discriminate rHGP from dHGP and predict the prognosis.

### CLINICAL RELEVANCE/APPLICATION

MR imaging features of colorectal liver metastases can discriminate histopathologic growth patterns and predict the prognosis.

## T5B-SPGI-12 EXTRACELLULAR VOLUME FRACTION BASED ON CONTRAST ENHANCED CT FOR PREOPERATIVE PREDICTING OF MACROTRABECULAR-MASSIVE HEPATOCELLULAR CARCINOMA

Xin Yang (*Abstract Co-Author*) Nothing to Disclose
Wenjian Wang (*Abstract Co-Author*) Nothing to Disclose
Xianfu Luo (*Abstract Co-Author*) Nothing to Disclose
Jiale Hang (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the potential of extracellular volume fraction (ECV) based on contrast-enhanced CT(CECT) in predicting macrotrabecular-massive hepatocellular carcinoma (MTM-HCC).

### METHODS AND MATERIALS

The preoperative CECT images of 79 patients with hepatocellular carcinoma were retrospectively analyzed. 23 cases of MTM-HCC and 56 cases of nMTM-HCC (none-macrotrabecular-massive hepatocellular carcinoma) were enrolled. All patients underwent abdominal plain scan and contrast-enhanced CT examination. The CT values of the abdominal aorta area, tumor area and normal liver parenchyma around the tumor were measured by circular region of interest (ROI) in the plain scan and equilibrium phase images, and the extracellular volume fraction (ECV) of the tumor area and normal liver parenchyma around the tumor was calculated. The differences of ECV between MTM-HCC group and nMTM-HCC group were compared. The ECV model for predicting MTM-HCC was developed, and its predictive efficacy was evaluated by the area under the receiver operating curve (AUC).

### RESULTS

The Etumor (CT value of the tumor area in equilibrium phase) was lower in the MTM-HCC group than that in nMTM-HCC group (64.5±16.8Hu vs.78.6±16.8Hu, P=0.001). The ?tumor (absolute enhancement value of the tumor area) was lower in MTM-HCC group than that in nMTM- HCC group (23.2±9.5 Hu vs. 36.3±14.2 Hu, P<0.001).The ECVtumor (ECV of the tumor area) value of the MTM-HCC group was lower than that of the nMTM-HCC group (16.8±5.2% vs. 26.6±7.9%, P<0.001), and the ECVliver (ECV of the normal liver parenchyma around the tumor) value of the MTM-HCC group was lower than that of the nMTM-HCC group (27.5±7.9% vs. 30.2±6.5%, P=0.132). The AUC of Etumor, ?tumor and ECVtumor for the diagnosis of MTM-HCC were 0.74, 0.77 and 0.87, respectively.

### CONCLUSION

Extracellular volume fraction based on CECT shows promise for predicting macrotrabecular-massive hepatocellular carcinoma.

### CLINICAL RELEVANCE/APPLICATION

Preoperative CECT based ECV for identifying of the aggressive HCC subtypes MTM-HCC may have strong prognostic and therapeutic implications.

Katsuhiro Sano, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Q-space trajectory imaging (QTI) is a state-of-the-art technique and yields not only fractional anisotropy (FA), but also isotropic, anisotropic, and total mean kurtosis (MKi, MKa and MKt), and microscopic anisotropy (μFA). The purpose of this study was to investigate these QTI values in focal liver lesions (FLLs).

**METHODS AND MATERIALS**

The study included 137 lesions in 93 consecutive patients (men: women=57: 36, 64.5±14.4 y.o.) who underwent gadoxetic acid-enhanced magnetic resonance imaging to diagnose FLLs between November 2022 and April 2024. Linear tensor encoding (LTE) and spherical tensor encoding (STE) were scanned using a 3T MR system, MAGNETOM Prisma (Siemens Healthcare). The scan parameters were as follows: TR/TE=1700/73; diffusion directions=47 (LTE) and 41 (STE); max b value = 1000; slice thickness=5. The diagnosis of FLLs (39.7±35.0mm) were as follows: 41 hepatocellular carcinomas (HCC); 9 intrahepatic cholangiocarcinomas (ICC); 43 metastatic tumor (META); 17 liver hemangiomas; 7 focal nodular hyperplasias (FNH); 15 simple cysts; 5 complicated cysts. A maximum of three lesions per person was included and nodules smaller than 10 mm were excluded. Diseases with fewer than five counts were excluded. ROIs were set in the liver parenchyma and FLLs in images b=0, and FA, μFA, and mean kurtosis (MKi, MKa, MKt) were calculated.

**RESULTS**

Mean results of liver parenchyma and FLLs of FA, μFA, and mean kurtosis were as follows: FA=0.38±0.14, μFA=0.52±0.11, MKi=0.94±0.33, MKa=0.44±0.28, MKt=1.37±0.44 for liver parenchyma; FA= 0.43±0.20, μFA=0.62±0.16, MKi=0.70±0.30, MKa=0.69±0.44, MKt=1.37±0.36 for HCCs; FA=0.44±0.20, μFA=0.63±0.22, MKi=0.45±0.41, MKa=0.74±0.67, MKt=1.13±0.33 for ICCs; FA=0.58±0.24, μFA=0.71±0.19, MKi=0.55±0.46, MKa=1.03±0.77, MKt=1.43±0.71 for METAs; FA=0.44±0.15, μFA=0.38±0.17, MKi=0.61±0.14, MKa=0.11±0.21, MKt=0.71±0.21 for hemangiomas; FA=0.36±0.11, μFA=0.31±0.13, MKi=0.99±0.13, MKa=0.15±0.12, MKt=1.14±0.10 for FNHs; FA=0.42±0.17, μFA=0.29±0.15, MKi=0.18±0.36, MKa=0.09±0.21, MKt=0.29±0.44 for simple cysts; FA=0.42±0.13, μFA=0.41±0.05, MKi=0.27±0.21, MKa=0.08±0.09, MKt=0.37±0.25 for complicated cysts. μFA and MKa were able to significantly differentiate between benign and malignant diseases.

**CONCLUSION**

QTI can provide new microstructural information for the diagnosis of FLL. In the future, the radiologic-pathologic correlation of malignant tumors should be considered.

**CLINICAL RELEVANCE/APPLICATION**

QTI can provide new microstructural information such as isotropic, anisotropic, and total mean kurtosis (MKi, MKa and MKt), and microscopic anisotropy.

## T5B-SPGI-3 DEVELOPMENT AND VALIDATION OF FUNCTIONAL LIVER IMAGING SCORE MODEL TO PREDICT PROGNOSIS IN HEPATOCELLULAR CARCINOMA

DING Feier (*Abstract Co-Author*) Nothing to Disclose
Gongzheng Wang (*Abstract Co-Author*) Nothing to Disclose
Lianbang Wang (*Abstract Co-Author*) Nothing to Disclose
Xinya Zhao (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop a model based on the functional liver imaging score (FLIS) derived from hepatobiliary-specific contrast enhanced magnetic resonance imaging (MRI) to predict long-term survival in HCC patients after surgical resection.

**METHODS AND MATERIALS**

Patients who underwent hepatobiliary-specific contrast enhanced MRI and surgical resection with pathologically proven HCC were retrospectively included from three medical centers. The FLIS derived from gadobenate dimeglumine-enhanced MRI was calculated by summing the points (0-2) of three hepatobiliary-phase features: hepatic enhancement, biliary excretion, and portal vein signal intensity. A nomogram was established integrating FLIS and clinical factors for better prediction. Overall survival (OS) and recurrence-free survival (RFS) were estimated by the Kaplan-Meier method and compared with the log-rank test.

**RESULTS**

This study included 467 patients (median age, 57 years). The area under the receiver operating characteristic curves of FLIS were 0.777, 0.818 and 0.741 in training cohort, internal validation cohort and external validation cohort, respectively. In multivariable analysis, FLIS, alpha-fetoprotein (AFP) > 400 ng/mL, major resection and tumor size > 5cm were independent predictors of OS. The FLIS model incorporating these variables was developed, and showed good concordance statistics of 0.950, 0.927, and 0.945 in training cohort, internal validation cohort and external validation cohort, respectively. Harrell's concordance index for the FLIS model was significantly higher than FLIS and other conventional systems (all $p < 0.05$). Kaplan-Meier curves demonstrate that patients in the FLIS model-low risk group show a longer OS and RFS than those in the FLIS model-high risk group ($p < 0.05$).

**CONCLUSION**

We developed a novel model based on FLIS to predict long-term survival in HCC patients after surgical resection. This tool could be used as a reference for clinicians and surgeons to help them in clinical decision-making.

**CLINICAL RELEVANCE/APPLICATION**

Compared with other prognostic systems, such as BCLC score, MELD score, and ALBI score, the FLIS showed greater prediction performance for predicting OS, indicating that the FLIS is a more reliable and effective diagnostic indicator for selecting eligible surgical candidates before performing surgical resections.

## T5B-SPGI-4 EVALUATION OF THE CONTRAST-ENHANCED ULTRASOUND NONRADIATION TREATMENT RESPONSE ASSESSMENT LI-RADS V2024 USING DATA FROM A MULTI-CENTER TRANSARTERIAL CHEMOEMBOLIZATION STUDY

**PURPOSE**

This study aims to evaluate the diagnostic performance of the new ACR contrast-enhanced ultrasound (CEUS) Nonradiation TRA LI-RADS v2024 in HCC treated with transarterial chemoembolization (TACE).

**METHODS AND MATERIALS**

This retrospective observational study included 87 patients treated with TACE from a previously reported cohort. At 15- and 30-days post-treatment, 68 and 72 HCC lesions were evaluated. Three blinded radiologists with different levels of CEUS experience interpreted the images independently. According to CEUS Nonradiation TRA LI-RADSv2024, both intralesional and perilesional tumor viability were evaluated and final TRA categories were as follows: TR-Nonviable, TR-Equivocal, and TR-Viable. Reference standard used was a composite of histology and imaging. Diagnostic performance and Cohen's kappa test was performed.

**RESULTS**

140 HCC lesions were analyzed. At 15 days post-treatment, the sensitivity (SN), specificity (SP), positive predictive value (PPV), negative predictive value (NPV), and accuracy of TR-Viable classification ranged from 72.5-94.3%, 72.2-86.4 86.8-91.4%, 65.6-86.7%, 76.9-86.8%, respectively. At 30 days post-treatment, the SN, PPV, and NPV of TR-Viable classification decreased, ranging from 65.9-84.2%, 85.7-90.6%, and 59.5-73.9%, respectively, while the SP increased, ranging from 80.0-88.0%. Kappa values ranged from 0.557-0.730, indicating moderate to substantial agreement.

**CONCLUSION**

CEUS Nonradiation TRA LI-RADS is a reliable tool for the detection of viable tumors in lesions treated with TACE and demonstrates reproducibility across readers.

**CLINICAL RELEVANCE/APPLICATION**

Using the new ACR CEUS Nonradiation TRA LI-RADS v2024 can lead to early detection of residual tumor post TACE treatment and prompt intervention as early as 15 days.

## T5B-SPGI-5 TO INVESTIGATE THE VALUE OF PRE-TREATMENT GADOXETIC ACID-ENHANCED MAGNETIC RESONANCE IMAGING (MRI) USING LIVER IMAGING REPORTING AND DATA SYSTEM (LI-RADS) V2018 IN PREDICTING THE RESPONSE TO INITIAL TRANSARTERIAL CHEMOEMBOLIZATION (TACE) IN HEPATOCELLULAR CARCINOMA (HCC)

Liqin Zhao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of pre-treatment gadoxetic acid-enhanced magnetic resonance imaging (MRI) using Liver Imaging Reporting and Data System (LI-RADS) v2018 in predicting the response to initial transarterial chemoembolization (TACE) in hepatocellular carcinoma (HCC).

**METHODS AND MATERIALS**

A total of 151 HCC patients who received gadoxetic acid-enhanced MRI before TACE were retrospectively recruited. Analysis was evaluated by LI-RADS v2018 and other image features. Independent factors were identified through logistic regression analyses, and a combined model incorporating clinical, laboratory and gadoxetic acid-enhanced MRI findings was established as a nomogram. The performance of the nomogram was assessed by receiver operating characteristic (ROC) curves and validated by fivefold cross-validation.

**RESULTS**

Among the 151 patients, 80 (52.98%) were TACE response (TR), while 71 (47.02%) were non-TACE response (nTR). Multivariate analysis revealed that TACE alone, central tumor zone, larger tumor size, and nonsmooth tumor margin were independent factors associated with nTR ($p < 0.05$). The area under the curve (AUC) and the corresponding 95% confidence interval (CI) of the nomogram were 0.767 (0.692-0.842), accuracy of 0.715, sensitivity of 0.789.

**CONCLUSION**

The nomogram incorporating clinical and gadoxetic acid-enhanced MRI features using LI-RADS v2018 achieved potential efficacy of response to TACE in HCC patients.

**CLINICAL RELEVANCE/APPLICATION**

LI-RADS v2018 may assist clinicians in selecting the most appropriate treatment options for individual HCC patients.

## T5B-SPGI-9 EARLY PREDICTION OF THE EFFICACY OF LIVER METASTASES CHEMOTHERAPY COMBINED WITH TARGETED THERAPY FOR COLORECTAL CANCER BASED ON CT RADIOMICS

Junlin Zhou, PhD (*Abstract Co-Author*) Nothing to Disclose
Shenglin Li, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the feasibility of contrast enhanced CT (CECT)-based radiomics for early efficacy prediction of chemotherapy combined with targeted therapy in colorectal cancer liver metastases (CRLM).

**METHODS AND MATERIALS**

Retrospectively collected CECT images of 90 patients (255 lesions) with CRLM diagnosed by pathology or imaging follow-up from May 2018 to October 2022 at multicentre before treatment and after early treatment (2-4 cycles), manually outlined and extracted the radiomics features within the target

lesions, and classified them with the long-term treatment efficacy of 12 cycles of treatment (RECIST v1.1) as a classification label Construct an imaging histology early efficacy prediction model. Target lesions were randomly divided into training set (n=135), test set (n=53) and external validation set (n=53). Models were constructed Model_Clinical, Model_Pre, Model_Pos, Model_Pre+Pos, Model_Ratio, Model_Detla, Model_ DetlaABS and Model_COMB efficacy prediction models. AUC values, sensitivity and specificity were used to assess the predictive efficacy of the models. The goodness of fit tests and calibration curves were used to assess the stability of the predictive models.

**RESULTS**

Among the clinical variables, only the mutation status of the K-RAS gene [odds ratio (OR): 0.17; 95%CI: 0.04-0.57, P= 0.003] and the BRAF gene (OR: 4.06; 95%CI: 0.91-22.75, P= 0.067) were found to be closely associated with the early treatment response of target lesions. The Model_Clinical exhibited AUCs of 0.728(95%CI: 0.644-0.812), 0.761(95%CI: 0.637-0.886), and 0.514(95%CI: 0.398-0.629) in the training, test, and external validation sets, respectively. The Model_COMB, which incorporated all radiomic features from pre- and post-treatment, AUC values of 0.956(95%CI: 0.926-0.986), 0.894(95%CI: 0.803-0.984), and 0.833(95%CI: 0.740-0.925) in the training, test, and external validation sets when using the treatment response of individual target lesions as the criterion. When using the overall patient disease progression as the standard, the Model_COMB prediction model achieved AUC values of 0.963(95%CI: 0.915-1.000), 1.00(95%CI: 1.00-1.00), and 0.858(95%CI: 0.727-0.989) in the training, test, and validation sets, respectively. Calibration curves and goodness of fit tests indicated that the model maintained stable predictive power in the training and test sets($P > 0.05$).

**CONCLUSION**

The radiomics features of target lesions from CECT images pre- and post- chemotherapy combined with bevacizumab can effectively predict the early efficacy of targeted therapy.

**CLINICAL RELEVANCE/APPLICATION**

Our study results are providing a favorable clinical evaluation scheme for precise targeted therapy for CRLM.

## T5B-SPGU-1 MRI AND MR VOIDING CYSTOURETHROGRAPHY IN THE EVALUATION OF MALE PRIMARY BLADDER NECK OBSTRUCTION

Marco Di Girolamo, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluation of male with Primary bladder neck obstruction (PBNO) using MRI and MR Voiding Cystourethrography (MR-VCU) to study both anatomical aspects of bladder neck and urethral lumen.

### METHODS AND MATERIALS

In this retrospective study 21 male patients (mean-age 33±14) with urodynamic diagnosis of PBNO and 5 healthy volunteers ((mean-age 28±2) as control group, were enrolled. Both patients and control group underwent 1.5T MRI. Sagittal and oblique coronal Turbo-Spin-Echo T2-weighted scans were performed. Only patients underwent MR Voiding -Cystourethrography (MR-VCU) performed with T1-weighted spoiled 3D Gradient-Echo sagittal acquisitions. Bladder lumen was filled with contrast-material-enhanced urine. Blinded test by two radiologists was performed to evaluate causes of bladder outlet obstruction evaluating MR-VCU. Anatomical MRI features of both control group and patients were compared in consensus by senior radiologist and urologist using the analysis of variance (ANOVA) test.

### RESULTS

MRI allowed evaluation of the bladder neck muscular structures. We found 4 groups of PBNO patients: 52% hypertrophy of posterior lip of bladder sphincter; 20% asymmetry of lateral portion of bladder sphincter; 14% bladder neck cyst; 14% showed normal aspect of bladder neck. Comparison between the control group and first and second PBNO groups was considered statistically significant ($p<0.05$) with diagnostic accuracy of 87%. Only 13 patients (61%) were able to perform MR-VCU and radiologists always made the diagnosis of PBNO.

### CONCLUSION

MRI together with MR-VCU provides useful anatomical and functional information in the study of bladder neck and urethral lumen. These preliminary results suggest that MRI could substitute for standard cystourethrogram in patients with PBNO.

### CLINICAL RELEVANCE/APPLICATION

MRI with voiding MR.cystourethrography could be performed in male patients with PBNO in order to diagnose and to visulize all the anatomical and functional aspect of the bladder neck.

## T5B-SPGU-2 MCW-171: A POPULATION-LEVEL T2W MRI PROSTATE TEMPLATE FOR ENHANCED GROUP ANALYSIS AND PATHOLOGY INTEGRATION

### PURPOSE

In neuroimaging, standardized brain templates like the MNI152 have significantly enhanced group-level analyses by enabling spatial normalization and facilitating comparisons across diverse datasets. However, the field of prostate imaging lacks a widely recognized anatomical template, which poses challenges due to the considerable anatomical variations between patients. To fill this gap, we developed a prostate template from T2-weighted (T2w) MR images of 171 patients with clinically confirmed prostate cancer (PCa). The MCW-171 template has been utilized to analyze the spatial distribution of cancer densities for different Gleason grades on a population level.

### METHODS AND MATERIALS

This study involved 171 prostate cancer patients who underwent MRI scans without an endorectal coil, using a 3T scanner. The images were intensity normalized and bias corrected using Advanced Normalization Tools (ANTs), then registered to a starting template to refine and optimize it over eight iterations, creating the high-quality 'MCW171' template. Following MRI, patients underwent radical prostatectomy, where a custom 3D-printed slicing jig was utilized to ensure the excised prostate tissue was oriented accurately according to the MRI scans. These slices from the tissue were then processed and stained with Hematoxylin and Eosin (HE) to enhance the visualization of tissue structure and cellular details. The slides were digitized and annotated by a board-certified pathologist to precisely identify cancerous regions. The digitized histological slides were carefully aligned to the MRI scans using non-linear control point warping techniques. The aligned histological data were then integrated into the MCW171 template using ANTs deformable registration, enabling precise anatomical correspondence. This process facilitated the generation of cancer probability maps across different Gleason grades, effectively illustrating the spatial variability of cancer occurrence within the prostate.

### RESULTS

The MCW171 template effectively delineates various regions of the prostate, highlighting critical landmarks. Notably, the analysis revealed a distinct asymmetry in the distribution of Gleason grades across the studied population, with a higher propensity for tumors in the Peripheral Zone. Additionally, higher-grade cancers were predominantly located in both the Peripheral and Transition Zones, with greater occurrence in the Peripheral Zone.

### CONCLUSION

The development of the 'MCW171' T2-weighted prostate templatey enhances prostate imaging by providing a reliable standard for comparison.

### CLINICAL RELEVANCE/APPLICATION

The MCW171 template refines prostate cancer diagnosis and management by providing precise mappings of cancer distributions.

## T5B-SPGU-3 KIDNEY TUMOR CHARACTERIZATION SCORING SYSTEM (KISSS): QUALITATIVE MRI BASE APPROACH USING MACHINE LEARNING

### PURPOSE

Renal cell tumors present diverse histological subtypes, each with unique prognostic andtherapeutic implications. Magnetic Resonance Imaging (MRI) plays a crucial role in the pre-surgical evaluation of renal masses, yet the interpretation of these images remains challenging andsubjective. This study leverages machine learning models to enhance the classification accuracyof renal cell tumors using MRI features, aiming to improve diagnostic accuracy.

### METHODS AND MATERIALS

We analyzed MRI data from 54 patients with 111 pathologically confirmed renal celltumors. Pathologies were, clear cell Renal Cell Carcinoma (ccRCC), Renal Angiomyolipoma(AML), Oncocytic Renal tumors (Oncocytoma), Papillary renal cell carcinoma (pRCC),Chromophobe renal tumors (Chromophobe). Patients were selected from a prospectivelymaintained registry from 2010 to 2023. Two expert radiologists evaluated the lesions acrossvarious MRI sequences, assigning scores based on predetermined criteria. A stacking Classifierwith Logistic Regression using Machine learning models, including XGBoost Classifier andFormatted: Indent: First line: 0.5", Line spacing:DoubleRandom Forest Classifier, were trained for categorizing 5 renal tumor pathologies and a binaryclassification of ccRCC versus non-ccRCC. Model performance was assessed using accuracy, F1-scores, positive predictive value (PPV), sensitivity, and SHapley Additive exPlanations (SHAP)for feature importance analysis.

### RESULTS

Among lesions, clear cell renal cell carcinoma (ccRCC) was identified as the most commontumor, accounting for 55 (50%) of the lesions, while Chromophobe carcinoma had the lowestprevalence with 10 (9.0%) lesions. The mean age of the patients was 49.8 ± 10.6 years. The studyfound moderate inter-reader reliability in most of the questioned features. The modelsdemonstrated an overall accuracy of 0.62 ± 0.051 for multi-class classification and 0.77 ± 0.064for binary classification, with ccRCC being the most accurately characterized pathology. SHAPanalysis highlighted the importance of T1 signal intensity, peak enhancement, and T2 signalintensity in lesion characterization.

### CONCLUSION

Using machine learning can help the radiologists to characterize the lesions usingqualitative image features with high accuracy and it can provide a precise decision forcharacterizing and classifying lesions.

### CLINICAL RELEVANCE/APPLICATION

The application of machine learning in MRI analysis enhances the characterization of renaltumors, facilitating more accurate and clinically relevant diagnoses, thereby aiding in personalizedtreatment planning.

### PURPOSE

To evaluate the efficacy and safety of MR-guided cryoablation for the treatment of local recurrence of prostate cancer in the seminal vesicles.

### METHODS AND MATERIALS

This single-center study included 164 patients with 187 ablation sites from 2013 to 2024. The ablation sites were distributed as follows: right seminal vesicle (74), left seminal vesicle (63), bilateral (35), and take-off (14). The mean age of patients was 72.44 years (range: 51-88). Cryoablation procedures were performed under MRI guidance, with 2-3 freeze/thaw cycles and a 3-5 mm margin. Normal saline was injected to form a protective separation between the ablated site and the rectum. Follow-up included PSA and PET PSMA, PET 11-C Choline, or MRI every 3±1 months for 24 months. An open-source large language model prescreened 3074 reports, and a radiologist reviewed the relevant reports and imaging.

### RESULTS

Out of 187 ablations, 21 (11.23%) led to local recurrences in 20 patients, with 76.19% (16 cases) occurring within the first year. The timing of recurrences was as follows: 2 at 3 months, 3 at 6 months, 7 at 9 months, and 4 at 12 months. Recurrences were noted predominantly in the left seminal vesicle (7), right seminal vesicle (5), bilateral vesicles (5), and take-off (2). Eleven of 21 patients with recurrences exhibited other lesions and had a higher Gleason score (mode: 8, range 7-9), contrasting with those with solitary seminal vesicle recurrence (mode: 7, range 6-9). PET was more effective than MRI in the initial detection of recurrences, identifying 9 cases compared to 7 by MRI in the first year.

### CONCLUSION

MR-guided cryoablation of seminal vesicles demonstrates a robust local control rate of 88.77%. This technique leverages MRI's superior soft tissue visualization and real-time monitoring capabilities to precisely delineate tumor margins and adjacent critical structures. The clear visualization of the ablation zone and distinct ice ball margins on MRI allows for accurate targeting, ensuring complete tumor coverage while minimizing collateral damage to surrounding nerves, blood vessels, and other healthy tissues. Moreover, MRI guidance enables access to lesions in anatomically complex or high-risk locations that may be challenging to reach with CT guidance alone.

### CLINICAL RELEVANCE/APPLICATION

By providing enhanced procedural precision and safety, MR-guided cryoablation emerges as a valuable therapeutic modality for effectively managing local recurrences of prostate cancer with minimal associated complications. This positions it as a promising option in the urological oncology armamentarium for achieving optimal oncologic outcomes while preserving functional integrity.

## T5B-SPGU-5 MR IMAGING CHARACTERISTICS OF PROSTATE ADENOCARCINOMA WITH NEUROENDOCRINE DIFFERENTIATION (PAND) AND PURE NEUROENDOCRINE TUMORS

Muhamad Serhal, MD (*Abstract Co-Author*) Nothing to Disclose
Eric Li, MD (*Abstract Co-Author*) Nothing to Disclose
Frank H. Miller, MD (*Abstract Co-Author*) Advisory Board, Bayer AG;Advisory Board, Guerbet SA
Amir Borhani, MD (*Abstract Co-Author*) Institutional research agreement, Siemens AG

Maryam Haghshomar, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Prostate neuroendocrine tumors are very rare and there is not enough literature on unique imaging characteristics of PAND and prostate neuroendocrine tumors. Diagnosing prostate adenocarcinoma and prostate adenocarcinoma with neuroendocrine differentiation (PAND) and pure neuroendocrine tumors on prostate MR can be a challenging task. Our objective was to compare the MR imaging features of PAND and pure neuroendocrine tumors with corresponding lab values and clinical presentation.

### METHODS AND MATERIALS

In this retrospective study, we included patients with pathology-confirmed PAND or pure neuroendocrine tumors. Immunohistochemical markers, including chromogranin and neuron-specific enolase, were utilized to confirm pathology. Two radiologists with more than 10 years of clinical practice read the prostate MR images and reported imaging findings on T2, DWI, post-contrast sequences. Further clinical data including PSA levels, and prostate health index (PHI) were collected.

### RESULTS

A total of 37 patients with PAND (mean age 68 years) and 3 patients with pure neuroendocrine tumors (mean age 67 years) were included in this study. The mean values for prostate volume, largest diameter, and density were 57.68 ml, 5.45 cm and 0.44. The mean size of lesions was 2.73 cm with the smallest lesion being 0.5 cm and largest lesion being 8.9. MRI findings of pure neuroendocrine tumor were as followed: 63% of patients had uniformly hypointense T2 signal 100% had Restricted diffusion, 63% had focal early enhancement, 100% had extracapsular extension, 33% had Seminal vesicle involvement, 63% had Bladder involvement and 33% had Lymph node involvement. There were false negative PSMA-PET results in highly evolved neuroendocrine tumor. MRI findings of PAND tumors were as followed: 76% were homogeneously hypointense, 59% had marked restriction diffusion, 53% had early enhancement, 59% had Extracapsular extension: 53% had Seminal vesicle involvement, 18% had Bladder involvement and 47% had LN involvement. Metastases to organs other than bone, brain, lungs, and liver were present. Bone metastasis lesions were lytic.

### CONCLUSION

Prostate neuroendocrine tumors present as large, heterogeneous tumors (low to intermediate T1, high T2, heterogeneous high DWI, moderate low signal on ADC, avid enhancement) with low PSA level when in pure neuroendocrine tumor.

### CLINICAL RELEVANCE/APPLICATION

Establishing unique imaging characteristics of PAND and pure prostate neuroendocrine tumors can help radiologists distinguish them from prostate adenocarcinoma with significant changes in management decisions.

## T5B-SPGU-6 INTRATUMOURAL AND PERITUMOURAL MPMRI-BASED DELTA-RADIOMICS RADIOMICS MODEL FOR THE PREDICTION OF THE RESPONSE TO ANDROGEN DEPRIVATION THERAPY IN PROSTATE CANCER

Shiyun Sun (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of the delta-radiomics of the intratumoural area (IA) and peritumoural area (PA) based on multiparameter magnetic resonance imaging (mpMRI) to predict the response to androgen deprivation therapy (ADT) in prostate cancer (PCa).

**METHODS AND MATERIALS**

Patients with PCa who underwent mpMRI before and after ADT were analysed retrospectively. The patients were divided into a significant residual (SR) group and complete remission and minimal residual (CR/MRD) group according to pathological results. Three types of volumes of interest (VOIs) were obtained for each lesion: IA VOI, IA + 3 mm PA VOI, and IA + 6 mm PA VOI. Radiomics features were extracted, and delta-radiomics data were calculated. The delta-radiomics model was built by the radiomics score (RS). & 9;The clinical model was constructed by univariate and multivariate analyses. The combined model was developed with the RS and selected clinical features. Model performance was assessed by the area under the curve (AUC).

**RESULTS**

In total, 69 patients in the SR group and 40 patients in the CR/MRD group were included. The AUCs of the IA, IA + 3 mm PA and IA + 6 mm PA delta-radiomics models were 0.78, 0.84 and 0.79, respectively. The AUC of the clinical model was 0.80. The AUCs of the combined models of IA, IA + 3 mm PA, and IA + 6 mm PA were 0.89, 0.92, and 0.90, respectively.

**CONCLUSION**

Delta-radiomics can effectively predict the response to ADT. And the combined model (IA + 3 mm PA) improved the prediction performance.

**CLINICAL RELEVANCE/APPLICATION**

Utilizing radiomics techniques to analyze mpMRI images features within and around the lesions in the response to ADT.

## T5B-SPGU-7 IS THERE ENOUGH EVIDENCE SUPPORTING THE CLINICAL ADOPTION OF CLEAR CELL LIKELIHOOD SCORE (CCLS)? AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

Huan Zhang (*Abstract Co-Author*) Nothing to Disclose
Yang Song (*Abstract Co-Author*) Nothing to Disclose
Weiwu Yao (*Abstract Co-Author*) Nothing to Disclose
Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To review the evidence for clinical adoption of clear cell likelihood score (ccLS) for identifying clear cell renal cell carcinoma (ccRCC) from small renal masses (SRM).

**METHODS AND MATERIALS**

We distinguished the literature on ccLS for identifying ccRCC via systematic search using PubMed, Embase, Web of Science, China National Knowledge Infrastructure, and Wanfang Data until 31 March, 2024. The risk of bias and concern on application was assessed using the modified Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2) tool. The diagnostic accuracy was estimated with the bivariate random-effects model. The level of evidence supporting clinical adoption of ccLS for identifying ccRCC was determined based on meta-analyses.

**RESULTS**

Eight MRI studies and three CT studies were included. The risk of bias and application were mainly related to the index test and flow and timing, due to incomplete imaging protocol, unclear rating process, and inappropriate interval between imaging and surgery. The diagnostic odds ratios (95% confidence intervals) of MRI and CT ccLS were 14.69 (9.71-22.22; 6 studies, 1429 SRM, 869 ccRCC), and 5.64 (3.34-9.54; 3 studies, 296 SRM, 147 ccRCC), respectively, for identifying ccRCC from SRM. The aeras under hierarchical summary receiver operating characteristic curve (95% conventional intervals) MRI and CT ccLS were 0.86 (95% CI 0.82-0.89), and 0.76 (95% CI 0.69-0.82), respectively. The evidence level for clinical adoption of MRI and CT ccLS were both rated as weak. MRI ccLS version 2.0 potentially has better diagnostic performance than version 1.0 (1 study, 700 SRM, 509 ccRCC). Both T2-weighted-imaging with or without fat suppression might be suitable for MRI ccLS version 2.0 (1 study, 111 SRM, 82 ccRCC).

**CONCLUSION**

ccLS has promising diagnostic performance for identifying ccRCC from SRM, but evidence for adopting ccLS in clinical routine is still weak.

**CLINICAL RELEVANCE/APPLICATION**

Both MRI and CT ccLS algorithms has promising diagnostic performance in identifying ccRCC from SRM. The clinical adoption of ccLS algorithms is yet hindered by unstandardized imaging protocol, nonadherence to the current guideline, and lacking in appropriate management suggestion. Nonetheless, the characterization of SRM can be in a more accurate and clinically useful fashion applying MRI and CT ccLS algorithms, thereby providing patients with optimized decision making for initial management.

## T5B-SPGU-8 LEVATOR ANI MUSCLE FAT INFILTRATION INFEMALES WITH AND WITHOUT STRESS URINARY INCONTINENCE EVALUATED BYSPECTRAL CT MATERIAL DECOMPOSITION TECHNIQUE AND IDEAL-IQ SEQUENCE: A PROSPECTIVE CASE-CONTROL STUDY ON108 VOLUNTEERS

Kun Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Kun Ou (*Presenter*) Nothing to Disclose

**PURPOSE**

Using IDEAL-IQ sequence of MRI and spectral CT material decomposition (MD) technique to evaluate fat infiltration of levator ani muscle in patients with stress urinary incontinence (SUI), comparing with healthy people.

**METHODS AND MATERIALS**

This study enrolled 50 healthy volunteers and 58 patients with SUI who underwent pelvic examinations including 3.0-T MR and non-enhanced CT gemstone spectral imaging. The fat fraction (FF) value was measured for levator ani muscle on axial FF images and the fat contents were measured on coronal fat-based MD images respectively. Then we evaluated the correlation between FF value and fat contents, and the differences between the healthy group and the SUI group. Receiver operating characteristic (ROC) analysis was used to access the performances of FF and fat content in differentiating SUI.

## RESULTS

There was no significant difference of FF value and fat contents between the left and right sides. The fat content and FF value had moderate correlation (r=0.625, P<0.001). Our result shows that the FF value of SUI group (28.78±3.83) was significantly higher than that of healthy group (25.90±4.98 P=0.005), and the fat content (90.09±12.39 mg·cm-3) was also higher than that of the healthy group (79.86±13.98 mg·cm-3, P=0.017). The area under curve (AUC) in differentiating SUI and healthy population was higher for FF (AUC=0.756) and lower for fat content (AUC=0.679).

## CONCLUSION

The fat content and FF value of levator ani muscle are moderately correlated; the fat infiltration of levator ani muscle of SUI patients is higher than that of healthy people.

## CLINICAL RELEVANCE/APPLICATION

The mechanism for SUI was complicated, which might be caused by muscle degeneration and injury manifested as deepening of fat infiltration. The IDEAL-IQ sequence can directly measure the muscle fat fraction, but the MRI scan takes long time and is prone to motion artifacts. Spectral CT imaging has the advantage of fast scanning. This study found that MD technique in spectral CT imaging was able to achieve comparable performance to IDEAL-IQ. It shows that MD technique in spectral CT imaging can also be used to evaluate the fat infiltration after pelvic floor muscle injury.

## T5B-SPHN-2 DEEP LEARNING-BASED RECONSTRUCTION OF DIFFUSION-WEIGHTED IMAGING IMAGES TO ASSESS THE ACTIVITY OF THYROID-ASSOCIATED OPHTHALMOPATHY

Yunmeng Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the value of deep learning reconstruction (DLR) orbital diffusion weighted imaging (DWI) images in the assessment of active and inactive stages of thyroid-associated ophthalmopathy (TAO).

### METHODS AND MATERIALS

This study included 73 clinically diagnosed TAO patients (46 active, 27 inactive) and 26 healthy controls from April to September 2023. All participants underwent orbital MRI scans using a 3.0 T MRI scanner. DWI sequences with FOCUS MUSE were reconstructed by conventional reconstruction (ConR) and DLR. Two diagnostic radiologists independently subjectively evaluated the image quality using a four-point Likert scale. The Wilcoxon was applied to test the difference of SNR, CNR, and ADC between ConR and DLR DWI, separately. Using the Clinical Activity Score (CAS) as the gold standard. The Kruskal-Wallis test was used to compare the difference of ADC between healthy controls, active and inactive TAO patients. The ROC were used to compare the diagnostic performance of EOM ADC for differentiating TAO activity between ConR and DLR DWI. The correlation between the EOM ADC and CAS of TAO patients was analyzed using Spearman's rank correlation coefficient.

### RESULTS

DLR DWI had higher subjective scores than ConR DWI for Sharpness of boundaries and overall image quality. The intra- and inter-reader agreement for both sequences was good (K>0.650). Significantly higher SNR and CNR in DLR DWI compared to ConR DWI (all P<0.001). However, there was no significant difference in ADC values (P>0.050). In both sequences, the EOM ADC obtained was significantly higher in the active TAO than in inactive TAO and healthy controls, respectively (all P<0.001). There was no significant difference of EOM ADC between inactive TAO and healthy controls (P>0.050). The EOM ADC extracted from both ConR DWI (R=0.637, P<0.001) and DLR DWI (R=0.662, P<0.001) was positively correlated with the CAS. Compared with ConR DWI, DLR DWI presented better performance for discriminating active from inactive TAO patients (AUC: 0.959 vs. 0.939, P=0.020).

### CONCLUSION

DLR improved the image quality of orbital DWI without increasing scan time. Compared to ConR, ADC values obtained based on DLR DWI were improved in identifying the activity of TAO and correlation with CAS.

### CLINICAL RELEVANCE/APPLICATION

Clinically, TAO is classified into active and inactive phases based on clinical activity scores. Active and inactive TAO were treated with hormonal/anti-inflammatory drugs and surgical decompression, respectively. DLR can improve the image quality of orbital DWI and further improve the prediction of the activity of TAO. Thus, it contributes to the precise and timely selection of treatment options in clinical practice.

## T5B-SPHN-3 IMAGING OF THE PARANASAL SINUSES WITH PHOTON-COUNTING CT, COMPARISON OF THE FEASIBILITY OF THE LOW-DOSE AND ULTRA-LOW-DOSE PROTOCOL IN SUSPECTED SINUSITIS

Thomas G. Flohr, PhD (*Abstract Co-Author*) Employee, Siemens AG
Bernhard Schmidt, PhD (*Abstract Co-Author*) Employee, Siemens AG
Stefan Ulzheimer, PhD (*Abstract Co-Author*) Employee, Siemens AG
Eva Ferdova, MD (*Abstract Co-Author*) Nothing to Disclose
Hynek Mirka, PhD (*Abstract Co-Author*) Nothing to Disclose
Jiri Ferda, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

to assess the feasibility of ultra-low dose CT with an integrated photon-counting-detector system (PC-CT) in the imaging paranasal sinuses

### METHODS AND MATERIALS

PC-CT examinations in suspected chronic or acute sinusitis were evaluated divided in the equal two groups per 100 patients: 1/ low-dose imaging with 100 kV and tin filtration, image quality level setting 20 with automatic exposure control, 2/ ultra-low-dose sinuses with the 90 kV and 4 mAs fixed setting without automatic exposure control. All examinations were performed with the use of detector element size of 0.4 mm, the images were reconstructed with the thickness of 1 mm, with kernel 60. The diagnostic quality of the acquired images was assessed based on the imaging of key structures -

osteomeatal unit and nasolacrimal duct and the brain noise level in five-point scale, 1 excellent, 5 - undiagnostic. The dose length product and noise level were compared within both groups using Wilcoxon test for independent samples, the independence was tested using Kruskal-Wallis test.

**RESULTS**

Ultra-low-dose images exhibited diagnostic sufficient image quality (mean quality value 1.5) compared with the low-dose (mean quality value 1.2), the dose was significantly lower - DLP in ultra-low-dose 4.2 mGycm, low-dose 45.2 respectively ($p < 0.0001$). Low-dose exhibited the significantly higher ratio between brain signal and background noise ($p < 0.0001$).

**CONCLUSION**

Ultra-low-dose PC-CT in patients with suspected sinusitis showed imaging sufficient diagnostic quality at extreme low-dose values, enabling sufficient imaging of the bone framework

**CLINICAL RELEVANCE/APPLICATION**

Ultra-low-dose imaging of the paranasal sinuses reaches the doses relevant to those obtained from X-ray

## T5B-SPHN-4 MULTIMODAL INVESTIGATION OF STRUCTURAL-FUNCTIONAL COUPLING IN POST-COVID AND POST-TRAUMATIC OLFACTORY DYSFUNCTION

Aocai Yang (*Abstract Co-Author*) Nothing to Disclose
Liu Jianfeng (*Abstract Co-Author*) Nothing to Disclose
Jixin Luan, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Olfactory dysfunction (OD) is manifested with disrupted topology of the structural connection network (SCN) and the functional connection network (FCN). However, the SCN and its interactions with the FCN remain to be further investigated. This multimodality study attempted to investigate the differences in structural-functional coupling between post-COVID olfactory dysfunction (PCOD), post-traumatic olfactory dysfunction (PTOD), and healthy control (HC) subjects.

**METHODS AND MATERIALS**

A total of 27 individuals with PCOD, 20 individuals with PTOD, and 27 HC subjects were enrolled who underwent diffusion tensor imaging (DTI) and resting state functional magnetic resonance imaging (rs-fMRI) to generate structural and functional networks. The topological prosperities of both the SCN and the FCN were analyzed, followed by quantification of the SCN-FCN couplings across scales. We defined each region of interest from automated anatomical labeling (AAL) atlas consisting of 90 regions as a network node. Topological properties werre performed by the GRETNA toolbox. The quantification of SCN-FCN coupling involves calculating correlation coefficients at two levels: global coupling across the entire SCN and FCN matrix and nodal coupling within each region of the matrix. In the patients group, the exploration of potential correlations between the SCN-FCN coupling and the network topology as well as between these metrics and clinical scale scores were conducted using the Spearman rank correlation test, respectively, at a statistically significant threshol d of p value $< 0.05$.

**RESULTS**

PCOD patients exhibited significantly lower Assortativity in both SCN ($p = 0.0077$) and FCN ($p = 0.0039$) compared to HC. In the FCN, PCOD patients displayed significantly lower Lambda ($p = 0.0017$). PTOD patients showed decreased Betweenness Centrality (BC), Degree Centrality (DC), and Nodal Local Efficiency (NLe) in specific regions compared to HC. Global SCN-FCN coupling was significantly reduced in PTOD compared to HC ($p = 0.0086$). PTOD group also demonstrated impaired nodal centrality in the visual network (VIS) compared to HC ($p < 0.05$). Impaired SCN-FCN coupling in the default mode network (DMN) was observed in PTOD compared to PCOD ($p < 0.05$). Correlation analysis revealed significant associations between SCN-FCN coupling and network topology in PCOD, but not in PTOD.

**CONCLUSION**

Our findings revealed disrupted topology in both the SCN and the FCN in PCOD patients compared to HC participants. PTOD patients also showed specific alterations in SCN and FCN.

**CLINICAL RELEVANCE/APPLICATION**

These findings provide insights into the distinct characteristics of PCOD and PTOD and shed light on the disrupted structural-functional coupling in olfactory dysfunction.

## T5B-SPIN-2 ASCENDING AORTIC DIAMETER MEASUREMENT ON A NON-ECG-GATED CHEST CT USING DEEP LEARNING

Ayaz Aghayev, MD (*Abstract Co-Author*) Nothing to Disclose
Yusuf Abdi (*Abstract Co-Author*) Nothing to Disclose
Fargana Aghayeva (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to develop a deep learning model (DLM) for automated segmentation and ascending aortic (AA) diameter measurement on non-ECG-gated chest CT scans. AA dilatation, defined as a diameter exceeding 4.0 cm, which increases the risk of aortic dissection, and carries a high risk of morbidity and mortality. Often, AA dilatation may go unnoticed in chest CT scans performed for other reasons. The goal is to improve the accuracy and efficiency of AA measurement, with potential applications in detecting AA dilatation in the large cohorts.

### METHODS AND MATERIALS

The study utilized the NIH Clinical Center's public imaging database (https://nihcc.app.box.com/v/DeepLesion) to analyze 280 chest CT scans. A radiologist identified the slice with the largest aortic aneurysm (AA) diameter as the "focus image" and labeled other slices as "non-focus," also manually delineating the AA contour on the focus image. A Convolutional Neural Network (CNN) was designed to classify these images accordingly. The model was trained with a custom dataset class for handling DICOM images, employing data augmentation and random splitting to improve robustness and generalization. The RMSprop optimizer was used for network parameter optimization, incorporating learning rate scheduling and gradient clipping. Visualization of segmentation results was done using matplotlib, showcasing the model’s accuracy in delineating AA contours. Additionally, a UNet architecture facilitated semantic segmentation, and diameter measurements of segmented regions were conducted using OpenCV, which calculated the largest contour's diameter within the segmented mask for quantitative AA assessment.

### RESULTS

The CNN model demonstrated high accuracy, achieving a confidence level of 99.9% in classifying focus and non-focus images. The segmentation performance of the UNet architecture effectively delineated the AA contours. During validation testing for diameter measurement, the results precisely matched the manually annotated mask images, correctly identifying AA diameters =4.0 cm.

### CONCLUSION

The study demonstrates that the developed DLM are reliable and efficient tools for identifying the dilated AA and measuring its max diameter.

### CLINICAL RELEVANCE/APPLICATION

The developed pipeline offers an effective and accurate means to detect AA dilatation on non-ECG-gated chest CT images, which might otherwise be overlooked by radiologists. This tool has significant potential for application across a large retrospective cohort of non-gated chest CT studies to detect AA dilatation, thereby aiding in the timely intervention to prevent severe complications.

## T5B-SPIN-3 GENERATING HIGH-RESOLUTION KNEE CT SCANS FROM BI-PLANAR RADIOGRAPHS USING A MODULAR DIFFUSION MODEL: POTENTIAL FOR REDUCED RADIATION DOSE AND ENHANCED PREOPERATIVE PLANNING

Cody Wyles, MD (*Abstract Co-Author*) Nothing to Disclose
Bradley J. Erickson, MD, PhD (*Abstract Co-Author*) Board of Directors, VoiceIt Technologies, LLC;Stockholder, VoiceIt Technologies, LLC;Board of Directors, FLOWSIGMA Inc;Officer, FLOWSIGMA Inc;Stockholder, FLOWSIGMA Inc;Officer, Yunu Inc;Stockholder, Yunu Inc
Pouria Rouzrokh, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Michael Taunton, MD (*Abstract Co-Author*) Consulting, DJO Global, Inc;Royalties, DJO Global, Inc
Bardia Khosravi, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a modular diffusion model capable of generating multi-resolution CT scans from bi-planar knee radiographs, reducing radiation dose and enhancing preoperative planning in orthopedic surgery.

### METHODS AND MATERIALS

A dataset of 16,730 CT scans and 54,340 AP and lateral knee radiographs from patients aged 28-90 (54% female) across three tertiary centers was used. The 400-million-parameter model is based on the Matryoshka diffusion architecture, which is a powerful generative model that iteratively denoises Gaussian noise to create realistic images. The model encodes radiographs using a ConvNext CNN, and the features are cross-attended during the diffusion process to generate CTs at $32^3$, $64^3$, and $128^3$ resolutions. The model is conditioned on pixel spacing and slice thickness. The $128^3$ volumes are

supersampled to $512^3$ using a patch-based diffusion super-resolution model. The model was incrementally trained on batch sizes of 224, 80, and 16. Generated bone accuracy was evaluated using the mean Hausdorff distance on 10 samples after registration.

**RESULTS**

Model training on 16 A100 GPUs took 10 days. The model generated $128^3$ CTs in 1 minute and 27 seconds, with supersampling to $512^3$ taking an additional 6 minutes (under 8 minutes total). The generated bone had a mean Hausdorff distance of 0.75 from the original, demonstrating high accuracy. The Fréchet Inception Distance (FID), a metric quantifying the similarity between real and generated images, was 32.8 on 1000 generated images.

**CONCLUSION**

The modular diffusion model successfully generates high-resolution CT scans from bi-planar knee radiographs, offering a radiation dose reduction solution. Validation on the OAI dataset will further confirm its performance and generalizability. The integration of this technology with robotic surgery, virtual reality, and augmented reality will enhance surgical planning and execution. Successful implementation could lead to improved patient outcomes and healthcare delivery worldwide, particularly in regions with limited access to advanced imaging.

**CLINICAL RELEVANCE/APPLICATION**

This model significantly reduces radiation exposure in patients requiring CT scans for orthopedic conditions. The high-resolution CTs enable enhanced preoperative planning, potentially improving surgical outcomes and patient care. It could greatly improve diagnostic capabilities as a rapid screening tool in resource-limited settings. Furthermore, this technology bridges the gap between 2D imaging and 3D surgical planning, allowing for precise anatomical characterization essential for accurate diagnosis and treatment planning across various medical specialties.

## T5B-SPIN-5 GEOGRAPHICAL GENERALIZABILITY OF AI MODELS: A CASE STUDY VALIDATING THE RSNA INTRACRANIAL HEMORRHAGE DETECTION CHALLENGE ON HEAD CTS FROM TANZANIA

Bardia Khosravi, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Frank J. Minja, MD (*Abstract Co-Author*) Nothing to Disclose
Judy W. Gichoya, MBChB, MS (*Abstract Co-Author*) Consultant, Softbrew Digital LTD
Frank Li (*Abstract Co-Author*) Nothing to Disclose
SAID SALUM (*Abstract Co-Author*) Nothing to Disclose
Aawez Mansuri (*Abstract Co-Author*) Nothing to Disclose
Balowa M. Baraka, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the geographical generalizability of the top-performing algorithms from the 2019 RSNA Intracranial Hemorrhage (ICH) Detection Challenge by applying them to a head CT dataset from Tanzania.

**METHODS AND MATERIALS**

The third-place algorithm from the 2019 RSNA ICH Detection Challenge, trained on data from two hospitals in the US and one hospital in Brazil, was applied to a dataset from Tanzania. This algorithm is an ensemble of 17 convolutional neural networks (CNNs) that processes consecutive slices of the CT image and predicts a probability for four different hemorrhage types (intraparenchymal, subdural (SDH), subarachnoid (SAH), and intraventricular (IVH)) and one study-level probability for the presence of any type of hemorrhage. The Tanzanian dataset comprised of 169 patients with 658 series, manually annotated by expert radiologists blinded to the model predictions. The maximum probability for each label was aggregated per series and used as the patient-level label. To evaluate the model's performance, the Youden index was used to determine the optimal threshold for calculating the threshold-based metrics.

**RESULTS**

The model achieved an AUROC of 0.72 for SDH and AUROCs of 0.90-0.98 for other hemorrhage types. For detecting any hemorrhage, the model had an AUROC of 0.84. The optimal thresholds ranged from 0.97 to 0.99 for the different hemorrhage types, showing the miscalibrated model outputs. The model achieved high sensitivity for IVH (100%) but lower sensitivity for SDH (75%) and SAH (73%). These results lag behind the previously reported overall AUROC of 0.98 for detecting any ICH in a recently published meta-analysis.

**CONCLUSION**

The discrepancy between the model's performance on the Tanzanian dataset and the reported performance in the meta-analysis underscores the importance of assessing the geographical generalizability of machine learning models before clinical deployment. Factors such as differences in patient populations, imaging protocols, and disease prevalence may contribute to the observed performance gap, highlighting the need for further research and model adaptation to ensure robust performance across diverse geographical settings.

**CLINICAL RELEVANCE/APPLICATION**

ICH is a critical condition requiring rapid diagnosis and intervention. Automated detection models have the potential to assist radiologists in prioritizing cases and reducing time to treatment, particularly in resource-constrained environments. However, the geographical generalizability of these models is a crucial consideration for their safe and effective implementation in clinical practice. This study emphasizes the need to validate and potentially adapt ICH detection models to local patient populations for optimal performance.

## T5B-SPIN-6 BRAIN AGE GAP ESTIMATION (BRAINAGE): INFLUENCE OF SCANNER MANUFACTURER, FIELD STRENGTH AND SEQUENCE PARAMETERS

Christian Rubbert, MD (*Abstract Co-Author*) Nothing to Disclose
Julian Caspers (*Abstract Co-Author*) Nothing to Disclose
Marius Vach (*Abstract Co-Author*) Nothing to Disclose
Daniel Weiss (*Abstract Co-Author*) Nothing to Disclose
Dennis Hedderich, MD (*Abstract Co-Author*) Nothing to Disclose
Luisa Wolf (*Abstract Co-Author*) Nothing to Disclose
Vivien Lorena Ivan, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

MRI-brain-scan-based Brain Age Gap Estimation (BrainAGE), the difference between a machine-learning predicted brain age and chronological age, is explored as an imaging biomarker for several conditions, e.g., lifestyle-choices-driven aging. In cognitively normal, healthy subjects a BrainAGE of zero is expected. This study investigates how variations in study criteria, MRI scanner characteristics, and sequence parameters impacts BrainAGE.

## METHODS AND MATERIALS

A total of 2,414 participants from four population-based studies (ADNI, HCPA, OASIS3 and PPMI) were included. BrainAGE was computed using a previously established model. In essence, gray matter features were extracted using CAT12 for SPM12, followed by smoothing, spatial resampling and principal component analysis. Gaussian process regression predicted age, and BrainAGE was calculated as predicted minus chronological age. BrainAGE was compared across different cohorts and differences in BrainAGE based on scanner manufacturer, field strength, and imaging type (unaccelerated or accelerated 3D T1) were analyzed when data was available. Significant differences ($p<0.05$) were assessed using Welch's two-sample t-test or ANOVA, including the Tukey post-hoc test, as applicable. Mean absolute error (MAE) between chronological and predicted age was calculated.

## RESULTS

Across the different cohorts, the BrainAGE MAE for ADNI was 6.7, for HCPA 5.9, for OASIS3 5.8, and for PPMI 5.3 with a $p<0.0001$ (ANOVA). Only OASIS3/HCPA ($p=0.17$) and PPMI/HCPA ($p=0.1$) did not show significant differences. Comparing the field strength, we found that scans performed at 1.5T resulted in a smaller BrainAGE (ADNI MAE 4.2; OASIS3 4.1, PPMI 4.2) than scans acquired at 3T (ADNI MAE 7.5; OASIS3 5.9, PPMI 5.8). $p<0.0001$ for ADNI, $p=0.007$ for OASIS3, and $p=0.03$ for PPMI. HCPA only acquired scans at 3T.Scans in ADNI and PPMI were acquired on scanners from different vendors. In ADNI, scans acquired on GE scanners resulted in a BrainAGE MAE 7.3, on Philips of 6, and on Siemens MAE 6.7. $p=0.03$ (ANOVA), with statistically significant differences between Philips/GE ($p=0.008$). For PPMI, the MAE was 6.2 for GE scanners, 5.1 for Philips and Siemens. $p=0.005$ (ANOVA), with statistically significant difference between Siemens/GE ($p=0.008$).In ADNI, accelerated (MAE 7.6) and unaccelerated (MAE 7.3) imaging was available acquired at 3T ($p=0.47$).

## CONCLUSION

Researchers and clinicians should be aware that several factors, such as choice of scanner manufacturer and field strength, may influence BrainAGE derivatives.

## CLINICAL RELEVANCE/APPLICATION

Comparisons of BrainAGE across different cohorts may not be suitable. Future research should try to make BrainAGE independent of factors such as scanner manufacturer or field strength.

# T5B-SPIN-7 EXPLORING PERCEPTIONS AND PERSPECTIVES: A QUALITATIVE SURVEY STUDY OF HEALTHCARE PROFESSIONALS' VIEWS ON AI-ASSISTED CHEST RADIOGRAPH INTERPRETATION

## PURPOSE

Few studies have investigated the attitudes of healthcare professionals towards the integration of artificial intelligence (AI) tools to support medical decisions. This study investigates the perceptions and perspectives of healthcare workers regarding an AI tool aiding chest radiograph (CR) interpretation, focusing on its tolerability and motivation to increase adoption in healthcare.

## METHODS AND MATERIALS

We conducted a cross-sectional study using an online-based questionnaire with healthcare professionals from various institutions across the country, who were recruited during a conference, in 2023. The survey was divided into sections that examining the respondents' opinions about the affinity towards AI tools in healthcare, their personal perceptions regarding the use of algorithms to assist in CR interpretation, and their sociodemographic characteristics. Fifteen closed-ended questions and twelve closed-ended questions were applied for physicians and non-physician, respectively. Additional questions were posed to physicians regarding CR interpretation, such as "would implementing an AI diagnostic tool do aid CR improve your work routines". None of the questions were deemed obligatory. Researchers discussed the statistical analysis of the questionnaire responses to reach a consensus on the final set of findings. The study has received approval from the Institutional Review Board (IRB) and participants gave their informed consent.

## RESULTS

From a total of 523 recruited participants, 63 agreed to participate and answered all questions. The majority of respondents (74.6%) did not have access to AI tools at work. Asked on their general perception, 98,9% of the respondents rated the use of an AI tool to aid CR interpretation in medical practice as positive, with only 0,1% as not beneficial. In general, the respondents denied concerns about AI replacing physician, but strongly agreed that it should be used in cooperation with them. Overall, participants denied any negative impact on doctor-patient interactions and some positive characteristics of AI pointed was the improved diagnosis accuracy. However, the primary worry appears to be data leaking.

## CONCLUSION

AI tools to aid medical imaging interpretation are not yet widely available in most healthcare services. However, there is a growing interest among healthcare workers in new technologies.

## CLINICAL RELEVANCE/APPLICATION

This study focused on the acceptability of AI software to aid chest x-ray interpretation and its potential to increase adoption in the healthcare industry, by examining the opinions of healthcare professionals about its use in assisting.

## T5B-SPIR-2 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) IN ADVANCED PANCREATIC CANCER: GERMAN EXPERIENCE

Milka Marinova, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Holger Strunk, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In patients with locally advanced pancreatic adenocarcinoma prognosis is extremely poor. Their quality of life is often reduced due to cancer-related pain. This prospective observational study aimed to evaluate ultrasound-guided high-intensity focused ultrasound (HIFU) in Caucasian patients with inoperable pancreatic cancer for feasibility, local tumor response, and changes in quality of life and symptoms.

### METHODS AND MATERIALS

HIFU was performed in 104 patients with locally advanced inoperable pancreatic carcinoma and tumor-related pain symptoms, 42 with UICC stage III, 59 with UICC stage IV. 98 patients underwent simultaneous standard chemotherapy. Ablation was performed using JC HIFU system (Chongqing, China HAIFU Company) with an ultrasonic device for real-time imaging. Clinical and imaging follow-up (US, CT, MRI) was performed before and up to 24 months after HIFU. Clinical assessment included evaluation of quality of life and symptom changes using standardized questionnaires.

### RESULTS

In 85% of patients, a significant early pain relief was achieved by US-guided HIFU independent of metastatic status which persisted during follow-up. Furthermore, 50% of patients did not require any analgesic treatment 6 weeks post-ablation. Tumor volumes could be considerably reduced over time in 80% of patients, with a mean tumor volume reduction of about 60% after 6 months in HIFU-treated pancreatic tumors. There were no severe or long-lasting HIFU-related complications. There were no severe or long-lasting HIFU-related complications.

### CONCLUSION

US-guided HIFU can be used successfully for local tumor control and pain relief in patients with locally advanced pancreatic cancer.

### CLINICAL RELEVANCE/APPLICATION

US-guided HIFU is feasible and safe for patients with unresectable pancreatic cancer. HIFU can considerably reduce tumour volume. Patients treated with HIFU experienced significant and lasting reduction of pain intensity. HIFU seems to have a potential survival benefit for advanced pancreatic cancer patients HIFU has a crucial clinical benefit for patients with pancreatic cancer.

## T5B-SPIR-3 PERCUTANEOUS IMAGE-GUIDED THERMAL ABLATION OF RENAL TUMORS: ANALYSIS OF THE PROSPECTIVE REGISTRY OF THE GERMAN SOCIETY FOR INTERVENTIONAL RADIOLOGY AND MINIMALLY INVASIVE THERAPY (DEGIR) 2018-2023

Michael Forsting, MD (*Abstract Co-Author*) Nothing to Disclose
Johannes Haubold, MD (*Abstract Co-Author*) Speaker, Siemens AG
Thomas Dertnig, MD (*Abstract Co-Author*) Nothing to Disclose
Sebastian Zensen, MD (*Abstract Co-Author*) Nothing to Disclose
Hannah Luisa Steinberg-Vorhoff, MD (*Abstract Co-Author*) Nothing to Disclose
Benedikt M. Schaarschmidt, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Percutaneous renal thermal ablation (TA) with cryoablation, microwave ablation (MWA) and radiofrequency ablation (RFA) is a highly effective treatment modality for small tumors that is underrepresented in most guidelines due to the lack of sufficient data. The aim of this evaluation was to analyze the use, technical success and complications of TA based on the prospectively managed multinational registry data of the German Society for Interventional Radiology and Minimally Invasive Therapy (DeGIR, Deutsche Gesellschaft für Interventionelle Radiologie und minimal-invasive Therapie).

### METHODS AND MATERIALS

A total of 1102 patients (mean patient age: 72.5±11.6 years; female: 33.6%, 370/1102; male: 66.4%, 732/1102) treated with TA between 2018 and 2023 in 92 centers in Germany and Austria were examined. TA with a ablative margin was considered technical success. Complications were classified according to the Society of Interventional Radiology in minor (Grade A-B) and major (Grade C-F). High-volume centers were defined as hospitals with =20 TAs during the analyzed time span.

### RESULTS

Cryoablation was used in 13.3% (147/1102), MWA in 41.9% (462/1102) and RFA in 43.6% (481/1102, other: 1.2%, 12/1002). The mean lesion diameter was 24 ± 11 mm. 94.6% (1043/1102) of TAs were technically successful. Heat-based TAs were significantly less successful in tumors measuring 3-4cm (89.8%, 97/108) compared to =3cm (96.1%, 567/590; p=0.005). In cryoablations, no significant difference between the groups was detected (3-4cm: 85.7%, 12/14; =3cm: 97.9%, 94/96; p=0.078). Treatment success of renal TA was not influenced by the volume of the treating center (high-volume center: 94.8%, 677/714; low-volume center: 94.1%, 365/388; p=0.602). Furthermore, heat-based TAs had a significantly higher overall complication rate (5.4%, 51/947) than cryoablations (1.4%, 2/145, p=0.034). However, no significant difference between the two groups could be found concerning the rate of major complications (heat-based TA: 2.5%, 24/947; cryoablation: 0.7%, 1/147; p=0.162).

### CONCLUSION

Percutaneous renal TA have a high technical success rate. However, cryoablation seems to be favorable in tumors measuring 3-4 cm and shows a lower overall complication rate than heat-based TA.

### CLINICAL RELEVANCE/APPLICATION

Thermal ablations of renal tumors are safe and effective interventions. However, cryoablation seems to be advantageous compared to heat-based procedures concerning tumors measuring 3-4 cm and overall complication rate.

## T5B-SPIR-4 ENHANCING TUMOR VISIBILITY IN RENAL ABLATION THROUGH SPECTRAL CT ELECTRON DENSITY COLOR OVERLAY

Thomas D. Atwell, MD (*Abstract Co-Author*) Nothing to Disclose
Daniel A. Adamo, MD (*Abstract Co-Author*) Nothing to Disclose
Andrea Ferrero, PhD (*Abstract Co-Author*) Nothing to Disclose

Rebecca Hibbert, MD, FRCPC (*Presenter*) Nothing to Disclose

### PURPOSE

Accurate visualization of renal tumors during CT-guided percutaneous ablation is crucial for effective procedural planning and precise probe placement. However, endophytic renal masses pose a challenge due to their limited visibility on non-contrast CT images. While intravenous (IV) contrast can enhance lesion detection, its use may be contraindicated in impaired renal function or contrast allergy. This study aims to assess whether a narrow window, electron density (ED) color overlay on conventional non-contrast CT can augment visualization of endophytic renal tumors, potentially reducing the need for additional contrast-enhanced CT imaging during renal ablation.

### METHODS AND MATERIALS

This IRB approved and HIPAA compliant retrospective study consisted of renal ablation cases performed from January to December 2023. Two interventional radiologists independently assessed 25 procedures involving endophytic tumors. Each radiologist reviewed and rated two series for each case: a conventional non-contrast CT series alone and an electron density color overlay series. Owing to its low noise properties, the ED spectral result was chosen for color overlay with a narrow dynamic range (WW/WL: 8/103 %EDW). Tumor conspicuity was evaluated on a continuous sliding scale ranging from poor (1) to exceptional (100). Each reader determined whether renal ablation could proceed based on visualization using the non-contrast CT series alone, using the color overlay series, or if additional IV contrast-enhanced CT would be advised for optimal guidance. Statistical assessment was performed using a two-sided Wilcoxon signed-rank test.

### RESULTS

There was a significant ($p < 0.001$) improvement in tumor conspicuity with the ED overlay series (MED = 36.3) compared to the conventional series alone (MED = 19.2). When evaluating adequacy of tumor visualization for procedural planning, readers were more likely to proceed without a contrast-enhanced CT when reviewing the ED color overlay series (44% of reads; 22/50) rather than the conventional series alone (22% of reads; 11/50). Moreover, a discernable parabolic relationship was noted between readers' scores and lesion density.

### CONCLUSION

The addition of a narrow window, electron density color overlay to non-contrast CT showed a significant improvement in the visibility of endophytic renal tumors, indicating a simple yet effective approach to reduce the need for additional IV contrast-enhanced imaging prior to probe placement during renal ablation.

### CLINICAL RELEVANCE/APPLICATION

Adequate tumor visibility is paramount for precise planning and execution of percutaneous renal ablation. This technique offers a viable alternative to using IV contrast to enhance tumor visibility during CT-guided renal ablation.

## T5B-SPIR-5 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) IN ADVANCED PANCREATIC CANCER - COMPARATIVE STUDY OF OVERALL SURVIVAL IN PATIENTS UNDERGOING PALLIATIVE THERAPY WITH VERSUS WITHOUT LOCAL HIFU TREATMENT

Holger Strunk, MD (*Abstract Co-Author*) Nothing to Disclose
Hans H. Schild, MD (*Abstract Co-Author*) Nothing to Disclose
Markus Essler, MD (*Abstract Co-Author*) Nothing to Disclose
Milka Marinova, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Pancreatic cancer remains a challenge in oncology, particularly in its advanced stages where therapeutic options are still limited. High-intensity focused ultrasound (HIFU) has emerged as a promising modality for local tumor ablation. This study aims to compare overall survival (OS) outcomes of patients with advanced pancreatic cancer undergoing palliative chemotherapy with and without local HIFU treatment.

### METHODS AND MATERIALS

A comparative analysis was conducted on a cohort of 285 patients diagnosed with advanced pancreatic cancer between 2014 and 2022. The HIFU cohort included a total of 161 patients: 67 with UICC stage III, 94 patients with UICC stage IV disease. 83 patients received local HIFU during 1st line, 40 during

2nd line, 10 during 3rd line, and 3 during 4th line palliative chemotherapy. 25 patients underwent HIFU while receiving best supportive care only. The historical cohort consisted of 124 patients, 35 in UICC stage III and 89 in UICC stage IV. Kaplan-Meier analysis was used to estimate the median OS of both patient cohorts.

**RESULTS**

The median OS was 15.8 months (95%CI, 12.4-19.1) for HIFU-treated patients versus 9.8 months (95%CI, 7.6-11.4) for the historical cohort (HR 0.52; 95%CI, 0.33-0.86; p=0.01), regardless of sex, tumor grading, ECOG, stage of disease and chemotherapy regimen (p<0.001). For UICC stage III, the median OS survival was 18.5 months (95%CI, 12.8-21.4) versus 10.8 months (95%CI, 6.6-15.1) with versus without HIFU treatment, respectively (p=0.0018). For UICC stage IV, the median OS was 13.1 (95%CI, 9.9-18.2) versus 9.3 months (95%CI, 6.4-11.4) with versus without HIFU treatment, respectively (p=0.006). The survival rate (6 months, 1 and 2 years) since palliative diagnosis was 92.8%, 61.5%, and 21.7% in the HIFU cohort versus 65.9%, 38.3%, and 10.9% in the historical cohort, respectively. The 1-, 2-, and 3-year OS showed a significant difference between both patient cohorts (p=0.0014, 0.0015, and 0.0094, respectively).

**CONCLUSION**

This study suggests that the addition of local HIFU treatment to palliative chemotherapy may offer a survival advantage in patients with advanced pancreatic cancer. Further prospective studies are warranted to validate these findings and elucidate the optimal integration of HIFU into the treatment paradigm for this patient population.

**CLINICAL RELEVANCE/APPLICATION**

In advanced pancreatic cancer, the addition of local HIFU treatment to palliative chemotherapy may confer a survival advantage for patients. These findings underscore the potential of HIFU as an adjunctive treatment option. Additional prospective studies are necessary to confirm these results and clarify the most effective incorporation of HIFU into the treatment approach for patients with advanced pancreatic cancer.

## T5B-SPIR-6 NK CELL INFUSION ENHANCES TUMOR CONTROL AFTER SUB-LETHAL HYPERTHERMIA IN VITRO AND IN VIVO: IMPLICATIONS OF MHC-1 SHEDDING

Janet Pham (*Abstract Co-Author*) Nothing to Disclose
Jillian Poulsen (*Abstract Co-Author*) Nothing to Disclose

Sara Huerta (*Abstract Co-Author*) Nothing to Disclose
Po-Chun Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

This in vitro and in vivo study assesses the effectiveness of NK-cell based immunotherapy after sub-lethal thermal ablation in treating hepatocellular carcinoma (HCC). Image-guided thermal ablation, the standard of care for unresectable early-stage HCC, exposes tumor cells to non-lethal hyperthermic temperatures near the ablation margins. Most residual and recurrent tumor growth after ablation occurs at ablation zone peripheries, with recent studies suggesting that poorly differentiated HCCs are linked to higher progression rates. This study focuses on the potential of NK cell immunotherapy to control residual disease in both well- and poorly differentiated HCC following ablation.

**METHODS AND MATERIALS**

Flow cytometry evaluated immunological stemness markers, particularly MHC-class I (MHC-I) expression and shedding after hyperthermia stress, in well- (HepG2) and poorly differentiated (SNU-423) HCC cell lines. HCC cells were heated at 37, 43, and 47°C for 10 minutes, followed by a 20 minute cooling at 25°C. After that, HCC cells were exposed to various NK cells—primary NK (pNK), IL-2 stimulated NK (IL-2+pNK), and supercharged NK (sNK) cells. NK cell cytotoxicity to these heat-treated HCC cells was assessed via real-time cell imaging and chromium release assays. The aggressiveness and susceptibility to NK cell-based therapy of HCC subtypes were further validated in an NSG orthotopic tumor mouse model, measuring tumor weight, size, and Gaussia luciferase level in the blood.

**RESULTS**

NK cell therapies showed enhanced cytotoxicity in non-lethal hyperthermia treated HCC at 47°C compared to 37°C, which was confirmed by the chromium release assay showing higher lytic units 30 in both IL-2+pNK and sNK cells. MHC-I surface expression notably decreased on HCC cells at 47°C, suggesting a potential mechanism for increased cytotoxicity. In vivo, NSG mice with SNU-423 tumors had shorter survival than those with HepG2 tumors. Additionally, sNK cell infusion trended towards reducing tumor weight and size, though not significantly. Notably, the luciferase levels indicated that sNK cells reduced the growth rates of HepG2 tumors by Day 46, with p-values of 0.0145 and 0.0604 at Day 43.

**CONCLUSION**

Our findings highlight the potential of sNK cell therapy to slow tumor growth in NSG mice with non-heated HCC tumors. Although thermal ablation alone offers significant benefits for controlling early stage HCC, augmenting this treatment with NK cell based therapy could further enhance therapeutic outcomes. Additional in vivo studies are necessary to validate the effectiveness and integration of this immunotherapy approach.

**CLINICAL RELEVANCE/APPLICATION**

Adding adjuvant NK cell infusion after standard of care thermal ablation can enhance treatment outcomes for HCC.

## T5B-SPIR-7 INJECTABLE X-RAY VISIBLE TARGETS FOR IN VIVO CBCT-GUIDED HISTOTRIPSY TREATMENTS

Grace Minesinger, BS (*Abstract Co-Author*) Nothing to Disclose

Martin Wagner, PhD (*Abstract Co-Author*) Research Consultant, HistoSonics, Inc
Katrina L. Falk, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Histotripsy is an emerging focused ultrasound (US) liver tumor therapy that is guided by US, which limits its use to only acoustic targeting windows. The therapeutic energy can be delivered to all areas, so a new targeting technique with cone beam CT (CBCT) is being developed to overcome this limitation. Given the expense and relative lack of large animal tumor models, research is done on healthy swine without tumor targets. The purpose of this work is to compare three percutaneously injectable surrogate targets that are visible on pretreatment CBCT images and non-disruptive to histotripsy treatment (tx).

**METHODS AND MATERIALS**

Barium sulfate paste (EZ Paste) mixed with either saline (n=2, 4:1 barium:saline, 0.175mL) or autologous blood (n=2, 2:1 or 4:1 barium:blood, 0.2mL), and a platinum pushable coil (n=1, Terumo AZUR 18, 6mm x 10cm) were used. The targets were percutaneously injected into the livers of 4 in vivo swine. Histotripsy treatment zones (TZ) (15-20 mm) were created over the 5 targets and 1 control (no target) using a 700kHz multi-element transducer (HistoSonics) and 2 mobile C-arms (Siemens CIOS, GE OEC). The average absolute error in TZ diameter (CC, AP, lateral) versus prescribed was measured. The average of 3 CNR measurements of the TZ was measured on the post tx MDCT w/ con and compared to the control. After tx, the swine were sacrificed and the liver with the coil and control tx was excised for histologic analysis.

**RESULTS**

During the tx planning workflow, cavitation was visible around the liquid injectable targets, but preferentially occurred at the coil edges in the coil tx. The TZ around the targets had CNR values of 7.3 and 4.5 for the barium-saline, 3.3 and 5.1 for the barium-blood, 4.8 for the coil and 5.9 for the control tx. The average absolute error in diameter from prescribed was 7.7 and 8.4 mm for the barium-saline and 10.3 and 9.5 mm for barium-blood mixture. The coil and control had an average absolute error of 14.1 and 7.6 mm, respectively. On histopathology, there was complete tissue homogenization adjacent to the coil and within the TZ. No thermal damage was identified near the coil. The transition between treated and untreated tissue were histologically the same in both the coil and control TZ.

**CONCLUSION**

Injectable barium and coil-based x ray visible targets were successfully treated with histotripsy. TZ CNRs and diameters were similar in the target and control cases suggesting the target did not disrupt the tx. Per histology, the metal coil did not change tx efficacy but did negatively impact tx planning workflow, which may decrease targeting accuracy.

**CLINICAL RELEVANCE/APPLICATION**

Developing X-Ray visible targets that do not disrupt histotripsy tx will help increase accuracy, precision, reproducibility and rigor of CBCT guided histotripsy.

## T5B-SPIR-8 EVALUATION OF A CT-MRI MULTIMODAL REGISTRATION SYSTEM FOR LOCALIZATION OF COLORECTAL CANCER LIVER METASTASES DURING CT GUIDED PERCUTANEOUS RADIOFREQUENCY/MICROWAVE ABLATION

Xia Wu (*Abstract Co-Author*) Nothing to Disclose
Lumin Chen, MD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Computed tomography (CT)-guided liver ablation is widely used in the treatment of colorectal cancer liver metastases (CRLMs) and often involves using unenhanced images for the procedure. However, during percutaneous radiofrequency/microwave ablation, the visibility of tumor metastases on CT may be poor, making the localization of target lesions challenging. This retrospective study aims to evaluate the accuracy of a novel deep-learning-based computer-aided system (DL-CAS) via CT-MRI multimodal registration for localization of colorectal cancer liver metastases during CT guided percutaneous radiofrequency/microwave ablation.

**METHODS AND MATERIALS**

From January 2021 to August 2023, paired CT and MRI images of 105 patients diagnosed with liver metastasis of colorectal cancer and treated with CT-guided liver microwave or radiofrequency ablation from one hospital were collected for performance evaluation in this retrospective study. The decision to ablate all liver metastases was discussed through MDT. DL-CAS was previously developed with a two-stage cascaded registration framework involving rigid and non-rigid deformation, which is employed to align the CT-MRI multimodal liver images. We calculated the distance between the predicted location of raters or DL-CAS with ground truth and then compared their deviation to evaluate the accuracy of detecting the liver metastases.

**RESULTS**

In total 220 liver metastases lesions in the external validation dataset were scored. Two junior physicians joined the comparative experiment as raters. DL-CAS showed a lower deviation (5.791 ± 2.817 mm vs. Rater1: 7.613 ± 9.21 mm or Rater2: 7.058 ± 9.5 mm, $p < 0.001$) compared to the two Raters.

**CONCLUSION**

DL-CAS for the localization of CRLMs during percutaneous radiofrequency/microwave ablation has shown favorable performance in the external validation dataset.

**CLINICAL RELEVANCE/APPLICATION**

Assisting interventional radiologists in localizing liver metastases from colorectal cancer during CT-guided percutaneous radiofrequency/microwave ablation procedures.

## T5B-SPIR-9 IMAGE-GUIDED HDR-BT TREATED PATIENT SERUM CAN INCREASE PROLIFERATION OF HCC IN VITRO AND IS ASSOCIATED WITH RESPONSE AND SEROLOGIC GROWTH FACTORS

Philipp M. Kazmierczak, MD (*Abstract Co-Author*) Nothing to Disclose
Moritz Nikolaus Groper (*Abstract Co-Author*) Nothing to Disclose
S. Nahum Goldberg, MD (*Abstract Co-Author*) Consultant, Cosman Medical, Inc;Consultant, Sarasota Interventional Radiology

Jens Ricke, MD, PhD (*Abstract Co-Author*) Research Grant, Sirtex Medical Ltd;Research Grant, Bayer AG;Research Grant, Terumo Corporation;Research Grant, Boston Scientific Corporation
Marianna Alunni-Fabbroni (*Abstract Co-Author*) Nothing to Disclose
Matthias M. Stechele, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To determine whether patient serum after CT-guided High-Dose-Rate Brachytherapy (HDR-BT) can induce HCC growth in vitro by release of growth factors and whether this correlates with outcome.

## METHODS AND MATERIALS

In this study, 24 HCC patients (BCLC AB) were treated by HDR-BT (1×15 Gy). Patients were either classified as Responders (R, n=12) who had no progression within 6m and no diffuse systemic progression within 2yrs or Non-responders (NR, n=12) who had recurrence within 6m and/or diffuse systemic tumor progression (i.e. exceeding 3 nodules/nodule diameter >3cm) or extrahepatic disease within 2yrs. Serum was obtained at baseline and 48hr post-procedure. Two HCC cell lines (HepG2 and Huh7) were incubated for 72hr in the presence of 20% patient serum in standard condition. Proliferative Indices (PI) were assessed comparing cell proliferation of serum incubation at 48hr post-HDR-BT and baseline. Results were correlated with response and serologic levels of EGF and Angiopoietin-1.

## RESULTS

PI of Non-responders were significantly elevated compared to Responders for both HepG2 (median R:0.74; median NR:1.12) and Huh7 (R:0.53; NR:1.96) ($p<0.05$, both comparisons). Kaplan-Meier analyses demonstrated significantly shorter time to systemic progression in patients with increased PI compared to those with decreased PI ($p<0.01$, both cell lines). Increased PI correlated best with increased EGF levels ($p<0.05$ for HepG2 and Huh7, respectively) and with increased Angiopoietin-1 ($p<0.05$ for Huh7).

## CONCLUSION

Poor outcome following image-guided HDR-BT is associated with increased growth of HCC cell lines in vitro after patient serum incubation as well as production of serologic growth factors.

## CLINICAL RELEVANCE/APPLICATION

Our in-vitro platform represents a potential predictor of outcome in HCC patients undergoing HDR-BT already at a very short time after therapy. Accordingly, this data can identify patients at risk and potential candidates for a personalized treatment approach.

## T5B-SPMK-1 THE ASSOCIATION BETWEEN TISSUE-SPECIFIC CHANGES IN BODY COMPOSITION WITH LOSS OF MUSCLE STRENGTH AND PHYSICAL PERFORMANCE: A 5-YEAR FOLLOW-UP STUDY

Fengyun Zhou (*Abstract Co-Author*) Nothing to Disclose
Ling Wang (*Abstract Co-Author*) Nothing to Disclose
Xiaoguang Cheng (*Abstract Co-Author*) Nothing to Disclose
Yandong Liu (*Abstract Co-Author*) Nothing to Disclose
Wenshuang Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yi Yuan (*Presenter*) Nothing to Disclose

### PURPOSE

Our objective was to examine longitudinal changes in body composition in older individuals in relation to changes in physical performance.

### METHODS AND MATERIALS

We included 120 community-dwelling individuals aged 60-85 years from the neighborhood of our hospital. CT scans and measurements of handgrip strength (HGS) and the Timed Up and Go test (TUG) were obtained at baseline and follow-up after 5 years. We assessed changes in muscle size and muscle density of the paraspinal muscles, psoas major muscles, pelvic muscles, thigh muscles, changes in adipose area (subcutaneous adipose area [SAA], visceral adipose area, [VAA], and total adipose area [TAA]) and changes in liver fat accumulation. Associations of changes in body composition with changes in HGS and TUG were tested in logistic regression models after adjusting for baseline age, height, weight and type 2 diabetes. Age strata < 70 years and > 70 years were compared in gender-stratified analyses using paired T-tests.

### RESULTS

Muscle atrophy was greater in individuals over 70 years ($P<0.05$) compared to younger individuals (psoas major, -11.6% vs. -8.9% for females, -12.2% vs. -9.2% for males; abductors, -8.0% vs. -3.0% for females, -8.9% vs. -4.7% for males; posterior compartment of the thigh muscles, -24.9% vs. -17.8% for females, -24.4% vs. -16.8% for males). In females over 70 years, increases in visceral adipose area (VAA) were less than in older women (8.5% vs. 16.3%, $P=0.03$), while liver fat content decline was greater (-17.4% vs. -5.8%, $P<0.01$) in the younger women. Among females, each decrease (per cm2) of anterior compartment of thigh muscle size was associated with a 10% decrease of HGS (95% confidence interval [CI], 1.02-1.19; $P=0.02$) and an 11% longer TUG (95%CI, 1.02-1.20; $P=0.01$). Among males, each decrease (per cm2) of anterior compartment of thigh muscle size was associated with a 15% decreased HGS (95%CI, 1.02-1.29; $P=0.02$) and a 44% longer TUG (95%CI, 1.10-1.88; $P<0.01$). Similarly, in males, each decrease (per cm2) of medial compartment of thigh muscle size was associated with a 12% decreased HGS (95%CI, 1.02-1.23; $P=0.02$).

### CONCLUSION

CT-based body composition changes atrophy of thigh muscles in particular associated with loss of muscle strength and physical performance.

### CLINICAL RELEVANCE/APPLICATION

The results from this longitudinal study showed that elderly individuals display atrophy of skeletal muscles, decrease of liver fat and hypertrophy of adipose areas during the sixth decade in males and females. Atrophy of thigh muscles was associated with loss of muscle strength and actual physical performance. A comprehensive understanding of body composition changes with aging would assist to make novel strategies to promote healthy aging and improve the quality of life in older individuals.

## T5B-SPMK-2 MRI APPEARANCE OF REGENERATIVE PERIPHERAL NERVE INTERFACE

Samer L. Soussahn, MD (*Abstract Co-Author*) Nothing to Disclose
Theodore Kung (*Abstract Co-Author*) Nothing to Disclose
Qiaochu Chen (*Abstract Co-Author*) Nothing to Disclose
Paul Cederna, MD (*Abstract Co-Author*) Nothing to Disclose
Yoav Morag, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To describe the MRI appearance of Regenerative peripheral nerve interface (RPNI) and potential association between the MR appearance and a following RPNI revision.

**METHODS AND MATERIALS**

A retrospective assessment of MRI studies performed following RPNI surgery performed at our institution between 1/1/2010- 7/29/2023 with clinical correlation.

**RESULTS**

14 patients (8 males, 6 females, age range 31-80 years, median age- 51 years) with technically adequate MRI of RPNIs were included in this study including 5 patients with below knee amputation (BKA) with 5 tibial and 4 CPN RPNI, 8 patients with above knee amputations (AKA) with a sciatic RPNI and one patient following forequarter amputation with a brachial plexus RPNI. Two patients had undergone revision RPNI surgery x3 (AKA-sciatic nerve) for a total of 6 RPNI revisions. On T1 weighted sequences, all RPNIs were isointense to muscle and blended with the surrounding scar and muscle tissues while on T2 weighted sequences, all RPNIs were hyperintense in signal compared to muscle. All but one RPNI underwent post contrast enhancement in variable patterns. No statistically significant difference in RPNI MR appearance was found between studies with or without a following RPNI revision surgery.

**CONCLUSION**

RPNI on MRI typically have a bright and intermediate signal on T2 and T1 weighted sequences accordingly, and typically undergo postcontrast enhancement in variable patterns without a statistically significant difference between cases with and without following RPNI revision.

**CLINICAL RELEVANCE/APPLICATION**

Persistent increased signal on T2 weighted sequences and post contrast enhancement of RPNIs should not be misconstrued as indicative of pathology.

## T5B-SPMK-3 EFFECTS OF BARIATRIC SURGERY ON GASTRIC VOLUME, BODY COMPOSITION, AND HEPATIC STEATOSIS: AI-BASED CT SCAN ANALYSIS

Jai Keun Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyung-Min Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Jimi Huh, MD (*Abstract Co-Author*) Nothing to Disclose
Kyung Won Kim, MD (*Presenter*) CEO, Trial Informatics Company

**PURPOSE**

To evaluate the changes in gastric volume, subcutaneous fat (Sfat), visceral fat (Vfat), skeletal muscle, bone mineral density (BMD), and hepatic steatosis following bariatric surgery from fully automatic AI measurement technique on opportunistic CT gastrography images.

**METHODS AND MATERIALS**

From prospectively collected 60 obese patients undergoing bariatric surgery, changes in body composition indicators were assessed on preoperative period and at 3 months and 1-year post-surgery follow-up CT scans. Using AI techniques, we assessed gastric volume, Sfat, Vfat, BMI-adjusted skeletal muscle index (SMI), BMD, and the liver/spleen attenuation ratio (L/S ratio). Linear Mixed Models (LMM) were employed to determine the statistical significance of changes over time, with age and sex adjustments.

**RESULTS**

Postoperative assessments revealed significant reductions in gastric volume, decreasing from a 954.7 ± 183.6 preoperatively to 180.6 ± 77.2 at 3-months and 245.8 ± 92.4 at 1-year post-surgery ($p<0.001$). Similarly, Sfat reduced from 476.8 ± 157.7 preoperatively to 365.8 ± 139.1 at 3-months and further to 242.7 ± 121.4 at 1-year post-surgery, while Vfat declined from 276.7 ± 85.2 preoperatively to 179.4 ± 70.5 at 3-months and 100.0 ± 71.5 at 1-year post-surgery ($p<0.001$ for both). Notably, there were no significant changes in bone mineral density (BMD) between pre- and post-surgery. The SMI has been gradually increased at 3-months and 1-year post-surgery. Additionally, the L/S ratio, a marker of hepatic steatosis, has been increased post-surgery.

**CONCLUSION**

AI measurement from opportunistic CT scans demonstrated that bariatic surgery not only significantly reduces body fat but also improves hepatic steatosis and SMI.

**CLINICAL RELEVANCE/APPLICATION**

These findings highlight the multifaceted benefits of bariatric surgery beyond mere weight loss, showcasing its potential in managing and potentially reversing complications associated with obesity.

Maurice Heimer, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the eligibility of patients with advanced or recurrent solid malignancies presented to a molecular tumor board (MTB) at a large precision oncology center for inclusion in trials with the endpoints objective response rate (ORR) or duration of response (DOR) based on Response Evaluation Criteria in Solid Tumors (RECIST version 1.1).

### METHODS AND MATERIALS

Prospective patients with available imaging at the time of presentation in the MTB were included. Imaging data was reviewed for objectifiable measurable disease (MD) according to RECIST v1.1. Additionally, we evaluated the patients with MD for representativeness of the identified measurable lesion(s) in relation to the overall tumor burden.

### RESULTS

262 patients with different solid malignancies were included. 177 patients (68%) had MD and 85 (32%) had non-measurable disease (NMD) at the time point of MTB presentation in accordance with RECIST v1.1. MD was not representative of the overall tumor burden in eleven patients (6%). The main reasons for NMD were lesions with longest diameter shorter than 10 mm (22%) and non-measurable peritoneal carc inomatosis (18%). Colorectal cancer and malignant melanoma displayed the highest rates of MD (>75%). In contrast, gastric cancer, head and neck malignancies, and ovarian carcinoma had the lowest rates of MD (<55%). In case of MD, the measurable lesions were representative of the overall tumor burden in the vast majority of cases (94%).

### CONCLUSION

Approximately one-third of cancer patients with advanced solid malignancies are not eligible for treatment response assessment in trials with endpoints ORR or DOR at the time of MTB presentation. The rate of patients eligible for trials with imaging endpoints differs significantly based on the underlying malignancy and should be taken under consideration during the planning of new precision oncology trials.

### CLINICAL RELEVANCE/APPLICATION

The findings of this study emphasize the need to tailor trial eligibility based on cancer type for precision oncology studies with imaging endpoints.

## T5B-SPMS-2 LESIONS DETECTION REVIEW IN LONGITUDINAL CROSS-SECTIONAL ONCOLOGICAL IMAGING WITH A GRAPH-BASED APPROACH

Richard Lederman, MD (*Abstract Co-Author*) Consultant, HighRAD Ltd
Jacob Sosna, MD (*Abstract Co-Author*) Stockholder, HighRAD Ltd
Beniamin Di Veroli (*Abstract Co-Author*) Nothing to Disclose
Leo Joskowicz, PhD (*Presenter*) Officer, HighRAD Ltd

### PURPOSE

Missed and misidentified neoplastic lesions in longitudinal studies of oncology patients are pervasive and may affect the evaluation of the disease status. Two newly identified patterns of lesion changes, lone lesions and non-consecutive lesion changes, may help radiologists to detect these lesions. This study evaluated a new interpretation revision workflow of lesion annotations in three or more consecutive scans based on these suspicious patterns.

**METHODS AND MATERIALS**

The interpretation revision workflow was evaluated on manual and computed lesion annotations in longitudinal oncology patient studies. For the manual revision, a senior radiologist and a senior neurosurgeon (the readers) manually annotated the lesions in each scan and later revised their annotations with the workflow using the automatically detected patterns of lone and non-consecutive lesions. For the computerized revision, lesion annotations were first computed with a previously trained nnU-Net and were then automatically revised with an AI-based method that automates the workflow readers' decisions. The evaluation included 67 patient studies with 2295 metastatic lesions in lung (19 patients, 83 CT scans, 1178 lesions), liver (18 patients, 77 CECT scans, 800 lesions) and brain (30 patients, 102 T1W-Gad MRI scans, 317 lesions).

**RESULTS**

Revision of the manual lesion annotations revealed 120 missed lesions and 20 misidentified lesions in 31 out of 67 (46%) studies. The automatic revision reduced the number of computed missed lesions by 55 and computed misidentified lesions by 164 in 51 out of 67 (76%) studies.

**CONCLUSION**

Our experimental studies demonstrate that the automated detection of two suspicious lesion change patterns, lone lesions and non-consecutive matching lesions that can be only found in three or more consecutive studies may help in identifying missing and misidentified lesions.

**CLINICAL RELEVANCE/APPLICATION**

Automatic analysis of three or more consecutive volumetric scans helps find missed and misidentified lesions and may improve the evaluation of temporal changes of oncological lesions, potentially improving disease management.

### PURPOSE

Prostate cancer (PC) is the second leading cause of cancer-related death and the most common cancer diagnosis for men in the United States (US). The incidence of PC among African American (AA) males is approximately 70% higher than Caucasian males. When stratified by race, one of the many risk factors contributing to poor PC outcomes is social determinants of health (SDOH). Radium-223 dichloride (Ra-223) is indicated in castrate-resistant prostate cancer with bone metastases and no visceral metastases. Patients with metastatic castrate-resistant prostate cancer (mCRPC) treated with Ra-223 experience prolonged overall survival (OS), particularly AAs, compared to Caucasians. The state of Mississippi struggles with various health metrics and has one of the worst cancer survival rates in the country. This study aims to elucidate the interplay between treatment outcomes of Ra-223 in mCRPC patients when stratified among races and SDOH.

### METHODS AND MATERIALS

A retrospective review is conducted for mCRPC patients diagnosed and treated with Ra-223 at an academic medical center to elucidate patient characteristics, staging, imaging characteristics, and SDOH variables that may affect patient outcomes. Race, the average income of the city of residence, healthcare access, and distances traveled for treatments are the primary SDOH variables, and the outcomes include OS, and treatment-related morbidity for a population in the Southern US. Univariate analysis by Kaplan-Meier is employed.

### RESULTS

After treatment with Ra-223, an overall median survival time of 14 months and 11 months is observed for AAs and Caucasians, respectively (p=0.359). 66.7% of AAs and 50% of Caucasians travel greater than 50 miles for treatments (p=0.635). 66.7% of AAs and 33.3% of Caucasians reside in cities with an average salary of less than $35,000 (p=0.343). Caucasian patients exhibit more treatment-related complications than AAs (66.7% vs. 33.3%), but AAs were diagnosed with anemia at higher rates (100% vs. 16.7%, p=0.018). All patients had healthcare insurance; none demonstrated KPS improvement (p=0.023); however, all patients achieved pain palliation.

### CONCLUSION

This study reports improved OS in AAs compared to Caucasians with mCRPC treated with Ra-223. As AAs in this study face more significant adversities with SDOH, this paradoxical observation may suggest a protective factor for AAs likely secondary to biological genetic factors. The study's primary limitations are a small cohort size and limited specificity of SDOH, which warrant further investigation.

### CLINICAL RELEVANCE/APPLICATION

mCRPC can be managed with various therapeutics. However, Ra-223 has been shown to palliate pain in all patients and may possess an additional overall survival benefit for AAs.

## T5B-SPNPM-1 PROJECTED IMAGING DEMAND, 2025-2055

Eric M. Rubin, MD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth Y. Rula, PhD (*Abstract Co-Author*) Nothing to Disclose
Jay R. Parikh, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Eric Christensen, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To project future imaging utilization through 2055 based on historical imaging utilization and U.S. Census population projections.

### METHODS AND MATERIALS

We used CMS Medicare claims from a 5% nationally representative sample of Medicare fee-for-service beneficiaries (2012-2021) to assess mean imaging use by sex, age, and modality in 2021 as well as time trends for how utilization was increasing, constant, or decreasing over this decade. Future imaging use was modeled by applying 2021 per person imaging rates to the U.S. Census projections of the future population, which include increases in the total population as well as an increasingly larger proportion of older individuals. This is a static projection based on 2021 utilization rates. We also modeled future utilization per person assuming the 2012-2021 trends in imaging use by modality will continue through 2030 or 2035 and thereafter be constant.

### RESULTS

The U.S. population size is projected to be 362.4 million in 2055, which is 8.2% larger than the 2023 population. This increase is driven by the 65+ population, which is projected to increase 43% by 2055 (and 164% for the 85+ population). Given the trends of Medicare beneficiaries shifting to Medicare Advantage (MA), the MA population is expected to increase 70.7% by 2055 compared with 8.9% for the Medicare fee-for-service population. Regression analysis shows a substantial increase in CT and MR studies per person between 2012 and 2021. For example, CT and MR use in 2021 were 43.3% and 23.7% higher than in 2012. Conversely, nuclear medicine (NM) and interventional radiology (IR) procedures for females were 22.0% and 27.5% lower, respectively, in 2021 than in 2012. Assuming per person imaging utilization remains static at 2021 levels, higher utilization is projected in 2055 compared with 2023 due to population increases and demographic changes: 26% for CT, 19% for MR, 25% for NM, 19% for ultrasound, 23% for radiography/fluoroscopy (XR), and 17% for IR. If current per person imaging utilization trends continue through 2035 and are constant thereafter, 2055 utilization compared with 2023 utilization will be higher for CT (86%), MR (40%), ultrasound (22%), and XR (22%) and lower for NM (-3%) and IR (-7%).

### CONCLUSION

Given population projections and historical imaging utilization, demand for CT, MR, ultrasound, and XR are projected to be larger than the overall population growth. This is driven by the disproportionate growth of the 65+ population and the higher imaging utilization rate of this population.

### CLINICAL RELEVANCE/APPLICATION

Modelling imaging utilization will facilitate future estimates of radiologist adequacy in the U.S. for interpretation of imaging studies and assist policy decision making regarding funding of radiology trainees.

## T5B-SPNPM-2 BEYOND THE BLACK BOX: THE NEED FOR MORE TRANSPARENCY IN REGULATING AI/ML RADIOLOGICAL DEVICES VIA THE FDA 510(K) PATHWAY

David B. Larson, MD, MBA (*Abstract Co-Author*) Research Grant, Siemens AG ;Advisor, Bunkerhill Health;Shareholder, Bunkerhill Health
John N. Grimes, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Lina Cheuy (*Abstract Co-Author*) Nothing to Disclose
Alaa Youssef, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The majority of marketed AI/ML medical devices, most of which have a radiological function, have been cleared through the FDA 510(k) pathway. This study assessed the publicly available 510(k) summaries of AI/ML-enabled computer-assisted detection (CAD) devices to evaluate if the summaries detailed the algorithmic input, how rigorously the devices were evaluated, and if there was substantial equivalence in function and modality with the claimed predicate device.

### METHODS AND MATERIALS

Using the FDA AI/ML public database, we identified all CAD devices cleared through the FDA 510(k) pathway from May 2018 to October 2023.We extracted details relevant to algorithm development, including image annotation instructions and ground truth definitions, from each device's 510(k)

summaries, product webpages, and relevant publications. The device details were cross-referenced using the AI Central database from the American College of Radiology - Data Science Institute. Predicate lineages were then mapped by manually tracing product numbers included within the 510(k) summaries.

**RESULTS**

In total, 98 CAD devices were cleared, with the majority being computer-assisted triage (CADt) devices (67/98). None of the cleared CAD devices provided image annotation details, and only one product mentioned access to its training data. More than half of the devices did not disclose how the ground truth was defined. Only 13 CAD devices were reported in peer-reviewed publications, and only two were evaluated in prospective studies. The mapped predicate lineages revealed significant variations in clinical function and imaging modality between the cleared devices and the claimed predicate.

**CONCLUSION**

The 510(k) summaries reveal a concerning lack of details describing the algorithmic development process and significant mismatches in clinical function and imaging modality between newly cleared medical devices and their claimed predicate device.

**CLINICAL RELEVANCE/APPLICATION**

The current FDA 510(k) process for clearing AI/ML medical devices has led to substantial gaps in transparency and consistency that could undermine public trust in such devices. Broad interpretations of the FDA requirements have led to questionable equivalence between the cleared devices and their claimed predicate devices. Coupled with the inconsistent availability of details describing the AI/ML algorithm development process in the public 510(k) summaries, these findings underscore existing concerns about the safety of diagnostic AI/ML medical devices cleared through the FDA 510(k) pathway for use in patient care. A more stringent and transparent regulatory process is needed to promote the public's trust in the clearance of AI/ML medical devices.

## T5B-SPNR-1 ADVANCED 3D PRINTED MODEL OF MIDDLE MENINGEAL ARTERY FOR ENDOVASCULAR NAVIGATION

Pouya Metanat, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Luis Savastano (*Abstract Co-Author*) Nothing to Disclose
Atakan Orscelik, MD (*Abstract Co-Author*) Nothing to Disclose
Yigit Can Senol (*Abstract Co-Author*) Nothing to Disclose
Nishanth Krishnan (*Abstract Co-Author*) Nothing to Disclose
Mona Asghariahmadabad, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Benchtop models have been extensively utilized to test a variety of endovascular devices. Our objective is to design and create a 3D printed model of the middle meningeal artery using both rigid and elastic resin, as well as a cast silicon model. This is intended to facilitate practice in catheter navigation through various tortuous geometries, particularly in older patients.

### METHODS AND MATERIALS

The DICOM files from cadaveric-derived CT angiography of the middle meningeal artery were exported and digitally converted into CAD files. These files were then modified to create a solid model for casting a silicone and a hollow-out structure for printing with both rigid and elastic resin materials. Consequently, the 3D printed model and silicone cast were connected to silicon or glass model replicate the vascular pathway from aortic arch.

### RESULTS

3D printed and silicon models mimicking the human middle meningeal artery were produced, demonstrating anatomical accuracy and comparable catheter navigability. All models provided clear visualization of catheters both by direct observation and under fluoroscopy.

### CONCLUSION

To the best of our knowledge, this study is the first of its kind to offer a detailed description of process for creating 3D-printed and silicon models of the middle meningeal artery. These models are intended for benchtop catheter navigation practice especially within tortuous vascular anatomy.

### CLINICAL RELEVANCE/APPLICATION

A 3D-printed model of the middle meningeal artery can significantly enhance anatomical understanding and interventional planning for procedures such as middle meningeal artery embolization used in treating subdural hematomas. By providing a tactile, spatial representation, these models allow clinicians to practice and refine their techniques in a risk-free environment before performing actual surgeries. Additionally, they serve as excellent educational tools, offering trainees a more interactive and engaging learning experience, which can improve their anatomical knowledge and technical skills.

## T5B-SPNR-10 Distinct Brain Network Patterns in Complete And Incomplete Spinal Cord Injury Patients Based on Graph Theory Analysis

Beining Yang (*Presenter*) Nothing to Disclose

### PURPOSE

Accurate functional assessment is crucial for patients with spinal cord injuries (SCI), but existing evidence has suggested challenges in differentiating between complete spinal cord injury (CSCI) and incomplete spinal cord injury (ICSCI). Therefore, this study aims to compare the changes in brain network topological properties and structure-function coupling in patients with CSCI and ICSCI, to unveil the potential neurobiological mechanisms underlying the different effects of CSCI and ICSCI on brain networks and identify objective neurobiological markers to differentiate between CSCI and ICSCI patients.

### METHODS AND MATERIALS

A total of 35 spinal cord injury (SCI) patients (20 with CSCI and 15 with ICSCI) and 32 healthy controls (HCs) were included. Network construction was based on resting-state functional magnetic resonance imaging to analyze functional connectivity (FC) and diffusion tensor imaging for structural connectivity (SC). Graph theory analysis was utilized to examine SC and FC networks, as well as to estimate SC-FC coupling values.

### RESULTS

The results of this study found that compared to HCs, ICSCI patients exhibited increased path length (Lp) and decreased global (Eg) and local efficiency (Eloc) in SC. For FC, ICSCI patients showed increased small-worldness, clustering coefficient (Cp), normalized clustering coefficient, and Eloc. ICSCI

patients also had increased Cp and Eloc compared to CSCI patients, along with reduced SC-FC coupling values. In CSCI patients, significant correlations were observed between SC network metrics (Lp and Eg) and motor scores, whereas in ICSCI patients, FC network metrics (Cp, Eloc) and SC-FC coupling values were correlated with sensory/motor scores.

**CONCLUSION**

The findings indicate that CSCI and ICSCI have distinct effects on brain networks. CSCI patients demonstrate decreased efficiency in the SC network, whereas ICSCI patients show increased local connections and decreased SC-FC coupling, suggesting different underlying neurobiological mechanisms.

**CLINICAL RELEVANCE/APPLICATION**

This study's identification of distinct neurobiological characteristics and objective markers for CSCI and ICSCI patients has significant clinical relevance. It provides a scientific basis for developing more accurate diagnostic tools and tailoring rehabilitation strategies to the specific neural alterations associated with each type of spinal cord injury. By understanding the unique effects of CSCI and ICSCI on brain networks, clinicians can better predict outcomes and optimize treatments, ultimately improving the functional assessment and care of SCI patients.

## T5B-SPNR-11 ASSESSMENT OF BRAIN IRON LEVELS IN THE LIMBIC SYSTEM'S WHITE MATTER IN PREECLAMPSIA: A CROSS-SECTIONAL AND LONGITUDINAL STUDY BASED ON QUANTITATIVE SUSCEPTIBILITY MAPPING

Qihao Zhang, BS (*Abstract Co-Author*) Nothing to Disclose
Tao Chen (*Abstract Co-Author*) Nothing to Disclose
Linfeng Yang (*Abstract Co-Author*) Nothing to Disclose
Meng Li (*Abstract Co-Author*) Nothing to Disclose
Lingfei Guo, MD (*Abstract Co-Author*) Nothing to Disclose
Chaofan Sui (*Presenter*) Nothing to Disclose

**PURPOSE**

The Papez circuit within the limbic system connects emotions, memory, cognition, and behavior. White matter (WM) changes in the Papez circuit may be crucial to alterations in emotion, memory, and cognition observed in preeclampsia. This study aimed to examine altered WM iron levels in the limbic system of preeclampsia using quantitative susceptibility mapping (QSM) and to explore influencing factors.

**METHODS AND MATERIALS**

A total of 152 women with preeclampsia, 73 pregnant healthy controls (PHC), and 125 non-pregnant healthy controls (NPHC) were included and underwent laboratory examinations, cognitive assessments, blood biochemical tests, and brain QSM imaging. One-way ANOVA was applied to evaluate the QSM values in WM fibers of the limbic system among the three groups. Multiple regression analysis was performed to analyze the influencing factors and the longitudinal changes of QSM, and its relationship with proteins and inflammatory factors in preeclampsia.

**RESULTS**

The QSM values of bilateral anterior thalamic radiation (ATR), the dorsal segment of right cingulum subsection (CBD), the peri-genual part of right cingulum subsection (CBP), the temporal part of bilateral cingulum subsection (CBT) and bilateral fornix (FX) of preeclampsia were significantly higher than those in the NPHC and PHC groups (FDR corrected, $P<0.05$). Multiple stepwise regression analysis showed that age, body mass index, hypoxia-inducible factor-1a (HIF-a), Aß1-42, total tau (T-tau), and group status significantly influenced the susceptibility values of different fibers in the limbic system. Notably, changes in QSM in the right CBP affected cognitive function regardless of pregnancy or preeclampsia status. In the longitudinal study of preeclampsia, susceptibility values in most WM fibers of the limbic system showed no significant changes, except the right CBD, which was lower than that from 3 years prior. Additionally, brain iron level changes in WM of the limbic system were related to the longitudinal changes of HIF-a, but not to the longitudinal changes of Aß1-42 and T-tau.

**CONCLUSION**

Iron concentration in WM fibers of the limbic system was higher in preeclampsia than in healthy controls, and most WM fibers did not change over time, suggesting that WM damage in preeclampsia is a long-term process. Both cross-sectional and longitudinal studies identified HIF-a as a significant factor affecting QSM values in preeclampsia.

**CLINICAL RELEVANCE/APPLICATION**

Cross-sectional and longitudinal changes in brain iron in preeclampsia and their relationships with clinical features have not been adequately studied. In this study, QSM can be used to measure brain iron noninvasively in pregnant women and can serve as a biological marker for detecting damage in some brain regions.

## T5B-SPNR-12 INTOLERANCE OF UNCERTAINTY MEDIATES THE LINK OF ORBITOFRONTAL CORTEX GRAY MATTER VOLUME TO DISTRESS SYMPTOMS DURING THE COVID-19 PANDEMIC

Xueling Suo (*Abstract Co-Author*) Nothing to Disclose
Li Chen (*Presenter*) Nothing to Disclose

**PURPOSE**

Intolerance of uncertainty (IU) is an underlying feature of different mood disorders that may mediates psychological distress problems associated with public health events (e.g., the COVID-19 pandemic). We attempted to identify the neuroanatomical features of IU and further explore potential neuropsychological mechanisms.

**METHODS AND MATERIALS**

Structural magnetic resonance imaging (MRI) data and behavioral tests were collected from 115 general college students before COVID-19 pandemic who were re-contacted COVID-related IU and follow-up general distress. We employed whole-brain voxel-based morphometry analysis and brain-behavioral correlation analysis to identify brain regions related to IU. Mediation analyses were conducted to explore the role of IU in the brain-general distress model.

**RESULTS**

In whole-brain correlation analyses, IU was significantly and positively correlated with the pre-pandemic gray matter volume (GMV) of right orbitofrontal cortex (R_OFC). Mediation analyses revealed that IU mediated the effect of R_OFC's GMV on COVID-related general distress. The above findings show relationships between brain structural signatures, IU and general distress.

### CONCLUSION

This study provided evidence for the structural neural markers of IU and reveal an underlying neuropsychological pathway to predict distress symptoms in which brain structural feature affects general distress via IU.

### CLINICAL RELEVANCE/APPLICATION

Our findings provided evidence for the neurobiological substrates of IU, which might serve as a mediator in the link between structural brain alterations and general distress, this might help to guide IU-related psychotherapeutic interventions.

## T5B-SPNR-13 IMPAIRED GLYMPHATIC SYSTEM FUNCTION IN RELATION TO CUMULATIVE BLOOD GLUCOSE EXPOSURE: A POPULATION-BASED COHORT STUDY

Han Lv, MD (*Abstract Co-Author*) Nothing to Disclose
Sihui Guo (*Abstract Co-Author*) Nothing to Disclose
Xiaoshuai Li (*Abstract Co-Author*) Nothing to Disclose
Jing Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Zhenchang Wang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yufan Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

The relationship between blood glucose exposure and the function of the glymphatic system in the brain remains unknown. This study aimed to investigate the association between cumulative blood glucose levels and brain glymphatic system function.

### METHODS AND MATERIALS

This study was conducted in a multicenter, community-based cohort study. Brain magnetic resonance imaging (MRI) data were collected once between 2020 and 2022. The neuroimaging indicator of brain glymphatic system function was assessed using diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) index. Cumulative fasting blood glucose (FBG) values from 2014 to 2018 were calculated for each participant to represent 4 years of prolonged exposure to hyperglycemia, while a single measurement of FBG levels at the same time of neuroimaging data acquisition represented short-term measurement. A generalized linear model was used to evaluate the association of blood glucose exposure and DTI-ALPS index.

### RESULTS

A total of 251 subjects aged 25-82 years were included in this study. Prolonged cumulative hyperglycemic exposure with FBG =7.0 mmol/L was significantly associated with lower average DTI-ALPS index(ß = -0.058, 95% confidence interval, -0.096 to -0.019). These findings remained significant only among participants over 60 years old and those not taking hypoglycemic medication. No significant associations were observed between single measurement FBG levels and DTI-ALPS values.

### CONCLUSION

Prolonged exposure to hyperglycemia plays a pivotal role in the impairment of glymphatic function, particularly among elder individuals. Hypoglycemic medication demonstrates a protective effect on maintaining glymphatic function. Maintaining long-term normal FBG levels and using appropriate hypoglycemic medication are essential for promoting optimal brain health.

### CLINICAL RELEVANCE/APPLICATION

Understanding the relationship between long-term hyperglycemia status and glymphatic system function may provide novel evidence for preventing and treating neurological diseases associated with impaired glymphatic function.In this study, glymphatic function is impaired when profound hyperglycemia persists for up to 4 years. There is an association between a lower DTI-ALPS index and long-term cumulative exposure to profound hyperglycemia. According to the results of this study, we should attach great importance to early preventive measures. For patients with moderate hyperglycemia, timely treatment and other means should be used to prevent the development of severe hyperglycemia, avoid continuous exposure to profound hyperglycemia, and avoid functional disorders of the glial lymphatic system leading to brain health damage.

## T5B-SPNR-14 ASSESSMENT THE IMPACT OF IDH MUTATION STATUS ON WHITE MATTER INTEGRITY IN GLIOMA PATIENTS: INSIGHTS FROM PEAK WIDTH OF SKELETONIZED MEAN DIFFUSIVITY AND FREE WATER METRICS

Hongquan Zhu (*Abstract Co-Author*) Nothing to Disclose
Yuanhao Li (*Abstract Co-Author*) Nothing to Disclose
Shihui Li (*Abstract Co-Author*) Nothing to Disclose
Jiaxuan Zhang (*Abstract Co-Author*) Nothing to Disclose
Wenzhen Zhu (*Abstract Co-Author*) Nothing to Disclose
Nanxi Shen (*Presenter*) Nothing to Disclose

### PURPOSE

To identify the utility of Peak Width of Skeletonized Mean Diffusivity (PSMD) and Peak Width of Skeletonized Free Water (PSFW), and Axonal Water Fraction (AWF) for evaluating glioma-induced alterations in normal-appearing white matter (NAWM), and their relationship with IDH1 mutation status.

### METHODS AND MATERIALS

105 glioma patients and 53 healthy controls (HCs) underwent DKI and conventional MRI. PSMD and PSFW were computed to quantify NAWM integrity, and to explore the association between these diffusion metrics and clinical variables, including IDH1 mutation status. Corpus callosum (CC) injury, quantified by the AWF, was evaluated to assess a mediated effect of IDH mutation on contralesional PSMD and PSFW values. Statistical analyses, including ANCOVA, linear regression, and mediation analysis, were performed to explore the relationships between these metrics, IDH mutations, and other clinical variables.

### RESULTS

Significant differences in PSMD and PSFW were observed between glioma patients and HCs ($p = 0.005$ and $p < 0.001$ for left-sided; $p < 0.001$ for right-sided gliomas), and between bilateral sides ($p < 0.001$). IDH1 mutant gliomas were associated with less severe changes in PSMD ($p < 0.01$) and PSFW ($p < 0.001$). The injury to the CC, quantified by AWF, acts as a critical mediator in the relationship between IDH1 mutation and changes in PSMD and PSFW in NAWM.

### CONCLUSION

PSMD and PSFW, along with AWF, are effective in detecting glioma-induced alterations in NAWM and assessing the extent of CC injury, revealing their association with IDH1 mutation status.

### CLINICAL RELEVANCE/APPLICATION

These findings underscore the potential of advanced diffusion metrics in enhancing the diagnostic and therapeutic strategies for glioma patients, providing insights into the molecular and structural factors affecting WM integrity.

## T5B-SPNR-18 EVALUATION OF GLYMPHATIC SYSTEM AND LENTICULOSTRIATE ARTERIES IN CEREBRAL SMALL VESSEL DISEASE

Peipei Chang (*Presenter*) Nothing to Disclose

### PURPOSE

To compare lenticulostriate arteries (LSAs) morphology, diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) index,and other imaging features of cerebral small vessel disease (CSVD) and to investigate the relationship between glymphatic system and other imaging features.

### METHODS AND MATERIALS

Fifty-six patients with suspected CSVD were prospectively enrolled. All subjects underwent multimodal magnetic resonance imaging (MRI) and high-resolution vascular wall MRI (3D HR VMI) to assess intracranial non-stenotic atherosclerotic plaques. Among 56 patients with CSVD, there were 28 with intracranial atherosclerotic plaque (IAP) and 28 with non-IAP. The morphological characteristics of visible LSAs (the number of stems and branches) were quantitatively analyzed by two radiologists. Typical image features indexes of CSVD including white matter hyperintensities (WMHs), lacunes, enlarged perivascular spaces (EPVS), microscopic bleedings (CMBs) and recent small subcortical infarct (RSSI) were assessed. We established index for diffusion tensor image analysis along the perivascular space (ALPS-index), which was calculated on diffusion tensor image (DTI). The periventricular white matter volume (PWMV) and deep white matter volume (DWMV) in both groups were measured by the uAI Research Portal V1.1 (Shanghai United Imaging Intelligence, Co., Ltd.). To assess the imaging parameters between groups, independent-samples t test, nonparametric tests and Chi-square test were used. To analyze the correlation between the ALPS index and other neuroimaging indicators, Spearman's correlation analysis can be employed.

### RESULTS

CSVD with IAP is more prone to RSSI ($p<0.001$), while there is no statistical difference in neuroimaging markers between the remaining two groups. Regardless of whether comparing overall or individually for each group, the ALPS index demonstrates a negative correlation with PWMV and DWMV. Upon overall comparison, the ALPS index exhibits a positive correlation with the stems and branches of the lenticulostriate arteries, except for the right stems. There were no relationship between ALPS index and CSVD burden.

### CONCLUSION

There is no difference in the ALPS index between CSVD with IAP and with non-IAP. The ALPS index is associated with white matter hyperintensity volume and the morphology of the lenticulostriate arteries.

### CLINICAL RELEVANCE/APPLICATION

Multi-parameters help clinically evaluate cerebral small vessel diseases and predict prognosis.

## T5B-SPNR-2 RELATING BRAIN GREY MATTER VOLUME TO FATIGUE IN A LONGITUDE SAMPLE OF COVID-19 PATIENTS USING GROUP REGULARIZED CANONICAL CORRELATION ANALYSIS

Xuan Niu (*Abstract Co-Author*) Nothing to Disclose
Tao Lu (*Abstract Co-Author*) Nothing to Disclose
Xingpu Quan (*Abstract Co-Author*) Nothing to Disclose
Gengchen Ye (*Abstract Co-Author*) Nothing to Disclose
Wenrui Bao (*Abstract Co-Author*) Nothing to Disclose
Ming Zhang (*Abstract Co-Author*) Nothing to Disclose
Qiange Zhu (*Presenter*) Nothing to Disclose

### PURPOSE

Fatigue has been reported to be one of the most common and debilitating symptoms during the acute COVID-19 disease as well as in the post-COVID syndrome. However, fatigue is unspecific and may manifest in various forms such as physical and mental fatigue during different phases after COVID-19. The neural mechanisms of post-COVID fatigue have not fully been elucidated yet. Brain gray matter volume (GMV) has been well characterized as a neurobiological marker to predict future behavioral performance in neuropsychiatric disease processes. This study aimed to identify associations between inter-individual variability in brain structure and fatigue in longitudinal cohorts by using multivariate method.

### METHODS AND MATERIALS

This multi-center, longitudinal cohort study, conducted from January to April 2023 across nine hospitals. All 258 participants following a mild SAS-COV2 infection completed MRI scans and fatigue assessments at one-month follow-up. By the three-month mark, the cohort reduced to 229.

### RESULTS

Using regularized canonical variate analysis, significant correlations were found between GMV and both mental and physical dimensions of fatigue. At one month, key regions included the superior frontal gyrus, precentral gyrus, superior temporal gyrus, and others, with notable weights for mental fatigue (0.67) and physical fatigue (0.66). After three months, a different set of regions was identified, including the superior frontal gyrus, basal ganglia and insular gyrus, with adjusted weights for mental fatigue (0.61) and physical fatigue (0.80). Crucially, the persistent fatigue group showed an increase in brain canonical variate scores compared to the non-persistent fatigue group.

### CONCLUSION

These results revealed different manifestations of fatigue associated with a whole-brain structural pattern, the neural mechanisms of post-COVID fatigue vary from phase after COVID-19 infection. brain canonical variate scores. Furthermore, increased brain canonical variate scores were associated with persistent fatigue.

### CLINICAL RELEVANCE/APPLICATION

The findings provide new insights into the neural mechanisms of post-COVID-19 fatigue and may facilitate the development of new treatments for this symptom of fatigue.

## T5B-SPNR-4 CAN EX VIVO MRI AND QUANTITATIVE SUSCEPTIBILITY MAPPING DISTINGUISH BETWEEN INTRAPLAQUE HEMORRHAGE AND LIPID-CONTAINING AREAS IN CAROTID ENDARTERECTOMY SAMPLES?

Hideki Ishimaru (*Abstract Co-Author*) Nothing to Disclose
Ryo Toya, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ayano Ishiyama, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Carotid plaque MR imaging visualizes a lipid-rich/necrotic core (LRNC) and intraplaque hemorrhage (IPH), which are considered risk factors for plaque rupture, but cannot reliably distinguish between the two. Quantitative susceptibility mapping (QSM), which provides a quantitative measure of tissue magnetic susceptibility, has been reported to be useful for characterizing the composition of carotid plaques. We aimed to investigate whether ex vivo high-resolution MRI, including QSM, can distinguish between intraplaque hemorrhage and lipid-containing areas.

### METHODS AND MATERIALS

24 carotid endarterectomy (CEA) specimens from 24 male patients (8 symptomatic and 16 asymptomatic) aged 63 to 88 years (mean age, 73.8 years) were included. CEA specimens were resected en bloc and immediately fixed in formaldehyde and embedded into 2% agarose gel, and were imaged on a 3T MR scanner. Spin-echo vessel wall images, including T1-, T2-, PD-weighted images, and multi-echo 3D FLASH were acquired. The first echo time images (TE = 4.38 msec) of 3D FLASH were used instead of time-of-flight (TOF). QSM was calculated from the phase images of the 3D FLASH. The specimens were continuously cut at the same angle as the MRI cross-section and examined histologically using immunostaining for glycophorin A (to highlight the presence of intact and degraded erythrocytes) and adipophilin (to highlight intracellular lipid).After the registration of histological and MRI cross-sections by a radiologist, a pathologist evaluated a total of 79 sections and determined the ROIs of the IPH and lipid-containing areas. These ROIs were traced on MRI and QSM by two radiologists, and the signals were measured and averaged. Contrast-to-noise ratio (CNR) on T1WI, T2WI, PDWI, and TOF) between each component and agarose gel was calculated. On QSM, relative susceptibility value (SV) was calculated.

### RESULTS

The pathologist identified 59 LRNC, 13 foam cell aggregates (FA), 41 lipid-rich loose matrices (LRLM) as lipid-containing areas, and 23 IPH. Compared to IPH, FA showed lower signal intensity on TOF and LRLM showed higher signal intensity on T2WI (p lt; 0.05). Conventional MR images (T1-, T2-, PDWI, and TOF) showed no significant differences in CNR between LRNC and IPH. Meanwhile, SV of IPH measured on QSM was higher than that of all lipid-containing areas (plt;.01).

### CONCLUSION

In atherosclerotic plaques, lipids existed as LRNC, LRLM, or FA. Conventional MR seemed to have difficulty distinguishing LRNC from IPH, however, SV measured on QSM was significantly higher in IPH than that of all lipid-containing areas, including LRNC.

### CLINICAL RELEVANCE/APPLICATION

Ex vivo QSM was able to reliably distinguish between IPH and lipid-containing areas.

## T5B-SPNR-5 CHOROID PLEXUS ENLARGEMENT INDUCED MOTOR DYSFUNCTION IN SPINOCEREBELLAR ATAXIA TYPE 3

Chen Liu (*Abstract Co-Author*) Nothing to Disclose
Zhiming Zhen (*Presenter*) Nothing to Disclose

### PURPOSE

Spinocerebellar ataxia type 3 (SCA3) is an autosomal-dominant inherited disorder caused by CAG repeats in the ATXN3 gene. Neuroinflammation exacerbates SCA3 pathology, which has also been verified to increase choroid plexus (CP) damage. CP is a crucial structure for cerebrospinal fluid (CSF) production and brain homeostatic regulation. Few previous studies have assessed the relationship between CP and SCA3. We investigated CP structural changes and their correlation with motor dysfunction and disease progression in SCA3 patients.

### METHODS AND MATERIALS

MRI scans and clinical assessment on 56 SCA3 patients (12 pre-symptomatic and 44 symptomatic) and 45 healthy controls were performed. The CP volume (CPV) and other brain regions were measured using Freeusurfer7.3 software. Partial correlation, structural equation modeling, and multivariate regression were analyzed to explore the relationships among CPV, CAG repeats, brain structures, and motor scales.

### RESULTS

CPV was significantly increased in symptomatic SCA3 patients compared to controls and pre-symptomatic patients. CPV was positively correlated with CAG repeats, CSF volume, motor impairment and negatively correlated with cerebellar and brainstem volume. Structural equation modeling revealed that CPV mediated the effect of CAG repeats on motor function through CSF volume and brainstem atrophy. CPV and brainstem volume were independent predictors of motor function and could distinguish pre-symptomatic from symptomatic patients.

### CONCLUSION

This article first demonstrates that CP enlargement is a novel biomarker of motor dysfunction in SCA3. CP may be involved in the pathogenesis of SCA3 by affecting CSF circulation and brain homeostasis. Targeting CP could be a potential therapeutic strategy for SCA3.

### CLINICAL RELEVANCE/APPLICATION

Prior to the onset of ataxia, previous evidence suggested that there was already an initiation of neuronal dysfunction and neurodegeneration within cerebral structures. We have increased the physiological understanding of this part.The results suggest that aberrant CPV may play a crucial role in regulating SCA3 dysmotility, and early biomarkers could be utilized for monitoring disease progression in SCA3.CP is expected to provide a new target for the protection of SCA3 motor function.

## T5B-SPNR-6 ROLE OF DIFFUSION TENSOR IMAGING AS AN IMAGING BIOMARKER IN AMYOTROPHIC LATERAL SCLEROSIS: INSIGHTS INTO WHITE MATTER INVOLVEMENT ACROSS VARIOUS BRAIN REGIONS IN LIMBVSBULBARONSET

Maulik P. Vora, MBBS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Amyotrophic lateral sclerosis (ALS) is a devastating neurodegenerative disease characterized by the progressive degeneration of motor neurons. This study aimed to investigate DTI metrics across various brain regions in ALS patients and explore their potential as imaging biomarkers.

**METHODS AND MATERIALS**

Twenty-one ALS patients were recruited and were classified according to the revised El-Escorial criteria as definite (n=7), probable (n=7), and possible (n=7) ALS. Patients were further categorized based on bulbar and limb onset. Thirteen healthy volunteers formed the control group. Standard MRI prescreening procedures were used to exclude subjects with contraindications or previous brain injury. DTI data were analyzed using commercial software. Regions of interest (ROIs) were manually defined in the white matter of the primary motor cortex, genu and splenium of the corpus callosum, mid-portion of the posterior limb of the internal capsule, and pyramidal eminence of the medulla oblongata. FA and MD values were measured by an experienced neuroradiologist and a radiologist.

**RESULTS**

Significant alterations in DTI metrics were observed, with decreased FA and increased MD values in the primary motor cortex and the posterior limb of the internal capsule bilaterally ($P < 0.05$). Additionally, reductions in FA and elevations in MD values were evident in the genu and splenium of the corpus callosum (CC) ($P < 0.05$). Significant differences was found in FA and MD values between ALS patients and controls across all examined brain regions in the definite disease group. In the probable disease group, significant alterations were observed in the primary motor cortex, posterior limb of the internal capsule, and CC. Among patients with possible disease, significant decreases in FA and increases in MD values were observed in the primary motor cortex and the posterior limb of the internal capsule ($P = 0.05$). However, no significant differences in FA or MD values were detected in the CC or pyramid in this subgroup.

**CONCLUSION**

DTI metrics revealed widespread white matter alterations in ALS patients, suggesting the involvement of various brain regions in disease pathology. The observed changes in FA and MD values may serve as potential imaging biomarkers for disease diagnosis and monitoring, particularly in differentiating between ALS subtypes and disease stages.

**CLINICAL RELEVANCE/APPLICATION**

The identification of distinct diffusion tensor imaging (DTI) patterns in amyotrophic lateral sclerosis (ALS), particularly in limb versus bulbar onset, provides crucial insights for early diagnosis, disease monitoring, and prognosis.

## T5B-SPNR-7 ADVANCED IMAGING TECHNIQUES USING A CARBON NANOTUBE-BASED MULTI-BEAM X-RAY SYSTEM WITH ANGIOGRAPHIC HEAD PHANTOM FOR VASCULAR IMAGING

Hanna Lee (*Abstract Co-Author*) Nothing to Disclose
Jehwang Ryu, PhD (*Abstract Co-Author*) Nothing to Disclose
Jinho Choi (*Presenter*) Nothing to Disclose

**PURPOSE**

This research aims to redefine the standards of vascular imaging by integrating a sophisticated multi-beam carbon nanotube (CNT) based X-ray system with the angiographic CT head phantom. The goal is to achieve unparalleled diagnostic precision planning in the field of neurovascular medicine.

**METHODS AND MATERIALS**

We have deployed the angiographic CT head phantom, featuring anatomically accurate synthetic skulls and precisely contrast-enhanced cerebral arteries, including the left anterior and middle cerebral arteries with diameters ranging from 0.5 mm to 4.0 mm. This high-fidelity phantom is used in conjunction with our advanced multi-beam X-ray system. The multi-beam system utilizes cutting-edge CNT technology, which allows for multiple simultaneous X-ray beams from diverse angles, thereby achieving comprehensive coverage and exceptional detail in the images captured. This system's capability for dynamic imaging is demonstrated through 3D reconstructions of CT data that vividly illustrate the cerebral vasculature's complexity.

**RESULTS**

The integration of the multi-beam X-ray system with the angiographic head phantom has produced striking imaging results. The enhanced resolution and multi-angle capability allow for detailed visualization of vascular pathologies, including the subtle features of cerebral aneurysms and arteriovenous malformations. The system has shown potential in providing clinicians with a more comprehensive understanding of vascular structures, essential for accurate diagnosis and strategic intervention planning. The 3D reconstructions derived from this system have significantly improved the visual assessment of vascular anomalies compared to traditional single-beam systems.

**CONCLUSION**

The use of a multi-beam system equipped with CNT technology in conjunction with an angiographic CT head phantom represents a significant advancement in the technology of vascular imaging. This system not only surpasses the capabilities of traditional X-ray imaging in terms of clarity and detail but also reduces exposure times and increases the efficiency of diagnostic processes. Its high-resolution, multi-perspective imaging offers a more thorough and nuanced understanding of complex vascular structures.

**CLINICAL RELEVANCE/APPLICATION**

The advanced imaging capabilities provided by this system are particularly beneficial for clinical practices specializing in neurology and vascular medicine. It enables detailed assessments that are critical for effective treatment planning and patient care in complex cerebrovascular conditions. As this technology continues to evolve, it is expected to play a pivotal role in advanced diagnostic, setting new benchmarks in the accuracy and efficacy of vascular imaging.

## T5B-SPNR-9 HYPOTHALAMIC SUBREGION VOLUMES AND FUNCTIONAL CONNECTIVITY IN ALCOHOL USE DISORDERS

Hyeonseok S. Jeong (*Abstract Co-Author*) Nothing to Disclose
Jin Kyoung Oh (*Abstract Co-Author*) Nothing to Disclose
Yong-An Chung, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The hypothalamus is involved in reward processing, with multiple nuclei having distinct functions and connectivity. However, in vivo human neuroimaging studies on their structural and functional alterations were scarce in drug addiction. This study investigated volumes and resting-state functional connectivity of the hypothalamic subregions in patients with alcohol use disorder (AUD) using the novel segmentation algorithm.

## METHODS AND MATERIALS

Twenty-four individuals with AUD and 24 healthy controls underwent brain magnetic resonance imaging. The hypothalamus was automatically segmented into five subregions. Volumes and functional connectivity of each subunit were compared between the two groups, and their clinical correlations were examined in the patients.

## RESULTS

AUD patients exhibited smaller volumes in the anterior- and tuberal-superior subregions, and altered functional connectivity in these subunits and anterior-inferior hypothalamus. Higher disease severity and longer duration of heavy drinking were associated with smaller volumes in the anterior- and tuberal-superior subunits, respectively, while total duration of abstinence was correlated with larger volumes in these subregions and enhanced functional connectivity of the tuberal-superior hypothalamus.

## CONCLUSION

This study provides initial evidence highlighting specific regional alterations within the hypothalamus associated with AUD. Our results suggest that both structural and functional abnormalities are predominant in the superior subregions and may be reversible with prolonged abstinence.

## CLINICAL RELEVANCE/APPLICATION

(1) Hypothalamic subregion volume and functional connectivity (FC) were examined in AUD. (2) AUD patients showed smaller volumes and altered FC in the superior subregions. (3) Disease severity and duration were inversely related to the superior unit volumes. (4) Abstinence period was positively associated with the superior unit volumes and FC. (5) Alcohol-induced deficits in the superior subregions may be recovered by abstinence.

## T5B-SPOB-1 CLINICAL VALIDATION OF EXPERT CONSENSUS STATEMENTS ON MRI EVALUATION OF ATYPICAL UTERINE MASSES

Audrey E. Jacques, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Sarah Natas, BSc, FRCR (*Abstract Co-Author*) Nothing to Disclose
Anum Pervez, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Sultana Hasso, MBBS (*Abstract Co-Author*) Nothing to Disclose
Salil Patel, MD (*Abstract Co-Author*) Nothing to Disclose
Stephan Edey, MBBS, FRCR (*Presenter*) Nothing to Disclose

### PURPOSE

To validate the expert consensus MRI criteria proposed by the NYU Grossman School of Medicine group in the Radiological Society of North America (RSNA) 2023 publication for evaluating the risk of leiomyosarcoma in atypical uterine masses.

### METHODS AND MATERIALS

This retrospective study included patients who underwent pelvic MRI from 2015 to 2023 with reported atypical fibroids and subsequent surgery with histology. Two radiologists independently interpreted the MRI data blinded to histology, applying the criteria outlined in the RSNA publication. Radiological suspicion of malignancy was compared to final histological diagnosis. Key MRI features analysed included lesion size, apparent diffusion coefficient (ADC) values (binary cut-off of =0.905 x 10-3 mm2/s), T2 signal intensity, high b-value diffusion-weighted imaging (DWI) signal, extrauterine disease, and overall impression.

### RESULTS

Peritoneal implants and abnormal lymph nodes, although rare (5%), showed high specificity for sarcoma (96-98% for both radiologists). ADC values =0.905 x 10-3 mm2/s demonstrated moderate sensitivity (50-75%) and specificity (54-61%) for both radiologists. The combination of high T2 signal, high b1000 DWI signal, and low ADC yielded variable sensitivity (25-75%) and specificity (73-89%) between radiologists. Lesion size and volume showed moderate sensitivity (25-50%) and specificity (48-50%). Radiologists' overall impression had 50% sensitivity and 72-85% specificity for sarcoma, with fair interobserver agreement (Cohen's kappa 0.18, 68% agreement). Feature importance analysis revealed lesion size, ADC, and T2 signal as top predictors. Impression-based predictions demonstrated comparable performance between radiologists.

### CONCLUSION

This study highlights the potential of MRI for evaluating leiomyosarcoma risk, with peritoneal implants and abnormal lymph nodes demonstrating high specificity. While ADC values below =0.905 x 10-3 mm2/s and signal characteristics showed variable performance, their combination with lesion size may improve sarcoma prediction. Fair interobserver agreement emphasizes the need for further standardization and validation of MRI criteria.

### CLINICAL RELEVANCE/APPLICATION

Integrating the RSNA consensus MRI criteria into multidisciplinary preoperative planning, with a focus on lesion size, ADC values below =0.905 x 10-3 mm2/s, and extrauterine disease, may enhance risk stratification for atypical uterine masses. Further refinement of these criteria could optimize clinical management, balancing fertility preservation with oncologic principles.

## T5B-SPOB-3 THE VALUE OF DWI AND HIGH SPATIAL-TEMPORAL RESOLUTION MULTIPHASIC CONTRAST-ENHANCED MRI IN THE DIAGNOSIS OF ENDOMETRIAL CARCINOMA WITH MICROCYSTIC, ELONGATED, AND FRAGMENTED (MELF) PATTERN INVASION

Toru Honda, MD (*Abstract Co-Author*) Nothing to Disclose
Kaketaka Koki, MD (*Abstract Co-Author*) Nothing to Disclose
Takahiro Tsuboyama, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the MRI findings of endometrial carcinoma with microcystic, elongated, and fragmented (MELF) pattern invasion and to evaluate the optimal sequences to detect deep myometrial invasion with MELF.

## METHODS AND MATERIALS

This retrospective study included 85 patients with endometrial cancer who underwent preoperative MRI, including high spatial-temporal resolution multiphasic dynamic contrast-enhanced MRI (DCE). DCE included 11 early phases (voxel size, 0.6*1.0*4.0 mm) in which the first 10 phases were acquired from 20 to 50 s after contrast injection with temporal resolution of 3 s, followed by 11th phase at 60 s. MELF pattern invasion was found pathologically in 17 patients. Three independent radiologists evaluated deep myometrial invasion and MRI findings possibly related to MELF. They first assessed T2WI and equilibrium phase CE-MRI, and then evaluated additional DWI and DCE. The MRI findings predictive of MELF were identified using a Chi-squared test and logistic regression analysis. The diagnostic performance for deep myometrial invasion was compared with and without additional DWI and DCE using the McNemar test in MELF and non-MELF groups.

## RESULTS

DWI signal gradation at the invasion front with DWI-CE mismatch (DG-DCM), tumor-myometrium synchronous early enhancement (TME), and peritumoral enhancement (PTE) type 2 were seen more frequently in the MELF group than in the non-MELF group by all readers ($P<0.05$). In logistic regression analysis, significant predictive factors for MELF were TME in all readers (sensitivity, 70.6-82.4%; specificity, 94.1-95.6%) and DG-DCM in 2 readers (sensitivity, 58.8-76.5%; specificity, 94.1-98.5%). For the diagnosis of deep myometrial invasion in the MELF group, the addition of DWI+DCE had significantly improved sensitivity for 2 readers (91.7 vs 16.7%, 83.3 vs 16.7%, $P < 0.01$), and accuracy for 1 reader (82.4 vs 35.3%, $P < 0.01$). In contrast, diagnostic accuracy did not change with the addition of DWI+DCE in the non-MELF group.

## CONCLUSION

Endometrial carcinoma with MELF may have characteristic MRI findings of DWI signal gradation with DWI-CE mismatch and TME. The value of DWI and DCE in detecting deep myometrial invasion may be high in MELF.

## CLINICAL RELEVANCE/APPLICATION

Endometrial carcinoma with MELF has been reported to be associated with a high frequency of lymphovascular invasion and underestimation of myometrial invasion on MRI. Our results may provide a clue for the correct preoperative diagnosis of MELF invasion and deep myometrial invasion.

## T5B-SPPD-1 ASSOCIATION OF QUANTITATIVE SUSCEPTIBILITY MAPPING (QSM) OF THE NEONATAL BRAIN WITH EARLY NEURODEVELOPMENTAL OUTCOMES IN CONGENITAL HEART DISEASE

Di Cui (*Abstract Co-Author*) Nothing to Disclose
Megan Martin (*Abstract Co-Author*) Nothing to Disclose
Janine M. Lupo, PhD (*Abstract Co-Author*) Grant, General Electric Company
Patrick McQuillen (*Abstract Co-Author*) Nothing to Disclose
Duan Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Shabnam Peyvandi (*Abstract Co-Author*) Nothing to Disclose
Jingwen Yao (*Abstract Co-Author*) Nothing to Disclose
Lauren Christopher (*Abstract Co-Author*) Nothing to Disclose
Elizabeth George, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Quantitative susceptibility mapping (QSM), due to its ability to distinguish oxyhemoglobin from deoxyhemoglobin, may provide noninvasive assessment of brain oxygenation in neonates in congenital heart disease (CHD). The purpose of this study is to assess the relationship of total and regional brain susceptibility (?) from QSM with 18-month neurodevelopmental outcomes in CHD.

### METHODS AND MATERIALS

Neonates with critical CHD who underwent MRI with 3D T2* GRE at 3T prior to surgical intervention were identified. QSM images were generated using custom-built processing pipeline and registered to the UNC brain atlas to derive total and regional (deep gray nuclei (DGN) and white matter (WM)) susceptibility (?). The total and regional ? were normalized to the ventricle ?. ND outcome was assessed at 18-months using Bayley Scales of Infant and Toddler Development (BSID). The primary outcomes were abnormal motor, cognition, or language defined as a score < 85 in the corresponding domain. The secondary outcome was death/severe neurodevelopmental delay defined as death or BSID motor, cognition, or language score <70. The median normalized total and regional susceptibility were compared between those with normal vs abnormal outcome using Wilcoxon rank sum test.

### RESULTS

The study included 21 neonates with neonatal MRI with QSM and neurodevelopmental outcomes. The cohort was majority male (81%, 17/21) with a mean gestational age (GA) at birth of 38.9 ± 1.0 weeks. The MRI was done at mean 6.0 ± 6.3 days of life and 39.6 ± 1.3 weeks GA. The cohort included 52.3% (11/21) transposition of great arteries, 38.1% (8/21) single ventricle physiology, and 9.5% (2/21) other CHD lesions.The median normalized DGN ? was higher among those with death/severe delay (-0.07 vs. -0.26, p=0.05, Figure). Those with abnormal motor, language, and cognition also tended to have higher median normalized DGN ? (p=0.06-0.15, Figure) than those with normal outcomes. The total and WM normalized ? were not significantly different among those with normal vs. abnormal neurodevelopmental outcome at 18 months.

### CONCLUSION

In this preliminary study, high neonatal normalized DGN ? tended to be associated with abnormal 18-month neurodevelopmental outcomes.

### CLINICAL RELEVANCE/APPLICATION

Regional ? may potentially be a marker of relative oxy- to deoxyhemoglobin content and hence of oxygenation in the neonatal brain and tended to be associated with early neurodevelopmental outcomes in CHD.

## T5B-SPPD-2 THE QUANTIFICATION OF CEREBRAL GLYMPHATIC SYSTEM IN CHILDREN DIAGNOSED WITH ATTENTION-DEFICIT/HYPERACTIVITY DISORDER IS LINKED TO INSUFFICIENT SLEEP

Wen Chen (*Abstract Co-Author*) Nothing to Disclose
Rui Hu, MS (*Abstract Co-Author*) Nothing to Disclose
Yanwei Miao (*Abstract Co-Author*) Nothing to Disclose
Wei Du (*Abstract Co-Author*) Nothing to Disclose
Fan Tan (*Presenter*) Nothing to Disclose

### PURPOSE

To quantitative evaluation whether the abnormal glymphatic system function is relevant to attention-deficit/hyperactivity disorder (ADHD) using multimodal MRI imaging and explore the association of these changes with clinical indicators and executive function.

### METHODS AND MATERIALS

83 patients with ADHD (61 males and 22 females), median age 9.1 (8.0, 10.3) and 52 HC (36 males and 16 females), median age 10.0 (8.0, 11.7) were recruited through advertisements and voluntarily participated in the study and signed informed consent. All of the participants underwent routine MRI sequences, 3D-T1 BRAVO, diffusion kurtosis imaging (DKI) on a GE SIGNA architect 3.0T MRI. Statistical analysis was conducted on the clinical data, diffusion indices, and analysis along the perivascular space (ALPS) index of the ADHD and HC groups. The diffusion indices and ALPS index were corrected for multiple comparisons using FWE ($p < 0.05/10$). Age, gender, and years of education were used as covariates in a partial correlation analysis. Use the AUC of the ROC to evaluate the ability of ALPS index to diagnose ADHD. Establishing a combined diagnostic model based on the ALPS index and sleeping time to evaluate the diagnostic performance using logistic regression.

### RESULTS

Compared with the HC group, ADHD group participants had shorter sleeping times than HC participants, and ADHD group participants performed worse on attention, hyperactivity, and BRIEF tests ($p < 0.05$). Compared with HC (1.479 ± 0.145), ADHD patients had a lower ALPS index (1.384 ± 0.122). Results from partial correlation analysis revealed that the ALPS index was negatively correlated with hyperactivity ($r = -0.419$, $p = 0.000$), attention deficit scores ($r = -0.423$, $p = 0.000$), and also negatively correlated with working memory ($r = -0.441$, $p = 0.000$) and MI ($r = -0.274$, $p = 0.014$) in BRIEF. The ALPS index is positively correlated with sleeping time ($r = 0.496$, $p = 0.000$). A negative correlation existed between sleeping time and hyperactivity score ($r = -0.229$, $p = 0.041$) and working memory ($r = -0.340$, $p = 0.002$). ROC indicated good diagnostic efficiency for the combined model based on the ALPS index and sleeping time, with an AUC of 0.820.

### CONCLUSION

The glymphatic system functions are reduced in the brain in ADHD patients, and its activity is closely linked to sleep, symptoms, and executive function. Pathogenesis of ADHD might be linked to changes in the glymphatic system.

### CLINICAL RELEVANCE/APPLICATION

DTI-ALPS provided neuroimaging evidence for the dysfunction of the glymphatic system in patients with ADHD, which had certain clinical significance for the diagnosis and might have potential to evaluate the pathological and physiological changes associated with ADHD.

## T5B-SPPD-3 ASSOCIATION BETWEEN NEONATAL BRAIN INJURY AND MRI-VISIBLE PERIVASCULAR SPACE VOLUME

Sewon Oh (*Abstract Co-Author*) Nothing to Disclose
Jimin Kim, MD (*Abstract Co-Author*) Nothing to Disclose
Oh Joon Kwon (*Abstract Co-Author*) Nothing to Disclose
Yoonho Nam (*Abstract Co-Author*) Nothing to Disclose
Dayeon Bak (*Abstract Co-Author*) Nothing to Disclose
Hyun Gi Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Arum Choi, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Injury can alter the glymphatic system in the neonatal brain. The objective of this study was to determine the association between MRI-visible perivascular space (PVS), which may reflect glymphatic system and brain injuries in neonates.

### METHODS AND MATERIALS

This retrospective study was performed at a single institution. Neonatal brain MRIs scanned at term-equivalent age were collcted. Neonates were grouped into those with visible brain injuries and those without injuries on brain MRIs. Using 3D T2-weighted sequences, automated segmentation and volume extraction were performed on the PVS in the basal ganglia (BG-PVS). By dividing the BG-PVS volume by the deep grey matter volume, the BG-PVS fraction was calculated. The volume and fraction of the BG-PVS were compared between neonates with and without brain injuries using the Mann-Whitney test.

### RESULTS

A total of 146 neonates (median [interquartile range, IQR] postmenstrual age at MRI scan, 38 [37-39] weeks; 74 [51%] females) were included, comprising 46 neonates with brain injuries (39 [37-40] weeks; 24 [52%] males) and 100 neonates without brain injuries (38 [37-39] weeks; 52 [52%] females). There were no significant differences in gestational age (P = .09) or postmenstrual age at MRI scan (P = .38) between the neonates with injuries and the control group. BG-PVS volumes were lower in neonates with brain injuries (median [IQR] volume in neonates with injury vs. without injury; 24 mm3 [14-42 mm3] vs. 34 mm3 [20-52 mm3]; P = .007). The BG-PVS fraction was significantly different between the two groups (median [IQR] fraction in neonates with injury vs. without injury; 0.003 [0.002-0.006] vs. 0.005 [0.003-0.008]; P = .04).

### CONCLUSION

Neonates with brain injuries had lower volumes and fractions of perivascular space in the basal ganglia, suggesting potential changes in glymphatic function in neonates with brain injuries.

### CLINICAL RELEVANCE/APPLICATION

This study show that neonates with brain injuries have reduced basal ganglia perivascular space volumes and fractions compared to their control group, suggesting glymphatic function alteration in the neonate with injuries. These findings underscore the clinical relevance of perivascular space evaluation in neonates to better understand the glymphatic system alterations associated with brain injuries, which may influence future diagnostic and therapeutic strategies.

## T5B-SPPH-1 ROBUST CBCT ENHANCING CONDITIONAL DDPM WITH STRUCTURE AND HISTOGRAM LOSS

Minkook Cho, PhD (*Abstract Co-Author*) Employee, Samsung Electronics
Seungyoung Kang (*Abstract Co-Author*) Nothing to Disclose
Sunjung Kim (*Abstract Co-Author*) Nothing to Disclose
Hyunwoo Lee, MS (*Abstract Co-Author*) Nothing to Disclose
Taeseong Kim (*Presenter*) Nothing to Disclose

### PURPOSE

Conventional CBCT images have lower uniformity compared to MDCT, and because of this, HU values are also inaccurate. To solve this problem, we propose a DDPM-based model with structure and histogram loss that improves CBCT using paired MDCT data.

### METHODS AND MATERIALS

CBCT were collected from 5 skull phantoms with a conventional dental CBCT scanner (T2 plus, Osstem Implant Co., Ltd., Seoul, South Korea) and paired MDCT were collected from 2 skull phantoms (skull 1 and 2). For skulls 3, 4 and 5, only CBCT was obtained and used for qualitative performance evaluation. MDCT was manually registered after changing voxel pitch, slice thickness, and FOV to match CBCT. For training, MDCT and CBCT were resized to 256 size. Skull 1 was used for model training, and skulls 2, 3, 4, and 5 were used for evaluation. Proposed model is based on conditional DDPM. MDCT and CBCT features were extracted using separate encoder, and concatenated at high level. Structure loss and histogram loss were added to MSE loss used in conventional DDPM. The structure part was taken from the SSIM as the structure loss, and the differentiable histogram loss was used as the histogram loss. The weight between each loss was set empirically. All models were trained using Nvidia GeForch RTX 4090 24GB and PyTorch, with 160k iteration.

### RESULTS

When structure loss is added to MSE loss, structural distortion does not occur during sampling process. MDCT, CBCT, and proposed method were compared in the same tissue (air, soft tissue, and teeth). In terms of HU value, the proposed method for all three tissues showed similar results to MDCT, and the difference in HU values depending on location on one slice was also reduced, showing better results in terms of uniformity compared to CBCT. Also line profile of proposed method showed the uniformity and HU value became more accurate with histogram loss. When sampling with skull 3, 4, 5 and clinical CBCT, the proposed method well performed without structural deformation even in severe cracks or airways that were not present in the training data.

### CONCLUSION

The proposed method maintained the structure of condition CBCT despite pixel-wise differences between CBCT and MDCT that existed even after manual registration. Also enhanced CBCT showed MDCT-level uniformity and HU accuracy. The proposed method can be applied to image translation in other modalities or between modalities

### CLINICAL RELEVANCE/APPLICATION

With CBCT scanning, MDCT level quality can be obtained, enabling accurate diagnosis and obtaining additional information such as bone density.

## T5B-SPPH-10 DIAGNOSTIC VALUE OF MR LYMPHANGIOGRAPHY IN PRIMARY CHYLURIA

Qi Hao (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the application value of MRL in the diagnosis of primary chyluria.

### METHODS AND MATERIALS

A total of 55 patients diagnosed with primary chyluria were retrospectively collected. All patients received MRL examinations. All MRL images were reviewed by two radiologists respectively. The statistical indexes included:?the morphology and dilatation of lymphatic vessels in the bilateral iliac, bilateral lumbar trunks, bilateral renal sinuses, thoracic duct, bilateral bronchial mediastinal trunks, bilateral cervical trunks, and bilateral subclavian trunks; ? the abnormalities of lymphatic vessels in the urinary system, abdominopelvic and thoracic region. The MRL signs of primary chyluria patients were statistically described by composition ratio of classification variables. Results Among the 55 cases of primary celiac disease, 45 (81.8%) had dilated left iliac lymphatics, 34 (61.8%) had dilated right iliac lymphatics, 54 (98.2%) had dilated retroperitoneal lymphatics, 53 (96.4%) had dilated left lumbar trunk, 34 (61.8%) had dilated right lumbar trunk, 15 (27.3%) had dilated left bronchial mediastinal trunk, 7 ( 12.7%) right bronchial mediastinal trunk dilation, 9 cases (16.4%) left cervical trunk dilation, 10 cases (18.2%) right cervical trunk dilation, 23 cases (41.8%) left subclavian trunk dilation, 15

cases (21.3%) right subclavian trunk dilation, 50 cases (90.9%) thoracic duct end dilation, 52 cases (94.5%) right thoracic duct dilation, 21 cases ( 38.2%) dilated left renal sinus lymphatics, 18 (32.7%) dilated right renal sinus lymphatics, 9 (16.4%) dilated pelvic lymphatics, 6 (10.9%) dilated mesenteric lymphatics, 3 (5.5%) dilated perineal lymphatics, 2 (3.6%) dilated bladder lymphatics, 1 (1.8%) dilated peripancreatic lymphatics, 8 (14.5%) splenic cystic lesions, and 3 (5.5%) skeletal cystic lesions.

**RESULTS**

MRL can clearly show the abnormalities of the central abdominal lymphatics in primary chyluria, and it can further show the site and degree of abnormal dilatation of the thoracic lymphatic trunk, the end of the thoracic duct, and the right lymphatic duct, and both can complement each other.

**CONCLUSION**

MRL can provide detailed image information for the diagnosis and treatment of primary chyluria, which is of great significance for preoperative evaluation and formulation of surgical plan.

**CLINICAL RELEVANCE/APPLICATION**

MRL can provide detailed image information for the diagnosis and treatment of primary chyluria, which is of great significance for preoperative evaluation and formulation of surgical plan.

## T5B-SPPH-11 FEASIBILITY OF DEEP LEARNING ALGORITHM-CONSTRUCTED SPECTRAL COMPUTED TOMOGRAPHY PULMONARY ANGIOGRAPHY IMAGES REPLACING AORTIC-PHASED IMAGING

Yuanfen Liu (*Abstract Co-Author*) Nothing to Disclose
Borong Tang (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine the feasibility of deep learning algorithm-reconstructed 40/50 keV monoenergetic Computed Tomography Pulmonary Angiography (CTPA) images for aortic phase imaging

**METHODS AND MATERIALS**

A retrospective analysis was conducted on 93 patients who underwent spectral CT pulmonary angiography (CTPA) and aortic phase (AP) imaging from July to August 2023. Monoenergetic CTPA images at 40keV and 50keV were reconstructed using deep learning image reconstruction algorithms at the medium (CTPA-40keV-DM) level. Additionally, 100-kVp and 120-kVp images for AP were reconstructed with an adaptive statistical iterative reconstruction (AR) algorithm, with a blending weight of 50% (AP-100kVp-AR, AP-120kVp-AR). Quantitative measurements and calculations were performed to assess the CT value (HU), standard deviation (SD), signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) within the aorta. Two board-certified radiologists independently performed subjective scoring on image quality using a 5-point scale.

**RESULTS**

On the aorta, CTPA-40keV-DM images showed comparable CT values with AP-100kVp-AR images, while CTPA-50keV-DM images had equal CT values to AP-120kVp-AR images (all $P > 0.05$). SD values were not statistically different between CTPA-50keV-DM and AP-120kVp-AR images ($P>0.05$). SNR comparisons indicated that CTPA-40keV-DM and AP-100kVp-AR, CTPA-50keV-DM and AP-120kVp-AR had comparable SNR values (all $P > 0.05$). In CNR comparisons, CTPA-40keV-DM and AP-100kVp-AR exhibited similar performance (all $P > 0.05$). For subjective scoring, the CTPA-50keV-DM images achieved the highest subjective score.

**CONCLUSION**

CTPA-50keV-DM images showed the same CT value and SD value as AP-120kVp-AR aortic phased-images, met the diagnostic requirement in terms of image quality, and even showed better in some parts.

**CLINICAL RELEVANCE/APPLICATION**

DLIR spectral CTPA images at low energies show potential for replacing AP scans to optimize patient radiation dose while maintaining diagnosis-required image quality.

## T5B-SPPH-12 ENHANCING BONE MRI: ADVANCED EDGE DETECTION, CS/CAIPI VIBE SEQUENCES, AND DEEP LEARNING RECONSTRUCTION ACROSS DIVERSE MODELS

Sheen-Woo Lee, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ieun Yoon, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To optimize MRI sequences for high-resolution bone imaging, comparing with CT. To develop an edge analysis method for quantitative assessment of phantom, CS VIBE, CAIPI-Dixon toward high resolution bone MRI.

**METHODS AND MATERIALS**

This IRB-approved study employed a 3.0-Tesla MR system and standard MDCT. The 3D CAIPI-DIXON VIBE sequence acquired four different contrast images, enhanced using a deep neural network (DNN) based on 2D U-net architecture (SwiftMR, AIRS Medical, Korea). ISMRM/NIST system phantom was imaged with following three MRI sequences: compressed sensing (CS), original (“Ori”) and deep learning-denoised (“Swi”) 3D CAIPI VIBE Dixon. MRI and CT images were analyzed for patients who underwent imaging within one month at a tertiary hospital. Five modalities were compared: conventional CT, original and DNN-enhanced Dixon MRI in both in- (“In”) and opposed-phase (“Op”) images. Linear regions of interest (ROIs) were drawn on high-contrast structures including phantom pin, glenohumeral cortex, and any bony Bankart lesion surfaces and then normalized against background noise. Metrics and grey scale values reflecting image sharpness—such as distances, value differences and gradients between the minimal and maximal points of greyscale values—were calculated. Qualitative assessments by a 4-point Likert scale were performed by two radiologists.

**RESULTS**

The difference between maximal and minimal grey values, indicating higher margin contrast, was highest in Swi-In compared to CS and Ori-In (CS, 891±81; Ori-In, 964±68; Swi-In, 1043±41; $p<0.05$) on phantom study. The study included 39 patients; 15 with and 24 without bony Bankart lesions. Cortex sharpness scores in both in- ($p<0.001$) and opposed-phase images ($p=0.02$) were higher with DNN and comparable to CT ($p=0.004$). The diagnostic accuracy for detecting bony Bankart lesions was excellent in all MRI modalities (93.3%±4.5%), similar to CT (97.5%). DNN reconstruction markedly reduced the noises in MRI ($p<0.001$). The value differences and the gradients between the greyscale values, after normalization, were significantly enhanced by DNN in both in- and opposed-phase images ($p<0.05$). The distances between minimal and maximal grey value points were significantly shorter in MRI than in CT for bony Bankart lesions and cortices ($p<0.05$), indicating greater sharpness in MRI images.

**CONCLUSION**

The 3D CAIPI VIBE Dixon MRI with DNN reconstruction provided sharply defined bone images, matching the diagnostic accuracy of CT. This suggests that Swi-CAIPI-Dixon can surpass conventional CS VIBE MRI in both quantitative and qualitative analyses.

**CLINICAL RELEVANCE/APPLICATION**

The 3D CAIPI VIBE Dixon MRI could potentially replace CT for evaluating bone, reducing radiation exposure and costs.

## T5B-SPPH-2 ADAPTIVE NOISE REDUCTION METHOD FOR FLAT-PANEL DIGITAL X-RAY DETECTORS

Minkook Cho, PhD (*Abstract Co-Author*) Employee, Samsung Electronics
Jinwoo Kim (*Abstract Co-Author*) Nothing to Disclose
Jongcheul Kim (*Presenter*) Nothing to Disclose

**PURPOSE**

The conventional denoising filters used to remove noise in x-ray images reduce noise but have the disadvantage of decreasing the spatial resolution of the image. In this study, we propose an adaptive denoising filter for x-ray projection images that minimizes the loss of spatial resolution while removing noise.

**METHODS AND MATERIALS**

The proposed denoising filter consists of a conventional smoothing filter and a logical mask restricting the filtering area. The logical mask checks whether the values of adjacent pixels fall within a pre-measured noise range for the signal of the pixel of interest. The logical mask can be calculated in two steps. First, the projections for several thicknesses of polymethyl methacrylate (PMMA) slabs are acquired for a specific x-ray spectrum. Second, the mean signal and noise are measured from the projections and curve fitting is performed. Each convolution operation is selectively performed by the logical operations. The logical mask prevents the blurring of material edges while smoothing uniform areas. The evaluations of the proposed method are performed for a commercial cone-beam computed tomography (CBCT) system (T2 Plus, Osstem Implant Co., Ltd., Seoul, KR).

**RESULTS**

Comparative analysis of modulation-transfer functions (MTFs) calculated from edge-knife images filtered by conventional and proposed filtering methods shows that the former significantly degraded the MTF performance, while the latter preserved the MTF curve. The visual inspection of the axial slices of a real-bone skull phantom reconstructed using raw and denoised projections shows that the material edges are well preserved in the proposed method, compared to the conventional mean filtering.

**CONCLUSION**

The proposed method can be used to denoise x-ray projections while minimizing spatial resolution loss. Further study includes extensive investigation of filter sizes, shapes, and logical masks for various imaging tasks.

**CLINICAL RELEVANCE/APPLICATION**

The proposed method will be helpful for the diagnosis of dental diseases by denoising CBCT images with minimal loss of spatial resolution.

## T5B-SPPH-3 DEEP LEARNING BASED METAL ARTIFACT REDUCTION IN DENTAL CBCT

Minkook Cho, PhD (*Abstract Co-Author*) Employee, Samsung Electronics
Sunjung Kim (*Abstract Co-Author*) Nothing to Disclose
Hyunwoo Lee, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

In dental cone-beam computed tomography (CBCT), it is essential to suppress metal artifacts caused by multiple metallic restorations. In this study, we propose an enhanced metal artifact reduction (MAR) approach that combines deep learning and a metal correction algorithm to improve the image quality of dental CBCTs.

**METHODS AND MATERIALS**

Firstly, metallic segments are accurately extracted from initial volume in an unsupervised manner. This step incorporates generative adversarial network (GAN) based domain transfer and convolutional neural network (CNN) based weakly supervised learning without using any predefined volumetric metal masks. After acquiring the corresponding metal-only projections, the metal regions in projection domain are restored using the proposed metal correction algorithm. This step includes gradient searching, hermite spline interpolation, and offset correction methods. Finally, after reconstructing a metal-free volume using the metal-corrected projections, the metallic segments extracted from initial volume are blended using the alpha-blending method.

**RESULTS**

After evaluated with intersection of union (IOU) and dice score (DCS), the proposed metal extraction method showed more than 90% accuracy regardless of the number of metallic segments. In addition, compared with conventional threshold-based method visually, the extracted metal masks showed high degree of similarity to the manual labels, reducing both false positive and negative errors. As for the MAR results, compared with conventional MAR method (LiMAR), proposed method achieved significant reduction of streak artifact and clearer edges of metallic segments in both axial and sagittal views.

**CONCLUSION**

The proposed method showed highly improved MAR performance. It is significant that the task of accurate metal extraction, fundamental to MAR, has been effectively addressed. Furthermore, the proposed metal correction algorithm substantially enhanced the representation around metallic segments by refined techniques such as calculation of surrounding gradients. Future work will involve comparative analysis with other MAR methods and evaluation of potential image distortions.

**CLINICAL RELEVANCE/APPLICATION**

In clinical settings, it is expected that the observation of surrounding teeth and bone tissues, often degraded by metal artifacts, will improve. Additionally, verifying the bone density around implants could help guide dental implant treatments.

## T5B-SPPH-4 EFFECTS OF DIFFERENT RECONSTRUCTION ALGORITHMS ON VIRTUAL MONOCHROMATIC AND IODINE/WATER MATERIAL DECOMPOSITION IMAGES BY CONTRAST-ENHANCED DUAL-ENERGY CT ON ROBUSTNESS OF

## RADIOMICS FEATURES OF RENAL CELL CARCINOMA

### PURPOSE

Radiomics analysis of virtual monochromatic (VMIs) and iodine/water material decomposition images (iodine MDIs) by contrast-enhanced dual-energy CT (ceDECT) is expected to predict the histological subtypes and grades of histological malignancy of renal cell carcinoma (RCC) and to monitor the tumor response to chemotherapy by machine learning at different iodine loads based on the patient's renal function. We performed a pilot study to investigate effects of different reconstruction algorithms on VMIs at various energy levels and iodine MDIs by ceDECT on robustness of the radiomics features.

### METHODS AND MATERIALS

We retrospectively enrolled 26 patients with clear-cell RCC who underwent ceDECT during the nephrographic phase with a 256-detector DECT scanner (Revolution CT, GE) using our routine protocol (the standard iodine load [600 mgI/kg], 9 patients with estimated glomerular filtration rate (eGFR) of = 45 mL/min/1.73 m2; 75% iodine load [450 mgI/kg], 10 patients with eGFR of = 30 and < 45; 50% iodine load [300 mgI/kg], 7 patients with eGFR of < 30; and volume CT dose index, 12.2 ± 3.3 [6.3-17.2] mGy) from March 2018 through December 2023 and were histologically proved. VMIs at 50, 60, and 70 keV and iodine MDIs of 1.25-mm slice thickness were reconstructed with iterative reconstruction (IR) and deep-learning reconstruction (DLR) algorithms (ASiR-V and TrueFidelity, respectively; GE). A region of interest was placed within each RCC semi-automatically segmented to extract the radiomics features, which were calculated using PyRadiomics, an open-source python library. We calculated 93 radiomics features of each RCC on the VMIs at 50, 60, and 70 keV and iodine MDIs to compare them between IR and DLR using Wilcoxon signed rank test.

### RESULTS

As shown in the Table, 44-66% of the radiomics features were comparable between IR and DLR (P = 0.09-0.98), except 52 features on the VMIs at 50 keV; 35 features, 60 keV; 32 features, 70 keV; and 42 features on the iodine MDIs. The robustness of the effects of these algorithms on the features was increased as the energy level on VMIs increased from 50 to 60 to 70 keV and more than a half of the features were robust on the VMIs at 60 and 70 keV and iodine MDIs.

### CONCLUSION

Effects of IR and DLR algorithms on the VMIs and iodine MDIs by ceDECT on 44-66% of the radiomics features of RCC are robust. Use of these algorithms on appropriate ceDECT images may allow image augmentation to train and build machine learning and/or deep learning models.

### CLINICAL RELEVANCE/APPLICATION

Use of IR and DLR algorithms may be helpful for developing computer-aided diagnosis systems and improving the diagnostic performance to predict the histological subtypes and grades of histological malignancy of RCC and to monitor the tumor response to chemotherapy by ceDECT.

## T5B-SPPH-5 DEEP LEARNING-BASED SPATIAL RESOLUTION IMPROVING ALGORITHM (PRECISE IQ ENGINE: PIQE) FOR MRI AT DIFFERENT ANATOMICAL AREAS: COMPARISON OF CAPABILITY FOR SCAN TIME REDUCTION AND IMAGE QUALITY IMPROVEMENT WITH CONVENTIONAL PROTOCOL WITH AND WITHOUT ZERO-INTERPOLATION FILLING (ZIP) AT 1.5 AND 3T SYSTEMS

Takahiro Ueda, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Masahiko Nomura, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoshiyuki Ozawa, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hiroyuki Nagata (*Abstract Co-Author*) Canon Medical Systems Corporation

Takeshi Yoshikawa, MD (*Abstract Co-Author*) Nothing to Disclose
Yoshiharu Ohno, MD, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

### PURPOSE

Deep learning reconstruction (DLR) and zero fill interpolation (ZIP) technique have been clinically applied for improving image quality and spatial resolution on routine clinical MRIs. Instead of ZIP technique, deep learning-based spatial resolution improving algorithm with denoising (Precise IQ Engine: PIQE) has been newly utilized to reduce scan time and transform MR data from original low-spatial resolution data to high-spatial resolution data. The purpose of this study was to directly compare utilities of PIQE for scan time reduction and image quality improvement of MRIs as compared with conventional MR protocols reconstructed by DLR with and without ZIP techniques at different anatomical areas.

### METHODS AND MATERIALS

28 consecutive patients suspected with 17 various brain tumors, 6 different spinal diseases and 5 musculoskeletal diseases were prospectively scanned with conventional MR protocols (224-382×256-512matrix) and new MR protocols (160-192×192-416matrix), which were obtained same sequences. Then, each conventional MR data was reconstructed by DLR with and without ZIP technique, and all new protocol data were reconstructed with and without ZIP or PIQE techniques (total five data sets). At each anatomical area, standard protocols were determined as conventional MR sequences reconstructed by DLR without ZIP technique. To compare scan time reduction and quantitative spatial resolution improvement among all protocols, mean examination time including reconstruction time and signal-to-noise ratios (SNRs) of different anatomical structures on each MR data at anatomical area were compared between standard protocol and others by Dunnett's test. To evaluate qualitative spatial resolution improvement, overall image quality,

artifact, normal structure visualization and diagnostic confidence level were assessed by 5-point scales and compared between standard protocol and others by Steel's multiple comparison test.

**RESULTS**

Mean examination times of new MR protocols were significantly shorter than that of conventional protocols ($p<0.05$), although SNRs had no significant differences between standard protocol and others. When compared with standard protocol at each anatomical area, overall image quality, artifact and normal structure visualization were significantly improved by conventional protocol reconstructed by DLR with ZIP and new protocol with PIQE ($p<0.05$).

**CONCLUSION**

PIQE can reduce examination time and has equal to or superior potential for image quality improvements, when compared with DLR with and without ZIP technique.

**CLINICAL RELEVANCE/APPLICATION**

PIQE can reduce examination time and has equal to or superior potential for image quality improvements, when compared with DLR with and without ZIP technique.

## T5B-SPPH-6 IMPROVED RESOLUTION AND PRECISION CARTILAGE T2 MAPPING USING DEEP LEARNING RECONSTRUCTION

Dawn Berkeley, BS (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Mo Kadbi, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation;
Wissam Alghuraibawi (*Abstract Co-Author*) Nothing to Disclose
Brian Tymkiw, ARRT, BS (*Abstract Co-Author*) Nothing to Disclose
Hung P. Do, PhD, MSc (*Presenter*) Employee, Canon Medical Systems Corporation

**PURPOSE**

Deep Learning Denoising Reconstruction (DLR) [1-2] has clinically used providing improved image quality, scan time, and resolution compared to Conventional reconstruction (CONV). Rigorous assessment of how DLR performs for quantitative imaging is needed before widespread clinical adoption. This study focuses on comparing T2 values and precision of the cartilage Multi-Echo Spin-Echo (MESE) T2 mapping sequence reconstructed with DLR and CONV.

**METHODS AND MATERIALS**

The MESE T2 mapping sequence with parameters shown in Fig 1 was performed at 3T on an NIST CaliberMRI Phantom (Boulder, CO) and in healthy subjects' knees. To assess the precision, the MESE T2 mapping sequence was scanned repeatedly 16 times. Vials with reference T2 of ~30-70ms were selected for the analysis [3]. Each MESE T2 data was reconstructed with both CONV and DLR.Regions of Interest (ROIs) were drawn identically on the DLR and CONV T2 maps on the selected vials. Mean and standard deviation (STD) of T2 values within each ROI were recorded for analysis. The precision for each vial was calculated as temporal STD of 16 repeated measurements [4]. Bland-Altman, Linear Regression, and paired Student's t-test were used to compare T2 values and precision between DLR and CONV [5].

**RESULTS**

T2 values from DLR and CONV are strongly correlated ($R2>0.997$) with negligible bias (<0.77ms) as shown in Fig 2 and 3. DLR provides an average of 33% smaller STD of T2 measurements compared to CONV.As seen in Fig 4, DLR improved precision by 35% and 54% ($p < 0.001$) compared to CONV for (256x256, R=2) and (320x320, R=3), respectively.Representative T2 maps acquired on a volunteer are shown in Fig 5. DLR provides T2 maps with higher SNR compared to CONV, especially in the short scan time and/or high-resolution settings (2nd and 3rd columns). DLR allows better delineations of the knee cartilage and small features, as indicated by the arrows.

**CONCLUSION**

High-resolution quantitative T2 mapping is often desired to reduce measurement errors due to partial volume effects and to better delineate superficial, middle, and deep layers of the cartilage. However, higher resolution leads to reduced SNR and longer scan time. This study demonstrated that, DLR allows acquisition of T2 maps with shorter scan time and/or higher resolution while maintaining T2 values with improved SNR and precision compared to CONV.

**CLINICAL RELEVANCE/APPLICATION**

DLR significantly improves SNR and precision of cartilage T2 mapping without affecting the T2 values. The SNR and precision gain allow DLR to acquire cartilage T2 maps with shorter scan time and higher resolution, making it clinically relevant (i.e., higher resolution than typically recommended [6] in less than 5-min scan time).

## T5B-SPPH-8 IMPACT OF MONOCHROMATIC ENERGY LEVELS AND ITERATIVE ALGORITHMS ON RIGHT ADRENAL GLAND IMAGE QUALITY INTHE PORTAL PHASEDUAL ENERGY CT

Mingyue Wang, BS (*Abstract Co-Author*) Nothing to Disclose
Zi Tian Tsang, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the influence of different monochromatic energy levels and adaptive statistical iterative reconstruction-Veo (ASiR-V) algorithm, on the image quality of the right adrenal gland in the portal phase dual energy CT (DECT).

**METHODS AND MATERIALS**

21 patients who underwent upper abdominal enhanced portal venous phase DECT scanning (Revolution CT, GE) were retrospectively enrolled. The virtual monochromatic images, including 40 keV,55keV and 70 keV, were reconstructed by ASiR-V at 0%,20%,40%,60%, and 80% strength levels, respectively. 15 image groups were reconstructed. The CT value, standard deviation (SD), the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of right adrenal gland in all image groups were calculated respectively. Additionally, subjective scoring using a 5-point scale (scores >3 for diagnosis) was conducted for the body, medial branch, and lateral branch of the right adrenal gland to evaluate anatomical structure, details, and edge visibility. The objective and subjective evaluations were compared at different image groups.

**RESULTS**

No significant statistical differences were found in the CT values of the right adrenal gland among six different ASiR-V reconstruction strength levels for each of the three monochromatic image sets (All $P >0.05$, such as CT values of ASIR-V weights from 0%-80% at 55 keV: 158.29±26.01Hu, 161.05±38.90Hu, 156.00±26.39Hu, 154.71±25.94Hu, 153.29±26.08Hu). As the ASiR-V strength increased, the SD values decreased gradually, while

SNR and CNR increased in different monochromatic image sets. (All P < 0.05, such as SD at 55 keV: decreased from 47.9±12.1 to 27.2±11.2, respectively). The subjective scoring of 60%ASiR-V have highest score at 40 and 55 keV (both were 5.00±0.00) than other image groups.

**CONCLUSION**

according to subjective and objective evaluation, ASiR-V at 60% strength provided optimal image quality for the right adrenal gland at 40 and 55 keV images.

**CLINICAL RELEVANCE/APPLICATION**

40~55 KeV with ASiR-V at 40% ~60%strength was clinically significant for observing fine anatomical structures in the abdomen, such as the right adrenal gland. This allows for clear visualization of anatomical structures, details, and edges, facilitating accurate diagnosis of lesions. ASiR-V weighting strength below 40% may increase image noise, while strength exceeding 60% may reduce spatial resolution. Therefore, ASiR-V at 40%~60% reconstruction is recommended for observing small anatomical structures.

Maayan Gerbi (*Abstract Co-Author*) Nothing to Disclose
Nieves Morales, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Abdominal aortic aneurysm (AAA) is a potentially life-threatening dilation of the abdominal aorta and is frequently undiagnosed until rupture. AAA affects between 0.4% and 7.6% of the general population. AAA is most commonly diagnosed using Computed Tomographic Angiography (CTA). This study retrospectively evaluated the performance of an FDA-approved artificial intelligence (AI)-based triage software to detect AAA for accuracy of detection in a large metropolitan healthcare system.

### METHODS AND MATERIALS

A total of 341 retrospective CTAs extracted from the Montefiore Health System from 2020 to 2023 were analyzed using an FDA-approved AAA identification algorithm (Viz.ai, inc), of which 158 of these CTAs were positive for AAA and 183 CTAs were negative. There were 25 positive scans that had a graft repair present at the time of CTA acquisition. Algorithm findings were compared with previous radiologist reads of the CTA scans and assessed for accuracy. Findings were reviewed by three board-certified radiologists and consensus was reached in all cases.

### RESULTS

Of the 341 total CTAs, there were 21 discrepancies between ground truth and AI software AAA identification. There were 161 CTA found to be positive by the AI software, and 3 false positives. Reasons for the false positives were aortic ectasia (1), aortic dissection pathology (1), and incorrect CTA location (1). All 25 patients with graft repairs were identified by the Viz AAA algorithm as positive. There were 201 CTAs read as negative by the AI software, of which 18 were found to be false negatives. Reasons for the false negatives were aortic thrombus or plaque (9), aortic dissection pathology (3), CTA scan artifacts (1), blurred scan boundaries (1), and unexplainable (4). AAA algorithm sensitivity was calculated to be 88.6%, and specificity was calculated to be 98.4%.

### CONCLUSION

These results further support AI-based detection and referral software for AAA is accurate and has the potential to assist radiologists to improve clinical care.

### CLINICAL RELEVANCE/APPLICATION

Abdominal aortic aneurysm is a common and life-threatening condition. This AI-based detection tool has the potential to improve diagnosis and facilitate proper follow-up.

## W2-SPBR-1 DIAGNOSTIC ACCURACY OF AN IMAGE-ONLY DEEP LEARNING MODEL TO PREDICT SPECTRUM OF DIVERSE TUMOR SUBTYPES

Madeline H. Carney, MD (*Abstract Co-Author*) Nothing to Disclose
Constance D. Lehman, MD, PhD (*Abstract Co-Author*) Institutional Grant, General Electric Company;Institutional Grant, Hologic, Inc;Co-founder, Clairity, Inc.
Sarah Mercaldo, PhD (*Abstract Co-Author*) Nothing to Disclose
Leslie Lamb, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Andrew R. Carney, MS (*Abstract Co-Author*) Nothing to Disclose
Heba Albasha, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Breast cancers have diverse biologic features associated with variable prognoses. Prognosis informs the course of illness, treatment selection, and stratification for experimental treatments. The purpose of this study is to assess the performance of an image-only deep learning (DL) risk model to predict breast cancer histologic subtypes, grades, and molecular subtypes.

### METHODS AND MATERIALS

This retrospective, multisite study included consecutive women >40 years undergoing routine bilateral screening mammography across six sites from 2015 to 2022. A DL 5-year image-only model was used to assess risk. Mammograms used for model development and those with bilateral cancers were excluded. Patient demographics were retrieved from electronic health records. Cancer outcomes were obtained through linkage to a regional tumor registry. Diagnostic accuracy of DL model in predicting histologic subtypes, grades, and molecular subtypes were estimated using areas under the receiver operating characteristic curve (AUCs) with DeLong test ($P<0.05$).

### RESULTS

258,753 bilateral screening mammograms in 92,454 patients met inclusion criteria. Mean age was 60y (IQR: 51-69y). 20.1% (51,896/258,753) had a family history of breast cancer, 79.2% (205,060/258,753) were post-menopausal, and 39.9% (102,994/258,154) had dense breasts. 1326 cancers were diagnosed: 78.1% (1035) invasive and 21.9% (291) DCIS. There was no evidence of a significant difference in predicting invasive cancer, AUC 0.83 (95% CI: 0.82, 0.84) vs DCIS, 0.85 (95% CI: 0.82, 0.87), P=0.28. The AUC was higher in predicting IDC, 0.84 (95% CI: 0.82, 0.85) vs ILC, 0.78 (95% CI: 0.74, 0.83), P=0.02. For invasive disease, the higher the grade, the higher the AUC (P range 0.05-<0.001). This trended for DCIS. The AUC in predicting luminal A cancers was 0.82 (95% CI: 0.80, 0.83), luminal B 0.90 (95% CI: 0.87, 0.94), triple negative 0.85 (95% CI: 0.79, 0.90), and HER2 enriched 0.90 (95% CI: 0.85, 0.96). For DCIS, the AUC of the model in predicting ER+ and/or PR+ disease was 0.85 (95% CI: 0.82, 0.88) and ER- and PR- 0.77 (95% CI: 0.68, 0.86).

### CONCLUSION

Mammograms contain highly predictive biomarkers of future cancer risk. A DL model using screening mammography alone can accurately discriminate patients at risk of developing diverse tumor histologic subtypes, grades, and molecular subtypes, including poor prognostic cancers.

### CLINICAL RELEVANCE/APPLICATION

An image-only DL risk model derived automatically at the time of screening mammography can accurately identify patients at risk of developing poor prognostic cancers. DL assisted radiomics has the potential to improve current prognostic models based on tumor biology and enhance future approaches to guide personalized treatment.

## W2-SPBR-10 ENHANCING DIAGNOSTIC EFFICACY OF ULTRASOUND LESIONS WITH CONTRAST-ENHANCED MAMMOGRAPHY (CEM)

Huizhi Cao (*Presenter*) Nothing to Disclose

### PURPOSE

The aim is to evaluate the diagnostic efficacy of contrast-enhanced mammography (CEM) in distinguishing between benign and malignant breast ultrasound lesions, with the goal of enhancing the accuracy of breast disease diagnosis.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on patient data from our hospital between September 2022 and October 2023. Patients with clinically diagnosed breast lesions underwent both CEM and ultrasound examinations. Pathological diagnosis served as the reference standard to analyze the diagnostic performance of single (CEM or ultrasound) and combined (CEM and ultrasound) examinations for breast lesions.

**RESULTS**

The study comprised 144 subjects, including 27 cases of breast cancer and 117 benign lesions, with an average age of 40.5 years (range: 22 to 69 years). Ultrasound exhibited sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV) of 70.4%, 92.3%, 88.2%, 67.9%, and 93.1%, respectively. Contrastingly, CEM demonstrated significantly improved sensitivity (100%) and NPV (100%), with a smaller change in accuracy (89.6%). Specificity (87.2%) and PPV (64.3%) decreased for CEM. CEM showed a significantly higher breast cancer detection rate than ultrasound ($P < 0.05$). Moreover, the combination of CEM and ultrasound yielded superior diagnostic performance compared to either modality alone, with significantly improved sensitivity (100%), specificity (99.1%), PPV (96.4%), NPV (100%), and accuracy (99.3%).

**CONCLUSION**

CEM enhances the sensitivity and NPV of ultrasound screening, suggesting its utility in improving diagnostic accuracy. Combining CEM with ultrasound boosts clinical diagnostic confidence.

**CLINICAL RELEVANCE/APPLICATION**

CEM, with its capability to detect calcifications and assess hemodynamic features, complements ultrasound findings. The combination of CEM and ultrasound substantially enhances the diagnostic efficiency of breast lesions, offering considerable clinical value.

## W2-SPBR-2 RETHINKING RADIAL SCARS: EFFECT OF RADIOLOGY-PATHOLOGY CONCORDANCE REVIEW ON RADIAL SCAR MANAGEMENT

Ramapriya Ganti, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Jessie Jahjah, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela K. Cunha, MD (*Abstract Co-Author*) Nothing to Disclose
Jonathan Nguyen, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Radial scars (RS) have typically been sent for excision despite a low rate of upgrade to malignancy on surgical excision. At our practice, we initiated a protocol of collaborative review by radiologists and pathologists for every RS found on core needle biopsy. We are now only recommending excision for RS cases that are suspicious on imaging, potentially undersampled, such as if the imaging finding is larger than 1 cm, or not largely excised on pathology. The purpose of this study is to evaluate the change in rate of upgrade to malignancy for RS that were recommended for excision after implementing this practice change and investigate the incidence of interval cancers in RS cases that were not recommended for excision.

**METHODS AND MATERIALS**

A HIPAA compliant retrospective review was performed at a single institution. Our biopsy database was reviewed to collect all RS found on core needle biopsy from 1/1/2022 after we implemented the change in managing RS (post-protocol) until 6/1/2023. For comparison time period, the database also collected all RS between the time period of 1/1/2018 until 12/31/20, when every RS was recommended for surgical excision at our institution (pre-protocol). RS associated with malignancy or with atypical ductal hyperplasia were excluded. For both time periods, the surgical pathology after excision was reviewed. For the patients who had imaging followup recommended, the patient's electronic medical record was reviewed and analyzed for subsequent breast cancer development within one year of biopsy.

**RESULTS**

During the 2022-2023 period, there were 61 cases of RS found on core needle biopsy. Of these, 28/61 (45.9%) patients had imaging surveillance recommended after radiology-pathology review with no interval cancers development seen in this group within a year after the biopsies. The remaining 33 (54.1%) patients were recommended for surgical excision after the biopsy. Of the 33 lesions that were surgically excised, 3/33 (9.1%) were found to have ductal carcinoma in situ (DCIS) on surgical pathology. In contrast, 72 cases of RS were found on core needle biopsy during the 2018-2020 time period, which were all recommended for surgical excision. 5 of those cases (6.9%) were upgraded to DCIS on surgical excision.

**CONCLUSION**

The upgrade rate of RS recommended for surgical excision increased after selective excision of RS based on radiology-pathology concordance review. No interval cancers developed in patients that appeared appropriately sampled.

**CLINICAL RELEVANCE/APPLICATION**

Clinicians should be aware of the upgrade potential of RS to malignancy. Understanding the upgrade potential of RS to malignancy and the role of radiology-pathology correlation may help tailor surgical decisions and potentially reduce surgery in certain cases.

## W2-SPBR-3 DISCORDANCE OF RADIOLOGIC AND PATHOLOGIC COMPLETE RESPONSE IN PATIENTS WITH TRIPLE-NEGATIVE BREAST CANCER UNDERGOING NEOADJUVANT CHEMOTHERAPY

Dezheng Huo (*Abstract Co-Author*) Nothing to Disclose
Frederick M. Howard, MD (*Abstract Co-Author*) Nothing to Disclose
Rita Nanda, MD (*Abstract Co-Author*) Advisory Board, Cardinal Health, Inc;Advisory Board, FUJIFILM Holdings Corporation;Advisory Board, ITeos Therapeutics;Advisory Board, OncoSec Medical Incorporated;Research funded, OncoSec Medical Incorporated;Advisory Board, Merck & Co, Inc;Research funded, Merck & Co, Inc;Research funded, Arvinas, Inc;Research funded, AstraZeneca PLC;Research funded, Bristol-Myers Squibb Company;Research funded, Corcept Therapeutics Inc;Research funded, F. Hoffmann-La Roche Ltd;Research funded, Immunomedics, Inc;Research funded, Merck & Co, Inc;Research funded, Cubist Pharmaceuticals;Research funded, Odonate Therapeutics;Research funded, Pfizer Inc;Research funded, Otsuka Holdings Co, Ltd
Kirti M. Kulkarni, MD (*Abstract Co-Author*) Nothing to Disclose
Wenji Guo (*Abstract Co-Author*) Nothing to Disclose
Asim Dhungana (*Presenter*) Nothing to Disclose

**PURPOSE**

Pathologic complete response (pCR) following neoadjuvant chemotherapy (NAC) is a key marker of long-term outcomes in patients with triple-negative breast cancer (TNBC). Accurate radiologic assessment of response to NAC using breast MRI and US plays an important role in guiding decisions regarding

choice and duration of treatment. We examined the discordance between post-NAC radiologic complete response (rCR) and pCR in patients with TNBC.

**METHODS AND MATERIALS**

This is a retrospective cohort study of patients from a single institution diagnosed between January 2013 and April 2022 with TNBC who underwent dynamic contrast-enhanced MRI or US breast imaging before and after NAC. Radiology reports of post-NAC MRI and US scans were examined for presence of rCR, and these findings were correlated with pathologic stage on surgical resection. Concordance between rCR and pCR was measured using Cohen's kappa (?) statistic. Association between the receipt of immunotherapy (IO) and pCR among patients without rCR on post-NAC MRI/US was measured using Fischer's exact test. P-values less than 0.05 were considered statistically significant.

**RESULTS**

We identified 186 patients (all female, mean age 52 years) from the cohort meeting the inclusion criteria, including 82 (44%) Black, 82 (44%) White, 12 (6.5%) Asian, 8 (4.3%) Hispanic, 1 (0.5%) Native American, and 1 (0.5%) Other. 166 (89%) patients had high tumor grade, 174 (94%) patients had ductal histologic subtype, 81 (44%) patients had pCR, and 34 (18%) patients received IO. Overall, concordance between pCR and MRI was found in 109/137 (80%) patients (? = 0.57), while concordance between pCR and US was found in 96/142 (68%) patients (? = 0.30). Among patients not receiving IO, pCR and MRI were moderately concordant (? = 0.60), and pCR and US were weakly concordant (? = 0.42). Discordance was pronounced in those receiving IO, with reduced concordance between pCR and MRI (? = 0.39), and no concordance between pCR and US (? = 0.05). Among patients with no rCR on MRI, there was a strong association between IO and pCR (p = 0.009) with a poor negative predictive value (NPV) of 50% in patients who received NAC with IO compared to an NPV of 84% in patients who received NAC without IO.

**CONCLUSION**

We present novel data that demonstrate a statistically significant reduction in the NPV of post-NAC MRI in patients with TNBC who received IO.

**CLINICAL RELEVANCE/APPLICATION**

These findings suggest that post-NAC MRI may overcall residual tumor in patients with TNBC receiving IO, potentially leading to unnecessary continuation of chemotherapy. Further research is necessary to better characterize the underlying radiologic features responsible for discordance and whether alternative metrics or modalities may better assess response to neoadjuvant therapy.

## W2-SPBR-4 CONTRAST ENHANCED MAMMOGRAPHY GUIDED BIOPSY USING A PRONE TABLE: INSIGHTS AND PRELIMINARY OUTCOMES

Vittorio Miele, MD (*Abstract Co-Author*) Nothing to Disclose
Cecilia Boeri (*Abstract Co-Author*) Nothing to Disclose
Ludovica Anna Incardona (*Abstract Co-Author*) Nothing to Disclose

Ermanno Vanzi, MD (*Abstract Co-Author*) Nothing to Disclose
Elsa Cossu, MD (*Abstract Co-Author*) Nothing to Disclose
Diego De Benedetto (*Abstract Co-Author*) Nothing to Disclose
Chiara Bellini, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To describe our single-center experience of contrast-enhanced mammography (CEM)-guided biopsy using a prone table in terms of procedural features and histopathological results.

**METHODS AND MATERIALS**

We retrospectively reviewed all consecutive CEM examinations performed at our institution for presurgical staging or problem solving for inconclusive findings from December 2023 to January 2024. We considered eligible for CEM-guided biopsy any suspicious finding visible just in recombined images (RC) and negative at conventional imaging, defined as "only-CEM lesion" (OCLs). All the biopsies were performed after intravenous administration of contrast media and dual-energy acquisition with a vacuum-assisted biopsy system. Patient age, breast density, background parenchymal enhancement (BPE), presence and type (mass, non-mass and enhancing asymmetry) of enhancement of the target lesion, procedural time, complications and histopathological results were collected.

**RESULTS**

A total of 19 suspicious OCLs in 19 patients (median age 63 years) were referred for CEM-guided biopsy in the study period. Breast density was predominantly B (42.1%) and C (26.3%), with background parenchymal enhancement (BPE) mostly mild (42.1%) or moderate (36.8%). Of the 19 OCLs referred for CEM-guided biopsy, 3 (15.8%) did not show a clearly visible enhancement during the procedure, while 9 (47.3%) presented as mass enhancements and 7 as non-mass enhancements (36.8%), with a median size of 17.26 mm. The median procedural time was 15.8 min (range 15 - 20 min). Complications were limited to self-limiting hematomas in 26% (5/19) of cases; no vasovagal reactions were recorded. Histological evaluation revealed 2 (10.5%) malignant lesions, one invasive ductal carcinoma (IDC) and one ductal carcinoma in situ (DCIS), and 2 (10.5%) lesions of uncertain malignant potential, including a radial scar and lobular intraepithelial neoplasia, with the remaining 15 lesions (78.9%) being benign, such as fibrocystic changes, mastopathy, and fibroadenomas.

**CONCLUSION**

Preliminary results from using prone-table for CEM-guided biopsies underscore its potential to enhance procedural comfort and efficiency, validating this innovative approach.

**CLINICAL RELEVANCE/APPLICATION**

CEM-guided biopsy using a prone-table system is feasible and can be a safe and comfortable procedure for enhancing-only lesions.

## W2-SPBR-7 PREDICTORS OF MALIGNANCY FOR INCIDENTAL BREAST FINDINGS DETECTED ON PRIOR NON-BREAST IMAGING

Ramin Khorasani, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Catherine S. Giess, MD (*Abstract Co-Author*) Nothing to Disclose
Fatima Salah, MD, FRCR (*Presenter*) Nothing to Disclose

**PURPOSE**

Incidental breast findings detected by radiologists in patients undergoing non-breast imaging exams frequently generate recommendations for diagnostic mammography. Purpose is to assess the rate and predictors of malignancy in diagnostic mammography of breast findings detected by radiologists on a prior non-breast imaging exam.

**METHODS AND MATERIALS**

This Institutional Review Board-approved, retrospective cohort study was conducted at a tertiary academic medical center and affiliated outpatient centers. The study cohort included all unique patients with diagnostic mammograms performed to evaluate breast findings detected on prior non-breast imaging exams between 1/1/2016-12/31/2018. Patient- and imaging-related factors were extracted from the institutional data warehouse; BIRADS score and tissue diagnosis from the electronic health record. Malignancy, the primary outcome, was defined as subsequent diagnosis of breast or other cancer (e.g., metastasis) at the original breast finding site =2 years after index mammogram. Percent of actionable findings (BIRADS =3) and of patients undergoing breast procedures was recorded. Univariate analysis and multivariable logistic regression determined factors associated with malignancy.

**RESULTS**

Overall 210 of 22,273 (0.94%) diagnostic mammography patients underwent imaging to evaluate a breast finding detected on prior CT, PET/CT, or non-breast MRI. Average patient age was 58.9 years, predominantly female (201/210, 95.7%), and almost half (47.6%; 100/210) were scored BIRADS =3. More than one-third (36.2%; 76/210) underwent a breast-related procedure based on a recommendation in the index mammogram report. 21.4% of all patients (45/210), and 47.4% (36/76) of those who underwent a procedure, were subsequently diagnosed with malignancy. On multivariate analysis, older age (Odds Ratio 1.03; 95%Confidence Interval 1.00-1.06) and PET/CT study as the initial imaging modality (Odds Ratio 5.74; 95%Confidence Interval 2.38-13.87) were more likely to be associated with malignancy. Prior personal or family history of breast cancer were not significantly associated with a malignancy outcome on univariate analysis. Asymmetry was the least likely initial finding to yield malignancy.

**CONCLUSION**

A substantial percentage of incidental breast findings initially detected by non-breast imaging and referred for diagnostic breast evaluation yield actionable findings, including malignancy.

**CLINICAL RELEVANCE/APPLICATION**

Incidental breast findings detected on non-breast imaging exams, particularly masses found on PET/CT, are commonly associated with malignancy, and should be carefully evaluated.

## W2-SPBR-8 MID-TERM OUTCOMES OF MRI/ULTRASOUND FUSION-GUIDED BIOPSY FOR MRI-DETECTED BREAST LESIONS: AN IN-DEPTH EVALUATION OF DIAGNOSTIC ACCURACY AND FALSE-NEGATIVE CASES

Takayoshi Uematsu, MD, PhD (*Abstract Co-Author*) Research collaboration, FUJIFILM Holdings Corporation;
Taiyo L. Harada (*Abstract Co-Author*) Nothing to Disclose
Kazuaki Nakashima, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

The objective of this study is to assess the mid-term diagnostic accuracy and false negatives of breast biopsy using MRI/ultrasound (US) fusion technology for breast lesions detected by MRI but not identified by second-look US.

**METHODS AND MATERIALS**

A total of 275 lesions in 255 Asian patients who underwent MRI/US fusion-guided biopsy between 2015 and 2023 were analyzed. The lesions were detected on contrast-enhanced breast MRI which was performed for the preoperative assessment of breast cancer or screening for hereditary breast and ovarian cancer, but not identified by following second-look US. MR and US images were synchronized and displayed simultaneously on the US monitor using a commercially available magnetic position tracking system composed of US scanner, magnetic field generator, and magnetic sensor. We evaluated the histopathological results of MRI/US fusion-guided biopsies and surgeries, the accuracy of the biopsies, and cases that were found to be malignant during follow-up observation after biopsy (false negatives).

**RESULTS**

The pathological results of the biopsies were as follows: invasive carcinoma (7%, 20 cases), non-invasive ductal carcinoma (16%, 43 cases), atypical ductal hyperplasia (ADH) or lobular neoplasia (7%, 19 cases), and benign (70%, 193 cases). The benign lesions were followed up for 0-105 months (median 39 months). Two non-mass enhancements, measuring 18mm and 28mm in diameter and initially diagnosed as benign, were later identified as invasive cancer and ADH in re-biopsies. Consequently, the false negative rate of MRI/US fusion-guided biopsies was determined to be 1% (2 out of 193 cases).

**CONCLUSION**

The false-negative rate of breast biopsy using MRI/US fusion for MRI-detected lesions was demonstrated to be very low. Most cases that were difficult to identify with fusion technology were benign lesions. Early diagnosis of non-invasive cancer prior to progression to invasive cancer seems to be possible even for such false-negative cases through appropriate imaging follow up.

**CLINICAL RELEVANCE/APPLICATION**

In the current situation where MRI is becoming more common for breast cancer screening according to breast cancer risk, this study has shown that MRI/US fusion technology can be safely used as an alternative option for MRI-guided biopsy, especially for Asian women.

## W2-SPBR-9 PURE DUCTAL CARCINOMA IN SITU (DCIS) AT VACUUM ASSISTED BIOPSY (VAB): ANALYSIS OF UPGRADE AND PREDICTORS OF INVASIVENESS

Daniela Bernardi, MD (*Abstract Co-Author*) Nothing to Disclose
Daria Volpe (*Abstract Co-Author*) Nothing to Disclose
Riccardo Levi (*Abstract Co-Author*) Nothing to Disclose
Francesco Patrone (*Abstract Co-Author*) Nothing to Disclose
Isabella Bolengo, MD (*Abstract Co-Author*) Nothing to Disclose
Alessandra Sapori (*Abstract Co-Author*) Nothing to Disclose
Rubina Manuela Trimboli (*Abstract Co-Author*) Nothing to Disclose
Giulia Vatteroni, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To report the upgrade rate to invasive breast cancer (IBC) of pure Ductal Carcinoma In Situ (DCIS) diagnosed at stereotactic-Vacuum Assisted Biopsy (VAB) and to identify preoperative variables associated with stromal invasion at subsequent surgical pathology.

## METHODS AND MATERIALS

We retrospectively reviewed all percutaneous stereotactic-guided VAB performed at our Institution from January 2018 to April 2023. Pure DCIS with a final surgical pathology were included in the analysis. Patient's age, lesion type (mass, calcification, architectural distortion) and size, calcification morphology and distribution, residual calcifications, BI-RADS category, needle gauge and nuclear grade were considered as preoperative variables. Chi-squared test was used to investigate the association between each preoperative variable and the occurrence of IBC considering $p<0.05$ as significant.

## RESULTS

Among 301 patients with pure DCIS at VAB, 271 with a mean age of 58-year-old (± 11 SD; range 30-92) were included in the analysis. There were 247/271 (91%) pure calcifications, 21/271 (8%) opacities/architectural distortion associated with calcifications and 3/271 (1%) architectural distortions. At final surgical pathology 56/271 (21%; IC: 95% 14.7%, 26.3%) cases were upgraded to IBC. Pre-operative variables associated with upgrade to invasiveness were: lesion size =20mm (vs<20 mm, $p<0.001$); fine linear and fine linear branching calcification morphology (vs amorphous, coarse heterogeneous and fine pleomorphic, $p<0.001$); segmental distribution (vs regional, grouped, linear, $p<0.001$) and residual post-biopsy calcifications (vs no residual calcifications, $p=0.002$). Lesion type ($p=0.459$), patients' age ($p=0.582$), BI-RADS categories ($p=0.025$), nuclear grade ($p=0.191$) and needle gauge ($p=0.758$) were not associated to underestimation. Invasive cancer was found in 17/90 (19%), 34/162 (21%), 5/19 (26%) cases using 7, 9 and 10 gauge needle.

## CONCLUSION

One out of five DCIS diagnosed at VAB is under-staged using large needle vacuum assisted biopsy, without differences between 7, 9 and 10 gauge. Preoperative variables associated with underestimation included morphology and distribution of calcifications and the presence of residual post-biopsy calcifications.

## CLINICAL RELEVANCE/APPLICATION

Fine linear and fine linear branching calcifications extended for =20mm in segmental distribution should be extensively sampled by vacuum assisted biopsy in order to reduce underestimation rate of invasive breast cancers and allow a one-stop final surgical treatment.

# Abstract Archives of the RSNA, 2024

W2-SPCA

**Cardiac Imaging Wednesday Morning Poster Discussions**

Wednesday, Dec. 4 9:00AM - 9:30AM Room: LEARNING CENTER

**Sub-Events**

## W2-SPCA-1 NON-INVASIVE DIFFERENTIATION OF IDIOPATHIC INFLAMMATORY MYOPATHY WITH CARDIAC INVOLVEMENT FROM ACUTE VIRAL MYOCARDITIS USING CARDIOVASCULAR MAGNETIC RESONANCE IMAGING T1 ,T2 MAPPINGAND FEATURE TRACKING

Zhang Yanling (*Presenter*) Nothing to Disclose

### PURPOSE

Idiopathic inflammatory myopathy (IIM) is a group of autoimmune diseases that may involve the myocardium with systemic myositis. Cardiac involvement in IIM is usually subclinical, but some patients may also present with clinical manifestations similar to acute viral myocarditis (AVM). The objective of this study was to Investigated the effectiveness of combined analysis of cardiovascular magnetic resonance (CMR) T1-mapping and T2-mapping parameters and myocardial strain in differentiating cardiac involvement between AVM and IIM.

### METHODS AND MATERIALS

This retrospective study included 42 subjects (age 45±16 years) : 22 patients with AVM, 20 patients with IIM and cardiac involvement, and 20 healthy controls. Both subjects and healthy control group were examined by CMR, and their T1-mapping, T2-mapping, ECV and feature tracking were analyzed by post-processing technology.

### RESULTS

The T1-mapping, T2-mapping and ECV values of the AVM group, IIM group and healthy control group were statistically different, and the T1-mapping and T2-mapping values of the IIM group were higher than those of the AVM group, and there was no statistically significant difference in ECV values between the two groups. Compared with healthy volunteers, IIM group and AVM group had significant differences in the overall left ventricular radial, circumferential and longitudinal strain and left ventricular ejection fraction, while IIM group had statistically significant differences in the overall left ventricular longitudinal strain (-17.4±2.4V.S. -20.1±2.2,P<0.001)and circumferential strain(-18.8±2.4V.S. -20.9±2.4,P<0.001) compared with AVM group, but no statistically significant differences in the overall left ventricular radial strain(36.8±7.0V.S. 42.4±7.6,P=0.003).

### CONCLUSION

Cardiac involvement of AVM and early IIM is often difficult to distinguish in clinical manifestations and laboratory tests, there for CMR T1-mapping, T2-mapping and FT-CMR may provide evidence for distinguishing them.

### CLINICAL RELEVANCE/APPLICATION

The use of non-invasive imaging techniques to distinguish viral myocarditis and idiopathic inflammatory myopathy heart damage, to provide evidence and support for early diagnosis and timely treatment of patients, reduce the medical burden, improve the survival rate of patients.

## W2-SPCA-3 DIAGNOSTIC PERFORMANCE OF CT-DERIVED EXTRACELLULAR VOLUME FRACTION IN AORTIC STENOSIS, CARDIAC AMYLOIDOSIS AND DUAL PATHOLOGY

Toshinori Hirai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takeshi Nakaura, MD (*Abstract Co-Author*) Nothing to Disclose

Yasunori Nagayama, MD (*Abstract Co-Author*) Nothing to Disclose
Hidetaka Hayashi, MD (*Abstract Co-Author*) Nothing to Disclose
Shinpei Yamaguchi (*Presenter*) Nothing to Disclose

### PURPOSE

There is limited evidence regarding the comparison of CT-derived extracellular volume fraction (CT-ECV) in patients with lone aortic stenosis (AS), dual pathology of AS and transthyretin cardiac amyloidosis (AS-ATTR), and ATTR cardiac amyloidosis without AS (lone ATTR). We investigated CT-ECV in patients with lone AS, AS-ATTR, and lone ATTR, and to examine the diagnostic performance and optimal cutoff values of CT-ECV for differentiating between patients with AS-ATTR and lone AS, and between patients with lone ATTR and lone AS.

**METHODS AND MATERIALS**

This retrospective study included patients with moderate-to-severe AS (including lone AS and AS-ATTR) and lone ATTR who underwent CT-ECV analysis between January 2018 and March 2024 in our university hospital. The diagnostic performance of CT-ECV for detecting cardiac amyloidosis was evaluated using the area under the receiver operating characteristic curve (AUC).

**RESULTS**

Of 153 patients (mean age, 79 years ± 8 [SD]; 109 men), 55 had lone AS, 21 had AS-ATTR and 77 had lone ATTR. CT-ECV of patients with lone AS, AS-ATTR, and lone ATTR was 31 ± 5%, 44 ± 12%, and 54 ± 13%, respectively. CT-ECV was significantly lower in patients with AS-ATTR than lone ATTR (44 ± 12% vs 54 ± 13%, P =.008). The AUC for differentiating patients with AS-ATTR from lone AS was lower than for lone ATTR from lone AS (0.89 [95% CI: 0.79, 0.95] vs 0.96 [95% CI: 0.91, 0.99]). The cutoff values of CT-ECV for differentiation between patients with lone AS and AS-ATTR were lower than those between patients with lone AS and lone ATTR (37% vs 38% [Youden index]; 30% vs 34% [for 95% sensitivity, suitable for screening for cardiac amyloidosis]).

**CONCLUSION**

CT-ECV of patients with AS-ATTR was lower than that of patients with lone ATTR, and the diagnostic performance and optimal cutoff values of CT-ECV for differentiating between patients with AS-ATTR and lone AS were lower than those between patients with lone ATTR and lone AS.

**CLINICAL RELEVANCE/APPLICATION**

The findings from this study may contribute to the accurate detection of cardiac amyloidosis and lead to early drug treatment.

## W2-SPCA-5 PROGNOSTIC VALUE OF RIGHT ATRIAL FUNCTION DERIVED FROM CARDIAC MAGNETIC RESONANCE IMAGING IN PATIENTS WITH LIGHT-CHAIN AMYLOIDOSIS

Yinqiu Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the prognostic value of right atrial (RA) function derived from cardiac magnetic resonance imaging (CMR) in patients with light-chain (AL) amyloidosis.

**METHODS AND MATERIALS**

From December 2011 to January 2020, patients with histologically proven AL amyloidosis who underwent CMR were included in this prospective cohort study. RA volume, RA emptying fraction (RAEF) and RA strain parameters were measured based on CMR. The primary endpoints were all-cause death. Cox regression analysis and Kaplan-Meier analysis were used to evaluate the association of variables with death. The incremental prognostic values evaluated using C indexes and ?2 value.

**RESULTS**

A total of 140 patients with AL amyloidosis were included (mean age, 58 years ± 10 [SD]; 84 male). Over a median follow-up of 31 months, 92 patients (65.7%) reached the primary endpoint. In multivariate Cox regression analysis, only RAEF total [hazard ratio (HR) 1.021 per 1% decrease, 95% confidence interval (CI) 1.001-1.041, P =0.038] and Mayo stage (HR 1.493, 95% CI 1.063-2.097, P=0.021) remained independently associated with the primary endpoint. The addition of RAEF total to Mayo stage model (C-statistic 0.692, ?2 30.3) improved model discrimination for the primary endpoints(C-statistic 0.732, ?2 37.4 P=0.004). Moreover, RAEF total with a cutoff of 29.3% further discriminated the survival probability in subgroups of patients with focal patchy LGE or global LGE (log-rank P<0.001, P=0.012, respectively).

**CONCLUSION**

RAEF total was an independent predictor of all-cause death in patients with AL amyloidosis and provided incremental prognostic value to Mayo stage.

**CLINICAL RELEVANCE/APPLICATION**

RAEF total could be a suitable non-invasive CMR parameter for predicting all-cause mortality in AL amyloidosis and could further improve risk stratification in patients with AL amyloidosis.

## W2-SPCA-7 CARDIAC MAGNETIC RESONANCE EVALUATION OF LEFT VENTRICULAR REMODELING INDEX IN LIGHT-CHAIN CARDIAC AMYLOIDOSIS

Yue Gao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to evaluate the ratio of left ventricular mass to LV end-diastolic volume (LVMVR) in patients with light-chain cardiac amyloidosis (AL-CA) and determine the effects on the occurrence of major adverse cardiac events (MACE).

**METHODS AND MATERIALS**

Fifty-five AL-CA patients who underwent cardiac magnetic resonance (CMR) scanning were included. LV function, LVMVR, and LV global peak strains were measured. The primary endpoint of the study was the occurrence of MACE. Pearson's analysis was performed to investigate the correlation between LVMVR and CMR parameters. Long-term MACE was assessed using Kaplan-Meier survival analysis and compared among the groups using the log-rank test.

**RESULTS**

LVMVR showed significantly correlation with LVEF (r = -0.298, P = 0.027) and LV global longitudinal peak strain (r = 0.516, P <0.001). All the patients with AL-CA have completed the follow-up analysis. The median follow-up duration for the entire cohort was 4.5 years (IQR, 3.2-5.9 years). Kaplan-Meier survival analysis revealed that AL-CA patients with higher LVMVR (>1.175) had a significantly higher risk of MACE during follow-up.

**CONCLUSION**

For patients with AL-CA, the increase of LVMVR was associated with poor cardiovascular outcomes at follow-up.

**CLINICAL RELEVANCE/APPLICATION**

Provide additional information for prognostic management and clinical decision making in patients with AL-CA.

## W2-SPCA-8 FEASIBILITY OF T2 MAPPING FOR THE DETECTION OF MYOCARDIAL INJURY IN HYPERTROPHIC CARDIOMYOPATHY: A CASE-CONTROL STUDY

Shihua Zhao, MD (*Abstract Co-Author*) Nothing to Disclose
Jiaxin Wang (*Abstract Co-Author*) Nothing to Disclose
Shujuan Yang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The application of T2 mapping has been introduced in hypertrophic cardiomyopathy (HCM). This study aims to explore the association between T2 value and myocardial injury in HCM patients.

### METHODS AND MATERIALS

25 HCM patients with elevated high-sensitivity cardiac troponin I (hs-cTn I), 25 age-matched HCM patients with normal hs-cTn I, and 20 healthy volunteers underwent CMR including parametric mapping. Hs-cTn I was defined as a marker of myocardial injury (>0.016ng/mL). Global T2 values were quantified for three left ventricular (LV) short-axis slices. The maximum T2 value and T2 value assessed conservatively within the septum (ConSept T2) were measured from the maximal value of 16 segments and the middle septum, respectively.

### RESULTS

The HCM group with elevated hs-cTnI (20 males, 50±13 years) had higher T2 global, ConSept T2, T2 max, T1 global, ConSept T1 values, and LGE extent($P<0.05$) than the HCM group with normal hs-cTnI (17 males, 49±14 years). The ConSept T2 value ($r=0.52$, $P<0.001$) and LGE extent ($r=0.52$, $P<0.001$) were all moderately correlated with hs-cTnI. Among all parametric parameters, ConSept T2 value showed the best performance in identifying myocardial injury (AUC=0.83). In bivariate logistic regression analyses, after adjusting LV ejection fraction, LV end-diastolic volume index, maximal ventricular wall thickness, LV myocardial mass index, LGE extent, T1 global, and ConSept T1 values, respectively, ConSept T2 value was still significantly associated with elevated hs-cTnI ($P<0.01$).

### CONCLUSION

In this case-control study, we confirmed the feasibility of T2 mapping for detecting myocardial injury in HCM. T2 value was associated with an elevated hs-cTnI, which provided in-vivo evidence by CMR for the ongoing myocardial injury in HCM.

### CLINICAL RELEVANCE/APPLICATION

This study confirmed the feasibility of T2 mapping for detecting myocardial injury in HCM. T2 value measured using the ConSept approach was highly reproducible and correlated with elevated hs-cTn I. T2 mapping might become an integral part of the comprehensive evaluation and management of patients with HCM.

## W2-SPCH-1 THE VALUE OF ARTIFICIAL INTELLIGENCE ITERATIVE RECONSTRUCTION ON DETECTABILITY OF SMALL PULMONARY NODULES AT ULTRA-LOW-DOSE CT SCAN PROTOCOLS: A PHANTOM EVALUATION

Guozhi Zhang (*Abstract Co-Author*) Nothing to Disclose
Yan Zhang (*Abstract Co-Author*) Nothing to Disclose
Jing Li (*Abstract Co-Author*) Nothing to Disclose
Xiaozheng Dong (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the effect of a new artificial intelligence iterative reconstruction (AIIR) algorithm on detectability of small pulmonary nodules under ultra-low-dose computed tomography (CT) scan protocols.

### METHODS AND MATERIALS

Six artificial pulmonary nodules of varying densities [two solid nodules (SNs) and four ground glass nodules (GGNs); densities: 100HU, -630 HU, -800 HU; diameter: 5 mm, 3 mm] were sequentially placed at the ten regions (right and left lung: up, middle, down, inside, and outside) in chest phantom and scanned on a 320-row CT scanner. Five scan protocols were performed at 5mAs with various tube voltages (120, 100, 80, 70, 60kVp). Raw data were reconstructed using filtered back-projection (FBP), hybrid iterative reconstruction (HIR), and the AIIR at 1.0mm thickness, respectively. All images were automatically analyzed using a commercially available artificial intelligence software. The effective radiation dose was recorded. The detection rate of pulmonary nodules was calculated. The score of image quality and nodule edge on the small pulmonary nodules were scored using a four-point scale (1: poor, 4: excellent).

### RESULTS

The corresponding radiation doses of five ultra-low-dose scanning protocols were 0.387, 0.227, 0.106, 0.062, and 0.032mGy, respectively. For the nodule with a density of 100HU, the detection rate of three algorithms was the same, with detection rate of 100% for 5mm and 50% for 3mm at ultra-low dose conditions of 0.032 mGy. The detection rates of AIIR algorithm were the highest (30%) for nodules with a density of -630 HU (0.032mGy for diameter of 5mm and 0.062 mGy for diameter of 3mm). For GGNs with density of -800 HU and 5mm, only the AIIR images could be successfully detected (50%) under ultra-low dose conditions of 0.106 mGy. Compared with FBP and HIR algorithms, the nodules edge were improved by the AIIR algorithm (proportion of scores 3 and 4: AIIR=96% vs. HIR=66% vs. FBP=66%).

### CONCLUSION

Compared to FBP and HIR algorithms, application of AIIR returns the highest detection rate for small pulmonary nodules, even at ultra-low radiation doses. The optimal ultra-low-dose scanning protocol for small pulmonary nodules is tube voltage of 80kV, a tube current of 5mAs, and the radiation dose of 0.057mSv.

### CLINICAL RELEVANCE/APPLICATION

The AIIR algorithm could be a promising reconstruction technique to enhance the detection rate of small pulmonary nodules and pulmonary micro-nodules in ultra-low dose lung screening.

## W2-SPCH-2 LUNG NODULE SIZE EVALUATION ON CHEST CT: A COMPARISON BETWEEN MANUAL AND AI ANALYSIS

Marly Van Assen, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Irene (tai-Lin) Lee (*Abstract Co-Author*) Nothing to Disclose
Benjamin Bottcher (*Abstract Co-Author*) Nothing to Disclose
Carlo N. De Cecco, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Covanos, Inc
Gianluca G. Siciliano, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study compares accuracy of manual and AI-based lung nodule diameters and volume assessment on baseline and follow-up chest CT scans.

### METHODS AND MATERIALS

The study included 142 patients who underwent baseline and follow-up chest CT for lung nodule evaluation, which were analyzed by two radiology residents independently. Up to 5 nodules per patient were selected and measured at baseline and follow-up. Using clinically available software (syngo.via VB60, Siemens Healthineers), volume (mm3), max diameter (mm), and mean diameters (mm) were recorded. After manual analysis, scans were analyzed by AI software (AIRC Research, Chest CT Explore, V1.3.4, Siemens Healthineers) in a fully automated approach. Using a CNN, the AI algorithm

detects lung nodules and measures diameters and volume. Agreement between readers and between manual and AI analysis was conducted with Pearson Correlation (r). Sub-analyses were performed based on nodule size, location, HU density, and shape. Manual and AI correlation was also evaluated in a 34 patient set read by an expert reader and a resident.

**RESULTS**

A total of 640 nodules were analyzed across baseline and follow-up. Median volume, max diameter, and mean diameter were 97 mm3 (52-268), 7 mm (5.6-9.5), and 6.2 mm (5-8.3); results will be presented in this order. Agreement between resident readers was excellent: r = 0.99, 0.97, and 0.97 ($p<0.001$). Manual and AI analysis correlation for the two readers were r = 0.91, 0.91, and 0.94 ($p<0.001$), and r = 0.91, 0.89, and 0.91 ($p<0.001$). Correlation using mean measures was r = 0.91, 0.91, and 0.93 ($p<0.001$). Sub-analysis on nodule size showed highest correlation between 10 and 20 mm: r = 0.96, 0.84, and 0.88 ($p<0.001$), and the lowest in nodules < 5 mm: r = 0.30, 0.16, and 0.23 ($p >0.05$). Correlation was good for all locations, with subpleural nodules showing the weakest correlation: r = 0.81, 0.89, and 0.89 ($p<0.001$). Other locations showed r > 0.90 ($p<0.001$) across all parameters. Density did not impact AI performance with r > 0.89 ($p<0.001$) overall. Non-spherical nodules showed the lowest correlation: r = 0.63, 0.84, and 0.85 ($p<0.001$), which increased in spherical nodules: r = 0.98, 0.94, 0.95 ($p<0.001$). Expert and resident reader agreement in the 34 patient set (144 nodules) was excellent: r = 0.99, 0.96, and 0.98 ($p<0.001$), as well as correlation with AI: r = 0.99, 0.97, and 0.98 ($p<0.001$).

**CONCLUSION**

The study shows high agreement between manual and AI analysis across low and high-experienced readers in assessing lung nodule volume, max, and mean diameters.

**CLINICAL RELEVANCE/APPLICATION**

AI-assisted lung nodule size assessment shows high accuracy comparable to manual methods, potentially streamlining lung nodules evaluation, and reducing time burden, and variability across readers.

## W2-SPCH-4 LUNG-CADEX: FULLY AUTOMATIC ZERO-SHOT DETECTION & CLASSIFICATION OF LUNG NODULES IN THORACIC CT IMAGES

Furqan Shaukat (*Abstract Co-Author*) Nothing to Disclose
Syed M. Anwar, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Lung cancer has been one of the major threats to human life for decades. Computer-aided diagnosis can help with early lung nodule detection and facilitate subsequent nodule characterization. Large Visual Language models (VLMs) have been found effective for multiple down-stream medical tasks that rely on both imaging and text data. However, lesion level detection and subsequent diagnosis using VLMs have not been explored yet.

**METHODS AND MATERIALS**

We propose CADe, for segmenting lung nodules in a zero-shot manner using a variant of the Segment Anything Model called MedSAM. CADe trains on a prompt suite on input computed tomography (CT) scans by using the CLIP text encoder through prefix tuning. We also propose, CADx, a method for the nodule characterization as benign/malignant by making a gallery of radiomic features and aligning image-feature pairs through contrastive learning. Training and validation of CADe and CADx have been done using one of the largest publiclyavailable datasets, called LIDC. To check the generalization ability ofthe model, it is also evaluated on a challenging dataset, LUNGx.

**RESULTS**

We have done our evaluations on two different datasets LIDC (Lung Image Database Consortium) containing 1186 nodules and 2) LUNGx which contains hard malignancy labels (pathology proven) of 73 nodules. Standard performance metrics, namely area under the curve, sensitivity, accuracy, and specificity, were used for evaluation. We have compared our test results with notable recent studies. Our experimental results show that the proposed methods achieve a sensitivity of 0.86 compared to 0.76 that of other fully supervised methods.

**CONCLUSION**

We present an end-to-end pipeline using both CADe and CADxfor lung nodule detection and its subsequent malignancy characterization. We used a variant of the Segment Anything Model called MedSAM in a zero-shot manner for the detection part and a CLIP model for further characterization of nodules into benign and malignant. We replaced the visual prompts of MedSAM with textual prompts and designed a prompt suite for this specific downstream task. After segmenting the nodule patches, we formed a radiomic feature gallery and trained the modified CLIP model with nodule patches and their associated radiomic feature sets. During inference, the model gave the most similar classfed to a linear classifier for the final decision.

**CLINICAL RELEVANCE/APPLICATION**

Our results have shown significant value in the detection of large and diverse data. The proposed tool can be used for early lung cancer screening in an end-to-end manner. It also has the potential to improve the quality of life of patients by assisting with early diagnosis, reducing misdiagnoses, and facilitating more informed follow-up recommendations.

## W2-SPCH-5 BENIGNITY/MALIGNANCY PREDICTION OF PART-SOLID PULMONARY NODULES BASED ON IMAGE FEATURES AND ARTIFICIAL INTELLIGENCE SOFTWARE QUANTITATIVE CHARACTERISTICS

Li Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Qi Wang, BSc (*Abstract Co-Author*) Nothing to Disclose
Gaofeng Shi, MD (*Abstract Co-Author*) Nothing to Disclose
Tongxin Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to analyze the predictive value of CT image features and artificial intelligence (AI) software quantitative characteristics of part-solid nodules (PSNs) in differentiating malignant PSNs from atypical benign PSNs that require surgical resection after failure of anti-inflammatory treatment

**METHODS AND MATERIALS**

A retrospective analysis was conducted on 192 patients with PSNs of = 30 mm in mean diameter which were surgically removed and pathologically confirmed . These patients were divided into a training set and a validation set at a ratio of 7:3. Thin-slice imaging was utilized to record clinical features, PSN image features (presence or absence of emphysema, PSN location and shape, tumor-lung interface, presence or absence of lobulation, burr, and pleural retraction sign, presence or absence of vacuole, air bronchogram, and traversing vessel, presence or absence of abnormal pulmonary veins, solid component location and boundary, mean diameters of nodules and solid components, and solid component diameter ratio), and AI quantitative characteristics (nodule volume and mass, solid component volume, mass, and their proportions, maximum, minimum, mean, and standard deviation of

nodule CT value, and solid component volume, mass, and ratio). In the training set, univariate and multivariate logistic regression analyses were performed on the recorded characteristics to identify the independent risk factors predictive of the benign or malignant nature of PSNs, so as to establish a combined model. The diagnostic performance of each independent risk factor and the combined model was assessed using the receiver operating characteristic (ROC) curve, and the area under the curve (AUC) was calculated. The AUCs of independent risk factors and the combined model were compared using DeLong's test.

**RESULTS**

In the training set, 8 independent risk factors for diagnosing of PSNs were identified by the multivariate logistic regression analysis ($P < 0.05$): nodule location and shape, tumor-lung interface, presence or absence of lobulation and burr, presence or absence of abnormal pulmonary vein, and solid component volume and mass. The ROC curve analysis showed that the combined model containing the 8 independent risk factors had the highest AUC (training set: AUC = 0.934, 95% CI: 0.893-0.974; validation set: AUC = 0.921, 95% CI: 0.856-0.986).

**CONCLUSION**

Based on image features and AI quantitative characteristics, the benign or malignant nature of PSNs with a mean diameter of = 30 mm can be effectively predicted.

**CLINICAL RELEVANCE/APPLICATION**

This study demonstrates good diagnostic performance in predicting the benign or malignant nature of pulmonary nodules, possessing substantial clinical application value.

## W2-SPCH-6 A MULTI-CENTER RETROSPECTIVE STUDY OF NODULE TYPE CLASSIFICATION USING ARTIFICIAL INTELLIGENCE FOR LUNG-RADS SCORING WITH CT

Junghyun Kang (*Abstract Co-Author*) Nothing to Disclose
Doohyun Park (*Abstract Co-Author*) Nothing to Disclose
Changhyun Park (*Abstract Co-Author*) Nothing to Disclose
Jonghun Jeong (*Presenter*) Nothing to Disclose

**PURPOSE**

The American College of Radiology regularly updates the guidelines for lung cancer screening, known as the Lung Imaging Reporting and Data System (Lung-RADS). Across all versions of the guidelines, it is always important to accurately classifying nodule types—solid, part-solid, and ground-glass nodules (GGN)—on computed tomography (CT) images. Therefore, the purpose of this study was to evaluate the performance of the computer-aided diagnosis (CADx) model in nodule type classification.

**METHODS AND MATERIALS**

We collected data from 238 patients at a referral hospital, where two radiologists identified 1,904 nodules by consensus. After excluding 11 part-solid and 8 segmentation fail nodules, 1,413 nodules were used to develop the model, and 472 nodules were used for testing. Additionally, we collected data from 170 patients at an independent hospital. Here, two radiologists reviewed the images. After the exclusion of 113 part-solid and 1 segmentation fail nodules, 941 nodules were used for external validation. By utilizing nodule segmentation masks to obtain radiomic features, we developed an artificial intelligence-based model for nodule type classification. This work operates end-to-end by using the CADx model.

**RESULTS**

In the internal and external validation sets, respectively, the classification of 472 and 941 nodules yielded an area under the receiver operating characteristic (ROC) curve (AUC) of 0.972 (0.951-0.992, 95% confidence interval [CI]) and 0.993 (0.989-0.997, 95% CI). In the internal set, the sensitivity was 0.953 for solid nodules (402 out of 422) and 0.900 for GGNs (45 out of 50). In the external set, the sensitivity was 0.993 for solid nodules (815 out of 821) and 0.808 for GGNs (97 out of 120). Consequently, the accuracy on the internal and external sets was 0.947 (447 out of 472) and 0.969 (912 out of 941), respectively.

**CONCLUSION**

The classification of nodule types using CT scans is a critical component of Lung-RADS scoring for lung cancer screening. In this study, the CADx model has proven to be a robust tool in distinguishing between solid and ground-glass nodules, setting the stage for more accurate and clinically dependable Lung-RADS scores. Future studies will validate the performance of the classification of part-solid and cystic nodules, in accordance with the latest Lung-RADS guidelines.

**CLINICAL RELEVANCE/APPLICATION**

This study demonstrated the clinical utility of the CADx model in practice, potentially improving diagnostic precision and thereby impacting patient management and outcomes in lung cancer screening.

## W2-SPCH-7 EFFECT OF DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM ON IMAGE QUALITY AND QUANTITATIVE ANALYSIS OF PULMONARY NODULES IN ULTRA-LOW-DOSE CHEST CT

Zhiming Xiang (*Abstract Co-Author*) Nothing to Disclose
Kun Ma (*Abstract Co-Author*) Nothing to Disclose
Zhijuan Zheng (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the image quality, detectability, and measurement accuracy of pulmonary nodules between deep learning image reconstruction (DLIR) and adaptive statistical iterative reconstruction-V (ASIR-V) in ultra-low-dose CT (ULD-CT) for facilitating large-scale lung cancer screening.

**METHODS AND MATERIALS**

Participants underwent ULD-CT (UL-A, 0.56±0.04 mSv and UL-B, 0.33±0.03 mSv) and standard-dose CT (SDCT) plain scans, with the 50%ASIR-V reconstructed SDCT serving as the reference standard. The ULD-CT was reconstructed using 50%ASIR-V and DLIR algorithms at medium (DLIR-M) and high (DLIR-H) levels. The objective measurements including image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were used to quantify the image quality performance of ULD-CT. A 5-point scale was used to analyze subjective image quality scores. The nodule detection results and nodule features of different reconstructed images were analyzed. The logistic regression analysis was used to determine the independent predictors of nodule detection.

### RESULTS

302 participants with 1541 nodules were included, including 814 nodules in UL-A group and 727 nodules in UL-B group. DLIR-H excellently exceeds 50%ASIR, not only has a significant advantage in image noise, SNR and CNR, but also can even compete with or exceed 50%ASIR-V in subjective evaluation in ULD-CT. Sensitivities for nodules detection of 50%ASIR-V, DLIR-M and DLIR-H in ULD-CT were identical (97.53%, 1503/1541). In ULD-CT, the detection sensitivity was 99.12% (1233/1244) for solid nodules (SN), 90.46% (256/283) for pure ground glass nodules (pGGN), and 100.00% (14/14) for partial solid nodules (PSN). In multivariate analysis, the body mass index (BMI), nodule diameter, and nodule type were independent predictors for the sensitivity of nodule detection ($p < 0.001$). Friedman test showed that the absolute percentage error (APE) in nodule volume of ULD-CT reconstructed with DLIR-M (-2.41%±43.33% and 2.87%±86.51%) and DLIR-H (-1.36%±82.16% and -0.81%±58.87%) was significantly lower than that of ULD-CT reconstructed with 50%ASIR-V (1.78%±41.41% and 10.79%±99.75%) ($P < 0.001$).

### CONCLUSION

The ULD-CT can significantly reduce the CT radiation dose while maintaining good sensitivity for nodule detection. DLIR can provide good image quality and improve the accuracy of the nodule measurement compared with ASIR-V in ULD-CT.

### CLINICAL RELEVANCE/APPLICATION

This is a clinical study designed to evaluate the clinical value of DLIR in participants with pulmonary nodules on ULD-CT. The application of ULD-CT scan combined with DLIR is of great significance in clinical practice, which can improve the quality of diagnosis and treatment of patients and reduce the potential adverse effects on patients.

## W2-SPCH-8 EFFECT OF DEEP LEARNING IMAGE RECONSTRUCTION ALGORITHM ON THE RADIOMIC QUANTIFICATION OF PULMONARY NODULES IN ULTRA-LOW-DOSE CT

Zhiming Xiang (*Abstract Co-Author*) Nothing to Disclose
Kun Ma (*Abstract Co-Author*) Nothing to Disclose
Zhijuan Zheng (*Presenter*) Nothing to Disclose

### PURPOSE

The lack of reproducibility of radiomic features in response to variations in reconstruction algorithm. The purpose of this study was to investigate the effects of the deep learning image reconstruction (DLIR) algorithm and adaptive statistical iterative reconstruction-V (ASIR-V) algorithm on the reproducibility of radiomic features between ultra-low-dose CT (ULD-CT) and standard-dose CT (SDCT).

### METHODS AND MATERIALS

The study prospectively enrolled 183 patients who underwent non-contrast ULD-CT (UL-A, 0.57±0.09 mSv or UL-B, 0.33±0.04 mSv)and standard-dose computed tomography (SDCT) (4.30±0.36 mSv). SDCT was reconstructed with 50%ASIR-V, and ULD-CT with 50%ASIR-V, DLIR-M, and DLIR-H. 102 radiomic features (shape, first order, texture features) of pulmonary nodules were extracted from both SDCT and ULD-CT images. The intraclass correlation coefficient (ICC) was used to evaluate the reproducibility of these radiomic features. The proportion of features with ICC >0.75 between ULD-CT and SDCT was also compared.

### RESULTS

221 solid nodules (SN) and 89 pure ground-glass nodules (pGGN) were analyzed. There was no significant difference for the proportion of features in SN between SDCT and ULD-CT reconstructed by 50%ASIR-V, DLIR-M, and DLIR-H, which were 35.29% (36/102), 32.35% (33/102), and 38.24% (39/102), respectively (P=0.68). The proportion of reproducibility of 50%ASIR-V, DLIR-M, and DLIR-H in pGGN were 60.78% (62/102), 61.76% (63/102), and 77.45% (79/102), respectively (P=0.02). In SN, DLIR-M and DLIR-H improved the ICC values from 0.67±0.21 to 0.71±0.17 and 0.73±0.15 compared with 50%ASIR-V (P<0.001). In pGGN, DLIR-M and DLIR-H improved the ICC values from 0.74±0.22 to 0.79±0.17 and 0.83±0.12 compared to 50%ASIR-V (P<0.001). In addition, both SN and pGGN have high reproducibility in 50%ASIR-V, DLIR-M, and DLIR-H, with the ICC value of over 0.75 for shape and first order features. In texture features, DLIR-M and DLIR-H showed improved the ICC values for pGGN from 0.69±0.23 to 0.75±0.18 and 0.81±0.12, respectively, compared to 50%ASIR-V. Similarly, the ICC values for SN increased from 0.60±0.19 to 0.66±0.14 and 0.69±0.13, respectively.

### CONCLUSION

The reconstruction algorithm significantly affects the quantification of ULD-CT radiomic features in pulmonary nodules. Compared with ASIR-V, the application of DLIR algorithm can improve the reproducibility of radiomic features in ULD-CT. Furthermore, pGGN is more reproducible than SN in ULD-CT.

### CLINICAL RELEVANCE/APPLICATION

DLIR can improve the reproducibility of radiomic features in ULD-CT. The ULD-CT combined with the DLIR algorithm can not only reduce the risk of patients receiving radiation, but also improve the diagnostic accuracy and reliability of clinical applications.

## W2-SPCH-9 LUNG NODULE GROWTH EVALUATION ON BASELINE AND FOLLOW-UP CHEST CT USING AI-ASSISTED ANALYSIS

Benjamin Bottcher (*Abstract Co-Author*) Nothing to Disclose
Marly Van Assen, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Carlo N. De Cecco, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Covanos, Inc
Irene (tai-Lin) Lee (*Abstract Co-Author*) Nothing to Disclose
Gianluca G. Siciliano, MD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to evaluate accuracy of lung nodule growth evaluation using manual and AI-based measurements using baseline and follow-up chest CT scans.

### METHODS AND MATERIALS

The study included 142 patients who underwent baseline and follow-up chest CT for lung nodule evaluation, which were analyzed by two radiology residents independently. A radiologist with 10+ years of experience in cardiothoracic imaging analyzed a subset of 34 patients. Nodules were selected and measured at baseline and follow-up. Using clinically available software (syngo.via VB60, Siemens Healthineers), volume (mm3), max diameter (mm), and mean diameter (mm) were recorded. Each nodule's growth between baseline and follow-up scans was assessed. After manual analysis, AI software (AIRC Research, Chest CT Explore, V1.3.4, Siemens Healthineers) analyzed the CT cases fully automatically, allowing for individual lung nodule analyses to be accepted or rejected based on clear mismatch, inclusion of vessels, or pleural tissue. Agreement on growth evaluation between residents and between manual and AI analysis for resident and expert readers was conducted using Pearson Correlation (r). Sub-analysis based on acceptance/rejection status was also conducted.

## RESULTS

A total of 320 nodules were measured on baseline and follow-up imaging. Median follow-up time was 5 months (3-7). Median growth was 2.5mm3 (-10-22), 0.15mm (-0.3-0.6), and 0.15mm (-0.2-0.5) for volume, max, and mean diameter respectively; results will be presented in this order. Agreement between residents was substantial: r = 0.97, 0.74, and 0.82 ($p<0.001$). For all cases analyzed, correlation between manual and AI analysis was good: r = 0.91, 0.76, and 0.73 ($p<0.001$). Analyzing only accepted nodules (n= 266, 83%) correlation increased, to r = 0.93, 0.85, and 0.86 ($p<0.001$), and decreased to 0.60, 0.16, and 0.16 ($p>0.05$) for rejected nodules (n=54, 17%). For the expert reader (34 patients, 72 nodules) correlation with AI analysis was good: r = 0.96, 0.69, and 0.77 ($p<0.001$). Analysis based on acceptance/rejection status showed r = 0.96, 0.86, and 0.88 ($p<0.001$) for accepted nodules (n=61, 85%), and r = 0.75, 0.10, and 0.15 ($p>0.05$) for rejected nodules (n=11, 15%).

## CONCLUSION

The study shows good concordance between manual and AI analysis across low and high-experienced readers in assessing lung nodule growth. AI-assisted lung nodule assessment showed higher performance in accepted nodules, emphasizing its use to assist radiologists, instead of an independent reader.

## CLINICAL RELEVANCE/APPLICATION

AI-assisted lung nodule growth evaluation shows high agreement with manual-only assessment. This could streamline lung nodule growth assessment and management pathway, reducing time burden, and variability.

## W2-SPER-1 EVALUATION OF DISCREPANCIES BETWEEN COMMUNITY RADIOLOGIST AND EMERGENCY RADIOLOGIST INTERPRETATION OF TRAUMA IMAGING PERFORMED FOR PATIENTS TRANSFERRED TO A LEVEL 1 TRAUMA CENTER

Allison Crone, MD (*Abstract Co-Author*) Nothing to Disclose
Scott D. Steenburg, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Second opinion overreads are common in the setting of trauma patients, who are often transferred to level 1 trauma centers to obtain a higher level of care and expertise. This study evaluated the rate of discrepancies between the outside radiologists' interpretations of trauma studies and those of emergency radiologists at an academic level 1 trauma center.

### METHODS AND MATERIALS

A search of the institution's Radiology Information System (RIS) was performed to find overreads of trauma patients that were performed by emergency radiologists in a 1-year period (Jan 1, 2023-Dec 31, 2023). The outside report was obtained, if possible, and comparison was made to our Emergency Radiology Division overread. Discrepancies between reports were divided into major and minor, with major discrepancy defined as change in interpretation that altered patient management (additional tests ordered, major change in medical management, IR procedure, or surgery) and minor discrepancy defined as change in interpretation that did not alter management. A one-way ANOVA test was used to compare the no change in interpretation, minor change, and major change groups.

### RESULTS

A total of 506 overreads for 266 patients were found during the study period. 383 (75.7%) exams were obtained in the setting of trauma, of which 82 did not have outside reports. The study cohort therefore consisted of the remaining 301 studies on 135 patients from 29 institutions. Mean age was 52.3 years (range 19-97), of which 63.7% of patients were male. The average Injury Severity Score (ISS) was 13 (range 1-51). The most common injury mechanisms were falls (43.0%) and motor vehicle collisions (31.1%). Major discrepancies were found in 26 exams (8.6%) affecting 25 patients (18.1%), resulting in 2 IR procedures and 5 surgeries. Minor discrepancies were found in 49 exams (16.3%) affecting 42 patients (30.4%). In total, some discrepancy was found in 75 (24.9%) exams affecting 62 patients (44.9%). There was no statistically significant difference in ISS between the no change (12.9), minor change (13.8), and major change (12.5) groups [p=0.815].

### CONCLUSION

Our emergency radiologists identified a discrepancy in nearly half of imaging exams performed on trauma transfer patients, with major discrepancies impacting patient management in 8.6% of trauma exams overread by our emergency radiology staff, affecting 18.9% of patients. There was no significant difference in discrepancy rate based on patient ISS.

### CLINICAL RELEVANCE/APPLICATION

These findings support the utility of second opinion overreads by dedicated emergency radiologists with expertise in trauma imaging, to provide potentially management-altering information for patients and the clinicians caring for them.

## W2-SPER-2 ANALYSIS OF RARE COMPLICATIONS CAUSED BY SWALLOWED PENETRATING OR MIGRATORY FOREIGN BODIES: A RETROSPECTIVE STUDY

Ci Cheng (*Presenter*) Nothing to Disclose

### PURPOSE

Ingestion of foreign bodies is a common etiology for emergency visits, but some rare complications caused by penetrating or migratory FBs are often unrecognized and not completely understood. This study aimed to analyze patients who encountered infrequent complications caused by foreign bodies to reduce occurrences of missed and inaccurate diagnoses.

### METHODS AND MATERIALS

We conducted a retrospective analysis of 21 patients who experienced atypical complications caused by penetrating or migratory foreign bodies. We analyzed and summarized the mechanisms, diagnoses and treatment modalities of rare complications related to foreign bodies. The role of imaging examinations was emphasized in this study.

## RESULTS

Among the 21 cases, the most common complication occurred in the digestive system, followed by the circulatory and respiratory systems. The most common complication was intestinal necrosis or inflammation (5/21, 23.8%), followed by cervical abscess or inflammation (3/21, 14.3%). Other complications included liver inflammatory mass or abscess (2/21, 9.5%), internal jugular vein penetration (1/21, 4.8%) and pericardial perforation (1/21, 4.8%), etc. The fishbone was the predominant type of foreign body. Fourteen patients underwent surgical treatment, five underwent endoscopic treatment, one opted for conservative treatment and one did not receive treatment.

## CONCLUSION

The symptoms and manifestations resulting from swallowed penetrating or migratory foreign bodies can vary greatly. Accordingly, clinicians should consider integrating patients' medical histories, clinical and imaging features to better exclude the possibility of foreign body ingestion, particularly when encountering relatively uncommon complications.

## CLINICAL RELEVANCE/APPLICATION

This study elaborated in detail the mechanisms of complications related to penetrating or migratory FBs, as well as misconceptions and recommendations regarding diagnosis and treatment. A series of infrequent complications of penetrating FBs were summarized, which could assist clinicians in reaching diagnostic accuracy and providing timely treatment for urgent patients.

## W2-SPGI-11 ASSESSMENTOF PREOPERATIVE STAGING OF RECTAL CANCER USINGRESTRICTION SPECTRUM IMAGING

Yu Shen (*Abstract Co-Author*) Nothing to Disclose
Nan Meng (*Abstract Co-Author*) Nothing to Disclose
Wei Wei (*Abstract Co-Author*) Nothing to Disclose
Yan Bai (*Abstract Co-Author*) Nothing to Disclose
Meiyun Wang (*Abstract Co-Author*) Nothing to Disclose
Xinhui Wang (*Presenter*) Nothing to Disclose

### PURPOSE

The accurate preoperative staging of rectal cancer patients is crucial for selecting appropriate surgical methods and assessing surgical prognosis. Restricted spectrum imaging (RSI) is a novel diffusion MRI model that can capture the unique diffusion characteristics of tumors. Our objective was to evaluate the ability of the RSI model in preoperative staging of rectal cancer.

### METHODS AND MATERIALS

Difusion-weighted MRI (DWI) data using a commercial 3.0 T scanner (SIGNA Architect, GE Healthcare) equipped with a 16-channel body coil were collected from twenty-one patients with diferent rectal cancer staging confrmed by biopsy in this study. Three experienced radiologists, who were blinded to the histopathological findings, manually delineated the region of interest (ROI) corresponding to the cancer on the DWI images. We obtained RSI, DKI, and ADC model parameters (including C1, C2, C3, DKI-D, DKI-K, and ADC). Mean ± standard deviation, two-sample t-test, and ROC analysis were employed in this study.

### RESULTS

The volume fraction of the restricted compartment C2 from RSI showed a significant difference between stage I and stage II-III (P=0.033), whereas no statistically significant difference was observed between ADC and DKI. The area under the curve (AUC) for C2 in differentiating between stage I and stage II-III was 0.789, with a sensitivity of 66.7% and a specificity of 86.7%.

### CONCLUSION

The three-compartment RSI model shows promising potential in distinguishing between stage I and stage II-III rectal cancer. These findings suggest that the model exhibits superior performance in the preoperative staging of rectal cancer when compared to traditional ADC and DKI models.

### CLINICAL RELEVANCE/APPLICATION

RSI was employed to assess the unique diffusion characteristics of tumor in rectal cancer, aiming to accurately determine the preoperative staging of the disease. This information is crucial in selecting the most appropriate treatment plan for patients and enhancing the overall treatment outcomes for rectal cancer.

## W2-SPGI-13 THE ADDED VALUE OF LIVER MR ELASTOGRAPHY IN THE MANAGEMENT OF TYPE 1 GAUCHER DISEASE

Marie-claude Miron, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Ramy El-Jalbout (*Abstract Co-Author*) Nothing to Disclose
Luca Panetta (*Presenter*) Nothing to Disclose

### PURPOSE

Gaucher disease is a rare genetic disorder characterized by the mutation of the lysosomal enzyme glucocerebrosidase. Its substrate, glucocerebroside, accumulates in the reticuloendothelial system and causes cytopenia, hepatomegaly, liver fibrosis, splenomegaly, and bone marrow infiltration. MR Elastography (MRE) has increasingly become an available tool for an accurate assessment of liver stiffness (LS) and liver fibrosis. The purpose of this study was to determine the relevance of MRE in the routine follow-up of patients with type 1 Gaucher disease (GD1). The study also aimed to analyze the variation of LS as compared to other parameters used in standard workup of GD1 patients with repeated MRE imaging.

### METHODS AND MATERIALS

A prospective IRB approved observational study was conducted for all GD1 patients between February 2020 and March 2024. A routine follow-up at two academic medical centers included outpatient visits, treatment regimen assessment, blood tests including complete blood count, liver enzymes, ferritin and angiotensin-converting enzyme, MRI of the abdomen, MRE, and bone imaging. Blood results were categorized as low, normal, or high according to lab reference values. The DS3 score for disease burden was calculated. MRE was conducted using a standardized protocol at 60 Hz on a 1.5T MRI machine. Spearman correlation and linear regression were used to analyze correlation between variables. Qualitative variables were analyzed via the

Kruskal-Wallis test. Additional analysis was done for patients with a follow-up MRE exam. The p value was significant if <0.05. For Spearman correlation, a positive tendency for significant correlation was considered if 0.05<p<0.2.

**RESULTS**

A total of 29 patients (17 females [58.6%]; mean age, 36.2 years ± 18.6 [SD]) with at least one MRE exam were included. Twenty patients had follow-up imaging. There was a positive but non-significant correlation between LS and splenic volume (r = 0.26, p = 0.17) and between LS and the DS3 score (r = 0.32, p = 0.08). Although not significant, LS values were higher in men. Though not significant, there was also a tendency for a positive correlation between LS and duration of treatment (r = 0.47, p = 0.06).

**CONCLUSION**

There was a tendency towards positive correlations between LS, splenic volume, DS3 scores, and duration of treatment in GD1 patients, but no statistically significant association. However, results were limited due to lack of power of the small sample size.

**CLINICAL RELEVANCE/APPLICATION**

Since patients with GD1 with suboptimal management are at increased long-term risk of liver fibrosis, there is an interest in the periodic assessment of LS. However, there is little scientific literature documenting the use and benefits of MRE for the routine follow-up of LS in GD1 patients.

## W2-SPGI-2 NON-CONTRAST LIVER MRI IS HIGHLY ACCURATE FOR DETECTION OF UVEAL MELANOMA LIVER METASTASIS

Hyun Jung Chung (*Abstract Co-Author*) Nothing to Disclose
June Park, MD (*Abstract Co-Author*) Nothing to Disclose
Kyunghwa Han, PhD (*Abstract Co-Author*) Nothing to Disclose
Nieun Seo, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We aimed to evaluate the diagnostic performance of different abbreviated MRI sets including non-contrast MRI (NC-MRI) from a complete gadoxetic acid-enhanced MRI, and to investigate potential additional value of hepatobiliary phase (HBP) to detect uveal melanoma liver metastasis.

**METHODS AND MATERIALS**

This retrospective study included 27 uveal melanoma patients who underwent gadoxetic acid-enhanced MRI for suspected liver metastasis. Two independent readers reviewed three MR imaging sets: NC-MRI (T1-weighted, T2-weighted, and diffusion-weighted imaging), dynamic-MRI (NC-MRI and dynamic phases), and full-MRI (dynamic-MRI and HBP) to detect hepatic metastases. Overall diagnostic performance for detecting metastases was evaluated using alternative free-response receiver operating characteristic curve analysis. The sensitivity, and positive predictive value (PPV) were compared among imaging sets by using logistic regression with generalized estimating equations.

**RESULTS**

Of 27 patients, 23 patients had 80 hepatic metastases. Overall diagnostic performance for detecting metastases was not significantly different among three MRI sets (P = 0.327). The reader-averaged area under the curve [AUC] was 0.951 (95% CI, 0.911-0.991) for NC-MRI, 0.967 (0.937-0.998) for dynamic-MRI, and 0.963 (0.930-0.995) for full-MRI, without significant difference between NC-MRI and full-MRI (P = 0.597), and between dynamic-MRI and full-MRI (P > 0.999). The sensitivity to detect liver metastasis was 86.9% (78.1-95.7) for NC-MRI, and 91.9% (86.8-97.0) for both dynamic-MRI and full-MRI, without significant difference between NC-MRI and others (P = 0.072). The PPV was 94.6% (90.0-99.1) for NC-MRI, 94.8% (90.4-99.2) for dynamic-MRI, and 93.6 (89.1-98.2) for full-MRI without significant difference among them (P = 0.282).

**CONCLUSION**

NC-MRI is highly accurate for diagnosis of uveal melanoma liver metastasis comparable to full-protocol gadoxetic acid-enhanced MRI. In addition, there was no incremental value of HBP compared to dynamic-MRI for uveal melanoma liver metastasis.

**CLINICAL RELEVANCE/APPLICATION**

NC-MRI can be an alternative to gadoxetic acid-enhanced MRI for detecting uveal melanoma liver metastasis. Furthermore, there is no advantage in using hepatobiliary contrast agent for liver MRI in patients with uveal melanoma.

## W2-SPGI-5 QUANTITATIVE EVALUATION OF LIVER METASTASES OPTIMIZATION IN ARTERIAL PHASE STUDY USING PHOTON COUNTING CT

Akio Hiwatashi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Masahiro Nakashima, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tatsuya Kawai, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Misugi Urano, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Toshihide Itoh, PhD (*Abstract Co-Author*) Employee, Siemens AG
Tatsuhito Yamamoto (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess characteristic CT findings of liver metastases on virtual monochromatic image (VMI) generated by a photon-counting detector CT(PCD-CT) and to explore conditions for their optimal visualization.

**METHODS AND MATERIALS**

This retrospective study included patients with liver metastasis who underwent contrast-enhanced PCD-CT (NAEOTOM Alpha, Siemens Healthineers, Forchheim, Germany) between March 1 and December 31. Early (40 seconds after injecting contrast medium) and delayed phase images were obtained. Subjects with =10 liver lesions or lesions measuring = 5-cm diameter were excluded. The CT value and its standard deviation (SD) in the ring-enhancing area (RE), central low-attenuating area (LAA), and unaffected liver parenchyma were measured on virtual monochromatic image (VMI) by placing region of interests (ROIs), thereafter, the contrast-noise ratios (CNRs) of RE and LAA relative to the liver parenchyma were calculated. These evaluations were performed on 40-keV, 55-keV, 70-keV, and 90-keV VMI with ROIs copied and pasted accordingly. Statistical analysis was performed using a paired t-test. P-values less than 0.05 was considered as statistically significant.

**RESULTS**

Seventy liver metastases in 35 patients (mean age: 64 years; 18 males) were subjected to analysis. The average CNR of the RE was 0.62, 0.43, 0.34, and 0.13 at 40, 55, 70, and 90 keV, respectively. Paired t-tests revealed significant differences between 70 vs. 40 keV, 70 vs. 55 keV, and 70 vs. 90keV. The average CNR of LAA was 0.39, 0.41, 0.49, and 0.46 at 40, 55, 70, and 90keV, respectively. A significant difference was observed only between 70 vs. 90 keV. SD(LAA) were 2.08, 1.37, 9.93, and 8.31 at 40, 55, 70, and 90keV, respectively. Significant differences were observed when comparing data obtained at 70 vs. 40 keV, 70 vs. 55 keV, and 70 vs. 90keV.

**CONCLUSION**

Quantitative evaluation of this study suggests ring enhancement and heterogeneous enhancement in low attenuation area of liver metastases visualize more clearly at 40 ,55keV, than at 70keV.

**CLINICAL RELEVANCE/APPLICATION**

Photon-counting detector CT enhances visualization of characteristic contrast-enhanced CT findings of liver metastasis by utilizing virtual monochromatic imaging, potentially leading to earlier therapeutic decisions in malignant diseases.

## W2-SPGI-9 THE ROLE OF HELICAL FLOW PHENOMENON IN MAIN PORTAL VEIN AS A BIOMARKER OF THE PRESENCE OF ESOPHAGEAL VARICES WITH RED COLOR SIGN IN PATIENTS WITH LIVER CIRRHOSIS

Chung-Man Moon (*Abstract Co-Author*) Nothing to Disclose
Sang Soo Shin, MD (*Abstract Co-Author*) Nothing to Disclose
Seong Woo Cho, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To verify the feasibility of helical flow phenomenon in main portal vein (PV) for assessing esophageal varices (EVs) with red color (RC) sign using four-dimensional flow magnetic resonance imaging (4D flow MRI).

**METHODS AND MATERIALS**

A total of 106 patients with liver cirrhosis (LC) caused by hepatitis B and/or C virus underwent 4D flow MRI using a 3-T scanner (Skyra; Siemens Healthcare, Erlangen, Germany), obtaining images at both proximal and distal main PV. Patients were classified into three groups: patients without EVs (Group 1, n = 46, 35-80 years); patients with EVs without RC sign (Group 2, n = 42, 41-81 years); patients with EVs and RC sign (Group 3, n = 18, 44-81 years). The presence of the RC sign was defined by the observation of erythrogenic findings on the varices during endoscopy. Hemodynamic information was acquired at the proximal and distal main PV, respectively. In-plane velocity data were analyzed to obtain through-plane vorticity, as a marker of rotational blood flow. The maximum vorticity (vorticitymax) was subsequently obtained throughout the cardiac cycles. The presence of helical flow was defined as a vorticitymax at the proximal PV higher than 0.7 s-1. The chi-square test and two-tailed unpaired t-test were performed to evaluate a statistical difference between the groups.

**RESULTS**

The helical flow was observed in 65.2%, 52.4%, and 22.2% of patients in groups 1, 2, and 3, respectively (P= 0.008). In addition, Group 1 exhibited 1.09 s-1 of vorticitymax at the proximal PV, and this value decreased to 0.83 s-1 for Group 2 (P< 0.05; with Group 1) and 0.60 s-1 for Group 3 (P< 0.05; with Group 1). Meanwhile, vorticitymax at the distal PV significantly decreased from 0.82 s-1 for Group 1 to 0.57 s-1 for Group 3 (P< 0.001). While a significant difference in vorticitymax at the proximal PV between Group 2 and Group 3 was not observed, vorticitymax at the distal PV for Group 3 significantly decreased to 0.57 s-1 (P< 0.05; with Group 2).

**CONCLUSION**

The helical flow phenomenon of the main portal vein was negatively correlated with the presence of esophageal varices with red color sign in patients with liver cirrhosis.

**CLINICAL RELEVANCE/APPLICATION**

The helical flow phenomenon of main portal vein derived from 4D flow MRI may play an important role in predicting the presence of esophageal varices with a high risk of bleeding in patients with liver cirrhosis.

## W2-SPGU-1 MRI-RADIOMICS MODEL PREDICTS PROGRAMMED CELL DEATH-LIGAND 1 EXPRESSION STATUS IN UROTHELIAL CARCINOMA

Young Taik Oh, MD (*Abstract Co-Author*) Nothing to Disclose
Jae Hyon Park, MD (*Abstract Co-Author*) Nothing to Disclose
Jongjin Yoon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Dae Chul Jung, MD (*Abstract Co-Author*) Nothing to Disclose
Insun Park (*Abstract Co-Author*) Nothing to Disclose
Byung Chul Kang (*Abstract Co-Author*) Nothing to Disclose
Taeyoun Lee, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop and validate an MRI-radiomics model with optimized feature selection and machine learning techniques for predicting programmed cell death-ligand 1 (PD-L1) expression status in urothelial carcinoma (UC) in the urinary bladder.

### METHODS AND MATERIALS

This retrospective study included consecutive patients with newly diagnosed and pathologically confirmed UC with PD-L1 immunohistochemistry results (74 patients in the training-set, 20 patients in the test-set). An MRI-radiomics model was built using 1308 radiomics features from T2-weighted images after optimizing various combinations of four feature selections and five machine learning techniques. Tumor characteristics (tumor length, radiologic tumor stage, multiplicity, and morphology), ADC values, and their combinations were used to construct the tumor model, the ADC model, and the tumor + ADC model, respectively. All models were trained using five-folds cross validation and evaluated on the test-set. The area under the receiver operating characteristic curve (AUROC) of these models was compared.

### RESULTS

A total of 94 patients (69.3±10.2 years; 75 [80%] men) were included, and oversampling was performed to account for the data imbalance between PD-L1 (+) and PD-L1 (-) UC (33% [31/94] vs. 67% [63/94]). The radiomics model using a correlation filer and random forest showed the highest AUROC (0.91, 95% CI, 0.62-0.99), followed by the tumor model (0.70, 95% CI, 0.45-0.89, P=0.082), the ADC model (0.66, 95% CI, 0.44-0.86, P=0.043), and the tumor + ADC model (0.59, 0.34-0.81, P=0.012).

### CONCLUSION

The radiomics model may hold clinical utility in screening PD-L1 (+) UC patients who could potentially benefit from immune checkpoint inhibitors.

### CLINICAL RELEVANCE/APPLICATION

MRI-based radiomics models could provide a non-invasive and cost-effective alternative to sequencing, with the potential to be utilized for drug selection and prognosis prediction in personalized treatment strategies.

## W2-SPGU-3 MRI DIFFUSION MODELS FOR NONINVASIVE ASSESSMENT OF RENAL INTERSTITIAL FIBROSIS AND ANNUAL LOSS OF KIDNEY FUNCTION OF CHRONIC KIDNEY DISEASE

Ping Liang (*Abstract Co-Author*) Nothing to Disclose
Zhouyan Liao (*Abstract Co-Author*) Nothing to Disclose
Chuou Xu (*Abstract Co-Author*) Nothing to Disclose
Guanjie Yuan (*Abstract Co-Author*) Nothing to Disclose
Zhen Li, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to explore the capability of seven diffusion models including DWI, IVIM, DKI, CTRW, FROC, SEM, and sADC to assess renal interstitial fibrosis (IF) and annual loss of kidney function of CKD.

### METHODS AND MATERIALS

106 CKD patients and 30 controls underwent a ZOOMit diffusion sequence scan. The CKD group was divided into mild (=25%) and moderate-to-severe (>25%) IF subgroups based on the percentage of interstitial fibrosis lesions in the sampled tissue area. Least absolute shrinkage and selection operator (LASSO) regression was used to select the significant diffusion parameters in assessing IF severity and ROC analysis was applied to evaluate the

diagnostic efficacy. Linear mixed-effects models were used to calculate annual patient-specific estimated glomerular filtration rate (eGFR) slope and evaluate the association between diffusion parameters and 1~3 years eGFR slope.

**RESULTS**

The Lasso regression showed that in assessing IF severity, combining cortical DFROC, MKDKI, fpIVIM, and Medullary sADC achieved good performance in the training (0.954, 95% CI 0.880-0.989) and testing (0.859, 95% CI 0.687-0.957) cohort, respectively. 52, 36, and 15 patients met the one-year, two-years, and three-years follow-up periods, with average eGFR slope of 1.371, -0.160, and -0.337, respectively. After adjustment for baseline covariates including age, sex, baseline eGFR group, etiology (primary or secondary), use of ACEI/ARB, use of immunosuppressants, fibrosis score, and fibrosis score×time, linear mixed effect model indicated that cortical fpIVIM was associated with change in eGFR over time of one year (cortical fpIVIM×time: 0.031, 95% CI 0.001-0.062, p=0.044), cortical aCTRW was associated with change in eGFR over time of two years (cortical aCTRW×time: 0.090, 95% CI 0.031-0.150, p=0.004), corticalaSEM was associated with change in eGFR over time of three years (cortical aSEM×time: 0.086, 95% CI 0.036-0.135, p=0.002).

**CONCLUSION**

MRI Diffusion parameters can serve as feasible and effective imaging biomarkers in identifying different degrees of renal IF and assessing the annual loss of kidney function of CKD. The combination of cortical DFROC, MKDKI, fpIVIM, and Medullary sADC can better evaluate the severity of fibrosis. The higher cortical fpIVIM, aCTRW, and aSEM reflect the lower loss of eGFR in one year, two years, and three years, respectively.

**CLINICAL RELEVANCE/APPLICATION**

The baseline diffusive MR parameters can reflect the severity of renal fibrosis and the level of 1~3 years eGFR loss, which can help patients avoid puncture pain and early understand prognosis, and help clinicians make treatment decisions and follow-up.

**PURPOSE**

To develop and assess a multimodal approach including clinical, laboratory and biparametric MRI-based AI model for determining the necessity of prostate biopsy in patients with PI-RADS 3 lesions.

**METHODS AND MATERIALS**

A retrospective analysis was conducted on a prospectively recruited patient cohort with PI-RADS 3 lesions between April 2019 and February 2024. All patients underwent multiparametric MRI, and subsequent MRI/US fusion-guided biopsy. Demographic data, PSA and PSA density (PSAD) levels, prostate volumes, lesion characteristics, prior biopsy history, and AI evaluations were retrospectively analyzed clinically significant prostate cancer (csPCa) (GG=2). Statistical analysis included Fisher's exact test, logistic regression (LR), and decision curve analysis (DCA).

**RESULTS**

In 248 patients, 312 PI-RADS 3 lesions underwent MRI/US fusion-guided biopsy (n=258 non-csPCa, n=44 csPCa). The AI model demonstrated a sensitivity of 57% for detecting csPCa, and a specificity of 62% for csPCa with a PPV of 18% and NPV of 89%. Subgroup analyses based on zonal origin, and index lesion PI-RADS category (3 vs =4) revealed notably a high NPV for transition zone lesions (88%). While the NPV for patients with an index lesion of PI-RADS 3 was found to be high (91%), no difference was observed in AI detection between csPCA and non-csPCA patients (OR= 2.1, p=.21). Similar analysis done for PSAD showed an NPV of 92%, a sensitivity of 61%, and a strong association between a higher PSAD (= .15 ng/mL2) and presence of csPCa in PI-RADS 3 index lesions (OR=6.6, p<.001). Combining AI and PSAD enhanced sensitivity to 78% while maintaining a high NPV of 93%. LR identified age (p=.03) and PSAD (p=.03) as significant predictors for csPCa. LR also did not identify any predictors of AI performance. DCA showed that using the AI model for minimizing unnecessary biopsies outperforms conventional biopsy strategies, providing greater net benefits within specific threshold probabilities (.206 - .348). Across all thresholds, the AI method outperforms both the biopsy-all and biopsy-none approaches, achieving a peak net reduction in interventions of .723, most notably within the .195 to .351 range by achieving the largest differences.

**CONCLUSION**

Integrating AI to PSAD maximizes csPCa detection performance. Moreover, the high capabilities of the multimodal approach in ruling out csPCa offer a promising strategy for improving biopsy decision-making for PI-RADS 3 lesions.

**CLINICAL RELEVANCE/APPLICATION**

Integrating AI with PSAD elevates biopsy precision, potentially reducing unwarranted procedures for PI-RADS 3 lesions and streamlining patient management.

## W2-SPGU-5 MULTIPARAMETRIC MAGNETIC RESONANCE IMAGING IN PROSTATE CANCER SCREENING AT THE AGE OF 45 - RESULTS FROM THE FIRST SCREENING ROUND OF THE PROBASE TRIAL

Peter Albers, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD (*Abstract Co-Author*) Nothing to Disclose

Lars Schimmoeller, MD (*Abstract Co-Author*) Nothing to Disclose
Kai Jannusch (*Abstract Co-Author*) Nothing to Disclose
Matthias Boschheidgen (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the efficacy of multiparametric MRI (mpMRI) in men aged 45 years participating in a PC screening trial (PROBASE) based on their baseline prostate-specific antigen (PSA) levels.

**METHODS AND MATERIALS**

Men with confirmed PSA levels =3 ng/ml were offered mpMRI followed by MRI/transrectal ultrasound fusion biopsy (FBx) comprising targeted and systematic cores. mpMRI scans from the initial screening round for men randomized to immediate PSA testing in the PROBASE trial were evaluated by local readers and two reference radiologists (each with experience exceeding 10,000 prostate MRI examinations) blinded to histopathology. Comparison of local and reference Prostate Imaging-Data and Reporting System (PI-RADS) scores, along with calculation of sensitivity, negative predictive value (NPV), and accuracy for both readings at various cutoffs (PI-RADS 3 vs. 4).

**RESULTS**

Among 186 participants, 114 underwent mpMRI and FBx, with 47 (41%) diagnosed with PC, of whom 33 (29%) had clinically significant PC (csPC; International Society of Urological Pathology grade group =2). Interobserver reliability between local and reference PI-RADS scores was moderate (? = 0.41). At a PI-RADS 4 cutoff, reference reading demonstrated superior performance for csPC detection (sensitivity 79%, NPV 91%, accuracy 85%) compared to local reading (sensitivity 55%, NPV 80%, accuracy 68%). No PC cases were missed by reference reading at a PI-RADS <3 cutoff. Employing PI-RADS =4 as a biopsy cutoff could reduce negative biopsies by 68% through mpMRI and avoid detection of nonsignificant PC in 71% of cases.

**CONCLUSION**

Interpreting prostate MRI in a young screening cohort poses challenges. The accuracy of MRI for detecting csPC is significantly influenced by reader experience, suggesting the potential benefit of double reading. Further data are warranted before incorporating MRI into PC screening protocols for men aged 45 years.

**CLINICAL RELEVANCE/APPLICATION**

Our results indicate that MRI accuracy is moderate for men aged 45 years but can be increased by a second reading of the images by expert radiologists. For broad application of MRI in routine screening, double reading may be advisable.

## W2-SPGU-6 MRI FEATURES AND ONCOLOGICAL SURVEILLANCE IN PATIENTS DIAGNOSED WITH HIGH-RISK PROSTATE CANCER

Birte Valentin, MD (*Abstract Co-Author*) Nothing to Disclose
Kai Jannusch (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD (*Abstract Co-Author*) Nothing to Disclose
Peter Albers, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lars Schimmoeller, MD (*Abstract Co-Author*) Nothing to Disclose
Jan P. Radtke (*Abstract Co-Author*) Nothing to Disclose
Matthias Boschheidgen (*Presenter*) Nothing to Disclose

**PURPOSE**

This single-center cohort study aimed to analyze the multiparametric MRI (mpMRI) features of patients diagnosed with International Society of Urological Pathology (ISUP) grade group (GG) 4 or 5 prostate cancer (PC) and to investigate the correlation between MRI parameters and the occurrence of biochemical recurrence (BCR) following radical prostatectomy (RPE).

**METHODS AND MATERIALS**

Consecutive patients with mpMRI and ISUP GG 4 or 5 PC were retrospectively assessed. Clinical data, MR-guided biopsy results, and diagnostic mpMRI parameters were analyzed. A subgroup of patients who underwent RPE with follow-up was examined separately. Univariate and multivariate analyses were conducted to identify parameters associated with BCR after RPE.

**RESULTS**

A total of 145 patients (mean age 70 years, median PSA 10.9 ng/ml) were included. Ninety-nine percent had a PI-RADS classification of 4 or 5, 48% showed MRI T3 stage, and the median diameter of the MRI index lesion (IL) was 15 mm. The IL exhibited a median ADC value of 668 ×10-6 mm2/s and showed contrast enhancement in 94% of cases. Among patients with follow-up after RPE (n = 82; mean follow-up time 68 ± 27 months), MRI parameters such as the contact length of the IL to the pseudocapsule (LCC), MRI T3 stage, and IL localization differed significantly ($p < 0.05$). Higher PSAD and MRI T3 stage were identified as independent predictors for the risk of BCR when considering clinical, biopsy, and MRI parameters.

**CONCLUSION**

ISUP GG 4 or 5 PC presents distinct characteristics on mpMRI, which were detected on MRI in all cases. Furthermore, higher PSAD and MRI T3 stage were significant predictors for BCR following RPE.

**CLINICAL RELEVANCE/APPLICATION**

Elevated MRI staging parameters alongside higher PSAD levels appear to correlate with an increased risk of biochemical recurrence (BCR) during follow-up, potentially aiding clinicians in the early identification of these patients. Nevertheless, integrating MRI into standardized PSA screening protocols may mitigate the underdiagnosis of advanced prostate cancer stages in older men.

## W2-SPGU-7 MRI CHARACTERISTICS PREDICT RISK OF DISEASE PROGRESSION OR POSSIBLE SAMPLING ERROR IN PATIENTS WITH ISUP GRADE GROUP 1 PROSTATE CANCER

Birte Valentin, MD (*Abstract Co-Author*) Nothing to Disclose
Kai Jannusch (*Abstract Co-Author*) Nothing to Disclose
Gerald Antoch, MD (*Abstract Co-Author*) Nothing to Disclose
Peter Albers, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Lars Schimmoeller, MD (*Abstract Co-Author*) Nothing to Disclose
Matthias Boschheidgen (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to analyse multiparametric MRI (mpMRI) characteristics of patients diagnosed with ISUP grade group (GG) 1 prostate cancer (PC) on initial target plus systematic MRI/TRUS fusion-guided biopsy and investigate histopathological progression during follow-up.

**METHODS AND MATERIALS**

A retrospective single-centre cohort analysis was conducted on consecutive patients with mpMRI visible lesions (PI-RADS=3) and detection of ISUP-1-PC at the time of initial biopsy. The study assessed clinical, mpMRI, and histopathological parameters. Subcohorts were analysed with i) patients who had confirmed ISUP-1-PC and ii) patients who experienced histopathological upgrading to ISUP = 2 PC during follow-up either at re-biopsy or radical prostatectomy (RP).

**RESULTS**

A total of 156 patients (median age 65y) between March 2014 and August 2021 were included. Histopathological upgrading to ISUP = 2 was detected in 55% of patients during a median follow-up of 9.5 month (IQR 2.2-16.4). When comparing subgroups with an ISUP upgrade and sustained ISUP 1 PC, they differed significantly in contact length of the index lesion to the pseudocapsule, ADC value, PI-RADS category, and the MRI grading group (mGG) ($p<0.05$). In the ISUP GG = 2 subgroup, 91% of men had PI-RADS category 4 or 5 and 82% exhibited highest mGG (mGG3). At multivariate analysis, mGG was the only independent parameter for predicting ISUP=2-PC in these patients.

**CONCLUSION**

MRI reveals important information about PC aggressiveness and should be incorporated into clinical decision making when ISUP-1-PC is diagnosed. In cases of specific MRI characteristics adverse to the histopathology early re-biopsy might be considered.

**CLINICAL RELEVANCE/APPLICATION**

In cases with clear MRI characteristics for a csPC (e.g., mGG 3 and/or PI-RADS 5, or clear focal PI-RADS 4 lesions on MRI) and missed/negative targeted biopsy early re-biopsy (e.g., within 6 months) might be considered.

## W2-SPGU-8 MULTIPARAMETRIC FUNCTIONAL MRI OF THE KIDNEYS IN ONCOLOGIC PATIENTS UNDERGOING RADIONUCLIDE THERAPY - PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

Fritz Schick, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Thomas Kuestner, DIPLENG (*Abstract Co-Author*) Nothing to Disclose
Christian La Fougere (*Abstract Co-Author*) Nothing to Disclose

Isabelle Loster (*Abstract Co-Author*) Nothing to Disclose
Brigitte Gueckel (*Abstract Co-Author*) Nothing to Disclose
Petros Martirosian, PhD (*Abstract Co-Author*) Nothing to Disclose
Helmut Dittmann (*Abstract Co-Author*) Nothing to Disclose
Ferdinand F. Seith, MD, BSc (*Abstract Co-Author*) Nothing to Disclose
Cecilia Liang, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Radionuclide therapy uses intravenously injected radiopharmaceuticals for targeted radiotherapy. Radiation-induced nephropathy is observed in up to 10%, which is difficult to detect at early stages and can limit the treatment options in individual patients. Multiparametric renal MRI has proven great potential in assessing functional and structural changes in different kidney diseases. The aim of this study was to evaluate if multiparametric MRI can detect changes in renal parenchyma in patients undergoing radionuclide therapy to potentially detect radiation-induced nephropathy.

**METHODS AND MATERIALS**

In this prospective study, 23 patients with advanced prostate cancer (n=9) or neuroendocrine tumor (n=14) scheduled for radionuclide therapy were recruited between April 2021 and April 2022 (mean age 71 y/o, 6f). Depending on the number of treatment cycles, up to 4 MR examinations/patient were performed with following MR-protocol: arterial spin labeling (ASL), diffusion weighted imaging (DWI), blood oxygen-dependent (BOLD) imaging, T1 and T2 mapping. Blood tests for serum creatinine and glomerular filtration rate (GFR) as well as renal scintigraphy were performed regularly. The radiation dose of the kidneys at each cycle was calculated using SPECT/CT. Additionally, MRI scans with the same protocol were performed in a reference group with 10 healthy volunteers (mean age 31 y/o, 5f).

**RESULTS**

In total, 82 MR-Examinations were performed: n=4 in 7 patients, n=3 in 5 patients, n=2 in 8 patients and 10 volunteers, n=1 in 3 patients. The radiation dose was 3630 ± 1571 mGy per kidney. Compared to healthy volunteers, patients showed lower values in ASL and kidney volume at the first treatment cycle ($p<0.05$). In patients with a significant decrease of GFR under therapy (>10% decrease, n=8), significant differences were found in following MR-parameters in follow-up scans: ASL, DWI, BOLD, T1 mapping. No significant correlation could be found between MR parameters and renal scintigraphy or MR parameters and radiation dose per kidney. No significant difference could be found between patients with neuroendocrine tumor and prostate cancer.

**CONCLUSION**

In this prospective pilot study, changes in multiparametric renal MRI were observed in patients with decreasing kidney function under radionuclide therapy. This might indicate a possible role for MRI in detecting radiation-induced nephropathy. Studies with larger patient cohorts are needed to confirm these results.

**CLINICAL RELEVANCE/APPLICATION**

Multiparametric renal MRI could serve as an additional non-invasive diagnostic tool to detect and monitor treatment-induced nephropathy under oncologic therapy. This might help to adapt treatment regimens to preserve kidney function in these patients in the future.

## W2-SPHN-1 COMPARISON OF TWO DIFFERENT IODINE IMAGING GENERATED FROM DUAL-ENERGY COMPUTED TOMOGRAPHY (CT) AND SUBTRACTION FOR THE EVALUATION OF SINONASAL AND NASOPHARYNGEAL MALIGNANCIES

Tatsushi Kobayashi, MD (*Abstract Co-Author*) Support, Canon Medical Systems Corporation
Hirofumi Kuno, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tomoaki Sasaki, MD (*Abstract Co-Author*) Nothing to Disclose
Shioto Oda, MD (*Abstract Co-Author*) Nothing to Disclose
Yusuke Miyasaka, MD (*Abstract Co-Author*) Nothing to Disclose
Takashi Hiyama, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Iodine images generated by dual-energy CT (DECT) or subtraction improve tumor delineation. This study aimed to investigate the iodine imaging modality superior for evaluating the extent of sinonasal and nasopharyngeal malignancies.

### METHODS AND MATERIALS

We enrolled 28 consecutive patients (15 men and 13 women; median of age, 66 years) diagnosed with sinonasal or nasopharyngeal malignancies who underwent non-contrast and contrast-enhanced DECT. Iodine images derived from DECT (DEII) were generated using commercial software. Subtraction iodine imaging (SII) was performed by subtracting the pre- and post-contrast scans using multi-energy virtual monochromatic images (45-75 keV in increments of 5 keV). The contrast-to-noise ratio (CNR) of the SII was calculated for each energy to determine the optimal energy. Two blinded radiologists evaluated tumor delineation using a 5-point scale with DEII and SII created from the energy with the highest CNR. Subsequently, two radiologists assessed the presence of invasion in the orbit, skull base, intracranial and prevertebral muscles, and paranasal sinuses using a 5-point scale with magnetic resonance imaging (MRI) as the standard reference. The assessment was conducted three times: CCT alone, CCT-plus DEII, and CCT-plus SII. The delineation scores were evaluated using the Wilcoxon signed-rank test. A score of 3 or above was considered positive to assess the diagnostic performance. Area under the curve (AUC) analysis was performed, and the inter-rater agreement between the two scores was evaluated using the kappa coefficient.

### RESULTS

The CNR of SII was the highest at 65 keV. The tumor delineation score was significantly higher for the SII than for the DEII (median: 2 and 4, respectively; $p < 0.001$). The AUC for each subsite showed no significant differences ($p>0.05$) among the CCT, CCT-plus SII, and CCT-plus DEII. In the overall assessment, CCT-plus-SII exhibited significant diagnostic performance compared with CCT and CCT-plus-DEII (AUC: 0.918, 0.928, and 0.960, respectively; $p < 0.017$). The CCT-plus-SII showed higher sensitivity (86.36%, 86.57%, 94.03%; $p < 0.05$) and specificity (83.33%, 84.91%, 94.34%; $p = 0.08$) than the CCT or CCT-plus-DEII. The inter-rater agreement rates were all > 0.8, indicating high consistency.

### CONCLUSION

SII outperforms DEII in tumor delineation and has the potential to assess accurately the extent of sinonasal and nasopharyngeal malignancies.

### CLINICAL RELEVANCE/APPLICATION

In CCT, the evaluation of the extent of sinonasal and nasopharyngeal malignancies is impeded by bony structures ; however, incorporating SII has the potential to facilitate a more precise assessment of tumor extension.

## W2-SPHN-2 PARAMETERS BASED ON DUAL ENERGY CT FOR THE PREDICTION RESPONSE TO INDUCTION CHEMOTHERAPY IN NASOPHARYNGEAL CARCINOMA

Junhao Huang (*Abstract Co-Author*) Nothing to Disclose
Yao Huang (*Abstract Co-Author*) Nothing to Disclose
Jing Zhang (*Abstract Co-Author*) Nothing to Disclose
Jiuquan Zhang (*Abstract Co-Author*) Nothing to Disclose
Daihong Liu (*Abstract Co-Author*) Nothing to Disclose
Huanhuan Ren (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to investigate whether the parameters from dual-energy computed tomography (DECT) can predict the response to chemotherapy in nasopharyngeal carcinoma (NPC) based on the Response Evaluation Criteria in Solid Tumors guidelines.

### METHODS AND MATERIALS

In this retrospective study, a total of 61 NPC patients [male: 48 (76.9%); average age: 52.04 ± 10.87] underwent a non-enhanced and venous phase of contrast-enhanced DECT from March 2019 to November 2023. The DECT-derived iodine concentration, effective atomic number, and electron density of the tumour lesions in non-enhanced and venous phases were calculated to predict the response to induction chemotherapy in NPC. We employed univariate analysis and stepwise backward multivariate analysis to identify significant clinical variables and DECT parameters of chemotherapy response. Subsequently, we developed a clinical model incorporating significant clinical variables and a DECT model integrating relevant DECT parameters using logistic regression. A combined model was developed using independent predictors. ROC analysis, calibration curves, and decision curve analysis were performed to evaluate the performance of the three predictive models.

### RESULTS

Sixty-one patients (including 39 responders and 22 non-responders) were enrolled. The combined model achieved an AUC of 0.77 [95% confidence interval (CI), 0.69-0.79], which was higher than that of the DECT model [AUC, 0.71 (95% CI, 0.54-0.78)] or clinical model (Ki67) [AUC, 0.63 (95% CI, 0.58-0.72)].

### CONCLUSION

The proposed simple combined model using iodine concentration from DECT provided accurate response prediction to induction chemotherapy for patients with NPC and may be used to facilitate clinical decision-making.

### CLINICAL RELEVANCE/APPLICATION

The prediction treatment response to induction chemotherapy can be easily obtained for all patients with NPC by inputting two types of information into the model. They help in the decision-making for optimal personalized treatment.

## W2-SPHN-3 IMAGE QUALITY OF VIRTUAL MONOCHROMATIC AND MATERIAL DENSITY IODINE IMAGES FOR EVALUATION OF HEAD AND NECK NEOPLASMS USING DEEP LEARNING-BASED CT IMAGE RECONSTRUCTION - A RETROSPECTIVE OBSERVATIONAL STUDY

Ulf K. Teichgraeber, MD (*Abstract Co-Author*) Research Consultant, W. L. Gore & Associates, Inc;Research Consultant, Siemens AG;Research Consultant, CeloNova BioSciences, Inc ;Research Consultant, General Electric Company
Lucja Mlynska, MD (*Abstract Co-Author*) Nothing to Disclose
Florian Burckenmeyer (*Abstract Co-Author*) Nothing to Disclose
Stephanie Graeger, MD (*Abstract Co-Author*) Nothing to Disclose
Felix V. Guettler (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the quality of deep learning image reconstructed (DLIR) virtual monochromatic images (VMI) and material density (MD) iodine images from dual-energy computed tomography (DECT) for the evaluation of head and neck neoplasms with CT scans from a conventional single-energy protocol.

### METHODS AND MATERIALS

A total of 294 head and neck CT scans (98 VMIs operated at 60 keV, 102 MD iodine images, and 94 images from a 120 kVp single-energy CT (SECT) protocol) were retrospectively evaluated. VMIs and MD iodine images were generated using the Gemstone Spectral Imaging (GSI) mode using DLIR and metal artifact reduction (MAR) algorithms. SECT images were generated using adaptive statistical iterative reconstruction (ASIR-V). Images were scored by two independent readers on a 6-point Likert-type scale for overall image quality, vessel contrast, soft tissue contrast, noise texture, noise intensity, artifact reduction, and sharpness.

### RESULTS

Subjective overall image quality was rated as superior or excellent in 98% of DLIR-based MD iodine images and VMIs, but only in 55% of ASIR-V-based SECT images. For each individual quality criterion, image quality of VMIs and MD iodine images was rated as better than that of SECT images ($p < 0.001$ in each case). Noise texture and intensity were rated better in MD iodine images than in VMIs.

### CONCLUSION

DECT using both DLIR and MAR for the generation of VMIs and MD iodine images resulted in higher subjective quality of oncologic head and neck images than ASIR-V-based SECT. Noise reduction and noise texture were best achieved with DLIR-based MD iodine images.

### CLINICAL RELEVANCE/APPLICATION

(1) Dual-energy CT with deep learning reconstruction improved contrast and sharpness. (2) Material density iodine images reduced noise intensity and improved noise texture. (3) The metal artifact reduction algorithm ideally complemented the dual-energy CT.

## W2-SPHN-4 MACHINE LEARNING-BASED MRI RADIOMICS FOR PREDICTING THE LYMPH NODE METASTASIS IN LARYNGEAL SQUAMOUS CELL CARCINOMA

E.Dilara Topcuoglu (*Presenter*) Nothing to Disclose

### PURPOSE

Laryngeal squamous cell carcinoma (LSCC) is one of the most prevalent tumor types among head and neck malignancies. The tumor stage is affected by lymph node (LN) involvement and distant metastasis, which in turn affects treatment strategies. The objective of this study is to investigate whether machine learning (ML)-based radiomic feature analysis of magnetic resonance imaging (MRI) can predict local metastasis in treatment-naİve patients with LSCC.

### METHODS AND MATERIALS

Between January 2010 and December 2023, patients with histologically confirmed LSCC and pre-treatment MRI were included. Presence of LN metastases were detected either by surgery or by FDG-PET scan. Tumor segmentation was obtained from the contrast-enhanced T1-weigthed (CET1W) images and radiomic features were extracted using the 3D Slicer application (version 5.5.0). Age, sex, tumor involvement site and T stage were also noted as clinical features. The dataset was partitioned into an 80:20 ratio for training and testing purposes. In the training set, more than 80% correlating features were eliminated, and the top 5 features were selected using SelectKBest method with 5-fold cross-validation. Subsequently, three distinct ML algorithms—Random Forest (RF), XGBoost (XGB), and Logistic Regression (LR)—were trained. Each trained algorithm was tested on an unseen test set. The performance metrics were calculated for each classifier.

## RESULTS

A total of 65 patients met the inclusion criteria out of 123 patients (M/L: 58/7). 8515 radiomics features were identified. The top five selected features were ranked as Coarseness, ZoneEntropy, GrayLevelNonUniformity, Idn, and Sphericity. AUC in the training set were 0.84±0.13 for LR, 0.83±0.13 for RF, and 0.77±0.10 for XGB. There were no significant differences in AUCs between models in the training set (p=0.196, Friedman test). In the test set, the AUCs were 0.81, 0.88 and 0.93 for LR, RF, XGB, respectively. Cochran's Q test showed no significant differences between the test set predictions (p=0.368). When the optimal cut-off was selected for each classifier according to Youden's index, sensitivity and specificity were found as 66.7% and 57.1% for LR, 66.7% and 85.7% for XGB, 83.3% and 71.4% for RF, respectively.

## CONCLUSION

ML-based MRI radiomics feature analysis can predict lymph node metastasis in patients with LSCC, in this series.

## CLINICAL RELEVANCE/APPLICATION

The potential of the ML-based pre-treatment MRI radiomics in predicting LN metastases in patients with LSCC, were demonstrated in the current study. The findings can augment future studies using larger datasets with standardized methods that could lead to a clinical guidance tool for optimal treatment planning.

# W2-SPHN-5 THE NATURAL HISTORY AND RADIOLOGICAL CONTROL OF WARTHIN TUMOR: THE UTILITY OF DIFFERENT IMAGING METHODS

Regina L. Elia Gomes, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Alcivan Morais Filho, MD (*Abstract Co-Author*) Nothing to Disclose
Amr Kalander, MD (*Abstract Co-Author*) Nothing to Disclose
Cleiton A. Freitas, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the natural progression of Warthin Tumors (WT) in an outpatient clinic, focusing on using radiological analysis tools (ultrasonography, CT, MRI) to determine tumor growth rates. Additionally, the study aimed to provide epidemiological and clinical evaluations of WT patients.

## METHODS AND MATERIALS

This observational study included 191 WT patients confirmed by histological or cytological analysis over 14 years. Data were collected from digital records and imaging reports. Inclusion criteria were age 18 or older, confirmed WT diagnosis, and available imaging records. Exclusion criteria were age under 18, missing imaging records, incomplete data, or refusal to participate. Fifty-two patients were excluded. Patients needed at least two imaging exams with a 180-day interval. Epidemiological and clinical data were statistically analyzed using IBM SPSS Statistics® version 29.0.

## RESULTS

Epidemiological analysis revealed a higher prevalence among males (53%) and Caucasians (85%), with a mean age of 64 years and 81% being smokers. Among 139 patients, 84 underwent serial imaging exams, totaling 124 ultrasonographies, 73 CT scans, and 7 MRIs. One hundred tumors were identified because some patients had bilateral lesions. The Spearman test correlation between time and volumetric increase was statistically significant ($p < 0.001$) for the one hundred tumors analyzed, with a volumetric increase of 1.5 $cm^3$ per year, representing a growth rate of 26% per year and a mean volume doubling time of 3.8 years, and the correlation coefficient (R) was 0.265. However, tumor volume reduction occurred in 27% of cases, and two tumors disappeared. In the subgroup evaluated solely by ultrasonography (34 tumors), the Spearman test correlation was also statistically significant ($p = 0.034$), with 0.43 $cm^3$ yearly increase, 15% growth/year, and 6.5 years mean doubling time ($R = 0.386$).

## CONCLUSION

The evaluation of Warthin tumors' progression can be performed using various imaging methods. Ultrasonography was predominantly used. The choice of imaging method was individualized and not yet standardized, but the data obtained suggest a preference for axial methods when the lesions had shorter volumetric doubling times, while there’s a preference for ultrasonography when lesions grew slowly (higher Spearman test correlation coefficient).

## CLINICAL RELEVANCE/APPLICATION

These observations may contribute to developing a radiological management protocol for WT. Considering some lesions may spontaneously regress, understanding Warthin tumors' growth patterns can aid treatment decisions and improve patient outcomes.

## W2-SPIN-1 NEXT STEP TOWARD FOUNDATION MODELS IN RADIOLOGY? QUANTITATIVE ASSESSMENT OF GPT-4V(ISION)'S MULTIMODAL CAPABILITIES

Laura Kupke (*Abstract Co-Author*) Nothing to Disclose
Gerardo Napodano (*Abstract Co-Author*) Nothing to Disclose
Isabel Wiesinger (*Abstract Co-Author*) Nothing to Disclose
Christian R. Stroszczynski, MD (*Abstract Co-Author*) Nothing to Disclose
Anna Katharina Murtz (*Abstract Co-Author*) Nothing to Disclose
Andreas Schicho (*Abstract Co-Author*) Nothing to Disclose
Christina Wendl (*Abstract Co-Author*) Nothing to Disclose
Okka W. Hamer, MD (*Abstract Co-Author*) Speaker, Intermune, Inc;Speaker, AstraZeneca PLC
Quirin Strotzer, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The potential of Large Language Models in processing medical texts is well-established. With the recent introduction of GPT-4V(ision), a multimodal vision-language model that accepts image inputs, further progress in medical imaging is to be expected. We aimed to conduct a quantitative evaluation of GPT-4V's ability to interpret radiological imaging.

### METHODS AND MATERIALS

This IRB-approved, HIPAA-compliant retrospective study encompassed a mix of common pathologies and normal controls across neuroradiology, chest imaging, and musculoskeletal radiology. A representative image for each case (CT or MRI section, or radiograph as appropriate) was used to generate reports via the application programming interface. The factual correctness of free-text reports and the performance in detecting pathologies in binary classification tasks (25 positive and negative images for each pathology) were assessed using accuracy, sensitivity, specificity, F1-score, and AUC. Binary classification performance was compared to that of a first-year non-radiological resident.

### RESULTS

In total, 515 images were included in the analysis. GPT-4V correctly identified modality and body part in 100% and 99.2% of images, respectively. Accuracy in diagnosing common conditions when tasked to create a free-text report was mixed with results between 0% for pneumothorax (CT and X-ray) up to 90% for brain tumors at MRI. In binary classification tasks, GPT-4V showed overall poor performance with AUCs between 0.46 [95% confidence interval: 0.32, 0.62] for ischemic stroke and 0.64 [0.54, 0.74] for pneumonia compared to an aggregated AUC of 0.97 [0.95, 0.98] for the non-radiological resident reader across all tasks. The model showed a clear tendency towards overdiagnosing pathologies, with 86.5% and 67.7% false-positive rates for the free text and binary classification tasks, respectively.

### CONCLUSION

GPT-4V, in its current version, reliably determines modality and anatomical region from single images. It must not be used to detect, classify, or rule out pathologies. Although the model still lacks performance, the technology may serve as a basis for future foundation models in radiology (models that can perform a wide range of different tasks without requiring special training). Currently, possible use cases include detecting out-of-distribution data in upstream analyses, obviating the need to create task-specific data sets and models.

### CLINICAL RELEVANCE/APPLICATION

Medical professionals and patients alike need to be aware that GPT-4V(ision) (or ChatGPT) is not able to interpret radiological images accurately.

## W2-SPIN-2 AI-DRIVEN ULTRASOUND DETECTION OF OVARIAN CANCER THAT GENERALIZES: AN INTERNATIONAL MULTICENTRE VALIDATION STUDY

Robert Welch (*Abstract Co-Author*) Nothing to Disclose
Pawel Herman (*Abstract Co-Author*) Nothing to Disclose
Elisabeth Epstein (*Abstract Co-Author*) Nothing to Disclose
Kevin Smith, MSc, PhD (*Abstract Co-Author*) Nothing to Disclose
Emir Konuk (*Abstract Co-Author*) Nothing to Disclose
Adithya Raju Ganeshan (*Abstract Co-Author*) Nothing to Disclose
Filip Christiansen, MSc, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Ovarian lesions are common, and often incidentally detected. A critical shortage of expert ultrasound examiners has raised concerns of unnecessary interventions and delayed cancer diagnoses. Artificial intelligence (AI)-driven diagnostic support has the potential to alleviate this burden and improve patient outcomes. Deep learning has shown promising results in ovarian cancer detection in ultrasound images; however, external validation is lacking. We aimed to develop an AI model for ovarian cancer detection, evaluate its robustness and ability to generalize in a large multicenter setting, and assess an AI-assisted triage strategy.

**METHODS AND MATERIALS**

We retrospectively collected 17,119 ultrasound images from 3,652 women with an ovarian lesion (2,224 benign, 1,428 malignant) from 20 centers in eight countries. A total of 2,660 cases were reviewed by a minimum of seven expert and six non-expert examiners. For each center in turn, we trained a transformer-based model using data from the remaining 19 centers and compared the models' diagnostic performance with that of 33 expert and 33 non-expert examiners, considering sensitivity, specificity, F1 score, and area under the receiver operating characteristic curve (AUC). Furthermore, we retrospectively simulated and assessed how these models could be used in AI-assisted triage and compared it to current practice.

**RESULTS**

The models demonstrated robust performance across centers, ultrasound systems, and histological diagnoses, with an AUC of 0.93 (95% CI 0.92-0.94) and F1 score of 83.5% (95% CI 82.1-84.9) on cases from unseen centers. They outperformed all expert and non-expert examiners, with F1 scores of 79.4% (95% CI 77.9-80.9; ? = 4.1 [95% CI, 2.6-5.5, p lt; 0.0001]) and 74.1% (95% CI 72.4-75.8; ? = 9.4 [95% CI, 7.8-11.0, p lt; 0.0001]), respectively. The models were further shown to produce well-calibrated predictions. In a retrospective simulation, AI-assisted diagnostic support reduced the number of referrals to experts by 63%, from 52% of cases (current practice) to 19%, while significantly increasing the diagnostic performance (F1 77.2% vs 82.7%; ? = 5.5 [95% CI, 4.3-6.7, p lt; 0.0001]).

**CONCLUSION**

The models exhibit strong generalization and outperform expert examiners in diagnostic accuracy. The models' robust performance under comprehensive evaluation indicates that they are ready for prospective clinical implementation studies, bringing us closer to the adoption of AI-assisted diagnostics in clinical settings.

**CLINICAL RELEVANCE/APPLICATION**

AI-driven diagnostic support has the potential to alleviate the shortage of expert ultrasound examiners and improve patient outcomes by increasing diagnostic accuracy and optimizing clinical workflow.

## W2-SPIN-3 MULTITASK MODEL FOR OPPORTUNISTIC SCREENING FOR CORONARY ARTERY CALCIUM DEPOSITION USING CHEST RADIOGRAPHS

Jiwoong J. Jeong, BS (*Abstract Co-Author*) Nothing to Disclose
Imon Banerjee, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Coronary calcium (CAC) score estimates coronary artery disease (CAD) burden and is an established and effective tool for cardiovascular risk assessment. It may guide clinical decisions and preventative measures However, CAC scans are not universally available and are subject to expense, resource constraints and additional radiation exposure. Leveraging artificial intelligence (AI) on chest x-ray (CXR) images to estimate CAC may provide transformative potential for universal opportunistic screening.

**METHODS AND MATERIALS**

We designed a multitask learning (MTL) paradigm - MTL CAC fusion model by combining major adverse cardiovascular events (MACE)prediction as an auxiliary task that is clinically correlated with CAC to support the primary categorical CAC prediction task. MACE was defined as acute myocardial infarction, ischemic stroke, hospitalization due to heart failure, and cardiovascular mortality. We trained a ResNeXt101 backbone with the MTL strategy that uses shared CNN for both tasks. Tabular data including patient demographics (age, gender) and X-ray manufacturer category were injected using a decision level fusion strategy. Model Performance was evaluated by area under the receiver operative curve (AUROC).

**RESULTS**

We evaluated the MTL CAC fusion model on a hold-out internal test set from Mayo clinic (n=341) and independent external dataset from Emory - EUH (n=386) and Taiwan - VGHTPE (n=499). On the internal testset, the model achieved 0.72 and 0.66 AUROC for the =100 CAC and 0 CAC respectively (which are clinically significant categories). The performance was suboptimal for the intermediate 0-99 CAC category (0.58 AUROC), with similar trend observed for the EUH and VGHTPE external datasets. We also evaluated the MTL fusion model performance for binary classification tasks to differentiate high CAC candidates and experimented with both '0 vs 100+' and '0 vs 400+'. The model demonstrated high performance (0.84 average AUROC) for differentiating high from low CAD burden using only CXR imaging and achieved fair performance (0.75 average AUROC) for moderate category on both internal and external datasets.

**CONCLUSION**

This novel and externally validated CXR-based AI model for opportunistic CAC screening can robustly identify patients with undiagnosed CAD.

**CLINICAL RELEVANCE/APPLICATION**

It may provide clinicians a simple, accessible and cost-efficient tool for opportunistic risk stratification of a wider population, ultimately facilitating preventative measures, timely interventions and improved patient outcomes for CAD.

## W2-SPIN-5 INTERPRETABLE CONVOLUTIONAL NEURAL NETWORK FOR PREDICTING MRI PROTON DENSITY FAT FRACTION FROM LIVER ULTRASOUND IMAGES: AN ATTENTION-BASED MULTIPLE INSTANCE LEARNING APPROACH

Neha Antil, MD (*Abstract Co-Author*) Nothing to Disclose
Luyao Shen, MD (*Abstract Co-Author*) Nothing to Disclose

Krishna Bhatraju (*Abstract Co-Author*) Nothing to Disclose
Thodsawit Tiyarattanachai (*Presenter*) Nothing to Disclose

**PURPOSE**

Hepatic steatosis is affecting 32.4% of the global population. In this work, we developed a convolutional neural network (CNN) using an Attention-based Multiple Instance Learning (MIL) approach, for prediction of MRI Proton Density Fat Fraction (MRI-PDFF) from B-mode liver ultrasound images. By using the attention mechanism, we demonstrated interpretability of the model and its capability in identifying key images that contribute to the predictions.

**METHODS AND MATERIALS**

A total of 8429 B-mode liver ultrasound images from 401 patients were included. Each patient has a corresponding ground truth MRI-PDFF value. The dataset was randomly split into training, validation and test sets in a 7:1:2 ratio. The Attention-based MIL CNN model is composed of two main components: a CNN backbone which extracts image-level features, and an attention module which aggregates image-level predictions into a patient-level prediction. The primary evaluation was regression of MRI-PDFF values. In addition, MRI-PDFF cutoffs were applied to evaluate performance in classifying steatosis grades: S0 vs =S1, =S1 vs =S2, and =S2 vs S3. We demonstrated interpretability of the model by visualizing ultrasound images along with corresponding attention weights.

**RESULTS**

On the test set, the models with and without attention module achieved Root mean square error (RMSE) of 5.72 vs 6.01, coefficient of determination (R2) of 0.684 vs 0.651, and Pearson correlation coefficient of 0.831 vs 0.828, respectively, in regression of MRI-PDFF values. After applying steatosis grade cutoffs and using the higher steatosis grades as the positive class, the models with and without attention module achieved sensitivities of 95.1% (95%CI: 88.5 - 100.0) vs 90.2% (81.2 - 99.3) and specificities of 79.5% (63.7 - 90.1) vs 92.3% (83.9 - 100.0) for classifying S0 vs =S1; sensitivities of 81.2% (62.1 - 100.0) vs 68.8% (46.0 - 91.5) and specificities of 87.5% (79.4 - 95.6) vs 93.8% (87.8 - 99.7) for classifying =S1 vs =S2; sensitivities of 70.0% (41.6 - 98.4) vs 30.0% (1.6 - 58.4) and specificities of 91.4% (84.9 - 98.0) vs 97.1% (93.2 - 100.0) for classifying =S2 vs S3. Examples of images to which the model assigned high attention weights include images with significant visible portion of the liver, images comparing echogenicity of the liver and kidney, and images visualizing the diaphragm.

**CONCLUSION**

The attention-based MIL approach could improve performance of CNN in predicting MRI-PDFF values from liver ultrasound images. The attention module enhanced interpretability as the model could identify key images in the steatosis assessment.

**CLINICAL RELEVANCE/APPLICATION**

Our motivation was to develop an approach that aligns with how radiologists assess hepatic steatosis on ultrasound examinations in practice.

## W2-SPIN-6 A MULTI-TASK DEEP-LEARNING MODEL ON CECT TO SEGMENT AND CLASSIFY ADRENAL NODULES AS LIPID-POOR ADENOMA AND NODULAR HYPERPLASIA: A MULTI-CENTER STUDY

Zhengyu Jin, MD (*Abstract Co-Author*) Nothing to Disclose
Zhong Zhang (*Abstract Co-Author*) Nothing to Disclose
Xiaopeng Guo (*Abstract Co-Author*) Nothing to Disclose
Hao Sun, MD (*Abstract Co-Author*) Nothing to Disclose
Gu Mu Yang Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Xin Bai III, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Differentiating between lipid-poor adrenal adenoma (LPA) and nodular hyperplasia is challenging on contrast-enhanced CT (CECT) images yet it is critical for determining the appropriate treatment approach. The study aimed to segment and classify adrenal nodules on CECT by developing a multi-task deep-learning model, and to evaluate its performance.

**METHODS AND MATERIALS**

This retrospective study enrolled 164 patients from two institutions (median age, 51 years; 93 women). They were divided into training (83 patients with LPA and 45 patients with nodular hyperplasia) and external test datasets (20 patients with LPA and 16 patients with nodular hyperplasia). All cases were pathologically and clinically confirmed. Adrenal glands and nodules were manually delineated by experienced radiologists on the portal-venous phase CT images. We proposed the Mamba-USeg framework, based on State Space Models (SSMs) and specifically designed to improve the modeling of long-range dependencies among pixels. Deep learning segmentation and classification models were developed on the training dataset and evaluated on the external test dataset. Segmentation performance was evaluated with the Dice similarity coefficient (DSC) and classification performance with sensitivity and specificity.

**RESULTS**

The model achieved a DSC of 0.855 for segmenting adrenal glands (interquartile range [IQR]: 0.809-0.932). The model for segmenting adrenal nodules yielded an average DSC of 0.869 (IQR: 0.827-0.938) for LPA and 0.863 (IQR: 0.781-0.943) for nodular hyperplasia. The classification sensitivity and specificity for LPA were 95.3% (95% confidence interval [CI]: 91.3%-96.6%) and 92.7% (95% CI: 91.9%-93.6%), respectively. For nodular hyperplasia, sensitivity was 94.2% (95% CI: 89.7%-97.7%) and specificity was 91.5% (95% CI: 90.4%-92.4%). The novel model's average DSC for LPA and nodular hyperplasia outperformed previous frameworks, MultiResUNet (LPA: 0.831 [IQR: 0.767-0.929], nodular hyperplasia: 0.847 [IQR: 0.772-0.935]) (P lt; 0.01) and CPFNet (LPA: 0.850, [IQR: 0.801-0.936]), nodular hyperplasia: 0.848 [IQR: 0.753-0.939]) (P lt; 0.05).

**CONCLUSION**

A multi-task deep-learning model comprising segmentation and classification of adrenal nodules can effectively and accurately discriminate between LPA and nodule hyperplasia on CECT images.

**CLINICAL RELEVANCE/APPLICATION**

The proposed model provides a reliable approach for the differential diagnosis of adrenal LPA and nodular hyperplasia, offers valuable guidance for clinical decision-making and reduces unnecessary surgeries for patients with hyperplasia.

## W2-SPIN-7 AUTOMATION OF CEREBRAL BLOOD FLOW MAPPING FROM CTA IMAGES WITH NNUNET

Abhinav Changa, MD (*Abstract Co-Author*) Nothing to Disclose
Jacky Cheung (*Abstract Co-Author*) Nothing to Disclose
Hayit Greenspan (*Abstract Co-Author*) Nothing to Disclose
Andy Ho Wing Chan (*Abstract Co-Author*) Nothing to Disclose

Benjamin Kummer (*Abstract Co-Author*) Nothing to Disclose
Nicholas J. Primiano, MD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Endovascular thrombectomy (EVT) is the standard of care for the treatment of patients presenting with acute ischemic stroke (AIS) due to large-vessel occlusions (LVO). Although CT perfusion (CTP) can aid patient selection for EVT, this imaging modality adds time to AIS care processes and can therefore cause patient harm. To potentially accelerate patient selection for EVT, we developed an AI model to directly generate cerebral blood flow (CBF maps) from head and neck CT angiography (CTA) images, which are more commonly obtained in standard stroke workflows.

**METHODS AND MATERIALS**

We identified patients who presented to our academic medical center between May 2019 and June 2021 with AIS from LVO and underwent CTA and CTP within a 30-minute time window. Using the raw CTA and CTP images from our institutional radiology imaging database, we manually extracted CBF volumes generated by a third-party post-processing algorithm (Viz.ai) as labels. We used a segmentation package (TotalSegmentator) to isolate brain structures from CTA images and co-registered CTA slices to corresponding CTP slices. We then trained a 3-dimensional, convolutional neural network (nnU-Net) against our labeled dataset to predict CBF maps directly from co-registered CTA mages. Ground-truth CBF maps were stratified into 5 intensity ranges.

**RESULTS**

We identified 106 patients that met study criteria. The nnU-Net model achieved a root mean square error of 0.24(±0.03) and a DSC of 0.45(±0.04).

**CONCLUSION**

Using a deep learning, cross-modality approach, we developed a segmentation model that demonstrated moderate performance in segmenting CBF maps directly from head and neck CTA images. Future work will aim to predict cerebral blood volume and time-to-maximum maps using a generative framework.

**CLINICAL RELEVANCE/APPLICATION**

Rapid generation of CBF maps from CTAs may facilitate earlier interventions in stroke care, enhancing triage and treatment decisions. This tool could be used to stratify patients where perfusion techniques or neurological expertise are unavailable, or to alert clinicians to occult regions of "at-risk" tissue in motion-degraded CTP studies, representing a step toward improved patient outcomes.

## W2-SPIN-8 ASSESSMENT OF A WEB-BASED TOOL FOR PRECISION MEASUREMENT OF ACETABULAR COMPONENT ORIENTATION IN TOTAL HIP ARTHROPLASTY

Christine Yoon (*Presenter*) Nothing to Disclose

**PURPOSE**

Hip dislocation after total hip arthroplasty can be linked to the orientation of acetabular component placement, characterized by acetabular inclination and anteversion angles obtained from pelvic radiographs. We introduce a novel web tool to streamline the subjective and lengthy process of manual measurement. This tool assists in collecting data that will be used to train an AI model for automation.

**METHODS AND MATERIALS**

One board-certified orthopedic surgeon annotated anteroposterior radiographs of 80 patients who underwent unilateral hip arthroplasty from 1/12/2017 to 12/18/2017. Manual and web tool measurements included abduction angle (degrees), S/TL ratio, and Liaw's anteversion angle (degrees). One board-certified orthopedic surgeon used the web tool to mark 6 points on the radiographs: each end of the teardrop line, each end of the horizontal diameter of the acetabular cup, 1 point along the circumference of the acetabular cup, and 1 point along the acetabular head. A line connecting the teardrop line, an ellipse around the acetabular cup perimeter, and an ellipse around the coronal view of the acetabulum were automatically mapped to measure the abduction angle and S/TL ratio, which were inputted into Liaw's formula to calculate acetabular angle and safe zone determination (Fig. 1). Results were obtained in under 10 seconds per radiograph. Differences between manual and web tool measurements were compared using a paired t-test. $P<0.05$ was considered statistically significant.

**RESULTS**

There were no statistically significant differences in abduction angle (43.59±5.97 annotated vs 42.82±5.49 web tool, p=0.251), anteversion angle (20.75±7.81 vs 22.80±10.79, p=0.080), and S/TL ratio (0.43±0.15 vs 0.44±0.16, p=0.456) between annotated and web tool measurements.

**CONCLUSION**

Preliminary results show the web tool is accurate compared to manual annotation. This tool improves efficiency of angle measurement for intraoperative use and data collection. Future work includes training AI models for automatic angle detection, safe zone determination, and adapting to mobile devices. The web tool may contribute to other areas of radiology where geometry bears relevance to outcomes.

**CLINICAL RELEVANCE/APPLICATION**

Our tool refines hip arthroplasty by enhancing the precision of acetabular measurements, aiding surgical planning, and reducing complications.

## W2-SPIR-1 CHARACTERIZING PRE-ABLATION PROTEOMIC SIGNATURES TO ENHANCE THERMAL ABLATION EFFICACY IN HEPATOCELLULAR CARCINOMA

Jason Chiang, MD,PhD (*Abstract Co-Author*) Consultant, Intuitive Surgical, Inc;Equipment support, Johnson & Johnson
Steven S. Raman, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson;Consultant, Bayer AG;Consultant, Merck & Co, Inc;Consultant, Amgen Inc;Consultant, Profound Medical Inc
Tu Nguyen (*Presenter*) Nothing to Disclose

### PURPOSE

Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer death worldwide. Thermal ablation has emerged as the standard of care for non-surgical HCC patients because of its similar efficacy to resection with fewer complications. However, more than 50% of ablation patients will have recurrence within 5 years, necessitating additional treatments. Recurrence rates are hypothesized to be related to underlying HCC biology. The goal of this study was to analyze the proteomic profiles of pre-ablation HCC biopsy samples and correlate proteomic changes to post-ablation outcomes. Proteomic markers of ablation resistance were then validated in an in vitro model.

### METHODS AND MATERIALS

Clinical HCC biopsy samples were obtained prior to microwave ablation (UCLA IRB#23-000131). Recurrence rates in ablation responders (n=12) versus non-responders (n=12) were then tracked for two years. Differential proteomic profiles acquired through LC-MS mass spectrometry were compared using biopsy samples between the responders and non-responders. The identified protein markers were confirmed with internally validated ablation-responsive and ablation-resistant HCC cells (SNU-423 and HepG2/C3a, respectively) via Western Blotting. Furthermore, a pharmacological approach was employed to demonstrate that these proteomic changes directly modulate thermal resistance in these cell lines.

### RESULTS

Proteomic analysis of HCC biopsy samples revealed that galectin-class proteins were upregulated two-fold in ablation non-responders versus responders ($p < 0.001$). Additionally, galectin-class proteins were found to be markedly upregulated in thermally-resistant HepG2/C3a. Subsequently, in-vitro studies using selective galectin inhibitors to target galectin proteins increased thermal sensitivity in thermally-resistant HepG2/C3a.

### CONCLUSION

This study revealed a key correlation between elevation of galectin-class proteins and thermal resistance in HCC biopsy samples. Moreover, galectin-class proteins were found to play a modulatory role in thermal resistance. These findings can be leveraged to develop novel galectin-based therapies to increase the efficacy of thermal ablation in HCC patients.

### CLINICAL RELEVANCE/APPLICATION

This project identified proteomic signatures that contribute to HCC resistance following ablation. These biomarkers can be used to determine the optimal windows of vulnerability to maximize the success of ablation and minimize the recurrence rates. They also hold immense promise for personalizing ablation therapy based on individual proteomic profiles, ultimately improving outcomes for HCC patients.

## W2-SPIR-2 CUSTOMIZED WHOLE-GLAND MR-GUIDED TRANSURETHRAL ULTRASOUND ABLATION (TULSA) FOR TREATMENT OF LOCALIZED PROSTATE CANCER: A SINGLE CENTRE RETROSPECTIVE ANALYSIS OF 73 PATIENTS

Roland Rose (*Abstract Co-Author*) Nothing to Disclose
Amanda Beserra (*Abstract Co-Author*) Senior Clinical Scientist, Profound Medical
Busch Kathy (*Abstract Co-Author*) Nothing to Disclose
Joseph J. Busch, MD (*Presenter*) Nothing to Disclose

### PURPOSE

MRI-guided transurethral ultrasound ablation (TULSA) is an interventional MRI procedure for treating prostate cancer that aims to reduce the sexual and urinary impacts of surgery. Regulatory studies applied whole-gland ablation without sparing of neurovascular bundles (NVB) or ejaculatory ducts (EJD). We report the real-world safety and efficacy of customized whole-gland TULSA (whole-gland ablation sparing the NVBs and/or EJD to optimize functional outcomes).

### METHODS AND MATERIALS

A retrospective analysis was performed in PCa patients with>=3-month follow-up after customized whole-gland TULSA at our clinic. NVB/EJD sparing was defined by patient preference and disease factors, using intraoperative DWI, ADC, and T2w imaging. Patients were followed daily for 2 weeks, PSA 3m, with MRI, IPSS, IIEF at 6-9 months. Radiologic recurrence was defined as PI-RR>=4 on mpMRI, or positive PSMA-PET after PI-RR=3. Biochemical recurrence (BCR) was defined as nadir + 2 ng/ml.

### RESULTS

73 patients were identified (62 primary PCa, 11 salvage). Median (IQR) age and follow-up duration were 63 (IQR 59-69) years and 11 (9-15) months. The proportions of men with primary GG 1-5 PCa were: 15%, 49%, 19%, 9%, 8%. Aside from 2 men with GG1 disease, all were MRI visible. Whole-gland ablation with no sparing was performed in 23% of men, uni/bilateral NVB sparing in 19%/45%, NVB+EJD sparing in 33%; the extreme apex was targeted in 36%. Prostate volume was 46cc (33-62, range 16-160); 99% (97-99%) of the target volume achieved lethal thermal dose >=240CEM43. PSA nadir after primary treatment was 0.7 (0.3-1.1) ng/mL. 84% (48/57) are free of radiologic and biochemical recurrence. 1/9 experienced BCR with no imaging follow-up available. 4/8 radiologic recurrences are BCR-free and remain on surveillance, 1/8 underwent salvage TULSA. 6/8 had residual disease near EJD sparing, which we have since discontinued. Failures occurred when either MRI thermometry or ultrasound propagation was compromised by significant calcifications or motion. Grade 1-2 adverse events in 8 men (LUTS, mild hematuria, bladder spasms) resolved within 4 weeks with oral medication. Two men had Grade 3 events requiring endoscopic intervention (retention/obstruction). Urinary symptoms (IPSS) were stable. Two men incurred early post-op urine leakage, 100% are pad-free beyond 4 months. 88% maintained erection firmness sufficient for penetration (IIEF Q2>=2).

### CONCLUSION

Customized whole-gland TULSA demonstrates promising real-world safety and efficacy. Continued refinement of patient selection and technique may further enhance prostate cancer treatment with TULSA.

### CLINICAL RELEVANCE/APPLICATION

Customized whole-gland TULSA balances effective disease control with favorable functional and safety outcomes.

## W2-SPIR-3 AI-BASED METAL ARTIFACT REDUCTION ALGORITHM IN SPECTRAL CT IMAGES FOR INTERVENTIONAL ONCOLOGY (SPECTRAL MARIO): READER-BASED ASSESSMENT OF MODEL PERFORMANCE ACROSS VIRTUAL MONOENERGETIC IMAGES

Daniel A. Adamo, MD (*Abstract Co-Author*) Nothing to Disclose
Andrea Ferrero, PhD (*Abstract Co-Author*) Nothing to Disclose
Rebecca Hibbert, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Wenchao Cao, PhD (*Abstract Co-Author*) Nothing to Disclose
Ahmad Parvinian, MD (*Abstract Co-Author*) Nothing to Disclose
Andrew Missert, PhD (*Abstract Co-Author*) Nothing to Disclose
Christopher P. Favazza, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the performance of a deep convolution neural network framework for metal artifact reduction in interventional oncology spectral CT images, spectral MARIO, to reduce metal artifact from ablation probes and assess its potential to enable low keV imaging intraprocedurally during CT-guided ablations.

### METHODS AND MATERIALS

Image domain data from phantom scans containing multiple configurations of ablation probes and pre-ablation patient planning images were used to generate a library of precisely registered spectral basis images (photoelectric and Compton scattering images, Spectral CT7500, Philips Healthcare) with and without metal artifacts. A modified U-Net architecture was trained using 100,000 128x128 pixel image patches derived from this library, with the photoelectric and Compton components stacked in the channel dimension. Spectral MARIO was then applied to 15 previously unseen patient images acquired during the 6-minute timepoint of a freeze cycle during renal cryoablation procedures. From the original and spectral MARIO basis images, 70 keV Virtual Monoenergetic Images (VMI) were generated. Three experienced, board-certified interventional radiologists performed an independent blinded review of the 15 image sets both with and without spectral MARIO. In this evaluation, the reader first scored the metal artifact in a 70 keV VMI on a 1(worst)-5(best) Likert scale. Then the reader adjusted the VMI energy level for each of the original and the spectral MARIO data to the lowest value in which the artifact rating was above average diagnostic quality (Likert Score = 4) A two-tailed Wilcoxon test was applied to the average of the paired original and spectral MARIO reader results.

### RESULTS

Compared to original images, spectral MARIO visually demonstrated substantial metal artifact reduction, particularly at lower VMI energy levels. The median artifact score at 70 keV improved from 3 to 4 ($p<0.001$) with spectral MARIO. The minimum keV required to achieve an above average diagnostic quality decreased from 112 keV (86-167) for the original data to 67 keV (44-108) with spectral MARIO ($p<0.001$).

### CONCLUSION

The spectral MARIO was effectively trained and applied to spectral basis images, which produced metal artifact reduction across various monoenergetic energy levels. Further, spectral MARIO was demonstrated to effectively reduce the monoenergetic energy level across all patient images.

### CLINICAL RELEVANCE/APPLICATION

Spectral MARIO significantly reduced metal artifact in virtual monoenergetic images (VMI)—especially at lower energy levels. These results suggest that spectral MARIO could be leveraged to enable low monoenergetic imaging, thus providing higher soft tissue and iodinated contrast in proximity metal ablation probes.

## W2-SPIR-4 IRREVERSIBLE ELECTROPORATION COMBINED WITH IMMUNOTHERAPY VERSUS IRREVERSIBLE ELECTROPORATION ALONE FOR LOCALLY ADVANCED PANCREATIC CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

Miriana E. Mariussi, MD (*Abstract Co-Author*) Nothing to Disclose
Stephan Altmayer, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Rodrigo Gobbo (*Abstract Co-Author*) Nothing to Disclose
Sofia D. Gambetta I, MD, MD (*Abstract Co-Author*) Nothing to Disclose

Laura Costa De Oliveira Lima (*Abstract Co-Author*) Nothing to Disclose

Giovanni B. Torri, MD (*Abstract Co-Author*) Nothing to Disclose
Luiza G. Schmitt, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

We performed a systematic review and meta-analysis to evaluate the safety and survival benefits of percutaneous irreversible electroporation (IRE) combined with immunotherapy compared to irreversible electroporation alone in patients with locally advanced pancreatic cancer (LAPC).

**METHODS AND MATERIALS**

We systematically searched Embase, Cochrane Central Register of Controlled Trials, and Pubmed from inception to January 10th of 2024 for studies published with the following medical subject heading terms: "irreversible electroporation", "immunotherapy" and "locally advanced pancreatic cancer". In addition, the references of included studies and systematic reviews were evaluated for additional studies. The outcomes of interest were progression-free survival (PFS), overall survival (OS), and adverse events. The PFS and OS were assessed using pooled hazard ratios (HR), while we used odds ratio (OR) for the adverse events.

**RESULTS**

Our pooled analysis included four studies (3 clinical trials and 1 observational study) with 310 patients. IRE combined with immunotherapy significantly prolonged PFS compared to IRE alone (HR: 0.56; 95% CI 0.39 - 0.80; $p < 0.002$; $I^2$: 9.65%). Additionally, patients on IRE plus immunotherapy achieved a greater OS compared to IRE alone (HR = 0.52; 95% CI 0.37 - 0.73; $p < 0.001$; $I^2$: 0%). There was no significant difference in the occurrence of adverse events such as nausea and vomiting (OR = 2.80; 95% CI 0.81 - 9.68; $p = 0.10$; $I^2$: 54%) and gastroparesis (OR = 0.88; 95% CI 0.23 - 3.40; $p = 0.86$; $I^2$: 0%) between the groups.

**CONCLUSION**

The combination of percutaneous irreversible electroporation with systemic immunotherapy has been shown to be an effective and safe local treatment method for pancreatic malignancies. The findings of this meta-analysis provide supporting evidence for the clinical utility of irreversible electroporation combined with immunotherapy in the management of advanced pancreatic cancer.

**CLINICAL RELEVANCE/APPLICATION**

Locally advanced pancreatic cancer includes tumors staged as III and IV, which are often unresectable due to vascular involvement, leaving patients with limited curative options. Palliative chemotherapy regimens have only moderately improved survival rates. IRE, which has demonstrated immunomodulatory effects and provides a safe non-thermal approach to ablating pancreatic tumors, can be further enhanced when combined with immunotherapy.

## W2-SPIR-5 INCREASED VOXEL-BASED Y90 RADIOEMBOLIZATION DOSE TO HEPATOCELLULAR CARCINOMA IMPROVES IMAGING RESPONSE

**PURPOSE**

To assess the correlation between radioembolization tumor dose and imaging response in hepatocellular carcinoma (HCC) treated with radioembolization.

**METHODS AND MATERIALS**

A retrospective single-institution study was conducted on treatment-naÏve HCC patients who underwent transarterial radioembolization (TARE) from November 2017 to September 2020. Dose-volume histograms (DVH) were generated from post-Y90 single photon emission computed tomography. Cross-sectional imaging was performed at 3 and 6 months post-radioembolization and reviewed by three blinded abdominal radiologists.

**RESULTS**

Forty-one eligible patients underwent radioembolization, with a median age of 67 years (range: 41-84), including 11 females. At 3 months, 23 (56%) patients showed complete response (CR), 9 (22%) had partial response (PR), and 8 (20%) exhibited stable disease (SD) according to mRECIST criteria. By 6 months, these numbers changed to 19 (76%) CR, 5 (20%) PR, and 1 (4%) progressive disease (PD). DVH analysis revealed that increased dose to various tumor volumes significantly correlated with complete imaging response at 3 months ($p < 0.05$ for all). Receiver operating characteristic (ROC) analysis identified a dose threshold of 687 Gy to 95% of the tumor volume with the highest area under the curve (AUC) of 0.86 (95% CI: 0.73-0.95) for predicting complete response by both mRECIST and LI-RADS criteria.

**CONCLUSION**

Voxel-based dosimetry indicates several dose thresholds predictive of complete imaging response using both mRECIST and LI-RADS criteria. A dose threshold of 687 Gy to at least 95% of the tumor volume demonstrated the highest accuracy in predicting complete response according to both criteria.

**CLINICAL RELEVANCE/APPLICATION**

Understanding the correlation between voxel-based tumor dose and imaging response to radioembolization in HCC can aid in treatment planning and predicting patient outcomes. This knowledge may facilitate personalized treatment approaches and improve the efficacy of radioembolization in managing HCC patients.

## W2-SPIR-6 TACKLING CERVICAL METASTASES FROM THYROID CARCINOMA: A PROSPECTIVE STUDY WITH CRYOABLATION, LASER OR RADIOFREQUENCY ABLATION UNDER ULTRASOUND GUIDANCE

Ana Amelia F. Hoff, PhD (*Abstract Co-Author*) Nothing to Disclose
Pedro Naime B. Araujo I, MD (*Abstract Co-Author*) Nothing to Disclose
Marco Aurelio V. Kulcsar, PhD,MD (*Abstract Co-Author*) Nothing to Disclose
Maria Cristina Chammas, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Ricardo M. Freitas, MD, PhD (*Presenter*) Research Grant, Varian Medical Systems, Inc

### PURPOSE

To evaluate:a. Safety and efficacy of thermal ablation of cervical metastases from thyroid carcinomab. Best response to thermal ablation defined as lymph node reduction or volume stabilityc. Tumor marker response after ablationd. Complications, side effects and tolerability differences among laser (LA), radiofrequency (RF) or cryoablation (CA)

### METHODS AND MATERIALS

This prospective clinical trial obtained IRB approval. All patients provided informed consent, including those with differentiated or medullary thyroid carcinoma confirmed by fine-needle aspiration biopsy. Ablation techniques (LA, RF, CA) were randomly assigned to participants. Eligible subjects presented with up to six concurrent lesions larger than 0.8 cm diameter. US examinations were conducted at baseline, 6, 12, and 24-months post-treatment. Data was systematically collected in a web-based tool. Evaluation criteria included changes in tumor volume, rates of technical success, complications, tumor marker response and need for additional surgery.

### RESULTS

Seventy-two patients (n=145 tumors) were evaluated. Mean age was 67.8±15.1 years, 54 (75%) being females. Technical success rate reached 100%. Baseline mean and standard deviation lymph node volumes (cc) for each ablation group were as follows: LA, 0.83±1.14 (range: 0.15-4.34); RF, 2.49±6.9 (range: 0.1-25.6); CA, 1.28±2.12 (range: 0.12-8.08). Significant lymph node volume reduction was observed at 6, 12, and 24 months up to 97.9% of volume reduction ratio (all $P < 0.001$). No instances of volume regrowth were detected. Absolute decrease of tumor markers was noted. Major complication rate was 1.4% (n=1): one vocal cord palsy, leading to bronchopneumonia, prolonged hospitalization and eventual fatality. Minor complications rates were 9.2% (n=7): 1.4% (n=1) of cutaneous fistulae with brief spontaneous resolution, and 7.9% (n=6) of transient vocal cord palsy with complete recovery after one month. Only 2.6% (n=2) patients were treated twice for tumor persistence. None of the patients required additional neck surgery due to ablation failure over time. All patients with new recurrent cervical metastases (n= 18, 25%) were treated by additional ablation sessions.

### CONCLUSION

a. Both thermal ablation modalities (LA, RF, CA) were feasible, effective and safe in well selected patients with cervical metastases from thyroid carcinoma.b. Adequate local control and overall tumor marker reduction was achieved.c. No significant difference among the thermal ablation methods in terms of complications, side effects and tolerability were observed.

### CLINICAL RELEVANCE/APPLICATION

??Thermal ablation is a feasible, safe, and effective alternative therapy for the treatment of cervical lymph node metastases from thyroid carcinoma.

## W2-SPIR-7 RADIOLOGY-PATHOLOGY EVALUATION OF HISTOTRIPSY-TREATED SWINE LIVERS DEMONSTRATES HIGH CORRELATION BETWEEN IMAGING AND GROSS PATHOLOGY

Jim K. White, BS (*Abstract Co-Author*) Nothing to Disclose
Edwarda Golden, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Histotripsy is a non-invasive, non-thermal focused ultrasound treatment modality that was recently FDA approved for the focal destruction of liver tumors. As clinical adoption accelerates, understanding the post-treatment imaging findings is imperative. This study evaluates the correlation between contrast-enhanced MRI images and gross pathology of histotripsy treatment zones.

### METHODS AND MATERIALS

Eleven histotripsy treatment zones were created in 10 swine livers using a clinical histotripsy unit (VortxRx, Histosonics, Inc., Plymouth, MN). All animals underwent MRI within 1 hour of treatment followed by euthanasia within 1 hour of imaging. Treated liver was fixed in formalin and subsequently sliced through the center of the treatment zone for gross pathologic analysis. Portal venous phase MRI series were reconstructed to match the gross pathology sections using internal fiducials such as blood vessels and the hepatic surface on a clinical PACS (Change Healthcare, Nashville, TN). The non-enhancing treatment zone on MRI and the treatment zone at gross pathology were each measured in equivalent orthogonal planes (M1 (longest) x M2 (perpendicular)) and the area of the treatment zone was calculated using an ellipsoid formula. Coefficient of determination was calculated for each measurement and the area of the treatment. Sections were obtained from multiple edges of each treatment zone for histopathologic correlation of complete treatment.

### RESULTS

The treatment zones (M1 x M2) averaged 3.5 x 2.9 cm (area 8.0 cm2) at imaging and 3.4 x 2.9 cm (area 7.5 cm2) at gross pathology. The M1 and M2 measures of the non-enhancing zone on MRI and the M1 and M2 measures of the treated zone at gross pathology differed by an average of 0.0 cm each (range -0.3 to +0.3 cm for M1 and -0.5 to +0.3 cm for M2) and the area by an average of 0.1 cm2 (range -2.0 to +1.5 cm2). There was strong correlation for M1 ($r2=0.75$), M2 ($r2=0.73$), and area ($r2=0.70$). Histopathologic analysis demonstrated a well-defined treatment zone with narrow zone of transition ranging from 1-3 mm.

## CONCLUSION

There is a strong correlation between the area of non-enhancement on portal venous phase MRI and gross pathology following hepatic histotripsy. The zone of non-enhancement can serve as a reliable biomarker for tissue destruction when evaluating post-histotripsy images.

## CLINICAL RELEVANCE/APPLICATION

As histotripsy begins commercial adoption, understanding the post-treatment appearance of complete cell death will allow evaluation of treatment efficacy.

## W2-SPIR-8 INCIDENCE OF HEPATOBILIARY INFECTION AFTER LIVER MICROWAVE ABLATION IN PATIENTS WITH COLONIZED BILIARY SYSTEMS

Steven S. Raman, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson;Consultant, Bayer AG;Consultant, Merck & Co, Inc;Consultant, Amgen Inc;Consultant, Profound Medical Inc
Daniel Kim, BA, MS (*Abstract Co-Author*) Nothing to Disclose
David S. Lu, MD (*Abstract Co-Author*) Nothing to Disclose
James Z. Hui, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Patients with colonized biliary systems, as seen in those with biliary-enteric anastomosis or indwelling biliary stents, are at higher risk of hepatobiliary infections, such as hepatic abscess formation or cholangitis, after radioembolization or radiofrequency ablation (RFA), with reported rates ranging from 11-50%. However, despite the rising popularity of microwave ablation (MWA) due its ability to deliver faster and larger treatments, the risk for infection after MWA has not been well defined. We aim to evaluate the rate of hepatobiliary infection in this at-risk population.

## METHODS AND MATERIALS

This IRB-approved, HIPAA-compliant retrospective study included 40 MWA procedures treating 56 primary or secondary malignant liver lesions, performed between February 2016 - February 2024, in 23 patients with either biliary stent (26%, 6/23) or biliary-enteric anastomosis (74%, 17/23). Patient demographics, treatment history, ablation details, periprocedural antibiotic management, and any postablation infectious complications were collected through electronic medical records.

## RESULTS

All 40 MWA procedures targeting 56 tumors were technically successful without immediate complications. Most patients received extended course post-ablation prophylactic antibiotics (up to 8 weeks), with regimens consisted of oral fluoroquinolone with or without concurrent metronidazole (37/40, 92.5%). Five cases of hepatic abscesses or cholangitis (12.5%, 5/40) occurred after a median of 30 days postprocedure (range: 15 - 51 days). Three abscesses (7.5%, 3/40) occurred while on an antibiotic regimen. One case of abscess occurred after completing a six-week antibiotic course, while a case of cholangitis occurred in a patient who did not receive post-procedural antibiotics. Abscess drainages and/or antibiotics were initiated in all cases. No death occurred due to the initial infection or subsequent drain placement.

## CONCLUSION

In this single-center retrospective study with the largest reported cohort to date of MWA procedures in patients with colonized biliary systems, the rates of hepatobiliary infection were found to be 10% in those receiving 6 weeks of prophylactic oral antibiotics regimen, which is favorable compared to the rates reported after RFA and radioembolization.

## CLINICAL RELEVANCE/APPLICATION

MWA is popular ablative modality for oligometastases in the liver. This study demonstrates MWA has a low risk for hepatobiliary infection when used along with the extended antibiotics in patients with colonized biliary systems.

## W2-SPMK-5 EVALUATING RADIOGRAPHIC AND MR CORRELATIONS TO FUNCTIONAL OUTCOMES IN SURGICALLY PROVEN HIP ABDUCTOR TEARS

Avneesh Chhabra, MD, MBA (*Abstract Co-Author*) Consultant, ICON plc;Consultant, Treace Medical Concepts, Inc;Author with royalties, Wolters Kluwer nv;Author with royalties, Jaypee Brothers Medical Publishers Ltd;Speaker, Siemens AG;Medical Advisor, ImageBiopsy Lab;Research Grant, ImageBiopsy Lab
Zuhair Zaidi, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To correlate inter-reader reliability with the accuracy of diagnosing hip abductor tendon tears in surgically confirmed cases. Additionally, we aim to evaluate how pre-operative radiographic and MRI findings correlate with functional outcomes in patients, both before and after undergoing surgical reconstruction.

### METHODS AND MATERIALS

From July 2022 to April 2024, 15 patients (16 hips: 5 left, 1 bilateral, and 9 right), predominantly female (12/15), with a mean BMI of 27.5 underwent abductor tendon reconstructions. Two independent MSK faculty readers analyzed the pre-operative imaging, and the findings were compared to pre- and post-operative functional outcomes using validated HOOS scores. Inter-reader reliability was assessed.

### RESULTS

Imaging of surgically confirmed abductor tendon tears were evaluated, revealing a spectrum of tear patterns with varying inter-reader reliability. On MRI, gluteus minimus displayed six partial- and six full-thickness tears, with four cases showing no tears; gluteus medius (lateral facet) revealed four partial and twelve full tears; the posterior superior facet attachment showed three partial- and one full-thickness tear; gluteus maximus tendon recorded one partial tear with fifteen intact tendons. Inter-reader agreement for tendon tears was moderate to high, scoring 0.73 for minimus, 0.59 for medius, and 0.64 for maximus. The presence of enthesophytes on radiographs had a moderate agreement at 0.45. In contrast, bursal fluid detection varied significantly, with fair agreement in submaximus bursa (0.31) and poor for subgluteus medius and minimus bursae. Pre-operatively, abductor strength was significantly correlated with avulsed fragment/calcification ($r = 0.57$) and gluteus subminimus fluid ($r = 0.57$), while hip tonnis grade negatively correlated with Activities of Daily Living Score ($r = -0.53$) and Total Hip Outcome Score ($r = -0.57$). Post-operatively, significant correlations persisted, such as subcortical sclerosis with iHOT 12 Score ($r = 0.52$) and Hip Osteoarthritis Outcome Score ($r = 0.51$), and gluteus minimus fluid with iHOT 12 Score_2 ($r = 0.78$). Notably, gluteus medius tears showed a significant negative correlation with hip abduction both pre- ($r = -0.83$) and post-operatively ($r = -0.53$). All values reached $p<0.05$ significance.

### CONCLUSION

Radiographic and MRI findings of gluteal pathology correlate significantly with functional outcomes and can be predictors of patient performance following tendon repair. This correlation shows the potential of imaging in guiding surgical management and prognostication.

### CLINICAL RELEVANCE/APPLICATION

Imaging allows pre-operative planning and can also be used to predict functional outcomes among surgically treated hip abductor tear patients.

El Mehdi Mniai, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Cancer and cancer treatments induce profound depletion of serum estrogen levels and can lead to an increased risk of vertebral fractures (VF). This study aimed to evaluate the performance of artificial intelligence (AI) in detecting vertebral fractures in cancer patients compared with radiological assessment. The secondary objective was to determine to what extent the detection of these VF, particularly for severe fractures, could have modified treatment management by offering an interventional radiology procedure.

### METHODS AND MATERIALS

Chest, abdominal and pelvis CT follow-up exams acquired from September to December 2023 for adult patients treated for stage IV cancer were retrospectively reviewed to evaluate the performance of an AI tool, CINA-VCF, to detect incidental VF. The AI tool quantifies intra-vertebral height loss and height loss relative to neighboring vertebrae. VF were categorized into three stages according to the degree of height loss: grade 1 with a loss of 20-25%; 26-40% for grade 2 and > 40% for grade 3. Grade 3 were considered as severe fractures. AI also calculated the mean value of L1 trabecular attenuation using a fully automated tool on healthy L1 vertebrae - to estimate bone mineral density and identify patients at risk of osteoporosis. We also collected relevant demographic and clinical information such as age, sex, type of cancer, type of treatment, bone metastatic status, and spinal treatment history. Two expert interventional radiologists in cancer treatment (IR1 and IR2), with over 10 and 2 year’s experience respectively, assessed whether or not they would have treated severe fractures with vertebroplasty.

### RESULTS

We included 1501 patients over a three-month period. Among these patients, AI detected VF in 501, with 436 true positives (TP) and 65 false positives (FP). The Predictive Positive Value was 87%. 51 % of patients were at risk of osteoporosis and 32 % had vertebral metastasis. 81 % of fractures detected by the AI tool had not been described on the initial radiological report, including 10 severe fractures, with 9 requiring an interventional treatment. Overall, based on expert opinion, 89.6 % of severe fractures had an indication for cementoplasty.

### CONCLUSION

AI detects more incidental VF than radiologists in cancer patients, including severe VF that, according to expert opinion, could have benefited from specific management.

### CLINICAL RELEVANCE/APPLICATION

AI could assist radiologists to detect more incidental vertebral fractures in adult cancer patients, optimizing timely treatment and reducing associated morbidity and economic burden. Automated assessment of L1 trabecular attenuation offers potential for osteoporosis screening, facilitating early identification of at-risk individuals.

Divya Yadav, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

To describe a cohort of patients with mCRPC and liver metastases treated on clinical trials of PSMA-TRT emphasizing on genetic mutations and quantitative imaging parameters and their effect on clinical outcomes.

### METHODS AND MATERIALS

We retrospectively analysed 39 patients with liver metastases who received alpha therapy (225Ac-J591), beta therapy (177Lu-PSMA-617, 177Lu-J591) or a combination of both (225Ac-591 and 177Lu-PSMA-IT) as part of PSMA-TRT trials between 2006-2022. 19 patients had PSMAPET-CT imaging available for analysis. Total tumor volume, whole body SUV mean, visual and quantitative PSG (qPSG) scores were calculated. PSG was classified into three groups: high, intermediate and low Imaging parameters and germline mutations were correlated to biochemical response defined as >50% PSA decline post-treatment (PSA50), PSA progression-free survival (PFS) and overall survival (OS).

### RESULTS

Median age was 69 years, with median PSA 85.7. 56.4% received more than 1 ARPI, 59.0% had more than 1 chemotherapy, 33.3% received sip-T, 17.9% had Ra-223, and 10.2% prior TRT. Median PSMA-imaging score (PSMA-IS) was 4 (range 1-4), with 7 (17.9%) 1-2 and 32 (82.1%) 3-4. 9 (23.0%) received alpha-TRT, 26 (66.7%) beta-TRT, and 4 (10.3%) combo-TRT. Mean whole body TTV was 1120.13, whole body SUV mean was 8.41, 55% of cases had high qPSG and visual PSG scores, 45% had intermediate qPSG vs 38.8% in visual PSG score and none had low qPSG versus 6.2% in visual PSG score. Somatic or germline analysis was completed in 15/39 patients. Overall 39 mutations were identified from all tissue samples, 27.5% of mutations were found in Androgen Receptor (AR) and TP53, 17.5% had TMPRSS2-ERG mutation and 15% had CHEK2 mutations. AR (100%), TMPRSS2-ERG and APC (80%) mutations were the most frequently found in the liver samples. PSA50 rate in alpha-TRT was 4 (44.4%), beta-TRT 8 (30.7%), combo-TRT 3 (75%). PSA50 in patients with PSMA-IS 1-2 was 1 (14.2%) compared to 14 (43.9%) in PSMA-IS 3-4. Median PFS was 66 days.

### CONCLUSION

This dataset adds to the collective literature of two subgroups of patients with mCRPC receiving TRT: those with liver disease and those with mutations in DNA repair pathways. The results of this study suggest higher rates of response in patients receiving alpha therapy, either alone or in combination with beta therapy.

### CLINICAL RELEVANCE/APPLICATION

The findings emphasize the significance of personalized treatment strategies for mCRPC, particularly with liver metastases and genetic mutations affecting DNA repair pathways. We highlight the potential efficacy of alpha therapy, especially when combined with beta therapy, and underscores the prognostic value of high radiotracer uptake on PSMA-PET imaging.

## W2-SPNMMI-2 EXTERNAL VALIDATION OF PREDICTION MODELS FOR PATIENTS WITH METASTATIC CASTRATION-RESISTANT PROSTATE CANCER RECEIVING $^{177}$LU-PSMA-617 THERAPY AND EXTENSIONS TO INCORPORATE PSMA-PET TOTAL TUMOR VOLUME

Alireza Ghodsi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Given the heterogeneous response to lutetium-177 prostate-specific membrane antigen (Lu-PSMA) in patients with metastatic castration-resistant prostate cancer (mCRPC), determining informative outcome predictors is crucial for effective clinical implementation. Here we validate previously developed nomograms in a real-world cohort and propose replacing a binary indicator of metastatic burden with continuous PSMA PET total tumor volume (TTV).

**METHODS AND MATERIALS**

This single-center retrospective cohort study included a consecutive series of eligible patients with PSMA-positive mCRPC who underwent PSMA PET/CT within 3 months of initiating Lu-PSMA. Quantitative analysis of PSMA PET scans used semi-automated whole-body tumor segmentation. Previously developed nomograms for overall survival (OS), PSA-progression-free survival (PSA-PFS), and PSA decline of =50% from baseline (PSA50) were fit and evaluated using the concordance index. The previously developed nomogram for OS includes variables such as time since diagnosis, chemotherapy status, baseline hemoglobin, dichotomized number of metastases (<20 vs. =20), tumor SUVmean, bone and liver involvement. We then replaced a binary indicator of the number of metastases with continuous TTV and tested the incremental improvement in concordance.

**RESULTS**

A total of 133 patients (median age: 73 years) with a median follow-up of 13 months (range: 1-20) were included. Patients received a median of 4 cycles (IQR: 2-6) of Lu-PSMA, and 53 (39.9%) patients deceased at last follow-up. Kaplan-Meier estimation found marginal evidence that OS was associated with a binary indicator of the number of metastases ($p=0.09$) and strong evidence of association with TTV partitioned into tertiles ($p<0.001$). The previously developed nomograms applied to our cohort achieved a concordance index of 0.69 (95% CI: 0.61-0.77) for OS, 0.67 (95% CI: 0.61-0.73) for PSA-PFS, and 0.70 (95% CI: 0.54-0.86) for PSA50, values numerically similar to published estimates. Replacing the binary number of metastases with continuous TTV significantly increased the concordance index by 0.07 (95% CI: 0.01-0.13; $p=0.009$) for OS.

**CONCLUSION**

Previously developed nomograms in patients with mCRPC receiving Lu-PSMA were prognostic in our independent cohort. Our analysis supports replacing a binary measure of metastatic burden with continuous TTV for predicting OS. External validation of the modified nomograms is warranted.

**CLINICAL RELEVANCE/APPLICATION**

The integration of PSMA PET TTV into a validated nomogram enhances prognostic accuracy for OS in patients with mCRPC receiving Lu-PSMA therapy, offering clinicians a more precise tool to guide treatment decisions and potentially improve patient outcomes.

## W2-SPNPM-1 FINANCIAL CONFLICTS OF INTEREST AND DISCLOSURE ACCURACY AMONG PHYSICIAN AUTHORS OF ACR APPROPRIATENESS CRITERIA

Mihir Khunte (*Abstract Co-Author*) Nothing to Disclose
Ajay Malhotra, MD, MMM (*Abstract Co-Author*) Nothing to Disclose
Dheeman Futela, MBBS (*Presenter*) Nothing to Disclose

### PURPOSE

The accuracy and completeness of self-disclosures by authors of imaging guidelines are not well known. This study aimed to assess the accuracy of financial disclosures by US authors of ACR appropriateness criteria (AC).

### METHODS AND MATERIALS

We reviewed financial disclosures provided by US-based authors of all ACR AC published in 2019, 2021, and 2023. For each US-based author, payment reports were extracted from the Open Payments Database (OPD) in the previous 36 months related to general category and research payments categories. We analyzed each author individually to determine if the reported disclosures matched results from OPD.

### RESULTS

A total of 633 authorships, including 333 unique authors were included from 38 ACR AC articles in 2019, 606 authorships (387 unique authors) from 35 ACR AC articles published in 2021, and 540 authorships (367 unique authors) from 32 ACR AC articles published in 2023. Among authors who received industry payments, the median amount received per authorship was $5038 in 2019, $3876 in 2021, and $6040 in 2023. Failure to disclose any financial relationship was seen in 125/147 unique authors in 2019, 142/148 unique authors in 2021, and 95/125 unique authors in 2023. The median non-disclosed amount per authorship was $4614 in 2019, $3876 in 2021, and $3272 in 2023. The proportion of non-disclosed total value of payments was 86.1% in 2019, 88.6% in 2021 and 56.7% in 2023. General category payments were non-disclosed up to 94.1% in 2019, 89.7% in 2021, and 94.4% in 2023 by payment value.

### CONCLUSION

Industry payments to authors of radiology guidelines are frequently undisclosed, and clear instructions for disclosure of all financial relationships would bring greater transparency.

### CLINICAL RELEVANCE/APPLICATION

The lack of transparency in disclosure of financial conflicts of interest may erode public trust in biomedical research and peer review processes. Inaccurate disclosure may undermine the integrity of ACR AC guidelines, diminishing physician and patient confidence in the recommendations. Clear, unambiguous journal guidelines for disclosure of all financial relationships whether related to the manuscript or not, are needed.

## W2-SPNPM-2 UNINTENDED CONSEQUENCES OF PRICE TRANSPARENCY INITIATIVES: IMPACT ON PATIENT DECISION-MAKING FOR IMAGING SERVICES

Gelareh Sadigh, MD (*Abstract Co-Author*) Nothing to Disclose
Ali Rashidi, MD (*Abstract Co-Author*) Nothing to Disclose
George Grant (*Presenter*) Nothing to Disclose

### PURPOSE

In the U.S. healthcare system, opaque pricing and the risk of accruing medical debt highlight the need for better price transparency to empower patients' informed decision making. However, impact of price transparency on adherence to recommended care is unclear. We aimed to assess the association between awareness of out-of-pocket cost (OOPC) estimates prior to receipt of imaging and the appointment completion status.

### METHODS AND MATERIALS

In this cross-sectional prospective study, we surveyed 608 patients with a scheduled imaging appointment (421 exam completions and 187 cancellations/no shows) at a tertiary imaging center between November 2022 to May 2023. Participants were asked about their pre-imaging OOPC estimate knowledge, information sources for the estimate, demographics, and insurance. We used descriptive statistics and multivariable logistic regression model to assess association between pre-imaging OOPC estimate knowledge and imaging completion status.

## RESULTS

Mean age of the 608 participants were 56.3 ± 15.8. A total of 58% were female; 54% were white, 20% Hispanic and 20% Asian. Majority (49%) had commercial insurance, followed by 36% Medicare, 11% Medicaid and 2% self-pay. A total of 14% were aware of their OOPC estimates prior to receipt of imaging. The most common sources for estimates were patients actively calling health insurance or imaging center billing office (32%), receipt of the estimate by imaging center without asking for it (20%), and use of price estimator tools offered by hospital or health plan (15%). A total of 48% of patients with pre-imaging OOPC estimate knowledge missed their appointment vs. 28% of those who did not know their estimate ($P<0.001$). Adjusting for demographics, comorbidities and neighborhood deprivation index, patients with pre-imaging OOPC estimate knowledge were 17.5-point percentage (95% CI, 6.2 - 28.8) less likely to complete their exam when compared with those without the knowledge ($P=0.002$).

## CONCLUSION

Our findings echo concerns regarding the unintended consequences of price transparency initiatives, potentially associated with appointment non-completion. We hypothesize that the absence of provider guidance in navigating cost information may contribute to this phenomenon.

## CLINICAL RELEVANCE/APPLICATION

Our findings underscore the complexity of implementing price transparency initiatives in healthcare and emphasize the importance of ensuring that transparency initiatives are effectively integrated into patient care pathways to avoid unintended consequences such as decreased care adherence.

## W2-SPNR-10 A RADIOMIC-RISK SCORE FOR SURVIVAL PREDICTION IN GLIOMA: A LARGE MULTI-INSTITUTIONAL RETROSPECTIVE VALIDATION STUDY

Michael C. Veronesi, PhD (*Abstract Co-Author*) Nothing to Disclose
Pallavi Tiwari, PhD (*Abstract Co-Author*) Nothing to Disclose
Marwa Ismail (*Abstract Co-Author*) Nothing to Disclose
Gustavo Adolfo Pineda Ortiz (*Presenter*) Nothing to Disclose

### PURPOSE

Gliomas are the most aggressive brain tumors with dismal survival. Radiomics has been extensively utilized as non-invasive biomarkers for survival prediction in gliomas, attempting to capture tumor heterogeneity and infiltration. However, rigorous validation for these techniques on large, multi-institutional data is still needed for them to become clinically actionable. This work attempts to evaluate a radiomic-based survival risk assessment score on a large multi-institutional cohort of Glioma patients. Our rationale is that optimizing and validating radiomic features that capture intensity-based textural variations and morphology-based changes (e.g., local curvature and global contour) on large multi-institutional cohorts can allow for robust risk assessment in Glioma.

### METHODS AND MATERIALS

A total of n=668 pre-operative T1w MRI scans for Glioma patients from 4 sites were analyzed. 2 sites were publicly available (University of California San Francisco "UCSF" (n=495), LUMIERE (n=86)) and the other 2 datasets were obtained from xCures (n=13), and Cleveland Clinic (CCF) (n=74). Subjects from UCSF, CCF, and xCures were used for training, whereas subjects from the LUMIERE cohort were used for hold-out testing. Pre-processing was conducted, including intensity-standardization for scans across all sites and tumor segmentation into Edema (ED) and Enhancing tumor (ET) regions. A total of n=1558 radiomic features were extracted from the tumor regions (779 per region), namely, 31 global contour features, 20 curvature-based features, 624 gradient co-occurrence statistics, and 104 Collage features. Cox regression models were employed on the radiomic features, to create a radiomic risk score (RRS) for every subject, as well as on clinical and demographic variables (IDH, MGMT, sex, age), for survival analysis.

### RESULTS

Our radiomics risk score (RRS) consisted of 43 top discriminative radiomic features from the regression model, and the associated clinical and demographic variables (CDS) which independently demonstrated significant differences between high and low risk groups in the training (RRS: p=0.043, HR = 2, CSD: p=0.0031, HR = 2.8) and testing sets (RRS: p=0.0096, HR = 1.8, CSD: p=0.0071, HR = 1.8). Combining RRS and CDS improved the OS prediction at group level (p=3.6e-6, 0.0011, HR=5.4, 2, for training and testing, respectively).

### CONCLUSION

Our multi-institutional radiomic analysis demonstrates promise in reliable risk-stratification in glioma patients

### CLINICAL RELEVANCE/APPLICATION

Radiomic features provide means for noninvasive survival prediction, which enable reliable risk assessment and efficient targeted therapies.

## W2-SPNR-13 A PRELIMINARY STUDY OF SUPER-RESOLUTION DEEP LEARNING RECONSTRUCTION WITH CARDIAC OPTION FOR EVALUATION OF ENDOVASCULAR-TREATED INTRACRANIAL ANEURYSMS

Chuluunbaatar Otgonbaatar, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Sung-Jin Cha, BS (*Abstract Co-Author*) Nothing to Disclose
Hackjoon Shim, PhD (*Abstract Co-Author*) Nothing to Disclose
Jin Woo Kim (*Abstract Co-Author*) Nothing to Disclose
JEON SANG HYUN (*Abstract Co-Author*) Nothing to Disclose
Jaekyun Ryu, PhD (*Abstract Co-Author*) Nothing to Disclose
Hyunjung Kim, MD (*Abstract Co-Author*) Nothing to Disclose
Pil-Hyun Jeon, PhD (*Abstract Co-Author*) Nothing to Disclose
Sung Min Ko, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the usefulness of super-resolution deep learning reconstruction (SR-DLR) with cardiac option in the assessment of image quality in patients with stent-assisted coil embolization, coil embolization, and flow-diverting stent placement compared with other image reconstructions.

### METHODS AND MATERIALS

This single-center retrospective study included fifty patients (mean age, 59 years; range, 44-81 years; 13 men) who were treated with stent-assisted coil embolization, coil embolization, and flow-diverting stent placement between January and July 2023. The images were reconstructed using filtered back projection (FBP), hybrid iterative reconstruction (IR), and SR-DLR. The objective image analysis included image noise in the Hounsfield unit (HU), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and full width at half maximum (FWHM). Subjectively, two radiologists evaluated the overall image quality for the visualization of the flow-diverting stent, coil, and stent.

### RESULTS

The image noise in HU in SR-DLR was 6.99±1.49, which was significantly lower than that in images reconstructed with FBP (12.32±3.01) and hybrid IR (8.63±2.12) ($p<0.001$). Both the mean SNR and CNR were significantly higher in SR-DLR than in FBP and hybrid IR ($p<0.001$ and $p<0.001$) (Fig. 1). The FWHMs for the stent ($p<0.004$), flow-diverting stent ($p<0.001$), and coil ($p<0.001$) were significantly lower in SR-DLR than in FBP and hybrid IR (Table 1 and Fig. 2). The subjective visual scores were significantly higher in SR-DLR than in other image reconstructions ($p<0.001$) (Table 2 and Fig. 3).

### CONCLUSION

SR-DLR with cardiac option is useful for follow-up imaging in stent-assisted coil embolization and flow-diverting stent placement in terms of lower image noise, higher SNR and CNR, superior subjective image analysis, and less blooming artifact than other image reconstructions.

### CLINICAL RELEVANCE/APPLICATION

SR-DLR with cardiac option allow better visualization of the peripheral and smaller cerebral arteries. SR-DLR with cardiac option can be beneficial for CT imaging of stent-assisted coil embolization and flow-diverting stent.

## W2-SPNR-14 DETECTION OF INTRACRANIAL HEMORRHAGE USING ULTRALOW-DOSE BRAIN COMPUTED TOMOGRAPHY WITH DEEP LEARNING RECONSTRUCTION VERSUS CONVENTIONAL-DOSE COMPUTED TOMOGRAPHY

Chuluunbaatar Otgonbaatar, MD, MS (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate the diagnostic performance, image quality, and radiation dose among ultralow-dose protocol with deep learning reconstruction (DLR), ultralow-dose computed tomography (CT) with iterative reconstruction (IR), and conventional-dose protocols for detecting intracranial hemorrhage.

### METHODS AND MATERIALS

This retrospective study enrolled 93 patients (median age: 67 years; interquartile range [IQR]: 59-76 years; 61 males). All patients underwent follow-up noncontrast CT with ultralow-dose setting after initial conventional-dose CT within 5 days. A conventional-dose CT was obtained using 123-188 mA and IR. Ultralow-dose CT was obtained using 50 mA with IR and DLR (Table 1). Qualitative assessments (CT attenuation, noise level, signal-to-noise ratio [SNR], and contrast-to-noise ratio [CNR]) and quantitative assessments (image noise, differentiation between gray and white matter, and artifact) were conducted. The diagnostic performance for detecting intracranial hemorrhage using ultralow-dose CT with IR and ultralow-dose CT with DLR was assessed.

### RESULTS

An approximately 84.0% reduction in median volume CT dose index was found in the ultralow-dose CT protocol (5.6 mGy) compared with conventional-dose CT (35.02 mGy; IQR: 33.09-37.36). Ultralow-dose CT with DLR significantly ($p < 0.001$) improved image noise, SNR, and CNR compared with ultralow-dose CT with IR and conventional-dose CT (Figure 1). Ultralow-dose CT with DLR resulted in higher sensitivity (99.3% vs. 98.6%) and specificity (97.5% vs. 97.5%) for detecting intracranial hemorrhage than ultralow-dose CT with IR (Table 2 and Figure 2).

### CONCLUSION

Ultralow-dose CT with DLR is an acceptable technique that provides higher image quality and diagnostic performance with a reduction in radiation dose of approximately 87.7% compared with conventional-dose CT.

### CLINICAL RELEVANCE/APPLICATION

The present study investigated the value of ultralow-dose CT with DLR for the assessment of image quality and the evaluation of intracranial hemorrhage compared with ultralow-dose CT with IR and conventional-dose CT. Image quality was significantly improved in terms of image noise, SNR, and CNR, and higher diagnostic performance was observed with ultralow-dose CT with DLR than with ultralow-dose CT with IR.

## W2-SPNR-15 ARTIFICIAL INTELLIGENCE ACCURATELY DIFFERENTIATES RADIONECROSIS FROM TRUE PROGRESSION IN BRAIN METASTASIS TREATED WITH STEREOTACTIC RADIOSURGERY: ANALYSIS OF 104 HISTOLOGICALLY ASSESSED LESIONS

### PURPOSE

To develop automated models able to discriminate radionecrosis from disease progression in brain metastases treated with stereotactic radiosurgery (SRS).

### METHODS AND MATERIALS

This single-centre retrospective study included all patients who underwent neurosurgery for suspected brain metastasis progression after SRS, between 2012 and 2022. Presurgical FLAIR and post-contrast T1 (T1ce) acquisitions were segmented using a convolutional neural network (CNN) into non-enhancing, enhancing, and edema volumes of interest (VOIs). Radiomics features (n=321) were extracted from each sequence and VOI, and their significance to radionecrosis was assessed through univariate and multivariate analyses. A Random Forest machine learning model was trained on 70% of the sample and evaluated on the remaining 30% using Bayesian optimization and 10-fold cross-validation. A 3D ResNet-based CNN was trained on the same split dataset. Post-surgical histology was available for all cases.

### RESULTS

104 lesions from 96 patients (n=40 males, mean age 56.4 years) were included. Sole radionecrosis was histologically detected in 29 cases (28%), while in the remaining varying percentages of neoplastic cells were present. Univariate analysis identified 131 significantly different radiomics features (RFs) between the two groups, including GLDM Dependence Non Uniformity Normalized (GLDM_DNUN, $p<0.001$) and GLDM Small Dependence Emphasis (GLDM_SDE, $p<0.001$) within the enhancing area of T1ce. Multivariate analysis confirmed these findings: GLDM_DNUN (OR 0.39, 95% CI 0.22-0.69, $p<0.001$) and GLDM_SDE (OR 0.28-0.69, $p<0.001$) were significantly associated with radionecrosis. The Random Forest model yielded a 0.79 of accuracy, 0.81 of AUROC and 0.87 of sensitivity in radionecrosis prediction, whereas the CNN ResNet model performed with higher accuracy (86.9%), AUROC (0.889) and sensitivity (87.8%).

### CONCLUSION

Artificial intelligence could be employed to differentiate between radionecrosis and disease progression upon-SRS, potentially reducing unnecessary brain surgery interventions.

### CLINICAL RELEVANCE/APPLICATION

Accurate discrimination between radionecrosis and tumor progression/recurrence in brain metastases post-SRS remains a significant diagnostic challenge. Conventional MRI together with advanced imaging modalities, such as diffusion/perfusion-weighted imaging and CT-PET with amino acid tracers, still present limitations, often requiring histopathologic assessment via brain surgery to achieve a definitive diagnosis. Integrating artificial intelligence models with conventional MRI offers a promising non-invasive approach, potentially revolutionizing diagnostic methodologies in this challenging clinical context.

## W2-SPNR-16 DEEP-LEARNING-ACCELERATED MPRAGE VERSUS STANDARD MPRAGE FOR QUANTITATIVE BRAIN MORPHOMETRY AND VISUAL GRADING OF CORTICAL VOLUME LOSS

Susie Y. Huang, MD, PhD (*Abstract Co-Author*) Research Grant, Siemens AG
Marcel D. Nickel (*Abstract Co-Author*) Employee, Siemens AG
Wei-Ching Lo (*Abstract Co-Author*) Employee, Siemens AG
Bryan Clifford, PhD (*Abstract Co-Author*) Employee, Siemens AG

Azadeh Hajati, MD (*Abstract Co-Author*) Nothing to Disclose
Azadeh Tabari, MD (*Abstract Co-Author*) Nothing to Disclose
Nelson H. Gil JR, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate a novel deep-learning-accelerated T1-weighted MPRAGE (DL-MPRAGE) sequence for quantitative volumetric brain MRI and qualitative assessment of cortical volume loss relative to a standard MPRAGE (STD-MPRAGE).

### METHODS AND MATERIALS

We prospectively recruited adult patients undergoing memory loss protocol MRI on 3T MRI scanners (MAGNETOM Vida, Siemens Healthineers, Forchheim, Germany). The research application DL-MPRAGE uses a two-step deep-learning-based image reconstruction. The first step alternates between data consistency updates and neural network evaluation and the second step incorporates a super-resolution algorithm. We estimated cortical volume in DL- and STD-MPRAGE images for each patient with the longitudinal FreeSurfer pipeline in 11 brain regions and quantified differences between the two sequences across patients with the absolute symmetrized percent change (ASPC). In addition, we performed Bland-Altman analysis to determine 95% limits of agreement for the mean differences between each anatomical region. For qualitative review, two blinded neuroradiologists rated levels of cortical volume loss for anatomical regions based on a standardized five-point scale. We computed the mean difference in ratings between DL- and STD-MPRAGE for each anatomical region.

### RESULTS

64 patients (29 female, 62.4 ± 16 years old) being evaluated for memory loss (N = 53, 83%) or traumatic brain injury (N = 11, 17%) were included. DL-MPRAGE achieved both superior image resolution by a factor of 2.0 (0.5 mm vs. 1.0 mm) and improved acquisition speed by a factor of ~2.5 (2 min, 11 sec vs. 5 min, 21 sec) compared to STD-MPRAGE. The mean regional volumes for DL-MPRAGE scans were lower than for STD-MPRAGE (e.g. 17226 vs. 17923 mm3 for the cingulate gyrus, $p < 0.005$, paired t-test). Nevertheless, corresponding ASPC values for these differences were low, averaging 2.8% across brain regions. Furthermore, mean differences between volumes almost all lay within the 95% limits of agreement, suggesting that observed differences in ASPC are driven by a few outliers. There was essentially no difference in qualitative ratings of regional cortical volume loss between DL-MPRAGE and STD-MPRAGE across anatomical regions among the two neuroradiologists. At least 94% of the differences in ratings were 0.

### CONCLUSION

DL-MPRAGE offers quantitatively and qualitatively equivalent volumetric estimation compared to STD-MPRAGE while achieving improved image resolution and acquisition speed.

### CLINICAL RELEVANCE/APPLICATION

DL-MPRAGE improves on the current standard in the assessment of brain volume loss by offering both improved image resolution and acquisition speed compared to STD-MPRAGE while maintaining equivalence for quantitative and qualitative analysis.

## W2-SPNR-18 AUTOMATED DETECTION OF STENO-OCCLUSIVE LESION ON TIME-OF-FLIGHT MAGNETIC RESONANCE ANGIOGRAPHY: AN OBSERVER PERFORMANCE STUDY

Jae-Hyeop Jung, MD (*Abstract Co-Author*) Nothing to Disclose
Sung Il Hwang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Leonard Sunwoo, MD (*Abstract Co-Author*) Nothing to Disclose
Hunjong Lim, MD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

Intracranial steno-occlusive lesions are responsible for acute ischemic stroke. However, the clinical benefits of artificial intelligence-based methods for detecting pathologic lesions in intracranial arteries have not been evaluated. We aimed to validate the clinical utility of an artificial intelligence model for detecting steno-occlusive lesions in the intracranial arteries.

**METHODS AND MATERIALS**

Overall, 138 TOF-MRA images were collected from two institutions, which served as internal (n = 62) and external (n = 76) test sets, respectively. Each study was reviewed by five radiologists (two neuroradiologists and three radiology residents) to compare the usage and non-usage of our proposed artificial intelligence model for TOF-MRA interpretation. They identified the steno-occlusive lesions and recorded their reading time. Observer performance was assessed using the area under the Jackknife free-response receiver operating characteristic curve and reading time for comparison.

**RESULTS**

The average area under the Jackknife free-response receiver operating characteristic curve for the five radiologists demonstrated an improvement from 0.70 without artificial intelligence to 0.76 with artificial intelligence (P = .027). Among three radiology residents, the average area under the Jackknife free-response receiver operating characteristic curve enhancement was more pronounced with artificial intelligence usage (increasing from 0.68 to 0.76, P = .002). Despite anincreased reading time upon using artificial intelligence, there was no significant change among the readings by radiology residents. Moreover, the use of artificial intelligence resulted in improved inter-observer agreement among the reviewers (the intraclass correlation coefficient increased from 0.734 to 0.752).

**CONCLUSION**

Our proposed artificial intelligence model offers a supportive tool for radiologists, potentially enhancing the accuracy of detecting intracranial steno-occlusion lesions on TOF-MRA. Less-experienced readers may benefit the most from this model.

**CLINICAL RELEVANCE/APPLICATION**

Our study advances knowledge by demonstrating the clinical utility of an AI model in improving radiologists' accuracy in detecting intracranial steno-occlusive lesions. This suggests that AI can be a valuable support tool, especially for less-experienced readers, potentially increasing diagnostic performance and contributing to better patient outcomes.

## W2-SPNR-2 DEEP LEARNING-BASED SIGNAL AMPLIFICATION OF T1-WEIGHTED SINGLE-DOSE IMAGES FOR METASTASIS DETECTION IN BRAIN MRI

Thomas Pinetz, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

To test the benefit in sensitivity and precision of a deep learning-based signal amplification of the contrast signal in true single-dose T1-weighted (T-SD) images creating artificial double-dose (A-DD) images for metastasis detection in brain MRI.

**METHODS AND MATERIALS**

In this prospective, multicentric study, a deep learning-based method for signal amplification originally trained on a diverse dataset of unenhanced, low-dose (10%-33% of a single-dose) and single-dose T1-weighted brain images was applied to single-dose images of a test dataset of 30 participants (mean age, 58.5±11.8 [SD] years, 23 women) prospectively acquired between November 2022 and June 2023 in an external institution not included in training. Two board-certified neuroradiologists searched for brain metastases on participants' T-SD and A-DD images in random order with a period of four weeks between readings. Cases were reviewed by a reference reader to determine any metastases present. Performances were compared using Mid-p McNemar tests for sensitivity and two-sided Wilcoxon signed-rank tests for false-positive findings.

**RESULTS**

88 metastases were identified by the reference reader. Reader 1 found significantly more metastases using the A-DD images (73/88, 83.0%) instead of T-SD images (62/88, 70.5%, p=.008) with a similar precision in both reads (A-DD: 79.3%, 19 false-positive lesions, T-SD: 81.6%, 14 false-positive lesions). In reader 2, no significant difference could be shown with three more metastases found on the A-DD images (A-DD: 65/88, 73.9%, T-SD: 62/88, 70.5%, p=.424) - also with a similar precision between sequences (A-DD: 81.3%, 15 false-positive lesions, T-SD: 84.9%, 11 false-positive lesions). The number of false-positive lesions did not differ significantly between sequences. For small metastases with a diameter of less than or equal to 5 mm, the difference in sensitivity was even more pronounced (Reader 1, A-DD: 33/48 (68.8%), T-SD: 25/48 (52.1%), p=.035; Reader 2: A-DD: 27/48 (56.3%), T-SD: 24/48 (50.0%), p=.424).

### CONCLUSION

Both readers found a comparable number of metastases in the T-SD images. One reader was able to strongly benefit from the use of artificial contrast enhancement with a significant increase in sensitivity for brain metastases without loss of precision. In this study with 30 test participants, eleven and three additional metastases were found using artificial double-dose images by readers 1 and 2, respectively. This benefit was particularly pronounced for small metastases.

### CLINICAL RELEVANCE/APPLICATION

The benefits of double-dose brain imaging conflict with concerns about the effects of gadolinium-based contrast agents on patients and the environment, preventing availability.

## W2-SPNR-4 A COPILOT FOR RADIOLOGY: VISION-LANGUAGE MODELS ACHIEVE ACCURATE BRAIN MRI INTERPRETATION

Harini Veeraraghavan (*Abstract Co-Author*) Nothing to Disclose
Maxime Kayser (*Abstract Co-Author*) Nothing to Disclose
Aneesh Rangnekar, PHD (*Abstract Co-Author*) Nothing to Disclose
Aleksandr Petrov (*Abstract Co-Author*) Nothing to Disclose
Nathaniel Swinburne, MD (*Presenter*) Nothing to Disclose

### PURPOSE

While artificial intelligence (AI) applications to radiology can automate tasks such as disease detection and lesion segmentation, the development of robust foundational models has been thwarted by the need for manual data annotation, preventing scalable training methods analogous to those achieving success in large language model (LLM) development. We aim to overcome these limitations by leveraging fully automated dataset curation to train a new vision-language model (VLM), "ViLaMet", to analyze brain MRIs and generate report text.

### METHODS AND MATERIALS

We data mined our cancer center's PACS to extract all brain MRIs acquired from 2012-2017 (77,228 MRIs from 24,262 patients), isolating the axial T1 post-contrast (T1C+) images and report text. After patient-wise dataset splitting (76,087 training and 1,141 test data pairs), the reports were pre-processed using GPT-3.5/4 to remove references to findings not visible on T1C+ images or to change from prior studies. To facilitate quantitative model evaluation, 16 close-ended, single- or multiple-choice instruction-answer pairs were created for each report (e.g. "List all the locations that contain enhancing lesions."). A subset of 50 randomly-selected test reports was manually labeled as ground truth.At this initial stage, our VLM has been trained on the original reports on the tasks of report generation (RRG) and image-report matching (IRM). ViLaMet incorporates a 3D vision encoder and an LLM connected via a bridging module, mapping MRI features into a latent space for language processing. We optimized model training using Low-Rank Adaptation and varied the architecture by comparing different vision encoders and LLM sizes.

### RESULTS

The best report generation scores (Bleu-1 0.247, Bleu-4 0.060, and Meteor 0.132) were obtained using an 8B Llama3 model with a frozen DenseNet-121, which was pre-trained via RRG and RM. ViLaMet correctly classifies 89.7% of image-report pairs as matching (random chance is 50%). Our GPT-4 report processing achieves 92% accuracy in extracting correct instruction-answer pairs (versus 81% for GPT-3.5).

### CONCLUSION

Our VLM achieves excellent accuracy at automated brain MRI report generation despite a heterogeneous and complex test patient population. The ability to harness massive clinical radiology datasets at scale for model training suggests a path to achieving generalizable foundational radiology AI models. In ongoing work we are training ViLaMet on the GPT-4 processed reports to reduce hallucinations and improve evaluation.

### CLINICAL RELEVANCE/APPLICATION

A VLM trained using data-mined brain MR images and report text achieves excellent accuracy in automated report generation, offering a path to next-generation radiology computer-aided diagnostics.

## W2-SPNR-5 FORTE: FEATURE-ORIENTED RADIOLOGY TASK EVALUATION FRAMEWORK FOR MULTIMODAL LARGE LANGUAGE MODELS IN VOLUMETRIC BRAIN CT REPORT GENERATION

Jiing-Feng Lirng, MD (*Abstract Co-Author*) Nothing to Disclose
Kao-Jung Chang (*Abstract Co-Author*) Nothing to Disclose
Cheng-Yi Li (*Presenter*) Nothing to Disclose

### PURPOSE

To relieve radiologists' time-consuming and tedious burden, this study aims to investigate the capability of Multi-modal large language models (MLLMs) to generate comprehensive image reports for 3D brain CT.

### METHODS AND MATERIALS

In this study, we curated a three-dimensional brain CT (3D-brainCT) dataset comprising 18,885 text-scan pairs. We trained BrainGPT to generate 3D brain CT reports using the visual instruction tuning (VIT) technique on the Otter foundation model. Then, we examined the caption efficacy by (1) applying traditional BLEU/ METEOR/ ROUGE-L/ CIDEr-R metrics, (2) proposing a clinical-oriented FORTE metric, (3) validating BrainGPT generalizability in the CQ500 dataset, and (4) conducting the physician Turing test.

### RESULTS

The performance of BrainGPT (BLEU-1 = 44.35, BLEU-4 = 20.38, METEOR = 30.13, ROUGE_L = 47.6, CIDEr-R = 211.17) was significantly higher than general Otter model (BLEU-1 = 6.87, BLEU-4 = 0.01, METEOR = 3.02, ROUGE_L = 7.88, CIDEr-R = 4.12). Our Pearson correlation analysis results demonstrated that, compared to traditional NLG metrics, FORTE better reflects the clinical essence of the medical context. In the CQ500 dataset, our BrainGPT captioned midline shift at decent 0.91 accuracy. A Turing test on 11 physician raters evaluated the writing styles and radiology context of the generated reports; in most cases, the BrainFlamingo reports are more challenging to distinguish (accuracy = 25.76%) than radiologist reports (46.97%) from physicians' viewpoints. The ensuing linguistic questionnaire highlights the importance of writing style as we connect physician accuracy and criteria importance.

### CONCLUSION

As the inaugural work to apply MLLM in 3D Brain CT, our study embodies a comprehensive framework that suggests modulated solutions and style-based optimization to the technical hurdles when applying MLLMs to brain CT and other complex medical captioning tasks.

### CLINICAL RELEVANCE/APPLICATION

Our study highlights the potential of MLLMs in enhancing diagnostic accuracy and report consistency in 3D brain CT scans, promising improved clinical decision-making and patient outcomes through advanced AI-driven report generation and analysis.

## W2-SPNR-6 DEEP LEARNING INSIGHTS INTO THE RADIOGRAPHIC FEATURES OF NORMAL PRESSURE HYDROCEPHALUS USING GRADIENT CLASS ACTIVATION MAPPING

Kevin S. King, MD (*Abstract Co-Author*) Nothing to Disclose
Emily Foldes (*Abstract Co-Author*) Nothing to Disclose
Matthew Borzage (*Abstract Co-Author*) Nothing to Disclose
Raza Mushtaq, MD (*Abstract Co-Author*) Nothing to Disclose
Joseph Wilson (*Abstract Co-Author*) Nothing to Disclose
Christian Henriksen (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a deep learning convolutional neural network (CNN) for the diagnosis of normal pressure hydrocephalus (NPH) from head computed tomography (CT) and to use gradient class activation mapping (GradCAM) to analyze which imaging features the CNN has learned to associate with NPH.

### METHODS AND MATERIALS

We collected 590 head CT images, 295 from patients with suspected NPH who had quantitative improvement in gait after lumbar tap test, and 285 CT images from age- and gender-matched controls that had normal CT findings. Collected CT images were pre-processed to include only the intracranial contents in the final CT image. We trained our CNN to convergence on 464 patients, and reserved 87 patients for validation and 29 patients for evaluation. The final model was evaluated using a confusion matrix. Using GradCAM, saliency maps were calculated for the final convolutional layer of the final model and color-mapped in 3D space for each CT exam in the validation and evaluation sets.

### RESULTS

The final model was able to accurately detect NPH with a sensitivity of 100% on the validation and evaluation sets and a specificity of 97.2% and 94.1%, respectively, misclassifying a single false positive in either set.On CT images that were classified as NPH, saliency maps revealed consistently strong positive attributions in the parafalcine area, the inferolateral and anteromedial regions of the ventricles, the choroid plexus, and the edges of the intracranial volume. Weak positive attributions were consistently observed throughout the sulcal topography of the brain, and occasionally observed at the Sylvian fissure. On CT images classified as normal, strong negative attributions were present in the parafalcine area, inferolateral and anteromedial regions of the ventricles, the choroid plexus, and the edges of the intracranial volume.

### CONCLUSION

The saliency maps of the model underscore the importance of the above features in the morphology of NPH. Continued work will involve strengthening the model as a feature extractor by using occlusion-based data augmentation techniques as well as improving the clinical applicability of the model and further clarifying the semantic precision of the saliency maps by collecting CT images of patients with non-NPH causes of dementia (e.g. Alzheimer's disease) as well as other pathologies and normal findings.

### CLINICAL RELEVANCE/APPLICATION

This project presents a model for the automated diagnosis of NPH from head CT. The saliency maps suggest the importance of the above features for the radiographic identification of NPH.

## W2-SPNR-7 DEEP LEARNING OF BRAIN CT SCANS TO IDENTIFY PEDIATRIC CARDIAC ARREST AND PREDICT OUTCOME

Shandong Wu, PhD (*Abstract Co-Author*) Nothing to Disclose
Amirreza Manteghinejad, MD (*Abstract Co-Author*) Nothing to Disclose
Dooman Arefan, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Matthew Kirschen (*Abstract Co-Author*) Nothing to Disclose
Arastoo Vossough, PhD, MD (*Abstract Co-Author*) Research Consultant, Syneos Health;Stockholder, DeepSight Technology, Inc
Alexis Topjian (*Abstract Co-Author*) Nothing to Disclose
Jonathan Elmer (*Abstract Co-Author*) Nothing to Disclose
Jiren Li (*Presenter*) Nothing to Disclose

### PURPOSE

Hypoxic-ischemic brain injury is the primary cause of morbidity and mortality after pediatric cardiac arrest. Brain computerized tomography (CT) scans performed early after cardiac arrest may be helpful for risk stratification, outcome prediction, and to direct clinical care. The goal of this study was to leverage deep learning to identify patients who had a cardiac arrest compared to controls and to predict outcome.

### METHODS AND MATERIALS

Retrospective observational study of patients at a single institution who had a brain CT scan performed as part of clinical care within 24 hours of cardiac arrest. Patient outcomes were measured by the pediatric cerebral performance category scale (PCPC) [1 (normal) to 6 (death)]. Unfavorable outcome was defined as PCPC 4-6 at hospital discharge and a change of =1 from pre-arrest baseline. We excluded patients with pre-arrest PCPC =4. Four age-matched controls for each cardiac arrest patient were abstracted from our radiology database. All control CT scans were verified to have no intracranial pathology. A preprocessing pipeline (including skull stripping, intensity normalization, and slice thickness resampling) was applied on each CT scan. We designed a convolutional neural network on the 3D CT scans to 1) classifying cardiac arrest patients vs. controls and 2) predicting survival and unfavorable outcomes for patients who had a cardiac arrest. We used 5-fold cross-validation for model evaluation, and the proportion of children younger than 1 year old is controlled the same in each fold. Model performance was measured by the area under the ROC curve (AUC). We generated heatmaps to visualize brain regions which were key in informing outcome metrics.

### RESULTS

We analyzed 714 patients including 146 post-cardiac arrest (41: < 1 year, 24: 1-2 years, 79: 2-18 years) and 568 age-matched controls. Among cardiac arrest patients 61 died (41.8%), and 88 (60.3%) had an unfavorable outcome. The mean AUC (mean±std) was 0.89±0.018 for classifying whether the CT scan was derived from a cardiac arrest vs control patient. The AUC to predict mortality was 0.80±0.025. For unfavorable vs favorable outcome prediction, there was a large variation across the five folds due to sample size limitation. The highest AUC was 0.73 (mean AUC: 0.57±0.048). The occipital region was frequently observed in heatmaps of the post-arrest patients.

### CONCLUSION

Deep learning of brain CT can identify distinct imaging features of cardiac arrest relative to control patients and predict post-cardiac arrest mortality. The model in predicting neurologic outcomes needs to be further evaluated on larger datasets.

### CLINICAL RELEVANCE/APPLICATION

Deep learning models on brain CT images may assist with risk stratification and outcome prediction after pediatric cardiac arrest.

## W2-SPNR-8 CLINICAL UTILITY OF DEEP-LEARNING RECONSTRUCTED ZERO-ECHO TIME MRI FOR ASSESSING CERVICAL SPINE DEGENERATION IN COMPARISON TO CT

Cynthia T. Chin, MD (*Abstract Co-Author*) Nothing to Disclose
Vinil Shah, MD (*Abstract Co-Author*) Nothing to Disclose

Sagar Mandava (*Abstract Co-Author*) Nothing to Disclose
Maggie M. Fung, MENG (*Presenter*) Employee, General Electric Company

### PURPOSE

Zero echo-time (ZTE) MRI has been developed to image cortical bone, facilitating the assessment of fractures, ossifications, and calcifications, similar to CT imaging. Deep-learning (DL) reconstruction, employing a deep convolutional neural network, has been increasingly used for various clinical MRI to reduce imaging time and to denoise while improving image sharpness. This study aims to assess the clinical utility of DL-reconstructed ZTE (DL ZTE) imaging for the cervical spine.

### METHODS AND MATERIALS

In vivo cervical spine scans were conducted using 3T GE Premier scanners (GE Healthcare, Waukesha, WI). ZTE sequence parameters (sagittal prescription) were first optimized through a healthy volunteer study as 24 x 24 cm2 FOV, 266 x 266 matrix size, 0.9 x 0.9 x 1 mm3 resolution, 192 slices, 4 NEX, ±62.5 kHz bandwidth, and 2° flip angle, with a total scan time 5 min 30 sec. ZTE imaging for patients was performed during routine clinical cervical spine exams. Offline DL reconstruction with a noise reduction factor set at 75% was applied to raw data from thirteen patients. Subsequently, N4 coil bias correction, additional image-based denoising, air/background removal, and image inversion were performed. Qualitative comparison between DL ZTE images and CT scans acquired within one year of MRI scans was conducted for seven patients.

### RESULTS

Our healthy control study revealed well-delineated bone structures using ZTE with both 1° and 2° flip angle. A flip angle of 2° additionally provided slight T1 contrast, resulting in myelographic signal difference between the spinal cord and the cerebrospinal fluid (CSF) within the subarachnoid space. Across all acquired patient exams, DL reconstruction notably improved image quality by enhancing SNR and image sharpness. DL ZTE was able to depict bone pathology such as osteophytes and fractures similar to CT though further comprehensive evaluation is warranted. Axial reformats demonstrated clear visualization of the subarachnoid space without significant CSF flow artifacts. Even in a case involving fusion hardware, DL ZTE maintained good depiction of the spinal canal, contrasting with CT images suffered from significant metal streak artifacts.

### CONCLUSION

DL reconstruction can improve ZTE image quality and detection of bone pathology. DL ZTE can also provide additional clinical utility for assessing the spinal canal by generating robust signal contrast between the spinal cord and CSF.

### CLINICAL RELEVANCE/APPLICATION

DL ZTE efficiently enables CT-like depiction of the vertebrae while allowing for a myelographic effect to aid in diagnosis of various spinal canal pathology. DL ZTE may be a potential noninvasive alternative to CT myelography.

## W2-SPNR-9 COMPARING ACCURACY OF GPT-4 AND A BAYESIAN INFERENCE-BASED PLATFORM IN DIAGNOSING BRAIN MRI PATHOLOGY

Suyash Mohan, MD (*Abstract Co-Author*) Research Grant, NovoCure Ltd;Research Grant, Galileo CDS, Inc;Consultant, Northwest Biotherapeutics, Inc;Consultant, AIRS Medical Inc;Consultant, Qynapse SAS
Shawn Lyo, MD (*Abstract Co-Author*) Nothing to Disclose
Mitul Gupta (*Abstract Co-Author*) Nothing to Disclose
R. Nick Bryan, MD, PhD (*Abstract Co-Author*) Stockholder, Galileo CDS, Inc;Officer, Galileo CDS, Inc
John Pruitt, MD (*Abstract Co-Author*) Nothing to Disclose
Felipe Rosero Castro, BS (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the diagnostic accuracy of GPT-4, a widely used large language model (LLM), to that of a Bayesian inference-based clinical decision support tool (Galileo CDS) in generating differential diagnoses on brain MRI studies using human-extracted key imaging features in real cases. Though LLMs have garnered attention for this purpose, Bayesian networks, unlike LLMs, can explain their reasoning.

### METHODS AND MATERIALS

Predefined characteristic imaging features of 476 MRIs from a prior study representing 120 clinically proven neurologic diseases were extracted by 2 resident radiologists, 2 fellow neuroradiologists, and 2 attending neuroradiologists. The 32 cases with the highest inter-reader key feature agreement were selected, and their key features were used to query GPT-4 and Galileo CDS. Key features included relative lesion signal intensity on FLAIR, T1, and T2, presence of enhancement, diffusion characteristics, presence of susceptibility on GRE, character of mass effect, number, side, location, and size of lesion(s), and patient age.Each platform generated a ranked list of most likely diagnoses, each of which were compared to clinical ground truth and given a score of 0 (correct diagnosis not included in top 3), 1 (correct diagnosis ranked first), or 3 (correct diagnosis in top 3, but not first). A composite value (1+3) represented scenarios where the correct diagnosis was “at least” within the top 3 diagnoses. The diagnostic accuracies of both tools were compared.

## RESULTS

GPT-4 and Galileo CDS showed a 18.8% and 46.9% accuracy by composite score, respectively. GPT-4 ranked the correct diagnosis first in 12.5% of cases, while Galileo did so in 21.9% of cases. Chi-square analysis yielded a statistically significant difference ($p<.05$) in scoring distribution between platforms. For perspective, a prior study showed an attending reader composite accuracy of 72.1% across diagnoses from the same source cases.

## CONCLUSION

While LLMs may eventually aid radiologic diagnosis, GPT-4 currently struggles to match human readers in generating clinically sound reports. We show here that a platform based on Bayesian inference outperforms GPT-4 in diagnostic accuracy across real cases. This may be partially explained by differences in reasoning; GPT-4 queries a broad, generic database of information, whereas Bayesian tools can incorporate focused prior knowledge in their evaluation despite demonstrating only modest accuracy when compared to human readers.

## CLINICAL RELEVANCE/APPLICATION

This study provides benchmarking data comparing the diagnostic accuracy of LLMs versus Bayesian inference-based software for neuroradiologic conditions, highlighting potential limitations of both computational techniques and the need for continued evaluation.

**Sub-Events**

## W2-SPPD-1 ABSOLUTE VS RELATIVE VOLUMETRY OF WHITE AND GRAY MATTER: IMPLICATIONS FOR THE CHARACTERIZATION OF SEXUAL DIMORPHISMS IN A LARGE COHORT OF EXTREMELY PRETERM ADOLESCENTS

Hernan Jara, PhD (*Abstract Co-Author*) Author with royalties, World Scientific Publishing;
Bindu Setty, MD (*Abstract Co-Author*) Nothing to Disclose
Laurie Douglass (*Abstract Co-Author*) Nothing to Disclose
Robert Joseph (*Abstract Co-Author*) Nothing to Disclose
Maha Alsufyani (*Abstract Co-Author*) Nothing to Disclose
Ali A. Elzieny (*Presenter*) Nothing to Disclose

### PURPOSE

To study the potential existence of sexual dimorphisms in a large American cohort of extremely preterm born adolescents using qMRI-based absolute vs. relative volumetry.

### METHODS AND MATERIALS

This prospective multicenter study (ELGAN-ECHO) included adolescents who were born extremely preterm (gestational ages<28 weeks) and underwent Triple Turbo Spin Echo brain MRI at age 15. The image processing pipeline consisted of semi-automated segmentation, volumetry, and qMRI mapping algorithms (Python with Anaconda Navigator), which required a preparation step for fine editing the intracranial matter (ICM) and deep gray matter (dGM) segments with Fiji (ImageJ). Absolute and ICM-relative volumetry outputs for all participants were generated and analyzed in a statistical package (SPSS) for sexual differences.

### RESULTS

A total of 368 participants were included (48.6% males). Males had significantly larger absolute volumes than females for ICM, total brain, gray matter, dGM, and white matter (1440.3±152.4 vs 1295.6±148.1, 1140.1±140.3 vs 1021.6±128.7, 751.1±105.1 vs 675.6±92.9, 65.9±11.9 vs 60.9±8.8, and 388.9±70.5 vs 345.9±60.9; p-value <0.001 respectively), and nonsignificant larger cerebrospinal fluid volumes (157.1±112.1 vs 143.5±92.4, p-value 0.206). These sexual differences were absent in the relative volumetry data, except for dGM where females had higher relative volume than males (4.7±0.5 vs 4.5±0.6, p-value 0.038).

### CONCLUSION

In a large cohort of extremely preterm adolescents, sexual dimorphisms observed in absolute brain volumetry are not maintained when data are adjusted to the total intracranial volume (relative volumetry).

### CLINICAL RELEVANCE/APPLICATION

Caution must be exercised when reporting absolute brain volumetry findings in radiological reports and scientific literature, as male and female brains appear equal in relative volumetry.

## W2-SPPD-2 ALTERATION OF WHITE-MATTER FUNCTIONAL NETWORK IN CHILDREN WITH DRUG REFRACTORY EPILEPSY:A GRAPH-THEORETICAL STUDY

Zhang T. Tijiang I, MD (*Abstract Co-Author*) Nothing to Disclose
YU XIN XIE (*Abstract Co-Author*) Nothing to Disclose
Haifeng Ran (*Abstract Co-Author*) Nothing to Disclose
HUANG KEXIN (*Presenter*) Nothing to Disclose

### PURPOSE

Previous studies on drug refractory epilepsy (DRE) mainly examined the structural architecture of white matter (WM) by diffusion tensor imaging, but it is not clear whether there are WM function alterations in children with DRE. Hence, this study was aimed to comprehensively analyze the topological properties of WM functional networks among children with DRE. To provide a new perspective for a deeper comprehension of the neuropathological mechanisms underlying this disease.

### METHODS AND MATERIALS

This study included 43 children with DRE and 48 healthy controls(HCs). All participants underwent MRI scans using a 3.0-T magnetic resonance scanner (GE Healthcare). Meanwhile, all DRTLE children underwent standardized neuropsychological assessments using the Wechsler Intelligence Scale-Fourth

Edition for Children-Revised, which measure five Intelligence quotient (IQ) variables in each subject. Global and nodal topological properties were assessed based on the weighted WM functional networks. Independent samples t-test was used for comparisons of global topological properties and nodal topological properties (FDR corrected) between groups. The correlation between the altered WM functional network topological properties and neuropsychological tests were analyzed using spearman's correlation analysis.

**RESULTS**

Both DRE and HCs showed a small-world topology(Sigma = 1.1) of the WM functional network. As compared to the HCs group, the Sigma and Network Efficiency in DRE group was significantly decreased. Further more, significant results were found in nodal properties as BetweennessCentrality(BC), DegreeCentrality(DC), Nodal Clustering coefficient(NCC), NodalEfficiency (NE) and Nodal Local efficiency(NLe)For association fibers, there is a decrease in node properties on multiple white matter fibers. Interestingly, increased nodal properties in the DRE group were found in the commissural fibers and projection fibers. There was a significant association between degree of nodes and one set age, verbal comprehension.

**CONCLUSION**

Our results suggested that global integration ability and functional segregation ability imbalance properties alteration in the white matter brain network of children DRE.The local network efficiency is also regionally reduced or improved, it is suggested a deeper understanding of the potential neuropathological mechanisms and biomarkers in seizure generation.

**CLINICAL RELEVANCE/APPLICATION**

Base on graph-theoretical brain networks, we found correlation between the level of the nodal brain network and the severity of cognitive impairment. Therefore, the white matter abnormalities and network alterations contribute to the discovery of new targets for DRE treatment.

## W2-SPPD-3 ALTERED NEUROVASCULAR COUPLING IN CHILDREN WITH REFRACTORY TEMPORAL LOBE EPILEPSY

Zhang T. Tijiang I, MD (*Abstract Co-Author*) Nothing to Disclose
YU XIN XIE (*Abstract Co-Author*) Nothing to Disclose
HUANG KEXIN (*Abstract Co-Author*) Nothing to Disclose
Guiqin Chen (*Abstract Co-Author*) Nothing to Disclose
Xuhong Li (*Abstract Co-Author*) Nothing to Disclose
Jie Hu (*Abstract Co-Author*) Nothing to Disclose
Haifeng Ran (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to evaluate the neurovascular coupling (NVC) alteration and its clinical significance in childhood refractory temporal lobe epilepsy (TLE) combining resting-state functional magnetic resonance imaging (rs-fMRI) and arterial spin labeling (ASL), providing a new perspective to understand the neuropathological mechanisms of this disease.

**METHODS AND MATERIALS**

The study finally included 63 right-handed subjects (34 children with refractory TLE and 29 healthy controls [HCs]). All participants underwent MRI scans. Amplitude of low-frequency fluctuation (ALFF) and cerebral blood flow (CBF) were calculated based on the rs-fMRI and ASL. For each participant, across-voxel correlation analyses were performed between ALFF and CBF in the whole gray matter to quantitatively evaluate the global NVC. For all voxels, we calculated the CBF/ALFF ratio using the original values of CBF and ALFF to represent the regional NVC. The intergroup differences in CBF, ALFF, and CBF/ALFF ratio maps were analyzed using two-sample t-test, adjusting for the covariates of age, sex, and years of education. For the resulting CBF, ALFF, and CBF/ALFF ratio maps, the Gaussian random field method ($P < 0.05$) was selected to correct for multiple comparisons. The mean value of each cluster with significant between-group differences in CBF, ALFF, and CBF/ALFF ratio was extracted and correlated with the clinical variables using Pearson correlation.

**RESULTS**

The refractory TLE group showed significantly higher regional NVC in the left superior frontal gyri (SFG) compared to the HCs group. The refractory TLE also showed a significantly lower CBF than the HCs group in the left midcingulate cortex, the right pars opercularis of the inferior frontal gyrus, and the right the orbitofrontal cortex. The refractory TLE group exhibited a lower ALFF in the right middle temporal gyrus compared to the HCs group, but the brain region of higher ALFF was not reported. The results showed a significant positive correlation ($r = 0.346$, $P = 0.045$)between the increased CBF/ALFF ratio in the left SFG and the processing speed scores of Wechsler Intelligence Scale.

**CONCLUSION**

These findings provide new neuroimaging evidence of neurovascular decoupling in children with refractory TLE and may be helpful for a deeper understanding of the potential neuropathological mechanisms in seizure generation, providing new biomarkers of cognitive performance in childhood refractory TLE.

**CLINICAL RELEVANCE/APPLICATION**

The study shed a new insight into the pathophysiology of epilepsy and provided the potential imaging biomarkers of cognitive performances in children with refractory TLE by combing rs-fMRI and ASL.

# Abstract Archives of the RSNA, 2024

**Sub-Events**

## W2-SPPH-10 CLINICAL APPLICATION OF ULTRAHIGH-FIELD-STRENGTH ROUTINE KNEE MRI: 3T AND 5T COMPARISON STUDY

Suwei Liu (*Presenter*) Nothing to Disclose

### PURPOSE

Ultrahigh-field-strength MRI at 5T may permit superior visualization of knee pathologic conditions, particularly due to its high signal-to-noise ratio compared with the clinical standard of 3 T, but direct comparison studies are lacking.

### METHODS AND MATERIALS

In this prospective study, patients experiencing knee underwent 3T and 5T MRI with 2D and 3D standard fast spin echo(FSE) sequences (2D sagittal T1WI, 2D sagittal fat-suppressed proton-density [FS_PDWI], 2D coronal FS_PDWI, 2D transversal FS_PDWI, 3D sagittal FS_PDWI and additional reconstruction sequences[coronal/transversal FS_PDWI] on the same day, from December 2023 to April 2024. For quantitative analysis, SNR was determined using these 5 sequences and 2 additional reconstruction sequences. For a semiquantitative assessment of diagnostic confidence, a diagnostic confidence score (DCS) was assigned, using a 5-point scale. Images were scored by three musculoskeletal radiologists. The overall image quality, presence of artifacts, homogeneity of fat suppression, and visualization of 22 potential pathological findings, in total, in 4 anatomically defined areas in the knee joint were semiquantitatively assessed and rated their diagnostic confidence.

### RESULTS

In total, 60 participants (mean age, 44 years ± 16; 39 men) were included. Overall image quality (P = .002) and less presence of artifacts at T1WI, 2D/3D FS_PDWI MRI were superior at 5T. Visualization of cartilage was superior at 5T (P < .001), while for the residual potential pathological findings, there was no statistically significant difference observed. Interreader reliability showed slight to substantial agreement for the detected pathologic conditions (? = 0.67-0.85).

### CONCLUSION

Ultra-high-field MRI at 5T improved the overall diagnostic confidence in routine MRI of the knee joint compared with that at 3 T.

### CLINICAL RELEVANCE/APPLICATION

This is especially true for small joint structures and subtle lesions, particularly in cartilage assessment. However, the problem of chemical shift artifacts needs to be solved.

## W2-SPPH-3 CLINICAL HEAD MRI IMAGE QUALITY IN FINNISH MR IMAGING SITES

Henri Leskinen, MSc (*Abstract Co-Author*) Nothing to Disclose
Nea Pulkkinen, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to evaluate three widely used clinical sequences for head magnetic resonance image (MRI) using a traveling test subject in all major MR imaging sites in Finland to gain understanding on the clinical image quality of head MR images. According to the Radiation and Nuclear Safety Authority of Finland, nearly one out of five of the MRI studies done annually in Finland are head MRIs.

### METHODS AND MATERIALS

The head of a volunteer was scanned in 14 hospitals participating in this study. 26 different MRI scanners were used; 17 with field strength of 1.5 T and 9 with 3 T. Scanners were from four different vendors: 16 Siemens, 4 GE, 4 Philips and 2 Canon. Three clinical sequences were obtained using site adaptations in the clinical routine protocol: 3D T1 weighted Ultrafast Gradient Echo, T2 weighted Turbo Spin Echo and T2 weighted motion correction with radial blades sequence. Three regions of interest (ROIs) were selected and segmented for the data analysis: cerebrospinal fluid (CSF), white matter (WM) and grey matter (GM) using the SynthSeg auto-segmentation tool. For each ROI, three image quality metrics were calculated: signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and SNR divided by acquisition time.

### RESULTS

Median SNR for the 3D T1 sequence was for CSF 15.66 and 22.78, for WM 45.25 and 49.52, for GM 42.18 and 46.79, for 1.5T and 3T, respectively. Median SNR for the T2 blade sequence was for CSF 90.59 and 175.97, WM 30.87 and 42.34, GM 61.81 and 91.48 for 1.5T and 3T, respectively. Median SNR for T2 TSE sequence was for CSF 110.56 and 107.38, WM 41.83 and 30.33, GM 78.99 and 62.58 for 1.5T and 3T scanners, respectively.

### CONCLUSION

Medians of the SNR were 46% and 94% higher for 3T scanners in 3D T1 and T2 Blade sequences, respectively, and 3% lower for the T2 TSE sequence. Few scanners had significantly lower noise levels due to image processing specific to the scanner, which produced outliers for the SNR. This was more significant in 3T scanners due to the lower number of such scanners. A few 1.5T scanners used AI image reconstruction algorithms in T2 TSE, which can affect the median SNR. A clear difference in visual image quality was seen between the lowest and highest SNR images for all sequence types.

### CLINICAL RELEVANCE/APPLICATION

Since head MRIs represent a significant proportion of MRI studies in Finland, a better understanding of the image quality, and of features that affect the quality between sites and vendors can help improve imaging practices at different imaging sites across Finland and elsewhere. Large variation of the image quality metrics between similar scanners highlights the significance of sequence optimization for each individual scanner. Results of this study can be used to better image quality in MR locally and across Finland.

## W2-SPPH-4 PREDICTING 15-MINUTE MYOCARDIAL EXTRACELLULAR VOLUME USING SYNTHETIC CONCENTRATION MAPS FROM DYNAMIC T1 MAPPING WITHIN 10 MINUTES WITH PHARMACOKINETIC ANALYSIS

Masaki Sakurai (*Abstract Co-Author*) Nothing to Disclose
Toshimitsu Tanaka, RT (*Presenter*) Nothing to Disclose

### PURPOSE

In cardiac MRI (CMR), myocardial extracellular volume (ECV) measurements may vary depending on the timing of T1 map imaging after contrast administration. Consistent timing is preferable for follow-up, but clinical practice often involves late-gadolinium enhancement imaging, causing variability in T1 map imaging times. This study aimed to determine whether synthetic concentration maps derived from a pharmacokinetic model using dynamic T1 maps at intervals of up to 10 minutes can accurately predict the ECV at 15 minutes, compared with the reference 15-minute T1 mapping during CMR.

### METHODS AND MATERIALS

In this IRB-approved prospective study, 40 patients (mean age: 66 years, 16 women) underwent 3T CMR for cardiomyopathy evaluation. T1 maps were acquired before and after contrast administration at 2, 5, 9, and 15 minutes. The time-series T1 maps were aligned using non-rigid registration, and a pharmacokinetic Brix model was applied to generate synthetic concentration maps for 15 minutes based on the data at 2, 5, and 9 minutes. Radiologists placed ROIs in segments #8 and 9 of the septum and the lumen. They then compared the ECV values at 15 minutes (ECV15min) from the actual T1 map with those derived from the synthetic concentration maps (Synthetic_ECV15min). Correlation coefficients and Bland-Altman analysis were used to evaluate ECV2min, ECV5min, ECV9min, and Synthetic_ECV15min compared with the reference ECV15min. Paired T-tests were employed to compare deviations from the reference ECV15min between ECV9min and Synthetic_ECV15min.

### RESULTS

For the 40 patients (80 segments), the reference ECV15min was 29.9±2.8%, while Synthetic_ECV15min was 29.6±3.2%. A strong correlation was observed (R=0.96 [95% CI 0.94-0.98]), with a mean difference of -0.3% (95% CI, -0.07 to 0.03). ECV2min, ECV5min, and ECV9min significantly underestimated the ECV compared to the reference ($P < .001$). The error in Synthetic_ECV15min was significantly lower than in ECV9min when compared to the reference ($P=0.01$).

### CONCLUSION

Dynamic T1 maps at three-time points within 10 minutes after contrast administration can accurately predict the ECV at 15 minutes using synthetic concentration maps generated from pharmacokinetic modeling.

### CLINICAL RELEVANCE/APPLICATION

These findings support using synthetic concentration maps to predict ECV, potentially enabling faster and more efficient cardiac MRI protocols.

## W2-SPPH-6 3D CHEMICAL EXCHANGE SATURATION TRANSFER (CEST) IMAGING VS. DIFFUSION-WEIGHTED IMAGING (DWI) WITH AND WITHOUT CEST IMAGING: CAPABILITY FOR DISTINGUISHING MALIGNANT FROM BENIGN PROSTATIC AREAS

Takahiro Ueda, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

3D Chemical exchange saturation transfer (CEST) imaging is recently reported as useful for obtain regional CEST information within entire tumor. The purpose of this study was to compare the capability for distinguishing malignant from benign prostatic areas among 3D CEST imaging, diffusion weighted imaging (DWI) and combined both information.

### METHODS AND MATERIALS

Fifty-two suspected prostatic cancer patients underwent DWI at b value as 0 and 1500 s/mm2 and 3D CEST imaging at a 3T MR system, surgical treatments and pathological examinations. According to the pathological results, 154 areas were determined as malignant prostatic areas, and 154 out of 470 areas were computationally selected as benign prostatic areas. On each 3D CEST imaging, magnetization transfer ratio asymmetry (MTRasym) at 3.5 ppm map was generated from z-spectra by pixel-by-pixel analyses. Then, 308 ROIs were placed over malignant or benign areas on each map, and MTRasym and ADC values were determined. Each index was compared between malignant and benign areas by Student's t-test. Then, logistic regression analysis was performed to investigate the discriminating factors. ROC analysis was performed to compare diagnostic performance among MTRasym, ADC and combined discriminators. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's test.

### RESULTS

MTRasym and ADC of malignant area had significant differences with those of benign area (MTRasym: $p<0.0001$, ADC: $p<0.0001$). MTRasym (Odds ratio [OR]: 1.01, $p<0.0001$) and ADC (OR: 0.03, $p<0.0001$) were determined as significant discriminators. Area under the curves (AUC) of combined discriminators (AUC=0.86) was significantly better than that of MTRasym (AUC=0.81, $p=0.001$) and ADC (AUC=0.76, $p<0.0001$). Specificity (SP) and accuracy (AC) of combined discriminators (SP: 72.1%, AC: 78.6%) were significantly higher than those of MTRasym (SP: 60.4%, $p<0.0001$; AC: 73.1%, $p<0.0001$) and ADC (SP: 64.2%, $p<0.0001$; AC: 74.0%, $p<0.0001$).

### CONCLUSION

3D CEST imaging is considered at least as valuable as DWI and can improve capability for differentiation of malignant from benign prostatic areas with DWI.

### CLINICAL RELEVANCE/APPLICATION

3D CEST imaging is considered at least as valuable as DWI and can improve capability for differentiation of malignant from benign prostatic areas with DWI.

## W2-SPPH-7 POSTURAL EFFECTS ON CARDIAC FUNCTION AND STRAIN: EVALUATION USING MULTIPOSTURE MRI

Tosiaki Miyati, PhD, PhD (*Abstract Co-Author*) Nothing to Disclose
Seiya Nakagawa, BA (*Abstract Co-Author*) Nothing to Disclose
Naoki Ohno, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Cardiac cine MRI and ultrasound (US) are widely used to assess cardiac function and diagnose heart diseases. Previous studies using US have indicated that body posture can influence measurements of cardiac function. However, US has limitations in terms of analytical accuracy. Although cine MRI can assess cardiac function with higher accuracy than US, measurements in different body postures, such as standing or sitting, have been limited by the architecture of conventional MRI systems. This study investigated the effects of body posture on cardiac function and strain using a multiposture MRI system, which allows for data acquisition in various body postures.

### METHODS AND MATERIALS

Cardiac function was assessed in ten healthy male subjects (mean age, 22.1 ± 0.5 years) in the supine and standing postures using a 0.4T multiposture MRI. Electrocardiogram-synchronized cardiac cine MRI in the short axis of the left ventricle was performed using a balanced steady-state free precession sequence. The left ventricular cavity in each image was automatically delineated using a cardiac function analysis software. Then, left ventricular end-diastolic volume (EDV), end-systolic volume (ESV), stroke volume (SV), heart rate (HR), cardiac output (CO), ejection fraction (EF), global radial strain (GRS), and global circumferential strain (GCS) were determined. We compared these parameters between the two postures using the Wilcoxon signed-rank test. Statistical significance was set at $P < 0.05$.

### RESULTS

In the standing posture, the EDV, ESV, and SV were significantly reduced compared to the supine posture, likely due to fluid redistribution to the lower body, which decreases venous return to the heart. The HR increased significantly in the standing posture, while the CO was significantly lower. These changes suggest that despite increased sympathetic activity in the standing posture, which raises HR, it does not fully offset the reduction in CO. The EF remained relatively stable across postures, suggesting minimal impact from changes in body posture. The GCS increased significantly in the standing posture, whereas the GRS did not show a significant difference between the postures.

### CONCLUSION

Standing posture decreases EDV, ESV, SV, and CO and increases HR and GCS compared with supine posture. Multiposture MRI enables the assessment of postural effects on cardiac function and strain.

### CLINICAL RELEVANCE/APPLICATION

Multiposture MRI has demonstrated differences in cardiac function and strain between standing and supine postures, offering new diagnostic insights into how the heart adapts to gravitational changes.

## W2-SPPH-8 INFLUENCE OF FAT SUPPRESSION AND FAT SIGNAL ON QUANTIFICATION OF MAGNETIZATION TRANSFER BASED ON SPIN-LOCK MRI

Winnie C. Chu, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Yiyou Sun (*Abstract Co-Author*) Nothing to Disclose
Jian Hou (*Abstract Co-Author*) Nothing to Disclose
Min Deng (*Abstract Co-Author*) Nothing to Disclose
Weitian Chen (*Abstract Co-Author*) Nothing to Disclose
Ziqin Zhou, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

A new magnetization transfer (MT) imaging technique to quantify macromolecule content, termed macromolecular proton fraction (MPF) mapping based on spin-lock (MPF-SL), has attracted increasing attention. We investigated whether different fat saturation (FS) methods and fat fraction (FF) influence on its quantification.

## METHODS AND MATERIALS

MPF-SL sequence comprises two measurements with individual off- resonance spin-lock (SL) preparation following MPF-SL condition, the SL RF amplitude and frequency offset were: ?1: 100Hz, ?2: 600Hz; ??:1 1000Hz, ??2: 6000Hz. Half-Fourier Acquisition Single-shot Turbo Spin Echo (HASTE) was selected for image acquisition (TR/TE: 4000/25ms; FOV: 200 x 200mm; resolution: 1mm x 1mm x 4mm). A map of a relaxation rate termed Rmpfsl was computed from difference of two measurements. Note Rmpfsl removes signal from water pool and can be converted to MPF based on a dictionary approach.Three FS methods were compared, including Short Tau Inversion Recovery (STIR), Spectral fat saturation (FatSats FatSatw), and Spectrally Adiabatic Inversion Recovery (SPAIRs SPAIRw) at both strong and weak settings. FF maps were collected with vender-provided DIXON. MPF-SL imaging was conducted on agar phantoms (concentration:1% to 5%) with peanut oil on top, and on two health volunteers, respectively. To estimate Rmpfsl changes, regions of interest were drawn on agar/oil junction and calf muscle. Bloch-McConnel simulation was performed using RF pulses used in three FS methods on skeletal muscle.

## RESULTS

The Rmpfsl difference between FS methods correlates with agar concentration reflecting increase in MT signal (Figure 1). Residual fat signal increases with FF, leading to decreased Rmpfsl in absence of FS (Figure 2). Rmpfsl difference between FS methods observed in calf muscle was substantially higher than that in phantoms (Figure 3 4). Validated by BM simulation, measured Rmpfsl with FatSat is slightly higher than reference value, while Rmpfsl decreases with SPAIR and STIR (Figure 5).

## CONCLUSION

The Rmpfsl of agar phantoms and human muscle shows visible dependence on FS methods and FF. In absence of fat, RF pulses used for FS affect MT signal, thus perturbing Rmpfsl quantification. Dictionary shall be built to account for this effect when calculating MPF from Rmpfsl. Conversely, with presence of fat, the residual fat signal due to imperfect FS may result in errors in MPF-SL quantification.

## CLINICAL RELEVANCE/APPLICATION

FS methods and FF variation may introduce bias into Rmpfsl. Bias correction with FS and FF factor may avoid misleading or erroneous Rmpfsl value interpretation. Effective solution is anticipated to obtain reliable MPF from Rmpfsl to benefit clinical trials where MPF is primary endpoint.

## W5A-SPBR-1 DIFFERENTIAL DIAGNOSIS OF BREAST MUCINOUS CARCINOMA AND FIBROADENOMA ON MRI BYINTRATUMORAL AND PERITUMORAL ADC MEASURESWITH MASSENHANCEMENT

Li Na Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Hongbing Liang (*Abstract Co-Author*) Nothing to Disclose
Siqi Zhao (*Abstract Co-Author*) Nothing to Disclose
Ning Ning (*Abstract Co-Author*) Nothing to Disclose
Yueqi Wu (*Abstract Co-Author*) Nothing to Disclose
Moyun Zhang (*Abstract Co-Author*) Nothing to Disclose
Yuanfei Li (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the value of the intratumoral and peritumoral ADC based on DWI for distinguishing breast mucinous carcinoma (MC) from fibroadenoma (FA) with mass enhancement (ME).

### METHODS AND MATERIALS

A total of 61 patients with ME were included in this study. The patients were categorized into the MC group (n=25) and FA group (n=36) according to pathology results. All the patients underwent preoperative 3.0T MRI (GE Signa HDxt 3.0T MR, GE healthcare, USA) with a 8-channel breast coil. The conventional MRI features (mass maximum diameter, T2WI signal, internal enhancement mode, TIC type), intratumoral ADC(ADCintra), peritumoral ADC (ADCperi) values and BI-RADS scores were recorded. The average ADC values of three regions of interest (ROIs) were placed in the different areas of the mass. The ROC curve was drawn, the differential diagnosis threshold was obtained and the diagnostic efficiency was analyzed. SPSS 25.0 was used for statistical analysis.

### RESULTS

Compared with the FA group, the MC group was older (50.64 ± 8.17years). The MC group mainly showed high signal intensity on T2WI, inhomogeneous enhancement, TIC type II. The ADCintra value was higher than the ADCperi value [(1.97 ± 0.36) × 10-3mm2/s, (1.48 ± 0.21) × 10-3mm2/s, P=0.028] of MC group. The ADCintra value and was lower than the ADCperi value of FA group [(1.50 ± 0.26)×10-3mm2/s and(1.54 ± 0.19)×10-3mm2/s respectively and there was no significant difference in the MC group (P =0.521). Furthermore, the ADCintra value in the FA group was lower than the MC group, and there was significant difference between them (P< 0.01). The ADCperi value of MC group was higher than that of FA group, and there was no significant difference between the two groups (P > 0.05). The area under the ROC curve of breast MC and FA the ADCintra was 0.608, the diagnostic threshold was 1.655 × 10-3mm2/s, the AUC was 0.877, the sensitivity was 92.0%, the specificity was 77.8%, and the diagnostic accuracy was 83.6%.

### CONCLUSION

This study validated the clinical use of ADCintra cutoffs for discrimination breast MC from FA disease manifesting as Mass Enhancement, which results in an increased number of avoidable biopsies.

### CLINICAL RELEVANCE/APPLICATION

This study highlights efficiency of the Intratumoral ADC cutoffs for discrimination breast MC from FA disease manifesting as Mass Enhancement.

## W5A-SPBR-2 TOMOELASTOGRAPHY COMPLEMENTING DIFFUSION-WEIGHTED IMAGING FOR THE PREDICTION OF PATHOLOGICAL COMPLETE RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN PATIENTS WITH BREAST CANCER

Jiuquan Zhang (*Abstract Co-Author*) Nothing to Disclose
Yao Huang (*Abstract Co-Author*) Nothing to Disclose
Xiaoxia Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To gain further knowledge about temporal trends of neoadjuvant chemotherapy (NAC)-associated ADC and biomechanical parameters quantified with tomoelastography and predict pCR.

### METHODS AND MATERIALS

In this prospective longitudinal study, participants with breast cancer who received NAC were enrolled from February 2021 to May 2022. Participants underwent breast MRI at pre-NAC (T1), after 2 cycles (T2), 4 cycles (T3), and 6 cycles of NAC (T4). ADC, shear-wave-speed (c) and loss-angle (f)

quantifying stiffness and fluidity were obtained and compared by generalized estimating equation. Predicative performance was assessed with area under the receiver operating characteristic curve (AUC) analysis.

**RESULTS**

A total of 109 participants (mean age, 50.15 years ± 7.86 [standard deviation]) were enrolled, 29 participants experienced pCR. The ADC showed a significant upward trend in total participants, c and f decreased significantly among total participants and three molecular subgroups (all $P < 0.001$). For predicting pCR, ADC combined with c and f achieved the highest predictive performance at T3 (AUC, 0.803; 95% confidence interval [CI]: 0.715, 0.874), better than either ADC ($P = 0.006$) or c ($P = 0.043$) alone. In Luminal B subtype, f at T3 was highly predictive of pCR (AUC, 0.832; 95% CI: 0.703, 0.921), while combining ADC, c and f at T2 achieved the highest predictive performance in human epidermal growth factor receptor 2-enriched (AUC, 0.771; 95% CI: 0.531, 0.921) and triple negative breast cancer subtypes (AUC, 0.864; 95% CI: 0.678, 0.965).

**CONCLUSION**

During the course of NAC, the increase in ADC and decreases in stiffness and fluidity were more significant in patients with pCR, combining ADC and biomechanical properties at mid-NAC could predict pCR with good accuracy.

**CLINICAL RELEVANCE/APPLICATION**

This prospective longitudinal study demonstrated that MRI parameters used to detect treatment-induced intratumoral changes in patients with breast cancer could predict pathologic response to neoadjuvant chemotherapy. Our findings confirmed them to be complementary and accurate in predicting pathological complete response, which will benefit clinical decision-making.

## W5A-SPBR-3 BREAST GALACTOGRAPHY WITH CONTRAST-ENHANCED MAMMOGRAPHY (CEM)—AN INNOVATIVE ATTEMPT

Shuyi Peng (*Abstract Co-Author*) Nothing to Disclose
Fan Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Wenying Zhu (*Abstract Co-Author*) Nothing to Disclose
Jie Liu (*Abstract Co-Author*) Nothing to Disclose
Juan Tao (*Presenter*) Nothing to Disclose

**PURPOSE**

This study used CEM protocol in galactography for the first time. To evaluation the application value of Contrast-enhanced mammography (CEM) in breast galactography.

**METHODS AND MATERIALS**

24 patients with pathological nipple discharge were examined using CEM-galactography and MRI. CEM-galactography presents two kinds of images per breast and per view— low-energy image and recombined image. Evaluation of the images created with the different imaging modalities was done by 3 investigators with varying levels of experience with complementary breast diagnostics (8 ,9 and 21 years), and their evaluations were compared with the histological findings. AGD differences were analyzed by Mann-Whitney U test.

**RESULTS**

The average age of the 24 patients was 45.9 years. The average glandular dose (AGD) of CEM-galactography (median:1.65 mGy) was 21.8% higher than low-energy imaging(1.29 mGy) ($P<0.001$) in CC view, while the AGD of CEM-galactography(1.65 mGy) increased by 21.8% compared with low-energy imaging(1.29 mGy)($P<0.001$)in ML view. Their evaluations were compared with the histopathological assessment of the surgical specimens resected from the 24 patients. There were 4 cases of intraductal carcinoma, 5 cases with ductal carcinoma in situ 11 cases with intraductal papilloma and 4 cases with duct ectasia. The recombined image generated by CEM showed that the size of the lesion was closer to that of histopathological findings.

**CONCLUSION**

CEM-galactography can better display the size of the lesions and the details of the catheter branch than the low-energy image. It could be a useful complementary procedure for the diagnosis of breast anomalies and could herald a new aissance of this method. Compared with low-energy imaging, the investigators achieved better results with recombined image, as confirmed by histopathological findings.

**CLINICAL RELEVANCE/APPLICATION**

This is the first time CEM was used in galactography. CEM displays better size than regular imaging, so it can better guide clinical surgical scope.

## W5A-SPBR-4 AXILLARY NODAL EVALUATION USING NODE REPORTING AND DATA SYSTEM (NODE-RADS) IN BREAST CANCER: INVASIVE DUCTAL CARCINOMA VS INVASIVE LOBULAR CARCINOMA

Hee Jeong Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hee Jung Shin, MD (*Abstract Co-Author*) Nothing to Disclose
Woo Jung Choi, MD (*Abstract Co-Author*) Nothing to Disclose
Joo Hee Cha, MD (*Abstract Co-Author*) Nothing to Disclose
Hak Hee Kim, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hye Joung Eom (*Abstract Co-Author*) Nothing to Disclose
Eun Young Chae, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Imaging characteristics may vary according to the histologic type of breast cancer, and we aimed to investigate the differences in the applicability of the recently introduced Node-RADS score in patients with invasive ductal carcinoma (IDC) or invasive lobular carcinoma (ILC).

**METHODS AND MATERIALS**

In this retrospective study, we reviewed 850 consecutive women with pathologically proven IDC or ILC who underwent breast MR imaging before surgery. Axillary nodal status was assessed using Node-RADS scores to predict the likelihood of lymph node metastases. Node-RADS scores were determined based on size and configuration criteria, which were then combined into scores ranging from 1 (very low likelihood) to 5 (very high likelihood). Diagnostic performance parameters using Node-RADS were calculated and compared according to histologic type of breast cancer (IDC vs ILC).

**RESULTS**

Of the 850 women, including 8 cases of bilateral breast cancer, 780 were diagnosed with IDC, and 78 were diagnosed with ILC. The frequency of lymph node metastasis did not show a significant difference between the two groups ($p=0.980$). Overall, Node-RADS demonstrated comparable performance of an AUC of 0.826 in IDC and 0.739 in ILC ($p=0.232$). With a Node-RADS score = 3 as a cut-off, the sensitivity, specificity, Youden's index were 66.7%,

84.9%, and 0.516 for IDC, and 52.6%, 86.4%, and 0.391 for ILC, respectively. The other performance parameters showed no significant difference between the two groups, however, the sensitivity was significantly lower in the ILC group (p=0.024).

**CONCLUSION**

Although Node-RADS scores demonstrated comparable performance for axillary nodal evaluation in IDC and ILC groups, a statistically significant difference was observed in terms of sensitivity.

**CLINICAL RELEVANCE/APPLICATION**

Node-RADS scores are expected to yield promising results in IDC patients, however, caution may be warranted in the adoption of this system in patients with ILC.

## W5A-SPBR-7 INVESTIGATION OF THE EFFECTIVENESS OF ULTRAFAST DCE-MRI ON A WIDELY USED 1.5T-MRI SYSTEM

Yoshihide Kanemaki (*Abstract Co-Author*) Nothing to Disclose
Takafumi Haraguchi, MD (*Abstract Co-Author*) Nothing to Disclose
Yukiko Michishita, MD (*Abstract Co-Author*) Nothing to Disclose
Yuka Goto, RT (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the diagnostic performance of ultrafast dynamic contrast enhanced (UF-DCE) MRI, which is expected to reduce examination time through initial contrast evaluation, with standard DCE MRI to differentiate malignant from benign breast lesions on a 1.5T-MRI system.

**METHODS AND MATERIALS**

Women who underwent standard DCE MRI and UF-DCE MRI for suspected breast cancer diagnosis at our institution from November 2022 to April 2023 were retrospectively assessed. 1.5T-MRI system with a 16-ch breast coil was used. UF-DCE MRI using high-speed 3D gradient-echo (GRE) with Compressed-SENSE was repeated 16 times for 6 sec/scan (two pre-contrast and 14 after contrast). The DCE MRI using fat suppressed 3D GRE was performed once pre-contrast and twice after contrast (early phase at 90 sec and delayed at 300 sec). Two radiologists (Reader-1 and Reader-2) independently placed ROIs using UF-DCE MRI and DCE MRI data sets on the most suspicious lesions. We calculated time to enhancement (TTE) and maximum slope (MS) as initial enhancement in UF-DCE MRI. The washout ratio (WR) was delivered from washout kinetic curve in DCE MRI; WR was calculated from the percentage difference in signal intensity between the early and delayed phases. Morphological assessment was performed using the Breast Imaging Reporting and Data System (BI-RADS) MRI 5th edition, and BI-RADS categories were defined in conjunction with WR.

**RESULTS**

In total 210 women (mean age 57) with 216 malignant and 54 benign lesions were included. Both TTE and MS showed significant differences between malignant and benign lesions (all, p <.001). The AUC values for Reader-1 and Reader-2 respectively were 0.780 and 0.744 in TTE (intra-class correlation coefficient=0.628), 0.795 and 0.771 in MS (0.760), 0.792 and 0.754 in WR (0.714), and 0.860 and 0.858 in BI-RADS categories (0.905). The AUC values for BI-RADS categories was statistically significantly superior to TTE only for Reader-1 (p =.028; MS and WR, p>.05) and to all kinetic parameters for Reader-2 (TTE, p=.006; MS, p=.044; WR, p=.012). The sensitivity was 58.3% for both readers in TTE, 89.4% and 87.0% in MS, and 73.6% and 83.3% in WR. The specificity was 85.2% and 81.5% in TTE, 63.0% for both readers in MS, and 80.0% and 66.7% in WR.

**CONCLUSION**

The MS demonstrated diagnostic performance equivalent to WR in differentiating benign and malignant breast lesions. On widely used 1.5T-MRI systems, by combining the BI-RADS morphological assessment with MS instead of WR, it is expected to reduce examination time while keeping diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

This is the first report regarding diagnostic performance of UF-DCE MRI on a widely used 1.5T-MRI systems. The current data will be useful for the development of more general protocols for UF-DCE MRI.

## W5A-SPBR-9 POSITIVE PREDICTIVE VALUE OF BI-RADS ASSESSMENT CATEGORY 4 SUBDIVISIONS FOR HIGH-RISK SCREENING AND DIAGNOSTIC MRIS

Jean M. Seely, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Mary B. Bissell, Md, MSc (*Abstract Co-Author*) Nothing to Disclose
Gianna Cox, BSc (*Presenter*) Nothing to Disclose

**PURPOSE**

Breast lesions identified at mammography (MG) and ultrasound (US) that require biopsy are risk-stratified based on their morphology into BI-RADS category 4 (BR4) or 5, which reflect the likelihood of a malignant diagnosis. For US and MG, BR4 is subdivided into 4A, 4B, and 4C, which respectively indicate an increasing likelihood of a malignant diagnosis. While BI-RADS does not currently mandate BR4 subdivisions for MRI detected lesions, our current institutional practice utilizes these subcategories to triage biopsy bookings.Our objective was to determine the positive predictive value (PPV2 and PPV3) of BR4 subcategory assessments for lesions detected at both diagnostic and screening breast MRI, and to determine if the predictive values are comparable to the existing benchmarks established for MG and US.

**METHODS AND MATERIALS**

A single-center retrospective review of all High-Risk Ontario Breast Screening Program (HR-OBSP) and diagnostic breast MRIs performed over a two-year period (01/01/2021 - 31/12/2022) was conducted. Data extracted from the patient chart included the BI-RADS assessment categories and, if applicable, biopsy result. PPV2 and PPV3 for each BR4 subcategory were calculated.

**RESULTS**

3348(54.0%) HR-OBSP and 2850(46.0%) diagnostic breast MRIs (excluding those without contrast) were performed over our two-year study period (01/01/2021 - 31/12/2022). For the HR-OBSP population, 234 biopsies (7.0% of total exams) were recommended with 123(52.6%) category 4A, 85(36.3%) category 4B, 22(9.4%) category 4C and 4(1.7%) category 5 assessments (cancer detection rate (CDR) of 9.0/1000). For diagnostic MRIs, 481 biopsies (16.9% of total exams) were recommended with 136(28.3%) category 4A, 199(41.4%) category 4B, 92(19.1%) category 4C and 54(11.2%) category 5 assessments (CDR of 55.4/1000). PPV2 for screening | diagnostic exams were Category 4A 4.9%|6.6%, Category 4B 12.9%|17.1%, Category 4C 45.5%|51.1% and Category 5 75.0%|74.1%. PPV3 for screening | diagnostic exams were Category 4A 7.5%|9.8%, Category 4B 17.7%|20.7%, Category 4C 45.5%|57.3% and Category 5 75.0%|93.0%.

## CONCLUSION

Malignancy predictive values of BI-RADS category 4 subdivisions for breast MRI align with the established benchmarks for MG and US for lesions identified on both screening and diagnostic breast MRI.

## CLINICAL RELEVANCE/APPLICATION

The current ACR BI-RADS does not subcategorize MRI-detected lesions, however the next iteration has announced this as a change. BI-RADS category 4 subdivisions offer an accurate and valuable method for triage of suspicious breast lesions detected via MRI. These subdivisions aid in optimizing resource allocation, ensure timely interventions for high-risk findings, and are a valuable communication tool between consultants.

## W5A-SPCA-10 FEATURE TRACKING STRAIN WITH RAPID CARDIAC MR FOR SUBCLINICAL MYOCARDIAL DYSFUNCTION IN THALASSEMIA PATIENTS

Priya Jagia, MD (*Abstract Co-Author*) Nothing to Disclose
Vineeta Ojha, MD (*Abstract Co-Author*) Nothing to Disclose
Aprateem Mukherjee, MD, FRCR (*Presenter*) Nothing to Disclose

### PURPOSE

In patients undergoing regular blood transfusion therapy for thalassemia syndromes, iron overload cardiomyopathy (IOC) is a serious problem and considered to be leading cause of cardiac dysfunction, failure and death. Strain analysis with feature tracking (FT)-CMR has been shown to detect subclinical myocardial dysfunction before conventional parameters such as left ventricular ejection fraction (LVEF) is deranged. Our aim was to detect whether strain analysis detects subclinical myocardial contractile dysfunction in myocardial iron overload (MIO) and whether it correlated with conventional marker of cardiac iron, that is, T2*.

### METHODS AND MATERIALS

100 consecutive thalassemia patients undergoing regular blood transfusion were prospectively included. All patients underwent CMR with T2* used as gold standard for detecting MIO. Patients were divided into two groups - those with MIO (T2* < 20ms) and those without MIO (T2* = 20 ms).

### RESULTS

100 patients (66 males and 34 females) underwent CMR cardiac iron assessment with mean age of 16.1 years. There were 22 patients (12 males, 10 females) with significant MIO (T2*< 20 ms) and 78 patients (54 males and 24 females) without significant MIO. LV GRS, LV GLS, RV GLS and RV GRS were significantly reduced in patients with MIO group compared to non-MIO group. LV GLS cut-off of>-14.1 had the highest AUC of 0.786 to detect myocardial iron (T2* < 20 ms) with a sensitivity of 63.64% and specificity 84.62%. There was significant but weak correlations between LV GRS and T2* (r = 0.2491, 95% CI 0.05539 to 0.4247, p = 0.0124) and LV GLS with T2* (r= -0.4212, 95% CI -0.5704 to -0.2450, p <0.0001). There was no statistically significant correlation between LV GCS, RV strain parameters (RV GCS, RV GRS, RV GLS) and myocardial T2*.

### CONCLUSION

Myocardial strain as determined by FT CMR analysis is deranged in patients with MIO compared to those without MIO, without any overt decline in cardiac functions in these patients likely signifying onset of subclinical ventricular dysfunction. LV GRS and LV GLS correlated with T2*. FT CMR may be used as an early marker for myocardial dysfunction in these patients.

### CLINICAL RELEVANCE/APPLICATION

Early myocardial dysfunction detected by strain analysis may help to initiate/upstage even earlier iron chelation therapy before overt myocardial dysfunction develops as detected by echocardiography, thereby help to prevent mortality caused by myocardial iron deposition in transfusion dependent thalassemia patients.

## W5A-SPCA-4 T1, T2, AND ECV MAPPING DERIVED FROM A SINGLE-SLICE MEASUREMENTS IS OFTEN NON-INFERIOR COMPARED TO MEAN OF MUTIPLE VIEWS IN DIAGNOSING MYOCARDITIS: INSIGHTS FROM THE MYORACER TRIAL

Borek Foldyna, MD (*Abstract Co-Author*) Nothing to Disclose
Patrick Seitz (*Abstract Co-Author*) Nothing to Disclose
Matthias Gutberlet, MD, PhD (*Abstract Co-Author*) Speaker, Siemens AG;Speaker, Koninklijke Philips NV;Speaker, Bayer AG;Speaker, Bracco Group;Author, Thieme Medical Publishers, Inc

Clara Frank (*Abstract Co-Author*) Nothing to Disclose
Karin Klingel, MD (*Abstract Co-Author*) Nothing to Disclose
Philipp Lurz (*Abstract Co-Author*) Nothing to Disclose
Christian Luecke, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Mapping aids to diagnose myocarditis on cardiac MRI. First aim: to compare the diagnostic performance of single slice T1, ECV, and T2 mapping vs. mean, performed in two-chamber-(2CH), four-chamber-(4CH) views and midventricular short-axis-orientation (SA). Second aim: to find the slice orientation with the best diagnostic performance compared to endomyocardial biopsy (EMB).

### METHODS AND MATERIALS

This study is a sub study of the prospective MyoRacer trial (Lurz et al. 2016) with imaging parameters as published. Mapping was acquired as single slices in 2CH, 4CH and SA orientations and measured on a dedicated cMR-workstation. The readers were blinded to the biopsy results. We compared the discriminative capacity of individual single-slice-mapping with the means of multi-slice measures using ROC analysis and biopsy as reference. Diagnostic performance was examined by using ROC-analysis, AUCs were compared.

### RESULTS

Among 88 included patients (20 (32%) women; 43±12y), 62 (70,4%) were EMB positive for myocarditis. AUC for T2 mapping were 0.696 for the mean, 0.693 for SA, 0.671 for 2CH, and 0.62 for 4CH and did not differ significantly p>0.125. AUC for T1 mapping were 0.667 for the mean, 0.667 for 4CH, 0.662 for the 2CH, and 0.583 for the SA orientation. The difference between mean and SA was statistically significant p=0.0256 (other differences p> 0.19). AUC for ECV calculation were 0.667 for the mean, 0.635 for SA, 0.679 for 2CH, and 0.629 for 4CH, not statistically significant (p>0.18).

### CONCLUSION

Although the mean of three measurements shows the best diagnostic performance, even a single slice of native T1 or T2 Mapping or ECV-analysis delivers similar diagnostic accuracy in patients with suspected myocarditis. Long axis T1 mapping can however outperform a single slice T1 mapping in midventricular short axis orientation.

### CLINICAL RELEVANCE/APPLICATION

The ability of single-slice T1, T2 mapping, and ECV analysis to match the diagnostic accuracy of multi-slice averages suggests that MRI protocols can be simplified. This can reduce scan times and improve patient throughput in busy clinical settings.

## W5A-SPCA-6 RIGHT VENTRICULAR CMR STRAIN ANALYSIS DETECTS SUBCLINICAL MYOCARDIAL DAMAGE AFTER ANTHRACYCLINE-BASED CHEMOTHERAPY IN PATIENTS WITH BREAST CANCER

Jennifer Erley, MD (*Abstract Co-Author*) Nothing to Disclose
Enver G. Tahir, MD (*Abstract Co-Author*) Nothing to Disclose
Gerhard B. Adam, MD (*Abstract Co-Author*) Nothing to Disclose
Destina Gizem Aydemir, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate possible anthracycline-induced cardiotoxicity by analyzing right ventricular (RV) function using cardiovascular magnetic resonance myocardial feature tracking (CMR-FT).

### METHODS AND MATERIALS

This prospective monocentric study included 30 female patients with first-time breast cancer (50±11 years), who received systemic anthracycline-based chemotherapy including 4 cycles of epirubicin (90 mg/m2) combined with cyclophosphamide (600 mg/m2) and 12 cycles of paclitaxel (80 mg/m2) according to the guidelines. CMR was performed on all patients before initiating chemotherapy and at a follow-up of 12 months after first administration. Right ventricular ejection fraction (RVEF), end diastolic (RVEDV), end systolic (RVESV) and stroke volumes (SV) were determined by CMR using a commercially available software (cvi42). CMR-FT was used to determine RV global longitudinal (GLS), radial (GRS) and circumferential strain (GCS). Paired t-test was used to assess the differences in strain values between baseline and follow-up.

### RESULTS

Only 7 out of 30 patients showed a reduction in RVEF after 12 months, but overall RVEF remained unchanged (54±6% vs. 56±6%, p=0.2). All patients with reduced RVEF demonstrated attenuated RV GLS at follow-up. RV GLS was attenuated at 12 months following chemotherapy (-25±4% vs. -21±4%, p<0.001). RV GRS (18±7% vs. 20±7%, p=0.08) and RV GCS (-11±4% vs. -12±3%, p=0.4) remained unchanged at 12 months after chemotherapy. No differences were observed for RVEDV, RVESV and RVSV (all p>0.05).

### CONCLUSION

Right ventricular strain analysis using CMR-FT can detect myocardial impairment following anthracycline-based chemotherapy. Right ventricular GLS could serve as an early marker of subclinical cardiotoxicity.

### CLINICAL RELEVANCE/APPLICATION

Changes in RV GLS after anthracycline-based chemotherapy could serve as an early marker of subclinical cardiotoxicity and should thus be routinely determined in patients with suspected chemotherapy-induced cardiomyopathy.

## W5A-SPCA-7 PERIVASCULAR INFLAMMATION IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY AND ITS POTENTIAL CLINICAL IMPLICATION

Yang Peng (*Abstract Co-Author*) Nothing to Disclose
Lin Peng (*Abstract Co-Author*) Nothing to Disclose
Jun Yuan (*Abstract Co-Author*) Nothing to Disclose
Yuying Chen (*Presenter*) Nothing to Disclose

### PURPOSE

To assess pericoronary adipose tissue inflammation in patients with hypertrophic cardiomyopathy (HCM) using a novel imaging biomarker, the perivascular fat attenuation index (FAI) derived from coronary computed tomography angiography (CCTA), and to investigate potential factors associated with FAI.

### METHODS AND MATERIALS

The retrospective study enrolled 34 patients diagnosed with HCM and 62 individuals with normal cardiac structure who underwent cardiac magnetic resonance (CMR) and CCTA scans within 2 weeks from January 2021 to December 2023. Perivascular FAI was evaluated using commercially available software (Shukun, FAI, V1.7, Beijing, China), evaluating specific segments of the proximal right coronary artery (RCA-FAI), left anterior descending artery (LAD-FAI), and left circumflex artery (LCX-FAI). The maximum wall thickness (MWT), end-diastolic volume index to body surface area (EDVi), mass index to body surface area (massi), ejection fraction (EF), and late gadolinium enhancement (LGE) percent was quantified using CVI 42 software. White blood cell count (WBC), high-sensitivity C-reactive protein (hsCRP), procalcitonin (PCT), high-sensitivity troponin (cTNT-T), and N-terminal pro-brain natriuretic peptide (NT-proBNP) were simultaneously assessed. The Correlations between continuous variables were assessed using either Pearson's correlation coefficient or Spearman's rank correlation coefficient, as appropriate.

### RESULTS

The LAD-FAI, LCX-FAI, and RCA-FAI exhibited significantly higher values in patients with HCM compared to controls (-75.71±11.02HU vs. -83.02±10.60HU, p=0.002; -70.00±9.74HU vs. -80.24±9.57HU, p<0.001; -77.09±10.50HU vs. -84.76±11.02HU, p=0.002; respectively). A moderately positive correlation was observed between LAD-FAI, LCX-FAI, and RCA-FAI and PCT level in patients with HCM (r=0.481, p=0.01; r=0.522, p=0.004; r=0.505, p=0.006, respectively).

### CONCLUSION

Pericoronary adipose tissue inflammation is elevated in patients with HCM and perivascular FAI is moderately correlated with PCT level.

### CLINICAL RELEVANCE/APPLICATION

Elevated levels of inflammatory cytokines are observed in HCM, accompanied by low-grade myocardial inflammation, narrowed intramyocardial small arteries, and perivascular fibrosis. Our study revealed a significant increase in perivascular FAI among HCM patients, which exhibited a moderate correlation with PCT level. This finding may suggest a potential association between FAI and congestive heart failure. However, the role of FAI in risk stratification and prognosis assessment for HCM patients remains undefined.

## W5A-SPCA-9 EFFECT OF TRIGLYCERIDE-GLUCOSE INDEX ON LEFT VENTRICULAR DEFORMATION DYSFUNCTION OF TYPE 2 DIABETES MELLITUS WITH OR WITHOUT DYSLIPIDEMIA

Zhigang Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Li Jiang, MD (*Presenter*) Nothing to Disclose

### PURPOSE

It remains unclear whether the association between dyslipidemia status and triglyceride-glucose index (TyG index) and left ventricular (LV) dysfunction is different and in what pattern varies in the context of type 2 diabetes mellitus (T2DM). Therefore, LV structure, function, myocardial perfusion microvascular function, and deformation were analyzed to determine the effect of TyG index on LV deformation dysfunction of T2DM with or without dyslipidemia.

### METHODS AND MATERIALS

A total of 235 T2DM patients, comprising 113 with dyslipidemia and 122 without dyslipidemia, were included, and were divided into three groups based on the TyG index tertiles: T1, T2 and T3 group. CMR-derived LV perfusion parameters, global function index (GFI) and strain were assessed and compared among the groups. A multivariable backward linear regression model was employed to evaluate the effects of various variables on LV strain.

### RESULTS

With the increase of TyG index, LV volume and LV ejection fraction showed no significant statistical difference (All $p > 0.05$), while the higher TyG index group showed higher LV mass, higher remodeling index and lower LV GFI (All $p = 0.001$). Patients with a higher TyG index presented a lower perfusion index, lower upslope, lower MaxSI, and higher TTM (All $p = 0.002$), however, there was no significant difference in microvascular perfusion parameters between the two groups with lower TyG index. The linear multivariate analysis showed that TyG index (PS-radial, ß = -0.176[-0.311, -0.041], $p = 0.011$; PS-circumferential, ß = 0.245[0.130, 0.361], $p < 0.001$; PS-longitudinal, ß = 0.372[0.246, 0.485], $p<0.001$) and LV EDVi (PS-radial, ß = -0.134[-0.259, -0.010], $p<0.001$; PS-circumferential, ß = 0.431(0.320, 0.549), $p<0.001$; PS-longitudinal, ß = 0.211[0.097, 0.321], $p<0.001$) were independent determinants of PS reduction in the three directions. Hypertension (PS-radial, ß = -0.206(-0.320, -0.098), $p<0.001$; PS-longitudinal, ß = 0.182(0.07, 0.291), $p = 0.001$) and perfusion index (PS-radial, ß = 0.150[0.036, 0.277], $p=0.011$; PS-longitudinal, ß = -0.124[-0.244, -0.011], $p=0.032$) were independently correlated with PS in radial and longitudinal direction, while dyslipidemia was not significantly correlated with reduced LV deformation (all $p > 0.05$).

### CONCLUSION

Patients with a higher TyG index had a higher LV remodeling index, lower LV GFI, decreased LV myocardial perfusion function and decreased LV strain. In patients with DM, TyG index, but not dyslipidemia status, independently predicted PS reduction in all three directions.

### CLINICAL RELEVANCE/APPLICATION

This highlights the importance of addressing quantitative, qualitative, and kinetic changes in major circulating lipids as therapeutic targets to mitigate associated LV dysfunctional.

## W5A-SPCH-1 UNVEILING THE IMPACT OF RIVERAIN'S VESSEL SUPPRESSION: BREAKTHROUGH OR BUST?

Jonathan R. Medverd, MD (*Abstract Co-Author*) Nothing to Disclose
Brian W. Bresnahan, PhD (*Abstract Co-Author*) Stockholder, Johnson & Johnson
Kenneth Tharp, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Nathan M. Cross, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hamid Chalian, MD (*Abstract Co-Author*) Nothing to Disclose
Charles Watt (*Abstract Co-Author*) Nothing to Disclose
Kevin Chorath, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The detection of pulmonary nodules on computed tomography (CT) chest scans is a critical yet time-consuming component of quality patient care, bearing significant clinical and medicolegal implications. ClearRead CT Vessel Suppression (Riverain Technologies, Miamisburg, Ohio), a novel computer-aided detection (CAD) software, aims to enhance nodule detection by highlighting nodules by suppressing vascular, bronchial, and fissural structures. While previous studies have demonstrated improvements in controlled settings, real-world radiology workflows and the software's impact on clinically significant nodules and reading times remain understudied.

### METHODS AND MATERIALS

This retrospective review assesses the impact of Vessel Suppression on reading speeds and detection of punctate (=2mm) pulmonary nodule by radiology residents at our institution over 14 months, both pre- and post implementation. The study includes CT chest exams targeting nodule detection in patients with active, past, or heightened malignancy risk. Reading times were calculated from study opening to preliminary sign timestamps. Using a natural language processing (NLP) algorithm (AIdoc, Tel Aviv, Israel), final reports were analyzed for the largest nodule size and mentions of nodules =2mm.

### RESULTS

In total, 4,429 unique CT chest scans were assessed (1,002 pre-implementation and 3,427 post-implementation). The average time from study opening to preliminary sign decreased significantly (19.1 minutes to 12.2 minutes; $p<0.01$). Moreover, there was a notable increase in punctate nodule reporting post-implementation (13.0% of studies pre-implementation vs. 24.2% post-implementation; $p<0.01$).

### CONCLUSION

Vessel Suppression proves beneficial for improving CT chest reading speeds among radiology residents, especially for patients with cancer or elevated cancer risk. However, it also increases the detection of punctate pulmonary nodules, whose clinical significance remains uncertain and requires further research and QI evaluation.

### CLINICAL RELEVANCE/APPLICATION

Vessel Suppression increases radiology resident's reading speeds for CT chest and leads to heightened detection of punctate pulmonary nodules, which are of uncertain clinical significance.

## W5A-SPCH-2 QUANTITY OR CERTAINTY: CAN AMBIGUOUSLY ANNOTATED DATA IMPROVE LUNG NODULE DETECTION PERFORMANCE?

Junghyun Kang (*Abstract Co-Author*) Nothing to Disclose
Chanmin Park (*Abstract Co-Author*) Nothing to Disclose
Doohyun Park (*Abstract Co-Author*) Nothing to Disclose
Jonghun Jeong (*Presenter*) Nothing to Disclose

### PURPOSE

In the field of deep learning (DL), constructing a large and well-curated dataset is essential. However, when developing DL-based computer-aided detection (CADe) models for pulmonary nodule detection in computed tomography scans, observer variability poses challenges to dataset curation. For example, under the LUNA16 dataset protocol, a nodule is identified only if at least three out of four observers agree on its presence. Therefore, this study aims to analyze how ambiguously annotated data affects model performance.

### METHODS AND MATERIALS

We collected a dataset consisting of 891 nodules identified by the radiologist across 223 cases sourced from the United States. In this study, the dataset was then divided into a 7-fold with case-level splits, with 161 cases (5 folds) containing 624 nodules for the training set and the remaining 62 cases (2

folds) containing 267 nodules for the test set. These nodules were re-annotated by a new radiologist. The training set was divided into Group A, consisting of 376 nodules on which both radiologists agreed, and Group B, consisting of 248 nodules on which only the initial radiologist agreed. Three models were subsequently trained with different groups to analyze the impact of ambiguously annotated data: 1) a model trained with Group A, 2) a model trained with Groups A and B, and 3) a model trained with Group B. All models used the same ResNext network architecture and were trained for approximately 100,000 iterations. The performance of these models was evaluated on 52 cases from the test set, containing 154 nodules approved by all radiologists.

**RESULTS**

Model performance was analyzed using the Free-Response ROC curve. The model trained with Group A achieved an average sensitivity of 0.880 across thresholds of 1, 2, 4, 8, and 16 false positives per scan. The model trained with Groups A and B showed an average sensitivity of 0.803, while the model trained with Group B, which was approved by only one radiologist, had the lowest average sensitivity of 0.729.

**CONCLUSION**

This study demonstrates that the performance of CADe systems improves when trained with data where multiple annotators consistently agree on a nodule. Conversely, an increase in ambiguous data leads to decreased performance. The results indicate that using reliable data verified by multiple experts enhances CADe system effectiveness, making lung nodule screening more accurate and efficient in clinical settings.

**CLINICAL RELEVANCE/APPLICATION**

Advancements in CADe development are important for early lung cancer screening through improved nodule detection. The findings of this study enable more accurate identification of nodules, thereby enhancing early lung cancer detection.

## W5A-SPCH-4 ULTRA-HIGH-RESOLUTION CT-BASED RADIOMICS TO PREDICT HIGH-GRADE PATTERNS OF LUNG INVASIVE ADENOCARCINOMA

Qinling Jiang (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to develop and validate a radiomics model based on pre-treatment ultra-high-resolution CT images to predict high-grade patterns of invasive lung adenocarcinoma.

**METHODS AND MATERIALS**

Patients with pathologically confirmed invasive lung adenocarcinoma from May 2016 to December 2023 from 2 hospitals were retrospectively analyzed. The lesions were classified into high-grade pattern (HGP) and non-high-grade pattern (n-HGP) groups according to the percentage of tissue types in the pathologic results. Preoperative conventional chest CT images were converted to high-resolution chest CT images (HRCT) and ultra-high-resolution target scan images (UHRCT) using a two-channel GAN Model. After segmenting the lung nodules from chest CT, the radiomics features including shape-based features, first order statistics, and textural features were extracted. Least absolute shrinkage and selection operator (Lasso) was applied to select the strong correlation features. A prediction model was consequently constructed using Gaussian Process Classification. The efficacy of the model was assessed through receiver operating curve analysis, and the performance of the model was validated both internally and externally.

**RESULTS**

A total of 540 patients from 2 hospitals were included (the HGP was found in 213 of the 540 patients, 39.4%). Hospital 1 was divided into the training set (n=320) and the internal test set (n=81), and hospital 2 was used as the external test set for the model (n=139). The AUC values of NRCT, HRCT, and UHRCT for the model were 0.945, 0.946, and 0.957 in the internal test and 0.759, 0.760, and 0.872 in the external test set, respectively.

**CONCLUSION**

UHRCT-based radiomic model can predict HGP effectively of invasive lung adenocarcinoma and outperforms conventional resolution images.

**CLINICAL RELEVANCE/APPLICATION**

According to the WHO Classification of Thoracic Tumors, 5th edition, any lung adenocarcinoma with a high-grade component of =20% should be classified as HGP, because these tumors have a more aggressive biological behavior and a worse prognosis. Therefore, preoperative prediction of lung adenocarcinoma with or without HGP is important to help accurately determine pathology, surgical selection, and patient management. In this study, the UHRCT-based radiomic model demonstrated good diagnostic performance and outperformed conventional resolution images, which can help clinically assess the prognosis of patients and determine the surgical method before surgery.

## W5A-SPCH-6 ROLE OF INTRATUMORAL AND PERITUMORAL CT-BASED RADIOMICS FEATURES FOR THE PREDICTION OF MALIGNANCY AND INVASIVENESS OF PULMONARY GROUND-GLASS NODULES

Menglong Zheng (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the predictive value of a CT-based radiomics model that incorporates intratumoral and peritumoral features for benign or malignant status of pulmonary ground-glass nodules (PGGNs) and the invasiveness of malignant PGGNs.

**METHODS AND MATERIALS**

A total of 1659 PGGNs from 1561 patients with preoperative CT scans were involved in this retrospective study; 236 PGGNs were diagnosed with inflamed or infected benign lesions, 55 atypical adenomatous hyperplasia (AAH,) 301 adenocarcinoma in situ (AIS), 728 minimally invasive adenocarcinoma (MIA) and 339 invasive adenocarcinoma (IAC). All patients were confirmed by operation and had complete pathological data. Malignant PGGNs are classified according to clinical management strategies, AAH, AIS, and MIA were classified as non-invasive lesions; IAC was classified as invasive lesions. Two types of regions of interest (ROIs), including gross tumor volume (GTV) and peritumoral volume (5mm and 10 mm around the tumor, PTV1 and PTV2), were annotated from the CT images. We extracted 3441 CT-based radiomics features from GTV, PTV1 and PTV2. After feature selection, 5 models were developed to predict the malignancy and invasiveness of PGGNs. The performance of all five models was evaluated by receiver operating characteristic (ROC) curves.

**RESULTS**

For malignancy predictions, all radiomics models demonstrated satisfactory discrimination abilities. GTV+PTV1+PTV2 model achieved highest performance in training set with AUC 0.929 (95% Confidence Interval 0.900, 0.962). In testing, GTV+PTV1 model achieved highest AUROC value of 0.895 (95% CI 0.774,0.925). For invasiveness predictions, GTV+PTV1+PTV2 model achieved highest AUROC in training dataset (AUC 0.829 [0.743,0.896]), GTV+PTV1 model achieved highest numerical AUROC in the testing set (AUC 0.781 [0.640, 0.849]).

### CONCLUSION

Both radiomic signatures of GTV and PTV had a good prediction ability in the prediction of malignancy and invasiveness of PGGNs. The predictive performance of the GTV+PTV-based model was more effective than that of the GTV-based model.

### CLINICAL RELEVANCE/APPLICATION

The proposed new radiomics strategy that extracts image features from the intra- and peritumoral regions could greatly improve the diagnostic performance for the prediction of benign or malignant status of PGGNs and the invasiveness of malignant PGGNs and may help serve as a powerful tool to assist clinicians in making personalized treatment strategies.

## W5A-SPCH-7 VIRTUAL BIOPSY THROUGH CT IMAGING: CAN RADIOMICS DIFFERENTIATE BETWEEN SUBTYPES OF NON-SMALL CELL LUNG CANCER?

Andrea Laghi, MD (*Abstract Co-Author*) Speaker, General Electric Company;Speaker, Bayer AG;Speaker, Bracco Group;Speaker, Merck & Co, Inc

Damiano Caruso, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Marta Zerunian, MD (*Abstract Co-Author*) Nothing to Disclose
Stefano Nardacci, MD (*Abstract Co-Author*) Nothing to Disclose
Federica Palmeri, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the performance of radiological and radiomic models in differentiating lung adenocarcinoma (ADC) from squamous cell carcinoma (SCC)

### METHODS AND MATERIALS

A total of 330 patients with available baseline contrast-enhanced CT scans were retrospectively enrolled between April 2014 and January 2023. Pathological diagnosis and radiological features (T and N radiological stage, peripheral or central location of the lesion, presence of emphysema) were collected for each patient. Inclusion criteria: a) histological diagnosis of ADC or SCC; b) baseline contrast-enhanced chest CT. Exclusion criteria: a) significant motion artifacts; b) nodules too small to be segmented (<3 mm). Patients were divided into two groups: adenocarcinoma and squamous cell carcinoma. Two expert radiologists in consensus manually segmented lung cancers on baseline CT scans at the portal-venous phase by using dedicated software (3DSlicer v5.2.2). Then, 107 radiomic features were extracted and compared between two groups (T-test or Mann-Withney-U). Radiomics and radiological features performance was assessed by receiver operating characteristic (ROC) curves; univariate and multivariate logistic regression were performed to build models to predict the histology (radiomics only, radiologic features only and combined). P< .05 was considered significant

### RESULTS

The final groups consisted of 200 patients with ADC and 100 with SCC. 53 radiomic features showed significant differences between the two groups. Among these, 2 features achieved the best performance: DifferenceVariance and Skewness (AUC: 0.708 and 0.67, respectively, P< .001). Among the radiological features, 2 features were also found to be statistically significant: location of the lesion and presence of emphysema (AUC: 0.67 and 0.62, respectively, P < .0001). Univariate analysis showed 2 radiological features and 27 radiomic features independently correlated with histology (all P< .04). The multivariate analysis of the radiological features showed an AUC of 0.733 with 72% of cases correctly diagnosed; all significant features included in the radiomics model showed an AUC of 0.811 with 73% of cases correctly classified, while the combined model was able to correctly classify 76% of cases with an AUC of 0.852 (all P < .0001)

### CONCLUSION

The combined radiologic-radiomics model showed the best performance to differentiate lung adenocarcinoma from squamous cell carcinoma and, in the future, might be used as a non-invasive method to overcome the limits of biopsy

### CLINICAL RELEVANCE/APPLICATION

Radiomics holds promise to be a non-invasive diagnostic tool for pulmonary nodules, overcoming biopsy tissue undersampling, with benefits expected to be higher in patients at high risk of periprocedural complications

## W5A-SPCH-8 APPLICATION OF DUAL-MODALITY ULTRASOUND DEEP LEARNING MODEL BASED ON VIDEO IMAGE RECOGNITION IN THE DIAGNOSIS OF SUBPLEURAL LUNG NODULES

Martin R. Prince, MD, PhD (*Abstract Co-Author*) Patent agreement, General Electric Company;
Ke Bi (*Abstract Co-Author*) Nothing to Disclose
Kaiwen Wu (*Abstract Co-Author*) Nothing to Disclose
Yin Wang, PhD, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Quantitative parameters of contrast-enhanced ultrasound (CEUS) showed excellent diagnostic accuracy for subpleural lung lesions (SLLs) with vertical diameters =3cm but limited diagnostic ability for subpleural lung nodules (SLNs) with vertical diameters <3 cm. The purpose of this study is to develop and validate a novel deep learning (DL) model based on gray-scale ultrasound (GSUS) and contrast-enhanced ultrasound (CEUS) video recognition to improve the diagnostic accuracy of SLN.

### METHODS AND MATERIALS

A dataset of US videos in patients with SLNs confirmed as malignant or benign by pathology and culture from A Hospital (193 studies on 193 patients from August 2017 to December 2020) and an independent external test set from B Hospital and C Hospital (26 studies on 26 patients from January to December 2021), had all SLNs labeled by Cardiothoracic Radiologists. The model, which includes video preprocessing based on medical domain knowledge and a video understanding model integrating features of time-intensity curve (TIC) and grayscale lung ultrasound (LUS) videos, was trained on 80% of A Hospital dataset and validated on the remaining 20%, as well as on the independent external test set. Model performance was analyzed using area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity, comparing to US, CT and other DL models.

### RESULTS

Our model diagnosed SLN as benign or malignant with an AUC of 0.85 (95% confidence interval [CI]: 0.63, 0.96) in the external test set, which was significantly higher than US, CT, and other models including TimeSformer, ViViT, I3D, and SlowFast (Table 1). The ablation study demonstrated that incorporation of dual-modality understanding, TIC analysis, and clinical information all independently contributed to model performance(Table 2). The accuracy (ACC), sensitivity, specificity, positive predictive value and negative predictive value were 77.3% (95% CI: 61.7, 82.0), 87.7% (95% CI: 68.3, 94.4), 73.3% (95% CI: 68.6, 77.3), 60% (95% CI: 42.7, 81.6) and 91.7% (95% CI: 88.8, 94.4), respectively.

### CONCLUSION

This DL model improves the discrimination of benign from malignant SLNs based on US videos recognition and may provide an early diagnostic strategy for SLNs.

### CLINICAL RELEVANCE/APPLICATION

Patients with SLNs can be assessed by contrast enhanced pulmonary ultrasound to determine whether they are benign or malignant. Our DL model will improve the diagnostic accuracy.

## W5A-SPCH-9 PERFORMANCE OF AI FOR PREOPERATIVE CT ASSESSMENT OF LUNG METASTASES: RETROSPECTIVE ANALYSIS OF 167 PATIENTS

Marie-Pierre Revel (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Gleamer;Speaker, Bracco Group;Speaker, Boehringer Ingelheim GmbH
Emma Canniff, FFR(RCSI) (*Abstract Co-Author*) Nothing to Disclose
Guillaume Chassagnon, MD (*Abstract Co-Author*) Nothing to Disclose
Arvin Calinghen, MD (*Abstract Co-Author*) Nothing to Disclose
Giorgio Maria Masci, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the performance of artificial intelligence (AI) in the preoperative detection of lung metastases on CT.

### METHODS AND MATERIALS

Patients who underwent lung metastasectomy in our institution between 2016 and 2020 were enrolled, their preoperative CT reports having been performed before an AI solution (Veye Lung Nodules, version 3.9.2, Aidence) became available as a second reader in our department.All CT scans were retrospectively processed by AI. The sensitivities of unassisted radiologists (original CT radiology reports), AI reports alone and both combined were compared. Ground truth was established by a consensus reading of two radiologists, who analyzed whether the nodules mentioned in the pathology report were retrospectively visible on CT. Multivariate analysis was performed to identify nodule characteristics associated with detectability.

### RESULTS

A total of 167 patients (men: 62.9%; median age, 59 years [47-68]) with 475 resected nodules were included. AI detected an average of 4 nodules (0-17) per CT, of which 97% were true nodules. The combination of radiologist plus AI (92.4%) had significantly higher sensitivity than unassisted radiologists (80.4%) ($p<0.001$). In 27/57 (47.4%) patients who had multiple preoperative CT scans, AI detected lung nodules earlier than the radiologist. Vascular contact was associated with non-detection by radiologists (OR:0.32[0.19, 0.54], $p<0.001$), whilst the presence of cavitation (OR:0.26[0.13, 0.54], $p<0.001$) or pleural contact (OR:0.10[0.04, 0.22], $p<0.001$) was associated with non-detection by AI.

### CONCLUSION

AI significantly increases the sensitivity of preoperative detection of lung metastases and enables earlier detection, with a significant potential benefit for patient management.

### CLINICAL RELEVANCE/APPLICATION

In this study, we demonstrated that AI assistance has the capacity to significantly increase the radiologists' sensitivity for the preoperative detection of lung nodules, at a cost of a few false positive detections, with potential benefit for patient's management.

## W5A-SPER-1 INTEGRATION OF A ROTATION-FREE GANTRY SPECTRAL CT INTO MOBILE STROKE UNITS: DESIGN, IMPLEMENTATION, AND CLINICAL IMPACT

Bo Kyung Cha, PhD (*Abstract Co-Author*) Nothing to Disclose
Minjae Lee (*Abstract Co-Author*) Nothing to Disclose
Minkook Cho, PhD (*Abstract Co-Author*) Employee, Samsung Electronics
Hyosung Cho (*Abstract Co-Author*) Nothing to Disclose
Jinwoo Kim (*Presenter*) Nothing to Disclose

### PURPOSE

The integration of mobile technologies such as transportable computed tomography (CT) scanners with emergency medical services and telemedicine presents a significant opportunity to enhance prehospital stroke care. Our study introduces a novel CT scanner design optimized for mobile use, featuring a rotation-free rectangular gantry and a photon-counting detector (PCD), coupled with a deep-learning approach for reconstructing under-sampled projections, aiming to maintain high diagnostic reliability within these constraints (i.e., compact environments like small ambulances without compromising safety in terms of radiation exposure).

### METHODS AND MATERIALS

In response to the need for compact and efficient medical imaging in prehospital settings, we designed a specialized CT system for use in mobile stroke units (MSU). This system includes a rectangular scanner configuration equipped with dual-line X-ray sources, each line housing 20 sources to a total of 40, operating at 120 kVp through a 2 mm aluminum filter. The system's geometry is defined by a source-to-detector distance (SDD) of 50 cm and a source-to-object distance (SOD) of 25 cm, which accommodates the restricted space within small ambulances while ensuring optimal imaging performance. The PCD utilizes cadmium telluride (CdTe) material for the detector, with a pixel resolution of 225 μm and adjustable energy thresholds at 20, 50, 65, and 80 keV to optimize imaging for various clinical needs. We developed and implemented a learning-based reconstruction to restore high-quality images from under-sampled data. This approach was validated through comparison with conventional methods like filtered back projection (FBP) and compressed sensing (CS), using fully sampled, diagnostic-quality CT images from established public datasets to ensure the system's efficacy and safety in a clinical setting.

### RESULTS

We successfully reconstructed various hemorrhages, including epidural, intracerebral, intraventricular, subarachnoid, and subdural hematomas, demonstrating superior efficacy and precision in detecting these critical conditions. Additionally, we implemented imaging of brain micro-hemorrhages using both low- and high-energy images obtained from the PCD.

### CONCLUSION

Our results indicate that the proposed scanner effectively shows potential for stroke detection in prehospital ambulances. The integration of a rotation-free gantry spectral CT into MSU is expected to significantly enhance the capacity for prehospital diagnosis and immediate treatment of strokes.

### CLINICAL RELEVANCE/APPLICATION

This novel prehospital spectral CT scanner enhances the rapid diagnosis of acute stroke in mobile units, significantly improving early treatment outcomes.

## W5A-SPER-2 FORECASTING TRENDS OF RISING EMERGENCY DEPARTMENT CHEST IMAGING USING MACHINE LEARNING

Nikhil H. Ramaiya, MD (*Abstract Co-Author*) Nothing to Disclose
Ashish R. Khandelwal, MD (*Abstract Co-Author*) Nothing to Disclose
Sirui Jiang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Kaustav Bera, MD (*Abstract Co-Author*) Nothing to Disclose
Satheesh Krishna, MD (*Abstract Co-Author*) Nothing to Disclose
Sishir Doddi (*Presenter*) Nothing to Disclose

### PURPOSE

Recent literature has shown that imaging studies have been steadily increasing in the United States, especially in emergency department and at urgent care facilities. In this report, we assess for trends in chest CT and chest CTA imaging in ED and UCF settings for trends from 2010 to 2021 and forecast future utilization with machine learning.

## METHODS AND MATERIALS

We queried chest CT claims billed from emergency departments and urgent care facilities from the Centers for Medicare and Medicaid to assess for compound annual growth rate (CAGR) and predict future trends with ARIMA modeling.

## RESULTS

Chest CT imaging in the ED or UCF settings has steadily from 2010 (273,063) to 2021 (540,047) in the US. Chest CTA imaging also saw an increase from 175,554 in 2010 to 705,727 in 2021. Analysis found that ED and urgent care Chest CT imaging has increased from 2010 to 2021 with a CAGR of 7.5% ($p<0.001$). Similarly, chest CTA imaging has also increased during this time period with an average CAGR or 13.0% ($p<0.001$). When attempting to forecast future trends, the ARIMA model forecast for ED and UCF CT chest imaging predicts a continued increase in volume of CT imaging reaching 614,995 in 2024 and 760,851 in 2030. Chest CTA is predicted to have an even higher increase up to 850,320 in 2024 and 1,139,505 in 2030 assuming the trend observed over the past decade is consistent.

## CONCLUSION

In conclusion, from 2010 to 2021, we found an increasing trend in ED chest CT and CTA imaging with forecast predicting volume up to twice of volume in 2030 compared to a decade ago.

## CLINICAL RELEVANCE/APPLICATION

While imaging holds a significant role in patient care, inappropriate utilization can result in unnecessary radiation exposure, prolonged wait times, and an increase in burden of healthcare resources.

## W5A-SPGI-1 DEEP LEARNING-BASED RECONSTRUCTION FOR T2-WEIGHTED AND CONTRAST-ENHANCED T1-WEIGHTED MAGNETIC RESONANCE ENTEROGRAPHY IN PATIENTS WITH CROHN'S DISEASE: ASSESSMENT OF IMAGE QUALITY AND DIAGNOSTIC UTILITY

Seong Jin Park, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Sung Kyoung Moon (*Abstract Co-Author*) Nothing to Disclose
Myung-Won You, MD (*Abstract Co-Author*) Nothing to Disclose
Choongwui Cho, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the image quality of deep learning-based reconstruction for T2-weighted half-Fourier single-shot turbo spin echo sequence (DL T2 HASTE) and for contrast-enhanced T1-weighted sequence (DL CE-T1W) in MR enterography(MRE).

### METHODS AND MATERIALS

Fifty-six patients with Crohn's disease who underwent MRE between December 2022 to November 2023 were enrolled. Deep learning-based reconstruction was applied to coronal T2 HASTE and dynamic CE T1W sequences. Two reviewers assessed subjective image quality at the patient level and active inflammation at the bowel segment level in T2 HASTE with and without DL reconstruction, and DL CE-T1W enteric phase. Comparison with CE-T1W enteric phase without DL reconstruction was performed in twenty-two patients with prior MRE.

### RESULTS

Mean image quality scores of two reviewers were compared between T2 HASTE and DL T2 HASTE images; sharpness (4.25 vs. 4, p=0.0014), motion artifact (5 vs. 4, p<0.0001), and blurring (4.25 vs.4, p=0.0009) were better in DL T2 HASTE images than in T2 HASTE images, while synthetic appearance was increased in DL T2 HASTE (3.75 vs. 4.5, p<0.0001). When comparing CE-T1W and DL CE-T1W, contrast (5 vs. 4.5, p=0.08) and sharpness (5 vs. 4.5, p=0.07) were slightly better with DL CE-T1W than with CE-T1W, although the difference was not statistically significant. Acquisition time decreased with DL T2W HASTE (15s) and DL CE-T1W enteric phase(13s) compared to T2W HASTE without DL (38s) and CE-T1W without DL (17s). The per-segment diagnostic performance of active inflammation was identical between T2 HASTE and DL T2 HASTE images for both reviewers (R1: sensitivity 76.2 % (48/63), specificity 89.5 % (94/105), R2: sensitivity 63.5 % (40/63), specificity 86.6 % (91/105)).

### CONCLUSION

DL T2 HASTE and DL CE-T1W images showed improved sharpness with reduced blurring, motion artifacts, and reduced acquisition time compared to T2 HASTE and CE-T1W without DL reconstruction. However, DL reconstruction also increased synthetic appearance, and the diagnostic performance of active inflammation was identical between DL T2 HASTE and T2 HASTE without DL reconstruction.

### CLINICAL RELEVANCE/APPLICATION

Deep learning-based reconstruction for MRE images has reduced acquisition time however, the actual benefit for image quality improvement is controversial

## W5A-SPGI-10 COST EFFECTIVENESS OF DIFFERENT IMAGING MODALITIES FOR THE STAGING OF OESOPHAGEAL CANCER IN WESTERN COUNTRIES

Naik Vietti Violi, MD (*Abstract Co-Author*) Nothing to Disclose
Nicolas Guignard (*Abstract Co-Author*) Nothing to Disclose
Clarisse Dromain, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Mario Jreige, MD (*Abstract Co-Author*) Nothing to Disclose
Laura Haefliger (*Abstract Co-Author*) Nothing to Disclose
Karine Moschetti (*Abstract Co-Author*) Nothing to Disclose
Vincent Levy, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Cost-effectiveness analysis of 4 different imaging strategies, including MRI, for the initial staging of oesophageal cancer (EC) in Switzerland, Australia, Italy, United Kingdom (UK) and United states of America (USA).

### METHODS AND MATERIALS

The cost-effectiveness of TNM stating using 4 different combinations of imaging (EUS + PET-CT, EUS + PET-CT + CECT, EUS + PET-CT + MRI and MRI + PET-CT) was prospectively analysed in 62 patients. Patients were classified into 3 groups based on treatment strategy : (1) upfront surgery (T1/T2/N0/M0), (2) neoadjuvant therapy (T3/T4a/N+/M0) and (3) palliative treatment (T4b/M+). The diagnostic performance was defined as the agreement between the classification made by each strategy compared to the multidisciplinary consensus. A dichotomized analysis (group 1 vs 2+3 and 1+2 vs 3) was employed to identify the most effective and accurate staging strategy.

### RESULTS

The cost (USD) of the TNM staging in Switzerland were 3044 for EUS + PET-CT (1010 in Australia, 1468 in Italy, 2555 in UK, 3578 in US), 3718 for EUS + PET-CT + CECT (1349 in Australia, 1775 in Italy, 3046 in UK, 4315 in US), 3719 for EUS + PET-CT + MRI (1302 in Australia, 1666 in Italy, 3303 in UK, 4044 in US) and 3071 for MRI + PET-CT (912 in Australia, 1390 in Italy, 2521 in UK, 2044 in US). Diagnostic performances for differentiating group 1 vs 2+3 were 0.944 for EUS + PET-CT, 0.935 for EUS + PET-CT + CECT, 0.932 for EUS + PET-CT + MRI and 0.915 for MRI + PET-CT. Diagnostic performances for differentiating group 1+2 vs 3 were 0.944 for EUS + PET-CT, 0.952 for EUS + PET-CT + CECT, 0.949 for EUS + PET-CT + MRI and 0.966 for MRI + PET-CT.

### CONCLUSION

The combination of MRI + PET-CT demonstrates non inferiority and lower cost when compared to the current strategy of EUS + PET-CT + CECT used in Switzerland for the initial staging of oesophageal cancer . The validity of this study extends beyond Switzerland to encompass countries such as the United States, Australia, the United Kingdom, and Italy.

### CLINICAL RELEVANCE/APPLICATION

This study advocates for replacing the current staging strategy of EUS + PET-CT + CECT with the combination of MRI + PET-CT, asserting it as a diagnostically accurate, cost effective and non-invasive approach for EC staging, thereby enhancing the overall efficiency and accessibility of EC staging.

## W5A-SPGI-11 ENHANCING RESPONSE ASSESSMENT IN RECTAL CANCER AFTER TOTAL NEOADJUVANT THERAPY: THE VALUE OF CONTRAST-ENHANCED MRI

Ying-Chieh Lai (*Abstract Co-Author*) Nothing to Disclose
An-Hsin Chen (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the benefit of adding contrast-enhanced sequences (CE) to routine T2-weighted imaging (T2WI) and diffusion-weighted imaging (DWI) in assessing treatment response for rectal cancer following total neoadjuvant therapy (TNT).

### METHODS AND MATERIALS

A retrospective review was conducted on patients with histopathologically confirmed rectal cancer who underwent MRI-based response assessment three months post-TNT. This study spanned from January 2020 to December 2022 and included 124 patients. Imaging features from T2WI, DWI, and CE sequences were evaluated to predict a complete response (CR), as outlined in Figure 1. CR was defined as either pathologic CR or no tumor regrowth for at least one year following clinical CR. Receiver operating characteristic (ROC) analysis assessed the accuracy of these imaging features. Logistic regression identified independent predictors of CR, and decision tree analysis determined the optimal combination of MRI features for predicting CR.

### RESULTS

Of the participants, 45 (36%) achieved CR. ROC analysis indicated that the "reversed mural sign" on CE is an effective predictor of CR, showing greater efficacy than T2WI and DWI, with an accuracy, sensitivity, and specificity of 72.6%, 73.3%, and 72.2%, respectively. In comparison, T2WI reached 66.1% accuracy, 53.5% sensitivity, and 72.8% specificity, and DWI recorded 70.2% accuracy, 68.9% sensitivity, and 70.9% specificity. Multivariate logistic regression analysis confirmed DWI and CE as independent predictors of CR (p-values of 0.032 and <.001, respectively). Decision tree analysis combining DWI and CE yielded the highest performance, achieving an accuracy of 76.6%, with a sensitivity of 60% and a specificity of 86.1%. This performance surpassed those from combining T2WI and DWI, which had 70.2% accuracy, 46.7% sensitivity, and 83.5% specificity.

### CONCLUSION

CE significantly enhances the MRI assessment of treatment response in rectal cancer after TNT.

### CLINICAL RELEVANCE/APPLICATION

Implementing the CE sequence to improve the accuracy of predicting CR via MRI post-TNT can assist in guiding decisions regarding curative-intent surgery or adopting organ-preserving strategies.

## W5A-SPGI-12 INCREASED IMPLEMENTATION OF EOB-MRI IN THE PATIENTS WITH PANCREATIC CANCER

Naoto Fujikawa, MSc, MBA (*Abstract Co-Author*) Nothing to Disclose
Satoshi Goshima, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takashi Tsuji, BS (*Abstract Co-Author*) Nothing to Disclose
Tomoyuki Taguchi (*Presenter*) Nothing to Disclose

### PURPOSE

It has been reported that gadoxetate sodium-enhanced MRI (EOB-MRI) have incremental value over contrast enhanced-computed tomography (CE-CT) in detecting liver metastases in patients (pts) with pancreatic cancer (PaC), particularly small lesions that may be missed on CE-CT. Although the recent development of adjuvant chemotherapy (AC) and neoadjuvant chemotherapy (NAC) has provided more treatment options for PaC than before, there have been no reports on how such evolvement of treatment options is related to the use of EOB-MRI over time. This study aimed to investigate the actual use of EOB-MRI in the treatment of PaC and the impact of EOB-MRI on the treatment choice.

### METHODS AND MATERIALS

This was a retrospective cohort study using a nationwide hospital-claims database in Japan. Pts diagnosed with PaC with a record of any treatments, who had one or more imaging modalities between January 2011 to October 2021 were included. Pts were grouped into EOB-MRI and non EOB-MRI groups, and the treatment patterns were described in both. In addition, pts were classified into year groups (A: 2011-12, B: 2013-18, C: 2019-21) by the start date of the initial treatment.

**RESULTS**

39,624 pts were included, of them, 4,477 (11.3%) pts had EOB-MRI prior to the initial treatment and the proportions of pts with EOB-MRI in the year groups were A: 7.0%, B: 9.8%, and C: 13.6%. Among the pts with EOB-MRI, 1,852 (41.4%) pts had surgical resection as initial treatment, and 1,243 (27.8%) pts had NAC and/or AC with surgery. Of 35,147 (88.7%) pts without EOB-MRI, 12,174 (34.6%) pts had any surgical resection as initial treatment, and 7,089 (20.2%) pts had NAC and/or AC with surgery. The proportions of pts with surgery in the EOB-MRI group in the year groups were A: 31.4%, B: 41.7%, and C: 41.7%, and the proportions of pts with NAC and/or AC were A: 18.3%, 26.3%, and 29.3%. The proportions of pts with surgery in the non EOB-MRI group in the year groups were A: 29.0%, B: 36.3%, and 33.3%, and the proportions of pts with NAC and/or AC were A: 14.4%, B: 20.7%, and C: 20.4%. The results by the year-group showed the proportion of pts with NAC or AC tended to increase in the EOB-MRI group.

**CONCLUSION**

Through this study, the actual status of diagnosis and treatment choices, including treatment modalities, in the management of PaC were clarified. The EOB-MRI performed for PaC is increasing year by year, and in parallel, pts followed with NAC or AC, rather than just undergoing surgery, is increasing among pts who had EOB-MRI.

**CLINICAL RELEVANCE/APPLICATION**

As effective treatment options for pts with PaC expand, more accurate imaging modalities, such as EOB-MRI, are being in the pathway of diagnosis and treatment of PaC.

## W5A-SPGI-13 MAGNETIC RESONANCE ELASTOGRAPHY OF LIVER IN HEALTHY TUNISIAN POPULATION

Younes Arous (*Abstract Co-Author*) Nothing to Disclose
Mariem GHARBI (*Abstract Co-Author*) Nothing to Disclose
Moncef Aloui (*Abstract Co-Author*) Nothing to Disclose
Sonia Esseghaier (*Abstract Co-Author*) Nothing to Disclose
Jihene Bettaieb (*Abstract Co-Author*) Nothing to Disclose
Malek Mokbli, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The diagnosis and the quantification of hepatic fibrosis during the follow-up of patients with chronic liver diseases are fundamental. Magnetic resonance elastography (MRE) is a novel method for quantifying hepatic fibrosis based on the calculation of the velocity of wave propagation in liver parenchyma.The purposes of our study were to establish the range of normal values for MRE and to determine the epidemiological and clinical factors that may influence MRE values.

**METHODS AND MATERIALS**

It was a descriptive cross sectional monocentric study, realised in the radiology department of Military Hospital of Tunis that included 163 volunteers.Regions of interest in each liver segment were delineated MRE sequence to determine the MRE value. We also examined the correlation between the MRE and epidemiological parameters, lifestyle habits, and medical history. Furthermore, we investigated the correlation between the elastography MRI value and "Fat-Fraction" and liver iron concentration (LIC)

**RESULTS**

The MRE value in the healthy population ranges from 1.6 to 2.6 kPa.Age is the most significant factor increasing the liver stiffness measured by MRE, in healthy population, (CC at 0,49 and $p<10-3$), with a strong linear correlation. BMI also affects the elastography MRI value.Ethnicity and gender do not interfere with MRE ( Pearson Coefficient at 0,31 and $p<10-3$).Sedentary increases MRE value. However, we did not find any variation in MRE with smoking ($p=0,75$) or moderate alcohol consumption($p=0,59$) .A history of diabetes($p=0,02$), hypertension ($p<10-3$), or dyslipidemia ($p<10-3$) increases the MRE value.

**CONCLUSION**

The mean value of MRE in healthy patients was 2.02 ± 0.16 kPa.Age was the most significant factor increasing liver stiffness.MRE is not affected by ethnicity and gender and varies only slightly with technical parameters.

**CLINICAL RELEVANCE/APPLICATION**

The originality of our study lies in the following points:Our study is the first in Africa and the Arab world to focus on establishing normal values for liver stiffness in healthy volunteers and the first globally to consider a study population across different age groups. Our results determined the range of normal values among a healthy Tunisian population using a 1.5 T MRI machine, thus enabling better interpretation of images in clinical practice to evaluate hepatic stiffness and fibrosis.Additionally, our study highlighted the high incidence and underdiagnosis of hepatic steatosis in an asymptomatic population. Our results underscored the role of MRI as a noninvasive technique, aided by new quantification sequences, in the diagnosis and monitoring of overload diseases.

## W5A-SPGI-2 RESPIRATORY TRIGGERED T2WI MRI WITH ARTIFICIAL INTELLIGENCE-ASSISTED TECHNIQUE IN ABDOMINAL IMAGING: COMPARISON WITH MOTIONE SUPPRESSED RESPIRATORY TRIGGERED T2 WEIGHTED IMAGING

Qingwei Song, MD (*Abstract Co-Author*) Nothing to Disclose
Ying Zhao JR (*Abstract Co-Author*) Nothing to Disclose
Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Dan YU (*Abstract Co-Author*) Nothing to Disclose
Qi An (*Abstract Co-Author*) Nothing to Disclose
Nan Wang (*Presenter*) Nothing to Disclose

**PURPOSE**

This study evaluates the effectiveness of respiratory-triggered T2-weighted imaging with artificial intelligence-assisted compressed sensing technique (ACS-RT T2WI) in abdominal MRI, compared to conventional standard-resolution acquisition with motion suppression RT T2WI sequence (ARMS-RT T2WI), both qualitatively and quantitatively.

**METHODS AND MATERIALS**

In this prospective study, 334 patients with upper abdominal discomfort underwent upper abdominal 3.0T MRI, including both ARMS-RT T2WI and ACS-RT T2WI. Image quality was assessed by two independent readers using a five-point Likert scale, along with quantitative analyses such as SNR, CNR, PSNR, and sharpness. Lesion detection rates and contrast ratios (CR) were also evaluated.

**RESULTS**

A significant reduction in median scanning time with the ACS-RT T2WI protocol compared to ARMS-RT T2WI, showcasing a decrease from 148.22 ± 38.37 seconds to just 13.86 ± 1.72 seconds. While ARMS-RT T2WI showed higher PSNR (39.87±2.72 VS 38.69±3.00, P < 0.05). For the 201 liver lesions, ARMS-RT T2WI detected 193 (96.0%) and ACS-RT T2WI detected 192 (95.5%) (P = 0.787). For the 97 biliary system lesions, ARMS-RT T2WI identified 92 (94.9%) and ACS-RT T2WI detected 94 (96.9%) (P = 0.721). Pancreatic lesion detection showed 102 out of 110 (92.7%) for ARMS-RT T2WI and 104 (94.5%) for ACS-RT T2WI (P = 0.784). CR analysis indicated superior performance of ACS-RT T2WI in certain lesion types.

**CONCLUSION**

ACS-RT T2WI ensures clinical reliability with substantial scan time reduction ( > 80%). Despite minor losses in detail and SNR reduction, ACS-RT T2WI does not impair lesion detection, marking its efficacy in abdominal imaging.

**CLINICAL RELEVANCE/APPLICATION**

The study confirms the clinical reliability of ACS-RT T2WI, despite potential shortcomings in fine structure depiction. While ACS-RT T2WI offers improved image quality and reduced scanning time compared to ARMS-RT T2WI, further validation and multi-center studies are needed to fully realize its potential benefits, especially in patients with irregular breathing or severe illness.

## W5A-SPGI-3 DIAGNOSTIC EVALUATION OF LIVER FIBROSIS USING B1-CORRECTED T1 MAPPING AND DWI-BASED VIRTUAL ELASTOGRAPHY

Yuanqiang Zou (*Abstract Co-Author*) Nothing to Disclose
Chen Hui Li (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess the diagnostic utility of virtual magnetic resonance elastography (vMRE) utilizing diffusion-weighted imaging (DWI) and B1-corrected T1 mapping for identifying CCl4-induced liver fibrosis in rabbits.

**METHODS AND MATERIALS**

Fifty rabbits were categorized into two groups: CCl4-induced fibrosis (n=43) and control (n=7). Following Gd-EOB-DTPA administration, DWI and T1 mapping sequences were executed at 5 and 10 minutes. Diagnostic efficacy and correlations of vMRE and T1 mapping in a rabbit liver fibrosis model were evaluated.

**RESULTS**

Rabbits were classified into three groups: Control (n=7), Nonadvanced fibrosis (F1-F2, n=20), and Advanced fibrosis (F3-F4, n=13). The AUC values for T1post_5min, T1post_10min, r?T1_10min, and μdiff in distinguishing controls from nonadvanced and advanced fibrosis groups were (0.78, 0.82, 0.71), (0.82, 0.85, 0.77), and (0.62, 0.69, 0.74), respectively, with μdiff showing (0.90, 0.93, 0.66). A significant positive correlation existed between μdiff and liver fibrosis grade (r=0.534, p<0.001).

**CONCLUSION**

Gd-EOB-DTPA-enhanced T1 mapping and DWI-based vMRE provide substantial noninvasive assessment of liver fibrosis.

**CLINICAL RELEVANCE/APPLICATION**

The study significantly contributes to noninvasive assessment of liver fibrosis induced by CCl4 in rabbits, combining Gd-EOB-DTPA-enhanced T1 mapping with DWI-based virtual MR elastography (vMRE), with vMRE demonstrating superior efficacy in fibrosis evaluation, enhancing diagnostic precision and staging in clinical practice.

## W5A-SPGI-4 CORRELATION OF R2 VALUES FROM MULTIECHO MRS AND R2* VALUES FROM MRI-PDFF FOR MEASURING HEPATIC IRON DEPOSITION

Seo Yeon Youn, MD (*Abstract Co-Author*) Nothing to Disclose
Joon-Il Choi, MD, PhD (*Abstract Co-Author*) Research Grant, Guerbet SA;Research Grant, Samsung Electronics Co, Ltd
Hokun Kim, MD (*Abstract Co-Author*) Research Grant, TAEJOON Pharmaceutical Co, Ltd
Ga-Eun Park, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

R2 and R2*, two MRI parameters that can assess hepatic iron concentration (HIC), utilize spin-echo and gradient-echo techniques, respectively. The relationship between the R2* obtained from multiecho PDFF and HIC is relatively well evaluated. However, for R2, the analysis value using a commercial program (Ferriscan) is known, but the threshold of R2 obtained by multiecho MRS is not well known. The aim of this study is to compare and correlate R2 measured by MRS with R2* measured by PDFF in liver transplant donor candidates and recipients who have already undergone transplantation.

**METHODS AND MATERIALS**

175 participants, comprising 115 potential donors and 60 recipients, underwent multiecho MRS (HISTO by Siemens Healthineers) and MRI-PDFF (Liver Evaluation by Siemens Healthineers) for hepatic fat signal fraction evaluation using three 3T MRIs (Magnetom Vida, Siemens Healthineers). To correct hepatic iron deposition, R2 values in multiecho MRS and R2* values for PDFF were calculated. In each participant, two distinct R2* values were derived: 1) from a segmented liver volume auto-segmented by software (R2*-seg), and 2) from an ROI equivalent to MRS (R2*-ROI). We correlated R2 and R2* values using simple correlation analysis. Also, we calculated mean values and standard deviation of R2 and R2* values.

**RESULTS**

Mean R2, R2*-seg, R2*-ROI were 38.0±5.2 (16.7-50.8), 55.3±13.7 (6.2-95.4) and 44.1±15.1 (15.1-125.2), respectively. Correlation coefficients were 0.5676 between R2 and R2*-seg, 0.5724 between R2 and R2*-ROI and 0.6076 between R2*-seg and R2*-ROI. Between R2 and R2* values, correlation graph shows curved shape correlation.

**CONCLUSION**

R2 measured by Multiecho MRS and R2* measured by PDFF were positively correlated. As R2* values, which has already proven useful, R2 values measured by multiecho MRS has the potential to be used to diagnose hepatic iron storage disease.

### CLINICAL RELEVANCE/APPLICATION

Using the R2 value obtained when performing Multiecho MRS to measure hepatic steatosis on 3T MRI, it may be possible to evaluate hepatic iron deposition disease at no additional cost.

## W5A-SPGI-5 EVALUATION OF RECTAL ADENOCARCINOMA USING DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING: A STUDY ON NEURAL INVASION IN RECTAL CANCER USING SINGLE AND MULTIPLE B-VALUES

Deshuo Dong (*Abstract Co-Author*) Nothing to Disclose
Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Wenjun Hu (*Abstract Co-Author*) Nothing to Disclose
Nan Wang (*Abstract Co-Author*) Nothing to Disclose
Liangjie Lin (*Abstract Co-Author*) Nothing to Disclose
Yue Wang (*Abstract Co-Author*) Nothing to Disclose
Chen Anliang (*Presenter*) Nothing to Disclose

### PURPOSE

Exploring the predictive ability of single and multiple b-values of apparent diffusion coefficient (ADC) in diffusion-weighted magnetic resonance imaging for neural invasion in rectal adenocarcinoma.

### METHODS AND MATERIALS

A retrospective analysis was performed on 25 rectal adenocarcinoma patients confirmed with neural invasion (NI) according to their postoperative pathology results who received pelvic 3.0 T MRI scan (Ingenia CX, Philips, Holland) in our hospital. They were divided into non-NI group (18 patients; 14 males, 4 females, mean age: 66.61 years, range: 51-88 years) and NI group (7 patients, 5 males, 2 females, mean age: 61.57 years, range: 27-75 years).Single and multiple b-value sequences obtained using IVIM sequences: 0, 800 s/mm2 (first sequence: DWI1), 0, 2000 s/mm2 (second sequence: DWI2), 0, 800, 2000 s/mm2 (third sequence: DWI3), and 200, 800, 2000 s/mm2 (fourth sequence: DWI4). Apparent diffusion coefficients (ADCs) of the rectal adenocarcinoma were calculated on ADC maps. The ADC values of different sequences were analyzed with Manny-whitey U test. The ROC curve was generated using the ADC value, and the area under curve (AUC) was calculated to analyze the diagnostic performance of using the ADC value in predicting NI of rectal adenocarcinoma.

### RESULTS

There was a statistically significant difference in the ADC value of DWI4 sequence between non-NI group (media 0.55 (0.54, 0.58) mm2/s) and NI group (media 0.66 (0.56, 0.76) mm2/s) ($p<0.05$). The AUC, maximum Youden index and diagnostic threshold of using the ADC value of DWI4 sequence for NI of rectal cancer was 0.778, 0.444 and 0.55 mm2/s, and the sensitivity and specificity were 100.0% and 44.4%, respectively. The ADC value of DWI1, DWI2 and DWI3 sequences between non-NI group and NI group were no statistically significant differences.

### CONCLUSION

ADC values determined with multiple b-values of 200, 800, 2000 s/mm2 sequence was useful for predicting neural invasion of rectal adenocarcinoma.

### CLINICAL RELEVANCE/APPLICATION

Compared with single b-value DWI sequence, ADC values determined with multiple b-values DWI sequence has a prospective clinical application in predicting the neural invasion of rectal adenocarcinoma for the treatment decision-making.

## W5A-SPGI-7 SPECTRAL CT PARAMETER COMBINATION WITH EXTRACELLULAR VOLUME FRACTION FOR PREOPERATIVELY PREDICTING COLORECTAL CANCER PERINEURAL INVASION

Ting LU (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of spectral CT parameters and extracellular volume fraction (ECV) in the preoperative prediction of perineural invasion (PNI) in colorectal cancer (CRC) .

### METHODS AND MATERIALS

123 CRC patients confirmed by postoperative pathology were retrospectively analyzed and all CRC patients underwent triple whole-abdomen enhanced spectral CT scans before surgery. Iodine concentration (IC), normalized IC (NIC), slope of the spectral curve (?H) at triple enhanced phase and extracellular volume fraction (ECV) were measured to compare the differences in each parameter between the PNI and nPNI groups. Parameters with statistically significant differences were included in binary logistic regression analyses to construct a combined model and to compare the performance of each parameter individually and in combination to differentiate between PNI and nPNI, and its capability was determined by the receiver operating characteristic (ROC) curves.

### RESULTS

In the stuty, a total of 123 patients were enrolled, including 71 cases of PNI and 52 cases of non-PNI (nPNI), the lesions in the PNI group were greater than those in the nPNI group, including triple enhanced phase IC, ?H, venous and delayed phase NIC and ECV, and the differences between the two groups were statistically significant ($P < 0.05$), while the differences between arterial phase NIC were showed no statistically significant difference between the two groups ($P > 0.05$). The area under the curve (AUC) of a single parameter for predicting PNI status was 0.632-0.820, and the AUC of the combined model for predicting PNI state was 0.859, and the sensitivity and specificity were 76.10% and 86.50%, respectively.

### CONCLUSION

Spectral CT parameters and ECV were able to predict PNI in CRC before surgery, which is expected to promote further research and long-term clinical application of spectral CT in preoperative prediction of PNI in CRC.

### CLINICAL RELEVANCE/APPLICATION

CRC is one of the malignancies of the digestive system with high morbidity and mortality in the world. PNI is a nerve fiber infiltrated by tumor cells in or around it, and is an independent predictor of poor prognosis in CRC. However, the gold standard for evaluating PNI is postoperative histopathological examination, which cannot guide the adjustment of preoperative treatment strategies for CRC. Spectral CT can obtain multiple parameters and has been widely used in tumor staging and treatment evaluation. ECV is mainly used for grading assessment of pancreatic and hepatic fibrosis. The purpose of this study was to investigate the value of spectral CT parameters combined with ECV in predicting PNI before CRC.

## W5A-SPGI-8 RESULTS AT 3 YEARS AFTER BEGINNING A WATCH AND WAIT PROGRAM FOR MANAGEMENT OF RECTAL CANCER IN A SINGLE CENTER

Raquel Bravo (*Abstract Co-Author*) Nothing to Disclose
Juan-Ramon R. Ayuso, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the performance of MRI, endoscopy/rectoscopy (E/R) and digital rectal examination (DRE) for evaluating clinical response in patients with rectal cancer (RC) treated with chemoradiotherapy (CRT) and to describe patient evolution after 3 years of implementing a Watch and Wait (WW) program in a tertiary Hospital in Spain.

### METHODS AND MATERIALS

Between June 2020 and May 2023, 63 out of 130 patients with RC had no metastatic disease and were scheduled for CRT as initial therapy. All of them were scanned for local staging with MRI and rescanned after CRT. Additionally, 45/63 and 44/63 patients underwent E/R and DRE, respectively after CRT. Pathologic results for resected patients or at least 1 year of recurrence-free clinical follow up for patients in WW were taken as gold standard for response evaluation. Criteria for response evaluation followed the International Consensus Recommendations. Receiver operating characteristic (ROC) curves and area under the curve (AUC) data were obtained to evaluate the sensitivity and specificity of each test to identify complete responses (CR) or near complete responses (nCR) after CRT. Patients who achieved a CR or an nCR were offered to be included in the WW program if there were no other contraindications.

### RESULTS

No differences were observed in the identification of CR/nCCR vs residual tumor between the three tests. However, AUC was slightly better for E/R (0.84) than for DRE or MRI (0.78 and 0.77, respectively) Sensitivities were 87%, 71%, and 55%, and specificities were 83%, 80%, and 93%, respectively. 18/63 patients (28.3%) met criteria to be included in the WW program. 6/18 patients (33.3%) had suspicion of tumor regrowth during the first year of follow-up and were resected. Two of them still maintained a pathologic CR. Therefore, 12/18 (66.6%) showed a sustained response allowing surveillance in the first year. One additional patient experienced local regrowth at 20 months. Consequently, 11/18 (61%) patients maintained long term organ preservation management.

### CONCLUSION

Over a quarter of patients with locally advanced RC (28.3%) could be selected for a WW program. Their follow-up must be strict as only 66.6% of them remain surgery- and regrowth-free in the first year after CRT completion. There were no differences in the performance of MRI, E/R, and DRE for the evaluation of response to CRT treatment, although the sensitivity of MRI was lower than the others to identify complete clinical responders.

### CLINICAL RELEVANCE/APPLICATION

The implementation of a WW program in patients with locally advanced rectal cancer allowed us to achieve comparable results to those described in the literature, following the recommendations of the International Consensus Group.

## W5A-SPGI-9 VALUE OF PREDICTING TRADITIONAL CHINESE MEDICINE SYNDROME TYPE OF PRIMARY LIVER CANCER BASED ON LI-RADS MAGNETIC RESONANCE SIGNS AND CLINICAL FEATURES

Xirong Zhang (*Abstract Co-Author*) Nothing to Disclose
Ying Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the efficacy of LI-RADS based on magnetic resonance signs and clinical features of nomogram in predicting traditional Chinese medicine (TCM) syndrome type of primary liver cancer (PLT).

### METHODS AND MATERIALS

The clinical data, TCM syndrome types and magnetic resonance characteristics of LI RADS of 147 patients with PLT were retrospectively analyzed, and randomly divided into training group and test group according to the ratio of 7:3. Siemens Skyra (VE11C) 3.0T MRI examination was performed in all patients, and T1WI scanning was performed first, DWI axis scanning parameters: b=50, 800 mm/s2, TR 6700 ms, TE 48 ms, voxel size 3.1mm × 3.1mm × 5.0mm, rotation Angle 5°, matrix 128 ×128, FOV 380 mm× 306 mm. Gd-DTPA was injected into the anterior cubital venous high pressure syringe at a rate of 2.5 ml/s and a dose of 0.1 mmol/kg. The images of arterial phase, portal vein phase and equilibrium phase were obtained by T1-weighted three dimensional (3D) gradient echo sequences at 20-30 s, 70 s and 180 s after injection of contrast agent, respectively. Firstly, the clinical data and magnetic resonance signs of LI-RADS were analyzed by single factor analysis, and the factors with statistical significance were analyzed by Logistics regression analysis to obtain independent risk factors. Construct a risk factor nomogram model and evaluate its effectiveness.

### RESULTS

There were statistically significant differences in Child-Pugh stage, Alb, AFP, AST, ALT, CEA, DBIL, TBIL, portal cancer embolus, extrahepatic metastasis, Mosaic sign, node-in-node-in-node-ring enhancement and envelope ($P < 0.05$) , as shown in Table 1 ,Table 2 . AFP, Alb, extrahepatic metastasis, Mosaic sign and halo ring enhancement were independent predictors of TCM syndrome types of PLT, as shown in Table 3. The AUC value, sensitivity, specificity and accuracy of the nomogram model in the training group and the test group were 0.835, 81.0%, 72.7%, 78.6%, 0.878, 90.5%, 88.9% and 90.0%, respectively, and the model had a high clinical net benefit, as shown in Table 4 , Figure 1 , Figure 2 , Figure 3.

### CONCLUSION

LI-RADS nomogram based on magnetic resonance signs and clinical characteristics can effectively assist in differentiating TCM syndrome differentiation of PLT, and provide an objective reference basis for it.

## CLINICAL RELEVANCE/APPLICATION

The LI-RADS nomogram model based on MRI signs and clinical indicators has a good performance in predicting the TCM syndrome types of PLT, enabling patients to obtain higher clinical benefits, providing an objective, standard and comprehensive imaging tool for TCM doctors to distinguish the syndrome types, so as to enable patients to obtain the most appropriate treatment.

## W5A-SPGU-1 PREDICTING GENETIC SUBTYPES OF PROSTATE CANCER USING RADIOMICS FEATURES FROM T2-WEIGHTED PROSTATE MRI IMAGES

Hyunho Han (*Abstract Co-Author*) Nothing to Disclose
Byung Chul Kang (*Abstract Co-Author*) Nothing to Disclose
Young Taik Oh, MD (*Abstract Co-Author*) Nothing to Disclose
Dae Chul Jung, MD (*Abstract Co-Author*) Nothing to Disclose
Jongsoo Lee (*Abstract Co-Author*) Nothing to Disclose
Jongjin Yoon, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Prostate cancer presents diverse genetic subtypes, affecting prognosis and treatment response. Four genetic subtypes have been identified using public single-cell RNA sequencing data: 1) Luminal A: Adipogenic/AR (Androgen Receptor)-active/Prostate Specific Antigen-high; 2) Luminal S: Secretory/Prostatic Acid Phosphatase-high; 3) AVPC-I: Aggressive Variant Prostate Cancer-Immune-infiltrative; and 4) ACPV-M: Myc-active. This study aims to develop a machine learning model to predict these genetic subtypes using radiomic features from T2-weighted prostate MRI images, potentially aiding in personalized treatment strategies.

### METHODS AND MATERIALS

In this prospective study, 195 patients (213 target lesions) with pathologically proven prostate cancer were enrolled from July 2020 to April 2022. RNA sequencing and CIBERSORT deconvolution were used to determine probabilities for the four genetic subtypes. T2-weighted MRI images were segmented in the train set (n = 128) through consensus between reader 1 (a faculty GU radiologist) and reader 2 (a fellow GU radiologist) and in the test set (n = 85) by reader 2. PyRadiomics was employed to extract 1,422 radiomic features. Feature selection was carried out using the ICC (intraclass correlation coefficient), least absolute shrinkage and selection operator, and multiple machine learning binary classifiers were utilized for classification. The synthetic minority oversampling technique was used to address imbalanced data. Performance evaluation considered AUROC and various binary classifier metrics. Scikit-learn and Python were used for statistical analysis.

### RESULTS

ICCs in train set demonstrated excellent agreement (excellent: 88.0%, good: 1.7%, fair: 0.2%, poor: 10.1%). For distinguishing the AR inhibitor-resistant subtype (AVPC subtype), the Random Forest (RF) model showed an AUROC of 0.98 in the train set and 0.84 in the test set. For differentiating docetaxel-resistant subtypes (Luminal A and AVPC-M subtypes), the RF model exhibited an AUROC of 0.95 in the train set and 0.77 in the test set. The RF model's performance was equivalent or superior to other classifiers (adaptive boosting, support vector machine, and naive Bayesian classifier).

### CONCLUSION

Our pilot study demonstrated promising results for a radiomics model capable of predicting genetic subtypes of prostate cancer. This model demonstrated its ability to predict AR inhibitor-resistant and docetaxel-resistant genetic subtypes with AUROCs of 0.84 and 0.77, respectively.

### CLINICAL RELEVANCE/APPLICATION

MRI-based radiomics models may provide a non-invasive and cost-effective alternative to RNA sequencing, with the potential to be utilized for drug selection and prognosis prediction in personalized treatment strategies.

## W5A-SPGU-2 NON-INVASIVE FUNCTIONAL MR IMAGING FOR STAGING OF DIABETIC KIDNEY DISEASE: EVALUATION OF CORTICOMEDULLARY DIFFERENTIATION USING SSPP WITH INVERSION RECOVERY PULSE WITH MULTI-INVERSION TIME

Mitsuru Takeuchi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Higaki, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tsutomu Tamada, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akihiko Kanki, MD (*Abstract Co-Author*) Nothing to Disclose

Hiroki Nakamura (*Abstract Co-Author*) Nothing to Disclose
Yu Ueda, PhD (*Abstract Co-Author*) Nothing to Disclose
Akira Yamamoto, MD, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Despite the complex pathology of diabetic kidney disease (DKD), staging diagnosis is currently only evaluated based on urinary albumin and GFR. Accurate assessment requires evaluation with multiple parameters. The purpose of this study is to evaluate the staging of DKD using functional MR imaging.

**METHODS AND MATERIALS**

A total of 122 cases, including 23 healthy volunteers and 99 diabetic patients, were studied. Diabetic patients were classified into 5 groups; low risk group (n=27), moderate risk group (n=19), high risk group (n=12), very high risk group (n=22), and highest risk group (n=19) based on the KDIGO 2022 Clinical Practice Guideline for Diabetes Management in CKD. All cases were imaged with a 3 Tesla MRI for T1 value, T2 value, and steady-state free precession with inversion recovery pulse with multi-inversion time (SSFP with IR pulse using multi TI) (TI=1000, 1100, 1200, 1300, 1400, 1500, 1600, 1700, 1800 msec). Corticomedullary differentiation (CMD) was calculated by "signal intensity (SI) of cortex / SI of medulla" for all images. The TI with the highest CMD value was adopted as the optimal inversion time (TI) for SSFP with IR pulse with multi TI. CMD values were compared among the staging classifications.

**RESULTS**

Significant differences were observed in T1 value between low risk group (0.78±0.03) vs. moderate risk group (0.82±0.04) (P<0.001) and moderate risk group (0.82±0.04) vs. high risk group (0.88±0.04) (P=0.001), in T2 value between healthy group (0.97±0.06) vs. low risk group (1.01±0.09), and in SSFP with IR pulse on optimal TI between healthy group (4.66±1.21) vs. low risk group (5.32±1.25) (P=0.016), low risk group (5.32±1.25) vs. moderate risk group (4.11±1.36) (P=0.004), very high risk group (2.79±0.82) vs. highest risk group (2.22±0.93) (P=0.011).

**CONCLUSION**

In DKD, increased cortical water content can be observed in the early stage due to glomerular hypertension and hyper filtration. The increase in CMD of T2 value is thought to reflect this phenomenon. In accordance with DKD more progresses, glomerulosclerosis and interstitial fibrosis are observed in the cortex. This result is thought to be reflected in the increase in CMD of T1 value. Since SSFP signal is T2/T1, it is reflect both the increase in water content in the early stage and the fibrosis in the progressive stage. By adopting the optimal TI with the largest CMD, the staging of DKD can be evaluated more sensitive. SSFP with IR pulse on optimal TI has the potential to be a new parameter for non-invasive evaluation of DKD.

**CLINICAL RELEVANCE/APPLICATION**

Urinary albumin and GFR only assess glomerular function, while MRI is thought to reflect not only glomerular changes but also changes including the interstitial change and may be a potential new parameter for evaluating the DKD.

## W5A-SPGU-3 NOVEL ADAPTIVE RADIOMIC FEATURE ENGINEERING METHODS FOR CLEAR CELL RENAL CELL CARCINOMA IMMUNE MICROENVIRONMENT PREDICTION

Vinay A. Duddalwar, MD, FRCR (*Abstract Co-Author*) Consultant, Radmetrix Inc;Consultant, DeepTek Inc;Consultant, Cohere Inc;Consultant, Westat Inc;Research Grant, Samsung Electronics Co, Ltd
Steven Cen, PhD (*Abstract Co-Author*) Nothing to Disclose
C. C. Jay Kuo (*Abstract Co-Author*) Nothing to Disclose
William Dean Wallace (*Abstract Co-Author*) Nothing to Disclose
Yixing Wu (*Abstract Co-Author*) Nothing to Disclose
Alexander Shieh, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Understanding the tumor immune microenvironment (TIME) in clear cell renal cell carcinoma (ccRCC) is crucial for patient selection and response assessment of emerging immunotherapies. Radiomic signatures from diagnostic imaging can be biomarkers for assessing ccRCC TIME. However, the prediction performance on specific TIME measurements needs to be improved in the existing literature. In this work, we investigated two markers that were shown to predict clinical outcomes: (1) elevated CD68+/PanCK+ cell ratio and (2) elevated PD1+CD8+/CD8+ ratio. We provided a baseline with a conventional radiomics pipeline and then used novel adaptive feature engineering strategies to enhance the prediction performance.

**METHODS AND MATERIALS**

A total of 78 primary ccRCC tumors from contrast-enhanced multiphase CT were segmented, and their radiomic signatures were generated using a phantom-validated pipeline. The tumor specimens obtained via nephrectomy were stained with PanCK, CD8, PD1, and CD68 using the Opal multiplex immunofluorescence (mIF) kit. After cell and tissue segmentation using the inForm software, the intratumoral CD68+/PanCK+ ratio and PD1+CD8+/CD8+ ratio were calculated. The novel feature engineering pipeline includes three stages: the redundancy removal stage to exclude highly correlated features, the discriminant feature test (DFT) stage to select important features, and the least-square normal transform (LNT) to generate new feature combinations. We compare the performance of this novel pipeline to conventional direct prediction by random forest. All experiments were conducted with five-fold cross-validation, and AUROC was used to compare model performance.

**RESULTS**

From mIF staining, we identified 3.2 million cells using our computational pathology analysis. After a grid search of DFT and LNT parameters (the number of selected and new features), AUROC improved from baseline 0.73 (95% CI: [0.60, 0.87]) to 0.85 (95% CI: [0.76, 0.93]). For the CD68+/PanCK+ experiment, the performance improved from 0.77 (95% CI: [0.63, 0.91]) to 0.79 (95% CI: [0.59, 1.00]).

**CONCLUSION**

Using the novel adaptive feature engineering strategies, we improved the performance of radiomic prediction to ccRCC TIME. These fast and data-efficient feature selection and generation techniques have been used in general computer vision tasks and can now be helpful in radiomic predictions.

**CLINICAL RELEVANCE/APPLICATION**

With a better performing and more robust CT radiomics pipeline, predicting ccRCC TIME non-invasively with routine diagnostic imaging can become a reality. These image-based biomarkers can provide dynamic TIME information for clinical decision-making in the future.

## W5A-SPGU-4 NOVEL ANATOMICAL OBSERVATIONS OF PENILE VENOUS DRAINAGE IN MEN WITH REFRACTORY POST-PROSTATECTOMY ERECTILE DYSFUNCTION

Sebastian Flacke, MD, PhD (*Abstract Co-Author*) Consultant, BTG International Ltd;Consultant, Surefire Medical, Inc;Consultant, Koninklijke Philips NV;Consultant, XACT Robotics Ltd
James Trussler, MD (*Abstract Co-Author*) Nothing to Disclose

Andrew McCullough, MD (*Abstract Co-Author*) Nothing to Disclose
Mohanned Alnammi, MD (*Abstract Co-Author*) Nothing to Disclose
Karl Benz, MD, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

To describe penile venous leak anatomy for the first time in men with medication refractory erectile dysfunction after radical prostatectomy.

**METHODS AND MATERIALS**

A prospectively maintained institutional CT cavernosography database was queried for men with medication refractory erectile dysfunction after radical prostatectomy and cystoprostatectomy. Exclusion criteria included a history of nodal positive disease at prostatectomy, pelvic radiation, and penile surgery. Data were collected with regards to demographics, comorbidities, and the procedure itself. 3D image reconstruction was used to anatomically define the venous leak pathways.

**RESULTS**

18 patients met inclusion criteria, 17 (94%) demonstrated venous leak. 16 men (89%) had venous leak through the superficial veins into the external pudendal vein and saphenofemoral system. 16 men (89%) had venous leak into the deep pelvic veins including internal pudendal and internal iliac veins. 15 men (83%) demonstrated venous leak from the corpus cavernosum into the corpus spongiosum, of which 14 (78%) communicated directly with the external pudendal system.

**CONCLUSION**

This study uncovers the uniquely novel finding that venous leak from the spongiosum communicates directly with the external pudendal system in 78% of patients in this population.

**CLINICAL RELEVANCE/APPLICATION**

Not only is this the first known study to anatomically describe venous leak anatomy in patients with medication refractory erectile dysfunction after radical prostatectomy, it uncovers a unique venous leak pathway and sets the stage for future prospective studies comparing venous anatomy pre- and post-radical prostatectomy. It raises numerous questions for future study. Is the newly described pathway a result of the procedure? Could the novel leak pathway reside outside the normal veno-occlusive mechanism and contribute to erectile dysfunction itself? Can pre-operative venous drainage variation predict those getting post-radical prostatectomy venous leak and severe ED? Answering such questions, among others, in future studies could alter the pre-operative workup, optimize pre-operative counseling, and deepen the understanding of the pathophysiology of severe erectile dysfunction after radical-prostatectomy.

## W5A-SPGU-5 NORMATIVE CURVES OF HEALTHY KIDNEY VOLUME FOR THE ADULT POPULATION: AN UPDATE USING AI-BASED KIDNEY VOLUMETRY

Lesley Cockmartin, PhD, MSc (*Abstract Co-Author*) Nothing to Disclose
Konstantinos Koukoutegos (*Abstract Co-Author*) Nothing to Disclose
Hilde Bosmans, PhD (*Abstract Co-Author*) Stockholder, Qaelum NV;Research Grant, Siemens AG;Research Grant, General Electric Company
Frederik De Keyzer (*Abstract Co-Author*) Nothing to Disclose
Liesbeth De Wever (*Abstract Co-Author*) Nothing to Disclose
Richard 's Heeren, MMEd (*Presenter*) Nothing to Disclose

**PURPOSE**

Total Kidney Volume (TKV) holds important clinical information about kidney function and patient's health. AI-based methods now enable accurate TKV measurement. Comparing TKV to 'healthy' kidney volume holds promise for improved diagnostic performance and potential automated detection of incidental findings. This study aims to establish normative curves of healthy TKV from abdominal CT scans and accounting for patient demographic and clinical data.

**METHODS AND MATERIALS**

This retrospective study included abdominal CT scans performed on the adult population (19-99 years) in our emergency department over one year. Medical files were reviewed chronologically, applying exclusion criterium to ensure no kidney pathologies were present. Cases were included until each 10-year age group reached 29 cases, with fewer in the >90-year group. An in-house developed 3D UNet convolutional neural network was applied to the CT scans to calculate the TKV. The AI predictions were verified for accuracy across all CT slices. Demographic and clinical data were collected from patient files. The relationship between these parameters and TKV was assessed using null hypothesis testing (with p-value) and linear regression for the continuous variables and univariate analysis of variance (ANOVA) for the nominal variables, with R2 values reported.

**RESULTS**

In total, 204 patients (66 men,138 women) were selected with mean age of 56 years, and mean TKV of 297 mL (standard deviation 69 mL). Significant correlations with TKV were found for age ($p<0.001$, $R^2=0.14$), length ($p<0.001$, $R^2=0.33$), weight ($p<0.001$, $R^2=0.24$), BMI ($p=0.027$, $R^2=0.031$), BSA ($p<0.001$, $R^2=0.32$), urea ($p<0.001$, $R^2=0.055$), and eGFR ($p<0.001$, $R^2=0.170$). Mean TKV differed significantly by gender ($p<0.001$, $R^2=0.14$), smoking ($p=0.002$, $R^2=0.056$), diuretic use ($p<0.001$, $R^2=0.072$), and vascular disease ($p=0.008$, $R^2=0.034$). The significant relationship with chronic hypertension ($p=0.022$, $R^2=0.032$) disappeared when length and weight were accounted for. Most blood values did not correlate. TKV could be predicted from TKV = -248.51 - 0.061 A2+ 5.86 A + 2.28 L + 0.97 W - 23.59 S, where A=age (years), L=height (cm), W=weight (kg) and S = 1 for women and 0 for men.

**CONCLUSION**

Utilizing an AI-based automatic kidney segmentation tool allowed, with a reasonable effort, to establish a normative curve equation for healthy TKV that aligns with previous scientific literature.

**CLINICAL RELEVANCE/APPLICATION**

Certain diseases cause changes in TKV. Comparing the patient's AI-based automatic TKV evaluation with their predicted healthy TKV, may allow to detect abnormalities in an early stage.

**PURPOSE**

The Pelvic Rosetta Classification (PRC) Project was initiated to create a landmark-based lymph node map of the pelvis for patients with prostate cancer (PCa) planned for surgical intervention. Aim of this new system is to harmonize communication between imaging specialists and urologists, and to facilitate localization of suspicious extraprostatic lesions during surgery.

**METHODS AND MATERIALS**

The project lead defined anatomical margins of eight pelvic (external iliac, obturator fossa cranial/caudal, dorsal internal iliac, vesico-prostatic pedicle, mesorectal, presacral, retropubic) and two extrapelvic (common iliac, intercommon) lymph node areas using anatomical landmarks that are consistently recognizable on MRI, CT, and intraoperatively. Regions were contoured by 21 experts on five representative axial contrast-enhanced CT images of a patient with PCa, depicting all defined areas. Contours were evaluated qualitatively and quantitatively. The mean Sųrensen-Dice coefficient and the corresponding standard deviation (SD) were calculated in comparison to a baseline contour that was created by the project lead, which was not available to the experts at the time of contouring to analyze the reproducibility of the proposed definitions.

**RESULTS**

Strong agreement between experts was found for the lymph node regions of the mesorectal and retropubic spaces. Largest variations were observed for regions bordering the peritoneum and without a continuously identifiable margin on CT (e.g., obturator fossa). The mean Sųrensen-Dice coefficients were lower for the vesico-prostatic pedicle (0.59, SD 0.27), obturator fossa (caudal: 0.54, SD 0.22; cranial: 0.67, SD 0.19), presacral (0.6, SD 0.17), and dorsal internal (0.64, SD 0.17) areas compared to the intercommon (0.71, SD 0.26), external (0.75, SD 0.2), common (0.77, SD 0.15), retropubic (0.83, SD 0.27), and mesorectal (0.86, SD 0.24) regions. In the first consensus meeting, the areas "obturator fossa" (cranial and caudal), "internal", and "vesico-prostatic pedicle" were revised, and the inguinal lymph node region was defined. Furthermore, techniques to differentiate the intraperitoneal and extraperitoneal spaces were elaborated (e.g., identifying the course of mesenteric vessels).

**CONCLUSION**

The proposed lymph node map of the pelvis for PCa already demonstrates fair reproducibility. Further development and validations are ongoing to ensure the successful implementation of the new classification in clinical practice.

**CLINICAL RELEVANCE/APPLICATION**

A multidisciplinary consensus-based map of pelvic lymph nodes in PCa will facilitate communication and improve patient care in individuals with suspected locoregional PCa metastases undergoing surgical treatment.

## W5A-SPGU-8 PERINEPHRIC MYXOID PSEUDOTUMOR OF FAT (PMPF): A RELATIVELY NEW ENTITY

Mark D. Sugi, MD (*Abstract Co-Author*) Consultant, Nextrast, Inc;Author with royalties, RELX
Kumaresan Sandrasegaran, MD (*Abstract Co-Author*) Nothing to Disclose
Alecio F. Lombardi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Given the limited literature on this subject, we wanted to identify the imaging features of PMPF in a large cohort.

**METHODS AND MATERIALS**

Institutional radiology and pathology databases were queried for PMPF for the period January 2010 to December 2023. Of 22 identified subjects, two were excluded due to non-availability of CT or MR images and five due to lack of pathological confirmation. The study cohort comprised of 15 subjects (males = 11) with median age of 59 years (range 26 to 83 years, involving a transplant in the youngest patient). Two abdominal radiologists in consensus reviewed all relevant CT and MRI images.

**RESULTS**

Eighteen tumors were analyzed since three subjects had bilateral lesions. The tumors were located at the renal hilum (n=15) or perinephric space (n=3). Two imaging patterns were seen: hazy ill-defined predominantly fatty mass (n=7) or a soft tissue mass (n=11) with variable fat content (estimated 30-90%). The tumors ranged in size from 3.8 to 18.7 cm (median 7.5 cm). The median precontrast and postcontrast CT densities were -21 and 42 Hounsfield units, respectively. Eight (n=8) cases had MR images available that showed areas of increased T1/T2 signal hyperintensity within the tumors consistent with myxoid content. Signal loss on opposed phase in four tumors corresponded to areas of fat density on CT images. One case had PET/CT images available which did not show FDG uptake within the tumor. Mild to moderate delayed enhancement was seen in all six tumors with multiphasic studies. The perihilar tumors encased central renal vessels without occlusion or thrombus. Mild hydronephrosis was seen in 3 of 18 kidneys. Most (9 of 13) of the affected native kidneys and all transplant kidneys (n=5) showed poor contrast enhancement. Slow progressive growth was seen in all 7 tumors with longer than 1-year follow up. Pathology showed diffuse fibromyxoid stroma, spindle cells and fat content. Negative MDM2 gene amplification on FISH testing excluded liposarcoma.

## CONCLUSION

PMPF may be considered in the diagnosis of tumors with soft tissue and fat components situated at the renal hilum or perinephric space. The delayed contrast enhancement, relative lack of mass effect for size, and poor function of affected kidney are diagnostic features.

## CLINICAL RELEVANCE/APPLICATION

The differential diagnosis among fat-containing retroperitoneal masses includes well known benign etiologies such as fat necrosis, perirenal lipomatosis and angiomyolipoma, as well as malignant ones among which liposarcoma is the most common. Perinephric myxoid pseudotumor is a relatively new entity that may arise from the fat surrounding native and transplanted kidneys. Knowing its imaging characteristics is important to narrow the differential diagnosis and exclude liposarcoma.

# W5A-SPGU-9 NORMALIZATION OF IODINE DENSITY IN RENAL CELL CARCINOMA AT CONTRAST-ENHANCED DUAL-ENERGY CT WITH DIFFERENT IODINE LOADS: A POTENTIAL INDICATOR TO MONITOR TUMOR RESPONSE TO CHEMOTHERAPY

## PURPOSE

Response of renal cell carcinoma (RCC) to chemotherapy, such as molecular targeted therapy, can be accurately monitored by quantifying intra-tumor iodine density at contrast-enhanced dual-energy CT (ceDECT), even complicated by intra-tumor hemorrhage. We retrospectively performed a pilot study to assess feasibility of normalizing iodine density in RCC at ceDECT with different iodine loads based on the patient's estimated glomerular filtration rate (eGFR) as a potential indicator to monitor the tumor response.

## METHODS AND MATERIALS

From February 2018 through March 2024, clear cell RCC (ccRCC) was postoperatively diagnosed in 54 patients and papillary RCC (pRCC), 7 patients who all underwent ceDECT during the nephrographic phase using routine (600 mgI/kg), 75% (450 mgI/kg), or 50% iodine load (300 mgI/kg) based on his/her eGFR with a 256-detector DECT scanner (Revolution CT, GE). We used deep learning reconstruction (TrueFidelity, GE) to generate 1.25-mm-slice iodine/water density images; placed regions of interest to quantify iodine density in the most avidly enhanced area of each RCC and in the abdominal aorta at the same level; divided the iodine density in each RCC by that in the aorta to normalize the intra-tumor iodine density. In patients with ccRCC, Kruskal-Wallis test with Bonferroni correction was used to compare the intra-tumor iodine density with/without the normalization among the different iodine loads. Mann-Whitney U test was used to compare the normalized iodine density between ccRCC and pRCC. A receiver operating characteristic (ROC) analysis was adopted to compare diagnostic performance to differentiate ccRCC from pRCC between the iodine density with/without the normalization.

## RESULTS

The routine, 75%, and 50% iodine loads were administered in 18, 22, and 14 patients with ccRCC, respectively. Whereas the intra-tumor iodine density decreased from the routine to 75% to 50% iodine load with significant differences between the routine and 50% iodine loads and between the routine and 75% iodine loads ($P < 0.001$ for both), the normalized intra-tumor iodine density was comparable among the different iodine loads ($P = 0.252$). The normalized iodine density was significantly greater in ccRCC ($0.82 \pm 0.21$) than in pRCC ($0.36 \pm 0.15$) ($P < 0.001$) and increased area under the ROC curve from 0.90 to 0.96.

## CONCLUSION

The normalized iodine density in RCC at ceDECT may be feasible to accurately monitor the tumor response to chemotherapy because it is independent of administered iodine load and more sensitive to the histological difference.

## CLINICAL RELEVANCE/APPLICATION

The normalized iodine density in RCC at ceDECT can accurately monitor tumor response to chemotherapy even with reduced iodine load in patients with renal impairment.

## W5A-SPHN-3 PERI-OPTIC NERVE ENHANCEMENT AS AN IMAGING FINDING AFTER RADIATION THERAPY

Kei Yamada, MD, PhD (*Abstract Co-Author*) Research funded, Fukushima SiC Applied Engineering, Inc;Research funded, Nihon Medi-Physics Co, Ltd;Research funded, PDR Network, LLC;Research funded, Doctor-NET. Inc
Katsumi Hayakawa, MD (*Abstract Co-Author*) Nothing to Disclose
Kentaro Akazawa (*Abstract Co-Author*) Nothing to Disclose
Keita Watanabe, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Kentaro Yuba, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Radiation therapy that includes the optic nerve in the irradiation field can occasionally lead to severe complications such as optic neuropathy. For the early detection of such damage, knowledge of post-radiotherapy imaging findings will be important. The aim of this study is to investigate the imaging findings of the optic nerve and its surrounding structures following radiotherapy.

### METHODS AND MATERIALS

This is a retrospective study that was carried out for cases between April 2019 and March 2024, targeting patients who received contrast-enhanced MRI following radiation therapy for periorbital malignancies at our institution, conducted as part of routine follow-up to check for recurrence. A total of sixteen patients were included with histological types: maxillary sinus carcinoma (n = 8), ethmoid sinus carcinoma (n = 3), nasal cavity malignant melanoma (n = 2), esthesioneuroblastoma (n = 2), and nasal cavity sarcoma (n = 1). Radiation treatment modalities consisted of proton beam therapy as monotherapy in 2 cases and chemoradiotherapy in 12 cases, delivering doses ranging from 64 Gy to 81.4 Gy. Additionally, postoperative radiation involved 30 Gy of proton beam therapy in 2 cases. Image evaluation around the optic nerve was performed conjointly by two experienced radiologists. The protocol included contrast enhanced 2D coronal T1-weighted images or 3D sagittal T1-weighted images with fat suppression. The optic nerve assessment included unilateral evaluation in cases of maxillary sinus carcinoma and lacrimal gland apocrine adenocarcinoma, with bilateral evaluation in all other instances, cumulatively assessing 24 optic nerve sides.

### RESULTS

Out of 24 sides examined, enhancement around the optic nerve was observed in 7 sides. Furthermore, enhancement within the optic nerve was noted in 4 sides. Naturally, all sites showing enhancement were within the irradiation field. The abnormal enhancement was observed post-radiation therapy at 627 ± 552 (median ± SD), range 78-1364 days. There was no significant difference in radiation dose between sites with and without abnormal enhancement ($p < 0.05$). A retrospective review of medical records revealed that one case with abnormal enhancement of the left optic nerve was diagnosed with a relative afferent pupillary defect by an ophthalmologist. However, no complaints of visual acuity or field deficits were reported in the other cases.

### CONCLUSION

Post-radiotherapy imaging can exhibit perineuritic-like enhancement around the optic nerve, which is often subclinical with few self-reported symptoms.

### CLINICAL RELEVANCE/APPLICATION

The knowledge of post radiation imaging is vital for radiologists to avoid misdiagnosis and to ensure proper patient management.

## W5A-SPHN-5 A NOVEL 3D VISUALIZATION AND ASSESSMENT TOOL IMPROVES SURGICAL PLANNING OF NECK DISSECTION

Tommaso D'Angelo, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Vitali Koch, MD (*Abstract Co-Author*) Nothing to Disclose
Christian Booz, MD (*Presenter*) Speaker, Siemens AG

### PURPOSE

To evaluate the impact of a dedicated software tool enabling 3D measurements and visualization of MRI/CT on surgical planning of neck dissection.

## METHODS AND MATERIALS

In this prospective study, a total of 96 patients (mean age 68 ± 13 years, range 39 - 101 years) with oral squamous cell carcinoma and preoperative MRI/CT were included. Dedicated postprocessing software was used for 3D visualization of primary tumour and cervical lymph node metastases including tumor volumetry and 3D distance and angulation measurements. Data such as tumour volume, 3D distances to cervical lymph node metastases and their cervical 3D localization as well as the corresponding freely rotatable colored 3D map were collected and shown to surgeons. Board-certified surgeons (n=3) rated software-based data concerning staging results display, diagnostic confidence and surgical work step planning of neck dissection compared to standard MRI/CT images using 5-pont-Likert scales. In addition, correlation analyses between tumor volume / T parameter and lymph node metastasis distance were performed using Spearman correlation.

## RESULTS

Colored 3D visualization and tumor volumetry as well as 3D distance and angulation measurements received superior ratings concerning staging results display, diagnostic confidence and surgical work step planning of neck dissection compared to standard MRI/CT images (all criteria, $p<.001$). In 9 cases surgical work steps of neck dissection were modified from standard approach due to information provided by the 3D tool. Correlation analyses showed low correlation between the volume of the primary tumor and the distance of cervical lymph node metastases with a Spearman correlation coefficient r of 0.374 ($p < .001$). No correlation was found between the volume of lymph node metastases and their distance ($r = 0.054$, $p = 0.601$) and between the distance and the T parameter of the TNM classification ($r = 0.157$, $p = 0.126$).

## CONCLUSION

A novel 3D visualization and assessment tool improves significantly surgical planning of neck dissection and leads directly to surgical work step modifications of neck dissection in certain cases compared with standard preoperative imaging.

## CLINICAL RELEVANCE/APPLICATION

Surgical planning of neck dissection can be improved by application of a novel 3D visualization and assessment tool for preoperative MRI/CT scans.

Robert A. Avery, DO (*Abstract Co-Author*) Research Consultant, Takeda Pharmaceutical Company Limited
Yucheng Tang, PhD (*Abstract Co-Author*) Nothing to Disclose
Zhifan Jiang, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Half of children with optic pathway gliomas secondary to neurofibromatosis type 1 (NF1-OPG) are at risk for visual acuity (VA) loss. NF1-OPGs manifest along the anterior visual pathway (optic nerve, chiasm, tract; AVP), where the overall shape and volume of AVP from magnetic resonance imaging (MRI) have been recently associated with VA loss. To investigate the added benefits of localized MRI features within the optic nerves (ONs) and chiasm, we introduce an automated deep-learning framework for VA loss detection through volumetric and radiomic analysis of ONs, chiasm, and AVP.

### METHODS AND MATERIALS

MRIs of 60 children with NF1-OPG from Site A (GE platform) and 75 from Site B (Siemens platform) were collected. MRI sequences included T1 (0.9×0.78×0.78 mm3), T2 (0.49×0.55×2 mm3) and T2-FLAIR (0.43×0.43×4.8 mm3). Volumetric ground truth was defined by expert delineation of the AVP. Neuro-ophthalmic evaluation identified VA loss (>= 0.2 LogMAR decline) in 52/135 children. Automatic AVP segmentation was performed using the Swin transformer network. The ONs and chiasm were segmented through template-based registration. We used brain volume, tumor location, child age, and 1,172 radiomic features to detect VA loss using support vector machines. Sequential feature selection based on sensitivity and univariate statistical tests (ANOVA) identified risk factors for VA loss. We initially assessed VA loss detection based on AVP alone and then investigated whether more detailed analysis on ONs and chiasm offered improvement.

### RESULTS

The average Dice volumetric overlap for automatic AVP segmentation was 0.791±0.075, consistent with the reported inter-observer variability for manual AVP segmentation (0.75±0.06). Cross-validated assessment of VA loss detection using AVP alone resulted in accuracy, sensitivity, specificity, and AUROC of 0.865, 0.647, 0.971, 0.728, respectively. Analyzing ONs and chiasm led to balance and improvements in these metrics, resulting in 0.865, 0.882, 0.857, 0.899, respectively. Significant risk factors were maximal image intensity and gray level run length entropy in T2-FLAIR for ONs, and image intensity range in T2-FLAIR for chiasm. The increase in AUROC was statistically significant (DeLong’s test, p=0.028).

### CONCLUSION

The use of deep learning to analyze MRI reveals that newly identified localized radiomic features within the ONs and chiasm are associated with VA loss. These features have improved predictive power for VA loss detection.

### CLINICAL RELEVANCE/APPLICATION

Reliable and relevant NF1-OPG MRI features can assess the risk of VA loss. If validated through larger data and longitudinal studies, this framework has the potential to guide the treatment decisions for children with NF1-OPGs.

## W5A-SPIN-3 ASSESSING THE PERFORMANCE OF AI ASSISTANCE FOR PROSTATE MULTIPARAMETRIC MRI: A TWO-CENTER STUDY INVOLVING EXPERIENCED AND LESS-EXPERIENCED RADIOLOGISTS

Xiaoying Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Wenpeng Huang (*Abstract Co-Author*) Nothing to Disclose
Kexin Wang (*Abstract Co-Author*) Nothing to Disclose
Zhaonan Sun (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the performance of both experienced and less-experienced radiologists in detecting clinically significant prostate cancer (csPCa) with and without the assistance of an AI algorithm.

### METHODS AND MATERIALS

A total of 900 multiparametric MRI datasets were retrospectively collected from two hospitals. Systematic combined with targeted biopsy served as the reference standard. Ten less-experienced radiologists and six experienced radiologists participated, with cases equally distributed among less-experienced radiologists. Additionally, 90 cases were randomly assigned to each experienced radiologist. Each case underwent two readings: one without AI assistance and one with AI assistance. The area under the curve (AUC), sensitivity, specificity, positive predictive value, and negative predictive value were compared between the two reading modes. Reading time and diagnostic confidence were also assessed, alongside inter-reader consistency among experienced radiologists across both reading modes.

### RESULTS

AI assistance significantly improved lesion-level sensitivity in detecting csPCa exclusively among less-experienced radiologists, elevating it from 0.78 to 0.88 ($P < 0.001$). Furthermore, with AI assistance, the AUC for detecting csPCa by less-experienced radiologists increased from 0.84 to 0.93 ($P < 0.001$) at the sextant level and from 0.84 to 0.89 ($P < 0.001$) at the patient level. Similarly, experienced radiologists exhibited an enhanced AUC in detecting csPCa, rising from 0.82 to 0.91 ($P < 0.001$) at the sextant level and from 0.91 to 0.94 ($P = 0.02$) at the patient level with AI assistance. AI-assisted readings resulted in reduced reading time (316 s vs. 164 s, $P < 0.001$) and increased diagnostic confidence (5 [4,5] vs. 5 [4,5], $P < 0.001$) across all experience levels, along with improved consistency among experienced radiologists (0.53 vs. 0.61, $P = 0.040$).

### CONCLUSION

AI-assisted reading improved the diagnostic performance of detecting csPCa on multiparametric MRI for both less-experienced and experienced radiologists, with greater benefits observed among less-experienced radiologists.

### CLINICAL RELEVANCE/APPLICATION

This study highlights the transformative potential of AI-assisted reading in improving the diagnostic accuracy and efficiency of detecting csPCa on multiparametric MRI. It emphasizes the particular benefits for less-experienced radiologists.

## W5A-SPIN-4 DEEP LEARNING-BASED BIOLOGICAL AGE ESTIMATION FROM MRI PREDICTS MAJOR ADVERSE CARDIOVASCULAR EVENTS IN THE GENERAL POPULATION

Michael T. Lu, MD, MPH (*Abstract Co-Author*) Stockholder, NVIDIA Corporation;Institutional Research Grant, Kowa Company, Ltd;Institutional Research Grant, AstraZeneca PLC;Stockholder, Advanced Micro Devices, Inc;Stockholder, Intel Corporation
Vineet K. Raghu, PhD (*Abstract Co-Author*) Nothing to Disclose

Jakob Weiss, MD (*Abstract Co-Author*) Nothing to Disclose
Susanne Rospleszcz (*Abstract Co-Author*) Nothing to Disclose
Marco Reisert (*Abstract Co-Author*) Nothing to Disclose
Matthias Jung, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Chronological age is an imperfect measure of aging. Measures of biological age, which reflect an individual's overall health status, could provide a more nuanced understanding of aging and improve medical decision-making. We propose a new deep learning framework (MRI-Age) for estimating biological age from MRI and investigate its value in predicting major adverse cardiovascular events (MACE) in the general population.

### METHODS AND MATERIALS

MRI-Age was developed using data from 30,389 asymptomatic individuals (20-75 years; 44.2% female) from the German National Cohort (NAKO): In Step 1, a model was trained to segment body composition (BC) including subcutaneous (SAT), visceral (VAT), intramuscular adipose tissue (IMAT) and skeletal muscle (SM) from the 1st to 5th lumbar vertebra. In Step 2, a second model was trained that takes the 3D BC segmentation masks as input and outputs an age estimate in years. Then, we calculated MRI-Age acceleration, defined as an age-specific z-score of Step 2 model output (Positive MRI-Age acceleration is biologically older, negative is younger). We validated this framework in an independent testing set of 36,317 UK Biobank (UKBB) participants. Primary outcome was incident MACE (fatal and non-fatal myocardial infarction, stroke, or heart failure). To investigate time to MACE, cumulative incidence curves were computed. Cox regression assessed the association between MRI-Age acceleration and MACE after adjustment for age, sex, BMI, race, BC volumes,diabetes, hypertension, cancer, alcohol consumption, smoking status. Results are for UKBB only.

### RESULTS

In 36,317 UKBB participants (65.1±7.8 y, 51.7% female; 2.7% [969/36,317] MACE; median follow-up 4.8 years), cumulative incidence curves showed a higher incidence of MACE in individuals with positive MRI-Age acceleration versus negative MRI-Age acceleration (Log-rank $p<0.0001$). Univariable Cox regression revealed an association between MRI-Age acceleration and MACE (HR per standard deviation of MRI-Age acceleration: 1.09, 95% CI 1.02-1.17, $p=0.01$). This signal remained robust after full adjustment for demographics and cardiometabolic risk factors (aHR: 1.09, 95% CI 1.01-1.18, $p=0.02$).

### CONCLUSION

A deep learning framework can estimate biological age from MR imaging and predict MACE in the general population beyond chronological age, MRI-derived BC measures, and cardiometabolic risk factors.

### CLINICAL RELEVANCE/APPLICATION

Our deep learning model leverages currently unused information about age-related changes in BC, which are widely available on existing clinical MRI scans of the abdomen. Applying our model to routine MRI scans can opportunistically extract biological age measures to inform cardiovascular risk assessment and clinical decision-making.

## W5A-SPIN-6 MULTI-TASK DEEP LEARNING FOR DETECTION OF PNEUMOPERITONEUM ON PLAIN RADIOGRAPHS IN NEONATAL INTENSIVE CARE UNIT

Hee Mang Yoon, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
JINWHA CHOI (*Abstract Co-Author*) Nothing to Disclose

Minsung Kim (*Abstract Co-Author*) Nothing to Disclose
Namkug Kim, PhD (*Abstract Co-Author*) Stockholder, Anymedi, Inc
Changhyun Park, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

To develop and validate a Multi-task Learning (MTL) model incorporating semantic segmentation (SEG) and classification (CLS) for detecting pneumoperitoneum (PP) on plain radiographs in neonatal intensive care unit (NICU).

**METHODS AND MATERIALS**

An X-ray dataset from NICU of a tertiary hospital for development of MTL model was used (N=244 without PP, and 281 with PP). The internal dataset was split into training, validation, and test sets (N=419:55:51). Gold standard (absence of PP, indeterminate, and presence of PP) was determined through review of clinical and surgical findings as well as ultrasound and follow-up imaging findings by a pediatric radiologist with 10 years of clinical experience. Region-of-interests were drawn in 281 cases with PP. An external dataset (N=165 without PP, and 216 with PP ) from different eleven tertiary hospitals were enrolled. Gold standards were defined by consensus reading of three pediatric radiologists with 3 to 24 years of clinical experience. To maximize sensitivity, indeterminate cases were considered as test positive. We developed a MTL model to leverage binary CLS and SEG tasks, employing a U-Net architecture with a DenseNet-169 encoder. MTL was implemented by extracting features from the model's bottleneck layer to generate the CLS output. We analyzed the area under receiver operating characteristic curve (AUROC), F1-score, and accuracy and compared the AUROC between the MTL model and CLS-only model using the Delong test.

**RESULTS**

In internal validation, the MTL model achieved significantly higher AUROC than the CLS-only model (0.98 vs. 0.77, p=0.001). In external validation, the MTL model outperformed the CLS-only model (AUROC, 0.89 vs. 0.58, p<0.001). For the MTL and CLS-only models, internal F1-scores were 0.94 and 0.69, and external F1-scores were 0.84 and 0.39; internal accuracies were 94% and 69%, and external accuracies were 84% and 57%, respectively.

**CONCLUSION**

The MTL model demonstrated high diagnostic performance for detecting pneumoperitoneum on NICU X-rays, outperforming the CLS-only model.

**CLINICAL RELEVANCE/APPLICATION**

Our enhanced MTL model, trained with a relatively small number of neonatal radiographs featuring subtle lesions of pneumoperitoneum, demonstrated strong performance and robustness on both internal and external datasets, even though these datasets were acquired from various clinical environments. It could be useful in actual clinical settings, assisting both physicians and non-expert pediatric radiologists.

## W5A-SPIN-7 DEEPSPINE: A COMPREHENSIVE DEEP LEARNING MODEL FOR MULTI-TASK LUMBAR SPINE MRI ANALYSIS

Stuart R. Pomerantz, MD (*Abstract Co-Author*) Support, General Electric Company
Christopher Bridge, DPhil (*Abstract Co-Author*) Institutional support, NVIDIA Corporation;Institutional support, General Electric Company;Institutional support, Nuance Communications, Inc
Satvik Tripathi (*Abstract Co-Author*) Nothing to Disclose
Kay Wu, MD, MS (*Presenter*) Nothing to Disclose

**PURPOSE**

A lumbar spine MRI is vital for diagnosing persistent low back pain etiologies. Spinal MR interpretation is time-consuming and subject to inter-reader variability. We extend upon a deep learning model tailored for comprehensive, automated analysis of lumbar spine MRI to detect and grade nine degenerative spinal conditions.

**METHODS AND MATERIALS**

DeepSPINE was trained and evaluated on a dataset of 54,739 T2-weighted lumbar MRI studies (31,439 female, 23,300 male, mean age 58.3 years) to predict the presence and severity of spinal pathologies: left (LFS) and right foraminal (RFS) and spinal canal stenosis (SCS), disc bulging (DB), disc osteophyte complex (DOC), left (LFA) and right facet arthropathy (RFA), ligamentum flavum thickening (LFT), and epidural lipomatosis (EL). Using natural language processing, intervertebral level-by-level ground-truth labels of pathological processes from associated radiology reports were extracted. From the studies, automatic segmentation of the vertebral bodies was performed. Using the segmentations, the intervertebral discs were localized and image volumes in the axial and sagittal planes of each disc were extracted. Each image volume was then fed into a convolutional neural network based on ResNeXt with softmax activation and categorical cross-entropy loss to perform the classification tasks.

**RESULTS**

DeepSPINE demonstrated within-one class accuracies of 96.1%, 96.1%, and 97.0% and quadratic Cohen's kappa of 0.745, 0.750, and 0.781 in classifying the severity of LFS, RFS, and SCS, respectively. For binary DB, DOC, LFA, RFA, LFT, and EL classification, AUC scores were 0.861, 0.838, 0.628, 0.632, 0.669, and 0.638.

**CONCLUSION**

We successfully trained an efficient multi-task, multi-class, and multi-input deep learning model to automatically predict and grade various spinal pathologic processes. DeepSPINE achieved strong performance across classification tasks at each spinal level. To our knowledge, this is the first model trained on such a large and robust dataset to generate more comprehensive, descriptive level-by-level predictions of lumbar spine disease.

**CLINICAL RELEVANCE/APPLICATION**

DeepSPINE's comprehensive analysis of lumbar spine MRI shows potential to improve patient care by enhancing diagnostic accuracy for spinal diseases, providing standardized interpretations, streamlining workflow, and facilitating tailored treatment planning for spinal diseases. We expect it to alleviate the burden on radiologists and enhance efficiency and timely access to care.

Manuel Gonzalez Leyte, MD (*Abstract Co-Author*) Nothing to Disclose
Paola Lopez-Gomez, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Hepatic resection is crucial in the curative treatment for primary or metastatic liver tumors but is hampered by postoperative liver failure, a leading cause of death. Patient selection criteria and efficient preoperative tools are needed to provide an adequate future liver remnant (FLR). Preoperative portal vein embolization (PVE) has extended liver resection indications and improved postoperative outcomes, becoming the gold standard for FLR hypertrophy. However, liver resection remains contraindicated in 30% of cases after PVE due to insufficient FLR hypertrophy or tumor progression. Recent alternative techniques aim to increase the number of patients eligible for curative resection. This study evaluated whether liver venous deprivation (LVD) offers advantages in inducing hypertrophy compared to single PVE.

### METHODS AND MATERIALS

We retrospectively gathered data from 52 patients who underwent either PVE (n=29) or LVD (n=23) from 2013 to 2024 before extended hepatectomy for primary or secondary liver tumors. FLR volume was measured using a computed tomography (CT) scan before and after embolization. The same experienced reader performed the volumetric measurements. FLR growth percentage was calculated and compared.

### RESULTS

During the study period, 52 patients underwent vascular interventional radiology procedures intending to optimize the FLR volume. Of these patients, 29 underwent PVE (PVE group), and 23 had LVD (LVD group). The mean age was 63,8, and male patients were predominant (63,7%). The most common tumor type was colorectal liver metastases (24 patients, 46,2%), followed by cholangiocarcinoma (22 patients, 42,3%). There was no statistical difference in the mean percentage of FLR ratio hypertrophy between LVD and PVE groups (8,5% vs 11,9%, p=0.14). None of the patients had complications after the procedure. The time to achieve hypertrophy was significantly lower in the LVD group compared to the PVE group (27,09 days vs 33 days, p=0,020). There was, however, no difference in the time elapsed between the procedure and the surgery (84,67 days in the LVD group vs 85,14 days in the PVE group, p=0.98), although the variability was considerably high (SD of 61,08 and 78,73 days respectively).

### CONCLUSION

Despite the limitations, including a small number of patients and a retrospective review, our survey reveals no difference between LVD and PVE regarding liver hypertrophy. Conversely, LVD might shorten the time of primary liver resection with no more morbidity.

### CLINICAL RELEVANCE/APPLICATION

The study of alternative techniques to single PVE is crucial to increase the number of patients with primary or metastatic liver tumors eligible for curative resection.

## W5A-SPIR-3 MULTIPARAMETRIC MRI-BASED RADIOMICS NOMOGRAM PREDICTS THE RECURRENCE OF HEPATOCELLULAR CARCINOMA AFTER POSTOPERATIVE ADJUVANT TRANSARTERIAL ARTERIAL CHEMOEMBOLIZATION

Jiansong Ji, MD (*Abstract Co-Author*) Nothing to Disclose
Liyun Zheng (*Abstract Co-Author*) Nothing to Disclose
Xinyu Guo (*Presenter*) Nothing to Disclose

**PURPOSE**

This study was undertaken to develop and validate a radiomics model baed on multiparametric magnetic resonance imaging (MRI) for predicting recurrence in patients with hepatocellular carcinoma (HCC) following postoperative adjuvant transcatheter arterial chemoembolization (PA-TACE).

**METHODS AND MATERIALS**

In this retrospective study, 117 HCC patients (81 for training, 36 for validation) treated with PA-TACE were included. Multiparametric radiomics features were extracted from three MRI sequences. Least absolute shrinkage and selection operator (LASSO)-COX regression was utilized to select radiomics features. Optimal clinical characteristics selected by multivariate Cox analysis were integrated with Rad-score to develop a recurrence-free survival (RFS) prediction model. The model performance was evaluated by time-dependent receiver operating characteristic (ROC) curves, Harrell's concordance index (C-index), and calibration curve.

**RESULTS**

Fifteen optimal radiomic features were selected and the median Rad-score value was 0.434. The median RFS of patients with low-risk signature was 47 months, much higher than those with high-risk signature(P<0.0001). Multivariate Cox analysis indicated that neutrophil-to-lymphocyte ratio (NLR) (hazard ratio (HR)=1.49, 95% confidence interval (CI): 1.1-2.1, P=0.022) and tumor size (HR=1.28, 95% CI: 1.1-1.5, P=0.001) were the independent predictors of RFS after PA-TACE. A combined model was established by integrating Rad-score, NLR, and tumor size in the training cohort (C-index 0.822; 95% CI 0.805-0.861) and validation cohort (0.823; 95% CI 0.771-0.876). The calibration curve exhibited a satisfactory correspondence in two cohorts.

**CONCLUSION**

A multiparametric MRI-based radiomics model can predict RFS of HCC patients recieving PA-TACE and a nomogram can be served as an individualized tool for prognosis.

**CLINICAL RELEVANCE/APPLICATION**

We have developed and validated a multiparametric MRI-based radiomics model that provides personalized assessments of HCC recurrence risk before treatment.

**PURPOSE**

Comprehensively understand the dynamics of micro-particles utilized in Magnetic Resonance Navigation (MRN), a new approach for liver tumor treatment which utilizes MRI magnetic fields to aggregate particles and guide them through vessels. Our ultimate objective is to optimize MRN for enhanced efficacy and clinical outcomes. This will be achieved through a synergistic approach combining computational modeling and in-vitro experimental validation.

**METHODS AND MATERIALS**

A glass phantom replicated the hepatic artery's initial stage, with systole/diastole transient flow induced by a cardiac heart pump. Outlet flow from the phantom's branches was manually measured and cross-validated with 2D cine phase-contrast MRI data. Aggregates of 10, 20, and 30 particles were injected into the phantom under MRI conditions, at different angulations relative to the MRI static magnetic fields (B0). The particles were guided by Magnetic Gradient, gravity, and flow drag force. Friction between particles and the phantom wall was determined by attracting aggregates with a magnetized metallic ball, measuring the distance at which the force overcame static friction.

**RESULTS**

The computational results of the fluid field were initially compared with 4D flow MRI data, demonstrating satisfactory agreement between in-vitro experimental outcomes and computational results as shown in Figure 1. Comparing particle motion in the computational model with experimental observations revealed insights into aggregate steering and efficiency. Without steering gradient, the distribution of aggregates between left and right branches varied with phantom angulation relative to B0. Specifically, at 0°, 45°, and 90° relative to B0, 55%, 25%, and 75% of aggregates respectively took the right branch. Perfect (100%) steering efficiency was achieved after injecting 20 aggregates for all gradient directions and phantom angulations.

**CONCLUSION**

Preliminary findings highlight the satisfactory agreement between the computational model and experimental outcomes, yet challenges in accurately modeling flow drag force underscore the need for further refinement. Despite this, the successful guidance of aggregates to desired branches emphasizes MRN potential for targeted therapy. Future investigation, particularly into random-shaped aggregates, is vital for optimizing MRN and improving clinical outcomes.

**CLINICAL RELEVANCE/APPLICATION**

The insights gained from this study hold significant promise for advancing MRN as a targeted approach for liver tumor treatment. By optimizing the understanding of micro-particle dynamics, we aim to improve MRN efficacy, ultimately enhancing patient outcomes in clinical practice.

## W5A-SPIR-5 ABLATIVE RADIOEMBOLIZATION IS CORRELATED WITH IMPROVED OUTCOMES FOR HEPATOCELLULAR CARCINOMA GREATER THAN 4 CM

Jeet Minocha (*Abstract Co-Author*) Nothing to Disclose
Kathryn J. Fowler, MD (*Abstract Co-Author*) Consultant, Bayer AG;Research support, General Electric Company;Research Grant, Pfizer Inc;Institutional Grant, MEDIAN Technologies;Consultant, General Electric Company
Zachary Berman, MD (*Abstract Co-Author*) Nothing to Disclose
Vasan Jagadeesh (*Abstract Co-Author*) Nothing to Disclose
Kurt Pianka, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

For smaller hepatocellular carcinoma (HCC) tumors, transarterial radioembolization (TARE) ablative doses (> 190 Gy) have led to better outcomes. This study examined whether ablative dosing correlated with better response outcomes in patients with tumors >= 4 cm.

**METHODS AND MATERIALS**

This retrospective single-center study included all patients with HCC undergoing TARE between June 2011 - December 2022 (n=205). Patients with HCC >= 4 cm without tumor in vein were included (n=50). All patients were treated with Y-90 glass microspheres. mRECIST response criteria were applied to 3-month post-TARE imaging. Single compartment dose was categorized as > 400 Gy (High), 190 - 400 Gy (Medium), or < 190 Gy (Low).

**RESULTS**

The High (n=21), Medium (n=19), and Low (n=10) groups were well-matched in baseline characteristics. The median HCC size was 5.4 cm (range 4.1 - 14.0 cm; interquartile range 2.7 cm). There was a positive correlation between higher dose and overall and target mRECIST response ($r=0.29$, $p < 0.05$; $r=0.43$, $p < 0.01$). Overall CR was obtained in 52% (11/21), 37% (7/19), and 10% (1/10) of the High, Medium, and Low dose groups, respectively ($p=0.08$). 57% (12/21) of High dose patients achieved target CR versus 42% (8/19) of Medium and 10% (1/10) of Low dose patients ($p < 0.05$). OS did not differ based on the > 400 Gy or > 190 Gy thresholds. However, a trend towards decreased probability of distant progression within 12-months was seen in the High dose group: 24% (5/21) versus 52% (15/29) in the Medium and Low dose patients ($p=0.09$).

**CONCLUSION**

There was a dose-response relationship for larger HCCs undergoing TARE with the best imaging responses noted with higher ablative dosing (> 400 Gy).

**CLINICAL RELEVANCE/APPLICATION**

Large HCC tumors without vascular invasion are more likely to achieve superior imaging response when treated with ablative dose TARE strategies.

## W5A-SPIR-6 THE DIAGNOSTIC VALUE OF SUBTRACTIONCT IN EVALUATING THE EFFICACY OF TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION IN HEPATOCELLULAR CARCINOMA PATIENTS COMPARED TO CONVENTIONAL CT AND MRI

Fucheng Ding (*Abstract Co-Author*) Nothing to Disclose
Mingyang Mao (*Abstract Co-Author*) Nothing to Disclose
Feng Duan (*Abstract Co-Author*) Nothing to Disclose
Fengxian Hu, MMEd (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to evaluate the diagnostic value of subtraction CT in assessing the efficacy of transcatheter arterial chemoembolization (TACE) in patients with hepatocellular carcinoma compared to conventional CT and MRI.

**METHODS AND MATERIALS**

73 pathologically confirmed hepatocellular carcinoma patients (97 lesions) who underwent TACE treatment were retrospectively collected. All patients underwent follow up examinations including multiphasic CT, multiphasic MRI and digital subtraction angiography (DSA). The subtraction images of arterial phase were obtained by using Subtraction Iodine Mapping software (Canon medical systems). Two senior radiologists classified the lesions into Liver Imaging Reporting and Data System (LI-RADS) v2018 treatment response (LR-TR) algorithm (LR-TR viable, LR-TR equivocal and LR-TR nonviable) and evaluated the diagnostic confidence of lesions in multiphase CT images, multiphase CT with subtraction images and multiphase MR images. The sensitivity, specificity and accuracy of LR-TR algorithm in three image sets were evaluated using DSA as the gold standard.

**RESULTS**

The sensitivity and accuracy of LR-TR viable category in multiphase CT with subtraction images were significantly higher than in multiphase CT images (89.4% vs 44.7%, 82.1% vs 47.8%, all $p<0.05$), respectively. The sensitivity, specificity and accuracy in multiphase CT with subtraction images were comparable with in multiphase MR images (all $p>0.05$). For diameter of lesion = 6 mm, the sensitivity and accuracy of LR-TR viable category in multiphase CT with subtraction images were significantly higher than in multiphase CT and MR images (92.3% vs 23.1%vs23.1%, 84.1% vs 21.1%vs 21.1%, all $p<0.05$). The interobserver agreement between two radiologists were good in multiphase CT with subtraction images (?=0.754). The diagnostic confidence in multiphase CT with subtraction images were higher than in multiphase CT and MR images (both $p<0.05$).

**CONCLUSION**

The multiphase CT with subtraction images can significantly improve the sensitivity and accuracy of LR-TR algorithm , especially in lesions with a diameter = 6mm. Subtraction images can improve the diagnostic confidence for detecting viable tumor in TACE-treated patients.

**CLINICAL RELEVANCE/APPLICATION**

Comparing with multiphase CT and MR, the multiphase CT with subtraction images provide high accuracy for evaluation of viability of tumor in HCC patients after TACE.

## W5A-SPIR-7 SUPER-RESOLUTION DEEP-LEARNING RECONSTRUCTION IMPROVES THE IMAGE QUALITY OF CT DURING HEPATIC ARTERIOGRAPHY

Kazuo Awai, MD (*Abstract Co-Author*) Research Grant, Canon Medical Systems Corporation;Research Grant, Hitachi, Ltd;Research Grant, Fujitsu Limited;Research Grant, Nemoto Kyorindo co, Ltd;Research Grant, FUJIFILM Holdings Corporation

Toru Higaki, PhD (*Abstract Co-Author*) Nothing to Disclose
Keigo Chosa (*Abstract Co-Author*) Nothing to Disclose
Kenji Kodakari, BA (*Presenter*) Nothing to Disclose

**PURPOSE**

CT during hepatic arteriography (CTHA) is essential for transcatheter arterial chemoembolization in patients with hepatocellular carcinoma because it increases the detection of tumor-feeding arteries compared to digital subtraction angiography. Super-resolution deep-learning reconstruction (SR-DLR) is a new image reconstruction method that provides CT images with higher spatial resolution and lower image noise by using a deep convolutional neural

networks trained on high-resolution CT images. The application of SR-DLR to CTHA is expected to improve its image quality. We investigated the clinical feasibility of SR-DLR-CTHA.

**METHODS AND MATERIALS**

We evaluated 30 patients who had undergone CTHA. The images were reconstructed with SR-DLR or conventional hybrid iterative reconstruction (Hybrid-IR). Curved multiplanar reformations (CPR) of the right and left hepatic artery were created and their CT value was recorded from their origin to their distal site. Attenuation of the hepatic parenchyma was measured; the standard deviation of the attenuation in the hepatic parenchyma was defined as the image noise. The contrast-to-noise ratio (CNR) = (ROIA - ROIL)/N was calculated; ROIA is the attenuation of the hepatic artery, ROIL the mean attenuation of the hepatic parenchyma, and N the noise. A 20-mm smoothing filter was applied to the CNR curve to reduce the influence of the image noise. The distance from the origin to the distal site of the hepatic artery with a CNR larger than 10 (CNRD10) was calculated on images subjected to both reconstruction methods. The longer the CNRD10, the better was the visualization of the small hepatic artery at the distal site. Differences between the two reconstruction methods were compared with the Wilcoxon signed-rank test.

**RESULTS**

Image noise was lower on SR-DLR- than Hybrid-IR images (median image noise 9.3 vs 19.2 HU, $p<0.01$). The CNRD10 was significantly longer on SR-DLR- than Hybrid-IR images (median for left hepatic artery 132.7 vs 111.3 mm, $p<0.01$; median for right hepatic artery 116.6 vs 98.0 mm, $p<0.01$).

**CONCLUSION**

The visualization of the hepatic arteries on CTHA images was better with SR-DLR than Hybrid-IR.

**CLINICAL RELEVANCE/APPLICATION**

As SR-DLR yielded better visualization of the hepatic arteries on CTHA images than Hybrid-IR, it is recommended for the visualization of small vessels.

## W5A-SPMK-1 ANALYSIS OF FAT FRACTIONS OF THE GLUTEUS MEDIUS AND MINIMUS MUSCLES IN ELDERLY ASYMPTOMATIC HIPS USING 2-POINT-DIXON MRI - WHAT IS NORMAL?

Sophia Goller, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Patrick Zingg, MD (*Abstract Co-Author*) Nothing to Disclose
Reto Sutter, MD (*Abstract Co-Author*) Nothing to Disclose
Georg Wilhelm Kajdi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To establish quantitative reference values for fatty infiltration of the main hip abductors in elderly asymptomatic hips - in patients suffering from unilateral greater trochanteric pain syndrome (GTPS) on the contralateral side - using 2-point-DIXON MRI derived fat fractions (FF).

### METHODS AND MATERIALS

In this prospective single-center study, two radiologists assessed fatty infiltration of the gluteus minimus (Gmin) and medius (Gmed) muscles in both hips of patients with unilateral GTPS using 2-point-DIXON MRI derived FF. Additionally, fatty infiltration was assessed using the Goutallier classification. Differences in fatty infiltration between the symptomatic and asymptomatic hip were assessed for both methods using the Wilcoxon signed-rank test.

### RESULTS

42 patients (mean age 65.1 ± 13.7 years, 28 females) with unilateral GTPS were analyzed. The mean FF in asymptomatic hips was 14.54 ± 13.70 % for the Gmin and 15.29 ± 10.28 % for the Gmed. Quantitative FF were significantly higher in symptomatic hips with FF of 15.05 ± 12.49 % ($P < 0.001$) for the Gmin and 19.36 ± 14.42 % ($P = 0.001$) for the Gmed, when compared to the asymptomatic side. There was a significant difference between the fatty infiltration of the symptomatic and asymptomatic sides using the Goutallier classification for the Gmin muscle ($P = 0.046$), whereas there was no significant difference for the Gmed muscle ($P = 1.00$).

### CONCLUSION

2-point-DIXON derived quantitative FF of Gmin and Gmed of elderly patients were significantly lower on the asymptomatic side compared to the contralateral symptomatic side, but notably higher compared to values reported in young healthy individuals. Asymptomatic hips of elderly individuals had a mean FF of 14.54 ± 13.70 % for the Gmin and 15.29 ± 10.28 % for the Gmed, respectively.

### CLINICAL RELEVANCE/APPLICATION

These results can serve as quantitative reference values for further studies on hip fatty infiltration.

## W5A-SPMK-2 THE RELATIONSHIP BETWEEN OSTEOARTHRITIS GRADING AND THE RISK OF SUBSEQUENT HIP FRACTURES IN OLDER WOMEN: A PROSPECTIVE COHORT STUDY

Ling Wang (*Abstract Co-Author*) Nothing to Disclose
Fengyun Zhou (*Abstract Co-Author*) Nothing to Disclose
Xiaoguang Cheng (*Abstract Co-Author*) Nothing to Disclose
Yandong Liu (*Abstract Co-Author*) Nothing to Disclose
Yi Yuan (*Abstract Co-Author*) Nothing to Disclose
Wenshuang Zhang, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the relationship between Kellgren-Lawrence (KL) grading of osteoarthritis (OA) and the risk of hip second fractures in older women.

### METHODS AND MATERIALS

Hip computed tomography (CT) and radiographic examinations were conducted post-first fracture. Areal bone mineral density (aBMD) at total hip (TH), femoral neck (FN), trochanter (TR), and intertrochanter (IT) of contralateral femur was measured using CT X-ray absorptiometry. HOA classification was assessed on baseline KL grades. HRs for the risk of second hip fractures were evaluated using Cox proportional hazards models. AUC with 95%CI was calculated using multivariate logistic regressions to assess predictive power of incorporating OA grading into models combining BMD parameters.

**RESULTS**

The average age at baseline was 74.9(±9.5) years. Initial HOA Grade distribution was 108 in Grade0, 79 in Grade1, 16 in Grade2, and 3 in Grade3. Over 4.5 years, 35 participants experienced second hip fractures, 153 without refractures, and 18 deceased. In second fracture group, HOA grades were distributed as 14 in Grade0, 17 in Grade1, 3 in Grade2, and 1 in Grade3. Significant HRs for predicting second hip fractures were observed for TH aBMD (HR,1.79;p=.02) and IT aBMD (HR,2.04;p<.01). Except for the combined HOA Grades2 and 3 (HR,4.27;p=.04), no significant HRs were found for HOA classification. The AUC for models incorporating OA grading was higher than 77%, but the difference in AUC between models with and without OA grading was not statistically significant.

**CONCLUSION**

The presence of OA in the contralateral hip may increase the risk of hip second fractures in older women, although the exact statistical impact of incorporating OA grading into predictive models requires further investigation.

**CLINICAL RELEVANCE/APPLICATION**

This study highlights a noteworthy association between the severity of osteoarthritis (OA) and the heightened risk of subsequent hip fractures in older women, particularly emphasizing the significant risk increase with higher OA grades. Despite this association, incorporating OA grading into predictive models did not markedly improve their accuracy beyond that achieved with traditional bone mineral density (BMD) assessments. These findings suggest that while OA severity is an important factor in evaluating fracture risk, it is one of many factors that need to be considered. The complexity of predicting hip fractures calls for further research to develop more comprehensive models that integrate both established and novel risk factors, aiming for a holistic approach to assess and mitigate fracture risk in this vulnerable population.

## W5A-SPMK-3 PROSPECTIVE DEEP LEARNING MRI OF THE PELVIS: A NOVEL APPROACH TO ENHANCE CLINICAL EFFICIENCY

Renate M. Hammerstingl, MD (*Abstract Co-Author*) Nothing to Disclose
Leon D. Gruenewald, MD (*Abstract Co-Author*) Nothing to Disclose

Katrin Eichler, MD (*Abstract Co-Author*) Nothing to Disclose
Ibrahim Yel, MD (*Abstract Co-Author*) Nothing to Disclose
Vitali Koch, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to investigate the effectiveness of combining deep learning (DL)-based parallel reconstruction technique (PAT) and simultaneous multislice (SMS) acceleration magnetic resonance imaging (MRI), in contrast to conventional pelvic imaging.

**METHODS AND MATERIALS**

Adults who underwent clinically indicated pelvic MRI were prospectively recruited between January 2024 and April 2024. The participants received coronal T2-weighted sequences with both conventional 2-fold PAT (P2) and DL-based 4-fold PAT combined with 2-fold SMS acceleration imaging (P4S2). Three independent readers assessed pelvic structures, overall image quality, image noise, and diagnostic confidence. Diagnostic performance was calculated using a consensus reading as the reference standard. For quantitative image assessment, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and radiomics features were calculated. Interreader agreement was measured using Fleiss ?.

**RESULTS**

A total of 28 patients (mean age, 46 ± 21 years; 15 women) were included in this study. The diagnostic performance for detecting pathologies and the overall image quality were similar among both protocols. SNR and CNR were lower using the DL-based SMS protocol than with conventional imaging ($P < 0.01$). Interreader and intermethod agreements were excellent (? = 0.870 and ? = 0.910, respectively). In addition, the mean acquisition time was reduced by 44% when using P4S2, compared with conventional P2 imaging.

**CONCLUSION**

Combined DL-accelerated imaging (4-fold PAT with 2-fold SMS) performed similarly to conventional 2-fold PAT for evaluating pelvic structures, with a 44% reduction in acquisition time.

**CLINICAL RELEVANCE/APPLICATION**

We showcase the signal preservation capabilities of combined DL-accelerated imaging, which provides comparable diagnostic performance while achieving improved SNR and CNR. Additionally, this approach allows for approximately 44% shorter acquisition times than conventional imaging, thus potentially improving clinical pelvic MRI efficiency.

## W5A-SPMK-5 CT-GUIDED PERCUTANEOUS SACROPLASTY: A STANDARD OF CARE FOR INSUFFICIENCY SACRAL FRACTURES?

Lara Berrocal, MD (*Abstract Co-Author*) Nothing to Disclose
Sonia C. Carbo, MD (*Abstract Co-Author*) Nothing to Disclose
Anna Marin, MD (*Abstract Co-Author*) Nothing to Disclose
Vladimir Cheranovskiy, MD (*Abstract Co-Author*) Nothing to Disclose
Jorge Garcia Gomez, MD (*Abstract Co-Author*) Nothing to Disclose
Alba Anton-Jimenez, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

- To describe the procedure of CT-guided percutaneous sacroplasty as a treatment for sacral insufficiency fractures.- To review efficacy of the technique in a series of patients with symptomatic sacral fractures in our population.- To study outcome predictors to clinical benefit and possible complications of the procedure.

**METHODS AND MATERIALS**

This retrospective study included 12 consecutive patients with sacral insufficiency fractures that were treated in our institution between 2012-2024, using CT-guided sacroplasty.After intravenous sedation, a 13-G needle was inserted percutaneously using a posterior short-axis approach (perpendicular to the dorsal cortex of the sacrum). Needle placement along the fracture lines was proved under CT-fluoroscopy guidance, prior to injection of polymethyl

methacrylate cement (PMMA) (see attached figures). Cement injection was monitored by axial CT-fluoroscopy acquisition to assess potential cement migration into the sacral foramen and spinal canal.To describe clinical outcomes, visual analogue scale (VAS) was assessed before and after 3 months of treatment. Complications during and after the procedure were reported.

**RESULTS**

Twelve patients (female n=10 and mean age 80,5 years, range 62-92) were treated with CT-guided sacroplasty.Sacroplasties were performed on unilateral (n=1) or bilateral sacral alae (n=11) in all patients, and an average of 3,7 mL (range, 2,5-7) of cement was injected at each sacral fracture site.Mean volume of cement injected into the unilateral sacral fracture was 2 mL.Technical success was achieved in almost all patients without any significant complication. One patient developed a small asymptomatic cement leak into the S1 foramen, without any significant neurological repercussion.All patients tolerated the procedure under intravenous sedation.The mean pre-procedure VAS for pain was 8 (range 7-9) with a mean symptom duration of 4 months, and the mean VAS score post-procedure was 2.So patients showed continued symptomatic relief defined as a VAS rate decrease of more than 5 points after the procedure (p<0,05).Only 1 patient experienced pain recurrence, probably due to the presence of other lumbar vertebral fractures.Volume of cement injected was independent of pain relief and functional improvement after the procedure (p>0,05).

**CONCLUSION**

Percutaneous sacroplasty is a reliable, safe and highly effective technique for pain relief in patients with insufficiency sacral fractures, with a significant functional improvement and no clinically relevant complications.

**CLINICAL RELEVANCE/APPLICATION**

CT-guided sacroplasty represents an excellent alternative treatment for sacral insufficiency fractures that are resistant to conservative management.

## W5A-SPMK-6 APPLICATION VALUE OF PROXIMAL FEMUR RADIOMICS MODEL BASED ON ABDOMEN- PELVIC CT IN OPPORTUNISTIC SCREENING OF OSTEOPOROSIS

Yijun Liu (*Abstract Co-Author*) Nothing to Disclose
Changyu Du (*Presenter*) Nothing to Disclose

**PURPOSE**

To establish an automatic BMD assessment model based on abdomen-pelvic CT images of proximal femur and explore its application value in opportunistic screening of osteoporosis.

**METHODS AND MATERIALS**

A total of 351 patients who underwent abdomen-pelvic plain CT examination in our hospital from November 2023 to March 2024 were retrospectively collected and randomly divided into the training cohort (n=245) and the test cohort (n=106) according to a ratio of 7:3. All images were transferred to the QCT post-processing workstation, and the BMD of the left proximal femur was measured. According to the QCT BMD T value, the patients were divided into osteoporosis group (T value =-2.5), bone loss group (-2.5 < T value < -1) and normal bone group (T value =-1). The left proximal femur (femoral head to minor trochanter) was dissected using an automatic segmentation model, and two three-classification BMD evaluation radiomics models were constructed using random forest (RF) and logistic regression (LR) classifiers, respectively. Receiver operating characteristic curve (ROC) was constructed, and indicators such as area under the curve (AUC), sensitivity and specificity were calculated to evaluate the diagnostic performance of the two models. Delong test was used to compare the differences between the models.

**RESULTS**

The AUC of RF model and LR model were 0.953 and 0.954 for osteoporosis, 0.894 and 0.870 for osteopenia, and 0.975 and 0.982 for normal bone, respectively. The results of model performance comparison showed that there was no statistical difference in the ability of RF model and LR model to identify the three bone states in the training set and the test set (P > 0.05).

**CONCLUSION**

Both RF and LR radiomics models based on abdomen-pelvic plain CT can be used for the screening of opportunistic osteoporosis with good diagnostic efficacy.

**CLINICAL RELEVANCE/APPLICATION**

The imaging model of proximal femur based on abdominal and pelvic plain scan CT can be used for the screening of opportunistic osteoporosis,and the three-classification diagnosis efficiency is good.

Qingxia Wu (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate three LLM chatbots - Claude-2, GPT-3.5, and GPT-4 - on assigning Reporting and Data Systems (RADS) categories to radiology reports and assess the impact of different prompting strategies.

### METHODS AND MATERIALS

This cross-sectional study compared three chatbots using 30 radiology reports (10 per RADS criteria), utilizing a three-level prompting strategy: zero-shot, few-shot, and guideline PDF-informed prompts. The cases were grounded in LI-RADS® CT/MRI v2018, Lung-RADS® v2022, and O-RADS™ MRI, meticulously prepared by board-certified radiologists. Each report underwent six assessments. Two blinded reviewers assessed the chatbots' response at patient-level RADS categorization and overall ratings. The agreement across repetitions was assessed using Fleiss's kappa.

### RESULTS

Claude-2 achieved the highest accuracy in overall ratings with few-shot prompts and guideline PDFs (Prompt-2), attaining 57% (17/30) average accuracy over six runs and 50% (15/30) accuracy with k-pass voting. Without prompt engineering, all chatbots performed poorly. The introduction of a structured exemplar prompt (Prompt-1) increased the accuracy of overall ratings for all chatbots. Providing Prompt-2 further improved Claude-2's performance, an enhancement not replicated by GPT-4. The inter-run agreement was substantial for Claude-2 (k=0.66 for overall rating, k=0.69 for RADS categorization), fair for GPT-4 (k=0.39 for both), and fair for GPT-3.5 (k=0.21 for overall rating and k=0.39 for RADS categorization). All chatbots showed significantly higher accuracy with LI-RADS v2018 compared to Lung-RADS v2022 and O-RADS (P<.05), with Prompt-2, Claude-2 achieved the highest overall rating accuracy of 75% (45/60) in LI-RADS v2018.

### CONCLUSION

When equipped with structured prompts and guideline PDFs, Claude-2 demonstrated potential in assigning RADS categories to radiology cases according to established criteria such as LI-RADS v2018. However, the current generation of chatbots lags in accurately categorizing cases based on more recent RADS criteria.

### CLINICAL RELEVANCE/APPLICATION

LLMs demonstrate potential in assigning RADS categories to radiology cases according to established criteria.

## W5A-SPNMMI-1 [18F]FDOPA HYBRID PET/ MRI IN BRAIN TUMORS AND SUSPECTED OF TUMOR RECURRENCE VERSUS RADIONECROSIS: DIAGNOSTIC VALIDITY AND INTEROBSERVER AGREEMENT

Laura Rodriguez-Bel (*Abstract Co-Author*) Nothing to Disclose
Michal Pudis (*Abstract Co-Author*) Nothing to Disclose
Montserrat Cortes (*Abstract Co-Author*) Nothing to Disclose
Javier Robles Barba, MD (*Abstract Co-Author*) Nothing to Disclose
Gabriel Reynes-Llompart (*Abstract Co-Author*) Nothing to Disclose
Marina Suarez-Pinera (*Presenter*) Nothing to Disclose

### PURPOSE

PET/MRI is an imaging technique that provides valuable metabolic, functional and morphological information needed in neuro-oncological diseases. At present, data on its performance in clinical practice are still limited. Ours aims hve been : 1. To analyse the diagnostic validity of [18F]FDOPA PET/MRI in patients with brain tumours (BT) and suspected tumour recurrence TR) versus radionecrosis (RNC) and 2. To assess interobserver variability in both visual and semi-quantitative analysis using this technique

### METHODS AND MATERIALS

Retrospective study of 29 PET/MRI FDOPA performed in 24 patients (12 female, mean age 57yrs) and 33 lesions evaluated: 6 primary tumors and 27 brain metastases. All BT have been treated previously and some patients were undergoing immunotherapy treatment during the PET/MRI scan. All PET/MRI examinations were carried out on a 3 tesla PET/MR (GE SIGNATM) at least 6 months after radiotherapy. Images were analyzed visually and quantitatively independently by two nuclear physicians. Ratios: SUVmaxlesion/SUVmaxstriatum(L/S), SUVmaxlesion/SUVmaxcortex (L/C) were calculated. Sensitivity (S), Specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated. Mann Whitney test was used to compare the difference between groups. Optimal FDOPA PET parameter cut-off was obtained by ROC analysis. Cohen's Kappa coefficient was assessed to measure interobserver PET agreement. Perfusion-weighted imaging (PWI) was visually and quantitatively analysed by a neuroradiologist. Results were compared with clinical-radiological follow-up and/or histopathology.

### RESULTS

Of 33 lesions 10(30%) were considered TR and 23 (70%) RNC. FDOPA PET/MRI showed higher ratios in TR (L/S 1.15±0.25,L/C 2.29±0.69) than RC (L/S 0.85±0.26, L/C1.5±0.69) p>0.05. These ratios were assessed in conjunction with the visual analysis. S, Sp, PPV, NPV of FDOPA were 100%,83%,69% and 100% respectively, 4 false positive and 0 false negative. The best cut-off points were L/ C 1.73 and L/S 0.91. Interobserver agreement was 91%, Cohen Kappa index 0.86. S, Sp, PPV, NPV of PWI MRI were 56%,73%,45% and 80% respectively, in 2 cases PWI was not valuable. The results of FDOPA and PWI were concordant in 23/31 (74%).

### CONCLUSION

Conclusions: [18F]FDOPA hybrid PET/MR showed high accuracy and high interobserver agreement in the diagnostic of TR versus RNC in brain tumors The information provided by PWI and FDOPA was not always concordant and the role of both techniques is likely to be complementary. The availability of hybrid PET/MR equipment allows this information to be obtained in a single scan while reducing the number of scans performed in these patients.

### CLINICAL RELEVANCE/APPLICATION

Impact in the management of neuro-oncology patients

### PURPOSE

In this study, ChatGPT, a Large Language Model (LLM), was applied to enhance the findings from radiology reports into patient-centric text. Utilizing the PRECISE (Patient-Focused Radiology Reports with Enhanced Clarity and Informative Summaries for Effective Communication) framework, the objective is to improve patient comprehension and care by providing insightful, accessible interpretations of complex medical images.

### METHODS AND MATERIALS

Utilizing a publicly available chest X-ray dataset from Indiana University, we produced patient-friendly and readable text summaries for the findings in 500 radiology reports with the ChatGPT (GPT-4) prompt “summarize the given radiology report.” We evaluated the PRECISE text’s readability with non-medical volunteers using standard metrics (Flesch Reading Ease, Gunning Fog Index, Automated Readability Index). For reliability, expert clinicians categorized the PRECISE text as "Appropriate," "Inappropriate," or "Unreliable," through comparison with the original reports. Understandability was assessed by 4 non-medical volunteers who rated the text on a 0-2 scale (0 = Not Understandable, 1 = Understandable with Clarifications Needed, 2 = Fully Understandable), after a blind review of 1000 mixed PRECISE and original reports.

### RESULTS

The PRECISE text performed well in all evaluations. Readability scores averaged 81±3.9 (Flesch Reading Ease), 7±1.9 (Gunning Fog Index), and 6±2.8 (ARI), indicating readability at a 6th-grade level or higher. In the reliability test averaged across graders, 95% was classified as "appropriate," 4% as "inappropriate," and 1% as "unreliable" or containing false medical information. In the understandability test, blind test volunteers, 97% of the time, chose “not-understandable” for the actual report and “fully understandable” for the PRECISE text.

### CONCLUSION

Our study shows that the PRECISE framework significantly enhances patient-centric radiology reporting. The PRECISE text’s readability and reliability effectively communicate complex medical details, aligning with expert clinician evaluations and making it accessible to non-medical readers.

### CLINICAL RELEVANCE/APPLICATION

With appropriate prompt engineering, general LLMs can help improve the comprehensibility of radiology reports while simultaneously producing medically appropriate summaries at 6th-grade level.

## W5A-SPNPM-2 HOW DO CLINICIANS READ MEDICAL IMAGING REPORTS ? A NATIONAL SURVEY

Yasmine Kassab (*Presenter*) Nothing to Disclose

### PURPOSE

There is growing interest in standardizing imaging practices and reports. However, limited attention has been given to how clinicians read radiological reports (RR). We developed a questionnaire for non-radiologists to better understand their approach to reading our radiology reports (CT, MRI) with the aim of improving report clarity and optimizing medical decision-making.

### METHODS AND MATERIALS

An anonymized questionnaire (16 questions) was distributed from July to December 2023 to physicians of all specialties across four French regions via mailing lists of private and hospital establishments and social networks. The questionnaire is divided in 3 sections: 1) respondent profile, 2) questions

about radiology reports (reading order of paragraphs, placement of key images...), 3) how practitioner utilize the RR and its therapeutic impact. The questionnaire ends with a free-form box.

## RESULTS

The response rate was 40% (1,000 out of 2,200). Section 1 revealed that 84.2% of respondents were aged between 20 and 34, with 61% women. 66.2% were interns or fellows, with 86.4% having a medical specialty, primarily in general or emergency medicine, intensive care anesthesia, and pediatrics. Section 2 indicated that 71.4% read the entire radiology report or its body, while 15.0% only read the conclusion. Key images were reported to enhance understanding and confidence in the radiologist's conclusion by 37.5% and 29.1% of respondents, respectively. Section 3 showed that 60.5% were confident in our diagnostic hypotheses, and 66.5% attempted to follow our recommendations for further imaging. Once obtained, 59.2% copied the radiologist's conclusion verbatim into their medical observations. In case of life-threatening emergencies, the fellows on duty often communicate the imaging results directly, but 76.0% read the radiology report retrospectively. In case of a life-threatening emergency, 18.9% report referring directly to specialists, regardless the radiologist's opinion. A recurrent request is that the clinician should be promptly contacted to prevent potential harm to the patient.

## CONCLUSION

Comprehensive reports are emphasized, , with 71.4% of clinicians reading the entire content. Diagnostic hypotheses take precedence over the purely descriptive elements. To our knowledge, the added value of key images has not been demonstrated yet. A significant portion of clinicians await validation of preliminary reports before making medical decisions, potentially causing delays in patient management. Feedback highlights the importance of prompt communication regarding significant modifications to preliminary reports to avoid patient harm.

## CLINICAL RELEVANCE/APPLICATION

Comprehensive but concise radiology report, importance of key images.

Printed on: 05/28/25

## W5A-SPNR-1 THE CLINICAL APPLICATION OF 5.0 T 3D TOF MRA IN THE IMAGING OF ACHA AND RELATED CEREBROVASCULAR DISEASES

Jianxian Liu (*Abstract Co-Author*) Nothing to Disclose
Jie Gan (*Abstract Co-Author*) Nothing to Disclose
Dan YU (*Abstract Co-Author*) Nothing to Disclose
Zhangzhu Li (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate and compare the image quality and diagnostic accuracy of 5.0T and 3.0T Time-Of-Flight (TOF) Magnetic Resonance Angiography (MRA) in visualizing the anterior choroidal artery.

### METHODS AND MATERIALS

A retrospective analysis was conducted on patients undergoing MRA, 2023. The study included 48 patients who underwent 3.0T MR scans and 46 patients who underwent 5.0T MR scans. All participants underwent Time-of-Flight Magnetic Resonance Angiography (TOF-MRA). The image quality was objectively assessed using the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) extracted. Additionally, the quality of cerebral artery visualization was subjectively rated using a 5-point scale. Measurements of the length and maximum diameter of the anterior choroidal arteries were performed. Quantitative data were compared between the two groups using independent sample t-tests and the Mann Whitney U test.

### RESULTS

The study involved 88 individuals, comprising 41 males and 47 females, with ages ranging from 16 to 87 years (mean age 59±13). The 5.0T MR Group exhibited higher SNR (93±5) and CNR (75±6) values compared to the 3.0T MR Group (65±3 and 52±4, respectively), with these differences being statistically significant ($P<0.001$). The lengths and diameters of the left and right anterior choroidal arteries imaged with 5.0T MR were (24.4±7.3 mm), (23.3±9.0 mm), (1.1±0.1 mm), and (1.1±0.1 mm), respectively. In contrast, the 3.0T MR Group showed (18.7±9.2 mm), (17.9±8.4 mm), (0.9±0.3 mm), and (0.9±0.2 mm), respectively, with these differences also being statistically significant ($P<0.05$).

### CONCLUSION

The 5.0T ultra-high field intensity MR scan demonstrates superior capabilities in delineating intracerebral arteries, significantly enhancing the clinical diagnosis and treatment of conditions related to the anterior choroidal artery.

### CLINICAL RELEVANCE/APPLICATION

The 5.0T MR imaging's superior visualization of AChA paves the way for better diagnosis and management of deep brain vascular diseases, potentially influencing treatment outcomes and advancing neurovascular research.

## W5A-SPNR-10 RADIOMICS FOR PREDICTING GRADES, IDH MUTATION AND MGMT PROMOTER METHYLATION OF ADULT DIFFUSE GLIOMAS: COMBINATION OF STRUCTURAL MRI, ADC AND SWI

Xin Zhang (*Abstract Co-Author*) Nothing to Disclose
Huiquan Yang, PhD (*Abstract Co-Author*) Nothing to Disclose
Bing Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Jingfei Shen (*Abstract Co-Author*) Nothing to Disclose
Jianan Zhou (*Abstract Co-Author*) Nothing to Disclose
Yu Sun (*Abstract Co-Author*) Nothing to Disclose
Zhengyang Zhu, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the predictive value of radiomics features extracted from Structural MRI, ADC, and SWI in determining WHO Grade, IDH mutation and MGMT promoter methylation status in patients with diffuse gliomas.

### METHODS AND MATERIALS

539 patients were enrolled in this study. The training, internal validation, external test cohort included 426(median aged 60 years, 168 female), 67(median aged 56 years, 31 female), 46(median aged 55 years, 22 female) patients, respectively. A total of 7896 radiomics features were extracted from 6 sequences within two ROIs. Feature selection was conducted using analysis of variance F-test, and the random forest classifier were employed to

establish predictive models. This research also compared the performance of radiomics models with that of both a 5-year-experienced radiologist and a 1-year-experienced radiologist.

**RESULTS**

For WHO Grade task, the combined model of Structural MRI, ADC and SWI achieved the highest AUC of 0.951 on the external test cohort. For IDH mutation task, the structural MRI model achieved the highest AUC of 0.917 on external test cohort. For MGMT task, the combined model of structural MRI and ADC achieved the highest AUC of 0.650 on the internal validation cohort.

**CONCLUSION**

The radiomics models have achieved promising performance in assessing WHO Grade and IDH mutation status but shown no efficacy in predicting MGMT methylation status. Adding SWI features cannot provide extra information to structural MRI and ADC features in predicting WHO grade and IDH mutation status.

**CLINICAL RELEVANCE/APPLICATION**

This work has considerable clinical significance that would help neuro-oncologists better understand the radiological manifestation and microstructure of adult diffuse gliomas and make more appropriate treatment plans for patients.

**PURPOSE**

Large animal models are recommended to improve selection of novel stroke therapies prior to clinical trial. Leveraging clinically relevant outcome measures such as MRI biomarkers facilitates translation. Portable, ultra low-field MRI (LF-MRI) systems may offer an accessible and affordable method to image the brain of large animal species at multiple time points. We developed and tested brain imaging protocols in a canine stroke and a swine intracranial hemorrhage (ICH) model on a LF-MRI scanner.

**METHODS AND MATERIALS**

Two mongrel dogs and 3 Yorkshire pigs were scanned on a 0.064T LF-MRI (Hyperfine, Inc., Guilford, CT.) under anesthesia. Dogs underwent left middle cerebral artery (MCA) coil embolization to create hemispheric stroke and were scanned with coronal FLAIR and DWI at 30min and 2.5 hours post-stroke in the first dog, and 1 hour and 6 hours in the second. Pigs were either healthy (n=2) or underwent craniotomy and injection of blood to develop a model of ICH (n=1). Healthy pigs underwent sagittal and axial T1 and T2-weighted scans. The ICH model was scanned with a combination of T1w, T2w, DWI and FLAIR 1 hour postoperatively. General image quality, animal positioning and DWI positivity were evaluated qualitatively.

**RESULTS**

The brain was on the periphery of the field-of-view (FOV) due to the long snout of both species, with 6.5mm between the center of the brain and the center of FOV. In both dogs, DWI positivity and FLAIR hyperintensity was evident in the left MCA territory on the second acquisition, although lesion conspicuity was variable between the 2 dogs and DWI hyperintensity was visible in the ipsilateral soft tissue. In the swine model, axial scans were least informative, while sagittal scans were helpful in assessing the position of the brain, and coronal T2w scans were most useful to assess the craniotomy, parenchymal damage, and fluid collection. These findings were not visualized on DWI or T1w scans.

**CONCLUSION**

Our initial findings demonstrate that LF-MRI can be used to detect hemispheric stroke and intracranial postsurgical changes in large animals. The long snout in both models positioned the brain suboptimally within the FOV, which could be overcome by using a different breed or with a dedicated coil. DWI artifacts created uncertainty in stroke detection. In ICH model, T2w coronal scan was the most useful in evaluating postsurgical changes. Sequence development and advances in post-processing are avenues for future research to improve feasibility of utilizing LF-MRI in large animals.

**CLINICAL RELEVANCE/APPLICATION**

Portable LF-MRI scanners can offer a more accessible and affordable way to evaluate brain tissue. Developing dedicated imaging protocols and hardware for large animal stroke models may contribute to improving translational research.

## W5A-SPNR-12 APPLICATION OF SYMRI QUANTITATIVE TECHNIQUE IN MEDIAL TEMPORAL LOBE EPILEPSY WITH HIPPOCAMPAL SCLEROSIS

Jian Li (*Abstract Co-Author*) Nothing to Disclose
Bing Chen (*Abstract Co-Author*) Nothing to Disclose
Jinqin Li (*Abstract Co-Author*) Nothing to Disclose
Yan Mengnan (*Abstract Co-Author*) Nothing to Disclose
Yanling Zhang (*Abstract Co-Author*) Nothing to Disclose
Yiting Wang (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the value of synthetic magnetic resonance imaging (SyMRI) in the quantitative study of various subregions in medial temporal lobe epilepsy (MTLE) with hippocampal sclerosis (HS).

### METHODS AND MATERIALS

51 patients with unilateral HS in our hospital from January 2021 to January 2024 were included as a case group. 88 volunteers were included as a control group. All subjects underwent T1-weighted three-dimensional magnetisation-prepared rapid gradient-echo (3D T1 MP-RAGE) and synthetic magnetic resonance imaging (MAGiC) scans. 3D T1 MP-RAGE was post-processed by Freesurfer V7 to obtain the regions of interest (ROI); After processing with SyMRI StandAlone 8.0.4, MAGiC can obtain T1, T2, and PD quantitative maps; The quantitative maps were fused with the ROI to obtain the T1, T2 and PD values. One way ANOVA and Kruskal-Wallis H test were used to compare the values of various parameters, and further multiple comparisons were made. Parameters with statistically significant differences between groups were screened for significant variables using stepwise regression analysis, and receiver operating characteristic curve (ROC) and area under curve (AUC) were used to evaluate the diagnostic efficacy of significant parameters and multi parameter combination.

### RESULTS

The differences between the three groups were statistically significant, except for PD values in the subiculum (SUB). The comparison between two groups showed that the T2 and T1 values of CA1, CA3, CA4 and dentate gyrus (DG) and the PD values of CA1 and CA3 were higher in the affected group than in the healthy group and the control group. The T2 and T1 values of SUB and the PD values of CA4 and DG in the affected group were higher than those in the control group; The T2 values of SUB, CA1, CA3, CA4 and DG, T1 and PD values of CA4 and T1 values of DG in the healthy group were higher than those in the control group ($P<0.05$). The stepwise regression method was used to show that the T2 values of CA1, CA3, and SUB were significant variables. The results of Delong test showed that the diagnostic efficiency of T2 value in CA1 and CA3 was better than that of SUB, and the combination of the three could improve the diagnostic efficiency, with an AUC of 0.995, and compared with the single index, the differences were statistically significant ($P<0.05$).

### CONCLUSION

The quantitative measurement of relaxation time in hippocampal subregions of MTLE-HS by SyMRI can provide a more accurate clinical imaging reference, especially the combined parameters of T2 values of CA1, CA3 and SUB can effectively improve the diagnostic efficacy.

### CLINICAL RELEVANCE/APPLICATION

The quantitative study of SyMRI subregions can effectively improve the diagnostic efficiency of HS,and have certain application value in the diagnosis and lateralization of HS.

## W5A-SPNR-13 ARTERIAL COLLATERAL STATUS AND ENDOVASCULAR TREATMENT EFFECT IN LARGE ISCHEMIC STROKES: A SECONDARY ANALYSIS OF THE TENSION TRIAL

Martin Bendszus (*Abstract Co-Author*) Nothing to Disclose
Jens Fiehler (*Abstract Co-Author*) Nothing to Disclose
Gotz Thomalla, MD (*Abstract Co-Author*) Consultant, Covidien, Medtronic, Inc;Consultant, Pfizer Inc;Consultant, Bayer AG;Consultant, Boehringer Ingelheim GmbH
Helge C. Kniep, DIPLENG (*Abstract Co-Author*) Nothing to Disclose
Fabian Flottmann (*Abstract Co-Author*) Nothing to Disclose
Laurens Winkelmeier, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Randomized clinical trials have demonstrated that endovascular thrombectomy is efficacious in reducing functional disability in patients with acute ischemic stroke and large infarction. We investigated whether arterial collateral status modifies the treatment effect of endovascular thrombectomy in patients with large infarction.

### METHODS AND MATERIALS

This study is a post-hoc analysis of the TENSION trial. TENSION (The Efficacy and Safety of Thrombectomy in Stroke with Extended Lesion and Extended Time Window) was a prospective, multicenter, randomized trial of patients with acute large ischemic stroke and large infarction due to anterior circulation large vessel occlusion. Patients were randomly assigned to receive endovascular thrombectomy with medical treatment or medical treatment alone up to 12 hours from stroke onset. The enrollment of patients was performed at 41 centers in Europe and Canada between February 2018 and January 2023. Large infarction was defined as an Alberta Stroke Program Early Computed Tomography Score (ASPECTS) of 3-5. The Tan score was used to assess the arterial collateral status on computed tomography angiography. Patients were subdivided into poor collaterals (grade 0-1) and good collaterals (grade 2-3). Primary outcome was the shift on the 90-day modified Rankin Scale (mRS).

### RESULTS

A total of 201 patients met the inclusion criteria (51.2% female; median age, 74 years [IQR, 66-80]). Of those, 103 patients (51%) received endovascular thrombectomy and 98 patients (49%) received medical treatment alone. Good collaterals were less frequent than poor collaterals (73 patients [36%] versus 128 patients [64%]). There was no modification of endovascular treatment effect by collateral status (interaction term, P=.88). There was a significant shift in the distribution of 90-day mRS scores favoring endovascular thrombectomy over medical treatment alone in patients with good collaterals (adjusted common odds ratio [acOR], 3.93, 95%CI, 1.65-9.69, P=.002) and in patients with poor collaterals (acOR, 3.92, 95%CI, 1.86-8.52, P<.001). Good collaterals were associated with improved 90-day mRS scores (acOR, 2.88, 95%CI, 1.63-5.11, P<.001).

### CONCLUSION

In this TENSION subanalysis, endovascular thrombectomy reduced functional disability in patients with acute ischemic stroke and large infarction irrespective of good or poor collateral status.

### CLINICAL RELEVANCE/APPLICATION

Our findings suggest that endovascular thrombectomy should not be withheld based on collateral status in patients with acute ischemic stroke and large infarction presenting within 12 hours after stroke.

## W5A-SPNR-14 CORRELATION OF CEREBRAL BLOOD FLOW AND INFLAMMATORY CYTOKINE ALTERATIONS WITH SYMPTOM SEVERITY IN PREMENSTRUAL SYNDROME

Kaixuan Zhou (*Presenter*) Nothing to Disclose

### PURPOSE

Premenstrual syndrome (PMS) causes persistent distress in females of reproductive age and increases the lifetime risk of depression. There is preliminary evidence showing that altered central nervous system (CNS) processing is associated with PMS, and inflammation alterations are related to its etiology. However, it's unclear whether serum levels of inflammatory cytokine are associated with neural substrate. This study aimed to identify the brain regions and inflammatory cytokines that potentially mediate PMS, as well as explore their relationship with premenstrual symptom severity.

### METHODS AND MATERIALS

A total of 54 females with PMS and 71 controls underwent CBF (Cerebral blood flow) measurements by arterial spin labeling (ASL) scanning, peripheral blood inflammatory cytokines analysis in the late-luteal phase of menstrual cycle, and all participants were evaluated by the Daily Record of Severity of Problems (DRSP) for two consecutive menstrual cycles. Whole-brain voxel-based and seed-based connectivity methods were combined to depict the CBF differences between the groups. Correlation analysis was performed to investigate the relationship between regional CBF, inflammatory cytokines, and premenstrual symptom severity.

### RESULTS

PMS had increased CBF in the parahippocampal gyrus, inferior temporal gyrus, fusiform gyrus, precuneus, and inferior occipital gyrus, and decreased CBF in the supplementary motor area relative to controls. We also found that inflammatory cytokines were raised in PMS. The following correlation results were observed: (1) there was a significant correlation between the DRSP scores and CBF of all regions with inter-group differences; (2) the DRSP scores were positively correlated with TNF-a; (3) TNF-a was correlated with the CBF of all regions with inter-group differences.

### CONCLUSION

The present study demonstrated altered CBF in the Default Mode Network (DMN) in PMS. The precuneus and parahippocampal gyrus, as key nodes of the DMN, are associated with pro-inflammatory cytokine and symptom severity. The findings may provide preliminary evidence for the underlying neuroinflammatory mechanism in PMS and contribute to a better understanding of its pathophysiology.

### CLINICAL RELEVANCE/APPLICATION

According to the findings, the precuneus and parahippocampal gyrus might serve as potential therapeutic targets for non-invasive neurostimulation.

## W5A-SPNR-15 WHITE MATTER HYPERINTENSITY IN THE BRAIN TO DIFFERENTIATE NEUROMYELITIS OPTICA SPECTRUM DISORDER FROM MULTIPLE SCLEROSIS USING AN EXPLAINABLE THREE-DIMENSIONAL FRAMEWORK - LPV-NET

Chunjie Guo, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The overlapping clinical characteristics and magnetic resonance (MR) imaging features of Neuromyelitis Optica Spectrum Disorder (NMOSD) and Multiple Sclerosis (MS) could lead to potential diagnostic confusion. Using deep learning as a supporting tool to differentiate between NMOSD and MS is a promising method. However, current models struggle with complexity, accuracy, and interpretability. Therefore, our objective of this study is to develop a deep learning model that is computationally efficient and interpretable, explicitly designed to distinguish between NMOSD and MS through analysis of brain MR images.

### METHODS AND MATERIALS

A multi-center dataset containing 30 subjects with MS and 30 with NMOSD from * hospital, and 39 MS and 47 NMOSD subjects from the # hospital, was used in this study. The 2-stage model, Lesion Probability Vector Net (LPV-Net), using T2 fluid-attenuated inversion recovery (T2-FLAIR) MR images of each subject as input to differentiate MS and NMOSD patients. The classification performance of LPV-Net was evaluated based on accuracy (ACC), sensitivity (SN), and specificity (SP).

### RESULTS

The proposed model demonstrates superior performance compared to other three-dimensional models, with lower computational cost. It achieved an ACC of 0.948±0.006, a SN of 0.894±0.067, and a SP of 0.973±0.019 in differentiating MS and NMOSD, surpassing the capabilities of experienced neuroradiologists.

### CONCLUSION

Through our interpretability method, the decision-making process of the model becomes apparent and distinctly illustrates the different lesion distribution between MS and NMOSD. As a result, the proposed deep learning method could serve as an effective and reliable diagnostic tool for supporting clinical practices in the diagnosis of MS and NMOSD.

### CLINICAL RELEVANCE/APPLICATION

The clinical application of the study aims to using the LPV-Net, a deep learning model, in accurately differentiating between NMOSD and MS based on brain MR images. This model provides a low-complexity, highly interpretable framework that surpasses the diagnostic accuracy of experienced neuroradiologists. It has the potential to serve as a robust clinical tool for the precise diagnosis of these two similar yet distinct neurological disorders.

## W5A-SPNR-2 REGIONAL STRUCTURAL-FUNCTIONAL CONNECTIVITY COUPLING IN MAJOR DEPRESSIVE DISORDER IS ASSOCIATED WITH NEUROTRANSMITTER AND GENETIC PROFILES

Haizhu Xie (*Abstract Co-Author*) Nothing to Disclose
Tongpeng Chu (*Abstract Co-Author*) Nothing to Disclose
Fanghui Dong (*Abstract Co-Author*) Nothing to Disclose
Qun Gai (*Abstract Co-Author*) Nothing to Disclose
Ning Mao (*Presenter*) Nothing to Disclose

**PURPOSE**

Abnormalities in structural-functional connectivity (SC-FC) coupling have been identified on a global scale in patients with major depressive disorder (MDD). However, investigations have neglected the variability and hierarchical distribution of these abnormalities across different brain regions. Furthermore, the biological mechanisms underlying regional SC-FC coupling patterns are not well understood.

**METHODS AND MATERIALS**

We enrolled 182 individuals diagnosed with MDD and 157 healthy control (HC) subjects, quantifying the intergroup differences in regional SC-FC coupling. XGBoost, SVM and RF models were constructed to assess the potential of SC-FC coupling as biomarkers for MDD diagnosis and symptom prediction. Then, we examined the link among changes in regional SC-FC coupling, neurotransmitter distributions, and gene expression in individuals with MDD.

**RESULTS**

We observed increased regional SC-FC coupling in default mode network ($T = 3.233$) and decreased coupling in frontoparietal Network ($T = -3.471$) in MDD relative to HC. The XGBoost (AUC = 0.853), SVM (AUC = 0.832) and RF ($p < 0.05$) models exhibited good prediction performance. The alterations in regional SC-FC coupling in the patients with MDD were correlated with the distributions of four neurotransmitters ($p < 0.05$) and the expression maps of specific genes. These genes were strongly enriched in genes implicated in excitatory neurons, inhibitory neurons, cellular metabolism, synapse function, and immune signaling. These findings were replicated on two brain atlases.

**CONCLUSION**

This study quantified differences in regional subcortical-cortical (SC-FC) coupling between patients with MDD and HC. It also linked regional SC-FC coupling to neurotransmitter levels and gene expression, supporting the notion that the DMN, FPN, protein binding, cellular metabolic processes, and organismal systems are implicated in the neuropathophysiology of MDD. Furthermore, we demonstrated that abnormalities in neuroexcitatory (Neuro-Ex) and neuroinhibitory (Neuro-In) cells may be associated with changes in regional SC-FC coupling in MDD patients.

**CLINICAL RELEVANCE/APPLICATION**

This work enhances our understanding of MDD and pave the way for the development of additional targeted therapeutic interventions.

## W5A-SPNR-3 REDUCED BRAIN VENTRICULAR VOLUME OBSERVED IN FETUSES WITH PRENATAL OPIOID EXPOSURE

Rupa Radhakrishnan, MD, MS (*Abstract Co-Author*) Nothing to Disclose
William Reynolds (*Abstract Co-Author*) Nothing to Disclose
Sanjali Kherde (*Abstract Co-Author*) Nothing to Disclose
Ashok Panigrahy, MD (*Abstract Co-Author*) Nothing to Disclose
Jonathan Class, MD (*Abstract Co-Author*) Nothing to Disclose
Senthilkumar Sadhasivam (*Abstract Co-Author*) Nothing to Disclose
Ramana V. Vishnubhotla, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Opioid use amongst pregnant women has been increasing over the past two decades. Prenatal opioid exposure (POE) carries the risk of neonatal opioid withdrawal syndrome (NOWS) and poor long term developmental outcomes in these infants. Imaging may help in prediction of these poor outcomes in POE. Therefore, this study aims to assess differences in brain development in fetuses with prenatal opioid exposure compared to control fetuses without opioid exposure.

**METHODS AND MATERIALS**

This was a prospective IRB approved study. Two-dimensional (2D) 3T MR images of the fetal brain were acquired using a Half-Fourier Single-shot Turbo spin-Echo (HASTE) sequence in the axial, coronal, and sagittal planes in pregnant women with POE and control unexposed pregnant women. Manual brain masking of the HASTE images were used to generate high resolution isotropic three-dimensional (3D). Gestational age-appropriate atlas-based segmentation identified whole brain volumes and lateral ventricle volumes. Linear regression was used to assess the association of POE and smoking exposure on brain and ventricular volumes, after accounting for fetal sex, race, maternal age, and gestational age.

**RESULTS**

There were 59 pregnant mothers, including 30 with POE. Average gestational age was (M=33.9, SD=3.5) in POE and (M=32.5, SD=3.6) in controls. There were 16 male fetuses in POE and 10 male fetuses in the control group. Lateral ventricular volumes were significantly lower in fetuses with opioid exposure ($p=0.015$). However, there were no significant differences associated with whole brain volume. No gross brain malformations were identified in this cohort.

**CONCLUSION**

Smaller lateral ventricular volumes were identified in fetuses with POE compared to control unexposed fetuses without differences in corresponding brain volumes.

**CLINICAL RELEVANCE/APPLICATION**

In the absence of major morphological abnormalities, reduced lateral ventricle size in fetuses POE may indicate subtle alterations in brain development and neuronal migration. Next steps include longitudinal postnatal evaluation of brain growth and development in these fetuses, as well as correlations with clinical outcomes such as NOWS.

## W5A-SPNR-5 DEVELOPMENT AND VALIDATION OF A DEEP LEARNING-BASED CT PLANNING BOX FOR STROKE, OFFERING HIGH ACCURACY AND REPRODUCIBILITY FOR CLINICAL APPLICATION

Yang Wang (*Abstract Co-Author*) Nothing to Disclose
Runqiu Huang (*Presenter*) Nothing to Disclose

**PURPOSE**

Computed tomography (CT) is pivotal in the classification of stroke, estimation of penumbra dimensions, and facilitation of studies relevant to stroke radiomics. The acquisition of standardized, precise, and replicable images for follow-up purposes presents significant challenges. To address this issue, we have developed an intelligent CT system designed for comprehensive evaluation of stroke throughout the follow-up period.

**METHODS AND MATERIALS**

To augment conventional computed tomography (CT) systems with artificial intelligence, we deployed a combination of a Region Proposal Network (RPN) and V-Net architecture. The RPN facilitated facial detection by pinpointing jaw-adjacent positions, using a dataset of 76,382 human faces and a 2D camera. V-Net was applied for segmenting two regions of interest (ROIs) from a dataset of 295 subjects. A calibration table enabled precise calculations for the scanning couch's movement. This system's effectiveness was verified using 1,124 patients across three clinical settings, demonstrating significant enhancement in CT imaging capabilities.

**RESULTS**

The CAPITAL-CT, a novel system for cranial imaging, was introduced, incorporating an RPN model that exhibited a training error of 4.46 ±0.02 pixels with a 98.7% accuracy, and in validation, achieved a perfect success rate with a 2.23 ±0.10 pixel error. V-Net segmentation maintained clinical acceptability with a mean distance error of 3 mm and angle deviation within 3°. This innovation enables real-time, accurate, and consistent scanning, markedly lowering radiation exposure ($P < 0.001$), showcasing significant advancements in neuroimaging technology.

**CONCLUSION**

The CAPITAL-CT system produced standardized and replicable images, potentially streamlining radiologists' tasks. This advancement is expected to significantly contribute to the monitoring of stroke patients and facilitate diverse research endeavors within the field of neuroscience.

**CLINICAL RELEVANCE/APPLICATION**

The introduction of CAPITAL-CT heralds a pivotal advancement in combining Artificial Intelligence (AI) with medical imaging to enhance stroke diagnosis and patient monitoring. Addressing a crucial deficiency in medical imaging's initial capture phase, CAPITAL-CT offers an innovative, standardized, and repeatable CT scanning methodology. It significantly aids in the meticulous follow-up of stroke patients by ensuring the consistent quality of CT images, critical for monitoring acute ischemic stroke progression and facilitating timely, informed treatment decisions. CAPITAL-CT's revolutionary approach streamlines radiologists' tasks and improves stroke diagnosis and care accuracy, marking a notable contribution to neuroscience.

## W5A-SPNR-6 COMPARATIVE ANATOMY OF VENOUS SINUSES: ENDOSCOPY, FLAT PANEL CT, AND ANGIOGRAPHY

Yigit Can Senol (*Abstract Co-Author*) Nothing to Disclose
Nishanth Krishnan (*Abstract Co-Author*) Nothing to Disclose
Atakan Orscelik, MD (*Abstract Co-Author*) Nothing to Disclose
Luis Savastano (*Abstract Co-Author*) Nothing to Disclose
Mona Asghariahmadabad, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The intracranial venous sinuses are receiving increasing attention due to advancements in neuroimaging techniques, which have led to a higher rate of diagnoses and intervention of cerebral venous diseases. However, there is limited knowledge regarding the intraluminal structures of these dural sinuses. Given this gap, there is a critical need for a deeper investigation into the anatomical structures of the cerebral venous sinuses. Therefore, we aim to conduct a comparative anatomical study using the venous phase of digital subtraction angiography (DSA), venous sinus flat panel computed tomographic (CT) imaging, and endoscopic images of a cadaveric model of the venous sinus.

**METHODS AND MATERIALS**

Fresh, never-frozen head and neck human cadaver models were obtained from Willed Body program at UCSF. The carotid arteries, vertebral arteries, and jugular veins were cannulated as part of the preparation. Following cannulation, the cadavers were perfused with 4% formalin for light embalming. Subsequently, saline was circulated using pumps and tubing to maintain physiological flow and pressure, and to clear any remaining clots from the vascular test bed. Venography of major dural sinuses and flat-panel CT scans were then conducted with contrast injected through the jugular veins. A small craniotomy was made at the rostral midline of the skull to allow the insertion of a borescope. During the endoscopy, saline was pumped through the jugular vein to maintain physiological flow and pressure.

**RESULTS**

Pre-procedural quality control revealed no distal occlusion in the vascular pathways on contrast-enhanced fluoroscopic images and roadmaps. The intraluminal endoscopic images identified the protrusion of arachnoid villi into the superior sagittal sinus’s lumen as well as multiple septations with a thickness of 0.1 to 1mm inside the sinus lumen. These features were not apparent in the DSA images or the flat-panel CT scans of the specimens.

**CONCLUSION**

Improving neuroimaging techniques to better visualize intraluminal septations and the protrusion of arachnoid villi into the venous sinus lumen is crucial for advancing our understanding of cerebral venous disease. Such improvements are essential for distinguishing between physiological and pathological septations and arachnoid villi. Additionally, these advancements would enhance the effectiveness of interventions in the cerebral venous sinuses.

**CLINICAL RELEVANCE/APPLICATION**

Comparing different imaging modalities enhances the understanding and details of intraluminal structures within the dural sinuses. These findings lead to improved diagnostic and treatment approaches, ultimately enhancing patient outcomes in modern neuro-angiography suites.

## W5A-SPNR-7 PHASE-CONTRAST MRI EVALUATION OF CEREBROSPINAL FLUID DYNAMICS IN PATIENTS WITH LEPTOMENINGEAL SEEDING FROM LUNG ADENOCARCINOMA

Chunmiao Xu (*Abstract Co-Author*) Nothing to Disclose
Hailiang Li (*Abstract Co-Author*) Nothing to Disclose
Zhe Ma (*Abstract Co-Author*) Nothing to Disclose
Bingjie Zheng, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This prospective study aims to utilize phase-contrast MRI (PC-MRI) to evaluate cerebrospinal fluid (CSF) dynamics in patients diagnosed with leptomeningeal seeding from lung adenocarcinoma and to assess the differences in CSF parameters between patients with and without leptomeningeal seeding.

**METHODS AND MATERIALS**

PC-MRI scans were prospectively obtained from 36 patients, with 20 patients diagnosed with leptomeningeal seeding and 16 without, recruited between October 2023 and March 2024. The MRI scans were performed using a 3.0-T superconducting scanner. Axial T1-weighted, T2-weighted, and phase-

contrast MRI (PC-MRI) sequences were acquired for each patient. Quantitative analyses of CSF flow dynamics were performed using dedicated PC-MRI angiography software. Various parameters were measured and compared between the two groups.

**RESULTS**

Patients with leptomeningeal seeding exhibited a significantly higher heart rate (82.30 ± 15.34 vs. 71.75 ± 12.77, p = 0.034) and lower forward flow volume (0.021 ± 0.019 vs. 0.042 ± 0.017, p = 0.002) compared to those without seeding. Additionally, patients with seeding had a significantly lower peak velocity (6.53 ± 2.63 vs. 8.48 ± 2.43, p = 0.030) and mean flux (0.16 ± 0.19 vs. 0.49 ± 0.46, p = 0.012) compared to patients without seeding. No significant differences were observed in other parameters between the two groups.

**CONCLUSION**

This prospective study demonstrates significant alterations in CSF dynamics in patients with leptomeningeal seeding from lung adenocarcinoma compared to those without seeding, as observed through phase-contrast MRI.

**CLINICAL RELEVANCE/APPLICATION**

Phase-contrast MRI offers valuable insights into the CSF dynamics of lung adenocarcinoma patients with leptomeningeal seeding. The observed alterations in CSF flow parameters, such as forward flow volume, velocity, and mean flux, highlight potential imaging biomarkers for disease progression and severity. These findings equip radiologists with essential diagnostic information for accurately identifying leptomeningeal seeding in patients, especially before traditional imaging abnormalities manifest. Moreover, the utilization of phase-contrast MRI in this context underscores its clinical utility as a non-invasive imaging modality for evaluating CSF dynamics and guiding therapeutic decision-making in oncological settings.

## W5A-SPNR-8 TRANSCRANIAL 3D CONTRAST-ENHANCED ULTRASOUND (3D-CEUS) FOR BEDSIDE CEREBRAL ANGIOGRAPHY AND PERFUSION IMAGING FOLLOWING ANEURISMAL SUBARACHNOID HEMORRHAGE (SAH)

Maxime Gauberti (*Abstract Co-Author*) Nothing to Disclose
Vincent Hingot (*Abstract Co-Author*) Nothing to Disclose
Sylvain Bodard (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the effectiveness of transcranial 3D contrast-enhanced ultrasound (3D-CEUS) in detecting early signs of cerebral vasospasm and hypoperfusion post-aneurysmal subarachnoid hemorrhage (SAH), aiming to prevent delayed cerebral ischemia (DCI).

**METHODS AND MATERIALS**

For this study, a custom 3D ultrasound scanner was developed to reach a 1kHz volume rate at 9 cm depth along a 30° pyramid using a 2 MHz matrix probe. Each imaging session involved a standard 2.4 ml bolus of SonoVue followed by a 10 ml saline flush, with continuous acquisition through the temporal window over 3 minutes to monitor the entire bolus progression and washout phases. Patients underwent 3 imaging sessions: within 72 hours of admission post-aneurysm rupture, on day 5 during peak cerebral vasospasm risk, and before 14 days or upon discharge, assessing both hemispheres.

**RESULTS**

In this observational study of 15 consecutive patients with aneurysmal SAH, Time Intensity Curves (TIC) derived from SonoVue injections provided a reliable measure of contrast enhancement, serving as the primary evaluative metric. We reconstructed angiographic and perfusion images to identify cerebral vasospasm and hypoperfusion signs, complemented by comparative analysis of routine care data, including daily Transcranial Doppler (TCD) measurements and Computed Tomography Angiography (CTA) and Perfusion (CTP) imaging.

**CONCLUSION**

Preliminary results suggest that 3D-CEUS could by a promising tool for monitoring cerebral hypoperfusion in SAH patients, offering real-time data essential for timely intervention.

**CLINICAL RELEVANCE/APPLICATION**

Implementing 3D-CEUS in neurocritical care could enhance the monitoring of cerebral blood flow, potentially reducing the risk of secondary brain injury in patient susceptible to DCI.

## W5A-SPOB-1 RETROSPECTIVE CLINICAL VALIDATION OF CONSENSUS MRI DIAGNOSTIC ALGORITHM FOR EVALUATION OF UTERINE MASSES AT RISK OF LEIOMYOSARCOMA

Pejman Ghanouni, MD, PhD (*Abstract Co-Author*) Medical Advisory Board, InSightec Ltd;Scientific Advisory Board, SonALASense
Priyanka Jha, MBBS (*Abstract Co-Author*) Nothing to Disclose
Stephan Altmayer, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Luyao Shen, MD (*Abstract Co-Author*) Nothing to Disclose
Sarah Miller, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In 2022 a consensus statement, developed with radiologists and gynecologists, that introduced an MRI-based imaging algorithm designed to classify atypical uterine masses, with preliminary reports indicating high accuracy. However, its clinical adoption hinges on further external validation studies. Our objective was to evaluate the algorithm diagnostic performance in differentiating benign and malignant masses on pelvic MRI.

### METHODS AND MATERIALS

In this institutional review board-approved single-center we identified radiology reported atypical uterine masses on pre-operative pelvic MRI. Final histological diagnosis was used as the reference standard. We adhered to the 2022 consensus guidelines to classify the masses as “benign”, “likely benign”, or “suspicious/highly suspicious” for malignancy. Imaging analysis was performed by a radiologist with >10 years of experience in interpreting pelvic MRI. Sensitivity and specificity were calculated along with the 95% confidence interval using Clopper-Pearson method. Data analysis was conducted using RStudio version 2023.06.0+421

### RESULTS

30 patients with atypical uterine masses were identified. Of those, 20 were ultimately diagnosed with leiomyosarcoma, whereas the remainder 10 had benign histology. No malignant mass was classified in the “benign” category. Three malignant cases (3/20; 15%) were categorized as “likely benign”, while 8/20 (40%) were “highly suspicious” due to extrauterine disease, and 9/20 (45%) as “suspicious” based on ADC signal intensity. Among benign masses, 5/10 (50%) were classified as “benign”, 2/10 (20%) as “likely benign”, and 3/10 (30%) as “suspicious for malignancy”. Using the threshold of “suspicious/highly suspicious for malignancy” to define malignancy, MRI algorithm had a sensitivity of 85% (95% CI, 47-83%) and specificity of 70% (95% CI, 35-93%). When patients with extrauterine disease were excluded from the analysis, the sensitivity and specificity of MRI were 75% (95% CI, 43-95%) and70% (95% CI, 35-93%). Analysis of false negative results showed lesions with large amount of necrosis, hemorrhage and atypical location.

### CONCLUSION

The MRI consensus algorithm demonstrated a sensitivity of 85% and a specificity of 70% for stratification of malignancy in atypical uterine masses. The sensitivity reduced to 75% upon the exclusion of patients with extrauterine disease.

### CLINICAL RELEVANCE/APPLICATION

The consensus algorithm for the evaluation of atypical uterine masses based on MRI shows moderate diagnostic performance to distinguish malignant from benign masses, particularly when patients with extrauterine disease are not considered in the analysis. Lesions with large amount of necrosis and atypical locations are at risk for false negative results.

## W5A-SPOB-2 A COMPARISON OF 2D AND 3D MAGNETIC RESONANCE IMAGING-BASED INTRATUMORAL AND PERITUMORAL RADIOMICS MODELS FOR THE PROGNOSTIC PREDICTION OF ENDOMETRIAL CANCER: A PILOT STUDY

Ning Lang, MD (*Abstract Co-Author*) Nothing to Disclose
Ruixin Yan (*Presenter*) Nothing to Disclose

### PURPOSE

Accurate prognostic assessment is vital for the personalized treatment of endometrial cancer (EC). Although radiomics models have demonstrated prognostic potential in EC, the impact of region of interest (ROI) delineation strategies and the clinical significance of peritumoral features remain uncertain. Our study thereby aimed to explore the predictive performance of varying radiomics models for the prediction of LVSI, DMI, and disease stage in EC.

## METHODS AND MATERIALS

Patients with 174 histopathology-confirmed EC were retrospectively reviewed. ROIs were manually delineated using the 2D and 3D approach on T2-weighted MRI images. Six radiomics models involving intratumoral (2Dintra and 3Dintra), peritumoral (2Dperi and 3Dperi), and combined models (2Dintra+peri and 3Dintra+peri) were developed. Models were constructed using the logistic regression method with five-fold cross-validation. Area under the receiver operating characteristic curve (AUC) was assessed, and was compared using the Delong's test.

## RESULTS

No significance differences in AUC was observed between the 2Dintra and 3Dintra models, or the 2Dperi and 3Dperi models in all prediction tasks ($P > 0.05$). Significant difference was observed between the 3Dintra and 3Dperi models for LVSI (0.738 vs. 0.805) and DMI prediction (0.719 vs. 0.804). The 3Dintra+peri models demonstrated significantly better predictive performance in all 3 prediction tasks compared to the 3Dintra model in both the training and validation cohorts ($P < 0.05$).

## CONCLUSION

Comparable predictive performance was observed between the 2D and 3D models. Combined models significantly improved predictive performance, especially with 3D delineation, suggesting that intra- and peritumoral features can provide complementary information for comprehensive prognostication of EC

## CLINICAL RELEVANCE/APPLICATION

1. Radiomics can provide the non-invasive prediction of LVSI, DMI, and FIGO stage of EC.2. 2D and 3D delineation showed comparable results both in intra- and peritumoral radiomics models.3. Combined intra- and peritumoral features can further enhance the models' predictive ability.

## W5A-SPPD-1 APPLICATION OF SYNTHETIC MRI QUANTITATIVE ASSESSMENT IN BRAIN DEVELOPMENT OF CHILDREN WITH BRONCHOPULMONARY DYSPLASIA

Shaoyu Wang (*Abstract Co-Author*) Nothing to Disclose
Shengfang Xu (*Presenter*) Nothing to Disclose

### PURPOSE

This study primarily investigates the application of SyMRI quantitative assessment in the brain development of children with BPD.

### METHODS AND MATERIALS

A total of 31 infants aged 2-24 months with BPD were prospectively collected as the observation group,and healthy infants matched for age and gender as the control group.NBNA was performed for all participants in both groups. All participants underwent multi-dynamic multi-echo (MDME) scanning on a 3.0 T MRI scanner(MAGNETOM Lumina, Siemens Healthineers, Erlangen, Germany).. MDME raw data were processed using in-house MDME post-processing software to automatically generate T1, T2, and PD maps. Using ITK-SNAP 4.0.1 software, anatomical regions of interest (ROI) were manually delineated on the T1, T2, and PD maps for both groups (Figure 1), and T1, T2, and PD values were calculated (Figure 2).while independent samples t-tests were employed for comparison of T1, T2, and PD values between different brain region ROIs in the two groups. Intergroup comparison of NBNA scores was also conducted. Pearson correlation analysis was performed to assess the correlation between regions showing differences in T1, T2, PD values and NBNA scores. ROC curves were generated to evaluate the diagnostic performance of T1 and T2 values with statistical significance in diagnosing abnormal brain development in BPD patients.

### RESULTS

In the observation group, the T1 and T2 values of the PLIC, PTR,CereP, CS, and Frontal White Matter were higher than those in the control group, with statistically significant differences for both T1 and T2 values. Additionally, the T2 value of occipital white matter in the observation group was higher than that in the control group, with statistical significance (Figure 3). Pearson correlation analysis revealed that NBNA scores in the observation group were lower than those in the control group. Furthermore, NBNA scores were negatively correlated with the T1 and T2 values of the PTR and CereP, as well as with the T1 value of Frontal White Matter (Table 1). ROC curve analysis demonstrated that the T1 and T2 values of the PTR, T1 value of CereP, T2 value of CS, and T1 value of Frontal White Matter had AUCs greater than 0.720 for diagnosing abnormal brain development in BPD patients (Figure 4).

### CONCLUSION

SyMRI quantitative assessment aids in the early detection of abnormal brain development in children with BPD, providing a basis for early clinical assessment and timely intervention.

### CLINICAL RELEVANCE/APPLICATION

SyMRI multiparameter indices can serve as imaging reference indices for brain development in children with BPD, assisting clinicians in early detection of neurodevelopmental issues in these patients and providing a basis for early clinical assessment and timely intervention.

## W5A-SPPD-3 RE-EVALUATING THE TIMING OF SEQUENTIAL CRANIAL ULTRASOUND SCREENING IN VERY PRETERM INFANTS FOR PREDICTING NEURODEVELOPMENTAL OUTCOMES

Sunaina Ramdass, MBChB (*Abstract Co-Author*) Nothing to Disclose
Jehier Afifi (*Abstract Co-Author*) Nothing to Disclose
Tahani M. Ahmad, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Among the myriad challenges in caring for preterm infants, the accurate prediction and early detection of neurodevelopmental impairment (NDI) stands as a crucial endeavour for healthcare providers. Sequential cranial ultrasound (CUS) remains the work horse for imaging evaluation of brain injury in this patient population. There is no worldwide consensus on the timing and frequency of CUS screening. At our institution, similar to the European Brain group and the 2001 Canadian Pediatric Society recommendations, at least 4 time point CUS are performed for routine screening in preterm infants. This includes CUS scanning at the 1st week, 2nd week, 6th week and at Term-Equivalent Age. Our hypothesis is that the 2-week CUS is not necessary in NDI prognostication, without a significant abnormality on the 1st week CUS, mandating a short-term interval follow up.

## METHODS AND MATERIALS

In this retrospective, single-centre, population-based cohort, we included all liveborn preterm infants 220-306 weeks' gestation who were born between January 2004 and December 2016 at our institution and had neurodevelopmental assessment at 36 months corrected age. A model dropping 2-week ultrasound was compared to a reference model that includes gestational age, infant sex as well as 2 and 6-week ultrasound gradings. Decision curves were fit for all proposed models to help guide the trade-off between accuracy and potential uptake.

## RESULTS

Out of 786 preterm babies born during the study period, 656 survivors were included in the analysis. Thirty percent of our cohort has NDI as per clinical assessment. The mean gestational age was 27.8 weeks with the mean birth weight being 1133 grams, and 55% being male infants. The negative predictive value of sequential CUS varied between 76 - 81% for CUS conducted at 2-week and 6-week time points, respectively. Overall, there does not appear to be strong evidence that the addition of the 2-weeks' CUS, following a normal initial CUS, meaningfully contributes to the risk prediction of any NDI or significant NDI when making predictions at the time of hospital discharge. Models with and without the 2-weeks' CUS showed near identical performance across a broad set of metrics.

## CONCLUSION

In this population-based cohort, we compared two methods of sequential CUS screening (3 and 4 time-points) and showed reliable performance of the 3 time points model to predict NDI at 36 months of corrected age.

## CLINICAL RELEVANCE/APPLICATION

The need for a 2-week CUS to predict NDI can be eliminated if no significant abnormalities are detected during the initial 1-week CUS, promoting prudent resource allocation and stewardship in healthcare.

Nathan Atkins (*Abstract Co-Author*) Nothing to Disclose
Alexander Cherlin, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Molecular Breast Imaging (MBI) demonstrates high sensitivity in detecting cancer, particularly in dense breast tissue. Nonetheless, long imaging time and higher radiation exposure compared to mammography hinder its widespread adoption. Following successful feasibility studies where a novel ultra-low-dose stationary tomographic MBI system demonstrated a potential for dose/measurement time reduction of a factor of ~8, a small field of view (FOV) prototype has been built and evaluated.

### METHODS AND MATERIALS

A small FOV prototype comprised of two camera heads. A head comprising a 6x4 array of Kromek's 3D position sensitive 5mm thick CZT detectors covering the FOV of 132 mm x 88 mm, and a densely packed multi-pinhole 3D printed tungsten collimator with ~300 pinholes. The detectors have an 11x11 array of 2mm pixels. The system produces tomographic images with significant multiplexing resulting in adverse artefacts which are mitigated by de-multiplexing algorithms utilising detector 3D position of interaction information. The detector data is analysed using a machine-learning-based (ML) model which provides strong improvement in sub-pixel position resolution. The initial calibration of the prototype is complete, and its performance evaluated using point sources and 99mTc-filled phantoms.

### RESULTS

The initial assessment of the prototype's performance, through reconstructed 2D images, has shown significant advancement in detector resolution achieving 5x5 sub-pixelization of physical 2 mm pixels. This performance leads to an major enhancement in the image resolution, surpassing any previous demonstration by a SPECT or MBI system with CZT detectors. These outcomes have been implemented in both simulated and experimental data image reconstruction, showcasing significant improvements in reconstructed tomographic image quality and de-multiplexing performance of reconstruction algorithms. The system's performance characterization with phantoms and quantification of dose/time reduction factors will be presented.

### CONCLUSION

These results reveal substantial improvement in detector performance, which in turn enhances the performance of tomographic image reconstruction. Building upon the outcomes reported last year, we anticipate further enhancements in our dose/time reduction efforts to reduce the injected patient dose to approximately 2 mCi/75 MBq (equivalent to a mammography dose of ~0.5 mSv) significantly shortening the MBI scan time to below the current 40 minutes.

### CLINICAL RELEVANCE/APPLICATION

Reduction of patient dose, scan time, and 3D localisation, aiding biopsy, should fulfil American College of Radiology's criteria (2018) for accepting MBI for cancer screening, especially for patients with dense breast tissue.

## W5A-SPPH-10 RELIABILITY, AGREEMENT, AND BIASES OF DEEP LEARNING RECONSTRUCTIONS FOR QUANTITATIVE SUSCEPTIBILITY MAPPING (QSM)

Dawn Berkeley, BS (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation
Wissam Alghuraibawi (*Abstract Co-Author*) Nothing to Disclose

Mo Kadbi, PhD (*Abstract Co-Author*) Employee, Canon Medical Systems Corporation;
Hung P. Do, PhD, MSc (*Presenter*) Employee, Canon Medical Systems Corporation

**PURPOSE**

Deep Learning Reconstruction (DLR) has been used clinically for qualitative imaging providing improved image quality, SNR, resolution, and scan time compared to conventional reconstruction (CONV) [1-4]. Rigorous assessment of DLR for quantitative imaging is needed before widespread clinical adoption. This study aimed to evaluate two DLR methods named Deep Learning-based Denoising Reconstruction (DL-DR) and Deep Learning-based Super-resolution Reconstruction (DL-SR) for quantitative susceptibility mapping (QSM) [5].

**METHODS AND MATERIALS**

Five patients were scanned using a 3T MRI scanner under approved IRB. The scan protocol consists of routine brain sequences and a 3D multi-echo gradient echo (mecho-GRE) sequence for QSM. Each mecho-GRE data was reconstructed with CONV, DL-DR, and DL-SR.Morphology Enabled Dipole Inversion (MEDI) [6] was used to generate QSM maps. Deep gray matter regions of interest (ROIs) on substantia nigra and red nucleus were drawn.Linear regression was used to assess reliability while Bland-Altman and Lin's concordance correlation coefficient were used to assess agreement as recommended by Berchtold et al. [7]. Quantitative metrics such as SSIM, PSNR, NRMSE were also calculated for comparison.

**RESULTS**

Fig 1 2 show representative GRE magnitude images and QSM maps from two subjects. Qualitatively, as seen in Fig 1, substantia nigra (green arrowhead) and red nucleus (red arrow) are darker compared to surrounding tissues in the first subject (top row) than in the other one (bottom row). However, the major drawback of the qualitative assessment is that the MR signal intensity, tissue contrast, SNR, and CNR are dependent on subject, scan protocol, and scanning conditions, which confound objective assessment of iron deposition.Alternatively, QSM provides an objective assessment of iron deposition. As shown in Fig 3, the quantitative regional QSM values for the two subjects can be objectively compared. It is noted that measured QSM values are similar among the three reconstructions.Fig 4 5 show correlations between CONV vs. DL-DR ($R2 > 0.99$) with biases of 5.93 ppb and between CONV vs. DL-SR ($R2>0.98$) with biases of 6.96 ppb. Lin's concordance correlation coefficients were all larger than 0.97 for QSM values for both comparisons.

**CONCLUSION**

Deep Learning-based Denoising Reconstruction and Deep Learning-based Super-Resolution Reconstruction have excellent correlation and agreement with conventional reconstruction for QSM.

**CLINICAL RELEVANCE/APPLICATION**

It is imperative to rigorously evaluate DLR for quantitative MRI before clinical adoption. This study demonstrated that DLR has excellent correlation and agreement with CONV for QSM quantification. That would facilitate the clinical adoption of DLRs for QSM.

## W5A-SPPH-2 APPLICATION OF CARDIAC MAGNETIC RESONANCE DWI SEQUENCE IN THE DIAGNOSIS OF MYOCARDIALFIBROSIS IN HYPERTROPHIC CARDIOMYOPATHY

Xiaowei Ruan (*Presenter*) Nothing to Disclose

**PURPOSE**

Given the importance of diagnosing HCM for predicting patient outcomes, our goal was to enhance the detection rate of myocardial fibrosis using DWI sequences.

**METHODS AND MATERIALS**

The clinical and CMR data of 14 HCM patients (HCM group) and 23 patients with normal CMR structure (control group) were retrospectively collected, and all patients underwent CMR examination, including T1 mapping sequence, DWI and delayed enhancement (LGE) scan, LGE was recorded as LGE+ ,LGE-, respectively, all images were imported into cardiovascular image post-processing software (CVI42) for analysis, and left ventricular Strain and nativeT1 were semi-automatically measured m and ECV. The ROI was placed in the significant myocardial thickening area (group A), the thickening area adjacent to the myocardium (group B), and the thickening area with distal myocardium (group C), and the ROI was manually delineated on the T1mpping diagram and the T1 and blood pool T1 values before and after intensification were calculated, and the ECV of the three groups was obtained. Subsequently, the images were imported into the cardiovascular image post-processing workstation (ISP), and the ROI was placed in the above-mentioned areas of the same layer DWI image on the left ventricular short-axis image according to the range of delay enhancement in the LGE image, and all DWI images were analyzed to obtain diffusion images and measure the ADC values of the three groups.

**RESULTS**

1. Clinical data. (See Table 1 for the basic information of the HCM group and the healthy control group). 2. The 3D global strain parameters of HCM patients and healthy control groups are detailed in Table 2. The peak values of circumferential and longitudinal strain in the HCM group were significantly lower than those in the healthy control group ($P<0.05$), and the peak radial strain was lower than that in the healthy control group, and the difference was not statistically significant. 3. The native T1 value of the HCM group was lower than that of the control group, and the difference was statistically significant ($t=P<0.05$), and the ECV of the HCM group was slightly lower than that of the healthy control group, and the difference was not statistically significant. 4. Comparison of ADC values: In the HCM group, the ADC values of group A were lower than those of groups B and C (both $P < 0.05$) Table 4

**CONCLUSION**

The results of this study suggest that cardiac DWI technology has a high value in identifying and quantifying myocardial fibrosis in cardiohypertrophic cardiomyopathy.

**CLINICAL RELEVANCE/APPLICATION**

The results of this study suggest that cardiac DWI technology has a high value in identifying and quantifying myocardial fibrosis in cardiohypertrophic cardiomyopathy.

## W5A-SPPH-6 DATA-DRIVEN RESPIRATORY GATING PATIENT MANAGEMENT FOR DIGITAL BGO PET/CT

Zohar Keidar, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tala Palchan Hazan, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Data-driven methods for respiratory gating (DDRG) in PET imaging have shown a positive impact on image quality. However, the use of quiescent period gating (QPG) in reconstruction methods that rely on DDRG typically require additional scan time to reduce image noise. Consequently, scans requiring this additional acquisition time alter patient workflow, relevant for the planning of radiotracer injection and scan times, as well as negatively affecting

patient comfort. This study evaluated the clinical application of a commercially available DDRG system that employs principal component analysis in a digital bismuth germanate (dBGO) PET/CT scanner.

**METHODS AND MATERIALS**

Forty-two whole-body ("head to thighs") PET/CT scans were collected using list mode data from a high-sensitivity dBGO scanner, with a two-minute scan duration per bed position. The DDRG tool targeted two specific bed positions, the thorax and abdomen, where respiratory motion is most predominant. This tool produces an R index, quantifying the degree of respiratory motion. The R-index needed to trigger the implementation of QPG was determined for each scan. The percentage of scans triggered at the manufacturer's default value (R = 15) was determined, as well as for R-indexes ranging from 0 to 50 (increments of 5). Reconstructions using QPG were compared against non-gated reconstructions with specific attention to the maximum standardized uptake value (SUVmax) of well-defined lesions in the thorax or abdomen.

**RESULTS**

Measurements of the R indexes, derived for the two bed positions in each scan, showed that 57% of the scanned population exhibited minimal R indexes of = 15, indicating that about half the scans would be triggered to require additional acquisition time for this threshold of respiration. In comparison, approximately one-third of the population demonstrated R indexes of 20 or higher. In terms of total daily PET scan times for 26 patients, this represents a decrease from 280 minutes for R = 15 to 250 minutes for R = 20. Females displayed a slightly higher average R index (23.5) compared to males (20.9) in the thoracic bed position. Employing DDRG significantly increased the SUVmax of focal lesions, by an average of 28% ($P<0.007$) observed in lesions located in bed positions with R value of = 15, indicating a more defined focal uptake.

**CONCLUSION**

Based on the distribution of R indexes, the threshold can be established for the R value needed to implement respiratory gated corrections during acquisition. This strategy aims to enhance clinical workflow by optimizing scan time while preserving image quality.

**CLINICAL RELEVANCE/APPLICATION**

Precise understanding of the implementation of data driven respiratory gating enables proper patient care via workflow planning for digital BGO PET/CT.

## W5A-SPPH-7 ROBUSTNESS OF MRI RADIOMICS FEATURES IN ABDOMEN: IMPACT OF DEEP LEARNING RECONSTRUCTION AND ACCELERATED ACQUISITION

Yang Song (*Abstract Co-Author*) Nothing to Disclose
Weiwu Yao (*Abstract Co-Author*) Nothing to Disclose
Huan Zhang (*Abstract Co-Author*) Nothing to Disclose
Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the impact of deep learning reconstruction and accelerated acquisition on reproducibility and variability of radiomic features in abdominal MRI.

**METHODS AND MATERIALS**

Seventeen volunteers were prospectively included to undergo abdominal MRI on a 3.0-T scanner for axial T2-weighted, axial T2-weighted fat-suppressed, and coronal T2-weighted sequences. Each sequence was scanned for four times using original acquisition with standard reconstruction, original acquisition with deep learning reconstruction, accelerated acquisition with standard reconstruction, and accelerated acquisition with deep learning reconstruction. The regions of interest were drawn for ten anatomical sites. Ninety-three radiomics features were extracted via PyRadiomics after z-score normalization. The reproducibility was evaluated using original acquisition with standard reconstruction as reference by intraclass correlation coefficient (ICC) and concordance correlation coefficient (CCC). The variability among four scans was assessed by coefficient of variation (CV) and quartile coefficient of dispersion (QCD).

**RESULTS**

The average ± standard deviation, median (quartile) of overall ICC and CCC values were 0.473 ± 0.226, 0.451 (0.305, 0.583) and 0.472 ± 0.226, 0.450 (0.304, 0.582). The overall percentage of radiomics features with ICC>0.90 and CCC>0.90 were 8.1% and 8.1%. The average ± standard deviation, median (quartile) of overall CV and QCD values were 17.4% ± 49.5%, 9.4%, (4.9%, 17.2%) and 9.6% ± 33.1%, 4.9%, (2.5%, 9.7%). The overall percentage of radiomics features with CV<10% and QCD<10% were 51.9% and 75.0%.

**CONCLUSION**

Deep learning reconstruction and accelerated acquisition led to a poor reproducibility of radiomics features, but more than a half of the radiomics feature values varied within an acceptable range.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning reconstruction and accelerated acquisition significantly impacts on radiomic features, necessitating caution to the generalizability when performing radiomic analysis using images from different reconstruction algorithms and acquisition protocols.

## W5A-SPPH-8 ROBUSTNESS OF RADIOMICS WITHIN PHOTON-COUNTING CT: IMPACT OF ACQUISITION AND RECONSTRUCTION FACTORS

Weiwu Yao (*Abstract Co-Author*) Nothing to Disclose
Huan Zhang (*Abstract Co-Author*) Nothing to Disclose
Lan Zhu, MD (*Abstract Co-Author*) Nothing to Disclose
Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To assess robustness of radiomics within photon-counting CT.

**METHODS AND MATERIALS**

A phantom with twenty-eight diverse texture materials was scanned with different acquisition and reconstruction factors including reposition, scan mode (standard and high pitch), tube voltage (120 and 140 kVp), slice thickness (1.0 and 0.4 mm), radiation dose level (0.5, 1.0, 3.0, 5.0, and 10.0 mGy), quantum iterative reconstruction level (0, 2, and 4), and reconstruction kernel (Qr40, Qr44, and Qr48). Thirteen sets of virtual monochromatic images at 70 keV were reconstructed. The regions of interest were drawn and copied with rigid registrations. Ninety-three radiomics features were extracted from each material per PyRadiomics. The reproducibility of radiomics features was evaluated using intraclass correlation coefficient (ICC) and concordance

correlation coefficient (CCC). The variability of radiomics features was assessed by coefficient of variation (CV) and quartile coefficient of dispersion (QCD).

**RESULTS**

The percentage of features with ICC>0.90 and CCC>0.90 were high when repositioned (88.2% and 88.2%) and tube voltage were changed (87.1% and 87.1%), but none of the features were with ICC>0.90 and CCC>0.90 when scan mode and slice thickness were different. The percentage of features with CV<10% and QCD<10% were high when repositioned (47.3% and 68.8%) and tube voltage were changed(64.2% and 71.0%), but that with CV<10% and QCD<10% were low between different scan modes (16.1% and 26.9%) and slice thickness (19.4% and 29.0%).

**CONCLUSION**

The radiomics features within photon-counting CT were robust against reposition and tube voltage, but brittle to scan mode and slice thickness.

**CLINICAL RELEVANCE/APPLICATION**

The scan mode and slice thickness should be set with careful attention to allow a higher robustness of radiomics features before its implementation of radiomics analysis in clinical routine.

## W5A-SPPH-9 ROBUSTNESS OF RADIOMICS AMONG FIVE CT SYSTEMS: A TEXTURE PHANTOM STUDY

Huan Zhang (*Abstract Co-Author*) Nothing to Disclose
Lan Zhu, MD (*Abstract Co-Author*) Nothing to Disclose
Weiwu Yao (*Abstract Co-Author*) Nothing to Disclose
Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate robustness of radiomics features on texture phantom scans.

**METHODS AND MATERIALS**

A texture phantom consisting of twenty-eight materials was scanned with one photon-counting detector CT (PCD-CT) system and four dual-energy CT (DECT) systems (dual-source, rapid kV-switching, dual-layer, and sequential scanning) at three dose levels twice. Thirty sets of virtual monochromatic images at 70 keV were reconstructed. Regions of interest were delineated for each material with a rigid registration. Ninety-three radiomics were extracted per PyRadiomics. The test-retest repeatability between repeated scans was assessed by Bland-Altman analysis. The intra-system reproducibility between dose levels, and inter-system reproducibility within the same dose level, were evaluated by intraclass correlation coefficient (ICC) and concordance correlation coefficient (CCC). Inter-system variability among five scanners was assessed by coefficient of variation (CV) and quartile coefficient of dispersion (QCD).

**RESULTS**

The test-retest repeatability analysis presented that 97.1% of features were repeatable between scan-rescans. The mean ± standard deviation ICC and CCC were 0.945 ± 0.079 and 0.945 ± 0.079 for intra-system reproducibility, respectively, and 86.0% and 85.7% of features were with ICC>0.90 and CCC>0.90, respectively, between different dose levels. The mean ± standard deviation ICC and CCC were 0.157 ± 0.174 and 0.157 ± 0.174 for inter-system reproducibility, respectively, and none of the features were with ICC>0.90 or CCC>0.90 within the same dose level. The inter-system variability suggested that 6.5% and 12.8% of features were with CV<10% and QCD<10%, respectively, among five CT systems.

**CONCLUSION**

The radiomics features were non-reproducible with significant variability in values among different CT techniques.

**CLINICAL RELEVANCE/APPLICATION**

The technique of photon-counting detector CT and dual-energy CT systems significantly influences radiomic features, necessitating careful attention to improve the cross-system generalizability of radiomic features before implementation of radiomics analysis in clinical routine.

## W5A-SPVA-1 FEASIBILITY OF DUAL-FLOW INJECTION TECHNIQUE COMBINED WITH LOW TUBE VOLTAGE BASED ON AI DEEP LEARNING RECONSTRUCTION IN AORTIC CTA

Enfu Du (*Abstract Co-Author*) Nothing to Disclose
Qianqian Han (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the feasibility of a dual-flow injection technique combined with low tube voltage scanning based on AI deep learning reconstruction in aortic CTA.

### METHODS AND MATERIALS

A total of 120 patients with post-operation or suspected aortic disease were divided into 3 groups: A(n=40; tube voltage: 100 kV; conventional injection), B(n=40; tube voltage: 100 kV; dual-flow injection)and C(n=40; tube voltage: 60 kV; dual-flow injection). The ratio of contrast medium to normal saline by volume was 55% : 45% for dual-flow injection. Group C was divided into two subgroups, C1 was reconstructed by traditional iterative algorithm (Clearview)and C2 was reconstructed by deep learning algorithm(AIClearInfinity), while groups A and B's algorithm were the same as C1. Scanning was performed from the thoracic inlet to the superior border of the pubic symphysis, the monitoring level was the plane of the pulmonary artery bifurcation, and the ROI was placed at the level of the descending aorta. The CT values of different cross-sectional levels of the aorta in the images of groups A, B, and C were measured. In groups A, B, C1, and C2, measure the CT values and standard deviation (SD) of subcutaneous fat or mediastinal fat at the same level as the aortic ROI to calculate the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). A 5-point scale was used for the subjective assessment of the images. Objective evaluation (the CT values of aorta, SD, SNR, and CNR), subjective scoring, contrast agent dose, and effective dose (ED) were compared and analyzed among groups.

### RESULTS

The CT values at different aortic levels in group C were higher than those in groups A and B (both $P<0.05$). The SD values of group C1 were higher than those of groups A, B, and C2 (all $P<0.05$). There was no statistical significance in SNR and CNR at most levels between groups A and C2 ($P>0.05$); the SNR and CNR values in groups A and C2 were higher than those in groups B and C1 (all $P<0.05$). The subjective scores of the image quality in groups A and C2 were higher than those in groups B and C1 (all $P<0.05$). The contrast medium dose in groups B and C had a 45% reduction compared to group A. Group C's ED was lower than groups A and B's (both $P<0.05$). [please refer to attached for details]

### CONCLUSION

In aortic CTA, a dual-flow injection technique combined with low-tube voltage scanning based on AI deep learning reconstruction significantly reduces contrast medium dose and radiation dose without compromising image quality.

### CLINICAL RELEVANCE/APPLICATION

The dual-flow injection technique combined with low tube voltage enables low contrast medium usage and low radiation dose; the AIClearInfinity reduces image noise, enhances contrast, and improves image quality. The aforementioned solutions are clinically feasible.

## W5B-SPBR-1 PREOPERATIVE PREDICTION OF HER2-ZERO, -LOW AND - POSITIVE BREAST CANCERS USING MULTIPARAMETRIC MRI AND MACHINE LEARNING MODELING

Meihao Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Yang Zhang, PhD (*Abstract Co-Author*) Nothing to Disclose
Jiejie Zhou, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Yan-Lin Liu (*Abstract Co-Author*) Nothing to Disclose
Jeon-Hor Chen, MD (*Abstract Co-Author*) Nothing to Disclose
Min-Ying Su, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

HER2-targeted therapies have dramatically improved the prognosis of HER2-positive breast cancer (BC) patients. Partial HER2-negative BCs express HER2, and HER2-low breast cancers could benefit from new anti-HER2 drug conjugate therapies. This study aimed to use breast MRI BI-RADS (Breast Imaging-Reporting and Data System) features to build models for classifying three HER2 levels, first to distinguish HER2-zero from HER2-low/positive (Task-1), and then to distinguish HER2-low from HER2-positive (Task-2).

### METHODS AND MATERIALS

Six hundred twenty-one patients pathologically confirmed with BC were retrospectively investigated. Pathological information (histological grade and molecular biomarkers) and BI-RADS features were compared using univariate and multivariate analyses. Random Forest algorithm was used to select MRI features, and then four machine learning algorithms: decision tree (DT), support vector machine (SVM), K-nearest neighbors (KNN), and artificial neural nets (ANN), were applied to build models. MRI features included morphology as mass or non-mass enhancement (NME), shape, margin, number of lesions, internal enhancement pattern (IEP), peritumoral edema, ADC value, largest diameter on MRI, DCE kinetic curve, suspicious invasion of adjacent tissue, BI-RADS category.

### RESULTS

Peritumoral edema was found in 69% HER2-positive, 54% HER2-low, and 49% HER2-zero. Multiple lesions were present in 40% HER2-positive, 27% HER2-low, and 24% HER2-zero. The presentation as non-mass enhancement (NME) was found in 36% HER2-positive and 26% HER2-low. For the first task of distinguishing HER2-zero from non-zero (low+positive), multiple lesions, edema, margin, and tumor size were selected, and the KNN model achieved the highest AUC of 0.86 in the training set and 0.79 in the testing set. For the second task of differentiating HER2-low from HER2-positive, multiple lesions, edema, and margin were selected, and the DT model achieved the highest AUC of 0.79 in the training set and 0.69 in the testing set.

### CONCLUSION

ML models could achieve a good classification performance, and suggested breast MRI could be used to help assess HER2, to determine patients with HER2-zero who were not eligible for targeted therapy, HER2-low who could benefit from new antibody-drug conjugates, and HER2-positive who can be well treated with trastuzumab and pertuzumab.

### CLINICAL RELEVANCE/APPLICATION

MRI features of breast cancer are associated with different HER2 expression levels. MRI-based ML models have the potential to preoperatively predict the HER2 expression status.

## W5B-SPBR-2 UNLOCKING THE MYSTERY: ARE INCIDENTAL OSSEOUS LESIONS ON BREAST MRI ALWAYS SIGNIFICANT?

Omar P. Nemer, MD (*Abstract Co-Author*) Stockholder, Novartis AG
Jonathan D. Pierce, MD (*Abstract Co-Author*) Nothing to Disclose
Anahita Tavana, MD (*Abstract Co-Author*) Nothing to Disclose
Donna M. Plecha, BA, MD (*Abstract Co-Author*) Hologic Inc., speaking engagement at SBI 2022.Mammotome Inc, speaking engagement at AsBRS 2022
Navid Faraji, MD (*Abstract Co-Author*) Nothing to Disclose
Shahrzad Tavana, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Incidental osseous lesions are frequently encountered on breast MRIs, involving the manubrium, sternum, ribs, as well as spine depending on the field of view. The objective of this study is to scrutinize the outcomes of incidentally detected osseous lesions encountered during diagnostic and screening breast MRIs.

### METHODS AND MATERIALS

A retrospective analysis of all the breast MRIs performed at a large academic medical center between 2010 and 2020 was performed using the keywords "incidental, sternum, sternal, osseous, manubrium, and rib." The analysis included all the diagnostic MRIs following diagnosis of breast cancer and all the screening MRIs, including the abbreviated screening protocol examinations and full protocol examinations for screening of patients with greater than 20% lifetime risk of breast cancer. Exclusion criteria were applied to eliminate examinations including the implant protocol MRIs, traumatic fractures or degenerative changes without underlying lesions, non-osseous incidental findings, invasion of chest wall structures by breast cancer, and the patients lost to follow-up. Osseous lesions were determined as malignant if they exhibited hypermetabolic activity on subsequent PET scans or radiotracer uptake on bone scans. Osseous lesions without hypermetabolic activity on the PET scan, radiotracer uptake on the bone scan, any corresponding suspicious abnormality on the follow-up chest CT, evidence of malignancy on a subsequent biopsy, or those that remained unchanged on follow-up imaging for two years were deemed to represent a benign process.

### RESULTS

The analysis included a total of 98 examinations after exclusions, comprising 44 screening MRIs and 54 diagnostic MRIs. In the screening group, no incidental osseous lesion was determined to be malignant, while 27.8% of the lesions in the diagnostic group were determined to be malignant. All malignant lesions in the diagnostic group were identified in patients already diagnosed with stage 4 breast cancer at the time of the MRI.

### CONCLUSION

The study findings suggest that incidentally discovered osseous lesions on screening breast MRIs are more inclined to represent benign processes. Conversely, in MRIs conducted for patients with stage 4 breast cancer, any incidental osseous lesion may indicate metastatic involvement, warranting a bone scan as a recommended confirmatory follow-up examination.

### CLINICAL RELEVANCE/APPLICATION

Given that bones serve as one of the primary sites for breast cancer metastasis, identification of osseous lesions on breast MRIs poses a clinical challenge for radiologists, impacting their assessment of clinical relevance and follow-up recommendations. This study seeks to ascertain the clinical importance of these incidental findings.

## W5B-SPBR-3 CLUSTER ANALYSIS OF KINETIC PARAMETERS FOR QUANTITATIVE ULTRAFAST DCE-MRI FOR GRADING DCIS

Hiroyuki Abe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hyunji Shim, BS (*Abstract Co-Author*) Nothing to Disclose
Xiaobing Fan, PhD (*Abstract Co-Author*) Nothing to Disclose
Kirti M. Kulkarni, MD (*Abstract Co-Author*) Nothing to Disclose
Gregory S. Karczmar, PhD (*Abstract Co-Author*) Stockholder, QMIS TBS Capital Group Corp
Zhen Ren, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To determine whether contrast media kinetics measured at high temporal resolution in DCIS can accurately stratify grade of DCIS at surgery. Since DCIS is typically diffuse and heterogenous, we tested whether cluster analysis based on kinetics would help to identify aggressive DCIS.

### METHODS AND MATERIALS

72 patients with histologically confirmed pure ductal carcinoma in situ (DCIS, low grade n = 4, intermediate grade n = 23, and high grade n = 29) or DCIS co-existing with IDC (microinvasion n = 11, IDC n = 5) who underwent ultrafast DCE-MRI (i.e., temporal resolution = 3 - 9 seconds per image, 3T/3D fast spoiled gradient echo) prior to surgery were enrolled in this retrospective study. DCIS lesions were segmented by an experienced breast MRI radiologist. Signal enhancement ratio over time per voxel within the DCIS was fitted with an empirical mathematic model (EMM) to calculate maximum uptake (A), uptake rate (a) and A·a. Then DCIS was divided into five clusters using K-means clustering (KMC) method based on A·a and which were sorted in ascending order. The arterial input function (AIF) was traced over the descending aorta or heart area. Averaged signal intensity as a function of time was calculated for each cluster and fitted with the EMM to characterize A and a. Contrast agent concentration curve was calculated and fitted with extended Tofts model to extract physiological parameters (Ktrans, ve, vp and kep). Grading in pure DCIS at surgical pathology was compared using kinetic parameters via Kruskal-Wallis test. Pure DCIS and DCIS with invasive cancer were compared via the Wilcoxon rank-sum test.

### RESULTS

The vp, which reflects vascular volume, of the 4th KM cluster was significantly higher in patients with DCIS with invasive cancer than in patients with pure DCIS ($p = 0.03$). Other parameters were not significant in separating pure DCIS from DCIS with invasive cancer. In patients with pure DCIS, on average low-grade DCIS had lower vp than intermediate- or high-grade DCIS. Although the differences in vp between low grade and high grade DCIS are not significant in this dataset ($p > 0.2$), the results suggest that this approach can identify ~31% of women who are likely to have DCIS with IDC and ~30% of women who are likely to have low grade DCIS.

### CONCLUSION

KMC analysis of quantitative ultrafast DCE-MRI could effectively distinguish pure DCIS from DCIS co-existing with invasive cancer. Vp could be a surrogate marker to identify the risk of DCIS upgrade. DCIS with low vp could be considered as a weakly vascularized lesion with low risk and that may be considered for less aggressive treatment or surveillance.

### CLINICAL RELEVANCE/APPLICATION

Quantitative ultrafast DCE-MRI may separate low risk DCIS patients who can benefit by surveillance from high-risk DCIS patients who need surgery.

## W5B-SPBR-4 COMPARISON BETWEEN ABBREVIATED MRI AND FULL MRI PROTOCOL FOR ASSESSING TUMOR EXTENT IN PATIENTS WITH NEWLY DIAGNOSED BREAST CANCER

Hye Jung Kim, PhD (*Abstract Co-Author*) Nothing to Disclose
Gab Chul Kim, PhD (*Abstract Co-Author*) Nothing to Disclose

Kyung Min Shin, MD (*Abstract Co-Author*) Nothing to Disclose
Won Hwa Kim, MD, PhD (*Abstract Co-Author*) Stockholder, BeamWorks
Seo Young Park, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The aim of this study was to assess the concordance rate and correlation between tumor extents measured using full protocol MRI (full-MRI) and abbreviated MRI (ab-MRI) with pathologic tumor extent according to tumor subtypes.

### METHODS AND MATERIALS

A total of 319 patients with 330 index breast cancers were enrolled in the study. Two radiologists had two review sessions of full- MRI and ab- MRI, respectively, with a 1-month wash-out period. The total tumor extent was determined by the maximum extent of the index lesion containing adjacent suspicious lesions less than 1.5cm from index cancer. The tumor extent and concordance rate were compared between full-MRI and ab-MRI with pathology (histopathologic and molecular subtypes). Additionally, the correlation and agreement of tumor extent between each MR and pathology were evaluated.

### RESULTS

Mean tumor extent and concordance rate between each MRI with pathology did not show significant difference (Ps = 1, Ps > 0.5). The concordance rate was highest in invasive ductal carcinoma (89.3% and 89.7%, reader 1; 89.3% and 89.7%, reader 2) and triple negative subtype (96.6% and 96.6%, reader 1 and 2) and lowest in DCIS (57.9% and 55.3%, reader 1; 52.6% and 60.5%, reader 2) and Her-2 subtype (54.2% and 58.3%, reader 1; 50.0% and 58.3%, reader 2). The correlation for tumor extent between each MR and pathology was highest in other type (0.73 and 0.80 reader 1; 0.73 and 0.77, reader 2) and triple negative subtype (0.79 and 0.81, reader 1; 0.84 and 0.81, reader 2) and lowest in ILC (0.49 and 0.60, reader 1; 0.47 and 0.58, reader 2) and Luminal A (0.65 and 0.66, reader 1) and Her-2 subtype (0.53 and 0.55, reader 2). The correlation and agreement of tumor extent between each MR and pathology was not significantly different (Ps >0.4).

### CONCLUSION

Ab-MRI demonstrated its feasibility for preoperative tumor extent in breast cancer patients, showing comparable concordance rate and correlation in tumor extent compared to full-MRI.

### CLINICAL RELEVANCE/APPLICATION

This suggests that ab-MRI can serve as a potential complement to full-MRI when patients having difficult condition including claustrophobia or socioeconomic reasons.

## W5B-SPBR-5 MULTIPARAMETRIC WHOLE BODY MAGNETIC RESONANCE IMAGING IN ADVANCED BREAST CANCER: ACCURACY AND THERAPEUTIC IMPLICATIONS

Michela Palleschi (*Abstract Co-Author*) Nothing to Disclose
Arrigo Cattabriga (*Abstract Co-Author*) Nothing to Disclose
Davide Bezzi (*Abstract Co-Author*) Nothing to Disclose
Danila Diano (*Abstract Co-Author*) Nothing to Disclose
Filippo Merloni (*Abstract Co-Author*) Nothing to Disclose
Andrea Prochowski Lamurri, MD (*Abstract Co-Author*) Nothing to Disclose
Alice Rossi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

In case of advanced bone advanced breast cancer (BC), standard imaging techniques (SITs) such as computed tomography (CT), bone scintigraphy (BS) and positron emission tomography (PET-CT) may not always produce reliable results. Our study sought to determine whether multiparametric whole-body magnetic resonance imaging (WB-MRI) could improve accuracy for detecting bone metastases when employed in cases of unclear outcome to CT, BS, and/or PET-CT. The main goal of the study was to examine the differences between SITs and WB-MRI. The secondary aim was to evaluate WB-MRI's impact on treatment planning and to determine which histological subtypes mostly benefit from WB-MRI assessment.

### METHODS AND MATERIALS

From January 2021 to January 2024, we enrolled into a prospective trial consecutive BC patients who underwent regular SITs employed in conjunction with WB-MRI for two distinct groups of BC patients. The first group included patients with bone-predominant lesions who were eligible for cyclin-dependent kinase 4 and 6 (CDK 4/6) inhibitors, while the second one was represented by BC patients with indeterminate imaging findings. All WB-MRI were performed following the Metastasis Reporting and Data System for Prostate Cancer (MET-RADS) guidelines.

### RESULTS

The study included 59 BC patients (mean age, 55 years ± 12 [SD]). They underwent a WB-MRI after a CT, BS, or PET-CT scan. Of these, 25 patients (42.4%) had undetermined lesions on SITs that were later determined by WB-MRI to be metastatic. In twenty-one patients (40%), WB-MRI resulted in change of treatment strategy. Specifically, the therapeutic decision changed in 11 patients (22%), due to the identification of new lesions or progressive disease on WB-MRI alone. It is noteworthy that in (18) 83% of patients with lobular tumors, additional metastases were found, and in (10) 45% of cases, the treatment plan was changed. Furthermore, biopsy was avoided in 13 cases (38%) since WB-MRI showed clear signs of disease progression. The concordance rate between WB-MRI and SITs was 47% among the 35 patients who had at least one reassessment. Seven of these patients had discordant data, which led to a 21% therapeutic strategy modification rate.

### CONCLUSION

This study demonstrated the potential value of WB-MRI in the staging and follow-up of BC patients, particularly in lobular cancer histotypes. Further prospective studies are required to confirm the role of WB-MRI as a clinical tool with consistent clinical impact.

### CLINICAL RELEVANCE/APPLICATION

Our prospective trial supports the potential utility of multiparametric WB-MRI in the staging and follow-up of BC patients, especially in case of lobular histology, overcoming the limitations of standard imaging techniques.

## W5B-SPBR-6 IMPACT OF BACKGROUND PARENCHYMAL ENHANCEMENT (BPE) ON DIAGNOSIS OF BREAST CANCER IN MRI: A ROI-BASED STUDY

Sonja Bechyna, MD,BSC (*Abstract Co-Author*) Nothing to Disclose
Ambra Santonocito, MD (*Abstract Co-Author*) Nothing to Disclose
Thomas H. Helbich, MD, MBA (*Abstract Co-Author*) Grant, Siemens AG;Grant, Bracco Group;Grant, Guerbet SA;Grant, Hologic, Inc;Grant, Novomed GmbH

Pascal A. Baltzer, MD (*Abstract Co-Author*) Nothing to Disclose
Paola Clauser, MD, PhD (*Presenter*) Speaker, Siemens AG

**PURPOSE**

Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) is highly sensitive for detecting breast cancer. However, not only suspicious lesions enhance on DCE-MRI, but also normal breast parenchyma, referred to as background parenchymal enhancement (BPE). There is controversial evidence regarding whether BPE compromises the accuracy of breast MRI by masking or mimicking suspicious enhancements. Our aim was to investigate the influence of BPE in the detection of breast lesions by DCE-MRI using a ROI-based approach.

**METHODS AND MATERIALS**

Images of consecutive patients that underwent MRI in line with ACR/EUSOBI recommendations between May 2020 to September 2022 were retrospectively analyzed. Both breasts were divided in 10 regions of interest (ROI) and BPE, BI-RADS and lesion type were assessed according to the BI-RADS lexicon for MRI for each ROI by two blinded readers. BPE was dichotomized in minimum/mild (BPE1) and moderate/marked (BPE2). The study included women with non-specific or suspicious findings on mammography or ultrasound (BI-RADS 0, 3, 4, 5). Patients without a standard reference were excluded. The standard reference was defined as histology or 1 year follow-up. The performance of MRI was assessed using ROC analysis in a region-based analysis. Inter-reader agreement was assessed using k statistics. P-values <.01 were considered statistically significant.

**RESULTS**

A total of 319 patients (mean of 53.9 years old SD 10,6; range 31-84) were included. Out of the 283 lesions histopathologically analysed, 126 were malignant and 158 were benign. BPE1 was observed in 78.3% patients and BPE2 in 21.7% patients. The area under the ROC curve did not differ between BPE1 (0.975) and BPE2 (0.987), p>0.05. Sensitivity of MRI was equally 95.7% in patients with BPE1 and BPE2 while specificity was nearly the same with BPE1 96.9% and BPE2 97.2%, p>0.05

**CONCLUSION**

Our study demonstrates that BPE does not affect the diagnostic accuracy of breast MRI. Our results provide strong evidence suggesting that the presence of BPE does not compromise the ability to detect and identify suspicious lesions on breast MRI.

**CLINICAL RELEVANCE/APPLICATION**

The study confirms that BPE doesn't influence the accuracy of breast MRI in the detection of suspicious lesions.

## W5B-SPBR-7 EFFECT OF BREAST MRI LESION SIZE ON MALIGNANCY RATE VARIES BY PATIENT AGE

Richard E. Sharpe JR, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Robert W. Maxwell, MD (*Abstract Co-Author*) Managing Member, Maxwell Publishing Company LLC
Aditya Khurana, MD (*Abstract Co-Author*) Nothing to Disclose
Tariq Rashid (*Abstract Co-Author*) Nothing to Disclose
Jacob Varner (*Abstract Co-Author*) Nothing to Disclose
Richard Ellis, MD (*Abstract Co-Author*) Nothing to Disclose
Alan Zhu, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the positive predictive values (PPVs) of different lesion sizes and age ranges in MRI-detected breast findings that underwent image-guided biopsy.

**METHODS AND MATERIALS**

This retrospective study was conducted across a multispecialty healthcare enterprise that provides care at 18 imaging sites across 4 US states. All findings detected by breast MRI that underwent image-guided biopsy from October 31, 2017 to April 26, 2024 were extracted. MRI examinations were performed using a 3T unit for indications including high-risk screening, extent of disease, and problem solving. Lesion size was reported prospectively by the radiologist prior to biopsy. The PPV was calculated by different lesion sizes and patient age ranges by decade. Significance between categorical variables was assessed using the 2-tailed chi-square test.

**RESULTS**

Of 5566 findings in 4242 patients (mean age 54.3 years ± 12.6 [SD]; 4242 female), the mean lesion size was 21.9 mm. There was no significant difference in PPV between findings =5 mm (19.1%, n=863) and >5 mm (20.0%, n=4614; p=0.543). Overall, PPV increased gradually with lesion size, with malignancy found in 550 of 2567 (21.4%) findings >10 mm, 270 of 1148 (23.5%) of findings >20 mm, 159 of 621 (25.6%) findings >30 mm, and 108 of 367 (29.4%) findings >40 mm. PPV differences among these 4 lesion size categories were significant in every decade of patient ages from 20-89 except for ages 30-39, when lesions >10 mm, >20 mm, >30 mm, >40 mm had PPVs of 7.0% (n=267), 7.0% (n=156), 6.3% (n=65), and 7.7% (n=25; p = 0.99) respectively. This decade of life (30-39) also had the lowest average PPV of all decades (7.4%), despite the PPV increasing with age in every other decade.

**CONCLUSION**

This is the largest study to date comparing PPVs of biopsy in MRI-detected breast findings by the lesion size and age range. Greater lesion size was associated with increased PPV except in the age range 30-39 that was also the only decade with no significant difference in PPV by lesion size.

**CLINICAL RELEVANCE/APPLICATION**

Radiologist awareness of the PPV by lesion size and age range in breast MRI-detected findings can support informed discussions and decision-making in patients potentially undergoing breast biopsy.

## W5B-SPBR-8 SYSTEMATIC REVIEW AND META-ANALYSIS OF SCREENING BREAST MRI OUTCOMES IN WOMEN WITHOUT PERSONAL HISTORY OF BREAST CANCER

Nikiforos Vasiniotis Kamarinos, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance of screening breast MRI in high-risk women without a personal history of breast cancer.

**METHODS AND MATERIALS**

Databases were searched to identify studies published from 2005 to 2024 related to the outcomes of screening breast MRI in women without a personal history of breast cancer. A meta-analysis was performed to obtain summary sensitivity and specificity values using a bivariate random-effects model. Studies without MRI outcome metrics in the specific population of interest and studies without false positive or false negative rates were excluded.

**RESULTS**

Eight studies with a total of 12911 screening MRIs were included in the final qualitative and quantitative meta-analysis. The pooled sensitivity and specificity for cancer detection were 85% (95% CI, 72%-93%) and 89% (95% CI, 83%-93%), respectively. Moderate study heterogeneity was identified (bivariate correlation coefficient = 0.5). Most of the cancers were detected at an early stage. Indications for screening MRI included lifetime risk of breast cancer =20%, history of genetic predisposition, high-risk lesion, chest irradiation for Hodgkin's lymphoma, and/or family history of breast cancer. The overall diagnostic odds ratio of screening MRI was 34.68 (95% CI, 18.16-66.24).

**CONCLUSION**

Screening breast MRI is a valuable diagnostic tool for high-risk women without a personal history of breast cancer and can detect cancer at an early stage.

**CLINICAL RELEVANCE/APPLICATION**

A meta-analysis of 8 studies, including 12911 screening breast MRIs in high-risk women without a personal history of breast cancer, demonstrates favorable cancer detection outcomes supporting the use of MRI in this patient population.

## W5B-SPBR-9 TIME TO ENHANCEMENT (TTE) RELATIVE TO BACKGROUND PARENCHYMAL ENHANCEMENT (BPE) AS A NOVEL PARAMETER DIFFERENTIATING BENIGN AND MALIGNANT SMALL MASSES ON ULTRAFAST BREAST MRI

Samantha L. Heller, MD, PhD (*Abstract Co-Author*) Research support, Koios Medical, Inc
Xiaochun Li (*Abstract Co-Author*) Nothing to Disclose
Judith Goldberg (*Abstract Co-Author*) Nothing to Disclose
Yiming Gao, MD (*Abstract Co-Author*) Nothing to Disclose
Helaina Regen-Tuero, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate whether clinically available kinetic features of ultrafast MRI (UFMRI) can classify malignancy of small masses.

**METHODS AND MATERIALS**

IRB-approved, HIPAA compliant retrospective review of all UF-MRI (July 1, 2019 to April 30, 2023) with subsequent MRI-guided biopsy of enhancing masses 5 mm or smaller (124 patients). The electronic medical record was reviewed to collect patient demographic and exam data (age, menopausal status, personal and family breast cancer history, genetic mutation, exam indication, breast density, and BPE, as well as lesion characteristics (size, TTE, T2 signal, stability, and distance from known cancer if applicable). The difference in TTE of the lesion versus TTE of BPE was calculated. Images were analyzed with DynaCAD to determine maximum slope (MS) of enhancement. Logistic regression was conducted. No multiple testing adjustments were made and a significance level of 0.05 (2-sided) was used.

**RESULTS**

124 patients (mean age 53, range 29-78) underwent MR-guided biopsy of 124 small masses. 51.6% (64/124) were postmenopausal and 57.3% (71/124) had a history of breast cancer. 65.3% (81/124) had a family history and 35.3% (33/94) of patients had a genetic mutation. The majority of exams were performed to evaluate extent of disease (47.6%; 59/124) followed by screening (41.9%; 52/124). Most patients had heterogeneously dense breasts (58.1%; 72/124) and mild BPE (57.3%; 71/124). Final pathology demonstrated 21 malignant lesions in 21 patients: 5 DCIS and 16 invasive. No demographic factors were associated with increased likelihood of malignancy. The odds of malignancy increased 1.054 with each second increase in the difference of TTE of the lesion compared to TTE of BPE (95% CI: 1.016, 1.094), p=0.006. No other kinetic parameters or lesion characteristics were useful for classification.

**CONCLUSION**

The relative difference of the TTE of small masses compared to the TTE of BPE may be a useful parameter to classify small masses as malignant or benign. Further studies are needed to evaluate how well this classification works in independent sets of patients.

**CLINICAL RELEVANCE/APPLICATION**

Improved classification of small mass malignancies on MR imaging could prevent unnecessary biopsies.

## W5B-SPCA-1 MYOCARDIAL EXTRACELLULAR VOLUME ASSESSMENT USING CT LATE ENHANCEMENT AND NON-CONTRAST CT SCANNED AT DIFFERENT TUBE VOLTAGE ON SINGLE-ENERGY CT

Yamato Shimomiya (*Abstract Co-Author*) Employee, Ziosoft, Inc
Teruhito Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yusuke Kobayashi (*Abstract Co-Author*) Nothing to Disclose
Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Kazuki Yoshida, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tomoyuki Kido (*Abstract Co-Author*) Nothing to Disclose
Hiroshi Suekuni (*Abstract Co-Author*) Nothing to Disclose
Takaaki Hosokawa (*Presenter*) Nothing to Disclose

### PURPOSE

Myocardial extracellular volume (ECV) is an established marker for myocardial fibrosis and infiltrative diseases. Cardiac CT is a possible alternative to MRI for ECV evaluation. On single-energy CT, ECV is calculated using subtraction of CT late enhancement (CT-LE) and non-contrast CT scanned at the same setting. However, CT-LE is commonly acquired at low tube voltage, necessitating an additional low-tube-voltage non-contrast CT scan. We hypothesized that coronary calcium CT (CAC CT) could be used instead of a low-tube-voltage non-contrast CT to estimate ECV. We aimed to assess the feasibility of estimated ECV (ECVest) calculated using CAC CT.

### METHODS AND MATERIALS

This retrospective study enrolled 70 patients who underwent pre-operative CT scans for transcatheter aortic valve implantation. All patients underwent 80 kVp non-contrast CT, 120 kVp CAC CT, and 80 kVp CT-LE. The patients were divided into derivation (n = 50) and validation (n = 20) groups. ECV was measured by subtracting non-contrast CT from CT-LE (ECVref) and subtracting CAC CT from CT-LE (ECVcac). The regression equation for ECVest was derived from ECVref and ECVcac for the derivation group. The accuracy of ECVest was evaluated using ECVref as the reference standard in the validation group.

### RESULTS

The regression equation for ECVest was ECVest = 0.892*ECVcac + 1.173. ECVref and ECVest were 27.6±3.6% and 27.6±3.8%, respectively, with no significant difference ($p = 0.95$) and a strong correlation ($r = 0.97$, $p < 0.001$). Bland-Altman analysis showed a bias of 0.01% and limits of agreement of -1.88 to 1.92%. The two one-sided tests showed significant equivalence between ECVref and ECVest ($p < 0.01$) with an equivalence bound of 2.5% of the mean ECVref value (0.69%).

### CONCLUSION

This study demonstrated that ECV estimation using CAC CT is feasible and accurate. ECV estimation allows a routine cardiac CT protocol with CT-LE to measure the ECV without additional low-tube-voltage non-contrast CT scans using single-energy CT.

### CLINICAL RELEVANCE/APPLICATION

Cardiac CT is expected to be an alternative modality for ECV evaluation. Accurate estimation of ECV using CAC CT offers high clinical availability without additional scans or radiation exposure with single-energy CT.

## W5B-SPCA-10 SEMI-QUANTITATIVE ANALYSIS OF RIGHT VENTRICULAR MYOCARDIAL FIRST-PASS PERFUSION USING CARDIAC MAGNETIC RESONANCE IMAGING: REPRODUCIBILITY ASSESSMENT

Steven L. Hsu, MD (*Abstract Co-Author*) Nothing to Disclose

Paul M. Hassoun, MD (*Abstract Co-Author*) Scientific Advisory Board, Gilead Sciences, Inc
Stephen M. Mathai (*Abstract Co-Author*) Nothing to Disclose
Ali Borhani, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

In this study, we aimed to employ a semi-quantitative approach in cardiac magnetic resonance (CMR) imaging to measure RV wall first-pass perfusion and to evaluate the intra- and inter-reader reproducibility of this approach.

**METHODS AND MATERIALS**

This study included 23 (69.5% male; 58.2.1 ± 12 years) patients who underwent rest and adenosine stress perfusion CMR imaging to assess pulmonary hypertension with a 3T scanner. Two readers delineated three regions of interest (ROIs) within the visible RV myocardium and manually traced the contours of endocardial and epicardial borders of LV in two planes. Semi-quantitative perfusion analysis was done with a dedicated software for the measurement of first-pass myocardial perfusion. The concordance correlation coefficient (CCC) test was employed to evaluate inter- and intra-reader agreement among measurements of two readers.

**RESULTS**

The agreement between two readers for semi-quantitative perfusion measurements of the RV for the rest phase was 0.85 (range: 0.74 - 0.95), for the stress phase was 0.92 (range: 0.86 - 0.98), and for the perfusion reserve index was 0.795 (range: 0.63 - 0.95). Regarding LV perfusion measurement, the agreement between two readers for the rest phase was 0.981 (range: 0.96-0.99), and for the stress phase, it was 0.99 (range: 0.98-0.99), with an agreement of 0.90 (range: 0.834-0.97) for the perfusion reserve index. The intra-reader agreement, for the RV for the rest phase was 0.90 (range: 0.77 to 1.00), for the stress phase, it was 0.99 (range: 0.98 to 1.00), and for the perfusion reserve, it was 0.66 (range: 0.30 to 1.00). For the LV, intra-reader agreement for the rest phase was 0.99 (range: 0.97 to 1.00), for the stress phase, it was 0.99 (range: 0.98 to 1.00), and for the perfusion reserve index, it was 0.87 (range: 0.72 to 1.00).

**CONCLUSION**

Our study underscores CMR's potential as a reliable tool for assessing first-pass RV perfusion as it is technically feasible and shows excellent inter-reader agreement.

**CLINICAL RELEVANCE/APPLICATION**

In clinical practice, it is beneficial to have a standardized and validated method for measuring myocardial perfusion of the RV. Semi-quantitative analysis offers a useful way to estimate myocardial perfusion in CMR. Its relative simplicity reduces variation across research and clinical groups and is less prone to methodological errors.

## W5B-SPCA-2 REDUCTION OF CT ARTIFACTS FROM THE LATEST-GENERATION LEADLESS PACEMAKER USING SINGLE-ENERGY METAL ARTIFACT REDUCTION ALGORITHM

Yan Xing II, PhD, MD (*Abstract Co-Author*) Nothing to Disclose
Hu Yahui (*Presenter*) Nothing to Disclose

**PURPOSE**

Previous studies have reported the superior feasibility and safety of leadless pacemakers (PMs), underscored by their comparatively favorable complication profiles. This study aimed to evaluate the efficacy of single-energy metal artifact reduction (SEMAR) algorithm in removing artifacts for patients implanted with leadless cardiac PMs compared to those with conventional transvenous PMs.

**METHODS AND MATERIALS**

Between March and August 2023, we prospectively included 30 patients with transvenous PMs and 30 patients with leadless PMs who underwent coronary CT angiography (CCTA) examinations at our institution. All images were reconstructed using two methods: a conventional hybrid-iterative reconstruction (HIR) algorithm, and the HIR combinedwith SEMAR algorithm. The artifact index (AI) was calculated for both image sets to quantitatively assess the artifact reduction. Two senior radiologists independently evaluated the images by overall extent artifact (5, best; 1, worst), and artifact-impaired tissues based on a 3-point scale (non-impaired, impaired, equivocal). The Wilcoxon Signed-Rank testand the Mann-Whitney U test were used for analyzing paired and independent samples, respectively. Inter-observer agreement was also determined.

**RESULTS**

he leadless-PMSEMAR exhibited significantly lower AIs than with the conventional algorithm ($p < 0.001$), with improved correction of hypodense artifacts ($p < 0.001$) and a significant reduction of hyperdense artifacts ($p < 0.001$). The AIs of leadless PMs performed with and without SEMAR were slightly lower than that of transvenous PMs, although no statistical difference existed (all $p > 0.05$). Qualitatively, the overall artifact extent of SEMAR significantly outperformed non-SEMAR in both types of PM ($p < 0.001$). The tissues such as aorta, right coronary artery, right atrium, and left ventricle were less in leadless-PMnon-SEMAR compared to transvenous-PMnon-SEMAR (all $p < 0.05$). Additionally, the RCA and RA showed fewer impairments in leadless-PMSEMAR than those in the transvenous-PMSEMAR ($p < 0.05$).

**CONCLUSION**

SEMAR provides effective reduction of metal artifacts from leadless PMs. The artifact-impaired tissues are fewer on leadless PMs than that on transvenous PMs.

**CLINICAL RELEVANCE/APPLICATION**

The results of this study demonstrate that SEMAR efficiently reduces metallic artifacts from leadless PMs, thereby improving the image quality of CCTA (Fig. 1-2). SEMAR can also enhance the diagnostic confidence of the cardiac and extra-cardiac complications associated with transvenous and leadless PMs.

## W5B-SPCA-4 PROGNOSTIC VALUE OF T2 MAPPING IN NON-ISCHEMIC CARDIOMYOPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Hui Zhou, MD (*Abstract Co-Author*) Nothing to Disclose
Jing Luo (*Abstract Co-Author*) Nothing to Disclose
Yangzhen Hou (*Abstract Co-Author*) Nothing to Disclose
Ji Yang, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this systematic review and meta-analysis was to evaluate the prognostic value of T2 mapping in patients with non-ischemic cardiomyopathy (NICM).

**METHODS AND MATERIALS**

PubMed and Web of Science were searched for studies focusing on the prognostic value of T2 mapping in patients with NICM. The primary endpoints included all-cause mortality, cardiac death and aborted sudden cardiac death (SCD), ventricular arrhythmia, and heart failure hospitalization. Pooling of hazard ratios was performed using a random-effects model, and heterogeneity was assessed using the I2 statistic.

**RESULTS**

Eight studies involving 1477 patients were included in this meta-analysis. The mean age range was 45.6 to 74.6 years, and 54.57% of patients were male. The results showed that patients with higher T2 values have a higher risk of cardiovascular events. The increase of native T2 per = 2ms was associated with the development of the primary endpoint [pooled adjusted hazard ratio (HR): 1.57 (1.20-2.07), I2=54%], whereas the increase per 1 ms was not significantly correlated with prognosis [pooled unadjusted HR: 1.07 (0.98-1.17), I2=59%].

**CONCLUSION**

Myocardial native T2 as a biomarker may be independently associated with prognosis in patients with NICM. Different definitions of the variable native T2 have different effects on risk stratification, and defining a range of increase in native T2 as a variable may be more helpful in identifying high-risk patients.

**CLINICAL RELEVANCE/APPLICATION**

Myocardial Native T2 may be a prognostic marker in patients with NICM. And the increase of T2 value caused by myocardial edema can occur before the clinical related indexes and positive manifestations of LGE, suggesting that clinical diagnosis and intervention can be performed before irreversible damage occurs, which may be more helpful in improving patient prognosis.

## W5B-SPCA-5 IS IT POSSIBLE TO IDENTIFY INFECTIVE ENDOCARDITIS ON ROUTINE ENHANCED CHEST CT?

Saebyol Ma, MD (*Abstract Co-Author*) Nothing to Disclose
Seung Min Yoo (*Abstract Co-Author*) Nothing to Disclose
Son Min Ji (*Presenter*) Nothing to Disclose

**PURPOSE**

Echocardiography is the primary method for diagnosing infective endocarditis (IE), but routine enhanced chest CT is frequently performed in the emergency room for non-specific symptoms like fever or dyspnea. The authors noted instances where patients who underwent routine chest CT were later confirmed to have IE. Despite this, no studies have assessed the diagnostic accuracy of routine chest CT for IE. This study aims to evaluate the accuracy of routine enhanced chest CT for diagnosing IE

**METHODS AND MATERIALS**

Approved by the Institutional Review Board (2023-12-028), this study examined 53 patients with fever or dyspnea diagnosed with IE between January 1, 2007, and April 3, 2024. Twenty were excluded due to missing CT data, prosthetic valves (3), or severe valvular calcification (3), leaving 27 patients. A control group of 35 randomly selected patients with similar symptoms during the same period was used. Routine enhanced chest CT and echocardiography were performed within one month for all subjects.Two thoracic radiologists analyzed CT findings of potential vegetation (nodular thickening on mitral or aortic valves; nodular thickening with a blind end or different orientation from normal aortic, mitral valve leaflets, potential CT sign of oscillating vegetation) and extracardiac findings visible on routine chest CT such as splenic or renal infarction as embolic phenomena of IE. These findings were compared between patient and control groups.

**RESULTS**

Nodular thickening on the aortic or mitral valves was found in 67% (18/27) of the patient group versus 8.6% (3/35) in the control group ($p < 0.0001$). Nodular thickening with a blind end or different orientation from normal valve leaflets was observed in 30% (8/27) of the patient group versus 0% (0/35) in the control group ($p = 0.0007$). Splenic or renal infarction occurred in 52% (14/27) of the patient group and 3% (1/35) of the control group ($p < 0.0001$). Combining nodular thickening with a blind end or different orientation from normal valve leaflets and splenic or renal infarction findings resulted in 100% specificity (35/35) and 100% positive predictive value (7/7), suggesting a strong association with IE.

**CONCLUSION**

Nodular aortic or mitral valve thickening with a blind end may be specific CT finding in patients with acute dyspnea or fever, particularly accompanied by splenic or renal infarction.

**CLINICAL RELEVANCE/APPLICATION**

Routine enhanced chest CT is commonly used in the emergency room for patients with fever or acute dyspnea. Recognizing key CT findings may lead to immediate diagnosis and proper management of IE.

## W5B-SPCA-6 UNVEILING SUBCLINICAL MYOCARDIAL CHANGES IN A COHORT OF TREATMENT-NAIVE CANCER POPULATION WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) AND BREAST CANCER: IS ADVANCED CANCER A CARDIOVASCULAR SYNDROME?

Marco Francone, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Costanza Lisi, MD (*Abstract Co-Author*) Nothing to Disclose
Federica Catapano, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Functional and myocardial tissue modifications can affect cancer patients naive to chemotherapy, as the result of uncontrolled inflammation and neuro-hormonal activation, as well as pathologic angiogenesis. All these mechanisms may cause myocardial alterations and could represent subclinical imaging markers of potential cardiac dysfunction, leading to a comprehensive cardiotoxicity assessment and improved patient's management. The present study aims to explore cardiac-MR (CMR) potentials in shedding light on cancer-associated uncontrolled immune activation hypothesis and to provide early biomarkers of myocardial damage.

**METHODS AND MATERIALS**

This is a prospective single-center study including 70 patients. Study population consisted of two matched groups of 35 healthy individuals and 35 patients with a de novo diagnosis of diffuse large B cell lymphoma (DLBCL) or breast cancer. They all underwent Cardiac-MR before starting chemotherapy. Uni- and multi-variate analysis was conducted to identify differences in myocardial tissue characterization and functional parameters between the two groups.

### RESULTS

A statistically significant difference in native T1 mapping time between the two groups was found (p<0.01) (median oncologic native T1=998 msec, median healthy native T1=979.5 msec). Furthermore, a significant difference between the two groups was also evident (p<0.01) in global longitudinal strain (GLS) values (median oncologic GLS =15.06, median healthy GLS =19.9). No correlation was demonstrated between native T1 increase and GLS decrease in the oncologic group.

### CONCLUSION

Advanced cancer is a complex syndrome deeply involving the cardiovascular system, which, inducing tissue inflammation, oxidative stress and neuro-hormonal activation, relevantly affects myocardial tissue. These changes may manifest as myocardial fibrosis and apoptosis, possibly responsible for native T1 increase and GLS decrease in the naȷve cancer group. Further studies should confirm these results and extend them to the general oncologic population.

### CLINICAL RELEVANCE/APPLICATION

This preliminary study focuses on early tissue modifications as sub-clinical biomarkers of cardio-toxicity and may leave space for a revised relevance attributed to chemotherapy-induced myocardial changes.

## W5B-SPCA-7 ASSESSING LEFT VENTRICULAR TRABECULAR COMPLEXITY BY CARDIAC COMPUTED TOMOGRAPHY: A CONSISTENCY ANALYSIS WITH CARDIAC MAGNETIC RESONANCE

Yang Peng (*Abstract Co-Author*) Nothing to Disclose
Lin Peng (*Abstract Co-Author*) Nothing to Disclose
Jun Yuan (*Abstract Co-Author*) Nothing to Disclose
Chuanbao Deng (*Abstract Co-Author*) Nothing to Disclose
Yuying Chen (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the consistency between fractal dimension (FD) by cardiac CT (CCT) and by cardiac MR (CMR) for evaluation of left ventricular trabecular complexity.

### METHODS AND MATERIALS

The retrospective study included 170 patients who underwent CMR and CCT scans within 2 weeks from January 2021 to December 2023, of which 92 had diastolic CCT datasets, 63 had systolic datasets, and 15 had both. Short-axis views in 8-mm thickness were reconstructed using the CCT datasets and aligned with the cine images of CMR. For each patient, 5 consecutive intermediate slices were obtained for analysis. Trabeculae were quantified with fractal analysis to estimate the FD using both the reconstructed CCT images (CT-FD) and end-diastolic short-axis cine slices of CMR (MR-FD). Since severe left ventricular hypertrophy can lead to inaccuracy of endocardium and trabeculae detection in the systole, patients with a maximum wall thickness over 15mm at end-diastolic short-axis cine images were recorded. The consistency between CT-FD and MR-FD was evaluated using intraclass correlation coefficient (ICC) and Bland-Altman plots.

### RESULTS

Of the 63 patients with systolic CCT datasets, 17 presented with severe left ventricular hypertrophy. The mean diastolic CT-FD and corresponding MR-FD were 1.2527±0.0899 and 1.2508±0.1011 with high consistency (n=535, ICC=0.882, 95%CI: 0.861-0.899, P<0.001). The mean systolic CT-FD and corresponding MR-FD were 1.2682±0.0703 and 1.2866±0.0850 with good consistency (n=390, ICC=0.724, 95% CI: 0.643-0.785, P<0.001). For patients without left ventricular hypertrophy, the consistency was much higher (n=305, ICC=0.776, 95%CI: 0.704-0.828, P<0.001) than those with myocardial hypertrophy (n=85, ICC=0.533, 95% CI: 0.308-0.690, P<0.001).

### CONCLUSION

CCT images can be used to assess left ventricular trabecular complexity with good accuracy compared with CMR, except for patients with severe left ventricular hypertrophy and systolic reconstruction.

### CLINICAL RELEVANCE/APPLICATION

Fractal analysis by CMR cine images can be used to assess the left ventricular trabecular complexity, and provide incremental prognostic value for adverse cardiac events. This study confirmed the good consistency between FD by CCT and by CMR, which suggests that CT-FD may serve as a more accessible alternative in case CMR is not applicable.

## W5B-SPCA-8 ULTRA-SHORT TERM LEFT VENTRICULAR EJECTION FRACTION ANALYSIS USING CORONARY CT ANGIOGRAPHY

Takuya Matsuda (*Abstract Co-Author*) Nothing to Disclose
Hiroshi Suekuni (*Abstract Co-Author*) Nothing to Disclose
Teruhito Kido, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Takanori Kouchi (*Abstract Co-Author*) Nothing to Disclose

Yuki Tanabe (*Abstract Co-Author*) Nothing to Disclose
Tomoro Morikawa, MD (*Abstract Co-Author*) Nothing to Disclose
SHUN SAWADA (*Presenter*) Nothing to Disclose

### PURPOSE

Coronary computed tomography angiography (CCTA) plays a crucial role in diagnosing coronary artery disease. While prospectively ECG-triggered acquisition is commonly utilized to minimize radiation exposure during CCTA scans, it does not facilitate left ventricular (LV) ejection fraction (EF) analysis. This study aims to assess the feasibility of ultra-short term LVEF (UST-LVEF) analysis based on volumetric changes over 100ms which is also available in prospectively ECG-triggered CCTA with padding technique.

### METHODS AND MATERIALS

This retrospective study included 77 patients who underwent retrospectively ECG-triggered CCTA and cardiac magnetic resonance (CMR). Nine CCTA data sets, each comprising three phases with a 50ms interval, were reconstructed: 1) 0-100ms, 2) 50-150ms, 3) 100-200ms, 4) 150-250ms, 5) 200-300ms, 6) 250-350ms, 7)300-400ms, 8) 350-450ms, and 9) 400-500ms post-QRS. The assessable rate was evaluated at a segment level in the nine CCTA data sets focusing on motion artifact to exclude data sets with poor image quality. UST-LVEF was calculated using the change rate between maximum and minimum LV volumes among the three phases. Additionally, full LVEF was assessed using CCTA data for one cardiac cycle. On the basis of CMR, LV

dysfunction was defined as LVEF <55% and severe LV dysfunction was defined as LVEF <35%. The diagnostic accuracy of UST-LVEF for detecting LV dysfunction was assessed using receiver operating characteristic curve analysis and compared with full LVEF.

**RESULTS**

Of 77 patients, 55 patients were defined as LV dysfunction, including 23 patients with severe LV dysfunction. The assessable rate in CCTA300-400ms was the highest of 96% with no significant difference compared to CCTA200-300ms, CCTA250-350ms, and CCTA350-450ms. The area under the curves (AUC) for detecting LV dysfunction were 0.87, 0.77, 0.67, 0.69, and 0.92 for UST-LVEF200-300ms, UST-LVEF250-350ms, UST-LVEF300-400ms, UST-LVEF350-450ms, and full LVEF, respectively. For detecting severe LV dysfunction, AUCs were 0.88, 0.79, 0.80, 0.82, and 0.97 for UST-LVEF200-300ms, UST-LVEF250-350ms, UST-LVEF300-400ms, UST-LVEF350-450ms, and full LVEF, respectively. There was no significant difference in the AUCs for detecting LV dysfunction and severe LV dysfunction between UST-LVEF200-300ms and full LVEF. However, significant differences in AUCs were observed for the other UST-LVEF in comparison with full LVEF ($p < 0.05$).

**CONCLUSION**

UST-LVEF200-300ms may serve as a comparable indicator to full LVEF for assessing LV dysfunction.

**CLINICAL RELEVANCE/APPLICATION**

In prospectively ECG-triggered CCTA imaging with padding technique, data acquisition at mid-systole timed 200-300ms after the QRS allows for assessing both coronary artery and LV function.

## W5B-SPCA-9 THE SHORTEST DISTANCE BETWEENLEFT ATRIAL APPENDAGEAND LEFT SUPERIORPULMONARY VEINDERIVED FROM CARDIAC COMPUTED TOMOGRAPHY PREDICTS ATRIAL FIBRILLATION RECURRENCE AFTER ABLATION

Yi Xu (*Abstract Co-Author*) Nothing to Disclose
Dandan Wu (*Presenter*) Nothing to Disclose

**PURPOSE**

Many predictors of atrial fibrillation (AF) recurrence after ablation have been described, such as left atrial (LA) enlarged, left atrial appendage (LAA) morphologies, and particular pulmonary vein anatomic variations. The purpose of this study was to investigate the shortest distance between LAA and left superior pulmonary vein(LSPV) derived from cardiac Computed Tomography (CT) in predicting AF recurrence after ablation within 2 years.

**METHODS AND MATERIALS**

Contrast-enhanced cardiac CT images of 342 consecutive AF patients (median age 64 years; 119 females) who underwent initial ablation from August 2018 to December 2021 were retrospectively analyzed. Clinical features and cardiac CT derived quantitative parameters were recorded. The shortest distance between LAA and LSPV(LAA-LSPV) was determined by visual using multiplanar projection images and measured from the posterior wall of LAA to the frontier border of LSPV. The diameter and area of LAA orifice, the LAA depth (LAAD), the LAA volume and LA volume were measured by using dedicated software. The body surface area indexed maximum and minimum volume of LA (LAVImax, LAVImin) and LAA (LAAVImax, LAAVImin) were calculated. Independent predictors of AF recurrence were determined using Cox regression analysis. The clinical model, the imaging model, and the combined model (clinical +imaging) were built to predict recurrence. The predictive performance of these models was assessed using the area under the receiver operating characteristics curve (AUC).

**RESULTS**

106 (31.0%) patients recurred AF within 2 years after ablation at a median follow-up of 24 months (IQR 18, 26). LAVImax, LAVImin, LAAVImax, LAAVImin and LAAD significantly increased in patients with AF recurrence (all $P<0.05$). The proportion of patients with LAA-LSPV<2mm was higher in AF recurrence group (47.2% vs 25.0%, $P<0.001$). Persistent AF (HR=1.600, 95%CI:1.068-2.397, P=0.023), NT-proBNP (HR=1.000, 95%CI: 1.000-1.000, P=0.044), LAAVImax (HR=1.162,95%CI:1.097-1.229,P<0.001) and LAA-LSPV<2mm (HR=1.923,95%CI:1.295-2.856,P=0.001) were independent predictors for AF recurrence. The combined model exhibited superior predictive performance than the clinical model (AUC 0.739 vs 0.656, P=0.006). Kaplan-Meier curves of AF recurrence-free survival shows that patients with LAA-LSPV<2mm (log-rank $P<0.001$) presented a higher risk of AF recurrence.

**CONCLUSION**

Cardiac CT-derived LAA-LSPV<2mm was an independent predictor for AF recurrence after ablation within 2 years and can provide a complementary value for AF recurrence risk assessment.

**CLINICAL RELEVANCE/APPLICATION**

Predicting the risk of post-operative recurrence before ablation is helpful for individualized prevention and treatment plans as for AF patients.

## W5B-SPCH-1 DUAL-ENERGY CT QUANTITATIVE PARAMETERS FOR EVALUATING THE KI-67 EXPRESSION LEVELS IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA

Dechun Zheng, MD (*Abstract Co-Author*) Nothing to Disclose
Jing Sun (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the value of quantitative parameters derived from dual-energy computed tomography (DECT) for evaluating the Ki-67 expression levels of esophageal squamous cell carcinoma (ESCC).

### METHODS AND MATERIALS

Fifty-seven patients with ESCC who underwent enhanced dual-phase DECT scans, including an arterial phase (AP) and venous phase (VP) from June 2019 to August 2020 were enrolled in this study. Iodine concentration (IC), water concentration (WC), normalized iodine concentration (NIC), the slope of the spectral Hounsfield unit curve (?Hu), and effective atomic number parameters (Zeff) of two phases were measured. Univariate and multivariate analyses were conducted to identify independent risk predictors of different Ki-67 expression status. In addition, the diagnostic capability of DECT of the statistically significant parameters was evaluated using receiver operating characteristic (ROC) curve analysis. Sensitivity, specificity, accuracy, and optimal thresholds were determined with 95% confidence intervals using Youden's index.

### RESULTS

The high-expression state of Ki-67 tended to display higher venous phase Zeff and IC compared with the low-expression state of Ki-67 (individually, P = 0.047, 0.049; area under the curve [AUC] of 0.67, 0.67). Patients with lower arterial phase WC had a higher rate of high-expression of Ki-67 than those with higher venous phase WC (P = 0.021; AUC of 0.70).Multiparametric analysis showed that venous phase IC and arterial phase WC were the most independent predictive factors ($p < 0.05$) for differentiating Ki-67 overexpression. The AUC of the two-factor combination for predicting the presence of Ki-67 overexpression was 0.802 (95% CI, 0.677-0.927; $p < 0.001$).

### CONCLUSION

Dual-energy CT parameters held great potential for detecting the Ki-67 status of ESCC.

### CLINICAL RELEVANCE/APPLICATION

Dual-energy spectral CT imaging parameters can provide supplementary information for the characterization of ki-67 status, especially for patients who cannot undergo biopsy or surgery and may be a useful method to guide clinical diagnosis and prognosis

## W5B-SPCH-2 DIAGNOSTIC PERFORMANCE OF NODE-RADS-BASED CLINICAL FEATURES COMBINED WITH CT TEXTURE ANALYSIS FOR PREDICTING THE BENIGN OR MALIGNANT STATUS OF ENLARGED MEDIASTINAL LYMPH NODES

Bin Shi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The conventional assessment of lymph node size possesses inherent limitations and remains a subject of ongoing controversy. The utilization of Node Reporting and Data Systems (Node-RADS) has facilitated the radiographic assessment of mediastinal lymph nodes in clinical practice, as well as the implementation of structured reports. Our study aimed to investigate the diagnostic performance of Node-RADS-based clinical features combined with CT texture analysis in accurately predicting the benign or malignant status of enlarged mediastinal lymph nodes.

### METHODS AND MATERIALS

The present retrospective study included 93 patients with pathologically confirmed 118 enlarged mediastinal lymph nodes (with a short axis =10 mm) that were accurately detected by endobronchial ultrasonography (EBUS). A total of 41 clinical features based on Node-RADS were individually assessed, including subcategories such as gender, age, size, CT values, configuration and Node-RADS scores. Additionally, 1874 texture features were extracted from CT images in venous phase. Feature selection was performed using Pearson Correlation,SelectKBest and LASSO algorithms. Then logistic regression analysis was utilized to construct predictive models. Finally, the diagnostic performance of each model was evaluated by constructing Receiver Operating Characteristic (ROC) curves.

### RESULTS

In discrimination analysis, the most informative predictive cues for constructing the aforementioned models included long axis, short axis, CT value of lesion in venous phase, sum score of configuration, Node-RADS score, as well as six texture features ($p<0.01$). The area under ROC curves of clinical model, radiomics model and conjoint model were 0.8383, 0.8095, 0.8403 in training sets; and 0.7188, 0.8359, 0.875 in testing sets, respectively. The calibration curve demonstrated that the predictive value of the optimal conjoint model remained consistent with the observed values.

### CONCLUSION

The integration of Node-RADS-based clinical features with CT texture analysis demonstrates promising potential in accurately predicting the benign or malignant status of enlarged mediastinal lymph nodes.

### CLINICAL RELEVANCE/APPLICATION

The findings of this study suggest that Node-RADS may serve as a suitable tool for structured reporting of mediastinal lymph nodes. Additionally, incorporating texture analysis could enhance the quantitative prediction in clinical relevance.

## W5B-SPCH-3 SUPER-EFFICIENT AI FOR LUNG NODULE CLASSIFICATION IN CT BASED ON SMALL-DATA MASSIVE-TRAINING ARTIFICIAL NEURAL NETWORK (MTANN)

Ze Jin, PhD (*Abstract Co-Author*) Nothing to Disclose
Takeyuki Watadani, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Osamu Abe, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kenji Suzuki, PhD (*Abstract Co-Author*) Nothing to Disclose
Seyed Mohammad Chavoshian (*Abstract Co-Author*) Nothing to Disclose
Shogo Kodera (*Presenter*) Nothing to Disclose

### PURPOSE

Deep learning (DL) AI for diagnostic aid has been successful in achieving high performance for various diseases. DL, however, requires "big data" for training and substantial work for radiologists to annotate them. To address this issue, we developed a novel approach based on our MTANN that requires a smaller number of cases to train while maintaining high performance in classification between malignant and benign lung nodules in CT.

### METHODS AND MATERIALS

The LIDC-IDRI database, consisting of 1018 chest CT scans with annotations, was used in this study. Our small-data 3D MTANN model employed an image-based teacher scheme and a patch-based learning scheme, which allow small-sample training. Its minimum network architecture with only 17,251 parameters allows super-efficient computation. To verify the performance and efficiency of our small-data model, we conducted two experiments in 10-fold cross-validation tests: Experiment 1 used a training-to-testing sample ratio of 9:1, with 616 training and 68 test nodules, to form a "large training set" scenario; Experiment 2 inverted this ratio to 1:9, with only 68 training and 616 test nodules, to form a "small training set" scenario.

### RESULTS

We evaluated our MTANN and the state-of-the-art DL models, i.e., nnU-Net, 3D ResNet and Vision Transformer (ViT) with transfer learning, using the area under the receiver-operating-characteristic (ROC) curve (AUC). Our model, with merely 0.05%-0.005% of the parameters of the conventional models, significantly surpassed all the state-of-the-art (SOTA) models in efficiency (reduction in training and inference times by factors of 75 and 15, respectively). Our model trained with small and large datasets (68 and 616 cases) achieved remarkable AUC of 0.92 and 0.96 with statistical significance ($P<.05$), compared to 0.59-0.86 and 0.83-0.89, respectively, by the SOTA models.

### CONCLUSION

We developed super-efficient AI based on a small-data MTANN model for lung nodule classification in CT (with an inference time of 8.15 ms), which achieved the highest performance (AUC of 0.92) of all SOTA models while using a small training dataset (only 68 cases). Our small-data model would resolve the issue of the requirement of "big data" for DL models; and it would mitigate the challenges for small to medium-sized hospitals due to the lack of the availability of a large number of cases.

### CLINICAL RELEVANCE/APPLICATION

Our small-data MTANN-based AI system would be helpful in assisting radiologists in efficient and effective diagnostic aid under the limited resources of training cases and computational power.

## W5B-SPCH-4 PREDICTING PULMONARY METASTATIC NODULES AT CHEST CT WITH MULTIMODAL DATA-BASED DEEP LEARNING MODELS IN PATIENTS WITH COLORECTAL CANCER

Qiuxia Yang (*Abstract Co-Author*) Nothing to Disclose
Jiahui Xu (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a multimodal data-based deep learning (DL) model for predicting metastatic nodules on enhanced thin-section chest CT in patients with colorectal cancer and investigate the potential improvement of model efficiency by incorporating a novel probabilistic fusion method.

### METHODS AND MATERIALS

A retrospective study encompassing 3367 nodules (2033 metastatic and 1334 benign) from 619 patients between January 2017 and April 2021 was conducted. These nodules were randomly divided into training (n = 2991), validation (n = 125), and testing cohort (n = 251). Six DL models were constructed to predict pulmonary metastatic nodules. Initially, three base models were developed: model 1 (DenseNet model), model 2 (MilNet + DenseNet model), and model 3 (Clinical information + MilNet + DenseNet model). Subsequently, an enhanced version of these models (models 4-6) was introduced, which integrated a novel probabilistic fusion technique that considers the maximum lesion probability (lesion_prob_max) for each individual patient. Model performance was evaluated using the area under curve (AUC), accuracy, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and F1-score.

### RESULTS

In testing cohort, the multimodal DL model with novel probabilistic fusion (model 6) achieved AUC 0.957 (95%CI: 0.935-0.980), accuracy 0.896, sensitivity 0.895, specificity 0.897, PPV 0.862, NPV 0.923, and F1-score 0.878. In comparison, without fusion (model 3), AUC was 0.950 (95%CI: 0.924-0.976), accuracy 0.884, sensitivity 0.886, specificity 0.884, PPV 0.845, NPV 0.915, and F1-score 0.865. The incorporation of a novel probabilistic fusion method demonstrated improvement of model efficiency.

### CONCLUSION

The multimodal data-based DL model incorporating a novel probabilistic fusion method, which takes into account the maximum lesion probability per patient, demonstrated excellent efficiency in predicting pulmonary metastatic nodules in patients with colorectal cancer.

### CLINICAL RELEVANCE/APPLICATION

This multimodal DL model, augmented by the probabilistic fusion method, has the potential to serve as a valuable adjunctive tool in clinical practice, assisting in the early detection and management of pulmonary metastases in patients with colorectal cancer.

## W5B-SPCH-5 SINGLE CLICK LUNG LESION SEGMENTATION AND TRACKING ACROSS LONGITUDINAL SCANS: COMPARISON WITH MANUAL ANNOTATION FOR TREATMENT MONITORING IN IMMUNOTHERAPY

Anant Madabhushi, PhD (*Abstract Co-Author*) Stockholder, Elucid Bioimaging Inc;License agreement, Elucid Bioimaging Inc;Stockholder, Inspirata, Inc;Grant, Inspirata, Inc;Scientific Advisory Board, Inspirata, Inc;Researcher, AstraZeneca PLC;Scientific Advisory Board, AstraZeneca PLC

### PURPOSE

Accurate tracking of lesion size is crucial in evaluating treatment response in oncology, yet it relies on time-consuming and often subjective manual measurement by radiologists. We have developed a single-click, multi-timepoint monitoring tool, ClickTrack, for delineating and tracking size of lesions across CT scans throughout treatment. We evaluate ClickTrack's ability to track changes in lung lesion size for treatment monitoring in the immunotherapy setting.

### METHODS AND MATERIALS

ClickTrack was evaluated on a dataset of 69 non-small cell lung cancer (NSCLC) patients receiving immunotherapy, each with a pre-treatment and follow-up scan 6 weeks later. From a single user-selected click point within a lesion on the pre-treatment scan, the system segments and measures the lesion across all imaging timepoints. Sum of lesion diameters (SLD) are computed for up to 2 target lesions. The algorithm was compared against measurements from manual annotations from two radiologists working in consensus. We computed the Pearson correlation coefficient (r) and Intraclass Correlation Coefficient (ICC) for both SLD measurements and percent change in lesion size between scans.

### RESULTS

The semi-automated SLD showed a strong correlation and agreement with manual measurements, yielding r=0.87 ($p < 1e-10$) and ICC=0.86 ($p < 1e-10$, CI 95%: 0.79 - 0.91) for the pre-treatment scans. Correlation was similarly high for on-treatment scans, with r=0.81 ($p < 1e-10$) and ICC=0.79 ($p < 1e-10$, CI 95%: 0.68 - 0.87), demonstrating accurate follow-up measurement without further user guidance. The percent change in SLD over time calculated by ClickTrack also aligned closely with manual evaluation (r: 0.71, $p < 1e-10$; ICC: 0.71, CI 95%: 0.56 - 0.81, $p < 1e-10$).

### CONCLUSION

ClickTrack, a system for longitudinal segmentation and monitoring of lesions across exams throughout cancer treatment, showed robust accuracy and reliability in SLD measurements and size changes of lung lesions compared to manual readers.

### CLINICAL RELEVANCE/APPLICATION

A semi-automated lesion tracking system could significantly accelerate response monitoring in both the clinical care and clinical trial settings, requiring only a single radiologist click to segment and track lesions across follow-up imaging.

## W5B-SPCH-6 DEEP LEARNING-BASED DETECTION OF LUNG NODULES ON WHOLE-BODY MAGNETIC RESONANCE IMAGING (WB-MRI) FOR CANCER SCREENING

Giuseppe Petralia, MD (*Abstract Co-Author*) Nothing to Disclose
Cristiano Girlando, MD (*Abstract Co-Author*) Nothing to Disclose
Fabio Zugni (*Abstract Co-Author*) Nothing to Disclose
Cornelius Jacob (*Presenter*) Nothing to Disclose

### PURPOSE

Lung nodules serve as critical indicators of emerging malignancies, necessitating accurate detection for early intervention. While whole-body MRI (WB-MRI) has shown efficacy in early cancer detection, a significant challenge persists due to the abundance of images across various contrasts, leading to time-intensive and error-prone image interpretation. This study aims to address this issue by developing and evaluating a deep learning (DL) model for the detection of lung nodules in WB-MRI for cancer screening (CS). The objective is to evaluate the potential of artificial intelligence (AI) compared to the performance of human readers in assessing lung nodules in WB-MRI of the general population.

### METHODS AND MATERIALS

A training dataset comprising 100 case-positive WB-MRI CS studies, including voxel-based annotations verified by a junior radiologist (5 years of experience in chest imaging), was used for network training. We utilized the nnDetection framework for DL development, using designated thoracic T1 GRE high-spatial-resolution images as network input. Performance evaluation was performed on a test dataset applying receiver operating characteristic (ROC) and free-response receiver operating characteristic (FROC) analysis. The dataset consisted of 148 consecutive WB-MRI CS studies, including 37 nodules (2.8 mm to 7.7 mm in diameter), across 33 patients. Ground truth was annotated by a senior radiologist with 20 years of experience in chest imaging. To compare AI's performance with human readers, we assessed the detection performance of six radiologists, divided into a junior radiologist group (5-8 years of experience in chest imaging) and a radiology resident group (1-2 years of experience in chest imaging).

### RESULTS

The DL network demonstrated comparable performance to both the junior reader group (AI: 53.0% Sensitivity (SE) at 0.06 false positives per patient (FPPP); junior radiologist group: 46.8% mean SE at 0.06 mean FPPP) and the radiology resident group (36.0% mean SE at 0.01 mean FPPP). At

increased false positive rates of 1.0 FPPP and 2.23 FPPP, the AI achieved a maximum SE of 92.1% and 100%, respectively. The patient-level Area Under the Curve (AUC) of the AI was 0.89.

**CONCLUSION**

Our study demonstrates the efficacy of a DL algorithm for detecting lung nodules in WB-MRI for CS. Our DL model exhibited performance on par with human readers which underscores the potential of incorporating AI-driven solutions into WB-MRI image evaluation.

**CLINICAL RELEVANCE/APPLICATION**

This study exhibits the potential of DL algorithms in WB-MRI for CS. By demonstrating comparable performance to human readers, we highlight a promising avenue for integrating AI into clinical workflows and streamline CS to improve early cancer detection and patient outcomes.

## W5B-SPCH-7 ANNOTATION-FREE AI LEARNING OF LUNG NODULE SEGMENTATION IN CT USING WEAKLY-SUPERVISED MASSIVE-TRAINING ARTIFICIAL NEURAL NETWORKS

Yuqiao Yang, MS (*Abstract Co-Author*) Nothing to Disclose
Tianyi Qu (*Abstract Co-Author*) Nothing to Disclose
Kenji Suzuki, PhD (*Abstract Co-Author*) Nothing to Disclose
Ze Jin, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Deep learning (DL) models show excellent performance in segmentation tasks, but their high-performance training requires a large number of cases with precise manual annotations by radiologists. We developed a novel annotation-free approach to segmentation of lung nodules in CT using weakly-supervised massive-training artificial neural networks (MTANNs). Instead of relying on precise manual annotations, our AI started from initial inexact labels which are free from annotations and proceeded with iterative refinements of the labels to realize annotation-free learning.

**METHODS AND MATERIALS**

In this study, we used the Lung Nodule Analysis 2016 (LUNA16) dataset, which included 888 thoracic CT scans featuring 1186 lung nodule candidates along with numerous non-nodule candidates. Our weakly supervised learning methodology was centered on an iterative training process that incrementally refined initial inexact teaching image labels by using an explainable AI (XAI) method within massive-training artificial neural networks (MTANNs). The process started with a rough Gaussian distribution image based on initial knowledge on lung structures. During each iteration, function maps generated by the XAI method in the MTANN model were utilized as refined teaching image labels. This iterative cycle continued until the performance did not improve further, at the point where the label images closely resembled manual segmentation.

**RESULTS**

Our proposed weakly supervised learning method refined the initial inexact teaching image label with a rough Gaussian distribution and created more exact segmentation labels as the training iterations went. During three iterative training cycles, the segmentation performance in terms of Dice scores of our weakly-supervised MTANN model increased from 0.716, to 0.753, and 0.788 ($P << 0.05$), which approached to a Dice score of the "gold-standard" fully-supervised model (trained with radiologists' manual segmentation) of 0.794 without statistical significance ($P > 0.05$).

**CONCLUSION**

We developed a revolutionary "annotation-free" scheme for the segmentation of lung nodules in CT, which eliminated the need for radiologists' manual precise annotations, but only using "one-click" input on the nodule by a person.

**CLINICAL RELEVANCE/APPLICATION**

Our "annotation-free" AI model performed on par with the gold-standard fully-supervised model in lung nodule segmentation in CT, which eliminated the need for labor-intense manual segmentation by radiologists.

## W5B-SPCH-8 SPEED AND EFFICIENCY: EVALUATING PULMONARY NODULE DETECTION WITH AI-ENHANCED 3D GRADIENT ECHO IMAGING

Kilian Weiss, PhD (*Abstract Co-Author*) Employee, Koninklijke Philips NV

Tristan Lemke (*Abstract Co-Author*) Nothing to Disclose
Sebastian Ziegelmayer, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander W. Marka, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aims to evaluate the diagnostic feasibility of accelerated pulmonary MR imaging for the detection and characterization of pulmonary nodules using artificial intelligence-boosted compressed sensing.

**METHODS AND MATERIALS**

A prospective trial was conducted with patients who had benign and malignant lung nodules and were admitted between December 2021 and December 2022. Participants underwent chest CT and pulmonary MRI using a respiratory-gated 3D gradient echo sequences. The MRI was accelerated using a combination of parallel imaging, compressed sensing, and deep learning, with three different acceleration factors (CS-AI 7, CS-AI 10, and CS-AI 15). Two readers, blinded to the CT results, evaluated image quality (using a 5-point Likert scale), nodule detection, and characterization (size, morphology) for all sequences. Reader agreement was determined using the intraclass correlation coefficient (ICC).

**RESULTS**

A total of 37 patients with 64 pulmonary nodules were analyzed in the study. Of these nodules, 65.5% were metastases, 12.5% were primary lung cancer, and 22% were benign (inflammatory or granuloma). The nominal scan times for the different acceleration factors were CS-AI 7 at 3:53 minutes, CS-AI 10 at 2:34 minutes, and CS-AI 15 at 1:50 minutes. The lowest acceleration factor (CS-AI 7) showed significantly higher image quality; however, image quality for all examined structures remained diagnostic even with the highest acceleration factor (CS-AI 15). Detection rates of pulmonary nodules were 100%, 98.4%, and 96.8% for CS-AI 7, CS-AI 10, and CS-AI 15, respectively. Nodule morphology was best assessed with the lowest acceleration

and was substantially inferior to CT in 5% of cases, compared to 10% for CS-AI 10 and 23% for CS-AI 15. The nodule size was comparable for all sequences, with an average deviation of <1 mm from the CT size.

**CONCLUSION**

The combination of compressed sensing and AI allows for a substantial reduction in lung MRI scan time while maintaining a high detection rate for pulmonary nodules. Although subjective image quality decreases with increasing acceleration, the images remain diagnostic and nodule size can be accurately displayed.

**CLINICAL RELEVANCE/APPLICATION**

Incorporating compressed sensing and AI in pulmonary MRI achieves significant time savings without compromising nodule detection or characteristics. This advancement holds clinical promise, enhancing efficiency in lung cancer screening without sacrificing diagnostic quality.

## W5B-SPCH-9 CT-BASED RADIOMICS NOMOGRAM OF LUNG AND MEDIASTINAL FEATURES TO IDENTIFY CARDIOVASCULARDISEASE IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE: A MULTICENTER STUDY

Xiaoqing Lin (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the performance of a CT-based lung or mediastinum or combined lung and mediastinum radiomics nomogram for identifying cardiovascular disease (CVD) in patients with chronic obstructive pulmonary disease (COPD).

**METHODS AND MATERIALS**

In total, 686 participants with COPD (328, 140 and 218 in training, internal and external validation cohorts, respectively) were included. Clinical data and visual coronary artery calcification (CAC) scores were analyzed. Radiomics features of whole lung and mediastinum were extracted from non-contrast chest CT images. Lung, mediastinum, and combined lung and mediastinum radiomics signatures were constructed. Multivariate logistic regression analysis was used to establish lung, mediastinum, combined lung and mediastinum radiomics nomograms, also including clinical risk factors, with AUC as outcome. The performance of the radiomics nomogram was evaluated by receiver operating characteristic curves, calibration curves and decision curve analysis.

**RESULTS**

Age, neutrophilic granulocyte percentage, hematokrit and GOLD were independent clinical risk factors for CVD in COPD patients. 1218 lung, 1218 mediastinum, and 2436 combined lung and mediastinum features were extracted, then reduced to 12, 6 and 6 features to build radiomics signatures, respectively. In the training cohort, internal and external validation cohort, the 3 models of radiomics combined with clinical factors(AUC: 0.788; 0.863; 0.863) showed better discriminatory capability ($p<0.05$) than the clinical risk factors model(AUC: 0.707) and visual CAC score model (AUC: 0.646), respectively. There was no significant difference in AUC between 3 combined models in internal and external validation cohorts($p>0.05$). Decision curve analysis demonstrated the lung, mediastinum, and combined lung and mediastinum nomograms outperformed the clinical factors model across the majority of the range of reasonable threshold probabilities.

**CONCLUSION**

We developed 3 CT-based nomograms to identify CVD in COPD patients, indicating radiomics nomogram on chest CT in COPD may help in CVD assessment, especially the whole-lung radiomics nomogram, suitable for lung cancer screening to screen COPD.

**CLINICAL RELEVANCE/APPLICATION**

We developed and compared 3 CT-based nomograms to identify CVD in COPD patients, all of them showed good performance, indicating each of them could identify the CVD in patients with COPD, especially the whole-lung radiomics nomogram, suitable for the large scale of lung cancer screening to screen COPD.

## W5B-SPER-1 INCIDENCE OF CONTRAST-INDUCEDACUTE KIDNEY INJURY (CI-AKI)INTRAUMA PATIENTS UNDERGOING CONTRAST-ENHANCED COMPUTEDTOMOGRAPHY USING ISO-OSMOLAR CONTRAST AGENT

Jimi Huh, MD (*Abstract Co-Author*) Nothing to Disclose
Jayoung Moon, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Iodixanol is a nonionic dimeric iso-osmolar contrast agent with expected effect to reduce contrast-induced acute kidney injury (CI-AKI). In trauma patients, no report has been published on the preventive effect of iso-osmolar contrast agent for CI-AKI. Thus, we aimed to evaluate the incidence and severity of CI-AKI, and those predictive factors in trauma patients.

### METHODS AND MATERIALS

From the institutional trauma registry in a regional trauma center of South Korea, patients who underwent CT scan with iodixanol and followed up at least 72 hours after CT scan were consecutively included. Patient demographic details, co-morbidities and laboratory test results were collected. CI-AKI was defined by the 2012 Kidney Disease Improving Global Outcomes (KDIGO) guideline. The severity of CI-AKI was classified by the RIFLE criteria. The severity of trauma was assessed by the injury severity score (ISS) category. The predictive factors of CI-AKI were evaluated by univariate and multivariate logistic regression.

### RESULTS

Of 1115 patients who underwent CT with iodixanol, 799 with completed data were included in this study. The incidence of CI-AKI was 3.80% (30/799). Of these, severe renal failure according to RIFLE criteria was 2.87% (23/799). The incidence of CI-AKI according to the ISS category were 1.52% (9/592) in minor group, 3.95% (7/177) in moderate group, 42.30% (11/26) in serious group, and 75.0% (3/4) in severe group. In univariate analysis, significant predictive factors of CI-AKI based odds ratio (OR) included hypertension [2.87 (95% CI, 1.37-6.00)], heart disease [4.06 (95% CI, 1.32-12.42)], ISS serious category [47.50 (95% CI, 17.14-131.63)], and ISS severe category [194.33 (95% CI, 18.40-2052.06)]. In multivariate analysis, significant predictive factors were ISS serious category [16.70 (95% CI, 16.70-138.96], and ISS severe category [245.22 (95% CI, 21.88-2748.38)].

### CONCLUSION

In trauma patients who underwent CT with iodixanol, the overall incidence of CI-AKI of 3.8% (30/799) was considerably low. The main predictive factors of CI-AKI involved hypertension, heart diseases and ISS serious and severe category, but its incidence and severity largely relied on the severity of trauma.

### CLINICAL RELEVANCE/APPLICATION

In trauma patients, the CT scans with iodixanol might be helpful to reduce the occurrence of CI-AKI.

## W5B-SPER-2 DIAGNOSTIC PERFORMANCE OF ANKLE ULTRASOUND FOR DIAGNOSING ANTERIOR TALOFIBULAR AND CALCANEOFIBULAR LIGAMENT INJURIES. A META-ANALYSIS

Sun Hwa Lee (*Abstract Co-Author*) Nothing to Disclose
Seong Jong Yun, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

This meta-analysis was aim to evaluate the diagnostic performance of ankle ultrasound for anterior tibiofibular ligament (ATFL) and calcaneofibular ligament (CFL) injuries.

### METHODS AND MATERIALS

PubMed and EMBASE databases were searched for diagnostic accuracy studies that used ultrasound for diagnosing ATFL and CFL injuries. Bivariate and hierarchical summary receiver operating characteristic (HSROC) modeling were used to evaluate diagnostic performance. Subgroup analysis was performed using studies according to severity of the injury (complete and partial ATFL tear). We performed meta-regression analyses for heterogeneity exploration.

### RESULTS

Ten articles involving a total of 380 patients were included. For ATFL injury, the summary sensitivity, summary specificity, and area under the HSROC (AUC) were 0.99, 0.92, and 0.99, respectively. For CFL injury, the summary sensitivity, summary specificity, and AUC were 0.95, 0.99, and 0.95,

respectively. In subgroup analysis, for complete ATFL tear, the summary sensitivity, summary specificity, and AUC were 0.96, 0.82, and 0.96, respectively. For partial ATFL tear, the summary sensitivity, summary specificity, and AUC were 0.90, 0.82, and 0.93, respectively. Among the various potential covariates, proportion of ATFL tear ($p<0.01$), ultrasound interpreter ($p=0.03$), and reference standard ($p<0.01$) were associated with specificity heterogeneity.

**CONCLUSION**

Ankle ultrasound demonstrates high diagnostic performance in the diagnosis of ATFL and CFL injuries. We recommend ultrasound performed by a musculoskeletal radiologist as a first-line diagnostic tool to diagnose ATFL and CFL injuries.

**CLINICAL RELEVANCE/APPLICATION**

Using US, accurate and timely diagnoses of ATFL and CFL injuries are possible without invasiveness or radiation.

## W5B-SPGI-11 DUAL-ENERGY CT-BASED RADIOMICS SIGNATURE IN PREDICTING THE PROGNOSIS OF RESECTABLE ADVANCED GASTRIC CANCER PATIENTS

LI YANG (*Abstract Co-Author*) Nothing to Disclose
Ao Liu (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to develop a radiomics prognosis model based on dual-energy computed tomography (DECT) venous-phase iodine map (IM) and 120 kVp equivalent mixed images (MIX) to predict the 1,3 and 5 years of overall survival (OS) and disease-free survival (DFS) of resectable advanced gastric cancer patients, thereby providing personalized treatment for patients.

### METHODS AND MATERIALS

183 resectable advanced gastric cancer patients underwent DECT scans. Radiomics features were extracted from manually segmented volume of interest (VOI) of the IM and MIX images by using the radiomics software. The least absolute shrinkage and selection operator (LASSO) algorithm and multivariate Cox regression analysis were used to determine the optimal texture features and build a radiomics prognosis model. Calculated Radscore based on radiomics features and correlation coefficients. Performed a Cox regression analysis on all clinical factors and select variables with P values<0.05 in univariate and multivariate analysis as risk factors to build a clinical prognosis model. Incorporated Radscore as an independent risk factor into the clinical prognosis model to construct a clinical-radiomics combined prognosis model. Compared the predictive performance of three models.

### RESULTS

Training set (n=128) and testing set (n=55) were randomly assigned at a ratio of 7:3. There was no statistically significant difference in baseline information between two sets. After correlation analysis and LASSO-COX regression analysis, 26 and 18 features were selected from 3382 to predict the OS and DFS of patients, of which 15 and 10 were derived from IM. Performed threshold effect analysis on Radscore and divided patients into low- and high-risk groups. The Log Rank test confirmed a statistically significant difference between the two groups(P<0.001). Chemotherapy, CEA, CA199 and stage were selected to predict the OS of patients. CEA was selected to predict the DFS of patients. The radiomics prognosis model has better predictive performance in predicting OS and DFS and a higher C-index(C-index of radiomics, clinical-radiomics combined and clinical prognosis model:0.89 vs. 0.85 vs. 0.74 and 0.85 vs. 0.79 vs. 0.61).

### CONCLUSION

The radiomics signature successfully stratified those patients into high- and low-risk groups with significant differences in DFS and OS. The radiomics prognosis model performed better than the clinical prognosis model, demonstrating well the incremental value of the radiomics signature for individualized DFS and OS estimation.

### CLINICAL RELEVANCE/APPLICATION

The radiomics prognosis model developed based on DECT could help clinicians determine which patients will benefit from more intensified treatment and prevent overtreatment in low-risk patients.

## W5B-SPGI-12 COMBINING RADIOMICS AND ARTIFICIAL INTELLIGENCE-BASED PATHOLOGICAL FEATURES TO PREDICT THE PROGNOSIS OF STAGE II COLORECTAL CANCER: A MULTI-CENTER RETROSPECTIVE STUDY

Zening Rong (*Abstract Co-Author*) Nothing to Disclose
Tong Tong, PHD (*Abstract Co-Author*) Nothing to Disclose
Huifen Ye, MMEd (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the predictive value of integrating radiomics features and artificial intelligence-based pathological features for prognosis and the benefit of postoperative adjuvant chemotherapy in stage II colorectal cancer (CRC) patients.

### METHODS AND MATERIALS

This study retrospectively included stage II CRC patients underwent CT examination and surgical treatment from 3 independent centers. CT radiomics features were extracted using PyRadiomics and pathological features were defined and calculated based on the tissue and nuclei segmentation using U-Net on HE-stained whole-slide images. To predict patients' survival, we developed radiomics model, pathological model and clinical model using Cox proportional hazards regression. Then a Patho-Radio model and a Patho-Radio-Clinical model were constructed. We used C-index and AUC to evaluate

model's performance. Pearson correlation coefficients between radiomics features and pathological features were calculated. Kaplan-Meier survival analysis was conducted to compare the prognosis between the high-risk group and low-risk group divided by models.

**RESULTS**

660 stage II CRC patients from 3 institutions were enrolled in this study (406 in the training cohort and 254 in the validation cohort). The Patho-Radio model exhibited improved OS prediction (C-index = 0.665, AUC = 0.682) over the Radiomics model (C-index = 0.638, AUC = 0.651) and Pathological model (C-index = 0.600, AUC = 0.599) in the external validation cohort, and the Patho-Radio-Clinical model demonstrated best performance (C-index = 0.727, AUC = 0.762). Kaplan-Meier analysis revealed distinct OS and DFS between high-risk and low-risk groups divided by all models in 2 cohorts ($p < 0.05$). Patients predicted as low-risk showed no significant difference in overall survival with or without adjuvant chemotherapy ($p = 0.58$), while for patients predicted as high-risk, postoperative adjuvant chemotherapy significantly improved survival ($p = 0.02$).

**CONCLUSION**

The fusion model integrating radiomics features, pathological features, and clinical risk factors can effectively predict the prognosis of stage II CRC patients and the benefit of adjuvant chemotherapy. Its performance surpasses that of single-modal models and exhibits robust performance in the external validation cohort.

**CLINICAL RELEVANCE/APPLICATION**

The Patho-Radio-Clinical model offers a comprehensive approach for guiding personalized clinical decision-making of stage II CRC patients.

## W5B-SPGI-13 PREDICTION OF PANCREATIC DUCTAL ADENOCARCINOMA GRADING USING DYNAMIC NOMOGRAM CONSTRUCTED ON THE BASIS OF CT FEATURES AND EXTRACELLULAR VOLUME FRACTION

Jiadong Song (*Abstract Co-Author*) Nothing to Disclose
Yang Dong (*Abstract Co-Author*) Nothing to Disclose
Meng Zhang (*Abstract Co-Author*) Nothing to Disclose
Tianyu Zhao (*Abstract Co-Author*) Nothing to Disclose
Wenhao Guan (*Abstract Co-Author*) Nothing to Disclose
Jinzhi Yang (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the value of CT imaging features and extracellular volume fraction (ECV) in the pathological grading evaluation of pancreatic ductal adenocarcinoma (PDAC) and construct a dynamic nomogram for predicting the pathological grading of PDAC.

**METHODS AND MATERIALS**

Patients with low- and high-grade PDAC who underwent unenhanced and equilibrium contrast-enhanced CT with a single-energy scanner between January 2018 and July 2023 were identified retrospectively. For each lesion, the CT features were analyzed, including location, tumor maximum diameter, bile duct dilatation, main pancreatic duct dilatation, pancreatic atrophy, peripancreatic tumor infiltration, suspicious lymph node metastasis, necrosis, arterial (celiac trunk, superior mesenteric artery, and common hepatic artery) involvement, portal and superior mesenteric vein involvement. The unenhanced and equilibrium contrast-enhanced attenuation in the solid area of PDAC and the aortic lumen at the same level were measured. CTenhancement (tumor equilibrium contrast-enhanced minus unenhanced attenuation [HU]) and ECV ((1- hematocrit) × [(tumor CT valueequilibrium - tumor CT valueunenhancement)/ (aortic CT valueequilibrium - aortic CT valueunenhancement)]×100%) were calculated. CT features and ECV were statistically analyzed for correlation with PDAC pathological grading. Multivariate logistic regression analysis was used to construct a diagnostic nomogram containing statistically significant features. Using the web application-R shiny and the R programming language software to build an immediately adjustable dynamic nomogram.

**RESULTS**

A total of 103 patients (65.1±10.3 years, 66 men) with PDAC were analyzed, including 46 cases of low-grade and 57 cases of high-grade. Tumor maximum diameter, necrosis, distant metastasis, CTenhancement, and ECV were significantly higher in low-grade vs high-grade PDAC ($P = 0.003$, 0.023, 0.007, 0.004, 0.015). ECV significantly correlated with the PDAC pathological grading ($P = 0.04$, $r = -0.240$). The combination of the significant parameters above had the highest area under the ROC curve (AUC = 0.73). Furthermore, we developed a dynamic web application utilizing the constructed nomograms available at https://liexiantu1.shinyapps.io/dynnomapp/.

**CONCLUSION**

CT features and ECV could provide information for the pathological grading diagnosis of PDAC. Dynamic nomogram based on the CT images could provide high diagnostic efficacy.

**CLINICAL RELEVANCE/APPLICATION**

The combination of the proposed CT features and ECV may contribute to evaluate the prediction of PDAC pathological grading. Meanwhile, we developed a network-based dynamic nomogram to assist doctors in preoperative evaluation of the PDAC pathological grading.

## W5B-SPGI-2 NEW METHOD TO EVALUATE CT COLONOGRAPHY USING TEXTURE ANALYSIS

Hisahiro Matsubara, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Atsushi Hirata (*Abstract Co-Author*) Nothing to Disclose
Gaku Ohira (*Abstract Co-Author*) Nothing to Disclose
Koichi Hayano, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Yoshihiro Kurata (*Abstract Co-Author*) Nothing to Disclose
Toru Tochigi, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

The texture analysis is a technique to quantify the heterogeneity of the figure. Recently some studies focused on the biomarker acquired by using texture analysis. We have studied computed tomographic colonography (CTC) images using texture analysis and tried to apply them to the prediction of the treatment effect of chemotherapy or diagnosis of malignancy of the tumor. The purpose of this study is to investigate whether texture analysis of CTC images could be a novel biomarker for colorectal cancer (CRC).

**METHODS AND MATERIALS**

This retrospective study investigated 263 patients with CRC who underwent contrast-enhanced CTC (CE-CTC) before curative surgery between January 2014 and December 2017. Multiple texture analyses (fractal, histogram, and gray-level co-occurrence matrix (GLCM) texture analyses) were applied to

CE-CTC (portal-venous phase), and fractal dimension (FD), skewness, kurtosis, entropy, and GLCM texture parameters, including GLCM-correlation, GLCM-autocorrelation, GLCM-entropy, and GLCM-homogeneity, of the tumor were calculated. These texture parameters were compared with pathological factors (tumor depth, lymph node metastasis, vascular invasion, and lymphatic invasion) and the overall survival (OS).

**RESULTS**

Tumor depth was significantly associated with FD, kurtosis, entropy, GLCM-correlation, GLCM-autocorrelation, GLCM-entropy, and GLCM-homogeneity (P=0.001, 0.001, 0.001, 0.001,0.018, 0.008, and 0.001, respectively); lymph node metastasis was associated with GLCM-homogeneity (P=0.004); lymphatic invasion was associated with GLCM-correlation and GLCM-homogeneity (P=0.001 and 0.012, respectively); and venous invasion was associated with FD, entropy, GLCM-correlation, GLCM-autocorrelation, and GLCM-entropy of the tumor (P=0.001, 0.033, 0.021, 0.046, respectively). In the Kaplan-Meier analysis, patients with high GLCM-correlation tumors or high GLCM-homogeneity tumors showed significantly worse OS than others (P=0.001 and 0.04, respectively). Multivariate analyses showed that the GLCM correlation was an independent prognostic factor for the OS (P=0.021).

**CONCLUSION**

texture parameters derived from CE-CTC may be clinically useful biomarkers for assessing the malignancy of CRC.

**CLINICAL RELEVANCE/APPLICATION**

texture analysis with CTC could give us beneficial information for practice and is useful for tailor-made medicine.

## W5B-SPGI-3 MRI DIAGNOSTIC PERFORMANCE IN THE EVALUATION OF THE DEGREE OF TUMOR REGRESSION IN RECTAL CANCER FOLLOWING NEOADJUVANT TREATMENT

Vicente Martinez de Vega, PhD (*Abstract Co-Author*) Nothing to Disclose
David Garcia, MD (*Abstract Co-Author*) Nothing to Disclose
Alejandro Diaz Moreno, MD (*Abstract Co-Author*) Nothing to Disclose
Mar Jimenez (*Abstract Co-Author*) Nothing to Disclose
Ana Fernandez Alfonso (*Abstract Co-Author*) Nothing to Disclose
Lucia Sanabria, MD (*Abstract Co-Author*) Nothing to Disclose
Julia Lopez Alcolea, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

• Locally advanced lower rectal tumors typically require treatment with abdominoperineal amputation, resulting in permanent colostomy and significant psychological impact on the patient. • Therefore, identifying 'good responders' to neoadjuvant treatment would be highly beneficial, as they could be managed with less aggressive approaches, such as endoanal resection surgery or even adopting a 'wait and see' surveillance strategy, with the option for rescue surgery if needed.

**METHODS AND MATERIALS**

We designed an observational, descriptive and retrospective study, which included patients with locally advanced rectal cancer (stages T4, T3, and/or with lymph node involvement) diagnosed by MRI and endoscopy, evaluated in a multidisciplinary committee of digestive oncology, who underwent neoadjuvant treatment with chemoradiotherapy at our center from 2015 to 2020, resulting in a sample size of 39 patients.The degree of tumor regression was assessed with a second MRI ((MR-TRG) using the Mercury Guide (2016)) and endoscopy, followed by surgery with subsequent histopathological analysis of the specimen using the Modified Ryan scheme (p-TRG) CAP 2020 protocols (College of American Pathologists). Patients were classified as good responders (MRI-TRG I and II, Ryan score 0-1), moderate responders (MRI-TRG III, Ryan score 2), and poor responders (MRI-TRG IV and V, Ryan score 3) to study the correlation between MRI and pathological anatomy results. Good responders were identified on the second post-treatment MRI to consider non-surgical treatment strategies.

**RESULTS**

The degree of agreement between MRI and histopathological response was fair (Cohen's Kappa= 0.305), consistent with findings from previous studies.

**CONCLUSION**

The agreement between radiologists and pathologists is fair. Therefore, MRI cannot be considered a precise predictor of rectal tumor regression post-neoadjuvant treatment.

**CLINICAL RELEVANCE/APPLICATION**

Locally advanced lower rectal tumors typically require treatment with abdominoperineal amputation, resulting in permanent colostomy and significant psychological impact on the patient. Therefore, identifying 'good responders' to neoadjuvant treatment would be highly beneficial, as they could be managed with less aggressive approaches, such as endoanal resection surgery or even adopting a 'wait and see' surveillance strategy, with the option for rescue surgery if needed.

## W5B-SPGI-4 THE CLINICAL VALUE OF SPECTRAL CT MULTIPARAMETER IN THE DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS OF DUODENAL TUMORS

Bo Duan (*Abstract Co-Author*) Nothing to Disclose
Ruibo Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

Energy spectrum CT measured the iodine concentration (IC) and standardized iodine concentration (NIC) of lesions to evaluate the accuracy of benign and malignant duodenal tumors, and to guide clinical treatment decisions.

**METHODS AND MATERIALS**

33 patients with duodenal tumor were selected as research objects, and the patient's pathologically confirmed and complete energy spectrum CT data before surgery were retrospectively collected, and the iodine concentration (IC) and standardized iodine concentration in the arterial and venous stages of the parenchymal area of the lesion were analyzed (the ratio of iodine concentration of the lesion to the iodine concentration of the aorta in the same layer, NIC). The diagnostic compliance rate of energy spectrum CT was calculated based on the pathological results, and the IC and NIC values of the parenchymal region of the lesion were used to evaluate the diagnostic efficacy of duodenal tumors.

**RESULTS**

The pathological results of the enrolled patients were 6 benign tumors (3 adenomas, 2 lipomas, 1 schwannoma), tumors with malignant potential (12 stromal tumors), and 15 malignant tumors (15 adenocarcinomas). The diagnostic compliance rate of energy spectrum CT was 73%; The IC and NIC

values of stromal tumor and adenocarcinoma in the arterial and venous stages were greater than those of benign tumors, with statistically significant differences ($p<0.05$), the area under the curve (AUC) in the arterial stage IC and NIC stage was 0.827 and 0.863, and the area under the curve (AUC) in the venous stage was 0.842 and 0.890, respectively.

**CONCLUSION**

Multi-parameter energy spectrum CT is helpful for the diagnosis and differential diagnosis of duodenal tumors, among which venous phase NIC has the best diagnostic performance.

**CLINICAL RELEVANCE/APPLICATION**

Multiparametric quantitative analysis of duodenal tumors by spectral CT

## W5B-SPGI-5 PREVALENCE AND MISSED RATE OF SACROILIITIS ON ABDOMEN-PELVIC COMPUTED TOMOGRAPHY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND ASSESSMENT OF ASSOCIATED FACTORS FOR SACROILIITIS [ON THE KOREAN MILITARY]

Dowon Yoon, MD (*Abstract Co-Author*) Nothing to Disclose
Dong Kyu Kim (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate the prevalence and missed rate of sacroiliitis on abdomen-pelvic computed tomography (APCT) in patients with inflammatory bowel disease (IBD). Factors associated with sacroiliitis were also assessed.

**METHODS AND MATERIALS**

From 2015 to 2021, a total of 210 IBD patients (mean age: 31.1 ± 8.1 years) who underwent APCT were included in this retrospective study. ??e? a?e a?? s??d?e?s, a?d ?e ???µed at t?e ???ea ??µed F???es ?ap?ta? ??sp?ta?.Based on a validated APCT scoring tool, bilateral sacroiliac (SI) joints on APCT in all study population were retrospectively reviewed. Then, the study patients were classified into two groups: sacroiliitis (+) group, patients with sacroiliitis; sacroiliitis (-) group, patients without sacroiliitis. Univariate and multivariate regression analysis was used to elucidate the factors associated with sacroiliitis.

**RESULTS**

Sacroiliitis was identified in 26 of 210 patients (12.4%). However, sacroiliitis was recognized on primary reading in only 5 of 26 patients (19.2%) and was missed on initial report in the remaining 21 patients (80.8%). Furthermore, of the 21 patients, 20 patients (95.2%) were finally diagnosed with axial spondyloarthritis (axSpA). There was more female sex ($p = 0.040$), upper gastrointestinal involvement ($p = 0.039$), and back pain ($p < 0.001$) in sacroiliitis (+) group than sacroiliitis (-) group. However, on multivariate analysis, presence of back pain was the only associated factor for sacroiliitis ($p = 0.010$).

**CONCLUSION**

Radiologists should pay attention to SI joints on APCT in patients with IBD for early diagnosis of sacroiliitis, which could result in early diagnosis of axSpA. If IBD patients complained of back pain, possibility of sacroiliitis should be considered.

**CLINICAL RELEVANCE/APPLICATION**

The prompt diagnosis and treatment of sacroiliitis are crucial for ensuring optimal long-term military service, particularly considering the significance of physical activity among service members. Such prompt management not only aids in alleviating immediate discomfort but also contributes significantly to facilitating sustained military readiness and performance.

## W5B-SPGI-6 SIGNIFICANCE OF PREOPERATIVE CT EVALUATION OF SOFT TISSUE REACTION AROUND ABDOMINAL AORTIC BRANCHES FOLLOWING NEOADJUVANT CHEMOTHERAPY FOR GASTRIC CANCER

Lei Tang, MD (*Abstract Co-Author*) Nothing to Disclose
Yiting Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

Perivascular soft tissue edema and fibrosis are commonly observed during surgery after neoadjuvant chemotherapy (NACT). This phenomenon lacks a pathological explanation but is common in clinical practice. This phenomenon increases the difficulty of surgical procedures for lymph nodes and vascular dissection. The authors identified the corresponding CT imaging signs to predict such changes preoperatively.

**METHODS AND MATERIALS**

A retrospective research at Beijing Cancer Hospital comprised 42 patients with SOX/XELOX NACT and 10 patients with direct-surgery. Ten gastrointestinal surgeons with 6-25 years of experience reviewed the surgical videos on perivascular operation without knowing patients' condition. They analyzed the videos and arranged patients into 2 groups: easy-to-dissect and hard-to-dissect. On preoperative CT before and after NACT, a 7-year-experienced radiologist examined the tissue around the celiac axis (CA), left gastric artery (LGA), common hepatic artery, superior mesenteric artery, and splenic artery. Intraoperative videos were utilized as the gold standard to evaluate the performance of CT after NACT to predict perivascular reactivity to surgical manipulation.

**RESULTS**

36 out of the 42 patients deemed difficult to resect by the surgeon displayed perivascular tissue edema and fibrosis in the surgical video, affecting the power of surgical instruments and the discrimination of tissue levels. 15 patients presented with a moderate perivascular reaction. In 83.3% (35/42) of NACT group, the reaction was severe; in 70% (7/10) of the direct surgery group, the reaction was modest. Of the 52 patients, a total of 36 patients were evaluated by the surgeon as "difficult to dissect". In the surgical videos, edema and fibrosis of the perivascular tissues were observed, differentiation of tissue levels and make surgery difficult. Another 16 patients were evaluated as "easy-to-dissect" In the neoadjuvant chemotherapy group, 83.3% (35/42) had a severe reaction; in the direct surgery group, 70% (7/10) had a mild reaction. Post-NACT CT images of difficult-to-operate patients showed a blurred increase in perivascular density and stripes (occurrence rate: CA 76.19%, LGA 45.24%). CT had a sensitivity of 91.67%, a specificity of 93.75%, and an accuracy of 92.3% in predicting perivascular reaction, and were correlated with longer operation duration ($p < 0.05$).

**CONCLUSION**

On CT, perivascular blur and stripe can indicate edema and fibrosis, which are good indicators of gastric cancer perivascular resection difficulty and longer surgical duration.

**CLINICAL RELEVANCE/APPLICATION**

CT signals of abdominal aortic branch perivascular tissue after NACT predict gastric cancer surgical vascular manipulation ease.

## W5B-SPGI-7 THE VALUE OF DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING WITH DIFFERENT B-VALUES IN EVALUATING LYMPHOVASCULAR INVASION IN RECTAL ADENOCARCINOMA

Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Nan Wang (*Abstract Co-Author*) Nothing to Disclose
Yue Wang (*Abstract Co-Author*) Nothing to Disclose
Liangjie Lin (*Abstract Co-Author*) Nothing to Disclose
Chen Anliang (*Abstract Co-Author*) Nothing to Disclose
Wenjun Hu (*Abstract Co-Author*) Nothing to Disclose
Deshuo Dong (*Presenter*) Nothing to Disclose

**PURPOSE**

To explore the value of apparent diffusion coefficient (ADC) in predicting lymphovascular invasion in rectal adenocarcinoma using diffusion-weighted magnetic resonance imaging with different b-values.

**METHODS AND MATERIALS**

A retrospective analysis was performed on 25 rectal adenocarcinoma patients confirmed with lymphovascular invasion (LVI) according to their postoperative pathology results who received pelvic 3.0 T MRI scan (Ingenia CX, Philips, Holland) in our hospital. They were divided into non-LVI group (16 patients; 13 males, 3 females, mean age: 66.94 years, range: 51-88 years) and LVI group (9 patients, 6 males, 2 females, mean age: 64.11 years, range: 27-77 years).The ADC value of different b-value obtained using IVIM sequences: 0, 800 s/mm2 (first sequence: DWI1), 0, 1200 s/mm2 (second sequence: DWI2), and 0, 2000 s/mm2 (third sequence: DWI3). Apparent diffusion coefficients (ADCs) of the rectal adenocarcinoma were calculated on ADC maps. The ADC values of different sequences and their differences were analyzed with Manny-whitey U test. The ROC curve was generated, and the area under curve (AUC) was calculated to analyze the diagnostic performance of using the ADC value or difference in predicting LVI of rectal adenocarcinoma.

**RESULTS**

There was a statistically significant difference in the ADC difference value of DWI1 (b=0, 800 s/mm2) and DWI2 (b=0, 1200 s/mm2) between non-LVI group (media 0.07 (0.05, 0.10) mm2/s) and LVI group (media 0.03 (-0.01, 0.08) mm2/s) ($p<0.05$). The AUC, maximum Youden index and diagnostic threshold of using the ADC difference value of DWI1 and DWI2 for LVI of rectal adenocarcinoma was 0.760, 0.494 and 0.04 mm2/s, and the sensitivity and specificity were 93.8% and 55.6%, respectively. The ADC value of DWI1, DWI2, DWI3 and ADC difference value of DWI1-DWI3, DWI2-DWI3 between non-LVI group and LVI group were no statistically significant differences.

**CONCLUSION**

The ADC difference value of DWI1 (b=0, 800 s/mm2) and DWI2 (b=0, 1200 s/mm2) was useful for predicting lymphovascular invasion of rectal adenocarcinoma.

**CLINICAL RELEVANCE/APPLICATION**

Compared with b-value DWI sequence, ADC difference value has a prospective clinical application in predicting the lymphovascular invasion of rectal adenocarcinoma for the treatment decision-making.

## W5B-SPGI-8 FAT SANDWICH SIGN - EVIDENCE OF AN INTACT SUBMUCOSA FOR THE DIAGNOSIS OF EARLY GASTRIC CANCER AT STAGE T1A

Zhilong Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Lei Tang, MD (*Abstract Co-Author*) Nothing to Disclose
Wanying Ji (*Abstract Co-Author*) Nothing to Disclose
Yiting Liu (*Presenter*) Nothing to Disclose

**PURPOSE**

In the normal gastric wall, submucosal fat can occasionally be observed. Fat density in the submucosal layer of EGC lesions may indicate that the submucosal layer remains unaffected, which is compatible with the limited mucosal invasion in stage T1a lesions. In our study, we utilized the new sign of "submucosal fat sign" to differentiate T1a and T1b stage lesions in preoperative CT.

**METHODS AND MATERIALS**

A total of 176 patients with EGC who underwent direct surgery from January 2019 to March 2024 at Beijing Cancer Hospital were included (Fig. 1), including 87 cases of T1a-stage and 88 cases of of T1b-stage EGC, and the fat sign was assessed using three-phase thin-slice CT images (plain, arterial, and venous phases). A chi-square test was used to assess whether the sign was statistically different between the two groups.

**RESULTS**

There were statistical differences in submucosal fat sign between T1a and T1b groups ($p<0.05$). We hypothesize the cause as follows: in the normal gastric wall, submucosal fat can occasionally be observed. Fat density in the submucosal layer of EGC lesions may indicate that the submucosal layer remains unaffected, which is compatible with the limited mucosal invasion in stage T1a lesions.

**CONCLUSION**

The submucosal fat sign of the primary tumor can assist in the diagnosis of T1a and T1b gastric cancer.

**CLINICAL RELEVANCE/APPLICATION**

According to the NCCN guideline, early gastric cancer (EGC) lesions in Tis and T1a stages locally invades the mucosal layer, so tumors are removed by minimally invasive treatments such as endoscopic mucosal resection (EMR) or endoscopic mucosal dissection (ESD). While T1b lesions require conventional surgical treatment. For T2 stage lesions, perioperative chemotherapy is preferred for better outcomes. In our study, we found a new sign, "submucosal fat sign", which is easier to diagnose in T1a stage and avoid excessive surgical treatment.

## W5B-SPGI-9 SARCOPENIA AND POSTOPERATIVE OUTCOMES IN PATIENTS WITH PERITONEAL CARCINOMATOSIS UNDERGOING CYTOREDUCTIVE SURGERY WITH HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY

Diego A.
Aguirre, MD (*Abstract Co-Author*) Nothing to Disclose
Sergio Valencia, MD (*Abstract Co-Author*) Nothing to Disclose
Manuela Gallo, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To determine the association of sarcopenia and postoperative outcomes in patients with peritoneal carcinomatosis (PC) undergoing cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (CRS-HIPEC).

**METHODS AND MATERIALS**

This retrospective observational analytic study included patients with PC who underwent CRS-HIPEC between January 2010 and December 2022. Sarcopenia was assessed using the L3 skeletal muscle index (SMI) on all subjects with available preoperative abdominal computed tomography (CT) to estimate the prevalence of sarcopenia. Cutoff values determined by Albano et. al were used to classify the participants as sarcopenic or nonsarcopenic. Clinical and surgical variables during hospitalization for surgery were assessed through univariate and bivariate analysis to determine the association between sarcopenia and outcomes after CRS-HIPEC.

**RESULTS**

A total of 156 participants were included, with a mean age of 52.33 years (± 11.01 [SD], with 112 [71,79%] women); 69 participants (44.52%) had appendiceal cancer. Sarcopenia was present in 101 participants [64.74%] based on preoperative CT, with a mean muscular mass of 109 $cm^2$ ± 27.76 [SD] and a mean Body Mass Index of 24.45 ± 3.41 [SD]. No differences in postoperative outcomes between sarcopenic and nonsarcopenic patients were found. Most relevant clinical outcomes included length of stay (23.5 days for the sarcopenic group (SG) vs. 21.73 days for the nonsarcopenic group (NSG); $p = 0.557$), intensive care unit length of stay (5.5 days for the SG vs. 4.1 days for the NSG; $p = 0.379$), and extubation time (17.8 hours for the SG vs. 26.6 hours for the NSG; $p = 0.107$). Among surgical outcomes, the most relevant measures were surgical reintervention (7 participants in the SG vs. 5 in the NSG; $p = 0.629$), surgical site infection (4 in the SG vs. 2 in the NSG; $p = 0.911$), thrombosis (30 in the SG vs. 22 in the NSG; $p = 0.192$), and the presence of postoperative fistulae (16 in the SG vs. 3 in the NSG; $p = 0.055$).

**CONCLUSION**

Assessing skeletal muscle depletion using non-invasive measures like CT-based SMI offers a straightforward method for nutritional screening in major surgery candidates. While prior studies have linked muscle mass assessment to prognostic value in various neoplasms in other clinical scenarios, the lack of correlation between sarcopenia and post-surgical outcomes in CRS-HIPEC patients suggests no need for preoperative nutritional reconditioning. This finding is advantageous, eliminating treatment delays and potentially enhancing survival rates by prompt intervention.

**CLINICAL RELEVANCE/APPLICATION**

CRS-HIPEC alters PC prognosis. Clarifying preoperative sarcopenia's role aids in reducing postoperative complications.

## W5B-SPGU-1 PREDICTION OF MEST SCORE USING ARTIFICIAL INTELLIGENCE AND DEVELOPMENT OF PERIODIC PROGNOSIS EVALUATION MODEL IN PATIENTS WITH IGA NEPHROPATHY

Jae Hyon Park, MD (*Abstract Co-Author*) Nothing to Disclose
Young Taik Oh, MD (*Abstract Co-Author*) Nothing to Disclose

Byung Chul Kang (*Abstract Co-Author*) Nothing to Disclose
Jongjin Yoon, MD, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

IgA nephropathy (IgAN) is the leading cause of end-stage renal disease in Asia, affecting over 1.5 individuals per 100,000 worldwide annually. In 2019, the International IgAN Prediction Tool(IIgAN-PT) was proposed, which utilizes clinical variables and the pathologic results of renal biopsy(MEST score) as predictors. However, its dependence on invasive biopsy limits its utility and makes repeated evaluation during the treatment period difficult. The purpose of this study is to develop a model that can predict the prognosis of IgAN patients by estimating the MEST score based on radiomics information extracted from precontrast CT of histologically proven IgAN patients.

### METHODS AND MATERIALS

A total of 326 patients with pathologically proven IgAN who underwent a precontrast CT scan within 1 month before renal biopsy were retrospectively enrolled from Mar 2010 to Feb 2023 and were randomly divided in an 8:2 ratio to create training and test sets. The Oxford criteria were used for histologic classification. Bilateral kidney segmentation was performed using a pre-trained nnUNet network. Radiomics features were extracted using PyRadiomics. Individual models were developed to predict mesangial(M)/endocapillary hypercellularity(E), segmental glomerulosclerosis(S), and tubular atrophy/interstitial fibrosis(T), respectively. To assess the performance of the nnUNet model, the DICE score was measured. Classification performance was evaluated using metrics, including AUROC et al. The R^2 was calculated to measure the correlation between the prognosis predicted by histologic MEST score and radiomics MEST score.

### RESULTS

The DICE score between handcrafted segmentation and the outputs of nnUNet for the right, left, and bilateral kidneys were 0.90, 0.91, and 0.89, respectively. The AUROC scores for predicting each category of MEST ranged from 0.80 to 0.92 in the training set and 0.69 to 0.80 in test set. A correlation of y=1.0536x and an R^2 of 0.79 were recorded between the probability of developing ESRD after 5 years as predicted by histologic MEST score and those predicted by radiomics MEST score when applied to the IIgAN-PT.

### CONCLUSION

We developed a machine learning model using nnUNet and binary classifiers to predict the MEST score for patients with IgAN based on precontrast CT of both kidneys. The model achieved moderate to high classification performance of MEST score and a strong correlation in the predicted prognosis between histologic and radiomics MEST scores.

### CLINICAL RELEVANCE/APPLICATION

This semi-automated MEST score prediction model can reduce the need for renal biopsies, enabling periodic prognosis assessments for IgAN patients. It is expected to improve the long-term outcomes of IgAN patients by enabling periodic re-assessment.

## W5B-SPGU-2 PREOPERATIVE INCREMENTAL VALUE OF NON-CONTRAST-ENHANCED VESSEL WALL MRI FOR T3 RENAL CELL CARCINOMA

Xin-Gui Peng, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Ying Cui, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the diagnostic performance of contrast-enhanced computed tomography (CECT), conventional MRI (con-MRI) and vessel wall MRI (VW-MRI) in preoperative assessment of T3 renal cell carcinoma (RCC), and to evaluate the incremental value of con-MRI and VW-MRI.

### METHODS AND MATERIALS

In this a single-centre retrospective study, RCC patients with pathological T3 stage from January 2016 to December 2023 were included. patients who did not undergo CECT or con-MRI or VW-MRI scan in our hospital were excluded. Images were independently and blindly evaluated at four-week intervals by

three readers. The T stage reported in the pathological report combined with clinical data was used as the reference standard. The incremental value in preoperative staging T3 were calculated using net reclassification improvement (NRI) and integrated discrimination improvement (IDI). A P value of less than 0.05 indicates that the result is statistical significance.

**RESULTS**

Eighty-two patients (median age, 65 years, 55 men) with T3 RCC were enrolled (Figure 1). The accuracy of T staging based on CECT (n = 59), con-MRI (n = 49) and VW-MRI (n = 30) images were 69.5%, 71.4% and 93.3%, respectively. In patients both had VW-MRI and CECT scans (n = 27), VW-MRI had a statistically incremental value for CECT in the preoperative evaluation of T3a-c stages (T3a: NRI = 0.066, P = 0.039; IDI = 0.013, P = 0.045. T3b: NRI = 0.085, P = 0.017; IDI = 0.673, P = 0.005. T3c: NRI = 0.178, P = 0.023; IDI = 0.283, P = 0.018), especially in assessing the invasion of renal pelvicalyceal (NRI = 0.154, P = 0.039; IDI = 0.222, P = 0.043) and vena cava wall invasion (NRI = 0.263, P = 0.011; IDI = 0.387, P = 0.027). Besides, statistically significant preoperative incremental effects were obtained in the assessment of T3a-c stages (T3a: NRI = 0.264, P = 0.013; IDI = 0.219, P = 0.018. T3b: NRI = 0.373, P = 0.029; IDI = 0.497, P = 0.032. T3c: NRI = 0.202, P = 0.045; IDI = 0.138, P = 0.031), renal vein invasion (NRI = 0.630, P = 0.032; IDI = 0.704, P = 0.049) and vena cava wall invasion (NRI = 0.185, P = 0.022; IDI = 0.237, P = 0.025) when added VW-MRI into CECT, in thirty patients had both con-MRI and VW-MRI scans (Table 1). In 27 patients with all three imaging scans, VW-MRI changed 24% (4/27) of the previous CECT- and con-MRI- based surgical plan, especially in patients undergoing primary resection and suturing of the vena cava.

**CONCLUSION**

VW-MRI added incremental value for evaluating preoperative T stage of T3 RCC, especially in the evaluation of tumor thrombus and vena cava wall invasion.

**CLINICAL RELEVANCE/APPLICATION**

The incremental value of VW-MRI in preoperative evaluation of T3 stage, especially in the evaluation of tumor thrombus and vena cava wall invasion, was helpful to guide clinical treatment and improve prognosis.

## W5B-SPGU-3 PRESENCE OF A FEEDING ARTERY AS AN INDICATOR OF CLINICALLY SIGNIFICANT PROSTATE CANCER

Leo L. Tsai, MD, PhD (*Abstract Co-Author*) Stockholder, Agile Devices Inc;Consultant, Agile Devices Inc
Abraham Fourie Bezuidenhout, MD (*Abstract Co-Author*) Nothing to Disclose
Noel Delgado, MD (*Abstract Co-Author*) Nothing to Disclose
Zeynep Nur Akyol Sari, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Prostate MRI is currently the imaging gold standard for detecting clinically significant prostate cancer (csPCa). The presence of a feeding prostate artery is not part of PIRADS criteria, nor has it been described. However, prior studies looking at ultrasound of prostatic capsular/feeding arteries have shown some utility in predicting csPCa. Our primary objectives with this project were to establish a definition for a feeding prostatic artery on MRI and determine if the presence of such an artery may be an indicator of csPCa, specifically for lesions in the peripheral zone.

**METHODS AND MATERIALS**

This study was a retrospective review of patients who underwent prostate MRI followed by tissue sampling for one or more suspicious lesions in the peripheral zone. 51 patients were included, of which 13 had a PIRADS 3 lesion, 19 had PIRADS 4, and 19 had PIRADS 5. The presence of a “feeding artery” was defined as an asymmetrically early enhancing and/or enlarged prostate artery (as compared to the contralateral side), coursing directly to an ipsilateral index lesion in the peripheral zone . Two radiologists agreed on the presence or absence of a feeding artery prior to reviewing the pathology results. Any association between categorical variables was determined by means of a Fischer’s exact test, with p lt 0.05 deemed statistically significant. Clinically significant prostate cancer was defined as prostatic adenocarcinoma Gleason 7 (3+4) or greater.

**RESULTS**

The presence of a feeding artery was strongly associated with underlying clinically significant prostate cancer (p lt 0.0001). The overall specificity of a feeding artery for csPCa was 93%, and overall sensitivity was 62%. The calculated positive predictive value was 79 and the negative predictive value was 85. Incidence was 23% in PIRADS 3 lesions, 16% in PIRADS 4 lesions and 47% in PIRADS 5 lesions, with a combined incidence of 29%. When a feeding artery was present, 67% of PI-RADS 3 lesions were found to have csPCa, versus 100% for PIRADS 4, and 89% for PIRADS 5. There was no difference in mean size for lesions with the presence of a feeding artery versus no artery (1.8 cm versus 1.4 cm, respectively, p=0.12).

**CONCLUSION**

The presence of a feeding artery may be a strong indicator of clinically significant prostate cancer for peripheral zone lesions.

**CLINICAL RELEVANCE/APPLICATION**

When present, the finding of a feeding artery may be a useful tool in identifying clinically significant prostate cancer on prostate MRI and recommending prostate biopsy. This may be especially valuable in cases when the imaging findings and thus the need for biopsy is deemed equivocal.

## W5B-SPGU-4 QUANTIFYING STRUCTURAL CHANGES OF THE BLADDER WALL WITH MRI AND MRF

Vikas Gulani, MD, PhD (*Abstract Co-Author*) Research support, Siemens AG;Consulting, Cook Group Incorporated
Jesse I. Hamilton, PhD (*Abstract Co-Author*) Nothing to Disclose
Hero K. Hussain, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose

Jesus Fajardo, MD (*Abstract Co-Author*) Nothing to Disclose
Shane A. Wells, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson
Maria Masotti (*Abstract Co-Author*) Nothing to Disclose
Aymen Bahsoun, BS, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To quantify T1 and T2 of the bladder in diabetic men with 3D MR Fingerprinting (MRF).

**METHODS AND MATERIALS**

Multiparametric MRI of the pelvis that included a 3D MRF method, that employs variable flip angles, repetition times, inversion recovery times and T2 preparation dephasing times, for mapping bladder T1 and T2 was performed on 51 men with very low and low-risk prostate cancer on active surveillance. Men voided prior to the scan session. Clinical (age, BMI, diabetes, hypertension, symptomatic benign prostatic hyperplasia) variables were collected from the EMR. The anterior bladder wall thickness, prostate, and transition zone (TZ) size were measured; prostate and TZ volume were estimated with the

ellipsoid formula. Two regions-of-Interest (ROI) were placed on the para-midline right and left anterior bladder wall. The Wilcoxin rank sum test and Kruskal-Wallis rank sum test associations between the clinical and imaging variables.

**RESULTS**

Diabetic men had significantly lower detrusor T1 [1239 (IQR: 1183-1251) vs 1633 (1368-2015), p<0.001] compared to non-diabetic men. Diabetic and non-diabetic men had similar detrusor T2 [86 (IQR: 60-91) vs 62 (IQR: 35-106), p=0.4]. Detrusor T1 and T2 and bladder wall thickness were not associated with age, prostate volume, symptomatic benign prostatic hyperplasia, BMI, or hypertension (p=0.1-0.9).

**CONCLUSION**

Structural changes of the detrusor in diabetic men can be quantified with MRI and MRF.

**CLINICAL RELEVANCE/APPLICATION**

There is a paucity of non-invasive, quantitative imaging techniques to evaluate the lower urinary tract. Development and validation of MRF could improve the diagnosis and clinical management of patients with diabetes-mediated bladder dysfunction.

## W5B-SPGU-5 RAPID MULTIPARAMETRIC MRI ASSESSMENT FOR CLEAR CELL RENAL CELL CARCINOMA IN SMALL RENAL MASSES: COMPARISON WITH THE CLEAR CELL LIKELIHOOD SCORE

Haiyi Wang, MD (*Abstract Co-Author*) Nothing to Disclose
Huanhuan Kang (*Abstract Co-Author*) Nothing to Disclose
Huiping Guo (*Abstract Co-Author*) Nothing to Disclose
Bai Xu, PhD (*Abstract Co-Author*) Nothing to Disclose
Yuanhao Ma (*Abstract Co-Author*) Nothing to Disclose
Xueyi Ning (*Abstract Co-Author*) Nothing to Disclose
Mengqiu Cui (*Abstract Co-Author*) Nothing to Disclose
Honghao Xu (*Presenter*) Nothing to Disclose

**PURPOSE**

To evaluate clinical usefulness of a rapid assessment for clear cell renal cell carcinoma (ccRCC) in small renal mass (SRM)

**METHODS AND MATERIALS**

This retrospective multicenter cross-sectional study included pathological confirmed SRM patients undergoing multiparametric MRI between December 2016 and August 2023 at three centers. Univariable and multivariable logistic regression were performed to determine significant imaging features for ccRCC. Rapid assessment was built based significant imaging features. In addition, Delong test and McNemar test was used to compare the performance between the rapid assessment and clear cell likelihood score (ccLS).

**RESULTS**

A total of 151 lesion from 147 patients (mean age, 53 years ± 12 [SD], 85 men) were evaluated. The mean size of lesion was 2.6 cm ± 0.9 (range: 0.8, 4.0). The pseudocapsule, intense enhancement in corticomedullary phase, and lipid was used for built rapid ccRCC assessment diagnostic flowchart. Compare with ccLS, the rapid assessment had a higher sensitivity of 86.25% (73 of 80 lesions [95%CI: 76.7, 92.9]) vs 71.25% (57 of 80 lesions [95%CI: 60.0, 80.8]) (P = 0.002), a similar specificity of 80.28% (53 of 71 lesions [95%CI: 69.1, 88.8]) vs 83.10% (59 of 71 lesions [95%CI: 72.3, 91.0]) (P = 0.201). The area under the curve of rapid and ccLS was 0.904 and 0.816, respectively (P = 0.013).

**CONCLUSION**

The rapid multiparametric MRI assessment could be quick and accurate to diagnose ccRCC in SRM compare with ccLS.

**CLINICAL RELEVANCE/APPLICATION**

Compared with ccLS, rapid assessment only requires three imaging features to quickly diagnose ccRCC, reducing the learning burden for radiologists and achieving fast diagnosis of ccRCC.

## W5B-SPGU-6 REAL-WORLD EFFICACY OF MRI-GUIDED TRANSURETHRAL ULTRASOUND ABLATION OF THE PROSTATE: INITIAL REPORT FROM THE CUSTOMIZED ABLATION REGISTRY (CARE)

Xiaosong Meng (*Abstract Co-Author*) Nothing to Disclose
Daniel N. Costa, MD (*Presenter*) Research support, Bayer AG

**PURPOSE**

The Customized TULSA-PRO Ablation Registry ("CARE", NCT05001477) was established to prospectively collect real-world data from patients treated with MRI-guided transurethral ultrasound ablation. Here we report the first multicenter efficacy outcomes from CARE for patients treated with focal to whole-gland ablation plans for primary, localized PCa.

**METHODS AND MATERIALS**

Between July 2020 and March 2024, patients across 5 U.S. centers (3 academic hospitals, 1 imaging center, and 1 private urology group) underwent TULSA according to the local standard of care and consented to prospective data collection. Follow-up included PSA, quality of life, and adverse events at 0, 3, 6, 12 months and annually thereafter, along with MRI, biopsy, and additional PCa treatment.

**RESULTS**

Of the 169 consented patients who received the TULSA procedure, 156 (92%) had primary localized PCa. At baseline, median (IQR) age, PSA, and prostate volume were 68 (64-68) years, 6.4 (4.9-9.3) ng/mL, and 41 (32-53) cc. The grade group (GG) distribution was 14% GG1, 59% GG2, 18% GG3, 3% GG4, 7% unknown. 86 patients completed 1-year follow-up; median (IQR) follow-up duration is 12 (3-24) months. At 1 year, the median prostate volume (not correcting for ablation cavity volume) decreased 50 (30-70)% to 23 (13-29) cc. Median (IQR) PSA decreased 89 (70-96)% to a nadir of 0.77

(0.28-1.78) ng/mL, stable to 0.99 (0.40-1.94) ng/mL at 1 year. 81 patients had 6-12 month follow-up MRI available; 13 were positive (PI-RADS=4, 16%). 33 underwent biopsy; 5 (6%) had clinically significant disease (all GG2). 5 men received salvage PCa treatment between 9-24 months without unexpected complications: 3 hormonal therapy, 2 external beam radiation therapy plus hormonal therapy.

**CONCLUSION**

This first multicenter report of real-world clinical efficacy for MRI-guided TULSA highlights excellent radiologic and histologic control of primary PCa in patients with GG1-GG4 disease treated with focal to whole-gland ablation. Level 1 evidence is being generated by an ongoing randomized controlled trial (CAPTAIN, NCT05027477) comparing safety and efficacy of TULSA to radical prostatectomy.

**CLINICAL RELEVANCE/APPLICATION**

First reported multicenter real-world evidence with TULSA demonstrates effective ablation and excellent early oncologic control. The CARE registry is generating evidence supporting TULSA as a safe and effective tool for managing PCa in the routine clinical care of broadly selected patients with tailored ablation plans.

**PURPOSE**

Prostate cancer (PCa) is one of the most common malignancies among biologically male individuals. Deep learning (DL)-based models have great potential to aid physicians in detecting PCa using MRI. However, current DL models for medical imaging are limited to using images, and the use of radiology reports, which contain valuable clinical information, is currently underexplored. Using recent advances in large language models and multi-modal fusion modules, we developed a novel model that learns from both MRI scans and radiology reports to improve prostate lesion detection.

**METHODS AND MATERIALS**

A large language model, Instructor, was used to encode radiology reports into embeddings tailored to the medical domain, and a multi-modal fusion module, pixel-word attention module (PWAM), combined the report with the nnU-Net architecture for segmentation. A cohort consisting of 1472 full MRI scans and their respective radiology reports coming from 1361 patients (median age = 72 years, median serum PSA = 6.8 ng/ml) scanned between 2015-2023 was queried from our institutional database. All scans contained actionable findings (2593 total lesions; 689 PI-RADS 5, 1128 PI-RADS 4, 778 PI-RADS 3 lesions) and each lesion was annotated by a genitourinary radiologist. Models were trained on 1106 scans and tested on a held-out test set of 366 scans. Performance was measured with Dice Similarity Coefficient (DSC), lesion-level sensitivity, and false positive (FP) lesions per scan.

**RESULTS**

Using only images for training, nnU-Net, currently state-of-the-art for prostate lesion detection, achieved a test DSC of 0.44. The model had a sensitivity of 0.60 while detecting 0.43 FP per scan. When using a lower threshold to maximize sensitivity, the model had 1 FP per scan with a sensitivity of 0.70 (sensitivity of 0.79 for PIRADS = 4). After integrating the radiology reports through multi-modal fusion, our model achieved a test DSC of 0.45. At a sensitivity of 0.60, the model had a lower number of FPs per scan at 0.37. At a lower threshold, achieved a sensitivity of 0.71 (sensitivity of 0.80 for PIRADS = 4) while detecting 1 FP per scan.

**CONCLUSION**

Our research presents a novel approach leveraging DL-based multi-modal techniques to enhance prostate lesion detection. By incorporating radiology reports with MRIs, our model demonstrates improved performance compared to state-of-the-art imaging data only methods, achieving a higher DSC with reduced false positives per scan while maintaining sensitivity.

**CLINICAL RELEVANCE/APPLICATION**

The multi-modal integration of radiology reports with MRIs enhances diagnostic accuracy by leveraging valuable clinical information alongside imaging data, promising more effective detection and management of prostate cancer in clinical practice.

Yoshimi Anzai, MD, MPH (*Presenter*) Nothing to Disclose

### PURPOSE

Hypoxia is a hallmark of treatment resistance and poor prognosis for head and neck cancer (HNC). Hypoxic tumors upregulate HIF-1 (hypoxia-inducible factor -1), which facilitates the cascade of hypoxia responses, including the activation of VEGF and Glucose transport. Those newly formed tumor vessels are disorganized and leaky, and they are not efficient in delivering oxygen. The ability to facilitate glucose metabolism despite inefficient or low perfusion is called metabolic-vascular uncoupling, and the affected subregion of the tumor is adapted to a hypoxic environment. The purpose of this study is to visualize the metabolic-perfusion uncoupling in patients with head and neck cancer.

### METHODS AND MATERIALS

This study is part of a multi-center prospective study, enrolling 20 subjects with newly diagnosed HNC. The patients underwent DCE MRI and FDG-PET/CT prior to the initiation of chemoradiotherapy (CRT). FDG-PET/CT was performed 3-4 months after CRT to assess treatment response. Semi-automated image co-registration of PET with DCE-MR Images was performed with Python developed at our lab. An expert radiologist annotated primary tumors and lymph node metastases on T2W images using ITKSnap, open-source software. First, the composites of FDG-PET images and Ktrans map on DCE MR images were created using the RGB color model. To reduce the millions of colors produced by the RGB approach, we then perform a statistical analysis of the annotated pixels across all subjects to find the median values. For each contrast, we compute the median value of all annotated pixels across all subjects. Pixels are then displayed with a color to indicate whether they fall below or above that median.

### RESULTS

In the RGB compositing approach, the co-registered PET images were assigned to the green channel with the quantitative Ktrans map assigned to a combination of the blue and red channels. The hypothetical “hypoxia quadrant” where high glucose metabolism with low perfusion, is displayed in shades between green-blue, whereas well-perfused, low glucose metabolic region is displayed between red and yellow. In contrast, a simplified approach reduced the millions of colors to 4, where the hypoxic quadrant is shown in red (Figure).

### CONCLUSION

We have developed an image analysis tool that visualizes a subregion of metabolic-perfusion uncoupling, indicative of tumor hypoxia in patients with newly diagnosed head and neck cancer, as a proof of concept.

### CLINICAL RELEVANCE/APPLICATION

The metabolic-perfusion compound map allows visualization of the hypoxia subregion, which has the potential to be incorporated into intensity-modulating radiotherapy.

## W5B-SPHN-4 JAW TUMORS IN CHILDREN: IMAGING MARKERS

### PURPOSE

The objective of this study was to review the imaging features of histologically proven jaw tumors in children less than 5 years old and to detect the key distinguishing features

## METHODS AND MATERIALS

We retrospectively assessed multidetector computed tomography (CT) images of 16 children (mean age 3 ± 1.8 years) with jaw tumors. Various CT image descriptors were used to characterize the lesions-Lytic/sclerotic/mixed, locularity, bone expansion, lesion border, multiplicity, cortical integrity, periosteal reaction, growth pattern of the lesion, associated soft tissue, resorption of tooth, peri coronal/periapical location.

## RESULTS

The ages of the children ranged from 3 months to 5 years (8 male and 8 female). The study revealed that 68.7% of tumors were benign, and 31.2% were malignant with eleven distinct histopathological entities were identified. However, there was no statistically significant difference between the two groups i.e. $p>0.05$, suggesting an overlap between the benign and malignant cases as malignant tumors did not show permeative pattern or periosteal reaction as seen in adults. Melanocytic neuroectodermal of infancy (MNTI) showed aggressive features but were exclusively seen in infants. Other common tumor types were LCH and metastatic neuroblastoma within the age group of 1-3 years.Most of the tumors were lytic (87.5%), of which 71.4 % were benign and 28.5 % were malignant. 60% of malignant tumors were unilocular, while most benign tumors were multilocular (63.6 %). Bone expansion and growth patterns in both groups were found to be similar. Multiplicity, loss of cortical integrity, and associated soft tissue were seen in malignant cases.

## CONCLUSION

Combination of age and radiological features allow confident diagnosis in certain entities such as MNTI, ABC, ossifying fibroma and the rest has overlapping features

## CLINICAL RELEVANCE/APPLICATION

Confident diagnosis in few characteristic entities can avoid unnecessary biopsy in children.

### PURPOSE

We explored the feasibility of applying a deep learning approach to non-contrast CT (NCT) scans for pulmonary embolism (PE) identification and embolism segmentation, which could potentially be employed as an economical, accessible, precise, and interpretable tool for PE identification in clinical practice.

### METHODS AND MATERIALS

We propose a novel cross-phase mutual learning framework that fosters knowledge transfer from computed tomography pulmonary angiography (CTPA) to NCT, while concurrently conducting embolism segmentation and abnormality classification in a multi-task manner. We trained the model using 1,150 paired NCT and CTPA scans from three hospitals, including 269 PE patients and 881 normal subjects. Three experienced radiologists (10-15 yrs cardiopulmonary specialist) manually annotate embolisms on the CTPA, referring to radiology reports and clinical records when necessary. Then, a robust image registration method is used to register the annotated mask from the CTPA to the NCT. The model was evaluated on a combined internal test set of 289 NCT scans (65 PE and 224 normal). A reader study was carried out involving: an expert radiologist (12 yrs experience), a senior radiologist (8 yrs experience), and a junior radiologist (3 yrs experience) on the test set.

### RESULTS

The model's ROC curve in the task of abnormality detection (PE vs normal) is above all three readers, with an area under the curve (AUC) of 0.990. The model achieves a patient-level sensitivity of 95.4% in PE identification, which significantly exceeds that of radiologists (18.5%, 43.1%, and 53.8%) while maintaining a high specificity of 99.6% (78.6% for mean radiologists). We additionally compare with the CTPA (gold standard), at a similar specificity level, our solution exhibits a marginally slight decrease in sensitivity (95.4% vs 96.9%). Compared with a state-of-the-art CTPA AI system for PE detection, the model achieves better embolism segmentation performance (Dice 78.5% vs 72.4%). More importantly, the extra information about predicted embolism masks and class activation map (CAM) generated from the classification head improves the interpretability of identification.

### CONCLUSION

The proposed model could identify PE on NCT, that achieves high sensitivity and specificity and outperforms the average of specialty radiologists by large margins.

### CLINICAL RELEVANCE/APPLICATION

We investigate a relatively convenient, simple, accurate detection solution for PE with NCT. Compared with the CTPA, our work suggests the good feasibility of using NCT scans as a promising clinical tool for PE identification and rule-out to reduce the risks of missed diagnosis and standardize diagnostic decisions on advanced imaging in the emergency department.

## W5B-SPIN-2 DETECTING DISTANT INTRACRANIAL RECURRENCE VIA CNN MODEL VISUALIZATION

Kurtis Johnson (*Abstract Co-Author*) Nothing to Disclose
Chi Zhang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kyuhak Oh, PhD (*Abstract Co-Author*) Nothing to Disclose
Justin Burr (*Abstract Co-Author*) Nothing to Disclose
Yu Lei, PhD (*Abstract Co-Author*) Nothing to Disclose
Isabella Zhang (*Abstract Co-Author*) Nothing to Disclose
Shuo Wang, PHD (*Presenter*) Nothing to Disclose

### PURPOSE

Distant intracranial recurrence after stereotactic radiosurgery (SRS) for brain metastases is common, with surveillance brain imaging recommended indefinitely after treatment. There are limited tools to accurately predict those at higher risk of recurrence. In this study, we aim to establish a convolutional neural network (CNN)-based model that can predict and visualize distant recurrence following SRS.

### METHODS AND MATERIALS

We retrospectively collected 121 patients who underwent SRS or fractionated SRS (fSRS). High-resolution T1-weighted MRI images with contrast were retrieved from 1 to 6 months before the radiographic diagnosis of a recurrent lesion. The recurrent lesion for each subject was delineated on the MRI that demonstrated recurrence. This MRI was then fused to the MRI acquired 1 to 6 months before diagnosis ("prior image") and the delineation was transferred to approximate the future location of recurrence on the "prior image" when the recurrent lesion was not detectable. An expansion area around the prospective recurrent lesion on the "prior image", along with a corresponding healthy area of the same size on the contralateral side, were extracted to form the binary classification groups (disease vs. healthy). We then employed a 17-layer 3D-CNN model for binary classification. The collected datasets were divided into training, validation, and testing sets, with an 80%-10%-10% split, respectively. Additionally, data augmentation (image rotation and resampling) was implemented to increase the data size and improve accuracy. Furthermore, we applied the Grad-CAM technique to generate 3D attention maps from the last convolutional layer within the 3D-CNN model for each patient to investigate interpretability of decision-making processes through visualization.

### RESULTS

The predictive model achieved 100% accuracy in predicting prospective recurrent brain metastases, though the accuracy was lower for identifying healthy tissue, initially recorded at 38.5%. With the incorporation of data augmentation, both prediction accuracies reached 100%. Moreover, 84.6% of the test subjects demonstrated that high attention (95th percentile) regions, revealed by Grad-CAM, coincided within a 1 cm expansion area of the prospective recurrent lesion.

### CONCLUSION

We have developed a deep-learning-based classification tool with robust predictive capabilities for identifying distant intracranial recurrence following stereotactic radiosurgery for brain metastases. Our visualization findings indicate that we may be able to identify suspicious areas of recurrence using an explainable CNN model.

### CLINICAL RELEVANCE/APPLICATION

Our study has the potential to detect distant intracranial recurrence following radiosurgery.

## W5B-SPIN-3 DEEP LEARNING-BASED DETECTION AND LOCALIZATION OF ENDOTRACHEAL TUBE ON CHEST RADIOGRAPHS OF PEDIATRIC PATIENTS

Hailong Li, DPhil (*Abstract Co-Author*) Nothing to Disclose
Neeraja Mahalingam, MSc,BSC (*Abstract Co-Author*) Nothing to Disclose
Alex Towbin, MD (*Abstract Co-Author*) Author, RELX;Consultant, Anderson Publishing, Ltd;Advisory Board, KLAS Enterprises LLC;Travel support, Merative LP
Lili He, MD (*Abstract Co-Author*) Nothing to Disclose
Bohan Zhang (*Abstract Co-Author*) Nothing to Disclose
Steve Standage (*Abstract Co-Author*) Nothing to Disclose
Elanchezhian Somasundaram, PhD, MS (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a deep learning algorithm that can automatically detect the presence of an endotracheal tube (ETT) on a pediatric chest radiograph (CXR) and localize its distal tip.

### METHODS AND MATERIALS

A retrospective study was performed. 1024 single-view CXRs performed in 2021 were randomly selected (494 with ETT and 530 without ETT). Supervised by a board-certified pediatric radiologist, two image analysts manually annotated pixel location (x, y coordinates) of the distal ETT tip using 3D slicer (version 4.1.1). The radiologist reviewed each annotated CXR and modified the annotation if needed. All images were normalized to a resolution of 1024×1024, and preprocessed with a CLAHE technique to enhance the contrast of details. A two-module deep learning pipeline was developed. First, a Vision Transformer (ViT)-based binary image classification model was created to detect the presence of ETT. If an ETT is not detected, the pipeline ends with 'No ETT detected.' If an ETT is detected, the CXR is sent to the second module, a ViT-based image regression model, to localize the x and y coordinates of the ETT tip. Instead of training the models from scratch, we used pre-trained ViT models with 12 transformer blocks based on ~1.2 million ImageNet images, then fine-tuned the ViT models for the detection and localization of ETTs. We randomly split the dataset into 7:1:2 for model training, validation, and testing at the subject level. For ETT detection, model accuracy, sensitivity, specificity, and AuROC were assessed. For tip localization, we determined mean absolute error (MAE), root mean squared error (RMSE), and Euclidean distance (ED) between ground truth and predicted coordinates in millimeters.

### RESULTS

1,024 CXRs from 551 pediatric patients [mean ± standard deviation age of 4.7 ± 7.8 years, 238 (43.2%) females] were included. Our ETT detection module had an accuracy of 92.5% [95% confidence interval (CI): 89.3%, 95.4%], sensitivity of 97.3% [94.6%, 99.4%], specificity of 87.9% [82.4%, 92.5%], and AuROC of 0.98 [0.97, 0.99]. We display the confusion matrix for the performance of ETT detection. The ETT tip localization module achieved a MAE of 13.4 [11.7, 14.3], RMSE of 20.5 [16.3, 21.2], and ED of 21.6 [18.6, 22.9]. We visualize the distribution of ground truth and predicted ETT tips.

### CONCLUSION

The model achieved promising performance on detecting the presence of ETT and localizing the distal ETT tip on pediatric CXRs.

### CLINICAL RELEVANCE/APPLICATION

Localizing the tip of an ETT in a mechanically ventilated patient in the pediatric ICU is a frequent and vital function. An automated tool that rapidly identifies the ETT tip would enhance patient care and potentially reduce patient harm.

## W5B-SPIN-4 UNVEILING HIDDEN SHORTCUTS: EXAMINING THE IMPACT OF EXPOSURE PARAMETERS IN CHEST RADIOGRAPHY ON AI MODELS

Po-Chih Kuo, PhD (*Abstract Co-Author*) Nothing to Disclose
Han-Jay Shu, BS (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to reveal the under-recognized influence of exposure parameters (e.g., exposure time) as potential shortcuts in AI models trained on chest X-ray (CXR) images. Identifying these shortcuts, often stemming from condition-specific exposure adjustments, is vital for improving model

robustness. This is particularly important as it highlights a common issue where models show strong internal performance but falter in external applications.

**METHODS AND MATERIALS**

We utilized two databases, MIMIC and MDRC, for our study. From MIMIC, we selected 25,861 AP CXR images, of which 5,706 were labeled with 'pneumothorax' and 20,155 with 'no findings'. From MIDRC, we collected 9,234 AP CXR images, including 804 COVID-positive cases. We classified the images from both datasets into two groups, A and B, based on four exposure parameters (Exposure, ExposureTime, XRayTubeCurrent, ExposureInuAs). Group A primarily included images labeled with the clinical condition (positive), while Group B mainly consisted of images without the condition (negative). This setup aimed to explore whether AI models, when trained under these conditions, would rely on exposure parameters as shortcuts instead of learning clinical indicators of the disease. The training set and test set 1 were primarily composed of Group A/Positive and Group B/Negative images while test set 2 was configured oppositely, containing Group A/Negative and Group B/Positive images.

**RESULTS**

Our analysis revealed significant model biases, evidenced by varying accuracies across different test sets. For pneumothorax, the accuracy declined from 83.2±0.7% in test set 1 to 47.7±3.2% in test set 2. Similarly, for COVID-19, the accuracies observed were 76.2±1.9% in test set 1 and 38.5±1.5% in test set 2. These results suggest that the models predominantly learned to recognize groups defined by exposure parameters rather than the actual clinical indicators of the diseases.

**CONCLUSION**

The significant drop of performance in model accuracy between test sets suggests that exposure parameters can act as shortcuts in learning processes, potentially compromising the clinical utility of X-ray imaging models and underscores the need for careful dataset curation.

**CLINICAL RELEVANCE/APPLICATION**

The identification of biases in machine learning models due to exposure parameters highlights a critical vulnerability in medical imaging AI. Understanding and mitigating this influence is essential to prevent models from relying on non-relevant features, thus ensuring that these tools support accurate clinical diagnostics. Our findings provide a foundation for future research aimed at preventing such shortcuts, ultimately improving the reliability and clinical utility of diagnostic AI systems.

## W5B-SPIN-6 ENHANCING PEDIATRIC FRACTURE DETECTION: ASSESSING THE EFFICACY OF A DEEP LEARNING AI MODEL AND ITS IMPACT ON RADIOLOGIST PERFORMANCE

John Simon, MD (*Abstract Co-Author*) Nothing to Disclose
Barry J. Sadegi, MD (*Abstract Co-Author*) Nothing to Disclose
Sean D. Raj, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study investigates the efficacy of a deep learning-based artificial intelligence (AI) model (Rayvolve), in detecting pediatric fractures on musculoskeletal (MSK) radiographs. Additionally, it evaluates how this AI assistance impacts the performance of both specialist and non-specialist radiologists.

**METHODS AND MATERIALS**

The study comprised two phases. In phase 1, the performance of the AI model was evaluated on 3016 MSK pediatric radiographs (mean age, 13.8 ± 4.8 years; range: 2-21 years) from 4 imaging centers, with a minimum of 26 radiographs per subgroup (age, gender, anatomic region, machine of acquisition, radiographic view, type of fracture). Ground truth was established by consensus among 3 MSK radiologists. In phase 2, a retrospective multi-reader multi-center study was conducted using 189 cases randomly selected from the phase 1. Twenty readers (including 10 MSK/pediatric radiologists and 10 non-specialist radiologists), participated in two separate reading sessions evaluating for fracture, with and without AI assistance, with a one-month washout period. Performance metrics (AUC, sensitivity and specificity) and reading time were compared with and without AI assistance.

**RESULTS**

The AI model achieved a high standalone accuracy (0.9399), sensitivity (0.9611), and specificity (0.8597). Subgroup analysis revealed that the AI model performed with high accuracy across the study types and potential confounders, including: age (AUC>0.9213; sensitivity>0.9389), gender (AUC>0.9373; sensitivity>0.9559), anatomic region (AUC>0.9263; sensitivity>0.9298), and type of fracture (sensitivity>0.9337). With AI assistance, reader accuracy increased significantly by 2.89% [95.8 % (95.3%; 96.3%) vs. 92.9% (92.1%; 96.6%), $p < 0.05$], sensitivity improved from 0.863 (95% CI: 0.843, 0.88) to 0.932 (95% CI: 0.918, 0.945), and specificity improved from 0.937 (95% CI: 0.927, 0.946) to 0.945 (95% CI: 0.936, 0.954). Average reading time per exam was shortened by 26% with AI assistance. Radiologist performance and improved reading times were more pronounced with non-specialist radiologists.

**CONCLUSION**

The AI model exhibited high accuracy in detecting pediatric fractures, and its integration significantly enhanced reader performance.

**CLINICAL RELEVANCE/APPLICATION**

The robust performance of the AI algorithm across diverse subgroups supports Rayvolve as a reliable tool for detecting fractures in pediatric patients in a real-world clinical setting.

## W5B-SPIN-7 TUMOR PROGRESSION QUANTIFICATION WITH UNSUPERVISED IMAGE REGISTRATION AND SPARSELY-SUPERVISED UNIVERSAL LESION SEGMENTATION

Brian Wehrle, MSc (*Abstract Co-Author*) Nothing to Disclose
Joel Schaerer (*Abstract Co-Author*) Nothing to Disclose
Erin M. Bowman, MD (*Abstract Co-Author*) Nothing to Disclose
Dharmendra Modi, BS (*Abstract Co-Author*) Nothing to Disclose
Alessandro Delmonte, MSc (*Presenter*) Nothing to Disclose

**PURPOSE**

According to RECIST 1.1 criteria, tumor progression and response is determined by repetitive annotation of lesions on serial cross-sectional imaging datasets. Automatic longitudinal propagation of these baseline lesions is highly desirable to reduce annotation burden at scale. We present an automatic tumor contour propagation method combining deep image registration and prompt-based universal lesion segmentation (ULS). Trained from sparsely

annotated RECIST findings, our solution tracks lesion progression and response, generalizing to multiple tumor types, lesion locations and acquisition protocols.

**METHODS AND MATERIALS**

An AI system performing universal lesion segmentation was prompted to contour longitudinal CT datasets based on radiologist's baseline lesion selection. ULS was trained on 4,238 target lesions by embedding radiologist knowledge using strong anatomical priors. Prompts were automatically issued by an anatomy-aware image registration AI method trained on 1,098 retrospective multiphasic CT datasets. A total of 667 datasets acquired using heterogeneous protocols were manually annotated by expert radiologists following RECIST 1.1 criteria for evaluation. The annotated lesions represented 22 anatomical sites and 5 primary tumor types. Both registration and segmentation performance were assessed with respect to follow-up manual annotations. Registration was evaluated using the mean Euclidean distance (mED), with a 50% limit on lesion area variation to limit bias due to tumor morphological changes. Dice Similarity Coefficient (DSC) and Pearson correlation were evaluated for lesion segmentation.

**RESULTS**

The registration error at lesions barycenter was 5.39 mm (median: 3.86 mm). Prompted at lesion center, ULS showed high overlap (DSC=75.77%) and very strong correlation for all RECIST biomarkers (SD r=0.91, LD r=0.88, Sum of axis r=0.91). No statistically significant differences were found in short axis (p=0.26). Strong correlation was confirmed for off-center prompts (DSC=68.90%, r=0.86) up to the 90th percentile of the registration error (ED90=10.09mm).

**CONCLUSION**

The AI system enabled precise longitudinal lesion location and contour propagation of primary tumors, metastases, and adenopathy in 22 anatomical locations. Barycenter estimation by image registration consistently allowed to exploit the remarkable segmentation performance of ULS to automatically propagate contours between time points.

**CLINICAL RELEVANCE/APPLICATION**

Automatic tumor propagation using the proposed AI system will allow for reproducible lesion segmentation over time which can decrease burden on the clinical radiologist and increase accuracy of the RECIST results over time.

## W5B-SPIR-2 PROGNOSTIC ROLE OF TRANSIENT HEPATIC INTENSITY DIFFERENCE FOLLOWING DRUG-ELUTING BEAD TRANSARTERIAL CHEMOEMBOLIZATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Yuan-Cheng Wang (*Abstract Co-Author*) Nothing to Disclose
Noble Chibuike Opara (*Abstract Co-Author*) Nothing to Disclose
Shuwei Zhou (*Presenter*) Nothing to Disclose

### PURPOSE

Transient Hepatic Intensity Differences (THID) observed on MRI may serve as a prognostic factor for patients who have undergone DEB-TACE for HCC. This study explores the potential link between THID and long-term clinical outcomes in these patients.

### METHODS AND MATERIALS

A retrospective, single-arm, multicenter study was conducted to assess the impact of Transient Hepatic Intensity Differences (THID) on 102 patients diagnosed with Hepatocellular Carcinoma (HCC) between December 2017 and December 2020. All patients had baseline MRI examinations for analysis. Two independent radiologists evaluated the presence of THID visually. Tumor response was evaluated using the modified Response Evaluation Criteria in Solid Tumors (mRECIST) criteria, focusing on changes in viable tumor volume. Additionally, the study investigated the association of THID with the development of various complications, including biliary injury, metastasis, and thrombosis. The evaluation of treatment outcomes such as Overall Survival (OS) and Progression-Free Survival (PFS) were performed using the Kaplan-Meier method. Finally, the Chi-square test was employed to assess the correlation between THID and the development of biliary injury, metastasis, and thrombosis. A logistic regression model was used to identify independent factors associated with the development of THID.

### RESULTS

A total of 74 patients (72.5%) developed THID following DEB-TACE treatment for HCC. Multivariable analysis identified; baseline direct bilirubin levels (odds ratio [OR] = 0.86; 95% confidence interval [CI] = 0.75-0.97; P = 0.020) and number of tumors (OR = 3.47, 95% [CI] = 1.17-10.24; P = 0.024) as independent predictors of THID development. Patients with THID showed a significantly increased risk of biliary injury compared to the non-THID group (P = 0.002). Analysis of patient survival revealed a statistically significant difference in both (OS) and (PFS) between the THID and non-THID groups (P = 0.019; P = 0.038, respectively).

### CONCLUSION

Our findings suggest that in patients who underwent DEB-TACE treatment for HCC, both the number of tumors and baseline direct bilirubin levels emerged as significant predictors of THID development. Patients with THID had a significantly increased risk of biliary injury compared to the non-THID group. The development of THID correlated to lower OS and PFS.

### CLINICAL RELEVANCE/APPLICATION

THID is a common observation following DEB-TACE for HCC, whereas it is always ignored in clinical practice. Our study indicated that THID is a potential biomarker for post-procedural complications like biliary injury and worse long-term survival (lower OS and PFS). Baseline factors including bilirubin levels and the number of tumors were predictive of THID development.

## W5B-SPIR-4 LIVER VENOUS DEPRIVATION VERSUS PORTAL VEIN EMBOLIZATION FOR PATIENTS WITH EXTENSIVE COLORECTAL LIVER METASTASES: PROPENSITY SCORE MATCHED ANALYSIS

**PURPOSE**

Portal vein embolization (PVE) is traditionally used to induce future liver remnant (FLR) hypertrophy in patients requiring liver resection. However, not all patients achieve sufficient FLR regeneration, especially those with multiple risk factors affecting liver hypertrophy. Liver venous deprivation (LVD), a relatively novel approach for concurrent PVE and hepatic vein embolization (HVE), has emerged as a superior alternative. The role of LVD, in comparison with PVE, in patients with colorectal liver metastases (CLM) and high-risk factors is not well known.

**METHODS AND MATERIALS**

This single-center retrospective cohort study included 301 patients undergoing PVE (n=279) or LVD (n=22) before planned hepatectomy for CLM from 1998 to 2023. Patients who underwent LVD were propensity score matched to patients who underwent PVE in a 1:3 match. Propensity score accounted for pre-procedure standardized FLR (sFLR), body mass index, number of systemic therapy cycles, extension of PVE to segment IV portal vein branches, prior resection, and suspicion of chemotherapy associated liver injury (CALI) based on pre-intervention imaging and lab tests. Pre- and post-intervention FLR volumes were quantified using CT volumetric analysis, and standardized liver volume was calculated using the previously described Vauthey formula. Key variables such as post-procedure sFLR, degree of hypertrophy (DH), and kinetic growth rate (KGR) were compared between the groups. Data regarding technical success and complications associated with each procedure was also recorded.

**RESULTS**

The matched cohort included 78 patients including 22 in the LVD group and 56 in the PVE group. The technical success was 100% for both LVD and PVE groups. There were no CTCAE>=3 grade complications in either arm. Patients who underwent LVD showed significantly higher DH (15.7% vs 10.5%, p=0.017) and KGR (3.9% vs 2.4%, p=0.006) compared to the PVE group. The rate of successful surgical resection was comparable between both groups (68% (15/22) for LVD vs 70% (39/56) for PVE, p=0.9). One patient in the PVE cohort had postoperative hepatic insufficiency (Peak Tbil >7 mg/dl) versus none in the LVD group without statistical significance (p =0.531).

**CONCLUSION**

LVD demonstrated significantly better sFLR hypertrophy compared to PVE alone in patients with extensive CLM and high-risk features, based on DH and KGR. However, the rate of successful surgical resection was similar between groups, which highlights the need for further prospective clinical trials to assess the efficacy of LVD in patients with CLM and high-risk factors.

**CLINICAL RELEVANCE/APPLICATION**

LVD shows higher potential over traditional PVE to achieve superior hypertrophy of FLR in patients with extensive colorectal liver metastases.

## W5B-SPIR-5 EFFICACY AND SAFETY OF TRANSARTERIAL EMBOLIZATION VERSUS PERCUTANEOUS SCLEROTHERAPY IN PATIENTS WITH HEPATIC VENOUS MALFORMATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Hadi Rokni Yazdi (*Abstract Co-Author*) Nothing to Disclose
Faeze Salahshour (*Abstract Co-Author*) Nothing to Disclose
Saharnaz Pezeshgi (*Abstract Co-Author*) Nothing to Disclose
Ramin Pourghorban, MD (*Abstract Co-Author*) Nothing to Disclose
Niloofar Ayoobi Yazdi (*Abstract Co-Author*) Nothing to Disclose
Hojat Dehghanbanadaki (*Abstract Co-Author*) Nothing to Disclose
Mohammad Mehdi M. Mehrabi Nejad (*Abstract Co-Author*) Nothing to Disclose
Seyed Mohammad Hossein Tabatabaei, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

There remains a conspicuous absence of randomized clinical trials (RCTs) comparing the efficacy and safety of transarterial embolization (TAE) versus percutaneous sclerotherapy (PS) in patients with hepatic venous malformations (HVMs), historically referred to as liver hemangiomas. This study aims to conduct a systematic review and meta-analysis of the literature, elucidating the aggregated efficacy and safety profiles of these two interventional radiology procedures.

**METHODS AND MATERIALS**

A comprehensive search encompassing PubMed-MEDLINE, Scopus, and Web of Science databases was undertaken to identify original articles reporting on the safety or efficacy of TAE or PS in adult patients with HVMs up to April 24, 2024. We pooled the weighted mean difference in volume and diameter of HVMs before and after intervention. Additionally, we pooled the weighted proportion of major complications (>grade 2), post-embolization syndrome (PES) and hepatic enzyme elevations following each intervention. We used the random effect model for meta-analysis in STATA.

**RESULTS**

From a total of 1334 identified studies, 33 met the inclusion criteria, comprising 25 studies investigating TAE and 8 focusing on PS in patients with HVMs. Our pooled analysis showed that both PS and TAE decreased the volume of HVMs, 384.52 cc (95%CI: 177.31, 591.72) and 193.50 cc (95%CI: 115.61, 271.39) and diameter of HVMs, 4.04 cm (95%CI: 3.13, 4.95) and 4.15 (95%CI: 2.70, 5.61), respectively; however, neither intervention was superior to the other in reducing volume and diameter (P=0.09 and P=0.90, respectively). Additionally, the pooled rate of major complications was 3% (95%CI: 0%, 7%) for TAE and 3% (95%CI: 0%, 13%) for PS (P-value of group difference=0.67). The pooled rate of post-intervention PES was 49% (95%CI= 26%, 72%) for TAE and 0% (95%CI: 0%, 1%) for PS (P-value of group difference<0.01). The pooled rate of post-procedure hepatic enzyme elevations was 54% (95%CI: 16%, 89%) for TAE and 0% (95%CI: 0%, 1%) for PS (P-value of group difference<0.01).

**CONCLUSION**

Both TAE and PS are effective and safe in the management of HVMs. Although no statistically significant disparity in lesion size reduction was observed between these interventions, PS exhibited lower incidences of PES and hepatic enzyme elevations post-procedure. Further, RCT studies are required to confirm our results.

**CLINICAL RELEVANCE/APPLICATION**

The study's findings offer clinicians valuable insights into the optimal interventional radiological approaches for treating HVMs. Moreover, the notably higher safety rate with PS underscores its potential as a preferred treatment option, aiding clinical decision-making and improving patient outcomes.

## W5B-SPIR-6 RADIOMICS FOR THE PREDICTION OF PATIENT RESPONSE TO IMMUNOEMBOLIZATION INTERVENTION IN METASTATIC UVEAL MELANOMA

Gabriel B. Casella, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

The liver is the primary site for secondary cancer deposition in metastatic uveal melanoma (MUM). The prognosis for these patients is generally poor despite various transarterial treatments, and predicting treatment outcomes remains a challenge. Dynamic contrast-enhanced (DCE) MRI, employing hepatocyte-specific contrast agents, is routinely conducted since these agents are not retained by metastases. Radiomics, have demonstrated significant diagnostic value in various oncologic settings. This study seeks to identify whether radiomics can predict which patients will benefit from a liver-directed immunoembolization (IE).

**METHODS AND MATERIALS**

A retrospective dataset of T1-weighted axial sequences of hepatocyte-avid DCE-MR studies from 401 patients taken before therapeutic interventions by IR. A total of ~1500 unique metastatic lesions have been annotated by expert radiologists. Studies are temporally registered, and lesions are segmented using a fuzzy C-means algorithm with bounding-box initialization. Radiomics features such as morphology, texture, margin, and contrast kinetics are extracted from each lesion, and Combat is used for covariate batch correction.

**RESULTS**

Seven frequent data curation challenges were identified, each with varying frequencies: such as acquisition protocol not fully followed (94/201; 46.7%), image stack inversion (22/87; 25.2%), temporal axial misalignment (78/87; 89.6%), and alternative contrast used (60/201; 29.8%). Furthermore, batching effects on radiomics features were associated with each study's imaging manufacturer of origin; however, Combat corrected these potential confounding effects. In the coming months, we will finalize the radiomics quantification of the fully annotated set of lesions, and will have final results on the prognostic utility of radiomics features for IE response.

**CONCLUSION**

Our team has assembled the most extensive imaging dataset for patients with MUM. We anticipate that our models will identify lesions likely to respond well to transarterial immunoembolization, particularly those showing strong arterial enhancement, and high intrinsic T1 signal intensity.

**CLINICAL RELEVANCE/APPLICATION**

Identifying in advance patients likely to have a favorable response to IE is crucial. This enables us to customize treatments more effectively, adjust how often patients are monitored, and improve communication of expectations to patients and healthcare providers. As healthcare continues to move towards precision medicine, radiomics stands out by facilitating the development of personalized treatment plans. Its integration into clinical practice could revolutionize how diseases are treated, making it a critical area for continued research in radiology.

## W5B-SPIR-7 AN INVESTIGATION INTO THE HETEROGENEITY OF YTTRIUM-90 (Y-90) MICROSPHERE DISTRIBUTION WITHIN TREATED TUMOR WITH CT VERSUS PET AFTER RADIOEMBOLIZATION USING MULTIMODAL Y-90 MICROSPHERES

Robert J. Abraham, MD, FRCPC (*Abstract Co-Author*) Co-Founder, ABK Biomedical Inc;Stockholder, ABK Biomedical Inc;Spouse, Stockholder, ABK Biomedical Inc;Chief Medical Officer, ABK Biomedical Inc;Co-founder, Covina Biomedical Inc;Stockholder, Covina Biomedical Inc;
Alasdair Syme (*Abstract Co-Author*) Nothing to Disclose
Amit Verma, PhD,MPH (*Abstract Co-Author*) Employee of ABK Biomedical
E Courtney Henry (*Abstract Co-Author*) Nothing to Disclose
David Dobrowski (*Abstract Co-Author*) ABK biomedical
Andrew Kennedy (*Abstract Co-Author*) Nothing to Disclose
Aravind Arepally, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

Histopathology studies have verified significant heterogeneity in Y-90 microsphere distribution following radioembolization1,2. However, current post-treatment PET demonstrates non-specific homogenous distribution mainly due to low spatial resolution and is also confounded by respiratory and subject motion. Investigational multimodal imageable Y-90 glass microspheres (Eye90) leverage the superior spatial and temporal resolution of Computed Tomography (CT) to directly image Y-90 microspheres and may depict the actual heterogeneous distribution. The purpose of this study was to extract and compare signal distribution of Y-90 microspheres in tumor on CT and PET after Eye90 radioembolization.

**METHODS AND MATERIALS**

4.7 GBq (401 mg) of Eye90 microspheres were selectively administered to treat a solitary liver tumor (38.6 mL). Post-administration, PET and CT imaging provided voxelized distributions with units of Y-90 activity concentration (MBq/mL) for PET and Hounsfield Units (HU) for CT. The voxelized signal (HU and MBq/mL) within the tumor volume was extracted and compared between the two modalities using the ratio of the signal median to the interquartile range (IQR) and the ratio of the full-width-at-half-maximum (FWHM) of the distribution’s peak to the signal maximum over the whole range of data (Smax).

**RESULTS**

Qualitatively, the PET signal appears smooth and uniform while the CT signal reveals discrete, isolated regions of microsphere uptake throughout the tumor. For both modalities, the signal distribution was roughly Gaussian with a tail extending into high-signal regions. The median/IQR of signal in the tumor was 310% and 87% for CT and PET imaging, respectively. The FWHM of the distribution’s peak was 20 HU for CT and 13.16 MBq/mL for PET, while Smax was 454 HU for CT and 83.93 MBq/mL for PET. The ratio of the FWHM to Smax was 0.157 and 0.044 for PET and CT, respectively. Given its high median/IQR and FWHM/Smax that is 3 times less than PET, CT reveals a more heterogeneous microsphere distribution.

**CONCLUSION**

CT imaging of Eye90 microspheres presents a novel opportunity to accurately define the heterogenous Y-90 activity distribution. Due to improved spatial resolution and mitigation of motion effects, CT-based evaluation of Eye90 microsphere distribution may be superior to PET-based evaluation.1. Kennedy et al. Int J Radiat Oncol Biol Phys. 2004 Dec 1;60(5):1552-63. 2. Högberg et al. EJNMMI Res. 2014 Dec;4(1):48.

## CLINICAL RELEVANCE/APPLICATION

Multimodal imageable radiopaque Y-90 microspheres depiction of the actual heterogenous microsphere distribution in tumor may improve tumor targeting and provide a better determination of Y-90 dose distribution and thereby improve outcomes.

## W5B-SPMK-1 ENHANCING ACCURACY IN ADOLESCENT IDIOPATHIC SCOLIOSIS DIAGNOSIS IN COMMUNITY HOSPITALS: A COMPARATIVE STUDY OF MACHINE LEARNING VERSUS MANUAL MEASUREMENT OF COBB ANGLES

Andrea S. Doria, MD, PhD (*Abstract Co-Author*) Baxalta-Shire (Research Grant), Novo Nordisk (Research Grant), Terry Fox Foundation (Research Grant), PSI Foundation (Research Grant), Society of Pediatric Radiology (Research Grant), Garron Family Cancer Centre (Research Grant)
Farzad Khalvati, PhD, MSc (*Abstract Co-Author*) Board of Directors, MESH Scheduling Inc
Dorothy Kim (*Abstract Co-Author*) Nothing to Disclose
Chaojun Chen (*Abstract Co-Author*) Nothing to Disclose
David E Lebel (*Abstract Co-Author*) Nothing to Disclose
Ayesha Hadi, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Nearly one-third of adolescent idiopathic scoliosis (AIS) patients present late, as likely surgical candidates. The accuracy of community spine radiology for AIS is suboptimal, impacting timely referrals. Our study objectives were (1) To evaluate the effectiveness of a machine learning (ML) algorithm in accurately assessing Cobb angles from community-obtained spine radiographs for patients with suspected adolescent idiopathic scoliosis (AIS). (2) To compare these measurements with those made manually by community and academic radiologists to determine potential improvements in diagnostic accuracy and referral timelines.

### METHODS AND MATERIALS

Our retrospective analysis included community acquired spine radiographs from 115 AIS patients previously seen for initial evaluation at a tertiary pediatric hospital. Cobb angle measurements were taken both manually by academic and community radiologists and were compared to those obtained through a two step- instance segmentation based deep learning architecture model called YOLACT model.

### RESULTS

The instance segmentation model demonstrated a Symmetric Mean Absolute Percentage Error (SMAPE) of 9.64% in comparison with community radiologists and 6.37% compared to trained academic radiologists. Further, the mean absolute difference between ML and community radiologists was 7.07 degrees in contrast to 4.40 degrees between ML and academic radiologists. This reflects a higher accuracy and reliability of the ML model in measuring Cobb angles than manual measurements obtained by community radiologists.

### CONCLUSION

There was a notable agreement between our ML model and measurements taken by academic radiologists, highlighting the model's precision. Conversely, significant discrepancies were observed between the ML model and the measurements taken by community radiologists. These findings suggest the utility of an ML model to support accurate measurements obtained by community radiologists, which may subsequently impact timely referral of AIS patients to tertiary care.

### CLINICAL RELEVANCE/APPLICATION

Inaccuracies between community radiology and tertiary care have a significant impact on the timely presentation of AIS patients, leading to missed opportunities for non-operative management and increasing the numbers of avoidable spine surgeries. To our knowledge, there is no previous literature validating an ML model for substandard community acquired spine radiographs. The integration of ML for Cobb angle measurements in community radiology may improve diagnostic accuracy of AIS patients, reduce measurement variability, and expedite appropriate referrals to tertiary care.

## W5B-SPMK-4 STUDY ON REDUCING METAL ARTIFACTS OF SPINAL PEDICLE SCREWS WITH VIRTUAL MONOENERGETIC IMAGE AND O-MAR

Jia Meng (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the effect of dual-layer detector spectral CT virtual monoenergetic images combined with O-MAR on reducing metal artifacts of pedicle screws.

### METHODS AND MATERIALS

In this prospective study, 40 patients who underwent spinal surgery for bone tumors, disc herniation, and prolapse from April to December 2022 were re-examined by dual-layer spectral CT. Male 19 cases, female 21 cases, with an average age: 56±13 years old. The screws were located in the cervical spine

in 3 cases, the thoracic spine in 5 cases, and the lumbar spine in 32 cases. CI, O-MAR images and 140-160 keV images were reconstructed respectively, with a total of 8 groups of VMI and VMI+O-MAR images at intervals of every 10 keV. The most severe metal artifact level was selected and ROI was mapped in the spinal canal, posterior pedicle nail, lateral soft tissue and artefact free adipose tissue of each group of images. CT value and SD were measured, and AI was calculated and analyzed statistically. Two subjective evaluations were conducted by a physician with reference to the Likert5-point scale for the cortical bone, trabecular bone and soft tissue around the vertebral body near the pedicle screw, and the mean value was taken as the final score.

**RESULTS**

The intravertebral AI values in 150keV VMI and 140-160keV VMI+O-MAR images were lower than CI, $P < 0.001$. The O-MAR image, 140-160keV VMI and VMI+O-MAR image AI in the posterior and lateral soft tissues of the pedicle screw were all lower than CI ($P < 0.05$). The subjective scores of the cortical bone and trabecular bone near the pedicle screw in 140-160 KeV VMI were higher than those in 140-160 KeV VMI+O-MAR images, and the difference was statistically significant ($P < 0.05$) when comparing the same energy levels. The subjective score of paravertebral soft tissue in 140-160 KeV VMI was lower than that in 140-160 KeV VMI+O-MAR image, and the difference was statistically significant when comparing the same energy level ($P < 0.001$).

**CONCLUSION**

VMI+O-MAR at 140-160keV significantly reduced spinal pedicle screw artifact, improved visualization of bone structure and soft tissue.

**CLINICAL RELEVANCE/APPLICATION**

For intravertebral lesions, 140-160keV VMI and VMI+O-MAR images can be reconstructed respectively for comparative observation to prevent new artifacts introduced by O-MAR.

## W5B-SPMK-5 A STANDARDIZED SPINAL MRI PROTOCOL FOR THE DIAGNOSIS OF SPONTANEOUS INTRACRANIAL HYPOTENSION AND CORRELATION ANALYSIS WITH BRAIN MRI FINDINGS

Eun Kyung Khil, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Sang Won Jo, MD (*Abstract Co-Author*) Nothing to Disclose
Yu Sung Yoon, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

To demonstrate the utility of a new uniform cervical-thoracic-lumbar (CTL) contrast-enhanced MRI protocol, analyze spinal findings in spontaneous intracranial hypotension (SIH) using a consistent protocol, and investigate correlation with brain MRI findings.

**METHODS AND MATERIALS**

This retrospective study included patients with suspected SIH who underwent 3T MRI using a new CTL MRI protocol between March 2019 and February 2023. Clinical diagnosis of SIH was made according to the ICHD-3 criteria, and MRI imaging criteria were evaluated as follows: spine MRI findings included epidural fluid collection (EFC), epidural vein/plexus engorgement, dural enhancement, C1-2 sign, and extraspinal fluid collection at other levels; brain MRI findings included three qualitative (venous sinus engorgement, pachymeningeal enhancement, subdural effusion, cerebellar sagging) and five quantitative (suprasellar cistern, prepontine, mamillopontine distance, pontomesencephalic angle]. Evaluation was conducted by two experienced musculoskeletal radiologists and one neuroradiologist. Only patients who underwent both spine and brain MRI were included in the final study population. Patients were divided into two groups based on positive brain findings (group 1) and absence of such findings (group 2), and demographic characteristics and symptoms of the patients were compared. Furthermore, spine findings were compared and analyzed by t-tests or chi-square statistics.

**RESULTS**

Of the 98 patients recruited, 53 met the criteria for SIH, and ultimately, 42 patients (mean age: 43.95 years, 66.7% female) with SIH were analyzed. Group 1 exhibited a significantly shorter pain duration (12.37 days, $p<0.001$) compared to group 2. Group 2 revealed more atypical headaches, fewer neurological symptoms, and higher persistence/recurrence; however, there were no significant differences. In group 1, spinal MRI demonstrated a wider extent of epidural fluid collection (EFC) involvement (encompassing C, T, L levels; $p<0.001$), circumferential axial location ($p = 0.011$), and a significantly higher prevalence of C1-C2 sign ($p = 0.024$).

**CONCLUSION**

This study highlights the importance of early comprehensive spinal MRI evaluation using a standardized CTL MRI protocol with contrast for suspected SIH, especially when brain MRI is negative or equivocal.

**CLINICAL RELEVANCE/APPLICATION**

Using a standardized protocol, early advocacy of comprehensive spinal MRI for suspected SIH, even with negative brain MRI, allowing optimal detection of spinal markers prevalent in brain MRI positive cases.

## W5B-SPMS-1 INTERNATIONAL PEER LEARNING: THE NEXT STEP IN GLOBAL RADIOLOGY

Karen Chetcuti, MD, FRCR (*Abstract Co-Author*) Nothing to Disclose
Damalawo Phiri, MBChB (*Abstract Co-Author*) Nothing to Disclose
Diana Nguyen (*Abstract Co-Author*) Nothing to Disclose
Benjamin Brown, BS (*Abstract Co-Author*) Nothing to Disclose
Katrina A. McGinty, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Educational initiatives are essential for capacity building in low- and middle-income countries (LMICs). One model has been partnership with a university or organization in a high-income country. This model is traditionally unidirectional and didactic, but there is a shift towards interactive, bidirectional learning, to benefit participants from both high and low resource settings, facilitating relationship building and reducing hierarchical imbalances. Our project was to create a bidirectional learning experience between an academic medical center in the Southeastern United States and a newly created radiology residency in Malawi by creating an international peer learning conference and assessing its impact on learners.

### METHODS AND MATERIALS

This conference started October 2022, structured in four-week blocks rotating by subspeciality. Weekly sessions using teleconferencing software alternated presentations between the US residents and Malawian residents. Cases were classified as great call, learning opportunity, interesting/classic case, or quality improvement. Open-source educational modules were created from the presented cases and teaching points for review following the conferences. Participant feedback was solicited at 1, 3, and 6 months.

### RESULTS

Over 10 months, there were 22 conferences reviewing 90 cases. Mean attendance was 13 participants (range 9-24) with an average of 4 cases per conference (range 1-8). The most common case type was interesting/classic case (80), followed by learning opportunity (8) and quality improvement (2). 38 cases have been made available via online modules. When surveyed, 85% of participants felt the conferences were relevant to their practice, 78% preferred a systems-based format, and 85% found the work required for the conference was manageable. Feedback was positive, with main criticisms related to internet connectivity, image viewing or material being advanced for level of training. Subjectively, there was increased communication and participation between trainees at both sites and improved presentation skills. Since its inception, the conference has become a regular and expected part of resident education for both the US based and Malawian residencies.

### CONCLUSION

International peer learning between high and low resources setting is an effective and low-cost method to bolster sustainable capacity building and education in LMICs.

### CLINICAL RELEVANCE/APPLICATION

To improve sustainability and capacity building in radiology, it is important to emphasize low cost, sustainable and replicable educational tools, and relationship building, such as this peer learning conferences. Additionally, this format can be replicated with minimal cost and infrastructure by other institutions.

## W5B-SPMS-2 US RADIOLOGY RESIDENCY PROGRAMS WITH CLINICIAN EDUCATOR TRACK AND BEYOND: WHO AND WHERE THEY ARE?

Mohamed Muneer, MD (*Presenter*) Nothing to Disclose

### PURPOSE

While the faculty clinician-educator track is an excellent pipeline to provide the academic community with physicians who excel in patient care, education, and research, specialized clinician-educator tracks for those in training are not as well developed (1,2) . We believe studying the currently available longitudinal clinical-educator tracks is the first step in further guiding the development of new ones, honing established ones, and directing future research.

### METHODS AND MATERIALS

A list of a total of 197 radiology residency programs in the US was generated via AMA-FRIEDA (3). Each program website was searched for the presence or absence of a longitudinal clinical-educator track, not including research-scholar tracks. Also, additional programs were added using the “Academic or Clinician Educator” special track filter tool. Additional programs were identified through personal communication/connection.

## RESULTS

A total of 23 radiology residency programs out of 197 (11.7%) were identified to have a clinician-educator track. Table 1 summarizes these programs and provides a direct link to their clinician-educator track and its details, when available. While the prevalence of longitudinal clinical-educator tracks across U.S. radiology residency programs is not high, these results do not capture other forms of health profession education efforts and capacity building by different programs. For example, Kansas University offers their 2nd-year radiology residents 10 half-day workshops on principles of health profession education, adult learning, and assessment as well as effective feedback. Other programs, such as our own ***, offer longitudinal protected time to their residents to foster their academic interests which could be dedicated towards medical education, as well as continuous development programs across the institute such as the *** Program.Other disciplines with more established longitudinal clinician-educator tracks, such as general internal medicine, have seen broad benefits to their residents (8,9). Also, a survey of Alliance of Directors and Vice Chairs of Education in Radiology (ADVICER) members showed that they support the development of a clinician-educator track as well as a national curriculum. Future research evaluating programs' experience, challenges, and success is warranted(10).

## CONCLUSION

These results support the increased development of clinician-educator pathways for radiology residents.

## CLINICAL RELEVANCE/APPLICATION

This abstract encompasses all the available radiology residency programs in the US with a clinician-educator track. which is helpful for collaboration, facilitating future research efforts, and guiding other programs trying to establish new tracks.

## W5B-SPNMMI-1 OPTIMIZING VOLUMETRIC $^{18}$F-FDG PET/CT TUMOR ASSESSMENT IN ENDOMETRIAL CANCERS

Camilla Krakstad, PhD (*Abstract Co-Author*) Nothing to Disclose
Julie Andrea Dybvik, MD (*Abstract Co-Author*) Nothing to Disclose
Sunniva Lindas (*Abstract Co-Author*) Nothing to Disclose
Ankush Gulati (*Abstract Co-Author*) Nothing to Disclose
Ingfrid H. Haldorsen, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Kristine E. Fasmer, PhD, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

To establish an optimal method for metabolic tumor volume (mtv) delineation in 18F-fluoro-deoxy-glucose (FDG) positron emission/computed tomography (PET/CT) of endometrial cancers, by assessing interobserver agreement for different mtv delineations, their correlation to anatomical tumor volume (atv) from magnetic resonance imaging (MRI), and ability to predict aggressive disease.

### METHODS AND MATERIALS

This study included 154 consenting patients with histologically confirmed endometrial cancer who had undergone preoperative FDG PET/CT on two scanners, Siemens TruePoint (n=74) and Siemens Vision (n=80). Reader 1 (R1) defined the outer primary tumor borders using a masking tool, in which six different thresholds were applied: mtv2.5 (suv > 2.5), mtv20%-60% (suv > 20, 30, 40, 50 and 60% of suvmax). Reader 2 (R2) independently measured mtv2.5 and mtv40%, and intraclass correlation coefficients (ICCs) between R1 and R2 were calculated. Preoperative contrast-enhanced T1-weighted MRIs were available for 153/154 patients, from which atv were segmented by reader 3 (R3). Correlation between atv and the mtvs were assessed using Spearman's rank coefficient (?). Combat harmonization of the mtvs was applied to correct for interscanner variation, before deriving area under receiver operating characteristic curves (AUC ROCs) and time dependent ROCs (AUC tdROC) for predicting lymph node metastases (LNM), advanced stage (International Federation of Gynecology and Obstetrics (FIGO) stage III-IV), and progressing disease, respectively.

### RESULTS

Interobserver agreement was highest for mtv2.5 (ICC [95% confidence interval (CI)]:0.98 [0.96-0.98]), while slightly lower for mtv40% (ICC [95% CI]: 0.91 [0.88, 0.93]). mtv2.5 yielded highest correlation to atv (?=0.90), while mtv20-60% yielded decreasing correlation with increasing thresholds (?: 0.75-0.87). The median % difference from atv was highest for mtv2.5 (87%) and lowest for mtv30% (-3%). The ROC/tdROC AUCs for predicting LNM, FIGO III-IV, and progression, were overall similar for mtv2.5 and mtv20-50% (0.69-0.72 for LNM; 0.77 for FIGO III-IV 0.72-0.74 for progression), however incrementally lower for mtv60% (0.66 for LNM; 0.74 for FIGO III-IV; 0.72 for progression).

### CONCLUSION

Of the investigated metabolic tumor thresholds, mtv2.5 yielded highest interreader agreement and correlation to atv, while mtv30% was most similar (in volume) to atv. For predicting advanced/aggressive disease, mtv2.5 and mtv20-50% yielded similar AUCs.

### CLINICAL RELEVANCE/APPLICATION

Calculating FDG PET/CT metabolic tumor volume using suv >2.5 as threshold, yields excellent interobserver agreement, high correlation to MRI tumor volume, and may aid in staging and prognostication of endometrial cancers.

## W5B-SPNPM-1 ARTIFICIAL INTELLIGENCE UTILIZATION IN U.S. RADIOLOGY PRACTICES

Jay R. Parikh, MD, FRCPC (*Abstract Co-Author*) Nothing to Disclose
Eric M. Rubin, MD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth H. Dibble, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the use of artificial intelligence (AI) in radiology practices in the United States

### METHODS AND MATERIALS

The ACR Commission on Human Resources fielded the 2023 ACR/RBMA Workforce Survey from 1/5/24-2/4/24. The sample drew from the ACR members (31,085) and non-members (11,565) and RBMA members (1,739). The survey used structured closed-end questions, consistent with earlier surveys. Responses were group practice deduplicated and weighted and compared to 2022 and 2021. Statistical significance was defined as $p<0.05$.

### RESULTS

1642 respondents completed the survey. There has been a significant growth in the proportion of practices using both clinical and non-clinical AI (Figure), now with nearly half of respondents indicate utilizing some form of AI in their practice, and 16% utilizing it for both clinical and non-clinical use in 2023 compared to 11% in 2022 (p=0.02). When examined by subspecialty, there has been a significant growth in the use of AI in neuroimaging in 2023 compared to 2022 (60% in 2023 versus 47% in 2022, p=0.01, Figure). AI use in thoracic imaging, emergency imaging, general radiology, cardiovascular imaging, and musculoskeletal imaging also grew in 2023, although these increases did not reach significance. Compared to 2023, there has been a significant growth in the utilization of AI for clinical productivity, now with 58% of respondents indicating utilization of AI to improve productivity compared to 41% in 2022, p=0.02 (Figure). Other non-clinical uses of AI include use for billing/coding, for research, for exam assignments, for patient scheduling, and for prior authorization.

### CONCLUSION

The utilization of AI in radiology grew in 2023 compared to 2022, with nearly half of survey respondents indicating some form of utilization of AI in their practice. Utilization of AI grew significantly in neuroradiology in 2023 compared to 2022, and utilization of AI for non-clinical purposes grew significantly in 2023 compared to 2022.

### CLINICAL RELEVANCE/APPLICATION

Knowledge of current AI use among radiology practices in the United States can help practices benchmark their utilization of AI compared to other practices and enable informed decisions regarding incorporation of AI into their practices.

## W5B-SPNPM-2 CORRELATION OF PRACTICE CHOICE BY GRADUATING RADIOLOGY RESIDENTS BASED ON US MACRO ECONOMIC GDP CYCLE: THE ECONOMY MATTERS!

William W. Mayo-Smith, MD (*Abstract Co-Author*) Nothing to Disclose
Sandra Palma (*Abstract Co-Author*) Nothing to Disclose
Sara M. Durfee, MD (*Abstract Co-Author*) Nothing to Disclose
Glenn C. Gaviola, MD (*Abstract Co-Author*) Nothing to Disclose
Dionne Zhen (*Abstract Co-Author*) Nothing to Disclose
Khushboo Jhala, MD,MBA (*Presenter*) Nothing to Disclose

### PURPOSE

To determine if there is a correlation between US Economic Cycle and Radiology Resident's Choice of Academic vs Private Practice.

### METHODS AND MATERIALS

United States Gross Domestic Product (GDP) from 2002-2023 was obtained to determine periods of GDP deceleration, notably the 2008 mortgage crisis and the 2020 COVID-19 pandemic. An alumni database including 3 years of graduating classes pre and post the two periods of GDP deceleration was created for the years 2005 - 2010 (n=53) and 2019 - 2024 (n=59). Public internet database search query was used to gather information on graduates' current practice type and leadership positions. Student's T-test was used to compare ratios of alumni in academic practices vs other practice model types (private, tele, community hybrid), for graduation years pre versus post GDP decelerations.

## RESULTS

64% (18/28) of alumni that graduated during the COVID GDP deceleration currently practice in an academic radiology setting vs 32% (10/31) of alumni that graduated during the post-COVID GDP acceleration ($P<0.05$). 31% (9/29) of alumni that graduated during the mortgage crisis GDP deceleration currently practice in an academic setting vs 8% (2/24) of those that graduated during the period of GDP acceleration before the crisis. Teleradiology was the largest growing new segment of practice model type in the past six years with 12% (7/59) of total 2019 - 2024 graduates currently signed to this type of practice model, compared to 0% (0/53) from 2005-2010. Alumni in private practices have “academic adjunct” leadership positions with examples including Director of AI and Global Outreach.

## CONCLUSION

There is an inverse relationship between alumni graduating during a period of economic growth, and practice in an academic radiology setting. Academic Radiology practices should develop new recruitment strategies during periods of economic growth to maintain a stable workforce.

## CLINICAL RELEVANCE/APPLICATION

Amidst global staffing shortages, there is higher market competition to recruit graduating radiology trainees. Understanding recruitment competition and competitive advantages based on GDP cycle can help academic practices triage when to invest resources in recruitment.

## W5B-SPNR-10 IMPACT OF ARTIFICIAL INTELLIGENCE-BASED DETECTION OF LARGE VESSEL OCCLUSION AMONG STROKE PATIENTS

Huanwen Chen (*Abstract Co-Author*) Nothing to Disclose
Dheeraj Gandhi, MBBS, MD (*Abstract Co-Author*) Research Grant, Stryker CorporationResearch Grant, Medtronic plc
Marco Colasurdo, MD (*Abstract Co-Author*) Nothing to Disclose
Mihir Khunte (*Abstract Co-Author*) Nothing to Disclose
Ajay Malhotra, MD, MMM (*Presenter*) Nothing to Disclose

### PURPOSE

To study the role of artificial intelligence (AI)-based detection algorithms for large vessel occlusion (LVO) strokes in comparison to standard human-guided detection methods.

### METHODS AND MATERIALS

The National Inpatient Sample Database 2021 was queried to identify adult patients (18 years or older) with a primary diagnosis code for cerebral infarction due to internal carotid artery (ICA) and middle cerebral artery (MCA) occlusion. The use of AI-based detection was determined based on the presence of the designated ICD-10 Procedure Code for AI software in LVO detection (4A03X5D). Patient demographics, medical comorbidities, stroke risk factors, treatment with intravenous thrombolysis and endovascular thrombectomy (EVT), and treatment center characteristics were identified. The rate of EVT, good outcomes, and mortality were compared between patients who received AI-based LVO detection and those who did not. Secondary outcomes include length of stay (LOS) and cost of hospitalization. Multivariable logistic regression analyses were conducted to adjust for confounders.

### RESULTS

163,460 LVO stroke patients were identified; 14,885 (9.1%) received AI-based LVO detection. The patients in the LVO group were a little older, more likely to have MCA strokes, and more likely to have an intermediate or high frailty score. Patient demographics such as race and income quartile were similar across both groups. After multivariable adjustments, AI patients had higher odds of receiving EVT (OR 1.55 [95% CI 1.35 - 1.79], p= <0.001). The odds of good outcome were similar (OR 0.94 [95% CI 0.83 - 1.06], p= 0.332) across both groups but the odds of morality were significantly lower in the AI group (OR 0.81 [95% CI 0.67 - 0.98], p= 0.029). The LOS was similar between both groups (+0.1 [95% CI -0.3- 0.5], p=0.563). AI was moderately associated with increased costs (+$1,716 [95% CI -$104 - $3,535], p=0.065).

### CONCLUSION

AI-based LVO detection software was associated with increased rates of EVT utilization and decreased mortality. The odds of good outcome and length of stay were similar between the AI and non-AI groups.

### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence-based large vessel occlusion detection software is associated with increased rates of endovascular thrombectomy utilization and decreased mortality. The odds of good outcome and length of hospital stay may not be impacted by the use of AI LVO detection software.

## W5B-SPNR-12 CHANGES OF GABA AND PH IN MILD COGNITIVE IMPAIRMENT USING BIOMAGNETIC RESONANCE

Xiaona Fu (*Presenter*) Nothing to Disclose

### PURPOSE

Mild cognitive impairment (MCI), an intermediate transition state between normal aging and dementia, is accompanied by changes in the internal environment within the brain, such as neurotransmitters, and PH. The purpose of this study was to investigate the GABA levels in the anterior and posterior cingulate cortex (ACC/PCC) and PH in the bilateral hippocampus of MCI patients using the MEGA-PRESS and CEST biomagnetic resonance technologies.

### METHODS AND MATERIALS

This study included 14 MCI patients and 15 healthy controls (HC), all of whom underwent neuropsychological assessments. Afterward, the ACC and PCC were scanned using MEGA-PRESS, and the bilateral hippocampus was scanned using CEST for all participants. The GABA levels were automatically calculated by the Gannet 3.1 software package. Measurement of in vivo absolute pH using AACID by multipool Lorentzian fitting of CEST MRI. P <0.05 was significant.

### RESULTS

Compared with HC, the MCI group had lower levels of GABA+/Cr (p=0.010) and Glx/Cr (p=0.012) in the ACC. In addition, the MCI group showed reduced amine (p=0.036) and AACID (p=0.021) in the right hippocampus and elevated AACID (p=0.021) in the left hippocampus. The MCI patients also had significantly worse MoCA and episodic memory. In addition, patients showed significantly worse FDS (p =0.005) and BDS (p =0.018) scores and longer STT-B (p<0.001) consumption time. Of all participants, the GABA+/Cr in the ACC was significantly positively correlated with MoCA (p=0.015), AVLT-immediate recall (p=0.006), and AVLT-delayed recall (p=0.016). The Glx/Cr in the ACC was positively correlated with MoCA (p=0.032) and AVLT-delayed recall (p=0.025). This study also showed that AACID in the right hippocampus was significantly negatively correlated with FDS scores (r=-0.485, p=0.012), and a tendency for AACID in the left hippocampus to be negatively correlated with AVLT-immediate recall scores (r=-0.385, p=0.052). However, there were no significant correlations between right hippocampal amine and cognitive scales.

### CONCLUSION

This study reveals that GABA in ACC and PCC and bilateral hippocampal AACID were altered in MCI patients compared to the HC group. Meanwhile, GABA and AACID are closely associated with cognitive function, which further suggests that the GABA levels in the ACC, and AACID in the bilateral hippocampus may be the potential imaging markers for diagnosing MCI patients.

### CLINICAL RELEVANCE/APPLICATION

The levels of GABA in the ACC and PH in the bilateral hippocampus hold promise as potential biomarkers for diagnosing and guiding therapeutic interventions in MCI patients.

## W5B-SPNR-13 EVALUATION OF GLYMPHATIC SYSTEM ACTIVITY IN PATIENTS WITH TYPE 2 DIABETES MELLITUS BY DIFFUSION MRI WITH DTI-ALPS

Wei-wei Wang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hongjun Jiang (*Abstract Co-Author*) Nothing to Disclose
Shuncheng Yu (*Presenter*) Nothing to Disclose

### PURPOSE

Our study aims to utilize the Diffusion tensor image analysis of the perivascular space (DTI-ALPS) technique to assess the function of the glymphatic system in T2DM patients, and to explore whether such changes are correlated with cognition level and diffusion parameters.

### METHODS AND MATERIALS

The study involved 41 patients with T2DM(mean age, 60.49±8.88 years) and 27 healthy controls(mean age, 58.00±7.63 years). All subjects underwent MRI examination, cognitive assessment, and laboratory tests. The ALPS index was used to evaluate glymphatic system function. Tract-based spatial statistics (TBSS) was used to evaluate white matter changes. GLM was performed to check the DTI-ALPS index difference between T2DM and HC groups. Spearman correlation analysis and partial correlation analysis was used to analyze the correlation between the DTI-ALPS index, diffusion properties, cognitive scales.

### RESULTS

Independent two-sample t-test revealed a lower ALPS index in the T2DM group compared to the HC group(P < 0.001). The mean value of the ALPS index was lower in T2DM (1.30±0.13) than in HC (1.44±0.11). After controlling for age, gender, years of education, BMI, triglyceride, total cholesterol , low-density lipoprotein, and high-density lipoprotein, GLM analysis showed a lower ALPS index in the T2DM group than in the HC group(P=0.007).Spearman correlation analysis showed that the Montreal Cognitive Assessment (MoCA) score was significantly correlated with the ALPS index in T2DM patients(r=0.387,P=0.012). Partial correlation analysis showed that MoCA score still correlates with ALPS index after including age, gender, years of education BMI, triglyceride, total cholesterol , low-density lipoprotein, and high-density lipoprotein as covariates(r=0.352,P=0.044). Patients with T2DM had a significant increase in both mean diffusivity (MD) and radial diffusivity (RD) and decrease in fractional anisotropy (FA) in these clusters compared to the HC group. No correlation between the DTI-ALPS index and TBSS index were observed in T2DM group, including MD(r=0.070, P=0.666), RD cluster 1(r=0.004,P=0.981), RD cluster 2(r=0.028,P=0.860), FA(r=0.012,P=0.943).

### CONCLUSION

The results suggest that the glymphatic system function is declined in T2DM patients and associates with cognitive level.

### CLINICAL RELEVANCE/APPLICATION

First, we found that the mean value of the ALPS index in T2DM patients was lower compared to healthy controls. Second, we found a significant correlation between ALPS index and MoCA score in T2DM patients.

## W5B-SPNR-14 THE MEDIATION EFFECTS OF WHITE MATTER MICROSTRUCTURAL ABNORMALITIES IN THE ASSOCIATIONS BETWEEN CEREBRAL SMALL VESSEL DISEASE BURDEN AND COGNITIVE IMPAIRMENT

Na Wang (*Abstract Co-Author*) Nothing to Disclose
Lingfei Guo, MD (*Abstract Co-Author*) Nothing to Disclose
Xinyue Zhang (*Abstract Co-Author*) Nothing to Disclose
Yian Gao (*Abstract Co-Author*) Nothing to Disclose
Changhu Liang, MD, PhD (*Abstract Co-Author*) Nothing to Disclose

Yuanyuan Wang (*Abstract Co-Author*) Nothing to Disclose
Pengcheng Liang (*Abstract Co-Author*) Nothing to Disclose
Chaofan Sui (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to characterize white matter (WM) microstructural abnormalities in subjects with cerebral small vessel disease (CSVD) coexisting with different CSVD burdens and further to investigate the exactly mechanism for how different CSVD burdens influence cognitive decline in CSVD.

### METHODS AND MATERIALS

Fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD) and radial diffusivity (RD) images from 56 subjects with severe CSVD burden (CSVD-s), 109 subjects with mild CSVD burden (CSVD-m) and 81 healthy controls were analyzed using diffusion tensor imaging (DTI)-derived tract-based spatial statistics to detect WM diffusion changes among groups. Partial correlations between cognitive parameters and regional diffusion metrics/CSVD burdens for CSVD subjects were investigated. Furthermore, mediation analysis was conducted to examine whether ROI-wise diffusion biomarkers could modulate the relationship between CSVD burdens and cognitive function.

### RESULTS

The CSVD-s group showed significantly decreased FA and increased AD, RD and MD in multiple WM clusters, mainly including the forceps minor, bilateral anterior thalamic radiation (ATR), corticospinal tract (CST), superior longitudinal fasciculus (SLF) and inferior fronto-occipital fasciculus (IFOF). Compared to FA and AD, the WM alterations characterized by RD and MD were more extensive. Furthermore, significant partial correlations were observed between cognitive parameters and regional diffusion metrics/CSVD burdens for CSVD subjects. The simple mediation model showed that the presence of brain WM diffusion biomarkers played a significant mediating role in the relationship between CSVD burden and the scores of Montreal Cognitive Assessment (MoCA), Symbol Digit Modalities Test (SDMT), Stroop Color and Word Test (SCWT).

### CONCLUSION

The CSVD-s group exhibits extensive WM microstructural deterioration and cognitive dysfunction. The presence of brain WM diffusion biomarkers played a significant mediating role in the relationship between CSVD burden and cognitive impairment. Combining DTI-derived diffusivity and anisotropy metrics can provide complementary information for assessing WM alterations associated with cognitive dysfunction, which helps us to understand the mechanism of cognitive impairment in CSVD-s.

### CLINICAL RELEVANCE/APPLICATION

CSVD is the main cause of stroke and cognitive impairment, which seriously affects people's quality of life. Combining DTI-derived diffusivity and anisotropy metrics can provide complementary information for assessing WM alterations associated with cognitive dysfunction and serve as a potential discriminative pattern to detect CSVD at the individual level.

## W5B-SPNR-15 EVALUATION OF EFFECTIVENESS OF ICH AND LVO DETECTION ALGORITHMS ON CT IMAGES ACQUIRED FROM THE MOBILE STROKE TREATMENT UNIT

Mohammadreza Hosseini-Siyanaki (*Abstract Co-Author*) Nothing to Disclose
Keith R. Peters, MD (*Abstract Co-Author*) Nothing to Disclose
Hakki S. Sagdic, MD (*Abstract Co-Author*) Nothing to Disclose
Abheek Raviprasad, MD (*Abstract Co-Author*) Nothing to Disclose
Evelyn Y. Anthony, MD (*Abstract Co-Author*) Nothing to Disclose
Bruno Hochhegger, MD,PhD (*Abstract Co-Author*) Nothing to Disclose
Reza Forghani, MD, PhD (*Presenter*) Consultant, General Electric Company;Research Grant, General Electric Company;Research Grant, Intel Corporation;Research Grant, Toronto-Dominion Bank;Research Grant, McGill University Health Centre Foundation;President, Montreal Imaging Experts Inc

### PURPOSE

Mobile stroke treatment units (MSTU) equipped with CT scanners enable expedited stroke diagnosis and care in the prehospital setting. Artificial intelligence (AI) algorithms that assist in detection of intracranial hemorrhage (ICH) and large vessel occlusion (LVO) potentially allow for more accurate and timely diagnosis and management of patients presenting with stroke. We evaluated the diagnostic ability of RAPID ICH and RAPID CTA on imaging acquired via the MSTU.

### METHODS AND MATERIALS

RAPID ICH and RAPID CTA algorithms were automatically applied to select non-contrast CT (NCCT) and head CTA studies acquired within the MSTU at our institution. A consensus reading between a board-certified neuroradiologist and vascular neurologist was used as the reference standard. In cases of discrepancy between neurologist and radiologist, another board-certified academic neuroradiologist provided the final reference standard. Examinations were considered positive if there was evidence of ICH, LVO, M2 and M3 segment occlusion, or an acute large territory infarct. The diagnostic accuracy of RAPID ICH and RAPID CTA were determined by calculating the sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV), and overall accuracy.

### RESULTS

One hundred eighty-four consecutive patients who presented with stroke-like symptoms via the MSTU were included for analysis, consisting of a mixture of NCCT only and head CTAs. RAPID ICH was applied to 179 NCCT studies and RAPID CTA was applied to 64 CTA studies. RAPID ICH correctly identified 5/5 ICH cases and 173/173 ICH negative cases, resulting in sensitivity of 100%, specificity of 99.42%, PPV of 83.33%, NPV of 100%, and accuracy of 96.73%. There was 1 false positive interpretation by the algorithm due to a partially calcified cavernoma. Using 45% relative vessel density threshold, RAPID CTA achieved sensitivity of 63.15%, specificity of 84.44%, PPV of 63.15%, NPV of 91.66%, and accuracy of 78.12%. When using a 60% relative vessel density threshold, sensitivity and NPV increased to 84.21% and 91.66%, respectively. Notably, 2 of the false positive RAPID CTA results were due to IV failures prior to CTA acquisition. In one case, RAPID CTA identified a mid M2 occlusion that was initially overlooked by the human expert.

### CONCLUSION

RAPID ICH and RAPID CTA at 60% vessel density threshold demonstrated high sensitivity for ICH and LVO detection on CT and CTA images, respectively, acquired on the MSTU.

### CLINICAL RELEVANCE/APPLICATION

Imaging acquired via the MSTU can often be technically deficient and is first evaluated by the vascular neurologist. High sensitivity automated detection algorithms can lead to more accurate interpretation of stroke imaging and expedited treatment.

## W5B-SPNR-16 LEFT FRONTAL CONNECTIVITY ATTENUATES THE ADVERSE EFFECT OF SYSTEMATIC INFLAMMATION ON MEMORY

Qihui Wang (*Abstract Co-Author*) Nothing to Disclose
Qi Yang, MD (*Abstract Co-Author*) Nothing to Disclose
Xiuqin Jia (*Presenter*) Nothing to Disclose

### PURPOSE

The current study aimed to examine the postoperative changes in congitive reserve (CR) and to explore its protective effect on memory function after cardiac surgery.

### METHODS AND MATERIALS

A total of 25 patients underwent heart valve replacement were recruited to complete neuropsychological assessments and MRI examinations at baseline, 7-day and 30-day after cardiac surgery compared to 25 age- and sex-matched healthy controls. CR was calculated by global left frontal cortex connectivity (gLFC-connectivity) using fMRI. Inflammatory markers were measured by blood levels of Interleukin-6 (IL-6) and tumor necrosis factor-a (TNF-a). In the moderation analysis, we tested the interaction term gLFC connectivity ×inflammatory biomarkers on variations in cognitive function following surgery.

### RESULTS

In the longitudinal follow-up study, gLFC-connectivity was significantly reduced at the 7-day post-surgery compared to the healthy control group ($p = 0.003$). However, there was no statistically difference at the 30-day post-surgery (Figure 1). After controlling for age, gender, and years of education, the study found that the increase in IL-6 from baseline to 7-day post-surgery was significantly negative association with the change of Corsi Block Test (ß [95 % CI] = -0.57 [-0.94, -0.21], $p = 0.004$) from 7-day to 30-day post-surgery. GLFC-connectivity at baseline moderated the negative relationship (ß [95 % CI] = 0.38 [0.07, 0.68], $p = 0.020$) (Figure 2).

### CONCLUSION

GLFC-connectivity attenuates the negative impact of systemic inflammation on postoperative memory recovery. Moreover, cognitive reserve, which aids in the recovery of cognitive function after surgery, can be partially attributed to the enhanced connectivity within the left frontal cortex.

### CLINICAL RELEVANCE/APPLICATION

GLFC-connectivity as a proxy for CR offers a more objective and dynamic reflection of the cognitive reserve. Enhancing preoperative gLFC-connectivity presents a novel approach that may aid in the postoperative recovery of patients' cognitive functions.

## W5B-SPNR-17 TO INVESTIGATE THE EVOLUTION OF EDEMA AROUND HEMATOMA OF HYPERTENSIVE INTRACEREBRAL HEMORRHAGE IN PLATEAU AREA BASED ON CT

Xueqian Zhang (*Abstract Co-Author*) Nothing to Disclose
Hai Hua Bao (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to explore the evolution of PHE in patients with hypertensive intracerebral hemorrhage at different altitudes in high-altitude areas through CT imaging technology.

### METHODS AND MATERIALS

We collected clinical data from patients with hypertensive intracerebral hemorrhage who underwent non-surgical treatment in our hospital from January 2022 to May 2023. These patients were divided into two groups based on altitude gradients: a medium altitude group and a high altitude group. CT scans were performed on the hematoma (HE) of these patients during the hyperacute, acute, subacute, and chronic phases. Using United Imaging Intelligence analysis software, we calculated the volumes and corresponding CT values of HE (HE1-HE4) and PHE (PHE1-PHE4) for each phase, and recorded other imaging features and clinical indicators. Initially, basic statistical methods were used to explore differences in imaging and clinical characteristics between the two groups. Subsequently, the Scheirer-Ray-Hare test was employed to compare the evolution trends of PHE between the two groups.

### RESULTS

A total of 135 patients with HICH were collected, including 77 in the medium altitude group and 58 in the high altitude group. Statistically significant differences were observed between the two groups in terms of HE1-HE4 volumes, HE1 CT value, (PHE1-PHE3) CT values, red blood cell count, hemoglobin, hematocrit, time from onset to treatment, D-dimer, gender, and ethnicity (all $p < 0.05$). The Scheirer-Ray-Hare test revealed a statistically significant difference in the evolution of PHE between the two groups ($p < 0.05$), and there were also statistically significant differences in PHE volumes across the four phases within the high altitude group ($p < 0.05$).

### CONCLUSION

There exist certain differences in imaging, clinical indicators, and the evolution of PHE between the two groups of patients with hypertensive intracerebral hemorrhage.

### CLINICAL RELEVANCE/APPLICATION

These findings contribute to the clinical personalization of treatment for patients at different altitudes and provide more targeted recommendations for clinical treatment and rehabilitation.

## W5B-SPNR-18 CORRELATION STUDY BETWEEN CHANGES IN BRAIN NEUROVASCULAR COUPLING ON MRI AND INTESTINAL FLORA IN PATIENTS WITH T2DM

Jianlin Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Xuyang Wang (*Abstract Co-Author*) Nothing to Disclose
Dong Yang, BMedSc, MMEd (*Presenter*) Nothing to Disclose

### PURPOSE

To quantitatively evaluates the changes in neurovascular coupling (NVC) in the gray matter within the T2DM patients and analyze their correlation with abnormal changes in gut microbiota.

### METHODS AND MATERIALS

Forty patients with type 2 diabetes mellitus and 24 healthy controls were prospectively collected in our study. The mTI-ASL sequence and resting state BOLD-fMRI sequence were preprocessed respectively to obtain the whole brain ReHo and CBF maps of all subjects. and the stool samples of all subjects were collected 1 day before the MRI examination . The ReHo/CBF ratio of each voxel under the gray template of all subjects was calculated. The two-sample t-test was performed on the ReHo/CBF ratios of the two groups, and the Mantel correlation analysis was performed on the ReHo/CBF ratios of the brain regions with statistically significant differences between the two groups.

### RESULTS

(1) T2DM group NVC showing increased ReHo/CBF ratios in bilateral inferior frontal gyrus, left central sulcus cap, left rectus gyrus, bilateral insula, bilateral anterior cingulate gyrus, right middle cingulate gyrus, bilateral superior temporal gyrus (all $P<0.05$, FDR correction);decreased ReHo/CBF ratios in left anterior central gyrus, left middle cingulate gyrus, bilateral fusiform gyrus, left posterior central gyrus, left parietal gyrus, bilateral caudate nucleus, left inferior temporal gyrus, left paracentral lobule (all $P<0.05$, FDR correction). (2) There was a correlation between intestinal flora disorder and brain NVC, showing positive correlations between the abundance of Actinobacteria and ReHo/CBF ratios in left rectus gyrus ($r =0.290$, $P=0.003$), left posterior central gyrus, and left paracentral lobule ($r=0.266$, $0.268$, $P=0.029$, $0.008$);positive correlations between the abundance of Bifidobacterium and ReHo/CBF ratios in left rectus gyrus ($r =0.283$, $P=0.001$), left anterior central gyrus, and left paracentral lobule ($r=0.186$, $0.218$, $P=0.014$, $0.004$).

### CONCLUSION

There is a correlation between the abnormal changes in NVC and the abundance and diversity of intestinal flora, indicating that they may play an important mutual regulatory mechanism through the flora-gut-brain axis, which is expected to provide new ideas and imaging and microbiological markers for the further research and clinical diagnosis and treatment of T2DM in the future.

### CLINICAL RELEVANCE/APPLICATION

The combination of the rs-fMRI and ASL technology can used to quantitatively evaluate changes in neurovascular coupling in T2DM patients , which is expected to provide new ideas and imaging and microbiological markers for the further research and clinical diagnosis and treatment of T2DM in the future.

## W5B-SPNR-2 METASTASIS DETECTION USING TRUE AND ARTIFICIAL T1-WEIGHTED POST-CONTRAST IMAGES IN BRAIN MRI

Robert Haase, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the sensitivity and precision in metastasis detection on true contrast-enhanced T1w images and artificial images synthesized by a deep-learning method using low-dose images.

### METHODS AND MATERIALS

In this prospective, multicentric study (five centers, twelve scanners), 917 patients received a brain MRI scan between October 2021 and March 2023 including T1w low-dose (0.033 mmol/kg) and full-dose images (0.1 mmol/kg). A stratified random sample of 60 participants was selected as test set. Of these, 40 participants with cerebral metastases or unremarkable brain findings were used as reading set (mean age, 54.3±15.1 [SD] years, 24 men). Participants' true and artificial T1w images were evaluated in random order with a period of four weeks between readings by two board-certified neuroradiologists. The readers guessed the assessed sequence's identity and marked all presumed metastases. Cases were reviewed by a reference reader, utilizing all available sequences, reports, and readers' findings to determine any metastases present. Performances were compared using Mid-p McNemar tests for sensitivity and two-sided Wilcoxon signed-rank tests for false-positive findings.

### RESULTS

Both readers guessed the correct identity in 40/80 cases. 97 metastases were identified by the reference reader. The sensitivity of reader 1 did not differ significantly between sequences (sensitivity [precision]; true: 66.0% [98.5%], artificial: 61.9% [98.4%], p=.38). Having a lower precision than reader 1, reader 2 found significantly more metastases using true images (sensitivity [precision]; true: 78.4% [87.4%], artificial: 60.8% [80.8%], p<.001). There was no significant difference in sensitivity for lesions larger than 5 mm. The number of false-positive lesions did not differ significantly between sequences.

### CONCLUSION

There was a similar detection performance for lesions larger than 5 mm. However, one reader showed a significantly higher overall sensitivity using true images when accepting a lower precision.

### CLINICAL RELEVANCE/APPLICATION

Small lesions are the limiting factor for reducing gadolinium-based contrast agents in brain MRI.

## W5B-SPNR-3 IMMEDIATE MODULATORY EFFECTS OF DIFFERENT FREQUENCIES OF TRANSCUTANEOUS AURICULAR VAGUS NERVE STIMULATION ON THE BRAIN NETWORKS IN SUBJECTIVE COGNITIVE DECLINE

Lingyan Liang (*Abstract Co-Author*) Nothing to Disclose
Xiaocheng Li (*Presenter*) Nothing to Disclose

**PURPOSE**

The aim of this study was to investigate the immediate modulatory effects of different frequencies of transcutaneous auricular vagus nerve stimulation (taVNS) on brain networks in subjective cognitive decline (SCD) .

**METHODS AND MATERIALS**

A total of 49 SCD patients and 39 age-, sex-, years of education-matched healthy controls (HCs) were included in this study. We used amplitude of low frequency (ALFF) to compare the differences of the brain activity between SCD and HCs at baseline, and to investigate the immediate modulatory effects of 1Hz-taVNS, 20Hz-taVNS and sham-taVNS (staVNS) on the spontaneous neural activities of SCD patients.

**RESULTS**

Compared with the HCs, the ALFF values of the right middle temporal gyrus, right inferior temporal gyrus, and right superior frontal gyrus decreased at baseline in SCD. At the time of taVNS stimulation, compared with baseline, the ALFF values increased in the right fusiform gyrus, right occipital gyrus and right middle temporal gyrus in the 1Hz-taVNS group, while decreased in the left dorsolateral superior frontal gyrus, left dorsolateral middle frontal gyrus, left precentral gyrus and left supplementary motor area; In the 20Hz-taVNS group, the ALFF values increased in the right middle temporal gyrus, right inferior temporal gyrus, right middle occipital gyrus, right inferior occipital gyrus, right fusiform gyrus and right angular gyrus, while decreased in the right medial and paracuneus gyrus, right supplementary motor area, right orbito frontal supramarginal gyrus, left precentral gyrus, left dorsalateral superior frontal gyrus; No significant changes of ALFF values of the brain could be found in staVNS group.

**CONCLUSION**

The spontaneous neural activities decreased and preferred the right hemisphere in SCD. taVNS could activate the neural activities of the right hemisphere and inhibit that of the left hemisphere to keep the balance in SCD, the barin regions mainly involved the limbic system, default mode network, central executive network, visual network, and sensory-motor network. 20Hz-taVNS made more extensive modulation effect on the brain networks related to cognitive functions than 1Hz-taVNS, and hold great potential for the treatment of SCD.

**CLINICAL RELEVANCE/APPLICATION**

SCD is regarded as the preclinical stage of Alzheimer's disease (AD) and may be a critical window of the prevention and treatment of AD. This study obtained the appropriate frequency of taVNS for the interventions of SCD and provided basis for its future clinical application.

## W5B-SPNR-5 COMPARATIVE ANALYSIS OF CERVICAL SPINE FRACTURES AND MECHANISMS OF INJURY IN DIFFERENT AGE COHORTS

Mahla Radmard, MD (*Abstract Co-Author*) Nothing to Disclose
David M. Yousem, MD, MBA (*Abstract Co-Author*) Royalties, RELX;Speaker, MRI Online;Board Member, MRI Online;
Akua Amoah, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Armin Tafazolimoghadam (*Abstract Co-Author*) Nothing to Disclose
Shuchi Zinzuwadia, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

There was a distinction made in the 2001, Canadian Cervical Spine Rule (CCR) regarding patients 65 and over and younger than 65 studied from 1996-1999 as far as indications for cervical spine computed tomography (CSCT) scanning. We sought to determine if there are differences in the fractures seen between these two age groups and their symptoms, mechanisms of injury, fracture locations, and types that are still relevant in 2024.

**METHODS AND MATERIALS**

This IRB-approved retrospective study of CSCT reports from two hospitals' emergency department practices in our health system reviewed 5 years of data on trauma patients. In addition to the primary variable of age, we looked at fracture types, sites, surgical or medical treatments, and also mechanism of injury. Patients were separated into symptomatic/asymptomatic and 65 and older/younger than 65 cohorts.

**RESULTS**

21,986 CSCTs reports were evaluated. 190/9455 (2.0%) of participants aged 65 and older and 199/12531 (1.6%) under 65 exhibited cervical spine fractures. Overall, fractures were identified in 1.8% of the scans. The data indicated a higher prevalence of upper cervical fractures in the older age group, with fewer fractures attributed to motor vehicle accidents. There were many more cases of falls from standing [106 (55.8%)] and falls from height [46 (24.2%)] in the older age group and this mechanism was associated with a higher risk of C1 and C2 fractures [52 (27.4%) and 78 (41.1%) respectively]. Among the C1 fractures, anterior and posterior arch fractures predominated [37(19.5%)]. For C2 fractures, types 2 and 3 odontoid fractures [39(20.5%) and 12(6.3%)] were more common in the older cohort. Motor vehicle collisions were more common in the younger cohort (89(44.7%) and they were associated with more C5-C7 fractures [47 (23.6%), (60 (30.2%), and 66 (33.2%) respectively] including the facets [49 (24.6%)], spinous processes [31 (15.6%)], and transverse processes [52 (26.1%)]. Overall the rates of instability, surgical intervention, and asymptomatic fractures were similar in the younger than and older than 65 age groups. These trends have not changed since the late 1990s CCR data.

**CONCLUSION**

Cervical spine fractures occur in about 1.8% of the CT scans performed in a busy ED environment. Fractures in the elderly occur more commonly due to falls, are located at C1 and C2, and may involve ligamentous injuries. Younger patients incur trauma more commonly due to MVCs and are more likely to affect the posterior elements, especially of C5-C7. These findings have persisted over time since the CCR was established.

**CLINICAL RELEVANCE/APPLICATION**

The study highlights how age-specific injury patterns in cervical spine fractures could enhance imaging guidelines and emergency care, potentially improving patient outcomes.

## W5B-SPNR-6 MESOPOROUS MANGANESE-DOPED NANO-ANTIOXIDANT SUPPRESSES PYROPTOSIS FOR EFFECTIVE ISCHEMIC STROKE THERAPY

Jun Zhang, MD (*Abstract Co-Author*) Nothing to Disclose
Jingyi Zhang (*Presenter*) Nothing to Disclose

**PURPOSE**

Ischemic stroke, a leading cause of global morbidity and mortality, induces cerebral ischemia/reperfusion (CI/R) injury, marked by reactive oxygen species (ROS) generation, oxidative stress, microglial M1 polarization, inflammatory cascade reactions, and cell pyroptosis. Traditional small molecular drugs face limitations, necessitating innovative therapies. Nanozymes, particularly cerium oxide, exhibit promise due to their enzymatic mimicking

capabilities. With this in mind, our goal is to develop a nanoenzyme that can be utilized for stroke diagnosis and treatment under MRI. This will be achieved by hindering cellular pyroptosis and mitigating oxidative stress, leveraging the nanoenzymes' catalytic activity alongside its specially designed drug-loading capability.

**METHODS AND MATERIALS**

In this study, we proposed the synthesis of mesoporous manganese-doped cerium oxide nanoparticles using a hard template method to enhance the catalytic activity of CeO2 through manganese loading and harness its MRI imaging capability. The caspase-1 inhibitor VX765 was encapsulated within the nanoparticles, and the surface was modified with Angiopoietin-2 (Ang2) and DSPE-PEG, yielding DSPE-Ang2-VX765@MMC. After establishing oxygen-glucose deprivation/reperfusion (OGD/R) and middle cerebral artery occlusion/reperfusion (MCAO/R) models in vitro and in vivo, we employed various techniques, including confocal laser microscopy, ELISA, cell and tissue immunofluorescence, and Western blotting, etc., to verify the possible outcomes.

**RESULTS**

The outcomes demonstrate that DSPE-Ang2-VX765@MMC effectively suppressed the complex pathways centered around oxidative stress, cell pyroptosis, and inflammatory cascade reactions, while also regulating the polarization of microglial cells toward the anti-inflammatory M2 phenotype. DSPE-Ang2-VX765@MMC also exhibited excellent MRI capability and the ability to penetrate the blood-brain barrier (BBB).

**CONCLUSION**

DSPE-Ang2-VX765@MMC serves as an ideal example for the integration of nanoenzyme in the diagnosis and treatment of ischemic stroke, offering a promising approach for future research in this field.

**CLINICAL RELEVANCE/APPLICATION**

It can provide strategies for the integration of stroke diagnosis and treatment based on magnetic resonance imaging.

## W5B-SPNR-7 3D STIR SYNTHESIS FOR SPINE MRI BY COMBINING 2D T1W AND 3D T2W INPUTS

Long Wang (*Abstract Co-Author*) Nothing to Disclose
Thomas C. Arnold, PhD (*Presenter*) Nothing to Disclose

**PURPOSE**

Algorithms that synthesize Short Tau Inversion Recovery (STIR) spinal sequences from sagittal T1w and T2w images have shown promise in reducing scan times. However, STIR synthesis algorithms typically require T1w and T2w inputs to have the same slice thickness. Here, we examine the performance of a STIR synthesis algorithm that combines 2D and 3D inputs of varying slice thicknesses.

**METHODS AND MATERIALS**

Data from 25 patients who underwent spinal MRI (cervical: 8, thoracic: 1, lumbar: 16) on a Siemens 3T scanner were analyzed. Each study included three sagittal sequences: 3D T2w, 2D T1w, and 2D STIR. STIR images were synthesized from 2D T1w and 3D T2w inputs using a deep-learning-based algorithm. As part of the preprocessing pipeline, 2D acquisitions are interpolated to match 3D sequence slice thickness. Synthetic STIR image resolution matches the higher resolution input (e.g. 3D T2w). For quantitative evaluation, we compared inputs and synthesized STIR images to the standard-of-care acquired STIR sequences using peak signal-to-noise ratio (PSNR), structural similarity (SSIM), and normalized root mean-squared error (NRMSE).

**RESULTS**

Synthesized and acquired STIR images exhibited comparable in-plane quality, with synthesized images demonstrating notable improvements in through-plane resolution over standard-of-care 2D STIR. Quantitatively, the algorithm yielded promising results, with synthesized images demonstrating increased quantitative performance across all three metrics (PSNR: 20.29 ± 1.58 dB, SSIM: 0.55 ± 0.05, NRMSE: 0.59 ± 0.12) compared to either input image (paired t-test, $p<0.001$). Synthesized images exhibited a 17% increase in PSNR, 15% increase in SSIM, and 58% decrease in NRMSE relative to input images.

**CONCLUSION**

Deep-learning-based methods for STIR synthesis are robust to different slice thickness values for T1w and T2w inputs. Synthesized STIR images generated with 3D sequence inputs showed improved through-plane resolution over standard-of-care 2D STIR sequences.

**CLINICAL RELEVANCE/APPLICATION**

Synthetic STIR generation can accelerate scan times by eliminating the need to collect a 2D STIR. Additionally, high-resolution 3D STIR could offer further acceleration by mitigating the need for axial GRE imaging.

## W5B-SPNR-8 CHANGE IN MANAGEMENT FOR DSA-IDENTIFIED FALSE-POSITIVE TVAI

Hamza A. Shaikh, MD (*Abstract Co-Author*) Nothing to Disclose
Daniel Tonetti (*Abstract Co-Author*) Nothing to Disclose
Corey Mossop (*Abstract Co-Author*) Nothing to Disclose
Jessica Vankawala (*Abstract Co-Author*) Nothing to Disclose
Jane Khalife (*Abstract Co-Author*) Nothing to Disclose
Nicole Fox, MD (*Abstract Co-Author*) Nothing to Disclose
Manisha Koneru (*Abstract Co-Author*) Nothing to Disclose
Renato Oliveira (*Abstract Co-Author*) Nothing to Disclose
Anna Goldenberg Sandau (*Abstract Co-Author*) Nothing to Disclose
Zixin Yi, BS (*Presenter*) Nothing to Disclose

**PURPOSE**

For patients with suspected Traumatic Vertebral Artery Injury (TVAI), CT Angiography (CTA) stands as the first-line screening modality. Digital Subtraction Angiography (DSA) serves as the confirmatory diagnostic imaging, and is the gold standard for cerebrovascular injury assessment, due to its higher sensitivity and specificity. Among patients with TVAI based on CTA who have undergone follow-up DSA, this study aims to investigate the prevalence and clinical significance of a negative result on follow-up DSA, with a specific focus on how diagnostic alterations affect clinical management.

**METHODS AND MATERIALS**

A retrospective review was conducted of a TVAI patient registry over 7 years (2016-2023) at a level 1 trauma center to screen for patients who underwent both CTA and DSA imaging. Patients undergoing angiography for neurointerventional purposes rather than diagnostic screening were excluded.

Among patients initially screened positive on CTA but subsequently negative on DSA, their pre- and post-intervention management was compared, and summarized utilizing odds ratio (OR) analysis.

**RESULTS**

Among the 72 patients studied (excluding 4 patients), 26.39% were determined to have false-positive TVAI upon subsequent DSA evaluation. The likelihood of a change in clinical management (i.e., stopping antithrombotic, adjusting intervention plans, etc.) in patients with negative DSA results was significant ($p < 0.01$). Furthermore, within the negative DSA group, 47.37% experienced immediate changes in clinical management following the revised diagnosis. Among patients maintaining the original treatment plan post negative DSA, a majority exhibited concurrent vascular injuries, warranting continued benefit from prescribed medication, such as continued anticoagulation.

**CONCLUSION**

While DSA typically remains reserved as a confirmatory study for CTA-negative patients with a high clinical suspicion of TVAI, there exists a potential advantage in extending DSA utilization to CTA-positive patients with low suspicion to rule out TVAI. Larger cohort analyses are needed to refine imaging algorithms and optimize clinical outcomes for TVAI patients.

**CLINICAL RELEVANCE/APPLICATION**

This study demonstrates that, despite initial CTA imaging suggestive of TVAI, follow-up DSA imaging negative for TVAI has a significant impact in changing clinical management, including cessation of antithrombotic therapy or modifications to surgical interventions. Thus, for TVAI patients with inconclusive CTA findings, DSA may be considered in the diagnostic workup.

## W5B-SPNR-9 ASSOCIATIONS OF CERVICAL CAROTID PLAQUE CALCIFICATION FEATURES WITH STENOSIS DEGREE IN PATIENTS WITH ISCHEMIC STROKE

Yu Sakai, MD (*Abstract Co-Author*) Nothing to Disclose

Elias Johansson (*Abstract Co-Author*) Nothing to Disclose
Grace Wang (*Abstract Co-Author*) Nothing to Disclose
Huy Q. Phi (*Presenter*) Nothing to Disclose

**PURPOSE**

Plaque calcifications (Pcalc) are prevalent in cervical carotid atherosclerosis, yet their relationship with stenosis and plaque vulnerability remains unclear. We investigated associations between carotid stenosis and Pcalc features on CTA neck exams in ischemic stroke patients.

**METHODS AND MATERIALS**

The Vascular Quality Initiative and institutional stroke registries were retrospectively reviewed to identify patients treated with carotid revascularization for symptomatic stenosis (>70%) and patients who met criteria for embolic stroke of undetermined source (<50% stenosis) and unilateral anterior circulation strokes, respectively. Patients with CTAs and carotid Pcalcs ipsilateral to stroke side were included. Pcalcs across the carotid bifurcation were manually segmented (3D-Slicer) to measure density (Hounsfield units, HU), diametermax, surface area, and volume. Maximum non-calcified plaque thickness was also manually measured. Per-plaque level analyses were performed. Mann-Whitney U tests compared Pcalc features between groups. Spearman correlation analysis examined Pcalc density and non-calcified plaque thicknessmax. Multivariate logistic regression examined associations of Pcalc features by stenosis, adjusting for age, sex, cardiovascular risk factors, and non-calcified plaque thicknessmax.

**RESULTS**

Twenty-six >70% stenotic (agemed=71years, N=6 female) and 60 <50% stenotic plaques (agemed=68years, N=27 female) met inclusion criteria. >70% stenotic plaques had higher total Pcalc volume and surface area per plaque, Pcalc diametermax, and non-calcified plaque thicknessmax ($p<0.001$). Pcalcs from >70% stenotic arteries had lower HUmin and HUmedian values than <50% stenotic arteries ($p<0.001$). Among the >70% stenotic plaques, HUmax showed a moderate negative correlation with non-calcified plaque thicknessmax (?=-0.50, p=0.01). Multivariate logistic regression analyses showed >70% stenotic plaque was associated with higher total Pcalc volumes (ß=0.032, p=0.02) and lower HUmedian (ß=-0.034, p=0.03).

**CONCLUSION**

Pcalcs in >70% stenotic carotid arteries were larger in volume, surface area, and diameter, indicating that Pcalc size contributes to structural stenosis. >70% stenotic plaque also had greater non-calcified plaque thicknessmax and Pcalcs with lower densities, suggesting lower density Pcalcs are associated with non-calcified inflammatory plaque components.

**CLINICAL RELEVANCE/APPLICATION**

Advanced plaques with hemodynamically severe stenosis may result from large Pcalcs or lower-density Pcalcs associated with vulnerable non-calcified plaque. Imaging biomarkers, accounting for plaque composition features, may provide further guidance on stroke risk stratification and treatment.

## W5B-SPOB-1 ANALYSIS OF STRESS CHANGES IN THE LIGAMENT-FREE UTERUS SUBJECTED TO ABDOMINAL PRESSURE BASED ON THREE-DIMENSIONAL PELVIC FLOOR MR MODELING

Ailian Liu, MD (*Abstract Co-Author*) Nothing to Disclose
Ye Li (*Presenter*) Nothing to Disclose

### PURPOSE

To analyze the stress changes of the ligament-less stretched uterus subjected to abdominal pressure using a three-dimensional model of the pelvic floor in healthy volunteers.

### METHODS AND MATERIALS

Data from pelvic floor magnetic resonance imaging (MRI) were collected from 29-year-old healthy women (BMI=21.09 kg/m2, anterior uterus) using an Ingenia 3.0T CX MR scanner (Philips Healthcare, Best, the Netherlands) to obtain compression-aware thin-layer high-resolution 3D T2WI based on the compression-aware thin-layer (5x CS-SENSE acceleration, TR/TE=1250ms/148ms, FOV=300×300mm2, FA: 90°, layer thickness/spacing:1.0mm/-0.5mm, number of layers 240, time 4min55s) to model and remodel the pelvis in 3D, which included the uterus (without cavity), bladder, and rectum. Stress analysis, strain analysis, and maximum displacement analysis of the uterine surface and interior in the Valsalva state were explored by finite elements.

### RESULTS

A three-dimensional model of a ligament-free pelvis was successfully established by pelvic floor MR. The uterus showed that: the stress analysis showed that the maximum stress of the uterus appeared in the anterior wall of the uterine isthmus (Fig. 1a), the maximum displacement appeared in the uterine fundus and body, and the peak appeared in the posterior wall of the uterine body (Fig. 1b). Inside the uterus: the stress analysis showed that the stresses inside the uterus appeared mainly in the body of the uterus (Fig. 2a), and the stresses in the body of the uterus were greater than those on the uterine surface (Fig. 2a vs. Fig. 1a). The maximum displacement occurred in the uterine body and peaked at the posterior wall of the uterine body (Fig. 2b), and the internal uterine displacement was smaller than that indicated by the uterus (Fig. 2b vs. Fig. 1b).

### CONCLUSION

For the uterus without ligament support, the internal uterine isthmus was subjected to the greatest force under abdominal compression, and the uterus showed more stress than the internal. The dorsal displacement of the body of the uterus was the greatest in the pressurized state, and the uterus indicated greater stress than the interior. Through the finite element analysis of the ligamentless uterus, the direct effects of abdominal pressure on the internal and external uterus were preliminarily determined, which can provide some references for clinical work.

### CLINICAL RELEVANCE/APPLICATION

Pelvic floor stress analysis provides an effective adjunct to clinical patient symptom imaging.

## W5B-SPOB-2 SIZE THRESHOLD AS A RISK FOR MALIGNANT TRANSFORMATION IN TYPICAL OVARIAN DERMOID CYSTS: A SCOPING REVIEW

Gavin Low, FRCR (*Abstract Co-Author*) Nothing to Disclose
Mitchell Wilson, MD, FRCPC (*Presenter*) Nothing to Disclose

### PURPOSE

The O-RADS malignancy risk stratification of typical ovarian dermoid cysts by using a 10 cm threshold is based on expert consensus rather than analysis of objective clinical data. This comprehensive scoping review consolidated all currently available studies evaluating typical benign ovarian dermoid cyst size and risk for malignant transformation.

### METHODS AND MATERIALS

A systematic review of MEDLINE, Embase, Scopus and the Cochrane library was performed from inception to January 14, 2024 using PRISMA-ScR guidelines. A grey literature search and forward searching of reference lists from included studies were additionally performed. Case reports and case series evaluating dermoid cyst size and malignant transformation as defined by a pathological reference standard were included in review. Studies were independently screened by one author with full text review and data extraction performed by a second author, both with prior experience in systematic reviews for diagnostic test accuracy studies. Data synthesis was provided as a qualitative review of the existing literature.

### RESULTS

Twenty-five studies were included in qualitative synthesis comprising 6 case reports and 19 retrospective studies with a total of 15,295 dermoid cysts. Of these, 215 lesions demonstrated malignant transformation. Studies reporting dermoid size with malignant transformation ranged from 1-32 cm with 44/180 total malignant transformation lesions measuring < 10 cm in studies where individual size measurements were reported. Solid enhancing components were infrequently reported but all measured > 1 cm when described.

### CONCLUSION

As many as 25% of dermoid cysts with malignant transformation may be missed with the current 10 cm O-RADS malignancy risk threshold. Although surveillance of lesions > 3 cm may improve sensitivity, lower size thresholds for recommending MRI O-RADS with evaluation of solid enhancing tissue may also be appropriate. A large prospective trial is ultimately needed for more accurate evaluation of diagnostic accuracy.

### CLINICAL RELEVANCE/APPLICATION

This study serves as the most comprehensive review and qualitative assessment of dermoid cysts with malignant transformation available to date. Future revisions of the US O-RADS risk stratification system may be improved with lower size thresholds recommendations for MRI O-RADS scoring in ovarian dermoid cysts.

## W5B-SPOB-3 MAGNETIC RESONANCE IMAGING FEATURES OF MESONEPHRIC-LIKE ADENOCARCINOMA OF THE UTERINE BODY

Harushi Mori, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hiroyuki Fujii, MD (*Abstract Co-Author*) Nothing to Disclose
Hiroki Kato (*Abstract Co-Author*) Nothing to Disclose
Kaori Yamada (*Abstract Co-Author*) Nothing to Disclose
Mitsuru Matsuki, MD (*Abstract Co-Author*) Nothing to Disclose
Yuki Himoto, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Tomohiro Kikuchi, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Saki Yamamoto, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Mesonephric-like adenocarcinoma (MLA) of the uterine body was adopted as a new histological type in the World Health Organization 2020 classification. It comprises 1% of all endometrial carcinomas and shares similar morphological, molecular, and immunophenotypic characteristics with mesonephric adenocarcinoma of the uterine cervix. Recent studies have hypothesized that coexisting adenomyosis in the Müllerian duct could be the origin of MLA of the uterine body. In this multi-institutional study, we retrospectively reviewed the magnetic resonance imaging (MRI) findings of 15 patients with MLA of the uterine body and investigated their characteristic features and associations with adenomyosis.

### METHODS AND MATERIALS

The mean age of the patients was calculated, and the presentation of MLA was examined at detection. The MRI scans of the 15 patients pathologically diagnosed with MLA of the uterine body were obtained from four institutions. The following MRI features were independently evaluated by two radiologists blinded to the clinical information: tumor size and apparent diffusion coefficient (ADC) values, tumor growth pattern (endophytic/exophytic), signal intensities compared to the skeletal muscle, heterogeneity on T2-weighted imaging (T2WI), intratumoral hemorrhage on T1-weighted imaging (T1WI), heterogeneity of enhancement on gadolinium (Gd)-enhanced T1WI, and coexistence of adenomyosis. Differences in evaluations were resolved by consensus.

### RESULTS

The mean age of the patients was 60.5 years. The patients were either symptomatic (n=9) or asymptomatic (n=6). The mean tumor size and ADC values were 58.0 ± 26.7 mm and 0.69 ± 0.10 × 10-3 mm2/s, respectively. The percentages of the respective features were as follows: endophytic growth, 87%; exophytic growth, 13%; heterogeneously high intensity on T2WI, 87%; intratumoral hemorrhage on T1WI, 27%; heterogeneous enhancement, 80%; and coexistence of adenomyosis, 53%.

### CONCLUSION

MLAs of the uterine body tend to be bulky tumors with endophytic growth in the myometrium. This characteristic endophytic growth pattern may explain the high frequency of asymptomatic cases despite a large tumor size. Moreover, in more than half of the cases, coexisting adenomyosis was identified on pathology and MRI, supporting the hypothesis of a Müllerian duct origin.

### CLINICAL RELEVANCE/APPLICATION

MLA of the uterine body infiltrates aggressively with endophytic growth pattern, and has a poor prognosis due to delayed detection. This study suggests that MLA of the uterine body may be associated with adenomyosis, thereby, periodic follow-up of the adenomyosis using MRI should be discussed in the future.

## W5B-SPPD-1 ALTERED STATES OF BRAIN WATER HOMEOSTASIS IDENTIFIED BY MULTIPARAMETER QMRI OF PD, T1, AND T2 IN A LARGE COHORT OF ADOLESCENTS BORN EXTREMELY PRETERM

Ali A. Elzieny (*Abstract Co-Author*) Nothing to Disclose
Bindu Setty, MD (*Abstract Co-Author*) Nothing to Disclose
Laurie Douglass (*Abstract Co-Author*) Nothing to Disclose
Hernan Jara, PhD (*Presenter*) Author with royalties, World Scientific Publishing;

### PURPOSE

Individuals born extremely preterm (GA <28 weeks) demonstrate a very wide range of cerebrospinal fluid (CSF) volumes, from about 3% to 45% of the total intracranial volume. Hence, the purpose herein is to study the different states of parenchyma-to-CSF homeostasis by multiparameter quantitative (MP-) MRI of the proton density (PD) and the relaxation times T1, and T2, parameters which are sensitive to water content.

### METHODS AND MATERIALS

This prospective multicenter study (ELGAN-ECHO) included 370 adolescents (181 males) who were born extremely preterm (gestational ages<28 weeks). Image acquisition: 3T (GE, Philips, Siemens): Triple Turbo Spin Echo brain MRI: voxel = 0.5x0.5x2mm3, 80 slices, scan time < 10min. Image processing: multiparameter (PD, T1, and T2) qMRI mapping algorithms, automated segmentation of white and gray matter (WM and GM), and volumetry (Python 3.9.13 with Anaconda Navigator 2.32).

### RESULTS

Representative MP-qMRI results are shown in Fig. 1A, B for an adolescent with a highly elevated CSF content of 44%. Full cohort results in the scatter plots below (Fig. 1 C, D), indicate that PD decreases (strong dependence: GM r -0.51 p-value <0.001 vs WM r -0.36 p-value <0.001), and the relaxation times increase as functions of %CSF (T2 strong dependence: GM r 0.84 p-value <0.001 vs WM r 0.82 p-value <0.001, and T1 weaker dependence: GM r 0.27 p-value <0.001 vs WM r 0.21 p-value <0.001).

### CONCLUSION

MP-qMRI shows distinct PD (decrease), T1 (weak increase), and T2 (strong increase) dependencies as functions of increasing %CSF. Therefore, for a fixed age (15 years), the brain parenchyma appears to adjust to the dyer and wetter conditions of CSF homeostasis by reducing intra-parenchymal water content as demonstrated by decreasing PD, and by augmenting water mobility as indicated by the increasing transverse relaxation time T2.

### CLINICAL RELEVANCE/APPLICATION

The primary qMRI parameters PD, T1, and T2 of the white and gray matter are dependent on the conditions of water homeostasis as represented by the intracranial CSF percentage. Hence, the conditions of water homeostasis should be considered to correct these qMRI measures. These findings could have clinical reporting implications and for research studies particularly, for qMRI studies as a function of age.

## W5B-SPPD-2 MATURATION AND REORGANIZATION OF STRUCTURAL CONNECTIVITY IN INFANTS WITHIN HALF A YEAR

Tingting Liu (*Presenter*) Nothing to Disclose

### PURPOSE

Although brain networks have been extensively investigated, networks based on diffusion imaging are remain under-explored, particularly for infants in the early postnatal period, during which time axons undergo overproduction and elimination, complicated by increased axon diameter and myelination, which may cause alterations in topology of intercortical connections. However, the structural network refinement in early life is still under-researched.

### METHODS AND MATERIALS

Totally, 104 preterm infants with few complications aged 0 and 6 months were enrolled. The whole-brain tractography was performed for each participant using the second-order integration over the fiber orientation distribution method, which were then sifted to 1 million streamlines. The network density was set from 0.2 to 0.3 with an interval of 0.01, and then averaged the measures at all densities.

### RESULTS

The present study discovered that although the clustering coefficients of the entire brain tended to increase with age, while the degree of the temporo-parieto-occipital lobe gradually decreased, whereas the frontal lobes demonstrated the opposite. The hub edges between the hemispheres mainly connected the bilateral cingulate gyrus, cuneus and calcarine cortex, and the betweenness of the cuneus and calcarine cortex increases with age. Besides,

the hub edges within the hemispheres were U-fibers, and their topology was gradually regular and symmetrical. Modularity in infants within half a year was found an age-related decline.

**CONCLUSION**

The present study discovered that the temporo-occipital lobe matures earlier in infancy in structural brain networks compared with the frontal lobe, manifesting as a decline in energy consumption along with a progressive increase in whole-brain information transfer efficiency. Besides, the visual cortex showed a rapid maturation within the first few months of life, which is sensitive to injury. Finally, the subcortical fibers are matured earlier than long fibers in infancy.

**CLINICAL RELEVANCE/APPLICATION**

This study revealed the developmental characteristics of structural brain networks in early infancy, deepened the understanding of infant brain development, and provided a reference for early identification of infants with abnormal development.

## W5B-SPPD-3 DENTIFY CHILDREN GROWTH HORMONE DEFICIENCY AND IDIOPATHIC SHORT STATURE (ISS): QUANTITATIVE MRI ASSESSMENT WITH A MULTIDYNAMIC MULTIECHO SEQUENCE

Yong Zhang, DO (*Abstract Co-Author*) Nothing to Disclose
Mengzhu Wang (*Abstract Co-Author*) Nothing to Disclose
Ankang Gao (*Abstract Co-Author*) Nothing to Disclose
Gaoyang Zhao, MD (*Presenter*) Nothing to Disclose

**PURPOSE**

This study aimed to explore the correlation between pituitary function and relaxivity values of T1, T2 and PD maps in short stature children with normal pituitary morphology using a multidynamic multiecho (MDME) sequence.

**METHODS AND MATERIALS**

From October 2023 to February 2024, children were recruited in the First Affiliated Hospital of Zhengzhou University, whose height below 2-3 standard deviations(SD) of the mean height for their age and sex, to exclude other diseases potentially causing short stature, according to growth hormone stimulation test. Children with peak growth hormone (GH) level between 5 and 10 ng/mL were diagnosed with partial growth hormone deficiency(PGHD), peak GH level of =5 ng/mL were diagnosed with complete growth hormone deficiency (CGHD) and GH peak of = 10 ng/mL were as idiopathic short stature (ISS) group. Coronal MDME sequence was performed on a 3 T MR scanner (VIDA, Siemens Healthineers, Erlangen, Germany) with a 64 channel of head-neck coil for signal reception. The scanning parameters were as follows: field of view 220 × 220 mm2, section thickness 2.0 mm; 20 slices; TR 4500 ms; TE 30,105 ms; TI 4303, 2053, 703, 253ms; bandwidth 101 Hz/Px; echo spacing 14.96 ms.T1, T2 and PD maps were derived from the MDME sequence using an inhouse developed MDME_BETA. Regions of interest (ROI) were delineated on anterior pituitary using ITK-snap, and histogram features were obtained via FAE software. The Mann-Whitney U test was performed to compare the GHD and ISS group. DeLong test was used to assess differences in the area under the receiver operating characteristic curve (AUC) for the extracted features.

**RESULTS**

75 children (4-17 year-old, 17 girls, 52 boys) diagnostic division ISS group (n=12), CGHD group (n=32) and PGHD group (n=31) were included. There were no statistically significant differences in all parameters between the CGHD and PGHD groups. However, significant differences were observed in the histogram features (10th, 90th percentile, mean, median, minimum, RMS) of T2 map between the ISS and CGHD groups, as well as in 10th percentile, mean, minimum, RMS of T2 map in ISS and PGHD group. For the ISS and CGHD groups, the AUCs for the 10th, 90th percentile, mean, median, minimum, and RMS of T2 map (0.77,0.71,0.76,0.73,0.76,0.74) showed no remarkable difference. Similarly, for the ISS and PGHD groups, AUC of 10th percentile, mean, minimum, RMS of T2 map (0.73,0.74,0.73,0.74) has no remarkable difference.

**CONCLUSION**

MDME as a quantitative MRI is a promising non-invasive method for distinguishing between ISS and GHD. T2 map may reflect the functional status of the anterior pituitary gland.

**CLINICAL RELEVANCE/APPLICATION**

These findings provide a reliable reference for distinguishing between ISS and GHD.

## W5B-SPPH-1 VOLUMETRIC BREAST DENSITY ESTIMATION IN DIGITAL MAMMOGRAPHY: APPLICATION OF A DEEP LEARNING FRAMEWORK TRAINED WITH VIRTUAL BREASTS TO CLINICAL IMAGES

Alessandra Tomal, PhD (*Abstract Co-Author*) Nothing to Disclose
Rodrigo T. Massera, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate a previously developed deep learning framework for volumetric breast density (VBD) estimation applied to clinical images of real patients. In addition, to compare the predicted values with a commercial well established software that calculates VBD.

### METHODS AND MATERIALS

The deep learning framework (DLF) consists of three distinct neural networks, one designed for a specific task. The first one segments the mammography image between background, skin plus nipple and inner tissues. The second neural network predicts the relative height for each pixel that is classified as inner tissue. Afterwards, the third network predicts the relative glandular height for each pixel. The first and second neural networks are based on the XNet architecture, while the third is an ensemble of 5 multi-layer perceptrons. The framework was previously trained and validated based on simulated images from virtual breasts. The dataset consists of 199 real mammography anonymized images (for processing, craniocaudal projection) of patients undergoing routine breast screening examinations, and were selected stochastically. For each image, the VBD was quantified using the DLF and Volpara software (Volpara Health, New Zealand, v. 1.5.1). The obtained VBD values were compared for all images, and the coefficient of determination (r2) was calculated.

### RESULTS

On each image, 20% (median) of the pixels analysed by the DLF returned density values outside the allowed range, which were rounded by the nearest possible one. The median(10%-90% percentiles) VBD intervals obtained were 8.6%(4.0%-21.1%) and 6.9%(3.1%-19.4%) using Volpara and DFL, respectively. The $r^2$ score for VBD between DLF and Volpara was 0.72, with average(standard deviation) differences of -1%(4%). When a linear fit is applied ($y=ax+b$), we found $a=0.99|b=-0.85|r^2=0.79$ between DLF and Volpara.

### CONCLUSION

The volumetric breast density predicted by the deep learning framework, trained with virtual breasts, presented a good agreement compared to Volpara software for this dataset of real images.

### CLINICAL RELEVANCE/APPLICATION

The application of a deep learning framework, trained with virtual breasts, could be a complementary method of determining breast density, which is one of the risk factors of developing breast cancer.

## W5B-SPPH-11 CLINICAL VALUE OF DEEP LEARNING IMAGE RECONSTRUCTION-BASED 60 KEV MONOENERGETIC IMAGES OF SUB-MILLIMETER THICKNESS FOR PATIENTS WITH DIFFERENT BODY MASS INDEX IN SPECTRAL CT PULMONARY ANGIOGRAPHY

Yuanfen Liu (*Abstract Co-Author*) Nothing to Disclose
Borong Tang (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the clinical value of deep learning image reconstruction-based 60 keV monoenergetic images (MIs) of 0.625 mm thickness for patients with different body mass index (BMI) in spectral CT pulmonary angiography (CTPA).

### METHODS AND MATERIALS

Ninety-three patients who underwent spectral CTPA were retrospectively analyzed. The patients were divided into two groups: 53 patients with BMI <25 kg/m2; 40 patients with BMI > 25 kg/m2. MIs at 60keV were reconstructed using adaptive statistical iterative reconstruction (AR) algorithm with weight of 50% at 1.25 mm thickness. Additionally, at 0.625 mm thickness, 60keV MIs were reconstructed using deep learning image reconstruction algorithms of middle level (DM) and high level (DH). CT values, standard deviation (SD), signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of the pulmonary trunk, right and left pulmonary artery, as well as the beam hardening artifact indexes (BHA) of the aortic arch and the anterior chest wall muscles affected by beam hardening artifacts were measured or calculated. Two radiologists performed independent and double-blind subjective assessment on the image quality using a 5-point scale.

**RESULTS**

CT values of the pulmonary trunk, right and left pulmonary artery for BMI<25 kg/m2 were slightly higher than those for BMI>25 kg/m2. SD values, SNR and CNR were slightly worse on the images for BMI>25 kg/m2 group than on the BMI<25 kg/m2 group. For all three pulmonary arteries, CT values were not statistically different on 60keV images with different layer thicknesses and reconstruction algorithms (all P > 0.05). SD value comparison: 0.625mm DH < 0.625mm DM < 1.25mm AR (all P < 0.05). SNR and CNR comparison: 1.25mm AR < 0.625mm DM < 0.625mm DH (all P < 0.05). Comparison of vascular and muscle BHA: 0.625mm DH < 0.625mm DM < 1.25mm AR (all P < 0.05). Comparison of subjective scoring: 0.625mm DH > 0.625mm DM > 1.25mm AR (all P < 0.05).

**CONCLUSION**

DLIR algorithm reduces image noise and beam hardening artifacts on 60keV images in spectral CTPA for patients with different BMI, and 0.625-mm DLIR images show higher image quality than 1.25-mm AR images.

**CLINICAL RELEVANCE/APPLICATION**

DLIR improves image quality of low-energy monochromatic images with sub-millimeter-thickness in spectral CTPA imaging for different-size patients, also shows potential for further dose reduction, with high clinical value.

## W5B-SPPH-2 EFFECTS OF DIFFERENT LEVELS OF ADAPTIVE STATISTICAL ITERATIVE RECONSTRUCTION -V TECHNIQUE ON CTPA IMAGE QUALITY AND RADIATION DOSE

Yanhong Zhao, MMed,MMed (*Presenter*) Nothing to Disclose

**PURPOSE**

To compare the image quality and radiation dose of computed tomography pulmonary angiography(CTPA) based on different levels of adaptive statistical iterative reconstruction V (ASiR-V) .

**METHODS AND MATERIALS**

Forty-five patients suspected pulmonary embolism were enrolled. The patients were randomly divided into three groups(A,B and C, n = 15 for each group).All the patients underwent CTPA on a 256 row wide-coverage volumetric CT (Revolution CT, GE healthcare, Milwaukee, WI). Automatic tube current modulation technique was applied to each patient. The Tube voltage (kV) were 100kV,Noise index(NI) were 13. ASiR- V was per-set as 30% for group A,50% for group B and 70% for group C respectively.The image noise ,the signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), the image quality subjective scores and effective dose (ED) were calculated and compared with one-way ANOVA.

**RESULTS**

Age, Scanning range and BMI were found not statistically different among the three groups. (P > 0.05). The CT numbers,the image noise,the SNR and CNR were not statistically different among the three groups. (P > 0.05).The ED in group B (1.3±0.2mSv) and group C (0.8±0.1mSv) were both lower than that in group A (2.1±0.70mSv) (each p <0.05), the decrease rates of ED in group B and C were 38.1% and 61.9% respectively. The image quality of three groups were all acceptable for the requirement of the diagnosis.There was no significant difference of subjective image quality between group A and group B (P>0.05).Subjective image quality score in group C were lower than that in group A (P <0.05).

**CONCLUSION**

With the level of Adaptive statistical iterative reconstruction V increase ,the radiation dose was significantly reduced ,but when the ASIR-V percentage level increased to 70%, the image quality decreased greatly. CT scans with Level of 50% of Adaptive statistical iterative reconstruction V could significantly reduce radiation dose without sacrificing image quality.

**CLINICAL RELEVANCE/APPLICATION**

With the level of Adaptive statistical iterative reconstruction V increase ,the radiation dose was significantly reduced ,but when the ASIR-V percentage level increased to 70%, the image quality decreased greatly. CT scans with Level of 50% of Adaptive statistical iterative reconstruction V could significantly reduce radiation dose without sacrificing image quality.

## W5B-SPPH-4 EVALUATION OF A DEEP LEARNING RECONSTRUCTION ALGORITHM FOR CORONARY SPECTRAL PHOTON-COUNTING CT ANGIOGRAPHY

**PURPOSE**

To evaluate image quality of a dedicated deep learning reconstruction (DLR) algorithm for coronary spectral photon-counting (SPCCT) CT angiography.

**METHODS AND MATERIALS**

A phantom study and prospective Human study in 5 patients after ethical approval were performed using a clinical SPCCT prototype. Matched acquisition parameters were used, i.e., retrospective ECG-gated protocol at 256 mAs, 120kVp. Reconstruction parameters consisted of 1024 matrix, 0.25 mm slice-thickness, 220 mm field of view and a data set with 2 high-frequency filters (Detailed 2, Sharp) and an iterative reconstruction algorithm (iDose4 6) and a data set with Sharp filter and DLR algorithm (100% level). Noise power spectrum (NPS), task-based transfer function (TTF) with f50 (mm-1) for bone and iodine inserts and detectability index (d') were assessed on phantom for two clinical tasks of 1mm diameter, i.e., stent and distal coronary arteries. Two radiologists rated overall noise, sharpness of stents and detectability of small vessels in patients using a 5-point-quality score. Objective analysis consisted in: noise measured in trachea, lumen stent sharpness as full-width half maximum of lumen stent and detectability index for distal vessels were assessed using an in-house Python code.

## RESULTS

Noise was reduced for DLR phantom images (8.20 HU) compared to Detailed 2 (47.7 HU) and Sharp (85.00 HU). Average frequency was similar for DLR images compared to Sharp (0.93 mm-1 vs 0.97mm-1) and higher compared to Detailed 2 (0.63 mm-1). f50 was similar for DLR, detailed 2, and Sharp for iodine insert (0.77mm-1) but slightly lower for DLR for bone insert (respectively 0.85, 0.89 and 0.94). d' was 9-foldhigher for DLR images compared to iDose4 images for stent imaging and for distal coronary vessels (respectively 80.92, 8.86 and 8.34 for iodine insert). DLR patient images had a 3-fold decrease in noise compared to Detailed 2 and an 8-fold decrease when compared to Sharp yet greater according to radiologists (respectively 5 [5;5], 4[3;4], 3[2;3], $p<0.05$). Sharpness of stent was slightly decreased for DLR images compared to Sharp and similar to Detailed 2 images (15.46 ± 4.63, 12.67±4.92 and 13.00 ±5.84) and was confirmed by subjective analysis (4[3;4], 5[4;5] and 4[4;4], $p<0.05$). Detectability of low contrast structures was improved for DLR patient images compared to Detailed 2 and Sharp (respectively 34.88 ± 7.17, 5.44 ± 4.88 and 2.68±3.09).

## CONCLUSION

In coronary SPCCT angiography, DLR algorithm outperformed in image quality in both phantom and patients, leading an improvement in detectability.

## CLINICAL RELEVANCE/APPLICATION

Coronary SPCCT angiography with DLR algorithm outperforms detectability of coronary vessels for a greater detection and characterization of coronary artery disease.

# W5B-SPPH-5 EVALUATING THE EFFICACY OF MULTIMODAL MACHINE LEARNING IN THE PREDICTION OF RETREATMENT FOR INTRACRANIAL ANEURYSM

## PURPOSE

This study investigates whether treatment failures in intracranial aneurysms (IAs) are linked to hemodynamic changes, evidenced by angiographic parametric imaging (API) from digital subtraction angiography (DSA). It also examines the impact of specific patient characteristics, identified in preclinical studies as vital to treatment outcomes. Employing a multimodal machine learning approach that combines deep learning with API and extensive patient data, we seek to improve the prognosis and predictability of treatment efficacy.

## METHODS AND MATERIALS

Data from 340 patients with treated IAs were analyzed, incorporating API parameters from DSA scans. We employed a dual normalization process on API data to control for variability in arterial input and pre-treatment conditions. This dataset was initially analyzed to assess quantitative angiographic parameters at the aneurysm dome, with outcomes recorded at 6 months post-treatment, determining whether the IA remained occluded, required retreatment, or needed continued observation. Further analysis included categorical information about IA location within the carotid segments and IA size. Additional patient characteristics such as age, gender, race, presence of subarachnoid hemorrhage, medication, hypertension, BMI, smoking history, and family history of IA were also included. A deep neural network (DNN) was trained on these data and evaluated using metrics like area under the ROC curve, sensitivity, and specificity, employing a 20-split Monte Carlo cross-validation.

## RESULTS

The integration of biomarkers and API parameters into our DNN significantly improved model performance. Using API parameters alone yielded an AUC of 0.74 (±0.4), with sensitivity at 72% (±2%) and specificity at 75% (±4%). Adding morphological parameters to API parameters modestly increased the AUC to 0.76 (±0.5), maintaining sensitivity at 72% (±2%) and increasing specificity to 76% (±4%). The combination of API parameters and full morphological parameters further improved the AUC to 0.80 (±0.5), with sensitivity rising to 76% (±2%) and specificity to 79% (±4%).

## CONCLUSION

This study validates the practicality of using DNN for predicting retreatment in aneurysm patients. While incorporating biomarkers enhance the precision of treatment predictions, adding excessive features does not improve sensitivity significantly, suggesting a need for careful selection of relevant biomarkers.

## CLINICAL RELEVANCE/APPLICATION

This study demonstrates the utility of DNNs in predicting retreatment for intracranial aneurysm patients. Integrating API data and patient-specific characteristics, our model enhances predictability of aneurysm outcomes, offering the potential for more personalized treatment strategies.

## W5B-SPPH-6 FROM HEPATIC LESION DIAMETER MEASUREMENTS TO VOLUMETRY: OBTAINING CONSISTENT ACCURACY USING DUAL ENERGY CT, INTELLIGENT AUTO-SEGMENTATION, AND MANUAL INTERVENTION

Christina M. Lee, BS,ARRT (*Abstract Co-Author*) Nothing to Disclose
Emi Eastman, BA (*Abstract Co-Author*) Nothing to Disclose
Yifang Zhou, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Focal hepatic lesions are currently evaluated using diameters with RECIST criteria. Although lesion volumetry is expected to be a better measure due to its more comprehensive spatial scope, the accuracy can be compromised by the uncertainty of three-dimensional segmentations. We hypothesized that the measurement accuracy can be significantly improved with the following approaches: dual energy CT for contrast enhancement, newer segmentation algorithms with built-in artificial intelligence, and manual intervention for necessary correction. We aimed to apply these approaches to find the volume and diameter measurement accuracies in a multi-phase environment.

### METHODS AND MATERIALS

An anthropomorphic liver phantom was custom made with composition substitutes consistent with ICRU report 44. To simulate the early arterial, late arterial, and portal venous phases, iodine of different concentrations (0, 0.68, and 1.89 mg/cc, with HU = 50, 65, and 88 at 80 keV) was perfused to three consecutive slabs. Iodinated lesions were placed with various shapes (spherical, ellipsoidal, and lobular), concentrations (0.05- 2.31 mg/cc), and sizes (0.09-8.57 cc, 10-35 mm). Repeated dual energy acquisitions were made using a GE Revolution CT (CT dose index CTDIvol =14 mGy, slice width=2.5 mm). Lengths in the longer dimension > 10 mm (diameters) and volumes > 0.5 cc were independently measured at 50- 100 keV by three investigators with an intelligent 3-D auto-segmentation tool (intelligent VCAR) from GE AW-3.2. Careful manual corrections were made. A figure-of-merit incorporating the volume measurement consistency and accuracy was used to obtain the optimal keV.

### RESULTS

The linear dimension (diameter) measurements were not found sensitive to keV variation and did not suggest a single optimal keV. The results showed root-mean-square (RMS) errors of 6.98% and 7.44%, at 75 keV and 100 keV, respectively. For volume measurements, optimal virtual monochromatic energies were found at 65 and 60 keV for the early arterial, and late arterial and venous phases, respectively. The RMS error was 8.51%.

### CONCLUSION

With optimal keV selection from dual energy and careful volume contouring combining intelligent auto-segmentation and necessary manual correction, the hepatic lesion volumetry was found to be nearly as accurate as the diameter measurements.

### CLINICAL RELEVANCE/APPLICATION

Liver lesion quantification.

## W5B-SPPH-7 BIAS REDUCTION IN 2D QUANTITATIVE ANGIOGRAPHY USING A COMBINATION OF FORESHORTENING AND INJECTION VARIABILITY CORRECTION: IN-SILICO STUDY

Parmita Mondal, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to enhance the accuracy of 2D Quantitative Angiography (QA) for applications in neurovascular interventions. By addressing biases such as projection-induced foreshortening and variability in contrast injection, this study aims to improve the reliability of QA used for diagnosing disease severity.

### METHODS AND MATERIALS

We employed Computational Fluid Dynamics (CFD) to create 3D virtual angiograms for three distinct aneurysm geometries, testing three inflow velocities (25 cm/sec, 35 cm/sec, and 45 cm/sec) and three contrast injection durations (0.5, 1.0, and 1.5 seconds) to simulate various angiographical conditions. To mitigate the bias from the tortuosity of neurovascular architecture in DSA pixel intensity, a path-length correction algorithm was developed. This involved employing ray-casting techniques to accurately trace the paths of X-rays through the vascular structures within the 3D model, from their origin to their intersection with the vascular geometry. These traced paths were used to correct the 2D DSA projections, thus compensating for foreshortening

biases and enhancing the accuracy of the resulting images. Time-density curves (TDCs) were generated for both the inlet and the aneurysm dome of the path-length corrected virtual angiograms. Variants of Single Value Decomposition (SVD)—including standard SVD (sSVD) with classical Tikhonov regularization, block-circulant SVD (bSVD), and oscillation index SVD (oSVD)—were applied to these TDCs to calculate impulse response functions (IRF). QA metrics such as Peak Height (PH_IRF), Area Under the Curve (AUC_IRF), and Mean Transit Time (MTT) were evaluated. Notably, we used the slope of MTT versus injection duration as a critical metric for data analysis, as MTT in the aneurysm, should remain consistent regardless of injection duration.

**RESULTS**

Path length correction and deconvolution significantly reduce the dependence of QA parameters on injection duration. Without correction, the average slope of MTT vs injection duration was 0.573, but with path-length correction and application of sSVD, bSVD, and oSVD, the slopes improved to 0.01, 0.029, and 0.019, respectively, demonstrating a substantial enhancement in measurement precision.

**CONCLUSION**

The integration of path-length correction and SVD-based deconvolution techniques effectively reduces foreshortening and injection variability in QA parameters, thereby enhancing the diagnostic capabilities of 2D QA.

**CLINICAL RELEVANCE/APPLICATION**

Using a combined method of SVD and path length correction in QA analysis removes the impact of injection variability and foreshortening error, thus resulting in pristine data. The pristine data may be valuable for improving neurovascular treatment prognosis.

## W5B-SPPH-9 EFFECTS OF RADIATION DOSE AND CALCIUM CONCENTRATION ON THE ACCURACY OF CALCIUM QUANTIFICATION USING DEEP LEARNING IMAGE RECONSTRUCTION IN DUAL-ENERGY SPECTRAL CT: A CALCIUM PHANTOM STUDY

Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Jianying Li, PhD (*Abstract Co-Author*) Employee, General Electric Company
Le Cao (*Presenter*) Nothing to Disclose

**PURPOSE**

To investigate the accuracy of calcium quantification in dual-energy CT (DECT) with deep learning image reconstruction (DLIR) at different radiation dose levels and calcium concentrations.

**METHODS AND MATERIALS**

A DECT quality control phantom simulating adult abdomen (Multi-Energy CT Quality Assurance Phantom; GPH-75B, Science in Kyoto) with three calcium inserts (100, 200, 300 mgCa/ml) was imaged using DECT mode. Scans were repeated 5 times at CT dose index (CTDIvol) levels of 4, 7, 10, 14mGy. Images were reconstructed using 50% adaptive statistical iterative reconstruction (ASIR-V) (ASIR-V50%) and DLIR at low (DLIR-L), medium (DLIR-M) and high (DLIR-H) settings. Calcium concentrations were measured. The coefficient of variation (CV) of calcium concentration was calculated as CV = standard deviation/ mean of the calcium concentrations *100%. The differences in calcium concentration and CV among different reconstructions were compared.

**RESULTS**

For the same calcium insert, the calcium quantification accuracy increased, and CV decreased with the increase of radiation dose. The decrease in CV was more obvious in high calcium concentration than in low calcium concentration. The calcium quantification did not differ significantly among reconstructions. The CV of the 100mgCa/ml calcium was significantly higher than that of the 200 and 300mgCa/ml calcium. With the increase of radiation dose, CV decreased significantly, and the difference was more obvious at low concentration. The CV values on ASIR-V50% images at 4, 7, 10, 14mGy were 10.20%, 7.64%, 8.12%, 7.88% for the 100mgCa/ml, 9.88%, 5.56%, 4.25%, 4.36% for the 200mgCa/ml, and 3.27%, 3.19%, 2.71%, 3.15% for the 300mgCa/ml calcium inserts, respectively. DLIR algorithms significantly reduced the measurement variability. At 4mGy, the CV values for the 100, 200, 300mgCa/ml calcium inserts (4.53%, 5.18%, 2.34%) were the lowest on DLIR-H images, and highest (10.20%, 9.88%, 3.27%) on ASIR-V50% images. $P<0.001$.

**CONCLUSION**

The calcium quantification accuracy increased with the increase of radiation dose, DLIR significantly reduces the image variability of calcium quantification.

**CLINICAL RELEVANCE/APPLICATION**

Deep learning image reconstruction to improve accuracy of calcium quantification.

## W5B-SPRO-1 ENHANCED-MRI SYNTHESIS FROM PLAIN SCAN USING A TUMOR GUIDED IMAGE SYNTHESIS NETWORK

Xiaowu Deng (*Abstract Co-Author*) Nothing to Disclose
Yutao Tang (*Abstract Co-Author*) Nothing to Disclose
Bin Wang (*Abstract Co-Author*) Nothing to Disclose
Yao Lu, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

Accurately identifying and segmenting brain tumors from medical images is important for diagnosis and treatment planning, and doctors often require multimodal MR Images or contrast-enhanced T1 images. Currently, patients are required to inject GBCA daily in magnetic resonance guided Adaptive radiotherapy (MRgART), and clinicians need to consider the safety of the patient's contrast agent and the patient's own tolerance. Therefore, synthesizing contrast-enhanced T1 images has the potential to alleviate this problem and assist physicians to better identify and segment brain tumors.

### METHODS AND MATERIALS

However, the existing methods often only consider from the perspective of synthetic images, and do not pay extra attention to the synthesis effect of tumor regions, resulting in unsatisfactory results. We propose a novel tumor-guided Image Synthesis network (TGSNet) that can efficiently obtain synthetic target images of end-to-end brain tumors, and can combine learning contrast enhancement image synthesis and tumor segmentation.

### RESULTS

The experimental results show that in this task of the tumor-guided Image Synthesis network in this study, Peak signal-to-noise ratio(PSNR) and Structural Similarity(SSIM) indexes increase from 28.69 and 0.904 to 31.11 and 0.946 respectively, and MAE indexes decrease from 0.102 to 0.075. The PSNR and SSIM indexes of tumor region in synthetic images increased from 23.65 and 0.652 to 24.05 and 0.708, respectively, and the MAE index decreased from 0.813 to 0.719.Image quality has been improved to a large extent. Based on the contour of T1c image, the average DSC values of GTV-T1w and GTV-synT1c are 0.752 and 0.792, respectively ($P<0.01$). Statistical analysis showed that the mean DSC of the target mapped based on synT1c was significantly higher than that of T1w.

### CONCLUSION

Compared to existing studies, this approach highlights the challenges of tumor regions in synthesis and optimizes their performance on synthetic images through tumor-guided knowledge integration. The experimental results show that compared with the existing synthetic network model, our TGSNet greatly improves the recognition rate of tumors, improves the accuracy of segmentation, and forms a more advanced image synthesis method in this task.

### CLINICAL RELEVANCE/APPLICATION

Contrast-enhanced MRI (CE-MRI) plays a very important role in the diagnosis of brain tumors and is the primary reference image for brain tumor diagnosis. Due to the current demand for daily GBCA injections in magnetic resonance guided Adaptive radiotherapy (MRgART), clinicians need to consider both the safety of the contrast agent and the patient's own tolerance. Therefore, this study can provide CE-MRI without contrast agent to alleviate this clinical problem.

Shuchi K. Rodgers, MD (*Presenter*) Royalties, RELX

### INTRODUCTION

According to 10 years of data reported to the FDA, there is approximately 1 safety event for every 300 MRI studies, 1 projectile event resulting in injury each month and 1 MRI-related death annually. Our enterprise experience echoed that data, underscoring the need to take action.

### METHODS

The MRI safety incidents across the enterprise for the past 2 years were reviewed to assess the magnitude of the problem and identify potential trends by the chair of the enterprise quality and safety council. Serious safety events were quantified to use as a key performance indicator. A steering committee was convened and a project charter created outlining the operational leaders, the project scope, the timeline and process and outcome metrics. Process maps were created to plan for site visits to observed the work as performed at the main hospitals in each of the enterprise divisions. Failure modes were identified and prioritized and a safe table was convened to brainstorm potential solutions. Solutions were ranked top solutions were slated for implementation.

### RESULTS

The top failure mode solutions were to optimize the MRI screening process, universally deploy and standardize the use of ferromagnetic detectors (FMDs) and minimize the utilization of unnecessary multipart MRI studies. An MRI safety task force including technologists, IT staff, nursing and physicians was convened to streamline the MRI screening form and process leading to a consolidation of screening form questions and an alignment with scope of practice. A capital request was submitted to acquire and replace FMDs and the MRI safety task force was tasked with creating a standardized workflow for their use. An EHR popup window was engineered to fire when duplicative MRI studies were ordered and the enterprise pathways and protocols council is working on a spine imaging algorithm to guide ordering practices. Enterprise MRI serious events dropped from 4 to 0 from pre- to post-FMECA completion. MRI near miss and no-harm incidents were also collected and reviewed.

### DISCUSSION

MRI safety incidents are often low-frequency, high-acuity events and demand process optimization to prevent. This requires detailed ethnographic assessment of existing processes and reengineering the process by identifying failure modes and promulgating and implementing solutions. Engineering the MRI process in this way prevents the potential for human error to lead to patient and/or staff harm.

## M2-QI-2 INCREASING USAGE OF PEDIATRIC PROTOCOLS AND LOWERING PEDIATRIC CT DOSE THROUGH AN IMPROVED PROTOCOLLING INTERFACE AND STAFF EDUCATION

### INTRODUCTION

Our institution monitors doses for CT exams and compares nationally with ACR Dose Index Registry (DIR) as part of our radiation safety program. Given concerns about radiosensitivity in children, we aim to use CT protocols designed for pediatric populations whenever possible. Our median doses for pediatric exams were usually below the median for all DIR facilities, but doses for abdomen/pelvis examinations for the 11-14 and 15-18 age groups were often higher. This project aimed to determine the factors leading to higher doses for pediatric abdomen/pelvis CT examinations in 11-18-year-olds and ultimately achieve median doses at or below the national median.

### METHODS

We initially collected data from 1 year (2022) for all routine pediatric abdomen/pelvis CT exams from 14 CT scanners across six facilities submitted to the DIR. Our local dose monitoring software (Bayer Radimetrics) was used to obtain patient data and exam info. We identified a significant portion of exams

for patients aged 11-18 performed using adult rather than pediatric protocols and identified three potential reasons and interventions. 1) A "Pediatric Protocol" header from the protocoling interface appeared for exams in the Pediatric Radiology division but not from other divisions, notably the ED. The software was changed to add the header to all CT exams for patients under 19. 2) Technologists may have chosen an adult protocol for larger pediatric patients due to their size, so they were instructed to use pediatric protocols for all patients under 19. 3) Residents or fellows protocoling may not have specified a pediatric protocol or, in rarer cases, specified an adult dose, so we implemented a follow-up with radiologists for cases where a pediatric protocol was overridden. Our measures for improvement were the percentage of exams using pediatric protocols and the total dose length product (DLP), which is used by the DIR and is readily comparable for single or multiphase exams. Trends in these measures were examined over several years.

**RESULTS**

Patient weight and exam protocol were the two factors most closely correlated with higher doses. Adult protocols were found to be more frequently used for larger patients, with an average patient weight of 73.7 kg for adult protocols versus 58.7 kg for pediatric protocols (p=6e-15). For the two years prior to the intervention, the percentage of CT exams performed on 11-18-year-olds using adult protocols was 46%, and in the following year, this was reduced significantly to 16% (p=2e-17). The mean DLP was also reduced from 480 to 374 mGy.cm after intervention (p=0.0002).

**DISCUSSION**

Limitations of this study include a lack of granular knowledge of the imaging situation leading to each choice of protocol. It is important to balance dose considerations with image quality, so our follow-up with radiologists provides opportunity to address image quality concerns.

## M2-QI-3 IMPROVING CT SCANS DELAYS FOR ED PATIENTS DURING NURSING HANDOVER

Farah Majeed, MD (*Abstract Co-Author*) Nothing to Disclose
Sam T. Beardsmore-Rust, MBBS,PhD (*Abstract Co-Author*) Nothing to Disclose
Stephen Perrio, MBBS (*Abstract Co-Author*) Nothing to Disclose
Jasmin Panesar, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Staff in the radiology department have observed persistent delays in transferring patients from the emergency department (ED) to the CT scanning unit at our UK local district general hospital, specifically during evening nursing handover when patient escorts are often necessary. This delay creates a backlog of CT scans after handover, leading to longer ED wait times, inefficient CT resource utilization, and extended shifts for on-call radiologists to report urgent scans. The aim of our study was to corroborate these delays and propose potential solutions to address them. By doing so, we aim to streamline ED workflow, enhance efficiency for radiology staff (including radiographers and reporting radiologists), and ultimately improve patient care.

**METHODS**

This retrospective review was conducted at a single site, focusing on data collected in 15-minute intervals during a 24-hour period from January 1st, 2023, to January 1st, 2024. The intervention involved implementing a twilight nurse to facilitate and optimize patient transport from the emergency department (ED) to the CT scanning unit, as well as several other staff rota changes during handover times (19.45-20.15). Following this change, a second cycle of data collection took place from April 15th to April 29th, 2024. Analysis of all collected data was performed using Microsoft Excel.

**RESULTS**

During the first cycle, analysis revealed a notable 40% decrease in CT scans conducted during the designated ED nursing handover period (19:45-20:15) compared to the preceding 30-minute interval (19:15-19:45). Additionally, there was a significant 62% surge in CT scans performed immediately after the handover concluded, between 20:15 and 20:45.In the second cycle, after implementing a number of rota changes there was an improvement in the number of scans performed during handover with a corresponding reduction in patient delays in the emergency department.

**DISCUSSION**

The findings thus far confirm a delay in CT scans during ED nursing handover, with the introduction of a twilight nurse and changes to other staff rotas emerging as practical and cost-effective solution to enhance ED-CT workflow. Following the intervention, there is a noteworthy 31.3% improvement of CT scans performed during the handover period, and a subsequent significant reduction in the number of scans delayed and then conducted within the 30 minutes following handover. The main limitation of this review is the relatively short duration of data collection for the second cycle; however, this project is ongoing, with plans to assess the impact over a one-year period. Whilst this study is conducted at a single site, the issues identified and proposed solutions hold potential for broader applicability, given the common occurrence of ED delays.

## M2-QI-4 ENHANCING RADIOLOGY REPORTING ACCURACY WITH AI DRIVEN ERROR DETECTION

Miguel Angarita, MD (*Abstract Co-Author*) Nothing to Disclose
Felipe Mendez, MD (*Abstract Co-Author*) Nothing to Disclose
Lina Maria Acosta Buitrago, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

The US healthcare system grapples with high costs and suboptimal outcomes, with inefficiencies in radiology reporting being a significant contributing factor. Despite the integration of voice recognition technology, preventable errors persist, leading to addendums, potential patient care delays, and increased healthcare expenditure. To address this, we present an innovative AI-powered solution designed to dynamically identify and rectify errors within radiology reports before finalization, promoting accuracy and efficiency.

**METHODS**

Our solution leverages a ChatGPT model, specifically fine-tuned on a comprehensive dataset encompassing 25 common reporting errors. These errors range from simple laterality mistakes to complex misinterpretations, ensuring a wide scope of detection. The system seamlessly integrates with existing web-based RIS/PACS systems through an API, dynamically extracting and analyzing the plain text of each report. Upon analysis, the model identifies potential errors and provides tailored suggestions for correction, all while maintaining patient privacy by refraining from storing any report data. Each identified error is categorized and logged for ongoing statistical analysis, facilitating continuous model improvement and refinement.

**RESULTS**

Initial results demonstrate the efficacy of our AI-driven approach, with the model successfully detecting up to 30% of errors spanning a range of severities. While large language models have demonstrated similar capabilities, they often incur substantial computational costs and latency issues. Our solution utilizes smaller, open-source models that, when fine-tuned, achieve comparable performance at a fraction of the cost and complexity. This affordability and efficiency broaden accessibility, even within resource-constrained environments.

### DISCUSSION

This AI-powered error detection system holds immense potential to revolutionize radiology reporting by enhancing both quality and efficiency. By proactively identifying and correcting errors prior to report finalization, we can minimize the need for addendums, expedite report turnaround times, and ultimately elevate the standard of patient care. Future research endeavors will concentrate on expanding the breadth of error detection capabilities, refining model performance, and exploring seamless integration with other healthcare workflows. Furthermore, we envision expanding the capabilities of this AI model to encompass a broader range of checks within the radiology report. This includes identifying textual inconsistencies, grammatical errors, and potential medical inconsistencies based on the presented information.

## M2-QI-5 IMPROVING TIME-OUT COMPLIANCE

Gaurav V. Watane, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Loren Cicero (*Abstract Co-Author*) Nothing to Disclose
Michael P. Spearman, MD (*Abstract Co-Author*) Nothing to Disclose
Jeffrey S. Mueller, MD (*Abstract Co-Author*) Nothing to Disclose
Warren Chang, MD, MBA (*Presenter*) Nothing to Disclose

### INTRODUCTION

Preprocedural timeout completion was either not performed or not documented properly which can potentially lead to errors such as wrong site, wrong patient, or wrong procedure. At our hospital, the timeout was reported to be performed in 84% of patients undergoing procedures in IR, CT, FL, US, Mammography, or MRI. The purpose of the project was to increase timeout completion and proper documentation to 100%.

### METHODS

Context and Intervention: Retrain and reeducate all parties involved in performing and documenting preprocedural timeout (including redistribution of related company policies and procedures). Identify workflow issues in each procedural area. Creation of visual controls to post in procedural areas. Review timeout compliance report pulling information properly in EHR. Study of the Intervention: Responsible, Accountable, Consulted, and Informed (RACI) Matrix utilized to identify the following parties involved in timeout compliance; responsible, consulted, informed, and accountable. EHR timeout compliance report pulled monthly for review.Measures/Metrics: Report pulled from EHR system to show monthly compliance percentage for each procedural imaging department/location, as well as each providers individual compliance.Analysis: A quantitative reporting system was used to collect the data. A qualitative approach was used to retrain, reeducate, and improve workflows completed by staff from August 2022 through October 2022. The data was collected and reviewed from January 2022 through November 2022; with an average of 84% timeout compliance rate from January-August 2022.

### RESULTS

November 2022 the timeout compliance rate was 98%; a 14% improvement from the January-August 2022 average of 84%. Implemented solutions included: (1) Staff education/training. (2) Monthly review of timeout compliance report. (3) Documented explanation provided for any non-compliant timeout. (4) Review non-compliance with individual in charge of documenting timeout to provide additional education.

### DISCUSSION

Overall, this was a successful project that improved hospital imaging department procedural timeout compliance, ultimately increasing patient safety and decreasing room for error. Reporting will need to continue to be reviewed monthly to ensure compliance does not fall off track, and to ensure if/when compliance is less than 100%, proper investigation and documentation occurs.

## M2-QI-7 CT SHOULDER: USING PDSA CYCLE IN REDUCING RADIATION DOSE AND MOTION ARTIFACTS

Xueci Lee (*Abstract Co-Author*) Nothing to Disclose
Bryan Choo (*Abstract Co-Author*) Nothing to Disclose
Shi Yun Teo (*Abstract Co-Author*) Nothing to Disclose
Mei Choo Chong (*Abstract Co-Author*) Nothing to Disclose
Nurarini Anwar, BSc (*Presenter*) Nothing to Disclose

### INTRODUCTION

Computed Tomography (CT) is a key modality for detailed anatomical visualization and preoperative planning, especially in the shoulder. Our hospital practices CT shoulder scans using helical scan mode and fixed tube current (mA) technique, resulting in higher radiation dose and motion artifact. A team consisting of radiographers and a musculoskeletal (MSK) radiologist was formed to strategize in reducing motion artifacts and effective dose (ED) by 40%.

### METHODS

This QI project was conducted in a radiology department in a tertiary hospital from January 2020 to Dec 2023. A total of 4 "Plan-Do-Study-Act (PDSA)" cycles were carried out while closely monitoring the image quality in achieving the best protocol to adopt.Radiation dose information retrieved were dose length product (DLP) and computed tomography dose index (CTDI). Effective dose (ED) was calculated using formula: k-factor of chest x DLP.1st PDSA cycle, breathing instructions were given to mitigate motion artifacts. A sample size of 5 was used. While artifacts reduced, radiation dose remained high. Volume scan mode was introduced in the 2nd cycle. At 0.75 second a scan, it eliminated the need for breathing instructions. However, the dose reduction was not significant.In the 3rd cycle, the CT scanner application specialist was consulted and introduced automatic tube current modulation (ATCM). This method reduces the tube current in regions of lower attenuation while maintaining an acceptable level of image noise, thus improving radiation dose efficiency. ATCM was tested in helical scan mode.In the 4th cycle, volume scan mode combined with ATCM further reduced radiation dose while maintaining image quality. 2 standard deviation (SD) technique were explored. Two independent radiologists rated the image quality of the fixed and modulated mA qualitatively and quantitatively using a five-point scale. Signal-to-noise ratio (SNR) also measured. The image quality defined in five criteria was analyzed using Chi-squared test. The CT scanners were updated to the desired shoulder protocol and utilized. The image quality and radiation dose indicators were closely monitored and audited by the team.

### RESULTS

The effective dose successfully reduced by 87.9% with minimization of breathing artifact. There was no significant difference in subjective image quality between ATCM and fixed mA in presence of artifact, noise and diagnostic acceptability. However, there is significant difference for sharpness and confidence in diagnosis at SD of 7.5. There was also no significant difference in SNR for inter and intra comparison of fixed and modulated mA.

### DISCUSSION

Volume scan mode with mA modulation is an effective technique for reducing radiation dose in CT shoulder imaging without compromising the diagnostic quality. Higher radiation dose does not necessarily warrant a good quality scan.

## M2-QI-8 REDUCING REDUNDANCY IN IMAGING FOR PATIENTS AND AUTOMATING VETTING: A DATA VISUALISATION SOLUTION BASED ON DATA WITHIN ELECTRONIC MEDICAL RECORDS

James Hallinan, MBChB (*Abstract Co-Author*) Nothing to Disclose
Andrew Makmur, MD (*Abstract Co-Author*) Nothing to Disclose
Desmond Lim Shi Wei, MBBS, FRCR (*Presenter*) Nothing to Disclose

### INTRODUCTION

In the era of sub-specialised patient care, different specialists may order imaging studies with overlapping anatomical coverage and similar diagnostic value thus creating redundancy. For e.g. a patient scheduled for an MRI liver and ultrasound of the hepatobiliary system within 1 month of each other.An internal audit over 20 months showed 211 redundant requests for CT scans in our tertiary healthcare institution. These requests were prevented but required disproportionate effort from technicians and radiologists.Redundant imaging should be prevented to minimise the risk of the patient to ionising radiation and contrast media. Furthermore, reducing redundant imaging relieves the workload on limited manpower to perform and interpret these scans.

### METHODS

We created a dashboard/visualisation tool of outpatient imaging requests based on the electronic medical records. The dashboard identifies patients with redundant imaging requests based on prior scans and incoming scan requests (mainly CT and MRI).In our institution, an average of 6500 CTs and 3600 MRIs are performed monthly in the outpatient setting. The dashboard allows us to automate part of the vetting process and thus reduce workload.The dashboard solution is built using an artificial intelligence-based analytics platform which receives EPIC-EMR data in real time hosted by our institution. The dashboard is an operational backend model consisting of Structured Query Language codes (SQL). As no external cloud software is required for data storage or training, patient privacy is preserved.

### RESULTS

The performance of the dashboard in identifying redundant imaging requests was compared against the radiologists.The dashboard had high negative predictive value of 99%, sensitivity and specificity of 91% and 95% respectively. The positive predictive value was 18%. Due to the high negative predictive value, the imaging requests excluded by the dashboard are no longer checked by the radiologist. We have experienced a reduction in serious reportable incidents pertaining to unnecessary radiation/investigation since the deployment of the dashboard.The use of this dashboard solution has reduced 90% of vetting time (previously 108 minutes per day). Preventing redundant CTs equates to cost savings of technician time amounting to $26,102 (USD) per year and cost savings in terms of CT Machine Utilization worth $97,064 (USD) (idle time cost avoidance). In terms of redundant MRI scans, the use of the dashboard has prevented 121 studies, equating to 4840mins (81 hours) of MRI scan time.

### DISCUSSION

Using this solution, our department has saved time/manpower in vetting imaging requests, saved considerable patient cost and reduced operational costs/workload. We are expanding the dashboard to also automate the checking of renal function, drug allergies, reactive airway disease and cross modality redundancy.

## M2-QI-9 TOTAL LEAD TIME REDUCTION FOR PLUVICTO TREATMENT PATIENTS

Kristi Rindels (*Presenter*) Nothing to Disclose

### INTRODUCTION

With the introduction of Pluvicto therapy in the nuclear medicine practice, there has been an increased need for access available for cancer patient treatments. Pluvicto therapy consists of six cycles of therapy, with the first cycle requiring a longer appointment duration. With current state lead times for cycle one appointments, there was limited room to add additional access in the schedule. The purpose of this project was to reduce the total lead time for cycle one Pluvicto therapy appointments, allowing for increased access to treat additional patients.

### METHODS

An improvement project team was formed including radiology leaders, nurses, nuclear medicine technologists, advanced practice providers, radiologists, and process improvement specialists. The team used the DMAIC (Define, Measure, Analyze, Improve, Control) framework to identify current gaps, measure current state, analyze root causes, and improve processes through tests of change (PDSAs). Current condition was obtained through value stream mapping, process observations and manual timings. Utilizing a fishbone diagram, the team brainstormed potential root causes leading to the increased lead times from appointment arrival to therapy completion. Based on root causes identified, a series of discussions were held to develop interventions to test with future cycle one patients. The interventions are being tested in a phased approach, with the first few phases completed. Continued interventions are currently being implemented and continued improvements are expected.

### RESULTS

The interventions brainstormed and tested were aimed to address the root causes of communication and handoff barriers, visual management barriers, and clarifications needed to address patient questions and concerns. The total lead time started at 164 minutes from check-in to therapy completion, for an appointment that has a scheduled duration of 120 minutes. Initial remeasurement, with interventions in place addressing visual management showed a decrease in total lead time of 22 minutes. We anticipate additional decreases in total lead time with the third and fourth rounds of PDSAs planned in the months of June and July. Overall final results will be available for final presentation.

### DISCUSSION

The evolution of theranostics in the nuclear medicine department shows a continued need for process improvement and efficiencies. Through the continued PDSAs that are planned over the next few months, the project team anticipates the ability to reduce the total lead time from check-in to completion of the therapy to below 120 minutes, which was our team goal. The team learned so many valuable lessons along the way, however the most influential part of the process was the collaboration and teamwork across many roles, coming together to deliver effective, efficient care to cancer patients.

## M5A-QI-1 QUIET- QUALITY IMPROVEMENT EDUCATION (IN) TRAINING FOR RESIDENTS

Jonathan A. Flug, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Shina Zehnder, MD (*Abstract Co-Author*) Nothing to Disclose
Cathy Hannafin, MBA,BSN (*Abstract Co-Author*) Nothing to Disclose
Amelia Eyshoy (*Abstract Co-Author*) Nothing to Disclose
Lisa Ponce, RT (*Presenter*) Nothing to Disclose

### INTRODUCTION

The Accreditation Council for Graduate Medical Education (ACGME) requires residents to participate in activities related to safety event root cause analysis and action planning. Compliance is assessed through the ACGME Survey which demonstrated a downward trend in our program in 2021-2022. A project was initiated to improve the resident educational experience with regards to quality improvement (QI) and patient safety. The specific project aim was to improve the ACGME score of the question "Participation in safety event investigation and analysis" by 33%, from 75% to 100%, by 6/30/23, without adversely impacting the education and clinical care balance.

### METHODS

A team comprised of residents, residency leadership, and radiology quality staff used DMAIC (Define, Measure, Analyze, Improve, Control) improvement methodology. Using a fishbone diagram and the 5 Whys tool, key causes were identified and selected, including: No defined process to notify residents of patient safety event reviews, no clear record keeping of safety event participation, lack of education for the residents related to interpreting survey questions, completing safety event reports, and knowing what constitutes a safety event. Five interventions were selected. First-year residents joined the Rad Quality Committee, increasing the opportunity to review safety events. A MedHub log was created to track participation in safety event investigation. Safety event reporting education was provided to the residents and the onboarding curriculum. The ACGME survey lecture was updated to clarify survey questions. Finally, a multi-disciplinary RCA simulation event requiring action plan creation was held. Residents were surveyed before and after the educational initiatives, which showed a significant increase in confidence levels regarding safety event reporting and identification (Figure 1).

### RESULTS

22-23 ACGME survey results were 100% compliance, meeting the project aim (Figure 2). The balancing measure score remained at 100%. Residents were surveyed before and after the mock RCA. Survey results showed a 50% increase in the ability to identify system issues and a 44% increase in the ability to identify process improvement actions (Figure 3).

### DISCUSSION

The project addressed gaps that residents face regarding safety event reporting and limited opportunities to engage in event investigation during training. A positive outcome of the project was the restructuring of the onboarding process. Lessons learned during the project were that QI tools help to eliminate “blind spots” while working through the DMAIC process, increased frequency of project meetings maintains momentum and allows more members to engage, and simulation is an effective experience to overcome scheduling barriers. Our hope is that these trainees will be more comfortable reporting and actively engaging in QI early in their practice.

## M5A-QI-2 HOW WE FIGHT FOR HEALTH EQUITY. A NOVEL APPROACH TO MOBILE SCREENING AND PATIENT EDUCATION IN RURAL COMMUNITIES: MAMMOGRAPHY AND BEYOND

Gwendolyn M. Bryant-Smith, MD (*Abstract Co-Author*) Nothing to Disclose
Daniela A. Ochoa, MD (*Abstract Co-Author*) Nothing to Disclose

### INTRODUCTION

Health disparities disproportionately affect the underserved population who have systematically experienced the geographic, racial, and socioeconomic barriers. The literature reflects the feasibility of mobile mammography for cancer screening. Our study evaluates the impact of multifaceted approach for cancer screening in rural communities with limited access to health care.

**METHODS**

With 41% of the population residing in rural areas, Arkansas's incidence and mortality rates for cancers are well above the national average. A phased collaborative care improvement model was implemented focused on counties with the lowest life expectancies (red counties) and underserved counties (pink counties) without permanent mammography facilities. A screening mobile mammography, MammoVan, was implemented with a team of a certified Mammography Quality Standards Act (MQSA) technologist, a technical assistant, fellowship trained breast radiologists, a multidisciplinary team of cancer physicians, and a navigation team that provide mammography at low or no cost through a state sponsored program. A phased approach was begun by involving the Mexican consulate and local primary and community centers to raise awareness and education for accessible screening. For the next phase in 2018, a colorectal cancer coordinator and team was introduced on the MammoVan to provide FIT tests to the patients aged 45 years or older or to those with a positive family history. For the next stage in 2022, we added lung cancer screening with the smoking cessation counselor who traveled on the MammoVan to provide education and referral for qualified patients for low dose CT scans. We obtained data from 2014-2022 on the screening trends including the number of screenings, retained follow up, racial/ethnic demographics and geographic location.

**RESULTS**

A total of 15,703 patients underwent screening mammography on the MammoVan between 2014-2022. The ethnic distribution for mammography is as follows: Black (28%), Hispanic (8%), Caucasian (61%) and others (3%). The graphical representation on yearly mammography with interventions has been represented in figure 1. The mammography screenings yielded in the diagnosis of 79 cancers (biopsy-proven). In addition to the screening mammography, the colorectal screening program identified 7773 referrals and 3979 screenings. The screenings yielded 418 positive FIT tests and diagnosed 59 malignancies. The lung cancer screening provided 441 smoking cessation interventions and referrals.

**DISCUSSION**

The implementation of the MammoVan through a multidisciplinary collaborative model to address rural health disparities for not only breast cancer screening but also colorectal screening and lung cancer education is a novel approach towards health equity.

## M5A-QI-3 TIME IS MONEY, SO IS "MEETING TIME": MEETING STRUCTURE PROCESS MAPPING AND ITS IMPACT ON ACADEMIC MEDICAL CENTRE - HOSPITAL SYSTEM

Dushyant Sahani, MD (*Abstract Co-Author*) Advisory Board, Koninklijke Philips NV;Advisory Board, Canon Medical Systems Corporation;Advisory Board, General Electric Company;
Sarabjeet Singh, MD, MBA (*Abstract Co-Author*) Research Grant, Siemens AG;Research Grant, Toshiba Corporation;Research Grant, General Electric Company;Research Grant, Koninklijke Philips NV
Karthika Devi D S, MBBS (*Abstract Co-Author*) Nothing to Disclose
Justin Deese, MBA (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Unnecessary meetings cost time, money as well as opportunity cost. On the other hand, meetings play an important role in decision making and collaboration. Finding the right balance of number of meetings as well as structure of the meetings becomes crucial, especially at executive/Vice-Chair level. The purpose of this study was to estimate time cost involved in meetings at the Vice-Chair level organized across the Academic Medical Center-Hospital System (AMC-HS).

**METHODS**

We retrospectively reviewed data from 2019 for our organization structure at AMC-HS, meetings organized, meeting attendees as well other relevant information available. We started by first creating a process map of meetings in 2019, including the committees, meeting attendees, time of meeting and frequency. We then prospectively reorganized the meeting structure gradually from 2019 to 2024, to reduce the executive committee size, stratify decision making at vice chair level, including operations, finance admin, quality safety, faculty affairs, education, research as well as EDI. We further estimated the hourly rate per attendees, based on salary range at vice-chair level. Meeting time, frequency and attendees was tabulated on Microsoft Excel and Microsoft Visio.

**RESULTS**

In 2019, highest level of meeting structure was the executive committee, which included 30 committee members and was meeting on monthly basis, see attached Figure 1. Finance and administration meetings included 5 attendees and on a weekly basis. Operational meetings occurred in person at each hospital site (University of Washington Medical Center [UWMC] {30 attendees}, Fred Hutch Cancer Center [FHCC] {15 attendees, 30 mins} Harborview Medical Center [HMC] {15 attendees}) on a weekly basis. Other meetings included education and research at Vice-Chair level, which were organized once a month with 20 25 attendees respectively. Total estimated cost of executive level meetings was $672,000 per year. Post reorganization, executive committee size reduced from 30 to 25, operations meetings became stratified and limited Vice-Chair level meetings to 8 attendees weekly with waterfall communication plans. Finance and administration, research, and education meetings remained largely the same. Vice-Chairs started meeting on monthly basis. The total cost of meetings was eventually reduced by 49% ($343,250/$672,000) per year in 2024.

**DISCUSSION**

Careful planning of meeting agendas, attendees and organizational structure help save time at the executive level. Furthermore, this time saving translated to an average saving of $102,750 per year and opening up executive time to reduce opportunity cost. Limitations for our study included inability to quantify productivity or engagement for meeting attendees. Future efforts to assess meetings productivity would include survey data to gauge meeting feedback.

## M5A-QI-4 IMPROVING RADIATION SAFETY COMPLIANCE AMONG RADIOLOGY RESIDENTS DURING FLUOROSCOPY PROCEDURES BY FACILITATING DOSIMETER ACCESS AND IMPLEMENTING A NOVEL PRE-PROCEDURAL SAFETY TIME OUT

Ali N. Harb, MD (*Abstract Co-Author*) Nothing to Disclose
Aniruddh Mannari, MD (*Abstract Co-Author*) Nothing to Disclose
Stephan Miller, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Ionizing radiation exposure during image-guided diagnostic and interventional procedures is an important occupational risk to operators and ancillary staff. Limited published studies have demonstrated the efficacy of protocol development to improve dosimeter compliance (Massey P et al., JBJS 2022). Currently, only 1 in 4 residents in our department wear dosimeters while working on procedural rotations. The purpose of our project was to increase compliance with wearing radiation dosimeter badges among radiology residents by 50% in one year.

### METHODS

This project was conducted in the radiology department of a large, urban, tertiary care academic medical center where dosimeter badges are provided in resident mailboxes, far from the procedural area. Resident survey showed the "lack of central accessibility" comprised 43% of responses. The target cohort is all resident physicians in the radiology residency program (n=40). We first relocated badges to a central workroom. Signage illustrating the proper use of the dosimetry badge was placed throughout the department. Notably, there were no other process improvement initiatives taking place, allowing us to attribute any changes to our interventions only. Compliance was measured during the intervention time frames. To address the issue of wearing dosimeters during fluoroscopic procedures, a pre-procedure dosimeter reminder was implemented after all residents had been made aware. The results of our interventions were evaluated using the Statistical Process Control (SPC) Chart with +/- 3 standard deviation control limits using standard parameters.

### RESULTS

Process control analysis shows that making dosimeters more easily accessible nominally increased compliance, with maximum compliance of 100% after 6 months. Subsequent implementation of the pre-procedural dosimeter checks corresponded to approximately 50% increased compliance with little variability in the system thereafter. This indicates that compliance with appropriately wearing personal dosimeter badges was optimized when we performed active pre-procedure checks of residents in the procedure room and they were easily available.

### DISCUSSION

Our interventions demonstrate that ease of access to dosimeters and verbal reminders to wear them as part of the pre-procedural time out protocol increased compliance as intended. Further process improvement methodologies are needed to optimize compliance and thereby improve radiation safety for the primary procedural operators in our department. Out study has some important limitations, including inconsistent pre-procedural checks due to time constraints and asynchronous resident scheduling on procedural rotations. Further education and optimization of this process is needed to improve occupational radiation safety.

## M5A-QI-5 REDUCTION OF SENTINEL WRONG LINE PLACEMENT EVENTS USING A STRUCTURED, LONGITUDINAL APPROACH TO SAFETY EVENT REVIEWS

Jared A. Christensen, MD (*Abstract Co-Author*) Advisory Board, F. Hoffmann-La Roche Ltd
Ellen J. Higgins, MS (*Abstract Co-Author*) Nothing to Disclose
Glenn E. Houck JR, MS, ARRT (*Abstract Co-Author*) Nothing to Disclose
Jason Battaglia, BS (*Abstract Co-Author*) Nothing to Disclose
Crystal Blank (*Presenter*) Nothing to Disclose

### INTRODUCTION

In a complex work environment it is important to address system issues that contribute to increased risk for patients. High reliability organizations incorporate a process of continuous improvement to mitigate risk and create a culture which works towards a zero-harm environment. HRO principles created a safety culture that resulted in an increase in reported safety events. This allowed us to identify several wrong line placement events in our interventional radiology unit using a structured longitudinal review process to implement interventions.

### METHODS

After the adoption of HRO principals, our institution developed structured formal review templates aimed at assisting reviewers in evaluating the individual failure modes that lead to patient risk. This format asks the same questions for each event, identifying recurring themes. An initial sentinel event for a wrong line placement was identified in Dec 2022. The review identified a causal risk related to the look-alike, sound-alike nature of two vascular access catheters. An initial intervention was implemented in February 2023 consisting of labeling these catheters with a red sticker indicating their intended use. After the initial intervention, we continued to have wrong line events reported. Formal reviews evaluating the system issues that contributed to the events were conducted with a significant gap in communication of the care plan from the consulting provider to the proceduralist was. In Oct 2023 additional interventions were implemented with the care plan documented in a note in the EMR. Compliance of documentation was audited on a regular basis. In addition, the treatment plan was confirmed during the preprocedural timeout process with all team members.

### RESULTS

Our first intervention did not address the gap in communication between all team members. The addition of a progress note into the EMR detailing the care plan was adopted to bridge that gap and to improve communication to the entire care team. Initial audits showed a documentation rate of 50%. Continued auditing and assignment of accountability has increased our compliance to 90%. Since the adoption of the new processes, there have been no additional wrong line events.

### DISCUSSION

A longitudinal, structured review system of similar safety events allowed us to identify key gaps in our processes. Addressing these gaps incrementally has led to elimination of sentinel events for wrong line placement. It is important to note that our first intervention did not address the root cause of wrong line placements, and that only the use of incremental structured review allowed us to identify the system issues. Adoption of these new processes was associated with challenges related to adding additional responsibilities to the workload of the IR teams. This was addressed using a regular audit with assignment of accountability by our safety team.

## M5A-QI-7 ENGINEERING STRUCTURAL WORKFLOW EFFICIENCIES IN THE OUTPATIENT IMAGING CENTER: THE SYNTHESIS OF HUMAN INTERVENTION (HI) AND ARTIFICIAL INTELLIGENCE (AI) FOR ACTIONABLE INCIDENTAL FINDINGS

Kirby Quinn, BS (*Abstract Co-Author*) Nothing to Disclose
Cinthia Del Toro (*Abstract Co-Author*) Nothing to Disclose
Felipe Munera, MD (*Abstract Co-Author*) Nothing to Disclose
Jean Jose, DO (*Abstract Co-Author*) Nothing to Disclose
Alexander M. McKinney IV, MD, BEng (*Abstract Co-Author*) CEO, VEEV, Inc
Thiago A. Braga, MD (*Abstract Co-Author*) Nothing to Disclose
Ayden Jacob, MD (*Presenter*) Consultant, Aidoc Medical Ltd

### INTRODUCTION

Incidental imaging findings, defined as a pathology detected by an imaging examination performed for an unrelated reason, will occur in 5%-30% of imaging studies. Actionable incidental findings (AIFs) discovered in the outpatient setting create an opportunity for radiologists to spearhead the most appropriate next best steps in clinical management. The purpose of this study was to build an operational workflow model whereby patients detected by artificial intelligence (AI) in the outpatient setting with incidental intracranial hemorrhage (ICH) or pulmonary emboli (PE) were directed to the emergency department (ED).

### METHODS

After obtaining IRB approval, an AI software was implemented at outpatient imaging centers which flagged all incidental PEs and ICHs. When the AI algorithm flags a positive case, the radiology technician contacts the Advanced Registered Nurse Practitioner (ARNP) and the patient is transferred to a nursing waiting area. The ARNP contacts the radiology clinical coordinator, who confirms with the attending radiologist that a true positive incidental finding is present. If an AIF is confirmed by the radiologist, the clinical coordinator contacts the ARNP to send the patient to the ED.

### RESULTS

Training of the ARNP and clinical radiology coordinators are of utmost importance in creating operational efficiencies with AIFs. Familiarity with the AI software requires robust information technology infrastructure. From July 2023 to February 2024, median turnaround time for positive incidental pulmonary emboli was 71.3 minutes (IQR: 448.3 minutes), compared to 267.6 minutes (IQR: 1322.3 minutes) for negative cases ($P<0.05$). The median turnaround time for outpatient positive incidental intracranial hemorrhages was 69.15 minutes (IQR: 255.8 minutes), compared to 176.9 minutes (IQR: 1665.5 minutes) for negative intracranial hemorrhage cases ($P<0.05$). AI flagged 51 patients with incidental PE and 150 patients with incidental ICH.

### DISCUSSION

This study underscores the potential of Point-of-Care AI Deployment (POC-AID) to augment the management of incidental findings encountered at outpatient imaging facilities. By expediting the detection and management of AIFs, such workflows have the capacity to enhance patient outcomes. Rapid identification of AIFs using POC-AID within the outpatient context enhances the radiologist's ability to direct clinical care in a manner that is timely and clinically relevant. Within the outpatient realm, radiologists can employ POC-AID to prioritize AIFs and collaborate with allied healthcare professionals to expedite patient referrals to the ED. The implementation of our POC-AID workflow demonstrates the viability of integrating AI with human intervention (HI) to facilitate swift and cost-effective clinical intervention.

## M5A-QI-8 INVESTIGATING THE QUALITY DIVIDE: ASSESSING DISPARITIES IN APPROPRIATE LUNG CANCER SCREENING FOLLOW-UP

Katie Decell (*Abstract Co-Author*) Nothing to Disclose

Adlai R. Grayson, MD (*Abstract Co-Author*) Nothing to Disclose
Michelle Ho, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Lung cancer is the leading cause of cancer mortality in the United States. Despite 10 years of guideline recommendations for lung cancer screening (LCS), studies document low uptake and poor follow-up adherence. Our institution previously identified delays in follow up for 47% of Lung RADS 3 and 4 studies from 1/1/2015-1/20/2021. In response, a centralized follow-up for all positive LCS findings was instituted. Our project investigated impacts on LCS adherence and if differences in follow-up of positive findings existed between at risk individuals empaneled in two distinct settings: an institution catering to vulnerable populations and an academic cancer care institution.

### METHODS

This project was conducted at a multi-site LCS program with a hybrid centralized-decentralized model. The LCS program serves many hospitals and clinics including academic teaching hospital, county safety net hospital, and Comprehensive Cancer Center.We reviewed medical records of patients screened from 1/1/2021 - 12/31/2023 with actionable findings (Lung-RADS 4A, 4B, or 4X) and 1/1/2023 -12/31/2023 with Lung-RADS 3 findings. LDCT with positive Lung-RADS 3, 4A, 4B, 4X findings were considered index scans.Adherence to recommended follow-up interval was defined as within 30 days of the Lung-RADS recommendation. Follow-up clinical visit was defined as any visit where LCS results were discussed. Follow-up imaging and procedures included diagnostic CT, PET/CT, and tissue sampling.Cohort A included patients whose index scan was ordered by county safety net affiliated hospital/clinic. Cohort B included all other LCS patients. We expected lower follow-up adherence for Cohort A than Cohort B (primary outcome), and a lower proportion in Cohort A to have PET/CT follow-up imaging (secondary).Statistical analysis was performed using chi-squared and fisher’s exact tests.

### RESULTS

Total of 175 patient records were reviewed (27 Lung RADS 3, 75 Lung RADS 4A, 53 Lung RADS 4B, 20 Lung RADS 4X).There was no significant difference in appropriate versus delayed follow-up (odds ratio: 0.837, $p = 0.8755$) between Cohort A and B. Appropriate follow-up rates were not significantly different between cohorts: 75% vs 74% Lung-RADS 3 and 80% and 83% Lung RADS 4, for Cohorts A and B, respectively.There was no significant difference in type of follow-up imaging/procedure between cohorts.

### DISCUSSION

We extended earlier work by assessing LCS program follow-up imaging rates among diverse settings in our system to better characterize racial, socio-economic, and geographic disparities. Our results suggest improvements in follow-up adherence after implementing centralized intervention and no difference in follow-up between safety-net and other settings. Future subgroup analysis in zip-code-specific areas may help identify and improve any, if at all, differences in access, follow up and adherence to LCS.

## M5A-QI-9 IMPROVING REPORTING OF CRITICAL RESULTS: DIAGNOSTIC RADIOLOGY RESIDENT QUALITY IMPROVEMENT PROJECT

Morgan P. McBee, MD (*Abstract Co-Author*) Nothing to Disclose
Claire Stephanie Adcock, MD (*Abstract Co-Author*) Nothing to Disclose
Daniel Holbrook, MD (*Abstract Co-Author*) Nothing to Disclose
Connor D. Crowley, MD (*Abstract Co-Author*) Nothing to Disclose
Kelly N. Howard, ARRT, MBA (*Abstract Co-Author*) Nothing to Disclose
Anna K. Fairfax, BS, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Timely communication of critical findings by radiologists can greatly influence patient outcomes. Missing or delayed communication of critical findings can lead to patient harm, delay in treatment, or even fatal consequences. Therefore, it is important that radiology residents recognize critical findings and appropriately document communication with clinical teams. In this project, we aimed to enhance radiology residents' knowledge of and adherence to our current "critical results" policy including which findings are defined as "critical" and how to appropriately document communications. We aimed to achieve a 10% increase in the identification of critical results over a 3-month period and decrease the incorrectly documented results by 20%. Our broader objective was to bolster timely and accurate reporting, thereby reducing patient harm.

## METHODS

Pre-Intervention Data were gathered for the months of July, September, and October and to provide a baseline number of reported “critical results” and how many were incorrectly documented. Intervention: An educational lecture was given to the radiology residents covering the significance of reporting critical results, criteria per department, protocols for reporting critical findings, and how to appropriately document our communication of these findings in final reports. The current department dictation macros for result communications were modified to include a pick-list where the resident must choose to either report a Critical Result or other “non-critical” finding. Additionally, documents outlining department-specific critical findings were installed throughout reading rooms as a constant visual reminder of critical findings. Post-intervention: Data gathered for the months of December, January, and February were analyzed to determine the number of times the “Critical Results” macro was used and determine if there were any instances where it was used incorrectly.

## RESULTS

There was increased awareness/reporting of critical results and improved adherence to timely reporting/appropriate documentation. Compared to pre-intervention data, there was a 225% increase in critical results documented with a concurrent decrease in the incorrectly documented/reported findings by 53.8%.

## DISCUSSION

Strengths of the project included buy-in and easy usability of the new macro. Additionally, the improved macro served as a forcing function for reporting radiologists to state whether a result was "critical" and the previous "critical results" macro auto-populated, seamlessly aligning with previous documentation practices. By empowering radiology residents with knowledge of the significance of timely reporting of critical findings and facilitating the ease of their documentation, we can contribute to a culture of patient safety, improving patient outcomes, and streamlining clinical workflow.

## M5B-QI-1 HIPAA COMPLIANT TEXT MESSENGER APP FOR REDUCTION OF PHONE CALL INTERRUPTIONS ON THE CARDIAC CT SERVICE

Brian B. Ghoshhajra, MD, MBA (*Abstract Co-Author*) Research Grant, Siemens AG;Consultant, Koninklijke Philips NV;Consultant, Siemens AG
Sandeep S. Hedgire, MD (*Abstract Co-Author*) Nothing to Disclose
Badr Badreldin, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Sadia Sultana, MRCP,FRCR (*Abstract Co-Author*) Nothing to Disclose
Mangun Randhawa, MD (*Abstract Co-Author*) Nothing to Disclose
Laura A. Naccarato, MD, MBA (*Presenter*) Nothing to Disclose

### INTRODUCTION

High volume of interruptions is a significant concern in radiology department workflow and the safe interpretation of imaging. Prior studies have shown that frequent interruptions in complex cognitive tasks lead to errors and decreased efficiency. On our Cardiac CT service, several factors, including a high percentage of studies requiring image checks, questions regarding protocol details, and administration of nitroglycerin, drive a large volume of phone interruptions. Our study's purpose was to evaluate the change in phone call volume before and after the implementation of a HIPAA compliant text messaging app.

### METHODS

Number, type, and timestamp of phone calls received by the Cardiac CT service between the hours of 8 AM and 5 PM were recorded over 1 week of the pre-intervention period. The HIPAA compliant texting application was implemented over 2 weeks. Technologists were encouraged to contact the radiologists for any non-urgent issues via the messenger application. Following the roll-out, type, number, and timestamp of phone calls received by the Cardiac CT service were again collected over a 1-week.The Chi-Square Test for Independence was initially employed to evaluate the overall difference in the number of calls between the pre- and post-intervention periods. Fisher's Exact Test was then applied for specific call types with lower frequencies, where the expected counts were less than 5. The average time between phone calls were compared using a T-test.

### RESULTS

Following intervention, the number of phone calls received by the radiology Cardiac CT service over a 1-week period declined from 275 to 191 ($p < 0.001$). A large driver of the change was driven by decrease in calls pertaining to non-urgent issues, including requests for protocols to be entered for upcoming studies, protocol clarifications, questions about contrast, and questions about nitroglycerin administration. These types of calls decreased from 78 to 31 (p .002). The number of minutes between phone calls also decreased, from 9.8 minutes in the pre-intervention period to 14.3 minutes in the post-intervention period ($p < 0.05$).

### DISCUSSION

Phone interruptions present a unique challenge to timely and accurate interpretation of imaging studies. Answering a phone call requires the interpreting physician’s immediate attention, irrespective of the actual urgency of the call. A large share of issues that will eventually require physician attention need to be addressed in a prompt, yet non-urgent timeframe. For these types of concerns, a text messaging system is particularly effective. In our study, the primary drivers of the reduction in volume were those that require the attention of the radiologist in a prompt, not emergent timeframe. The triage of these phone calls to a message allows radiologists to focus on interpretation of studies and address these questions between times of active study interpretation.

## M5B-QI-2 STRATEGIC IMPLEMENTATION OF AN AI FRACTURE DETECTION ALGORITHM SEQUENTIALLY ACROSS FOUR HOSPITALS IN NORWAY TO ENHANCE RADIOLOGY DEPARTMENT WORKFLOW EFFICIENCY

Line Tveiten, BMedSc (*Abstract Co-Author*) Nothing to Disclose
Jonas Vardal, MD (*Abstract Co-Author*) Nothing to Disclose
Bjorn Anton Graff (*Abstract Co-Author*) Nothing to Disclose
Ramprabananth Sivanandan, MD, MBBS (*Presenter*) Nothing to Disclose

### INTRODUCTION

Annually, the volume of radiological investigations increases by approximately 15 %, a growth rate that outpaces the availability of reporting radiologists. To address this imbalance, a CE-approved, commercially available AI-based fracture detection algorithm was integrated into the real-world workflow at the Vestre-Viken Hospital Trust (VV) in Norway. The objective was to delegate simpler tasks to AI, thereby enabling radiologists to concentrate on more complex cases and enhance overall workflow efficiency in the radiology department.

### METHODS

This pioneering initiative in Norway entailed the external validation and pilot implementation of the selected AI application at one hospital, followed by a sequential rollout to other three hospitals. This AI application detected fractures in digital skeletal X-rays taken for patients with a history of recent trauma. Following implementation, workflow patterns were streamlined from six to one pattern. Patient waiting times at the radiology department ranged from 8 to 30 minutes, waiting time for consultation varied from 33 to 174 minutes, and consultation durations for patients without fractures spanned 10 to 15 minutes across hospitals. Workflow triaging for radiologists was enhanced by integrating AI results into the Radiology Information System (RIS). Team collaboration played a crucial role in change management, and user manuals for the AI application were created and distributed among team members, including radiologists, radiographers, clinicians, and emergency doctors. A follow-up system was established to report false negative AI results.

### RESULTS

The external validation showed that the AI's accuracy was 91.3%, compared to 95,2% for radiologists (Fig.1). And with AI assistance, radiologists' accuracy improved to 98.4%. The implementation also significantly reduced patient waiting times by 10% to 35% across hospitals (Fig.2). Additionally, triaging in RIS increased the efficiency of radiologists in prioritized reporting of doubtful and positive cases. The created user manual streamlined the adoption of the AI applications among different stakeholders in the AI team. A feedback system for reporting false negative cases supports the secure usage of the AI application.

### DISCUSSION

The implementation of the AI application prioritized patients with fractures for treatment and significantly reduced waiting times for those without fractures and were sent home. The streamlined workflow processes increased efficiency within the radiology department and facilitated the development of a structured five-phase implementation process for future AI applications. This strategic approach (Fig.3) not only decluttered existing workflows but also set a precedent for the integration of other AI applications getting installed in our healthcare settings.

## M5B-QI-3 AI-POWERED TOOLS FOR ADMINISTRATIVE TASKS: TIME SAVINGS DRAFTING LETTERS OF PROMOTION

Ryan L. Melvin, PhD,MA (*Abstract Co-Author*) Nothing to Disclose
Ryan Godwin, MS, PhD (*Abstract Co-Author*) Nothing to Disclose
Srini Tridandapani, MD, PhD (*Abstract Co-Author*) Co-founder, Camerad Technologies, LLC;Spouse, Co-founder, Camerad Technologies, LLC;Officer, Camerad Technologies, LLC;Spouse, Officer, Camerad Technologies, LLC
Steven A. Rothenberg, MD (*Abstract Co-Author*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC
Alexander Lee (*Abstract Co-Author*) Nothing to Disclose
Jonah Barrett (*Presenter*) Nothing to Disclose

### INTRODUCTION

Physicians' time spent on administrative tasks has been shown to increase their risk of burnout while decreasing their work satisfaction. Generative AI techniques have the potential to reduce the burden from administrative tasks by assisting with non-clinical responsibilities. The purpose of this study was to investigate the utility of large language models (LLMs) for streamlining non-interpretive tasks for drafting letters of promotion for academic faculty.

### METHODS

The single-center prospective study was determined to be exempt by the IRB. A custom web application was developed using the OpenAI API and LangChain to implement a custom retrieval-augmented generation (RAG) workflow that ingests a curriculum vitae (CV) and career information as inputs to generate personalized promotion letter drafts. Physicians at our institution were solicited via email to provide their CVs before receiving an AI-generated promotion letter and a link to an online survey. Descriptive statistics and a Net Promoter Score (NPS) were calculated based on the physicians' responses.

### RESULTS

The 22 physicians who agreed to participate in the study varied in their academic rank and time since their last training. Of the physicians, 15 (68.2%) were radiologists of various subspecialties. 19 physicians completed the study survey. The average estimated time savings for using the tool was 64.5 minutes (SD = 47.0). On a scale of 1-10, the most common response to the question, "How likely are you to recommend this tool to a friend or colleague?" was 10 endorsed by 5 (26.3%) physicians. The NPS was 15.8, indicating the tool had more promoters than passives and detractors. 14 physicians (73.7%) indicated that they were planning on using the tool in the future to generate letters of support for a friend or colleague. 3 (15.8%) of the physicians indicated there was a hallucination in their promotion letter.

### DISCUSSION

A single-center investigation of the utility of a custom generative AI workflow for assisting with non-interpretive tasks demonstrated potential time savings for drafting letters of promotion. However, as evidenced by multiple hallucinations in the study's AI-drafted letters, these tools are not without faults and may occasionally fabricate or embellish information. Therefore, users of this tool need to carefully review the AI-generated content for accuracy. Limitations of this study include recruiting only faculty members from a single academic institution, a small sample size, and a lack of variance in CV formats used to generate promotion letters. Further, developers of similar applications need to take appropriate measures to ensure data privacy as CVs contain personal information with content that could be used for identity theft. Letter writers should ensure that letters capture their true impressions of each candidate's merit to maintain the integrity of the faculty promotion process.

## M5B-QI-4 IMPROVING SELF REPORTING OF COMPLICATIONS: CURRENT STATUS AND CONCEPT OF GLOBAL TRIGGER TO IMPROVE AUTOMATED CAPTURE OF COMPLICATIONS USING AI ALGORITHMS

Anil K. Pillai, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Rakesh K. Varma, MD, MBBS (*Abstract Co-Author*) Speaker, Becton, Dickinson and Company
Jayesh Soni, MD (*Abstract Co-Author*) Nothing to Disclose
Daniel Lamus, MD (*Abstract Co-Author*) Nothing to Disclose
Ahmad Arar (*Presenter*) Nothing to Disclose

### INTRODUCTION

10% of hospitalized patients experience an adverse event with half occurring during invasive disciplines such as surgery and other procedural specialty. Medical errors in interventional radiology (IR) result from various causes, including procedure complexity, patient factors, workflows, provider experience, organizational expertise, and the specific safety measures in place. Identification of improvement opportunities heavily depends on self-reporting. We present the status of self-reporting of complications and discuss a novel automated process to improve the identification of adverse events.Purpose-Discuss the current status of self-reporting of complications in medicine

**METHODS**

We delve into the factors contributing to the low levels of self-reporting in IR, including subjectivity in complication identification, the added burden of self-reporting, the absence of follow-up mechanisms, and provider reluctance. Furthermore, we introduce an innovative automated system designed to identify complications using billing data and artificial intelligence. This system leverages the association between ICD 10 and CPT codes, employing a Global trigger concept to prompt chart reviews for potential complications.

**RESULTS**

Our examination of previous studies underscores the high incidence of preventable errors during procedures and the adverse consequences of underreporting. Notably, only a fraction of medical errors are self-reported, underscoring the need for alternative detection methods. We describe the potential role of an automated tool in identifying outliers and potential complications without relying on traditional self-reporting mechanisms.The automated identification of complications using the billing data based on association of ICD 10 (indication for procedure) and CPT code (Procedure code) is an effective way to identify outliers (complications). If the CPT codes do not correspond to the ICD 10 code, a chart review can be triggered to identify the reason for extra procedures and identify complications- the concept of Global trigger. Creating an artificial intelligence dashboard for weekly identification of outliers and reviewing the triggered charts removes the need for dependence on self-reporting to identify complications.

**DISCUSSION**

We discuss the challenges of self-reporting of complications in a tertiary-level academic center. By implementing the automated tool presented in this abstract, we anticipate significant advancements in patient safety through the timely identification of complications. A pilot to automate the identification of potential complications utilizing billing information and an AI algorithm will be presented in this report.

## M5B-QI-5 RADIUS: COMMUNITY-DRIVEN RADIOLOGY AI LARGE LANGUAGE MODEL AND VISION LANGUAGE MODEL LEADERBOARD

Jaron Chong, MD (*Abstract Co-Author*) Nothing to Disclose
David Li, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

The recent exponential growth of large language models (LLMs) and nascent vision-language models (VLMs) presents tremendous potential to transform radiology. However, evaluating and comparing LLM and VLM performance has proven exceedingly challenging, necessitating rigorous, standardized, and transparent benchmarks to ensure reliability and reproducibility. We developed the Radiology AI LLM and VLM Leaderboard (RADIUS), with the aim of establishing a community-driven benchmarking platform to assess LLM and VLM performance in radiology.

**METHODS**

RADIUS features a standardized platform for evaluating and comparing LLMs and VLMs across diverse radiological datasets encompassing both text and images, ensuring comprehensive assessment of each model. An evaluation and voting framework is devised, incorporating domain-specific criteria to accurately assess model performance. The leaderboard was initialized using existing results published in the academic literature. Leading AI researchers and industry partners are invited to submit their model evaluations using both public and proprietary datasets to this community-driven initiative.

**RESULTS**

The feasibility and effectiveness of RADIUS in evaluating LLMs for radiology tasks has been demonstrated. Multiple LLMs and VLMs are assessed across different radiology-specific tasks and datasets. Model performance is transparently reported and ranked, with longitudinal analysis provided for each dataset and task over time. The performance of three proprietary and one open-access LLMs on a text-based differential diagnoses task is illustrated (Fig. 1). For subjective interpretive tasks, a blinded voting system allows registered academic and industry researchers to submit model outputs, with pairwise competitions reported and ranked using the Elo rating system.

**DISCUSSION**

The establishment of RADIUS represents a significant step towards standardizing the evaluation of LLMs and VLMs in radiology. By providing a centralized benchmarking platform, RADIUS promotes fairness, transparency, and collaboration within the radiology and AI communities. Continued development and expansion will facilitate the safe integration of generative AI into clinical practice. Early results suggest that the ranking of top-performing LLMs and VLMs on radiology-specific tasks may differ from general purpose or computer science leaderboards, further making the case for scalable radiology-specific quality improvement efforts.

## M5B-QI-6 IMPROVING THE RATE OF LUNG CANCER SCREENING AT AN URBAN SAFETY-NET HOSPITAL

Christina A. LeBedis, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Christian J. Ashby, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Lung cancer is one of the leading causes of morbidity and mortality in the United States. Lung cancer screening with low-dose computed tomography reduces lung cancer mortality by 20% and all-cause mortality by 6.7%. In 2013, the United States Preventive Services Task Force began recommending annual LCS with LDCT in adults aged 55-80 years with a 30 pack-year smoking history and currently smoke or quit within the past 15 years. In 2021, the USPSTF updated their guidelines to include more at-risk populations by decreasing the age of screening initiation to 50 years, and by decreasing the smoking history threshold to 20 pack-years. In 2015, our institution, Boston Medical Center, implemented a comprehensive LCS program targeting our at-risk population. However, internal retrospective analysis revealed that only 16% of LCS-eligible patients ultimately received their screening LDCT. The purpose of this QI project is to increase smoking history gathering and identification of high-risk smokers so we can enroll more of these patients in LDCT exams.

**METHODS**

We offered an LCS Questionnaire to all BMC patients arriving for radiology appointments in the radiology waiting areas. The questionnaires assessed patient demographics, lung cancer risk, LCS eligibility, relevant past medical history, and relevant family history, and were available in the five languages spoken. For patients who self-identified as LCS-eligible, we performed chart review to determine whether they were currently undergoing LCS. If not, we contacted the patient's primary care physician via EPIC to notify them of this finding and to emphasize the importance of LCS.

**RESULTS**

We collected 1644 questionnaires from 3/11/2021 to 4/21/2021 (41 days). 113 patients (6.9 %) self-identified as LCS eligible; 56 (49.6%) met the 2013 USPSTF LCS criteria, of whom 21 (37.5%) were not currently undergoing LCS; 57 additional patients (50.4%) met only the 2021 USPSTF LCS criteria, and none were currently undergoing LCS. Most patients were women (75 of 113, 66.4%), median age 62.5 years, average 40.1 pack-years, with high

school education or less (57 of 113, 50.4%), and were either Black (44 of 113, 38.9%) or White (47 of 113, 41.6%). Most patients did not have a previous diagnosis of COPD (85 of 113, 75.2%) or emphysema (99 of 113, 87.6%). 7 of 113 (6.2%) had a previous diagnosis of lung cancer, and 7 of 113 (6.2%) had a previous diagnosis of breast cancer. Most patients did not have a family history of lung cancer (101 of 113, 89.4%). As of 4/27/2021, after notifying primary care providers of patient LCS eligibility, 3 of the 21 patients (14.3%) meeting 2013 LCS criteria had baseline LCS exams ordered for 2021.

**DISCUSSION**

Over one-third of LCS-eligible patients are not currently undergoing LCS. By administering voluntary patient questionnaires, we improved smoking history collection and identification of high-risk patients qualifying for LCS.

## M5B-QI-7 WHEN TIME IS OF THE ESSENCE: OPTIMIZING TRAUMA RADIOGRAPH WORKFLOW TO DECREASE TIME TO CT

Christopher I. Fung, MD (*Abstract Co-Author*) Stockholder, Mikata Health
Brett Mador (*Abstract Co-Author*) Nothing to Disclose
Jessica Kwok (*Abstract Co-Author*) Nothing to Disclose
Brendan C. Kelly, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Time to intervention is a critical metric in trauma care with increased length of stay in the Emergency Department (ED) being directly associated with increased patient mortality (Mowery N, J Trauma 2011). Computed tomography (CT) is heavily relied on in this setting to rapidly diagnose life-threatening injuries that require urgent management. Recommendations for time from patient arrival in the ED to transfer to CT vary, with the notion of the "Golden Hour" to initiate definitive trauma care often considered the standard. At our center, transfer to CT has at times been delayed due to excessive time spent perfecting patient positioning or repeating radiographs in the trauma room despite acute findings often being evident on single or incomplete views. Therefore, the objectives of this study were to optimize trauma radiograph workflow to decrease the average time to complete chest/pelvic radiographs to under 10 minutes, extremity radiographs to under 20 minutes, and transfer to CT to under 45 minutes.

**METHODS**

The project was completed at a quaternary care hospital with the initiative team including Radiology Technologists, Radiologists, Trauma Surgeons, and Emergency Medicine Physicians. After consultation with stakeholders, it was determined trauma room radiograph workflow be altered to instead perform limited radiograph series prior to transfer to CT with delay of additional views until after CT is complete. A memorandum outlining these changes was distributed on April 25, 2023 with changes effective May 1, 2023. Intervention impact was determined by recording the average time to complete chest/pelvic radiographs, extremity radiographs and transfer the patient to CT for trauma activations in the 6 months preceding and following the intervention. The study population included 146 pre-intervention and 159 post-intervention patients. Time to complete radiographs was defined as the difference between the exam start time and latest radiograph upload time. Transfer time to CT was defined as the difference between the upload time of the first scout CT image and the earliest documented time of patient arrival in the ED. Statistical analysis was completed using a two sample T-Test.

**RESULTS**

The average time to complete chest/pelvic radiographs was decreased from 13.1 minutes to 7.3 minutes (plt;0.001), and the average time to complete extremity radiographs was decreased from 22.3 minutes to 17.5 minutes (p=0.04). The average transfer time to CT was decreased from 49.6 minutes to 44.8 minutes (p=0.02).

**DISCUSSION**

Through a relatively simple initiative, the study objectives were met, and the average time taken to complete trauma room radiographs and transfer the patient to CT was significantly decreased. Limitations of the study include potential confounding bias related to concurrent improvements in trauma care that occurred over the course of the study.

## M5B-QI-8 TIME IS SPINE: EFFECT OF A SPINE ONCOLOGY REPORTING MACRO ON TIME TO TREATMENT FOR PATIENTS WITH SPINE METASTASES

Charles E. Kahn JR, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Alvand Hassankhani, MD (*Abstract Co-Author*) Nothing to Disclose
Raghav Mattay, MD (*Abstract Co-Author*) Nothing to Disclose
Laurie A. Loevner, MD (*Abstract Co-Author*) Research Grant, Guerbet SA;Investigator, Guerbet SA
Colbey W. Freeman, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Spine metastases affect approximately 30% of patients with cancer. Communication gaps between radiology and treatment teams are a source of delayed treatment, potentially leading to adverse outcomes and reduced quality of life, and a common source of litigation. The purpose of this study was to determine the impact of a standardized spine MRI reporting macro coupled with an automated electronic notification to treatment teams on reducing the time to radiation oncology or spine surgery consultations and treatment initiation for outpatients with spine metastases.

**METHODS**

We developed a Spine Oncology Imaging Score (SOIS) and optional text macro for spine oncology MRI reports comprising MRI features from the Spine Instability Neoplastic Score and the Epidural Spinal Cord Compression scale. Immediately after a macro-containing report was signed, an automated script sent an email to a monitored spine oncology treatment team account. Outpatient reports containing the macro between April 2021 and February 2023 were retrospectively identified. Spine MRIs during the same period with osseous metastases but no macro were identified as controls and retrospectively assigned SOIS scores. Time intervals between MRI completion and subsequent radiation oncology or spine surgery consultation and initiation of radiation or surgery were calculated from the medical record. Data were analyzed using multivariate multiple linear regression. To control for potential confounders, patient age, sex, STAT status, visit department, treatment type, and SOIS score were included as independent variables with days to consultation and treatment as dependent variables.

**RESULTS**

The macro system was activated in April 2021. During the study period, 274 outpatients had spine MRI reports containing the macro: 213 with follow-up visits and 154 with subsequent treatment. Of 152 control patients, 117 had follow-up visits and 58 had subsequent treatment. Age (mean 63.2 years with macro, 62.4 years without, p=0.52), sex (58.8% female with macro, 57.2% without, p=0.76), and epidural scores (p=0.30) were not significantly different between groups. Studies with the macro were more likely to be STAT (33.2% vs 19.7%, p = 0.003) and had lower SOIS numerical scores (mean 5.4 of 13 vs 6.0, p=0.009). Time to consultation (mean 5.4 days vs. 9.1 days, p=0.02) and to treatment (16.2 days vs. 22.2 days, p=0.03) were both shorter for the macro group.

### DISCUSSION

The SOIS reporting system supplements other methods of communication. In a statistical model that controlled for several potential confounders, the macro and notification system were associated with earlier consultations and treatment by the spine oncology team. Ultimately, such reporting systems may help address gaps in communication and facilitate and direct multidisciplinary care by delivering structured imaging results to treatment teams.

## M5B-QI-9 REFERRAL GUIDELINES: A DESCRIPTIVE COMPARISON OF TWO NATIONAL RADIOLOGY SOCIETIES' GUIDELINES DEVELOPMENT AND DISSEMINATION ACTIVITIES WITH DATA ANALYSIS

Amanda Wells (*Abstract Co-Author*) Nothing to Disclose
David Kurth (*Presenter*) Nothing to Disclose

### INTRODUCTION

Radiology referral guidelines aid clinicians to select appropriate imaging to answer a diagnostic question. These guidelines help avoid unnecessary care and facilitate timely access to the appropriate treatment by ensuring the patient starts their care pathway with the right image. During these times of global workforce shortages in healthcare, referral guidelines directly help address the demand for imaging and reduce the burden of low value care. The American College of Radiology (ACR) and the Royal College of Radiology (RCR) have produced radiology referral guidelines for over 30 years, from the US and UK respectively, varying in format to align to different healthcare systems and needs but similar in rigor of evidenced based methodology. This presentation will demonstrate their intrinsic value beyond meeting requirements and will demonstrate the benefits of radiology referral guidelines through the analysis of data available from the National Health Service (NHS) in England.

### METHODS

A descriptive comparison regarding the development and dissemination successes and barriers is illustrated in a slide presentation. We will describe two approaches to referral guidelines, both have informed development guideline systems in other countries. The presenters will describe the challenge of guideline development as an evidence-based, transparent process and will highlight variations in their processes. Clinical Decision Support (CDS) systems are implemented in secondary and primary care in approximately 55% of hospital trusts in England. Impact data were gathered that showed the change or cancellation rate, the impact on overall appropriateness and rejection rates, and calculated cost savings based on changed behavior. The presenters will discuss literature that indicates the benefit of using CDS for image ordering in the US. This literature will be contrasted with the other approach which has rich CDS data illustrating improvements in patient care.

### RESULTS

Both societies have successfully developed and disseminated robust radiology referral guidance to ordering providers. Data seems to indicate that implementation of clear, in-workflow guidelines can improve appropriate imaging. Use of CDS in radiology referrals shows an impact of 10-15% and extrapolated yearly cost savings of around £300k per hospital based on the referral impacts against NHS tariffs.

### DISCUSSION

The data gathered demonstrates a positive impact, supporting the hypothesis that use of radiology guidelines are impactful in terms of patient care, management of backlogs, efficiencies of service and reduction in exposure to ionizing radiation, with an increase in appropriateness and decrease in rejections if vetting is performed. Further analysis in various settings may demonstrate how this varies globally. Taking England as one model is a useful step to understand global impact potential.

## R2-QI-2 PIPELINE DEVELOPMENT TO IMPROVE DIVERSITY, EQUITY, AND INCLUSION IN RADIOLOGY: A DATA-DRIVEN PROGRAM

Hrishikesh Bhaththiwala, MBA, BA (*Abstract Co-Author*) Nothing to Disclose
Viraja Alluri, BS (*Abstract Co-Author*) Nothing to Disclose
Karen L. Xie, DO (*Abstract Co-Author*) Nothing to Disclose
Emily Chuang (*Abstract Co-Author*) Nothing to Disclose
Divya M. Surabhi, MD, MPH (*Presenter*) Nothing to Disclose

### INTRODUCTION

Despite growing awareness of the persistent gender, racial, and ethnic imbalance in the radiology training and workforce, there are improvements to be made at targeting the gap. Our institution has designed and implemented a longitudinal education program to increase knowledge, awareness, and interest in radiology among undergraduate and medical students. We used the 5C's of Radiology (5C's) (curriculum, coaching, collaborating, career, and commitment) as a framework for our program, and data-driven strategies were incorporated for baseline evaluation and continued monitoring and improvement. The goal is to target leaky pipelines and increase the racial and gender diversity of medical students pursuing a career in radiology.

### METHODS

Virtual and in-person events were conducted at an urban, academic medical school and affiliated university from 2022-2024. Medical student events included 9 career advising sessions, 8 skills workshops, 3 procedure workshops, 5 shadowing/mentorship programs, and 2 intersectionality in radiology events. 7 undergraduate outreach events were held. At the end of each event, students completed a demographics and knowledge questionnaire. The demographics questionnaire gathered information regarding gender, race/ethnicity, school year, and radiology exposure; the knowledge questionnaire assessed students' misconceptions and perception of work-life balance along with event quality and future interest. Responses were obtained using a Likert scale. Surveys were analyzed for trends by question type, race/ethnicity, gender, radiology exposure, and school year. There were 287 attendees with a 64% survey completion rate (184 responses). Two-tailed t-tests assessed statistical significance for race/ethnicity, gender, radiology exposure, and year in medical school trends.

### RESULTS

Undergraduate students had a statistically significant improvement in knowledge regarding misconceptions and a positive trend in perceived quality of events compared to medical students.?

### DISCUSSION

Limitations include limited follow-up, as we have not captured data regarding how many program participants apply to radiology residency. In 2024, we are expanding undergraduate outreach, career advising and intersectionality in radiology events, and outreach to women. Future data analysis includes exploring the differences in in-person and virtual events along with longitudinal follow-up with participants.

## R2-QI-4 REMOTE OR ON-SITE DIAGNOSTIC BREAST IMAGING: PERFORMANCE COMPARISON AND ACCEPTANCE

Margarita L. Zuley, MD (*Abstract Co-Author*) Investigator, Hologic, Inc
Carley Siedlecki (*Abstract Co-Author*) Nothing to Disclose
Luisa Wallace (*Abstract Co-Author*) Nothing to Disclose
Avery Wang, BS (*Presenter*) Nothing to Disclose

### INTRODUCTION

Breast imaging practices have evolved significantly due to technological advancements and COVID-19, with many radiologists favoring hybrid work primarily for screening and MRI interpretation. Literature indicates increased productivity and high patient satisfaction. However, concern remains for understanding of patient, staff and physician acceptance and accuracy with remote diagnostic care.

### METHODS

One breast imaging radiologist with 24 years experience who previously left our academic subspecialty practice for relocation, returned and began remote diagnostic breast imaging in October 2021. Performance metrics were compared between remote and on-site assessments and to pre-implementation metrics. Cancer detection rate (CDR), positive predictive value (PPV2), and frequency of BI-RADS 3 ratings were assessed. Patient and technologist attitudes were assessed with retrospective, anonymous surveys. Patient responses were obtained immediately following a visit. Ten participating technologists with varying degrees of experience were surveyed.

### RESULTS

De-identified assessment data was obtained from 9,596 patients seen by this radiologist before and after hybrid reading, with 2,305 under the hybrid reading model (1,903 remote, 402 on-site). Beginning with the year of implementation, no statistically significant differences were found between remote and on-site diagnosis in CDR (remote: 30.91 - 49.92, on-site: 37.59 - 57.21), PPV2 (remote: 38% - 43%, on-site: 42% - 57%), and the frequency of BI-RADS 3 (remote: 7.38% - 14.02%, on-site: 8.70% - 10.98%). An increase was seen in BI-RADS 3 ratings after implementation, but CDR and PPV2 remained consistent.Patients returned 101 surveys (86 remote care, 15 on-site) and reported high overall satisfaction with their radiologist, with satisfaction rates of 91% (72/79) when remote and 86% (12/14) when on-site. Of those with a remote radiologist, 73/82 (89%) were satisfied with visit duration, compared to 15/15 (100%) on-site. No patients reported experiencing technical issues, and only one patient was unlikely to return to a remote breast radiologist.With the radiologist remote, all technologists (10/10) rated clinic functionality positively and communication as easy. 7/10 (70%) reported experiencing technical issues less than 25% of the time, relating to image transfer delays and auditory clarity.

### DISCUSSION

The lack of significant differences in performance metrics suggests comparable diagnostic accuracy and reliability between remote and on-site diagnostic care. The observed frequency of BI-RADS 3 diagnoses after 2016 could be attributable to a change in reading style following return to our practice. High patient and technologist satisfaction indicates acceptance of remote reading, supporting continued utilization and optimization of remote breast radiology services in clinical practice.

## R2-QI-5 DIRECTING CARE WITH POINT OF CARE ARTIFICIAL INTELLIGENCE DEPLOYMENT (POC-AID): CLINICAL IMPACT OF ESTABLISHING PURPOSEFUL OUTPATIENT AI-DIRECTED MANAGEMENT OF INCIDENTAL PULMONARY EMBOLI

Jean Jose, DO (*Abstract Co-Author*) Nothing to Disclose
Cinthia Del Toro (*Abstract Co-Author*) Nothing to Disclose
Felipe Munera, MD (*Abstract Co-Author*) Nothing to Disclose
Thiago A. Braga, MD (*Abstract Co-Author*) Nothing to Disclose

Kirby Quinn, BS (*Abstract Co-Author*) Nothing to Disclose
Ayden Jacob, MD (*Presenter*) Consultant, Aidoc Medical Ltd

### INTRODUCTION

Translating imaging AI results into clinically relevant information that guides appropriate medical therapy requires streamlined IT infrastructure and advanced practitioner support. The purpose of this study was to evaluate the impact of an outpatient point of care AI-guided triage solution on appropriately directing patients with positive incidental pulmonary emboli (iPE) on CT imaging to the emergency department for medically necessary therapy in an expedited fashion.

### METHODS

An AI software was implemented in July 2023 at outpatient imaging centers which flagged all iPE. 11,700 outpatient CT chest and CT abdomen scans were analyzed with an AI-based software from July 2023- March 2024. When the AI algorithm flags a positive case, the radiology technician contacts the Advanced Registered Nurse Practitioner (ARNP) and the patient is transferred to a nursing waiting area. The ARNP contacts the radiology clinical coordinator, who confirms with the attending radiologist that a true positive incidental finding is present. If an iPE is confirmed by a radiologist, the clinical coordinator contacts the ARNP to send the patient to the emergency department (ED).

### RESULTS

A total of 80 iPEs were detected by the AI software and confirmed by a radiologist. The average age for patients with iPE was 62.7, with 60% being male and 40% female. 94% of iPE patients had an oncologic diagnosis as part of their past medical history. Median turnaround time for positive incidental pulmonary emboli detected by AI was 66.4 minutes (IQR: 526.3 minutes), compared to 383.6 minutes (IQR: 1502.3 minutes) for negative cases ($P<0.05$), resulting in an observed 82.7% (317.2 minutes) decreases in wait time for the AI notified cases. 35% of iPEs were categorized as segmental. 29% of patients with iPE went directly to the ED from the outpatient imaging center. Of those ED patients, 78% were admitted to the hospital with an average length of stay of 4.4 days. 83% of patients with an iPE who went to the ED were started on anticoagulation. 1 patient underwent mechanical thrombectomy and the Pulmonary Embolism Response Team was activated in 4 patients.

### DISCUSSION

Our study demonstrates the effectiveness of an outpatient POC-AID triage solution in expediting the identification and management of iPE. By integrating AI into imaging workflows, we observed a significant reduction in turnaround time for positive iPE cases, enabling prompt referrals to the ED and initiation of necessary therapy. The streamlined process facilitated by the AI triage system led to expedited transitions from outpatient imaging centers to the ED, minimizing delays in care delivery. Our study demonstrates the clinical utility of AI technology in improving patient outcomes and optimizing resource utilization in the management of incidental findings in the outpatient imaging setting.

## R2-QI-6 IMPACT OF A COLLABORATIVE SMALL BOWEL OBSTRUCTION IMAGING AND CARE PROTOCOL WITH THE GENERAL SURGERY SERVICE ON RADIOLOGY WORKFLOW AND RESOURCE UTILIZATION

Stephen M. Seedial, MD (*Abstract Co-Author*) Nothing to Disclose
Mark Glover (*Abstract Co-Author*) Nothing to Disclose
Bashir H. Hakim, MD (*Abstract Co-Author*) Nothing to Disclose
Trevena Metias (*Abstract Co-Author*) Nothing to Disclose
Amy Braddock (*Abstract Co-Author*) Nothing to Disclose
Nathaniel Sertu (*Abstract Co-Author*) Nothing to Disclose
Kaitlin M. Zaki-Metias, MD, FRCPC (*Presenter*) Nothing to Disclose

### INTRODUCTION

Small bowel obstruction (SBO) is a common cause of diagnostic imaging, hospital admission, and surgical consultation. At our institution, following initial CT imaging without oral contrast demonstrating SBO, a second CT with oral contrast was typically obtained. A new protocol has been implemented in a collaboration between the department of surgery to eliminate the second CT, using water-soluble oral contrast and serial abdominal radiographs for further assessment of SBO in clinically stable patients. This study aims to assess the impact of this protocol on radiation exposure and resource utilization.

### METHODS

A retrospective cohort study was conducted on patients with SBO diagnosed on initial abdominopelvic CT for whom the general surgery service was consulted. Patients who underwent two abdominopelvic CT scans within 24 hours, one after the administration of oral contrast and one without, prior to

implementation of the new protocol were selected for the control group. Ionizing radiation exposure, contrast media utilization, and CT technologist time were recorded for both groups.

**RESULTS**

Eighteen patients were included in the experimental group and 38 patients were included in the control group. Total effective dose (mSv) and CT technologist time were significantly less with the new protocol ($p=0.02$ and $p<0.001$, respectively). There was decreased use of intravenous contrast media in the experimental group relative to the control group, although this was not statistically significant ($p=0.06$).

**DISCUSSION**

The implementation of a collaborative SBO imaging and care algorithm between general surgery and radiology resulted in reduced radiation exposure to patients and decreased CT technologist time.

## R2-QI-7 A REVISED CLASSIFICATION SYSTEM FOR COMMUNICATION ERRORS IN RADIOLOGY TO FACILITATE IMPLEMENTATION OF PREVENTIVE MEASURES

Suzanne Swedeen, MSc (*Abstract Co-Author*) Nothing to Disclose
Jennifer M. Cutts, MD (*Abstract Co-Author*) Nothing to Disclose
Olga R. Brook, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Bettina Siewert, MD (*Abstract Co-Author*) Editor, Wolters Kluwer nv;Reviewer, Wolters Kluwer nv
Meghavi Mashar, MBBChir, MA (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Communication errors are a major contributor or the sole cause of 65% of serious adverse events. In radiology, 38% directly impact patient care with moderate to severe adverse impact on outcomes. Errors stem from many causes, such as information transfer, appropriate understanding by the recipient and timeliness of the message. Creation of effective countermeasures is based on root cause analysis (RCA) and identification of contributors. Whilst communication classification systems exist, none are specific to radiology. This study aimed to characterise communication errors in radiology and develop a dedicated classification system to aid the development of countermeasures.

**METHODS**

We searched hospital and radiology quality assurance (QA) databases for incidents reported under the categories "communication/coordination/handoff" and "communication issue" and performed RCA. Errors were categorised using the observation classification created by Lingard et al. into one of audience, content, occasion, and purpose. During RCA, additional themes were noted allowing subcategory development.

**RESULTS**

285 incident reports were recorded, 17 with two errors, totalling 302 communication events. Purpose errors were most frequent (146/ 302, 48.1%), then content (137/302, 45.4%), occasion (14/302, 4.6%) and audience (5/302, 1.7%) (Table 1). Subcategories were developed for content (missing information, inaccurate information and unclear information), occasion (communication occurred too early or too late), and purpose (key individual (KI) could not be contacted, KI could not be reached, misunderstanding, lack of understanding and lack of closed loop). Occasion errors were limited to timing of communication, and purpose errors consisted of transfer issues.

**DISCUSSION**

We revised the classification system by Lingard et al. for use in radiology. Errors in the purpose category related to transfer of information. We suggest renaming this category as such. Occasion errors were related to timing of communication. This was the major cause of the error for real-time communication in the operating room for which Lingard et al.'s classification was designed. The new subcategories for content outlined above are helpful as each requires different countermeasures. Missing information may benefit from inclusion on checklists or in the electronic health record. In the purpose subcategories: "KI could not be reached" needs better contact information for referring provider, a known issue in large healthcare networks. "KI not contacted" would benefit from communication policy development. Closed loop protocol development is key in many scenarios. A limitation is that errors not listed under communication categories in QA databases may have been missed.

## R5A-QI-2 TECHNOLOGIST-FOCUSED PROCESS IMPROVEMENT STRATEGIES FOR IMPLEMENTATION OF SPECTRAL CT TECHNIQUES IN RADIOLOGY WORKFLOW TO GUIDE RENAL STONE MANAGEMENT

Ramandeep Singh, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Natally AlArab, MD, MSc (*Abstract Co-Author*) Nothing to Disclose
Jacob Elam, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Dual-energy computed tomography (DECT) has been documented to be valuable non-invasive modality for characterizing renal stone composition, impacting treatment per American Urological Association guidelines. However, integrating DECT into radiologic workflows for stone analysis is challenging and largely underexplored. We aimed to implement process improvement technologist-focused interventions in a Plan Do Study Act fashion (PDSA) for renal/ureteric stone analysis (RSA), streamlining and integrating the derived results to picture archiving and communication system (PACS) for accurate stone composition.

### METHODS

Aimed at a step wise approach, surveys were given to the CT technologists asking various questions about their experience, training, and confidence using RSA tools in SyngoVia prior to their education session. Serial meetings with CT technologists were conducted which included tiered education sessions on generating material decomposition (MD) images and using RSA tools in SyngoVia (Siemens Healthineers, Forchheim, Germany) organized for CT technologists (techs) by a PGY-2 resident under the supervision of a board-certified radiologist/medical director. DECT data gathered with stone protocols from 1/11/24 to 3/15/24 was processed by CT techs through SyngoVia for MD and exported to PACS. This marked PDSA 1. RSA during this time was performed manually for some cases to demonstrate as example cases to the techs. Following this, CT techs underwent training on RSA, with subsequent workflow implementation (PDSA 2). PDSA 3 was conducted to reduce pitfalls, such as phleboliths and prostatic calcifications.

### RESULTS

Baseline data included (11/11/23 to 1/10/24) 117 patients scanned with DECT stone protocol without MD or RSA with 65 (56%) positive for stones. From 1/11/24 to 3/15/24 (PDSA 1), 128 patients were scanned using DECT stone protocol with 128 (100%) MD and 3 (2%) RSA. In total, 67 (52%) had renal (RS) and 38 (30%) ureteric (US) stones. From 3/18/24 to 4/18/24 (PDSA 2), 34 DECTs were performed with MD in 34 (100%), RS in 21 (62%) and US in 12 (35%), 18 (53%) underwent RSA (RS 14, US 10). From 4/18/24 to 4/30/24 (PDSA 3), 33 patients were scanned using DECT stone protocol. 33 (100%) underwent MD. 9 studies (27%) were positive and 4 (12%) underwent RSA. 1 case (3%) was missed with a clinically significant stone (> 3 mm).

### DISCUSSION

Our study showcases effective technologist-driven process improvements, integrating RSA into the radiology workflow. In PDSA 2, techs accurately identified positives but also marked pitfalls and produced false positives. However, in PDSA 3, techs improved significantly, correctly identifying most clinically significant stones (> 3 mm) while avoiding pitfalls. Notably, cases with stones < 3 mm bypassed RSA due to software limitations. Given the questionable clinical significance of such stones, this approach is deemed acceptable.

## R5A-QI-3 AUTOMATED ASSESSMENT OF BREAST POSITIONING QUALITY IN TOMOSYNTHESIS SCREENING USING AN AI-BASED EVALUATION SYSTEM

Ying Guo (*Abstract Co-Author*) Nothing to Disclose
Xuefei Lv (*Abstract Co-Author*) Nothing to Disclose
Fang Fang (*Abstract Co-Author*) Nothing to Disclose
Ellisa 1020 (*Presenter*) Nothing to Disclose

### INTRODUCTION

Mammography quality assurance initiatives are priorities in the implementation of public health screening services. The passive audit approach consists of regularly repeated rounds of review of random samples followed by a training effort and a monitoring work. It has been a time-consuming process and less efficiency. Automation and standardization of quality assessment enable real-time feedback to technicians and radiologists that shall reduce a number of inadequate examinations and provide a dependable training platform for inexperienced technicians.

### METHODS

2396 images of digital mammography over three consecutive quarters were evaluated according to the standards regulated by the Mammography Quality Standards Act (MQSA) on a four-point-scale (1 = poor, 4 = perfect). Incidence of inadequate positioning, which was defined by AI system as any of the following errors were recorded and compared: incomplete gland coverage, incomplete pectoralis major muscle inclusion, over or insufficient exposure,

skin fold, nipple not in the contour line, shoulder overlap shadow, abdominal skin, contralateral breast, and foreign body.The percentage of views rated perfect or good and the percentage of views with inadequate positioning were used to assess changes in performance.

**RESULTS**

After the implementation of quality control, the percentage of images rated as perfect or good in both CCs and MLOs were significantly increased. Improvements ranged from 10 to 15% for CC and 8 to 12% for MLO views. Compared to the second quarter, the positioning pass rates for CC views significantly improved in the third (OR=2.1, 95%CI:1.8-2.5) and fourth quarters (OR=2.5, 95%CI:2.1-3.0). MLO views exhibited a similar trend (third quarter OR=1.9, 95%CI:1.6-2.3; fourth quarter OR=2.7, 95%CI:2.2-3.3).There were significant differences in image score distributions across the three quarters (P<0.001), with the fourth quarter scoring significantly higher than the second (P<0.001). Within each quarter, CC view scores were significantly higher than MLO views (all P<0.001). Images score increases of 2.6 (P<0.001) and 3.5 (P<0.001) in the third and fourth quarters, respectively, compared to the second. CC view scores were 2.1 points higher (P<0.001) than MLO views.

**DISCUSSION**

In this study for all quarters, the positioning pass rates and image quality scores for CC views were significantly better than MLO views, potentially due to the higher technical difficulty of MLO views. Over time, the radiographer's positioning pass rates and image quality scores improved significantly for both CC and MLO views, reflecting the substantial improvement brought about by accumulated experience.The AI quality control system effectively provided objective data support for mammographic quality control.

## R5A-QI-4 BOOSTING STAFF CONFIDENCE AND EFFICIENCY: TRANSFORMING A COMPUTED TOMOGRAPHY (CT) PROTOCOL MANAGEMENT SYSTEM (PMS)

Christopher P. Favazza, PhD (*Abstract Co-Author*) Nothing to Disclose
Shuai Leng, PhD (*Abstract Co-Author*) License agreement, Siemens AG
Michael R. Bruesewitz, RT (*Abstract Co-Author*) Nothing to Disclose
Lifeng Yu, PhD (*Abstract Co-Author*) Nothing to Disclose
Andrea Ferrero, PhD (*Abstract Co-Author*) Nothing to Disclose
Joseph R. Swicklik, RT, BS (*Presenter*) Nothing to Disclose

**INTRODUCTION**

CT technologists and RN staff often struggle to find the correct scanning instructions due to a growing number of protocols and a difficult-to-navigate protocol instruction management system (PMS). This led to outdated instructions due to staff shortages and minimal editing time. The project aimed to improve scan instruction usability for frontline staff and expedite the editing process for the lead team.

**METHODS**

On average, 112 staff accessed 2,132 instruction documents daily through a PMS using PDFs and WordPress, which was cumbersome and error prone. To address these issues, a new PMS was developed using Microsoft SharePoint, simplifying navigation and editing with a user-friendly interface (Figure 1-A,B,C). The launch included a three-week parallel run with the old system, supported by comprehensive training and presentations to ease the transition.Three user groups assessed the impact: lead technologists on editing efficiency, and nurses and CT technologists on locating and using the correct instructions. Improvements were measured in time savings and confidence. Satisfaction levels were measured for all groups comparing the usability of the new PMS with the old system.

**RESULTS**

Time saved by the lead technologist group was on average 27 minutes for each document. Their Net Promoter Score (NPS) for the usability of the site increased by 89% (Figure-1D). Nursing staff, when assessed for time finding protocols, showed a savings of 3.75 minutes per document (Figure-1A). Their NPS score for usability of the site increased by 51%, and 95% of staff surveyed said their confidence in selecting the correct protocol increased (Figure-1E). 93% of CT technologists also stated their confidence increased with the new system (Figure-1F). The analysis of the data revealed that staff's ability to find protocols and increased confidence were due to the new system's search capabilities and the ability to add protocol number metadata to each instruction document (Figure-1G). Additionally, with staff now viewing the source file type, broken links proved to no longer be an issue.

**DISCUSSION**

Leveraging SharePoint’s infrastructure, a new PMS was designed which increased confidence, usability, and should allow for easier upkeep. Limitations of our study include the absence of timed data to evaluate time savings and the reliance on staff surveys, which had a limited response rate.

## R5A-QI-5 ENHANCING REAL-WORLD EVIDENCE ANALYSIS IN MEDICAL IMAGING WITH GENERATIVE AI

Victor Gadelha (*Abstract Co-Author*) Nothing to Disclose
Flavia P. Lopes, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Leonardo Vedolin, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Gustavo Corradi, MD (*Abstract Co-Author*) Nothing to Disclose
Eduardo M. Farina, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

In medical research, the integration of artificial intelligence (AI) is increasingly prevalent, particularly in real-world evidence (RWE) analysis. This study explores the utilization of Google's Medpalm2, a generative AI model, to scrutinize patterns within medical imaging reports, aiming to augment RWE accuracy.

**METHODS**

We employed Medpalm2 to parse through endoscopic imaging reports, comparing its efficacy against traditional methods like regular expressions (regex) in identifying medical findings. Through rigorous testing, we evaluated Medpalm2's accuracy and efficiency in processing data and extracting insights.

**RESULTS**

Comparing the performance metrics, we observed that the traditional method of regex achieved an accuracy rate of 73.4%, whereas Medpalm2 surpassed this with an impressive accuracy rate of 86.7% for the identification of adenocarcinoma suspicious lesions described. This notable difference underscores the efficacy of utilizing Medpalm2 for RWE analysis in medical imaging. By leveraging its generative AI capabilities, Medpalm2 demonstrated a significant improvement in accuracy, thus enhancing the reliability of findings extracted from medical imaging reports. This suggests that Medpalm2 not only outperforms traditional methods but also holds immense promise in revolutionizing the landscape of RWE studies. Its ability to process vast datasets with greater precision not only streamlines the analysis process but also augments the depth and quality of insights garnered. Consequently, Medpalm2 emerges as a cornerstone tool for researchers and healthcare professionals seeking to extract meaningful insights from complex medical data, thereby driving advancements in healthcare research and practice.

### DISCUSSION

In conclusion, our study underscores the pivotal role of generative AI, exemplified by Medpalm2, in advancing RWE analysis in medical imaging. Its demonstrated accuracy and efficiency herald a promising future for AI integration in medical research, shaping the trajectory of RWE studies and fostering enhanced insights in healthcare.

## R5A-QI-6 OPTIMIZING HRCT PROTOCOLS IN A LARGE COMMUNITY HOSPITAL SETTING WITH PRONE EXPIRATORY IMAGING

Sagar B. Amin, MD (*Abstract Co-Author*) Nothing to Disclose
Muhammad Naeem, MD, MBBS (*Abstract Co-Author*) Nothing to Disclose
Robin Jaleel, MD (*Abstract Co-Author*) Nothing to Disclose
Thangalakshmi Sivathapandi, MD (*Abstract Co-Author*) Nothing to Disclose
Chenxi Wu, MD, PhD (*Presenter*) Nothing to Disclose

### INTRODUCTION

High-resolution computed tomography (HRCT) is indispensable in the diagnosis of interstitial lung diseases. In our large safety net hospital (Grady Memorial Hospital), different HRCT protocols were used before with suboptimal and inconsistent diagnostic quality. This quality improvement project aimed at creating and implementing a new HRCT protocol which standardized prone expiratory imaging to improve imaging quality and increase the diagnostic accuracy and confidence among radiologists.

### METHODS

The new HRCT protocol consisted of supine inspiratory and prone expiratory scans. Technologists' education was conducted before initiation. HRCT data before (Feb to Aug 2023, 91 scans) and after the implementation of new protocol (Aug 2023 to Jan 2024, 139 scans) was reviewed. The evaluation of inspiratory effor, expiratory effort, and motion was analyzed. "Good expiration effort" was defined by posterior membrane bowing or flattening, and no such findings was considered "good inspiratory effort." Exclusion criteria included patients on research protocol, could not lay prone, and if any of the data was missing on the old HRCT. Imaging data from the old and new HRCT group were analyzed using Pearson Chi-square test, and $p < 0.01$ is considered statistically significant. A structured questionnaire was distributed to cardiothoracic radiologists 6 months after starting new HRCT protocol. Responses were scored using a 4 and 5-point Likert scale system.

### RESULTS

89 old HRCT and 109 new HRCT scans were included. There was good consistency and reproducibility among technologists after the training on performing the new protocol. Only 3 scans (3/109, 2.8%) had quality issues or were not performed in accordance with the new protocol. The new protocol led to an enhanced expiratory effort on proning (49.4% vs 78.3%, $p < 0.01$) and reduction in motion (62.9% vs 20.2%, $p < 0.01$). Inspiratory efforts were identical among the two groups (88.8% vs 96.3%, $p > 0.05$). Four radiologists' questionnaires were collected. All considered the overall imaging quality under new protocol was "excellent" or "good" (average score 3.5 out of 4) Image quality for prone expiratory was "much better" or "somewhat better" compared to supine expiratory (4.5 out of 5). The visibility and clarity of ILD patterns has "significantly improved" or "somewhat improved" (4.5 out of 5), their diagnostic confidence has "significantly improved" or "somewhat improved" (4.5 out of 5), and this new HRCT protocol was "very useful" or "moderately useful" in clinical decision-making for ILD patients (3.75 out of 4).

### DISCUSSION

Prone expiratory scan is technically easy, reproducible, and can significantly improve the evaluation of air trapping. Furthermore, this new protocol improves efficiency in our busy practice by not having to decide if additional prone imaging is needed, while also maintaining only two acquisitions.

## R5A-QI-7 OBJECTIVE JUSTIFICATION OF CT AND MRI EXAMS IN LARGE SAMPLES

Oskar Lofgren, MD (*Abstract Co-Author*) Nothing to Disclose
Henriettae Stahlbrandt, MD, PhD (*Presenter*) Nothing to Disclose

### INTRODUCTION

In Sweden, as in most countries, cross-sectional imaging is steadily increasing. National data shows a 56% increase in CT exams and a 49% increase in MRI exams between 2012-2021. Justification of exams should be based on guidelines, and is a joint responsibility between referrers and radiologists. Guidelines are however not integrated in the referral system, and justifications are most of the time based upon the individual knowledge of the physicians. In this study, the largest in Europe to date, a retrospective analysis of CT and MRI exams was performed to study the ratio of justified and non-justified exams, as well as referrer patterns in justification.

### METHODS

All CT and MRI exams of patients 18 years and above within four Swedish healthcare regions during October 2021 were collected (n=25,032). The data included was: gender, age, exam, level of healthcare referring (university hospital/other hospital/primary care). CT and MRI protocols were matched to equivalent protocols in the European iGuide database v.15, translated to Swedish (matching rate 93%, n=23,196) . iGuide, as ACR Select, is a profession-driven knowledge database including over 2,300 indications and over 1,000 protocols, giving guidance on which exams/protocols are justified (score 7-9; green); may be justified (score 4-6; yellow), or probably not justified (score1-3; red). All exams performed with matched protocols were consequently matched on indication level (matching rate = 56%, n=13,075).

### RESULTS

Overall results of justified exams (score 7-9) were 63% for CT and 75% for MRI. Primary care units had the lowest justification of CT exams (46.9%), but the highest justification for MRIs (81.1%). University hospitals and other hospitals had the same level of justified CTs (66%), but the university hospitals had a lower degree of justified MRIs (72.5% compared to 76.6% for other hospitals). Of the CT exams with scores 1-6, 32% could achieve higher levels of justification by changing to another CT protocol, 24% to x-ray, and 5% did not have a corresponding exam with a higher score. Of the MRI exams with scores 1-6, 33% could achieve higher levels of justification by changing to CT, 21% to x-ray, and 17% did not have a corresponding exam with a higher score.

### DISCUSSION

Not all CT and MRI exams were justified despite being evaluated by a referring physician and a radiologist in beforehand. The number of potential non-justified exams, and thus the total number of exams, can be reduced by following existing guidelines. Discussions regarding justification and guideline accessibility need to continue at all levels of healthcare, from primary care to university hospitals, since potential non-justified exams come from all referrer levels. A limitation of the study of the mapping rate of indications of 56%. However, the final number of mapped exams is large, and the results are comparable to previous studies.

## R5A-QI-8 IMPACT OF REVISED ORAL CONTRAST GUIDELINES ON CT EFFICIENCY IN PEDIATRIC EMERGENCY DEPARTMENTS: A MULTI-SITE STUDY

Geetika Khanna, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Erica Riedesel, MD (*Abstract Co-Author*) Nothing to Disclose
Ashishkumar K. Parikh, MD (*Abstract Co-Author*) Nothing to Disclose
Farid Hajibonabi, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Oral contrast media (OCM) was used in all routine computed tomography (CT) imaging for non-traumatic acute abdominal pain in our children's hospital system. Prior literature has demonstrated diminishing benefits in usage of OCM, resulting in prolonged wait times and increased costs. This study aims to assess the effects of revised OCM guidelines within a large multi-site children's hospital system.

### METHODS

Following the identification of the high rate of OCM utilization at our institution, an effort was made to revise the OCM guidelines (Figure 1). Prior to this, OCM was given to any patient presenting with acute non-traumatic abdominal pain of greater than 48 hours duration. In 2021, we revised guidelines for administering OCM for abdominal CT scans to restrict its usage to clinical request only. Then we evaluated all abdominal CT scans during the years 2019 and 2023 which were indicative of pre and post intervention periods. Data were gathered from electronic health records. We assessed OCM usage rates and turnaround time (TAT) before and after guideline implementation, employing multiple linear regression analysis to evaluate the impact of the intervention. Measures included OCM usage rates and TAT. Analysis involved quantitative methods, including multiple linear regression with significance at $p<0.05$ and using SPSS (IBM v29.0).

### RESULTS

A total of 2,259 abdominal CT exams from the ED were evaluated, including 1101 (48.7%, 1101/2259) and 1158 (51.3%, 1158/2259) before and after OCM guideline change respectively. Patient demographics and chief complaint did not differ significantly between time periods. Mean (SD) TAT for hospital 1 was 114.38 (79.51) and for hospital 2 was 109.01 (104.31) . Prior to OCM guideline change, OCM was used in 278 (32.7%, 278/851) exams at Hospital 1 and 104 (41.6%, 104/250) exams at Hospital 2. Following the change, OCM use decreased at Hospital 1 to 5.4% and at Hospital 2 to 2.5% (p-value for both < 0.001). With decreased use of OCM, mean TAT at Hospital 1 decreased from 129 min to 100 min ($p<0.001$) and at Hospital 2 decreased from 152 min to 76 min ($p<0.001$). Additionally, controlling for age and year of the exam, multiple regression analysis showed that contrast utilization was significantly associated with increased TAT in hospital 1 (Beta = 139.10; CI [131.47 - 146.74], $p<0.001$) and hospital 2 (Beta = 163.14; CI [144.11 - 182.17]).

### DISCUSSION

Revisions to oral contrast media (OCM) guidelines for abdominal CT scans in our pediatric emergency departments resulted in significant reductions in OCM usage and turnaround time (TAT). Limitations include the retrospective design and uncertainty regarding the clinical impact of missed or delayed diagnoses. Future research should explore the specific clinical scenarios in which administering OCM for abdominal CT provides the most benefit.

Caoimhe Byrne, MBBCh (*Presenter*) Nothing to Disclose

### INTRODUCTION

Surveillance of intraductal pancreatic mucinous neoplasms (IPMNs), a common premalignant cystic neoplasm is typically performed by MRI. Surveillance is a growing demand on resources at a time when there is a need for imaging departments to deliver more sustainable healthcare. Standard pancreas MRI (PMRI) includes contrast enhanced sequences. Studies have shown abbreviated protocols omitting gadolinium (AMRI) are suitable for detecting worrisome features and high risk stigmata without missing malignancy. AMRI is safe and has time and cost savings. This is supported by a review performed at our institution, following which AMRI was introduced for follow up of IPMNs. The purpose of this study was to quantify the effects of AMRI in terms of environmental, time and cost savings.

### METHODS

A process map was created. Estimates of energy consumed by each protocol were calculated and were based on total time actively scanning as well as time in idle and ready-to-scan states. An inventory of materials saved by AMRI (e.g. cannula, disposable injector kit) was made. Savings in energy and materials were used as input to a life cycle assessment (LCA) using SimaPro software. The ReCiPe 2016 Endpoint methodology was used to quantify environmental benefits of AMRI compared to PMRI.

### RESULTS

Time taken and energy used during the AMRI is less than PMRI. In our institution, the impact of material consumption is the same magnitude as energy consumption. This owes to the fact that electricity in our region is generated from ~95% renewable sources. When the model is recomputed using data specific to the US, including electricity generated through burning of fossil fuels, environmental impact is dominated by energy consumption.Regarding time and cost savings P-MRI has an active scan time of 24:42. It is booked in a 45 minute time slot during daytime hours. AMRI has an active scan time of 11:07. It is booked in a 25 minute slot and can be booked outside of daytime hours. Cost of equipment to administer gadolinium is $64.16 (CAD) per examination. Cost savings in terms of energy expenditure is $1.63 per scan.

### DISCUSSION

A limitation of this study is that calculations regarding energy expenditure of MRI are based on available published data. Also, gadobutrol is not available in the SimaPro database. Gadolinium is a contaminant of aquatic ecosystems, the full effects of which are not currently known.AMRI for follow up of IPMNs provides safe and effective surveillance while reducing environmental effects through decreased consumption of energy and single use materials. Cobenefits include lower costs, more flexible scheduling and improved patient comfort through shorter scan times and the avoidance of cannulation.

## R5B-QI-3 DOLLARS AND DISPLAYS: AN ACTIVITY-BASED COSTING APPROACH TO ASSESSING THE TOTAL COST OF OWNERSHIP OF COMMERCIAL-GRADE DISPLAYS VERSUS DIAGNOSTIC-GRADE DISPLAYS FOR REMOTE DIAGNOSTIC STATIONS

### INTRODUCTION

With increasing demand for hybrid or remote work, the adoption of diagnostic Workstations with Commercial-grade Displays (WCDs) is on the rise, sometimes replacing Workstations with Diagnostic-grade Displays (WDDs). While WCDs promise substantial upfront cost savings, they also bring complex

financial implications due to increased manual efforts in quality control (QC), deployment, and maintenance. We applied an activity-based costing (ABC) approach to evaluate the overall economic impact of WCDs versus WDDs.

### METHODS

Our study examined the lifecycle of a WCD from procurement through to operation. We evaluated both indirect costs, ranging from equipment requests to IT support, and direct costs including hardware and software. Analysis assumed mean hourly wages of IT analysts, physicists, and radiologists reported by the US Bureau of Labor Statistics. Equipment and supply costs were based on the manufacturer's suggested retail prices (MSRP), averaging MSRP values from various vendors for comparable equipment where necessary. Although activity-based costing (ABC) typically spreads equipment costs through depreciation, we recorded these costs in year one to reflect the immediate cash outlay required for deploying a workstation. Each activity was scrutinized to identify significant cost drivers. We estimated the total cost of ownership (TCO) for both WCD and WDD by projecting the annual costs of each over the expected lifespan (assumed to be 5 years).

### RESULTS

Analysis revealed 18 indirect cost activities and several direct cost components. Because WCDs necessitated stations be built in full the purposes of calibration, acceptance testing, and radiologist QC training, and then disassembled for distribution, overall deployment activities were estimated to add an additional $784, on average, to the TCO for WCD, compared to $348 for WDD. Incremental yearly costs for WCD depended on frequency of manual QC (calibration, etc.) and QC failures, and time required to track and enforce routine user-initiated QC. Year one cost for WCD was $8,813, compared to $17,039 for WDD, mainly driven by equipment cost. The activity-cost for yearly maintenance was ~$664 for WCD, compared to ~$160 for WDD. The major contributing drivers for WCD's higher yearly activity cost were manual QC and calibration, IT support for QC failures, and physicist oversight related to QC. TCO for WCD was $11,469-$20,006 (pending frequency and failure-rate of QC), compared to $17,678 for WDD.

### DISCUSSION

Radiology workstations with commercial-grade displays offer significant initial cost savings compared to those with diagnostic-grade displays. However, the higher ongoing operational expenses for maintenance and support of WCDs may negate these initial savings over time. The balance between short-term savings and long-term financial benefits depends on the budgetary needs of the radiology practice.

## R5B-QI-4 ASSESSING FOR ALGORITHM BIAS: DIFFERENTIAL PERFORMANCE OF AN AI ALGORITHM BETWEEN US AND AFRICAN HOSPITALS

Houman Sotoudeh, MD (*Abstract Co-Author*) Nothing to Disclose
Steven A. Rothenberg, MD (*Abstract Co-Author*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC
Kevin L. Junck, PhD (*Abstract Co-Author*) Nothing to Disclose
Jordan D. Perchik, MD (*Abstract Co-Author*) Nothing to Disclose
Grant D. Smith, BS (*Presenter*) Nothing to Disclose

### INTRODUCTION

The number of artificial intelligence (AI) applications entering the radiology marketplace continue to increase each year, however there are gaps in AI testing that can result in patient harm. Algorithm bias, degraded performance of an AI application on specific patient populations, is notoriously difficult to detect and monitor. Patients from underrepresented backgrounds and from low- and middle-income countries are particularly susceptible to algorithm bias due to underrepresentation in algorithm training data. This project compares the performance of an intracranial hemorrhage detection algorithm between patients at a US hospital and two African hospital systems.

### METHODS

Non-contrast head CTs performed at two hospital systems in Africa (Cameroon and Ethiopia) from January 1, 2024 to March 31, 2024 were reviewed. Precision, recall, and accuracy of the ICH algorithm were calculated and compared to the host US hospital and to published results by the AI vendor.

### RESULTS

266 exams were performed during the study period. A higher number of false positives were observed during the first two months of data collection, resulting in a recall of 0.74 and 0.55 compared to a published recall of >0.95. This prompted an intervention by the vendor between the second and third months of data collection, resulting in an improved recall of 0.92. Accuracy also increased from 0.90 and 0.88 during the first two months to 0.96 after the intervention compared to a published accuracy of >0.90. A low number of false positives were observed, resulting in a high precision of the algorithm throughout the study period, measuring 0.89, 1.0, and 0.96. This was higher than the precision observed at the US hospital of 0.78.

### DISCUSSION

Initial evaluation of algorithm performance demonstrated a significant disparity between the African and US cohorts. After vendor intervention, algorithm performance approached or exceeded the baseline. Assessing for algorithm bias between different geographic locations and between different patient populations can uncover disparities in algorithm performance.

## R5B-QI-5 QUALITY CONTROL OF DEEP LEARNING MR IMAGE RECONSTRUCTION AT 0.55 TESLA

### INTRODUCTION

The integration of deep learning (DL) into magnetic resonance (MR) imaging reconstruction at 0.55 Tesla (T) is a recent development with limited clinical validation for various clinical applications. The goals of DL image reconstruction for MRI are to improve diagnostic accuracy by increasing signal to noise and spatial resolution while avoiding creation of artifacts that lead to false positives or negatives. The objective of this quality improvement report is to highlight clinically-relevant unexpected image findings encountered while implementing DL into MR imaging reconstruction at 0.55T.

### METHODS

27 volunteers underwent various body (n=15) and musculoskeletal (n=12) MRI exams on a 0.55T Siemens scanner. For comparison, images were reconstructed in pairs, using traditional methods and then separately using DL reconstruction methods. Three board-certified academic radiologists conducted a comprehensive visual assessment of the image pairs. Each radiologist assessed the image quality of the routine and DL reconstructed images, focusing on parameters such as tissue contrast, image noise, spatial resolution, and overall diagnostic clarity. Potential false positives and negatives were described.

### RESULTS

For MSK applications, there were limitations in identifying meniscal tears (n=3), and assessing cartilage morphology (n=1) using the DL reconstruction images, which tended to mask pathologies due to exuberant smoothing, contributing to potential false negatives. In addition, the DL reconstructed images led to abnormal signal hyperintensities and potential false positive meniscus tears on T1, Proton density (PD), and PD fat-saturated series, which were contradicted by negative findings on PD fat-saturated coronal images and the volunteer's denial of medial joint line pain. For body MRI applications, there was variability in obtaining respiratory gated abdominal images using the provided navigation sequence, contributing to long acquisition times that exceeded 20 minutes for a single series. Despite some obstacles, there were also instances of improvements in image quality with DL reconstruction, though this was variable across the volunteers and body regions.

### DISCUSSION

While DL reconstruction of MR images at 0.55T is intended to improve image quality, significant artifacts and clinically-relevant suboptimal performance were found in our prospective evaluation of volunteers on a new scanner. There was masking of pathology and abnormal signal hyperintensities that could contribute to false negatives and positives, respectively. Further investigation is needed prior to widespread adoptions.

## R5B-QI-6 CHEST X-RAY IMAGE QUALITY IMPROVEMENT

Ai-lee Chang, MD, FRCR (*Presenter*) Nothing to Disclose

### INTRODUCTION

There was perception that planar chest imaging in our department was not of the standard expected quality. The purpose of this quality improvement project was to bring back the culture of standard planar chest images in all settings.

### METHODS

Using the Plan, do, study and act format.Plan : All out patient chest x-rays to be of standard quality Standard quality is specified as : - Every effort should be made to perform a PA erect chest x-ray - The standard will vary between different referral groups - ie in-patient (IP), general practice (GP), out patient (OP) or Emergency department (ED) referral. - The standard includes, technical adequacy of exposure/penetration, inspiratory effort, rotation, angulation .Target : 75% PA erect for IP and ED patientsDo: Following local ethics committee approval, team engagement from planar imaging leads, radiology manager, education lead, initial retrospective audit of 100 chest x-rays performed in the ED over 3 days in March 2023. Portable radiographs were excluded. Study :The following observations were made :- AP or PA- Presence of artefacts (removable eg clothing )- Number of images acquired for the episode- Lordosis (if any)- Rotation (if any)- Sub lordotic angulation (if any)- Suboptimal inspiration- Supine view- Image cut off - Good PA / APAct:Interventions June to October 2023 / March 20241. Feedback to Radiographer leads and Radiology manager 2. One on one confidential feedback to individual radiographers by Radiographer leads3. Educational sessions by Education Lead and Radiographer Leads The audit cycle was repeated in November 2023 and March 2024.

### RESULTS

There is progressive improvement of the culture of standard chest x-ray quality, with zero artefacts and increase to 70% of PA images from 43%. See figure 1Taking 2 images is down to 4% from 15%.Good PA images increased from 4% to 55%. Good AP images increased from 0% to 17%

### DISCUSSION

Recommendations: 1. Continue one on one feedback 2. Continue practical and educational sessions and mentorship. 3. If issues with the equipment, radiographer leads / manager to attend. 4. Radiographers are encouraged to record specific issues and suggestions 5. Radiologists educational sessions emphasing the diagnostic importance of good quality chest x-rays. Limitations : the mode of transport has not been ascertained.Conclusions: The culture of standard chest x-rays and quality has become an expression of pride in our radiographer teams in seeing the product. Bringing out the best of oneself has been a great reward for the entire team. T

## R5B-QI-7 PERCUTANEOUS TRANSTHORACIC NEEDLE LUNG BIOPSY:A SINGLE INSTITUTION REVIEW

### INTRODUCTION

The purpose of our study was to investigate the associations between patient characteristics and complication (overall, pneumothorax, hemorrhage, and hemoptysis) rates following computed-tomography (CT) guided transthoracic percutaneous lung biopsies.

### METHODS

At the OSF St. Francis radiology department, 620 patients with CT-guided percutaneous lung biopsies, dating from January 2017 to December 2019, were retrospectively analyzed. We collected data including past medical history, patient positioning, lesion location, lesion size, biopsy needle size, number of passes, blood patch use, complication and diagnostic yield were acquired from electronic medical records (EMR), specifically procedure reports and CT images.

### RESULTS

Our study involved 620 patients, yielding a biopsy diagnostic rate of 98.4%. Complications occurred in 38.2% of cases, with pneumothorax being the most common (30.2%). COPD was associated with higher complication rates ($p = .015$). We also found using 20G needles increased complication ($p < .001$) and hemorrhage rates ($p < .001$). Larger lesion sizes correlated with fewer overall complication ($p = .0001$), pneumothorax ($p = .0015$), and hemorrhage rates ($p = .0046$). Multivariate analysis confirmed COPD, needle gauge size, and lesion size as independent predictors of complication rates. Adjusted odds ratios showed COPD patients were 1.485 times more likely to experience complications ($p = 0.0356$), and 20G needles associated with a 1.965-fold increase in complication likelihood ($p = .0002$). Larger lesion sizes were inversely associated with complication ($p = .0003$) and pneumothorax

rates (p = .0019). 20G needles resulted in 3.889 times higher hemorrhage rates (p = .0002), while larger lesion sizes resulted in .675 times lower hemorrhage likelihood (p = .0065).

**DISCUSSION**

Transthoracic percutaneous lung biopsy is a valuable diagnostic tool, yet associated with notable complications. Our single-institution study reaffirms PTX, hemorrhage, and hemoptysis as common post-biopsy complications, occurring in 38.2% of patients. COPD significantly increases complication risk (43.4%). Needle gauge size influences hemorrhage rates, though technique likely plays a larger role. Larger lesions are associated with lower complication rates. Age, hypertension, diabetes, lesion location, patient position, and smoking status do not significantly impact outcomes. Our findings inform risk assessment and procedural planning, emphasizing tailored interventions for high-risk patients and optimizing biopsy techniques to improve safety and efficacy.

## R5B-QI-8 DIGITALIZATION OF ULTRASOUND QUALITY CONTROL - A STREAMLINED SOLUTION TO COVER HOSPITAL DISTRICT -WIDE OPERATION

Juha Peltonen, DSc (*Abstract Co-Author*) Nothing to Disclose
Anne-Mari Vitikainen, PhD (*Abstract Co-Author*) Nothing to Disclose
Mika K. Kortesniemi, PhD (*Abstract Co-Author*) Nothing to Disclose
Satu Inkinen (*Abstract Co-Author*) Nothing to Disclose
Juuso Ketola, PhD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Technical quality control (QC) of medical ultrasound (US) systems is essential to secure diagnostic image quality and safety. Image quality deviations in US are usually attributable to transducer damage resulting from impact or wearing. Damaged crystals can be seen as signal voids in in-air reverberation (IAR) patterns. External damage can be visually inspected. Measurements using phantoms are meaningful in quantitative assessment, but have little impact in routine QC, are time-consuming, and require trained personnel. The purpose of this study was to streamline our US QC program by focusing on monthly inspection and IAR image acquisition by local staff. Additionally, we developed a web-based QC result browser for documentation and automated analysis.

**METHODS**

A web application was developed for documenting and viewing QC results. It was built on top of our modular platform containing QC applications also for other modalities. A digital form is filled with queries regarding the general condition of the device and transducers. A form for inspecting the monitor using the AAPM TG18 image is also included. IAR images taken with a standardized protocol are automatically sent from PACS to a DICOM QC server and saved to the database. Signal depth and uniformity measures are also calculated. Site-specific QC report pages display local US devices and inspection records, and transducer-specific pages display IAR images, quantitative results, and observations.

**RESULTS**

During first four months, 16 sites with 50 US devices and 183 transducers deployed the new QC program. During this time, signal voids were identified in 26 transducers. Faulty connector was the cause of four defects. Four transducers were either repaired or replaced. One transducer exhibited only a subtle signal void and a minor lens cut, but electrical safety measurements revealed excess leakage current leading to replacement. Rest of the defective transducers are monitored if further degradation occurs.

**DISCUSSION**

Focusing QC practices to most relevant tasks allows for more frequent and efficient testing. A web-based QC platform enables prompt input of observations and browsing of history. There are over 80 US devices and 270 transducers in our department with large geographical coverage. Thus, it’s not feasible to perform phantom measurements with frequency recommended by guidelines (such as EFSUMB, BMUS, IPEM and AIUM). Based on our initial experience, simple monthly tests are justified and effective. This also saves resources when on-site QC experts or special equipment are not required. Our platform also removes the need for manual image processing. In future, we aim to improve our system by developing automatic signal void detection and deviation alerts. By adopting the new QC program our department has been able to receive QC reports more frequently, enabling prompt reaction to transducer defects.

## S3A-QI-1 OPTIMIZATION OF OUTPATIENT INTERVENTIONAL RADIOLOGY SCHEDULING AND APPROVAL PROCESS

Timothy M. Baran, PhD (*Abstract Co-Author*) Nothing to Disclose
Erin Panter (*Abstract Co-Author*) Nothing to Disclose
Lindsay Marchetti (*Abstract Co-Author*) Nothing to Disclose
Tanisha Henderson (*Abstract Co-Author*) Nothing to Disclose
Andrew J. Cantos, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Interventional Radiology (IR) is a multifaceted sub-speciality that performs a wide array of minimally invasive procedures, with services spanning the full spectrum of patient populations across outpatient, inpatient, and emergency room (ED) settings. The convergence of these variables poses a unique challenge in the workflow of IR. In the outpatient setting, IR consults for procedures require review and approval prior to scheduling. Inefficiencies in this process risk delayed patient care and reduced patient satisfaction. The purpose of this project was to streamline the current outpatient approval process of IR procedures with the goal to turnaround time (TAT).

### METHODS

This project was performed by the division of Interventional Radiology at a tertiary care, large academic institution. TAT for outpatient IR consults were obtained over a 22-month period. For each subset of data, two time points were obtained: time from consult placement to scheduling and time from consult placement to procedure completion. The differences in TAT was calculated and analyzed. Interventions included transitioning to electronic requests (July 2022) and implementation of swing shift and consult approval to daily responsibilities (July 2023). Statistical analysis was performed using Mann-Whitney test and Kruskal-Wallis test to determine significance. Multiple performance improvement methodologies, including Gemba walks, control charts, and fishbone diagrams were devised.

### RESULTS

During the 22-month period, 13,456 procedures were performed, 6,664 (50%) of which were from the outpatient population. From June 2022 to June 2023, the average IR order to procedure completion TAT (days) was 19.2, with average IR review TAT 7.07. From July 2023 to March 2024, the average procedure completion TAT was 14.7 ($p < 0.0001$) with average IR review TAT 4.94 ($p < 0.0001$). When divided into smaller 6-month increments, the average procedure completion TAT reduced: 21.1 (June 22-Dec 22), 17.1 (Jan 23-June 23), 16.0 (July 23 to Dec 23), 13.2 (Jan 24-March 24), with an overall decrease of 37% ($p < 0.0001$). Similarly, the average IR review TAT reduced: 8.12 (June 22-Dec 22), 5.79 (Jan 23-June 23), 4.9 (July 23 to Dec 23), 3.6 (Jan 24-March 24), with an overall decrease of 56% ($p < 0.0001$). During the reviewed 22 months, the average outpatient case volume increased by 18%, from 270 to 318 cases per month.

### DISCUSSION

IR scheduling is a complex process, balancing patient populations across multiple settings with different workflows. By optimizing the outpatient IR consultation process, there was a decrease in TAT for consultation approval by 56% and reduced TAT for procedure completion by 37%. By improving the TAT process, outpatient procedural volumes ultimately increased 18% during this time period. Continued efforts to enhance outpatient workflows are vital for improving timely access to IR services.

## S3A-QI-2 QUALITY IMPROVEMENT (SAFETY, EFFICIENCY) THROUGH RADIOGRAPHER COMPETENCY BASED KEY PERFORMANCE INDICATORS

Siok Mei Ng, BMedSc, MMedSc (*Abstract Co-Author*) Nothing to Disclose
Michael Ong, BSc, MSc (*Presenter*) Nothing to Disclose

### INTRODUCTION

Key Performance Indicators (KPI) that are specific, measurable, achievable, relevant and time bound are needed to objectively measure radiographers' performance and to drive quality improvement.

### METHODS

IOM's domains of quality, Ensure Safer Systems standards (JCI collaboration) and healthcare cluster goals were used to establish competency based KPIs for radiographers. The KPIs and targets were reviewed yearly using the Plan-Do-Check-Act tool. Performance data for the KPI data is obtained through observational audits, retrospective audits, system generated data or externally generated data. Radiographers make up the audit teams measuring different indicators. The smallest data collection audit team for reflective reports is a 3-man team while the largest audit team for General image quality audits is an 80-man team. Core audit teams are formed to consolidate data collection, perform analyses, set targets, and implement interventions to

drive improvement. Audits that have >90% sampling rate are x-ray image reject rate and RIS/PACS errors. Quality improvement (QI) is achieved through QIP projects, educational talks, journal club sessions and meeting updates.

**RESULTS**

Over the period of 10 years from 2011 to 2023, despite 58% increase in workload, the monitoring data was used to drive quality improvement:Hand hygiene compliance rate: 57% (2011) - 94% (2023)2 Patient ID documentation compliance rate: 59% (2011) - 99% (2023), patients visually verify their information and sign on the imaging form. This has reduced Sentinel Events reportable to the Ministry of Health to zero for the last 6 years.Reject rates: 7% (2014) to 6.9% (2023). In 2014, replacement of CR x-ray equipment with DR units started and it was observed that with DR, benchmark reject rates were higher than the CR reject rates. Despite increase in workload of 58%, PACS and RIS Errors have reduced by 70% from 2014 (10,000 errors/year) to 2023 (3,000 errors/year) ensuring timely reporting and no wrong images uploaded. Significant manpower savings from correcting errors was also observed.

**DISCUSSION**

Apart from KPI data collection, other data that drives patient safety like near-miss incidences of patients arriving with MRI contraindications is also monitored so interventions can be done to prevent actual incidences. Objectivity in performance appraisal increases radiographers' satisfaction and provides tangible goals to strive towards.CONCLUSION: The value of manpower invested to track data is reflected in quality improvement and patient safety. KPIs is a measure of a radiographers' competency.

## S3A-QI-3 REDUCING ANESTHESIA REQUESTS FOR ADULT INPATIENT MRI EXAMS

Jay K. Pahade, MD (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;
David Facchini, MBA, BS (*Abstract Co-Author*) Nothing to Disclose
Sandra Barbiero (*Abstract Co-Author*) Nothing to Disclose
Carly Brown (*Abstract Co-Author*) Nothing to Disclose
Marie Hausner, ARRT, RT (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Use of the Department of Anesthesia to sedate patients in need of an inpatient or ED MRI is associated with increased healthcare costs and delays. At our institution, we noted that many anesthesia requests for MRI orders were not needed. For example, claustrophobia may not be relevant when an exam involves positioning of the head outside of the bore and many patients can be scanned using floor prescribed anxiolytics, eliminating need for anesthesia team. A multidepartment team launched an initiative to reduce the number of inpatient MRI anesthesia orders by 25%, from baseline mean of 56 orders per month, within 3 months.

**METHODS**

Baseline data was collected for 6 months to investigate order-to-begin (O-B) times for adult inpatient and ED MRI exams ordered with anesthesia, types of MR orders, patient positioning in relation to the bore, and MR scan times. The primary intervention for this project was creation of an inpatient MRI anesthesia care pathway embedded into our medical record. The pathway included guidance for ordering providers on non-pharmacological options, patient position for common exams (head within or outside of bore), and floor prescribed pharmacological options with links to the appropriate drug orders.

**RESULTS**

Scan time ranged from 10-120 minutes. At baseline mean O-B time for inpatient MRI exams with anesthesia versus those without was six times longer (129 vs 22 hours). After pathway launch, the number of MRI exams ordered with anesthesia per month decreased by 23% (baseline 56, post intervention 43) with 16% improvement in O-B of MRI exams with anesthesia (129 vs 108 hours). To study the effect of using the pathway, a one-month (January 2024) assessment was completed looking at all uses of the pathway in patients who subsequently had an inpatient MRI completed. There were 43 unique patients where the ordering provider utilized the pathway. For those patients, 63% had an exam completed without anesthesia, 9% were completed with anesthesia and 28% did not have a completed MRI. During this month, a total of 27 patients had an MRI ordered with anesthesia, of which 85% did not utilize the pathway.

**DISCUSSION**

Implementation of a clinical care pathway led to a reduction in anesthesia requests for adult inpatient MRI exams by 23%, reducing healthcare costs and resource utilization. The O-B time for anesthesia MRI cases also improved by 16%. The pathway provided guidance and made it easy to order premedication for anxiety, pain control or movement disorders. Use of the pathway was associated with a reduction in anesthesia orders compared to non-utilization of the pathway. When the pathway was utilized, only 9% of patients ended up having an MRI with anesthesia. However, most MRI exams ordered with anesthesia (85%) did not consult the pathway. Suggesting the pathway has been successful in providing anesthesia alternatives, and there is opportunity to increase pathway utilization.

## S3A-QI-4 DECREASING INCORRECTLY SCHEDULED SCREENING ULTRASOUNDS FOR HIP DYSPLASIA IN PREMATURE INFANTS

Lauren J. Ehrlich, MD (*Abstract Co-Author*) Nothing to Disclose
Daniella Asch, MD (*Abstract Co-Author*) Nothing to Disclose
Landra Knoth (*Abstract Co-Author*) Nothing to Disclose
Jay K. Pahade, MD (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;
Janelle Van Luling, RT, ARRT (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Screening ultrasound (US) for developmental hip dysplasia in infants with risk factors should be performed after 6 weeks corrected gestational age (CGA). Scanning before this age leads to higher false positive rates and potential need for repeat exam, creating waste and undue stress on child and family. Our pediatric radiologists observed many premature infants arrived too early for their screening ultrasounds. This study aimed to reduce incorrectly scheduled screening exams from a baseline rate of 50% to less than 25% within 6 months.

**METHODS**

Our quality improvement (QI) team along with pediatric radiology and orthopedics, ultrasound, IT, and scheduling utilized model for improvement QI methodology to assess current state, identify key drivers and test interventions to decrease exams scheduled before CGA of 6 weeks. In our initial PDSA cycle, an order question was added in the Electronic Health Record (EHR) to clearly identify which exams were ordered for positive physical exam finding vs screening and thus should be scheduled after 6 weeks CGA. The question also embedded scheduling guidance and displayed CGA (if available). Scheduling error rates were calculated by manual audit of all hip US orders that had a screening clinical indication and CGA available. In the next PDSA cycle, a special work queue was created to leverage expertise of certain schedulers.

### RESULTS

Baseline 6 month mean rate of incorrectly scheduled exams was 50%. After intervention 1 (provider education; report to facilitate manually rescheduled exams), mean rate decreased to 29%. After intervention 2 (EHR order question with scheduling guidance), mean rate reduced to 27%. Investigation showed exams were ordered via fax, requiring schedulers to select proper indication based on the provided history. Additionally, CGA was not calculated in the EHR for many infants requiring calling parents to obtain age and schedule properly. Since scheduling many exams could not be accomplished with available EHR information and inconsistencies in scheduling based on CGA by scheduling, decision was made to trial a special work queue (intervention 3) managed by a small group of trained schedulers. After this change, mean error rate decreased to 10%.

### DISCUSSION

This project decreased incorrectly scheduled screening pediatric hip ultrasounds by 80%. People-, process-, and system-related interventions were tested and implemented to drive change. The initial project goal was to create an IT-driven scheduling solution to prevent screening exams from being booked before 6 weeks CGA. However, given EHR programming limitations, missing patient information and many paper orders, initial IT modifications prevented us from achieving our goal. Subsequent PDSA cycles led to a solution using informatics and scheduling process changes. A limitation is that error rates could only be tracked for patients with CGA in the EHR.

## S3A-QI-5 IMPROVING PROSTATE MR IMAGE QUALITY COLLABORATIVELY

Ben C. Wandtke, MD, MS (*Abstract Co-Author*) Clinical Advisory Board, CAK Tech, Inc
Eric P. Weinberg, MD (*Abstract Co-Author*) Nothing to Disclose
Wing-Chi E. Kwok, PhD (*Abstract Co-Author*) Nothing to Disclose
Peter A. Rosella, MD (*Abstract Co-Author*) Nothing to Disclose
Andrei S. Purysko, MD (*Abstract Co-Author*) Contract, Profound Medical Inc;Research support, Blue Earth Diagnostics Ltd;Consultant, KOELIS;
Erin Panter (*Presenter*) Nothing to Disclose

### INTRODUCTION

Approximately 13% of men are diagnosed with prostate cancer during their lifetime.(1) High quality magnetic resonance imaging (MRI) serves a valuable role in the detection of prostate cancer, yet image quality is not routinely audited. Poor image quality limits diagnostic confidence and the accuracy of image guided biopsies. The project's goal was to improve prostate MRI image quality through use of the Prostate Imaging Quality (PI-QUAL) scoring metric, improving detection of prostate cancer.

### METHODS

In partnership with the ACR Learning Network®,this project was performed at two outpatient MRI facilities within a large academic medical center. The PI-QUAL scoring system was utilized to evaluate the diagnostic quality of multiparametric prostate MRI exams. The system used a 5-point Likert scale to determine if the exam had sufficient quality to "rule-in" or "rule-out" clinically significant prostate cancers. (2,3)The project team consisting of fellows, radiologists and radiologic technologists (RT) were trained in the use of PI-QUAL. To obtain baseline data, the team audited 276 exams over 8 weeks. As DWI poses the greatest challenge to high-quality prostate MR exams, we decided to focus on our DWI images in addition to the overall PI-QUAL score. Our goal was to improve the number of exams meeting a PI-QUAL score of >4 (91% to 93%) and optimal DWI images (71% to 80%). 30 exams/week were then audited over 6 months.Using the A3 performance improvement methodology, our multidisciplinary team identified multiple potential root causes for poor image quality. From these, key drivers were determined, and interventions tested and implemented using PDSA cycles.

### RESULTS

1,206 exams were audited. Weekly PI-QUAL scoring >4 increased from an average of 91% to 99% (9%) and DWI images rated optimal increased from an average of 71% to 88% (24%).

### DISCUSSION

Key drivers included: (1) a sustainable process for evaluating image quality and (2) standard day of exam preparation. Since baseline PI-QUAL scores were deemed exceptional without an enema preparation and potential patient dissatisfiers, the team focused on bowel gas reduction techniques. Patients were told to refrain from consuming caffeine and carbonated beverages beginning eight hours prior to their MRI. Patient instructions were scripted and shared with staff who perform pre-MRI screening. To help troubleshoot artifacts, an MRI technologist was assigned as "coach of the day". Manual retrospective PI-QUAL auditing was time consuming. This process was improved by implementing an imbedded PI-QUAL score within the standardized report template. At many institutions, enemas are standard in the preparation for prostate MRI. Without adding an enema and without increasing examination duration, we significantly improved our outcomes. This project helped our MRI team gain a better understanding of each member's role in image quality.

## S3A-QI-6 IMPROVING PROSTATE MRI QUALITY

Kevin McDermott (*Abstract Co-Author*) Nothing to Disclose
Andrei S. Purysko, MD (*Abstract Co-Author*) Contract, Profound Medical Inc;Research support, Blue Earth Diagnostics Ltd;Consultant, KOELIS;
Rachel Harris (*Abstract Co-Author*) Nothing to Disclose
Ryan Ward, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

High quality prostate MRI is important for cancer detection and reader confidence. Artifacts, primarily due to rectal gas and motion, and noncompliance with MR technical standards can limit the assessment for prostate cancer on MRI. The purpose of this project was to improve prostate MR image quality, as assessed by the Prostate Imaging Quality (PI-QUAL) scoring framework.

### METHODS

In collaboration with ACR Learning Network, this performance improvement project was performed at the main campus of a large multihospital health system. We sought to 1) Increase the rate of prostate MRI exams that received a PI-QUAL score = 4 from 55% to 80%, and 2) Increase the rate of Diffusion Weighted Images (DWI) scored as "optimal" from 60% to 80% during the 9-month study period.The A3 performance improvement methodology was employed to assess the nature of the problem. Weekly volumes of prostate MRIs were tracked and scored for quality. Additional patient, technologist, and scanner-level data was tracked and assessed for contribution to poor image quality. Data was reported within a dashboard, viewable by key stakeholders.

### RESULTS

1370 prostate MRIs (from 1366 patients) were scored using the PI-QUAL framework in the 12 months between March 2023 March 2024. Key drivers of poor quality included bowel gas and motion artifact, no or incorrect patient preparation, inconsistent technologist training, lack of standards in image

quality, and variability in scanner protocols. Compared to pre-intervention scans, post-intervention scans were similar with respect to patient age, scanner vendor, model, and magnetic field. Image quality scores increased after the intervention, with overall PI-QUAL score rates reaching 93% and DWI score rates reaching 83% by the end of the study period, exceeding the established goal benchmarks. PI-QUAL scores have also remained above benchmarks in ongoing quality assessments.

**DISCUSSION**

Interventions included standardized technologist troubleshooting and scanner protocols, delivering consistent, timely, and effective patient preparation instructions, and developing consensus on image quality. The most important interventions to improve image quality related to removing gas from the patient's rectal vault with improved observed image quality, particularly on the diffusion weighted images. Using a team-based approach, our organization was able to achieve sustainable performance improvement. The project has also facilitated a sustainable quality control process through the development of tools to automate quality reporting. To date, over 2000 prostate MRIs have been scored using the PI-QUAL scoring system with results available in a real-time dashboard.

## S3A-QI-7 REDUCING THE OCCURRENCE OF UNFILLED OUTPATIENT APPOINTMENTS IN GIGU DEPARTMENT

Ravinder Sidhu, MD (*Abstract Co-Author*) Nothing to Disclose
Erin Panter (*Abstract Co-Author*) Nothing to Disclose
Susan Perry (*Abstract Co-Author*) Nothing to Disclose
Ben C. Wandtke, MD, MS (*Presenter*) Clinical Advisory Board, CAK Tech, Inc

**INTRODUCTION**

Fluoroscopy procedures are performed to diagnose conditions within the gastrointestinal track or genitourinary systems (GIGU). GIGU appointments canceled without notification result in inefficiency. In October 2023, there was an 8-week scheduling backlog for GIGU appointments, and average resource utilization was 76%. The no-show and same day cancellation rate was higher than other modalities in the department. We intended to improve GIGU room utilization by reducing unused appointment slots.

**METHODS**

This project was performed in a large urban academic hospital. We aimed to improve GIGU fluoroscopy room utilization from 76% to 85% within 6 months. Resource utilization and same day cancellations were measured weekly. Same-day cancellations were defined as patients who cancel the day of appointment or no-show. Using several performance improvement methodologies including Gemba walks, control charts, fishbone diagrams, and PDSA cycles our multidisciplinary team was able to identify multiple potential root causes. Key drivers were determined, interventions tested and implemented. Reports were generated and analyzed weekly to determine exam volume, cancelations, and scheduling backlog. The scheduling backlog was defined as the day of the 3rd next available examination.

**RESULTS**

Room utilization increased from an average of 76% to 86% (13%). Same day cancelation rate decreased from 22% to 13% (41%). Average exam volume increased from 52 exams to 58 exams per week (12%). GIGU scheduling backlog decreased from 8.3 weeks to 7.2 weeks.

**DISCUSSION**

Our lengthy GIGU appointment scheduling backlog and the inability to backfill same day cancellations were primary root causes of poor room utilization. During initial Gemba observations, it was realized that one of the cancelation reports was no longer accessible by the scheduling staff, which immediately improved the no-show rate. The interdisciplinary team of scheduling and front-line staff worked with EPIC® to develop an imaging appointment waitlist and create a new workflow for cancelations. Scheduling reviewed open appointments and notified waitlist patients of available appointments. An imaging waitlist workflow was implemented which immediately improved room utilization and increased exam volumes performed. While these efficiency gains resulted in a modest 1-week improvement in scheduling backlog, the new system should continue to have a slow but steady impact on backlog over time. Since the primary intervention performed, the development of an EMR based waitlist workflow, was developed in a shared EMR with numerous other sites providing GIGU fluoroscopy services, we anticipate being able scale this process system wide. Prior to scaling our new workflow, our Department is exploring a technical solution to replace our manual waitlist process utilizing the EMR to automatically back fill open available slots.

## S3A-QI-8 DECREASING INAPPROPRIATE MRCP WITHOUT AND WITH IV CONTRAST EXAMS: IMPACT OF EMR-EMBEDDED CLINICAL CARE PATHWAY

Jay K. Pahade, MD (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;
Gowthaman Gunabushanam, MD (*Abstract Co-Author*) Nothing to Disclose
Marie Hausner, ARRT, RT (*Abstract Co-Author*) Nothing to Disclose
Kelsey Cole (*Abstract Co-Author*) Nothing to Disclose
Daniella Asch, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Magnetic resonance cholangiopancreatography (MRCP) exams are commonly performed in the emergency department (ED) and inpatient population. Frequently, a noncontrast MRCP protocol is sufficient to answer the clinical question, but many of these exams are ordered without and with contrast due to insufficient understanding by the ordering provider as well as lack of guidance from radiology at the point of order entry. Changing to noncontrast exams after a contrast-enhanced exam has been ordered typically requires discussion with the clinical team and can be a time-consuming process. When exams are performed with contrast unnecessarily, they increase health care costs, expose patients to gadolinium-based contrast unnecessarily and increase MR scan times. The goal of this project was to decrease utilization of MRCP with contrast by 20%.

**METHODS**

A team of radiology quality improvement specialists, hospital Care Signature Team, and GI physicians, worked to establish consensus on indications for MRCP and preferred imaging protocols. An MRCP order panel with care pathway was created with embedded clinical guidance and links to the appropriate orders. MRCP orders were removed from the electronic medical record for ED and inpatients, with all providers directed to the clinical care pathway to place orders. Number of MRCP exams performed without IV contrast vs with IV contrast were tracked over time. Retrospective chart review for one month of data was performed by abdominal radiology fellows before and after intervention to assess appropriateness of MRCP with IV contrast orders based on clinical history/indication.

**RESULTS**

At baseline, 77% of MRCPs were performed with IV contrast which decreased to 58% after the intervention (25% relative reduction). At baseline, 50% of these were deemed inappropriate based on chart review at our tertiary care center which improved to 25% after intervention (50% improvement). Mean MRCP with IV contrast scan time was 10 minutes longer than MRCP exams without IV contrast. A decrease in MRCP orders with contrast and concomitant increase in MRCPs without contrast after intervention was noted. Total number of MRCPs (both without contrast and with IV contrast) declined by 15% after intervention (mean 180/month vs 153/month).

## DISCUSSION

Creation of an order panel and clinical care pathway at the point of order entry successfully decreased ordering of contrast-enhanced MRCP exams for ED and inpatients by 25% and improved clinical appropriateness of MRCP with contrast orders by 50%. By correctly "nudging" ordering providers to noncontrast MRCP orders, healthcare costs and unnecessary gadolinium exposure can be reduced, and MR scanner efficiency improved. This model can be applied to other imaging exams for which there is an opportunity to decrease waste by hard-coding well-designed, clinical ordering guidance created by a multidisciplinary team.

## S3A-QI-9 IMPROVING THE EFFICIENCY OF THE FETAL MRI SERVICE AT AN OUTPATIENT CLINIC

Jennifer D. Smith, MD (*Abstract Co-Author*) Nothing to Disclose
Jeannie K. Kwon, MD (*Abstract Co-Author*) Nothing to Disclose
Rebekah L. Clarke, MD (*Abstract Co-Author*) Nothing to Disclose
Veena Peraka (*Presenter*) Nothing to Disclose

## INTRODUCTION

Fetal MRI is a crucial tool to characterize an abnormality detected on prenatal ultrasound, and the results can be difficult for patients to receive. At our institution, radiologists provide an immediate face-to-face counseling session with patients to review results, so it is a significant aberration from the typical radiology workflow. With increasing volumes, radiologists are rushed to evaluate images and discuss results which can negatively affect quality of care. Issues with patient-centered care can arise since radiologists may not have all available information to discuss complex cases. The aim of this project is to improve the workflow of pediatric radiologists performing fetal MRI scans without compromising patient satisfaction, by decreasing the time spent per patient on all patient-related activities by 25% on a fetal MRI workday in 12 weeks.

## METHODS

This project was performed using the PDSA methodology at an outpatient clinic at an academic medical center. At baseline, it takes radiologists approximately 90 minutes per patient to complete all patient activities. Counseling comprised a significant amount of time, an average of 20 minutes per patient. Our first intervention tested the idea of eliminating counseling for patients referred by willing providers. The second iteration of this intervention fully eliminated counseling for all patients.The intervention was assessed live each workday by the process measure of average number of minutes spent per patient. The outcome measure was the turnaround time for patient reports, defined as the difference between imaging exam end time and report completion, as documented in the electronic medical record. The balancing measure was assessed by a survey administered pre-scan to determine patients' preference for receiving results, to ensure patient values were not compromised. No other changes occurred that would impact results. Analysis was performed using statistical process control charts (SPC) with analysis of variation done through observing the 3-sigma control limits.

## RESULTS

SPC analysis revealed that the average time spent per patient decreased from 89.8 to 60.5 minutes (p=.0003). This was a 32% reduction in time spent which exceeded our goal of 25% reduction. The turnaround time for patient reports decreased from an average of 6.32 to 2.79 hours per patient, a 55% reduction (p=.0249). Patient survey results showed that 81.3% of respondents preferred receiving results from their maternal fetal medicine specialist or OB/Gyn over the radiologist.

## DISCUSSION

The removal of counseling in the fetal MRI service improves radiologist efficiency without compromising patient satisfaction. Future advantages include increased appointment and radiologist availability. Limitations of the study include the lack of follow up with patients and providers to determine satisfaction with results communication.

## S3B-QI-1 AUTOMATIC GENERATION OF PRESURGICAL IMAGING CHECKLISTS USING INTERACTIVE MULTIMEDIA REPORT DATA

Adrian Prisacariu (*Abstract Co-Author*) Employee, Patrisoft Outsourcing Srl
Andreea Pitici (*Abstract Co-Author*) Consultant, VisionSR, Inc
Ciprian Dorin Craciun (*Abstract Co-Author*) Consultant, VisionSR, Inc
Cristian Popovici (*Abstract Co-Author*) Software engineer, Patrisoft Outsourcing SRL
Mark Kontak (*Abstract Co-Author*) Consultant, VisionSR, Inc
David J. Vining, MD (*Presenter*) Royalties, Bracco Group;CEO, VisionSR, Inc;Stockholder, VisionSR, Inc

### INTRODUCTION

Radiology is an important component of presurgical evaluation. Surgeons often seek specific information from a radiology report about the extent of disease, vascular involvement, and comorbidities before operating. Due to the success of the World Health Organization's Surgical Safety Checklist, presurgical imaging checklists are being advocated for certain procedures to make certain that radiology reports contain essential information. Extracting desired information from unstructured narrative reports can be tedious, time-consuming, and hindered by missing information. A solution is to dictate a radiology report into a specific template, but that product may not meet the needs of all users. An alternative solution shown in this exhibit employs interactive multimedia reporting (IMR) to populate an anatomical-based template or any number of presurgical imaging checklists using interchangeable discrete data elements.

### METHODS

We developed a radiology reporting solution that records key images and voice descriptions of findings, tags the findings with metadata using natural language processing referenced to an ontology describing the anatomic location and radiological diagnosis/observation of each finding, and assembles an IMR report formatted according to an anatomical hierarchy. However, the interchangeable discrete data can be used for other purposes, including the creation of presurgical imaging checklists that highlight the essential information required by a surgeon. The anatomy, diagnosis, or combination of anatomy-diagnosis metadata are specified in an extensible markup language (XML)-formatted template to direct findings to specific sections of a report. For any report section without specific radiographic findings, normal verbiage is inserted into that section. A user can automatically select what style of report is output from the system. The presurgical imaging checklists that have been constructed to date include those used for hepatic resection, ovarian cancer debulking, and pancreaticoduodenectomy.

### RESULTS

The system has been used to date to create 3,579 multimedia reports of which approximately 100 have been performed for hepatic surgery planning, 25 for ovarian cancer debulking, and 20 for pancreaticoduodenectomy.

### DISCUSSION

A benefit of IMR is that it employs discrete data elements that can be used for multiple purposes, including the generation of presurgical imaging checklists and data mining for medical outcomes. Radiological data that traditionally has been trapped in static documents can be transformed into a much more valuable commodity.

## S3B-QI-2 A QUANTITATIVE STUDY ON IMPROVING RADIOLOGY REPORT DESCRIPTIVENESS USING LARGE LANGUAGE MODELS

Dr. Praveen Shastry (*Abstract Co-Author*) Nothing to Disclose
Naveen K (*Abstract Co-Author*) Nothing to Disclose
Kishore Prasath Venkatesh (*Abstract Co-Author*) Nothing to Disclose
Bargava Subramanian (*Abstract Co-Author*) Nothing to Disclose
Sivasailam Kalyan (*Presenter*) Nothing to Disclose

### INTRODUCTION

A quantitative study on improving radiology report descriptiveness using large language models Problem Description: India faces a critical shortage of radiologists relative to its population needs, which poses significant challenges in maintaining consistent and accurate radiology reports. This shortfall leads to potential delays and variability in clinical decision-making, impacting patient care across the country.Available Knowledge: Standard radiology reporting varies greatly, depending on individual skill levels, leading to variability in report quality.Purpose: This project aimed to systematically improve the quality and accuracy of radiology reports through the integration of LLMs, thereby standardizing reports and enhancing clinical outcomes.

**METHODS**

General: Utilizing the Plan, Do, Study, Act (PDSA) methodology, this study implemented a series of interventions involving LLMs to improve the descriptiveness and accuracy of radiology reports.Context and Intervention: Challenges such as ambiguous reports and lack of detailed descriptions set the stage for this intervention. Initially, 150 radiologists conducted baseline assessments of 109,639 reports to establish metrics that included descriptive scores and error rates. These reports covered over 400 pathologies in CT Abdomen Pelvis studies.Study of the Intervention: Following the baseline assessment, a phased approach was used to gradually integrate three different AI models (RAG, RAG + Instruction Fine-tuning, RAG + RLHF), allowing for the evaluation of performance improvements against a set of predefined KPIs.Measures/Metrics: Metrics focused on descriptive scores, error rates, and turnaround times. RADPEER Scoring Analysis was used to categorize errors, and improvements were measured across multiple phases of LLM integration.

**RESULTS**

At baseline, the average descriptive score was 5.59, and the error rate was 8.37%. Over the course of the study, the integration of AI models yielded significant improvements:RAG: Achieved a descriptive score of 6.1 and an error rate of 7.45%, but faced limitations in capturing the nuanced understanding of complex pathologies, leading to increased report turnaround times.RAG + Instruction Fine-tuning: Enhanced accuracy with a descriptive score of 7.6 and an error rate of 4.5%, demonstrating improved report quality while occasionally diverging from human preferences.RAG + RLHF: This final phase saw a descriptive score rise to 8.75 and an error rate decrease to 1.2%, indicating substantial improvements in report actionability and diagnostic reliability.

**DISCUSSION**

Conclusions: Integrating LLMs into radiology reporting processes significantly enhances report quality and consistency, reduces error rates, and decreases turnaround times, which may contribute to better clinical decision-making and patient outcomes.

## S3B-QI-3 PRIORITIZE, OPTIMIZE AND ACHIEVE: ENHANCING STAT IMAGING ORDER EFFICIENCY FOR REDUCED TURN AROUND TIME!

Rajendra P. Kedar, MD, DMRD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

STAT priority is typically used to indicate a medical emergency Misuse of the STAT priority is also widespread1. Inappropriate STATradiology orders could have a negative impact on patient care. Our institution's STAT priority was used to expedite imaging delays, obtain non-urgent radiologic tests before discharge, and ensure imaging was complete before rounds. This misuse of the STAT priority led to an upward of 67% of Head CT orders being ordered as STAT.

**METHODS**

Our team included radiology leadership, inpatient physicians, radiology technologists, and information technology support. Through workgroup consensus, we defined radiology priorities for our institution. We piloted our intervention with the CT head as this had the highest percentage of STAT priority. We added an attestation to the image order requiring the physician to attest they agree with the priority. We created a priority and process for an ASAP pathway and monitored the number of orders, ordering priority, and order-to-completion time (OTC) in a Qlik dashboard. The order priority definition and order to completion time were as follows: 1. Stat: Loss of life and limb -2 hours. 2. ASAP: Urgent treatment or surgery -6 hours. 3. Routine: Investigate or stable for more than 12 hours - 12 hours

**RESULTS**

We educated all providers on the new definitions and order changes through flyers and division meetings. One month after the order change, we saw a 58.5% decrease in the number of STAT image orders sustained over four months. We improved our OTC from 3hr 8m to 2hr. We increased our ASAP orders from 0-3 to over 80 per month. OTC for ASAP was less than our goal of 6 hours. Since the project started, data was shared weekly with physician champions to disseminate with their colleagues.

**DISCUSSION**

Clear institutional definitions of radiology priorities and order attestations improved appropriate ordering compliance.Involving physician champions helps promote physician engagement.

## S3B-QI-4 RADIOLOGY PRE-APPOINTMENT COMMUNICATION SYSTEMS: IMPACT ON REDUCING MISSED CARE OPPORTUNITIES FOR OUT-PATIENT CT EXAMS

James J. Sheehan, BA (*Abstract Co-Author*) Nothing to Disclose
Saurabh Gupta (*Abstract Co-Author*) Nothing to Disclose
Jay K. Pahade, MD (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;
Gowthaman Gunabushanam, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Missed care opportunities (MCO) (defined as patients who do not arrive for their appointment or cancel on day of appointment) can lead to delayed care and reduced scanner operational efficiency. The purpose of this project was to assess the impact of a pre-appointment reminder communication system (primarily via texting) in reducing MCO for out-patient CT at our institution.

**METHODS**

We implemented a pre-appointment texting system on 8/24/2023 for our institution’s 4 out-patient CT locations. Patients who listed a cell phone in the medical record received text messages, and the remaining patients received interactive voice response (IVR) phone calls. Unique to our texting program is the inclusion of appointment reminders, scan preparation, way finding information and niche reminders for select tests that have diet restrictions. Content was developed in English and Spanish. We assessed our MCO % rate, defined as number of MCO/ total scheduled scans for 6 months before (baseline) and after program implementation (post-launch). We also assessed patient engagement with the text messages (by tracking replies back via text) and performed subgroup analysis to study health equity differences based on age, race and ethnicity.

**RESULTS**

A total of 46,581 appointments for CT scans were created between 2/24/2023 and 2/23/2024. At baseline (2/24/2023 - 8/23/2023), the MCO rate was 13.67% (3159/23110) versus 13.20% (3097/23471) post-launch (8/24/2023 - 2/23/2024). This represented a 3.47% relative reduction (RR) and 0.47% absolute reduction (AR) in MCO. Among patients gt;= 80 years of age, the MCO rate was 11.90% (299/2513) at baseline versus 10.24% (262/2558) post-launch, a 13.92% RR and 1.66% AR in MCO rate. Among African Americans, the MCO rate was 27.64% (866/3133) at baseline versus 25.36%

(760/2997) post-launch, a 8.26% RR and 2.28% AR in MCO rate. For Hispanics, the MCO rate was 22.39% (544/2430) at baseline versus 21.06% (502/2384) post launch, a 5.94% RR and 1.33% AR in MCO rate. Communication was primarily via texting (97%, 22697/23471) with 3% (774/23471) receiving IVR calls. Engagement with the program was similar across all groups, ranging from 79-81%. Patient initiated appointment cancellation was 11% (2544/22697) via text message and 15% (114/774) for IVR phone calls.

**DISCUSSION**

Use of a pre-appointment communication program for out-patient CT led to a nominal reduction in overall missed care opportunities for our study population. However, more robust decreases in MCO rates were noted for demographic groups typically considered at higher risk of MCOs with a relative reduction of 8% for African Americans and 6% for Hispanics. The more pronounced impact for these demographic groups suggests that this may represent a better way to engage these populations to encourage out-patient CT completion. A limitation of our study is we did not correlate results with poverty indices.

## S3B-QI-5 DEVELOPMENT OF A FRAMEWORK TO EVALUATE RADIOLOGY AI MODELS FOR POTENTIAL CLINICAL DEPLOYMENT

**INTRODUCTION**

With nearly 500 FDA-cleared radiology AI models available, selecting the right one for a clinical setting remains challenging. Adoption is often influenced by marketing rather than objective metrics. To address this, we established a Radiology AI Clinical Council to develop a reproducible framework for evaluating AI models, ensuring that large hospital systems can make informed decisions amid growing demands for AI integration in healthcare.

**METHODS**

Sixteen representatives across all radiology clinical divisions plus revenue cycle, operations, and research were recruited for the Radiology AI Council. A rubric for AI model evaluation for deployment was developed over a 3-month period with a structured approach that considers available evidence, integration complexity, radiologists' needs, operational impact, medicolegal challenges, financial considerations, and post-deployment monitoring. The framework is currently being used to evaluate several proposed radiology AI solutions.

**RESULTS**

The framework comprises 50 questions across 10 sections. Eleven questions have scoring metrics attached to yield a final scorecard for the model. Select sections are summarized:1. Validation - Models are scored based on presence of peer-reviewed evidence, subgroup evaluation for bias assessment, and validation using data from our institution.2. Deployment and Integration: Assessment includes model compatibility with current systems, deployment type, integration points within existing infrastructure, whether clinicians may receive results before radiologists3. Monitoring and Management: Post-deployment monitoring strategies, management of alerts to multiple users, and responsibilities for ongoing model performance evaluations.4. Impact: Department and enterprise-wide alignment of strategic priorities, impact on radiologist and clinicians, patient safety concerns, workflow efficiency, addressing burnout,5. Financial implications: model cost, expected revenue generation or cost recovery, direct reimbursement opportunities.6. Legal and Ethical Considerations: Potential medicolegal issues, compliance with existing policies, durability of model results

**DISCUSSION**

Appropriate selection of AI models for clinical deployment has widespread and potential longstanding impacts on care quality, radiologist quality of life, and business considerations within a radiology department. We introduce a framework to standardize the evaluation of Radiology AI models for clinical use, aiming to develop a comprehensive assessment mechanism to address both scientific and practical considerations of model selection. This framework can assist in selecting models that align with the needs of patients, radiologists, and the healthcare system.

## S3B-QI-6 IMAGING SELF-SCHEDULING

Tarek N. Hanna, MD (*Abstract Co-Author*) Nothing to Disclose
Susan Reich (*Abstract Co-Author*) Nothing to Disclose
Laura A Benson (*Abstract Co-Author*) Nothing to Disclose
Nadja Kadom, MD (*Abstract Co-Author*) Nothing to Disclose
Patricia Balthazar, MD, MPH (*Presenter*) Dr. Balthazar received research support from the Association of University Radiologists GE Radiology Research Academic Fellowship.

**INTRODUCTION**

Problem Description Wait times for outpatient imaging exams are a critical quality metric that reflects system efficiency and patient access. Extended lead times from order to exam schedule and completion can delay patient care and contribute to network leakage.Available Knowledge Rising volumes and clinical demands complicate access to healthcare services, influencing the efficiency of outpatient imaging services.Purpose The purpose of this study was to perform a series of scheduling optimizations to decrease the order-to-schedule time (OTS) in the radiology department and simultaneously improve patient satisfaction with the scheduling experience.

**METHODS**

General This quality improvement project employed the Plan, Do, Study, Act (PDSA) cycle methodology, appropriate for iterative interventions.Context and Intervention The study was conducted at a large urban quaternary care academic healthcare system in the US South. Interventions included scheduling slot optimization through interchangeable templating with standard slot lengths and enabling an online patient portal self-scheduling feature for certain examination types.Study of the Intervention The primary outcome measures were the median OTS time (in days) and the percentage of OTS

within 10 days by imaging modality (XR, US, CT, MR). These outcomes were used to assess the impact of the interventions.Measures/Metrics Measures chosen for the study included median OTS time and percentage of OTS within 10 days by imaging modality. The rationale for choosing these metrics was their direct reflection on scheduling efficiency and patient accessibility.Analysis The quantitative analysis included a comparison of metrics before and after intervention implementation to draw inferences and understand data variation over the study period.

**RESULTS**

The overall median OTS time improved from 16.9 days in FY 22-23 to 5.6 days in the first 5 months of FY 23-24. By modality, significant improvements were noted (CT: from 17.2 to 5.6; MR: from 18.3 to 6.9; US: from 16.4 to 5.1; XR: from 17.7 to 6.1). The percentage of OTS times within 10 days increased across all modalities, with overall improvement from 73% to 86%. The implementation of patient self-scheduling led to 19,950 self-scheduled exams, distributed among the modalities (CT: 1647; MR: 1298; US: 5989; XR: 1606).

**DISCUSSION**

Limitations The study is limited by its single-center design and the short duration of post-intervention follow-up.Conclusions Scheduling slot optimization and the introduction of patient self-scheduling significantly decreased OTS time across all imaging modalities and improved patient scheduling experience. Future directions include enhancing schedule-to-arrival times and enabling scheduling “fast-pass” (waitlist for earlier slots for patients with certain health insurances that do not require pre-authorization).

## S3B-QI-7 SEQUENTIAL IMPROVEMENT IN PARATHYROID ADENOMA LOCALISATION (SIMPAL)

Amit Parekh, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Jennifer Downs (*Abstract Co-Author*) Nothing to Disclose
Emma O'Shaughnessy (*Abstract Co-Author*) Nothing to Disclose
Tristan Richardson (*Abstract Co-Author*) Nothing to Disclose
Kat Dixon (*Abstract Co-Author*) Nothing to Disclose
Peter Jarvis, FRCR, MBBS (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Parathyroidectomy is the treatment of choice in primary hyperparathyroidism. Localisation of an adenoma allows a surgeon to perform focused excision rather than full neck exploratory surgery, leading to reduced complication rate, recovery time and cost. This study implemented multiple rounds of quality improvement in our parathyroid localisation service to ensure the maximum number of patients benefited from minimally invasive surgery.

**METHODS**

Following discussion with radiologists, physicists, endocrinologists, technologists and surgeons, a series of improvements were proposed.Cycle 1: Acquisition of new SPECT/CT scanners.Cycle 2: Optimise image acquisition in 3 ways. 1, moving to step and shoot acquisition over our previous continuous acquisition. 2, increasing administered activity from 750MBq to 900MBq 99mTc-Sestamibi and 3, Using phantom data applied to patients to change SPECT reconstruction parameters (reducing iterations and increasing subsets).Cycle 3: Addition of arterial phase iodinated contrast.We collected baseline and post intervention data following each cycle. Successful adenoma localisation was confirmed using the pathological specimen report at surgery. A 5-point scale was used to assess the degree of confidence in the radiologist report. Sensitivity, specificity and receiver operating characteristic (ROC) curves were calculated following each intervention.

**RESULTS**

Baseline audit of 194 patients showed 31% of studies failed to localise an adenoma and only 44% of studies were confident in their localisation. 163 patients underwent surgery with sufficient data to calculate ROC with area under the curve (AUC) of 0.92 (sensitivity 69.8%, specificity 95.7%).Following cycle 1, an audit of 59 patients showed a reduction in localisation failure to 24% and increase in confident localisations to 54%. 47 patients underwent surgery with improved AUC to 0.95 (p0.22, sensitivity 77.6%, specificity 93.3%).Following cycle 2, an audit of 103 patients showed further reduction in localisation failure to 18%, with 48% showing confident localisation. 72 patients underwent surgery with significant improvement in AUC to 0.98 (p0.004, sensitivity 84.3%, specificity 95.9%).Following cycle 3, an audit of 71 patients showed further reduction in localisation failure to 6% and increase in confident localisations to 67%. 22 patients have undergone surgery with significant improvement in AUC to 0.99 (p0.002, sensitivity 100%, specificity 82.6%).

**DISCUSSION**

We demonstrated improved adenoma localisation and reporter confidence following each intervention, with significant improvement in AUC on ROC analysis. Better adenoma localisation has resulted in fewer exploratory surgeries and therefore improved patient safety and reduced cost. Patient numbers in the final cycle are low due to limited follow up time, however data collection is ongoing.

## S3B-QI-8 IMPROVING ORDERING OF ED AND IN-PATIENT SPINE MRI: IMPACT OF ORDERING PANEL AND CARE PATHWAYS

Daniella Asch, MD (*Abstract Co-Author*) Nothing to Disclose
Marie Hausner, ARRT, RT (*Abstract Co-Author*) Nothing to Disclose
Amit Mahajan, MBBS (*Abstract Co-Author*) Nothing to Disclose
Kelsey Cole (*Abstract Co-Author*) Nothing to Disclose
Gowthaman Gunabushanam, MD (*Abstract Co-Author*) Nothing to Disclose
Jay K. Pahade, MD (*Presenter*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;

**INTRODUCTION**

Spine MRI reflects a complex study that is often confusing to order for inpatient and ED providers. At our institution, ordering error review revealed 3 recurrent issues: 1. Over-ordering of total spine (vs limited) imaging 2. Inappropriate ordering of contrast 3. Lack of awareness and limited access to an abbreviated acute cord compression (ACC) total spine MRI protocol.Incorrect order placement creates waste for radiologists secondary to time spent fixing the order, while failure to change the order may result in suboptimal or excessive imaging. This is particularly problematic for total spine orders, as they are resource intensive, both for MR scan time and radiologist interpretation time. The purpose of this QI project was to redesign spine MRI ordering in our electronic health record (EHR) by creating a new spine MRI order panel and pathway, with a goal of reducing total spine MRI exams performed by 20% and steering ordering providers to an abbreviated noncontrast total spine MRI order when acute cord compression (ACC protocol) was suspected.

**METHODS**

A multidisciplinary team was formed, consisting of experts from Radiology Quality and Safety, Neuroradiology, Neurosurgery, Neurology and our Care Signature Team, to redesign how clinicians order spinal MRI. Sixteen unique spine orders were “hidden” and replaced with a single MRI order panel which was iteratively tested using human-centered design principles. Six months of data were assessed before and after intervention, tracking total spine MRI orders and use of ACC spine MRI protocol across a health system compromised of a single academic tertiary center and 5 additional free-standing hospitals. The ACC protocol was made accessible at all hospital sites during this project (previously limited to tertiary care center only).

## RESULTS

At our institution, total spine MRI scan time takes 60-90 minutes , while the abbreviated acute cord compression total spine MRI takes 10-20 minutes. After launching the new order panel, the mean monthly total spine orders (without contrast and without and with contrast) decreased from 129 to 105 (19% reduction), while use of ACC protocol increased from 12 to 26 (117% increase).

## DISCUSSION

This QI report describes successful creation of a new order panel and pathway for spine MRI that significantly altered how ED and inpatient providers place orders. Instead of relying on the provider to know the correct order based on the clinical indication, the panel provides the most common indications for spinal MRI and then links the provider to the correct order. Feedback from ordering providers has been positive, with many noting that the panel has removed uncertainty about what test to pick. These interventions successfully reduced total spine MRI volume by 19% and increased use of an abbreviated, noncontrast total spine protocol by 117%, allowing for more timely, tailored, and cost-effective care.

# S3B-QI-9 IMPROVING THE THYROID ABLATION ORDERING PROCESS THROUGH STANDARDIZED WORKFLOWS

Chance Colvin, BS (*Presenter*) Nothing to Disclose

## INTRODUCTION

The Radiology Ablation Scheduling Team is experiencing large numbers of incorrect thyroid ablation orders. There is no standardized process to request a thyroid ablation for a patient, this results in delays in Radiology triage of potential thyroid ablation candidates and scheduling of procedures. The purpose of this study was to develop a standardized thyroid ablation ordering process to reduce the number of incorrect orders being placed. The goal of the project is to simplify the ordering process reducing the number of incorrect orders from 66% to 35% by October of 2024, working towards eliminating incorrect orders.

## METHODS

A team of Radiology Ablation and Endocrinology staff including physicians, nurses, schedulers, and Radiant architects. The help quality improvement personnel worked together using the Define Measure Analyze Improve Control and the Plan Do Study Act frameworks. A report of ordered procedures was pulled to determine which orders were placed incorrectly, and a description of why the order was incorrect. The team performed a root cause analysis using a swimlane to map out the current process for ordering a Thyroid Ablation. This allowed the team to see how confusing and disorganized the process was. This also allowed the team to see where the confusion stemmed from early in the process, showing that there was no process for ordering these procedures. As the first phase of this improvement the team worked together to develop a new standard process to improve efficiency for the ordering providers. Not only did the team develop a new standardized process, but they also worked with a Radiant architect to build a new order panel. This consisted of providing developed pathways for each thyroid process, preselected labs and imaging, and options for any pre-procedural additions if needed. Education was provided to all physicians in Rochester involved with these procedures, including a presentation during the Endocrinology Divisional Business meeting. Instructions detailing how to add the order panel number to their preference list was sent to providers in Radiology and Endocrinology, to reduce the risk of providers defaulting to the old process.

## RESULTS

The outcome of the project has slowly progressed with physicians adopting the new order panel process. Since the order panel has gone live the number of incorrect orders has decreased by 15% from 66% to 51% since November 16, 2023. The team continues to record and monitor the ordering data. The next phase is to set the new order panel as the default order by an electronic change request.

## DISCUSSION

During this project the team has learned that having all necessary stakeholders involved with the process is vital, the team could not have been able to get to the root cause without everyone’s different perspectives. Teamwork is a vital portion of this project, having clear communication is key since the project involves multiple areas.

## T2-QI-1 ENHANCING TIMELY SERVICE FOR HIGH-PRIORITY (STAT) PORTABLE DR/XR EXAMS IN PICU: ENSURING ACCURATE PRIORITIZATION OF CASES

Summer L. Kaplan, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Hannah Stinson, MD (*Abstract Co-Author*) Nothing to Disclose
Eatrice Hinton (*Abstract Co-Author*) Nothing to Disclose
Marcy Hutchinson (*Abstract Co-Author*) Nothing to Disclose
Valerie Rigby (*Abstract Co-Author*) Nothing to Disclose
Mohammad Jalloul, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Timely response to urgent portable x-ray orders is crucial for safe management of patient care. Without a shared understanding of a STAT level response, and standard language methods for communicating the urgency reason for exam, the volume of STAT orders can become unmanageable. This leads to failure to provide optimal patient care. The current state analysis of the workflow revealed that only 59% of STAT portable XR exams in the Pediatric ICU (PICU) meet the order-to-begin-exam time (response time) of = 30 minutes and 36% align with STAT criteria. The global aim of this project is to provide timely and effective patient care by enhancing imaging stewardship and ensuring that the right patient receives the right exam at the right time. Our project goal is to increase the % of STAT exams with a response time of = 30 minutes from 59% to 80% and increase the % of STAT orders that meet STAT criteria from 37% to 80% by the July 2024.

### METHODS

A multidisciplinary team including critical care and radiology services collaborated to investigate portable XR exams conducted on inpatients in the PICU, spanning all hours and days of the week. Through Gemba walks, the root causes of delayed response times were attributed to unclear communication processes, ambiguous prioritization and timing of orders, and lack of clarity regarding the clinical need for STAT exams. Moreover, STAT exams were not meeting criteria due to frequent ordering of exams for unurgent conditions and misuse of STAT priority for non-clinical reasons. Interventions are being tested to shorten duration of STAT response, including a nursing tip sheet to guide clear communication to the technologist, use of a “triage tech” to manage and assign all in-coming portable exam orders, and changing the staffing model so technologists cover specific areas of the hospital. To ensure STAT appropriateness, the team proposed instructing radiologists to follow a defined list of clinical criteria to determine priority. Process measures used for STAT appropriateness included % of exams correctly ordered according to the criteria list. The project outcome metric is the % of STAT exams done in =30 minutes from exam order.

### RESULTS

As of now, the % of exams done =30 minutes and aligning with the STAT priority list remain at baseline performance of 59% 36% respectively. This is due to the project being in early testing phase focused in a small area of PICU. Additional PDSA cycles for interventions will be tested across all areas of PICU. We anticipate measurable improvement in both the process and outcome metrics.

### DISCUSSION

Development of a shared understanding between the PICU and Radiology as to what makes an exam STAT and how we best communicate that to illicit a timely response is the key take away from this project. Using a systematic, team-based approach to improvement contributes to the success by opening the lines of communication between the two departments.

## T2-QI-2 TAKING THE FEAR OUT OF MRI SAFETY QUERIES. TRAINING THE EXPERTS

Jenny Wu, MD (*Abstract Co-Author*) Nothing to Disclose
Alexander Scott, MD (*Abstract Co-Author*) Nothing to Disclose
Olivia Hallas, DO (*Presenter*) Nothing to Disclose

### INTRODUCTION

Radiologists are tasked with a range of MRI safety issues including approving MRI exams on patients with implants, answering questions related to MRI safety, and responding to contrast reactions. Having a foundation in MRI safety knowledge is critical to functioning as a MR radiologist. Inadequate training with ACR MRI safety guidelines and protocols may lead to delayed exams, inappropriately canceled exams, or adverse safety events.Within our academic imaging institute, 39% of 105 staff radiologists did not feel confident making decisions or performing tasks involving MRI safety. The purpose of this study was to provide MR safety education to increase the reported confidence of radiologists on making MRI safety related decisions.

### METHODS

Utilizing the SOLVE curriculum, we analyzed the institutional conditions of MRI safety training and knowledge of radiologists. A survey of staff radiologists was conducted to assess institutional knowledge and confidence in MRI safety topics. Process maps of commonly reported MRI safety deficits were created with points of interest for possible areas of system failure. A root cause analysis was conducted. Based on an effort-impact matrix, a mandatory, recurring training module was recommended as the highest impact countermeasure. A training module for radiologists was developed with the assistance of the MRI safety team.Intervention outcomes were determined by two measures. Measure 1 was 'reported confidence with MRI safety protocols' which was measured by the percentage of radiologists who responded 'yes' to, 'has your confidence level in making decisions or performing tasks involving MRI safety increased after taking this module?', in a post training survey. Measure 2 was 'ability to correctly answer MRI safety questions' which was measured by the percent of correct answers on an MRI safety pre and post-intervention test and with number of attempts to achieve a perfect score on the post-intervention test.

### RESULTS

277 in-training and staff radiologists completed the training module in 2023. 95% of radiologists who completed the training module reported that the module increased their confidence level in making decisions or performing tasks related to MRI safety. Average post-intervention first attempt test score increased by 39% from the pre-intervention test. Median of two attempts to achieve a perfect score on the post-test.

### DISCUSSION

Mandatory MRI safety training for radiologists was well received at our institution and improved subjective confidence and objective competency in MRI safety tasks. It has been implemented as an annual training requirement for all radiologists at our institution. MRI Safety knowledge may be a commonly overlooked deficit for radiologists across the country. Implementing a formal, recurring MRI safety training for radiologists can help ensure that your MRI safety experts are indeed experts.

## T2-QI-3 INCREASING UTILIZATION OF A RAPID OSTEOMYELITIS MRI PROTOCOL TO IMPROVE PATIENT THROUGHPUT

Geetika Khanna, MD, MS (*Abstract Co-Author*) Nothing to Disclose
Ashishkumar K. Parikh, MD (*Abstract Co-Author*) Nothing to Disclose
Nadja Kadom, MD (*Abstract Co-Author*) Nothing to Disclose
Olivia Ries (*Abstract Co-Author*) Nothing to Disclose
Christabell C. Ndibe, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Problem Description: The clinical standard for imaging evaluation of possible osteomyelitis requires MRI with and without intravenous contrast. The length of the scan and need for sedation in young patients results in delays in scheduling and diagnosis. Available Knowledge: Rapid MRI protocols are being developed for many indications to facilitate patient throughput. Prior studies have shown that intravenous contrast is not essential for diagnosis of primary osteomyelitis in children beyond the neonatal age group. The available knowledge was used to develop an institutional rapid osteomyelitis (rOM) MRI protocol. Purpose To increase use of the rOM MRI protocol to greater than 50% in children with suspected acute musculoskeletal infection.

### METHODS

General: We used the Scientific Method for Improvement and Model for Improvement Methodologies and tested our theory with PDSA cycles. Control chart was used to monitor improvement. Context and Intervention: Our initial state analysis showed about 9% usage of the rOM MRI protocol. Team members were a group dedicated to musculoskeletal imaging which comprised of MRI technologists, physicists, and pediatric subspecialist physicians. Our root cause analysis showed lack of physician awareness of the availability of the rOM protocol and lack of an order set in the electronic health record (EHR) as barriers preventing its use. Interventions: Presentations about the rOM protocol was given to our consulting colleagues in 2022 and 2023. A new order set for rOM was also developed and implemented in September 2023. Study of the Intervention: We recorded the number of MRI exams performed using the rapid osteomyelitis protocol vs. standard protocol for suspected osteomyelitis in all eligible inpatients between August 2022 and March 2024. Measures/Metrics: 1. Rate of utilization pre and post education for awareness. 2. Rate of utilization pre and post implementation of the electronic order set. Analysis: We analyzed our data results using a statistical process p chart with 3-sigma control limits.

### RESULTS

Out of a total of 158 osteomyelitis MRIs from Aug 2022 to March 2024, 72 were performed with the rOM MRI protocol. The p chart showed an increased use of the rOM MRI protocol after education in April 2023, but then fell to baseline levels. A drastic and sustained change occurred in usage of the rOM MRI protocol once a specific order set was available in the EHR in September 2023 (0 to 100%).

### DISCUSSION

Use of our rOM MRI protocol increased transiently after educating our clinical partners. Creation of an order set in the EHR led to a sustained increase in utilization. Consistent use of this protocol in the long term will require continuous education on its availability and regular quality assurance. A limitation of our study is the relative infrequency of MRIs performed for osteomyelitis at our institution, averaging around 8 cases a month.

## T2-QI-4 STRUCTURED REPORTING AND SEMI-AUTOMATED RULE BASED TNM CLASSIFICATION FOR NSCLC STAGING IN A MULTICENTER FEASIBILITY STUDY

Clemens C. Cyran, MD (*Abstract Co-Author*) Nothing to Disclose
Matthias P. Fabritius, MD (*Abstract Co-Author*) Nothing to Disclose
Yevgeniy Dikhtyar (*Abstract Co-Author*) Nothing to Disclose
Boj Friedrich F. Hoppe, MD (*Abstract Co-Author*) Research Grant, Siemens AG
Judith Spiro (*Abstract Co-Author*) Nothing to Disclose
Maurice Heimer, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

While structured reporting has shown to improve report completeness and interdisciplinary communication in NSCLC staging, the majority of radiology reports are written in prose and lack TNM classification. This multi-center study harmonized imaging protocols and proposed a structured reporting framework for structured reporting of NSCLC. The aim of this study was to develop and evaluate a software based structured reporting tool with semi-automated, rule based TNM classification.

### METHODS

The Bavarian Oncology Radiology Network (BORN) has evolved as radiological platform for protocol and reporting harmonization for a variety of tumor entities including NSCLC. Six major academic centers participated. The framework was translated into an interactive image-based software for TNM based structured reporting with data warehousing capacity (mint Lesion TM, Mint Medical GmbH, Heidelberg, Germany). A rule-based algorithm was developed

to generate semi-automated TNM classification based on annotations and descriptions. The structured reporting tool was tested by 9 radiologists of five of the institutions on n = 20 representative 18F-FDG-PET/CT studies staging NSCLC. Readers received pictorial-based guidance to simulate a multidisciplinary team meeting which was used as reference to compare correctness of TNM-classification with and without assistance of the structured reporting and classification tool. Also, participants were surveyed on their experience with structured reporting and TNM classification at their respective radiology departments, as well as perceptions and expectations regarding structured reporting.

**RESULTS**

The reporting framework culminated in an image-based structured report template that provided semi-automated, rule-based TNM classification at staging. The semi-automated TNM classification was non-inferior to classification without assistance, compared to the reference. All annotation based classifications were correct with regard to input. However, incorrect annotation resulted in inaccurate classification by the algorithm. Overall, participants rated the potential impact of structured reporting and the semi-automated TNM classification tool as positive; the pre- and post-analysis demonstrates that raters improved their TNM-knowledge (p=0.039) using the algorithm, trust the semi-automated algorithm (p=0.041) and that the structured reporting tool improved M-staging (p=0.041).

**DISCUSSION**

This multi-center study facilitated multi center protocol harmonization and yielded a robust software-based structured reporting tool for NSCLC with semi-automated classification capacity. The survey results reflect an overall positive perception on structured reporting in NSCLC, promising potential for clinical translation.

## T2-QI-5 EMPOWERING CHILDREN IN MRI: USING VIRTUAL REALITY TO BUILD COMFORT AND AVOID ANESTHESIA

Anastasia Peacock (*Abstract Co-Author*) Nothing to Disclose
Hari Gopalan (*Abstract Co-Author*) Nothing to Disclose
Tania Dafer (*Abstract Co-Author*) Nothing to Disclose
Jennifer Boucher (*Abstract Co-Author*) Nothing to Disclose
Cassandra Kapoor, BSC (*Abstract Co-Author*) Nothing to Disclose
Matthew Head (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Pediatric patients under 6 years of age often require general anesthesia (GA) during their magnetic resonance imaging (MRI) exam to ensure immobility for quality diagnostic images. However, the use of GA requires the child to fast for 4-6 hours beforehand, has potential side effects including nausea or sore throat, and impacts to motor function for up to 24 hours. Furthermore, MRIs with GA require longer appointment times, increased costs, and lengthy wait times for an appointment. The aim of our program, the MR Success Clinic (MRSC), is to use a virtual reality (VR) platform to empower patients and families by increasing their knowledge of the MRI exam, instilling confidence and reducing overall anxiety related to MRI. Through VR simulation, children can experience the sight, sound and feeling of an MRI in a safe environment where they are in control.

**METHODS**

Children between 3-7 years of age referred for a GA MRI are scheduled for a MRSC visit. During the MRSC visit, children meet one on one with a pediatric MRI Technologist (MRT) and have a VR simulation with an avatar-led game that simulates an MRI exam. The VR platform is managed by the MRT who can detect real-time head movement which is used to (1) coach the child to stay still and (2) determine whether the child could undergo a successful MRI without GA. Following the MRSC visit, children are scheduled for their MRI exam within 1 week, further improving the chance of success by maintaining recency of a familiar experience.

**RESULTS**

To date, the MRSC has had 13 patients (mean age of 5.8 years +/- 2.15), with 100% completing a diagnostically acceptable MRI within 1 week. An initial proof of concept (POC) study also showed 100% success in 18 patients (mean age of 5.03 years +/- 1.28). The greatest measurable impact to the families is the amount of time spent in hospital, an average of 1.5 hours for a MRSC visit and MRI without GA compared to 5 hours for a pre-anesthesia visit and GA MRI.

**DISCUSSION**

The MRSC offers a simple and accessible solution to empower children before undergoing an MRI without GA. From the initial POC, the VR simulation was limited to children with head MRIs and the visit took place 2 hours before the non-GA MRI, but the staffing model was not sustainable. Recognizing the potential patient impact, the MRSC was established with a dedicated MRT, and the criteria was expanded to all scans with a 30-minute duration. Although the MRSC and POC have small cohorts of patients, we have heard positive patient feedback, and 100% success of patients shows this is an encouraging tool. Our future direction includes expanding criteria to oncology children with serial staging MRIs who would benefit the most. Our goal remains empowering children, normalizing the MRI experience, and placing patient-centered care at the forefront.

## T2-QI-6 LEVERAGING A QUALITY & SAFETY CONTINUOUS PROCESS IMPROVEMENT FRAMEWORK TO ADDRESS DISPARITIES IN BREAST CANCER SCREENING

Pragya Dhar, MPH (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Disparities in breast cancer disproportionately historically underserved populations and screening mammography (SM) can decrease these disparities through early detection. However, we experienced high cancellation rates (up to 52%) at two of our sites: A community health center serving predominately Hispanic/Latino women, and a mobile mammography unit serving predominantly racial/ethnic minorities and people with Limited English Proficiency. Quality Safety (QS) frameworks provide systematic approaches to identify factors influencing SM cancellations and inform scalable interventions to address them. Our purpose was to leverage a QS continuous process improvement (QS-CPI) framework to reduce SM cancellations at these sites with high cancellation rates.

### METHODS

Process mapping, driver diagram and Pareto chart with key radiology partners and patients were done to identify factors for SM cancellations and to develop a multilevel intervention. Plan, Study, Do, Act (PDSA) cycles with continuous data monitoring were used to develop and refine our multilevel intervention that included: multimedia text message (TM) reminder program in multiple languages sent 48-hrs prior to SM appointment, rideshare transportation assistance, and culturally-tailored, multilingual 1-min educational videos about annual SM. These were developed and implemented over 12 months (Jan 2023 - Jan 2024). To assess the effect of the multilevel intervention on SM cancellation rate, we collected EHR data on patient demographics and the following SM appointment metrics: appointments scheduled/completed/cancelled, and appointments confirmed via TM. We also collected data on number rideshare roundtrips, and SM educational video views. Statistical analyses were performed to assess for differences in SM cancellation rate after intervention implementation.

### RESULTS

2728 SM appointments were scheduled post-intervention, 72% (1968/2728) appointments completed, and 66% (1792/2728) received TM reminders. Overall cancellation rate was 28%, and those that confirmed SM appointment via TM had a 19% cancellation rate. 18% (488/2728) of patients cancelled or confirmed SM appointment via TM. 22% (107/488) of patients who cancelled/confirmed via TM clicked the SM educational video link, and 69% of those who clicked completely or partially watched the video. 10% of patients used the rideshare service accounting for 270 roundtrips completed for patients called back for BIRADS 0.

### DISCUSSION

Multilevel intervention designed through a QS-CPI lowered SM cancellation rate among those who confirmed their appointment via TM. This framework allows us to systematically scale the intervention to allow our radiology workforce to focus on delivering person-centered care, increase capacity by decreasing cancellations, and decrease appointment reminder administrative tasks.

## T2-QI-7 IMPLEMENTING APPROPRIATENESS CRITERIA FOR USE OF IMAGING TECHNOLOGY (PROJECT ACUITY) ON MRI LUMBAR SPINE - A SINGAPORE EXPERIENCE

Cher Heng Tan, MBBS, FRCR (*Abstract Co-Author*) Nothing to Disclose
Lai-Peng Chan, FRCR,MBBS (*Abstract Co-Author*) Nothing to Disclose

### INTRODUCTION

Acute low back pain is a leading cause of years lived with disability. Majority of uncomplicated acute low back pain is self-limiting which does not warrant imaging. However, despite current indications for judicious imaging, many patients with low back pain continue to receive routine spinal imaging (XR, CT, MR) . Inappropriate MRI lumbar spine orders result in increase healthcare costs and manpower resources. The Singapore's Ministry of Health convened a multidisciplinary workgroup to develop and incorporate a consensus MRI lumbar spine guideline into the electronic radiology order forms. We review and analyse the outpatient MRI lumbar spine orders following implementation of this guideline.

### METHODS

A list of "appropriate" and "inappropriate" indications was developed based on existing literature (ACR Appropriateness Criteria and NICE guidelines). These indications were inserted into the MRI lumbar spine request form in the electronic system. It was made mandatory for clinicians to specify on a drop-down list of indications. For those who selected an "inappropriate" indication, a free-text "pop-up" was required for clinicians to elaborate on their clinical reasoning.

### RESULTS

Baseline pre-intervention data was collected over 3 months. A total of 492 MRI lumbar spine scans were performed of which 74 (15.0%) orders were classified as "inappropriate". Post-intervention, we analysed two sets of data over 3 months in 2021 and 3 months in 2022. In 2021, there were 86 (9.1%) "inappropriate" orders out of 940 scans performed. In 2022, there were 38 (7.3%) "inappropriate" studies out of 521 studies performed. There was a statistical significant overall decrease in inappropriate scans from 15.0% pre-intervention to 7.3% post-intervention (p-value <0.001). Among all the 124 "inappropriate" studies post intervention, only 1 patient eventually required surgery. On subgroup analysis, most imaging orders came from the Orthopaedic surgery followed by internal medicine and neurology.

### DISCUSSION

Overuse of MRI in low back pain is widely prevalent. Acute and non-specific back pain has poor correlation with imaging findings. "Inappropriate" imaging result in higher costs to the patient (unnecessary surgery and invasive treatment), healthcare system (manpower, delaying other patients' appropriate scans) and society (delayed return to work, higher disability compensation). There is no clear evidence on the most effective method to reduce overuse of imaging. We believe the best form of educating clinicians will be compulsory "appropriate" or "inappropriate" indications to serve as a last line of check. Our study demonstrates the positive impact of EMR implementation of a local guideline in reducing inappropriate MRI studies for low back pain. Further studies on the impact of other behavioural nudges are recommended.

## T2-QI-9 DEVELOPMENT OF READABLE AND UNDERSTANDABLE RADIOLOGIC PATIENT EDUCATION MATERIALS USING CHATGPT-4.0 AND PATIENT AND FAMILY ADVISOR REVIEW

Jada Hislop, BA (*Abstract Co-Author*) Nothing to Disclose
DeAngelo Harris, MD,MS (*Abstract Co-Author*) Nothing to Disclose
Nadja Kadom, MD (*Abstract Co-Author*) Nothing to Disclose
Timothy Arleo, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Problem: Our Department of Radiology lacked simplified and standardized patient education materials (PEM). Available Knowledge: Health literacy influences health outcomes, with lower health literacy increasing risk of adverse outcomes by 1.5-3x. The average adult reads at an 8th-grade level in the USA, yet a recent review found PEM from radiologyinfo.org read at the 12th-grade level. Artifical intelligence (AI) platforms like ChatGPT can aid in improving readability and understandability of PEM. Additionally, there is best practice for design of PEM that facilitates understandability and actionability. Purpose: To develop new standardized PEM that meets readability levels below 12th grade and are designed to enhance understandability and actionability.

## METHODS

General: We used a multi-disciplinary team approach, including patients, and performed iterative improvements. Context: This project was conducted at an urban quaternary academic hospital radiology department lacking standardized, patient-reviewed PEM. Intervention: Documents for the following examinations were created: CT, MRI, ultrasound, fluoroscopy, and radiography. We used a tiered approach to create new documents: (1) Source existing PEM; (2) Combine multiple content sources; (3) Simplify language below the 8th grade level using chatGPT4.0; (4) Subject matter expert review; (5) Patient and family advisor (PFA) review using the Patient Educational Material Assessment Tool (PEMAT-P) survey; (6) Final edits and institution-specific branding. Study of the Intervention/Metrics: Readability and understandability/actionability were assessed with the Flesch-Kincaid readability test and the PEMAT-P, respectively. We also collected qualitative input from subject-matter experts and patients. Analysis: The average PEMAT-P scores were compared to the recommended PEMAT-P minimum score (70%).

## RESULTS

The readability of the baseline documents (step 3) was at a 7th grade reading level using the Flesch-Kincaid readability test. The final CT, MRI, and fluoroscopy documents were readable at a 7th grade reading level, while ultrasound and radiography were readable at an 8th grade level.40 PFA were invited to participate, and 26 patients responded (65% response rate). The ratings yielded an average PEMAT-P score of 94.5%, and standard deviation of 9.7%. All average PEM scores exceeded the recommended understandability criteria by PEMAT-P (>70%).

## DISCUSSION

Our process utilized AI for language simplification, subject matter expert review for accuracy, and PFA review to assure understandability/actionability from the patients' perspective. This project establishes a pipeline for future educational materials on specific imaging procedures. As a next step, we aim to integrate PEM into our system's electronic health record system and patient portal.

## T5A-QI-1 THE ROUTINE COLLECTION OF "JUST IN CASE" THYROID ASPIRATES FOR MOLECULAR TESTING AT THE TIME OF INITIAL FINE NEEDLE ASPIRATION. IMPACT ON WORKFLOW

Adrian A. Dawkins, MBBS (*Presenter*) Nothing to Disclose

### INTRODUCTION

Molecular testing has become commonplace in the evaluation of thyroid nodules. In particular, nodules assigned a Bethesda III classification on cytologic analysis may benefit from genomic sequencing to determine the likelihood of underlying malignancy. This avoids unnecessary surgical intervention for Bethesda III nodules since the majority of these nodules turn out to be benign. Genomic sequencing requires dedicated samples from the thyroid nodule and the decision to acquire these samples is typically made after the formal cytologic interpretation. This creates anxiety and inconvenience for patients who must return for a repeat biopsy on another day. At our institution, a recent change was made to routinely collect "just in case" samples from each thyroid nodule, in addition to the regular cytology samples. We evaluate the impact of this change on workflow.

### METHODS

Over a seven month period, we made the workflow change to routinely acquire two further “just in case” passes for molecular testing, at the time of initial biopsy, prior to cytologic interpretation. Thus, a minimum of four samples were acquired for each nodule, two for routine cytologic analysis and two for possible genomic sequencing. Nodules subsequently determined to be Bethesda III, were further evaluated via sending the prospectively acquired material for genomic sequencing. We retrospectively reviewed the medical record of all consecutive patients over the seven month period to gauge impact on workflow and outcome.

### RESULTS

Patient ages ranged from 24 to 88 years. 16 were male and 63 were female. Of the 69 patients, 6 had two nodules sampled, yielding total of 75 nodules. Of the 75 nodules, 23 (30.7%) were classified as TI-RADS 3, 33 (44%) TI-RADS 4 and19 (25.3%) TI-RADS 5. Of these 75 nodules, 4 (5.3%) were Bethesda I, 37 (49.3%) Bethesda II, 30 (40%) Bethesda III, 0 (0%) Bethesda IV, 1 (1.3%) Bethesda V and 3 (4%) Bethesda VI. Of the 30 Bethesda III, 18 (60%) were deemed benign-4% risk by genomic testing. 9 (30%) were deemed with 50% or 75% suspicious for malignancy. Two (6.7%) were deemed to provide insufficient material for analysis and one (3.3%) analysis was canceled due to nonpayment. There were no patient complications.

### DISCUSSION

40% of FNA samples within our practice were determine to be Bethesda III. This would have resulted in a fairly high call-back rate for repeat biopsy for genomic testing, with the alternative being unnecessary surgery for the majority of these patients. While two additional passes were obtained for genomic testing, there were no complications at the time of the procedure or subsequently. Thus, we find the routine collecting of samples for possible genomic testing at the time of initial biopsy to be worthwhile and efficient. It is also well-tolerated and is more convenient for patients.

## T5A-QI-2 LONGITUDINAL PATIENT RECORD - A NEW CONCEPT FOR RADIOLOGY REPORTING

Mark Kontak (*Abstract Co-Author*) Consultant, VisionSR, Inc
Ciprian Dorin Craciun (*Abstract Co-Author*) Consultant, VisionSR, Inc
Andreea Pitici (*Abstract Co-Author*) Consultant, VisionSR, Inc
Adrian Prisacariu (*Abstract Co-Author*) Employee, Patrisoft Outsourcing Srl
Cristian Popovici (*Abstract Co-Author*) Software engineer, Patrisoft Outsourcing SRL
David J. Vining, MD (*Presenter*) Royalties, Bracco Group;CEO, VisionSR, Inc;Stockholder, VisionSR, Inc

### INTRODUCTION

Traditional radiology practice produces an independent narrative report for each exam that is performed. Information continuity across exams exists only when a radiologist explicitly dictates a comparison of prior findings to current observations. When patients have large numbers of prior studies, information discontinuity often exists. A longitudinal patient record combines data from various sources to produce a comprehensive medical history, but implementing this concept in radiology is challenging due to the pervasive nature of unstructured reports. A solution involves the use of interactive multimedia reporting (IMR) with discrete data elements to assimilate data from prior exams into a single integrated report. The IMR longitudinal record efficiently communicates a patient’s health status via graphs, tables, and hyperlinked content.

### METHODS

We developed an IMR solution that records radiological images and voice descriptions of image findings, tags the findings with metadata using natural language processing referenced to an ontology describing each anatomical location and the diagnosis/observation, and assembles a longitudinal patient record with connected information linked in timelines. The system presents integrated multidisciplinary information over a patient’s lifetime, and the data

can be filtered to show information for a particular anatomy, disease, and/or time interval. Data can be added asynchronously, and warnings are sounded when unrelated data is linked to a finding. Furthermore, patient cohorts can be created with these longitudinal patient records to support clinical trials, generate real-world evidence for regulatory decision-making, and calculate medical outcomes.

**RESULTS**

The system has been used to date to create 3,579 longitudinal patient records containing 22,544 timelines comprising 68,804 items of connected information. Each timeline represents a finding of connected items. The system is currently in use to support 51 clinical trials.

**DISCUSSION**

A longitudinal patient record built on IMR principles represents an evolution in radiology reporting. Rather than creating independent reports, data integrated into a single interactive multimedia report can efficiently communicate a patient's complete medical history and health status. The visual presentation of data in graphs, tables and hyperlinked content provides physicians with efficient access to information at the point of care, facilitates information exchange between medical specialists, mitigates potential medical record errors, and supports the derivation of medical outcomes.

## T5A-QI-3 RETROSPECTIVE WRONG-PATIENT ERROR ANALYSIS USING POINT-OF-CARE VISIBLE LIGHT IMAGING

Carson A. Wick, PhD (*Abstract Co-Author*) Employee, CameRad Technologies, LLC ;Co-founder, CameRad Technologies, LLC;Officer, CameRad Technologies, LLC
Nabile M. Safdar, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Srini Tridandapani, MD, PhD (*Presenter*) Co-founder, Camerad Technologies, LLC;Spouse, Co-founder, Camerad Technologies, LLC;Officer, Camerad Technologies, LLC;Spouse, Officer, Camerad Technologies, LLC

**INTRODUCTION**

Errors in radiology imaging are often corrected without adequate reporting resulting in the nature of the error being lost for downstream users. This missing information makes it difficult, or even impossible, for the user to determine the type of error, e.g., wrong-patient, wrong-site, wrong-exam-type, laterality, and positioning errors. Point-of-care (POC) patient visible light (VL) images can be used to efficiently classify and confirm imaging errors. This work focuses specifically on confirming and quantifying wrong-patient errors.

**METHODS**

An existing deployment of a POC patient VL imaging system on portable radiography machines at a large academic hospital was used to automatically obtain patient VL images. These VL images were automatically paired to the corresponding radiograph images in PACS as a new DICOM series. Retrospective querying of PACS using the logs of the VL imaging system was performed for studies with VL images to find radiology imaging errors for a 30-day period. PACS was queried for each radiograph image with a corresponding VL image, according to the VL imaging system logs, to find images that were no longer present in the hospital PACS, indicating an error.For errors found this way, archived VL images and patient information were compared against that patient's data that was still present in PACS. The patient's other radiograph studies still present in PACS also contain VL images allowing for a visual comparison against the VL image from the error study. If the VL images were of different patients, a wrong-patient error had occurred.

**RESULTS**

Over a 30-day period, 1781 portable radiography studies with POC VL images were acquired. Of these, 12 (0.7%) were no longer present in PACS under the same Accession Number and Study/Series/SOPInstanceUIDs (unique identifiers). The patient VL images for these 12 studies were manually reviewed and compared against other VL images of that patient still in PACS. Within these 12 studies, 3 wrong-patient errors were confirmed as indicated by non-matching patient VL images. This results in an estimated wrong-patient error rate of 1 in 594.

**DISCUSSION**

An extensible method for detecting errors in radiology imaging by quantifying discrepancies in images in PACS over time was developed. Results of this method, in conjunction with POC VL images, were used to investigate and quantify wrong-patient errors. The wrong-patient error rate found was higher than previously assumed (~1/600 vs 1/4000). These techniques will be used to provide insight into which radiology areas to direct improvement measures.

## T5A-QI-4 FROM THE SCANNER TO THE READING ROOM: A NOVEL SYSTEM THAT AUTO-POPULATES ACCURATE MUSCULOSKELETAL RADIOGRAPHIC VIEWS IN REPORT TEMPLATES

Peter H. Pham, MD (*Abstract Co-Author*) Nothing to Disclose
Jeremy Johnson, MD (*Abstract Co-Author*) Nothing to Disclose
Christopher Sahagian (*Presenter*) Nothing to Disclose

**INTRODUCTION**

The number of radiographic views documented in radiology reports are used by medical billing coders to create reimbursement claims. Given large volume of musculoskeletal (MSK) radiographs, and wide breadth of views we obtain to evaluate MSK patients, it may be difficult for radiologists to accurately report views. This is especially true for the many views for the shoulder. This QI project seeks to outline a potential solution: designing software within the electronic medical records (EMR) that accurately auto-populates radiographic views directly into report templates. The goal is to improve workflow efficiency, enhance report accuracy, and ensure appropriate reimbursement of radiologists' work.

**METHODS**

We planned to promote efficiency and fair reimbursement of MSK radiographic reads. We designed and integrated a multiple-choice questionnaire into the EMR system, for technologists to mark which views they obtained after scanning patients. We ensured proper training for all participants. Data entered by technologists was linked to our dictation software via a ubiquitous radiology information system and were programmed to auto-populate special fields within the report template. We studied efficiency by surveying average time spent manually reporting MSK views. We gauged awareness of how reimbursement claims are generated and surveyed intended use of this workflow. We also studied report accuracy by counting shoulder radiograph reports that incorrectly reported technique views, before (March 2023) and after (March 2024) implementation of this project. We then acted upon our data to refine and expand the workflow to include knees, spine, and arms.

**RESULTS**

At our institution, radiologists spend an average of 7 seconds manually reporting MSK radiographic views for each report. Thus, if an average MSK radiologist reads about 100 radiographs per 8-hour workday, and works 230 days per year, using this semi-automated workflow could save approximately 5.6 workdays per year. When gauging awareness of how reimbursement of MSK radiographs is determined by coders, only 30% of radiologists knew it was pulled from the views listed in reports. After training participants, all radiologists and technologists expressed the intent to utilize it daily. 4% of sampled shoulder radiograph reports in March 2023 reported less views than actual number of views obtained; samples from March 2024 had no such errors.

### DISCUSSION

Employing this semi-automated workflow could save radiologists substantial time spent drafting reports for MSK radiographs every year, effectively improving productivity, while also enhancing accuracy, which ensures correct reimbursement. As a single-center project, limitations include its probable lack of universal replicability or feasibility. Additionally, our time analyses exclude the potential added time of inputting data by the technologists.

## T5A-QI-5 CLOSING THE GAP: TAKING CT IMAGING ON THE ROAD TO RURAL COMMUNITIES

Oliver Mulcock, BSc (*Presenter*) Nothing to Disclose

### INTRODUCTION

Our Local Health District is geographically a similarly size to Germany, but with a population of around 284,000. In such a rural area, access to a CT Scanner often means extensive travel (400km) to bigger cities.The use of telehealth and video consultations were accelerated during the recent COVID-19 pandemic, pathology can be collected at point of care and tested off site, however radiology has long been a sticking point of diagnostics where travel to a suitable facility is essential.Our Mobile CT Service has allowed us to close this gap with access to diagnostic imaging which many of us in metro areas take for granted these days. Instead of asking many patients to travel, we are now taking the scanner closer to them.Globally, Mobile CT is not a new concept, however, more often than not, mobile scanners are used to add capacity to existing facilities rather than being the sole service in a rural acute care setting.

### METHODS

The idea of taking CT Scanner on the road in the back of truck originally came from one of our Radiologists back in 2010, and we spent 10 years formulating the business case, sourcing funding and developing the project.We reviewed health facilities within our district located with good road access, appropriate facilities, staff support and located where residents of nearby smaller towns could access imaging without significant travel.We settled on 3 main locations to travel between and used data from the Ministry of Health and local health practitioners to estimate the demand for service.We spent a further 2 years designing our mobile scannerand having it built into a rigid framed truck.

### RESULTS

We scanned our first patient in May 2023, and in our first 11 months of operation, we have scanned 1,420 patients over our 3 sites, (1226 Outpatients, 81 Inpatients and 113 Emergency).From outpatient scans alone, we have saved 713,000 kilometres of patient travel, which leads to AU$285,000 of cost savings from the statewide Isolated Patients Travel and Accommodation Scheme.In addition, we are also able to avoid inter-hospital patient transfers in an acute setting where a CT scan can be the difference between surgical management in a larger hospital rather than medical management in the community.We are also ensuring Emergency Department patients are diagnosed promptly and, where required, transferred to suitable tertiary centre for ultimate end point care.

### DISCUSSION

Taking CT Scanning to the rural communities of our local health district has transformed the care they are able to receive in a primary setting, enabling faster diagnostics and earlier treatment.The benefits in the acute care setting are limited by the fact we are a travelling service an only in each location for 1 week at a time, however the benefits for chronic and non-urgent patients is much more permanent as they can be confident of access to a CT appointment within 3 weeks, local to home and any support they may require.

## T5A-QI-7 FROM IMAGING FINDINGS TO FRACTURE LIAISON SERVICE: ARE RADIOLOGY REPORTS FOR VERTEBRAL FRAGILITY FRACTURES ACTED UPON?

Christopher Watura, FRCR, MBChB (*Abstract Co-Author*) Nothing to Disclose
Henry Conchie, MBChB, BSc (*Presenter*) Nothing to Disclose

### INTRODUCTION

Vertebral Fragility Fractures (VFFs) are common yet increasingly under-diagnosed on imaging. This is a missed opportunity to refer patients to the Fracture Liaison Service (FLS) for assessment and prevention of further fractures, at the detriment of patient morbidity and cost to the health service. Patients with incidental vertebral fractures have a 41% risk of developing a further fracture in the subsequent year, and severe vertebral fracture strongly predicts subsequent hip fracture. UK National guidance is in place, which advocates the use of VFF Alert systems for ensuring timely signposting of VFF cases to the FLS.We assess the imaging referral pathway for VFFs to a FLS at our tertiary level institution, with the aim to optimise the radiology alert system for VFFs.

### METHODS

To evaluate the extent of the problem, all radiology reports completed during a three-month period were retrieved from the picture archiving system (PACS) for CT scans which included terms associated with VFFs for patient aged over 50 years. The amount of VFF Alerts were recorded, and those cases were then investigated by the Rheumatology team to evaluate the FLS referral rate. Institutional changes were subsequently made following our findings, and a second analysis performed.

### RESULTS

In the first analysis, only 7% (13/175) of the VFF reports included the VFF Alerts. Of the VFF Alert cases, none were referred to the FLS. This prompted the employment of a new dedicated FLS nurse to ensure the safety of the referral pathway, whose role involves monitoring of the Alert email inbox notifications. Additionally a new Rheumatology Consultant was employed with a designated managerial role within the FLS service. Within the Radiology Department, we increased awareness amongst consultants and trainees regarding the VFF Alert and its importance through departmental meetings, emails and mobile phone group messages.In the repeat analysis, again only 7% (11/162) included of VFF reports included the VFF Alert. However, all cases with the Alert had been appropriately acted upon by the newly appointed FLS nurse.

### DISCUSSION

It is incumbent on the full multidisciplinary team to engage with an electronic alert system in order for it to be 'fail-safe'. Significant shortcomings were detected in the FLS system on the first study cycle, and there is still work to be done to increase non-specialist radiologists' and referrers' awareness regarding the importance of the detection, reporting and appropriate further investigation and treatment of VFFs. Automated email alert systems can serve as robust pathway for referring VFFs from radiology to the FLS when the Alerts are correctly recorded and the generated referrals are appropriately monitored.

## T5A-QI-8 KANGAROO MOTHER CARE MRI: A NOVEL APPROACH TO HIGH QUALITY IMAGING IN NEUROPEDIATRICS

Elida Vazquez, MD (*Abstract Co-Author*) Nothing to Disclose
Ignacio Delgado, MD (*Abstract Co-Author*) Nothing to Disclose

German Ramos Rubio, MD (*Abstract Co-Author*) Nothing to Disclose
Ana Coma, MD (*Abstract Co-Author*) Nothing to Disclose
Angel Sanchez-Montanez, MD (*Presenter*) Nothing to Disclose

## INTRODUCTION

It is widely acknowledged that studying infants via MRI poses challenges. Many infants may experience discomfort, exhibit movement, and require sedation, which may not always be available or even possible. Consequently, alternative techniques have been sought to enhance comfort and minimize motion artifacts. Over the past 15 years, our efforts have been focused on improving imaging quality in neuropediatrics. A recent innovation from our group involves adapting the method pioneered by Rey and Martinez in 1983 for use in pediatric neuroradiology.

## METHODS

By securing the infant within the mother's embrace and implementing skin-to-skin contact on the mother's bare chest, we alleviate the infant's stress and reduce motion artifacts. This approach enhances image fidelity and provides superior spatial and temporal resolution for both brain and spine studies. Employing body coils to envelop both mother and infant during breastfeeding ensures a tranquil and relaxed environment. This method offers an easy, straightforward, cost-effective, and replicable means of achieving the necessary goals in pediatric radiology.

## RESULTS

In recent years, we have explored the implementation of Kangaroo mother care (KMC) technique. The idea first arose during a spinal cord MRI study involving a non-sedatable infant, following exhaustive attempts and tips and tricks to mitigate motion. Technological strategies included PROPELLER/BLADE sequences and single-section T2-weighted sequences like HASTE (Half fourier Single-shot Turbo spin-Echo), alongside new sequences designed for sound reduction. Classical techniques involving the collaborative efforts of our technicians and nurses proved invaluable in securing the child, providing acoustic protection, and fostering a serene environment. Our initial endeavor with KMC proved successful, prompting further application in brain and spinal MRI for non-sedatable patients. Feedback from both mothers and our medical team has been overwhelmingly positive. The team of technicians and nurses also appreciate it, and we believe the child even more so.

## DISCUSSION

Kangaroo mother care MRI emerges as a valuable alternative when sedation is either impractical or contraindicated due to airway concerns or inadequate fasting time for anesthesia. However, its effectiveness is limited in non-breastfed children. Our experience indicates that images obtained using this technique are sufficient for accurate diagnosis, obviating the need for repeat studies. We urge other centers to adopt and promote this simple method, feasible in hospitals worldwide, irrespective of resource constraints.

## T5B-QI-2 REDUCING WASTE OF IODINATED CONTRAST AND PLASTIC IN A MULTI-SITE ACADEMIC CT PRACTICE

Kim Pongsatianwong, RDMS, RVT (*Abstract Co-Author*) Nothing to Disclose
Jessica M. Forsythe, MBA, RT (*Abstract Co-Author*) Nothing to Disclose
Kelly Albury, BA (*Abstract Co-Author*) Nothing to Disclose
Xunbo Xu, ARRT (*Abstract Co-Author*) Nothing to Disclose
Lakshmi Ananthakrishnan, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Iodine is a nonrenewable resource that is expensive to mine and process. Iodinated contrast media (ICM) used in CT is supplied in single-use vials of varying sizes and 500-mL multi-use vials (4-6 patients per vial, expire after 8 hours). Strategies to decrease ICM and plastic waste in CT include using multi-use vials (500 mL, 4-6 patients per vial, expire after 8 hours) and syringeless injectors (decrease plastic consumables compared to dual headed syringe injectors, and may decrease ICM waste). In addition, ICM recycling programs are now available; unused ICM is collected and sent back to the manufacturer for recycling, with a 90% reported iodine harvest rate. The global ICM shortage of 2022 forced us to assess ICM waste during routine practice. The goal was to decrease ICM waste in CT while implementing environmentally conscious processes, including reducing plastic waste and recycling ICM waste.

### METHODS

This project was carried out at a large academic center that provides hospital- and outpatient-based CT services. Prior to 2022, single-use 100-mL vials were used with 1-2 vials opened per patient; unused ICM was discarded. Dual-headed syringe injectors were used, requiring two large syringes and plastic tubing per patient. Three interventions were performed. Two targeted waste reduction; quantity of ICM opened and given to the patient was tracked for one week prior to and one week after the intervention. Differences in ICM waste and estimated cost were recorded. The third intervention targeted ICM recycling. 1) Outpatient: multi-use vials were used with a dual-headed syringe injector. 2) Hospital: multi-use vials were used with syringeless injectors. In addition to tracking ICM waste, the differences in cost of plastic tubing was estimated. 3) ICM recycling containers were placed in two CT suites at one busy outpatient site. Amount of ICM collected and total quantity of ICM supplied to the CT department during a 10-month time period were recorded.

### RESULTS

1) Outpatient: Adoption of multi-use 500 mL vials reduced ICM waste by 12.6 mL per injection, projected to yield $9,270 cost savings over 6 months. 2) Hospital: Interventions decreased the amount of disposable plastic tubing used, projected at $29,850 cost savings over 6 months. Unexpectedly, a marked increase in ICM waste was noted, estimated at 68.8 mL ICM per patient. 3) Over the course of 10 months, the recycling program collected 19.5 liters of ICM, or 2.8% of all ICM pulled from that outpatient location.

### DISCUSSION

Multi-use vials led to a decrease in ICM waste in the outpatient setting, but this same intervention increased ICM waste in the hospital. Suspected causes include low utilization of certain scanners, unpredictable scan volume, and the vial's 8-hour expiration. Future work will target these areas. Syringeless injectors may decrease plastic waste, and ICM may be recycled via manufacturer-led programs.

## T5B-QI-3 SAVING LIVES: INCREASING CAPACITY IN BREAST IMAGING

Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc;Stock options, CureMetrix, Inc

### INTRODUCTION

Breast cancer is the most common malignancy in American women. The most common way breast cancer is detected is by screening mammograms. Screening mammograms are indicated for average-risk asymptomatic women, starting at age 40 and every year thereafter.

### METHODS

Problem statement: Low capacity in the breast imaging center leads to backlogs and patients either not undergoing recommended imaging or going to other facilities for their care. Numerous analyses were performed, including time observations, reviewing data from the RIS (radiology information system), and reviewing PACS (picture achieving and communication systems) time stamps. The observed data was reflective of actual room utilization and statistically significantly different from data extracted from RIS and PACS. A small group was convened to analyze the data, and a series of PDSA cycles were performed. Observation data showed that the median time of patient in the room to out of the room during a screening mammogram was 10 minutes. A modeling was performed by analyzing the templates showing an increase in capacity with various adjustments, which included standardizing allowing patients to use changing rooms (previously closed due to COVID and leading to procedure room underutilization) rather than changing in

examination rooms. We also standardized technologists' procedures, such as the start and end times of exams in EPIC. The screening templates were adjusted to q15-minute intervals from the current 20 minutes. Tests after a week showed that we failed, and capacity decreased rather than increased. This failing (not a failure) motivated a second template review, adjustments, and data analysis round. After an additional observation period, further analysis showed increased capacity!

**RESULTS**

We compared historical data for screening mammograms to current data for a matched period. This is done because we had shown fluctuation in visits over the year (surge during October breast cancer awareness month or lows during summer vacations). Comparing January to June of 2022 to 2023 showed a net increase of 1441 screening studies, representing a 15.2% increase (we had targeted a 10% increase in volume). Net increase and percent change were recorded. This increase translates to an estimated $400,252.16 to $1,233,207.80 of additional revenue. Most importantly, the changes implemented saved lives, which is priceless. The patient satisfaction scores were unchanged from before and after changes were implemented.

**DISCUSSION**

This is an ongoing quality improvement project. After further data analysis, a second decrease in the screening time to 12 minutes (current 15) will be undertaken to increase capacity further. Additional attention is being paid to the increase in diagnostic volume, with interventions being planned. Finally, capacity will be added by offering evening and weekend screening appointments.

## T5B-QI-4 ENHANCING PATIENT SAFETY IN CT EXAMINATIONS: ESTABLISHMENT OF A STANDARDIZED MANUAL TO REDUCE HIGH-VOLUME CONTRAST EXTRAVASATIONS AND PREVENT AIR EMBOLISMS

Choong Beom Seo, RT, BS (*Abstract Co-Author*) Nothing to Disclose
Yong Hwan Chung, RT (*Abstract Co-Author*) Nothing to Disclose
Chang Min Dae (*Abstract Co-Author*) Nothing to Disclose
BYOUNGJUN KIM, BSc (*Presenter*) Nothing to Disclose

**INTRODUCTION**

In 2021, a total of 144,602 contrast-enhanced examinations were conducted at our institution, among which 66 incidents of extravasation occurred. Of these, 21 cases involved large volumes of over 30 CC, accounting for a rate of 31%. In 2022, out of 152,136 examinations, 27 large-volume incidents of more than 30 CC were recorded, increasing the rate to 41%. Additionally, there were 2 cases of significant air embolism in 2022. Currently, the Extravasation Detection Accessory (EDA) is only attached during bolus tracking exams, while timed exams are conducted through manual palpation and visual inspection by the operator. Therefore, we aim to develop and implement a standard CT examination protocol that not only minimizes the risk of large-volume extravasation during contrast administration but also fundamentally prevents air embolism, thereby enhancing patient safety.

**METHODS**

From September 2023 to February 2024, we evaluated 80,745 patients who underwent contrast-enhanced CT examinations at our institution. To reduce large-volume extravasation the Nemoto Extravasation Sensor was attached to all eligible patients, and a Patient Safety Process was developed to prevent air embolism and evaluate its adherence rate. To improve the application rate of the patches, we prepared necessary items for better attachment of the extravasation sensor in the examination room and conducted training on the effectiveness and proper use of the EDA for the operators. In order to prevent air embolism, we changed the settings of the Auto Injector air check and improved the environment to facilitate the verification of the remaining contrast volume. Periodically, we conducted training on the causes and risks of extravasation and air embolism, and shared actual case studies with the staff.

**RESULTS**

During the measurement period, the application rate to patients of the Extravasation Sensor Patch increased from 32% to 95%. There were a total of 70 incidents of extravasation, of which 18 were large-volume incidents involving more than 30 CC, decreasing from 40.9% to 25.7%, a reduction of 15.2%. There were no occurrences of significant air embolism during the measurement period.

**DISCUSSION**

By attaching the Extravasation Sensor to all patients using contrast agents and implementing the Patient Safety Process, we can prevent and reduce patient safety incidents during CT examinations. Continued education and activities can also contribute to an increase in medical staff confidence.

## T5B-QI-5 THE IMPACT OF SOCIAL DETERMINANTS OF HEALTH ON FOLLOW-UP OF ACTIONABLE INCIDENTAL FINDINGS

Susan K. Hobbs, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Akshya Gupta, MD (*Abstract Co-Author*) Nothing to Disclose
Kristen Hans (*Abstract Co-Author*) Nothing to Disclose
Arjun Byju, MD (*Abstract Co-Author*) Nothing to Disclose
Ben C. Wandtke, MD, MS (*Abstract Co-Author*) Clinical Advisory Board, CAK Tech, Inc
Timothy M. Baran, PhD (*Abstract Co-Author*) Nothing to Disclose
Aniruddh Mandalapu (*Abstract Co-Author*) Nothing to Disclose
Denes Szekeres, BS (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Multistage recommendation-tracking systems improve patient adherence to imaging follow-up recommendations for actionable incidental findings. Our institution implemented such a system with escalating reminders to the ordering provider via the electronic health record, mail, and by phone. While there were improvements in follow-up across the study population, it is unclear if these are equitably distributed across socioeconomic groups. The present study reviews data from our institutions' recommendation-tracking system to determine how different social determinants of health impact completion of recommended follow-up imaging.

**METHODS**

A post-hoc analysis of our recommendation-tracking system dataset was analyzed including data on insurance, area deprivation index (ADI), race and ethnicity, use of language interpretation. The outcome of imaging examination completion after notification was compared between demographic variables using McNemar's test, with prediction of examination completion analyzed with univariate and multivariable logistic regression.

**RESULTS**

The study cohort included 1336 patients with associated imaging follow-up recommendations. The recommendation-tracking system increased imaging examination completion from 46.8% to 72.8% in patients with Medicare/Medicaid and 46.3% to 68.3% in all other forms of payment. Imaging follow-up improved from 43.5% to 63.0% in Black patients and from 47.3% to 72.3% in White patients. Univariate analysis showed higher odds of imaging completion for patients with Medicare/Medicaid versus other forms of payment (1.24, 95%CI [0.95, 1.63], p = 0.11) and significantly lower odds for

patients identifying as Black versus White (0.65, 95%CI [ 0.43, 0.99], p = 0.04). There were no significant differences by ADI, modality, imaging site, ethnicity, or use of language interpretation. However, when including ADI in multivariable regression, there were no longer any significant differences by race (0.62, 95%CI [0.34, 1.13], p = 0.12) but instead by insurance (1.45 95%CI [1.03, 2.04], p = 0.03).

**DISCUSSION**

The data suggests that insurance status plays a key role in exam completion when follow-up recommendations are made. This may reflect differences in deductible cost for patients on Medicare/Medicaid compared to other forms of payment. On univariate analysis, patients identifying as Black were less likely to complete follow-up imaging, potentially introducing a disparity by implementation of multi-stage tracking. However, incorporating ADI, this difference was no longer statistically significant. Similarly, ethnicity and language barriers did not appear to contribute to inequitable examination completion. Additional research to understand barriers to completing follow-up imaging should be explored to better suit the needs of the community.

## T5B-QI-6 IMPACT OF HIGH RELIABILITY ORGANIZATION TRAINING ON QUANTITY AND EFFECTIVENESS OF RISK REPORTING IN RADIOLOGY AT A LARGE ACADEMIC CENTER

Crystal Blank (*Abstract Co-Author*) Nothing to Disclose
Prachi P. Agarwal, MD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth Lee, MD (*Abstract Co-Author*) Nothing to Disclose
Glenn E. Houck JR, MS, ARRT (*Abstract Co-Author*) Nothing to Disclose
Ashok Srinivasan, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Electronic reporting of quality and safety concerns allows for appropriate event documentation, evaluation of contributing factors and creation of action plan for problem solving. Our organization transitioned to a high reliability organization (HRO) in 2019 including an extensive and focused employee training to emphasize basic principles reiterating the non-punitive nature of reporting quality/safety concerns, which rely on identifying system issues rather than individual level factors. However, when training ended, there were also concerns about a potential increase in frivolous and non-actionable risk reports. The aim of this study was to therefore study the long term impact of HRO training on the quantity of risk reports and effectiveness when pertaining to Radiology.

**METHODS**

In this study, we analyzed reporting of all risk events pertaining to Radiology, pre and post HRO training, with the goal of identifying trends after implementation. The following metrics were measured before and after HRO training: - overall volume of risk reports (events), number of events categorized as >E3 (defined as more than temporary harm-physical), number of reports filed by different employee types number of action items (including local reviews, apparent cause analysis, multidisciplinary reviews). The data was analyzed from 1/1/2018 till 12/31/2023. Since the Program Manager position for Radiology Safety commenced only in 2021, accurate data for action items was available only from 2022-2024.

**RESULTS**

The overall number of events and those with harm >E3 from 2018-2023 were {1555, 1764, 1580, 1801, 1988 and 2373} and {157, 259, 188, 228, 227 and 341} respectively. Number of action items in 2022 and 2023 were 6 and 28 respectively. Analysis of employee types filing risk reports showed a steady increase in the physician (including faculty and trainees) category with no significant trends in other employee categories (technologist, nursing staff, physician assistants, manager/supervisor/administrative personnel).

**DISCUSSION**

3 years post HRO training, there was an increase in overall number of events and those with significant harm. While the data for action items was limited to 2 years only, there was a year over year increase in this number. We also found that the physician group, which was historically not associated with risk report filing, showed a year over year increase in number of reports filed. Thus, HRO training is associated with increased reporting of quality safety events that also result in more action items, and probably increased awareness amongst physicians about the process. This can help institutions identify system related issues and empower more employees to express their concerns.

## T5B-QI-7 ENHANCING CONVENTIONAL BIOPSIES: ULTRASOUND-GUIDED PERCUTANEOUS BONE MARROW BIOPSY AND ASPIRATION

Caroline Cushman (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Percutaneous bone marrow aspiration and biopsy play a crucial role in the histopathological and microbiological assessment of various hematological disorders. Traditionally, these procedures have relied on either open surgical techniques or x-ray guided methods, which carry risks such as radiation exposure and invasiveness. However, ultrasound guidance offers a radiation-free alternative with rapid image acquisition. This quality improvement study proposes a hybrid ultrasound-guided technique integrating landmark and image-guided methods, along with interdisciplinary efforts to enhance patient safety and biopsy sample integrity.

**METHODS**

This quality improvement study was conducted in an urban, academic hospital. Prior to this initiative, bone marrow biopsies at our institution were guided by either CT imaging or fluoroscopy. With the patient-centered goal of refining biopsy accuracy and reducing risk, we implemented ultrasound guidance due to its significant benefits, including the elimination of ionizing radiation, rapid image acquisition, detailed structural and vascular analysis, and bedside convenience.We employed a novel ultrasound-guided approach designed for lesions with osteolysis and extensive cortical disruption. This technique involved administering local anesthetic and moderate IV conscious sedation, and ultrasound-guided access with the patient placed prone and a 10-gauge needle advanced to the iliac bone of the pelvis.Our methodology included direct pathologist involvement at the bedside to verify sample accuracy, which helped to address possible repeat sample collection and need for reintervention. Success metrics measured included (1) patient satisfaction, (2) precision of sample acquisition, and (3) technical procedural success, to best gauge the intervention's impact on clinical outcomes and patient experience.

**RESULTS**

Since its implementation, our technique has been utilized in a sample of n=1,246 patients, achieving a 100% accuracy rate in sample collection without any significant adverse events or need for repeated biopsies due to inadequate sampling. Moreover, there have been no reported patient complaints; instead, we have received positive feedback.

**DISCUSSION**

Ultrasound-guided percutaneous bone marrow biopsy and aspiration presents as a promising technique, providing several benefits compared to traditional approaches. This innovation has proven effective in our institution and holds promise for wider adoption in clinical settings focused on enhancing diagnostic accuracy, technique safety, and patient experience.

## T5B-QI-8 UTILIZATION OF QA NOTES TO IMPROVE X-RAY IMAGE QUALITY IN THE DIGITAL AGE

Brian D. Gale, MD, MBA (*Abstract Co-Author*) Nothing to Disclose
Mina Al-Ani, MBBCh (*Abstract Co-Author*) Nothing to Disclose
Aala Saadallah, MBChB (*Abstract Co-Author*) Nothing to Disclose
Deborah L. Reede, MD (*Abstract Co-Author*) Nothing to Disclose
Adil N. Afridi, MD (*Abstract Co-Author*) Nothing to Disclose
Zenab Jamil, BA (*Presenter*) Nothing to Disclose

### INTRODUCTION

Currently, the assessment of radiological image quality of digital radiographs is performed by radiology technicians and physicians reading the image. Quality Assurance (QA) notes in the Radiology Information System (RIS) enable radiologists to report image artifacts, poor technique, missing images, and defective equipment. This can improve image quality, diagnostic accuracy, and communication between radiologists and technicians. This project aimed to institute department-wide QA note training sessions in an academic radiology department to encourage radiologists to use QA notes, identify preventable imaging issues, and establish short-term and long-term solutions to improve image quality.

### METHODS

We structured the project using the PDSA model and evaluated QA notes from January-June 2023. Radiology attendings and residents documented quality or workflow problems in the RIS QA system. Radiology house staff dictate preliminary reports that were subsequently signed off by faculty. Radiologists' reporting rates were quantified. House staff and faculty reports were compared. If the resident did not report an issue that the attending identified, it was labeled a "miss."A PowerPoint presentation was developed to teach radiologists how to log QA notes and identify common QA issues and their impact on image quality and patient safety. This tutorial included long-term solutions to rectify common issues. All residents took a pre- and post-training quiz; scores were analyzed using paired T-Test. Post-training analysis of QA notes from September 2023-February 2024 was performed to evaluate changes in the number/type of imaging problems reported and conduct a root cause analysis. Outcomes were measured using the frequency of QA notes, categorized by issues, and analyzed using graphical analysis. During the second phase of the study, a teaching module was developed for radiology technicians. Post-training analysis was performed to re-evaluate QA issue frequency.

### RESULTS

The average resident score rose significantly between the pre-test and post-test ($p= 0.05$). Compared to the January-June analysis, the September-February analysis demonstrated a significant increase in reported QA issues. Post-training analysis showed the total number of QA notes entered per month by radiologists increased by 53.4% following the didactic session. Resident failure to report rates dropped from 30% to 19% after the didactic session demonstrating that residents were more likely to report common QA issues when reading exams.

### DISCUSSION

Educating radiologists about the RIS QA note system resulted in an overall increase in the reporting rate, which can improve image quality of digital radiographic images and enhance the accuracy of radiological reports. Study limitations include a small data sample restricted to plain film radiography.

## W2-QI-1 TELEMEDICINE RADIOLOGY PROVIDER CONSULTATION SERVICE POST-ACQUISITION OF OUTPATIENT SPINE IMAGING: A PILOT STUDY

Todd L. Siegal, MD (*Abstract Co-Author*) Nothing to Disclose
Khuram S. Kazmi, MD (*Abstract Co-Author*) Nothing to Disclose
Manisha Koneru (*Abstract Co-Author*) Nothing to Disclose
Hamza A. Shaikh, MD (*Abstract Co-Author*) Nothing to Disclose
Lucinda Lau, BS (*Presenter*) Nothing to Disclose

### INTRODUCTION

As the use of electronic medical records (EMR) increases, outpatient imaging results are now readily available to patients, often before their follow-up with the referring provider. The language within reports may cause confusion and stress from otherwise clinically insignificant findings. As patient understanding is paramount, radiology consultation services are a potential solution to allow patients to clarify questions regarding their imaging report. Still, little is known about the scale of potential benefit, optimal format, and barriers to implementing this service. The purpose of this pilot study is to explore how consultation services may enhance patient comprehension of their imaging, enabling them to make informed healthcare decisions.

### METHODS

Adult patients scheduled for a magnetic resonance imaging study of the lumbar spine with the complaint of “back pain” and associated diagnoses will be extracted and contacted via EMR messaging service prior to their scan and offered the opportunity to receive a free 30-minute virtual consultation with a neuroradiologist. A survey will be administered prior to follow-up with the referring physician. The survey assessed points including: patient understanding of their imaging, satisfaction with the service, preference for visit duration, and amount willing to pay for the service. Descriptive analyses were used to summarize survey responses.

### RESULTS

Of 7 participants, median age was 59 years (IQR 41-76), and 85.7% were female. 42.9% of patients listed bachelor’s degree as their highest level of education. Most were referred by pain management (42.9%). On a scale of 1 (none) to 5 (high), median rating of patient understanding of the imaging pre-consultation was 3 (IQR 2-4) and post-consultation was 5 (IQR 5-5). All agreed that the service was helpful and would opt for a similar service in the future. Majority had no preference whether on virtual or in-person meetings (57.1%). Patients noted that the highest they would pay was $40-$60 (28.6%) or $80-100 (28.6%), with a high degree of variation in reported preferences. Overall, all patients reported the highest satisfaction score with this experience.

### DISCUSSION

Use of radiology consultation services enhance health competency, allowing for better patient satisfaction and care. The virtual setting allows for greater accessibility and is generally accepted by most patients. Furthermore, there is potential to enact this as a billable telemedicine service, as evident through patient willingness to pay for the service. This pilot study is limited by small sample size and extensive process of patient enrollment and scheduling through EMR review. Automation of scheduling through EMR integration to select pre-set time slots can optimize the workflow. Future studies with a larger cohort can explore the impact of this novel consultation service on patient experiences.

## W2-QI-2 CULTIVATING RADIOLOGY LEADERSHIP: FORGING A PATH TO A FAIR & JUST CULTURE

Nadja Kadom, MD (*Abstract Co-Author*) Nothing to Disclose
Lisa Reynolds (*Abstract Co-Author*) Nothing to Disclose
Zachary Grunewald (*Abstract Co-Author*) Nothing to Disclose
Susan Reich (*Presenter*) Nothing to Disclose

### INTRODUCTION

Problem Description: Currently, our Department of Radiology lacks a dedicated training program tailored to foster this cultural change. Existing training programs are not specifically designed for radiology and lack sufficient depth to address our department's unique needs. Available Knowledge: Creating a culture of safety and trust is critical cornerstone for healthcare institutions seeking to achieve optimal patient safety. It is well known that healthcare organizations with enhanced cultures of safety and expectations of interpersonal management have increases in safety event reporting, greater trust among colleagues, improved employee experience, and increased leadership engagement. Purpose: Accordingly, we implemented a comprehensive training seminar on Fair Just Culture (FJC) for our radiology leaders within Emory Healthcare and determined the impact on knowledge of key concepts.

### METHODS

General: Ninety-nine leaders with roles within our Emory Healthcare Department of Radiology underwent a structured 2.5-hour long course on FJC principles and knowledge was assessed. Leadership roles in included executive leaders, directors, managers, and supervisors. Context and Intervention: The course reviewed key concepts in FJC, human-factors engineering, human errors, Emory Healthcare's FJC algorithm, error reporting, investigation, as well as psychology concepts on the second victim syndrome, giving feedback, and apologizing. Study of the Intervention: Pre- and post-test survey data was collected via Microsoft Forms. Measures:/Metrics: A 21-question test was given to participants to test their knowledge of key concepts and gather feedback. Analysis: Data was analyzed in Excel via T-test under three key domains: skill, attitude, and knowledge.

### RESULTS

Ninety-nine individuals completed the pre-test while 93 completed the post-test. Following the training, participants increased the number of correct responses across all domains by 67.1% (P=0.00002). Increases in correct responses were observed in the following domains: knowledge 1.54-fold (P=0.0004), skills 3.68-fold (P=0.04), attitude 1.74 (P=0.38, NS). Notably, within these domains, participants noted increased levels of confidence in coaching methods, investigation abilities, and understanding of FJC principles in qualitative free response feedback.

### DISCUSSION

We found that implementing a structured course on FJC specific to radiology resulted in enhanced knowledge, skills, and attitude among our leaders. Future work will seek to understand the impact our structured training had on employee experience metrics, patient safety events, and leader coaching within our radiology department. We encourage others to consider implementing FJC training in their organizations to help increase outcomes related to patient safety, employee trust, and inter-personal communication.

## W2-QI-3 BUILDING A QUALITY AND SAFETY TEAM TO INCREASE EVENT REPORTING FOR PATIENT SAFETY IN RADIOLOGY

Janelle Van Luling, RT, ARRT (*Abstract Co-Author*) Nothing to Disclose
Daniella Asch, MD (*Abstract Co-Author*) Nothing to Disclose
Marie Hausner, ARRT, RT (*Abstract Co-Author*) Nothing to Disclose
Jay K. Pahade, MD (*Abstract Co-Author*) Consultant, General Electric Company;Consultant, Clario Medical Imaging, Inc;
Nicole Nardecchia, MBA, ARRT (*Presenter*) Nothing to Disclose

### INTRODUCTION

Patient safety in healthcare is a global top priority. According to the World Health Organization, 1 in 10 patients is harmed in healthcare each year[1]. It is estimated at least 50% of these are preventable. In radiology, areas with high process variability are most error prone. Errors include incorrect protocol, patient falls, and misadministration of contrast/radioisotopes. Quality improvement (QI) teams are an essential part of radiology to aid in event investigations, coach teams on QI methodology, and drive process change. We aimed to improve reporting by developing a supportive culture.[1] https://www.who.int/news-room/fact-sheets/detail/patient-safety#:~:text=Around%201%20in%20every%2010,annually%20due%20to%20unsafe%20care.

### METHODS

The purpose of this improvement report is to explain the structure and evolution of our Quality and Safety team and correlate it with event reporting. We wanted to understand the impact of expanding our team with event reporting culture. We analyzed the number of event reports submitted to our reporting software (RL Solutions, Performance Health Partners) over time as each member/role was added to the team. Our team members consist of one manager, two coordinators, one data/epic analyst, and three radiologists. We work closely with operational staff to encourage reporting.

### RESULTS

In 2017 (with 1 manager and 1 radiologist) 303 events were reported. With each additional team member/role added over time, our team increased event reporting by supporting safety culture and by addressing issues brought forward by frontline staff. By adding 1 coordinator the first year, reporting increased from 303 event reports to 925 (205%), which remained largely steady for the next three years, increasing another 38% by 2021. When our team expanded again in 2021, reporting rose another 53% within the next three years. The total annual events reported in 2023 (with 1 manager, 2 coordinators, 3 radiologists, and 1 data/epic analyst) increased 543% to 1950. The rise in reporting helped our team create QI initiatives and increased stewardship of imaging services (including those requiring ancillary support).

### DISCUSSION

Over the last 7 years, our department has seen a 543% growth in safety event reporting which has correlated with a growth in our team size. The growth of our quality and safety team has encouraged reporting as our team has greater resources to address process/safety issues and help support initiatives improving care for patients and staff. Increased event reporting is proven to decrease patient safety events and improve patient experience. A limitation in using event reporting as a success measure is its reliance on people taking time to fill out forms. All institutions likely have untapped potential in areas with reduced reporting, which may be due to time constraints, competing priorities, and technology barriers.

## W2-QI-5 PULSE SURVEYS FOR DEPARTMENTAL ENGAGEMENT: FINDING THE PEBBLE IN YOUR SHOES

Steven A. Rothenberg, MD (*Abstract Co-Author*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC
Rachel Z. Bass, MD (*Abstract Co-Author*) Nothing to Disclose
Elainea N. Smith, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Feedback is essential to creating an optimal work environment to improve job satisfaction and solve problems within an organization. Traditional surveys are performed infrequently, typically have low engagement and only reflect a single moment in time. The purpose of this quality improvement project was to create a mechanism to improve employee feedback by more frequent engagement while decreasing the activation energy required through pulse surveys.

### METHODS

A longitudinal departmental and wellness survey was developed with the goal of answering short 1-2 pulse survey questions that would take 60 seconds or less to complete. The amount of data collected was the same as standard survey except at a higher frequency over a longer time period. The surveys also included open-ended questions for faculty and trainees to voice opinions on select topics. The initiative was first introduced at a faculty meeting before surveying began. The results from the pulse surveys were included in a departmental weekly newsletter and anonymous comments were reviewed by radiology leadership. Engagement was determined by the number of participants that responded per pulse survey.

### RESULTS

Thirteen pulse surveys were sent between October 23, 2023 and April 22, 2024 on a bimonthly basis. Weeks of major holidays and major radiology conferences were omitted to maximize participation. Initial participation was low - with an average of 23 responses in weeks 1-5. In weeks 6-10, participation increased to a weekly average of 44 (p=0.04). Faculty provided 127 free text responses with largest engagement providing kudos to coworkers (N=23) and ideas for improving job satisfaction (N=25).

### DISCUSSION

Longitudinal email surveys can be a valuable tool to gain department-wide feedback on various topics. Bimonthly surveys with single questions are best with minimal time and effort required for engagement. Our brief experience demonstrated after a few weeks of distribution and discussion, engagement gradually increased. With continued future use, this could ideally track wellness or resiliency changes within the department longitudinally over a period of time. Further, these data identified key issues for leadership to intervene on workplace inefficiencies such as our outside image interpretation workflows and utilization of departmental incidental findings macros. Continued experience is needed to gain an understanding of most ideal format and best phrasing of questions.

## W2-QI-6 VALUE OF INJECTION SITE MONITORING USING A SMARTPHONE DURING DYNAMIC CONTRAST-ENHANCED CT

Noriyuki Tomiyama, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Hisayo Suzuki (*Abstract Co-Author*) Nothing to Disclose
Yukihiro Enchi (*Abstract Co-Author*) Nothing to Disclose
SHUCHI KAWABATA (*Abstract Co-Author*) Nothing to Disclose
Kazuhiko Satoh, MBBS (*Abstract Co-Author*) Nothing to Disclose
Takahiro Tsuboyama, MD (*Presenter*) Nothing to Disclose

### INTRODUCTION

Contrast media extravasation is particularly problematic when performing dynamic contrast-enhanced CT (DCE-CT) because visual assessment of the injection site is not possible due to bolus tracking scans that begin shortly after the start of contrast injection. Although pressure monitoring is the main method to detect extravasation, it may not be reliable in all cases. Therefore, we developed an injection site monitoring method using a smartphone and evaluated its value for injection site safety during DCE-CT.

### METHODS

From February to March 2024, 26 radiology department members, including 14 radiologists and 12 technologists, who performed a total of 156 DCE-CT examinations, participated in this survey. Each participant conducted three examinations with pressure monitoring only and three examinations with both pressure and injection site monitoring during contrast injection. Injection site monitoring was performed using an iPhone which was attached to the overhead arm support on the CT bed, with the monitoring video output to a tablet device in the operating room. For each examination, the participants assigned a confidence score regarding the safety of the contrast injection. The Mann-Whitney test was used to compare the 78 examinations conducted with and without the injection site monitoring system. For the per-staff confidence analysis, the Wilcoxon test was used to compare the mean scores of three examinations each with and without the injection site monitoring system in the 26 participants.

### RESULTS

There were no significant differences in the injection rate and volume ($P = 0.16$) between DCE-CT examinations with and without injection site monitoring. Confidence scores were significantly higher in examinations with injection site monitoring than those without the system (mean, 4.3 and 2.9, $P < 0.01$). For the per-staff analysis, the confidence scores were significantly increased by the addition of injection site monitoring to the pressure monitoring ($P < 0.01$). Two extravasations occurred in each of the examinations with and without injection site monitoring. The two extravasations were unnoticed during the contrast injection with pressure monitoring only, and the estimated leaked volumes were 20 and 30 ml. In contrast, the injection site monitoring system successfully detected the two extravasations immediately after their occurrence, with an estimated leaked volume of less than 5 ml.

### DISCUSSION

The limitations of this study include the small sample size of extravasation cases and the lack of generalizability due to the single-center study design. Despite these limitations, the method is simple, widely available, and has the potential for future integration of artificial intelligence in automated detection of extravasation.

## W2-QI-7 IMPLEMENTING AN INNOVATIVE SAFETY-CHECKPOINT PROCESS FOR CLINICAL DEPLOYMENT OF AI IN BREAST CANCER SCREENING: FIRST RESULTS AND EXPERIENCES AT 14 SITES

### INTRODUCTION

AI shows promise for improving breast screening quality. Study results are encouraging, but their translation into everyday practice is not guaranteed. A step-wise, safety-focused deployment process with comprehensive monitoring is required to confirm whether experimentally measured benefits translate into real-world deployments. This service evaluation demonstrates the implementation of initial stages of a safety-checkpoint (SC) process, which has evolved through extensive experience in developing, validating, deploying, monitoring and working with AI. The first SC involves technical integration and testing. The second involves assessing local generalisability and expected outcomes when using AI in its intended workflows using recent historic cases. The third involves clinical review of real-world cases with the AI. Subsequent SCs involve clinical training, live pilots, and live use with monitoring. This work covers the first three SCs at 14 sites in varied regions.

### METHODS

A commercially available AI system was deployed across 14 new sites (never previously used in the AI's development or validation) in 2 cohorts: 1) with 6 sites who underwent SC 1 and 3, and 2) with 8 sites who underwent SC 1-3. A checklist was developed to ensure standardised reporting and facilitate performance comparisons for SC 2. The workflow presented for SC 2 uses AI as Reader-2 when the AI and Reader-1 agreed to not recall, otherwise the human Reader-2 opinion was used (Fig 1). In SC 3, the AI was deployed as a 'silent' reader of prospective cases. Clinical teams reviewed AI-flagged cases not recalled by standard double reading (DR) (positive discordant cases).

### RESULTS

118,584 cases were included in the generalisability evaluations (SC 2) across Cohort 2. The AI's AUC ranged from 0.94-0.96. Modelling DR with AI resulted in an expected relative -3.0% recall rate (reduction range: 1.6-4.4%), a rel. -0.3% screen-detected cancer detection rate (reduction range: 0.0-1.1%), a rel. +2.8% positive predictive value (increase range: 1.6-4.6%), and 20-28% workload savings. 4,778 positive discordant cases (8.5%) were reviewed at the first 5 Cohort 1 sites. 18 women were recalled from these reviews, 9 (50.0%) of whom were found to have cancer. Clinical reviews at the remaining 9 sites are in process.

### DISCUSSION

The use of a specially-designed safety-checkpoint process for clinical deployment of AI has been demonstrated. Conducting it at 14 sites with varying levels of clinical experience with AI enabled a standardised way of confirming the generalisability of the AI system and it's expected benefits translating locally and showed that the approach is scalable. Trialling the initial stages of the safety-checkpoint process across multiple sites from different regions has demonstrated its suitability for moving safely towards the next safety-checkpoints: training and live use with monitoring.

## W2-QI-8 LARGE SCALE ARTIFICIAL INTELLIGENCE DEPLOYMENT IN THE EMERGENCY AND RADIOLOGY DEPARTMENTS IN 17 HOSPITALS IN A CITY FOR THE DETECTION, TRIAGE AND MANAGEMENT OF PATIENTS WITH ACUTE INTRACRANIAL HEMORRHAGE

Wai-lun Poon, FRCR, MPH (*Abstract Co-Author*) Nothing to Disclose
K.W.S. Ko (*Abstract Co-Author*) Nothing to Disclose
Neeraj R. Mahboobani, MBBS, FRCR (*Presenter*) Nothing to Disclose

### INTRODUCTION

Intracranial hemorrhage (ICH) is a diagnosis that needs to be detected and managed promptly, and failure to do so can have serious consequences. An automated workflow incorporating vendor artificial intelligence (AI) software was devised for the detection and management of patients with ICH in the Emergency (ED) and Radiology (RD) departments of a tertiary hospital. This workflow was subsequently scaled for use in 17 hospitals in the city.

### METHODS

A validation study was performed to ascertain the accuracy of ICH detection and segmentation by the AI software. A pilot study was then performed to establish proof of concept (POC) of detecting patients with ICH and facilitating timely management of such patients in the ED. To this end, an automated workflow incorporating the AI software was established, whereby the AI results could be accessed by ED physicians and radiologists on an interactive portal on the hospital's intranet, and this was made accessible in all clinical bays in the ED and on all PACS workstations in the RD. The portal included a dashboard and notification mechanism to identify patients with ICH, thereby alerting physicians to attend to them promptly. This workflow was then subsequently scaled for use in 17 hospitals.

### RESULTS

The validation study included 811 CT brain scans. The sensitivity, specificity and accuracy of ICH detection were 97.3%, 96.7% and 96.8% respectively. The AI result for each scan was available within 1 minute after the CT scan. An automated workflow was then established, whereby the AI results and notifications of 'Critical' findings, if any, could be accessed by authorized ED physicians on the hospital's clinical management workstations and by radiologists on the PACS workstations via an interactive portal established on the hospital's local intranet by the Information Technology Department (ITD). This workflow was well received by ED physicians and radiologists, and was subsequently scaled for use in 17 hospitals in the city. It analyses approximately 180,000 CT brain scans a year, and is accessible by about 900 authorized doctors on approximately 1,200 workstations across the 17 hospitals.

### DISCUSSION

This quality improvement project describes augmenting the detection and management of patients with ICH presenting to the ED using AI software to devise an automated and authenticated workflow which is readily accessible via an interactive portal established on a hospital's intranet. This workflow acted as an 'assistant' to ED physicians and radiologists, and reduced 'stress' in detecting ICH in patients, especially in patients with subtle ICH, or at times of constrained manpower or fatigue during overnight shifts. The process of validation, establishment of POC, and workflow covering network infrastructure, data and cyber security, user access control, and means to subsequently scale up to cover 17 hospitals will be discussed.

## W5A-QI-1 OPTIMIZING SCREENING MAMMOGRAM TAT: A QUALITY IMPROVEMENT MISSION

Thomas Brim, DO (*Abstract Co-Author*) Nothing to Disclose
Nanditha George, MBBS (*Presenter*) Nothing to Disclose

### INTRODUCTION

Screening mammograms remain an important tool for the detection of breast cancer in asymptomatic women, 40 years and older. The FDA requires that facilities provide patients with an easy-to-understand report within 30 days of their mammogram. Prior imaging is paramount in reporting screening mammograms. Obtaining priors, among other causes, can lead to reporting delays and in turn patient anxiety. In our institution, all radiology studies have to be reported within a certain time frame to prevent loss of departmental revenue. A color scheme was implemented to identify studies at risk of falling out of turn-around time compliance and thus preventing the loss of department revenue.

### METHODS

The implementation of a color-coded interface for the screening mammogram list was created to provide a quick visual representation of which studies needed to be read before falling out of compliance. Red was used for studies that were on the last day, yellow for 2-3 days and green for 4 days before running out of compliance. Grey was used for the remaining studies on the list. All breast radiologists were made aware of the new color-coding scheme. The change was implemented on 12/1/2023. The 3 months prior to and after the change was analyzed to gauge impact.

### RESULTS

The number of screening mammograms performed before and after the change were similar i.e. 3922 from September 2023 to November 2023 (pre-implementation) and 3838 from December 2023 to February 2024 (post-implementation). There was an 86.45% decrease in the number of screening mammograms that fell out of compliance and a commensurate 81.81% decrease in lost revenue in the post-implementation phase.

### DISCUSSION

The implementation of a simple, quick and cost-effective change to the mammography user interface greatly impacted the ability to report screening mammograms in a timely manner as well as decrease the loss of departmental revenue. This project highlights how a color-coded interface can capture the attention of a reader and thus facilitate efficiency. This process could be easily adopted by other radiology divisions or satellite centers and help to prioritize specific studies on the worklist.

## W5A-QI-2 CONTRAST COST REDUCTION FOR CT PULMONARY ANGIOGRAPHY AND ABDOMEN AND PELVIS

Maureen Gregory (*Abstract Co-Author*) Nothing to Disclose
Gaurav V. Watane, MBBS, MD (*Abstract Co-Author*) Nothing to Disclose
Jeffrey S. Mueller, MD (*Abstract Co-Author*) Nothing to Disclose
Michael P. Spearman, MD (*Abstract Co-Author*) Nothing to Disclose
Warren Chang, MD, MBA (*Presenter*) Nothing to Disclose

### INTRODUCTION

From May 2023 through October 2023, the average cost for contrast used on PE and standard Abdominal CT scans has been calculated to be $6,907/month. This results in greater cost to the patient and the department. The goal of this project is to reduce the average monthly cost of contrast by 10% or decrease the monthly contrast cost to $6217/month by August 31, 2024.

### METHODS

Using the DMAIC (define/measure/analyze/improve/control) technique, we identified, categorized, and prioritized causes of contrast waste that result in increased cost to the patient and the department. The identified drivers for the need to reduce monthly contrast cost are summarized as waste reduction, procedure failure, and staff process. Both the current and future state injection processes were arranged. We measured the contrast cost in milliliters used per month. The Bayer Certegra Manager website provided drilled down data that included contrast volume used and volume wasted for each patient on each injector. Patient volume was also measured. We analyzed our standard injection protocols and our staff workflow. Consistent use of the P3T weight based contrast volume software was implemented. Communication about the importance project became, and remains, a priority.

### RESULTS

The project start date was December 2023. Solutions were implemented starting January 1, 2024. The average cost of contrast from January - March 2024 was $6276/month, barely shy of the 10% cost reduction goal. Wasted contrast cost for PE Standard AP studies was reduced dramatically from

$1050 in October 2023 to $198 in March 2024. Consulted Radiologists agree that we are maintaining quality imaging with this reduction in contrast volume.

**DISCUSSION**

One identified root cause of contrast waste that is not controlled by Radiology is the fact that there are many occasions when contrast orders are placed at different times resulting in the patient receiving multiple contrast doses within hours of one another. Ideally, the goal would be to prevent this from occurring. In conclusion, the front-line staff must be recognized for their workflow implementation and continuous, conscious effort to reduce contrast waste.

## W5A-QI-3 INTEGRATED DIAGNOSTICS SHARED RESOURCE'S QUALITY IMPROVEMENT WORKFLOW FOR RADIOLOGY-PATHOLOGY CORRELATION OF PROSTATECTOMY

Dieter R. Enzmann, MD (*Abstract Co-Author*) Nothing to Disclose
Steven S. Raman, MD (*Abstract Co-Author*) Consultant, Johnson & Johnson;Consultant, Bayer AG;Consultant, Merck & Co, Inc;Consultant, Amgen Inc;Consultant, Profound Medical Inc
William Hsu, PhD (*Abstract Co-Author*) Nothing to Disclose
Preeti Ahuja, PhD (*Abstract Co-Author*) Nothing to Disclose
Nashla Barroso (*Abstract Co-Author*) Nothing to Disclose
Alondra Prado, BS (*Presenter*) Nothing to Disclose

**INTRODUCTION**

The diagnosis and treatment of prostate cancer (PCa) depends on a series of interconnected results, including imaging and pathology, which do not always correlate, complicating treatment decisions for patients. The Integrated Diagnostics Shared Resource (IDx) is an interdisciplinary program integrating imaging with histopathology and molecular diagnostics to understand the nature and biology of cancers. IDx uniquely operationalizes quality control (QC) metrics through structured correlation workflows that identify radiological-pathological (RadPath) discrepancies and, in turn, creates a curated dataset available for researchers to use. In this study, we aim to assess the impact of IDx's QC-centered workflow by quantifying the improved accuracy of RadPath findings.

**METHODS**

The IDx operational team tracks all PCa prostatectomies (RALPs) at our institution and helps create patient-specific, 3D-printed prostate molds. Surgical pathology uses the molds during prostate grossing to generate high-quality whole-mount histopathology slides (WMHP) for clinical reports. RALPs are then reviewed at IDx Multidisciplinary "Match" Meetings, where radiologists and pathologists consensually match PCa WMHP lesions (the gold-standard) to MRI lesions, while the operational team captures the results in an IDx database. Between 2023-2024, we reviewed/matched 190 unique cases, including 242 MRI lesions and 361 WMHP lesions. We filtered all MRI/WMHP lesions for discrepancies between originally reported characteristics versus characteristics retrospectively noted and/or amended upon retrospective review.

**RESULTS**

Of 242 MRI lesions reviewed, 228 were noted on clinical reports, 4 were not visible upon retrospective review (1.7%) and 16 were amended (6.6%) due to inaccurate location. The radiologists retrospectively identified 14 (5.8%) new lesions. Of 361 WMHP lesions reviewed, 352 were noted on clinical reports, 3 were not visible upon retrospective review (0.8%) and 33 were amended (9.1%) due to inaccurate location (73.4%) and grading/histology (27.3%). The pathologists retrospectively identified 9 (2.5%) new lesions.

**DISCUSSION**

Previously missed lesions and clinically-relevant characteristics are among the many corrections resulting from IDx's QC workflows. Implementation of such workflows and creation of curated datasets at high-volume academic medical centers can help improve the accuracy of image-based cancer detection by accurately correlating results with pathology, ultimately improving patient care. Obtaining a second review of imaging and WMHP serves as a valuable educational tool for meeting attendees, including trainees. IDx plays a critical role in ongoing PCa research by implementing unique QC-centered workflows that help address and improve RadPath discrepancies, ultimately helping improve the image-based detection of PCa.

## W5A-QI-4 LEVERAGING ARTIFICIAL INTELLIGENCE IN RADIOLOGY MULTIDISCIPLINARY ROUNDS: ENHANCING CLINICAL DECISION-MAKING AND COLLABORATION

Waqas Ahmad I, MBBS (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Radiology multidisciplinary rounds (MDRs) are pivotal for collaborative patient care. Integrating artificial intelligence (AI) into these rounds holds promise for enhancing clinical decision-making. This abstract explores the role of AI in radiology MDRs and its potential to improve outcomes.

**METHODS**

This study involved the integration of AI-powered decision support tools into radiology MDRs at a tertiary care hospital. AI algorithms were trained to analyze imaging studies and provide automated insights into findings, differential diagnoses, and recommended next steps. Radiologists, clinicians, surgeons, oncologists, and other relevant specialists participated in MDRs where AI-generated reports were presented alongside traditional radiology interpretations.To evaluate the impact of AI on MDRs, data on clinical decision-making, treatment planning, and patient outcomes were collected before and after the implementation of AI. Surveys and interviews were conducted to gather feedback from healthcare professionals regarding the usability, accuracy, and perceived benefits of AI in MDRs. Additionally, key performance indicators such as time to diagnosis, treatment initiation etc were assessed to measure the effectiveness of AI-enabled MDRs.

**RESULTS**

The integration of AI in MDRs facilitated more informed discussions, leading to consensus-driven treatment decisions and personalized care plans. AI contributed to reductions in time to diagnosis and treatment initiation, improving patient outcomes and satisfaction. Healthcare professionals reported high satisfaction with the usability and accuracy of AI tools, appreciating the efficiency gains and diagnostic support provided.

**DISCUSSION**

AI-enabled MDRs hold promise for improving clinical decision-making and patient care outcomes. By providing timely information and fostering collaboration, AI enhances the effectiveness of MDRs. However, ongoing evaluation and refinement of AI algorithms, as well as attention to issues of data privacy and bias, are crucial for responsible integration.

## W5A-QI-5 MULTIDISCIPLINARY PROCESS FOR QUALITY IMPROVEMENT OF MULTIPARAMETRIC MRI OF THE PROSTATE AND PROSTATE BIOPSIES

Samir S. Taneja, MD (*Abstract Co-Author*) Royalties, Reed Elsevier;Consultant, TROD Medical;Consultant, InSightec Ltd;Consultant, Francis Medical;Consultant, Exact Imaging Inc;Consultant, Johnson & Johnson;Investigator, MDxHealth SA
Fang-Ming Deng, MD, PhD (*Abstract Co-Author*) Nothing to Disclose
Angela Tong, MD (*Presenter*) Equipment support, Siemens AG

**INTRODUCTION**

Multiparametric MRI of the prostate (mpMRI) in conjunction with targeted prostate biopsy have been incorporated in the normal workflow for prostate cancer workup, thus increasing the number of both mpMRIs and biopsies we perform. A process to assess rad/path discordances is necessary to maintain and improve patient care in prostate cancer diagnosis.

**METHODS**

To localize problem areas in our mpMRI and biopsy program, we implemented a structured multidisciplinary meeting to review discordant radiology/pathology findings. Radiology, urology, and pathology were present for each meeting. The structured process included: 1) defining the type of discordance, 2) evaluating a list of reasons for the discordances including image quality, image interpretation with expert prostate imager and consensus reads if necessary, biopsy targeting error, and histologic etiology, 3) classifying the type of discordance from the evaluation, and 4) validating the discordant result. We investigated discordant prostate biopsy results from 1/25/2022 to 2/13/2023 and recorded the steps for each discordance to reveal any areas of improvement in our workflow. Descriptive statistics were performed.

**RESULTS**

A total of 472 biopsies were performed during the time period with 61 discordant cases (mean age 69±7 years). Mean time between MRI and biopsy included 69±47 days, 13% (8/61) were post focal therapy cases. 19% (12/61) had mpMRI performed at an outside institution with consultation interpretation in house. Of the 61 discordances, the types of discordances were as follows: Targeting errors 23%, High Prostate Imaging Reporting Data System (PI-RADS) score with benign/non-clinically significant prostate cancer (grade group (GG) 1) 18%, Incorrect PI-RADS 16% (clinically significant prostate cancer (csPCa) defined as >GG1 occult on mpMRI) 15%, Histologic reasons for discordance 13%, Low volume of csPCa disease (<10% pattern 4) 11%, Poor image quality 3%.

**DISCUSSION**

39% of the discordances were from targeting errors and image interpretation errors, which will be further investigated and corrected with education. 46% were validated to be true discordances on imaging and histology including high PI-RADS with benign or non-csPCa, histologic reasons for discordance, and occult csPCa on MRI, which will all require hypothesis driven research to understand further. Uncovering the distribution of discordance types has given us directions to improve our mpMRI/biopsy program and also important research questions. Continued structured assessment is needed to track the efficacy of our interventions and to uncover any other areas for improvement.

## W5A-QI-6 3D-PRINTED MODELS FOR COMPLEX PEDIATRIC SURGICAL CASES - MULTI-DISCIPLINARY PERSPECTIVES ON A "MODEL" FOR QUALITY IMPROVEMENT

Gregory M. Sturgeon, MS (*Abstract Co-Author*) Nothing to Disclose
Joseph Y. Cao, MD (*Abstract Co-Author*) Nothing to Disclose
Elizabeth Horne (*Abstract Co-Author*) Nothing to Disclose
Mary Moya-Mendez (*Abstract Co-Author*) Nothing to Disclose

Cathlyn Medina (*Abstract Co-Author*) Nothing to Disclose
Elisabeth Tracy (*Abstract Co-Author*) Nothing to Disclose
Harold Leraas (*Abstract Co-Author*) Nothing to Disclose
Catherine Beckhorn (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Three-dimensional (3D) modeling has been increasingly used in surgical planning across multiple disciplines. At our institution, 3D-printed models have recently been incorporated into our pediatric general surgery practice for several complex cases; however, we have yet to seek clinician feedback regarding their use. Therefore, we aimed to assess the impact of 3D-printed models on surgical planning and multidisciplinary team discussion.

**METHODS**

We utilized the "Plan-Do-Study-Act" (PDSA) framework, focusing on the "Study" of recent implementation of these models. A survey was distributed to the care team (pediatric oncologists, anesthesiologists, cardiothoracic surgeons, neurosurgeons, resident/fellow trainees) involved in recent complex pediatric surgical cases utilizing 3D-printed models at a large academic institution. Using Likert scales (1 = strongly disagree; 5 = strongly agree) and free responses, we assessed the models' usefulness in preoperative and intraoperative planning. Basic descriptive statistics were performed.

**RESULTS**

Eight respondents completed the survey (two pediatric oncologists, two pediatric anesthesiologists, one pediatric cardiothoracic surgeon, and two general surgery residents and one medical student on the pediatric surgery service). All participants (8/8; 100%) reviewed the models with the primary pediatric general surgeon. All either strongly agreed or somewhat agreed that the model helped them better understand the "tumor location" (mean 4.5) and "anatomy close to the tumor" (mean 4.6). The majority (7/8; 88%) strongly agreed or somewhat agreed that the model impacted their case preparation (4.3), noting its help with "visualization of location of mass and associated anatomic structures of importance," and "preoperative planning for access, blood availability, and resuscitation strategy." Even "reviewing the model in virtual tumor board" helped clinicians; only 5/8 (63%) strongly agreed that physically holding the model (mean 4.3) was necessary for it to be helpful.

**DISCUSSION**

In conclusion, providers across multiple specialties and levels of training (resident, fellow, attending) found reviewing 3D models (in person or virtually) helpful for planning complex pediatric surgeries. While limitations exist, such as the cost and time required for 3D-printing, their use should be considered in anatomically or technically challenging cases. Although a small sample size, our institutional experience with 3D-printed models has been promising. Results can iteratively shape PDSA quality improvement efforts and inform clinical practice at our institution, while serving as a model for other institutions seeking to incorporate this technology. Future research should capture perspectives from other key stakeholders, such as pediatric general surgeons, patients, and their caregivers.

## W5A-QI-7 NEURORADIOLOGISTS IDENTIFY AND TRACK LOW VALUE STUDIES AT THE TIME OF DICTATION FOR INTERDEPARTMENTAL QUALITY IMPROVEMENT

Vivek P. Patel, MD,PhD (*Abstract Co-Author*) Nothing to Disclose

Rebecca Simstein, MD (*Abstract Co-Author*) Nothing to Disclose
Grace Tewkesbury, MD (*Abstract Co-Author*) Nothing to Disclose
Douglas Roberts-Wolfe, MD, PhD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Low value neuroimaging in the Emergency Department harms patients, burdens healthcare systems, and is unsustainable. To address this issue, we incorporated a dictation macro into our clinical workflow, enabling neuroradiologists to flag suspected low value studies with minimal clinical disruption. We hypothesized that flagged studies would be driven either by a subset of "superuser" ordering providers and/or systemic overutilization of specific exam types (e.g. CT head, MRI brain, etc.)

**METHODS**

Between March and December 2023, studies were flagged with an alphanumeric code enabling subsequent retrieval by Nuance Montage. Pareto analysis was used to determine whether 20% of causes ("superusers" vs. exam types) drove 80% of flagged studies. Studies prioritized by Pareto analysis underwent retrospective chart review by neuroradiology attendings and residents. Each exam component of the report was individually judged "reasonable" or "unnecessary" and an overall rationale was provided. A subset of exams were re-reviewed for interrater reliability. Rationales were categorized by reason for exam inappropriateness, and for clinical indications common to unnecessary exams.

**RESULTS**

775 reports comprising 1531 exams were flagged. Pareto analysis did not support our hypothesis that "superusers" disproportionately drive flagged studies (the top 20% of ordering providers drove ~60% of flagged studies). However, the top 20% most common exams drove 80% of flagged studies. Further, the top 5% drove 65%, and were components of workup for large vessel occlusion (LVO), including CTA head, CTA neck, CT head, and CT perfusion. Studies including both CTA head and neck were thus prioritized for chart review. 257 reports comprising 731 exams underwent chart review (135 charts were reviewed by two reviewers and 122 by one reviewer). Though differing somewhat by exam type, interrater reliability was ~70% overall, and ~60% of studies were confirmed unnecessary. Supporting rationales included low NIHSS, alternative neurologic etiology, non-neurologic etiology, duplicate imaging, and chronic symptoms. Three clinical presentations appeared commonly in unnecessary CTA head/neck: vertigo, headache, and seizure.

**DISCUSSION**

Neuroradiologists can identify suspected low value imaging with negligible impact on the clinical workflow. 60% of studies thus identified are confirmed to be of low value after chart review. Low value imaging is driven by system-wide overutilization of LVO imaging (CTA head/neck and CT perfusion), rather than by individual "superuser" ordering providers. Low value LVO imaging in turn is most commonly performed in patients presenting with vertigo, headache, or seizure. In collaboration with neurology and emergency medicine we will next turn our attention to development of clinical and imaging pathways for patients presenting with these conditions.

## W5A-QI-8 INCREASING LUNG CANCER SCREENING PARTICIPANTS AT THE MEDICAL UNIVERSITY OF SOUTH CAROLINA

Reginald F. Munden, MD, MBA (*Abstract Co-Author*) Investor, TheraBionic GmbH;Advisory Board, Optellum Ltd;Stock options, Optellum Ltd
Dhiraj Baruah, MBBS, MD (*Abstract Co-Author*) Grant, Blue Eye Soft Corp;Consultant, ImBio, LLC
Anthony Poole (*Abstract Co-Author*) Nothing to Disclose
Cassie Frazier (*Abstract Co-Author*) Nothing to Disclose
Kelly N. Howard, ARRT, MBA (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Patients underutilize our lung cancer screening program, which leads to missed opportunities for early cancer detection and management

**METHODS**

Identifying four key root causes impeding the effectiveness of our LCS program- incomplete documentation, limited patient awareness, provider unfamiliarity with LCS processes, and inadequate data utilization. Collectively, these interventions represent a proactive approach to addressing systemic barriers, promoting provider engagement, enhancing data quality, and improving the efficacy and impact of LCS programs. All data for the study was collected through Eon Health, a third-party vendor that MUSC uses to track lung cancer screening throughout the health system. The weekly volume for the year before the study was evaluated. Receiving a weekly volume report allowed us to quickly identify significant positive and negative changes at each site to determine if interventions were impactful. Monthly reports were also generated to track LDCT total volume, LDCT through the centralized programs, short interval CT chest follow-up, PET scans, cases requiring multi-disciplinary review, referrals to lung nodule clinic, procedures (bronchoscopy, needle biopsy, surgery), lung cancer diagnoses, and other cancer diagnoses. The other measure evaluated was adherence rates to annual LDCT.

**RESULTS**

The weekly volume of LDCTs improved from an average of 55 in 2022 to 91 in 2023. This was in part due to changes in the national guidelines for LCS, lowering the starting age from 55 to 50 and the pack years from 30 to 20. However, additional volume increases were noted after the interventions were implemented. The monthly reports also reveal an increase in LDCT volume as well as referral to the centralized program, procedures, multi-disciplinary review, and lung cancer diagnoses from 2022 to 2023. Adherence to annual lung cancer screening was higher in patients screened through the centralized programs at all four sites. The relationships built through this project between the lung cancer screening program, the quality team, radiology, and primary care have resulted in other project ideas and one grant submission.

**DISCUSSION**

Many of the interventions tested were done in conjunction with other changes happening outside of the project, making it difficult to determine what had the most significant impact on volume.There has been no recent follow-up with the primary care providers to see if the changes to the BPA are helping or hindering their workflow. No interventions were implemented to decrease open referrals for lung cancer screening (patients with orders for LDCTs that were not completed or referrals to the centralized program that never established care).This project focused on systems and tools within an academic healthcare system to improve identification of eligible patients and referrals for lung cancer screening.

## W5B-QI-1 UTILIZING 3D PRINTED ANATOMICAL MODELS TO IMPROVE PATIENT EDUCATION IN A NORMAL PRESSURE HYDROCEPHALUS CLINIC

Kevin S. King, MD (*Abstract Co-Author*) Nothing to Disclose
Christian Henriksen (*Abstract Co-Author*) Nothing to Disclose
Elise Dunning (*Abstract Co-Author*) Nothing to Disclose
Justin Hoskin (*Abstract Co-Author*) Nothing to Disclose
Daniel Spalinski, BSc (*Presenter*) Nothing to Disclose

### INTRODUCTION

Patient and family education for normal pressure hydrocephalus (NPH) relies heavily on discussions of radiographic findings and the anatomy of ventriculoperitoneal shunt placement. Providing the best possible patient education experience in this setting has become a quality improvement effort among our neurology and neuroradiology departments. The purpose of this project is to assess the effects of the usage of 3D-printed models on patient understanding, patient perceived understanding, and patient satisfaction in the setting of newly diagnosed NPH.

### METHODS

This project was performed in the neurology division of an urban, quaternary, academic hospital. Sagittal- and axial- split models of both NPH and normal neuroanatomy were printed using a Formlabs Form 3 SLA Resin printer. Patients were randomized into control and educational intervention groups. In the control group, patients received the standard-of-care physician education utilizing patient MRI imaging. In the educational intervention group, patient received physician education that utilized 3D printed models of a NPH and control brain in addition to MRI imaging. Exclusion criteria included patients working in healthcare, requiring the use of a translator, and/or with a MoCA score < 21.The impact of the educational intervention was assessed using a standardized two-part patient questionnaire. The experience portion of the survey quantified patients' satisfaction with their education, comfort, and stress levels on a 1 to 5 rating scale. Patients who received the educational intervention were also asked to quantify model usefulness on a 1 to 5 rating scale. The knowledge portion of the survey quantified patients' understanding of NPH with 7 multiple choice questions regarding the anatomy and pathophysiology of the condition.

### RESULTS

Questionnaires were collected from 30 patients, with 15 in the intervention group and 15 in the control group. Results of the questionnaires were compared using chi-squared and independent t-tests where p=0.05 was considered significant. For patients receiving the educational intervention, there was a significant increase in the mean number of correct answers for the knowledge survey (p=0.05) as well as a significant decrease in the number of "I don't know" responses (p=0.05). There was no significant difference in levels of patient satisfaction (p=0.50), stress (p=0.36), or comfort (p=0.29). Usefulness of the 3D model received a mean score of 4.29/5.

### DISCUSSION

Limitations of our study include variations in patient cognitive impairment despite MoCA score screening and a single-center, single-physician study population. Using a 3D printed brain anatomical model during visits for newly diagnosed NPH, we were able to improve patient knowledge regarding their condition while maintaining patient levels of satisfaction, stress, and comfort.

## W5B-QI-2 TEACHING CHEST RADIOGRAPH INTERPRETATION THROUGH SIMULATED RESUSCITATION SCENARIOS: A NOVEL APPROACH TO MEDICAL STUDENT EDUCATION

Nuran Seneviratne, MA, MBBS (*Abstract Co-Author*) Nothing to Disclose
Mirza Shaheer Baig (*Abstract Co-Author*) Nothing to Disclose
Sagar Kulkarni, MBBS, BS (*Presenter*) Nothing to Disclose

### INTRODUCTION

Chest radiograph (CXR) interpretation is an important skill in medical student education, however, CXR teaching provided by medical schools is often insufficient. This study's aim was to evaluate whether CXR interpretation could be taught via an engaging, simulation-based approach.

### METHODS

We recruited third year medical students on their internal medicine and surgery clinical rotations. The programme consisted of three 15-minute simulation scenarios (tension pneumothorax, pleural effusion and pneumonia) on a simulated ward. Low-fidelity mannequins were used and students were expected to use an advanced cardiovascular life support (ACLS) approach and to request appropriate imaging to aid their diagnosis and management. At each scenario, a CXR was provided upon request of the student participant. Students rotated through each scenario sequentially in pairs and were debriefed on

CXR interpretation and acute illness management at the end of the session. Pre- and post-session questionnaires using 5-point Likert scales were taken using Google Forms. Statistical significance was calculated using the paired samples t-test.

**RESULTS**

20 participants attended the sessions. Before the session, the mean confidence at interpreting CXRs was 2.55 out of 5. After the session, mean confidence rose to 4.25 out of 5 (increased by 1.70, $p < 0.00001$) . In terms of usefulness, participants rated the session 4.8 out of 5 on average. Free text comments mentioned the case mix, integration of radiographs into the ACLS assessment and teaching on systematic methods to interpret radiographs as being assets of the program.

**DISCUSSION**

Simulation can improve student confidence in CXR interpretation. Students find simulation-based scenarios to be an engaging and interactive way to learn about imaging. To improve student confidence and ability further, we could introduce multiple radiology-based sessions throughout their rotation.

## W5B-QI-3 SIMULATION TRAINING IN RADIOLOGY: IMPROVING RADIOLOGISTS KNOWLEDGE IN CONTRAST REACTIONS

Julie G. Champine, MD (*Abstract Co-Author*) Nothing to Disclose
Jessica H. Porembka, MD (*Abstract Co-Author*) Nothing to Disclose
Kristen Bishop, MD (*Abstract Co-Author*) Nothing to Disclose
Jennifer G. Schopp, MD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Allergic reactions to IV contrast, occur 0.2-3% of the time, most are mild and self limited, although 2-3% of the reactions are severe and life threatening. Given the infrequency of severe reactions, a radiologist may go years without managing a severe reaction. There are 5 key reactions to contrast, each of which can be life threatening. Knowledge of contrast reaction management is essential and can be life saving. Specialized training is needed to maintain skills in identification of reaction type and selection of proper medications to treat. We aimed to improve recognition and treatment of contrast reactions through creation of a simulation program for radiology faculty.

**METHODS**

The team was assembled with three physician course directors writing 5 key scenarios. Supplies were obtained from pharmacy to create mimic contrast reaction kits, CT backdrop was created, dry runs performed, and budgeting was planned. Scheduling of faculty was performed. Scenarios include 5 radiologists in 3 hour sessions, each radiologist leading 1 of the 5 key reaction scenarios. A 5 question pre-test was administered, with a brief introductory lecture to follow. The scenarios were carried out, with post session debriefing, followed by the post test.

**RESULTS**

Total of 28 faculty have been trained at Simulation Center within a 4 month period, on track for 100 faculty within 1 year (all within 2 years). Post testing improvement is demonstrated on each key concept, with nearly all at 100% (except vasovagal concept).

**DISCUSSION**

Our Multidisciplinary approach was effective in creating and implementing training, with excellent post test scoring indicating improvement post simulation training. Future improvements to implement include a pre simulation training vasovagal lecture and pre and post confidence testing, as the vasovagal post test improvements were not as robust compared to other key teaching points. Interdisciplinary team will prove useful for future plans, including our RNs and technologists for team training and scope of practice awareness.

## W5B-QI-4 IMPROVING PROSTATE MRI REPORTING STANDARDS: REFLECTIVE PRACTICES AND SIMPLE FEEDBACK

Alex P. Kirkham, MBChB, MD (*Abstract Co-Author*) Nothing to Disclose
Shonit Punwani, MBBS (*Abstract Co-Author*) Nothing to Disclose
Tom Syer (*Abstract Co-Author*) Nothing to Disclose
Adam Retter, MD, PhD (*Presenter*) Nothing to Disclose

**INTRODUCTION**

Pre-biopsy mpMRI with targeted biopsy has shown high sensitivity and negative predictive value (NPV) for the diagnosis of clinically significant cancer (ISUP grade=/>2). However, positive predictive value (PPV) and the proportion of scans scored 3 (or indeterminate) varies across centres. A score of 3/5 can cause uncertainty and complicate clinical discussion, and too many scores of 3/5 can lead to over biopsy and over diagnosis of insignificant tumour.Problem: Observation suggests that 'cautious' radiologists may lean towards scoring 3/5 rather than 2/5, possibly leading to unnecessary biopsies and a subsequent decrease in PPV.

**METHODS**

An initial audit retrospectively assessed all new patients referred to the UCLH one-stop suspected prostate cancer clinic who underwent mpMRI (including contrast) for suspicion of prostate cancer Feb-April 2021. The audit was repeated following an intervention for a further 3-month period (June-August 2021). Descriptive statistics are presented for Likert scores and biopsy outcomes for all included patients and by individual radiologists. Positive predictive values with Wilson's 95% confidence intervals were calculated for the pre-specified Likert score cut-offs. All analysis was undertaken with Stata v17. 81 patients were required to ensure a 95% confidence level that the proportion of Likert 3 scores were within 10% of the 30% target.Standard There is no agreed standard for the proportion of Likert scores or PPV of MRI prostate reporting. However, PROMIS indicated 29% of patients scored 2/5 or less and 30% 3/5. Similarly, Westphalen et al indicated that in 5030 patients, 29.1% scored 3/5, and estimated overall PPV across all centres following biopsies for =3, =4, 3, 4 and 5 were 35%, 49%, 15%, 39% and 72% respectively. Multiple studies show minimal differences between PI-RADS and Likert scores, so we have used the same standards for this audit.InterventionThe results of the audit were discussed with each included radiologist, including personal scores and comparison with the group.

**RESULTS**

136 patients were included in the analysis who attended clinic prior to the intervention and 135 following. Proportions for all Likert scores and of Likert2 to 3 scores for individual reporting radiologists indicate that at preintervention, standards were not met with 40% scans reported as Likert3 and 19% as Likert2. Postintervention scoring proportions showed improvement approaching initial set standards, with 31% Likert3 (reduced by 9%) and 27% Likert2 (increased by 8%). An overall reduction in biopsies was observed across all Likert scores, with rates decreasing from 50% (68/136) pre-intervention to 44% (59/135) post-intervention with insignificant change in PPV for significant cancer detection.

**DISCUSSION**

Simple feedback can help radiologists stay aligned and meet standards.

## W5B-QI-5 LEVERAGING A QUALITY IMPROVEMENT FRAMEWORK TO IMPROVE TRANSGENDER CARE IN ULTRASOUND: THE BRIITE-US EDUCATIONAL SESSION

Robin P. Goldenson, MD, MPH (*Abstract Co-Author*) Nothing to Disclose
Efren J. Flores, MD (*Abstract Co-Author*) Speaker, WebMD LLC;Speaker, Consulting Medical Associates, Inc
Nicolas Freeman, MD, BA (*Presenter*) Nothing to Disclose

### INTRODUCTION

Transgender and gender diverse (TGD) patients face significant health inequities, worse health outcomes, and poor patient experiences in medicine including radiology. At our academic radiology center, the challenges TGD patients encounter had not been addressed. Using a quality improvement (QI) framework, the [Institution Name] Radiology Initiative for Inclusive Transgender Experiences in Ultrasound (BRIITE-US) assessed actionable areas of TGD patient experiences and led to interventions emphasizing patient autonomy and respect with trauma-informed care within ultrasound (US). This study evaluated the effectiveness, acceptability, and feasibility of a TGD educational session for radiologists and staff as part of BRIITE-US.

### METHODS

The IRB-exempt study evaluated the BRIITE-US educational session that targeted patient interactions in a process map. Session Design and Implementation: The session was created by the study team with experience and expertise in TGD care. It was designed for radiologists, sonographers, and radiology staff and included (1) a presentation on foundational TGD terms/concepts, gender pronouns, staff responses for modeling challenging TGD interactions, and US exam practices, and (2) a question-and-answer session. Effectiveness and Acceptability: A twelve-item, pre- and post-educational session survey was designed based on a previously validated survey and given to participants. Eight items used a 5-point Likert scale analyzed using the logrank test between timepoints. Feasibility: Needed resources, time, and costs were assessed.

### RESULTS

Effectiveness and Acceptability: In the pre-session survey (n=39), 36% had prior TGD training. In the post-session survey (n=28), 96% found the session helpful. Four survey items showed a significant improvement: (1) Worrying about making mistakes or offending TGD patients ($P=0.002$); (2) Feeling comfortable asking about pronouns ($P<0.001$); (3) Responding to mistakes where the wrong name or pronouns were used ($P<0.001$); and (4) Accessing gender-related data on the exam requisition ($P=0.002$). Feasibility: Sessions were administered in less than an hour either in person or online and incurred no additional costs.

### DISCUSSION

Leveraging a QI framework to help improve TGD US experiences in radiology, the BRIITE-US educational session was highly effective, acceptable, and feasible. The session improved participants' knowledge, competency, and preparedness for TGD interactions. Respondents were less worried about making mistakes or unintentionally offending TGD patients and were better prepared to ask about pronouns, respond to instances of misgendering, and find gender-related information on requisitions. This QI initiative increased organizational readiness to improve TGD patient experiences while promoting institutional values of diversity, inclusion, and belonging.

## W5B-QI-6 IMPROVING IMAGE QUALITY AND EFFICIENCY OF CARDIAC FOUR-CHAMBER VIEW SCANNING USING THREE-POINT POSITIONING METHOD

Ning Pan (*Abstract Co-Author*) Nothing to Disclose
Jianxin Guo (*Abstract Co-Author*) Nothing to Disclose
Lihong Chen (*Presenter*) Nothing to Disclose

### INTRODUCTION

Four-chamber view is the basic acquisition in CMR to simultaneously visualize the mitral valve, tricuspid valve, and cardiac apex, providing important morphological information. It is also the anatomical basis for subsequent acquisitions such as left ventricle, outflow tract, and myocardial perfusion imaging. This study aimed to evaluate the application value of the three-point positioning method in improving the image quality and scanning efficiency of the four-chamber view in CMR.

### METHODS

A total of 215 patients who underwent four-chamber view imaging from January 2022 to October 2023 were retrospectively collected and divided into two groups. The control group (before the introduction of the three-point positioning method, n=109) used the conventional positioning method, while the study group (n=106) used the three-point positioning method. Image quality of the mitral valve, tricuspid valve, and cruciform structure in the four-chamber view images were assessed by two radiologists using a 4-point Likert scale. The time from scout imaging to completion of the four-chamber view imaging was recorded. Chi-squared test and two-sample t-test were used to compare constituent data and numerical data, respectively. The kappa test was used to analyze the interobserver consistency.

### RESULTS

There were no significant inter-group differences in the experience of radiographer, as well as the gender, age, and disease profile of patients. The mean quality scores of mitral valve, tricuspid valve, and cruciform structure for the control group and study group were $3.44 \pm 0.64$ and $3.63 \pm 0.49$ ($P=0.023$), $3.43 \pm 0.67$ and $3.53 \pm 0.60$ ($P=0.202$), $3.71 \pm 0.49$ and $3.83 \pm 0.35$ ($P=0.047$), respectively. The difference in image quality scores for mitral valve and cruciform structure reached statistical significance. The mean time to complete a four-chamber view acquisition for the control group and study group were $11.67 \pm 3.49$ minutes and $7.212 \pm 1.83$ minutes, respectively, with statistically significant differences ($P<0.001$).

### DISCUSSION

It was found that the image quality of the mitral valve and the cruciform structure in the four-chamber view obtained by the three-point positioning method was significantly better than that of the conventional positioning technique, and the scanning efficiency was also significantly improved. This study has several limitations. First, the time for patients to complete all CMR sequences was not analyzed. Second, the radiographer for the control group and the study group were not strictly identical because of shift changes and personal rotation. Compared with the conventional positioning method, the four-chamber view obtained by the three-point positioning method can better display the mitral valve, tricuspid valve, and cruciform structure, and also shorten the imaging time.

## W5B-QI-7 LEVERAGING ROBOTIC PROCESS AUTOMATION TO IMPROVE WORKPLACE EFFICIENCY THROUGH IDENTIFICATION OF DUPLICATE SCANS

Tan Yang Loo (*Abstract Co-Author*) Nothing to Disclose
Jia Jun Ng, MSc (*Abstract Co-Author*) Nothing to Disclose
Jiang Peng Ng, BSc (*Presenter*) Nothing to Disclose

## INTRODUCTION

Advancement in technology and ease of access to imaging has led to notable increase in imaging requests. These lead to a rise in duplicate requests. which are often manually identified before patients enter the scan room. A lapse in service exists as patient care is not provided in a timely or efficient manner. The purpose of this initiative is to utilize robotic process automation (RPA) to identify and reduce duplicate requests.

## METHODS

An analysis of computed tomography (CT) orders cancelled in 2022 was conducted. Out of a total of 41020 orders, there were 407 duplicates (1%). This number is non exhaustive. Despite the low number, it is significant as CT involves radiation which should be kept as low as reasonably achievable. Root cause analysis was performed using cause and effect diagram. Educating multidisciplinary teams emerged as a key area in reducing duplicate CT orders. The Plan Do Study Act (PDSA) method was utilized to facilitate the change. The first PDSA cycle did not lead to change due to lack of continual education. Clinicians were also commonly rotated through various local hospitals with differing policies. A second PDSA cycle was conducted, and RPA identified as the new change agent. Current workflow and radiological information system (RIS) capabilities were analyzed to determine steps in the workflow for RPA injection. Various key factors and unique identifiers were labelled. Proof of concept using Microsoft Excel confirmed the project's feasibility. A working database was set up to ensure the dataset validity, allowing RPA to perform with increased sensitivity. Effectiveness of RPA will be measured by number of duplicates it captures before patients' scheduled appointments. A three month test period will be set aside for data collection.

## RESULTS

Early results show that RPA identified 89 potential duplicates across 588 scheduled CT orders. These cases form the department's average weekly workload. With further analysis, there were three true positive duplicate. RPA reduced identification of duplicates by 84.9%. Remaining false positives were shown in an easy to view format, enhancing workflow for duplicate orders identification. It is forecasted that RPA will be able to capture 95% of duplicate orders.

## DISCUSSION

Current RPA model is not integrated in RIS due to security limitations. Manual upload of scheduled scan orders and refreshing worklists are required. There exists a chance of data loss that will be reduced upon integration with RIS. RPA requires human input to trigger decision making in early models. Through Artificial intelligence (AI) upgrades, automation is achievable. With a combination of AI and standardized guidelines, it is expected that enhanced RPA model would be able to identify and cancel duplicate requests. The automation will improve patients' experience; as radiographers' time and attention are diverted towards direct patient care.

# W5B-QI-8 IMPROVED DETECTION OF ACUTE INTRACRANIAL HEMORRHAGE DETECTION: A DEEP LEARNING APPROACH ON A NON-CONTRAST HEAD CTS

Ross W. Filice, MD (*Abstract Co-Author*) Advisor, BunkerHill Health, Inc;Shareholder, BunkerHill Health, Inc;Speaker, General Electric Company;Speaker, Koios Medical;Researcher, Koios Medical
Joseph H. Yacoub, MD, MD (*Abstract Co-Author*) Stockholder, NVIDIA Corporation
Rashmi S. Thakkar, MD (*Presenter*) Nothing to Disclose

## INTRODUCTION

Timely and precise identification of acute intracranial hemorrhages (ICH) is imperative for prompt medical interventions, mitigating neurological damage, and enhancing overall patient outcomes. Swift and effective response to these critical medical emergencies significantly influences survival rates and quality of life. This study aims to assess the efficacy of a commercial deep learning algorithm to retrospectively detect missed acute ICHs on non-contrast head CTs.

## METHODS

Between March 27, 2023, and April 10, 2023, non-contrast head CT studies were consecutively gathered at our institutions. A natural language processing (NLP) algorithm was employed to classify radiological reports as negative or positive for ICH. A commercial deep learning AI algorithm was applied to imaging data to identify instances of missed acute ICH (negative by NLP, positive by AI). Ground truth was assumed for concordant cases. Discordant cases underwent review by a neuroradiologist to establish ground truth.

## RESULTS

There were 2,052 consecutive retrospective cases collected over a two-week period. The prevalence of acute ICH was 5.1% (105/2052) based on positive reports. The algorithm flagged 22 cases as suspected missed acute ICH. 31.8% (7/22) of these cases were determined to be true positive ICH, resulting in a 6.6% (7/105) enhanced detection rate. There were 11 false positive cases flagged by the algorithm. Sensitivity and specificity for radiologist was 93.75% and 99.85% respectively; and for AI it was 95.54% and 99.43% respectively.

## DISCUSSION

This study underscores the potential of deep learning systems as quality improvement tools to help identify missed acute intracranial hemorrhages, showcasing the promise of advancements in medical imaging technologies.Clinical Relevance A commercially available AI algorithm for acute ICH may be beneficial in detecting additional hemorrhages in 3.4 out of every 1,000 patients who undergo a non-contrast head CT.
